## Release information

| Date        | Version                        | Changes                                                                                                                                      |
|-------------|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| 2022/Jun/30 | B.t<br>Non-Confidential<br>EAC | • Twentieth release of the v8.0-M manual with integrated v8.1-M material, Custom Datapath Extension material and PACBTI Extension material   |
| 2022/Apr/01 | B.s<br>Non-Confidential<br>EAC | • Nineteenth release of the v8.0-M manual with integrated v8.1-M material, Custom Datapath Extension material and PACBTI Extension material  |
| 2021/Dec/17 | B.r<br>Non-Confidential<br>EAC | • Eighteenth release of the v8.0-M manual with integrated v8.1-M material, Custom Datapath Extension material and PACBTI Extension material  |
| 2021/Sep/30 | B.q<br>Non-Confidential<br>EAC | • Seventeenth release of the v8.0-M manual with integrated v8.1-M material, Custom Datapath Extension material and PACBTI Extension material |
| 2021/Jun/30 | B.p<br>Non-Confidential<br>EAC | • Sixteenth release of the v8.0-M manual with integrated v8.1-M material, Custom Datapath Extension material and PACBTI Extension material   |
| 2021/Mar/31 | B.o<br>Non-Confidential<br>EAC | • Fifteenth release of the v8.0-M manual with integrated v8.1-M material, Custom Datapath Extension material and PACBTI Extension material   |
| 2020/Dec/18 | B.n<br>Non-Confidential<br>EAC | • Fourteenth release of the v8.0-M manual with integrated v8.1-M material and Custom Datapath Extension material                             |
| 2020/Oct/02 | B.m<br>Non-Confidential<br>EAC | • Thirteenth release of the v8.0-M manual with integrated v8.1-M material and Custom Datapath Extension material                             |
| 2020/Jun/30 | B.l<br>Non-Confidential<br>EAC | • Twelfth release of the v8.0-M manual with integrated v8.1-M material and Custom Datapath Extension material                                |
| 2020/Mar/31 | B.k<br>Non-Confidential<br>EAC | • Eleventh release of the v8.0-M manual with integrated v8.1-M material                                                                      |
| 2019/Dec/17 | B.j<br>Non-Confidential<br>EAC | • Tenth release of the v8.0-M manual with integrated v8.1-M material                                                                         |
| 2019/Oct/02 | A.m<br>Non-confidential<br>EAC | • Eleventh EAC release                                                                                                                       |
| 2019/Oct/02 | B.i<br>Non-Confidential<br>EAC | • Ninth release of the v8.0-M manual with integrated v8.1-M material                                                                         |
| 2019/Jun/28 | A.l<br>Non-confidential<br>EAC | • Tenth EAC release                                                                                                                          |
| 2019/Jun/28 | B.h<br>Non-Confidential<br>EAC | • Eighth release of the v8.0-M manual with integrated v8.1-M material                                                                        |
| 2019/Mar/29 | A.k<br>Non-confidential<br>EAC | • Ninth EAC release                                                                                                                          |
| 2019/Mar/29 | B.g<br>Non-Confidential<br>EAC | • Seventh release of the v8.0-M manual with integrated v8.1-M material                                                                       |

| Date        | Version                         | Changes                                                               |
|-------------|---------------------------------|-----------------------------------------------------------------------|
| 2019/Feb/14 | B.f<br>Non-Confidential<br>EAC  | • Sixth release of the v8.0-M manual with integrated v8.1-M material  |
| 2018/Dec/14 | A.j<br>Non-confidential<br>EAC  | • Eighth EAC release                                                  |
| 2018/Dec/14 | B.e<br>Confidential<br>EAC      | • Fifth release of the v8.0-M manual with integrated v8.1-M material  |
| 2018/Jun/29 | A.i<br>Non-confidential<br>EAC  | • Seventh EAC release                                                 |
| 2018/Jun/29 | B.d<br>Confidential<br>Beta     | • Fourth release of the v8.0-M manual with integrated v8.1-M material |
| 2018/Mar/31 | A.h<br>Non-confidential<br>EAC  | • Sixth EAC release                                                   |
| 2018/Mar/31 | B.c<br>Confidential<br>Beta     | • Third release of the v8.0-M manual with integrated v8.1-M material  |
| 2017/Dec/15 | A.g<br>Non-confidential<br>EAC  | • Fifth EAC release                                                   |
| 2017/Dec/15 | B.b<br>Confidential<br>Beta     | • Second release of the v8.0-M manual with integrated v8.1-M material |
| 2017/Sep/29 | A.f<br>Non-confidential<br>EAC  | • Fourth EAC release                                                  |
| 2017/Sep/29 | B.a<br>Confidential<br>Beta     | • First release of the v8.0-M manual with integrated v8.1-M material  |
| 2017/Jun/02 | A.e<br>Non-confidential<br>EAC  | • Third EAC release                                                   |
| 2016/Nov/30 | A.d<br>Non-confidential<br>EAC  | • Second EAC release                                                  |
| 2016/Sep/30 | A.c<br>Non-confidential<br>EAC  | • EAC release                                                         |
| 2016/Jul/28 | A.b<br>Non-confidential<br>Beta | • Beta release                                                        |
| 2016/Mar/29 | A.a<br>Confidential<br>Beta     | • Beta release, limited circulation                                   |

## Part A Armv8-M Architecture Introduction and Overview

### Chapter A1

#### Introduction

|                                                                                    |    |
|------------------------------------------------------------------------------------|----|
| A1.1 Document layout and terminology . . . . .                                     | 48 |
| A1.1.1 Structure of the document . . . . .                                         | 48 |
| A1.1.2 Scope of the document . . . . .                                             | 49 |
| A1.1.3 Intended audience . . . . .                                                 | 49 |
| A1.1.4 Terminology, phrases . . . . .                                              | 49 |
| A1.1.5 Terminology, Armv8-M specific terms . . . . .                               | 50 |
| A1.2 About the Armv8 architecture, and architecture profiles . . . . .             | 51 |
| A1.3 The Armv8-M architecture profile . . . . .                                    | 52 |
| A1.3.1 The Armv8-M instruction set . . . . .                                       | 52 |
| A1.3.2 Baseline implementation . . . . .                                           | 52 |
| A1.3.3 Nested Vectored Interrupt Controller . . . . .                              | 52 |
| A1.4 Optional Extensions . . . . .                                                 | 53 |
| A1.4.1 CDE - The Custom Datapath Extension . . . . .                               | 53 |
| A1.4.2 Debug . . . . .                                                             | 53 |
| A1.4.3 DSP - The Digital Signal Processing Extension. . . . .                      | 54 |
| A1.4.4 The DSP Debug Extension . . . . .                                           | 54 |
| A1.4.5 The Floating-point Extension . . . . .                                      | 54 |
| A1.4.6 The Main Extension . . . . .                                                | 54 |
| A1.4.7 MPU model . . . . .                                                         | 55 |
| A1.4.8 M-Profile Vector Extension, MVE . . . . .                                   | 55 |
| A1.4.9 Pointer Authentication and Branch Target Identification Extension . . . . . | 55 |
| A1.4.10 Performance Monitors Extension . . . . .                                   | 55 |

|         |                                                         |    |
|---------|---------------------------------------------------------|----|
| A1.4.11 | Reliability, Availability, and Serviceability . . . . . | 55 |
| A1.4.12 | Security Extension . . . . .                            | 56 |
| A1.4.13 | The System Timer Extension . . . . .                    | 56 |

## Part B Armv8-M Architecture Rules

### Chapter B1

#### Resets

|      |                                              |    |
|------|----------------------------------------------|----|
| B1.1 | Resets, Cold reset, and Warm reset . . . . . | 59 |
|------|----------------------------------------------|----|

### Chapter B2

#### Power Management

|        |                                                    |    |
|--------|----------------------------------------------------|----|
| B2.1   | Power management . . . . .                         | 61 |
| B2.1.1 | The Wait for Event (WFE) instruction . . . . .     | 61 |
| B2.1.2 | The Event register . . . . .                       | 62 |
| B2.1.3 | The Wait for Interrupt (WFI) instruction . . . . . | 62 |
| B2.2   | Sleep on exit . . . . .                            | 64 |

### Chapter B3

#### Programmers' Model

|         |                                                                           |     |
|---------|---------------------------------------------------------------------------|-----|
| B3.1    | PE modes, Thread mode and Handler mode . . . . .                          | 67  |
| B3.2    | Privileged and unprivileged execution . . . . .                           | 68  |
| B3.3    | Registers . . . . .                                                       | 69  |
| B3.4    | Special-purpose CONTROL register . . . . .                                | 71  |
| B3.5    | XPSR, APSR, IPSR, and EPSR . . . . .                                      | 72  |
| B3.5.1  | Interrupt Program Status Register (IPSR) . . . . .                        | 72  |
| B3.5.2  | Execution Program Status Register (EPSR) . . . . .                        | 73  |
| B3.6    | Security states: Secure state, and Non-secure state . . . . .             | 74  |
| B3.7    | Security states and register banking between Security states . . . . .    | 75  |
| B3.8    | Stack pointer . . . . .                                                   | 76  |
| B3.9    | Exception numbers and exception priority numbers . . . . .                | 78  |
| B3.10   | Exception enable, pending, and active bits . . . . .                      | 82  |
| B3.11   | Security states, exception banking . . . . .                              | 85  |
| B3.12   | Faults . . . . .                                                          | 88  |
| B3.13   | Priority model . . . . .                                                  | 93  |
| B3.14   | Secure address protection . . . . .                                       | 97  |
| B3.15   | Security state transitions . . . . .                                      | 98  |
| B3.16   | Function calls from Secure state to Non-secure state . . . . .            | 100 |
| B3.17   | Function returns from Non-secure state . . . . .                          | 101 |
| B3.18   | Exception handling . . . . .                                              | 103 |
| B3.19   | Exception entry, context stacking . . . . .                               | 105 |

| B3.36   | Coprocessor support . . . . .                                                                             | 154 |
| B3.37   | The Custom Datapath Extension . . . . .                                                                   | 156 |
| B3.37.1 | Overview of the Custom Datapath Extension . . . . .                                                       | 156 |
| B3.37.2 | Enabling CDE instructions . . . . .                                                                       | 156 |
| B3.37.3 | Execution of CDE instructions . . . . .                                                                   | 158 |

## Chapter B4

### Floating-point Support

|        |                                                                                                   |     |
|--------|---------------------------------------------------------------------------------------------------|-----|
| B4.1   | The optional Floating-point Extension, FPUv5 . . . . .                                            | 161 |
| B4.2   | About the Floating-point Status and Control Registers . . . . .                                   | 163 |
| B4.3   | Registers for Floating-point data processing, S0-S31, or D0-D15 . . . . .                         | 165 |
| B4.4   | Floating-point standards and terminology . . . . .                                                | 166 |
| B4.5   | Floating-point data representable . . . . .                                                       | 167 |
| B4.6   | Floating-point encoding formats, half-precision, single-precision, and double-precision . . . . . | 168 |
| B4.7   | The IEEE 754 Floating-point exceptions . . . . .                                                  | 170 |
| B4.8   | The Flush-to-zero mode . . . . .                                                                  | 171 |
| B4.8.1 | The Flush to zero mode half-precision calculations . . . . .                                      | 172 |
| B4.9   | The Default NaN mode, and NaN handling . . . . .                                                  | 173 |
| B4.10  | The Default NaN . . . . .                                                                         | 174 |
| B4.11  | Combinations of Floating-point exceptions . . . . .                                               | 175 |
| B4.12  | Priority of Floating-point exceptions relative to other Floating-point exceptions . . . . .       | 176 |

## Chapter B5

### Vector Extension

|        |                                                             |     |
|--------|-------------------------------------------------------------|-----|
| B5.1   | Vector Extension operation . . . . .                        | 178 |
| B5.2   | Vector register file . . . . .                              | 179 |
| B5.3   | Lanes . . . . .                                             | 180 |
| B5.4   | Beats . . . . .                                             | 181 |
| B5.5   | Exception state . . . . .                                   | 184 |
| B5.6   | Predication/conditional execution . . . . .                 | 188 |
| B5.6.1 | Loop tail predication . . . . .                             | 188 |
| B5.6.2 | VPT predication . . . . .                                   | 189 |
| B5.6.3 | Effects of predication . . . . .                            | 192 |
| B5.6.4 | IT block . . . . .                                          | 193 |
| B5.7   | MVE interleaving/de-interleaving loads and stores . . . . . | 194 |

## Chapter B6

### Pointer authentication and branch target identification Extension

|        |                                        |     |
|--------|----------------------------------------|-----|
| B6.1   | Implementing PAC and BTI . . . . .     | 196 |
| B6.1.1 | Pointer authentication . . . . .       | 197 |
| B6.1.2 | Branch target identification . . . . . | 201 |

## Chapter B7

### Memory Model

|        |                                                |     |
|--------|------------------------------------------------|-----|
| B7.1   | Definition of the Armv8 memory model . . . . . | 206 |
| B7.1.1 | Locations . . . . .                            | 206 |
| B7.2   | Atomicity . . . . .                            | 209 |
| B7.2.1 | Single-copy atomicity . . . . .                | 209 |
| B7.2.2 | Multi-copy atomicity . . . . .                 | 210 |

|         |                                                                                                      |     |
|---------|------------------------------------------------------------------------------------------------------|-----|
| B7.2.3  | Ordering and observability . . . . .                                                                 | 210 |
| B7.2.4  | Ordering and observability at a Location . . . . .                                                   | 212 |
| B7.2.5  | Ordering constraints . . . . .                                                                       | 216 |
| B7.2.6  | Completion and endpoint ordering . . . . .                                                           | 217 |
| B7.2.7  | External ordering constraints . . . . .                                                              | 219 |
| B7.2.8  | Globally-completes-before order . . . . .                                                            | 220 |
| B7.2.9  | Memory barriers . . . . .                                                                            | 221 |
| B7.2.10 | Instruction Synchronization Barrier . . . . .                                                        | 222 |
| B7.2.11 | Data Memory Barrier . . . . .                                                                        | 222 |
| B7.2.12 | Data Synchronization Barrier . . . . .                                                               | 223 |
| B7.2.13 | Consumption of Speculative Data Barrier . . . . .                                                    | 223 |
| B7.2.14 | Physical Speculative Store Bypass Barrier . . . . .                                                  | 224 |
| B7.2.15 | Speculative Store Bypass Barrier . . . . .                                                           | 224 |
| B7.2.16 | Synchronization requirements for System Control Space . . . . .                                      | 224 |
| B7.3    | Memory accesses . . . . .                                                                            | 226 |
| B7.4    | Address space . . . . .                                                                              | 227 |
| B7.5    | Endianness . . . . .                                                                                 | 228 |
| B7.6    | Alignment behavior . . . . .                                                                         | 231 |
| B7.7    | Concurrent modification and execution of instructions . . . . .                                      | 232 |
| B7.8    | Access rights . . . . .                                                                              | 234 |
| B7.9    | Normal memory . . . . .                                                                              | 236 |
| B7.10   | Cacheability attributes . . . . .                                                                    | 238 |
| B7.11   | Device memory . . . . .                                                                              | 239 |
| B7.12   | Device memory attributes . . . . .                                                                   | 241 |
| B7.12.1 | Gathering and non-Gathering Device memory attributes . . . . .                                       | 242 |
| B7.12.2 | Reordering and non-Reordering Device memory attributes . . . . .                                     | 242 |
| B7.12.3 | Early Write Acknowledgement and no Early Write Acknowledgement<br>Device memory attributes . . . . . | 243 |
| B7.13   | Shareability attributes . . . . .                                                                    | 244 |
| B7.14   | Shareability domains . . . . .                                                                       | 245 |
| B7.15   | Memory access restrictions . . . . .                                                                 | 247 |
| B7.16   | Mismatched memory attributes . . . . .                                                               | 248 |
| B7.17   | Load-Exclusive and Store-Exclusive accesses to Normal memory . . . . .                               | 250 |
| B7.18   | Load-Acquire and Store-Release accesses to memory . . . . .                                          | 251 |
| B7.19   | Caches . . . . .                                                                                     | 253 |
| B7.20   | Cache identification . . . . .                                                                       | 255 |
| B7.21   | Cache visibility . . . . .                                                                           | 256 |
| B7.22   | Cache coherency . . . . .                                                                            | 257 |
| B7.23   | Cache enabling and disabling . . . . .                                                               | 258 |
| B7.24   | Cache behavior at reset . . . . .                                                                    | 259 |
| B7.25   | Behavior of Preload Data (PLD) and Preload Instruction (PLI) instructions with<br>caches . . . . .   | 260 |
| B7.26   | Branch predictors . . . . .                                                                          | 261 |
| B7.27   | Cache maintenance operations . . . . .                                                               | 262 |
| B7.28   | Ordering of cache maintenance operations . . . . .                                                   | 266 |
| B7.29   | Branch predictor maintenance operations . . . . .                                                    | 267 |

## Chapter B8

### The System Address Map

|      |                                                       |     |
|------|-------------------------------------------------------|-----|
| B8.1 | System address map . . . . .                          | 269 |
| B8.2 | The System region of the system address map . . . . . | 270 |
| B8.3 | The System Control Space (SCS) . . . . .              | 272 |

