The source registers can be either general-purpose registers or the Condition flags, specified by use of APSR\_nzcv.

The destination registers are a consecutive pair of general-purpose registers.

The significance of the words in each pair is consistent with the current data endianness.

| 1  | 1  | 1  | A  | 1  | 1  | 1 | 0 | 1 | op1 |   |   |   | Rn |   |   |    | Rm |    |    |    | 0  | coproc |   |   |   | op2 | 1 | op3 |   |   |   | Rd |  |  |  |

#### Accumulator variant

Applies when **A == 1**

CX3DA<c>, <coproc>, <Rd>, <Rd+1>, <Rn>, <Rm>, #<imm>

#### Non-accumulator variant

Applies when **A == 0**

CX3D <coproc>, <Rd>, <Rd+1>, <Rn>, <Rm>, #<imm>

#### Decode for this encoding

```

1 if CoprocType(UInt(coproc)) != CP_CDEv1 then SEE "Coprocessor instructions";
2 if !HaveMainExt() then UNDEFINED;
3 cp = UInt(coproc);
4 d = UInt(Rd);
5 n = UInt(Rn);
6 m = UInt(Rm);
7 imm = op1:op2:op3;
8 acc = (A == '1');
9 ExecuteCPCheck(cp);
10 // Register pairs containing SP or PC are UNPREDICTABLE.
11 if d > 10 then UNPREDICTABLE;
12 if n == 13 || m == 13 then UNPREDICTABLE;
13 if Rd[0] == '1' then UNPREDICTABLE;
14 if !acc && InITBlock() then UNPREDICTABLE;
```

#### CONSTRAINED UNPREDICTABLE behavior

If **d** is odd, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction returns and UNKNOWN value in **Rd**, **Rd + 1** and **Rd - 1**.
- The instruction executes as NOP.

#### CONSTRAINED UNPREDICTABLE behavior

If **d == 12**, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction returns and UNKNOWN value in **SP**.

- The instruction executes as NOP.

#### CONSTRAINED UNPREDICTABLE behavior

If `d == 12 || d == 13`, then one of the following behaviors must occur:

- It is UNKNOWN whether a stack limit check is performed.

#### CONSTRAINED UNPREDICTABLE behavior

If `d == 14`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

#### CONSTRAINED UNPREDICTABLE behavior

If `n == 13 || m == 13`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The value in the destination register is UNKNOWN.
- The instruction executes as NOP.

#### CONSTRAINED UNPREDICTABLE behavior

If `!acc && InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP.

### Assembler symbols for all encodings

|          |                                                                                                                                                                                           |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <A>      | Accumulate with existing register contents. This parameter must be one of the following values:<br>– Encoded as <code>A = 0</code><br>A Encoded as <code>A = 1</code>                     |
| <c>      | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                                             |
| <coproc> | Is the name of the coprocessor, encoding in the "coproc" field. Valid names are p0 to p7 inclusive.                                                                                       |
| <Rd>     | Is the general-purpose register R0 – R10 specifying the first of destination register pair, encoded in the "Rd" field. For accumulator variants, <Rd> also specifies the source register. |
| <Rn>     | Is the general-purpose R0 – R14 or APSR_nzcv source register, encoded in the "Rn" field. APSR_nzcv is encoded by the "Rn" field value 0b1111.                                             |
| <Rm>     | Is the general-purpose R0 – R14 or APSR_nzcv source register, encoded in the "Rm" field. APSR_nzcv is encoded by the "Rm" field value 0b1111.                                             |
| <imm>    | Is the immediate encoded in <code>op1:op2:op3</code> .                                                                                                                                    |

### Operation for all encodings

```

1 if ConditionPassed() then
2     EncodingSpecificOperations();
3     if (!Coprocc_Accepted(cp, ThisInstr())) then
4         GenerateCoproccorException();
5     elseif acc then
6         RFD[d] = CX_op3(ThisInstr(), RFD[d], RF[n], RF[m], 64);
7     else
8         RFD[d] = CX_op2(ThisInstr(), RF[n], RF[m], 64);

```

## C2.4.57 DBG

Debug hint. Debug Hint provides a hint to debug trace support and related debug systems. See debug architecture documentation for what use (if any) is made of this instruction.

DBG is a NOP-compatible hint.

 <option> Is a 4-bit unsigned immediate, in the range 0 to 15, encoded in the "option" field.

### Operation for all encodings

```
1 if ConditionPassed() then
2     EncodingSpecificOperations();
3     Hint_Debug(option);
```

## C2.4.58 DMB

Data Memory Barrier. Data Memory Barrier acts as a memory barrier. It ensures that all explicit memory accesses that appear in program order before the DMB instruction are observed before any explicit memory accesses that appear in program order after the DMB instruction. It does not affect the ordering of any other instructions executing on the PE.

### T1

Armv8-M

### Assembler symbols for all encodings

<c> See [C1.2.5 Standard assembler syntax fields](#).  
 <q> See [C1.2.5 Standard assembler syntax fields](#).  
 <option> Specifies an optional limitation on the barrier operation. Values are:  
     SY Full system barrier operation, encoded as option = 0b1111. Can be omitted.  
 All other encodings of option are reserved. The corresponding instructions execute as full system barrier operations, but must not be relied upon by software.

### Operation for all encodings

```
1 if ConditionPassed() then
2   EncodingSpecificOperations();
3   DataMemoryBarrier(option);
```

## C2.4.59 DSB

**Data Synchronization Barrier.** Data Synchronization Barrier acts as a special kind of memory barrier. No instruction in program order after this instruction can execute until this instruction completes. This instruction completes only when both:

- Any explicit memory access made before this instruction is complete.
- The side effects of any SCS access that performs a context-altering operation are visible.

2 if !HaveMainExt() then UNDEFINED;
3 d = UInt(Rd); n = UInt(Rn); setflags = (S == '1');
4 (imm32, carry) = T32ExpandImm_C(i:imm3:imm8, APSR.C);
5 if d == 13 || (d == 15 && S == '0') || n IN {13,15} then UNPREDICTABLE;
```

### Assembler symbols for all encodings

|         |                                                                                                                                                                                    |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <c>     | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                                      |
| <q>     | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                                      |
| <Rd>    | Is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.                                                             |
| <Rn>    | Is the general-purpose source register, encoded in the "Rn" field.                                                                                                                 |
| <const> | Is an immediate value derived from the 12-bit immediate that is encoded in the "i:imm3:imm8" field. See <a href="#">C1.5 Modified immediate constants</a> for the range of values. |

### Operation for all encodings

```

1 if ConditionPassed() then
2     EncodingSpecificOperations();
3     result = R[n] EOR imm32;
4     R[d] = result;
5     if setflags then
6         APSR.N = result[31];
7         APSR.Z = IsZeroBit(result);
8         APSR.C = carry;
9         // APSR.V unchanged
```

### Restricted behavior

#### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the N, Z, C, V flags.
- The point at which an asynchronous exception is taken does not vary based on any of the following:
  - The values of the data supplied in any the registers bwing used in this instruction.
  - The values of the N, Z, C, V flags.

### C2.4.61 EOR (register)

**Exclusive OR (register).** Exclusive OR (register) performs a bitwise Exclusive OR of a register value and an optionally-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

| <c>      | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                                                                                                                                         |
| <q>      | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                                                                                                                                         |
| <Rdn>    | Is the first general-purpose source register and the destination register, encoded in the "Rdn" field.                                                                                                                                                                                |
| <Rd>     | Is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.                                                                                                                                                                |
| <Rn>     | Is the first general-purpose source register, encoded in the "Rn" field.                                                                                                                                                                                                              |
| <Rm>     | Is the second general-purpose source register, encoded in the "Rm" field.                                                                                                                                                                                                             |
| <shift>  | Is the type of shift to be applied to the second source register, encoded in the "sr_type" field. It can have the following values:<br><div style="margin-left: 20px;"> LSL when sr_type = 00<br/> LSR when sr_type = 01<br/> ASR when sr_type = 10<br/> ROR when sr_type = 11 </div> |
| <amount> | Is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm3:imm2" field as <amount> modulo 32.                                                                                                                  |

### Operation for all encodings

```
1 if ConditionPassed() then
2   EncodingSpecificOperations();
3   (shifted, carry) = Shift_C(R[m], shift_t, shift_n, APSR.C);
4   result = R[n] EOR shifted;
5   R[d] = result;
6   if setflags then
7     APSR.N = result[31];
8     APSR.Z = IsZeroBit(result);
9     APSR.C = carry;
10    // APSR.V unchanged
```

### Restricted behavior

#### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the N, Z, C, V flags.
- The point at which an asynchronous exception is taken does not vary based on any of the following:
  - The values of the data supplied in any the registers bwing used in this instruction.
  - The values of the N, Z, C, V flags.

## C2.4.62 ESB

Error Synchronization Barrier. Error Synchronization Barrier is used to synchronize any asynchronous RAS exceptions. That is, RAS errors notified to the PE will not silently propagate past this instruction. This is a NOP-compatible hint.

### T1: ESB variant

ESB<c><q>

### Decode for this encoding

```
1
2 if !HaveMainExt() then UNDEFINED;
```

### Assembler symbols for all encodings

<c, q> See [C1.2.5 Standard assembler syntax fields](#).

### Operation for all encodings

```
1 if ConditionPassed() then
2     EncodingSpecificOperations();
3
4     supported = boolean IMPLEMENTATION_DEFINED "Detection of Unrecoverable errors supported";
5     if HasArchVersion(Armv8p1) && supported then
6         exc = SynchronizeBusFault();
7         // When an ESB is executed, the return address for any resulting exception is the
8         // ESB instruction. This is accomplished by indicating that any exception that will
9         // preempt should terminate the execution of the ESB.
10        if exc.fault != NoFault then
11            if ExceptionPriority(exc.fault, exc.isSecure, TRUE) < ExecutionPriority() then
12                exc.termInst = TRUE;
13            HandleException(exc);
14            // An ESB acts as a Data Synchronization Barrier when either:
15            // - There is a pending BusFault (which might have been forced to be recognised as
16            //   a direct result of the call to SynchronizeBusFault() above).
17            // - There is a pending HardFault (which might have been caused by an asynchronous
18            //   BusFault which escalated due to the BusFault exception being disabled).
19            //
20            // This behavior guarantees that a subsequent load of the memory mapped syndrome
21            // registers and pending bits (BFSR, RFSR, and SHCSR) return the correct values.
22            //
23            // If a BusFault exception is recognized or escalated as a result of the ESB
24            // instruction affects the current Security state, then the values in the syndrome
25            // registers must be congruent with the current Security state.
26            // When determining whether the ESB instruction also acts as an implicit DSB, only
27            // the corresponding exception bits associated with the current Security state must
28            // be checked.
29            if SHCSR.BUSFAULTPENDE == '1' || SHCSR.HARDFFAULTPENDE == '1' then
30                DataSynchronizationBarrier('1111');
```

### C2.4.63 FLDMDBX, FLDMIAX

FLDMX (Decrement Before, Increment After). FLDMX (Decrement Before, Increment After) loads multiple extension registers from consecutive memory locations using an address from a general-purpose register.

Arm deprecates use of FLDMDBX and FLDMIAX, except for disassembly purposes, and reassembly of disassembled code.

#### T1

*Armv8-M Floating-point Extension, Armv8.1-M Floating-point Extension, or Armv8.1-M MVE*

#### Decrement Before variant

**Applies when P == 1 && U == 0 && W == 1.**

FLDMDBX{<c>}{<q>} <Rn>{!}, <dreglist>

#### Increment After variant

**Applies when P == 0 && U == 1.**

FLDMIAX{<c>}{<q>} <Rn>{!}, <dreglist>

#### Decode for this encoding

```

1 if P == '0' && U == '0' && W == '0' then SEE "Related encodings";
2 if P == '0' && U == '1' && W == '0' && Rn == '1111' then SEE "VSCCLRM";
3 if P == '1' && W == '0' then SEE VLDR;
4 CheckDecodeFaults(ExtType_MveOrFp);
5 if P == U && W == '1' then UNDEFINED;
6 // Remaining combinations are PUW = 010 (IA without !), 011 (IA with !), 101 (DB with !)
7 single_regs = FALSE; add = (U == '1'); wback = (W == '1'); imm8 = imm7 : imm1;
8 d = UInt(D:Vd); n = UInt(Rn); imm32 = ZeroExtend(imm8:'00', 32);
9 regs = UInt(imm8) DIV 2;
10 if n == 15 then UNPREDICTABLE;
11 if regs == 0 || (d+regs) > 32 then UNPREDICTABLE;
12 if !HasArchVersion(Armv8pl) then
13     if VFPSmallRegisterBank() && (d+regs) > 16 then UNPREDICTABLE;
```

#### CONSTRAINED UNPREDICTABLE behavior

If `regs == 0`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as a FLDMX with the same addressing mode but loads no registers.

#### CONSTRAINED UNPREDICTABLE behavior

If `(d+regs) > 32`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

- One or more of the floating-point registers are UNKNOWN. If the instruction specifies write-back, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

### Assembler symbols for all encodings

45         // the limit is violated
46         if wback then RSPCheck[n] = regval;

```

## C2.4.64 FSTMDBX, FSTMIAX

FSTMX (Decrement Before, Increment After). FSTMX (Decrement Before, Increment After) stores multiple extension registers to consecutive memory locations using an address from a general-purpose register.

Arm deprecates use of FSTMDBX and FSTMIAX, except for disassembly purposes, and reassembly of disassembled code.

### T1

*Armv8-M Floating-point Extension, Armv8.1-M Floating-point Extension, or Armv8.1-M MVE*

#### Decrement Before variant

Applies when **P == 1 && U == 0 && W == 1**.

FSTMDBX{<c>}{<q>} <Rn>{!}, <dreglist>

#### Increment After variant

Applies when **P == 0 && U == 1**.

FSTMIAX{<c>}{<q>} <Rn>{!}, <dreglist>

#### Decode for this encoding

```

1 if P == '0' && U == '0' && W == '0' then SEE "Related encodings";
2 if P == '1' && W == '0' then SEE VSTR;
3 CheckDecodeFaults(ExtType_MveOrFp);
4 if P == U && W == '1' then UNDEFINED;
5 // Remaining combinations are PUW = 010 (IA without !), 011 (IA with !), 101 (DB with !)
6 single_regs = FALSE; add = (U == '1'); wback = (W == '1'); imm8 = imm7 : imm1;
7 d = UInt(D:Vd); n = UInt(Rn); imm32 = ZeroExtend(imm8:'00', 32);
8 regs = UInt(imm8) DIV 2;
9 if n == 15 then UNPREDICTABLE;
10 if regs == 0 || (d+regs) > 32 then UNPREDICTABLE;
11 if !HasArchVersion(Armv8p1) then
12     if VFPSmallRegisterBank() && (d+regs) > 16 then UNPREDICTABLE;
```

#### CONSTRAINED UNPREDICTABLE behavior

If **regs == 0**, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as a FSTMX with the same addressing mode but stores no registers.

#### CONSTRAINED UNPREDICTABLE behavior

If **(d+regs) > 32**, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

- The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies write-back, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

## Assembler symbols for all encodings

### T1 variant

ISB{<c>}{<q>} {<option>}

### Decode for this encoding

```
1 // No additional decoding required
```

### Assembler symbols for all encodings

<c> See [C1.2.5 Standard assembler syntax fields](#).  
 <q> See [C1.2.5 Standard assembler syntax fields](#).  
 <option> Specifies an optional limitation on the barrier operation. Values are:  
     SY Full system barrier operation, encoded as option = 0b1111. Can be omitted.  
 All other encodings of option are reserved. The corresponding instructions execute as full system barrier operations, but must not be relied upon by software.

### Operation for all encodings

```
1 if ConditionPassed() then
2     EncodingSpecificOperations();
3     InstructionSynchronizationBarrier(option);
```

## C2.4.66 IT

If-Then. If Then makes up to four following instructions (the IT block) conditional. The conditions for the instructions in the IT block can be the same, or some of them can be the inverse of others.

**IT** does not affect the condition code flags. Branches to any instruction in the IT block are not permitted, apart from those performed by exception returns.

16-bit instructions in the IT block, other than **CMP (register)**, **CMN (register)**, and **TST (register)**, do not set the condition code flags. The AL condition can be specified to get this changed behavior without conditional execution.

### T1

*Armv8-M Main Extension only*

|    |    |    |    |    |    |   |   |           |   |   |   |              |   |   |   |
|----|----|----|----|----|----|---|---|-----------|---|---|---|--------------|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7         | 6 | 5 | 4 | 3            | 2 | 1 | 0 |
| 1  | 0  | 1  | 1  | 1  | 1  | 1 | 1 | firstcond |   |   |   | mask != 0000 |   |   |   |

#### T1 variant

IT{<x>{<y>{<z>}}} {<q>} <cond>

#### Decode for this encoding

```
1 if mask == '0000' then SEE "Related encodings";
2 if !HaveMainExt() then UNDEFINED;
3 if firstcond == '1111' || (firstcond == '1110' && BitCount(mask) != 1) then UNPREDICTABLE;
4 if InITBlock() then UNPREDICTABLE;
```

#### CONSTRAINED UNPREDICTABLE behavior

If `firstcond == '1111' || (firstcond == '1110' && BitCount(mask) != 1)`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The '1111' condition is treated as being the same as the '1110' condition, meaning always, and the ITSTATE state machine is progressed in the same way as for any other cond\_base value.

#### Assembler symbols for all encodings

### Decode for this encoding

```
1 t = UInt(Rt); n = UInt(Rn);
2 if t IN {13,15} || n == 15 then UNPREDICTABLE;
```

### Assembler symbols for all encodings

<c> See [C1.2.5 Standard assembler syntax fields](#).  
 <q> See [C1.2.5 Standard assembler syntax fields](#).  
 <Rt> Is the general-purpose register to be transferred, encoded in the "Rt" field.  
 <Rn> Is the general-purpose base register, encoded in the "Rn" field.

### Operation for all encodings

```
1 if ConditionPassed() then
2   EncodingSpecificOperations();
3   address = R[n];
4   SetExclusiveMonitors(address, 1);
5   R[t] = ZeroExtend(MemO[address, 1], 32);
```

### Restricted behavior

#### Data Independent Timing behavior

If [AIRCR.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data being loaded.
- The point at which an asynchronous exception is taken does not vary based on the value or values being loaded by this instruction.

The timing invariance does not apply to the addresses being accessed.

## C2.4.72 LDAEXH

Load-Acquire Exclusive Halfword. Load-Acquire Exclusive Halfword loads a halfword from memory, zero-extends it to form a 32-bit word, writes it to a register, and:

- If the address has the Shareable memory attribute, marks the physical address as exclusive access for the executing PE in a global monitor.
- Causes the executing PE to indicate an active exclusive access in the local monitor.

The instruction also has memory ordering semantics.

10     address = if index then offset_addr else R[n];
11
12     // Determine if the stack pointer limit check should be performed
13     if wback && n == 13 then
14         violatesLimit = ViolatesSPLim(LookUpSP(), offset_addr);
15     else
16         violatesLimit = FALSE;
17
18     // Memory operation only performed if limit not violated
19     if !violatesLimit then
20         repeat
21             Coproc_SendLoadedWord(MemA[address, 4], cp, thisInstr);
22             address = address + 4;
23         until Coproc_DoneLoading(cp, thisInstr);
24
25     // If the stack pointer is being updated a fault will be raised
26     // if the limit is violated
27     if wback then RSPCheck[n] = offset_addr;

```

## Restricted behavior

### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data being loaded.
- The point at which an asynchronous exception is taken does not vary based on the value or values being loaded by this instruction.

The timing invariance does not apply to the addresses being accessed.

### C2.4.75 LDC, LDC2 (literal)

Load Coprocessor (literal). Load Coprocessor loads memory data from a sequence of consecutive memory addresses to a coprocessor. If no coprocessor can execute the instruction, a UsageFault exception is generated.

This is a generic coprocessor instruction. The D bit and the CRd field have no functionality defined by the architecture and are free for use by the coprocessor instruction set designer.

Arm reserves coprocessors CP8 to CP15, and this manual defines the valid instructions when coproc is in this range.

2 if CoprocType(UInt(coproc)) == CP_CDEv1 then SEE "CDE instructions";
3 if P == '0' && U == '0' && D == '1' && W == '0' then SEE "MRRC, MRRC2";
4 if P == '0' && U == '0' && D == '0' && W == '0' then UNDEFINED;
5 if !HaveMainExt() then UNDEFINED;
6 index = (P == '1'); // Always TRUE in the T32 instruction set
7 add = (U == '1'); cp = UInt(coproc); imm32 = ZeroExtend(imm8:'00', 32);
8 if W == '1' || P == '0' then UNPREDICTABLE;

```

## CONSTRAINED UNPREDICTABLE behavior

If `W == '1' || P == '0'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without write-back of the base address.
- The instruction executes as LDC with write-back to the PC.

## Assembler symbols for all encodings

| <c>      | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <q>      | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <coproc> | Is the name of the coprocessor, encoded in the "coproc" field. The generic coprocessor names are p0 to p15.                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <CRd>    | Is the coprocessor register to be transferred, encoded in the "CRd" field.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <label>  | The label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the <a href="#">Align</a> (PC, 4) value of the instruction to this label. Permitted values of the offset are multiples of 4 in the range -1020 to 1020. If the offset is zero or positive, <code>imm32</code> is equal to the offset and <code>add == TRUE</code> (encoded as <code>U == 1</code> ). If the offset is negative, <code>imm32</code> is equal to minus the offset and <code>add == FALSE</code> (encoded as <code>U == 0</code> ). |
| +/-      | Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values: <ul style="list-style-type: none"> <li>- when <code>U = 0</code></li> <li>+ when <code>U = 1</code></li> </ul>                                                                                                                                                                                                                                                                                                   |
| <imm>    | Is the immediate offset used for forming the address, a multiple of 4 in the range 0-1020, defaulting to 0 and encoded in the "imm8" field, as <imm>/4.                                                                                                                                                                                                                                                                                                                                                                                                                            |

## Operation for all encodings

```

1 if ConditionPassed() then
2     EncodingSpecificOperations();
3     ExecuteCPCheck(cp);
4
5     thisInstr = ThisInstr();
6     if !Coproc_Accepted(cp, thisInstr) then
7         GenerateCoproprocessorException();
8     else
9         offset_addr = if add then (Align(PC,4) + imm32) else (Align(PC,4) - imm32);
10        address = if index then offset_addr else Align(PC,4);
11        repeat
12            Coproc_SendLoadedWord(MemA[address, 4], cp, thisInstr); address = address + 4;
13        until Coproc_DoneLoading(cp, thisInstr);

```

## Restricted behavior

### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data being loaded.
- The point at which an asynchronous exception is taken does not vary based on the value or values being loaded by this instruction.

The timing invariance does not apply to the addresses being accessed.

## C2.4.76 LDM, LDMIA, LDMFD

Load Multiple (Increment After, Full Descending). Load Multiple loads multiple registers from consecutive memory locations using an address from a base register. The sequential memory locations start at this address, and the address just above the last of those locations can optionally be written back to the base register.

The registers loaded can include the PC. If they do, the word loaded for the PC is treated as a branch address, a function return value, or an exception return value. Bit[0] of the address in the PC complies with the Arm architecture interworking rules for switching between the A32 and T32 instruction sets. However, Armv8-M only supports the T32 instruction set, so bit[0] must be 1. If bit[0] of the target address is 0, and the target address is not FNC\_RETURN or EXC\_RETURN, the PE takes an INVSTATE UsageFault exception on the instruction at the target address.

This instruction is used by the alias [POP \(multiple registers\)](#).

This instruction is a BTI setting instruction when all of the following are true:

- The PACBTI Extension is implemented.
- BTI is enabled for the destination security and privilege state.
- The operation is not a FNC\_RETURN or an EXC\_RETURN.
- PC is used.
- The base register is either:
  - Not SP.
  - The SP and a write-back does not occur.

This instruction is interrupt-continuable.

### T1

Armv8-M

|    |    |    |    |    |    |   |   |   |               |   |   |   |   |   |   |
|----|----|----|----|----|----|---|---|---|---------------|---|---|---|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6             | 5 | 4 | 3 | 2 | 1 | 0 |
| 1  | 1  | 0  | 0  | 1  | Rn |   |   |   | register_list |   |   |   |   |   |   |

### T1 variant

```
LDM{IA}{<c>}{<q>} <Rn>{!}, <registers>
// Preferred syntax
LDMFD{<c>}{<q>} <Rn>{!}, <registers>
// Alternate syntax, Full Descending stack
```

### Decode for this encoding

```
1 n = UInt(Rn); registers = '0000000':register_list; wback = (registers[n] == '0');
2 if BitCount(registers) < 1 then UNPREDICTABLE;
```

### CONSTRAINED UNPREDICTABLE behavior

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as LDM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies write-back, the modification to the base address on write-back might differ from the number of registers loaded.

## T2

Armv8-M Main Extension only

|    |    |    |    |    |    |   |   |   |   |   |   |            |   |   |     |               |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|----|----|----|----|----|----|---|---|---|---|---|---|------------|---|---|-----|---------------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|

### T2 variant

```
LDM{IA}{<c>}.W <Rn>{!}, <registers>
    // Preferred syntax
    // if <Rn>, '!' and <registers> can be represented in T1
LDMFD{<c>}.W <Rn>{!}, <registers>
    // Alternate syntax
    // Full Descending stack, if <Rn>, '!' and
    // <registers> can be represented in T1
LDM{IA}{<c>}{<q>} <Rn>{!}, <registers>
    // Preferred syntax
LDMFD{<c>}{<q>} <Rn>{!}, <registers>
    // Alternate syntax, Full Descending stack
```

### Decode for this encoding

```
1 if Rn == '1111' && HasArchVersion(Armv8p1) then SEE "CLRM";
2 if !HaveMainExt() then UNDEFINED;
3 n = UInt(Rn); registers = P:M:'0':register_list; wback = (W == '1');
4 if n == 15 || BitCount(registers) < 2 || (P == '1' && M == '1') then UNPREDICTABLE;
5 if registers[15] == '1' && InitBlock() && !LastInitBlock() then UNPREDICTABLE;
6 if wback && registers[n] == '1' then UNPREDICTABLE;
```

### CONSTRAINED UNPREDICTABLE behavior

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as LDM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies write-back, the modification to the base address on write-back might differ from the number of registers loaded.

### CONSTRAINED UNPREDICTABLE behavior

If `wback && registers<n> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

### CONSTRAINED UNPREDICTABLE behavior

If `BitCount(registers) == 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

- The instruction loads a single register using the specified addressing modes.
- The instruction executes as LDM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

### CONSTRAINED UNPREDICTABLE behavior

If  $P == '1'$  &&  $M == '1'$ , then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction loads the register list and either R14 or R15, both R14 and R15, or neither of these registers.

### T3

Armv8-M

|    |    |    |    |    |    |   |   |               |   |   |   |   |   |   |   |
|----|----|----|----|----|----|---|---|---------------|---|---|---|---|---|---|---|

| <Rn>        | Is the general-purpose base register, encoded in the "Rn" field.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| !           | For encoding T1: the address adjusted by the size of the data loaded is written back to the base register. It is omitted if <Rn> is included in <registers>, otherwise it must be present.<br>For encoding T2: the address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the "W" field as 1, otherwise this field defaults to 0.                                                                                                                                                                                                                                                                            |
| <registers> | For encoding T1: is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The registers in the list must be in the range R0-R7, encoded in the "register_list" field. For encoding T2: is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The registers in the list must be in the range R0-R12, encoded in the "register_list" field, and can optionally contain one of the LR or the PC. If the LR is in the list, the "M" field is set to 1, otherwise it defaults to 0. If the PC is in the list, the "P" field is set to 1, otherwise it defaults to 0. If the PC is in the list: |

- The LR must not be in the list.
  - The instruction must be either outside any IT block, or the last instruction in an IT block.
- For encoding T3: is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The registers in the list must be in the range R0-R7, encoded in the "register\_list" field, and can optionally include the PC. If the PC is in the list, the "P" field is set to 1, otherwise this field defaults to 0. If the PC is in the list, the instruction must be either outside any IT block, or the last instruction in an IT block.

## Operation for all encodings

```

1  if ConditionPassed() then
2      EncodingSpecificOperations();
3      address = R[n];
4      if n == 13 && wback then
5          // If memory operation is not performed as a result of a stack limit violation,
6          // and the write-back of the SP itself does not raise a stack limit violation, it
7          // is "IMPLEMENTATION_DEFINED" whether a SPLIM exception is raised.
8          // Arm recommends that any instruction which discards a memory access as
9          // a result of a stack limit violation, and where the write-back of the SP itself
10         // does not raise a stack limit violation, generates an SPLIM exception.
11         if boolean IMPLEMENTATION_DEFINED "SPLIM exception on invalid memory access" then
12             if ViolatesSPLim(LookUpSP(), address) then
13                 if HaveMainExt() then
14                     UFSR.STKOF = '1';
15                     // If the Main Extension is not implemented the fault always escalates to
16                     // a HardFault
17                     excInfo = CreateException(UsageFault);
18                     HandleException(excInfo);
19             applylimit = TRUE;
20         else
21             applylimit = FALSE;
22
23         for i = 0 to 14
24             // If R[n] is the SP, memory operation only performed if limit not violated
25             if registers[i] == '1' && !(applylimit && ViolatesSPLim(LookUpSP(), address)) then
26                 if i != n then

28                 else
29                     newBaseVal = MemA[address, 4];
30                     address = address + 4;
31             if registers[15] == '1' && !(applylimit && ViolatesSPLim(LookUpSP(), address)) then
32                 newPCVal = MemA[address, 4];
33
34             // If the register list contains the register that holds the base address it
35             // must be updated after all memory reads have been performed. This prevents
36             // the base address being overwritten if one of the memory reads generates a
37             // fault.
38             if registers[n] == '1' then
39                 wback = TRUE;
40             else
41                 newBaseVal = R[n] + 4*BitCount(registers);
42             // If the PC is in the register list update that now, which might raise a fault
43             // Likewise if R[n] is the SP writing back might raise a fault due to SP limit violation
44             if registers[15] == '1' then
45                 // If BTI is enabled, this branch sets the EPSR.B flag to ensure that the target
46                 // instruction is BTI clearing.
47                 setBti = BTIEnabled() && (n != 13 || (n == 13 && !wback));
48                 LoadWritePC(newPCVal, n, newBaseVal, wback, FALSE, setBti);
49             elseif wback then
50                 RSPCheck[n] = newBaseVal;

```

## Restricted behavior

### Data Independent Timing behavior

If [AIRCR.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data being loaded.
- The point at which an asynchronous exception is taken does not vary based on the value or values being loaded by this instruction.

The timing invariance does not apply to values being loaded into R15, but does apply to all values being loaded into any other specified register even if R15 is being used.

The timing invariance does not apply to the addresses being accessed.

## C2.4.77 LDMDB, LDMEA

Load Multiple Decrement Before (Empty Ascending). Load Multiple Decrement Before (Load Multiple Empty Ascending) loads multiple registers from sequential memory locations using an address from a base register. The sequential memory locations end just below this address, and the address of the first of those locations can optionally be written back to the base register.

The registers loaded can include the PC. If they do, the word loaded for the PC is treated as a branch address or an exception return value. Bit[0] complies with the Arm architecture interworking rules for switching between the A32 and T32 instruction sets. However, Armv8-M only supports the T32 instruction set, so bit[0] must be 1. If bit[0] is 0 the PE takes an INVSTATE UsageFault exception on the instruction at the target address.

This instruction is a BTI setting instruction when all of the following are true:

- The PACBTI Extension is implemented.
- BTI is enabled for the destination security and privilege state.
- The operation is not a FNC\_RETURN or an EXC\_RETURN.
- PC is used.
- The base register is either:
  - Not SP.
  - The SP and a write-back does not occur.

This instruction is interrupt-continuable.

### T1

Armv8-M Main Extension only

|    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |    |    |    |     |               |    |    |   |   |   |   |   |   |   |   |   |   |
|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|----|----|----|-----|---------------|----|----|---|---|---|---|---|---|---|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0  | 15 | 14 | 13  | 12            | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 1  | 1  | 1  | 0  | 1  | 0  | 0 | 1 | 0 | 0 | W | 1 |   |   |   | Rn | P  | M  | (0) | register_list |    |    |   |   |   |   |   |   |   |   |   |   |

### T1 variant

```
LDMDB{<c>}{<q>} <Rn>{!}, <registers>
// Preferred syntax
LDMEA{<c>}{<q>} <Rn>{!}, <registers>
// Alternate syntax, Empty Ascending stack
```

### Decode for this encoding

```
1 if !HaveMainExt() then UNDEFINED;
2 n = UInt(Rn); registers = P:M:'0':register_list; wback = (W == '1');
3 if n == 15 || BitCount(registers) < 2 || (P == '1' && M == '1') then UNPREDICTABLE;
4 if registers[15] == '1' && !InitBlock() && !LastInitBlock() then UNPREDICTABLE;
5 if wback && registers[n] == '1' then UNPREDICTABLE;
```

### CONSTRAINED UNPREDICTABLE behavior

If wback && registers<n> == '1', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

### CONSTRAINED UNPREDICTABLE behavior

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as LDM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies write-back, the modification to the base address on write-back might differ from the number of registers loaded.

### CONSTRAINED UNPREDICTABLE behavior

If `BitCount(registers) == 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction loads a single register using the specified addressing modes.
- The instruction executes as LDM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

### CONSTRAINED UNPREDICTABLE behavior

If `P == '1' && M == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction loads the register list and either R14 or R15, both R14 and R15, or neither of these registers.

### Assembler symbols for all encodings

|                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <code>&lt;Rn&gt;</code>        | Is the general-purpose base register, encoded in the "Rn" field.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>!</code>                 | The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the "W" field as 1, otherwise this field defaults to 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>&lt;registers&gt;</code> | Is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The registers in the list must be in the range R0-R12, encoded in the "register_list" field, and can optionally contain one of the LR or the PC. If the LR is in the list, the "M" field is set to 1, otherwise it defaults to 0. If the PC is in the list, the "P" field is set to 1, otherwise it defaults to 0. If the PC is in the list: <ul style="list-style-type: none"> <li>- The LR must not be in the list.</li> <li>- The instruction must be either outside any IT block, or the last instruction in an IT block.</li> </ul> |

### Operation for all encodings

```

1  if ConditionPassed() then
2      EncodingSpecificOperations();
3      address = R[n] - 4*BitCount(registers);
4
5      // Determine if the stack pointer limit should be checked
6      if n == 13 && wback && registers[n] == '0' then
7          violatesLimit = ViolatesSPLim(LookUpSP(), address);
8      else
9          violatesLimit = FALSE;
10
11     for i = 0 to 15
12         // Memory operation only performed if limit not violated
13         if registers[i] == '1' && !violatesLimit then

```

```
14      data      = MemA[address, 4];
15      address = address + 4;
16      if i == 15 then
17          newPCVal = data;
18      elseif i == n then
19          newBaseVal = data;
20      else
21          R[i]      = data;
22
23      // If the register list contains the register that holds the base address it
24      // must be updated after all memory reads have been performed. This prevents
25      // the base address being overwritten if one of the memory reads generates a
26      // fault.
27      if registers[n] == '1' then
28          wback      = TRUE;
29      else
30          newBaseVal = R[n] - 4*BitCount(registers);
31      // If the PC is in the register list update that now, which may raise a fault
32      if registers[15] == '1' then
33          // If BTI is enabled, this branch sets the EPSR.B flag to ensure that the target
34          // instruction is BTI clearing.
35          setBti = BTIEnabled() && (n != 13 || (n == 13 && !wback));
36          LoadWritePC(newPCVal, n, newBaseVal, wback, TRUE, setBti);
37      elseif wback then
38          RSPCheck[n] = newBaseVal;
```

## Restricted behavior

### Data Independent Timing behavior

If [AIRCR.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data being loaded.
- The point at which an asynchronous exception is taken does not vary based on the value or values being loaded by this instruction.

The timing invariance does not apply to values being loaded into R15, but does apply to all values being loaded into any other specified register even if R15 is being used.

The timing invariance does not apply to the addresses being accessed.

## C2.4.78 LDR (immediate)

Load Register (immediate). Load Register (immediate) calculates an address from a base register value and an immediate offset, loads a word from memory, and writes it to a register. It can use offset, post-indexed, or pre-indexed addressing.

The register loaded can be the PC. If it is, the word loaded for the PC is treated as a branch address or an exception return value. Bit[0] complies with the Arm architecture interworking rules for switching between the A32 and T32 instruction sets. However, Armv8-M only supports the T32 instruction set, so bit[0] must be 1. If bit[0] is 0 the PE takes an INVSTATE UsageFault exception on the instruction at the target address.

This instruction is used by the alias [POP \(single register\)](#).

This instruction is a BTI setting instruction when all of the following are true:

- The PACBTI Extension is implemented.
- BTI is enabled for the destination security and privilege state.
- The operation is not a FNC\_RETURN or an EXC\_RETURN.
- PC is used.
- The base register is either:
  - Not SP.
  - The SP and a write-back does not occur.

### Offset variant

Applies when **P == 1 && U == 0 && W == 0**.

```
LDR{<c>}{<q>} <Rt>, [<Rn> {, #-<imm>}]
```

### Post-indexed variant

Applies when **P == 0 && W == 1**.

```
LDR{<c>}{<q>} <Rt>, [<Rn>], #{+/-}<imm>
```

### Pre-indexed variant

Applies when **P == 1 && W == 1**.

```
LDR{<c>}{<q>} <Rt>, [<Rn>, #{+/-}<imm>]!
```

### Decode for this encoding

```
1 if Rn == '1111' then SEE "LDR (literal)";
2 if P == '1' && U == '1' && W == '0' then SEE LDRT;
3 if P == '0' && W == '0' then UNDEFINED;
4 if !HaveMainExt() then UNDEFINED;
5 t = UInt(Rt); n = UInt(Rn);
6 imm32 = ZeroExtend(imm8, 32); index = (P == '1'); add = (U == '1'); wback = (W == '1');
7 if (wback && n == t) || (t == 15 && InITBlock() && !LastInITBlock()) then UNPREDICTABLE;
```

## CONSTRAINED UNPREDICTABLE behavior

If **wback && n == t**, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

### Alias conditions

| Alias                 | preferred when                                                                     |
|-----------------------|------------------------------------------------------------------------------------|
| POP (single register) | Rn == `1101` &&<br>P == `0` &&<br>U == `1` &&<br>W == `1` &&<br>imm8 == `00000100` |

### Assembler symbols for all encodings

|       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| +     | Specifies the offset is added to the base register.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <imm> | For the post-indexed or pre-indexed variant: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, encoded in the "imm8" field.<br>For encoding T1: is the optional positive unsigned immediate byte offset, a multiple of 4 in the range 0 to 124, defaulting to 0 and encoded in the "imm5" field as <imm>/4.<br>For encoding T2: is the optional positive unsigned immediate byte offset, a multiple of 4, in the range 0 to 1020, defaulting to 0 and encoded in the "imm8" field as <imm>/4.<br>For encoding T3: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.<br>For encoding T4: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field. |

### Operation for all encodings

```

1  if ConditionPassed() then
2      EncodingSpecificOperations();
3      offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
4      address = if index then offset_addr else R[n];
5
6      // Determine if the stack pointer limit should be checked
7      if n == 13 && wback then
8          violatesLimit = ViolatesSPLim(LookUpSP(), offset_addr);
9      else
10         violatesLimit = FALSE;
11     // Memory operation only performed if limit not violated
12     if !violatesLimit then

```

```
13     data = MemU[address, 4];
14
15     // If the stack pointer is being updated a fault will be raised if
16     // the limit is violated
17     if t == 15 then
18         if address[1:0] == '00' then
19             // If BTI is enabled, this branch sets the EPSR.B flag to ensure that the target
20             // instruction is BTI clearing.
21             setBti = BTIEnabled() && (n != 13 || (n == 13 && !wback));
22             LoadWritePC(data, n, offset_addr, wback, TRUE, setBti);
23         else
24             UNPREDICTABLE;
25     else
26         if wback then RSPCheck[n] = offset_addr;
27         R[t] = data;
```

### CONSTRAINED UNPREDICTABLE behavior

If `t == 15 && address<1:0> != '00'`, then one of the following behaviors must occur:

- The instruction executes as described, with no change to its behavior and no additional side effects.
- The instruction generates an UNALIGNED UsageFault.

### Restricted behavior

#### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1, and R15 is not being used as the destination register:

- The execution time of this instruction is insensitive to the value or values of the data being loaded.
- The point at which an asynchronous exception is taken does not vary based on the value or values being loaded by this instruction.

The timing invariance does not apply to the addresses being accessed.

## C2.4.79 LDR (literal)

Load Register (literal). Load Register (literal) calculates an address from the PC value and an immediate offset, loads a word from memory, and writes it to a register.

The register loaded can be the PC. If it is, the word loaded for the PC is treated as a branch address or an exception return value. Bit[0] complies with the Arm architecture interworking rules for switching between the A32 and T32 instruction sets. However, Armv8-M only supports the T32 instruction set, so bit[0] must be 1. If bit[0] is 0 the PE takes an INVSTATE UsageFault exception on the instruction at the target address.

If the PACBTI Extension is implemented, BTI is enabled for the destination security and privilege state, the operation is not a FNC\_RETURN or an EXC\_RETURN, and the destination register is PC, then this instruction is a BTI setting instruction, and when this instruction is executed it will set EPSR.B to one.

### T1

Armv8-M

|    |    |    |    |    |    |   |   |      |   |   |   |   |   |   |   |

| <label> | For encoding T1: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the <a href="#">Align</a> (PC, 4) value of the instruction to this label. Permitted values of the offset are Multiples of four in the range 0 to 1020.<br>For encoding T2: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the <a href="#">Align</a> (PC, 4) value of the instruction to this label. Permitted values of the offset are -4095 to 4095. If the offset is zero or positive, imm32 is equal to the offset and add == TRUE, encoded as U == 1. If the offset is negative, imm32 is equal to minus the offset and add == FALSE, encoded as U == 0. |
| +/-     | Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:<br>- when U = 0<br>+ when U = 1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <imm>   | Is a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Operation for all encodings

```

1  if ConditionPassed() then
2      EncodingSpecificOperations();
3      base = Align(PC, 4);
4      address = if add then (base + imm32) else (base - imm32);
5      data = MemU(address, 4);
6      if t == 15 then
7          if address[1:0] == '00' then
8              // If BTI is enabled, this branch sets the EPSR.B flag to ensure that the target
9              // instruction is BTI clearing.
10             LoadWritePC(data, 0, Zeros(32), FALSE, FALSE, BTIEnabled());
11         else
12             UNPREDICTABLE;
13     else
14         R[t] = data;
```

## CONSTRAINED UNPREDICTABLE behavior

If `t == 15` && `address<1:0> != '00'`, then one of the following behaviors must occur:

- The instruction executes as described, with no change to its behavior and no additional side effects.
- The instruction generates an UNALIGNED UsageFault.

## Restricted behavior

### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1, and R15 is not being used as the destination register:

- The execution time of this instruction is insensitive to the value or values of the data being loaded.
- The point at which an asynchronous exception is taken does not vary based on the value or values being loaded by this instruction.

The timing invariance does not apply to the addresses being accessed.

## C2.4.80 LDR (register)

Load Register (register). Load Register (register) calculates an address from a base register value and an offset register value, loads a word from memory, and writes it to a register. The offset register value can be shifted left by 0, 1, 2, or 3 bits.

The register loaded can be the PC. If it is, the word loaded for the PC is treated as a branch address or an exception return value. Bit[0] complies with the Arm architecture interworking rules for switching between the A32 and T32 instruction sets. However, Armv8-M only supports the T32 instruction set, so bit[0] must be 1. If bit[0] is 0 the PE takes an INVSTATE UsageFault exception on the instruction at the target address.

If the PACBTI Extension is implemented, BTI is enabled for the destination security and privilege state, the operation is not a FNC\_RETURN or an EXC\_RETURN, and the destination register is PC, then this instruction is a BTI setting instruction, and when this instruction is executed it will set EPSR.B to one.

7 if t == 15 && InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

### Assembler symbols for all encodings

<c> See C1.2.5 *Standard assembler syntax fields*.  
 <q> See C1.2.5 *Standard assembler syntax fields*.  
 <Rt> For encoding T1: is the general-purpose register to be transferred, encoded in the "Rt" field.

For encoding T2: is the general-purpose register to be transferred, encoded in the "Rt" field. The SP can be used. The PC can be used, provided the instruction is either outside an IT block or the last instruction of an IT block. If the PC is used, the instruction branches to the address (data) loaded to the PC.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.  
+ Specifies the index register is added to the base register.  
<Rm> Is the general-purpose index register, encoded in the "Rm" field.  
<imm> If present, the size of the left shift to apply to the value from <Rm>, in the range 1-3. <imm> is encoded in imm2. If absent, no shift is specified and imm2 is encoded as 0b00.

## Operation for all encodings

```

1  if ConditionPassed() then
2      EncodingSpecificOperations();
3      offset = Shift(R[m], shift_t, shift_n, APSR.C);
4      offset_addr = if add then (R[n] + offset) else (R[n] - offset);
5      address = if index then offset_addr else R[n];
6
7      // Determine if the stack pointer limit should be checked
8      if n == 13 && wback then
9          violatesLimit = ViolatesSPLim(LookUpSP(), offset_addr);
10     else
11         violatesLimit = FALSE;
12     // Memory operation only performed if limit not violated
13     if !violatesLimit then
14         data = MemU[address, 4];
15
16     // If the stack pointer is being updated a fault will be raised if
17     // the limit is violated
18     if t == 15 then
19         if address[1:0] == '00' then
20             // If BTI is enabled, this branch sets the EPSR.B flag to ensure that the target
21             // instruction is BTI clearing.
22             LoadWritePC(data, n, offset_addr, wback, TRUE, BTIEnabled());
23         else
24             UNPREDICTABLE;
25     else
26         if wback then RSPCheck[n] = offset_addr;
27         R[t] = data;

```

## CONSTRAINED UNPREDICTABLE behavior

If `t == 15 && address<1:0> != '00'`, then one of the following behaviors must occur:

- The instruction executes as described, with no change to its behavior and no additional side effects.
- The instruction generates an UNALIGNED UsageFault.

## Restricted behavior

### Data Independent Timing behavior

If `AIRCR.DIT` is 1, and R15 is not being used as the destination register:

- The execution time of this instruction is insensitive to the value or values of the data being loaded.
- The point at which an asynchronous exception is taken does not vary based on the value or values being loaded by this instruction.

The timing invariance does not apply to the addresses being accessed.

## C2.4.81 LDRB (immediate)

Load Register Byte (immediate). Load Register Byte (immediate) calculates an address from a base register value and an immediate offset, loads a byte from memory, zero-extends it to form a 32-bit word, and writes it to a register. It can use offset, post-indexed, or pre-indexed addressing.

#### Offset variant

Applies when Rt != 1111 && P == 1 && U == 0 && W == 0.

LDRB{<c>}{<q>} <Rt>, [<Rn> {, #-<imm>}]

#### Post-indexed variant

Applies when P == 0 && W == 1.

LDRB{<c>}{<q>} <Rt>, [<Rn>], #{+/-}<imm>

### Pre-indexed variant

Applies when **P == 1 && W == 1**.

LDRB{<c>}{<q>} <Rt>, [<Rn>, #{+/-}<imm>]!

### Decode for this encoding

```
1 if Rt == '1111' && P == '1' && U == '0' && W == '0' then SEE "PLD (immediate)";
2 if Rn == '1111' then SEE "LDRB (literal)";
3 if P == '1' && U == '1' && W == '0' then SEE LDRBT;
4 if P == '0' && W == '0' then UNDEFINED;
5 if !HaveMainExt() then UNDEFINED;
6 t = UInt(Rt); n = UInt(Rn); imm32 = ZeroExtend(imm8, 32);
7 index = (P == '1'); add = (U == '1'); wback = (W == '1');
8 if t == 13 || (wback && n == t) then UNPREDICTABLE;
9 if t == 15 && W == '1' then UNPREDICTABLE;
```

### CONSTRAINED UNPREDICTABLE behavior

If **wback && n == t**, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

| <q>   | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <Rt>  | Is the general-purpose register to be transferred, encoded in the "Rt" field.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <Rn>  | For encoding T1: is the general-purpose base register, encoded in the "Rn" field.<br>For encoding T2 and T3: is the general-purpose base register, encoded in the "Rn" field. For PC use see <a href="#">C2.4.82 LDRB (literal)</a> .                                                                                                                                                                                                                                                                                                                                                             |
| +/-   | Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values: <ul style="list-style-type: none"> <li>- when U = 0</li> <li>+ when U = 1</li> </ul>                                                                                                                                                                                                                                                                                                                                            |
| +     | Specifies the offset is added to the base register.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <imm> | For the post-indexed or pre-indexed variant: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, encoded in the "imm8" field.<br>For encoding T1: is an optional 5-bit unsigned immediate byte offset, in the range 0 to 31, defaulting to 0 and encoded in the "imm5" field.<br>For encoding T2: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.<br>For encoding T3: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field. |

### Operation for all encodings

```
1 if ConditionPassed() then
2   EncodingSpecificOperations();
3   offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
4   address = if index then offset_addr else R[n];
5
6   // Determine if the stack pointer limit should be checked
```

```

7      if n == 13 && wback then
8          violatesLimit = ViolatesSPLim(LookUpSP(), offset_addr);
9      else
10         violatesLimit = FALSE;
11
12         // Memory operation only performed if limit not violated
13         if !violatesLimit then
14             R[t] = ZeroExtend(MemU[address, 1], 32);
15
16         // If the stack pointer is being updated a fault will be raised if
17         // the limit is violated
18         if wback then RSPCheck[n] = offset_addr;

```

## Restricted behavior

### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1, and R15 is not being used as the destination register:

- The execution time of this instruction is insensitive to the value or values of the data being loaded.
- The point at which an asynchronous exception is taken does not vary based on the value or values being loaded by this instruction.