## Chapter B9

### Synchronization and Semaphores

|      |                                         |     |
|------|-----------------------------------------|-----|
| B9.1 | Exclusive access instructions . . . . . | 274 |
| B9.2 | The local monitors . . . . .            | 275 |

|                    |                                                                      |     |
|--------------------|----------------------------------------------------------------------|-----|
| B9.3               | The global monitor . . . . .                                         | 277 |
| B9.3.1             | Load-Exclusive and Store-Exclusive . . . . .                         | 278 |
| B9.3.2             | Load-Exclusive and Store-Exclusive in Shareable memory . . . . .     | 279 |
| B9.4               | Exclusive access instructions and the monitors . . . . .             | 281 |
| B9.5               | Load-Exclusive and Store-Exclusive instruction constraints . . . . . | 282 |
| <b>Chapter B10</b> | <b>The Armv8-M Protected Memory System Architecture</b>              |     |
| B10.1              | Memory Protection Unit . . . . .                                     | 285 |
| B10.2              | Security attribution . . . . .                                       | 288 |
| B10.3              | Security attribution unit (SAU) . . . . .                            | 291 |
| B10.4              | IMPLEMENTATION DEFINED Attribution Unit (IDAU) . . . . .             | 292 |
| <b>Chapter B11</b> | <b>The System Timer, SysTick</b>                                     |     |
| B11.1              | The system timer, SysTick . . . . .                                  | 294 |
| <b>Chapter B12</b> | <b>Nested Vectored Interrupt Controller</b>                          |     |
| B12.1              | NVIC definition . . . . .                                            | 297 |
| B12.2              | NVIC operation . . . . .                                             | 298 |
| <b>Chapter B13</b> | <b>Debug</b>                                                         |     |
| B13.1              | Debug feature overview . . . . .                                     | 301 |
| B13.1.1            | Debug mechanisms . . . . .                                           | 304 |
| B13.1.2            | Debug resources . . . . .                                            | 304 |
| B13.1.3            | Trace . . . . .                                                      | 305 |
| B13.2              | Accessing debug features . . . . .                                   | 307 |
| B13.2.1            | ROM table . . . . .                                                  | 307 |
| B13.2.2            | Debug System registers . . . . .                                     | 310 |
| B13.2.3            | CoreSight and identification registers . . . . .                     | 310 |
| B13.3              | Debug authentication interface . . . . .                             | 312 |
| B13.3.1            | Halting debug authentication . . . . .                               | 313 |
| B13.3.2            | Non-invasive debug authentication . . . . .                          | 316 |
| B13.3.3            | DebugMonitor exception authentication . . . . .                      | 317 |
| B13.3.4            | DAP access permissions . . . . .                                     | 319 |
| B13.4              | Debug event behavior . . . . .                                       | 325 |
| B13.4.1            | About debug events . . . . .                                         | 325 |
| B13.4.2            | Debug stepping . . . . .                                             | 331 |
| B13.4.3            | Vector catch . . . . .                                               | 336 |
| B13.4.4            | Breakpoint instructions . . . . .                                    | 338 |
| B13.4.5            | External debug request . . . . .                                     | 339 |
| B13.5              | Debug state . . . . .                                                | 341 |
| B13.6              | Exiting Debug state . . . . .                                        | 346 |
| B13.7              | Multiprocessor support . . . . .                                     | 347 |
| B13.7.1            | Cross-halt event . . . . .                                           | 347 |
| B13.7.2            | External restart request . . . . .                                   | 347 |
| <b>Chapter B14</b> | <b>Debug and Trace Components</b>                                    |     |
| B14.1              | Instrumentation Trace Macrocell . . . . .                            | 349 |
| B14.1.1            | About the ITM . . . . .                                              | 349 |
| B14.1.2            | ITM operation . . . . .                                              | 350 |
| B14.1.3            | Timestamp support . . . . .                                          | 353 |
| B14.1.4            | Synchronization support . . . . .                                    | 356 |
| B14.1.5            | Continuation bits . . . . .                                          | 357 |
| B14.2              | Data Watchpoint and Trace unit . . . . .                             | 358 |
| B14.2.1            | About the DWT . . . . .                                              | 358 |
| B14.2.2            | DWT unit operation . . . . .                                         | 359 |
| B14.2.3            | Constraints on programming DWT comparators . . . . .                 | 364 |

|          |                                                   |     |
|----------|---------------------------------------------------|-----|
| B14.2.4  | CMPMATCH trigger events . . . . .                 | 368 |
| B14.2.5  | Matching in detail . . . . .                      | 369 |
| B14.2.6  | DWT match restrictions and relaxations . . . . .  | 372 |
| B14.2.7  | DWT trace restrictions and relaxations . . . . .  | 374 |
| B14.2.8  | CYCCNT cycle counter and related timers . . . . . | 375 |
| B14.2.9  | Profiling counter support . . . . .               | 377 |
| B14.2.10 | Program Counter sampling support . . . . .        | 379 |
| B14.3    | Embedded Trace Macrocell . . . . .                | 381 |
| B14.4    | Trace Port Interface Unit . . . . .               | 382 |
| B14.5    | Flash Patch and Breakpoint unit . . . . .         | 384 |
| B14.5.1  | About the FPB unit . . . . .                      | 384 |
| B14.5.2  | FPB unit operation . . . . .                      | 384 |
| B14.5.3  | Cache maintenance . . . . .                       | 386 |

## Chapter B15

### The Performance Monitors Extension

|          |                                                                               |     |
|----------|-------------------------------------------------------------------------------|-----|
| B15.1    | Counters . . . . .                                                            | 388 |
| B15.2    | Accuracy of the performance counters . . . . .                                | 389 |
| B15.3    | Security, access, and modes . . . . .                                         | 390 |
| B15.4    | Attributability . . . . .                                                     | 391 |
| B15.5    | Coexistence with the DWT Performance Monitors . . . . .                       | 392 |
| B15.6    | Interrupts and Debug events . . . . .                                         | 393 |
| B15.7    | Performance Monitors and Debug state . . . . .                                | 394 |
| B15.8    | List of supported architectural and microarchitectural events . . . . .       | 395 |
| B15.9    | Generic architectural and microarchitectural events . . . . .                 | 406 |
| B15.9.1  | CTI_TRIGOUT (Cross-trigger Interface output trigger , for = 4 to 7) . . . . . | 406 |
| B15.9.2  | TRCEXTOUT (PE Trace Unit external output , for = 0 to 3) . . . . .            | 406 |
| B15.9.3  | DWT_CMPMATCH (DWT comparator match, for = 0 to 7) . . . . .                   | 406 |
| B15.9.4  | LI_CACHE_REFILL (Level instruction cache refill) . . . . .                    | 406 |
| B15.9.5  | LD_CACHE_REFILL (Level data cache refill) . . . . .                           | 406 |
| B15.9.6  | LD_CACHE_MISS_RD (Level data cache miss on read) . . . . .                    | 407 |
| B15.9.7  | LD_CACHE_WB (Level data cache write-back) . . . . .                           | 407 |
| B15.9.8  | LI_CACHE (Level instruction cache access) . . . . .                           | 408 |
| B15.9.9  | LD_CACHE (Level data cache access) . . . . .                                  | 408 |
| B15.9.10 | LD_CACHE_RD (Level data cache access, read) . . . . .                         | 408 |
| B15.10   | Common event descriptions . . . . .                                           | 409 |
| B15.11   | Required PMU events . . . . .                                                 | 431 |
| B15.12   | IMPLEMENTATION DEFINED event numbers . . . . .                                | 432 |

## Chapter B16

### Reliability, Availability, and Serviceability (RAS) Extension

|         |                                                                |     |
|---------|----------------------------------------------------------------|-----|
| B16.1   | Overview . . . . .                                             | 434 |
| B16.2   | Taxonomy of errors . . . . .                                   | 435 |
| B16.2.1 | Architectural error propagation . . . . .                      | 435 |
| B16.2.2 | Architecturally infected, contained, and uncontained . . . . . | 436 |
| B16.2.3 | Architecturally consumed errors . . . . .                      | 436 |
| B16.2.4 | Other errors . . . . .                                         | 436 |
| B16.3   | Generating error exceptions . . . . .                          | 437 |
| B16.3.1 | Error correction and deferment . . . . .                       | 439 |
| B16.4   | Error Synchronization Barrier (ESB) . . . . .                  | 440 |
| B16.4.1 | ESB and Unrecoverable errors . . . . .                         | 440 |
| B16.4.2 | ESB and other containable errors . . . . .                     | 440 |
| B16.4.3 | ESB and other errors . . . . .                                 | 441 |
| B16.5   | Implicit Error Synchronization (IESB) . . . . .                | 442 |
| B16.6   | Fault handling . . . . .                                       | 444 |
| B16.7   | RAS error records . . . . .                                    | 446 |
| B16.8   | Multiple BusFault exceptions . . . . .                         | 449 |

|        |                                      |     |
|--------|--------------------------------------|-----|
| B16.9  | Error Recovery reset . . . . .       | 450 |
| B16.10 | Minimal RAS implementation . . . . . | 451 |

## Part C Armv8-M Instruction Set

### Chapter C1

#### Instruction Set Overview

|        |                                                                                                                                 |     |
|--------|---------------------------------------------------------------------------------------------------------------------------------|-----|
| C1.1   | Instruction set . . . . .                                                                                                       | 454 |
| C1.2   | Format of instruction descriptions . . . . .                                                                                    | 455 |
| C1.2.1 | The title . . . . .                                                                                                             | 455 |
| C1.2.2 | A short description . . . . .                                                                                                   | 455 |
| C1.2.3 | The instruction encoding or encodings . . . . .                                                                                 | 455 |
| C1.2.4 | Any alias conditions, if applicable . . . . .                                                                                   | 457 |
| C1.2.5 | Standard assembler syntax fields . . . . .                                                                                      | 457 |
| C1.2.6 | Pseudocode describing how the instruction operates . . . . .                                                                    | 459 |
| C1.2.7 | Use of labels in UAL instruction syntax . . . . .                                                                               | 460 |
| C1.2.8 | Using syntax information . . . . .                                                                                              | 461 |
| C1.3   | Conditional execution . . . . .                                                                                                 | 463 |
| C1.3.1 | Conditional instructions . . . . .                                                                                              | 464 |
| C1.3.2 | Pseudocode details of conditional execution . . . . .                                                                           | 464 |
| C1.3.3 | Conditional execution of undefined instructions . . . . .                                                                       | 465 |
| C1.3.4 | Interaction of undefined instruction behavior with UNPREDICTABLE or<br>CONSTRAINED_UNPREDICTABLE instruction behavior . . . . . | 465 |
| C1.3.5 | ITSTATE . . . . .                                                                                                               | 465 |
| C1.3.6 | Pseudocode details of ITSTATE operation . . . . .                                                                               | 466 |
| C1.3.7 | SVC and ITSTATE . . . . .                                                                                                       | 466 |
| C1.3.8 | CONSTRAINED_UNPREDICTABLE behavior and IT blocks . . . . .                                                                      | 467 |
| C1.4   | Instruction set encoding information . . . . .                                                                                  | 469 |
| C1.4.1 | UNDEFINED and UNPREDICTABLE instruction set space . . . . .                                                                     | 469 |
| C1.4.2 | Pseudocode descriptions of operations on general-purpose registers<br>and the PC . . . . .                                      | 469 |
| C1.4.3 | Use of 0b1111 as a register specifier . . . . .                                                                                 | 470 |
| C1.4.4 | Use of 0b1101 as a register specifier . . . . .                                                                                 | 471 |
| C1.4.5 | 16-bit T32 instruction support for SP . . . . .                                                                                 | 472 |
| C1.4.6 | Branching . . . . .                                                                                                             | 472 |
| C1.4.7 | Instruction set, interworking and interstating support . . . . .                                                                | 473 |
| C1.5   | Modified immediate constants . . . . .                                                                                          | 475 |
| C1.5.1 | Operation of modified immediate constants . . . . .                                                                             | 475 |
| C1.6   | NOP-compatible hint instructions . . . . .                                                                                      | 477 |
| C1.7   | SBZ or SBO fields in instructions . . . . .                                                                                     | 478 |

### Chapter C2

#### Instruction Specification

|         |                                                               |     |
|---------|---------------------------------------------------------------|-----|
| C2.1    | Top level T32 instruction set encoding . . . . .              | 480 |
| C2.2    | 16-bit T32 instruction encoding . . . . .                     | 481 |
| C2.2.1  | Shift (immediate), add, subtract, move, and compare . . . . . | 481 |
| C2.2.2  | Data-processing (two low registers) . . . . .                 | 483 |
| C2.2.3  | Special data instructions and branch and exchange . . . . .   | 484 |
| C2.2.4  | Load/store (register offset) . . . . .                        | 485 |
| C2.2.5  | Load/store word/byte (immediate offset) . . . . .             | 485 |
| C2.2.6  | Load/store halfword (immediate offset) . . . . .              | 485 |
| C2.2.7  | Load/store (SP-relative) . . . . .                            | 486 |
| C2.2.8  | Add PC/SP (immediate) . . . . .                               | 486 |
| C2.2.9  | Miscellaneous 16-bit instructions . . . . .                   | 487 |
| C2.2.10 | Load/store multiple . . . . .                                 | 489 |
| C2.2.11 | Conditional branch, and Supervisor Call . . . . .             | 489 |

|         |                                                         |     |
|---------|---------------------------------------------------------|-----|
| C2.3    | 32-bit T32 instruction encoding                         | 491 |
| C2.3.1  | Coprocessor, floating-point, and vector instructions    | 491 |
| C2.3.2  | Load/store (multiple, dual, exclusive, acquire-release) | 506 |
| C2.3.3  | Data-processing (shifted register)                      | 510 |
| C2.3.4  | Branches and miscellaneous control                      | 512 |
| C2.3.5  | Data-processing (modified immediate)                    | 515 |
| C2.3.6  | Data-processing (plain binary immediate)                | 516 |
| C2.3.7  | Load/store single                                       | 518 |
| C2.3.8  | Data-processing (register)                              | 524 |
| C2.3.9  | Multiply, multiply accumulate, and absolute difference  | 526 |
| C2.3.10 | Long multiply and divide                                | 527 |
| C2.4    | Alphabetical list of instructions                       | 529 |
| C2.4.1  | ADC (immediate)                                         | 530 |
| C2.4.2  | ADC (register)                                          | 532 |
| C2.4.3  | ADD (SP plus immediate)                                 | 534 |
| C2.4.4  | ADD (SP plus register)                                  | 536 |
| C2.4.5  | ADD (immediate)                                         | 538 |
| C2.4.6  | ADD (immediate, to PC)                                  | 541 |
| C2.4.7  | ADD (register)                                          | 543 |
| C2.4.8  | ADR                                                     | 546 |
| C2.4.9  | AND (immediate)                                         | 548 |
| C2.4.10 | AND (register)                                          | 550 |
| C2.4.11 | ASR (immediate)                                         | 552 |
| C2.4.12 | ASR (register)                                          | 554 |
| C2.4.13 | ASRL (immediate)                                        | 556 |
| C2.4.14 | ASRL (register)                                         | 557 |
| C2.4.15 | ASRS (immediate)                                        | 558 |
| C2.4.16 | ASRS (register)                                         | 560 |
| C2.4.17 | AUT                                                     | 562 |
| C2.4.18 | AUTG                                                    | 564 |
| C2.4.19 | B                                                       | 566 |
| C2.4.20 | BF, BFX, BFL, BFLX, BFCSEL                              | 568 |
| C2.4.21 | BFC                                                     | 572 |
| C2.4.22 | BFI                                                     | 574 |
| C2.4.23 | BIC (immediate)                                         | 576 |
| C2.4.24 | BIC (register)                                          | 578 |
| C2.4.25 | BKPT                                                    | 580 |
| C2.4.26 | BL                                                      | 581 |
| C2.4.27 | BLX, BLXNS                                              | 582 |
| C2.4.28 | BTI                                                     | 584 |
| C2.4.29 | BX, BXNS                                                | 585 |
| C2.4.30 | BXAUT                                                   | 587 |
| C2.4.31 | CBNZ, CBZ                                               | 589 |
| C2.4.32 | CDP, CDP2                                               | 590 |
| C2.4.33 | CINC                                                    | 592 |
| C2.4.34 | CINV                                                    | 593 |
| C2.4.35 | CLREX                                                   | 594 |
| C2.4.36 | CLRM                                                    | 595 |
| C2.4.37 | CLZ                                                     | 596 |
| C2.4.38 | CMN (immediate)                                         | 598 |
| C2.4.39 | CMN (register)                                          | 599 |
| C2.4.40 | CMP (immediate)                                         | 601 |
| C2.4.41 | CMP (register)                                          | 603 |
| C2.4.42 | CNEG                                                    | 606 |
| C2.4.43 | CPS                                                     | 607 |

|         |                       |     |
|---------|-----------------------|-----|
| C2.4.44 | CSDB                  | 609 |
| C2.4.45 | CSEL                  | 610 |
| C2.4.46 | CSET                  | 612 |
| C2.4.47 | CSETM                 | 613 |
| C2.4.48 | CSINC                 | 614 |
| C2.4.49 | CSINV                 | 616 |
| C2.4.50 | CSNEG                 | 618 |
| C2.4.51 | CX1                   | 620 |
| C2.4.52 | CX1D                  | 622 |
| C2.4.53 | CX2                   | 624 |
| C2.4.54 | CX2D                  | 626 |
| C2.4.55 | CX3                   | 628 |
| C2.4.56 | CX3D                  | 630 |
| C2.4.57 | DBG                   | 632 |
| C2.4.58 | DMB                   | 633 |
| C2.4.59 | DSB                   | 634 |

## Part E Armv8-M Pseudocode

### Chapter E1

#### Arm Pseudocode Definition

|        |                                                 |      |
|--------|-------------------------------------------------|------|
| E1.1   | About the Arm pseudocode . . . . .              | 1904 |
| E1.1.1 | General limitations of Arm pseudocode . . . . . | 1904 |
| E1.2   | Data types . . . . .                            | 1905 |
| E1.2.1 | General data type rules . . . . .               | 1905 |
| E1.2.2 | Bitstrings . . . . .                            | 1905 |
| E1.2.3 | Integers . . . . .                              | 1906 |
| E1.2.4 | Reals . . . . .                                 | 1906 |
| E1.2.5 | Booleans . . . . .                              | 1907 |
| E1.2.6 | Enumerations . . . . .                          | 1907 |
| E1.2.7 | Structures . . . . .                            | 1908 |
| E1.2.8 | Tuples . . . . .                                | 1909 |
| E1.2.9 | Arrays . . . . .                                | 1909 |
| E1.3   | Operators . . . . .                             | 1911 |
| E1.3.1 | Relational operators . . . . .                  | 1911 |
| E1.3.2 | Boolean operators . . . . .                     | 1911 |
| E1.3.3 | Bitstring operators . . . . .                   | 1912 |
| E1.3.4 | Arithmetic operators . . . . .                  | 1913 |
| E1.3.5 | The assignment operator . . . . .               | 1914 |
| E1.3.6 | Precedence rules . . . . .                      | 1915 |
| E1.3.7 | Conditional expressions . . . . .               | 1915 |
| E1.3.8 | Operator polymorphism . . . . .                 | 1915 |
| E1.4   | Statements and control structures . . . . .     | 1917 |
| E1.4.1 | Statements and Indentation . . . . .            | 1917 |
| E1.4.2 | Function and procedure calls . . . . .          | 1917 |
| E1.4.3 | Conditional control structures . . . . .        | 1918 |
| E1.4.4 | Loop control structures . . . . .               | 1919 |
| E1.4.5 | Special statements . . . . .                    | 1920 |
| E1.4.6 | Comments . . . . .                              | 1921 |
| E1.5   | Built-in functions . . . . .                    | 1922 |
| E1.5.1 | Bitstring manipulation functions . . . . .      | 1922 |
| E1.5.2 | Arithmetic functions . . . . .                  | 1923 |
| E1.6   | Arm pseudocode definition index . . . . .       | 1925 |
| E1.7   | Additional functions . . . . .                  | 1927 |
| E1.7.1 | IsSee() . . . . .                               | 1927 |
| E1.7.2 | IsUndefined() . . . . .                         | 1927 |

### Chapter E2

#### Pseudocode Specification

|        |                                        |      |
|--------|----------------------------------------|------|
| E2.1   | Alphabetical Pseudocode List . . . . . | 1929 |
| E2.1.1 | _AdvanceVPTState . . . . .             | 1929 |
| E2.1.2 | _ITStateChanged . . . . .              | 1929 |
| E2.1.3 | _Mem . . . . .                         | 1929 |
| E2.1.4 | _NextInstrAddr . . . . .               | 1929 |

|         |                                     |      |
|---------|-------------------------------------|------|
| E2.1.5  | _NextInstrITState                   | 1929 |
| E2.1.6  | _PCChanged                          | 1929 |
| E2.1.7  | _PendingReturnOperation             | 1929 |
| E2.1.8  | _RName                              | 1929 |
| E2.1.9  | _S                                  | 1930 |
| E2.1.10 | _SP                                 | 1930 |
| E2.1.11 | Abs                                 | 1930 |
| E2.1.12 | AccessAttributes                    | 1931 |
| E2.1.13 | AccType                             | 1931 |
| E2.1.14 | ActivateException                   | 1931 |
| E2.1.15 | ActiveFPState                       | 1931 |
| E2.1.16 | AddressDescriptor                   | 1932 |
| E2.1.17 | AddrType                            | 1932 |
| E2.1.18 | AddWithCarry                        | 1932 |
| E2.1.19 | AdvSIMDEExpandImm                   | 1932 |
| E2.1.20 | AlgorithmPAC                        | 1933 |
| E2.1.21 | Align                               | 1933 |
| E2.1.22 | ArchVersion                         | 1933 |
| E2.1.23 | ASR                                 | 1933 |
| E2.1.24 | ASR_C                               | 1934 |
| E2.1.25 | BeatComplete                        | 1934 |
| E2.1.26 | BeatSchedule                        | 1934 |
| E2.1.27 | BigEndian                           | 1935 |
| E2.1.28 | BigEndianReverse                    | 1935 |
| E2.1.29 | BitCount                            | 1935 |
| E2.1.30 | BitReverseShiftRight                | 1935 |
| E2.1.31 | BranchCall                          | 1936 |
| E2.1.32 | BranchReturn                        | 1936 |
| E2.1.33 | BranchTo                            | 1937 |
| E2.1.34 | BTIEnabled                          | 1937 |
| E2.1.35 | BusFaultBarrier                     | 1937 |
| E2.1.36 | CallSupervisor                      | 1938 |
| E2.1.37 | CanDebugAccessFP                    | 1938 |
| E2.1.38 | CanHaltOnEvent                      | 1938 |
| E2.1.39 | CanPendMonitorOnEvent               | 1938 |
| E2.1.40 | CdeImpDefValue                      | 1939 |
| E2.1.41 | CheckCPEEnabled                     | 1939 |
| E2.1.42 | CheckDecodeFaults                   | 1939 |
| E2.1.43 | CheckFPDecodeFaults                 | 1940 |
| E2.1.44 | CheckPermission                     | 1940 |
| E2.1.45 | ClearEventRegister                  | 1941 |
| E2.1.46 | ClearExclusiveByAddress             | 1941 |
| E2.1.47 | ClearExclusiveLocal                 | 1941 |
| E2.1.48 | ClearInFlightInstructions           | 1941 |
| E2.1.49 | ComparePriorities                   | 1941 |
| E2.1.50 | ComputePAC                          | 1942 |

## Part G Glossary

# Preface

This preface introduces the Armv8-M Architecture Reference Manual. It contains the following sections:

[About this book.](#)

[Using this book.](#)

[Conventions.](#)

[Additional reading.](#)

[Feedback.](#)

## About this book

This manual documents the microcontroller profile of version 8 of the Arm Architecture, the Armv8-M architecture profile. For short definitions of all the Armv8 profiles, see [A1.2 About the Armv8 architecture, and architecture profiles](#).