The timing invariance does not apply to the addresses being accessed.

## C2.4.82 LDRB (literal)

Load Register Byte (literal). Load Register Byte (literal) calculates an address from the PC value and an immediate offset, loads a byte from memory, zero-extends it to form a 32-bit word, and writes it to a register.

### T1

| <Rt>    | Is the general-purpose register to be transferred, encoded in the "Rt" field.                                                                                                                                                                                                                                                                                                                                                                                        |
| <label> | The label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the <a href="#">Align</a> (PC, 4) value of the instruction to this label. Permitted values of the offset are -4095 to 4095. If the offset is zero or positive, imm32 is equal to the offset and add == TRUE, encoded as U == 1. If the offset is negative, imm32 is equal to minus the offset and add == FALSE, encoded as U == 0. |
| +/-     | Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:<br>- when U = 0<br>+ when U = 1                                                                                                                                                                                                                                                                    |
| <imm>   | Is a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.                                                                                                                                                                                                                                                                                                                                                                    |

### Operation for all encodings

```
1 if ConditionPassed() then
2   EncodingSpecificOperations();
3   base = Align(PC, 4);
4   address = if add then (base + imm32) else (base - imm32);
5   R[t] = ZeroExtend(MemU[address, 1], 32);
```

### Restricted behavior

#### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data being loaded.

- The point at which an asynchronous exception is taken does not vary based on the value or values being loaded by this instruction.

The timing invariance does not apply to the addresses being accessed.

### C2.4.83 LDRB (register)

Load Register Byte (register). Load Register Byte (register) calculates an address from a base register value and an offset register value, loads a byte from memory, zero-extends it to form a 32-bit word, and writes it to a register. The offset register value can be shifted left by 0, 1, 2, or 3 bits.

|       |                                                                                                                                                                                   |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <c>   | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                                     |
| <q>   | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                                     |
| <Rt>  | Is the general-purpose register to be transferred, encoded in the "Rt" field.                                                                                                     |
| <Rn>  | Is the general-purpose base register, encoded in the "Rn" field.                                                                                                                  |
| +     | Specifies the index register is added to the base register.                                                                                                                       |
| <Rm>  | Is the general-purpose index register, encoded in the "Rm" field.                                                                                                                 |
| <imm> | If present, the size of the left shift to apply to the value from <Rm>, in the range 1-3. <imm> is encoded in imm2. If absent, no shift is specified and imm2 is encoded as 0b00. |

#### Operation for all encodings

```
1 if ConditionPassed() then
```

```

2   EncodingSpecificOperations();
3   offset = Shift(R[m], shift_t, shift_n, APSR.C);
4   offset_addr = if add then (R[n] + offset) else (R[n] - offset);
5   address = if index then offset_addr else R[n];
6   R[t] = ZeroExtend(MemU[address, 1], 32);

```

## Restricted behavior

### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data being loaded.
- The point at which an asynchronous exception is taken does not vary based on the value or values being loaded by this instruction.

The timing invariance does not apply to the addresses being accessed.

## C2.4.84 LDRBT

Load Register Byte Unprivileged. Load Register Byte Unprivileged calculates an address from a base register value and an immediate offset, loads a byte from memory, zero-extends it to form a 32-bit word, and writes it to a register.

When privileged software uses an [LDRBT](#) instruction, the memory access is restricted as if the software was unprivileged.

### T1

### T1 variant

LDRBT{<c>}{<q>} <Rt>, [<Rn> {, #<+><imm>}]

### Decode for this encoding

```

1 if Rn == '1111' then SEE "LDRB (literal)";
2 if !HaveMainExt() then UNDEFINED;
3 t = UInt(Rt); n = UInt(Rn); postindex = FALSE; add = TRUE;
4 register_form = FALSE; imm32 = ZeroExtend(imm8, 32);
5 if t IN {13,15} then UNPREDICTABLE;
```

### Assembler symbols for all encodings

|       |                                                                                                                              |
|-------|------------------------------------------------------------------------------------------------------------------------------|
| <c>   | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                |
| <q>   | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                |
| <Rt>  | Is the general-purpose register to be transferred, encoded in the "Rt" field.                                                |
| <Rn>  | Is the general-purpose base register, encoded in the "Rn" field.                                                             |
| +     | Specifies the offset is added to the base register.                                                                          |
| <imm> | Is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field. |

### Operation for all encodings

```

1 if ConditionPassed() then
2     EncodingSpecificOperations();
3     address = R[n] + imm32;
4     R[t] = ZeroExtend(MemU_unpriv[address, 1], 32);
```

### Restricted behavior

#### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data being loaded.
- The point at which an asynchronous exception is taken does not vary based on the value or values being loaded by this instruction.

The timing invariance does not apply to the addresses being accessed.

## C2.4.85 LDRD (immediate)

Load Register Dual (immediate). Load Register Dual (immediate) calculates an address from a base register value and an immediate offset, loads two words from memory, and writes them to two registers. It can use offset, post-indexed, or pre-indexed addressing.

### T1

Armv8-M Main Extension only

|    |    |    |    |    |    |   |   |   |   |   |   |            |   |   |   |     |    |    |    |      |    |   |   |   |   |   |   |   |   |   |   |
|----|----|----|----|----|----|---|---|---|---|---|---|------------|---|---|---|-----|----|----|----|------|----|---|---|---|---|---|---|---|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3          | 2 | 1 | 0 | 15  | 14 | 13 | 12 | 11   | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 1  | 1  | 1  | 0  | 1  | 0  | 0 | P | U | 1 | W | 1 | Rn != 1111 |   |   |   | Rt  |    |    |    |      |    |   |   |   |   |   |   |   |   |   |   |
|    |    |    |    |    |    |   |   |   |   |   |   |            |   |   |   | Rt2 |    |    |    | imm8 |    |   |   |   |   |   |   |   |   |   |   |

#### Offset variant

Applies when **P == 1 && W == 0**.

LDRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn> {, # {+/-} <imm>}]

#### Post-indexed variant

Applies when **P == 0 && W == 1**.

LDRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>], # {+/-} <imm>

#### Pre-indexed variant

Applies when **P == 1 && W == 1**.

LDRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>, # {+/-} <imm>] !

### Decode for this encoding

```

1 if P == '0' && W == '0' then SEE "Related encodings";
2 if Rn == '1111' then SEE "LDRD (literal)";
3 if !HaveMainExt() then UNDEFINED;
4 t = UInt(Rt); t2 = UInt(Rt2); n = UInt(Rn); imm32 = ZeroExtend(imm8:'00', 32);
5 index = (P == '1'); add = (U == '1'); wback = (W == '1');
6 if wback && (n == t || n == t2) then UNPREDICTABLE;
7 if t IN {13,15} || t2 IN {13,15} || t == t2 then UNPREDICTABLE;
```

### CONSTRAINED UNPREDICTABLE behavior

If **wback && (n == t || n == t2)**, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

### CONSTRAINED UNPREDICTABLE behavior

If **t == t2**, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The load instruction executes but the destination register takes an UNKNOWN value.

## Assembler symbols for all encodings

|       |                                                                                                                                                                                                                                                                                                                                                       |

| <C>   | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                                                                                                                                                                                                         |
| <q>   | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                                                                                                                                                                                                         |
| <Rt>  | Is the first general-purpose register to be transferred, encoded in the "Rt" field.                                                                                                                                                                                                                                                                   |
| <Rt2> | Is the second general-purpose register to be transferred, encoded in the "Rt2" field.                                                                                                                                                                                                                                                                 |
| <Rn>  | Is the general-purpose base register, encoded in the "Rn" field. For PC use see <a href="#">C2.4.86 LDRD (literal)</a> .                                                                                                                                                                                                                              |
| +/-   | Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values: <ul style="list-style-type: none"> <li>- when U = 0</li> <li>+ when U = 1</li> </ul>                                                                                                |
| <imm> | For the offset variant: is the optional unsigned immediate byte offset, a multiple of 4, in the range 0 to 1020, defaulting to 0 and encoded in the "imm8" field as <imm>/4.<br>For the post-indexed and pre-indexed variant: is the unsigned immediate byte offset, a multiple of 4, in the range 0 to 1020, encoded in the "imm8" field as <imm>/4. |

## Operation for all encodings

```

1  if ConditionPassed() then
2      EncodingSpecificOperations();
3      offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
4      address = if index then offset_addr else R[n];
5
6      // Determine if the stack pointer limit should be checked
7      if n == 13 && wback then
8          violatesLimit = ViolatesSPLim(LookUpSP(), offset_addr);
9      else
10         violatesLimit = FALSE;
11     // Memory operation only performed if limit not violated
12     if !violatesLimit then
13         R[t] = MemA[address, 4];
14         R[t2] = MemA[address+4, 4];
15
16     // If the stack pointer is being updated a fault will be raised if
17     // the limit is violated
18     if wback then RSPCheck[n] = offset_addr;
```

## Restricted behavior

### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data being loaded.
- The point at which an asynchronous exception is taken does not vary based on the value or values being loaded by this instruction.

The timing invariance does not apply to the addresses being accessed.

## C2.4.86 LDRD (literal)

Load Register Dual (literal). Load Register Dual (literal) calculates an address from the PC value and an immediate offset, loads two words from memory, and writes them to two registers.

For the M profile, the PC value must be word-aligned, otherwise the behavior of the instruction is UNPREDICTABLE.

### T1

Armv8-M Main Extension only

### T1 variant

```
LDRD{<c>}{<q>} <Rt>, <Rt2>, <label>
    // Normal form
LDRD{<c>}{<q>} <Rt>, <Rt2>, [PC, #{+/-}<imm>]
    // Alternative form
```

### Decode for this encoding

```
1 if P == '0' && W == '0' then SEE "Related encodings";
2 if P == '1' && W == '1' && U == '0' then SEE SG;
3 if !HaveMainExt() then UNDEFINED;
4 t = UInt(Rt); t2 = UInt(Rt2);
5 imm32 = ZeroExtend(imm8:'00', 32); add = (U == '1');
6 if t IN {13,15} || t2 IN {13,15} || t == t2 then UNPREDICTABLE;
7 if W == '1' then UNPREDICTABLE;
```

### CONSTRAINED UNPREDICTABLE behavior

If  $t == t2$ , then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The load instruction executes but the destination register takes an UNKNOWN value.

### CONSTRAINED UNPREDICTABLE behavior

If  $W == '1'$ , then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without write-back of the base address.
- The instruction uses post-indexed addressing when  $P == '0'$  and uses pre-indexed addressing otherwise.

|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <label> | The label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the <a href="#">Align</a> (PC, 4) value of the instruction to this label. Permitted values of the offset are multiples of 4 in the range -1020 to 1020. If the offset is zero or positive, imm32 is equal to the offset and add == TRUE, encoded as U == 1. If the offset is negative, imm32 is equal to minus the offset and add == FALSE, encoded as U == 0. |
| +/-     | Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:<br>- when U = 0<br>+ when U = 1                                                                                                                                                                                                                                                                                                |
| <imm>   | Is the optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field.                                                                                                                                                                                                                                                                                                                                                                    |

### Operation for all encodings

```

1 if ConditionPassed() then
2     EncodingSpecificOperations();
3     if PC[1:0] != '00' then UNPREDICTABLE;
4     address = if add then (PC + imm32) else (PC - imm32);
5     R[t] = MemA[address, 4];
6     R[t2] = MemA[address+4, 4];

```

### CONSTRAINED UNPREDICTABLE behavior

If PC<1:0> != '00', then one of the following behaviors must occur:

- The instruction executes as described, with no change to its behavior and no additional side effects.
- The instruction generates an UNALIGNED UsageFault.

### Restricted behavior

#### Data Independent Timing behavior

If [AIRCR.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data being loaded.
- The point at which an asynchronous exception is taken does not vary based on the value or values being loaded by this instruction.

The timing invariance does not apply to the addresses being accessed.

## C2.4.87 LDREX

Load Register Exclusive. Load Register Exclusive calculates an address from a base register value and an immediate offset, loads a word from memory, writes it to a register, and:

- If the address has the Shareable memory attribute, marks the physical address as exclusive access for the executing PE in a global monitor.
- Causes the executing PE to indicate an active exclusive access in the local monitor.

#### Offset variant

Applies when Rt != 1111 && P == 1 && U == 0 && W == 0.

LDRH{<c>}{<q>} <Rt>, [<Rn> {, #-<imm>}]

#### Post-indexed variant

Applies when P == 0 && W == 1.

LDRH{<c>}{<q>} <Rt>, [<Rn>], #{+/-}<imm>

### Pre-indexed variant

Applies when **P == 1 && W == 1**.

LDRH{<c>}{<q>} <Rt>, [<Rn>], #{+/-}<imm>!

### Decode for this encoding

```
1 if Rn == '1111' then SEE "LDRH (literal)";
2 if Rt == '1111' && P == '1' && U == '0' && W == '0' then SEE "Related encodings";
3 if P == '1' && U == '1' && W == '0' then SEE LDRHT;
4 if P == '0' && W == '0' then UNDEFINED;
5 if !HaveMainExt() then UNDEFINED;
6 t = UInt(Rt); n = UInt(Rn); imm32 = ZeroExtend(imm8, 32);
7 index = (P == '1'); add = (U == '1'); wback = (W == '1');
8 if t == 13 || (t == 15 && W == '1') || (wback && n == t) then UNPREDICTABLE;
```

### CONSTRAINED UNPREDICTABLE behavior

If **wback && n == t**, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

### Assembler symbols for all encodings

| <q>   | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <Rt>  | Is the general-purpose register to be transferred, encoded in the "Rt" field.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <Rn>  | For encoding T1: is the general-purpose base register, encoded in the "Rn" field.<br>For encoding T2 and T3: is the general-purpose base register, encoded in the "Rn" field. For PC use see <a href="#">C2.4.91 LDRH (literal)</a> .                                                                                                                                                                                                                                                                                                                                                                                            |
| +/-   | Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values: <ul style="list-style-type: none"> <li>- when U = 0</li> <li>+ when U = 1</li> </ul>                                                                                                                                                                                                                                                                                                                                                                           |
| +     | Specifies the offset is added to the base register.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <imm> | For the post-indexed or pre-indexed variant: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, encoded in the "imm8" field.<br>For encoding T1: is the optional positive unsigned immediate byte offset, a multiple of 2 in the range 0 to 62, defaulting to 0 and encoded in the "imm5" field as <imm>/2.<br>For encoding T2: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.<br>For encoding T3: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field. |

### Operation for all encodings

```
1 if ConditionPassed() then
2   EncodingSpecificOperations();
3   offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
4   address = if index then offset_addr else R[n];
5
6   // Determine if the stack pointer limit should be checked
7   if n == 13 && wback then
```

```

8      violatesLimit = ViolatesSPLim(LookUpSP(), offset_addr);
9      else
10         violatesLimit = FALSE;
11         // Memory operation only performed if limit not violated
12         if !violatesLimit then
13             R[t] = ZeroExtend(MemU[address, 2], 32);
14
15         // If the stack pointer is being updated a fault will be raised if
16         // the limit is violated
17         if wback then RSPCheck[n] = offset_addr;

```

## Restricted behavior

### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1, and R15 is not being used as the destination register:

- The execution time of this instruction is insensitive to the value or values of the data being loaded.
- The point at which an asynchronous exception is taken does not vary based on the value or values being loaded by this instruction.

The timing invariance does not apply to the addresses being accessed.

## C2.4.91 LDRH (literal)

Load Register Halfword (literal). Load Register Halfword (literal) calculates an address from the PC value and an immediate offset, loads a halfword from memory, zero-extends it to form a 32-bit word, and writes it to a register.

### T1

| <Rt>    | Is the general-purpose register to be transferred, encoded in the "Rt" field.                                                                                                                                                                                                                                                                                                                                                                                        |
| <label> | The label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the <a href="#">Align</a> (PC, 4) value of the instruction to this label. Permitted values of the offset are -4095 to 4095. If the offset is zero or positive, imm32 is equal to the offset and add == TRUE, encoded as U == 1. If the offset is negative, imm32 is equal to minus the offset and add == FALSE, encoded as U == 0. |
| +/-     | Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:<br>- when U = 0<br>+ when U = 1                                                                                                                                                                                                                                                                    |
| <imm>   | Is a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.                                                                                                                                                                                                                                                                                                                                                                    |

### Operation for all encodings

```
1 if ConditionPassed() then
2   EncodingSpecificOperations();
3   base = Align(PC, 4);
4   address = if add then (base + imm32) else (base - imm32);
5   data = MemU[address, 2];
6   R[t] = ZeroExtend(data, 32);
```

### Restricted behavior

#### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data being loaded.

- The point at which an asynchronous exception is taken does not vary based on the value or values being loaded by this instruction.

The timing invariance does not apply to the addresses being accessed.

## C2.4.92 LDRH (register)

Load Register Halfword (register). Load Register Halfword (register) calculates an address from a base register value and an offset register value, loads a halfword from memory, zero-extends it to form a 32-bit word, and writes it to a register. The offset register value can be shifted left by 0, 1, 2, or 3 bits.

| <imm> | If present, the size of the left shift to apply to the value from <Rm>, in the range 1-3. <imm> is encoded in imm2. If absent, no shift is specified and imm2 is encoded as 0b00. |

### Operation for all encodings

```
1 if ConditionPassed() then
```

```

2      EncodingSpecificOperations();
3      offset = Shift(R[m], shift_t, shift_n, APSR.C);
4      offset_addr = if add then (R[n] + offset) else (R[n] - offset);
5      address = if index then offset_addr else R[n];
6      data = MemU(address, 2);
7      if wback then R[n] = offset_addr;
8      R[t] = ZeroExtend(data, 32);

```

## Restricted behavior

### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data being loaded.
- The point at which an asynchronous exception is taken does not vary based on the value or values being loaded by this instruction.

The timing invariance does not apply to the addresses being accessed.

## C2.4.93 LDRHT

Load Register Halfword Unprivileged. Load Register Halfword Unprivileged calculates an address from a base register value and an immediate offset, loads a halfword from memory, zero-extends it to form a 32-bit word, and writes it to a register.

When privileged software uses an [LDRHT](#) instruction, the memory access is restricted as if the software was unprivileged.

The timing invariance does not apply to the addresses being accessed.

## C2.4.94 LDRSB (immediate)

Load Register Signed Byte (immediate). Load Register Signed Byte (immediate) calculates an address from a base register value and an immediate offset, loads a byte from memory, sign-extends it to form a 32-bit word, and writes it to a register. It can use offset, post-indexed, or pre-indexed addressing.

#### Offset variant

Applies when **P == 1 && U == 0 && W == 0**.

LDRSB{<c>}{<q>} <Rt>, [<Rn> {, #-<imm>}]

#### Post-indexed variant

Applies when **P == 0 && W == 1**.

LDRSB{<c>}{<q>} <Rt>, [<Rn>], #<+/-><imm>

#### Pre-indexed variant

Applies when **P == 1 && W == 1**.

LDRSB{<c>}{<q>} <Rt>, [<Rn>, #<+/-><imm>]!

#### Decode for this encoding

```
1 if Rt == '1111' && P == '1' && U == '0' && W == '0' then SEE "PLI (immediate, literal)";
2 if Rn == '1111' then SEE "LDRSB (literal)";
3 if P == '1' && U == '1' && W == '0' then SEE LDRSBT;
4 if P == '0' && W == '0' then UNDEFINED;
5 if !HaveMainExt() then UNDEFINED;
6 t = UInt(Rt); n = UInt(Rn); imm32 = ZeroExtend(imm8, 32);
7 index = (P == '1'); add = (U == '1'); wback = (W == '1');
8 if t == 13 || (t == 15 && W == '1') || (wback && n == t) then UNPREDICTABLE;
```

## CONSTRAINED UNPREDICTABLE behavior

If `wback && n == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

## Assembler symbols for all encodings

|       |                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <Rt>  | Is the general-purpose register to be transferred, encoded in the "Rt" field.                                                                                                                                                                                                                                                                                                                                                                     |
| <Rn>  | Is the general-purpose base register, encoded in the "Rn" field. For PC use see <a href="#">C2.4.95 LDRSB (literal)</a> .                                                                                                                                                                                                                                                                                                                         |
| +/-   | Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values: <ul style="list-style-type: none"> <li>- when U = 0</li> <li>+ when U = 1</li> </ul>                                                                                                                                                                                            |
| +     | Specifies the offset is added to the base register.                                                                                                                                                                                                                                                                                                                                                                                               |
| <imm> | For the post-indexed or pre-indexed variant: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, encoded in the "imm8" field.<br>For encoding T1: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.<br>For encoding T2: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field. |

## Operation for all encodings

```

1  if ConditionPassed() then
2      EncodingSpecificOperations();
3      offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
4      address = if index then offset_addr else R[n];
5
6      // Determine if the stack pointer limit should be checked
7      if n == 13 && wback then
8          violatesLimit = ViolatesSPLim(LookUpSP(), offset_addr);
9      else
10         violatesLimit = FALSE;
11     // Memory operation only performed if limit not violated
12     if !violatesLimit then
13         R[t] = SignExtend(MemU(address, 1), 32);
14
15     // If the stack pointer is being updated a fault will be raised if
16     // the limit is violated
17     if wback then RSPCheck[n] = offset_addr;
```

## Restricted behavior

### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1, and R15 is not being used as the destination register:

- The execution time of this instruction is insensitive to the value or values of the data being loaded.
- The point at which an asynchronous exception is taken does not vary based on the value or values being loaded by this instruction.

The timing invariance does not apply to the addresses being accessed.

## C2.4.95 LDRSB (literal)

Load Register Signed Byte (literal). Load Register Signed Byte (literal) calculates an address from the PC value and an immediate offset, loads a byte from memory, sign-extends it to form a 32-bit word, and writes it to a register.

| <Rt>    | Is the general-purpose register to be transferred, encoded in the "Rt" field.                                                                                                                                                                                                                                                                                                                                                                                        |
| <label> | The label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the <a href="#">Align</a> (PC, 4) value of the instruction to this label. Permitted values of the offset are -4095 to 4095. If the offset is zero or positive, imm32 is equal to the offset and add == TRUE, encoded as U == 1. If the offset is negative, imm32 is equal to minus the offset and add == FALSE, encoded as U == 0. |
| +/-     | Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values: <ul style="list-style-type: none"> <li>- when U = 0</li> <li>+ when U = 1</li> </ul>                                                                                                                                                                                                               |
| <imm>   | Is a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.                                                                                                                                                                                                                                                                                                                                                                    |

### Operation for all encodings

```
1 if ConditionPassed() then
2   EncodingSpecificOperations();
3   base = Align(PC, 4);
4   address = if add then (base + imm32) else (base - imm32);
5   R[t] = SignExtend(MemU[address, 1], 32);
```

### Restricted behavior

#### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data being loaded.

- The point at which an asynchronous exception is taken does not vary based on the value or values being loaded by this instruction.

The timing invariance does not apply to the addresses being accessed.

## C2.4.96 LDRSB (register)

Load Register Signed Byte (register). Load Register Signed Byte (register) calculates an address from a base register value and an offset register value, loads a byte from memory, sign-extends it to form a 32-bit word, and writes it to a register. The offset register value can be shifted left by 0, 1, 2, or 3 bits.

| <Rt>  | Is the general-purpose register to be transferred, encoded in the "Rt" field.                                                                                                     |
| <Rn>  | Is the general-purpose base register, encoded in the "Rn" field.                                                                                                                  |
| +     | Specifies the index register is added to the base register.                                                                                                                       |
| <Rm>  | Is the general-purpose index register, encoded in the "Rm" field.                                                                                                                 |
| <imm> | If present, the size of the left shift to apply to the value from <Rm>, in the range 1-3. <imm> is encoded in imm2. If absent, no shift is specified and imm2 is encoded as 0b00. |

## Operation for all encodings

```
1 if ConditionPassed() then
```

```

2      EncodingSpecificOperations();
3      offset = Shift(R[m], shift_t, shift_n, APSR.C);
4      offset_addr = if add then (R[n] + offset) else (R[n] - offset);
5      address = if index then offset_addr else R[n];
6      R[t] = SignExtend(MemU[address, 1], 32);

```

## Restricted behavior

### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data being loaded.
- The point at which an asynchronous exception is taken does not vary based on the value or values being loaded by this instruction.

The timing invariance does not apply to the addresses being accessed.

## C2.4.97 LDRSBT

Load Register Signed Byte Unprivileged. Load Register Signed Byte Unprivileged calculates an address from a base register value and an immediate offset, loads a byte from memory, sign-extends it to form a 32-bit word, and writes it to a register.

When privileged software uses an **LDRSBT** instruction, the memory access is restricted as if the software was unprivileged.

3     address = R[n] + imm32;
4     R[t] = SignExtend(MemU_unpriv[address, 1], 32);

```

### Restricted behavior

#### Data Independent Timing behavior

If **AIRCR.DIT** is 1:

- The execution time of this instruction is insensitive to the value or values of the data being loaded.
- The point at which an asynchronous exception is taken does not vary based on the value or values being loaded by this instruction.

The timing invariance does not apply to the addresses being accessed.

## C2.4.98 LDRSH (immediate)

Load Register Signed Halfword (immediate). Load Register Signed Halfword (immediate) calculates an address from a base register value and an immediate offset, loads a halfword from memory, sign-extends it to form a 32-bit word, and writes it to a register. It can use offset, post-indexed, or pre-indexed addressing.

#### Offset variant

Applies when Rt != 1111 && P == 1 && U == 0 && W == 0.

LDRSH{<c>}{<q>} <Rt>, [<Rn> {, #-<imm>}]

#### Post-indexed variant

Applies when P == 0 && W == 1.

LDRSH{<c>}{<q>} <Rt>, [<Rn>], #{+/-}<imm>

#### Pre-indexed variant

Applies when P == 1 && W == 1.

LDRSH{<c>}{<q>} <Rt>, [<Rn>, #{+/-}<imm>]!

#### Decode for this encoding

```
1 if Rn == '1111' then SEE "LDRSH (literal)";
2 if Rt == '1111' && P == '1' && U == '0' && W == '0' then SEE "Related encodings";
3 if P == '1' && U == '1' && W == '0' then SEE LDRSHT;
4 if P == '0' && W == '0' then UNDEFINED;
5 if !HaveMainExt() then UNDEFINED;
6 t = UInt(Rt); n = UInt(Rn); imm32 = ZeroExtend(imm8, 32);
7 index = (P == '1'); add = (U == '1'); wback = (W == '1');
8 if t == 13 || (t == 15 && W == '1') || (wback && n == t) then UNPREDICTABLE;
```

## CONSTRAINED UNPREDICTABLE behavior

If `wback && n == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

| <Rt>  | Is the general-purpose register to be transferred, encoded in the "Rt" field.                                                                                                                                                                                                                                                                                                                                                                     |
| <Rn>  | Is the general-purpose base register, encoded in the "Rn" field. For PC use see <a href="#">C2.4.99 LDRSH (literal)</a> .                                                                                                                                                                                                                                                                                                                         |
| +/-   | Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values: <ul style="list-style-type: none"> <li>- when U = 0</li> <li>+ when U = 1</li> </ul>                                                                                                                                                                                            |
| +     | Specifies the offset is added to the base register.                                                                                                                                                                                                                                                                                                                                                                                               |
| <imm> | For the post-indexed or pre-indexed variant: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, encoded in the "imm8" field.<br>For encoding T1: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.<br>For encoding T2: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field. |

## Operation for all encodings

```

1  if ConditionPassed() then
2      EncodingSpecificOperations();
3      offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
4      address = if index then offset_addr else R[n];
5      // Determine if the stack pointer limit should be checked
6      if n == 13 && wback then
7          violatesLimit = ViolatesSPLim(LookUpSP(), offset_addr);
8      else
9          violatesLimit = FALSE;
10     // Memory operation only performed if limit not violated
11     if !violatesLimit then
12         R[t] = SignExtend(MemU(address, 2), 32);
13
14     // If the stack pointer is being updated a fault will be raised if
15     // the limit is violated
16     if wback then RSPCheck[n] = offset_addr;
```

## Restricted behavior

### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1, and R15 is not being used as the destination register:

- The execution time of this instruction is insensitive to the value or values of the data being loaded.
- The point at which an asynchronous exception is taken does not vary based on the value or values being loaded by this instruction.

The timing invariance does not apply to the addresses being accessed.

## C2.4.99 LDRSH (literal)

Load Register Signed Halfword (literal). Load Register Signed Halfword (literal) calculates an address from the PC value and an immediate offset, loads a halfword from memory, sign-extends it to form a 32-bit word, and writes it to a register.

| <Rt>    | Is the general-purpose register to be transferred, encoded in the "Rt" field.                                                                                                                                                                                                                                                                                                                                                                                        |
| <label> | The label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the <a href="#">Align</a> (PC, 4) value of the instruction to this label. Permitted values of the offset are -4095 to 4095. If the offset is zero or positive, imm32 is equal to the offset and add == TRUE, encoded as U == 1. If the offset is negative, imm32 is equal to minus the offset and add == FALSE, encoded as U == 0. |
| +/-     | Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:<br>- when U = 0<br>+ when U = 1                                                                                                                                                                                                                                                                    |
| <imm>   | Is a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.                                                                                                                                                                                                                                                                                                                                                                    |

### Operation for all encodings

```
1 if ConditionPassed() then
2   EncodingSpecificOperations();
3   base = Align(PC, 4);
4   address = if add then (base + imm32) else (base - imm32);
5   data = MemU(address, 2);
6   R[t] = SignExtend(data, 32);
```

### Restricted behavior

#### Data Independent Timing behavior

If [AIRCR.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data being loaded.

- The point at which an asynchronous exception is taken does not vary based on the value or values being loaded by this instruction.

The timing invariance does not apply to the addresses being accessed.

## C2.4.100 LDRSH (register)

Load Register Signed Halfword (register). Load Register Signed Halfword (register) calculates an address from a base register value and an offset register value, loads a halfword from memory, sign-extends it to form a 32-bit word, and writes it to a register. The offset register value can be shifted left by 0, 1, 2, or 3 bits.

| <imm> | If present, the size of the left shift to apply to the value from <Rm>, in the range 1-3. <imm> is encoded in imm2. If absent, no shift is specified and imm2 is encoded as 0b00. |

### Operation for all encodings

```
1 if ConditionPassed() then
```

```

2      EncodingSpecificOperations();
3      offset = Shift(R[m], shift_t, shift_n, APSR.C);
4      offset_addr = if add then (R[n] + offset) else (R[n] - offset);
5      address = if index then offset_addr else R[n];
6      data = MemU(address, 2);
7      if wback then R[n] = offset_addr;
8      R[t] = SignExtend(data, 32);

```

## Restricted behavior

### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data being loaded.
- The point at which an asynchronous exception is taken does not vary based on the value or values being loaded by this instruction.

The timing invariance does not apply to the addresses being accessed.

### C2.4.101 LDRSHT

Load Register Signed Halfword Unprivileged. Load Register Signed Halfword Unprivileged calculates an address from a base register value and an immediate offset, loads a halfword from memory, sign-extends it to form a 32-bit word, and writes it to a register.

When privileged software uses an **LDRSHT** instruction, the memory access is restricted as if the software was unprivileged.

```

### Restricted behavior

#### Data Independent Timing behavior

If [AIRCR.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data being loaded.
- The point at which an asynchronous exception is taken does not vary based on the value or values being loaded by this instruction.

The timing invariance does not apply to the addresses being accessed.

### C2.4.103 LE, LETP

Loop End, Loop End with Tail Predication. If additional iterations of a loop are required this instruction branches back to the <label>. It also stores the loop information in the loop info cache so that future iterations of the loop will branch back to the start just before the LE instruction is encountered. The first variant of the instruction checks a loop iteration counter (stored in LR) to determine if additional iterations are required. It also decrements the counter ready for the next iteration.

The second variant does not use an iteration count and always triggers another iteration of the loop.

The third (TP) variant also checks the loop iteration counter to determine if additional iterations are required. However the counter is decremented by the number of elements of a vector (as indicated by the FPSCR.LTPSIZE field). On the last iteration of the loop, this variant disables tail predication.

This instruction is not permitted in an IT block.

27     // Branch to the start of the loop
28     BranchTo(jumpAddr);

```

### C2.4.104 LSL (immediate)

Logical Shift Left (immediate). Logical Shift Left (immediate) shifts a register value left by an immediate number of bits, shifting in zeros, and writes the result to the destination register.

This instruction is an alias of the [MOV \(register\)](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [MOV \(register\)](#).
- The description of [MOV \(register\)](#) gives the operational pseudocode for this instruction.

#### T2

### Operation for all encodings

The description of [MOV \(register\)](#) gives the operational pseudocode for this instruction.

### Restricted behavior

#### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the N, Z, C, V flags.
- The point at which an asynchronous exception is taken does not vary based on any of the following:
  - The values of the data supplied in any the registers bwing used in this instruction.
  - The values of the N, Z, C, V flags.

### C2.4.105 LSL (register)

Logical Shift Left (register). Logical Shift Left (register) shifts a register value left by a variable number of bits, shifting in zeros, and writes the result to the destination register. The variable number of bits is read from the bottom byte of a register.

This instruction is an alias of the [MOV, MOVS \(register-shifted register\)](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [MOV, MOVS \(register-shifted register\)](#).
- The description of [MOV, MOVS \(register-shifted register\)](#) gives the operational pseudocode for this instruction.

### Operation for all encodings

The description of [MOV \(register\)](#) gives the operational pseudocode for this instruction.

### Restricted behavior

#### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the N, Z, C, V flags.
- The point at which an asynchronous exception is taken does not vary based on any of the following:
  - The values of the data supplied in any the registers bwing used in this instruction.
  - The values of the N, Z, C, V flags.

### C2.4.109 LSLS (register)

Logical Shift Left, Setting flags (register). Logical Shift Left, Setting flags (register) shifts a register value left by a variable number of bits, shifting in zeros, writes the result to the destination register, and updates the condition flags based on the result. The variable number of bits is read from the bottom byte of a register.

This instruction is an alias of the [MOV, MOVS \(register-shifted register\)](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [MOV, MOVS \(register-shifted register\)](#).
- The description of [MOV, MOVS \(register-shifted register\)](#) gives the operational pseudocode for this instruction.

#### T1

*Armv8-M*

|    |    |    |    |    |    |           |   |   |   |    |   |   |     |   |   |
|----|----|----|----|----|----|-----------|---|---|---|----|---|---|-----|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9         | 8 | 7 | 6 | 5  | 4 | 3 | 2   | 1 | 0 |
| 0  | 1  | 0  | 0  | 0  | 0  | op = 0010 |   |   |   | Rs |   |   | Rdm |   |   |

#### Logical shift left variant

```
LSLS{<q>} {<Rdm>, } <Rdm>, <Rs>
// Outside IT block
```

is equivalent to

```
MOVS{<q>} <Rdm>, <Rdm>, LSL <Rs>
```

and is the preferred disassembly when `!InITBlock()`.

#### T2

*Armv8-M Main Extension only*

|    |    |    |    |    |    |   |   |   |   |   |   |    |   |   |   |    |    |    |    |    |    |   |   |   |   |   |   |    |   |   |   |
|----|----|----|----|----|----|---|---|---|---|---|---|----|---|---|---|----|----|----|----|----|----|---|---|---|---|---|---|----|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3  | 2 | 1 | 0 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3  | 2 | 1 | 0 |
| 1  | 1  | 1  | 1  | 1  | 0  | 1 | 0 | 0 |   |   |   | Rm |   |   |   | 1  | 1  | 1  | 1  | Rd |    |   |   | 0 | 0 | 0 | 0 | Rs |   |   |   |

sr\_type = 00
S = 1

#### Flag setting variant

```
LSLS.W {<Rd>, } <Rm>, <Rs>
// Outside IT block, and <Rd>, <Rm>, <sr_type>, <Rs> can be represented in T1
```

is equivalent to

```
MOVS{<c>}{<q>} <Rd>, <Rm>, LSL <Rs>
```

and is always the preferred disassembly.

#### Flag setting variant

```
LSLS{<c>}{<q>} {<Rd>, } <Rm>, <Rs>
```

is equivalent to

```
MOVS{<c>}{<q>} <Rd>, <Rm>, LSL <Rs>
```

and is always the preferred disassembly.

### Assembler symbols for all encodings

|       |                                                                                                                       |
|-------|-----------------------------------------------------------------------------------------------------------------------|
| <C>   | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                         |
| <q>   | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                         |
| <Rdm> | Is the first general-purpose source register and the destination register, encoded in the "Rdm" field.                |
| <Rd>  | Is the general-purpose destination register, encoded in the "Rd" field.                                               |
| <Rm>  | Is the first general-purpose source register, encoded in the "Rm" field.                                              |
| <Rs>  | Is the second general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field. |

### Operation for all encodings

The description of [MOV, MOVS \(register-shifted register\)](#) gives the operational pseudocode for this instruction.

### Restricted behavior

#### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the N, Z, C, V flags.
- The point at which an asynchronous exception is taken does not vary based on any of the following:
  - The values of the data supplied in any the registers bwing used in this instruction.
  - The values of the N, Z, C, V flags.

### C2.4.110 LSR (immediate)

Logical Shift Right (immediate). Logical Shift Right (immediate) shifts a register value right by an immediate number of bits, shifting in zeros, and writes the result to the destination register.

This instruction is an alias of the [MOV \(register\)](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [MOV \(register\)](#).
- The description of [MOV \(register\)](#) gives the operational pseudocode for this instruction.

### Operation for all encodings

The description of [MOV \(register\)](#) gives the operational pseudocode for this instruction.

### Restricted behavior

#### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the N, Z, C, V flags.
- The point at which an asynchronous exception is taken does not vary based on any of the following:
  - The values of the data supplied in any the registers bwing used in this instruction.
  - The values of the N, Z, C, V flags.

### C2.4.114 LSRS (register)

Logical Shift Right, Setting flags (register). Logical Shift Right, Setting flags (register) shifts a register value right by a variable number of bits, shifting in zeros, writes the result to the destination register, and updates the condition flags based on the result. The variable number of bits is read from the bottom byte of a register.

This instruction is an alias of the [MOV, MOVS \(register-shifted register\)](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [MOV, MOVS \(register-shifted register\)](#).
- The description of [MOV, MOVS \(register-shifted register\)](#) gives the operational pseudocode for this instruction.

```

#### Restricted behavior

##### Data Independent Timing behavior

If [AIRC.RDIT](#) is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the N, Z, C, V flags.
- The point at which an asynchronous exception is taken does not vary based on any of the following:

- The values of the data supplied in any the registers bwing used in this instruction.
- The values of the N, Z, C, V flags.

## C2.4.118 MLS

Multiply and Subtract. Multiply and Subtract multiplies two register values, and subtracts the least significant 32 bits of the result from a third register value. These 32 bits do not depend on whether signed or unsigned calculations are performed. The result is written to the destination register.

#### T2 variant

MOV<c>{<q>} <Rd>, <Rm> {, <shift> #<amount>}  
// Inside IT block  
MOVS{<q>} <Rd>, <Rm> {, <shift> #<amount>}  
// Outside IT block

#### Decode for this encoding

```
1 if op == '11' then SEE "Related encodings";
2 d = UInt(Rd); m = UInt(Rm); setflags = !InITBlock();
3 (shift_t, shift_n) = DecodeImmShift(op, imm5);
4 if op == '00' && imm5 == '00000' && InITBlock() then UNPREDICTABLE;
```

#### CONSTRAINED UNPREDICTABLE behavior

If op == '00' && imm5 == '00000' && InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passed its condition code check.
- The instruction executes as [NOP](#), as if it failed its condition code check.
- The instruction executes as MOV Rd, Rm.

## T3

Armv8-M Main Extension only

- In Armv8.0-M, bit[15] (lower 16 bits of the encoding) [0] represents (0).
- In Armv8.1-M, bit[15] (lower 16 bits of the encoding) [0] represents 0.

| <Rd>     | For encoding T1: is the general-purpose destination register, encoded in the "D:Rd" field. If the PC is used: <ul style="list-style-type: none"> <li>- The instruction causes a simple branch to the address moved to the PC.</li> <li>- The instruction must either be outside an IT block or the last instruction of an IT block.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <Rm>     | For encoding T2 and T3: is the general-purpose destination register, encoded in the "Rd" field. For encoding T1: is the general-purpose source register, encoded in the "Rm" field. The PC can be used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <shift>  | For encoding T2 and T3: is the general-purpose source register, encoded in the "Rm" field. For encoding T2: is the type of shift to be applied to the source register, encoded in the "op" field. It can have the following values: <ul style="list-style-type: none"> <li>LSL when <math>sr\_type = 00</math></li> <li>LSR when <math>sr\_type = 01</math></li> <li>ASR when <math>sr\_type = 10</math></li> </ul> For encoding T3: is the type of shift to be applied to the source register, encoded in the "sr_type" field. It can have the following values: <ul style="list-style-type: none"> <li>LSL when <math>sr\_type = 00</math></li> <li>LSR when <math>sr\_type = 01</math></li> <li>ASR when <math>sr\_type = 10</math></li> <li>ROR when <math>sr\_type = 11</math></li> </ul> |
| <amount> | For encoding T2: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32. For encoding T3: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm3:imm2" field as <amount> modulo 32.                                                                                                                                                                                                                                                                                                                                                                                                                         |

### Operation for all encodings

```

1  if ConditionPassed() then
2      EncodingSpecificOperations();
3      (result, carry) = Shift_C(R[m], shift_t, shift_n, APSR.C);
4      if d == 15 then
5          BranchTo(result); // setflags is always FALSE here
6      else
7          RSPCheck[d] = result;
8          if setflags then
9              APSR.N = result[31];
10             APSR.Z = IsZeroBit(result);
11             APSR.C = carry;
12             // APSR.V unchanged

```

## Restricted behavior

### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the N, Z, C, V flags.
- The point at which an asynchronous exception is taken does not vary based on any of the following:
  - The values of the data supplied in any the registers bwing used in this instruction.
  - The values of the N, Z, C, V flags.

### C2.4.121 MOV, MOVS (register-shifted register)

Move (register-shifted register). Move (register-shifted register) copies a register-shifted register value to the destination register. It can optionally update the condition flags based on the value.

This instruction is used by the aliases [ASRS \(register\)](#), [ASR \(register\)](#), [LSLS \(register\)](#), [LSL \(register\)](#), [LSRS \(register\)](#), [LSR \(register\)](#), [RORS \(register\)](#), [ROR \(register\)](#).

#### T1

Armv8-M

|    |    |    |    |    |    |    |   |   |    |   |   |     |   |   |   |
|----|----|----|----|----|----|----|---|---|----|---|---|-----|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8 | 7 | 6  | 5 | 4 | 3   | 2 | 1 | 0 |
| 0  | 1  | 0  | 0  | 0  | 0  | op |   |   | Rs |   |   | Rdm |   |   |   |

#### Arithmetic shift right variant

Applies when **op == 0100**.

```
MOV<c>{<q>} <Rdm>, <Rdm>, ASR <Rs>
// Inside IT block
MOVS{<q>} <Rdm>, <Rdm>, ASR <Rs>
// Outside IT block
```

#### Logical shift left variant

Applies when **op == 0010**.

```
MOV<c>{<q>} <Rdm>, <Rdm>, LSL <Rs>
// Inside IT block
MOVS{<q>} <Rdm>, <Rdm>, LSL <Rs>
// Outside IT block
```

#### Logical shift right variant

Applies when **op == 0011**.

```
MOV<c>{<q>} <Rdm>, <Rdm>, LSR <Rs>
// Inside IT block
MOVS{<q>} <Rdm>, <Rdm>, LSR <Rs>
// Outside IT block
```

#### Rotate right variant

Applies when **op == 0111**.

```
MOV<c>{<q>} <Rdm>, <Rdm>, ROR <Rs>
// Inside IT block
MOVS{<q>} <Rdm>, <Rdm>, ROR <Rs>
// Outside IT block
```

#### Decode for this encoding

```
1 if !(op IN {'0010', '0011', '0100', '0111'}) then SEE "Related encodings";
2 d = UInt(Rdm); m = UInt(Rdm); s = UInt(Rs);
3 setflags = !InITBlock(); shift_t = DecodeRegShift(op[2]:op[0]);
```

#### T2

Armv8-M Main Extension only

### Flag setting variant

Applies when **S == 1**.

```
MOVS.W <Rd>, <Rm>, <sr_type> <Rs>
// Outside IT block, and <Rd>, <Rm>, <sr_type>, <Rs> can be represented in T1
MOVS{<c>}{<q>} <Rd>, <Rm>, <sr_type> <Rs>
```

### Non flag setting variant

Applies when **S == 0**.

```
MOV<c>.W <Rd>, <Rm>, <sr_type> <Rs>
// Inside IT block, and <Rd>, <Rm>, <sr_type>, <Rs> can be represented in T1
MOV{<c>}{<q>} <Rd>, <Rm>, <sr_type> <Rs>
```

### Decode for this encoding

```
1 if !HaveMainExt() then UNDEFINED;
2 d = UInt(Rd); m = UInt(Rm); s = UInt(Rs);
3 setflags = (S == '1'); shift_t = DecodeRegShift(sr_type);
4 if d IN {13,15} || m IN {13,15} || s IN {13,15} then UNPREDICTABLE;
```

### Alias conditions

| Alias           | variant                     | preferred when               |

| ROR (register)  | T1 (rotate right)           | op == '0111' && InITBlock()  |
| ROR (register)  | T2 (non flag setting)       | sr_type == '11' && S == '0'  |

### Assembler symbols for all encodings

<c> See [C1.2.5 Standard assembler syntax fields](#).  
 <q> See [C1.2.5 Standard assembler syntax fields](#).  
 <Rdm> Is the general-purpose source register and the destination register, encoded in the "Rdm" field.  
 <Rd> Is the general-purpose destination register, encoded in the "Rd" field.  
 <Rm> Is the general-purpose source register, encoded in the "Rm" field.  
 <sr\_type> Is the type of shift to be applied to the second source register, encoded in the "sr\_type" field. It can have the following values:  
     LSL when sr\_type = 00  
     LSR when sr\_type = 01

ASR   when `sr_type = 10`  
ROR   when `sr_type = 11`  
<Rs>   Is the general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.

### Operation for all encodings

```
1  if ConditionPassed() then
2      EncodingSpecificOperations();
3      shift_n = UInt(R[s][7:0]);
4      (result, carry) = Shift_C(R[m], shift_t, shift_n, APSR.C);
5      R[d] = result;
6      if setflags then
7          APSR.N = result[31];
8          APSR.Z = IsZeroBit(result);
9          APSR.C = carry;
10         // APSR.V unchanged
```

### Restricted behavior

#### Data Independent Timing behavior

If [AIRCR.DIT](#) is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the N, Z, C, V flags.
- The point at which an asynchronous exception is taken does not vary based on any of the following:
  - The values of the data supplied in any the registers bwing used in this instruction.
  - The values of the N, Z, C, V flags.

## C2.4.122 MOVt

Move Top. Move Top writes an immediate value to the top halfword of the destination register. It does not affect the contents of the bottom halfword.

### T1 variant

MOVt{<c>}{<q>} <Rd>, #<imm16>

### Decode for this encoding

```
1 d = UInt(Rd); imm16 = imm4:i:imm3:imm8;
2 if d IN {13,15} then UNPREDICTABLE;
```

### Assembler symbols for all encodings

<c> See [C1.2.5 Standard assembler syntax fields](#).  
 <q> See [C1.2.5 Standard assembler syntax fields](#).  
 <Rd> Is the general-purpose destination register, encoded in the "Rd" field.  
 <imm16> Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm4:i:imm3:imm8" field.

### Operation for all encodings

```
1 if ConditionPassed() then
2     EncodingSpecificOperations();
3     R[d][31:16] = imm16;
4     // R[d][15:0] unchanged
```

### Restricted behavior

#### Data Independent Timing behavior

If [AIRCR.DIT](#) is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the N, Z, C, V flags.
- The point at which an asynchronous exception is taken does not vary based on any of the following:
  - The values of the data supplied in any the registers bwing used in this instruction.
  - The values of the N, Z, C, V flags.

### C2.4.123 MRC, MRC2

Move to Register from Coprocessor. Move to Register from Coprocessor causes a coprocessor to transfer a value to a general-purpose register or to the condition flags.

Arm reserves coprocessors CP8 to CP15, and this manual defines the valid instructions when coproc is in this range.

|          |                                                                                                                                                                                                                     |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <c>      | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                                                                       |
| <q>      | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                                                                       |
| <coproc> | Is the name of the coprocessor, encoded in the "coproc" field. The generic coprocessor names are p0 to p15.                                                                                                         |
| <opc1>   | Is a coprocessor-specific opcode in the range 0 to 7, encoded in the "opc1" field.                                                                                                                                  |
| <Rt>     | Is the general-purpose register to be transferred or APSR_nzcv (encoded as 0b1111), encoded in the "Rt" field. If APSR_nzcv is used, bits [31:28] of the transferred value are written to the APSR condition flags. |
| <CRn>    | Is the first coprocessor register, encoded in the "CRn" field.                                                                                                                                                      |
| <CRm>    | Is the second coprocessor register, encoded in the "CRm" field.                                                                                                                                                     |
| <opc2>   | Is a coprocessor-specific opcode in the range 0 to 7, defaulting to 0 and encoded in the "opc2" field.                                                                                                              |

### Operation for all encodings

```
1  if ConditionPassed() then
2      EncodingSpecificOperations();
3      ExecuteCPCheck(cp);
4      if !Cproc_Accepted(cp, ThisInstr()) then
5          GenerateCoproprocessorException();
6      else
7          value = Coproc_GetOneWord(cp, ThisInstr());
8          if t != 15 then
9              R[t] = value;
10         else
11             APSR.N = value[31];
12             APSR.Z = value[30];
13             APSR.C = value[29];
14             APSR.V = value[28];
15             // value[27:0] are not used.
```

## C2.4.124 MRRC, MRRC2

Move to two Registers from Coprocessor. Move to two Registers from Coprocessor causes a coprocessor to transfer values to two general-purpose registers.

If no coprocessor can execute the instruction, a UsageFault exception is generated.

Arm reserves coprocessors CP8 to CP15, and this manual defines the valid instructions when coproc is in this range.

The following encodings are UNPREDICTABLE:

- SYSm = 00000100
- SYSm = 000011xx
- SYSm = 00010101
- SYSm = 0001011x
- SYSm = 00011xxx
- SYSm = 00101xxx
- SYSm = 0011xxxx
- SYSm = 01xxxxxx
- SYSm = 10000xxx
- SYSm = 100011xx
- SYSm = 10010010
- SYSm = 10010101
- SYSm = 1001011x
- SYSm = 10011001
- SYSm = 1001101x
- SYSm = 100111xx
- SYSm = 10101xxx
- SYSm = 1011xxxx
- SYSm = 11xxxxxx

An access to a register not ending in \_NS returns the register associated with the current Security state. Access to a register ending in \_NS in Secure state returns the Non-secure register. Access to a register ending in \_NS in Non-secure state is RAZ/WI. Access to BASEPRI\_MAX returns the contents of BASEPRI.

## Operation for all encodings

```

1  if ConditionPassed() then
2      EncodingSpecificOperations();
3      R[d] = Zeros(32);
4
5      // NOTE: the MSB of SYSm is used to select between either the current
6      // domains view of the registers and other domains view of the register.
7      // This is required so that the Secure state can access the Non-secure
8      // versions of banked registers. For security reasons the Secure versions of
9      // the registers are not accessible from the Non-secure state.
10     case SYSm[7:3] of
11         when '0000' // XPSR accesses

```

## CONSTRAINED UNPREDICTABLE behavior

If SYSm not valid special register, then one of the following behaviors must occur:

- The instruction is UNDEFINED.

- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

## Restricted behavior

### Data Independent Timing behavior and the PACBTI extension

If the PACBTI extension is implemented the timing of this instruction is insensitive to the value of the data being loaded or stored regardless of the value of [AIRCR.DIT](#) when accessing any of the following:

- [PAC\\_KEY\\_P\\_n](#).
- [PAC\\_KEY\\_U\\_n](#).

## C2.4.126 MSR (register)

Move to Special register from Register. Move to Special register from Register moves the value of a general-purpose register to the specified special-purpose register.

### T1

Armv8-M

|    |    |    |    |    |    |   |   |   |   |   |     |    |   |   |   |    |     |    |      |     |     |      |   |   |   |   |   |   |   |   |   |
|----|----|----|----|----|----|---|---|---|---|---|-----|----|---|---|---|----|-----|----|------|-----|-----|------|---|---|---|---|---|---|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4   | 3  | 2 | 1 | 0 | 15 | 14  | 13 | 12   | 11  | 10  | 9    | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

### T1 variant

MSR{<c>}{<q>} <spec\_reg>, <Rn>

### Decode for this encoding

```

1 n = UInt(Rn);
2 if HaveMainExt() then
3     if mask == '00' || (mask != '10' && !(UInt(SYSm) IN {0..3})) then UNPREDICTABLE;
4 else
5     if mask != '10' then UNPREDICTABLE;
6 if n IN {13,15} then UNPREDICTABLE;
```

### CONSTRAINED UNPREDICTABLE behavior

If combination of SYSm and mask not supported, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction treats mask and SYSm as UNKNOWN.

### Encoding conditions

| <bits>   | Effect                                    | mask encoding | Notes                         |
|----------|-------------------------------------------|---------------|-------------------------------|
| _nzcvcq  | Write the N, Z, C, V, Q bits, APSR[31:27] | 0b10          | Always supported              |
| _g       | Write the GE[3:0] bits, APSR[19:16]       | 0b01          | Supported only if the PE      |
| _nzcvcqg | Write the N, Z, C, V, Q, GE[3:0] bits     | 0b11          | implements the DSP extension. |

### Assembler symbols for all encodings

The following encodings are UNPREDICTABLE:

- SYSm = 00000100
- SYSm = 000011xx
- SYSm = 00010101
- SYSm = 0001011x
- SYSm = 00011xxx
- SYSm = 00101xxx
- SYSm = 0011xxxx
- SYSm = 01xxxxxx
- SYSm = 10000xxx
- SYSm = 100011xx
- SYSm = 10010010
- SYSm = 10010101
- SYSm = 1001011x
- SYSm = 10011001
- SYSm = 1001101x
- SYSm = 100111xx
- SYSm = 10101xxx
- SYSm = 1011xxxx
- SYSm = 11xxxxxx

An access to a register not ending in `_NS` returns the register associated with the current Security state. Access to a register ending in `_NS` in Secure state returns the Non-secure register. Access to a register ending in `_NS` in Non-secure state is RAZ/WI. Access to `BASEPRI_MAX` writes to `BASEPRI` if the priority that is written is higher than the existing priority in `BASEPRI`. Otherwise, the access is ignored.

<Rn>

Is the general-purpose source register, encoded in the "Rn" field.

### Operation for all encodings

```

1 if ConditionPassed() then
2     EncodingSpecificOperations();
3
4     // NOTE: the MSB of SYSm is used to select between either the current

```

```

5      // domains view of the registers and other domains view of the register.
6      // This is required to that the Secure state can access the Non-secure
7      // versions of banked registers. For security reasons the Secure versions of
8      // the registers are not accessible from the Non-secure state.
9      case SYSm[7:3] of

156                     // MSR SP_NS is subject to SP limit check. If a STKOF UsageFault is
157                     // generated then it can target either the Secure or Non-secure state
158                     - = _SP(spName, FALSE, FALSE, R[n]);
159                 otherwise
160                     UNPREDICTABLE;
161     when '10100' // Access to Non-secure PAC keys
162         if !HavePACBTIExt() then UNPREDICTABLE; // PACBTI Extension required
163         if CurrentModeIsPrivileged() && CurrentState == SecurityState_Secure then
164             PACKeyReg[SYSm[2:0], FALSE] = R[n];
165     otherwise
166         UNPREDICTABLE;

```

### CONSTRAINED UNPREDICTABLE behavior

If SYSm not valid special register, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction treats SYSm as UNKNOWN.

### Restricted behavior

#### Data Independent Timing behavior and the PACBTI extension

If the PACBTI extension is implemented the timing of this instruction is insensitive to the value of the data being loaded or stored regardless of the value of [AIRCR.DIT](#) when accessing any of the following:

- [PAC\\_KEY\\_P\\_n](#).
- [PAC\\_KEY\\_U\\_n](#).

## C2.4.127 MUL

**Multiply.** Multiply multiplies two register values. The least significant 32 bits of the result are written to the destination register. These 32 bits do not depend on whether signed or unsigned calculations are performed.

It can optionally update the condition flags based on the result. In the T32 instruction set, this option is limited to only a few forms of the instruction. Use of this option adversely affects performance on many implementations.

### T1

| <c>   | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                  |
| <q>   | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                  |
| <Rdm> | Is the second general-purpose source register holding the multiplier and the destination register, encoded in the "Rdm" field. |
| <Rd>  | Is the general-purpose destination register, encoded in the "Rd" field.                                                        |
| <Rn>  | Is the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.                              |
| <Rm>  | Is the second general-purpose source register holding the multiplier, encoded in the "Rm" field.                               |
|       | If omitted, <Rd> is used.                                                                                                      |

### Operation for all encodings

```
1 if ConditionPassed() then
```

```

2      EncodingSpecificOperations();
3      operand1 = SInt(R[n]); // operand1 = UInt(R[n]) produces the same final results
4      operand2 = SInt(R[m]); // operand2 = UInt(R[m]) produces the same final results
5      result = operand1 * operand2;
6      R[d] = result[31:0];
7      if setflags then
8          APSR.N = result[31];
9          APSR.Z = IsZeroBit(result[31:0]);
10         // APSR.C unchanged
11         // APSR.V unchanged

```

## Restricted behavior

### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the N, Z, C, V flags.
- The point at which an asynchronous exception is taken does not vary based on any of the following:
  - The values of the data supplied in any the registers bwing used in this instruction.
  - The values of the N, Z, C, V flags.

## C2.4.128 MVN (immediate)

Bitwise NOT (immediate). Bitwise NOT (immediate) writes the bitwise inverse of an immediate value to the destination register. It can optionally update the condition flags based on the value.

### T1

4 if d IN {13,15} || m IN {13,15} then UNPREDICTABLE;
```

## Assembler symbols for all encodings

<c> See [C1.2.5 Standard assembler syntax fields](#).  
 <q> See [C1.2.5 Standard assembler syntax fields](#).  
 <Rd> Is the general-purpose destination register, encoded in the "Rd" field.  
 <Rm> Is the general-purpose source register, encoded in the "Rm" field.  
 <shift> Is the type of shift to be applied to the source register, encoded in the "sr\_type" field. It can have the following values:  
     LSL when sr\_type = 00  
     LSR when sr\_type = 01  
     ASR when sr\_type = 10  
     ROR when sr\_type = 11  
 <amount> Is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm3:imm2" field as <amount> modulo 32.

## Operation for all encodings

```
1 if ConditionPassed() then
2     EncodingSpecificOperations();
3     (shifted, carry) = Shift_C(R[m], shift_t, shift_n, APSR.C);
4     result = NOT(shifted);
5     R[d] = result;
6     if setflags then
7         APSR.N = result[31];
8         APSR.Z = IsZeroBit(result);
9         APSR.C = carry;
10        // APSR.V unchanged
```

### C2.4.130 NOP

No Operation. No Operation does nothing.

The architecture makes no guarantees about any timing effects of including a NOP instruction.

This is a NOP-compatible hint.

| <q>     | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                                      |
| <Rd>    | Is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.                                                             |
| <Rn>    | Is the general-purpose source register, encoded in the "Rn" field.                                                                                                                 |
| <const> | Is an immediate value derived from the 12-bit immediate that is encoded in the "i:imm3:imm8" field. See <a href="#">C1.5 Modified immediate constants</a> for the range of values. |

#### Operation for all encodings

```

1 if ConditionPassed() then
2     EncodingSpecificOperations();
3     result = R[n] OR NOT(imm32);
4     R[d] = result;
5     if setflags then
6         APSR.N = result[31];
7         APSR.Z = IsZeroBit(result);
8         APSR.C = carry;
9         // APSR.V unchanged
```

#### Restricted behavior

##### Data Independent Timing behavior

If [AIRCR.DIT](#) is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the N, Z, C, V flags.
- The point at which an asynchronous exception is taken does not vary based on any of the following:
  - The values of the data supplied in any the registers bwing used in this instruction.
  - The values of the N, Z, C, V flags.

### C2.4.132 ORN (register)

Logical OR NOT (register). Logical OR NOT (register) performs a bitwise (inclusive) OR of a register value and the complement of an optionally-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

#### T1

Armv8-M Main Extension only

#### ORN, rotate right with extend variant

Applies when **S == 0** && **imm3 == 000** && **imm2 == 00** && **sr\_type == 11**.

ORN{<c>}{<q>} {<Rd>}, {<Rn>}, <Rm>, RRX

#### ORN, shift or rotate by value variant

Applies when **S == 0** && **!(imm3 == 000 && imm2 == 00 && sr\_type == 11)**.

ORN{<c>}{<q>} {<Rd>}, {<Rn>}, <Rm> {, <shift> #<amount>}

#### ORNS, rotate right with extend variant

Applies when **S == 1** && **imm3 == 000** && **imm2 == 00** && **sr\_type == 11**.

ORNS{<c>}{<q>} {<Rd>}, {<Rn>}, <Rm>, RRX

#### ORNS, shift or rotate by value variant

Applies when **S == 1** && **!(imm3 == 000 && imm2 == 00 && sr\_type == 11)**.

ORNS{<c>}{<q>} {<Rd>}, {<Rn>}, <Rm> {, <shift> #<amount>}

#### Decode for this encoding

```

1 if Rn == '1111' then SEE "MVN (register)";
2 if !HaveMainExt() then UNDEFINED;
3 d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); setflags = (S == '1');
4 (shift_t, shift_n) = DecodeImmShift(sr_type, imm3:imm2);
5 if d IN {13,15} || n == 13 || m IN {13,15} then UNPREDICTABLE;
```

#### Assembler symbols for all encodings

|          |                                                                                                                                                                                                                                         |

| <q>      | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                                                                                           |
| <Rd>     | Is the general-purpose destination register, encoded in the "Rd" field.                                                                                                                                                                 |
| <Rn>     | Is the first general-purpose source register, encoded in the "Rn" field.                                                                                                                                                                |
| <Rm>     | Is the second general-purpose source register, encoded in the "Rm" field.                                                                                                                                                               |
| <shift>  | Is the type of shift to be applied to the second source register, encoded in the "sr_type" field. It can have the following values:<br>LSL when sr_type = 00<br>LSR when sr_type = 01<br>ASR when sr_type = 10<br>ROR when sr_type = 11 |
| <amount> | Is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm3:imm2" field as <amount> modulo 32.                                                                    |

### Operation for all encodings

```
1 if ConditionPassed() then  
2     EncodingSpecificOperations();  
3     (shifted, carry) = Shift_C(R[m], shift_t, shift_n, APSR.C);  
4     result = R[n] OR NOT(shifted);  
5     R[d] = result;  
6     if setflags then  
7         APSR.N = result[31];  
8         APSR.Z = IsZeroBit(result);  
9         APSR.C = carry;  
10        // APSR.V unchanged
```

### Restricted behavior

#### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the N, Z, C, V flags.
- The point at which an asynchronous exception is taken does not vary based on any of the following:
  - The values of the data supplied in any the registers bwing used in this instruction.
  - The values of the N, Z, C, V flags.

### C2.4.133 ORR (immediate)

Logical OR (immediate). Logical OR (immediate) performs a bitwise (inclusive) OR of a register value and an immediate value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

| <Rdn>    | Is the first general-purpose source register and the destination register, encoded in the "Rdn" field.                                                                                                                                  |
| <Rd>     | Is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.                                                                                                                  |
| <Rn>     | Is the first general-purpose source register, encoded in the "Rn" field.                                                                                                                                                                |
| <Rm>     | Is the second general-purpose source register, encoded in the "Rm" field.                                                                                                                                                               |
| <shift>  | Is the type of shift to be applied to the second source register, encoded in the "sr_type" field. It can have the following values:<br>LSL when sr_type = 00<br>LSR when sr_type = 01<br>ASR when sr_type = 10<br>ROR when sr_type = 11 |
| <amount> | Is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm3:imm2" field as <amount> modulo 32.                                                                    |

### Operation for all encodings

```
1 if ConditionPassed() then
2     EncodingSpecificOperations();
3     (shifted, carry) = Shift_C(R[m], shift_t, shift_n, APSR.C);
4     result = R[n] OR shifted;
5     R[d] = result;
6     if setflags then
7         APSR.N = result[31];
8         APSR.Z = IsZeroBit(result);
9         APSR.C = carry;
10        // APSR.V unchanged
```

### Restricted behavior

#### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the N, Z, C, V flags.
- The point at which an asynchronous exception is taken does not vary based on any of the following:

- The values of the data supplied in any the registers bwing used in this instruction.
- The values of the N, Z, C, V flags.

### C2.4.135 PAC

Pointer Authentication Code for the link register, using key. This instruction computes a pointer authentication code using LR as the address, SP as the modifier and, a key. The computed PAC is written to R12. The intended use of this instruction is for signing return addresses where the link register value should match the address used for function return.

This instruction is not permitted in an IT block.

This is a NOP-compatible hint.

#### T1 variant

PAC R12, LR, SP

#### Decode for this encoding

```
1 if !HaveMainExt() then UNDEFINED;
2 if InITBlock() then CONSTRAINED_UNPREDICTABLE;
```

#### CONSTRAINED UNPREDICTABLE behavior

If InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes unconditionally.
- The instruction executes conditionally.

#### Assembler symbols for all encodings

LR LR register, this instruction must always use this register.  
SP SP register, this instruction must always use this register.  
R12 R12 register, this instruction must always use this register.

#### Operation for all encodings

```
1 EncodingSpecificOperations();
2
3 if PACEEnabled() then
4     R[12] = CreatePAC(LR, SP);
```

#### Restricted behavior

##### Data Independent Timing behavior and the PACBTI extension

The timing of this instruction is insensitive to the value of the data being loaded or stored regardless of the value of AIRCR.DIT when accessing any of the following:

- PAC\_KEY\_P\_n.
- PAC\_KEY\_U\_n.

- The pointer value.
- The modifier value.
- The PAC value.

The point at which an asynchronous exception is taken does not vary based on any of the following:

- [PAC\\_KEY\\_P\\_n](#).
- [PAC\\_KEY\\_U\\_n](#).
- The pointer value.
- The modifier value.
- The PAC value.

## C2.4.136 PACBTI

Pointer Authentication Code for the link register with BTI clearing, using key. This instruction computes a pointer authentication code using LR as the address, SP as the modifier and, a key. The computed PAC is written to R12. The intended use of this instruction is for signing return addresses where the link register value should match the address used for function return.

This instruction is a valid BTI landing pad when the PACBTI Extension is implemented and EPSR.B is one.

This instruction is not permitted in an IT block.

This is a NOP-compatible hint.

| <Rd>  | Is the general-purpose destination register, encoded in the "Rd" field.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <Rn>  | Is the first general-purpose source register, encoded in the "Rn" field.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <Rm>  | Is the second general-purpose source register, encoded in the "Rm" field.                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <imm> | The shift to apply to the value read from <Rm>, encoded in imm3:imm2. For PKHBT, it is one of:<br>1-31 Left shift by specified number of bits, encoded as a binary number.<br>omitted No shift, encoded as 0b00000.                                                                                                                                                                                                                                                                                                                                     |
| <imm> | The shift to apply to the value read from <Rm>, encoded in imm3:imm2. For PKHTB, it is one of:<br>1-32 Arithmetic right shift by specified number of bits. A shift by 32 bits is encoded as 0b00000. Other shift amounts are encoded as binary numbers.<br>omitted Instruction is a pseudo-instruction and is assembled as though PKHBT<c><q><Rd>, <Rm>, <Rn> had been written.<br>For both variants an assembler can permit <imm> = 0 to mean the same thing as omitting the shift, but this is not standard UAL and must not be used for disassembly. |

#### Operation for all encodings

```
1 if ConditionPassed() then
2   EncodingSpecificOperations();
3   operand2 = Shift(R[m], shift_t, shift_n, APSR.C); // APSR.C ignored
4   bits(32) result;
5   result[15:0] = if tbform then operand2[15:0] else R[n][15:0];
```

```
6      result[31:16] = if tbform then R[n][31:16]      else operand2[31:16];  
7      R[d] = result;
```

## Restricted behavior

### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the N, Z, C, V flags.
- The point at which an asynchronous exception is taken does not vary based on any of the following:
  - The values of the data supplied in any the registers bwing used in this instruction.
  - The values of the N, Z, C, V flags.

### C2.4.139 PLD (literal)

Preload Data (literal). Preload Data signals the memory system that data memory accesses from a specified address are likely in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as pre-loading the cache line containing the specified address into the data cache.

|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <c>     | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                                                                                                                                                                                                                                                                                                 |
| <q>     | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                                                                                                                                                                                                                                                                                                 |
| <label> | The label of the literal data item that is likely to be accessed in the near future. The assembler calculates the required value of the offset from the <a href="#">Align</a> (PC, 4) value of the instruction to this label. The offset must be in the range -4095 to 4095. If the offset is zero or positive, imm32 is equal to the offset and add == TRUE. If the offset is negative, imm32 is equal to minus the offset and add == FALSE. |
| +/-     | Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values: <ul style="list-style-type: none"> <li>- when U = 0</li> <li>+ when U = 1</li> </ul>                                                                                                                                                                                        |
| <imm>   | Is a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.                                                                                                                                                                                                                                                                                                                                             |

#### Operation for all encodings

```
1 if ConditionPassed() then
2     EncodingSpecificOperations();
3     address = if add then (Align(PC, 4) + imm32) else (Align(PC, 4) - imm32);
4     Hint_PreloadData(address);
```

### C2.4.140 PLD, PLDW (immediate)

Preload Data (immediate). Preload Data signals the memory system that data memory accesses from a specified address are likely in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as pre-loading the cache line containing the specified address into the data cache.

The PLD instruction signals that the likely memory access is a read, and the PLDW instruction signals that it is a write.

The effect of a PLD or PLDW is IMPLEMENTATION DEFINED.

5     Hint_PreloadInstr(address);

```

### C2.4.144 POP (multiple registers)

Pop multiple registers from stack. Pop multiple registers from stack loads multiple general-purpose registers from the stack, loading from consecutive memory locations starting at the address in SP, and updates SP to point above the loaded data.

If the registers loaded include the PC, the word loaded for the PC is treated as a branch address or an exception return value. Bit[0] complies with the Arm architecture interworking rules for switching between the A32 and T32 instruction sets. However, Armv8-M only supports the T32 instruction set, so bit[0] must be 1. If bit[0] is 0 the PE takes an INVSTATE UsageFault exception on the instruction at the target address.

This instruction is interrupt-continuable.

This instruction is an alias of the [LDM](#), [LDMIA](#), [LDMFD](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [LDM](#), [LDMIA](#), [LDMFD](#).
- The description of [LDM](#), [LDMIA](#), [LDMFD](#) gives the operational pseudocode for this instruction.

#### T2

*Armv8-M Main Extension only*

#### T2 variant

POP{<c>}{<q>} <registers>

is equivalent to

LDM{<c>}{<q>} SP!, <registers>

and is the preferred disassembly when BitCount (register\_list) > 1.

#### T3

*Armv8-M*

#### T3 variant

POP{<c>}{<q>} <registers>

is equivalent to

LDM{<c>}{<q>} SP!, <registers>

and is always the preferred disassembly.

#### Assembler symbols for all encodings

<c>                      See [C1.2.5 Standard assembler syntax fields](#).  
<q>                      See [C1.2.5 Standard assembler syntax fields](#).

<registers> For encoding T2: is a list of two or more registers to be loaded, separated by commas and surrounded by { and }. The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. The registers in the list must be in the range R0-R12, encoded in the "register\_list" field, and can optionally contain one of the LR or the PC. If the LR is in the list, the "M" field is set to 1, otherwise it defaults to 0. If the PC is in the list, the "P" field is set to 1, otherwise it defaults to 0. The PC can be in the list. If it is, the instruction branches to the address loaded to the PC, and: If the PC is in the list:

- The LR must not be in the list.
- The instruction must be either outside any IT block, or the last instruction in an IT block.

For encoding T3: is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The registers in the list must be in the range R0-R7, encoded in the "register\_list" field, and can optionally include the PC. If the PC is in the list, the "P" field is set to 1, otherwise this field defaults to 0. If the PC is in the list, the instruction must be either outside any IT block, or the last instruction in an IT block.

## Operation for all encodings

The description of [LDM](#), [LDMIA](#), [LDMFD](#) gives the operational pseudocode for this instruction.

## Restricted behavior

### Data Independent Timing behavior

If [AIRCR.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data being loaded.
- The point at which an asynchronous exception is taken does not vary based on the value or values being loaded by this instruction.

The timing invariance does not apply to values being loaded into R15, but does apply to all values being loaded into any other specified register even if R15 is being used.

The timing invariance does not apply to the addresses being accessed.

## C2.4.145 POP (single register)

Pop single register from stack. Pop single register from stack loads a single general-purpose register from the stack, loading from the address in SP, and updates SP to point above the loaded data.

This instruction is an alias of the [LDR \(immediate\)](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [LDR \(immediate\)](#).
- The description of [LDR \(immediate\)](#) gives the operational pseudocode for this instruction.

### T4

| <register> | Is the general-purpose register <Rt> to be loaded surrounded by { and }.                                                                                                                                                                                                             |
| <Rt>       | Is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used, provided the instruction is either outside an IT block or the last instruction of an IT block. If the PC is used, the instruction branches to the address (data) loaded to the PC. |

### Operation for all encodings

The description of [LDR \(immediate\)](#) gives the operational pseudocode for this instruction.

### Restricted behavior

#### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data being loaded.
- The point at which an asynchronous exception is taken does not vary based on the value or values being loaded by this instruction.

The timing invariance does not apply to the addresses being accessed.

## C2.4.146 PSSBB

Physical Speculative Store Bypass Barrier. Physical Speculative Store Bypass Barrier is a memory barrier which prevents speculative loads from bypassing earlier stores to the same physical address.

The semantics of the Physical Speculative Store Bypass Barrier are:

- When a load to a location appears in program order after the PSSBB, then the load does not speculatively read an entry earlier in the coherence order for that location than the entry generated by the latest store satisfying all of the following conditions:
  - The store is to the same location as the load.
  - The store appears in program order before the PSSBB.
  - The memory attributes of the store are the same as the memory attributes of the load.
- When a load to a location appears in program order before the PSSBB, then the load does not speculatively read data from any store satisfying all of the following conditions:
  - The store is to the same location as the load.
  - The store appears in program order after the PSSBB.
  - The memory attributes of the store are the same as the memory attributes of the load.

PSSBB does not have any impact on the rules associated with mismatched attributes.

| <registers> | For encoding T1: is a list of one or more registers to be stored, separated by commas and surrounded by { and }. The lowest-numbered register is stored to the lowest memory address, through to the highest-numbered register to the highest memory address. The registers in the list must be in the range R0-R12, encoded in the "register_list" field, and can optionally contain the LR. If the LR is in the list, the "M" field is set to 1, otherwise it defaults to 0.<br>For encoding T2: is a list of one or more registers to be stored, separated by commas and surrounded by { and }. The registers in the list must be in the range R0-R7, encoded in the "register_list" field, and can optionally include the LR. If the LR is in the list, the "M" field is set to 1, otherwise this field defaults to 0. |

## Operation for all encodings

The description of [STMDB](#), [STMFD](#) gives the operational pseudocode for this instruction.

## Restricted behavior

### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data being stored.
- The point at which an asynchronous exception is taken does not vary based on the value or values being stored by this instruction.

The timing invariance does not apply to the addresses being accessed.

## C2.4.148 PUSH (single register)

Push single register to stack. Push single register to stack stores a single general-purpose register to the stack, storing to the 32-bit word below the address in SP, and updates SP to point to the start of the stored data.

This instruction is an alias of the [STR \(immediate\)](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [STR \(immediate\)](#).
- The description of [STR \(immediate\)](#) gives the operational pseudocode for this instruction.

### T4

*Armv8-M Main Extension only*

### Pre-indexed variant

```
PUSH{<c>}{<q>} <register>
// Standard syntax
```

### is equivalent to

```
STR{<c>}{<q>} <Rt>, [SP, #-4]!
```

and is always the preferred disassembly.

### Assembler symbols for all encodings

<c> See [C1.2.5 Standard assembler syntax fields](#).  
 <q> See [C1.2.5 Standard assembler syntax fields](#).  
 <register> Is the general-purpose register <Rt> to be stored surrounded by { and }.  
 <Rt> Is the general-purpose register to be transferred, encoded in the "Rt" field.

### Operation for all encodings

The description of [STR \(immediate\)](#) gives the operational pseudocode for this instruction.

### Restricted behavior

#### Data Independent Timing behavior

If [AIRCR.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value of the data being stored.
- The point at which an asynchronous exception is taken does not vary based on the value being stored by this instruction.

The timing invariance does not apply to the addresses being accessed.

## C2.4.149 QADD

Saturating Add. Saturating Add adds two register values, saturates the result to the 32-bit signed integer range  $-2^{31}$  to  $2^{31}-1$ , and writes the result to the destination register. If saturation occurs, it sets the Q flag in the APSR.

4     result[31:8] = SignExtend(R[m][7:0], 24);  
5     result[7:0]  = R[m][15:8];  
6     R[d] = result;
```

### Restricted behavior

#### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data subject to this instruction.
- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

### C2.4.163 ROR (immediate)

Rotate Right (immediate). Rotate Right (immediate) rotates a register value by a constant number of bits, inserting the bits that are rotated off the right end into the vacated bit positions on the left, and writes the result to the destination register.

This instruction is an alias of the [MOV \(register\)](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [MOV \(register\)](#).
- The description of [MOV \(register\)](#) gives the operational pseudocode for this instruction.

#### T3

*Armv8-M Main Extension only*

- In Armv8.0-M, bit[15] (lower 16 bits of the encoding) [0] represents (0).
- In Armv8.1-M, bit[15] (lower 16 bits of the encoding) [0] represents 0.

**MOV, shift or rotate by value variant**

**Applies when ! (imm3 == 000 && imm2 == 00).**

ROR{<c>}{<q>}{<Rd>,} <Rm>, #<imm>

**is equivalent to**

MOV{<c>}{<q>}<Rd>, <Rm>, ROR #<imm>

**and is always the preferred disassembly.**

#### Assembler symbols for all encodings

|       |                                                                              |
|-------|------------------------------------------------------------------------------|
| <c>   | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                |
| <q>   | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                |
| <Rd>  | Is the general-purpose destination register, encoded in the "Rd" field.      |
| <Rm>  | Is the general-purpose source register, encoded in the "Rm" field.           |
| <imm> | Is the shift amount, in the range 1 to 31, encoded in the "imm3:imm2" field. |

#### Operation for all encodings

The description of [MOV \(register\)](#) gives the operational pseudocode for this instruction.

#### Restricted behavior

##### Data Independent Timing behavior

If [AIRCR.DIT](#) is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the N, Z, C, V flags.
- The point at which an asynchronous exception is taken does not vary based on any of the following:
  - The values of the data supplied in any the registers bwing used in this instruction.

- The values of the N, Z, C, V flags.

## C2.4.164 ROR (register)

Rotate Right (register). Rotate Right (register) rotates a register value by a variable number of bits, inserting the bits that are rotated off the right end into the vacated bit positions on the left, and writes the result to the destination register. The variable number of bits is read from the bottom byte of a register.

This instruction is an alias of the [MOV, MOVS \(register-shifted register\)](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [MOV, MOVS \(register-shifted register\)](#).
- The description of [MOV, MOVS \(register-shifted register\)](#) gives the operational pseudocode for this instruction.

### T1

*Armv8-M Main Extension only*

|    |    |    |    |    |    |           |   |   |    |   |   |     |   |   |   |
|----|----|----|----|----|----|-----------|---|---|----|---|---|-----|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9         | 8 | 7 | 6  | 5 | 4 | 3   | 2 | 1 | 0 |
| 0  | 1  | 0  | 0  | 0  | 0  | op = 0111 |   |   | Rs |   |   | Rdm |   |   |   |

#### Rotate right variant

```
ROR<c>{<q>} {<Rdm>, } <Rdm>, <Rs>
// Inside IT block
```

#### is equivalent to

```
MOV<c>{<q>} <Rdm>, <Rdm>, ROR <Rs>
```

and is the preferred disassembly when `InITBlock()`.

### T2

*Armv8-M Main Extension only*

|    |    |    |    |    |    |   |   |   |   |   |   |    |   |   |   |    |    |    |    |    |    |   |   |   |   |   |    |   |   |   |   |

| <Rdm> | Is the first general-purpose source register and the destination register, encoded in the "Rdm" field.                 |
| <Rd>  | Is the general-purpose destination register, encoded in the "Rd" field.                                                |
| <Rm>  | Is the first general-purpose source register, encoded in the "Rm" field.                                               |
| <Rs>  | Is the second general-purpose source register holding a rotate amount in its bottom 8 bits, encoded in the "Rs" field. |

### Operation for all encodings

The description of [MOV, MOVS \(register-shifted register\)](#) gives the operational pseudocode for this instruction.

### Restricted behavior

#### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the N, Z, C, V flags.
- The point at which an asynchronous exception is taken does not vary based on any of the following:
  - The values of the data supplied in any the registers bwing used in this instruction.
  - The values of the N, Z, C, V flags.

### C2.4.165 RORS (immediate)

Rotate Right, Setting flags (immediate). Rotate Right, Setting flags (immediate) rotates a register value by a constant number of bits, inserting the bits that are rotated off the right end into the vacated bit positions on the left, writes the result to the destination register, and updates the condition flags based on the result.

This instruction is an alias of the [MOV \(register\)](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [MOV \(register\)](#).
- The description of [MOV \(register\)](#) gives the operational pseudocode for this instruction.

#### T3

*Armv8-M Main Extension only*

- In Armv8.0-M, bit[15] (lower 16 bits of the encoding) [0] represents (0).
- In Armv8.1-M, bit[15] (lower 16 bits of the encoding) [0] represents 0.

**MOVS, shift or rotate by value variant**

**Applies when ! (imm3 == 000 && imm2 == 00).**

RORS {<c>} {<q>} {<Rd>}, {<Rm>}, #<imm>

**is equivalent to**

MOVS {<c>} {<q>} <Rd>, <Rm>, ROR #<imm>

**and is always the preferred disassembly.**

#### Operation for all encodings

The description of [MOV \(register\)](#) gives the operational pseudocode for this instruction.

#### Restricted behavior

##### Data Independent Timing behavior

If [AIRCR.DIT](#) is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the N, Z, C, V flags.
- The point at which an asynchronous exception is taken does not vary based on any of the following:
  - The values of the data supplied in any the registers bwing used in this instruction.

- The values of the N, Z, C, V flags.

## C2.4.166 RORS (register)

Rotate Right, Setting flags (register). Rotate Right, Setting flags (register) rotates a register value by a variable number of bits, inserting the bits that are rotated off the right end into the vacated bit positions on the left, writes the result to the destination register, and updates the condition flags based on the result. The variable number of bits is read from the bottom byte of a register.

This instruction is an alias of the [MOV, MOVS \(register-shifted register\)](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [MOV, MOVS \(register-shifted register\)](#).
- The description of [MOV, MOVS \(register-shifted register\)](#) gives the operational pseudocode for this instruction.

### T1

|-------|------------------------------------------------------------------------------------------------------------------------|
| <C>   | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                          |
| <q>   | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                          |
| <Rdm> | Is the first general-purpose source register and the destination register, encoded in the "Rdm" field.                 |
| <Rd>  | Is the general-purpose destination register, encoded in the "Rd" field.                                                |
| <Rm>  | Is the first general-purpose source register, encoded in the "Rm" field.                                               |
| <Rs>  | Is the second general-purpose source register holding a rotate amount in its bottom 8 bits, encoded in the "Rs" field. |

### Operation for all encodings

The description of [MOV, MOVS \(register-shifted register\)](#) gives the operational pseudocode for this instruction.

### Restricted behavior

#### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the N, Z, C, V flags.
- The point at which an asynchronous exception is taken does not vary based on any of the following:
  - The values of the data supplied in any the registers bwing used in this instruction.
  - The values of the N, Z, C, V flags.

## C2.4.167 RRX

Rotate Right with Extend. Rotate Right with Extend shifts a register value right by one bit, shifting the Carry flag into bit[31], and writes the result to the destination register.

This instruction is an alias of the [MOV \(register\)](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [MOV \(register\)](#).
- The description of [MOV \(register\)](#) gives the operational pseudocode for this instruction.

### T3

*Armv8-M Main Extension only*

- In Armv8.0-M, bit[15] (lower 16 bits of the encoding) [0] represents (0).
- In Armv8.1-M, bit[15] (lower 16 bits of the encoding) [0] represents 0.

### MOV, rotate right with extend variant

RRX{<c>}{<q>} {<Rd>, } <Rm>

is equivalent to

MOV{<c>}{<q>} <Rd>, <Rm>, RRX

and is always the preferred disassembly.

### Assembler symbols for all encodings

|      |                                                                         |
|------|-------------------------------------------------------------------------|
| <c>  | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .           |
| <q>  | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .           |
| <Rd> | Is the general-purpose destination register, encoded in the "Rd" field. |
| <Rm> | Is the general-purpose source register, encoded in the "Rm" field.      |

### Operation for all encodings

The description of [MOV \(register\)](#) gives the operational pseudocode for this instruction.

### Restricted behavior

#### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the N, Z, C, V flags.
- The point at which an asynchronous exception is taken does not vary based on any of the following:
  - The values of the data supplied in any the registers bwing used in this instruction.
  - The values of the N, Z, C, V flags.

## C2.4.168 RRXS

Rotate Right with Extend, Setting flags. Rotate Right with Extend, Setting flags shifts a register value right by one bit, shifting the Carry flag into bit[31] and bit[0] into the Carry flag, writes the result to the destination register and updates the condition flags (other than Carry) based on the result.

This instruction is an alias of the [MOV \(register\)](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [MOV \(register\)](#).
- The description of [MOV \(register\)](#) gives the operational pseudocode for this instruction.

### T3

*Armv8-M Main Extension only*

- In Armv8.0-M, bit[15] (lower 16 bits of the encoding) [0] represents (0).
- In Armv8.1-M, bit[15] (lower 16 bits of the encoding) [0] represents 0.

### MOVS, rotate right with extend variant

RRXS {<c>} {<q>} {<Rd>}, {<Rm>}

is equivalent to

MOVS {<c>} {<q>} <Rd>, <Rm>, RRX

and is always the preferred disassembly.

### Assembler symbols for all encodings

|      |                                                                         |
|------|-------------------------------------------------------------------------|
| <c>  | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .           |
| <q>  | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .           |
| <Rd> | Is the general-purpose destination register, encoded in the "Rd" field. |
| <Rm> | Is the general-purpose source register, encoded in the "Rm" field.      |

### Operation for all encodings

The description of [MOV \(register\)](#) gives the operational pseudocode for this instruction.

### Restricted behavior

#### Data Independent Timing behavior

If [AIRCR.DIT](#) is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the N, Z, C, V flags.
- The point at which an asynchronous exception is taken does not vary based on any of the following:
  - The values of the data supplied in any the registers bwing used in this instruction.
  - The values of the N, Z, C, V flags.

### C2.4.169 RSB (immediate)

Reverse Subtract (immediate). Reverse Subtract (immediate) subtracts a register value from an immediate value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

#### T1

Armv8-M

|    |    |    |    |    |    |   |   |   |   |    |   |   |    |   |   |

| <Rd>     | Is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.                                                                                                                                                                                   |
| <Rn>     | Is the first general-purpose source register, encoded in the "Rn" field.                                                                                                                                                                                                                                 |
| <Rm>     | Is the second general-purpose source register, encoded in the "Rm" field.                                                                                                                                                                                                                                |
| <shift>  | Is the type of shift to be applied to the second source register, encoded in the "sr_type" field. It can have the following values: <ul style="list-style-type: none"> <li>LSL when sr_type = 00</li> <li>LSR when sr_type = 01</li> <li>ASR when sr_type = 10</li> <li>ROR when sr_type = 11</li> </ul> |
| <amount> | Is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm3:imm2" field as <amount> modulo 32.                                                                                                                                     |

### Operation for all encodings

```
1 if ConditionPassed() then  
2     EncodingSpecificOperations();  
3     shifted = Shift(R[m], shift_t, shift_n, APSR.C);  
4     (result, carry, overflow) = AddWithCarry(NOT(R[n]), shifted, '1');  
5     R[d] = result;  
6     if setflags then  
7         APSR.Z = IsZeroBit(result);  
8         APSR.N = result[31];  
9         APSR.C = carry;  
10        APSR.V = overflow;
```

### Restricted behavior

#### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the N, Z, C, V flags.
- The point at which an asynchronous exception is taken does not vary based on any of the following:
  - The values of the data supplied in any the registers bwing used in this instruction.
  - The values of the N, Z, C, V flags.

### C2.4.171 SADD16

Signed Add 16. Signed Add 16 performs two 16-bit signed integer additions, and writes the results to the destination register. It sets the APSR.GE bits according to the results of the additions.

| <Rm>     | Is the second general-purpose source register, encoded in the "Rm" field.                                                                                                                                                                                                             |
| <shift>  | Is the type of shift to be applied to the second source register, encoded in the "sr_type" field. It can have the following values:<br><div style="margin-left: 20px;"> LSL when sr_type = 00<br/> LSR when sr_type = 01<br/> ASR when sr_type = 10<br/> ROR when sr_type = 11 </div> |
| <amount> | Is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm3:imm2" field as <amount> modulo 32.                                                                                                                  |

### Operation for all encodings

```
1 if ConditionPassed() then
2   EncodingSpecificOperations();
3   shifted = Shift(R[m], shift_t, shift_n, APSR.C);
4   (result, carry, overflow) = AddWithCarry(R[n], NOT(shifted), APSR.C);
5   R[d] = result;
6   if setflags then
7     APSR.N = result[31];
8     APSR.Z = IsZeroBit(result);
9     APSR.C = carry;
10    APSR.V = overflow;
```

### Restricted behavior

#### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the N, Z, C, V flags.
- The point at which an asynchronous exception is taken does not vary based on any of the following:
  - The values of the data supplied in any the registers bwing used in this instruction.
  - The values of the N, Z, C, V flags.

## C2.4.176 SBFX

Signed Bit Field Extract. Signed Bit Field Extract extracts any number of adjacent bits at any position from one register, sign extends them to 32 bits, and writes the result to the destination register.

### T1

Armv8-M Main Extension only

|    |    |    |    |    |     |   |   |   |   |   |   |    |   |   |   |    |      |    |    |    |    |   |   |   |      |     |         |   |   |   |   |
|----|----|----|----|----|-----|---|---|---|---|---|---|----|---|---|---|----|------|----|----|----|----|---|---|---|------|-----|---------|---|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10  | 9 | 8 | 7 | 6 | 5 | 4 | 3  | 2 | 1 | 0 | 15 | 14   | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6    | 5   | 4       | 3 | 2 | 1 | 0 |

### T1 variant

SBFX{<c>}{<q>} <Rd>, <Rn>, #<lsb>, #<width>

### Decode for this encoding

```

1 if !HaveMainExt() then UNDEFINED;
2 d = UInt(Rd); n = UInt(Rn);
3 lsbit = UInt(imm3:imm2); widthminus1 = UInt(widthm1);
4 msbit = lsbit + widthminus1;
5 if msbit > 31 then UNPREDICTABLE;
6 if d IN {13,15} || n IN {13,15} then UNPREDICTABLE;
```

### CONSTRAINED UNPREDICTABLE behavior

If `msbit > 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

### Assembler symbols for all encodings

## C2.4.180 SG

Secure Gateway. Secure Gateway marks a valid branch target for branches from Non-secure code that call Secure code.

This instruction sets the Security state to Secure if its address is in Secure memory. If the address of this instruction is in Non-secure memory, the instruction behaves as a NOP.

If the PE was previously in Non-secure state:

- This instruction sets bit[0] of LR to 0, to indicate that the return address will cause a transition from Secure to Non-secure state.
- If the Floating-point Extension is implemented, this instruction marks Secure floating-point state as inactive, by setting CONTROL\_S.SFPA to 0. This indicates that the floating-point registers do not contain active state that belongs to the Secure state.

An INVEP SecureFault is generated if the PE attempts to reenter Thread mode when CCR\_S.TRD is set to 1 and either or both of the following are true:

- CONTROL\_S.SPSEL is 0.
- The current Stack Pointer of the Secure state points to an address that contains the value 0xFEFA125A[31:1].

If the Security Extension is not implemented, this instruction behaves as a NOP.

**SG** is an unconditional instruction and executes as such both inside and outside an **IT** instruction block. Arm recommends that software does not place SG inside an **IT** instruction block.

This instruction is a valid BTI landing pad when the PACBTI Extension is implemented and EPSR.B is one.

- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

## C2.4.187 SMLABB, SMLABT, SMLATB, SMLATT

Signed Multiply Accumulate (halfwords). Signed Multiply Accumulate (halfwords) performs a signed multiply accumulate operation. The multiply acts on two signed 16-bit quantities, taken from either the bottom or the top half of their respective source registers. The other halves of these source registers are ignored. The 32-bit product is added to a 32-bit accumulate value and the result is written to the destination register.

If overflow occurs during the addition of the accumulate value, the instruction sets the Q flag in the APSR. It is not possible for overflow to occur during the multiplication.

7   if result != SInt(result[31:0]) then // Signed overflow  
8     APSR.Q = '1';
```

## C2.4.188 SMLAD, SMLADX

Signed Multiply Accumulate Dual. Signed Multiply Accumulate Dual performs two signed 16-bit by 16-bit multiplications. It adds the products to a 32-bit accumulate operand.

Optionally, the instruction can exchange the halfwords of the second operand before performing the arithmetic.

This instruction sets the Q flag if the accumulate operation overflows. Overflow cannot occur during the multiplications.

### Operation for all encodings

```

1 if ConditionPassed() then
2     EncodingSpecificOperations();
3     result = SInt(R[n]) * SInt(R[m]) + SInt(R[dHi]:R[dLo]);
4     R[dHi] = result[63:32];
5     R[dLo] = result[31:0];
```

### Restricted behavior

#### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data subject to this instruction.

- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

## C2.4.190 SMLALBB, SMLALBT, SMLALTB, SMLALTT

Signed Multiply Accumulate Long (halfwords). Signed Multiply Accumulate Long (halfwords) multiplies two signed 16-bit values to produce a 32-bit value, and accumulates this with a 64-bit value. The multiply acts on two signed 16-bit quantities, taken from either the bottom or the top half of their respective source registers. The other halves of these source registers are ignored. The 32-bit product is sign-extended and accumulated with a 64-bit accumulate value.

Overflow is possible during this instruction, but only as a result of the 64-bit addition. This overflow is not detected if it occurs. Instead, the result wraps around modulo  $2^{64}$ .

```

## Restricted behavior

### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data subject to this instruction.
- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

## C2.4.192 SMLAWB, SMLAWT

Signed Multiply Accumulate (word by halfword). Signed Multiply Accumulate (word by halfword) performs a signed multiply accumulate operation. The multiply acts on a signed 32-bit quantity and a signed 16-bit quantity. The signed 16-bit quantity is taken from either the bottom or the top half of its source register. The other half of the second source register is ignored. The top 32 bits of the 48-bit product are added to a 32-bit accumulate value and the result is written to the destination register. The bottom 16 bits of the 48-bit product are ignored.

If overflow occurs during the addition of the accumulate value, the instruction sets the Q flag in the APSR. No overflow can occur during the multiplication.

6     result = product1 - product2 + SInt(R[a]);
7     R[d] = result[31:0];
8     if result != SInt(result[31:0]) then // Signed overflow
9         APSR.Q = '1';
```

#### Restricted behavior

##### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data subject to this instruction.
- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

### C2.4.194 SMLS LD, SMLS LD X

Signed Multiply Subtract Long Dual. Signed Multiply Subtract Long Dual performs two signed 16-bit by 16-bit multiplications. It adds the difference of the products to a 64-bit accumulate operand.

Optionally, the instruction can exchange the halfwords of the second operand before performing the arithmetic.

Overflow is possible during this instruction, but only as a result of the 64-bit addition. This overflow is not detected if it occurs. Instead, the result wraps around modulo  $2^{64}$ .

4   operand2 = if m_high then R[m][31:16] else R[m][15:0];
5   result = SInt(operand1) * SInt(operand2);
```

```
6   R[d] = result[31:0];  
7   // Signed overflow cannot occur
```

## Restricted behavior

### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data subject to this instruction.
- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

## C2.4.200 SMULL

Signed Multiply Long. Signed Multiply Long multiplies two 32-bit signed values to produce a 64-bit result.

### T1 variant

SMULL{<c>}{<q>} <RdLo>, <RdHi>, <Rn>, <Rm>

### Decode for this encoding

```

1 if !HaveMainExt() then UNDEFINED;
2 dLo = UInt(RdLo); dHi = UInt(RdHi); n = UInt(Rn); m = UInt(Rm); setflags = FALSE;
3 if dLo IN {13,15} || dHi IN {13,15} || n IN {13,15} || m IN {13,15} then UNPREDICTABLE;
4 if dHi == dLo then UNPREDICTABLE;
```

### CONSTRAINED UNPREDICTABLE behavior

If `dHi == dLo`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

### Assembler symbols for all encodings

```

### Restricted behavior

#### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data subject to this instruction.
- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

### C2.4.201 SMULWB, SMULWT

Signed Multiply (word by halfword). Signed Multiply (word by halfword) multiplies a signed 32-bit quantity and a signed 16-bit quantity. The signed 16-bit quantity is taken from either the bottom or the top half of its source register. The other half of the second source register is ignored. The top 32 bits of the 48-bit product are written to the destination register. The bottom 16 bits of the 48-bit product are ignored. No overflow is possible during this instruction.

- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

## C2.4.202 SMUSD, SMUSDX

Signed Dual Multiply Subtract. Signed Dual Multiply Subtract performs two signed 16-bit by 16-bit multiplications. It subtracts one of the products from the other, and writes the result to the destination register.

Optionally, the instruction can exchange the halfwords of the second operand before performing the arithmetic.

Overflow cannot occur.

7     APSR.GE[3:2] = if diff >= 0 then '11' else '00';
```

#### Restricted behavior

##### Data Independent Timing behavior

If [AIRCR.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data subject to this instruction.
- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

### C2.4.212 SSBB

Speculative Store Bypass Barrier. Speculative Store Bypass Barrier is a memory barrier which prevents speculative loads from bypassing earlier stores to the same address under certain conditions.

The semantics of the Speculative Store Bypass Barrier are:

- When a load to a location appears in program order after the SSBB, then the load does not speculatively read an entry earlier in the coherence order for that location than the entry generated by the latest store satisfying all of the following conditions:
  - The store is to the same location as the load.
  - The store appears in program order before the SSBB.
- When a load to a location appears in program order before the SSBB, then the load does not speculatively read data from any store satisfying all of the following conditions:
  - The store is to the same location as the load.
  - The store appears in program order after the SSBB.

### T1 variant

SSUB8 {<c>} {<q>} {<Rd>, } <Rn>, <Rm>

### Decode for this encoding

```

1 if !HaveDSPExt() then UNDEFINED;
2 d = UInt(Rd); n = UInt(Rn); m = UInt(Rm);
3 if d IN {13,15} || n IN {13,15} || m IN {13,15} then UNPREDICTABLE;
```

### Assembler symbols for all encodings

<c> See [C1.2.5 Standard assembler syntax fields](#).  
 <q> See [C1.2.5 Standard assembler syntax fields](#).  
 <Rd> Is the general-purpose destination register, encoded in the "Rd" field.  
 <Rn> Is the first general-purpose source register, encoded in the "Rn" field.  
 <Rm> Is the second general-purpose source register, encoded in the "Rm" field.

### Operation for all encodings

```

1 if ConditionPassed() then
2   EncodingSpecificOperations();
3   diff1 = SInt(R[n][7:0]) - SInt(R[m][7:0]);
4   diff2 = SInt(R[n][15:8]) - SInt(R[m][15:8]);
5   diff3 = SInt(R[n][23:16]) - SInt(R[m][23:16]);
6   diff4 = SInt(R[n][31:24]) - SInt(R[m][31:24]);
7   R[d] = diff4[7:0] : diff3[7:0] : diff2[7:0] : diff1[7:0];
8   APSR.GE[0] = if diff1 >= 0 then '1' else '0';
9   APSR.GE[1] = if diff2 >= 0 then '1' else '0';
10  APSR.GE[2] = if diff3 >= 0 then '1' else '0';
11  APSR.GE[3] = if diff4 >= 0 then '1' else '0';
```

### Restricted behavior

#### Data Independent Timing behavior

If [AIRCR.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data subject to this instruction.
- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

### C2.4.215 STC, STC2

Store Coprocessor. Store Coprocessor stores data from a coprocessor to a sequence of consecutive memory addresses.

If no coprocessor can execute the instruction, a UsageFault exception is generated.

Arm reserves coprocessors CP8 to CP15, and this manual defines the valid instructions when coproc is in this range.

#### Assembler symbols for all encodings

|          |                                                                                                                                                                                                                                                        |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| L        | If specified, selects the D == 1 form of the encoding. If omitted, selects the D == 0 form.                                                                                                                                                            |
| <c>      | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                                                                                                          |
| <q>      | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                                                                                                          |
| <coproc> | Is the name of the coprocessor, encoded in the "coproc" field. The generic coprocessor names are p0 to p15.                                                                                                                                            |
| <CRd>    | Is the coprocessor register to be transferred, encoded in the "CRd" field.                                                                                                                                                                             |
| <Rn>     | Is the general-purpose base register, encoded in the "Rn" field.                                                                                                                                                                                       |
| <option> | Is a coprocessor option, in the range 0 to 255 enclosed in { }, encoded in the "imm8" field.                                                                                                                                                           |
| +/-      | Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values: <ul style="list-style-type: none"> <li>- when U = 0</li> <li>+ when U = 1</li> </ul> |
| <imm>    | Is the immediate offset used for forming the address, a multiple of 4 in the range 0-1020, defaulting to 0 and encoded in the "imm8" field, as <imm>/4.                                                                                                |

#### Operation for all encodings

```
1 if ConditionPassed() then
2     EncodingSpecificOperations();
3     ExecuteCPCheck(cp);
4     if !Coproc_Accepted(cp, ThisInstr()) then
5         GenerateCoproprocessorException();
6     else
7         offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
8         address = if index then offset_addr else R[n];
9
10        // Determine if the stack pointer limit check should be performed
11        if wback && n == 13 then
12            violatesLimit = ViolatesSPLim(LookUpSP(), offset_addr);
13        else
```

```
14         violatesLimit = FALSE;
15
16         // Memory operation only performed if limit not violated
17         if !violatesLimit then
18             repeat
19                 MemA[address, 4] = Coproc_GetWordToStore(cp, ThisInstr());
20                 address           = address + 4;
21             until Coproc_DoneStoring(cp, ThisInstr());
22
23         // If the stack pointer is being updated a fault will be raised
24         // if the limit is violated
25         if wback then RSPCheck[n] = offset_addr;
```

## Restricted behavior

### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value of the data being stored.
- The point at which an asynchronous exception is taken does not vary based on the value being stored by this instruction.

The timing invariance does not apply to the addresses being accessed.

## C2.4.216 STL

Store-Release Word. Store Release Word stores a word from a register to memory. The instruction also has memory ordering semantics.

#### Operation for all encodings

```
1 if ConditionPassed() then
2     EncodingSpecificOperations();
3     address = R[n];
4     MemO[address, 1] = R[t][7:0];
```

#### Restricted behavior

##### Data Independent Timing behavior

If [AIRCR.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value of the data being stored.
- The point at which an asynchronous exception is taken does not vary based on the value being stored by this instruction.

The timing invariance does not apply to the addresses being accessed.

## C2.4.218 STLEX

Store-Release Exclusive Word. Store Release Exclusive Word stores a word from a register to memory if the executing PE has exclusive access to the memory addressed. The instruction also has memory ordering semantics.

### T1

Armv8-M

|    |    |    |    |    |    |   |   |   |   |   |   |    |   |   |   |    |    |    |    |     |     |     |     |   |   |   |   |    |   |   |   |
|----|----|----|----|----|----|---|---|---|---|---|---|----|---|---|---|----|----|----|----|-----|-----|-----|-----|---|---|---|---|----|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3  | 2 | 1 | 0 | 15 | 14 | 13 | 12 | 11  | 10  | 9   | 8   | 7 | 6 | 5 | 4 | 3  | 2 | 1 | 0 |
| 1  | 1  | 1  | 0  | 1  | 0  | 0 | 0 | 1 | 1 | 0 | 0 | Rn |   |   |   | Rt |    |    |    | (1) | (1) | (1) | (1) | 1 | 1 | 1 | 0 | Rd |   |   |   |

### T1 variant

STLEX{<c>}{<q>} <Rd>, <Rt>, [<Rn>]

### Decode for this encoding

```

1 d = UInt(Rd); t = UInt(Rt); n = UInt(Rn);
2 if d IN {13,15} || t IN {13,15} || n == 15 then UNPREDICTABLE;
3 if d == n || d == t then UNPREDICTABLE;
```

### CONSTRAINED UNPREDICTABLE behavior

If  $d == t$ , then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

### CONSTRAINED UNPREDICTABLE behavior

If  $d == n$ , then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs the store to an UNKNOWN address.

### Assembler symbols for all encodings

|      |                                                                                                                                                                                                                                                                                                        |

| <Rd> | Is the destination general-purpose register into which the status result of the store exclusive is written, encoded in the "Rd" field. The value returned is: <ul style="list-style-type: none"> <li>1 If the operation fails to update memory.</li> <li>0 If the operation updates memory.</li> </ul> |
| <Rt> | Is the general-purpose register to be transferred, encoded in the "Rt" field.                                                                                                                                                                                                                          |
| <Rn> | Is the general-purpose base register, encoded in the "Rn" field.                                                                                                                                                                                                                                       |

### Operation for all encodings

```

1 if ConditionPassed() then
2   EncodingSpecificOperations();
3   address = R[n];
4   if ExclusiveMonitorsPass(address,4) then
5     MemO[address, 4] = R[t];
6     R[d] = ZeroExtend('0');
7   else
8     R[d] = ZeroExtend('1');
```

## Restricted behavior

### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value of the data being stored.
- The point at which an asynchronous exception is taken does not vary based on the value being stored by this instruction.

The timing invariance does not apply to the addresses being accessed.

### C2.4.219 STLEXB

Store-Release Exclusive Byte. Store Release Exclusive Byte stores a byte from a register to memory if the executing PE has exclusive access to the memory addressed. The instruction also has memory ordering semantics.

2 if t IN {13,15} || n == 15 then UNPREDICTABLE;
```

#### Assembler symbols for all encodings

<c> See [C1.2.5 Standard assembler syntax fields](#).  
 <q> See [C1.2.5 Standard assembler syntax fields](#).  
 <Rt> Is the general-purpose register to be transferred, encoded in the "Rt" field.  
 <Rn> Is the general-purpose base register, encoded in the "Rn" field.

#### Operation for all encodings

```
1 if ConditionPassed() then
2     EncodingSpecificOperations();
3     address = R[n];
4     MemO[address, 2] = R[t][15:0];
```

#### Restricted behavior

##### Data Independent Timing behavior

If [AIRCR.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value of the data being stored.
- The point at which an asynchronous exception is taken does not vary based on the value being stored by this instruction.

The timing invariance does not apply to the addresses being accessed.

## C2.4.222 STM, STMIA, STMEA

**Store Multiple.** Store Multiple stores multiple registers to consecutive memory locations using an address from a base register. The consecutive memory locations start at this address, and the address just above the last of those locations can optionally be written back to the base register.

This instruction is interrupt-continuable.

### T1

*Armv8-M*

|    |    |    |    |    |    |   |   |               |   |   |   |   |   |   |   |
|----|----|----|----|----|----|---|---|---------------|---|---|---|---|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7             | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 1  | 1  | 0  | 0  | 0  | Rn |   |   | register_list |   |   |   |   |   |   |   |

#### T1 variant

```
STM{IA}{<c>}{<q>} <Rn>!, <registers>
    // Preferred syntax
STMEA{<c>}{<q>} <Rn>!, <registers>
    // Alternate syntax, Empty Ascending stack
```

#### Decode for this encoding

```
1 n = UInt(Rn); registers = '00000000':register_list; wback = TRUE;
2 if BitCount(registers) < 1 then UNPREDICTABLE;
```

### CONSTRAINED UNPREDICTABLE behavior

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as an STM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies write-back, the modification to the base address on write-back might differ from the number of registers stored.

    // if <Rn>, '!' and <registers> can be represented in T1
STMEA{<c>}.W <Rn>{!}, <registers>
    // Alternate syntax
    // Empty Ascending stack
    // if <Rn>, '!' and <registers> can be represented in T1
STM{IA}{<c>}{<q>} <Rn>{!}, <registers>
    // Preferred syntax
STMEA{<c>}{<q>} <Rn>{!}, <registers>
    // Alternate syntax, Empty Ascending stack
```

### Decode for this encoding

```
1 if !HaveMainExt() then UNDEFINED;
2 n = UInt(Rn); registers = '0':M:'0':register_list; wback = (W == '1');
3 if n == 15 || BitCount(registers) < 2 then UNPREDICTABLE;
4 if wback && registers[n] == '1' then UNPREDICTABLE;
```

### CONSTRAINED UNPREDICTABLE behavior

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as an STM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies write-back, the modification to the base address on write-back might differ from the number of registers stored.

### CONSTRAINED UNPREDICTABLE behavior

If `BitCount(registers) == 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as described, with no change to its behavior and no additional side effects.
- The instruction operates as an STM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

### CONSTRAINED UNPREDICTABLE behavior

If `wback && registers<n> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored for the base register is UNKNOWN.

| <Rn>        | Is the general-purpose base register, encoded in the "Rn" field.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| !           | The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the "W" field as 1, otherwise this field defaults to 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <registers> | For encoding T1: is a list of one or more registers to be stored, separated by commas and surrounded by { and }. The registers in the list must be in the range R0-R7, encoded in the "register_list" field. If the base register is not the lowest-numbered register in the list, such an instruction stores an UNKNOWN value for the base register.<br>For encoding T2: is a list of one or more registers to be stored, separated by commas and surrounded by { and }. The registers in the list must be in the range R0-R12, encoded in the "register_list" field, and can optionally contain the LR. If the LR is in the list, the "M" field is set to 1, otherwise it defaults to 0. |

### Operation for all encodings

```
1 if ConditionPassed() then
2   EncodingSpecificOperations();
```

```

3      address      = R[n];
4      endAddress = R[n] + 4*BitCount(registers);
5
6      // Determine if the stack pointer limit should be checked
7      if n == 13 && wback && registers[n] == '0' then
8          violatesLimit = ViolatesSPLim(LookUpSP(), endAddress);
9      else
10         violatesLimit = FALSE;
11
12     for i = 0 to 14
13         // Memory operation only performed if limit not violated
14         if registers[i] == '1' && !violatesLimit then
15             if i == n && wback && i != LowestSetBit(registers) then
16                 MemA[address, 4] = bits(32) UNKNOWN; // encoding T1 only
17             else
18                 MemA[address, 4] = R[i];
19                 address = address + 4;
20
21     // If the stack pointer is being updated a fault will be raised if
22     // the limit is violated
23     if wback then RSPCheck[n] = endAddress;

```

## Restricted behavior

### Data Independent Timing behavior

If [AIRCR.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data being stored.
- The point at which an asynchronous exception is taken does not vary based on the value or values being stored by this instruction.

The timing invariance does not apply to the addresses being accessed.

### C2.4.223 STMDB, STMFD

Store Multiple Decrement Before (Full Descending). Store Multiple Decrement Before stores multiple registers to consecutive memory locations using an address from a base register. The consecutive memory locations end just below this address, and the address of the first of those locations can optionally be written back to the base register.

This instruction is used by the alias [PUSH \(multiple registers\)](#).

This instruction is interrupt-continuable.

If the LR is in the list, the "M" field is set to 1, otherwise this field defaults to 0. |

### Operation for all encodings

```
1 if ConditionPassed() then
2   EncodingSpecificOperations();
3   address = R[n] - 4*BitCount(registers);
4   applyLimit = n == 13 && wback;
5
6   for i = 0 to 14
7     // If R[n] is the SP, memory operation only performed if limit not violated
8     if registers[i] == '1' && !(applyLimit && ViolatesSPLim(LookUpSP(), address)) then
9       MemA[address, 4] = R[i];
10      address = address + 4;
```

```
12 // If R[n] is the SP, stack pointer update will raise a fault if limit violated
13 if wback then RSPCheck[n] = R[n] - 4*BitCount(registers);
```

## Restricted behavior

### Data Independent Timing behavior

If [AIRCR.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data being stored.
- The point at which an asynchronous exception is taken does not vary based on the value or values being stored by this instruction.

The timing invariance does not apply to the addresses being accessed.

### C2.4.224 STR (immediate)

Store Register (immediate). Store Register (immediate) calculates an address from a base register value and an immediate offset, and stores a word from a register to memory. It can use offset, post-indexed, or pre-indexed addressing.

This instruction is used by the alias [PUSH \(single register\)](#).

| <q>  | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                                     |
| <Rt> | Is the general-purpose register to be transferred, encoded in the "Rt" field.                                                                                                     |
| <Rn> | Is the general-purpose base register, encoded in the "Rn" field.                                                                                                                  |
| +/-  | Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:<br>- when U = 0 |

+                   +   when  $U = 1$   
+                   Specifies the offset is added to the base register.  
<imm>           For the post-indexed or pre-indexed variant: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, encoded in the "imm8" field.  
                 For encoding T1: is the optional positive unsigned immediate byte offset, a multiple of 4 in the range 0 to 124, defaulting to 0 and encoded in the "imm5" field as <imm>/4.  
                 For encoding T2: is the optional positive unsigned immediate byte offset, a multiple of 4, in the range 0 to 1020, defaulting to 0 and encoded in the "imm8" field as <imm>/4.  
                 For encoding T3: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.  
                 For encoding T4: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field.

### Operation for all encodings

```

1  if ConditionPassed() then
2      EncodingSpecificOperations();
3      offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
4      address = if index then offset_addr else R[n];
5
6      // Determine if the stack pointer limit should be checked
7      if n == 13 && wback then
8          violatesLimit = ViolatesSPLim(LookUpSP(), offset_addr);
9      else
10         violatesLimit = FALSE;
11     // Memory operation only performed if limit not violated
12     if !violatesLimit then
13         MemU[address, 4] = R[t];
14
15     // If the stack pointer is being updated a fault will be raised if
16     // the limit is violated
17     if wback then RSPCheck[n] = offset_addr;
```

### Restricted behavior

#### Data Independent Timing behavior

If [AIRCR.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value of the data being stored.
- The point at which an asynchronous exception is taken does not vary based on the value being stored by this instruction.

The timing invariance does not apply to the addresses being accessed.

### C2.4.225 STR (register)

Store Register (register). Store Register (register) calculates an address from a base register value and an offset register value, stores a word from a register to memory. The offset register value can be shifted left by 0, 1, 2, or 3 bits.

| <q>   | See C1.2.5 Standard assembler syntax fields.                                                                                                                                      |
| <Rt>  | Is the general-purpose register to be transferred, encoded in the "Rt" field.                                                                                                     |
| <Rn>  | Is the general-purpose base register, encoded in the "Rn" field.                                                                                                                  |
| +     | Specifies the index register is added to the base register.                                                                                                                       |
| <Rm>  | Is the general-purpose index register, encoded in the "Rm" field.                                                                                                                 |
| <imm> | If present, the size of the left shift to apply to the value from <Rm>, in the range 1-3. <imm> is encoded in imm2. If absent, no shift is specified and imm2 is encoded as 0b00. |

#### Operation for all encodings

```
1 if ConditionPassed() then
```

```
2   EncodingSpecificOperations();
3   offset = Shift(R[m], shift_t, shift_n, APSR.C);
4   address = R[n] + offset;
5   MemU[address, 4] = R[t];
```

## Restricted behavior

### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value of the data being stored.
- The point at which an asynchronous exception is taken does not vary based on the value being stored by this instruction.

The timing invariance does not apply to the addresses being accessed.

### C2.4.226 STRB (immediate)

Store Register Byte (immediate). Store Register Byte (immediate) calculates an address from a base register value and an immediate offset, and stores a byte from a register to memory. It can use offset, post-indexed, or pre-indexed addressing.

| 1  | 1  | 1  | 1  | 1  | 0  | 0 | 0 | 0 | 0 | 0 | 0 | Rn != 1111 |   |   |   | Rt |    |    |    | 1  | P  | U | W | imm8 |   |   |   |   |   |   |   |

#### Offset variant

Applies when **P == 1 && U == 0 && W == 0.**

STRB{<c>}{<q>} <Rt>, [<Rn> {, #-<imm>}]

#### Post-indexed variant

Applies when **P == 0 && W == 1.**

STRB{<c>}{<q>} <Rt>, [<Rn>], #{+/-}<imm>

### Pre-indexed variant

Applies when **P == 1 && W == 1**.

STRB{<c>}{<q>} <Rt>, [<Rn>], #{+/-}<imm>!

### Decode for this encoding

```
1 if P == '1' && U == '1' && W == '0' then SEE STRBT;
2 if Rn == '1111' || (P == '0' && W == '0') then UNDEFINED;
3 if !HaveMainExt() then UNDEFINED;
4 t = UInt(Rt); n = UInt(Rn); imm32 = ZeroExtend(imm8, 32);
5 index = (P == '1'); add = (U == '1'); wback = (W == '1');
6 if t IN {13,15} || (wback && n == t) then UNPREDICTABLE;
```

### CONSTRAINED UNPREDICTABLE behavior

If **wback && n == t**, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

### Assembler symbols for all encodings

| <Rt>  | Is the general-purpose register to be transferred, encoded in the "Rt" field.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <Rn>  | Is the general-purpose base register, encoded in the "Rn" field.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| +/-   | Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values: <ul style="list-style-type: none"> <li>- when U = 0</li> <li>+ when U = 1</li> </ul>                                                                                                                                                                                                                                                                                                                                            |
| +     | Specifies the offset is added to the base register.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <imm> | For the post-indexed or pre-indexed variant: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, encoded in the "imm8" field.<br>For encoding T1: is an optional 5-bit unsigned immediate byte offset, in the range 0 to 31, defaulting to 0 and encoded in the "imm5" field.<br>For encoding T2: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.<br>For encoding T3: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field. |

### Operation for all encodings

```
1 if ConditionPassed() then
2   EncodingSpecificOperations();
3   offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
4   address = if index then offset_addr else R[n];
5
6   // Determine if the stack pointer limit should be checked
7   if n == 13 && wback then
8     violatesLimit = ViolatesSPLim(LookUpSP(), offset_addr);
9   else
10    violatesLimit = FALSE;
11   // Memory operation only performed if limit not violated
12   if !violatesLimit then
13     MemU[address, 1] = R[t][7:0];
14
```

```
15 // If the stack pointer is being updated a fault will be raised if
16 // the limit is violated
17 if wback then RSPCheck[n] = offset_addr;
```

## Restricted behavior

### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value of the data being stored.
- The point at which an asynchronous exception is taken does not vary based on the value being stored by this instruction.

The timing invariance does not apply to the addresses being accessed.

## C2.4.227 STRB (register)

Store Register Byte (register). Store Register Byte (register) calculates an address from a base register value and an offset register value, and stores a byte from a register to memory. The offset register value can be shifted left by 0, 1, 2, or 3 bits.

### T1

Armv8-M

| <q>   | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                                     |
| <Rt>  | Is the general-purpose register to be transferred, encoded in the "Rt" field.                                                                                                     |
| <Rn>  | Is the general-purpose base register, encoded in the "Rn" field.                                                                                                                  |
| +     | Specifies the index register is added to the base register.                                                                                                                       |
| <Rm>  | Is the general-purpose index register, encoded in the "Rm" field.                                                                                                                 |
| <imm> | If present, the size of the left shift to apply to the value from <Rm>, in the range 1-3. <imm> is encoded in imm2. If absent, no shift is specified and imm2 is encoded as 0b00. |

### Operation for all encodings

```
1 if ConditionPassed() then
```

```
2   EncodingSpecificOperations();  
3   offset = Shift(R[m], shift_t, shift_n, APSR.C);  
4   address = R[n] + offset;  
5   MemU[address, 1] = R[t][7:0];
```

## Restricted behavior

### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value of the data being stored.
- The point at which an asynchronous exception is taken does not vary based on the value being stored by this instruction.

The timing invariance does not apply to the addresses being accessed.

## C2.4.228 STRBT

Store Register Byte Unprivileged. Store Register Byte Unprivileged calculates an address from a base register value and an immediate offset, and stores a byte from a register to memory. When privileged software uses an [STRBT](#) instruction, the memory access is restricted as if the software was unprivileged.

| <Rt>  | Is the general-purpose register to be transferred, encoded in the "Rt" field.                                                |
| <Rn>  | Is the general-purpose base register, encoded in the "Rn" field.                                                             |
| +     | Specifies the offset is added to the base register.                                                                          |
| <imm> | Is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field. |

### Operation for all encodings

```

1 if ConditionPassed() then
2     EncodingSpecificOperations();
3     address = R[n] + imm32;
4     MemU_unpriv[address, 1] = R[t][7:0];

```

### Restricted behavior

#### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value of the data being stored.
- The point at which an asynchronous exception is taken does not vary based on the value being stored by this instruction.

The timing invariance does not apply to the addresses being accessed.

## C2.4.229 STRD (immediate)

Store Register Dual (immediate). Store Register Dual (immediate) calculates an address from a base register value and an immediate offset, and stores two words from two registers to memory. It can use offset, post-indexed, or pre-indexed addressing.

### T1

Armv8-M Main Extension only

|    |    |    |    |    |    |   |   |   |   |   |   |            |   |   |   |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|----|----|----|----|----|----|---|---|---|---|---|---|------------|---|---|---|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3          | 2 | 1 | 0 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

|    |    |    |    |    |    |   |   |   |   |   |   |            |   |   |   |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

#### Offset variant

Applies when **P == 1** && **W == 0**.

STRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn> {, # {+/-}<imm>}]

#### Post-indexed variant

Applies when **P == 0** && **W == 1**.

STRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>], # {+/-}<imm>

#### Pre-indexed variant

Applies when **P == 1** && **W == 1**.

STRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>, # {+/-}<imm>]!

### Decode for this encoding

```

1 if P == '0' && W == '0' then SEE "Related encodings";
2 if !HaveMainExt() then UNDEFINED;
3 t = UInt(Rt); t2 = UInt(Rt2); n = UInt(Rn); imm32 = ZeroExtend(imm8:'00', 32);
4 index = (P == '1'); add = (U == '1'); wback = (W == '1');
5 if wback && (n == t || n == t2) then UNPREDICTABLE;
6 if n == 15 || t IN {13,15} || t2 IN {13,15} then UNPREDICTABLE;
```

### CONSTRAINED UNPREDICTABLE behavior

If wback && (n == t || n == t2), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

### Assembler symbols for all encodings

|       |                                                                                                                                                                                                                                                        |

| <q>   | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                                                                                                          |
| <Rt>  | Is the first general-purpose register to be transferred, encoded in the "Rt" field.                                                                                                                                                                    |
| <Rt2> | Is the second general-purpose register to be transferred, encoded in the "Rt2" field.                                                                                                                                                                  |
| <Rn>  | Is the general-purpose base register, encoded in the "Rn" field.                                                                                                                                                                                       |
| +/-   | Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values: <ul style="list-style-type: none"> <li>- when U = 0</li> <li>+ when U = 1</li> </ul> |

<imm> For the offset variant: is the optional unsigned immediate byte offset, a multiple of 4, in the range 0 to 1020, defaulting to 0 and encoded in the "imm8" field as <imm>/4.  
For the post-indexed and pre-indexed variant: is the unsigned immediate byte offset, a multiple of 4, in the range 0 to 1020, encoded in the "imm8" field as <imm>/4.

### Operation for all encodings

```

1  if ConditionPassed() then
2      EncodingSpecificOperations();
3      offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
4      address = if index then offset_addr else R[n];
5
6      // Determine if the stack pointer limit should be checked
7      if n == 13 && wback then
8          violatesLimit = ViolatesSPLim(LookUpSP(), offset_addr);
9      else
10         violatesLimit = FALSE;
11     // Memory operation only performed if limit not violated
12     if !violatesLimit then
13         MemA[address, 4] = R[t];
14         MemA[address+4, 4] = R[t2];
15
16     // If the stack pointer is being updated a fault will be raised if
17     // the limit is violated
18     if wback then RSPCheck[n] = offset_addr;

```

### Restricted behavior

#### Data Independent Timing behavior

If [AIRC.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value of the data being stored.
- The point at which an asynchronous exception is taken does not vary based on the value being stored by this instruction.

The timing invariance does not apply to the addresses being accessed.

### C2.4.230 STREX

Store Register Exclusive. Store Register Exclusive calculates an address from a base register value and an immediate offset, and stores a word from a register to memory if the executing PE has exclusive access to the memory addressed.

#### T1

Armv8-M

|    |    |    |    |    |    |   |   |   |   |   |   |    |   |   |   |            |    |    |    |    |    |   |   |      |   |   |   |   |   |   |   |

```

```
4      if ExclusiveMonitorsPass(address, 4) then  
5          MemA[address, 4] = R[t];  
6          R[d] = ZeroExtend('0');  
7      else  
8          R[d] = ZeroExtend('1');
```

## Restricted behavior

### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value of the data being stored.
- The point at which an asynchronous exception is taken does not vary based on the value being stored by this instruction.

The timing invariance does not apply to the addresses being accessed.

### C2.4.231 STREXB

Store Register Exclusive Byte. Store Register Exclusive Byte derives an address from a base register value, and stores a byte from a register to memory if the executing PE has exclusive access to the memory addressed.

#### T1

| <Rt>  | Is the general-purpose register to be transferred, encoded in the "Rt" field.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <Rn>  | Is the general-purpose base register, encoded in the "Rn" field.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| +/-   | Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values: <ul style="list-style-type: none"> <li>- when U = 0</li> <li>+ when U = 1</li> </ul>                                                                                                                                                                                                                                                                                                                                                                           |
| +     | Specifies the offset is added to the base register.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <imm> | For the post-indexed or pre-indexed variant: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, encoded in the "imm8" field.<br>For encoding T1: is the optional positive unsigned immediate byte offset, a multiple of 2 in the range 0 to 62, defaulting to 0 and encoded in the "imm5" field as <imm>/2.<br>For encoding T2: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.<br>For encoding T3: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field. |

### Operation for all encodings

```
1 if ConditionPassed() then
2   EncodingSpecificOperations();
3   offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
4   address = if index then offset_addr else R[n];
5
6   // Determine if the stack pointer limit should be checked
7   if n == 13 && wback then
8     violatesLimit = ViolatesSPLim(LookUpSP(), offset_addr);
9   else
10    violatesLimit = FALSE;
11   // Memory operation only performed if limit not violated
12   if !violatesLimit then
13     MemU[address, 2] = R[t][15:0];
14
```

```
15 // If the stack pointer is being updated a fault will be raised if
16 // the limit is violated
17 if wback then RSPCheck[n] = offset_addr;
```

## Restricted behavior

### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value of the data being stored.
- The point at which an asynchronous exception is taken does not vary based on the value being stored by this instruction.

The timing invariance does not apply to the addresses being accessed.

### C2.4.234 STRH (register)

Store Register Halfword (register). Store Register Halfword (register) calculates an address from a base register value and an offset register value, and stores a halfword from a register to memory. The offset register value can be shifted left by 0, 1, 2, or 3 bits.

STRT{<c>}{<q>} <Rt>, [<Rn> {, #<+><imm>}]

#### Decode for this encoding

```

1 if Rn == '1111' then UNDEFINED;
2 if !HaveMainExt() then UNDEFINED;
3 t = UInt(Rt); n = UInt(Rn); postindex = FALSE; add = TRUE;
4 register_form = FALSE; imm32 = ZeroExtend(imm8, 32);
5 if t IN {13,15} then UNPREDICTABLE;
```

#### Assembler symbols for all encodings

|       |                                                                                                                              |
|-------|------------------------------------------------------------------------------------------------------------------------------|
| <c>   | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                |
| <q>   | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                |
| <Rt>  | Is the general-purpose register to be transferred, encoded in the "Rt" field.                                                |
| <Rn>  | Is the general-purpose base register, encoded in the "Rn" field.                                                             |
| +     | Specifies the offset is added to the base register.                                                                          |
| <imm> | Is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field. |

#### Operation for all encodings

```

1 if ConditionPassed() then
2     EncodingSpecificOperations();
3     address = R[n] + imm32;
4     data = R[t];
5     MemU_unpriv[address, 4] = data;
```

#### Restricted behavior

##### Data Independent Timing behavior

If [AIRCR.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value of the data being stored.
- The point at which an asynchronous exception is taken does not vary based on the value being stored by this instruction.

The timing invariance does not apply to the addresses being accessed.

### C2.4.237 SUB (SP minus immediate)

Subtract from SP (immediate). Subtract (SP minus immediate) subtracts an immediate value from the SP value, and writes the result to the destination register.

3 if d == 15 then UNPREDICTABLE;
```

### Assembler symbols for all encodings

|         |                                                                                                                                                                                    |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <c>     | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                                      |
| <q>     | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                                      |
| <imm7>  | Is an unsigned immediate, a multiple of 4 in the range 0 to 508, encoded in the "imm7" field as <imm7>/4.                                                                          |
| <Rd>    | Is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP.                                                                       |
| <imm12> | Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the "i:imm3:imm8" field.                                                                                        |
| <const> | Is an immediate value derived from the 12-bit immediate that is encoded in the "i:imm3:imm8" field. See <a href="#">C1.5 Modified immediate constants</a> for the range of values. |

### Operation for all encodings

```
1 if ConditionPassed() then
2     EncodingSpecificOperations();
3     (result, carry, overflow) = AddWithCarry(SP, NOT(imm32), '1');
4     RSPCheck[d] = result;
5     if setflags then
6         APSR.N = result[31];
7         APSR.Z = IsZeroBit(result);
8         APSR.C = carry;
9         APSR.V = overflow;
```

### C2.4.238 SUB (SP minus register)

Subtract from SP (register). Subtract (SP minus register) subtracts an optionally-shifted register value from the SP value, and writes the result to the destination register.

#### T1

Armv8-M Main Extension only

#### SUB, rotate right with extend variant

Applies when **S == 0** && **imm3 == 000** && **imm2 == 00** && **sr\_type == 11**.

SUB{<c>}{<q>} {<Rd>}, SP, <Rm>, RRX

#### SUB, shift or rotate by value variant

Applies when **S == 0** && **!(imm3 == 000 && imm2 == 00 && sr\_type == 11)**.

SUB{<c>}.W {<Rd>}, SP, <Rm>

// <Rd>, <Rm> can be represented in T1 or T2

SUB{<c>}{<q>} {<Rd>}, SP, <Rm> {, <shift> #<amount>}

#### SUBS, rotate right with extend variant

Applies when **S == 1** && **imm3 == 000** && **Rd != 1111** && **imm2 == 00** && **sr\_type == 11**.

SUBS{<c>}{<q>} {<Rd>}, SP, <Rm>, RRX

#### SUBS, shift or rotate by value variant

Applies when **S == 1** && **!(imm3 == 000 && imm2 == 00 && sr\_type == 11)** && **Rd != 1111**.

SUBS{<c>}{<q>} {<Rd>}, SP, <Rm> {, <shift> #<amount>}

#### Decode for this encoding

```

1 if Rd == '1111' && S == '1' then SEE "CMP (register)";
2 if !HaveMainExt() then UNDEFINED;
3 d = UInt(Rd); m = UInt(Rm); setflags = (S == '1');
4 (shift_t, shift_n) = DecodeImmShift(sr_type, imm3:imm2);
5 if d == 13 && (shift_t != SRTYPE_LSL || shift_n > 3) then UNPREDICTABLE;
6 if (d == 15 && S == '0') || m IN {13,15} then UNPREDICTABLE;
```

#### Assembler symbols for all encodings

|         |                                                                                                                                                              |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <c>     | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                |
| <q>     | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                |
| <Rd>    | Is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP.                                                 |
| <Rm>    | Is the second general-purpose source register, encoded in the "Rm" field.                                                                                    |
| <shift> | Is the type of shift to be applied to the second source register, encoded in the "sr_type" field. It can have the following values:<br>LSL when sr_type = 00 |

LSR   when `sr_type` = 01  
 ASR   when `sr_type` = 10  
 ROR   when `sr_type` = 11  
 <amount>   Is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm3:imm2" field as <amount> modulo 32.

### Operation for all encodings

```

1  if ConditionPassed() then
2    EncodingSpecificOperations();
3    shifted = Shift(R[m], shift_t, shift_n, APSR.C);
4    (result, carry, overflow) = AddWithCarry(SP, NOT(shifted), '1');
5    RSPCheck[d] = result;
6    if setflags then
7      APSR.N = result[31];
8      APSR.Z = IsZeroBit(result);
9      APSR.C = carry;
10     APSR.V = overflow;
  
```

### C2.4.239 SUB (immediate)

Subtract (immediate). Subtract (immediate) subtracts an immediate value from a register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

| <q>     | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                                                                                                                                                                                                                                                                                                                               |
| <Rdn>   | Is the general-purpose source and destination register, encoded in the "Rdn" field.                                                                                                                                                                                                                                                                                                                                                                                         |
| <imm8>  | Is an 8-bit unsigned immediate, in the range 0 to 255, encoded in the "imm8" field.                                                                                                                                                                                                                                                                                                                                                                                         |
| <Rd>    | Is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.                                                                                                                                                                                                                                                                                                                                                      |
| <Rn>    | For encoding T1: is the general-purpose source register, encoded in the "Rn" field.<br>For encoding T3: is the general-purpose source register, encoded in the "Rn" field. If the SP is used, see <a href="#">C2.4.237 SUB (SP minus immediate)</a> .<br>For encoding T4: is the general-purpose source register, encoded in the "Rn" field. If the SP is used, see <a href="#">C2.4.237 SUB (SP minus immediate)</a> . If the PC is used, see <a href="#">C2.4.8 ADR</a> . |
| <imm3>  | Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "imm3" field.                                                                                                                                                                                                                                                                                                                                                                                            |
| <imm12> | Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the "i:imm3:imm8" field.                                                                                                                                                                                                                                                                                                                                                                                 |
| <const> | Is an immediate value derived from the 12-bit immediate that is encoded in the "i:imm3:imm8" field. See <a href="#">C1.5 Modified immediate constants</a> for the range of values.                                                                                                                                                                                                                                                                                          |

## Operation for all encodings

```
1 if ConditionPassed() then
2   EncodingSpecificOperations();
```

```

3      (result, carry, overflow) = AddWithCarry(R[n], NOT(imm32), '1');
4      R[d] = result;
5      if setflags then
6          APSR.N = result[31];
7          APSR.Z = IsZeroBit(result);
8          APSR.C = carry;
9          APSR.V = overflow;

```

## Restricted behavior

### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the N, Z, C, V flags.
- The point at which an asynchronous exception is taken does not vary based on any of the following:
  - The values of the data supplied in any the registers bwing used in this instruction.
  - The values of the N, Z, C, V flags.

## C2.4.240 SUB (immediate, from PC)

Subtract from PC. Subtract from PC subtracts an immediate value from the `Align(PC, 4)` value to form a PC-relative address, and writes the result to the destination register. Arm recommends that, where possible, software avoids using this alias.

This instruction is an alias of the [ADR](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [ADR](#).
- The description of [ADR](#) gives the operational pseudocode for this instruction.

### T2

*Armv8-M Main Extension only*

### T2 variant

`SUB{<c>}{<q>} <Rd>, PC, #<imm12>`

**is equivalent to**

`ADR{<c>}{<q>} <Rd>, <label>`

**and is the preferred disassembly when `i:imm3:imm8 == '000000000000'`.**

### Assembler symbols for all encodings

|         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <c>     | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <q>     | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <Rd>    | Is the general-purpose destination register, encoded in the "Rd" field.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <label> | For encoding T1: the label of an instruction or literal data item whose address is to be loaded into <Rd>. The assembler calculates the required value of the offset from the <a href="#">Align</a> (PC, 4) value of the ADR instruction to this label. Permitted values of the size of the offset are multiples of 4 in the range 0 to 1020.<br>For encoding T2 and T3: the label of an instruction or literal data item whose address is to be loaded into <Rd>. The assembler calculates the required value of the offset from the <a href="#">Align</a> (PC, 4) value of the ADR instruction to this label. If the offset is zero or positive, encoding T3 is used, with <code>imm32</code> equal to the offset. If the offset is negative, encoding T2 is used, with <code>imm32</code> equal to the size of the offset. That is, the use of encoding T2 indicates that the required offset is minus the value of <code>imm32</code> . Permitted values of the size of the offset are 0-4095. |
| <imm12> | Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the "i:imm3:imm8" field.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

### Operation for all encodings

The description of [ADR](#) gives the operational pseudocode for this instruction.

### C2.4.241 SUB (register)

Subtract (register). Subtract (register) subtracts an optionally-shifted register value from a register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

sr\_type

#### SUB, rotate right with extend variant

Applies when **S == 0** && **imm3 == 000** && **imm2 == 00** && **sr\_type == 11**.

```
SUB{<c>}{<q>} {<Rd>}, <Rn>, <Rm>, RRX
```

#### SUB, shift or rotate by value variant

Applies when **S == 0** && **!(imm3 == 000 && imm2 == 00 && sr\_type == 11)**.

```
SUB<c>.W {<Rd>}, <Rn>, <Rm>
    // Inside IT block, and <Rd>, <Rn>, <Rm> can be represented in T1
SUB{<c>}{<q>} {<Rd>}, <Rn>, <Rm> {, <shift> #<amount>}
```

#### SUBS, rotate right with extend variant

Applies when **S == 1** && **imm3 == 000** && **Rd != 1111** && **imm2 == 00** && **sr\_type == 11**.

```
SUBS{<c>}{<q>} {<Rd>}, <Rn>, <Rm>, RRX
```

#### SUBS, shift or rotate by value variant

Applies when **S == 1** && **!(imm3 == 000 && imm2 == 00 && sr\_type == 11)** && **Rd != 1111**.

```
SUBS.W {<Rd>}, {<Rn>}, <Rm>
// Outside IT block, and <Rd>, <Rn>, <Rm> can be represented in T1
SUBS{<c>}{<q>} {<Rd>}, {<Rn>}, <Rm> {, <shift> #<amount>}
```

### Decode for this encoding

```
1 if Rd == '1111' && S == '1' then SEE "CMP (register)";
2 if Rn == '1101' then SEE "SUB (SP minus register)";
3 if !HaveMainExt() then UNDEFINED;
4 d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); setflags = (S == '1');
5 (shift_t, shift_n) = DecodeImmShift(sr_type, imm3:imm2);
6 if d == 13 || (d == 15 && S == '0') || n == 15 || m IN {13,15} then UNPREDICTABLE;
```

### Assembler symbols for all encodings

|          |                                                                                                                                                                                                                                                                  |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <c>      | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                                                                                                                    |
| <q>      | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                                                                                                                    |
| <Rd>     | Is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.                                                                                                                                           |
| <Rn>     | For encoding T1: is the first general-purpose source register, encoded in the "Rn" field.<br>For encoding T2: is the first general-purpose source register, encoded in the "Rn" field. If the SP is used, see <a href="#">C2.4.238 SUB (SP minus register)</a> . |
| <Rm>     | Is the second general-purpose source register, encoded in the "Rm" field.                                                                                                                                                                                        |
| <shift>  | Is the type of shift to be applied to the second source register, encoded in the "sr_type" field. It can have the following values:<br>LSL when sr_type = 00<br>LSR when sr_type = 01<br>ASR when sr_type = 10<br>ROR when sr_type = 11                          |
| <amount> | Is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm3:imm2" field as <amount> modulo 32.                                                                                             |

### Operation for all encodings

```
1 if ConditionPassed() then
2   EncodingSpecificOperations();
3   shifted = Shift(R[m], shift_t, shift_n, APSR.C);
4   (result, carry, overflow) = AddWithCarry(R[n], NOT(shifted), '1');
5   R[d] = result;
6   if setflags then
7     APSR.N = result[31];
8     APSR.Z = IsZeroBit(result);
9     APSR.C = carry;
10    APSR.V = overflow;
```

### Restricted behavior

#### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the N, Z, C, V flags.
- The point at which an asynchronous exception is taken does not vary based on any of the following:
  - The values of the data supplied in any the registers bwing used in this instruction.
  - The values of the N, Z, C, V flags.

## C2.4.242 SVC

Supervisor Call. The Supervisor Call instruction generates a call to a system supervisor.

Use it as a call to an operating system to provide a service.

In older versions of the Arm architecture, SVC was called SWI, Software Interrupt.

### T1

Armv8-M

|    |    |    |    |    |    |   |   |      |   |   |   |   |   |   |   |  |
|----|----|----|----|----|----|---|---|------|---|---|---|---|---|---|---|--|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7    | 6 | 5 | 4 | 3 | 2 | 1 | 0 |  |
| 1  | 1  | 0  | 1  | 1  | 1  | 1 | 1 | imm8 |   |   |   |   |   |   |   |  |

### T1 variant

SVC{<c>}{<q>} {#}<imm>

### Decode for this encoding

```
1 imm32 = ZeroExtend(imm8, 32);
2 // imm32 is for assembly/disassembly. SVC handlers in some
3 // systems interpret imm8 in software, for example to determine the required service.
```

### Assembler symbols for all encodings

<c> See [C1.2.5 Standard assembler syntax fields](#).  
 <q> See [C1.2.5 Standard assembler syntax fields](#).  
 <imm> Is an 8-bit unsigned immediate, in the range 0 to 255, encoded in the "imm8" field.

### Operation for all encodings

```
1 if ConditionPassed() then
2     EncodingSpecificOperations();
3     CallSupervisor();
```

### C2.4.243 SXTAB

Signed Extend and Add Byte. Signed Extend and Add Byte extracts an 8-bit value from a register, sign-extends it to 32 bits, adds the result to the value in another register, and writes the final result to the destination register. The instruction can specify a rotation by 0, 8, 16, or 24 bits before extracting the 8-bit value.

#### T1

*Armv8-M DSP Extension only*

#### T1 variant

SXTAB{<c>}{<q>} {<Rd>,<Rn>,<Rm> {,<ROR #<amount>}}

#### Decode for this encoding

```
1 if Rn == '1111' then SEE SXTB;
2 if !HaveDSPExt() then UNDEFINED;
3 d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); rotation = UInt(rotate:'000');
4 if d IN {13,15} || n == 13 || m IN {13,15} then UNPREDICTABLE;
```

| <q>      | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                                                                                                                                                                                                    |
| <Rd>     | Is the general-purpose destination register, encoded in the "Rd" field.                                                                                                                                                                                                                                                                          |
| <Rn>     | Is the first general-purpose source register, encoded in the "Rn" field.                                                                                                                                                                                                                                                                         |
| <Rm>     | Is the second general-purpose source register, encoded in the "Rm" field.                                                                                                                                                                                                                                                                        |
| <amount> | Is the rotate amount, encoded in the "rotate" field. It can have the following values:<br><div style="margin-left: 20px;"> 0 when rotate = 00<br/> 8 when rotate = 01<br/> 16 when rotate = 10<br/> 24 when rotate = 11 </div> ROR #<amount> can be omitted, meaning a rotate amount of 0. This is the preferred disassembly for rotate == 0b00. |

#### Operation for all encodings

```
1 if ConditionPassed() then
2   EncodingSpecificOperations();
3   rotated = ROR(R[m], rotation);
4   R[d] = R[n] + SignExtend(rotated[7:0], 32);
```

#### Restricted behavior

##### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data subject to this instruction.
- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

### C2.4.244 SXTAB16

Signed Extend and Add Byte 16. Signed Extend and Add Byte 16 extracts two 8-bit values from a register, sign-extends them to 16 bits each, adds the results to two 16-bit values from another register, and writes the final results to the destination register. The instruction can specify a rotation by 0, 8, 16, or 24 bits before extracting the 8-bit values.

#### T1

Armv8-M DSP Extension only

#### T1 variant

SXTAB16{<c>}{<q>} {<Rd>,<Rn>,<Rm> {,<ROR #<amount>}}

#### Decode for this encoding

```
1 if Rn == '1111' then SEE SXTB16;
2 if !HaveDSPExt() then UNDEFINED;
3 d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); rotation = UInt(rotate:'000');
4 if d IN {13,15} || n == 13 || m IN {13,15} then UNPREDICTABLE;
```

#### Assembler symbols for all encodings

| <Rn>     | Is the first general-purpose source register, encoded in the "Rn" field.                                                                                                                                                                                                                                                                                       |
| <Rm>     | Is the second general-purpose source register, encoded in the "Rm" field.                                                                                                                                                                                                                                                                                      |
| <amount> | Is the rotate amount, encoded in the "rotate" field. It can have the following values:<br><div style="margin-left: 20px;"> 0     when rotate = 00<br/> 8     when rotate = 01<br/> 16    when rotate = 10<br/> 24    when rotate = 11 </div> ROR #<amount> can be omitted, meaning a rotate amount of 0. This is the preferred disassembly for rotate == 0b00. |

#### Operation for all encodings

```
1 if ConditionPassed() then
2   EncodingSpecificOperations();
3   rotated = ROR(R[m], rotation);
4   bits(32) result;
5   result[15:0] = R[n][15:0] + SignExtend(rotated[7:0], 16);
6   result[31:16] = R[n][31:16] + SignExtend(rotated[23:16], 16);
7   R[d] = result;
```

#### Restricted behavior

##### Data Independent Timing behavior

If [AIRCR.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data subject to this instruction.

- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

## C2.4.245 SXTAH

Signed Extend and Add Halfword. Signed Extend and Add Halfword extracts a 16-bit value from a register, sign-extends it to 32 bits, adds the result to a value from another register, and writes the final result to the destination register. The instruction can specify a rotation by 0, 8, 16, or 24 bits before extracting the 16-bit value.

### T1

Armv8-M DSP Extension only

### T1 variant

SXTAH{<c>}{<q>} {<Rd>,<Rn>,<Rm> {,<ROR #<amount>}}

### Decode for this encoding

```

 <Rd> Is the general-purpose destination register, encoded in the "Rd" field.  
 <Rm> Is the general-purpose source register, encoded in the "Rm" field.  
 <amount> Is the rotate amount, encoded in the "rotate" field. It can have the following values:  
     0 when rotate = 00  
     8 when rotate = 01  
     16 when rotate = 10  
     24 when rotate = 11  
 ROR #<amount> can be omitted, meaning a rotate amount of 0. This is the preferred disassembly for rotate == 0b00.