This manual has the following parts:

**Part A** Provides an introduction to the Armv8-M architecture.

**Part B** Describes the architectural rules.

**Part C** Describes the T32 instruction set.

**Part D** Describes the registers.

**Part E** Describes the Armv8-M pseudocode.

**Part F** Describes the packet protocols.

# Using this book

The information in this manual is organized into parts, as described in this section.

## **Part A, Armv8-M Architecture Introduction and Overview**

Part A gives an overview of the Armv8-M architecture profile, including its relationship to the other Arm PE architectures. It introduces the terminology that describes the architecture, and gives an overview of the optional architectural extensions. It contains the following chapter:

### [Chapter A1 \*Introduction\*](#)

Read this for an introduction to the Armv8-M architecture.

## **Part B, Armv8-M Architecture Rules**

Part B describes the architecture rules. It contains the following chapters:

### [Chapter B1 \*Resets\*](#)

Read this for a description of the reset rules.

### [Chapter B2 \*Power Management\*](#)

Read this for a description of the power management rules.

### [Chapter B3 \*Programmers' Model\*](#)

Read this for a description of the programmers model rules.

### [Chapter B4 \*Floating-point Support\*](#)

Read this for a description of the floating-point support rules.

### [Chapter B5 \*Vector Extension\*](#)

Read this for a description of the Vector Extension support rules.

### [Chapter B7 \*Memory Model\*](#)

Read this for a description of the memory model rules.

### [Chapter B8 \*The System Address Map\*](#)

Read this for a description of the system address map rules.

### [Chapter B9 \*Synchronization and Semaphores\*](#)

Read this for a description of the rules on non-blocking synchronization of shared memory.

### [Chapter B10 \*The Armv8-M Protected Memory System Architecture\*](#)

Read this for a description of the protected memory system architecture rules.

### [Chapter B11 \*The System Timer, SysTick\*](#)

Read this for a description of the system timer rules.

### [Chapter B12 \*Nested Vectored Interrupt Controller\*](#)

Read this for a description of the *Nested Vectored Interrupt Controller* (NVIC) rules.

### [Chapter B13 \*Debug\*](#)

Read this for a description of the debug rules.

[Chapter B14 \*Debug and Trace Components\*](#)

Read this for a description of the debug and trace component rules.

[Chapter B15 \*The Performance Monitors Extension\*](#)

Read this for a description of the Performance Monitors Extension.

[Chapter B16 \*Reliability, Availability, and Serviceability \(RAS\) Extension\*](#)

Read this for a description of the Reliability, Availability, and Serviceability (RAS) Extension.

**Part C, Armv8-M Instructions**

Part C describes the instructions. It contains the following chapters:

[Chapter C1 \*Instruction Set Overview\*](#)

Read this for an overview of the instruction set and the instruction set encoding.

[Chapter C2 \*Instruction Specification\*](#)

Read this for a description of each instruction, arranged by instruction mnemonic.

**Part D, Armv8-M Registers**

Part D describes the registers. It contains the following chapter:

[Chapter D1 \*Register and Payload Specification\*](#)

Read this for a description of the registers.

**Part E, Armv8-M Pseudocode**

Part E describes the pseudocode. It contains the following chapters:

[Chapter E1 \*Arm Pseudocode Definition\*](#)

Read this for a definition of the pseudocode that Arm documentation uses.

[Chapter E2 \*Pseudocode Specification\*](#)

Read this for a description of the pseudocode.

**Part F, Packet Protocols**

Part F describes the packet protocols. It contains the following chapter:

[Chapter F1 \*ITM and DWT Packet Protocol Specification\*](#)

Read this for a description of the protocol for packets that are used to send the data generated by the ITM and DWT to an external debugger.

# Conventions

The following sections describe conventions that this book can use:

[Typographical conventions.](#)

[Signals.](#)

[Numbers.](#)

[Pseudocode descriptions.](#)

[Assembler syntax descriptions.](#)

## Typographical conventions

The typographical conventions are:

*italic*

Introduces special terminology, and denotes citations.

**bold**

Denotes signal names, and is used for terms in descriptive lists, where appropriate.

`monospace`

Used for assembler syntax descriptions, pseudocode, and source code examples.

Also used in the main text for instruction mnemonics and for references to other items appearing in assembler syntax descriptions, pseudocode, and source code examples.

SMALLCAPS

Used for a few terms that have specific technical meanings, and that are included in the Glossary.

**Colored text** Indicates a link. This can be:

- A URL, for example <https://developer.arm.com/>.
- A cross-reference, that includes the page number of the referenced information if it is not on the current page, for example, [Chapter B2 \*Power Management\*](#).
- A link, to a chapter or appendix, or to a glossary entry, or to the section of the document that defines the colored term, for example [tail-chaining](#).

## Signals

In general this specification does not define processor signals, but it does include some signal examples and recommendations.

The signal conventions are:

**Signal level** The level of an asserted signal depends on whether the signal is active-HIGH or active-LOW. Asserted means:

- HIGH for active-HIGH signals.
- LOW for active-LOW signals.

**Lowercase n** At the start or end of a signal name denotes an active-LOW signal.

## Numbers

Numbers are normally written in decimal. Binary numbers are preceded by `0b`, and hexadecimal numbers by `0x`. In both cases, the prefix and the associated value are written in a `monospace` font, for example `0xFFFF0000`.

For both binary and hexadecimal numbers, where a bit is represented by the letter `x`, the value is irrelevant. For example a value expressed as `0b1x` can be either `0b11` or `0b10`.

To improve readability, long numbers can be written with an underscore separator between every four characters, for example `0xFFFF_0000_0000_0000`. Ignore any underscores when interpreting the value of a number.

## Pseudocode descriptions

This book uses a form of pseudocode to provide precise descriptions of the specified functionality. This pseudocode is written in a `monospace` font, and is described in [Chapter E1 \*Arm Pseudocode Definition\*](#).

## Assembler syntax descriptions

This book contains numerous syntax descriptions for assembler instructions and for components of assembler instructions. These are shown in a `monospace` font, and use the conventions described in [C1.2.5 \*Standard assembler syntax fields\*](#).

## Additional reading

This section lists relevant publications from Arm and third parties.

See <https://developer.arm.com>, for access to Arm documentation.

### Arm publications

- *Arm® Debug Interface Architecture Specification ADIv5.0 to ADIv5.2* (ARM IHI 0031).
- *Arm® Debug Interface Architecture Specification ADIv6.0* (ARM IHI 0074).
- *Arm® CoreSight™ Architecture Specification* (ARM IHI 0029).
- *Arm® Embedded Trace Macrocell Architecture Specification ETMv4.0 to ETMv4.4* (ARM IHI 0064).
- *Embedded Trace Macrocell® ETMv1.0 to ETMv3.5 Architecture Specification* (ARM IHI 0014).
- *Arm® v6-M Architecture Reference Manual* (ARM DDI 0419).
- *Arm® v7-M Architecture Reference Manual* (ARM DDI 0403).
- *Arm® Architecture Reference Manual, for A-profile architecture* (ARM DDI 0487).
- *Arm® Reliability, Availability, and Serviceability (RAS) Specification, Armv8, for the Armv8-A architecture profile* (ARM DDI587).

### Other publications

The following publications are referred to in this manual, or provide more information:

- ANSI/IEEE Std 754-1985 and ANSI/IEEE Std 754-2008, IEEE Standard for Binary Floating-Point Arithmetic. Unless otherwise indicated, references to IEEE 754 refer to either issue of the standard.

#### Note

This document does not adopt the terminology defined in the 2008 issue of the standard.

- JEP106, Standard Manufacturers Identification Code, JEDEC Solid State Technology Association.

# Feedback

Arm welcomes feedback on its documentation.

## Feedback on this book

If you have comments on the content of this book, send an e-mail to [errata@arm.com](mailto:errata@arm.com). Give:

- The title.
- The number, DDI0553B.t
- The page numbers to which your comments apply.
- The rule identifiers to which your comments apply, if applicable.
- A concise explanation of your comments.

Arm also welcomes general suggestions for additions and improvements.

### Note

Arm tests PDFs only in Adobe Acrobat and Acrobat Reader, and cannot guarantee the appearance or behavior of any document when viewed with any other PDF reader.

## Progressive Terminology Commitment

Arm values inclusive communities. Arm recognizes that we and our industry have used terms that can be offensive. Arm strives to lead the industry and to create change.

Previous issues of this document included terms that can be offensive. We have replaced these terms.

If you find offensive terms in this document, please contact [terms@arm.com](mailto:terms@arm.com).

# **Part A**

## **Armv8-M Architecture Introduction and Overview**

## Chapter A1

# Introduction

This chapter introduces the Armv8 architecture, the architecture profiles it defines, and the Armv8-M architecture profile defined by this manual. It contains the following sections:

*A1.1 Document layout and terminology.*

*A1.2 About the Armv8 architecture, and architecture profiles.*

*A1.3 The Armv8-M architecture profile.*

## A1.1 Document layout and terminology

This section describes the structure and scope of this manual. This section also describes the terminology that this manual uses. It does not constitute part of the manual, and must not be interpreted as implementation guidance.

### A1.1.1 Structure of the document

This architecture manual describes the behavior of the processing element as a set of individual rules.

Each rule is clearly identified by the letter R, followed by a random group of subscript letters that do not reflect any intended order or priority, for example R<sub>B<sub>S</sub>H<sub>J</sub></sub>. In the following example, R<sub>B<sub>S</sub>H<sub>J</sub></sub> is simply a random rule identifier that has no significance apart from uniquely identifying a rule in this manual.

Rules must not be read in isolation, and where more than one rule relating to a particular feature exists, individual rules are grouped into sections and subsections to provide the proper context. Where appropriate, these sections contain a short introduction to aid the reader.

An implementation that conforms to all the rules described in this specification constitutes an Armv8-M compliant implementation. An implementation whose behavior deviates from these rules is not compliant with the Armv8-M architecture.

Some sections contain additional information and guidance that do not constitute rules. This information and guidance is provided purely as an aid to understanding the architecture. Information statements are clearly identified by the letter I, followed by a random group of subscript letters, for example I<sub>P<sub>R</sub>T<sub>D</sub></sub>.

A line below each rule or information statement gives additional information indicating the architecture version, the extensions that are required for the rule or information statement to apply, and any other notes. Some extensions depend on the implementation of other extensions, for example [FP](#).

#### Note

Arm strongly recommends that implementers read *all* chapters and sections of this document to ensure that an implementation is compliant.

An implementation that conforms to all the rules described in this specification but chooses to ignore any additional information and guidance is compliant with the Armv8-M architecture.

In the following parts of this manual, architectural rules are not identified by a specific prefix and a random group of subscript letters:

- Parts of [Chapter B15 The Performance Monitors Extension](#).

*Applies to an implementation of the architecture Armv8.1-M onward.*

- Parts of [Part C Armv8-M Instruction Set](#).
- [Part D Armv8-M Register and Payload Specification](#).
- [Part E Armv8-M Pseudocode](#).
- [Part F Armv8-M Debug Packet Protocols](#).

### A1.1.2 Scope of the document

This manual contains only rules and information that relate specifically to the Armv8-M architecture. It does not include any information about other Arm architectures, nor does it describe similarities between Armv8-M and other architectures.

Readers must not assume that the rules provided in this specification are applicable to an Armv7-M or Armv6-M implementation, nor must they assume that the rules that are applicable to an Armv7-M or Armv6-M implementation are equally applicable to an Armv8-M implementation.

### A1.1.3 Intended audience

This manual is written for users who want to design, implement, or program an Armv8-M PE in a range of Arm-compliant implementations from simple uniprocessor implementations to complex multiprocessor systems. It does not assume familiarity with previous versions of the M-Profile architecture.

The manual provides a precise, accurate, and correct set of rules that must be followed in order for an Armv8-M implementation to be architecturally compliant. It is an explicit reference manual, and not a general introduction to, or user guide for, the Armv8-M architecture.

### A1.1.4 Terminology, phrases

This subsection identifies some standard words and phrases that are used in the Arm architecture documentation. These words and phrases have an Arm-specific definition, which is described in this section.

#### **Architecturally visible**

Something that is visible to the controlling agent. The controlling agent might be software.

#### **Arm recommends**

A particular usage that ensures consistency and usability. Following all the rules listed in this manual leads to a predictable outcome that is compliant with the architecture, but might produce an unexpected output. Adhering to a recommendation ensures that the output is as expected.

#### **Arm strongly recommends**

Something that is essentially mandatory, but that is outside the scope of the architecture described in this manual. Failing to adhere to a strong recommendation can break the system, although the PE itself remains compliant with the architecture that is described in this manual.

#### **Finite time**

An action will occur at some point in the future. Finite time does not make any statement about the time involved. However, delaying an action longer than is absolutely necessary might have an adverse impact on performance.

#### **Permitted**

Allowed behavior.

#### **Required**

Mandatory behavior.

**Support**

The implementation has implemented a particular feature.

### **A1.1.5 Terminology, Armv8-M specific terms**

For definitions of Armv8-M specific terms, see the [Glossary](#).

## A1.2 About the Armv8 architecture, and architecture profiles

Armv8-M is documented as one of a set of architecture profiles.

Arm defines three architecture profiles:

**A** Application profile:

- Supports a *Virtual Memory System Architecture* (VMSA) based on a *Memory Management Unit* (MMU).
- Supports the A64, A32, and T32 instruction sets.

**R** Real-time profile:

- Supports the AArch64 or AArch32 Execution states.
- Supports A64, or A32 and T32 instruction sets.
- Supports a *Protected Memory System Architecture* (PMSA) based on a *Memory Protection Unit* (MPU).
- Supports a VMSA.

**M** Microcontroller profile, described in this manual:

- Implements a programmers' model designed for low-latency interrupt processing, with hardware stacking of registers and support for writing interrupt handlers in high-level languages.
- Optionally implements a variant of the PMSA based on an MPU.
- Supports a variant of the T32 instruction set.

This Architecture Reference Manual describes only the Armv8-M profile.

## A1.3 The Armv8-M architecture profile

The M-Profile architecture includes:

- The opportunity to include simple pipeline designs offering leading edge system performance levels in a broad range of markets and applications.
- Highly deterministic operation:
  - Single or low cycle count execution.
  - Minimal interrupt latency, with short pipelines.
  - Capable of cacheless operation.
- Excellent targeting of C/C++ code. This aligns with the Arm programming standards in this area:
  - Exception handlers are standard C/C++ functions, entered using standard calling conventions.
- Design support for deeply embedded systems:
  - Low pincount devices.
- Support for debug and software profiling for event-driven systems.

A line below each rule or information statement indicates the architecture version, the extensions that are required for the rule or information statement to apply, and any other notes. Some extensions depend on the implementation of other extensions, for example [FP](#).

### A1.3.1 The Armv8-M instruction set

Armv8-M only supports execution of T32 instructions.

For more information about the instructions, see [Chapter C1 Instruction Set Overview](#) and Chapter C2, Instruction Specification.

### A1.3.2 Baseline implementation

The simplest Armv8.0-M implementation, without any of the optional extensions, is a Baseline implementation. The Armv8.0-M Baseline offers improvements over previous M-Profile architectures in the following areas:

- An improved *Memory Protection Unit* (MPU) model.
- Alignment with Armv8-A and Armv8-R memory types.
- Stack pointer limit checking.
- Improved support for multi-processing.
- Better alignment with C11 and C11++ standards.
- Enhanced debug capabilities.

In this architecture reference manual a Baseline implementation is referred to as an implementation without the Main Extension.

If an implementation does not include the Main Extension [CPUID.Architecture](#) reads as 0b1100.

*Applies to an implementation of the architecture Armv8.0-M onward.*

### A1.3.3 Nested Vectored Interrupt Controller

The Nested Vectored Interrupt Controller (NVIC) is used for integrated interrupt and exception handling and prioritization. Armv8-M increases the number of interrupts that can potentially be supported by the NVIC is 480 for external sources, and includes automatic vectoring and priority management, and automatic state preservation.

For more information see [Chapter B12 Nested Vectored Interrupt Controller](#).

The NVIC is always implemented.

## A1.4 Optional Extensions

### A1.4.1 CDE - The Custom Datapath Extension

The Custom Datapath Extension is an OPTIONAL feature available from the Armv8-M architecture. An implementation that includes the Custom Datapath Extension must implement all of the features that are required by the Main Extension ([M](#)), and might implement the following OPTIONAL features:

- The features that are provided by the Floating-point Extension ([FP](#)).
- The features that are provided by the Armv8.1 M Vector Extension ([MVE](#)).

Instructions that operate on the S or D register file require either [FP](#) or [MVE](#). Instructions that operate on the Q register file require [MVE](#).

For more information see [B3.37 The Custom Datapath Extension](#).

#### Note

The Custom Datapath Extension can also be referred to as Arm Custom Instructions for Armv8-M.

*Applies to an implementation of the architecture Armv8.0-M onward.*

### A1.4.2 Debug

The Armv8-M architecture introduces:

- Enhanced breakpoint and watchpoint functionality.
- Improvements to the Instrumentation Trace Macrocell (ITM).
- Comprehensive trace and self-hosted debug extensions to make embedded software easier to debug and trace.

The following OPTIONAL peripherals might be implemented:

- The Data Trace and Watchpoint Unit.
- The Embedded Trace Macrocell Unit.
- The Instrumentation Trace Macrocell Unit.
- The Flash Patch and Breakpoint Unit.
- The Trace Port Interface Unit.

Halting debug is an OPTIONAL feature that allows the debugger to halt the PE.

The Main Extension is required to generate trace packets.

Support for the Armv8-M debug architecture is indicated by [ID\\_DFR0.MProfDbg](#) reading as a nonzero value.

*Applies to an implementation of the architecture Armv8.0-M onward.*

In an Armv8.1-M implementation, the optional *Unprivileged Debug Extension* adds support for unprivileged debug.

The restrictions on access to a number of registers is relaxed to allow a debugger to write to the register when the PE is not in Debug state.

Support for the Armv8-M debug architecture is indicated by [ID\\_DFR0.UDE](#) reading as nonzero value.

*Applies to an implementation of the architecture Armv8.1-M onward.*

For more information about debug, see [Chapter B13 Debug](#) and [Chapter B14 Debug and Trace Components](#).

### A1.4.3 DSP - The Digital Signal Processing Extension.

The Digital Signal Processing Extension, DSP, is an OPTIONAL feature. The DSP adds support for [SIMD](#) instructions.

A PE that implements the DSP Extension must implement the Main Extension ([M](#)).

Support for DSP is indicated by the following:

- [ID\\_ISAR1](#) reads as 0x02212000.
- [ID\\_ISAR2](#) reads as 0x20232032.
- [ID\\_ISAR3](#) reads as 0x01111131.

*Applies to an implementation of the architecture Armv8.0-M onward.*

### A1.4.4 The DSP Debug Extension

Armv8.1-M adds OPTIONAL debug support for the DSP.

If DSPDE is implemented, halting debug must be implemented.

If [MVE](#) and [DWT-D](#) are implemented then DSPDE must be implemented.

*Applies to an implementation of the architecture Armv8.1-M onward.*

### A1.4.5 The Floating-point Extension

A PE that implements the Floating-point Extension must implement the Main Extension ([M](#)).

The Floating-point Extension supports either single-precision floating-point instructions or both single-precision and double-precision floating-point instructions.

*Applies to an implementation of the architecture Armv8.0-M onward.*

#### HP - Half-precision floating-point instructions

The Armv8.1-M architecture extends the Floating-point extension to include half-precision data types. If single-precision data types are implemented, half-precision data types must also be implemented.

*Applies to an implementation of the architecture Armv8.1-M onward.*

### A1.4.6 The Main Extension

A PE that implements the Main Extension implements the System Timer Extension.

#### Note

- A PE with the Main Extension is also referred to as a Mainline implementation.
- A PE without the Main Extension is also referred to as a Baseline implementation. A Baseline implementation has a subset of the instructions, registers, and features, of a Mainline implementation.
- Armv7-M compatibility requires the Main Extension.
- Armv6-M compatibility is provided by all Armv8-M implementations.

If an implementation supports the Main Extension [CPUID.Architecture](#) reads as 0b1111.

*Applies to an implementation of the architecture Armv8.0-M onward.*

### A1.4.7 MPU model

The Armv8-M architecture provides a system address map and permits implementations to include an OPTIONAL MPU. The optional MPU uses the Protected Memory System Architecture (PMSAv8) and contains improved flexibility in the MPU region definition.

The Armv8.1-M architecture introduces a further attribute for MPU regions, [MPU\\_RLAR.PXN](#).

*Applies to an implementation of the architecture Armv8.1-M onward.*

For further information see [Chapter B10 The Armv8-M Protected Memory System Architecture](#).

### A1.4.8 M-Profile Vector Extension, MVE

This extension provides operations on various SIMD data types.

It consists of MVE-I (integer) and MVE-F (floating-point).

A PE that implements MVE-I requires the features that are provided by the Main Extension, [\(M\)](#), and the DSP Extension [\(DSP\)](#).

A PE that implements MVE-F requires the implementation of the Floating-point Extension [\(FP\)](#), and MVE-I.

For more information see [Chapter B5 Vector Extension](#).

Support for MVE is indicated in ID\_MVFR1.MVE reading as a nonzero value.

#### Note

The Armv8-M MVE can also be referred to as Arm Helium™ for Armv8-M.

*Applies to an implementation of the architecture Armv8.1-M onward.*

### A1.4.9 Pointer Authentication and Branch Target Identification Extension

The OPTIONAL Pointer Authentication and Branch Target Identification Extension (PACBTI) for Armv8.1-M adds support for the authentication of the contents of a register before that register is used as a load or as the target of an indirect branch, and for the authentication of the stack pointers.

For more information see [Chapter B6 Pointer authentication and branch target identification Extension](#).

Support for the PACBTI extension is indicated by ID\_ISAR5.PACBTI reading as a nonzero value.

*Applies to an implementation of the architecture Armv8.1-M onward.*

### A1.4.10 Performance Monitors Extension

In an Armv8.1-M implementation, the optional *Performance Monitors Extension* adds support for a Performance Monitor Unit (PMU).

For more information see [Chapter B15 The Performance Monitors Extension](#).

Support for the Performance Monitors Extension is indicated by PMU\_TYPE.N reading as nonzero value.

*Applies to an implementation of the architecture Armv8.1-M onward.*

### A1.4.11 Reliability, Availability, and Serviceability

In an Armv8.1-M implementation, the *Reliability, Availability, and Serviceability (RAS) Extension* adds additional debug support. The minimum RAS Extension is mandatory in an Armv8.1-M implementation.

For more information see [Chapter B16 Reliability, Availability, and Serviceability \(RAS\) Extension](#).

Support for RAS is indicated by [ID\\_PFR0.RAS](#) reading as a nonzero value.

*Applies to an implementation of the architecture Armv8.1-M onward.*

### A1.4.12 Security Extension

The Armv8-M architecture introduces a number of new instructions to the M-Profile architecture to support asset protection. These instructions are only available to implementations that support the Security Extension.

From Armv8.1-M Thread mode re-entrancy can be disabled on [SG](#) instructions.

*Applies to an implementation of the architecture Armv8.1-M onward.*

In PE with the Main Extension support for the Security extension is indicated by [ID\\_PFR1.Security](#) reading as a nonzero value.

#### Note

The Armv8-M Security Extension can also be referred to as Arm TrustZone for Armv8-M.

### A1.4.13 The System Timer Extension

The System Timer Extension, also known as SysTick, provides a decrementing, wrap-on-zero, clear-on-write counter.

It is an OPTIONAL feature of a PE without the Main Extension, and it is IMPLEMENTATION DEFINED if none, one or two counters are implemented. If one timer is implemented it is shared between Security states, if the Security Extension is implemented. If two timers are implemented each Security state has a dedicated timer.

In an implementation with the Main Extension one timer is implemented per Security state.

For more information see [Chapter B11 The System Timer, SysTick](#).

[Chapter B13 Debug](#).

## Chapter B2

# Power Management

This chapter specifies the Armv8-M power management rules. It contains the following section:

[B2.1 \*Power management\*.](#)

[B2.2 \*Sleep on exit\*.](#)

## B2.1 Power management

**I<sub>HCVL</sub>** The following instructions and pseudocode functions hint to the PE hardware that it can suspend execution and enter a low-power state:

- `WaitForEvent()`.
- `WaitForInterrupt()`.
- `SleepOnExit()`.

*Applies to an implementation of the architecture Armv8.0-M onward.*

### B2.1.1 The Wait for Event (WFE) instruction

**R<sub>DCMH</sub>** When a [WFE](#) instruction is executed, if the state of the Event register is clear, the PE can suspend execution and enter a low-power state.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>HDXV</sub>** When a [WFE](#) instruction is executed, if the state of the Event register is set, the instruction clears the register and completes immediately.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>KDND</sub>** If the PE enters a low-power state on a WFE instruction, it remains in that low-power state until it receives a *WFE wakeup event*. When the PE recognizes a WFE wakeup event, the WFE instruction completes. The following are WFE wakeup events:

- The execution of a [SEV](#) instruction by any PE.
- When [SCR.SEVONPEND](#) is 1, any exception entering the pending state.
- Any exception at a priority that would preempt the current execution priority, taking into account any active exceptions and including the effects of any software-controlled priority boosting by [AIRCR.PRIS](#) == 1 and [PRIMASK](#), [FAULTMASK](#), or [BASEPRI](#).
- If debug is enabled, a debug event.
- Any IMPLEMENTATION DEFINED event.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>TRPP</sub>** When [SCR.SLEEPDEEP](#) is 1 and [SCR.SEVONPEND](#) is 1, it is IMPLEMENTATION DEFINED whether any exception entering the pending state will act as a *WFE wakeup event* and wake up the PE.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>YRDC</sub>** The Armv8-M architecture does not define the exact nature of the low-power state that is entered on an instruction, except that it does not cause a loss of [memory coherency](#).

*Applies to an implementation of the architecture Armv8.0-M onward.*

**I<sub>TZJZ</sub>** Arm recommends that software always uses the [WFI](#) instruction in a loop.

*Applies to an implementation of the architecture Armv8.0-M onward.*

## B2.1.3 The Wait for Interrupt (WFI) instruction

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| R <sub>HRMJ</sub> | When a <a href="#">WFI</a> instruction is executed, the PE can suspend execution and enter a low-power state. If it does, it remains in that state until it receives a <i>WFI wakeup event</i> . When the PE recognizes a <a href="#">WFI</a> wakeup event, the <a href="#">WFI</a> instruction completes. The following are <a href="#">WFI</a> wakeup events: <ul style="list-style-type: none"><li>• A reset.</li><li>• Any asynchronous exception at a priority that, ignoring the effect of <a href="#">PRIMASK</a> (so that behavior is as if <a href="#">PRIMASK</a> is 0), would preempt any currently active exceptions.</li><li>• An IMPLEMENTATION DEFINED <a href="#">WFI</a> wakeup event.</li><li>• If debug is enabled, a debug event.</li></ul> <i>Applies to an implementation of the architecture Armv8.0-M onward.</i> |
| I <sub>WCBD</sub> | A debug event will be a wakeup event if either: <ul style="list-style-type: none"><li>• Halting Debug is permitted for the current Security state of the PE and the PE is required to enter Debug state.</li><li>• A DebugMonitor exception is asserted and the exception has sufficient priority to preempt the current priority of the PE.</li></ul> Setting <a href="#">DEMCR.MON_PEND</a> to one is not required to cause a wakeup event.<br><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">DB</a>. Note, DebugMonitor exceptions require M.</i>                                                                                                                                                                                                                  |

Chapter B2. Power Management  
B2.1. Power management

$I_{PDKN}$  An unprivileged debug event will be a wakeup event if unprivileged debug is permitted for the current Security state and privilege mode of the PE. If unprivileged debug is not enabled the event will be pended and taken when unprivileged debug is permitted.

*Applies to an implementation of the architecture **Armv8.1-M** onward. The extension requirements are - **DB** && **UDE**.*

$I_{CGNL}$  Arm recommends that software always uses the **WFI** instruction in a loop.

*Applies to an implementation of the architecture **Armv8.0-M** onward.*

[B3.13 Priority model.](#)

[Chapter B13 Debug](#)

[WaitForInterrupt\(\)](#)

## B2.2 Sleep on exit

R<sub>JXGW</sub> It is IMPLEMENTATION DEFINED whether the [SleepOnExit \(\)](#) function causes the PE to enter a low-power state during a return from the only active exception and to Thread mode.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>BHSL</sub> The PE is permitted to enter a low-power state on return from the only active exception when all the following are true:

- [EXC\\_RETURN.Mode](#) == 1.
- [SCR.SLEEPONEXIT](#) == 1.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>WWDW</sub> If the sleep-on-exit function is enabled, it is IMPLEMENTATION DEFINED at which point in the exception return process the PE enters a low-power state.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>LLQF</sub> The wakeup events for the sleep-on-exit function are identical to the [WFI](#) instruction wakeup events.

*Applies to an implementation of the architecture Armv8.0-M onward.*

## Chapter B3

# Programmers' Model

This chapter specifies the Armv8-M programmers' model architecture rules. It contains the following sections:

- B3.1 PE modes, Thread mode and Handler mode.*
- B3.2 Privileged and unprivileged execution.*
- B3.3 Registers.*
- B3.4 Special-purpose CONTROL register.*
- B3.5 XPSR, APSR, IPSR, and EPSR.*
- B3.6 Security states: Secure state, and Non-secure state.*
- B3.7 Security states and register banking between Security states.*
- B3.8 Stack pointer.*
- B3.9 Exception numbers and exception priority numbers.*
- B3.10 Exception enable, pending, and active bits.*
- B3.11 Security states, exception banking.*
- B3.12 Faults.*
- B3.13 Priority model.*
- B3.14 Secure address protection.*
- B3.15 Security state transitions.*
- B3.16 Function calls from Secure state to Non-secure state.*
- B3.17 Function returns from Non-secure state.*

B3.18 *Exception handling.*

B3.19 *Exception entry, context stacking.*

B3.20 *Exception entry, register clearing after context stacking.*

B3.21 *Stack limit checks.*

B3.22 *Exception return.*

B3.23 *Integrity signature.*

B3.24 *Exceptions during exception entry.*

B3.25 *Exceptions during exception return.*

B3.26 *Tail-chaining.*

B3.27 *Exceptions, instruction resume, or instruction restart.*

B3.28 *Low overhead loops.*

B3.29 *Branch future.*

*Applies to an implementation of the architecture Armv8.1-M onward.*

B3.30 *Vector tables.*

B3.31 *Hardware-controlled priority escalation to HardFault.*

B3.32 *Special-purpose mask registers, PRIMASK, BASEPRI, FAULTMASK, for configurable priority boosting.*

B3.33 *Lockup.*

B3.34 *Data independent timing.*

*Applies to an implementation of the architecture Armv8.1-M onward.*

B3.35 *Context Synchronization Event.*

B3.36 *Coprocessor support.*

B3.37 *The Custom Datapath Extension.*

## B3.1 PE modes, Thread mode and Handler mode

R<sub>CNMS</sub>

There are two PE modes:

- Thread mode.
- Handler mode.

*Applies to an implementation of the architecture Armv8.0-M onward.*

I<sub>FDVT</sub>

A common usage model for the PE modes is:

- **Thread mode:** Applications.
- **Handler mode:** OS kernel and associated functions, that manage system resources.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>RPKP</sub>

The PE handles all exceptions in Handler mode.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>CMQP</sub>

Thread mode is selected on reset.

*Applies to an implementation of the architecture Armv8.0-M onward.*

See also:

[B3.2 Privileged and unprivileged execution.](#)

[B3.5.1 Interrupt Program Status Register \(IPSR\).](#)

[B3.6 Security states: Secure state, and Non-secure state.](#)

## B3.2 Privileged and unprivileged execution

R<sub>WVRK</sub>

### Thread mode

Execution can be privileged or unprivileged.

### Handler mode

Execution is always privileged.

*Applies to an implementation of the architecture Armv8.0-M onward.*

I<sub>WCFH</sub>

**CONTROL.nPRIV** determines whether execution in Thread mode is unprivileged.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>SBQF</sub>

In a PE without the Main Extension, it is IMPLEMENTATION DEFINED whether **CONTROL.nPRIV** can be set to 1.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>JSSW</sub>

Execution privilege can determine whether a resource is accessible.

*Applies to an implementation of the architecture Armv8.0-M onward.*

I<sub>GNSC</sub>

Privileged execution typically has access to more resources than unprivileged execution.

*Applies to an implementation of the architecture Armv8.0-M onward.*

[B3.1 PE modes, Thread mode and Handler mode.](#)

## B3.3 Registers

R<sub>KGST</sub>

There are the following types of registers:

### General-purpose registers, all 32-bit:

- R0-R12 (**Rn**).
- R13. This is the stack pointer (**SP**).
- R14. This is the Link Register (**LR**).

### Program Counter, 32-bit:

- R15 is the Program Counter (**PC**).

### Special-purpose registers:

- Mask Registers:
  - 1-bit exception mask register, **PRIMASK**.
  - 8-bit base priority mask register, **BASEPRI**.
  - 1-bit fault mask register, **FAULTMASK**.
- A **CONTROL** register which is:
  - 2-bit when the Floating-point Extension, MVE, the Security Extension, and the PACBTI Extension are all not implemented.
  - 3-bit when either the Floating-point Extension or MVE are implemented, but the Security Extension, and the PACBTI Extension are not implemented.
  - 4-bit when both the Security Extension and at least one of Floating-point Extension or MVE are implemented, but the PACBTI Extension is not implemented.
  - 8-bit when the PACBTI Extension is implemented.
- Two 32-bit stack pointer limit registers, **MSPLIM** and **PSPLIM**, if the Main Extension is not implemented the Non-secure versions of these registers are RAZ/WI.
- A combined 32-bit Program Status Register (**XPSR**), comprising:
  - Application Program Status Register (**APSR**).
  - Interrupt Program Status Register (**IPSR**).
  - Execution Program Status Register (**EPSR**).

### Memory-mapped registers:

All other registers.

*Applies to an implementation of the architecture Armv8.0-M onward. Note, Armv8.1-M is required for MVE and PACBTI.*

I<sub>CJWV</sub>

A 32-bit combined exception return Program Status Register, **RETPSR**, contains a payload of the saved state derived from the **XPSR**.

*Applies to an implementation of the architecture Armv8.0-M onward.*

I<sub>DHVL</sub>

Extensions might add more registers to the base register set.

*Applies to an implementation of the architecture Armv8.0-M onward.*

I<sub>BLXF</sub>

**SP** refers to the active stack pointer, the Main stack pointer or the Process stack pointer.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>PLRT</sub>

If the Main Extension is implemented, the **LR** is set to 0xFFFFFFFF on Warm reset.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **M**.*

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## B3.6 Security states: Secure state, and Non-secure state

R<sub>HKKL</sub>

A PE with the Security Extension has two Security states:

- Secure state.
  - Secure Thread mode.
  - Secure Handler mode.
- Non-secure state.
  - Non-secure Thread mode.
  - Non-secure Handler mode.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - S.*

R<sub>PBGT</sub>

If the Security Extension is implemented, memory areas and other critical resources that are marked as secure can only be accessed when the PE is executing in Secure state.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - S.*

R<sub>HWFV</sub>

A PE with the Security Extension resets into Secure state on both of the Armv8-M resets, Cold reset and Warm reset.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - S.*

R<sub>PLGH</sub>

A PE without the Security Extension resets into Non-secure state on both of the Armv8-M resets, Cold reset and Warm reset.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - !S.*

See also:

[B3.2 Privileged and unprivileged execution.](#)

[B3.7 Security states and register banking between Security states.](#)

[B3.11 Security states, exception banking.](#)

[B3.15 Security state transitions.](#)

[Chapter B5 Vector Extension.](#)

*Applies to an implementation of the architecture Armv8.1-M onward.*

## B3.7 Security states and register banking between Security states

**I<sub>MGRQ</sub>** In a PE with the Security Extension, some registers are banked between the Security states. When a register is banked in this way, there is a distinct instance of the register in Secure state and another distinct instance of the register in Non-secure state.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - S.*

**R<sub>BHDK</sub>** In a PE with the Security Extension:

- The general-purpose registers that are banked are:
  - R13. This is the stack pointer (SP).
- The special-purpose registers that are banked are:
  - The Mask registers, PRIMASK, BASEPRI, and FAULTMASK.
  - Some bits in the CONTROL register.
  - The Main and Process stack pointer Limit registers, MSPLIM and PSPLIM.
- All registers in the System Control Space (SCS) have a Non-secure alias which is only accessible from Secure state.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - S.*

**I<sub>GBWT</sub>** For MRS and MSR (register) instructions, SYSm[7] in the instruction encoding specifies whether the Secure or the Non-secure instance of a Banked register is accessed:

| Access from      | SYSm[7]             |                     |
|------------------|---------------------|---------------------|
|                  | 0                   | 1                   |
| Secure state     | Secure instance     | Non-secure instance |
| Non-secure state | Non-secure instance | RAZ/WI              |

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - S.*

**R<sub>ZJKL</sub>** This specification uses the following naming convention to identify a Banked register:

- <register name>\_S: The Secure instance of the register.
- <register name>\_NS: The Non-secure instance of the register.
- <register name>: The instance that is associated with the current Security state.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - S.*

See also:

[B3.3 Registers.](#)

[B3.6 Security states: Secure state, and Non-secure state.](#)

[B3.8 Stack pointer.](#)

[B8.3 The System Control Space \(SCS\).](#)

## B3.8 Stack pointer

**R<sub>RDLR</sub>** In a PE with the Security Extension, four stacks and four stack pointer registers are implemented:

| Stack      | Stack pointer register |        |
|------------|------------------------|--------|
| Secure     | Main                   | MSP_S  |
|            | Process                | PSP_S  |
| Non-secure | Main                   | MSP_NS |
|            | Process                | PSP_NS |

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - **S**.