#### Operation for all encodings

```
1 if ConditionPassed() then
```

```
2   EncodingSpecificOperations();  
3   rotated = ROR(R[m], rotation);  
4   R[d] = SignExtend(rotated[7:0], 32);
```

## Restricted behavior

### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data subject to this instruction.
- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

## C2.4.247 SXTB16

Signed Extend Byte 16. Signed Extend Byte 16 extracts two 8-bit values from a register, sign-extends them to 16 bits each, and writes the results to the destination register. The instruction can specify a rotation by 0, 8, 16, or 24 bits before extracting the 8-bit values.

### T1

Armv8-M DSP Extension only

### T1 variant

SXTB16{<c>}{<q>} {<Rd>, } <Rm> {, ROR #<amount>}

### Decode for this encoding

```
1 if !HaveDSPExt() then UNDEFINED;
2 d = UInt(Rd); m = UInt(Rm); rotation = UInt(rotate: '000');
3 if d IN {13,15} || m IN {13,15} then UNPREDICTABLE;
```

### Assembler symbols for all encodings

<c> See [C1.2.5 Standard assembler syntax fields](#).  
 <q> See [C1.2.5 Standard assembler syntax fields](#).  
 <Rd> Is the general-purpose destination register, encoded in the "Rd" field.  
 <Rm> Is the general-purpose source register, encoded in the "Rm" field.  
 <amount> Is the rotate amount, encoded in the "rotate" field. It can have the following values:  
     0     when rotate = 00  
     8     when rotate = 01  
     16    when rotate = 10  
     24    when rotate = 11  
 ROR #<amount> can be omitted, meaning a rotate amount of 0. This is the preferred disassembly for rotate == 0b00.

### Operation for all encodings

```
1 if ConditionPassed() then
2     EncodingSpecificOperations();
3     rotated = ROR(R[m], rotation);
4     bits(32) result;
5     result[15:0] = SignExtend(rotated[7:0], 16);
6     result[31:16] = SignExtend(rotated[23:16], 16);
7     R[d] = result;
```

### Restricted behavior

#### Data Independent Timing behavior

If [AIRCR.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data subject to this instruction.
- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

### C2.4.248 SXTB

Signed Extend Halfword. Signed Extend Halfword extracts a 16-bit value from a register, sign extends it to 32 bits, and writes the result to the destination register. The instruction can specify a rotation by 0, 8, 16, or 24 bits before extracting the 16-bit value.

- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

## C2.4.249 TBB, TBH

Table Branch Byte or Halfword. Table Branch Byte causes a PC-relative forward branch using a table of single byte offsets. A base register provides a pointer to the table, and a second register supplies an index into the table. The branch length is twice the value of the byte returned from the table.

Table Branch Halfword causes a PC-relative forward branch using a table of single halfword offsets. A base register provides a pointer to the table, and a second register supplies an index into the table. The branch length is twice the value of the halfword returned from the table.

#### T1 variant

TST{<c>}{<q>} <Rn>, #<const>

#### Decode for this encoding

```
1 if !HaveMainExt() then UNDEFINED;
2 n = UInt(Rn);
3 (imm32, carry) = T32ExpandImm_C(i:imm3:imm8, APSR.C);
4 if n IN {13,15} then UNPREDICTABLE;
```

#### Assembler symbols for all encodings

<c> See [C1.2.5 Standard assembler syntax fields](#).  
 <q> See [C1.2.5 Standard assembler syntax fields](#).  
 <Rn> Is the general-purpose source register, encoded in the "Rn" field.  
 <const> Is an immediate value derived from the 12-bit immediate that is encoded in the "i:imm3:imm8" field. See [C1.5 Modified immediate constants](#) for the range of values.

#### Operation for all encodings

```
1 if ConditionPassed() then
2   EncodingSpecificOperations();
3   result = R[n] AND imm32;
4   APSR.N = result[31];
5   APSR.Z = IsZeroBit(result);
6   APSR.C = carry;
7   // APSR.V unchanged
```

#### Restricted behavior

##### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the N, Z, C, V flags.
- The point at which an asynchronous exception is taken does not vary based on any of the following:
  - The values of the data supplied in any the registers bwing used in this instruction.
  - The values of the N, Z, C, V flags.

### C2.4.253 TST (register)

Test (register). Test (register) performs a bitwise AND operation on a register value and an optionally-shifted register value. It updates the condition flags based on the result, and discards the result.

| <c>     | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                             |
| <q>     | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                             |
| <Rn>    | Is the first general-purpose source register, encoded in the "Rn" field.                                                                                                  |
| <Rm>    | Is the second general-purpose source register, encoded in the "Rm" field.                                                                                                 |
| <shift> | Is the type of shift to be applied to the second source register, encoded in the "sr_type" field. It can have the following values:<br>LSL when <code>sr_type = 00</code> |

LSR when `sr_type = 01`  
ASR when `sr_type = 10`  
ROR when `sr_type = 11`  
<amount> Is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm3:imm2" field as <amount> modulo 32.

### Operation for all encodings

```
1 if ConditionPassed() then
2   EncodingSpecificOperations();
3   (shifted, carry) = Shift_C(R[m], shift_t, shift_n, APSR.C);
4   result = R[n] AND shifted;
5   APSR.N = result[31];
6   APSR.Z = IsZeroBit(result);
7   APSR.C = carry;
8   // APSR.V unchanged
```

### Restricted behavior

#### Data Independent Timing behavior

If [AIRCR.DIT](#) is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the N, Z, C, V flags.
- The point at which an asynchronous exception is taken does not vary based on any of the following:
  - The values of the data supplied in any the registers bwing used in this instruction.
  - The values of the N, Z, C, V flags.

### C2.4.254 TT, TTT, TTA, TTAT

Test Target (Alternate Domain, Unprivileged). Test Target (TT) queries the Security state and access permissions of a memory location.

Test Target Unprivileged (TTT) queries the Security state and access permissions of a memory location for an unprivileged access to that location.

Test Target Alternate Domain (TTA) and Test Target Alternate Domain Unprivileged (TTAT) query the Security state and access permissions of a memory location for a Non-secure access to that location. These instructions are only valid when executing in Secure state, and are UNDEFINED if used from Non-secure state.

These instructions return the Security state and access permissions in the destination register. See TT\_RESP for the format of the destination register.

### T1 variant

UBFX{<c>}{<q>} <Rd>, <Rn>, #<lsb>, #<width>

### Decode for this encoding

```

1 if !HaveMainExt() then UNDEFINED;
2 d = UInt(Rd); n = UInt(Rn);
3 lsbit = UInt(imm3:imm2); widthminus1 = UInt(widthm1);
4 msbit = lsbit + widthminus1;
5 if msbit > 31 then UNPREDICTABLE;
6 if d IN {13,15} || n IN {13,15} then UNPREDICTABLE;
```

### CONSTRAINED UNPREDICTABLE behavior

If `msbit > 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

### Assembler symbols for all encodings

|         |                                                                                                                      |
|---------|----------------------------------------------------------------------------------------------------------------------|
| <c>     | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                        |
| <q>     | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                        |
| <Rd>    | Is the general-purpose destination register, encoded in the "Rd" field.                                              |
| <Rn>    | Is the general-purpose source register, encoded in the "Rn" field.                                                   |
| <lsb>   | Is the bit number of the least significant bit in the field, in the range 0 to 31, encoded in the "imm3:imm2" field. |
| <width> | Is the width of the field, in the range 1 to 32-<lsb>, encoded in the "widthm1" field as <width>-1.                  |

### Operation for all encodings

```

1 if ConditionPassed() then
2     EncodingSpecificOperations();
3     if msbit <= 31 then
4         R[d] = ZeroExtend(R[n][msbit:lsbit], 32);
5     else
6         R[d] = bits(32) UNKNOWN;
```

### Restricted behavior

#### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data subject to this instruction.

- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

## C2.4.259 UDF

Permanently Undefined. Permanently Undefined generates an Undefined Instruction exception.

```

### Restricted behavior

#### Data Independent Timing behavior

If [AIRCR.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data subject to this instruction.
- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

## C2.4.289 UXTAB

Unsigned Extend and Add Byte. Unsigned Extend and Add Byte extracts an 8-bit value from a register, zero-extends it to 32 bits, adds the result to the value in another register, and writes the final result to the destination register. The instruction can specify a rotation by 0, 8, 16, or 24 bits before extracting the 8-bit value.

### T1

Armv8-M DSP Extension only

### T1 variant

UXTAB{<c>}{<q>} {<Rd>,<Rn>,<Rm> {,<ROR #<amount>}}

### Decode for this encoding

```
1 if Rn == '1111' then SEE UXTB;
2 if !HaveDSPExt() then UNDEFINED;
3 d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); rotation = UInt(rotate:'000');
4 if d IN {13,15} || n == 13 || m IN {13,15} then UNPREDICTABLE;
```

### Assembler symbols for all encodings

### Operation for all encodings

```
1 if ConditionPassed() then
2   EncodingSpecificOperations();
3   rotated = ROR(R[m], rotation);
4   R[d] = R[n] + ZeroExtend(rotated[15:0], 32);
```

### Restricted behavior

#### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data subject to this instruction.
- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

## C2.4.292 UXTB

Unsigned Extend Byte. Unsigned Extend Byte extracts an 8-bit value from a register, zero extends it to 32 bits, and writes the result to the destination register. The instruction can specify a rotation by 0, 8, 16, or 24 bits before extracting the 8-bit value.

| <q>      | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                                                                                                                                                                                                                       |
| <Rd>     | Is the general-purpose destination register, encoded in the "Rd" field.                                                                                                                                                                                                                                                                                             |
| <Rm>     | Is the general-purpose source register, encoded in the "Rm" field.                                                                                                                                                                                                                                                                                                  |
| <amount> | Is the rotate amount, encoded in the "rotate" field. It can have the following values: <ul style="list-style-type: none"> <li>0 when rotate = 00</li> <li>8 when rotate = 01</li> <li>16 when rotate = 10</li> <li>24 when rotate = 11</li> </ul> ROR #<amount> can be omitted, meaning a rotate amount of 0. This is the preferred disassembly for rotate == 0b00. |

### Operation for all encodings

```
1 if ConditionPassed() then
```

```
2   EncodingSpecificOperations();  
3   rotated = ROR(R[m], rotation);  
4   R[d] = ZeroExtend(rotated[15:0], 32);
```

## Restricted behavior

### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data subject to this instruction.
- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

## C2.4.295 VABAV

Vector Absolute Difference and Accumulate Across Vector. Subtract the elements of the second source vector register from the corresponding elements of the first source vector and accumulate the absolute values of the results. The initial value of the general-purpose destination register is added to the result.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

### C2.4.301 VADC

Whole Vector Add With Carry. Add with carry across beats, with carry in from and out to FPSCR.C. Initial value of FPSCR.C can be overridden by using the I variant. FPSCR.C is not updated for beats disabled because of predication. FPSCR.N, .V and .Z are zeroed whenever FPSCR.C is updated.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

```

## Restricted behavior

### Data Independent Timing behavior

If [AIRCR.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data subject to this instruction.
- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

### C2.4.304 VADD (vector)

Vector Add. Add the value of the elements in the first source vector register to either the respective elements in the second source vector register or a general-purpose register. The result is then written to the destination vector register.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

## Restricted behavior

### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data subject to this instruction.
- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

### C2.4.305 VADDLV

Vector Add Long Across Vector. Add across the elements of a vector accumulating the result into a scalar. The 64-bit result is stored across two registers, the upper-half is stored in an odd-numbered register and the lower half is stored in an even-numbered register. The initial value of the general-purpose destination registers can optionally be added to the result.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

### C2.4.307 VAND

Vector Bitwise And. Compute a bitwise AND of a vector register with another vector register. The result is written to the destination vector register.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

## Restricted behavior

### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data subject to this instruction.
- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

### C2.4.312 VCADD

Vector Complex Add with Rotate. This instruction performs a complex addition of the first operand with the second operand rotated in the complex plane by the specified amount. A 90 degree rotation of this operand corresponds to a multiplication by a positive imaginary unit, while a 270 degree rotation corresponds to a multiplication by a negative imaginary unit. Even and odd elements of the source vectors are interpreted to be the real and imaginary components, respectively, of a complex number. The result is then written to the destination vector register.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

### C2.4.313 VCADD (floating-point)

Vector Complex Add with Rotate. This instruction performs a complex addition of the first operand with the second operand rotated in the complex plane by the specified amount. A 90 degree rotation of this operand corresponds to a multiplication by a positive imaginary unit, while a 270 degree rotation corresponds to a multiplication by a negative imaginary unit. Even and odd elements of the source vectors are interpreted to be the real and imaginary components, respectively, of a complex number. The results are written into the destination vector register.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

### C2.4.316 VCMLA (floating-point)

Vector Complex Multiply Accumulate. This instruction operates on complex numbers that are represented in registers as pairs of elements. Each element holds a floating-point value. The odd element holds the imaginary part of the number, and the even element holds the real part of the number. The instruction performs the computation on the corresponding complex number element pairs from the two source registers and the destination register. Considering the complex number from the second source register on an Argand diagram, the number is rotated counterclockwise by 0, 90, 180, or 270 degrees. If the transformation was a rotation by 0 or 180 degrees, the two elements of the transformed complex number are multiplied by the real element of the first source register. If the transformation was a rotation by 90 or 270 degrees, the two elements are multiplied by the imaginary element of the complex number from the first source register. The result of the multiplication is added on to the existing value in the destination vector register. The multiplication and addition operations are fused and the result is not rounded.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

### C2.4.317 VCMF

Floating-point Compare. Floating-point Compare compares two registers, or one register and zero. It writes the result to FPSCR condition flags. These are normally transferred to the APSR condition flags by a subsequent [VMRS](#) instruction.

It raises an Invalid Operation exception only if either operand is a signaling NaN.

## Assembler symbols for T1 encodings

<dt>                      Size: indicates the size of the elements in the vector.  
This parameter must be one of the following values:  
I8      Encoded as    size = 00  
I16     Encoded as    size = 01  
I32     Encoded as    size = 10

<fc>                      The comparison condition to use.  
This parameter must be one of the following values:  
EQ      Encoded as    fc = 0  
NE      Encoded as    fc = 1

## Assembler symbols for T2 encodings

<dt>                      Size: indicates the size of the elements in the vector.  
This parameter must be one of the following values:  
U8      Encoded as    size = 00  
U16     Encoded as    size = 01  
U32     Encoded as    size = 10

<fc>           The comparison condition to use.  
This parameter must be one of the following values:  
CS   Encoded as   fc = 0  
HI   Encoded as   fc = 1

### Assembler symbols for T3 encodings

<dt>           Size: indicates the size of the elements in the vector.  
This parameter must be one of the following values:  
S8   Encoded as   size = 00  
S16   Encoded as   size = 01  
S32   Encoded as   size = 10  
  
<fc>           The comparison condition to use.  
This parameter must be one of the following values:  
GE   Encoded as   fch = 0,   fcl = 0  
LT   Encoded as   fch = 0,   fcl = 1  
GT   Encoded as   fch = 1,   fcl = 0  
LE   Encoded as   fch = 1,   fcl = 1

### Assembler symbols for T4 encodings

<dt>           Size: indicates the size of the elements in the vector.  
This parameter must be one of the following values:  
I8    Encoded as   size = 00  
I16   Encoded as   size = 01  
I32   Encoded as   size = 10  
  
<fc>           The comparison condition to use.  
This parameter must be one of the following values:  
EQ   Encoded as   fc = 0  
NE   Encoded as   fc = 1

### Assembler symbols for T5 encodings

<dt>           Size: indicates the size of the elements in the vector.  
This parameter must be one of the following values:  
U8    Encoded as   size = 00  
U16   Encoded as   size = 01  
U32   Encoded as   size = 10  
  
<fc>           The comparison condition to use.  
This parameter must be one of the following values:  
CS   Encoded as   fc = 0  
HI   Encoded as   fc = 1

### Assembler symbols for T6 encodings

<dt>           Size: indicates the size of the elements in the vector.  
This parameter must be one of the following values:  
S8    Encoded as   size = 00  
S16   Encoded as   size = 01  
S32   Encoded as   size = 10  
  
<fc>           The comparison condition to use.  
This parameter must be one of the following values:  
GE   Encoded as   fch = 0,   fcl = 0  
LT   Encoded as   fch = 0,   fcl = 1  
GT   Encoded as   fch = 1,   fcl = 0  
LE   Encoded as   fch = 1,   fcl = 1

## Assembler symbols for all encodings

|        |                                                               |
|--------|---------------------------------------------------------------|
| <v, q> | See <a href="#">C1.2.5 Standard assembler syntax fields</a> . |
| <Qn>   | First source vector register                                  |
| <Qm>   | Second source vector register                                 |
| <Rm>   | Source general-purpose register (ZR is permitted, PC is not). |

## Operation for all encodings

```

1 EncodingSpecificOperations();
2 ExecuteFPCheck();
3

20
21 Elem[VPR.P0, curBeat, 4] = beatPred AND elmtMask;
```

## Restricted behavior

### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data subject to this instruction.
- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

## C2.4.320 VCMPE

Floating-point Compare, raising Invalid Operation on NaN. Floating-point Compare, raising Invalid Operation on NaN compares two registers, or one register and zero. It writes the result to FPSCR condition flags. These are normally transferred to the APSR condition flags by a subsequent [VMRS](#) instruction.

It raises an Invalid Operation exception if either operand is any type of NaN.

## Restricted behavior

### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data subject to this instruction.
- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

### C2.4.321 VCMUL (floating-point)

Vector Complex Multiply. This instruction operates on complex numbers that are represented in registers as pairs of elements. Each element holds a floating-point value. The odd element holds the imaginary part of the number, and the even element holds the real part of the number. The instruction performs the computation on the corresponding complex number element pairs from the two source registers and the destination register. Considering the complex number from the second source register on an Argand diagram, the number is rotated counterclockwise by 0, 90, 180, or 270 degrees. If the transformation was a rotation by 0 or 180 degrees, the two elements of the transformed complex number are multiplied by the real element of the first source register. If the transformation was a rotation by 90 or 270 degrees, the two elements are multiplied by the imaginary element of the complex number from the first source register. The results are written into the destination vector register.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

```

## C2.4.322 VCTP

Create Vector Tail Predicate. Creates a predicate pattern in VPR.P0 such that any element numbered the value of Rn or greater is predicated. Any element numbered lower than the value of Rn is not predicated. If placed within a VPT block and a lane is predicated, the corresponding VPR.P0 pattern will also be predicated. The generated VPR.P0 pattern can be used by an ensuing predication instruction to apply tail predication on a vector register.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

12 Elem[VPR.P0, curBeat, 4] = elmtMask AND Elem[fullMask, curBeat, 4];
```

### C2.4.323 VCVT (between double-precision and single-precision)

Convert between double-precision and single-precision. This instruction does one of the following:

- Converts the value in a double-precision register to single-precision and writes the result to a single-precision register.
- Converts the value in a single-precision register to double-precision and writes the result to a double-precision register.

```

## C2.4.324 VCVT (between floating-point and fixed-point)

Floating-point Convert (between floating-point and fixed-point). Floating-point Convert (between floating-point and fixed-point) converts a value in a register from floating-point to fixed-point, or from fixed-point to floating-point, and places the result in the destination register. Software can specify the fixed-point value as either signed or unsigned.

The fixed-point value can be 16-bit or 32-bit. Conversions from fixed-point values take their operand from the low-order bits of the source register and ignore any remaining bits. Signed conversions to fixed-point values sign-extend the result value to the destination register width. Unsigned conversions to fixed-point values zero-extend the result value to the destination register width.

The floating-point to fixed-point operation uses the Round towards Zero rounding mode. The fixed-point to floating-point operation uses the Round to Nearest rounding mode.

### T1

| <Ddm>   | Is the 64-bit name of the floating-point destination and source register, encoded in the "D:Vd" field.                                                                                                                                                              |
| <fbits> | The number of fraction bits in the fixed-point number:<br>- If <dt> is S16 or U16, <fbits> must be in the range 0-16. (16 - <fbits>) is encoded in [imm4, i]<br>- If <dt> is S32 or U32, <fbits> must be in the range 1-32. (32 - <fbits>) is encoded in [imm4, i]. |

### Operation for all encodings

```

1 if ConditionPassed() then
2     EncodingSpecificOperations();
3     ExecuteFPCheck();
4     if to_fixed then
5         case sf of
6             when '01'
7                 result = FPToFixed(S[d][15:0], esize, fract, unsigned, round_zero, TRUE);
8                 S[d] = if unsigned then ZeroExtend(result, 32) else SignExtend(result, 32);
```

```

9      when '10'
10         result = FPToFixed(S[d], esize, fract, unsigned, round_zero, TRUE);
11         S[d] = if unsigned then ZeroExtend(result, 32) else SignExtend(result, 32);
12     when '11'
13         result = FPToFixed(D[d], esize, fract, unsigned, round_zero, TRUE);
14         D[d] = if unsigned then ZeroExtend(result, 64) else SignExtend(result, 64);
15 else
16     case sf of
17     when '01'
18         fp16 = FixedToFP(S[d][esize-1:0], 16, fract, unsigned, round_nearest, TRUE);
19         S[d] = Zeros(16):fp16;
20     when '10'
21         S[d] = FixedToFP(S[d][esize-1:0], 32, fract, unsigned, round_nearest, TRUE);
22     when '11'
23         D[d] = FixedToFP(D[d][esize-1:0], 64, fract, unsigned, round_nearest, TRUE);

```

### C2.4.325 VCVT (between floating-point and fixed-point) (vector)

Vector Convert between floating-point and fixed-point. Convert between floating-point and fixed-point values in elements of a vector register. The number of fractional bits in the fixed-point value is specified by an immediate. Fixed-point values can be specified as signed or unsigned. The floating-point to fixed-point operation uses the Round towards Zero rounding mode. The fixed-point to floating-point operation uses the Round to Nearest rounding mode. For floating-point to fixed-point operation, if the source value is outside the range of the target fixed-point type, the result is saturated.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

21         Elem[Q[d, curBeat], e, 8] = Elem[result, e, 8];

```

## C2.4.326 VCVT (between floating-point and integer)

Vector Convert between floating-point and integer. Convert between floating-point and integer values in elements of a vector register. When converting to integer the value is rounded towards zero, when converting to floating-point the value is rounded to nearest. For floating-point to integer operation, if the source value is outside the range of the target integer type, the result is saturated.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

```

## C2.4.327 VCVT (between single and half-precision floating-point)

Vector Convert between half-precision and single-precision. Convert between half-precision and single-precision floating-point values in elements of a vector register. For half-precision to single-precision operation, the top half (T variant) or bottom half (B variant) of the source vector register is selected. For single-precision to half-precision operation, the top half (T variant) or bottom half (B variant) of the destination vector register is selected and the other half retains its previous value.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

## C2.4.328 VCVT (floating-point to integer)

Convert floating-point to integer with Round towards Zero. Convert floating-point to integer with Round towards Zero converts a value in a register from floating-point to a 32-bit integer, using the Round towards Zero rounding mode, and places the result in the destination register.

## C2.4.329 VCVT (from floating-point to integer)

Vector Convert from floating-point to integer. Convert each element of a vector from floating-point to integer using the specified rounding mode and place the results in a second vector. If a source element is outside the range of the target integer type, the result element is saturated.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

### Operation for all encodings

```
1 EncodingSpecificOperations();
2 ExecuteFPCheck();
3
4 (curBeat, elmtMask) = GetCurInstrBeat();
5
6 result = Zeros(32);
7 op1     = Q[m, curBeat];
8 for e = 0 to elements-1
9     // Avoid Floating-point exceptions on a predicated lane by checking the element mask
10    pred = (elmtMask[e*(esize>>3)] == '0');
11    U     = unsigned;
12    Elem[result, e, esize] = FPToFixedDirected(Elem[op1, e, esize], 0, U, RM, FALSE, pred);
13
14 for e = 0 to 3
15     if elmtMask[e] == '1' then
16         Elem[Q[d, curBeat], e, 8] = Elem[result, e, 8];
```

### C2.4.330 VCVT (integer to floating-point)

Convert integer to floating-point. Convert integer to floating-point converts a value in a register from a 32-bit integer to floating-point, using the rounding mode specified by FPSCR, and places the result in the destination register.

```

### C2.4.332 VCVTB

Floating-point Convert Bottom. Floating-point Convert Bottom does one of the following:

- Converts the half-precision value in the bottom half of a single-precision register to single-precision and writes the result to a single-precision register.
- Converts the value in a single-precision register to half-precision and writes the result into the bottom half of a single-precision register, preserving the other half of the target register.
- Converts the half-precision value in the bottom half of a single-precision register to double-precision and writes the result to a double-precision register, without intermediate rounding.
- Converts the value in the double-precision register to half-precision and writes the result into the bottom half of a single-precision register, preserving the other half of the target register, without intermediate rounding.

```

### C2.4.337 VCVTT

Floating-point Convert Top. Floating-point Convert Top does one of the following:

- Converts the half-precision value in the top half of a single-precision register to single-precision and writes the result to a single-precision register.
- Converts the value in a single-precision register to half-precision and writes the result into the top half of a single-precision register, preserving the other half of the target register.
- Converts the half-precision value in the top half of a single-precision register to double-precision and writes the result to a double-precision register, without intermediate rounding.
- Converts the value in the double-precision register to half-precision and writes the result into the top half of a double-precision register, preserving the other half of the target register, without intermediate rounding.

```

### C2.4.339 VCX1 (vector)

Custom Extension Instruction Class 1 Vector. Custom extension register instruction class 1 vector computes a value based on an immediate, and optionally the destination value, and writes the result to the destination register. The source and destination registers are within the Floating-point and SIMD register file, and require the current execution state to have access to these registers.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

14          else
15              S[d] = VCX_op2(ThisInstr(), S[n], S[m], 32);

```

### C2.4.343 VCX3 (vector)

Custom Extension Instruction Class 3 Vector. Custom extension register instruction class 3 vector computes a value based on two source registers, an immediate, and optionally the destination value, and writes the result to the destination register. The source and destination registers are within the Floating-point and SIMD register file, and require the current execution state to have access to these registers.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

#### T1

Armv8-M Custom Datapath Extension with Armv8.1-M MVE

|    |    |    |    |    |    |   |     |   |   |     |    |   |   |    |   |    |    |        |    |    |    |   |   |     |    |   |   |   |   |   |   |

| 1  | 1  | 1  | A  | 1  | 1  | 0 | op1 | 1 | D | op2 | Vn |   |   | Vd |   |    | 0  | coproc |    |    | N  | 1 | M | op3 | Vm |   |   |   |   |   |   |

#### Accumulator variant

Applies when **A == 1**

VCX3A<v> <coproc>, <Qd>, <Qn>, <Qm>, #<imm>

#### Non-accumulator variant

Applies when **A == 0**

VCX3<v> <coproc>, <Qd>, <Qn>, <Qm>, #<imm>

#### Decode for this encoding

```

1 if CoprocType(UInt(coproc)) != CP_CDEv1 then SEE "Coprocessor instructions";
2 cp = UInt(coproc);
3 ExecuteCPCheckCDE(cp, TRUE);
4 if D == '1' || M == '1' || N == '1' || Vd[0] == '1' || Vm[0] == '1' || Vn[0] == '1' then
5     UNDEFINED;
6 imm = op1:op2:op3;
7 acc = (A == '1');
8 d = UInt(D:Vd[3:1]);
9 n = UInt(N:Vn[3:1]);
10 m = UInt(M:Vm[3:1]);
11 if InITBlock() then UNPREDICTABLE;
```

#### CONSTRAINED UNPREDICTABLE behavior

If InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP.

#### Assembler symbols for all encodings

A Accumulate with existing register contents. This parameter must be one of the following values:

- Encoded as A = 0
- A Encoded as A = 1

<v> See [C1.2.5 Standard assembler syntax fields](#).

|          |                                                                                                     |
|----------|-----------------------------------------------------------------------------------------------------|
| <coproc> | Is the name of the coprocessor, encoding in the "coproc" field. Valid names are p0 to p7 inclusive. |
| <Qm>     | Is the source vector register Q0 – Q7, encoded in the "M:Vm" fields as <Qm>*2.                      |
| <Qd>     | Is the source and destination vector register Q0 – Q7, encoded in the "D:Vd" fields as <Qd>*2.      |
| <Qn>     | Is the source vector register Q0 – Q7, encoded in the "N:Vn" fields as <Qn>*2.                      |
| <imm>    | Is the immediate encoded in "op1:op2:op3".                                                          |

### Operation for all encodings

```

1 EncodingSpecificOperations();
2 ExecuteFPCheck();
3 if (!CoproccAccepted(cp, ThisInstr())) then GenerateCoproccorException();
4
5 // Get current beat number and predication mask
6 (curBeat, elmtMask) = GetCurInstrBeat();
7
8 result = Zeros(32);
9 if acc then
10     // If the accumulator variant is used, then the 32-bit value from the vector
11     // source-destination register is used as an input to the custom operation
12     result = VCX_op3(ThisInstr(), Q[d, curBeat], Q[n, curBeat], Q[m, curBeat], 32,
13                     TRUE, curBeat, elmtMask);
14 else
15     result = VCX_op2(ThisInstr(), Q[n, curBeat], Q[m, curBeat], 32,
16                     TRUE, curBeat, elmtMask);
17
18 for e = 0 to 3
19     // If the vector lane is not predicated
20     if elmtMask[e] == '1' then
21         Elem[Q[d, curBeat], e, 8] = Elem[result, e, 8];

```

### C2.4.344 VDDUP, VDWDUP

Vector Decrement and Duplicate, Vector Decrement with Wrap and Duplicate. Creates a vector with elements of successively decrementing values, starting at an offset specified by Rn. The value is decremented by the specified immediate value, which can take the following values: 1, 2, 4, 8. For all variants, the updated start offset is written back to Rn. For the wrapping variant, the operation wraps so that the values written to the vector register elements are in the range [0, Rm). However, if Rn and Rm are not a multiple of imm, or if Rn >= Rm, the operation is CONSTRAINED UNPREDICTABLE, with the resulting values of Rn and Qd UNKNOWN.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

| <Qn>   | Source vector register.                                                                                                                                                    |
| <Qm>   | Source vector register.                                                                                                                                                    |

#### Operation for all encodings

```

1 EncodingSpecificOperations();
2 ExecuteFPCheck();
3
4 (curBeat, elmtMask) = GetCurInstrBeat();
5
6 result = Q[n, curBeat] EOR Q[m, curBeat];
7
8 for e = 0 to 3
9     if elmtMask[e] == '1' then
10         Elem[Q[d, curBeat], e, 8] = Elem[result, e, 8];
```

#### Restricted behavior

##### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data subject to this instruction.

- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

## C2.4.348 VFMA

Floating-point Fused Multiply Accumulate. Floating-point Fused Multiply Accumulate multiplies two registers, adds the product to the destination register, and places the result in the destination register. The result of the multiply is not rounded before the addition.

### C2.4.349 VFMA (vector by scalar plus vector, floating-point)

Vector Fused Multiply Accumulate. Multiply each element of a vector register by a general-purpose register value to produce a vector of results. Each result is then added to its respective element in the destination register. The result of each multiply is not rounded before the addition.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

```

### C2.4.353 VFNMA

Floating-point Fused Negate Multiply Accumulate. Floating-point Fused Negate Multiply Accumulate negates one floating-point register value and multiplies it by another floating-point register value, adds the negation of the floating-point value in the destination register to the product, and writes the result back to the destination register. The result of the multiply is not rounded before the addition.

### C2.4.355 VHADD

Vector Halving Add. Add the value of the elements in the first source vector register to either the respective elements in the second source vector register or a general-purpose register. The result is halved before being written to the destination vector register.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

## Operation for all encodings

```

1  EncodingSpecificOperations();
2  ExecuteFPCheck();
3
4  (curBeat, elmtMask) = GetCurInstrBeat();
5
6  result = Zeros(32);
7  op1    = Q[n, curBeat];
8  if !withScalar then
9      op2 = Q[m, curBeat];
10 for e = 0 to elements-1
11     if withScalar then
12         value = Int(Elem[op1, e, esize], unsigned) + Int(R[m][esize-1:0], unsigned);
13     else
14         value = Int(Elem[op1, e, esize], unsigned) + Int(Elem[op2, e, esize], unsigned);
15     Elem[result, e, esize] = value[esize:1];
16
17 for e = 0 to 3
18     if elmtMask[e] == '1' then
19         Elem[Q[d, curBeat], e, 8] = Elem[result, e, 8];

```

## Restricted behavior

### Data Independent Timing behavior

If [AIRCR.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data subject to this instruction.
- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

### C2.4.356 VHCADD

Vector Halving Complex Add with Rotate. This instruction performs a complex addition of the first operand with the second operand rotated in the complex plane by the specified amount. A 90 degree rotation of this operand corresponds to a multiplication by a positive imaginary unit, while a 270 degree rotation corresponds to a multiplication by a negative imaginary unit. Even and odd elements of the source vectors are interpreted to be the real and imaginary components, respectively, of a complex number. The result is halved before being written to the destination register.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

## Operation for all encodings

```

1  EncodingSpecificOperations();
2  ExecuteFPCheck();
3
4  (curBeat, elmtMask) = GetCurInstrBeat();
5
6  result = Zeros(32);
7  op1    = Q[n, curBeat];
8  if !withScalar then
9      op2 = Q[m, curBeat];
10 for e = 0 to elements-1
11     if withScalar then
12         value = Int(Elem[op1, e, esize], unsigned) - Int(R[m][esize-1:0], unsigned);
13     else
14         value = Int(Elem[op1, e, esize], unsigned) - Int(Elem[op2, e, esize], unsigned);
15     Elem[result, e, esize] = value[esize:1];
16
17 for e = 0 to 3
18     if elmtMask[e] == '1' then
19         Elem[Q[d, curBeat], e, 8] = Elem[result, e, 8];

```

## Restricted behavior

### Data Independent Timing behavior

If [AIRCR.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data subject to this instruction.
- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

### C2.4.358 VIDUP, VIWDUP

Vector Increment and Duplicate, Vector Increment with Wrap and Duplicate. Creates a vector with elements of successively incrementing values, starting at an offset specified by Rn. The value is incremented by the specified immediate value, which can take the following values: 1, 2, 4, 8. For all variants, the updated start offset is written back to Rn. For the wrapping variant, the operation wraps so that the values written to the vector register elements are in the range [0, Rm). However, if Rn and Rm are not a multiple of imm, or if Rn >= Rm, the operation is CONSTRAINED UNPREDICTABLE, with the resulting values of Rn and Qd UNKNOWN.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

#### T1

Armv8.1-M MVE

#### T1: VIWDUP variant

VIWDUP<v><q>.<dt> Qd, Rn, Rm, #<imm>

#### Decode for this encoding

```

1 if Rm == '111' then SEE "VIDUP";
2 if size == '11' then SEE "Related encodings";
3 CheckDecodeFaults(ExtType_Mve);
4 if D == '1' then UNDEFINED;
5 d = UInt(D:Qd);
6 m = UInt(Rm:'1');
7 n = UInt(Rn:'0');
8 wrap = TRUE;
9 imm2i = 1 << UInt(immh:imml);
10 esize = 8 << UInt(size);
11 elements = 32 DIV esize;
12 if InITBlock() then CONSTRAINED_UNPREDICTABLE;
13 if Rm == '110' then CONSTRAINED_UNPREDICTABLE;
```

#### T2

Armv8.1-M MVE

#### T2: VIDUP variant

VIDUP<v><q>.<dt> Qd, Rn, #<imm>

#### Decode for this encoding

```

1 if size == '11' then SEE "Related encodings";
2 CheckDecodeFaults(ExtType_Mve);
3 if D == '1' then UNDEFINED;
4 d      = UInt(D:Qd);
5 n      = UInt(Rn:'0');
6 m      = integer UNKNOWN;
7 wrap   = FALSE;
8 imm2i  = 1 << UInt(immh:imm1);
9 esize  = 8 << UInt(size);
10 elements = 32 DIV esize;
11 if InitBlock() then CONSTRAINED_UNPREDICTABLE;

```

### Assembler symbols for T1 encodings

<Rn> Current offset to start writing into Qd. Must be a multiple of imm. This must be an even numbered register.

### Assembler symbols for T2 encodings

<Rn> Current offset to start writing into Qd. This must be an even numbered register.

### Assembler symbols for all encodings

<v, q> See C1.2.5 *Standard assembler syntax fields*.  
 <dt> Size: indicates the size of the elements in the vector.  
 This parameter must be one of the following values:  
     U8    Encoded as   size = 00  
     U16   Encoded as   size = 01  
     U32   Encoded as   size = 10  
 <Qd> Destination vector register.  
 <Rm> Size of the range. Must be a multiple of imm. This must be an odd numbered register.  
 <imm> The increment between successive element values.  
 This parameter must be one of the following values:  
     #1    Encoded as   immh = 0,   imm1 = 0  
     #2    Encoded as   immh = 0,   imm1 = 1  
     #4    Encoded as   immh = 1,   imm1 = 0  
     #8    Encoded as   immh = 1,   imm1 = 1

### Operation for all encodings

```

1 EncodingSpecificOperations();
2 ExecuteFPCheck();

### Decode for this encoding

```

1 CheckDecodeFaults (ExtType_HpFp);
2 if InITBlock() then UNPREDICTABLE;
3 d = UInt (Vd:D); m = UInt (Vm:M);

```

### Assembler symbols for all encodings

<q> See [C1.2.5 Standard assembler syntax fields](#).  
 <Sd> Is the 32-bit name of the floating-point destination register, encoded in the "Vd:D" field.  
 <Sm> Is the 32-bit name of the floating-point source register, encoded in the "Vm:M" field.

### Operation for all encodings

```

1 if ConditionPassed() then
2     EncodingSpecificOperations();
3     ExecuteFPCheck();
4     S[d][31:16] = S[m][15:0];

```

## C2.4.360 VLD2

Vector Deinterleaving Load - Stride 2. Loads two 64-bit contiguous blocks of data from memory and writes them to parts of 2 destination registers. The parts of the destination registers written to, and the offsets from the base address register, are determined by the pat parameter. If the instruction is executed 2 times with the same base address and destination registers, but with different pat values, the effect is to load data from memory and to deinterleave it into the specified registers with a stride of 2. The base address register can optionally be incremented by 32.

This instruction is subject to beat-wise execution.

This instruction is not VPT compatible.

This instruction is not permitted in an IT block.

```

### Restricted behavior

#### Data Independent Timing behavior

If [AIRCR.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data being loaded.
- The point at which an asynchronous exception is taken does not vary based on the value or values being loaded by this instruction.

The timing invariance does not apply to the addresses being accessed.

## C2.4.361 VLD4

Vector Deinterleaving Load - Stride 4. Loads two 64-bit contiguous blocks of data from memory and writes them to parts of 4 destination registers. The parts of the destination registers written to, and the offsets from the base address register, are determined by the pat parameter. If the instruction is executed 4 times with the same base address and destination registers, but with different pat values, the effect is to load data from memory and to deinterleave it into the specified registers with a stride of 4. The base address register can optionally be incremented by 64.

This instruction is subject to beat-wise execution.

This instruction is not VPT compatible.

This instruction is not permitted in an IT block.

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the floating-point registers are UNKNOWN. If the instruction specifies write-back, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

### Alias conditions

| Alias | preferred when                                            |
|-------|-----------------------------------------------------------|
| VPOP  | P == '0' &&<br>U == '1' &&<br>W == '1' &&<br>Rn == '1101' |

## Assembler symbols for all encodings

|            |                                                                                                                                                                                                                                                            |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <c>        | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                                                                                                              |
| <q>        | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                                                                                                              |
| <size>     | An optional data size specifier. If present, it must be equal to the size in bits, 32 or 64, of the registers being transferred.                                                                                                                           |
| <Rn>       | Is the general-purpose base register, encoded in the "Rn" field.                                                                                                                                                                                           |
| !          | Specifies base register write-back. Encoded in the "W" field as 1 if present, otherwise 0.                                                                                                                                                                 |
| <sreglist> | Is the list of consecutively numbered 32-bit floating-point registers to be transferred. The first register in the list is encoded in "Vd:D", and "imm8" is set to the number of registers in the list. The list must contain at least one register.       |
| <dreglist> | Is the list of consecutively numbered 64-bit floating-point registers to be transferred. The first register in the list is encoded in "D:Vd", and "imm8" is set to twice the number of registers in the list. The list must contain at least one register. |

## Operation for all encodings

```

1  if ConditionPassed() then
2      EncodingSpecificOperations();
3      ExecuteFPCheck();
4      address = if add then R[n]          else R[n]-imm32;
5      regval  = if add then R[n]+imm32 else R[n]-imm32;
6
7      // Determine if the stack pointer limit must be checked
8      if n == 13 && wback then
9          // If memory operation is not performed as a result of a stack limit violation,
10         // and the write-back of the SP itself does not raise a stack limit violation, it
11         // is "IMPLEMENTATION_DEFINED" whether a SPLIM exception is raised.
12         // Arm recommends that any instruction which discards a memory access as
13         // a result of a stack limit violation, and where the write-back of the SP itself
14         // does not raise a stack limit violation, generates an SPLIM exception.
15         if boolean IMPLEMENTATION_DEFINED "SPLIM exception on invalid memory access" then
16             if ViolatesSPLim(LookUpSP(), address) then
17                 if HaveMainExt() then
18                     UFSR.STKOF = '1';
19                     // If the Main Extension is not implemented the fault always escalates to
20                     // a HardFault
21                     excInfo = CreateException(UsageFault);

37                         // Combine the word-aligned words in the correct order for
38                         // current endianness.
39                         D[d+r] = if BigEndian(address, 8) then word1:word2 else word2:word1;
40                     elseif boolean UNKNOWN then
41                         - = MemA[address, 4]; - = MemA[address+4, 4];
42                         address = address+8;
43

```

```
44 // If the stack pointer is being updated a fault will be raised if
45 // the limit is violated
46 if wback then RSPCheck[n] = regval;
```

## Restricted behavior

### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data being loaded.
- The point at which an asynchronous exception is taken does not vary based on the value or values being loaded by this instruction.

The timing invariance does not apply to the addresses being accessed.

### C2.4.363 VLDR

Floating-point Load Register. Floating-point Load Register loads a Floating-point Extension register from memory, using an address from a general-purpose register, with an optional offset.

| .32     | Optional data size specifiers.                                                                                                                                                                                                                                                                                                                                                                                             |
| <Sd>    | The destination register for a singleword load.                                                                                                                                                                                                                                                                                                                                                                            |
| <label> | The label of the literal data item to be loaded. The assembler calculates the required value of the offset from the <a href="#">Align</a> (PC, 4) value of the instruction to this label. Permitted values are multiples of 4 in the range -1020 to 1020. If the offset is zero or positive, imm32 is equal to the offset and add == TRUE. If the offset is negative, imm32 is equal to minus the offset and add == FALSE. |
| <Rn>    | Is the general-purpose base register, encoded in the "Rn" field.                                                                                                                                                                                                                                                                                                                                                           |
| +/-     | Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values: <ul style="list-style-type: none"> <li>- when U = 0</li> <li>+ when U = 1</li> </ul>                                                                                                                                                                     |
| <imm>   | The immediate offset used for forming the address. For the immediate forms of the syntax, <imm> can be omitted, in which case the #0 form of the instruction is assembled. Permitted values are multiples of 4 in the range 0 to 1020.                                                                                                                                                                                     |

### Operation for all encodings

```
1 if ConditionPassed() then
2   EncodingSpecificOperations();
3   ExecuteFPCheck();
4   base = if n == 15 then Align(PC,4) else R[n];
5   address = if add then (base + imm32) else (base - imm32);
6   case fp_size of
7     when 16
8       S[d] = Zeros(16) : MemA[address, 2];
9     when 32
10      S[d] = MemA[address, 4];
11     when 64
12      word1 = MemA[address, 4]; word2 = MemA[address+4, 4];
13      // Combine the word-aligned words in the correct order for current endianness.
14      D[d] = if BigEndian(address, 8) then word1:word2 else word2:word1;
```

## **Restricted behavior**

### **Data Independent Timing behavior**

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data being loaded.
- The point at which an asynchronous exception is taken does not vary based on the value or values being loaded by this instruction.

The timing invariance does not apply to the addresses being accessed.

### C2.4.364 VLDR (System Register)

Load System Register. Load a system register from memory. The target address is calculated from a base register plus an immediate offset. Access to the FPCXT payloads generates an UNDEFINED exception if the instruction is executed from Non-secure state. If CP10 is not enabled and either the Main extension is not implemented or the Floating-point context is active, access to FPCXT\_NS will generate a NOCP UsageFault. Accesses to FPCXT\_NS will not trigger lazy state preservation if there is no active Floating-point context. Accesses to FPCXT\_NS do not trigger Floating-point context creation regardless of the value of FPCCR.ASPEN. FPSCR\_nzcvqc allows access to FPSCR condition and saturation flags. The VPR register can only be accessed from privileged mode. FPCXT\_NS, enables saving and restoration of the Non-secure floating-point context. If neither the Floating-point extension nor MVE are implemented and Floating-point context is active then the current FPSCR value is accessed. FPCXT\_S, enables saving and restoration of the Secure floating-point context.

## Restricted behavior

### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data being loaded.
- The point at which an asynchronous exception is taken does not vary based on the value or values being loaded by this instruction.

The timing invariance does not apply to the addresses being accessed.

## C2.4.365 VLDRB, VLDRH, VLDRW

Vector Load Register. Load consecutive elements from memory into a destination vector register. Each element loaded will be the zero or sign-extended representation of the value in memory. In indexed mode, the target address is calculated from a base register offset by an immediate value. Otherwise, the base register address is used directly. The sum of the base register and the immediate value can optionally be written back to the base register. Predicated lanes are zeroed instead of retaining their previous values.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

#### Assembler symbols for T1 encodings

<dt> This parameter determines the following values:  
– Unsigned flag: S indicates signed, U indicates unsigned.  
– Size: indicates the size of the elements in the vector.  
This parameter must be one of the following values:

|     |            |            |       |
|-----|------------|------------|-------|
| S16 | Encoded as | size = 01, | U = 0 |
| U16 | Encoded as | size = 01, | U = 1 |
| S32 | Encoded as | size = 10, | U = 0 |
| U32 | Encoded as | size = 10, | U = 1 |

<imm> The signed immediate value that is added to base register to calculate the target address.

#### Assembler symbols for T2 encodings

<dt> This parameter determines the following values:  
– Unsigned flag: S indicates signed, U indicates unsigned.  
– Size: indicates the size of the elements in the vector.  
This parameter must be one of the following values:

|     |            |            |       |
|-----|------------|------------|-------|
| S32 | Encoded as | size = 10, | U = 0 |
| U32 | Encoded as | size = 10, | U = 1 |

<imm> The signed immediate value that is added to base register to calculate the target address. This value must be a multiple of 2.

#### Assembler symbols for T5 encodings

<dt> Data size. This parameter must be ".8".  
<imm> The signed immediate value that is added to base register to calculate the target address.

#### Assembler symbols for T6 encodings

<dt> Data size. This parameter must be ".16".  
<imm> The signed immediate value that is added to base register to calculate the target address. This value must be a multiple of 2.

## Assembler symbols for T7 encodings

<dt> Data size. This parameter must be ".32".  
<imm> The signed immediate value that is added to base register to calculate the target address. This value must be a multiple of 4.

## Assembler symbols for all encodings

<v, q> See [C1.2.5 Standard assembler syntax fields](#).  
<Qd> Destination vector register.  
<Rn> The base register for the target address.

## Operation for all encodings

```

1  EncodingSpecificOperations();
2  ExecuteFPCheck();
3
4  (curBeat, elmtMask) = GetCurInstrBeat();
5
6  result      = Zeros(32);
7  offsetAddr = if add then (R[n] + imm32) else (R[n] - imm32);
8  address    = if index then offsetAddr else R[n];
9  address    = address + (curBeat * mbytes * elements);
10
11 for e = 0 to elements-1
12     if elmtMask[e*(esize >> 3)] == '1' then
13         Elem[result, e, esize] = Extend(MemA_MVE[address + (e * mbytes), mbytes], unsigned);
14
15 // The optional write back to the base register is only performed on the
16 // last beat of the instruction.
17 if wback && IsLastBeat() then
18     R[n] = offsetAddr;
19
20 Q[d, curBeat] = result;
```

## Restricted behavior

### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data being loaded.
- The point at which an asynchronous exception is taken does not vary based on the value or values being loaded by this instruction.

The timing invariance does not apply to the addresses being accessed.