**R<sub>TGHV</sub>** In a PE without the Security Extension, two stacks and two stack pointer registers are implemented:

| Stack   | Stack pointer register |
|---------|------------------------|
| Main    | MSP                    |
| Process | PSP                    |

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - **!S**.

**R<sub>LDGJ</sub>** On exception return the Armv8-M architecture only supports doubleword aligned stack pointers.

Applies to an implementation of the architecture *Armv8.0-M* onward.

**R<sub>XKZV</sub>** If, on exception return, the stack pointers are not doubleword aligned, the CONSTRAINED UNPREDICTABLE behavior is either:

- Treating the stack pointer as the actual value.
- Treating the stack pointer as if it were aligned.

Applies to an implementation of the architecture *Armv8.0-M* onward.

**R<sub>TXRW</sub>** In Handler mode, the PE uses the main stack.

Applies to an implementation of the architecture *Armv8.0-M* onward.

**I<sub>DMLS</sub>** In Thread mode, **CONTROL.SPSEL** determines whether the PE uses the main or process stack.

Applies to an implementation of the architecture *Armv8.0-M* onward.

**R<sub>BTVD</sub>** In a PE without the Security Extension, MSP is selected and initialized on reset.

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - **!S**.

**R<sub>MDXK</sub>** In a PE with the Security Extension, the Secure main stack, MSP\_S, is selected and initialized on reset.

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - **S**.

**I<sub>LVWN</sub>** On Warm reset, the selected Stack Pointer either the MSP or MSP\_S, is set to the value contained in the Vector table, as described in **TakeReset ()**.

Applies to an implementation of the architecture *Armv8.0-M* onward. Note, **S** is required for MSP\_S.

**R<sub>XPWM</sub>** Bits [1:0] of the MSP or PSP, in either Security state, are **RES0H**, so that all stack pointers are always guaranteed to be word-aligned.

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - **S**.

**R<sub>MQVJ</sub>** Where an instruction states that the **SP** is UNPREDICTABLE and **SP** is used:

- The value that is read or written from or to the **SP** is UNKNOWN.
- The instruction is permitted to be treated as UNDEFINED.

- If the [SP](#) is being written, it is UNKNOWN whether a stack limit check is applied.

*Applies to an implementation of the architecture **Armv8.0-M** onward.*

R<sub>JXJM</sub>

After the successful completion of an exception entry stacking operation, the stack pointer of the stack pushed because of the exception entry is doubleword-aligned.

*Applies to an implementation of the architecture **Armv8.0-M** onward.*

I<sub>PWRQ</sub>

Arm recommends that the Secure stacks be located in Secure memory.

*Applies to an implementation of the architecture **Armv8.0-M** onward. The extension requirements are - [S](#).*

## B3.9 Exception numbers and exception priority numbers

I<sub>DCJS</sub> Each exception has an associated *exception number* and an associated *priority number*.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>CMTc</sub> In a PE with the Main Extension, the exceptions, their associated numbers, and their associated priority numbers are as follows:

| Exception                                                   | Exception Number | Priority Number       |
|-------------------------------------------------------------|------------------|-----------------------|
| Reset                                                       | 1                | -4 (Highest Priority) |
| Secure HardFault when <a href="#">AIRC.R.BFHFNMINs</a> is 1 | 3                | -3                    |
| NMI                                                         | 2                | -2                    |
| Secure HardFault when <a href="#">AIRC.R.BFHFNMINs</a> is 0 | 3                | -1                    |
| Non-secure HardFault                                        | 3                | -1                    |
| MemManage fault                                             | 4                | Configurable          |

| -                                                           | -                | -                     |
| -                                                           | -                | -                     |
| -                                                           | -                | -                     |
| External interrupt N                                        | 16+N             | Configurable          |

When [AIRC.R.BFHFNMINs](#) is 1, faults that target Secure state that are escalated to HardFault are still Secure HardFaults. That is, the value of [AIRC.R.BFHFNMINs](#) does not affect faults that target Secure state that are escalated to HardFaults. This table row applies to such faults.

If the Security Extension is not implemented exception 7 is reserved.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are -M. Note, S is required for Secure faults.*

R<sub>MGNV</sub>

In a PE without the Main Extension, the exceptions, their associated numbers, and their associated priority numbers are as follows:

| Exception                                                   | Exception Number | Priority Number       |
|-------------------------------------------------------------|------------------|-----------------------|
| Reset                                                       | 1                | -4 (Highest Priority) |
| Secure HardFault when <a href="#">AIRC.R.BFHFNMINS</a> is 1 | 3                | -3                    |
| NMI                                                         | 2                | -2                    |
| Secure HardFault when <a href="#">AIRC.R.BFHFNMINS</a> is 0 | 3                | -1                    |
| Non-secure HardFault                                        | 3                | -1                    |
| Reserved                                                    | 4-10             | -                     |
| SVCall                                                      | 11               | Configurable          |
| Reserved                                                    | 12-13            | -                     |
| PendSV                                                      | 14               | Configurable          |
| SysTick                                                     | 15               | Configurable          |
| External Interrupt 0                                        | 16               | Configurable          |
| -                                                           | -                | -                     |
| -                                                           | -                | -                     |
| -                                                           | -                | -                     |
| External interrupt N                                        | 16+N             | Configurable          |

When [AIRC.R.BFHFNMINS](#) is 1, faults that target Secure state that are escalated to HardFault are still Secure HardFaults. That is, the value of [AIRC.R.BFHFNMINS](#) does not affect faults that target Secure state that are escalated to HardFaults. This table row applies to such faults.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - !M. Note, S is required for Secure faults. ST is required for SysTick fault.*

I<sub>FPJD</sub>

The maximum supported number of external interrupts is 496, regardless of whether the Main Extension is implemented.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>QQT</sub>

The architecture permits an implementation to omit external configurable interrupts where no external device is connected to the corresponding interrupt pin. Where an implementation omits such an interrupt, the corresponding pending, active, enable, and priority registers are RES0.

*Applies to an implementation of the architecture Armv8.0-M onward.*

I<sub>QWTM</sub>

In a PE with the Main Extension, the following exceptions with configurable priority numbers can be configured with [SHPR1](#)-[SHPR3](#) in the System Control Block (SCB):

- MemManage Fault.
- BusFault.
- UsageFault.
- SecureFault (if the Security Extension is implemented).
- SVCall.
- DebugMonitor exception.
- PendSV.
- SysTick.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - M.*

**I<sub>SGBC</sub>** In a PE without the Main Extension the following exceptions with configurable priority numbers can be configured with [SHPR2](#) and [SHPR3](#) in the System Control Block (SCB):

- SVCall.
- PendSV.
- SysTick.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - !M.*

**I<sub>JQPH</sub>** All other configurable exceptions can be configured using the [NVIC\\_IPRn.PRI\\_<n>](#) register fields.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>NFSM</sub>** Configurable priority numbers start at 0, the highest configurable exception priority number.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>GGCP</sub>** In a PE with the Main Extension, the number of configurable priority numbers is an IMPLEMENTATION DEFINED power of two in the range 8-256:

| Number of priority bits of SHPRIn.PRI_n implemented | Number of configurable Priority numbers | Minimum Priority Number (highest priority) | Maximum Priority Number (lowest priority) |
|-----------------------------------------------------|-----------------------------------------|--------------------------------------------|-------------------------------------------|
| 3                                                   | 8                                       | 0                                          | 0b11100000 = 224                          |
| 4                                                   | 16                                      | 0                                          | 0b11110000 = 240                          |
| 5                                                   | 32                                      | 0                                          | 0b11111000 = 248                          |
| 6                                                   | 64                                      | 0                                          | 0b11111100 = 252                          |
| 7                                                   | 128                                     | 0                                          | 0b11111110 = 254                          |
| 8                                                   | 256                                     | 0                                          | 0b11111111 = 255                          |

All low-order bits of SHPRIn.PRI\_n that are not implemented as priority bits are RES0, as shown in the maximum priority number column.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - M.*

**R<sub>CMGH</sub>** In a PE without the Main Extension, the number of configurable priority numbers is 4:

| Number of priority bits of SHPRIn.PRI_n implemented | Number of configurable Priority numbers | Minimum Priority Number (highest priority) | Maximum Priority Number (lowest priority) |
|-----------------------------------------------------|-----------------------------------------|--------------------------------------------|-------------------------------------------|
| 2                                                   | 4                                       | 0                                          | 0b11000000 = 192                          |

SHPRn.PRI\_n[5:0] are RES0, as shown in the maximum priority number column.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - !M.*

## B3.10 Exception enable, pending, and active bits

$I_{QDQ}$  The [SHCSR](#), [ICSR](#), [DEMCR](#), [NVIC\\_IABRn](#), [NVIC\\_ISPRn](#) contain exception enable, pending, and active fields. [STIR](#) can be used to pend exceptions.

*Applies to an implementation of the architecture Armv8.0-M onward.*

$I_{GHGW}$  The following exceptions are always enabled and therefore do not have an exception enable bit:

- Secure HardFault or Non-secure HardFault if the Security Extension is not implemented.
- NMI.
- SVCall.
- PendSV.

*Applies to an implementation of the architecture Armv8.0-M onward. Note, S is required for Secure HardFault.*

$I_{LHSX}$  In a PE without the Security Extension:

- Privileged execution can pend interrupts by writing to the [NVIC\\_ISPRn](#).
- When [CCR.USERSETMPEND](#) is 1, unprivileged execution can pend interrupts by writing to the [STIR](#).

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - !S.*

$I_{QDKX}$  In a PE with the Security Extension:

- The [STIR](#) can pend any Secure or Non-secure interrupt, as follows:

|                        | Secure state                                                                                                                                                                                           | Non-secure state                                                                                                                                                                              |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Privileged execution   | Can use <a href="#">STIR</a> to pend any Secure or Non-secure interrupt.                                                                                                                               | Can use <a href="#">STIR</a> to pend a Non-secure interrupt.                                                                                                                                  |
| Unprivileged execution | When <a href="#">CCR_S.USERSETMPEND</a> is 1, can use <a href="#">STIR</a> to pend any Secure or Non-secure interrupt, otherwise when <a href="#">CCR_S.USERSETMPEND</a> is 0 a BusFault is generated. | When <a href="#">CCR_NS.USERSETMPEND</a> is 1 can use <a href="#">STIR</a> to pend any Non-secure interrupt, otherwise when <a href="#">CCR_NS.USERSETMPEND</a> is 0 a BusFault is generated. |

- The [STIR\\_NS](#) can pend a Non-secure interrupt, as follows:

|              | Secure state                                                                                                                                                                                    | Non-secure state |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| Privileged   | Can use <a href="#">STIR_NS</a> to pend a Non-secure interrupt.                                                                                                                                 | RES0             |
| Unprivileged | When <a href="#">CCR_NS.USERSETMPEND</a> is 1, can use <a href="#">STIR_NS</a> to pend a Non-secure interrupt, otherwise when <a href="#">CCR_NS.USERSETMPEND</a> is 0 a BusFault is generated. | BusFault         |

- The [NVIC\\_ISPRn](#) can pend any Secure or Non-secure interrupt, as follows:

|                        | Secure state                                                                  | Non-secure state                                                  |
|------------------------|-------------------------------------------------------------------------------|-------------------------------------------------------------------|
| Privileged execution   | Can use <a href="#">NVIC_ISPRn</a> to pend any Secure or Non-secure interrupt | Can use <a href="#">NVIC_ISPRn</a> to pend a Non-secure interrupt |
| Unprivileged execution | BusFault                                                                      | BusFault                                                          |

- The [NVIC\\_ISPRn\\_NS](#) can pend a Non-secure interrupt, as follows:

|                        | Secure state                                                         | Non-secure state |
|------------------------|----------------------------------------------------------------------|------------------|
| Privileged execution   | Can use <a href="#">NVIC_ISPRn_NS</a> to pend a Non-secure interrupt | RES0             |
| Unprivileged execution | BusFault                                                             | BusFault         |

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - [S](#).

The following table identifies the fault enable, status and active bits:

| Fault, Enable<br>( <a href="#">SHCSR</a> ) and Trap Bits | Status bit                                                                                                                                                                                      | Pending bit<br><a href="#">SHCSR</a> , <a href="#">ICSR</a> | Active bit<br><a href="#">SHCSR</a> |

Applies to an implementation of the architecture *Armv8.0-M* onward.

## B3.11 Security states, exception banking

R<sub>PJHV</sub>

Some exceptions are banked. A banked exception has all the following:

- Banked enabled, pending, and active bits.
- A banked [SHPRn.PRI](#) field.
- A banked exception vector.
- A state relevant handler.

| Exception            | Banked              |
|----------------------|---------------------|
| Reset                | No                  |
| HardFault            | Yes (conditionally) |
| NMI                  | No                  |
| MemManage fault      | Yes                 |
| BusFault             | No                  |
| UsageFault           | Yes                 |
| SecureFault          | No                  |
| SVCall               | Yes                 |
| DebugMonitor         | No                  |
| PendSV               | Yes                 |
| SysTick              | Yes                 |
| External interrupt 0 | No                  |
| -                    | -                   |
| -                    | -                   |
| -                    | -                   |
| External interrupt N | No                  |

MemManage Fault, UsageFault, BusFault and the DebugMonitor exception require the Main Extension to be implemented. SecureFault requires the Security Extension to be implemented.

The SysTick exception is banked if the Main Extension is implemented. If the Main Extension is not implemented, it is IMPLEMENTATION DEFINED if the exception is banked or if there is a single instance that has a configurable target Security state.

*Applies to an implementation of the architecture Armv8.0-M onward. Note, some exceptions require M, S, DebugMonitor exception or ST.*

R<sub>LNWV</sub>

A banked synchronous exception targets the Security state that it is taken from, except for the following cases:

- When accessing a coprocessor that is disabled only by the [NSACR](#), any NOCP UsageFault that is generated as a result of that access will target Secure state, even though the PE was executing in Non-secure state.
- When accessing a coprocessor that is disabled only by the [CPPWR](#), any NOCP UsageFault that is generated as a result of that access will target the Secure state if the corresponding [CPPWR.SUSm](#) bit is set to 1, otherwise the NOCP UsageFault will target the current Security state.
- If an instruction triggers lazy floating-point state preservation, then the banked exception will be raised as if the current Security state was the same as that of the floating-point state, as indicated by [FPCCR.S](#).
- Banked faults and exceptions which arise from instruction fetch will target the Security state associated with

the instruction address instead of the current Security state.

- Where Non-secure HardFault is enabled, because [AIRCR.BFHFNMINS](#) is set to 1, the following applies:
  - HardFault exceptions generated through escalation will target the Security state of the original exception before its escalation to HardFault.
  - A HardFault generated as a result of a failed vector fetch will target the Security state of the exception raised during the failed vector fetch and not the current Security state.
- Faults triggered by the stacking of callee registers always target the Secure state.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [S](#). Note, a UsageFault requires M, Floating-point state requires FP.*

**R<sub>GVP</sub>** If [AIRCR.BFHFNMINS](#) == 0, then all Non-secure HardFaults are escalated to Secure HardFaults, and Non-secure pending bits behave as zero for everything except explicit reads and writes.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>WLGH</sub>** Where an implementation has two SysTick timers, one in each Security state, each timer targets its owning Security state and not the current Execution state of the PE.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [S](#) && [ST](#).*

**I<sub>DDKC</sub>** NMI can be configured to target either Security state, by using [AIRCR.BFHFNMINS](#).

*Applies to an implementation of the architecture Armv8.0-M onward.*

**I<sub>HGFM</sub>** BusFault can be configured to target either Security state, by using [AIRCR.BFHFNMINS](#).

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>MQWN</sub>** SecureFault always targets Secure state.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [S](#).*

**I<sub>WSSL</sub>** The DebugMonitor exception targets Secure state if the status bit [DEMCR.SDME](#) is 1. Otherwise, it targets Non-secure state.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**I<sub>DQLX</sub>** Each external interrupt, 0-N, targets the Security state that its [NVIC\\_ITNSn](#)[bit number] dictates.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>HXRW</sub>** When <exception> targets Secure state, the Non-secure view of its priority field, any enabled, pending, and active bits, are RAZ/WI.

<exception> is one of:

- NMI.
- BusFault.
- DebugMonitor.
- External interrupt N.
- In a PE without the Main Extension, and a single instance of the SysTick Timer, SysTick.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [S](#). Note, a BusFault exception requires M, a DebugMonitor exception requires DebugMonitor exception.*

**I<sub>QRDM</sub>** Secure software must ensure that when changing the target Security state of an exception, the exception is not pending or active. A change to the Security state of an exception when the exception is pending or active might lead to UNPREDICTABLE behavior.

*Applies to an implementation of the architecture Armv8.0-M onward. Note, S.*

## B3.12 Faults

I<sub>NHTB</sub>

There are the following Fault Status Registers:

- HardFault Status Register **HFSR**. Present only if the Main Extension is implemented.
- MemManage Fault Status Register **MMFSR**. Present only if the Main Extension is implemented.
- BusFault Status Register **BFSR**. Present only if the Main Extension is implemented.
- UsageFault Status Register **UFSR**. Present only if the Main Extension is implemented.
- SecureFault Status Register **SFSR**. Present only if the Main Extension is implemented.
- Debug Fault Status Register **DFSR**. Present only if Halting debug or the Main Extension is implemented.
- Auxiliary Fault Status Register **AFSR**. The contents of this register are IMPLEMENTATION DEFINED.
- RAS Fault Status Register **RFSR**.

In a PE with the Main Extension, the **BFSR**, **MMFSR**, and **UFSR** combine to form one register, called the Configurable Fault Status Register (**CFSR**).

There are the following Fault Address Registers:

- MemManage Fault Address Register (**MMFAR**). Present only if the Main Extension is implemented.
- BusFault Address Register (**BFAR**). Present only if the Main Extension is implemented.
- SecureFault Address Register (**SFAR**). Present only if the Main Extension is implemented.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **M** && **RAS**. Note, RAS is present only in the Armv8.1-M architecture.*

R<sub>XMRH</sub>

Unless otherwise stated, **MMFAR** is updated only for a MemManage fault on a direct data access.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **M**.*

R<sub>DDJJ</sub>

Unless otherwise stated, **BFAR** is updated only for a BusFault on a data access, a precise fault.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **M**.*

R<sub>BFFR</sub>

Unless otherwise stated, **SFAR** is updated only for a SecureFault on a memory access that caused a Security Attribution Unit violation.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **M** && **S**.*

R<sub>FLDT</sub>

Each fault address register has an associated valid bit. When the PE updates the fault address register, the PE sets the valid bit to 1.

| Fault address register | Valid bit              |
|------------------------|------------------------|
| <b>MMFAR</b>           | <b>MMFSR.MMARVALID</b> |
| <b>BFAR</b>            | <b>BFSR.BFARVALID</b>  |
| <b>SFAR</b>            | <b>SFSR.SFARVALID</b>  |

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **M**.*

R<sub>TSCP</sub>

If a fault occurs that would otherwise set a FAR valid bit to 1, which has already been set by an earlier fault it is IMPLEMENTATION DEFINED whether:

- The FAR register is updated with the new syndrome.
- The FAR register retains the syndrome of the original fault.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>TSCP</sub>

If the Security Extension is not implemented, it is IMPLEMENTATION DEFINED whether separate **BFAR** and **MMFAR** are implemented. If one shared fault address register is implemented, then on a fault that would otherwise update the shared fault address register, if one of the other valid bits is set to 1, it is IMPLEMENTATION DEFINED whether:

- The shared fault address register is updated, the valid bit for the fault is set, and the other valid bit is cleared.
- The shared fault address register is not updated, and the valid bits are not changed.