## C2.4.366 VLDRB, VLDRH, VLDRW, VLDRD (vector)

Vector Gather Load. Load a byte, halfword, word, or doubleword from memory at the address contained in either:

- a) A base register R[n] plus an offset contained in each element of Q[m], optionally shifted by the element size, or
- b) Each element of Q[m] plus an immediate offset. The base element can optionally be written back, irrespective of predication, with that value incremented by the immediate or by the immediate scaled by the memory element size.

Each element loaded will be the zero or sign-extended representation of the value in memory. The result is written back into the corresponding element in the destination vector register Q[d]. Predicated lanes are zeroed instead of retaining their previous values.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

#### Assembler symbols for T1 encodings

<dt> This parameter determines the following values:

- Unsigned flag: S indicates signed, U indicates unsigned. Operations that do not perform widening are always unsigned (encoded with U=1), the equivalent sized floating and signless datatypes are allowed but are an alias for the unsigned version.
- Size: indicates the size of the elements in the vector.

This parameter must be one of the following values:

|     |            |            |       |
|-----|------------|------------|-------|
| U8  | Encoded as | size = 00, | U = 1 |
| S16 | Encoded as | size = 01, | U = 0 |
| U16 | Encoded as | size = 01, | U = 1 |
| S32 | Encoded as | size = 10, | U = 0 |
| U32 | Encoded as | size = 10, | U = 1 |

<Qm> Vector offset register. The elements of this register contain the unsigned offsets to add to the base address.

#### Assembler symbols for T2 encodings

<dt> This parameter determines the following values:

- Unsigned flag: S indicates signed, U indicates unsigned. Operations that do not perform widening are always unsigned (encoded with U=1), the equivalent sized floating and signless datatypes are allowed but are an alias for the unsigned version.
- Size: indicates the size of the elements in the vector.

This parameter must be one of the following values:

|     |            |            |       |
|-----|------------|------------|-------|
| U16 | Encoded as | size = 01, | U = 1 |
| S32 | Encoded as | size = 10, | U = 0 |

U32 Encoded as size = 10, U = 1  
<Qm> Vector offset register. The elements of this register contain the unsigned offsets to add to the base address.

### Assembler symbols for T3 encodings

<dt> Unsigned flag: S indicates signed, U indicates unsigned. Operations that do not perform widening are always unsigned (encoded with U=1), the equivalent sized floating and signless datatypes are allowed but are an alias for the unsigned version.  
This parameter must be the following value:  
U32 Encoded as size = 10, U = 1  
<Qm> Vector offset register. The elements of this register contain the unsigned offsets to add to the base address.

### Assembler symbols for T4 encodings

<dt> Unsigned flag: S indicates signed, U indicates unsigned. Operations that do not perform widening are always unsigned (encoded with U=1), the equivalent sized floating and signless datatypes are allowed but are an alias for the unsigned version.  
This parameter must be the following value:  
U64 Encoded as size = 11, U = 1  
<Qm> Vector offset register. The elements of this register contain the unsigned offsets to add to the base address.

### Assembler symbols for T5 encodings

<dt> Data size. This parameter must be ".32".  
<Qm> The base register for the target address.  
<imm> The signed immediate value that is added to base register to calculate the target address. This value must be a multiple of 4.

### Assembler symbols for T6 encodings

<dt> Data size. This parameter must be ".64".  
<Qm> The base register for the target address.  
<imm> The signed immediate value that is added to base register to calculate the target address. This value must be a multiple of 8.

### Assembler symbols for all encodings

<v, q> See [C1.2.5 Standard assembler syntax fields](#).  
<Qd> Destination vector register.  
<Rn> The base register for the target address.  
<os> The amount by which the vector offset is left shifted by before being added to the general-purpose base address. If the value is present it must correspond to memory transfer size (1=half word, 2=word, 3=double word).  
This parameter must be one of the following values:  
<omitted> Encoded as os = 0  
<Offset scaled> Encoded as os = 1

### Operation for all encodings

```

## Restricted behavior

### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data being loaded.
- The point at which an asynchronous exception is taken does not vary based on the value or values being loaded by this instruction.

The timing invariance does not apply to the addresses being accessed.

## C2.4.367 VLLDM

Floating-point Lazy Load Multiple. Floating-point Lazy Load Multiple restores the contents of the Secure Floating-point registers that were protected by a VLSTM instruction, and marks the Floating-point context as active.

If the lazy state preservation set up by a previous VLSTM instruction is active (FPCCR.LSPACT == 1), this instruction deactivates lazy state preservation and enables access to the Secure Floating-point registers.

If lazy state preservation is inactive (FPCCR.LSPACT == 0), either because lazy state preservation was not enabled (FPCCR.LSPEN == 0) or because a Floating-point instruction caused the Secure Floating-point register contents to be stored to memory, this instruction loads the stored Secure Floating-point register contents back into the Floating-point registers.

If Secure Floating-point is not in use (CONTROL\_S.SFPA == 0), this instruction behaves as a NOP.

This instruction is only available in Secure state, and is UNDEFINED in Non-secure state.

If the Floating-point Extension and MVE are not implemented, this instruction is available in Secure state, but behaves as a NOP.

## Restricted behavior

### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data being loaded.
- The point at which an asynchronous exception is taken does not vary based on the value or values being loaded by this instruction.

The timing invariance does not apply to the addresses being accessed.

## C2.4.368 VLSTM

Floating-point Lazy Store Multiple. Floating-point Lazy Store Multiple stores the contents of Secure Floating-point registers to a prepared stack frame, and clears the Secure Floating-point registers.

If Floating-point lazy preservation is enabled (FPCCR.LSPEN == 1), then the next time a Floating-point instruction other than VLSTM or VLLDM is executed:

- The contents of Secure Floating-point registers are stored to memory.
- The Secure Floating-point registers are cleared.

If Secure Floating-point is not in use (CONTROL\_S.SFPA == 0), this instruction behaves as a NOP.

This instruction is only available in Secure state, and is UNDEFINED in Non-secure state.

If the Floating-point Extension and MVE are not implemented, this instruction is available in Secure state, but behaves as a NOP.

## Restricted behavior

### Data Independent Timing behavior

If [AIRCR.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value of the data being stored.
- The point at which an asynchronous exception is taken does not vary based on the value being stored by this instruction.

The timing invariance does not apply to the addresses being accessed.

## C2.4.369 VMAX, VMAXA

Vector Maximum, Vector Maximum Absolute. Find the maximum value of the elements in the source operands, and store the result in the corresponding destination elements.

The absolute variant takes the elements from the destination vector, treating them as unsigned, and compares them to the absolute values of the corresponding elements in the source vector. The larger values are stored back into the destination vector.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

## Assembler symbols for T1 encodings

<dt> This parameter determines the following values:

- Unsigned flag: S indicates signed, U indicates unsigned.
- Size: indicates the size of the elements in the vector.

This parameter must be one of the following values:

|     |            |            |       |
|-----|------------|------------|-------|
| S8  | Encoded as | size = 00, | U = 0 |
| U8  | Encoded as | size = 00, | U = 1 |
| S16 | Encoded as | size = 01, | U = 0 |
| U16 | Encoded as | size = 01, | U = 1 |
| S32 | Encoded as | size = 10, | U = 0 |
| U32 | Encoded as | size = 10, | U = 1 |

## Assembler symbols for T2 encodings

<dt> Size: indicates the size of the elements in the vector.

This parameter must be one of the following values:

|     |            |           |
|-----|------------|-----------|
| S8  | Encoded as | size = 00 |
| S16 | Encoded as | size = 01 |
| S32 | Encoded as | size = 10 |

## Assembler symbols for all encodings

|        |                                                               |
|--------|---------------------------------------------------------------|
| <v, q> | See <a href="#">C1.2.5 Standard assembler syntax fields</a> . |
| <Qd>   | Destination vector register.                                  |
| <Qda>  | Source and destination vector register.                       |
| <Qm>   | Source vector register.                                       |
| <Qn>   | Source vector register.                                       |

## Operation for all encodings

```

1 EncodingSpecificOperations();
2 ExecuteFPCheck();
3
4 (curBeat, elmtMask) = GetCurInstrBeat();
5
6 result = Zeros(32);
7 op1    = Q[n, curBeat];
8 op2    = Q[m, curBeat];
9 for e = 0 to elements-1
10     value1 = Int(Elem[op1, e, esize], unsigned || absolute);
11     value2 = Int(Elem[op2, e, esize], unsigned);
12     if absolute then
13         value2 = Abs(value2);
14     Elem[result, e, esize] = Max(value1, value2)[esize-1:0];
15
16 for e = 0 to 3
17     if elmtMask[e] == '1' then
18         Elem[Q[d, curBeat], e, 8] = Elem[result, e, 8];

```

## Restricted behavior

### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1, and the T1 variant of this instruction is being executed:

- The execution time of this instruction is insensitive to the value or values of the data subject to this instruction.
- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

## C2.4.370 VMAXNM

Floating-point Maximum Number. Floating-point Maximum Number determines the floating-point maximum number.

NaN handling is specified by IEEE754-2008.

### T2

*Armv8-M Floating-point Extension only*, size == 11 UNDEFINED in single-precision only implementations.

|    |    |    |    |    |    |   |   |   |   |   |   |    |   |   |    |    |    |    |    |      |    |   |   |        |   |    |   |   |   |   |   |

```

### C2.4.371 VMAXNM, VMAXNMA (floating-point)

Vector Maximum, Vector Maximum Absolute. Find the floating-point maximum number of the elements in the source operands, and store the result in the corresponding destination elements. It handles NaNs in consistence with the IEEE754-2008 specification, and returns the numerical operand when one operand is numerical and the other is a quiet NaN.

The absolute variant takes the absolute values of the elements from the destination vector and compares them to the absolute values of the corresponding elements in the source vector. The larger values are stored back into the destination vector.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

### C2.4.372 VMAXNMV, VMAXNMAV (floating-point)

Vector Maximum Across Vector, Vector Maximum Absolute Across Vector. Find the maximum value of the elements of a vector register. Store the maximum value in the general-purpose destination register only if it is larger than the starting value of the general-purpose destination register. The general-purpose register is read as the same width as the vector elements. For half-precision the upper half of the general-purpose register is cleared on write-back. This instruction handles NaNs in consistence with the IEEE754-2008 specification, and returns the numerical operand when one operand is numerical and the other is a quiet NaN.

The absolute variant of the instruction compares the absolute value of vector elements.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

### Assembler symbols for all encodings

<v, q> See [C1.2.5 Standard assembler syntax fields](#).  
 <dt> Size: indicates the floating-point format used.  
 This parameter must be one of the following values:  
     F32 Encoded as sz = 0  
     F16 Encoded as sz = 1  
 <Rda> General-purpose source and destination register.  
 <Qm> Source vector register.

### Operation for all encodings

```
1 EncodingSpecificOperations();
2 ExecuteFPCheck();
3
4 (curBeat, elmtMask) = GetCurInstrBeat();
5
6 op1 = Q[m, curBeat];
7 result = Elem[R[da], 0, esize];
8 for e = 0 to elements-1
9     if elmtMask[e*(esize>>3)] == '1' then
10         value = Elem[op1, e, esize];
11         result = FPConvertNaN(result, FALSE);
12         value = FPConvertNaN(value, FALSE);
13         if absolute then
14             value = FPAbs(value);
15         result = FPMaxNum(value, result, FALSE);
16
17 R[da] = ZeroExtend(result);
```

### C2.4.373 VMAXV, VMAXAV

Vector Maximum Across Vector, Vector Maximum Absolute Across Vector. Find the maximum value of the elements of a vector register. Store the maximum value in the general-purpose destination register only if it is larger than the starting value of the general-purpose destination register. The general-purpose register is read as the same width as the vector elements. The result of the operation is sign-extended to 32 bits before being stored back.

The absolute variant of the instruction compares the absolute value of signed vector elements and treats the value in the general-purpose register as unsigned.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

### Assembler symbols for T1 encodings

<dt> This parameter determines the following values:

- Unsigned flag: S indicates signed, U indicates unsigned.
- Size: indicates the size of the elements in the vector.

This parameter must be one of the following values:

|     |            |            |       |
|-----|------------|------------|-------|
| S8  | Encoded as | size = 00, | U = 0 |
| U8  | Encoded as | size = 00, | U = 1 |
| S16 | Encoded as | size = 01, | U = 0 |
| U16 | Encoded as | size = 01, | U = 1 |
| S32 | Encoded as | size = 10, | U = 0 |
| U32 | Encoded as | size = 10, | U = 1 |

### Assembler symbols for T2 encodings

<dt> Size: indicates the size of the elements in the vector.

This parameter must be one of the following values:

|     |            |           |
|-----|------------|-----------|
| S8  | Encoded as | size = 00 |
| S16 | Encoded as | size = 01 |
| S32 | Encoded as | size = 10 |

### Assembler symbols for all encodings

<v, q> See [C1.2.5 Standard assembler syntax fields](#).

<Rda> General-purpose source and destination register.

<Qm> Source vector register.

### Operation for all encodings

```

1 EncodingSpecificOperations();
2 ExecuteFPCheck();
3
4 (curBeat, elmtMask) = GetCurInstrBeat();
5
6 op1    = Q[m, curBeat];
7 result = Int(Elem[R[da], 0, esize], absolute || unsigned);
8 for e = 0 to elements-1
9     if elmtMask[e*(esize>>3)] == '1' then
10         value = Int(Elem[op1, e, esize], unsigned);
11         if absolute then
12             value = Abs(value);
13         result = Max(value, result);
14
15 R[da] = result[31:0];

```

### C2.4.374 VMIN, VMINA

Vector Minimum, Vector Minimum Absolute. Find the minimum value of the elements in the source operands, and store the result in the corresponding destination elements.

The absolute variant takes the elements from the destination vector, treating them as unsigned, and compares them to the absolute values of the corresponding elements in the source vector. The smaller values are stored back into the destination vector.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

8 op2    = Q[m, curBeat];
9 for e = 0 to elements-1
10     value1 = Int(Elem[op1, e, esize], unsigned || absolute);
11     value2 = Int(Elem[op2, e, esize], unsigned);
12     if absolute then
13         value2 = Abs(value2);
14     Elem[result, e, esize] = Min(value1, value2)[esize-1:0];
15
16 for e = 0 to 3
17     if elmtMask[e] == '1' then
18         Elem[Q[d, curBeat], e, 8] = Elem[result, e, 8];

```

### Restricted behavior

#### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1, and the T1 variant of this instruction is being executed:

- The execution time of this instruction is insensitive to the value or values of the data subject to this instruction.
- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

## C2.4.375 VMINNM

Floating-point Minimum Number. Floating-point Minimum Number determines the floating-point minimum number.

NaN handling is specified by IEEE754-2008.

### T2

*Armv8-M Floating-point Extension only*, size == 11 UNDEFINED in single-precision only implementations.

```

### C2.4.376 VMINNM, VMINNMA (floating-point)

Vector Minimum, Vector Minimum Absolute. Find the floating-point minimum number of the elements in the source operands, and store the result in the corresponding destination elements. It handles NaNs in consistence with the IEEE754-2008 specification, and returns the numerical operand when one operand is numerical and the other is a quiet NaN.

The absolute variant takes the absolute values of the elements from the destination vector and compares them to the absolute values of the corresponding elements in the source vector. The smaller values are stored back into the destination vector.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

17     Elem[result, e, esize] = FPMinNum(value1, value2, FALSE, predicated);
18
19 for e = 0 to 3
20     if elmtMask[e] == '1' then
21         Elem[Q[d, curBeat], e, 8] = Elem[result, e, 8];

```

### C2.4.377 VMINNMV, VMINNMAV (floating-point)

Vector Minimum Across Vector, Vector Minimum Absolute Across Vector. Find the minimum value of the elements of a vector register. Store the minimum value in the general-purpose destination register only if it is smaller than the starting value of the general-purpose destination register. The general-purpose register is read as the same width as the vector elements. For half-precision the upper half of the general-purpose register is cleared on write-back. This instruction handles NaNs in consistence with the IEEE754-2008 specification, and returns the numerical operand when one operand is numerical and the other is a quiet NaN.

The absolute variant of the instruction compares the absolute value of vector elements.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

### C2.4.378 VMINV, VMINAV

Vector Minimum Across Vector, Vector Minimum Absolute Across Vector. Find the minimum value of the elements of a vector register. Store the minimum value in the general-purpose destination register only if it is smaller than the starting value of the general-purpose destination register. The general-purpose register is read as the same width as the vector elements. The result of the operation is sign-extended to 32 bits before being stored back.

The absolute variant of the instruction compares the absolute value of signed vector elements and treats the value in the general-purpose register as unsigned.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

## Restricted behavior

### Data Independent Timing behavior

If [AIRCR.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data subject to this instruction.
- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

### C2.4.381 VMLADAV

Vector Multiply Add Dual Accumulate Across Vector. The elements of the vector registers are handled in pairs. In the base variant, corresponding elements from the two source registers are multiplied together, whereas the exchange variant swaps the values in each pair of values read from the first source register, before multiplying them with the values from the second source register. The results of the pairs of multiply operations are combined by adding them together. At the end of each beat these results are accumulated and the lower 32 bits written back to the general-purpose destination register. The initial value of the general-purpose destination register can optionally be added to the result.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

## Assembler symbols for T1 encodings

<dt> This parameter determines the following values:

- Unsigned flag: S indicates signed, U indicates unsigned.
- Size: indicates the size of the elements in the vector.

This parameter must be one of the following values:

|     |            |         |       |
|-----|------------|---------|-------|
| S16 | Encoded as | sz = 0, | U = 0 |
| U16 | Encoded as | sz = 0, | U = 1 |
| S32 | Encoded as | sz = 1, | U = 0 |
| U32 | Encoded as | sz = 1, | U = 1 |

## Assembler symbols for T2 encodings

<dt> Unsigned flag: S indicates signed, U indicates unsigned.  
This parameter must be one of the following values:

|    |            |       |
|----|------------|-------|
| S8 | Encoded as | U = 0 |
| U8 | Encoded as | U = 1 |

## Assembler symbols for all encodings

<A> Accumulate with existing register contents.  
This parameter must be one of the following values:

|   |            |       |
|---|------------|-------|
| – | Encoded as | A = 0 |
| A | Encoded as | A = 1 |

<X> Exchange adjacent pairs of values in Qm.  
This parameter must be one of the following values:

|   |            |       |
|---|------------|-------|
| – | Encoded as | X = 0 |
| X | Encoded as | X = 1 |

<v, q> See [C1.2.5 Standard assembler syntax fields](#).

<Rda> General-purpose source and destination register. This must be an even numbered register.

<Qn> First source vector register.

<Qm> Second source vector register.

## Operation for all encodings

```

1  EncodingSpecificOperations();

<v, q> See C1.2.5 *Standard assembler syntax fields*.  
 <dt> Size: indicates the size of the elements in the vector.  
 This parameter must be one of the following values:  
     I8     Encoded as   size = 00  
     I16    Encoded as   size = 01  
     I32    Encoded as   size = 10  
 <Qda> Source and destination vector register.  
 <Qn> Source vector register.  
 <Rm> Source general-purpose register.

#### Operation for all encodings

```

1 EncodingSpecificOperations();
2 ExecuteFPCheck();
3
4 (curBeat, elmtMask) = GetCurInstrBeat();
5
6 result = Zeros(32);
7 op1    = Q[n, curBeat];
8 op2    = Q[da, curBeat];
9 element3 = SInt(R[m][esize-1:0]);
10 for e = 0 to elements-1
11     element1 = SInt(Elm[op1, e, esize]);
12     element2 = SInt(Elm[op2, e, esize]);
```

```

13     value      = (element1 * element2) + element3;
14     Elem[result, e, esize] = value[esize-1:0];
15
16 for e = 0 to 3
17     if elmtMask[e] == '1' then
18         Elem[Q[da, curBeat], e, 8] = Elem[result, e, 8];

```

## Restricted behavior

### Data Independent Timing behavior

If [AIRCR.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data subject to this instruction.
- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

## C2.4.385 VMLAV

Vector Multiply Accumulate Across Vector. This is an alias of VMLADAV without exchange.

This is an alias of [VMLADAV](#) with the following condition satisfied: X==0.

This alias is the preferred disassembly.

- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

**C2.4.386 VMLS**

**Floating-point Multiply Subtract.** Floating-point Multiply Subtract multiplies two floating-point registers, subtracts the product from the destination floating-point register, and places the result in the destination floating-point register.

Arm recommends that software does not use the **VMLS** instruction in the Round towards +Infinity and Round towards -Infinity rounding modes, because the rounding of the product and of the sum can change the result of the instruction in opposite directions, defeating the purpose of these rounding modes.

```

### C2.4.387 VMLSDAV

Vector Multiply Subtract Dual Accumulate Across Vector. The elements of the vector registers are handled in pairs. In the base variant, corresponding elements from the two source registers are multiplied together, whereas the exchange variant swaps the values in each pair of values read from the first source register, before multiplying them with the values from the second source register. The results of the pairs of multiply operations are combined by subtracting one from the other. At the end of each beat these results are accumulated and the lower 32 bits written back to the general-purpose destination register. The initial value of the general-purpose destination register can optionally be added to the result.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

## Restricted behavior

### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data subject to this instruction.
- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

## C2.4.388 VMLS�DAV

Vector Multiply Subtract Long Dual Accumulate Across Vector. The elements of the vector registers are handled in pairs. In the base variant, corresponding elements from the two source registers are multiplied together, whereas the exchange variant swaps the values in each pair of values read from the first source register, before multiplying them with the values from the second source register. The results of the pairs of multiply operations are combined by subtracting one from the other. At the end of each beat these results are accumulated. The 64-bit result is stored across two registers, the upper-half is stored in an odd-numbered register and the lower half is stored in an even-numbered register. The initial value of the general-purpose destination registers can optionally be added to the result.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

```

## Restricted behavior

### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data subject to this instruction.
- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

### C2.4.403 VMOVL

Vector Move Long. Selects an element of 8 or 16-bits from either the top half (T variant) or bottom half (B variant) of each source element, sign- or zero-extends, and places the 16 or 32-bit results in the destination vector.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

## Restricted behavior

### Data Independent Timing behavior

If [AIRCR.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data subject to this instruction.
- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

## C2.4.404 VMOVN

Vector Move and Narrow. Performs an element-wise narrowing to half-width, writing the result to either the top half (T variant) or bottom half (B variant) of the result element. The other half of the destination vector element retains its previous value.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

```

## Restricted behavior

### Data Independent Timing behavior

If [AIRCR.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data subject to this instruction.
- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

## C2.4.405 VMOVX

Floating-point Move extraction. Floating-point Move extraction copies the upper 16 bits of the 32-bit source floating-point register into the lower 16 bits of the 32-bit destination floating-point register, while clearing the remaining bits to zero.

### T1

Armv8.1-M Floating-point Extension

### Decode for this encoding

```
1 CheckDecodeFaults (ExtType_HpFp);
2 if InITBlock() then UNPREDICTABLE;
3 d = UInt (Vd:D); m = UInt (Vm:M);
```

### Assembler symbols for all encodings

<q> See [C1.2.5 Standard assembler syntax fields](#).  
 <Sd> Is the 32-bit name of the floating-point destination register, encoded in the "Vd:D" field.  
 <Sm> Is the 32-bit name of the floating-point source register, encoded in the "Vm:M" field.

### Operation for all encodings

```
1 if ConditionPassed() then
2   EncodingSpecificOperations();
3   ExecuteFPCheck();
4   S[d] = Zeros(16) : S[m][31:16];
```

### Restricted behavior

#### Data Independent Timing behavior

If [AIRCR.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data subject to this instruction.
- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

## C2.4.406 VMRS

Move to general-purpose Register from Floating-point Special register. Move to general-purpose Register from Floating-point Special register moves the value of FPSCR, FPCXT\_NS, FPCXT\_S, VPR, or VPR.P0 to a general-purpose register, or the values of FPSCR condition flags to the APSR condition flags.

Access to the FPCXT payloads generates an UNDEFINED exception if the instruction is executed from Non-secure state.

If CP10 is not enabled and either the Main extension is not implemented or the Floating-point context is active, access to FPCXT\_NS will generate a NOCP UsageFault. Accesses to FPCXT\_NS will not trigger lazy state preservation if there is no active Floating-point context. Accesses to FPCXT\_NS do not trigger Floating-point context creation regardless of the value of FPCCR.ASPEN.

### T1

Armv8-M Floating-point Extension, Armv8.1-M Floating-point Extension, or Armv8.1-M MVE.

- For Armv8.1-M, FPCXT access instructions are required. The `reg` field is configurable, and all of the listed registers can be accessed.
- For Armv8.0-M, only access to FPSCR is permitted, and the `reg` field is not configurable.

## Restricted behavior

### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1 and this instruction accesses the FPSCR.N, Z, C, V, Q flags or VPR.P0:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the FPSCR.N, Z, C, V, Q flags or VPR.P0.
- The point at which an asynchronous exception is taken does not vary based on any of the following:
  - The values of the data supplied in any of its registers.
  - The values of the FPSCR.N, Z, C, V, Q flags or VPR.P0.

## C2.4.407 VMSR

Move to Floating-point Special register from general-purpose Register. Move to Floating-point Special register from general-purpose Register moves the value of a general-purpose register to FPSCR, FPCXT\_NS, FPCXT\_S, VPR, or VPR.P0.

Access to the FPCXT payloads generates an UNDEFINED exception if the instruction is executed from Non-secure state.

If CP10 is not enabled and either the Main extension is not implemented or the Floating-point context is active, access to FPCXT\_NS will generate a NOCP UsageFault. Accesses to FPCXT\_NS will not trigger lazy state preservation if there is no active Floating-point context. Accesses to FPCXT\_NS do not trigger Floating-point context creation regardless of the value of FPCCR.ASPEN.

### Assembler symbols for all encodings

<c> See [C1.2.5 Standard assembler syntax fields](#).  
 <q> See [C1.2.5 Standard assembler syntax fields](#).  
 <spec\_reg> Is the special register to be accessed, encoded in the "reg" field. The permitted values are:  
     0b1110 FPCXT\_NS, enables saving and restoration of the Non-secure floating-point context. If the Floating-point extension or MVE are implemented and Floating-point context is active then the current FPSCR value is accessed, otherwise the instruction behaves as a NOP. If Armv8.1-M is not implemented, access to this register is UNPREDICTABLE.  
     0b1111 FPCXT\_S, enables saving and restoration of the Secure floating-point context. If Armv8.1-M is not implemented, access to this register is UNPREDICTABLE.  
     0b0001 FPSCR.  
     0b0010 FPSCR\_nzcvqc, access to FPSCR condition and saturation flags. If Armv8.1-M is not implemented, access to this register is UNPREDICTABLE.  
     0b1101 P0, if MVE is implemented access to VPR.P0 predicate field is permitted, otherwise the access is UNPREDICTABLE.

0b1100 VPR register. If MVE is not implemented, access to this register is UNPREDICTABLE. The VPR register can only be accessed from privileged mode, unprivileged accesses behave as a NOP.

<Rt> Is the general-purpose source register to be transferred to <spec\_reg>, encoded in the "Rt" field.

### Operation for all encodings

```

1  if ConditionPassed() then

45         otherwise
46             UNPREDICTABLE;

```

### Restricted behavior

#### Data Independent Timing behavior

If [AIRCR.DIT](#) is 1 and this instruction accesses the FPSCR.N, Z, C, V, Q flags or VPR.P0:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the FPSCR.N, Z, C, V, Q flags or VPR.P0.

- The point at which an asynchronous exception is taken does not vary based on any of the following:
  - The values of the data supplied in any of its registers.
  - The values of the FPSCR.N, Z, C, V, Q flags or VPR.P0.

## C2.4.408 VMUL

Floating-point Multiply. Floating-point Multiply multiplies two floating-point register values, and places the result in the destination floating-point register.

## C2.4.409 VMUL (floating-point)

Vector Multiply. Multiply the value of the elements in the first source vector register by either the respective elements in the second source vector register or a general-purpose register.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

## Operation for all encodings

```

1  EncodingSpecificOperations();
2  ExecuteFPCheck();
3
4  (curBeat, elmtMask) = GetCurInstrBeat();
5
6  result = Zeros(32);
7  op1 = Q[n, curBeat];
8  if withScalar then
9      for e = 0 to elements-1
10         value = SInt(Elem[op1, e, esize]) * SInt(R[m][esize-1:0]);
11         Elem[result, e, esize] = value[esize-1:0];
12 else
13     op2 = Q[m, curBeat];
14     for e = 0 to elements-1
15         value = SInt(Elem[op1, e, esize]) * SInt(Elem[op2, e, esize]);
16         Elem[result, e, esize] = value[esize-1:0];
17
18 for e = 0 to 3
19     if elmtMask[e] == '1' then
20         Elem[Q[d, curBeat], e, 8] = Elem[result, e, 8];

```

## Restricted behavior

### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data subject to this instruction.
- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

### C2.4.411 VMULH, VRMULH

Vector Multiply Returning High Half, Vector Rounding Multiply Returning High Half. Multiply each element of a vector register by its respective element in another vector register and return the high half of the result. The result is optionally rounded before the high half is selected.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

## Operation for all encodings

```

1 EncodingSpecificOperations();
2 ExecuteFPCheck();
3
4 (curBeat, elmtMask) = GetCurInstrBeat();
5
6 result = Zeros(32);
7 op1 = Q[n, curBeat];
8 op2 = Q[m, curBeat];
9 rVal = if round then 1 << (esize-1) else 0;
10 for e = 0 to elements-1
11     value = (Int(Elem[op1, e, esize], unsigned) * Int(Elem[op2, e, esize], unsigned)) + rVal;
12     Elem[result, e, esize] = value[(2*esize)-1:esize];
13
14 for e = 0 to 3
15     if elmtMask[e] == '1' then
16         Elem[Q[d, curBeat], e, 8] = Elem[result, e, 8];

```

## Restricted behavior

### Data Independent Timing behavior

If [AIRCR.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data subject to this instruction.
- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

### C2.4.412 VMULL (integer)

Vector Multiply Long. Performs an element-wise integer multiplication of two single-width source operand elements. These are selected from either the top half (T variant) or bottom half (B variant) of double-width source vector register elements. The operation produces a double-width result.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

24         Elem[Q[d, curBeat], e, 8] = Elem[result, e, 8];

```

## Restricted behavior

### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data subject to this instruction.
- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

### C2.4.413 VMULL (polynomial)

Vector Multiply Long. Performs an element-wise polynomial multiplication of two single-width source operand elements. These are selected from either the top half (T variant) or bottom half (B variant) of double-width source vector register elements. The operation produces a double-width result.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

## Restricted behavior

### Data Independent Timing behavior

If [AIRCR.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data subject to this instruction.
- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

### C2.4.414 VMVN (immediate)

Vector Bitwise NOT. Set each element of a vector register to the bitwise inverse of the immediate operand value. The immediate is generated by the AdvSIMDExpandImm() function based on the requested data type and immediate value.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

## C2.4.419 VNMLA

Floating-point Multiply Accumulate and Negate. Floating-point Multiply Accumulate and Negate multiplies two floating-point register values, adds the negation of the floating-point value in the destination register to the negation of the product, and writes the result back to the destination register.

Arm recommends that software does not use the [VNMLA](#) instruction in the Round towards +Infinity and Round towards -Infinity rounding modes, because the rounding of the product and of the sum can change the result of the instruction in opposite directions, defeating the purpose of these rounding modes.

| <Qda>  | Source and destination vector register.                                                                                                                                                                                                                                                                                                                                     |
| <imm>  | The immediate value to load in to each element. This must be an immediate that can be encoded for use with the AdvSIMDExpandImm() function.                                                                                                                                                                                                                                 |

### Operation for all encodings

```

1 EncodingSpecificOperations();
2 ExecuteFPCheck();
3
4 (curBeat, elmtMask) = GetCurInstrBeat();
5
6 opd = Q[da, curBeat];
7 imm32 = if curBeat[0] == '0' then imm64[31:0] else imm64[63:32];
8 result = opd OR imm32;
9
```

```
10 for e = 0 to 3
11     if elmtMask[e] == '1' then
12         Elem[Q[da, curBeat], e, 8] = Elem[result, e, 8];
```

## Restricted behavior

### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data subject to this instruction.
- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

## C2.4.426 VPNOT

Vector Predicate NOT. Inverts the predicate condition in VPR.P0. The VPR.P0 flags for predicated lanes are zeroed.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

### Decode for this encoding

```
1 CheckDecodeFaults(ExtType_Mve);
2
3 if InITBlock() then CONSTRAINED_UNPREDICTABLE;
```

### Assembler symbols for all encodings

<v, q> See [C1.2.5 Standard assembler syntax fields](#).

### Operation for all encodings

```
1 EncodingSpecificOperations();
2 ExecuteFPCheck();
3
4 (curBeat, elmtMask) = GetCurInstrBeat();
5
6 Elem[VPR.P0, curBeat, 4] = (NOT Elem[VPR.P0, curBeat, 4]) AND elmtMask;
```

## C2.4.427 VPOP

Pop Floating-point registers from stack. Pop Floating-point registers from stack loads multiple consecutive Floating-point registers from the stack.

This instruction is interrupt-continuable.

This instruction is an alias of the [VLDM](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [VLDM](#).
- The description of [VLDM](#) gives the operational pseudocode for this instruction.

### T1

*Armv8-M Floating-point Extension, Armv8.1-M Floating-point Extension, or Armv8.1-M MVE*

#### Increment After variant

VPOP{<c>}{<q>}{.<size>} <dreglist>

is equivalent to

VLDM{<c>}{<q>}{.<size>} SP!, <dreglist>

and is always the preferred disassembly.

### T2

*Armv8-M Floating-point Extension, Armv8.1-M Floating-point Extension, or Armv8.1-M MVE*

#### Increment After variant

VPOP{<c>}{<q>}{.<size>} <sreglist>

is equivalent to

VLDM{<c>}{<q>}{.<size>} SP!, <sreglist>

and is always the preferred disassembly.

12
13 for e = 0 to 3
14     if elmtMask[e] == '1' then
15         Elem[Q[d, curBeat], e, 8] = Elem[result, e, 8];
```

### Restricted behavior

#### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1 and this instruction sets the FPSCR.N, Z, C, V, Q flags or VPR.P0:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the N, Z, C, V, Q flags or VPR.P0.
- The point at which an asynchronous exception is taken does not vary based on any of the following:
  - The values of the data supplied in any of its registers.
  - The values of the N, Z, C, V, Q flags or VPR.P0.

## C2.4.429 VPST

Vector Predicate Set Then. Predicates the following instructions, up to a maximum of four instructions. This instruction is similar to VPT. However no comparison is performed and instead the current value of VPR.P0 is used as the predicate condition.

This instruction is subject to beat-wise execution.

This instruction is not VPT compatible.

This instruction is not permitted in an IT block.

```

### Assembler symbols for all encodings

|     |                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <q> | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                                                                                                                                                                                                                                                                                  |
| <x> | Specifies the condition for an optional second instruction in the VPT block, and whether the condition is the same as for the first instruction (T) or its inverse (E). This is encoded in the mask field in a similar way to the IT instruction, except that rather than encoding T and E directly into f_cond[0], a 1 in the corresponding mask bit indicates that the previous predicate value in VPR.P0 should be inverted |
| <y> | Specifies the condition for an optional third instruction in the VPT block. It is encoded in the mask field in the same way as the x field.                                                                                                                                                                                                                                                                                    |
| <z> | Specifies the condition for an optional fourth instruction in the VPT block. It is encoded in the mask field in the same way as the x field.                                                                                                                                                                                                                                                                                   |

### Operation for all encodings

```

1 EncodingSpecificOperations();
2 ExecuteFPCheck();
3
4 (curBeat, -) = GetCurInstrBeat();
5
6 // Only one mask field per pair of beats, so the mask is only updated on odd beats.
7 if curBeat[0] == '1' then
8     SetVPTMask(curBeat, mask);
```

## C2.4.430 VPT

Vector Predicate Then. Predicates the following instructions, up to a maximum of four instructions, by masking the operation of instructions on a per-lane basis based on the VPR.P0 predicate values. The predicated instructions are referred to as the Vector Predication Block or simply the VPT Block. The VPR.P0 predicate values may be inverted after each instruction in the VPT block based on the mask fields (see x, y, and z).

This instruction is subject to beat-wise execution.

This instruction is not VPT compatible.

This instruction is not permitted in an IT block.

### Assembler symbols for T1 encodings

**<dt>** Size: indicates the size of the elements in the vector.  
This parameter must be one of the following values:

|     |            |           |
|-----|------------|-----------|
| I8  | Encoded as | size = 00 |
| I16 | Encoded as | size = 01 |
| I32 | Encoded as | size = 10 |

**<fc>** The comparison condition to use.  
This parameter must be one of the following values:

|    |            |        |
|----|------------|--------|
| EQ | Encoded as | fc = 0 |
| NE | Encoded as | fc = 1 |

### Assembler symbols for T2 encodings

**<dt>** Size: indicates the size of the elements in the vector.  
This parameter must be one of the following values:

|     |            |           |
|-----|------------|-----------|
| U8  | Encoded as | size = 00 |
| U16 | Encoded as | size = 01 |
| U32 | Encoded as | size = 10 |

**<fc>** The comparison condition to use.  
This parameter must be one of the following values:

|    |            |        |
|----|------------|--------|
| CS | Encoded as | fc = 0 |
| HI | Encoded as | fc = 1 |

### Assembler symbols for T3 encodings

**<dt>** Size: indicates the size of the elements in the vector.  
This parameter must be one of the following values:

|     |            |           |
|-----|------------|-----------|
| S8  | Encoded as | size = 00 |
| S16 | Encoded as | size = 01 |
| S32 | Encoded as | size = 10 |

**<fc>** The comparison condition to use.  
This parameter must be one of the following values:

|    |            |                  |
|----|------------|------------------|
| GE | Encoded as | fch = 0, fcl = 0 |
| LT | Encoded as | fch = 0, fcl = 1 |
| GT | Encoded as | fch = 1, fcl = 0 |
| LE | Encoded as | fch = 1, fcl = 1 |

### Assembler symbols for T4 encodings

**<dt>** Size: indicates the size of the elements in the vector.  
This parameter must be one of the following values:

|     |            |           |
|-----|------------|-----------|
| I8  | Encoded as | size = 00 |
| I16 | Encoded as | size = 01 |
| I32 | Encoded as | size = 10 |

**<fc>** The comparison condition to use.  
This parameter must be one of the following values:

|    |            |        |
|----|------------|--------|
| EQ | Encoded as | fc = 0 |
| NE | Encoded as | fc = 1 |

### Assembler symbols for T5 encodings

**<dt>** Size: indicates the size of the elements in the vector.  
This parameter must be one of the following values:

|     |            |           |
|-----|------------|-----------|
| U8  | Encoded as | size = 00 |
| U16 | Encoded as | size = 01 |
| U32 | Encoded as | size = 10 |

<fc> The comparison condition to use.  
This parameter must be one of the following values:

|    |            |        |
|----|------------|--------|
| CS | Encoded as | fc = 0 |
| HI | Encoded as | fc = 1 |

### Assembler symbols for T6 encodings

<dt> Size: indicates the size of the elements in the vector.  
This parameter must be one of the following values:

|     |            |           |
|-----|------------|-----------|
| S8  | Encoded as | size = 00 |
| S16 | Encoded as | size = 01 |
| S32 | Encoded as | size = 10 |

<fc> The comparison condition to use.  
This parameter must be one of the following values:

|    |            |                  |
|----|------------|------------------|
| GE | Encoded as | fch = 0, fcl = 0 |
| LT | Encoded as | fch = 0, fcl = 1 |
| GT | Encoded as | fch = 1, fcl = 0 |
| LE | Encoded as | fch = 1, fcl = 1 |

### Assembler symbols for all encodings

<q> See [C1.2.5 Standard assembler syntax fields](#).  
 <Qn> Source vector register.  
 <Qm> Source vector register.  
 <Rm> Source general-purpose register (ZR is permitted, PC is not).  
 <x> Specifies the condition for an optional second instruction in the VPT block, and whether the condition is the same as for the first instruction (T) or its inverse (E). This is encoded in the mask field in a similar way to the IT instruction, except that rather than encoding T and E directly into f\_cond[0], a 1 in the corresponding mask bit indicates that the previous predicate value in VPR.P0 should be inverted  
 <y> Specifies the condition for an optional third instruction in the VPT block. It is encoded in the mask field in the same way as the x field.  
 <z> Specifies the condition for an optional fourth instruction in the VPT block. It is encoded in the mask field in the same way as the x field.

### Operation for all encodings

```

1 EncodingSpecificOperations();
2 ExecuteFPCheck();
3
4 (curBeat, elmtMask) = GetCurInstrBeat();
5
6 op1 = Q[n, curBeat];
7 beatPred = Zeros(4);
8 if withScalar then
9     op2 = RZ[m][esize-1:0];
10 else
11     opm = Q[m, curBeat];
12 for e = 0 to elements-1
13     if !withScalar then
14         op2 = Elem[opm, e, esize];
15     (result, flC, flV) = AddWithCarry(Elem[op1, e, esize], NOT(op2), '1');
16     flN = result[esize-1];
17     flZ = IsZeroBit(result);
18     pred = ConditionHolds(f_cond, flN, flZ, flC, flV);
19     Elem[beatPred, e, ebytes] = Replicate(if pred then '1' else '0');
20
21 Elem[VPR.P0, curBeat, 4] = beatPred AND elmtMask;
22 // Only one mask field per pair of beats, so the mask is only updated on odd beats.
23 if curBeat[0] == '1' then

```

24      `SetVPTMask(curBeat, mask);`

### C2.4.431 VPT (floating-point)

Vector Predicate Then. Predicates the following instructions, up to a maximum of four instructions, by masking the operation of instructions on a per-lane basis based on the VPR.P0 predicate values. The predicated instructions are referred to as the Vector Predication Block or simply the VPT Block. The VPR.P0 predicate values may be inverted after each instruction in the VPT block based on the mask fields (see x, y, and z).

This instruction is subject to beat-wise execution.

This instruction is not VPT compatible.

This instruction is not permitted in an IT block.

| <Rm> | Source general-purpose register (ZR is permitted, PC is not).                                                                                                                                                                                                                                                                                                                                                                  |
| <x>  | Specifies the condition for an optional second instruction in the VPT block, and whether the condition is the same as for the first instruction (T) or its inverse (E). This is encoded in the mask field in a similar way to the IT instruction, except that rather than encoding T and E directly into f_cond[0], a 1 in the corresponding mask bit indicates that the previous predicate value in VPR.P0 should be inverted |
| <y>  | Specifies the condition for an optional third instruction in the VPT block. It is encoded in the mask field in the same way as the x field.                                                                                                                                                                                                                                                                                    |
| <z>  | Specifies the condition for an optional fourth instruction in the VPT block. It is encoded in the mask field in the same way as the x field.                                                                                                                                                                                                                                                                                   |

## Operation for all encodings

```

1 EncodingSpecificOperations();
2 ExecuteFPCheck();
3
4 (curBeat, elmtMask) = GetCurInstrBeat();
5
6 op1 = Q[n, curBeat];
7 beatPred = Zeros(4);
8 if withScalar then
9     op2 = RZ[m][esize-1:0];
10 else
11     opm = Q[m, curBeat];
12 for e = 0 to elements-1
13     if !withScalar then
14         op2 = Elem[opm, e, esize];
15         // Avoid Floating-point exceptions on a predicated lane by checking the element mask
16         predicated = (elmtMask[e*(esize>>3)] == '0');
17         (flN, flZ, flC, flV) = FPCompare(Elem[op1, e, esize], op2, TRUE, FALSE, predicated);
18         pred = ConditionHolds(f_cond, flN, flZ, flC, flV);
19         Elem[beatPred, e, ebytes] = Replicate(if pred then '1' else '0');
20
21 Elem[VPR.P0, curBeat, 4] = beatPred AND elmtMask;
22 // Only one mask field per pair of beats, so the mask is only updated on odd beats.
23 if curBeat[0] == '1' then
24     SetVPTMask(curBeat, mask);

```

## C2.4.432 VPUSH

Push Floating-point registers to stack. Push Floating-point registers to stack stores multiple consecutive registers from the Floating-point register file to the stack.

This instruction is interrupt-continuable.

This instruction is an alias of the [VSTM](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [VSTM](#).
- The description of [VSTM](#) gives the operational pseudocode for this instruction.

### T1

*Armv8-M Floating-point Extension, Armv8.1-M Floating-point Extension, or Armv8.1-M MVE*

#### Decrement Before variant

`VPUSH{<c>}{<q>}{.<size>} <dreglist>`

is equivalent to

`VSTMDB{<c>}{<q>}{.<size>} SP!, <dreglist>`

and is always the preferred disassembly.

### T2

*Armv8-M Floating-point Extension, Armv8.1-M Floating-point Extension, or Armv8.1-M MVE*

#### Decrement Before variant

`VPUSH{<c>}{<q>}{.<size>} <sreglist>`

is equivalent to

`VSTMDB{<c>}{<q>}{.<size>} SP!, <sreglist>`

and is always the preferred disassembly.

### Assembler symbols for all encodings

|            |                                                                                                                                                                                                                                                      |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <c>        | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                                                                                                        |
| <q>        | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                                                                                                        |
| <size>     | An optional data size specifier. If present, it must be equal to the size in bits, 32 or 64, of the registers being transferred.                                                                                                                     |
| <sreglist> | Is the list of consecutively numbered 32-bit floating-point registers to be transferred. The first register in the list is encoded in "Vd:D", and "imm8" is set to the number of registers in the list. The list must contain at least one register. |

`<dreglist>` Is the list of consecutively numbered 64-bit floating-point registers to be transferred. The first register in the list is encoded in "D:Vd", and "imm8" is set to twice the number of registers in the list. The list must contain at least one register.

### Operation for all encodings

The description of [VSTM](#) gives the operational pseudocode for this instruction.

### C2.4.433 VQABS

Vector Saturating Absolute. Compute the absolute value of and saturate each element of a vector register.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

#### T1

9     value = Abs(SInt(Elm[op1, e, esize]));
10    (Elm[result, e, esize], sat) = SignedSatQ(value, esize);
11    if sat && elmtMask[e*(esize>>3)] == '1' then
12        FPSCR.QC = '1';
13
14 for e = 0 to 3
15     if elmtMask[e] == '1' then
16         Elem[Q[d, curBeat], e, 8] = Elem[result, e, 8];

```

### C2.4.434 VQADD

Vector Saturating Add. Add the value of the elements in the first source vector register to either the respective elements in the second source vector register or a general-purpose register. The result is saturated before being written to the destination vector register.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

## Operation for all encodings

```

1  EncodingSpecificOperations();
2  ExecuteFPCheck();
3
4  (curBeat, elmtMask) = GetCurInstrBeat();
5
6  result = Zeros(32);
7  op1    = Q[n, curBeat];
8  if !withScalar then
9      op2 = Q[m, curBeat];
10 for e = 0 to elements-1
11     if withScalar then
12         value = Int(Elem[op1, e, esize], unsigned) + Int(R[m][esize-1:0], unsigned);
13     else
14         value = Int(Elem[op1, e, esize], unsigned) + Int(Elem[op2, e, esize], unsigned);
15     (Elem[result, e, esize], sat) = SatQ(value, esize, unsigned);
16     if sat && elmtMask[e*(esize>>3)] == '1' then
17         FPSCR.QC = '1';
18
19 for e = 0 to 3
20     if elmtMask[e] == '1' then
21         Elem[Q[d, curBeat], e, 8] = Elem[result, e, 8];

```

### C2.4.435 VQDMLADH, VQRDMLADH

Vector Saturating Doubling Multiply Add Dual Returning High Half, Vector Saturating Rounding Doubling Multiply Add Dual Returning High Half. The elements of the vector registers are handled in pairs. In the base variant, corresponding elements from the two source registers are multiplied together, whereas the exchange variant swaps the values in each pair of values read from the first source register, before multiplying them with the values from the second source register. The results of the pairs of multiply operations are combined by adding them together and doubling the result. The high halves of the resulting values are selected as the final results. The base variant writes the results into the lower element of each pair of elements in the destination register, whereas the exchange variant writes to the upper element in each pair. The results are optionally rounded before the high half is selected and saturated.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

```

### C2.4.436 VQDMLAH, VQRDMLAH (vector by scalar plus vector)

Vector Saturating Doubling Multiply Accumulate, Vector Saturating Rounding Doubling Multiply Accumulate. Multiply each element in the source vector by a scalar value, double the result and add to the respective element from the destination vector High Half. Store the high half of each result in the destination register. The result is optionally rounded before the high half is selected and saturated.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

### C2.4.438 VQDMLSDH, VQRDMLSDH

Vector Saturating Doubling Multiply Subtract Dual Returning High Half, Vector Saturating Rounding Doubling Multiply Subtract Dual Returning High Half. The elements of the vector registers are handled in pairs. In the base variant, corresponding elements from the two source registers are multiplied together, whereas the exchange variant swaps the values in each pair of values read from the first source register, before multiplying them with the values from the second source register. The results of the pairs of multiply operations are combined by subtracting one from the other and doubling the result. The high halves of the resulting values are selected as the final results. The base variant writes the results into the lower element of each pair of elements in the destination register, whereas the exchange variant writes to the upper element in each pair. The results are optionally rounded before the high half is selected and saturated.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

### C2.4.439 VQDMULH, VQRDMULH

Vector Saturating Doubling Multiply Returning High Half, Vector Saturating Rounding Doubling Multiply Returning High Half. Multiply a general-purpose register value by each element of a vector register to produce a vector of results or multiply each element of a vector register by its corresponding element in another vector register, double the results, and place the most significant half of the final results in the destination vector. The results are optionally rounded before being saturated.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

## C2.4.440 VQDMULL

Vector Multiply Long. Performs an element-wise integer multiplication of two single-width source operand elements. These are selected from either the top half (T variant) or bottom half (B variant) of double-width source vector register elements or the lower single-width portion of the general-purpose register. The product of the multiplication is doubled and saturated to produce a double-width product that is written back to the destination vector register.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

```

## C2.4.441 VQMOVN

Vector Saturating Move and Narrow. Performs an element-wise saturation to half-width, writing the result to either the top half (T variant) or bottom half (B variant) of the result element. The other half of the destination vector element retains its previous value.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

```

## C2.4.442 VQMOVUN

Vector Saturating Move Unsigned and Narrow. Performs an element-wise saturation to half-width, writing the result to either the top half (T variant) or bottom half (B variant) of the result element. The other half of the destination vector element retains its previous value. The result is always saturated to an unsigned value.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

```

## C2.4.444 VQRSHL

Vector Saturating Rounding Shift Left. The vector variant shifts each element of the first vector by a value from the least significant byte of the corresponding element of the second vector and places the results in the destination vector.

The register variants shift each element of a vector register by the value specified in a source register. The direction of the shift depends on the sign of the element from the second vector register.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

25         Elm[Q[d, curBeat], e, 8] = Elm[result, e, 8];

```

### C2.4.445 VQRSHRN

Vector Saturating Rounding Shift Right and Narrow. Performs an element-wise saturation to half-width, with shift, writing the rounded result to either the top half (T variant) or bottom half (B variant) of the result element. The other half of the destination vector element retains its previous value.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

#### Assembler symbols for all encodings

<T> Specifies which half of the result element the result is written to.  
This parameter must be one of the following values:

- B Encoded as T = 0  
Indicates bottom half
- T Encoded as T = 1  
Indicates top half

<v, q> See [C1.2.5 Standard assembler syntax fields](#).

<dt> This parameter determines the following values:

- Unsigned flag: S indicates signed, U indicates unsigned.
- The size of the elements in the vector.

This parameter must be one of the following values:

- S16 Encoded as sz = 01, U = 0
- U16 Encoded as sz = 01, U = 1
- S32 Encoded as sz = 1x, U = 0
- U32 Encoded as sz = 1x, U = 1

<Qd> Destination vector register.

<Qm> Source vector register.

<imm> The number of bits to shift by, in the range 1 to <dt>/2. The encoding of this field is a logical OR of the most significant bits of the imm parameter and the least significant bits of the size field (sz).

### Operation for all encodings

```
1 EncodingSpecificOperations();

## C2.4.447 VQSHL, VQSHLU

Vector Saturating Shift Left, Vector Saturating Shift Left Unsigned. The register variants shift each element of a vector register by the value specified in a source register. The direction of the shift depends on the sign of the element from the second vector register.

The immediate variant shifts each element of a vector register to the left by the immediate value.

The vector variant shifts each element of the first vector by a value from the least significant byte of the corresponding element of the second vector and places the results in the destination vector.

The unsigned variant produces unsigned results, although the operands are signed.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

### Assembler symbols for T1 encodings

<dt>

This parameter determines the following values:

- Unsigned flag: S indicates signed, U indicates unsigned.
- Size: indicates the size of the elements in the vector.

This parameter must be one of the following values:

|     |            |            |       |
|-----|------------|------------|-------|
| S8  | Encoded as | size = 00, | U = 0 |
| U8  | Encoded as | size = 00, | U = 1 |
| S16 | Encoded as | size = 01, | U = 0 |
| U16 | Encoded as | size = 01, | U = 1 |
| S32 | Encoded as | size = 10, | U = 0 |
| U32 | Encoded as | size = 10, | U = 1 |

### Assembler symbols for T2 encodings

<dt>

This parameter determines the following values:

- Unsigned flag: S indicates signed, U indicates unsigned.
- The size of the elements in the vector.

This parameter must be one of the following values:

|     |            |           |       |
|-----|------------|-----------|-------|
| S8  | Encoded as | sz = 001, | U = 0 |
| U8  | Encoded as | sz = 001, | U = 1 |
| S16 | Encoded as | sz = 01x, | U = 0 |
| U16 | Encoded as | sz = 01x, | U = 1 |
| S32 | Encoded as | sz = 1xx, | U = 0 |
| U32 | Encoded as | sz = 1xx, | U = 1 |

### Assembler symbols for T3 encodings

<dt>

The size of the elements in the vector.

This parameter must be one of the following values:

|     |            |          |
|-----|------------|----------|
| S8  | Encoded as | sz = 001 |
| S16 | Encoded as | sz = 01x |
| S32 | Encoded as | sz = 1xx |

### Assembler symbols for T4 encodings

<dt>

This parameter determines the following values:

- Unsigned flag: S indicates signed, U indicates unsigned.
- Size: indicates the size of the elements in the vector.

This parameter must be one of the following values:

|    |            |            |       |
|----|------------|------------|-------|
| S8 | Encoded as | size = 00, | U = 0 |
|----|------------|------------|-------|

|     |            |            |       |
|-----|------------|------------|-------|
| U8  | Encoded as | size = 00, | U = 1 |
| S16 | Encoded as | size = 01, | U = 0 |
| U16 | Encoded as | size = 01, | U = 1 |
| S32 | Encoded as | size = 10, | U = 0 |
| U32 | Encoded as | size = 10, | U = 1 |

### Assembler symbols for all encodings

|        |                                                                                                                                                                                                               |

```

## C2.4.448 VQSHRN

Vector Saturating Shift Right and Narrow. Performs an element-wise saturation to half-width, with shift, writing the result to either the top half (T variant) or bottom half (B variant) of the result element. The other half of the destination vector element retains its previous value.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

### Assembler symbols for all encodings

<T> Specifies which half of the result element the result is written to.  
This parameter must be one of the following values:

- B Encoded as T = 0  
Indicates bottom half
- T Encoded as T = 1  
Indicates top half

<v, q> See [C1.2.5 Standard assembler syntax fields](#).

<dt> This parameter determines the following values:

- Unsigned flag: S indicates signed, U indicates unsigned.
- The size of the elements in the vector.

This parameter must be one of the following values:

- S16 Encoded as sz = 01, U = 0
- U16 Encoded as sz = 01, U = 1
- S32 Encoded as sz = 1x, U = 0
- U32 Encoded as sz = 1x, U = 1

<Qd> Destination vector register.

<Qm> Source vector register.

<imm> The number of bits to shift by, in the range 1 to <dt>/2. The encoding of this field is a logical OR of the most significant bits of the imm parameter and the least significant bits of the size field (sz).

### Operation for all encodings

#### Assembler symbols for all encodings

<v, q> See [C1.2.5 Standard assembler syntax fields](#).  
 <dt> This parameter determines the following values:  
 – Unsigned flag: S indicates signed, U indicates unsigned.  
 – Size: indicates the size of the elements in the vector.  
 This parameter must be one of the following values:

|     |            |            |       |
|-----|------------|------------|-------|
| S8  | Encoded as | size = 00, | U = 0 |
| U8  | Encoded as | size = 00, | U = 1 |
| S16 | Encoded as | size = 01, | U = 0 |
| U16 | Encoded as | size = 01, | U = 1 |
| S32 | Encoded as | size = 10, | U = 0 |
| U32 | Encoded as | size = 10, | U = 1 |

<Qd> Destination vector register.  
 <Qn> First source vector register.  
 <Qm> Second source vector register.

#### Operation for all encodings

```

1 EncodingSpecificOperations();
2 ExecuteFPCheck();
3
4 (curBeat, elmtMask) = GetCurInstrBeat();
5

```

```

6 result = Zeros(32);
7 op1    = Q[n, curBeat];
8 op2    = Q[m, curBeat];
9 for e = 0 to elements-1
10     value = Int(Elem[op1, e, esize], unsigned) + Int(Elem[op2, e, esize], unsigned);
11     Elem[result, e, esize] = (value + 1)[esize:1];
12
13 for e = 0 to 3
14     if elmtMask[e] == '1' then
15         Elem[Q[d, curBeat], e, 8] = Elem[result, e, 8];

```

## Restricted behavior

### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data subject to this instruction.
- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

## C2.4.455 VRINT (floating-point)

Vector Round Integer. Round a floating-point value to an integer value. The result remains in floating-point format. It is not converted to an integer.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

```

## C2.4.456 VRINTA

Floating-point Round to Nearest Integer with Ties to Away. Floating-point Round to Nearest Integer with Ties to Away rounds a floating-point value to an integral floating-point value of the same size using the Round to Nearest with Ties to Away rounding mode. A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

```

## C2.4.459 VRINTP

Floating-point Round to Integer towards +Infinity. Floating-point Round to Integer towards +Infinity rounds a floating-point value to an integral floating-point value of the same size using the Round towards +Infinity rounding mode. A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

## C2.4.461 VRINTX

Floating-point Round to Integer, raising Inexact exception. This instruction rounds a floating-point value to an integral floating-point value of the same size. A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

**VRINTX** uses the rounding mode specified in FPSCR, and raises an Inexact exception when the result value is not numerically equal to the input value.

### C2.4.463 VRMLALDAVH

Vector Rounding Multiply Add Long Dual Accumulate Across Vector Returning High 64 bits. The elements of the vector registers are handled in pairs. In the base variant, corresponding elements from the two source registers are multiplied together, whereas the exchange variant swaps the values in each pair of values read from the first source register, before multiplying them with the values from the second source register. The results of the pairs of multiply operations are combined by adding them together. At the end of each beat these results are accumulated. The upper 64 bits of a 72-bit accumulator value is selected and stored across two registers, the top 32 bits are stored in an even-numbered register and the lower 32 bits are stored in an odd-numbered register. The initial value of the general-purpose destination registers can optionally be shifted up by 8 bits and added to the result. The result is rounded before the top 64 bits are selected.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

## C2.4.465 VRMLSLDAVH

Vector Rounding Multiply Subtract Long Dual Accumulate Across Vector Returning High 64 bits. The elements of the vector registers are handled in pairs. In the base variant, corresponding elements from the two source registers are multiplied together, whereas the exchange variant swaps the values in each pair of values read from the first source register, before multiplying them with the values from the second source register. The results of the pairs of multiply operations are combined by subtracting one from the other. At the end of each beat these results are accumulated. The upper 64 bits of a 72-bit accumulator value is selected and stored across two registers, the top 32 bits are stored in an even-numbered register and the lower 32 bits are stored in an odd-numbered register. The initial value of the general-purpose destination registers can optionally be shifted up by 8 bits and added to the result. The result is rounded before the top 64 bits are selected.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

|        |                                                                                                                                                                                                                                                     |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <I>    | Specifies where the initial carry in for wide arithmetic comes from.<br>This parameter must be one of the following values:<br>– Encoded as I = 0<br>Indicates carry input comes from FPSCR.C.<br>I Encoded as I = 1<br>Indicates carry input is 1. |
| <v, q> | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                                                                                                       |
| <Qd>   | Destination vector register.                                                                                                                                                                                                                        |
| <Qn>   | First source vector register.                                                                                                                                                                                                                       |
| <Qm>   | Second source vector register.                                                                                                                                                                                                                      |

### Operation for all encodings

```

1 EncodingSpecificOperations();
2 ExecuteFPCheck();
3
4 (curBeat, elmtMask) = GetCurInstrBeat();
5
6 op1 = Q[n, curBeat];
7 op2 = NOT(Q[m, curBeat]);
8 if carryInit && IsFirstBeat() then
9     (FPSCR.N, FPSCR.Z, FPSCR.C, FPSCR.V) = ('0', '0', '1', '0');
10 (result, carryOut, -) = AddWithCarry(op1, op2, FPSCR.C);
11 if elmtMask[0] == '1' then
12     (FPSCR.N, FPSCR.Z, FPSCR.C, FPSCR.V) = ('0', '0', carryOut, '0');

```

```
13  
14 for e = 0 to 3  
15     if elmtMask[e] == '1' then  
16         Elem[Q[d, curBeat], e, 8] = Elem[result, e, 8];
```

## Restricted behavior

### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data subject to this instruction.
- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

## C2.4.470 VSCCLRM

Floating-point Secure Context Clear Multiple. Zeros VPR and the specified floating-point registers if there is an active floating-point context. This instruction is UNDEFINED if executed in Non-secure state. This instruction is present on all PEs that implement the Armv8.1-M architecture, even if the Floating-point Extension is not present. It is IMPLEMENTATION DEFINED whether this instruction is interrupt-continuable. See EPSR.ICI. If an exception returns to this instruction with nonzero EPSR.ICI bits, and the PE does not support interrupt-continuable behavior, the instruction restarts from the beginning. It is permissible to specify any or none of the the floating-point registers to be cleared, but the VPR must always be specified.

14          VPR = Zeros(32);

```

## C2.4.471 VSEL

Floating-point Conditional Select. Floating-point Conditional Select allows the destination register to take the value from either one or the other of two source registers according to the condition codes in the APSR.

The condition codes for VSEL are limited to GE, GT, EQ, and VS. The effect of LT, LE, NE, and VC can be achieved by exchanging the source operands.

10        D[d] = if ConditionHolds(cond) then D[n] else D[m];

```

## C2.4.472 VSHL

Vector Shift Left. The immediate variant shifts each element of a vector register to the left by the immediate value.

The register variants shift each element of a vector register by the value specified in a source register. The direction of the shift depends on the sign of the element from the second vector register.

The vector variant shifts each element of the first vector by a value from the least significant byte of the corresponding element of the second vector and places the results in the destination vector.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

### Assembler symbols for T1 encodings

<dt> The size of the elements in the vector.  
This parameter must be one of the following values:

|     |            |          |
|-----|------------|----------|
| I8  | Encoded as | sz = 001 |
| I16 | Encoded as | sz = 01x |
| I32 | Encoded as | sz = 1xx |

### Assembler symbols for T2 encodings

<dt> This parameter determines the following values:

- Unsigned flag: S indicates signed, U indicates unsigned.
- Size: indicates the size of the elements in the vector.

This parameter must be one of the following values:

|     |            |                  |
|-----|------------|------------------|
| S8  | Encoded as | size = 00, U = 0 |
| U8  | Encoded as | size = 00, U = 1 |
| S16 | Encoded as | size = 01, U = 0 |
| U16 | Encoded as | size = 01, U = 1 |
| S32 | Encoded as | size = 10, U = 0 |

U32 Encoded as size = 10, U = 1

### Assembler symbols for T3 encodings

<dt> This parameter determines the following values:  
 – Unsigned flag: S indicates signed, U indicates unsigned.  
 – Size: indicates the size of the elements in the vector.  
 This parameter must be one of the following values:

|     |            |            |       |
|-----|------------|------------|-------|
| S8  | Encoded as | size = 00, | U = 0 |
| U8  | Encoded as | size = 00, | U = 1 |
| S16 | Encoded as | size = 01, | U = 0 |
| U16 | Encoded as | size = 01, | U = 1 |
| S32 | Encoded as | size = 10, | U = 0 |
| U32 | Encoded as | size = 10, | U = 1 |

### Assembler symbols for all encodings

| <Qda>  | Source and destination vector register.                                                                                                                                                                       |
| <Qm>   | Source vector register.                                                                                                                                                                                       |
| <Qn>   | Source vector register, the elements of which containing the amount to shift by.                                                                                                                              |
| <Rm>   | Source general-purpose register containing the amount to shift by.                                                                                                                                            |
| <imm>  | The number of bits to shift by, in the range 0 to <dt>-1. The encoding of this field is a logical OR of the most significant bits of the imm parameter and the least significant bits of the size field (sz). |

### Operation for all encodings

```

1 EncodingSpecificOperations();
2 ExecuteFPCheck();
3
4 (curBeat, elmtMask) = GetCurInstrBeat();
5
6 result = Zeros(32);
7 op1 = Q[m, curBeat];
8 if withVector then
9     op2 = Q[n, curBeat];
10 if withScalar then
11     shiftAmount = SInt(R[n][7:0]);
12 for e = 0 to elements-1
13     if withVector then
14         shiftAmount = SInt(Elem[op2, e, esize][7:0]);
15     operand = Int(Elem[op1, e, esize], unsigned);
16     Elem[result, e, esize] = (operand << shiftAmount)[esize-1:0];
17
18 for e = 0 to 3
19     if elmtMask[e] == '1' then
20         Elem[Q[d, curBeat], e, 8] = Elem[result, e, 8];
    
```

### Restricted behavior

#### Data Independent Timing behavior

If [AIRCR.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data subject to this instruction.
- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

## C2.4.473 VSHLC

Whole Vector Left Shift with Carry. Logical shift left by 1-32 bits, with carry across beats, carry in from general-purpose register, and carry out to the same general-purpose register. Permits treating a vector register as a single 128-bit scalar. The carry in is from the lower <imm> bits of the general-purpose register, not the upper bits.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

## C2.4.474 VSHLL

Vector Shift Left Long. Selects an element of 8 or 16-bits from either the top half (T variant) or bottom half (B variant) of each source element, performs a signed or unsigned left shift by an immediate value, and places the 16 or 32-bit results in the destination vector.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

### Assembler symbols for T1 encodings

<dt> This parameter determines the following values:

- Unsigned flag: S indicates signed, U indicates unsigned.
- The size of the elements in the vector.

This parameter must be one of the following values:

|     |            |          |       |
|-----|------------|----------|-------|
| S8  | Encoded as | sz = 01, | U = 0 |
| U8  | Encoded as | sz = 01, | U = 1 |
| S16 | Encoded as | sz = 1x, | U = 0 |
| U16 | Encoded as | sz = 1x, | U = 1 |

### Assembler symbols for T2 encodings

<dt> This parameter determines the following values:

- Unsigned flag: S indicates signed, U indicates unsigned.
- Size: indicates the size of the elements in the vector.

This parameter must be one of the following values:

|     |            |            |       |
|-----|------------|------------|-------|
| S8  | Encoded as | size = 00, | U = 0 |
| U8  | Encoded as | size = 00, | U = 1 |
| S16 | Encoded as | size = 01, | U = 0 |
| U16 | Encoded as | size = 01, | U = 1 |

### Assembler symbols for all encodings

<T> Specifies which half of the source element is used.  
This parameter must be one of the following values:

|   |                       |       |
|---|-----------------------|-------|
| B | Encoded as            | T = 0 |
|   | Indicates bottom half |       |
| T | Encoded as            | T = 1 |
|   | Indicates top half    |       |

<v, q> See [C1.2.5 Standard assembler syntax fields](#).

<Qd> Destination vector register.

<Qm> Source vector register.

<imm> The number of bits to shift by, in the range 1 to <dt>. The encoding of this field is a logical OR of the most significant bits of the imm parameter and the least significant bits of the size field (sz). If <imm> == <dt> the encoding is T2, otherwise the encoding is T1

### Operation for all encodings

```

- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

## C2.4.476 VSHRN

Vector Shift Right and Narrow. Performs an element-wise narrowing to half-width, with shift, writing the result to either the top half (T variant) or bottom half (B variant) of the result element. The other half of the destination vector element retains its previous value.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

14     if elmtMask[e] == '1' then
15         Elem[Q[d, curBeat], e, 8] = Elem[result, e, 8];
```

## C2.4.477 VSLI

Vector Shift Left and Insert. Takes each element in the operand vector, left shifts them by an immediate value, and inserts the results in the destination vector. Bits shifted out of the left of each element are lost.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

## Restricted behavior

### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data subject to this instruction.
- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

## C2.4.480 VST2

Vector Interleaving Store - Stride 2. Saves two 64-bit contiguous blocks of data to memory made up of multiple parts of 2 source registers. The parts of the source registers written to, and the offsets from the base address register, are determined by the pat parameter. If the instruction is executed 2 times with the same base address and source registers, but with different pat values, the effect is to interleave the specified registers with a stride of 2 and to save the data to memory. The base address register can optionally be incremented by 32.

This instruction is subject to beat-wise execution.

This instruction is not VPT compatible.

This instruction is not permitted in an IT block.

21             y = UInt(curBeat[0]);
22             xE = 0;
23     MemA_MVE[address, esize DIV 8] = Elem[Q[d + y, xBeat], xE, esize];
24
25 // The optional write back to the base register is only performed on the
26 // last beat of the instruction.
27 if wback && IsLastBeat() then
28     R[n] = R[n] + 32;

```

### Restricted behavior

#### Data Independent Timing behavior

If [AIRCR.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value of the data being stored.
- The point at which an asynchronous exception is taken does not vary based on the value being stored by this instruction.

The timing invariance does not apply to the addresses being accessed.

## C2.4.481 VST4

Vector Interleaving Store - Stride 4. Saves two 64-bit contiguous blocks of data to memory made up of multiple parts of 4 source registers. The parts of the source registers written to, and the offsets from the base address register, are determined by the pat parameter. If the instruction is executed 4 times with the same base address and source registers, but with different pat values, the effect is to interleave the specified registers with a stride of 4 and to save the data to memory. The base address register can optionally be incremented by 64.

This instruction is subject to beat-wise execution.

This instruction is not VPT compatible.

This instruction is not permitted in an IT block.

26 // last beat of the instruction.
27 if wback && IsLastBeat() then
28     R[n] = R[n] + 64;

```

### Restricted behavior

#### Data Independent Timing behavior

If [AIRCR.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value of the data being stored.
- The point at which an asynchronous exception is taken does not vary based on the value being stored by this instruction.

The timing invariance does not apply to the addresses being accessed.

## C2.4.482 VSTM

Floating-point Store Multiple. Floating-point Store Multiple stores multiple extension registers to consecutive memory locations using an address from a general-purpose register.

This instruction is used by the alias [VPUSH](#).

This instruction is interrupt-continuable.

### T1

*Armv8-M Floating-point Extension, Armv8.1-M Floating-point Extension, or Armv8.1-M MVE*

#### Decrement Before variant

Applies when **P == 1 && U == 0 && W == 1**.

VSTMDB{<c>}{<q>}{.<size>} <Rn>!, <dreglist>

#### Increment After variant

Applies when **P == 0 && U == 1**.

VSTM{<c>}{<q>}{.<size>} <Rn>{!}, <dreglist>

VSTMIA{<c>}{<q>}{.<size>} <Rn>{!}, <dreglist>

#### Decode for this encoding

```

1 if P == '0' && U == '0' && W == '0' then SEE "Related encodings";
2 if P == '1' && W == '0' then SEE VSTR;
3 CheckDecodeFaults(ExtType_MveOrFp);
4 if P == U && W == '1' then UNDEFINED;
5 // Remaining combinations are PUW = 010 (IA without !), 011 (IA with !), 101 (DB with !)
6 single_regs = FALSE; add = (U == '1'); wback = (W == '1'); imm8 = imm7 : imm1;
7 d = UInt(D:Vd); n = UInt(Rn); imm32 = ZeroExtend(imm8:'00', 32);
8 regs = UInt(imm8) DIV 2;

10 if regs == 0 || (d+regs) > 32 then UNPREDICTABLE;
11 if !HasArchVersion(Armv8pl) then
12     if VFPSmallRegisterBank() && (d+regs) > 16 then UNPREDICTABLE;
```

#### CONSTRAINED UNPREDICTABLE behavior

If **regs == 0**, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as a [VSTM](#) with the same addressing mode but stores no registers.

#### CONSTRAINED UNPREDICTABLE behavior

If **(d+regs) > 32**, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

- The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies write-back, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

| <size>     | An optional data size specifier. If present, it must be equal to the size in bits, 32 or 64, of the registers being transferred.                                                                                                                           |
| <Rn>       | Is the general-purpose base register, encoded in the "Rn" field.                                                                                                                                                                                           |
| !          | Specifies base register write-back. Encoded in the "W" field as 1 if present, otherwise 0.                                                                                                                                                                 |
| <sreglist> | Is the list of consecutively numbered 32-bit floating-point registers to be transferred. The first register in the list is encoded in "Vd:D", and "imm8" is set to the number of registers in the list. The list must contain at least one register.       |
| <dreglist> | Is the list of consecutively numbered 64-bit floating-point registers to be transferred. The first register in the list is encoded in "D:Vd", and "imm8" is set to twice the number of registers in the list. The list must contain at least one register. |

## Operation for all encodings

```

1  if ConditionPassed() then
2      EncodingSpecificOperations();
3      ExecuteFPCheck();
4      address = if add then R[n]          else R[n]-imm32;
5      regval  = if add then R[n]+imm32 else R[n]-imm32;
6
7      // Determine if the stack pointer limit should be checked
8      if n == 13 && wback then
9          violatesLimit = ViolatesSPLim(LookUpSP(), regval);
10     else
11         violatesLimit = FALSE;
12
13     // Memory operation only performed if limit not violated
14     if !violatesLimit then
15         for r = 0 to regs-1
16             if single_regs then
17                 if (d+r) < 32 || !VFPSmallRegisterBank() then
18                     MemA[address, 4] = S[d+r];
19                     address = address+4;
20             else
21                 // Store as two word-aligned words in the correct order for current
22                 // endianness.
23                 if (d+r) < 16 || !VFPSmallRegisterBank() then
24                     bigEndian = BigEndian(address, 8);
25                     MemA[address, 4] = if bigEndian then D[d+r][63:32] else D[d+r][31:0];
26                     MemA[address+4, 4] = if bigEndian then D[d+r][31:0] else D[d+r][63:32];
27                 elsif boolean UNKNOWN then

30                     address = address+8;
31
32     // If the stack pointer is being updated a fault will be raised if
33     // the limit is violated
34     if wback then RSPCheck[n] = regval;

```

## Restricted behavior

### Data Independent Timing behavior

If [AIRCR.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value of the data being stored.

- The point at which an asynchronous exception is taken does not vary based on the value being stored by this instruction.

The timing invariance does not apply to the addresses being accessed.

## C2.4.483 VSTR

Floating-point Store Register. Floating-point Store Register stores a single Floating-point Extension register to memory, using an address from a general-purpose register, with an optional offset.

14             MemA[address+4, 4] = if bigEndian then D[d][31:0] else D[d][63:32];

```

## Restricted behavior

### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value of the data being stored.
- The point at which an asynchronous exception is taken does not vary based on the value being stored by this instruction.

The timing invariance does not apply to the addresses being accessed.

## C2.4.484 VSTR (System Register)

Store System Register. Store a system register in memory. The target address is calculated from a base register plus an immediate offset. Access to the FPCXT payloads generates an UNDEFINED exception if the instruction is executed from Non-secure state. If CP10 is not enabled and either the Main extension is not implemented or the Floating-point context is active, access to FPCXT\_NS will generate a NOCP UsageFault. Accesses to FPCXT\_NS will not trigger lazy state preservation if there is no active Floating-point context. Accesses to FPCXT\_NS do not trigger Floating-point context creation regardless of the value of FPCCR.ASPEN. FPSCR\_nzcvqc allows access to FPSCR condition and saturation flags. The VPR register can only be accessed from privileged mode. FPCXT\_NS, enables saving and restoration of the Non-secure floating-point context. If the Floating-point context is active then the current FPSCR value is accessed and the default value in FPDSCR\_NS is written into FPSCR, otherwise the default value in FPDSCR\_NS is accessed. The payloads cannot be accessed if neither the Floating-point extension nor MVE are implemented. FPCXT\_S, enables saving and restoration of the Secure floating-point context.

## Restricted behavior

### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value of the data being stored.
- The point at which an asynchronous exception is taken does not vary based on the value being stored by this instruction.

The timing invariance does not apply to the addresses being accessed.

## C2.4.485 VSTRB, VSTRH, VSTRW

Vector Store Register. Store consecutive elements to memory from a vector register. In indexed mode, the target address is calculated from a base register offset by an immediate value. Otherwise, the base register address is used directly. The sum of the base register and the immediate value can optionally be written back to the base register.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

## Restricted behavior

### Data Independent Timing behavior

If [AIRCR.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value of the data being stored.
- The point at which an asynchronous exception is taken does not vary based on the value being stored by this instruction.

The timing invariance does not apply to the addresses being accessed.

## C2.4.486 VSTRB, VSTRH, VSTRW, VSTRD (vector)

Vector Scatter Store. Store data from elements of  $Q[d]$  into a memory byte, halfword, word, or doubleword at the address contained in either:

- a) A base register  $R[n]$  plus an offset contained in each element of  $Q[m]$ , optionally shifted by the element size, or
- b) Each element of  $Q[m]$  plus an immediate offset. The base element can optionally be written back, irrespective of predication, with that value incremented by the immediate or by the immediate scaled by the memory element size.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

### Assembler symbols for T1 encodings

<dt>            Size: indicates the size of the elements in the vector.  
This parameter must be one of the following values:

|    |            |           |
|----|------------|-----------|
| 8  | Encoded as | size = 00 |
| 16 | Encoded as | size = 01 |
| 32 | Encoded as | size = 10 |

<Qm>            Vector offset register. The elements of this register contain the unsigned offsets to add to the base address.

### Assembler symbols for T2 encodings

<dt>            Size: indicates the size of the elements in the vector.  
This parameter must be one of the following values:

|    |            |           |
|----|------------|-----------|
| 16 | Encoded as | size = 01 |
| 32 | Encoded as | size = 10 |

<Qm>            Vector offset register. The elements of this register contain the unsigned offsets to add to the base address.

### Assembler symbols for T3 encodings

<dt>            This parameter must be the following value:

|    |            |           |
|----|------------|-----------|
| 32 | Encoded as | size = 10 |
|----|------------|-----------|

<Qm>            Vector offset register. The elements of this register contain the unsigned offsets to add to the base address.

### Assembler symbols for T4 encodings

<dt>            This parameter must be the following value:

|    |            |           |
|----|------------|-----------|
| 64 | Encoded as | size = 11 |
|----|------------|-----------|

<Qm>            Vector offset register. The elements of this register contain the unsigned offsets to add to the base address.

### Assembler symbols for T5 encodings

|       |                                                                                                                                |
|-------|--------------------------------------------------------------------------------------------------------------------------------|
| <dt>  | Data size. This parameter must be ".32".                                                                                       |
| <Qm>  | The base register for the target address.                                                                                      |
| <imm> | The signed immediate value that is added to base register to calculate the target address. This value must be a multiple of 4. |

### Assembler symbols for T6 encodings

|       |                                                                                                                                |
|-------|--------------------------------------------------------------------------------------------------------------------------------|
| <dt>  | Data size. This parameter must be ".64".                                                                                       |
| <Qm>  | The base register for the target address.                                                                                      |
| <imm> | The signed immediate value that is added to base register to calculate the target address. This value must be a multiple of 8. |

### Assembler symbols for all encodings

41     if wback then
42         Elem[Q[m, curBeat], e, esize] = address[esize-1:0];

```

## Restricted behavior

### Data Independent Timing behavior

If [AIRCR.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value of the data being stored.
- The point at which an asynchronous exception is taken does not vary based on the value being stored by this instruction.

The timing invariance does not apply to the addresses being accessed.

## C2.4.487 VSUB

Floating-point Subtract. Floating-point Subtract subtracts one floating-point register value from another floating-point register value, and places the results in the destination floating-point register.

### T2

*Armv8-M Floating-point Extension only*, size == 11 UNDEFINED in single-precision only implementations.

10         D[d] = FPSub(D[n], D[m], TRUE);
```

## C2.4.488 VSUB (floating-point)

Vector Subtract. Subtract the value of the elements in the second source vector register from either the respective elements in the first source vector register or a general-purpose register.

This instruction is subject to beat-wise execution.

This instruction is VPT compatible.

This instruction is not permitted in an IT block.

```

## Restricted behavior

### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data subject to this instruction.
- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

## C2.4.490 WFE

Wait For Event. Wait For Event is a hint instruction. If the Event Register is clear, it suspends execution in the lowest power state available consistent with a fast wakeup without the need for software restoration, until a reset, exception or other event occurs.

This is a NOP-compatible hint.

3   WaitForInterrupt();
```

## C2.4.492 WLS, DLS, WLSTP, DLSTP

While Loop Start, Do Loop Start, While Loop Start with Tail Predication, Do Loop Start with Tail Predication. This instruction partially sets up a loop. A LE or LETP (Loop End) instruction completes the setup. The base variants of this instruction (WLS and DLS) set LR to the number of loop iterations to be performed, whereas the TP variants of this instruction set LR to the number of vector-elements that must be processed. For the TP variants, if the number of elements required is not a multiple of the vector length then the appropriate number of vector elements will be predicated on the last iteration of the loop. When using WLS or WLSTP, if the number of iterations required is zero, then these instructions branch to the label specified. Each loop start instruction is normally used with a matching LE or LETP instruction.

This instruction is not permitted in an IT block.

### T1

*Armv8.1-M Low Overhead Branch Extension*

#### T1: WLS variant

WLS<q> LR, Rn, <label>

#### Decode for this encoding

```

1 if !HaveLOBExt() then UNDEFINED;
2 n      = UInt(Rn);
3 tSize  = 4[2:0]; // No truncation. Set size to full vector length
4 imm32  = ZeroExtend(immh:imml:'0', 32);
5 isWhileLoop = TRUE;
6 if InITBlock() then CONSTRAINED_UNPREDICTABLE;
7 if Rn == 'l1x1' then CONSTRAINED_UNPREDICTABLE;
```

### T2

*Armv8.1-M Low Overhead Branch Extension*

#### T2: DLS variant

DLS<q> LR, Rn

#### Decode for this encoding

```

1 if !HaveLOBExt() then UNDEFINED;
2 n      = UInt(Rn);
3 tSize  = 4[2:0]; // No truncation. Set size to full vector length
4 imm32  = Zeros(32);
5 isWhileLoop = FALSE;
6 if InITBlock() then CONSTRAINED_UNPREDICTABLE;
7 if Rn == 'l1x1' then CONSTRAINED_UNPREDICTABLE;
```

### T3

#### Armv8.1-M Low Overhead Branch Extension and MVE

#### T3: WLSTP variant

WLSTP<q>.<size> LR, Rn, <label>

#### Decode for this encoding

```

1 if Rn == '1111' then SEE "Related encodings";
2 if !HaveLOBExt() then UNDEFINED;
3 if !HaveMve() then UNDEFINED;
4 HandleException(CheckCPEnabled(10));
5 n = UInt(Rn);
6 tSize = '0':size;
7 imm32 = ZeroExtend(immh:imml:'0', 32);
8 isWhileLoop = TRUE;
9 if InITBlock() then CONSTRAINED_UNPREDICTABLE;
10 if Rn == '1101' then CONSTRAINED_UNPREDICTABLE;
```

#### T4

#### Armv8.1-M Low Overhead Branch Extension and MVE

#### T4: DLSTP variant

DLSTP<q>.<size> LR, Rn

#### Decode for this encoding

```

1 if Rn == '1111' then SEE "Related encodings";
2 if !HaveLOBExt() then UNDEFINED;
3 if !HaveMve() then UNDEFINED;
4 HandleException(CheckCPEnabled(10));
5 n = UInt(Rn);
6 tSize = '0':size;
7 imm32 = Zeros(32);
8 isWhileLoop = FALSE;
9 if InITBlock() then CONSTRAINED_UNPREDICTABLE;
10 if Rn == '1101' then CONSTRAINED_UNPREDICTABLE;
```

#### Assembler symbols for T1 encodings

<LR> LR is used to hold the iteration counter of the loop, this instruction must always use this register.

<Rn> The register holding the number of loop iterations to perform.

<label> Specifies the label of the instruction to branch to if no loop iterations are required.

#### Assembler symbols for T2 encodings

<LR> LR is used to hold the iteration counter of the loop, this instruction must always use this register.

<Rn>                    The register holding the number of loop iterations to perform.

### Assembler symbols for T3 encodings

<LR>                    LR is used to hold the number of elements to process, this instruction must always use this register.  
<Rn>                    The register holding the number of elements to process.  
<label>                Specifies the label of the instruction after the loop (the first instruction after the LE).

### Assembler symbols for T4 encodings

<LR>                    LR is used to hold the number of elements to process, this instruction must always use this register.  
<Rn>                    The register holding the number of elements to process.

### Assembler symbols for all encodings

<q>                      See [C1.2.5 Standard assembler syntax fields](#).  
<size>                The size of the elements in the vector to process. This value is stored in the FPSCR.LTPSIZE field, and causes tail predication to be applied on the last iteration of the loop. This parameter must be one of the following values:

|    |            |           |
|----|------------|-----------|
| 8  | Encoded as | size = 00 |
| 16 | Encoded as | size = 01 |
| 32 | Encoded as | size = 10 |
| 64 | Encoded as | size = 11 |

### Operation for all encodings