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - *M* && *!S*.

R<sub>XPWN</sub>

If the Security Extension is implemented, it is IMPLEMENTATION DEFINED whether separate fault address registers for each fault are implemented. If one shared fault address register per Security state is implemented, then on a fault that would otherwise update the shared fault address register, if one of the other FAR valid bits for the same Security state is set to 1, it is IMPLEMENTATION DEFINED whether:

- The shared fault address register is updated, the valid bit for the fault is set, and the other valid bit is cleared.
- The shared fault address register is not updated, and the valid bits are not changed.

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - *M* && *S*.

I<sub>LQFZ</sub>

**AIRCR.BFHFNMINs** dictates which shared fault registers are used depending on the Security state:

- In Secure state, the fault registers that might be shared are **SFAR** and **MMFAR\_S**, and when **AIRCR.BFHFNMINs** is 0, **BFAR**.
- In Non-secure state, the fault registers that might be shared are **MMFAR\_NS** and when **AIRCR.BFHFNMINs** is 1, **BFAR**.

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - *M* && *S*.

I<sub>DGDG</sub>

For example in an implementation that contains a shared Fault Address Register, the shared fault register might be written to with the address of the memory location being accessed that caused a BusFault fault, and **BFSR.BFARVALID** is set to 1. If the **BFSR.BFARVALID** is still set when a MemManage fault subsequently occurs that might update the shared fault address register it is an IMPLEMENTATION DEFINED choice between:

- The shared fault address register being updated with the syndrome that caused the MemManage fault, the **BFSR.BFARVALID** being cleared and **MMFSR.MMARVALID** for the MemManage fault being set.
- The address of the memory location that caused the BusFault is retained and the fault address information generated by the MemManage fault is discarded without clearing **BFSR.BFARVALID** or updating **MMFSR.MMARVALID** for the MemManage fault.

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - *M* && *!S*.

I<sub>NSSB</sub>

If a Secure MemManage fault occurs that targets Secure state, as described by **ExceptionTargetsSecure()**, the Secure shared fault register is written to with the address of the memory location that caused the MemManage fault, and **MMFSR\_S.MMARVALID** is set to 1. If the **MMFSR\_S.MMARVALID** is still set when a SecureFault subsequently occurs it is an IMPLEMENTATION DEFINED choice between:

- The shared fault address register being updated with the address of the memory location that that caused the SecureFault, **MMFSR\_S.MMARVALID** being cleared and **SFSR.SFARVALID** being set.
- The address of the memory location that caused the MemManageFault is retained and the fault address information generated by the SecureFault is discarded without out clearing **MMFSR\_S.MMARVALID** or updating **SFSR.SFARVALID**.

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - *M* && *S*.

I<sub>SMVQ</sub>

Arm strongly recommends that if a separate **BFAR** is implemented, the associated **BFAR** and **BFSR.BFARVALID** bit is cleared when changing **AIRCR.BFHFNMINs** so as not to expose the last accessed address to Non-secure state.

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - *M* && *S*.

I<sub>LRNV</sub>

When the Security extension is implemented:

- If **AIRCR.BFHFNMINs** is 0 a read of **BFAR\_NS** will return 0.
- If **AIRCR.BFHFNMINs** is 1 a read of **BFAR\_NS** and **BFAR\_S** might return the same value. This behavior cannot be relied on if there is a change to **AIRCR.BFHFNMINs** between the reads of **BFAR** in different Security states.

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - *M* && *S*.

R<sub>KJPM</sub>

In a PE with the Main Extension, the faults are:

| Exception Number | Exception       |                                                                                                                                                                                                                           | Fault Status Bit                 |
|------------------|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------|
| 3                | HardFault       | HardFault on Vector table entry read error                                                                                                                                                                                | <a href="#">HFSR.VECTTBL</a>     |
|                  |                 | HardFault on fault escalation                                                                                                                                                                                             | <a href="#">HFSR.FORCED</a>      |

|                  | SecureFault, attribution unit violation                                                                                             | <a href="#">SFSR.AUVIOL</a>    |
|                  | SecureFault, invalid transition from Secure state                                                                                   | <a href="#">SFSR.INVTRAN</a>   |
|                  | SecureFault, lazy Floating-point context preservation error                                                                         | <a href="#">SFSR.LSPERR</a>    |
|                  | SecureFault, lazy Floating-point context error                                                                                      | <a href="#">SFSR.LSERR</a>     |

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **M**. Note, Secure Faults require S, EPSR.ECI requires MVE & Armv8.1-M.*

**R<sub>XVNN</sub>** Exception vector reads use the default system address map.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>LLRP</sub>** In an Armv8.1-M implementation when a HardFault is generated as a result of a read of the Vector table [HFSR.FORCED](#) is not set. In an Armv8.0-M implementation it is IMPLEMENTATION DEFINED whether a HardFault generated as a result of Vector table read sets [HFSR.FORCED](#).

*Applies to an implementation of the architecture Armv8.1-M onward.*

**I<sub>XJQC</sub>** RAS faults can generate BusFaults, and these are recorded in [RFSR](#).

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **RAS**.*

$I_{NKHG}$  In a PE without the Main Extension, the enable, pending, and active bits in [SHCSR](#) are RES0 for those faults that are only included in a PE with the Main Extension.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [M](#).*

$R_{WHBK}$  In a PE without the Main Extension, the faults are:

| Exception number | Exception |
|------------------|-----------|
| 3                | HardFault |

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [M](#).*

$R_{FQJV}$  Fault conditions that would generate a SecureFault in a PE with the Main Extension instead generate a Secure HardFault in a PE without the Main Extension.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [S](#).*

$I_{CCXG}$  For the exact circumstances under which each of the Armv8-M faults is generated, see the appropriate Fault Status Register description.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [M](#).*

## B3.13 Priority model

I<sub>CTFJ</sub>

An exception, other than reset, has the following possible states:

**Active:**

An exception that either:

- Is being handled.
- Was being handled. The handler was preempted by a handler for a higher priority exception.

**Pending:**

An exception that has been generated, but that is not active.

**Inactive:**

The exception has not been generated.

**Active and pending:**

One instance of the exception is active, and a second instance of the exception is pending. Only asynchronous exceptions can be active and pending. Synchronous exceptions are either inactive, pending, or active.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>CJDM</sub>

Lower priority numbers take precedence over higher priority numbers.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>HLJC</sub>

When no exception is active and no priority boosting is active, the instruction stream that is executing has a priority number of (maximum supported priority number+1). The instruction stream that is executing can be interrupted by an exception with sufficient priority.

If any exceptions are active the current execution priority is determined by:

1. In a PE with the Main Extension, the calculation of the effect of [AIRCR.PRIGROUP](#) on the comparison of BASEPRI to the [SHPRn.PRI](#) and [NVIC\\_IPRn](#) values.
2. In a PE with or without the Main Extension applying the effects of [PRIMASK.PM](#) and [AIRCR.PRIS](#).
3. In a PE with the Main Extension applying the effects of [FAULTMASK.FM](#).
4. The execution priority is the either:
  - The exception with the lowest priority number.
  - The exception with the lowest priority group value.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>RKCQ</sub>

Execution at a particular priority can only be preempted by an exception with a lower group priority value.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>LLCX</sub>

In thread mode, when there are no active exceptions and no priority boosting is enabled, the execution priority is 256.

*Applies to an implementation of the architecture Armv8.0-M onward.*

I<sub>DPSP</sub>

In a PE with the Main Extension, [BASEPRI](#) and each [SHPRn.PRI\\_n](#) and [NVIC\\_IPRn.PRI\\_Nn](#) are 8-bit fields that [AIRCR.PRIGROUP](#) splits into two fields, a group priority field and a subpriority field:

| BASEPRI, SHPRn.PRI_n [7:0], and NVIC_IPRn.PRI_Nn [7:0] |                      |                   |
|--------------------------------------------------------|----------------------|-------------------|
| AIRCR.PRIGROUP value                                   | Group priority field | Subpriority field |
| 0                                                      | [7:1]                | [0]               |
| 1                                                      | [7:2]                | [1:0]             |
| 2                                                      | [7:3]                | [2:0]             |
| 3                                                      | [7:4]                | [3:0]             |
| 4                                                      | [7:5]                | [4:0]             |
| 5                                                      | [7:6]                | [5:0]             |
| 6                                                      | [7]                  | [6:0]             |
| 7                                                      | -                    | [7:0]             |

In a PE without the Main Extension, AIRCR.PRIGROUP is RES0, therefore each SHPR.PRI\_n and NVIC\_IPRn.PRI\_Nn is split into two as follows:

| AIRCR.PRIGROUP SHPRn.PRI_n [7:0], and NVIC_IPRn.PRI_Nn [7:0] |                      |                   |
|--------------------------------------------------------------|----------------------|-------------------|
|                                                              | Group priority field | Subpriority field |
| RES0                                                         | [7:1]                | [0]               |

SHPRn.PRI\_n[5:0] are RES0 in a PE without the Main Extension.

All low order bits of BASEPRI, SHPRn.PRI, and NVIC\_IPRn are not implemented as priority bits are RES0.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R\_WQWK

When AIRCR.PRIS is 1, each Non-secure SHPRn\_NS.PRI\_n priority field value [7:0] has the following sequence applied to it, it:

1. Is divided by two.
2. The constant 0x80 is then added to it.

This is equivalent to the priority field value  $\text{output\_pri} = \text{'1':input\_pri}[7:1]$  and the priority comparisons are done on the effective field value after the division by 2 + 0x80 has been performed.

This maps the Non-secure SHPRn\_NS.PRI\_n group priority field values to the bottom half of the priority range. When this sequence is applied, any effects of AIRCR.PRIGROUP have already been taken into account, so the subpriority field is dropped and the sequence is only applied to the group priority field.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - S. Note, Subpriority requires M.*

R\_CQRV

After applying AIRCR.PRIS:

- If there are multiple pending exceptions, the pending exception with the lowest group priority field value takes precedence.
- If multiple pending exceptions have the same group priority field value, the pending exception with the lowest subpriority field value takes precedence.
- If multiple pending exceptions have the same group priority field value and the same subpriority field value, the pending exception with the lowest exception number takes precedence.
- If a pending Secure exception and a pending Non-secure exception both have the same group priority field value, the same subpriority field value, and the same exception number, the Secure exception takes precedence.

*Applies to an implementation of the architecture Armv8.0-M onward. Note, a Secure exception requires S.*

$R_{KNHG}$  If there are multiple pending exceptions it is IMPLEMENTATION DEFINED whether the [AIRCR.PRIGROUP](#) mask is applied to:

- The active tree only.
- The active tree and the pending tree.

*Applies to an implementation of the architecture Armv8.0-M onward.*

$I_{NCDS}$  The following is an example of exceptions with different priorities:

This example considers the following exceptions, that all have configurable priority numbers:

- A has the highest priority.
- B has medium priority.
- C has lowest priority.

Example sequence of events:

1. No exception is active and no priority boosting is active.
2. B is generated. The PE takes exception B and starts executing the handler for it. Exception B is now active and the current execution priority is that of B.
3. A is generated. A is higher priority, therefore A preempts B, and the PE starts executing the handler for A. Exception A is now active and the current execution priority is that of A. Exception B remains active.
4. C is generated. C has the lowest priority, therefore it is pending.
5. The PE reduces the priority of A to a priority that is lower than C. B is now the highest priority active exception, therefore the execution priority moves to that of B. The PE continues executing the handler for A at the priority of B. After completing A, the PE restarts the handler for B. After completing B, the PE takes exception C and starts executing the handler for it. C is now active and the current execution priority is that of C.

*Applies to an implementation of the architecture Armv8.0-M onward.*

$I_{XFEVH}$  The following diagram shows an example. In this example, all 8 bits of [SHPRn\\_NS.PRI\\_n](#) are implemented as priority bits and [AIRCR.PRIGROUP\\_NS](#) is set to 0.

In this example, the mapping is:

| SHPRn_NS.PRI_n value | Mapped to |
|----------------------|-----------|
| 0x00                 | 0x80      |
| 0x02                 | 0x81      |
| 0x04                 | 0x82      |
| 0x06                 | 0x83      |
| .                    | .         |
| .                    | .         |
| .                    | .         |
| 0xFE                 | 0xFF      |

In this example, Secure exceptions in the range 0x00-0x7F have priority over all Non-secure exceptions.

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - **M** & **S**.

I\_WPCP

In a PE without the Main Extension but with the Security Extension, when **AIRCR.PRIS** is set to 1 the Non-secure exception is mapped to the lower half of the priority range, as shown in the table:

| Non-secure group priority value | Mapped to |
|---------------------------------|-----------|
| 0x00                            | 0x80      |
| 0x40                            | 0xA0      |
| 0x80                            | 0xC0      |
| 0xC0                            | 0xE0      |

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - **S** & **!M**.

[ComparePriorities\(\)](#).

[RawExecutionPriority\(\)](#).

## B3.14 Secure address protection

$R_{CHJX}$  *NS-Req* defines the Security state that the PE or DAP requests that a memory access is performed in.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - S.*

$R_{MSNJ}$  *NS-Attr* marks a memory access as Secure or Non-secure.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - S.*

$R_{VHRL}$  For PE data accesses, *NS-Req* is equal to the current Security state.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - S.*

$R_{XSPQ}$  For PE and DAP data accesses, *NS-Attr* is determined as follows:

| NS-Req     | Security attribute of the location being accessed | NS-Attr    |
|------------|---------------------------------------------------|------------|
| Non-secure | Non-secure                                        | Non-secure |
|            | Secure                                            | N/a        |
| Secure     | Non-secure                                        | Non-secure |
|            | Secure                                            | Secure     |

If the *NS-Req* is Non-secure and the Security attribute of the location being accessed is Secure *NS-Attr* is not generated and an AUVIOL or INVEP exception is generated.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - S.*

$R_{GBLK}$  For instruction fetches *NS-Attr* is the Security state associated with the location being accessed. Instruction fetches never generate AUVIOL SecureFaults.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - S.*

[B10.2 Security attribution.](#)

## B3.15 Security state transitions

R<sub>PQHT</sub>

For a transition to an address in the other Security state, the following table shows when the PE changes Security state:

| Current Security state | Security attribute of the branch target address | Conditions for a change in Security state                                                                                                                                                                                                                                                                      |
|------------------------|-------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Secure                 | X                                               | Change to Non-secure state if the branch was an <i>interstating branch</i> instruction, <a href="#">BXNS</a> or <a href="#">BLXNS</a> , with the least significant bit of its target address set to 0.                                                                                                         |
| Non-secure             | Secure and Non-secure callable                  | Change to the Secure state if both: <ul style="list-style-type: none"> <li>- The branch target address contains an <a href="#">SG</a> instruction which is fetched and executed.</li> <li>- The whole of the instruction at the branch target address is flagged as Secure and Non-secure callable.</li> </ul> |

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [S](#).*

R<sub>HPPQ</sub>

The PE will transition from Non-secure to Secure state when all of the following apply:

- The security attribute of the branch target address is Secure and Non-secure callable.
- The branch target address contains an [SG](#) which is fetched and executed.
- The whole of the instruction at the branch target address is flagged as Secure and Non-secure callable.
- The execution of the [SG](#) instruction does not raise a fault.

*Applies to an implementation of the architecture Armv8.0-M onward.*

I<sub>KWMP</sub>

[SG](#) instructions in Secure memory are valid entry points to Secure code. They prevent Non-secure code from being able to jump to arbitrary addresses in Secure code.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [S](#).*

I<sub>WJRL</sub>

When an interstating branch is executed in Secure state, the least significant bit of the target address indicates the target Security state:

**1:** The target Security state is Secure.

**0:** The target Security state is Non-secure.

Interstating branches are UNDEFINED in Non-secure state.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [S](#).*

R<sub>WKXR</sub>

On transition from Secure to Non-secure state, if the least significant bit of an interstating branch is set to one, the execution of the next instruction will generate either an INVTRAN SecureFault or Secure HardFault.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [S](#). Note, an INVTRAN SecureFault requires [M](#).*

R<sub>JKJD</sub>

On transition from Non-secure to Secure state, if there is no [SG](#) instruction or the whole instruction at the branch target address is not flagged as Secure and Non-secure callable the execution of the next instruction will generate either an INVEP SecureFault or Secure HardFault.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - S. Note, an INVTRAN SecureFault requires M.*

**R<sub>XNVW</sub>** If sequential instruction execution crosses from Non-secure memory to Secure memory, then if the Secure memory entry point contains an SG instruction and the whole of the instruction at the Secure memory entry point is flagged as Secure and Non-secure callable, it is CONSTRAINED UNPREDICTABLE whether:

- The PE changes to Secure state.
- Either an INVTRAN SecureFault or Secure HardFault is generated:

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - S. Note, an INVTRAN SecureFault requires M.*

**I<sub>NGXH</sub>** Except for an SG, it is not possible to execute Secure code in Non-secure state, or Non-secure code in Secure state.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - S.*

**R<sub>DWXH</sub>** When an exception is taken to the other Security state, the PE automatically transitions to that other Security state.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - S.*

**R<sub>QVPC</sub>** When the following conditions are met, the value indicated by the current Secure stack pointer is loaded from memory:

- The SG instruction is executed in Non-secure state.
- Either the SAU or IDAU, or both, indicate that the SG instruction was fetched from Secure memory.
- The PE is executing in Thread mode.

The load of the value indicated by the current Secure stack pointer is performed with the privilege level indicated by CONTROL\_S.nPriv and NS-req set to Secure.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - S.*

**R<sub>XCXC</sub>** An INVEP SecureFault is raised if the all of the following are true:

- CCR\_S.TRD is set to 1.
- Either, or both, of the following conditions are met:
  - CONTROL\_S.SPSEL is 0.
  - The top 31 bits of the value indicated by the current Secure stack pointer loaded from memory matches the top 31 bits of 0xFEFA125A.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - S.*

[C1.4.7 Instruction set, interworking and interstating support.](#)

[Chapter B10 The Armv8-M Protected Memory System Architecture.](#)

## B3.16 Function calls from Secure state to Non-secure state

R<sub>CVBB</sub>

If a [BLXNS](#) interstating branch generates a change from Secure state to Non-secure state, then before the Security state change:

- The return address, which is the address of the instruction after the instruction that caused the function call, the [IPSR](#) value and [CONTROL.SFPA](#) are stored onto the current stack, as shown in the following figure. ReturnAddress[0] is set to 1 to indicate a return to the T32 instruction set state. The [IPSR](#) is stacked in the partial [RETPSR](#), and [CONTROL.SFPA](#) is stacked in bit [20] of the partial [RETPSR](#).

- If the PE is in Handler mode, [IPSR](#) has the value of 1.
- The [FNC\\_RETURN](#) value is saved in the [LR](#).