```

1  EncodingSpecificOperations();
2
3  count = R[n];
4  if isWhileLoop && count == Zeros(32) then
5      BranchTo(PC + imm32);
6  else
7      // To avoid creating unnecessary floating-point context, the
8      // LTPSIZE is only set if tail predication is being used.
9      if tSize != 4[2:0] then
10         ExecuteFPCheck();
11         FPSCR.LTPSIZE = tSize;
12         // Set up the new iteration count
13         LR = count;
```

## C2.4.493 YIELD

Yield hint. Yield is a hint instruction. It enables software with a multithreading capability to indicate to the hardware that it is performing a task, for example a spinlock, that could be swapped out to improve overall system performance. Hardware can use this hint to suspend and resume multiple code threads if it supports the capability.

This is a NOP-compatible hint.

## D1.2 Alphabetical list of registers

## D1.2.1 ACTLR, Auxiliary Control Register

The ACTLR characteristics are:

### Purpose

Provides **IMPLEMENTATION DEFINED** configuration and control options.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

### Configurations

This register is always implemented.

### Attributes

32-bit read/write register located at 0xE000E008.

Secure software can access the Non-secure version of this register via ACTLR\_NS located at 0xE002E008. The location 0xE002E008 is **RES0** to software executing in Non-secure state and the debugger.

It is **IMPLEMENTATION DEFINED** whether this register is banked between Security states.

From Armv8.1-M onwards it is **IMPLEMENTATION DEFINED** whether a debugger write to this register is ignored when the PE is not in Debug state.

## Field descriptions

The ACTLR bit assignments are:

### **IMPLEMENTATION DEFINED, bits [31:0]**

**IMPLEMENTATION DEFINED.** The contents of this field are **IMPLEMENTATION DEFINED**.

## D1.2.2 AFSR, Auxiliary Fault Status Register

The AFSR characteristics are:

### Purpose

Provides **IMPLEMENTATION DEFINED** fault status information.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

### Configurations

This register is always implemented.

### Attributes

32-bit read/write register located at 0xE000ED3C.

Secure software can access the Non-secure version of this register via AFSR\_NS located at 0xE002ED3C. The location 0xE002ED3C is **RES0** to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

From Armv8.1-M onwards it is **IMPLEMENTATION DEFINED** whether a debugger write to this register is ignored when the PE is not in Debug state.

## Field descriptions

The AFSR bit assignments are:

### IMPLEMENTATION DEFINED, bits [31:0]

**IMPLEMENTATION DEFINED**. The contents of this field are **IMPLEMENTATION DEFINED**.

### D1.2.3 AIRCR, Application Interrupt and Reset Control Register

The AIRCR characteristics are:

#### Purpose

Sets or returns interrupt control and reset configuration.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

#### Configurations

This register is always implemented.

#### Attributes

32-bit read/write register located at 0xE00ED0C.

Secure software can access the Non-secure version of this register via AIRCR\_NS located at 0xE002ED0C. The location 0xE002ED0C is **RES0** to software executing in Non-secure state and the debugger.

This register is banked between Security states on a bit by bit basis.

### Field descriptions

The AIRCR bit assignments are:

On a read:

On a write:

#### VECTKEY, bits [31:16], on a write

Vector key. Writes to the AIRCR must be accompanied by a write of the value 0x05FA to this field. Writes to the AIRCR fields that are not accompanied by this value are ignored for the purpose of updating any of the AIRCR values or initiating any AIRCR functionality.

This field is not banked between Security states.

The possible values of this field are:

#### 0x05FA

Permit write to AIRCR fields.

**Not 0x05FA**

Accompanying write to AIRCR fields ignored.

**VECTKEYSTAT, bits [31:16], on a read**

Vector key status. Returns the bitwise inverse of the value required to be written to VECTKEY.

This field is not banked between Security states.

This field reads as 0xFA05.

**ENDIANNESS, bit [15]**

Data endianness. Indicates how the PE interprets the memory system data endianness.

This bit is not banked between Security states.

The possible values of this bit are:

**0**

Little-endian.

**1**

Big-endian.

This bit is read-only.

This bit reads as an **IMPLEMENTATION DEFINED** value.

**PRIS, bit [14]**

Prioritize Secure exceptions. The value of this bit defines whether Secure exception priority boosting is enabled.

This bit is not banked between Security states.

The possible values of this bit are:

**0**

Priority ranges of Secure and Non-secure exceptions are identical.

**1**

Non-secure exceptions are de-prioritized.

To allow lock down of this bit, it is **IMPLEMENTATION DEFINED** whether this bit is writable.

This bit is RAZ/WI from Non-secure state.

This bit resets to zero on a Warm reset.

**BFHFNMINs, bit [13]**

BusFault, HardFault, and NMI Non-secure enable. The value of this bit defines whether BusFault and NMI exceptions are Non-secure, and whether exceptions target the Non-secure HardFault exception.

This bit is not banked between Security states.

The possible values of this bit are:

**0**

BusFault, HardFault, and NMI are Secure.

**1**

BusFault and NMI are Non-secure and exceptions can target Non-secure HardFault.

If an implementation resets into Secure state, this bit resets to zero. If an implementation does not support Secure state, this bit is RAO/WI. To allow lock down of this field it is **IMPLEMENTATION DEFINED** whether this bit is writable. The effect of setting both BFHFNMINs and PRIS to 1 is **UNPREDICTABLE**.

This bit is read-only from Non-secure state.

This bit resets to zero on a Warm reset.

**Bits [12:11]**

Reserved, [RES0](#).

**PRIGROUP, bits [10:8]**

Priority grouping. The value of this field defines the exception priority binary point position for the selected Security state.

This field is banked between Security states.

The possible values of this field are:

**0b000**

Group priority [7:1], subpriority [0].

**0b001**

Group priority [7:2], subpriority [1:0].

**0b010**

Group priority [7:3], subpriority [2:0].

**0b011**

Group priority [7:4], subpriority [3:0].

**0b100**

Group priority [7:5], subpriority [4:0].

**0b101**

Group priority [7:6], subpriority [5:0].

**0b110**

Group priority [7], subpriority [6:0].

**0b111**

No group priority, subpriority [7:0].

If the Main Extension is not implemented, this field is [RES0](#).

This field resets to zero on a Warm reset.

**Bits [7:6]**

Reserved, [RES0](#).

**IESB, bit [5]**

Implicit ESB Enable. This bit indicates and allows modification of whether an implicit Error Synchronization Barriers occurs around lazy state preservation, and on every exception entry and return.

This bit is not banked between Security states.

The possible values of this bit are:

**0**

No Implicit ESB.

**1**

Implicit ESB are enabled.

Enabling implicit ESB's also causes imprecise BusFault exceptions to escalate as if they were precise, however because the address of the instruction that caused the fault is not known they are still reported as an IMPRECISERR in BFSR.

If a PE does not allow configuring implicit ESB insertion, this bit is WI and the value read indicates whether the PE never or always inserts an implicit ESB around lazy state preservation, and on exception entry and return.

If AIRCR.BFHFNMINS is zero this bit is RAZ/WI from Non-secure state.

If RAS is not implemented, this bit is **RES0**.

This bit resets to zero on a Warm reset.

#### **DIT, bit [4]**

Data Independent Timing. This bit indicates and allows modification of whether for the selected Security state data independent timing operations are guaranteed to be timing invariant with respect to the data values being operated on.

This bit is banked between Security states.

The possible values of this bit are:

**0**

The architecture makes no statement about the timing properties of any instructions.

**1**

The architecture requires that the timing of every load and store instruction is insensitive to the value of the data being loaded or stored.

For certain data processing instructions, the instruction takes a time which is independent of:

- The values of the data supplied in any of its registers.
- The values of the NCZV flags.

For certain data processing instructions, the response of the instruction to asynchronous exceptions does not vary based on:

- The values of the data supplied in any of its registers.
- The values of the NZCV flags.

If configuration of timing invariance is not supported this bit is **WI**, and the value read indicates whether the PE always or never exhibits timing invariant behavior.

This bit resets to zero on a Warm reset.

#### **SYSRESETREQS, bit [3]**

System reset request Secure only. The value of this bit defines whether the SYSRESETREQ bit is functional for Non-secure use.

This bit is not banked between Security states.

The possible values of this bit are:

**0**

SYSRESETREQ functionality is available to both Security states.

**1**

SYSRESETREQ functionality is only available to Secure state.

This bit is **RAZ/WI** from Non-secure state.

This bit resets to zero on a Warm reset.

#### **SYSRESETREQ, bit [2]**

System reset request. This bit allows software or a debugger to request a system reset.

This bit is not banked between Security states.

The possible values of this bit are:

**0**

Do not request a system reset.

**1**

Request a system reset.

When SYSRESETREQS is set to 1, the Non-secure view of this bit is RAZ/WI.

This bit resets to zero on a Warm reset.

**VECTCLRACTIVE, bit [1]**

Clear active state.

A debugger write of one to this bit when the PE is halted in Debug state:

- IPSR is cleared to zero.
- If DHCSR.S\_NSUIDE==0, the active state for all Non-secure exceptions is cleared.
- If DHCSR.S\_SUIDE==0 and DHCSR.S\_SDE==1, the active state for all Secure exceptions is cleared.

This bit is not banked between Security states.

The possible values of this bit are:

**0**

Do not clear active state.

**1**

Clear active state.

Writes to this bit while the PE is in Non-debug state are ignored.

This bit reads as zero.

**Bit [0]**

Reserved, [RES0](#).

## D1.2.4 APSR, Application Program Status Register

The APSR characteristics are:

### Purpose

Provides privileged and unprivileged access to the PE Execution state fields.

### Usage constraints

Privileged and unprivileged access permitted.

### Configurations

This register is always implemented.

### Attributes

32-bit read/write special-purpose register.

This register is not banked between Security states.

## Field descriptions

The APSR bit assignments are:

### N, bit [31]

Negative condition flag. When updated by a flag setting instruction this bit indicates whether the result of the operation when treated as a two's complement signed integer is negative.

The possible values of this bit are:

**0**

Result is positive or zero.

**1**

Result is negative.

See individual instruction pages for details.

This bit resets to an **UNKNOWN** value on a Warm reset.

### Z, bit [30]

Zero condition flag. When updated by a flag setting instruction this bit indicates whether the result of the operation was zero.

The possible values of this bit are:

**0**

Result is nonzero.

**1**

Result is zero.

See individual instruction pages for details.

This bit resets to an **UNKNOWN** value on a Warm reset.

### C, bit [29]

Carry condition flag. When updated by a flag setting instruction this bit indicates whether the operation resulted in an unsigned overflow or whether the last bit shifted out of the result was set.

The possible values of this bit are:

**0**  
No carry occurred, or last bit shifted was clear.

**1**  
Carry occurred, or last bit shifted was set.

See individual instruction pages for details.

This bit resets to an **UNKNOWN** value on a Warm reset.

**V, bit [28]**

Overflow condition flag. When updated by a flag setting instruction this bit indicates whether a signed overflow occurred.

The possible values of this bit are:

**0**  
Signed overflow did not occur.

**1**  
Signed overflow occurred.

See individual instruction pages for details.

This bit resets to an **UNKNOWN** value on a Warm reset.

**Q, bit [27]**

Sticky saturation flag. When updated by certain instructions this bit indicates either that an overflow occurred or that the result was saturated. This bit is cumulative and can only be cleared to zero by software.

The possible values of this bit are:

**0**  
Saturation or overflow has not occurred since bit was last cleared.

**1**  
Saturation or overflow has occurred since bit was last cleared.

See individual instruction pages for details.

If the Main Extension is not implemented, this bit is **RES0**.

This bit resets to an **UNKNOWN** value on a Warm reset.

**Bits [26:20]**

Reserved, **RES0**.

**GE, bits [19:16]**

Greater than or equal flags. When updated by parallel addition and subtraction instructions these bits record whether the result was greater than or equal to zero. SEL instructions use these bits to determine which register to select a particular byte from.

See individual instruction pages for details.

If the DSP Extension is not implemented, this field is **RES0**.

This field resets to an **UNKNOWN** value on a Warm reset.

**Bits [15:0]**

Reserved, **RES0**.

## D1.2.5 BASEPRI, Base Priority Mask Register

The BASEPRI characteristics are:

### Purpose

Changes the priority level required for exception preemption.

### Usage constraints

Privileged access only. Unprivileged access is RAZ/WI, unless otherwise stated.

### Configurations

Present only if the Main Extension is implemented.

This register is [RES0](#) if the Main Extension is not implemented.

### Attributes

32-bit read/write special-purpose register.

This register is banked between Security states.

## Field descriptions

The BASEPRI bit assignments are:

### Bits [31:8]

Reserved, [RES0](#).

### BASEPRI, bits [7:0]

Base priority mask. BASEPRI changes the priority level required for exception preemption. It has an effect only when BASEPRI has a lower value than the unmasked priority level of the currently executing software.

The possible values of this field are:

**0**

Disables masking by BASEPRI.

**1-255**

Priority value.

The number of implemented bits in BASEPRI is the same as the number of implemented bits in each field of the priority registers, and BASEPRI has the same format as those fields.

This field resets to zero on a Warm reset.

## D1.2.6 BFAR, BusFault Address Register

The BFAR characteristics are:

### Purpose

Shows the address associated with a precise data access BusFault.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

### Configurations

Present only if the Main Extension is implemented.

This register is **RES0** if the Main Extension is not implemented.

### Attributes

32-bit read/write register located at 0xE000ED38.

Secure software can access the Non-secure version of this register via BFAR\_NS located at 0xE002ED38. The location 0xE002ED38 is **RES0** to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

From Armv8.1-M onwards it is **IMPLEMENTATION DEFINED** whether a debugger write to this register is ignored when the PE is not in Debug state.

## Field descriptions

The BFAR bit assignments are:

### ADDRESS, bits [31:0]

Data address for a precise BusFault. This register is updated with the address of a location that produced a BusFault. BFSR shows the reason for the fault. This field is valid only when BFSR.BFARVALID is set, otherwise it is **UNKNOWN**.

In implementations without unique SFAR, BFAR and MMFAR registers, the value of this register is **UNKNOWN** if MMFSR.MMARVALID or SFSR.SFARVALID is set.

If AIRCR.BFHFNMIN is zero this field is RAZ/WI from Non-secure state.

This field resets to an **UNKNOWN** value on a Warm reset.

### Note

If an implementation shares a common SFAR, BFAR and MMFAR it must not leak Secure state information to the Non-secure state. One possible implementation is that BFAR shares resource with the Secure MMFAR if AIRCR.BFHFNMIN is zero, and with the Non-secure MMFAR if AIRCR.BFHFNMIN is set.

## D1.2.7 BFSR, BusFault Status Register

The BFSR characteristics are:

### Purpose

Shows the status of bus errors resulting from instruction fetches and data accesses. This includes errors resulting from RAS errors.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

If the Main Extension is implemented, this register is word, halfword, and byte accessible.

If the Main Extension is not implemented, this register is word accessible only, halfword and byte accesses are [UNPREDICTABLE](#).

### Configurations

Present only if the Main Extension is implemented.

This register is [RES0](#) if the Main Extension is not implemented.

### Attributes

8-bit read/write-one-to-clear register located at 0xE000ED29.

Secure software can access the Non-secure version of this register via BFSR\_NS located at 0xE002ED29. The location 0xE002ED29 is [RES0](#) to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

This register is part of CFSR.

From Armv8.1-M onwards it is [IMPLEMENTATION DEFINED](#) whether a debugger write to this register is ignored when the PE is not in Debug state.

## Field descriptions

The BFSR bit assignments are:

### BFARVALID, bit [7]

BFAR valid. Indicates validity of the contents of the BFAR register.

The possible values of this bit are:

0

BFAR content not valid.

1

BFAR content valid.

If AIRCR.BFHFNMINS is zero this bit is RAZ/WI from Non-secure state.

This bit resets to zero on a Warm reset.

**Bit [6]**

Reserved, [RES0](#).

**LSPERR, bit [5]**

Lazy state preservation error. Records whether a precise BusFault occurred during floating-point lazy state preservation.

The possible values of this bit are:

**0**

No BusFault occurred.

**1**

BusFault occurred.

If AIRCR.BFHFNMINS is zero this bit is RAZ/WI from Non-secure state.

This bit resets to zero on a Warm reset.

**STKERR, bit [4]**

Stack error. Records whether a precise derived BusFault occurred during exception entry stacking.

The possible values of this bit are:

**0**

No derived BusFault occurred.

**1**

Derived BusFault occurred during exception entry.

If AIRCR.BFHFNMINS is zero this bit is RAZ/WI from Non-secure state.

This bit resets to zero on a Warm reset.

**UNSTKERR, bit [3]**

Unstack error. Records whether a precise derived BusFault occurred during exception return unstacking.

The possible values of this bit are:

**0**

No derived BusFault occurred.

**1**

Derived BusFault occurred during exception return.

If AIRCR.BFHFNMINS is zero this bit is RAZ/WI from Non-secure state.

This bit resets to zero on a Warm reset.

**IMPRECISERR, bit [2]**

Imprecise error. Records whether an imprecise data access error has occurred.

The possible values of this bit are:

**0**

No imprecise data access error has occurred.

**1**

Imprecise data access error has occurred.

If AIRCR.BFHFNMINS is zero this bit is RAZ/WI from Non-secure state.

This bit resets to zero on a Warm reset.

**PRECISERR, bit [1]**

Precise error. Records whether a precise data access error has occurred.

The possible values of this bit are:

**0**

No precise data access error has occurred.

**1**

Precise data access error has occurred.

When a precise error is recorded, the associated address is written to the BFAR and BFSR.BFARVALID bit is set.

If AIRCR.BFHFNMINS is zero this bit is RAZ/WI from Non-secure state.

This bit resets to zero on a Warm reset.

**IBUSERR, bit [0]**

Instruction bus error. Records whether a precise BusFault on an instruction prefetch has occurred.

The possible values of this bit are:

**0**

No BusFault on instruction prefetch has occurred.

**1**

A BusFault on an instruction prefetch has occurred.

An IBUSERR is only recorded if the instruction is issued for execution.

If AIRCR.BFHFNMINS is zero this bit is RAZ/WI from Non-secure state.

This bit resets to zero on a Warm reset.

## D1.2.8 BPIALL, Branch Predictor Invalidate All

The BPIALL characteristics are:

### Purpose

Invalidate all entries from branch predictors.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are [UNPREDICTABLE](#).

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

### Configurations

This register is always implemented.

### Attributes

32-bit write-only register located at 0xE000EF78.

Secure software can access the Non-secure version of this register via BPIALL\_NS located at 0xE002EF78.

The location 0xE002EF78 is [RES0](#) to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

## Field descriptions

The BPIALL bit assignments are:

### Ignored, bits [31:0]

Ignored. The value written to this field is ignored.

## D1.2.9 CCR, Configuration and Control Register

The CCR characteristics are:

### Purpose

Sets or returns configuration and control data.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible to read accesses through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set. Write accesses through unprivileged DAP requests are not permitted.

### Configurations

This register is always implemented.

### Attributes

32-bit read/write register located at 0xE000ED14.

Secure software can access the Non-secure version of this register via CCR\_NS located at 0xE002ED14. The location 0xE002ED14 is **RES0** to software executing in Non-secure state and the debugger.

This register is banked between Security states on a bit by bit basis.

From Armv8.1-M onwards it is **IMPLEMENTATION DEFINED** whether a debugger write to this register is ignored when the PE is not in Debug state.

## Field descriptions

The CCR bit assignments are:

### Bits [31:21]

Reserved, **RES0**.

### TRD, bit [20]

Thread reentrancy disabled. Enables checking for exception stack frame integrity signatures on SG instructions. If enabled this check causes a fault to be raised if an attempt is made to re-enter Secure Thread mode while a call to Secure Thread mode is already in progress.

This bit is not banked between Security states.

The possible values of this bit are:

**0**

Integrity signature checking not performed.

**1**

Integrity signature checking performed.

This bit is RAZ/WI from Non-secure state.

If version Armv8.1-M of the architecture is not implemented, this bit is [RES0](#).

This bit resets to zero on a Warm reset.

**LOB, bit [19]**

Loop and branch info cache enable. Enables the branch cache used by loop and branch future instructions for the selected Security state.

This bit is banked between Security states.

The possible values of this bit are:

**0**

Branch cache disabled for the selected Security state.

**1**

Branch cache enabled for the selected Security state.

If version Armv8.1-M of the architecture is not implemented, this bit is [RES0](#).

If the branch cache is not supported, this bit is RAZ/WI.

This bit resets to zero on a Warm reset.

**BP, bit [18]**

Branch prediction enable. Enables program flow prediction for the selected Security state.

This bit is banked between Security states.

The possible values of this bit are:

**0**

Program flow prediction disabled for the selected Security state.

**1**

Program flow prediction enabled for the selected Security state.

If program flow prediction cannot be disabled, this bit is RAO/WI. If the program flow prediction is not supported, this bit is RAZ/WI. Arm recommends that the RAO/WI behavior should only be used where the branch predictor is static and does not display any dynamic behavior.

If the Main Extension is not implemented, this bit is [RES0](#).

This bit resets to zero on a Warm reset.

**IC, bit [17]**

Instruction cache enable. This is a global enable bit for instruction caches in the selected Security state.

This bit is banked between Security states.

The possible values of this bit are:

**0**

Instruction caches disabled for the selected Security state.

**1**

Instruction caches enabled for the selected Security state.

If the PE does not implement instruction caches, this bit is RAZ/WI.

If the Main Extension is not implemented, this bit is [RES0](#).

This bit resets to zero on a Warm reset.

**DC, bit [16]**

Data cache enable. Enables data caching of all data accesses to Normal memory.

This bit is banked between Security states.

The possible values of this bit are:

**0**

Data caching disabled.

**1**

Data caching enabled.

The secure version of this bit controls the Cacheability of accesses to secure memory.

The Non-secure version of this bit controls the Cacheability of accesses to Non-secure memory.

If the PE does not implement data caches, this bit is RAZ/WI.

If the Main Extension is not implemented, this bit is [RES0](#).

This bit resets to zero on a Warm reset.

**Bits [15:11]**

Reserved, [RES0](#).

**STKOFHFNIGN, bit [10]**

Stack overflow in HardFault and NMI ignore. Controls the effect of a stack limit violation while executing at a requested priority less than 0 for the Security state with which the stack limit register is associated.

This bit is banked between Security states.

The possible values of this bit are:

**0**

Stack limit faults not ignored.

**1**

Stack limit faults at requested priorities of less than 0 ignored.

If the Main Extension is not implemented, this bit is [RES0](#).

This bit resets to zero on a Warm reset.

**Bit [9]**

Reserved, [RES1](#).

**BFHFNIGN, bit [8]**

BusFault in HardFault or NMI ignore. Determines the effect of precise BusFaults arising from data accesses performed by code running at a requested priority less than 0.

This bit is not banked between Security states.

The possible values of this bit are:

**0**

Precise BusFaults not ignored.

**1**

Precise BusFaults at requested priorities of less than 0 ignored.

If AIRCR.BFHFNMIN is 0, this bit is read-only from Non-secure state.

If the Main Extension is not implemented, this bit is [RES0](#).

This bit resets to zero on a Warm reset.

**Bits [7:5]**

Reserved, [RES0](#).

**DIV\_0\_TRP, bit [4]**

Divide by zero trap. Controls the generation of a DIVBYZERO UsageFault when attempting to perform integer division by zero.

This bit is banked between Security states.

The possible values of this bit are:

**0**

DIVBYZERO UsageFault generation disabled.

**1**

DIVBYZERO UsageFault generation enabled.

If the Main Extension is not implemented, this bit is [RES0](#).

This bit resets to zero on a Warm reset.

**UNALIGN\_TRP, bit [3]**

Unaligned trap. Controls the trapping of unaligned word or halfword accesses.

This bit is banked between Security states.

The possible values of this bit are:

**0**

Unaligned accesses permitted from LDR, LDRH, STR, and STRH.

**1**

Any unaligned transaction generates an UNALIGNED UsageFault.

Unaligned load/store multiples and atomic/exclusive accesses always generate an UNALIGNED UsageFault.

If the Main Extension is not implemented, this bit is [RES1](#).

This bit resets to zero on a Warm reset if the Main Extension is implemented.

**Bit [2]**

Reserved, [RES0](#).

**USERSETMPEND, bit [1]**

User set main pending. Determines whether unprivileged accesses are permitted to pend interrupts via the STIR.

This bit is banked between Security states.

The possible values of this bit are:

**0**

Unprivileged accesses to the STIR generate a fault.

**1**

Unprivileged accesses to the STIR are permitted.

If the Main Extension is not implemented, this bit is [RES0](#).

This bit resets to zero on a Warm reset.

**Bit [0]**

Reserved, [RES1](#).

## D1.2.10 CCSIDR, Current Cache Size ID register

The CCSIDR characteristics are:

### Purpose

The CCSIDR provides information about the architecture of the currently selected cache.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If CSSELR points to an unimplemented cache, the value of this register is **UNKNOWN**.

### Configurations

This register is always implemented.

### Attributes

32-bit read-only register located at 0xE000ED80.

Secure software can access the Non-secure version of this register via CCSIDR\_NS located at 0xE002ED80.

The location 0xE002ED80 is **RES0** to software executing in Non-secure state and the debugger.

This register is banked between Security states.

### Preface

Provides indirect read access to the architecture of the cache currently selected by CSSELR. The parameters NumSets, Associativity, and LineSize in these registers define the architecturally visible parameters that are required for the cache maintenance by Set/Way instructions. They are not guaranteed to represent the actual microarchitectural features of a design. You cannot make any inference about the actual sizes of caches based on these parameters.

### Field descriptions

The CCSIDR bit assignments are:

### WT, bit [31]

Write-Through. Indicates whether the currently selected cache level supports Write-Through.

The possible values of this bit are:

**0**  
Not supported.

**1**  
Supported.

This bit reads as an **IMPLEMENTATION DEFINED** value.

**WB, bit [30]**

Writeback. Indicates whether the currently selected cache level supports Write-Back.

The possible values of this bit are:

**0**

Not supported.

**1**

Supported.

This bit reads as an **IMPLEMENTATION DEFINED** value.

**RA, bit [29]**

Read-allocate. Indicates whether the currently selected cache level supports read-allocation.

The possible values of this bit are:

**0**

Not supported.

**1**

Supported.

This bit reads as an **IMPLEMENTATION DEFINED** value.

**WA, bit [28]**

Write-Allocate. Indicates whether the currently selected cache level supports write-allocation.

The possible values of this bit are:

**0**

Not supported.

**1**

Supported.

This bit reads as an **IMPLEMENTATION DEFINED** value.

**NumSets, bits [27:13]**

Number of sets. Indicates (Number of sets in the currently selected cache) - 1. Therefore, a value of 0 indicates that 1 is set in the cache. The number of sets does not have to be a power of 2.

This field reads as an **IMPLEMENTATION DEFINED** value.

**Associativity, bits [12:3]**

Associativity. Indicates (Associativity of cache) - 1. A value of 0 indicates an associativity of 1. The associativity does not have to be a power of 2.

This field reads as an **IMPLEMENTATION DEFINED** value.

**LineSize, bits [2:0]**

Line size. Indicates (Log<sub>2</sub>(Number of words per line in the currently selected cache)) - 2.

This field reads as an **IMPLEMENTATION DEFINED** value.

## D1.2.11 CFSR, Configurable Fault Status Register

The CFSR characteristics are:

### Purpose

Contains the three Configurable Fault Status Registers.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

If the Main Extension is implemented, this register is word, halfword, and byte accessible.

If the Main Extension is not implemented, this register is word accessible only, halfword and byte accesses are **UNPREDICTABLE**.

### Configurations

Present only if the Main Extension is implemented.

This register is **RES0** if the Main Extension is not implemented.

### Attributes

32-bit read/write-one-to-clear register located at 0xE000ED28.

Secure software can access the Non-secure version of this register via CFSR\_NS located at 0xE002ED28. The location 0xE002ED28 is **RES0** to software executing in Non-secure state and the debugger.

This register is banked between Security states on a bit by bit basis.

From Armv8.1-M onwards it is **IMPLEMENTATION DEFINED** whether a debugger write to this register is ignored when the PE is not in Debug state.

## Field descriptions

The CFSR bit assignments are:

### UFSR, bits [31:16]

UsageFault Status Register. Provides information on UsageFault exceptions.

This field is banked between Security states.

See UFSR.

This field resets to zero on a Warm reset.

### BFSR, bits [15:8]

BusFault Status Register. Provides information on BusFault exceptions.

This field is not banked between Security states.

See BFSR.

This field resets to zero on a Warm reset.

### MMFSR, bits [7:0]

MemManage Fault Status Register. Provides information on MemManage exceptions.

This field is banked between Security states.

See MMFSR.

This field resets to zero on a Warm reset.

## D1.2.12 CLIDR, Cache Level ID Register

The CLIDR characteristics are:

### Purpose

Identifies the type of caches implemented and the level of coherency and unification.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are [UNPREDICTABLE](#).

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

### Configurations

This register is always implemented.

### Attributes

32-bit read-only register located at 0xE000ED78.

Secure software can access the Non-secure version of this register via CLIDR\_NS located at 0xE002ED78.

The location 0xE002ED78 is [RES0](#) to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

## Field descriptions

The CLIDR bit assignments are:

|     |      |     |       |        |        |        |        |        |        |        |    |    |    |    |   |   |   |   |   |   |   |
|-----|------|-----|-------|--------|--------|--------|--------|--------|--------|--------|----|----|----|----|---|---|---|---|---|---|---|
| 31  | 30   | 29  | 27    | 26     | 24     | 23     | 21     | 20     | 18     | 17     | 15 | 14 | 12 | 11 | 9 | 8 | 6 | 5 | 3 | 2 | 0 |
| ICB | LoUU | LoC | LoUIS | Ctype7 | Ctype6 | Ctype5 | Ctype4 | Ctype3 | Ctype2 | Ctype1 |    |    |    |    |   |   |   |   |   |   |   |

### ICB, bits [31:30]

Inner cache boundary. This field indicates the boundary between inner and outer domain.

The possible values of this field are:

**0b00**

Not disclosed in this mechanism.

**0b01**

L1 cache is the highest inner level.

**0b10**

L2 cache is the highest inner level.

**0b11**

L3 cache is the highest inner level.

This field reads as an [IMPLEMENTATION DEFINED](#) value.

### LoUU, bits [29:27]

Level of Unification Uniprocessor. This field indicates the Level of Unification Uniprocessor for the cache hierarchy.

This field reads as an [IMPLEMENTATION DEFINED](#) value.

### LoC, bits [26:24]

Level of Coherence. This field indicates the Level of Coherence for the cache hierarchy.

This field reads as an [IMPLEMENTATION DEFINED](#) value.

**LoUIS, bits [23:21]**

Level of Unification Inner Shareable. This field indicates the Level of Unification Shareable for the cache hierarchy.

This field reads as an **IMPLEMENTATION DEFINED** value.

**Ctypem, bits [3(m-1)+2:3(m-1)], for m = 1 to 7**

Cache type field *m*. Indicates the type of cache implemented at level *m*.

The possible values of this field are:

**0b000**

No cache.

**0b001**

Instruction cache only.

**0b010**

Data cache only.

**0b011**

Separate instruction and data caches.

**0b100**

Unified cache.

All other values are reserved.

If Ctype<*m*> is set to 0b000, and *m* < 7, then all of the following apply.

Level *m* represents the last level of software-visible cache.

Ctype<*m*=1> through to Ctype7 must read as zero.

Software must treat Ctype<*m*+1> through Ctype7 as if they are invalid and read as an **UNKNOWN** value.

This field reads as an **IMPLEMENTATION DEFINED** value.

### D1.2.13 CONTROL, Control Register

The CONTROL characteristics are:

## Purpose

Provides access to the PE control fields.

## Usage constraints

Privileged access only, unprivileged reads are permitted but unprivileged writes are ignored unless otherwise specified.

## Configurations

This register is always implemented.

## Attributes

32-bit read/write special-purpose register.

This register is banked between Security states on a bit by bit basis.

## Field descriptions

The CONTROL bit assignments are:

**Bits [31:8]**

Reserved, RES0.

**UPAC\_EN, bit [7]**

Unprivileged pointer authentication enable. When this feature is enabled the pointer authentication instructions can create and validate the PAC in unprivileged mode. An INVSTATE UsageFault is generated if the PAC validation operation fails.

This bit is banked between Security states.

The possible values of this bit are:

0

Pointer authentication is disabled for unprivileged accesses.

**1**

Pointer authentication is enabled for unprivileged accesses.

If the PACBTI Extension is not implemented, this bit is **RES0**.

This bit resets to zero on a Warm reset.

**PAC\_EN, bit [6]**

Privileged pointer authentication enable. When this feature is enabled the pointer authentication instructions can create and validate the PAC in privileged mode. An INVSTATE UsageFault is generated if the PAC validation operation fails.

This bit is banked between Security states.

The possible values of this bit are:

**0**  
Pointer authentication is disabled for privileged accesses.

**1**  
Pointer authentication is enabled for privileged accesses.  
If the PACBTI Extension is not implemented, this bit is [RES0](#).  
This bit resets to zero on a Warm reset.

**UBTI\_EN, bit [5]**

Unprivileged branch target identification enable. Unless otherwise stated, when this feature is enabled the branch target for BTI setting instructions in unprivileged mode must be a BTI clearing instruction otherwise an INVSTATE UsageFault is generated.

This bit is banked between Security states.

The possible values of this bit are:

**0**  
Branch target identification disabled for unprivileged accesses.

**1**  
Branch target identification enabled for unprivileged accesses.

If the PACBTI Extension is not implemented, this bit is [RES0](#).  
This bit resets to zero on a Warm reset.

**BTI\_EN, bit [4]**

Privileged branch target identification enable. Unless otherwise stated, when this feature is enabled the branch target for BTI setting instructions in privileged mode must be a BTI clearing instruction, otherwise an INVSTATE UsageFault is generated.

This bit is banked between Security states.

The possible values of this bit are:

**0**  
Branch target identification disabled for privileged accesses.

**1**  
Branch target identification enabled for privileged accesses.

If the PACBTI Extension is not implemented, this bit is [RES0](#).  
This bit resets to zero on a Warm reset.

**SFPA, bit [3]**

Secure Floating-point active. Indicates that the Floating-point registers contain active state that belongs to the Secure state.

This bit is not banked between Security states.

The possible values of this bit are:

**0**  
The Floating-point registers do not contain state that belongs to the Secure state.

**1**  
The Floating-point registers contain state that belongs to the Secure state.

This bit accessible from both privileged and unprivileged modes using the MRS or MSR instructions.

This bit is RAZ/WI from Non-secure state.

If the Security Extension is not implemented, this bit is [RES0](#).

If neither the Floating-point Extension or MVE are implemented, this bit is [RES0](#).

This bit resets to zero on a Warm reset.

**FPCA, bit [2]**

Floating-point context active. Defines whether the Floating-point Extension is active in the current context.

This bit is not banked between Security states.

The possible values of this bit are:

**0**

Floating-point Extension is not active.

**1**

Floating-point Extension is active.

When NSACR.CP10 is set to zero, the Non-secure view of this bit is read-only. If FPCCR.ASPEN is set to 1, enabling automatic Floating-point state preservation, then the PE sets this bit to 1 on successful completion of any Floating-point instruction.

If neither the Floating-point Extension or MVE are implemented, this bit is [RES0](#).

This bit resets to zero on a Warm reset.

**SPSEL, bit [1]**

Stack-pointer select. Defines the stack pointer to be used.

This bit is banked between Security states.

The possible values of this bit are:

**0**

Use SP\_main as the current stack.

**1**

In Thread mode use SP\_process as the current stack.

This bit resets to zero on a Warm reset.

**nPRIV, bit [0]**

Not privileged. Defines the execution privilege in Thread mode.

This bit is banked between Security states.

The possible values of this bit are:

**0**

Thread mode has privileged access.

**1**

Thread mode has unprivileged access only.

If the Main Extension is not implemented, it is [IMPLEMENTATION DEFINED](#) whether this field is RW or RAZ/WI.

This bit resets to zero on a Warm reset.

### D1.2.14 CPACR, Coprocessor Access Control Register

The CPACR characteristics are:

## Purpose

Specifies the access privileges for coprocessors and the Floating-point Extension. If MVE is implemented, this register specifies the access privileges for MVE.

## Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

## Configurations

Present only if the Main Extension is implemented.

This register is **RES0** if the Main Extension is not implemented.

## Attributes

32-bit read/write register located at 0xE000ED88.

Secure software can access the Non-secure version of this register via CPACR\_NS located at 0xE002ED88. The location 0xE002ED88 is **RES0** to software executing in Non-secure state and the debugger.

This register is banked between Security states.

From Armv8.1-M onwards it is **IMPLEMENTATION DEFINED** whether a debugger write to this register is ignored when the PE is not in Debug state.

## Field descriptions

The CPACR bit assignments are:

|      |  |  |  |  |  |      |    |      |    |      |    |     |  |     |  |     |    |     |    |     |    |     |   |     |   |     |   |   |   |   |   |   |
|------|--|--|--|--|--|------|----|------|----|------|----|-----|--|-----|--|-----|----|-----|----|-----|----|-----|---|-----|---|-----|---|---|---|---|---|---|
| 31   |  |  |  |  |  | 24   | 23 | 22   | 21 | 20   | 19 |     |  |     |  | 16  | 15 | 14  | 13 | 12  | 11 | 10  | 9 | 8   | 7 | 6   | 5 | 4 | 3 | 2 | 1 | 0 |
| RES0 |  |  |  |  |  | CP11 |    | CP10 |    | RES0 |    | CP7 |  | CP6 |  | CP5 |    | CP4 |    | CP3 |    | CP2 |   | CP1 |   | CP0 |   |   |   |   |   |   |

**Bits [31:24]**

Reserved, RES0.

**CP11, bits [23:22]**

CP11 Privilege. The value in this field is ignored. If the CP10 field is RAZ/WI this field is also RAZ/WI. If the value of this field is not programmed to the same value as the CP10 field, then the value is **UNKNOWN**.

This field resets to an **UNKNOWN** value on a Warm reset.

**CP10, bits [21:20]**

**CP10 Privilege.** Defines the access rights for the Floating-point functionality.

The possible values of this field are:

## 0b00

All accesses to the Floating-point Extension and MVE result in NOCP UsageFault.

## 0b01

Unprivileged accesses to the Floating-point Extension and MVE result in NOCP UsageFault.

## 0b11

Full access to the Floating-point Extension and MVE.

All other values are reserved.

The features controlled by this field are:

- Unless otherwise specified, the execution of any instructions within the encoding space defined by IsCPIInstruction() for CP10.
- Access to any Floating-point registers in the range D0-D16.

See individual instruction pages for details.

If neither the Floating-point Extension or MVE are implemented, this field is [RES0](#).

This field resets to an [UNKNOWN](#) value on a Warm reset.

**Bits [19:16]**

Reserved, [RES0](#).

**CPm, bits [2m+1:2m], for m = 0 to 7**

Coprocessor m privilege. Controls access privileges for coprocessor m.

The possible values of this field are:

**0b00**

Access denied. Any attempted access generates a NOCP UsageFault.

**0b01**

Privileged access only. An unprivileged access generates a NOCP UsageFault.

**0b10**

Reserved.

**0b11**

Full access.

If coprocessor m is not implemented, this field is RAZ/WI.

This field resets to an [UNKNOWN](#) value on a Warm reset.

## D1.2.15 CPPWR, Coprocessor Power Control Register

The CPPWR characteristics are:

### Purpose

Specifies whether coprocessors are permitted to enter a non-retentive power state.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

### Configurations

Present only if the Main Extension is implemented.

This register is **RES0** if the Main Extension is not implemented.

### Attributes

32-bit read/write register located at 0xE000E00C.

Secure software can access the Non-secure version of this register via CPPWR\_NS located at 0xE002E00C. The location 0xE002E00C is **RES0** to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

From Armv8.1-M onwards it is **IMPLEMENTATION DEFINED** whether a debugger write to this register is ignored when the PE is not in Debug state.

## Field descriptions

The CPPWR bit assignments are:

### Bits [31:24]

Reserved, **RES0**.

### SUS11, bit [23]

State **UNKNOWN** Secure only 11. The value in this field is ignored. If the value of this bit is not programmed to the same value as the SUS10 field, then the value is **UNKNOWN**.

If SU10 is always RAZ/WI this field is also RAZ/WI.

This bit is RAZ/WI from Non-secure state.

This bit resets to zero on a Warm reset.

### SU11, bit [22]

State **UNKNOWN** 11. The value in this field is ignored. If the value of this bit is not programmed to the same value as the SU10 field, then the value is **UNKNOWN**.

When SUS10 is set to 1, the Non-secure view of this bit is RAZ/WI. If SU10 is always RAZ/WI this field is also RAZ/WI.

This bit resets to zero on a Warm reset.

#### **SUS10, bit [21]**

State **UNKNOWN** Secure only 10. This bit indicates and allows modification of whether the SU10 field can be modified from Non-secure state.

The possible values of this bit are:

**0**

The SU10 field is accessible from both Security states.

**1**

The SU10 field is only accessible from the Secure state.

If SU10 is always RAZ/WI this field is also RAZ/WI.

This bit is RAZ/WI from Non-secure state.

This bit resets to zero on a Warm reset.

#### **SU10, bit [20]**

State **UNKNOWN** 10. This bit indicates and allows modification of whether the state associated with the Floating-point and MVE units is permitted to become **UNKNOWN**. This can be used as a hint to power control logic that these units might be powered down.

The possible values of this bit are:

**0**

The Floating-point and MVE state is not permitted to become **UNKNOWN**.

**1**

The Floating-point and MVE state is permitted to become **UNKNOWN**.

When SUS10 is set to 1, the Non-secure view of this bit is RAZ/WI. It is **IMPLEMENTATION DEFINED** whether this bit is always RAZ/WI.

This bit resets to zero on a Warm reset.

#### **Bits [19:16]**

Reserved, **RES0**.

#### **SUS<sub>m</sub>, bit [2<sub>m</sub>+1], for $m = 0$ to 7**

State **UNKNOWN** Secure only  $m$ . This field indicates and allows modification of whether the SUs<sub>m</sub> field can be modified from Non-secure state.

The possible values of this field are:

**0**

The SUs<sub>m</sub> field is accessible from both Security states.

**1**

The SUs<sub>m</sub> field is only accessible from the Secure state.

If SUs<sub>m</sub> is always RAZ/WI this field is also RAZ/WI.

This field is RAZ/WI from Non-secure state.

This field resets to zero on a Warm reset.

#### **SUs<sub>m</sub>, bit [2<sub>m</sub>], for $m = 0$ to 7**

State **UNKNOWN**  $m$ . This field indicates and allows modification of whether the state associated with coprocessor  $m$  is permitted to become **UNKNOWN**. This can be used as a hint to power control logic that the coprocessor might be powered down.

The possible values of this field are:

**0**

The coprocessor state is not permitted to become **UNKNOWN**.

**1**

The coprocessor state is permitted to become **UNKNOWN**.

When  $SUSm$  is set to 1, the Non-secure view of this bit is RAZ/WI. It is **IMPLEMENTATION DEFINED** whether this bit is always RAZ/WI.

This field resets to zero on a Warm reset.

## D1.2.16 CPUID, CPUID Base Register

The CPUID characteristics are:

### Purpose

Provides identification information for the PE, including an implementer code for the device and a device ID number.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are [UNPREDICTABLE](#).

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

### Configurations

This register is always implemented.

### Attributes

32-bit read-only register located at 0xE00ED00.

Secure software can access the Non-secure version of this register via CPUID\_NS located at 0xE002ED00. The location 0xE002ED00 is [RES0](#) to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

## Field descriptions

The CPUID bit assignments are:

### Implementer, bits [31:24]

Implementer code. This field must hold an implementer code that has been assigned by Arm.

The possible values of this field are:

#### 0x41

'A': Arm Limited.

#### Not 0x41

Implementer other than Arm Limited.

Arm can assign codes that are not published in this manual. All values not assigned by Arm are reserved and must not be used.

This field reads as an [IMPLEMENTATION DEFINED](#) value.

### Variant, bits [23:20]

Variant number. [IMPLEMENTATION DEFINED](#) variant number. Typically, this field is used to distinguish between different product variants, or major revisions of a product.

This field reads as an [IMPLEMENTATION DEFINED](#) value.

### Architecture, bits [19:16]

Architecture version. Defines the Architecture implemented by the PE.

The possible values of this field are:

**0b1100**

Armv8-M architecture without Main Extension.

**0b1111**

Armv8-M architecture with Main Extension.

All other values are reserved.

This field reads as an **IMPLEMENTATION DEFINED** value.

**PartNo, bits [15:4]**

Part number. **IMPLEMENTATION DEFINED** primary part number for the device.

This field reads as an **IMPLEMENTATION DEFINED** value.

**Revision, bits [3:0]**

Revision number. **IMPLEMENTATION DEFINED** revision number for the device.

This field reads as an **IMPLEMENTATION DEFINED** value.

### D1.2.17 CSSELR, Cache Size Selection Register

The CSSELR characteristics are:

## Purpose

Selects the current Cache Size ID Register, CCSIDR, by specifying the required cache level and the cache type (either instruction or data cache)

## Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

## Configurations

This register is always implemented.

## Attributes

32-bit read/write register located at 0xE000ED84.

Secure software can access the Non-secure version of this register via CSSELR\_NS located at 0xE002ED84. The location 0xE002ED84 is **RES0** to software executing in Non-secure state and the debugger.

This register is banked between Security states.

From Armv8.1-M onwards it is **IMPLEMENTATION DEFINED** whether a debugger write to this register is ignored when the PE is not in Debug state.

## Field descriptions

The CSSELR bit assignments are:

**Bits [31:4]**

Reserved, RES0.

**Level, bits [3:1]**

Cache level. Selects which cache level is to be identified. Permitted values are from 0b000, indicating Level 1 cache, to 0b110 indicating Level 7 cache.

The possible values of this field are:

0b000

Level 1 cache.

0b001

Level 2 cache.

0b010

Level 3 cache.

0b011

Level 4 cache.

0b100

Level 5 cache.

**0b101**

Level 6 cache.

**0b110**

Level 7 cache.

All other values are reserved.

Writing a reserved value or value corresponding to an unimplemented level of cache is **CONSTRAINED UNPREDICTABLE**.

This field resets to an **UNKNOWN** value on a Warm reset.

**InD, bit [0]**

Instruction not data. Selects whether the instruction or the data cache is to be identified.

The possible values of this bit are:

**0**

Data or unified cache.

**1**

Instruction cache.

This bit resets to an **UNKNOWN** value on a Warm reset.

### D1.2.18 CTR, Cache Type Register

The CTR characteristics are:

## Purpose

Provides information about the architecture of the caches.

## Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

## Configurations

This register is always implemented.

## Attributes

32-bit read-only register located at 0xE000ED7C.

Secure software can access the Non-secure version of this register via CTR\_NS located at 0xE002ED7C. The location 0xE002ED7C is **RES0** to software executing in Non-secure state and the debugger.

This register is banked between Security states.

## Field descriptions

The CTR bit assignments are:

**When Format!='0b100':**

### When Format=='0b100':

**Format, bits [31:29]**

Cache Type Register format. Indicates whether cache type information is provided.

The possible values of this field are:

0b000

No cache type information is provided.

0b100

Cache type information is provided.

All other values are reserved.

The value of this field is an **IMPLEMENTATION DEFINED** choice of either 0b000 or 0b100.

If CLIDR is nonzero then this field must read as 0b100.

This field reads as an **IMPLEMENTATION DEFINED** value.

**Bits [28:0], when Format!=’0b100’**

Reserved, RES0.

**Bit [28], when Format==‘0b100’**

Reserved, [RES0](#).

**CWG, bits [27:24], when Format==‘0b100’**

Cache Write-Back Granule.  $\log_2$  of the number of words of the maximum size of memory that can be overwritten as a result of the eviction of a cache entry that has had a memory location in it modified.

The possible values of this field are:

**0b0000**

Indicates that this register does not provide Cache Write-Back Granule information and either the architectural maximum of 512 words (2KB) must be assumed, or the Cache Write-Back Granule can be determined from maximum cache line size encoded in the Cache Size ID Registers.

**0b0001-0b1000**

$\log_2$  of the number of words.

All other values are reserved.

This field reads as an [IMPLEMENTATION DEFINED](#) value.

**ERG, bits [23:20], when Format==‘0b100’**

Exclusives Reservation Granule.  $\log_2$  of the number of words of the maximum size of the reservation granule that has been implemented for the Load-Exclusive and Store-Exclusive instructions.

The possible values of this field are:

**0b0000**

Indicates that this register does not provide Exclusives Reservation Granule information and the architectural maximum of 512 words (2KB) must be assumed.

**0b0001-0b1000**

$\log_2$  of the number of words.

All other values are reserved.

This field reads as an [IMPLEMENTATION DEFINED](#) value.

**DminLine, bits [19:16], when Format==‘0b100’**

Data cache minimum line length.  $\log_2$  of the number of words in the smallest cache line of all the data caches and unified caches that are controlled by the PE.

This field reads as an [IMPLEMENTATION DEFINED](#) value.

**Bits [15:14], when Format==‘0b100’**

Reserved, [RES1](#).

**Bits [13:4], when Format==‘0b100’**

Reserved, [RES0](#).

**IminLine, bits [3:0], when Format==‘0b100’**

Instruction cache minimum line length.  $\log_2$  of the number of words in the smallest cache line of all the instruction caches that are controlled by the PE.

This field reads as an [IMPLEMENTATION DEFINED](#) value.

## D1.2.19 DAUTHCTRL, Debug Authentication Control Register

The DAUTHCTRL characteristics are:

### Purpose

This register allows the **IMPLEMENTATION DEFINED** authentication interface to be overridden from software.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

If Armv8.1-M is implemented, this register is word, halfword and byte accessible.

This register is **RES0** if accessed via the debugger.

### Configurations

Present if Halting debug or the Main Extension is implemented.

This register is **RES0** if both Halting debug and Main Extension are not implemented.

### Attributes

32-bit read/write register located at 0xE000EE04.

Secure software can access the Non-secure version of this register via DAUTHCTRL\_NS located at 0xE002EE04. The location 0xE002EE04 is **RES0** to software executing in Non-secure state and the debugger.

This register is banked between Security states on a bit by bit basis.

## Field descriptions

The DAUTHCTRL bit assignments are:

### Bits [31:11]

Reserved, **RES0**.

### UIDEN, bit [10]

Unprivileged Invasive Debug Enable. Enables halting debug for unprivileged modes, regardless of the state of other debug controls.

This bit is banked between Security states.

The possible values of this bit are:

**0**

Halting debug operates as normal.

**1**

Unprivileged halting debug allowed.

See UnprivHaltingDebugEnabled() and UpdateDebugEnabled().

If version Armv8.1 of the architecture and UDE are not implemented, this bit is **RES0**.

This bit resets to zero on a Warm reset.

#### UIDAPEN, bit [9]

Unprivileged Invasive DAP Access Enable. Enables unprivileged DAP access to specific PPB registers.

This bit is banked between Security states.

The possible values of this bit are:

**0**

No unprivileged DAP access.

**1**

Unprivileged DAP access allowed.

Unprivileged DAP access is allowed if either of the banked fields is set.

If version Armv8.1 of the architecture and UDE are not implemented, this bit is [RES0](#).

This bit resets to zero on a Cold reset.

#### FSDMA, bit [8]

Force Secure DebugMonitor Allowed. Allows Secure DebugMonitor to be enabled without having to enable secure halting debug.

This bit is not banked between Security states.

The possible values of this bit are:

**0**

Secure DebugMonitor determined by other means.

**1**

Secure DebugMonitor allowed.

This bit is RAZ/WI from Non-secure state.

If version Armv8.1-M of the architecture is not implemented, this bit is [RES0](#).

This bit resets to zero on a Warm reset.

#### Bits [7:4]

Reserved, [RES0](#).

#### INTSPNIDEN, bit [3]

Internal Secure non-invasive debug enable. Overrides the external Secure non-invasive debug authentication interface.

This bit is not banked between Security states.

The possible values of this bit are:

**0**

Secure Non-invasive debug prohibited.

**1**

Secure Non-invasive debug allowed.

Ignored if DAUTHCTRL.SPNIDENSEL == 0. See SecureNoninvasiveDebugEnabled().

This bit is RAZ/WI from Non-secure state.

This bit resets to zero on a Cold reset.

#### SPNIDENSEL, bit [2]

Secure non-invasive debug enable select. Selects between DAUTHCTRL and the [IMPLEMENTATION DEFINED](#) external authentication interface for control of Secure non-invasive debug.

This bit is not banked between Security states.

The possible values of this bit are:

**0**

Secure non-invasive debug controlled by the **IMPLEMENTATION DEFINED** external authentication interface. In the CoreSight authentication interface, this is controlled by the SPNIDEN signal.

**1**

Secure non-invasive debug controlled by DAUTHCTRL.INTSPNIDEN.

The PE ignores the value of this bit and Secure non-invasive debug is allowed if DHCSR.S\_SDE == 1. See SecureNoninvasiveDebugAllowed().

This bit is RAZ/WI from Non-secure state.

This bit resets to zero on a Cold reset.

#### **INTSPIDEN, bit [1]**

Internal Secure invasive debug enable. Overrides the external Secure invasive debug authentication interfaces.

This bit is not banked between Security states.

The possible values of this bit are:

**0**

Secure halting and self-hosted debug prohibited.

**1**

Secure halting and self-hosted debug allowed.

Ignored if DAUTHCTRL.SPIDENSEL == 0. See SecureHaltingDebugEnabled() and SecureDebugMonitorAllowed().

This bit is RAZ/WI from Non-secure state.

This bit resets to zero on a Cold reset.

#### **SPIDENSEL, bit [0]**

Secure invasive debug enable select. Selects between DAUTHCTRL and the **IMPLEMENTATION DEFINED** external authentication interface for control of Secure invasive debug.

This bit is not banked between Security states.

The possible values of this bit are:

**0**

Secure halting and self-hosted debug controlled by the **IMPLEMENTATION DEFINED** external authentication interface. In the CoreSight authentication interface, both are controlled by the SPIDEN signal.

**1**

Secure halting and self-hosted debug controlled by DAUTHCTRL.INTSPIDEN.

See SecureHaltingDebugEnabled() and SecureDebugMonitorAllowed().

This bit is RAZ/WI from Non-secure state.

This bit resets to zero on a Cold reset.

## D1.2.20 DAUTHSTATUS, Debug Authentication Status Register

The DAUTHSTATUS characteristics are:

### Purpose

Provides information about the state of the **IMPLEMENTATION DEFINED** authentication interface for debug.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

If the Main Extension is not implemented then it is **IMPLEMENTATION DEFINED** whether this register is accessible only to the debugger and **RES0** for software. Otherwise the register is accessible to the debugger and software.

### Configurations

Present only if Halting debug is implemented.

This register is **RES0** if Halting debug is not implemented.

### Attributes

32-bit read-only register located at 0xE000EFB8.

Secure software can access the Non-secure version of this register via DAUTHSTATUS\_NS located at 0xE002EFB8. The location 0xE002EFB8 is **RES0** to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

## Field descriptions

The DAUTHSTATUS bit assignments are:

### Bits [31:24]

Reserved, **RES0**.

### SUNID, bits [23:22]

Secure Unprivileged Non-invasive Debug Allowed. Indicates that Unprivileged Non-invasive debug is allowed for the Secure state.

The possible values of this field are:

#### 0b00

Security Extension or Unprivileged Non-invasive Debug not implemented.

#### 0b01

Reserved.

#### 0b10

Secure Non-invasive debug prohibited.

**0b11**

Secure Non-invasive debug allowed in unprivileged mode.

If version Armv8.1 of the architecture and UDE are not implemented, this field is [RES0](#).

**SUID, bits [21:20]**

Secure Unprivileged Invasive Debug Allowed. Indicates that Unprivileged Halting Debug is allowed for the Secure state.

The possible values of this field are:

**0b00**

Security Extension or Unprivileged Debug not implemented.

**0b01**

Reserved.

**0b10**

Secure halting debug prohibited.

**0b11**

Secure halting debug allowed in unprivileged mode.

If version Armv8.1 of the architecture and UDE are not implemented, this field is [RES0](#).

**NSUNID, bits [19:18]**

Non-secure Unprivileged Non-invasive Debug Allowed. Indicates that Unprivileged Non-invasive Debug is allowed for the Non-secure state.

The possible values of this field are:

**0b00**

Unprivileged Non-invasive debug not implemented.

**0b01**

Reserved.

**0b10**

Non-secure Non-invasive debug prohibited.

**0b11**

Non-secure Non-invasive debug allowed in unprivileged mode.

If version Armv8.1 of the architecture and UDE are not implemented, this field is [RES0](#).

**NSUID, bits [17:16]**

Non-secure Unprivileged Invasive Debug Allowed. Indicates that Unprivileged Halting Debug is allowed for the Non-secure state.

The possible values of this field are:

**0b00**

Unprivileged halting debug not implemented.

**0b01**

Reserved.

**0b10**

Non-secure halting debug prohibited.

**0b11**

Non-secure halting debug allowed in unprivileged mode.

If version Armv8.1 of the architecture and UDE are not implemented, this field is [RES0](#).

**Bits [15:8]**

Reserved, [RES0](#).

**SNID, bits [7:6]**

Secure Non-invasive Debug. Indicates whether Secure non-invasive debug is implemented and allowed.

The possible values of this field are:

**0b00**

Security Extension not implemented.

**0b01**

Reserved.

**0b10**

Security Extension implemented and Secure non-invasive debug prohibited.

**0b11**

Security Extension implemented and Secure non-invasive debug allowed.

**SID, bits [5:4]**

Secure Invasive Debug. Indicates whether Secure invasive debug is implemented and allowed.

The possible values of this field are:

**0b00**

Security Extension not implemented.

**0b01**

Reserved.

**0b10**

Security Extension implemented and Secure invasive debug prohibited.

**0b11**

Security Extension implemented and Secure invasive debug allowed.

**NSNID, bits [3:2]**

Non-secure Non-invasive Debug. Indicates whether Non-secure non-invasive debug is allowed.

The possible values of this field are:

**0b0x**

Reserved.

**0b10**

Non-secure non-invasive debug prohibited.

**0b11**

Non-secure non-invasive debug allowed.

**NSID, bits [1:0]**

Non-secure Invasive Debug. Indicates whether Non-secure invasive debug is allowed.

The possible values of this field are:

**0b0x**

Reserved.

**0b10**

Non-secure invasive debug prohibited.

**0b11**

Non-secure invasive debug allowed.

## D1.2.21 DCCIMVAC, Data Cache line Clean and Invalidate by Address to PoC

The DCCIMVAC characteristics are:

### Purpose

Clean and invalidate data or unified cache line by address to PoC.

### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are [UNPREDICTABLE](#).

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

### Configurations

This register is always implemented.

### Attributes

32-bit write-only register located at 0xE000EF70.

Secure software can access the Non-secure version of this register via DCCIMVAC\_NS located at 0xE002EF70. The location 0xE002EF70 is [RES0](#) to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

## Field descriptions

The DCCIMVAC bit assignments are:

### ADDRESS, bits [31:0]

Address. Writing to this field initiates the maintenance operation for the address written.

### D1.2.22 DCCISW, Data Cache line Clean and Invalidate by Set/Way

The DCCISW characteristics are:

## Purpose

Clean and invalidate data or unified cache line by set/way.

## Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are **UNPREDICTABLE**.

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

## Configurations

This register is always implemented.

## Attributes

32-bit write-only register located at 0xE000EF74.

Secure software can access the Non-secure version of this register via DCCISW\_NS located at 0xE002EF74.

The location 0xE002EF74 is **RES0** to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

## Field descriptions

The DCCISW bit assignments are:

**SetWay, bits [31:4]**

Cache set/way. Contains two fields: Way, bits[31:32-A], the number of the way to operate on. Set, bits[B-1:L], the number of the set to operate on. Bits[L-1:4] are [RES0](#). A =  $\text{Log}_2(\text{ASSOCIATIVITY})$ , L =  $\text{Log}_2(\text{LINELEN})$ , B = (L + S), S =  $\text{Log}_2(\text{NSETS})$ . ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on. The values of A and S are rounded up to the next integer.

**Level, bits [3:1]**

Cache level. Cache level to operate on, minus 1. For example, this field is 0 for operations on L1 cache, or 1 for operations on L2 cache.

**Bit [0]**

Reserved, RES0.

### D1.2.23 DCCMVAC, Data Cache line Clean by Address to PoC

The DCCMVAC characteristics are:

#### Purpose

Clean data or unified cache line by address to PoC.

#### Usage constraints

Privileged access permitted only. Unprivileged accesses generate a fault.

This register is word accessible only. Halfword and byte accesses are [UNPREDICTABLE](#).

From Armv8.1-M, this register is accessible through unprivileged DAP requests when DAUTHCTRL.UIDAPEN (either bank) is set.

#### Configurations

This register is always implemented.

#### Attributes

32-bit write-only register located at 0xE000EF68.

Secure software can access the Non-secure version of this register via DCCMVAC\_NS located at 0xE002EF68. The location 0xE002EF68 is [RES0](#) to software executing in Non-secure state and the debugger.

This register is not banked between Security states.

### Field descriptions

The DCCMVAC bit assignments are:

#### ADDRESS, bits [31:0]

Address. Writing to this field initiates the maintenance operation for the address written.

## D1.2.24 DCCMVAU, Data Cache line Clean by address to PoU

The DCCMVAU characteristics are:

### Purpose

Clean data or unified cache line by address to PoU.

### Usage constraints