*Applies to an implementation of the architecture [Armv8.0-M](#) onward. The extension requirements are - [S](#). Note, [CONTROL.SFPA](#) requires FP.*

R<sub>MNOV</sub>

Behavior is CONSTRAINED UNPREDICTABLE when a function call stack frame is not doubleword-aligned, and one of the following behaviors must occur:

- The instruction uses the current value of the stack pointer.
- The instruction behaves as though bits [2:0] of the stack pointer are 0b000.

*Applies to an implementation of the architecture [Armv8.0-M](#) onward. The extension requirements are - [S](#).*

I<sub>KWZD</sub>

Arm recommends that when Secure code calls a Non-secure function, any registers not passing function arguments are set to 0.

*Applies to an implementation of the architecture [Armv8.0-M](#) onward. The extension requirements are - [S](#).*

See also:

[C1.4.7 Instruction set, interworking and interstating support.](#)

## B3.17 Function returns from Non-secure state

R<sub>HPFG</sub>

An interstating function return begins when one of the following instructions loads a **FNC\_RETURN** value into the PC:

- A **POP (multiple registers)** or **LDM** that includes loading the PC.
- An **LDR** with the PC as a destination.
- A **BX** with any register.
- A **BXNS** with any register.

On detecting a **FNC\_RETURN** value in the PC:

- The **FNC\_RETURN** stack frame is unstacked.
- **EPSR.IT** is set to 0x00.
- The following *integrity checks on function return* are performed:
  - A check that **IPSR** is zero or 1 before the value of it is restored.
  - A check that if the stacked **IPSR** value is zero the return is in Thread mode.
  - A check that if the stacked **IPSR** value is nonzero the return is to Handler mode.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - S.*

I<sub>QBJN</sub>

Behavior is CONSTRAINED UNPREDICTABLE when a function call stack frame is not doubleword-aligned.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - S.*

R<sub>DWTF</sub>

The **FNC\_RETURN** value is:

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 1  | 1  | 1  | 1  | 1  | 1  | 1  | 0  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | S |

### Bits[31:1]

This is what identifies the value as an **FNC\_RETURN** value.

**Bit[0], S:** The function return was from:

**0:** Secure state.

**1:** Non-secure state.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - S.*

R<sub>FRSP</sub>

Any fault raised on function return is synchronous to the instruction that loaded the **FNC\_RETURN** value into the PC.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - S.*

R<sub>PBNM</sub>

Any failed integrity check on function return generates a Secure INVPC UsageFault.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - M && S.*

R<sub>JKGF</sub>

Any failed integrity check on function return generates a Secure HardFault.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - S && !M.*

R<sub>FGNB</sub>

If **FNC\_RETURN** does not fail the integrity checks then the PE behaves as follows:

- ReturnAddress bits [31:1] is written to the PC.
- ReturnAddress bit [0] is written to **EPSR.T**.
- The partial **RETPSR** is written to **IPSR** Exception and **CONTROL.SFPA**.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - S. Note, CONTROL.SFPA requires FP.*

$R_{LNFB}$  If the [IPSR](#) retrieved from [RETPSR](#) is not supported by the PE the value is UNKNOWN.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - S.*

$I_{KBXQ}$  Any Secure INVPC UsageFault, Secure HardFault, or INVSTATE UsageFault generated on [FNC\\_RETURN](#) are subject to the rules in respect of escalation of faults and potentially [Lockup](#).

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - S.*

$I_{BGTC}$  If a precise BusFault is raised during [FNC\\_RETURN](#) stack frame unstacking, then it is permitted to ignore the value of [CCR.BFHFNMIGN](#).

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - S.*

See also:

[B3.16 Function calls from Secure state to Non-secure state.](#)

[B3.31 Hardware-controlled priority escalation to HardFault.](#)

[B3.33 Lockup.](#)

## B3.18 Exception handling

- R<sub>XGKT</sub>** In the absence of a specific requirement to take an exception, the architecture requires that pending exceptions are taken within finite time.
- Applies to an implementation of the architecture Armv8.0-M onward.*
- R<sub>KFRF</sub>** If an exception was pending but is changed to not pending before it is taken, then the architecture permits the exception to be taken but does not require that the exception is taken. If the exception is taken it must be taken before the first **Context synchronization event** after the exception was changed to not pending.
- Applies to an implementation of the architecture Armv8.0-M onward.*
- R<sub>YFHR</sub>** An exception that does not cause **lockup** sets both:
- The pending bit of its handler, or the pending bit of the HardFault handler, to 1.
  - The associated fault status information.
- Applies to an implementation of the architecture Armv8.0-M onward.*
- R<sub>VLDB</sub>** When a pending exception has a lower group priority value than current execution, including accounting for any priority adjustment by **AIRCR.PRIS**, the pending exception preempts current execution.
- Applies to an implementation of the architecture Armv8.0-M onward.*
- R<sub>WBND</sub>** Preemption of current execution causes the following basic sequence:
1. R0-R3, R12, **LR**, **RETSPSR**, including **CONTROL.SFPA**, are stacked.
  2. The return address is determined and stacked.
  3. Optional stacking of Floating-point context, which might be any one of the following:
    - No stacking or preservation of the Floating-point context.
    - Stacking the basic Floating-point context.
    - Stacking the basic Floating-point context and the additional Floating-point context.
    - Activation of Lazy Floating-point state preservation.
  4. **LR** is set to **EXC\_RETURN**.
  5. Optional clearing of Floating-point registers, depending on the Security state transition.
  6. The following flags are also cleared:
    - IT State is cleared, if the Main Extension is implemented.
    - **CONTROL.FPCA** is cleared, if the Floating-point Extension is implemented.
    - **CONTROL.SFPA** is cleared, if the Floating-point Extension and the Security Extension are implemented.
  7. The exception to be taken is chosen, and **IPSR** Exception is set accordingly. The setting of **IPSR** Exception to a nonzero value causes the PE to change to Handler mode.
  8. **CONTROL.SPSEL** is set to 0, to indicate the selection of the main stack, dependent on the Security state being targeted.
  9. The pending bit of the exception to be taken is set to 0. The active bit of the exception to be taken is set to 1.
  10. The Security state is changed to the Security state of the exception that is being activated.
  11. The registers are cleared, depending on the transition of the Security state. The registers are divided between the caller and callee registers. If the Security state transition is from Secure to Non-secure state, all the registers are cleared to 0. In all other cases, the caller registers are set to an UNKNOWN value and the callee registers remain unchanged and are not stacked.
  12. **EPSR.T** is set to bit[0] of the exception vector for the exception to be taken.
  13. The **PC** is set to the exception vector for the exception to be taken.

*Applies to an implementation of the architecture Armv8.0-M onward. Note, some steps might require additional extensions.*

R<sub>NJVF</sub>

When, during exception entry, the target Security state of an exception differs from the Security state of the memory the exception vector targets:

- An INVEP SecureFault is generated if the exception is Non-secure and the exception vector targets Secure memory.
  - The INVEP SecureFault can be avoided if the exception is associated with Non-secure state and is targeting an [SG](#) instruction that is located in memory that is Secure and Non-secure callable.
- An INVTRAN SecureFault is generated if the exception is Secure and the exception vector targets Non-secure memory.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [S](#). Note, an INVEP or INVTRAN SecureFault requires M.*

R<sub>QLHB</sub>

The return address is one of the following:

- For a synchronous exception, other than an SVCcall exception and a [SVC](#) instruction that escalates to HardFault, the address of the instruction that caused the exception.
- For an asynchronous exception, the address of the next instruction in the program order.
- For an SVCcall exception and a [SVC](#) instruction that escalates to HardFault, the address of the next instruction in the program order.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>XKDD</sub>

The least significant bit of the return address from an exception is RES0.

*Applies to an implementation of the architecture Armv8.0-M onward.*

[Chapter B5 Vector Extension](#)

*Applies to an implementation of the architecture Armv8.1-M onward.*

## B3.19 Exception entry, context stacking

R<sub>PWWG</sub>

On taking an exception, the PE hardware saves *state context* onto the stack that the SP register points to. The state context that is saved is eight 32-bit words:

- RETPSR.
- ReturnAddress.
- LR.
- R12.
- R3-R0.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>PTRL</sub>

In a PE without the Security Extension but with the Floating-point Extension, on taking an exception, the PE hardware saves state context onto the stack that the SP register points to. If CONTROL.FPCA is 1 when the exception is taken, then in addition to the state context being saved, there are the following possible modes for the *Floating-point context*:

- Stack the Floating-point context.
- Reserve space on the stack for the Floating-point context. This is called *lazy Floating-point context preservation*.

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - *!S*. Note, FP is required for the extended stack frame.

R<sub>PLHM</sub>

In a PE with the Security Extension, on taking an exception, the PE hardware:

1. Saves state context onto the stack that the *SP* register points to.
2. If exception entry requires a transition from Secure state to Non-secure state, the PE hardware extends the stack frame and also saves *additional state context*.

Exception taken from Secure state with Stacking of additional state context

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - **S**.

R<sub>BLQS</sub>

If a Secure exception is taken from a Secure context of execution, it is IMPLEMENTATION DEFINED whether:

- The additional state context stacking is not attempted and **EXC\_RETURN.DCRS** is set to 1.
- The additional state context stacking is attempted and **EXC\_RETURN.DCRS** is set to 0.

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - **S**.

I<sub>KJRL</sub>

If a higher priority Secure exception occurs during exception entry after the PE has begun stacking the additional state context, but before any exception handler has started execution, in preparation to take a Non-secure exception the PE might:

- Discard the stacking of the additional state context and **EXC\_RETURN.DCRS** is not updated.
- Complete the stacking of the additional state context and **EXC\_RETURN.DCRS** is set to 0.

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - **S**.

R<sub>DHPD</sub>

In a PE with the Security Extension and the Floating-point Extension, on taking an exception from:

#### Non-secure state

Behavior is the same as a PE without the Security Extension but with the Floating-point Extension.

#### Secure state when **CONTROL.FPCA** is 0

Behavior is the same as for a PE with the Security Extension but without the Floating-point Extension.

#### Secure state when **CONTROL.FPCA** is 1

The PE hardware:

1. Saves state context onto the stack that the **SP** register points to.

2. If `FPCCR.S.TS` is 0 or the background state is Non-secure when the exception is taken, the PE hardware either stacks the Floating-point context or when lazy state preservation is active reserves space on the stack for the Floating-point context.

If `FPCCR.S.TS` is 1 and the background state is Secure state when the exception is taken, the PE hardware either stacks both the Floating-point context and additional Floating-point context, or when lazy state preservation is active reserves space on the stack for both the Floating-point context and additional Floating-point context.

3. If exception entry is to Non-secure state, including when a higher priority derived or late-arriving exception targeting Secure state occurs, the PE hardware extends the stack frame, and also saves the additional state context. The PE also performs the exception handling steps common to exception entry.

The following figure shows PE stacking behavior when `CONTROL.FPCA` is 1, `FPCCR.S.TS` is 1 (and both the Floating-point context and additional Floating-point context is stacked), and exception entry is to Non-secure state and the background state is Secure state:

<sup>†</sup> Or at offset 0xD4 if at a word-aligned but not doubleword-aligned address.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - S && FP.*

R<sub>BKVD</sub>

On an exception, the RETPSR value that is stacked is all the following:

- The APSR, IPSR, and EPSR.
- CONTROL.SFPA, in RETPSR[20] if the background state is Secure state.

In addition, on an exception, the PE uses RETPSR.SPREALIGN to indicate whether the PE realigned the stack to make it doubleword-aligned:

0: The PE did not realign the stack.

1: The PE realigned the stack.

*Applies to an implementation of the architecture Armv8.0-M onward. Note, CONTROL.SFPA requires S && FP || MVE. MVE is only available in an Armv8.1-M implementation.*

R<sub>QDKQ</sub>

When stacking the context on exception entry, full descending stacks are used.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>PWBW</sub>

In a PE with the Floating-point Extension:

- Because setting FPCCR.ASPEN to one causes the PE to automatically set CONTROL.FPCA to 1 on the execution of a floating-point instruction, setting FPCCR.ASPEN to 1 means that the PE hardware automatically either:
  - Stacks Floating-point context on taking an exception.
  - Uses lazy Floating-point context preservation on taking an exception.

If CONTROL.FPCA == 1, it is FPCCR.LSPEN that determines whether the PE hardware performs stacking or lazy Floating-point preservation:

0: The PE hardware automatically stacks Floating-point context on taking an exception. In a PE that also includes the Security Extension, if FPCCR.S.TS == 1 and the background state is Secure state, the hardware stacks the additional Floating-point context and the Floating-point context.

1: The PE hardware uses lazy Floating-point context preservation on taking an exception, and sets all of:

- The FPCAR, to point to the reserved S0 stack address.
- FPCCR.LSPACT to 1.
- FPCCR.{USER, THREAD, HFREEDY, MMRDY, BFRDY, SFRDY, MONRDY, UFRDY}, to record the permissions and fault possibilities to be applied to any subsequent Floating-point context save.

In a PE that also includes the Security Extension, if FPCCR.S.TS is 1 and the background state is Secure state, the hardware reserves space on the stack for both the Floating-point context and the additional Floating-point context. Otherwise, the hardware only reserves space on the stack for the Floating-point context.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - FP. Note, space is reserved for both the Floating-point context and the additional Floating-point context if the Security Extension is implemented. MVE is only available in an Armv8.1-M implementation.*

R<sub>GHDJ</sub>

Execution of a floating-point instruction while FPCCR.LSPACT == 1 indicates that lazy Floating-point context preservation is active.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - FP || MVE. Note, MVE is only available in an Armv8.1-M implementation.*

R<sub>TZLM</sub>

If an attempt is made to execute a floating-point instruction while lazy Floating-point context preservation is active, the access permissions that CPACR and NSACR define are checked against the context that activated lazy Floating-point context preservation, in addition to the checks defined in FPCCR.

- If no permission violation is detected, the PE:
  1. Saves Floating-point context to the reserved area on the stack, as identified by the FPCAR.

2. Saves the additional Floating-point context if `FPCCR.TS == 1` and `FPCCR.S == 1`.
  3. Sets `FPCCR.LSPACT` to 0 to indicate that lazy Floating-point context preservation is no longer active.
  4. Clears the floating-point registers if `FPCCR.TS == 1` and `FPCCR.S == 1`. Otherwise, the PE sets the floating-point registers to an UNKNOWN value.
  5. Processes the floating-point instruction.
- If a permission violation is detected, the PE generates a NOCP UsageFault and does not save Floating-point context to the reserved area on the stack.
  - If there is a Security violation or other exception on context stacking the PE will take that exception if the priority of the exception is lower than the execution priority.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **FP** || **MVE**. Note, MVE is only available in an Armv8.1-M implementation.*

R<sub>LGNS</sub>

When the following conditions are met on exception entry, the PE generates a Secure NOCP UsageFault, skips all Floating-point register saving, clearing or lazy-state preservation activation and does not allocate space on the stack for Floating-point context:

- `CONTROL.FPCA == 1`.
- `NSACR.CP10` is 0.
- The **Background state** is Non-secure state.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **FP** || **MVE** && **S**. Note, MVE is only available in an Armv8.1-M implementation.*

R<sub>LRTP</sub>

It is IMPLEMENTATION DEFINED whether beat-wise instructions that check for lazy Floating-point state preservation (by directly or indirectly calling `PreserveFPState()`) do so before the execution of every beat or once before the first beat to be executed of an instruction. The first beat might not be beat 0 if the instruction is executed with a nonzero ECI value.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **MVE**.*

R<sub>QYYT</sub>

When performing lazy Floating-point state preservation that does not cause the execution of the current instruction to terminate, it is IMPLEMENTATION DEFINED whether only the `FPCCR.LSPACT` flag associated with the Security state indicated by `FPCCR.S` is cleared or the `FPCCR.LSPACT` flags are cleared for both Security states.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - (**FP** || **MVE**) && **S**.*

I<sub>TWPT</sub>

Arm recommends that when performing lazy Floating-point state preservation both the Secure and Non-secure `FPCCR.LSPACT` flags should be cleared.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - (**FP** || **MVE**) && **S**.*

R<sub>QLGM</sub>

Unless otherwise stated, a NOCP UsageFault takes precedence over UNDEFINSTR faults for all instructions that fall into the range described by the `IsCPInstruction()` function, except for the following instructions:

- `VLLDM`.
- `VLSTM`.
- `VSCCLRM`.

*Applies to an implementation of the architecture Armv8.1-M onward. Note, For further information see the instruction descriptions.*

R<sub>DKCR</sub>

For the following instructions, UNDEFINSTR faults take precedence over NOCP UsageFaults when they are attempting to access FPCXT payloads from Non-secure state:

- `VLDR (System Register)`.
- `VMRS`.
- `VMSR`.
- `VSTR (System Register)`.

*Applies to an implementation of the architecture Armv8.1-M onward. Note, For further information see the instruction descriptions.*

|        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| R_LDPT | <p>In an Armv8.1-M implementation, saving Secure Floating-point context to a general-purpose register using <a href="#">VMRS</a> or <a href="#">VSTR (System Register)</a> clears <a href="#">CONTROL.SFPA</a> to 0.</p> <p><i>Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - <a href="#">FP</a> &amp;&amp; <a href="#">S</a>.</i></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| I_GJGL | <p>To ensure future compatibility Arm recommends that the value used to seal the top of the stack is <code>0xFEFE5EDA5</code>. This value has the following properties:</p> <ul style="list-style-type: none"> <li>• It is not a valid <a href="#">FNC_RETURN</a> or <a href="#">EXC_RETURN</a> value.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

- It is not the integrity signature used to secure the bottom of the stack frame and cannot be used to inadvertently mark the stack as containing a valid exception stack frame.
- The value starts with 0xF and is therefore not a valid instruction address and will result in a fault if interpreted as a FNC\_RETURN stack frame.

*Applies to an implementation of the architecture Armv8.0-M onward.*

I\_FKBH

If a MemManage fault, BusFault, or AUViol SecureFault occurs on a stacking memory access during exception entry, then stacking of additional state context is optional.

Whether or not the option of stacking the additional state context is exercised, the clearing of additional state context is still required on exception entry as described in [ExceptionTaken\(\)](#).

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - S.*

I\_CNTN

The order in which registers are saved to the stack during exception entry or during lazy state preservation is not architected.

*Applies to an implementation of the architecture Armv8.0-M onward. Note, FP required of lazy state preservation.*

[B3.20 Exception entry, register clearing after context stacking.](#)

[B3.23 Integrity signature.](#)

[PushStack\(\)](#).

## B3.20 Exception entry, register clearing after context stacking

R<sub>DJRX</sub>

On exception entry:

- The PE hardware sets R0-R3, R12, [APSR](#), and [EPSR](#) to an UNKNOWN value after it has pushed state context to the stack.
- The PE hardware sets S0-S15 and the [FPSCR](#) to an UNKNOWN value after it has pushed Floating-point context to the stack.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [!S](#). Note, FP is required for S0-S15 and FPSCR.*

R<sub>SND8</sub>On exception entry, including [tail-chaining](#), the PE sets:

- R0-R3, R12, [APSR](#), and [EPSR](#) to:
  - Unless otherwise stated, an UNKNOWN value if the exception is taken to Secure state.
  - Zeros.
- If the background state was Secure and the exception targets the Secure state and [EXC\\_RETURN.DCRS](#) == 0 then R4 to R11 become UNKNOWN.
- If the background state was Secure and the exception targets Non-secure state then R4 to R11 are set to zeros.

Otherwise the register values are not changed.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [S](#).*

R<sub>KPZV</sub>

On exception entry the PE sets R0-R3, R12, [APSR](#), and [EPSR](#) to zero regardless of the Security state the exception targets.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [S](#).*

R<sub>JWBK</sub>

Register clearing behavior after context stacking is as follows:

- If [FPCCR.S.TS](#) is 0 when the Floating-point context is pushed to the stack, S0-S15 and the [FPSCR](#) are set to an UNKNOWN value after stacking.
- If [FPCCR.S.TS](#) is 1 when the Floating-point context and additional Floating-point context are both pushed to the stack, S0-S31 and the [FPSCR](#) are set to zero after stacking.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [FP](#) && [S](#).*

## B3.21 Stack limit checks

**R<sub>PCRT</sub>** A PE that does not implement the Main Extension, and does not implement the Security Extension does not implement stack limit checking.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - !M && !S.*

**R<sub>NHBX</sub>** In a PE without the Main Extension but with the Security Extension, there are two stack limit registers in Secure state for the purposes of stack limit checking.

| Security state | Stack   | Stack limit registers |
|----------------|---------|-----------------------|
| Secure         | Main    | MSPLIM_S              |
|                | Process | PSPLIM_S              |

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - S && !M.*

**R<sub>JPEX</sub>** In a PE with the Main Extension but without the Security Extension, there are two stack limit registers:

| Stack   | Stack limit registers |
|---------|-----------------------|
| Main    | MSPLIM                |
| Process | PSPLIM                |

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - M && !S.*

**R<sub>XQDS</sub>** In a PE with the Main Extension and the Security Extension, there are four stack limit registers:

| Security state | Stack   | Stack limit registers |
|----------------|---------|-----------------------|
| Secure         | Main    | MSPLIM_S              |
|                | Process | PSPLIM_S              |
| Non-secure     | Main    | MSPLIM_NS             |
|                | Process | PSPLIM_NS             |

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - M && S.*

**I<sub>KDPG</sub>** A stack can descend to its stack limit value. Any attempt to descend the stack further than its stack limit value is a violation of the stack limit.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>TCXN</sub>** xSPLIM\_x[2:0] are treated as RES0, so that all stack pointer limits are always guaranteed to be doubleword-aligned. Bits [31:3] of the xSPLIM\_x registers are writable.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>DKSR</sub>** Stack limit checks are performed during the creation of a stack frame for all of the following:

- Exception entry.
- [Tail-chaining](#) from a Secure to a Non-secure exception.
- A function call from Secure code to Non-secure code.

*Applies to an implementation of the architecture Armv8.0-M onward. Note, Secure exceptions and secure code require S.*

**R<sub>ZLZG</sub>** On a violation of a stack limit during either exception entry or [tail-chaining](#):

- In a PE with the Main Extension, a synchronous STKOF UsageFault is generated. Otherwise, a HardFault is generated.
- The stack pointer is set to the stack limit value.
- Push operations to addresses below the stack limit value are not performed.

- It is IMPLEMENTATION DEFINED whether push operations to addresses equal to or above the stack limit value are performed.

*Applies to an implementation of the architecture Armv8.0-M onward. Note, A UsageFault requires M.*

**R<sub>ZXDN</sub>** Where an exception entry or [tail-chaining](#) accesses bytes on the stack that span the top or bottom of the 32-bit memory address space, it is IMPLEMENTATION DEFINED whether stack limit checking is applied.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>CCSC</sub>** On a violation of a Secure stack limit during a function call:

- In a PE with the Main Extension, a synchronous STKOF UsageFault is generated. Otherwise, a Secure HardFault is generated.
- Push operations to addresses below the stack limit value are not performed.
- It is IMPLEMENTATION DEFINED whether push operations to addresses equal to or above the stack limit value are performed.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [S](#). Note, A UsageFault requires M.*

**R<sub>GGRH</sub>** Unstacking operations are not subject to stack limit checking.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>YVWT</sub>** Updates to the stack pointer by the following instructions are subject to stack limit checking:

- [ADD \(SP plus immediate\)](#).
- [ADD \(SP plus register\)](#).
- [SUB \(SP minus immediate\)](#).
- [SUB \(SP minus register\)](#).
- [BLX, BLXNS](#).
- [LDC, LDC2 \(immediate\)](#).
- [LDM, LDMIA, LDMFD](#).
- [LDMDB, LDMEA](#).
- [LDR \(immediate\)](#).
- [LDR \(literal\)](#).
- [LDR \(register\)](#).
- [LDRB \(immediate\)](#).
- [LDRD \(immediate\)](#).
- [LDRH \(immediate\)](#).
- [LDRSB \(immediate\)](#).
- [LDRSH \(immediate\)](#).
- [MOV \(register\)](#)
- [POP \(multiple registers\)](#).
- [PUSH \(multiple registers\)](#).
- [VPOP](#).
- [VPUSH](#).
- [STC, STC2](#)

- STM, STMIA, STMEA.
- STMDB, STMFD.
- STR (immediate).
- STRB (immediate).
- STRD (immediate).
- STRH (immediate).
- VLDM.
- VSTM.

Updates to the stack pointer by the MSR instruction targeting SP\_NS are subject to stack limit checking. Updates to the stack pointer and stack pointer limit by any other MSR instruction are not subject to stack limit checking.

LDR instructions write to two registers, the address register and the destination register. The stack limit check is only carried out against the address register. Updates to the stack pointer by the LDR instructions are only subject to stack limit checking if the stack pointer is the address register.

For all other instructions that can update the stack pointer and stack pointer limit, it is IMPLEMENTATION DEFINED whether stack limit checking is performed.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R\_JCCR

Updates to the stack pointer by the following instructions are subject to stack limit checking:

- VLDR (System Register).
- VSTR (System Register).

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - FP || MVE.*

R\_HRDG

If a STKOF UsageFault is generated when the Non-secure stack pointer is accessed through a MSR{SP\_NS} instruction in Secure state, the STKOF UsageFault can target either the Secure or Non-secure state.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - S.*

I\_JSPJ

Arm recommends that a STKOF UsageFault generated by a MSR instruction in Secure state accessing the Non-secure stack pointer should target the Non-secure state.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - S.*

I\_BJHX

When an instruction updates the stack pointer, if it results in a violation of the stack limit, it is the modification of the stack pointer that generates the exception, rather than an access that uses the out-of-range stack pointer.

*Applies to an implementation of the architecture Armv8.0-M onward.*

I\_RRDx

CCR.STKOFHFNMIGN controls whether stack limit violations are IGNORED while executing at a requested execution priority that is negative.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R\_XCQL

It is UNKNOWN whether a stack limit check is performed on any use of the SP marked as UNPREDICTABLE.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R\_QFPF

A write to the current stack pointer by an instruction subject to stack limit checking with a value less than the stack limit will generate a STKOF UsageFault.

*Applies to an implementation of the architecture Armv8.0-M onward.*

I\_DSJN

There is no architectural requirement for stack limit checking to be carried out on exception return as the current stack pointer will only increment and will not decrement.

*Applies to an implementation of the architecture Armv8.0-M onward.*

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## B3.22 Exception return

R<sub>KPSS</sub>

The PE begins an exception return when both of the following are true:

- The PE is in Handler mode.
- One of the following instructions loads an **EXC\_RETURN** value, 0xFFXXXXXX, into the **PC**:
  - A **POP (multiple registers)** or **LDM** that includes loading the **PC**.
  - An **LDR** with the **PC** as a destination.
  - A **BX** with any register.
  - A **BXNS** with any register.

When both of these are true, then on detecting an **EXC\_RETURN** value in the **PC**, the PE unstacks the exception stack frame and resumes execution of the unstacked context.

If an **EXC\_RETURN** value is loaded into the **PC** by an instruction other than those listed, or from the vector table, the value is treated as an address.

If an **EXC\_RETURN** value is loaded into the **PC** when the PE is in Thread mode, the value is treated as an address.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>TXDW</sub>

Behavior is UNPREDICTABLE if **EXC\_RETURN.FType** is 0 and the Floating-point Extension register file is not implemented.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>TNSK</sub>

Behavior is UNPREDICTABLE if **EXC\_RETURN**[23:7] are not all 1 or if bit[1] is not 0.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>LLBT</sub>

On exception return the following procedures are carried out:

1. In a PE with the Security Extension, the integrity check that is called the **EXC\_RETURN.ES** validation check, as follows:
  - If the PE was in Non-secure state when **EXC\_RETURN** was loaded into the **PC** and either **EXC\_RETURN.DCRS** is 0 or **EXC\_RETURN.ES** is 1, an INVER SecureFault is generated and the PE sets **EXC\_RETURN.ES** to 0. In a PE without the Main Extension a Secure HardFault is generated.
2. A check that the exception number being returned from, as held in the **IPSR**, is shown as active. When the Security Extension is implemented the exception must be active for the Security state indicated by **EXC\_RETURN.ES**. If the exception being returned from can be configured to target either Security state, then it must target the Security state indicated by **EXC\_RETURN.ES**. If this check fails:
  - In a PE with the Main Extension, an INVPC UsageFault is generated.
  - In a PE without the Main Extension, a HardFault is generated.
  - If the Security Extension is implemented the HardFault or UsageFault targets the Security state that the exception return instruction was executed in.
3. A check that if the return is to Thread mode, the value that is restored to the **IPSR** from the **RETPSR** is zero, or that if the return is to Handler mode, the value that is restored to the **IPSR** from the **RETPSR** is nonzero. If this check fails:
  - In a PE with the Main Extension, an INVPC UsageFault is generated.
  - In a PE without the Main Extension, a HardFault is generated.
  - If the Security Extension is implemented the HardFault or UsageFault targets the the background Security state.

*Applies to an implementation of the architecture Armv8.0-M onward. Note, some steps require additional extensions, as listed in the rule.*

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| R <sub>CGML</sub> | <p>When the following conditions are met on exception return, the PE hardware sets S0-S15 and the <a href="#">FPSCR</a> to 0:</p> <ul style="list-style-type: none"> <li>• <a href="#">CONTROL.FPCA</a> is 1.</li> <li>• <a href="#">FPCCR.CLONRET</a> is 1.</li> <li>• If the PE implements the Security Extension <a href="#">FPCCR.S.LSPACT</a> is 0.</li> </ul> <p>If the PE implements the Security Extension and all these fields are 1 on exception return, the PE generates an LSERR SecureFault instead.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">FP</a>. Note, a SecureFault requires <i>S</i>.</i></p> |
| R <sub>ZXTR</sub> | <p>In an Armv8.1-M implementation, the PE hardware also sets VPR to 0 when:</p> <ul style="list-style-type: none"> <li>• <a href="#">CONTROL.FPCA</a> is 1.</li> <li>• <a href="#">FPCCR.CLONRET</a> is 1.</li> <li>• If the PE implements the Security Extension <a href="#">FPCCR.S.LSPACT</a> is 0.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                  |

If the PE implements the Security Extension and all these fields are 1 on exception return, the PE generates an LSERR SecureFault instead.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - MVE.*

**I<sub>BVMJ</sub>** The register clearing described in **R<sub>CGML</sub>** and **R<sub>ZXTR</sub>** only applies if a NOCP UsageFault is not generated due to **R<sub>XLTP</sub>**.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - FP || MVE.*

**R<sub>XLTP</sub>** When the following conditions are met on exception return, a NOCP UsageFault is generated:

- **CONTROL.FPCA** == 1.
- **FPCCR.LSPACT** == 0.
- **FPCCR.CLRONRET** == 1.
- Access to CP10 from the Security state of the returning exception, as indicated by **EXC\_RETURN.ES**, is disabled by **NSACR**, **CPACR**, or **CPPWR**.

The target Security state of the NOCP UsageFault is as follows:

- Secure state, if blocked by **NSACR**.
- The same Security state as the returning exception as indicated by **EXC\_RETURN.ES**, if blocked by **CPACR**.
- If the access is blocked by **CPPWR**, the NOCP Usage fault targets Secure state, if **CPPWR.SUS10** == 1. Otherwise, the NOCP UsageFault targets the same Security state as the returning exception as indicated by **EXC\_RETURN.ES**.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - FP || MVE. Note, Secure state requires S.*

**I<sub>RHNB</sub>** **IsCPEnabled()** indicates the prioritization if the access is blocked by multiple registers.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>XNNG</sub>** When the following conditions are met on exception return, the PE generates an LSERR SecureFault:

- **EXC\_RETURN.FType** is 0.
- The stack might contain Secure Floating-point context or Secure lazy floating-point context, that would be unstacked on return. That is, **FPCCR.S.LSPACT** is 1.
- The return is to Non-secure state.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - FP && S.*

**R<sub>VGGF</sub>** A check of **FPCCR.S.LSPACT**, **CPACR.CP10**, and the relevant fields in **NSACR** and **CPPWR** is undertaken prior to unstacking of the floating-point registers.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - FP.*

**R<sub>WCSC</sub>** The floating-point registers, **FPSCR**, and **VPR** are not modified if the checks prior to unstacking fail.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - FP. Note, VPR requires Armv8.1-M with MVE.*

**R<sub>HNNW</sub>** If the PE abandons unstacking of the floating-point registers to **tail-chain** into another exception, then if the Security Extension is implemented, the PE clears to zero any floating-point registers, **FPSCR**, and **VPR** that would have been unstacked.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - FP && S. Note, VPR requires Armv8.1-M with MVE.*

**R<sub>LMNG</sub>** If the PE abandons unstacking of the floating-point registers to **tail-chain** into another exception, then if the Security Extension is not implemented, then the floating-point registers, **FPSCR**, and **VPR** that would have been unstacked become UNKNOWN.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - FP && !S. Note, VPR requires Armv8.1-M with MVE.*

R<sub>HRJH</sub>

Following completion of the requirements of the [EXC\\_RETURN](#) the PE returns to execution and the following occurs:

- The registers pushed to the stack as part of the exception entry are restored from the stack frame (in accordance with the [EXC\\_RETURN](#) flags).
- [APSR](#), [EPSR](#), and [IPSR](#) are restored from [RETPSR](#).
- The [PC](#) is set to `ReturnAddress [31:1]`: '0'.
- Bit[0] of the `ReturnAddress` is discarded.

*Applies to an implementation of the architecture [Armv8.0-M](#) onward.*

I<sub>GTDH</sub>

The order in which registers, including floating-point registers, are restored from the stack is not architected.

*Applies to an implementation of the architecture [Armv8.0-M](#) onward.*

See also:

[B3.18 Exception handling](#).

[Chapter B5 Vector Extension](#).

*Applies to an implementation of the architecture [Armv8.1-M](#) onward.*

[ExceptionReturn\(\)](#)

## B3.23 Integrity signature

$R_{PHBP}$

In a PE with the Floating-point Extension register file, the integrity signature value is:

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0    |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|------|
| 1  | 1  | 1  | 1  | 1  | 1  | 1  | 0  | 1  | 1  | 1  | 1  | 1  | 0  | 1  | 0  | 0  | 0  | 0  | 1  | 0  | 0  | 1 | 0 | 0 | 1 | 0 | 1 | 1 | 0 | 1 | SFTC |

Stack Frame Type Check  $\neg$

In a PE with the Floating-point Extension, when returning from a Non-secure exception to Secure state, if the unstacked integrity signature does not match this value, including if SFTC does not match [EXC\\_RETURN.FType](#), a SecureFault is generated.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [S](#) && [FP](#).*

$R_{MVK}$

In a PE without the Floating-point Extension register file, the integrity signature value is:

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 1  | 1  | 1  | 1  | 1  | 1  | 1  | 0  | 1  | 1  | 1  | 1  | 1  | 0  | 1  | 0  | 0  | 0  | 0  | 1  | 0  | 0  | 1 | 0 | 0 | 1 | 0 | 1 | 1 | 0 | 1 | 1 |

- In a PE with the Main Extension, when returning from a Non-secure exception to Secure state, if the unstacked integrity signature does not match this value, a SecureFault is generated.
- In a PE without the Main Extension, when returning from a Non-secure exception to Secure state, if the unstacked integrity signature does not match this value, a Secure HardFault is generated.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [S](#) && [!FP](#). Note, a SecureFault requires [M](#).*

$I_{FFTS}$

The integrity signature is an XN address. When performing a function return from Non-secure code, if the integrity signature value is restored to the PC as the function return address, a MemManage fault, if the Main Extension is implemented, or a HardFault, in an implementation without the Main Extension, is generated when the PE attempts execution.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [S](#).*

[B3.22 Exception return.](#)

## B3.24 Exceptions during exception entry

**I<sub>LBGQ</sub>** During exception entry exceptions can occur, for example asynchronous exceptions, or the exception entry sequence itself might cause an exception, for example a MemManage fault on the push to the stack.

Any exception that occurs during exception entry is a late-arriving exception, and:

- The exception that caused the original entry sequence is the *original exception*.
- The priority of the code stream running at the time of the original exception is the *preempted priority*.

When the exception entry sequence itself causes an exception, the latter exception is a *derived exception*.

The following mechanism is called *late-arrival preemption*. The PE takes a late-arriving exception during an exception entry if the late-arriving exception is higher priority, including accounting for any priority adjustment by [AIRCR.PRIS](#).

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>NMTT</sub>** In late-arrival preemption:

- The late-arriving exception uses the exception entry sequence started by the original exception. The original exception remains pending.
- The PE takes the original exception after returning from the late-arriving exception.
- The PE ignores non-terminal faults on taking a derived exception on late-arrival preemption.

The pseudocode [DerivedLateArrival\(\)](#) describes this.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>MRTR</sub>** For Derived exceptions, late-arrival preemption is mandatory.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>BXTB</sub>** For late-arriving asynchronous exceptions, it is IMPLEMENTATION DEFINED whether late-arrival preemption is used. If the PE does not implement late-arrival preemption for late-arriving asynchronous exceptions, late-arriving asynchronous exceptions become pending.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>GVHV</sub>** If a higher priority late-arriving Secure exception occurs during entry to a Non-secure exception when the Background state is Secure, it is IMPLEMENTATION DEFINED whether:

- The stacking of the additional state context is rolled back.
- The stacking of the additional state context is completed and [EXC\\_RETURN](#) is set to 0.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - S.*

**R<sub>GDNT</sub>** If the group priority value of a derived exception is higher than or equal to the preempted priority:

- If the derived exception is a DebugMonitor exception, it is IGNORED.
- Otherwise, the PE escalates the derived exception to HardFault or [Lockup](#) if the HardFault cannot be taken due to the current priority.

*Applies to an implementation of the architecture Armv8.0-M onward. Note, a DebugMonitor Exception requires the Debug-Monitor exception.*

**I<sub>NJCW</sub>** The architecture does not specify the point during exception entry at which the PE recognizes the arrival of an asynchronous exception.

*Applies to an implementation of the architecture Armv8.0-M onward.*

## B3.26 Tail-chaining

R\_FKXX

*Tail-chaining* behavior is as follows:

On detecting an **EXC\_RETURN** value in the **PC**, if there is a pending exception or a derived exception is raised that has a lower priority value than the execution priority being returned to, the PE hardware:

1. Does not unstack the stack.
2. Takes the pending exception or derived exception.
  - The PE will **tail-chain** any pending exception or derived exception on exception return if the pending or derived exception has a lower priority value than the execution priority being returned to.
  - If the pending or derived exception is escalated to HardFault and the execution priority is higher than that of the HardFault the PE will enter **Lockup**.
  - The PE will **tail-chain** any synchronous fault on exception return if the synchronous exception has higher priority than the execution priority being returned to.
3. When **tail-chaining** the PE will not execute any instructions from the background state that has been preempted by the exception.

*Applies to an implementation of the architecture Armv8.0-M onward.*

I\_FJWK

**Tail-chaining** is an optimization. It removes unstacking and stacking operations. In the following example the second exception is a *tail-chained exception*:

All in Non-secure state:

*Applies to an implementation of the architecture Armv8.0-M onward.*

I\_RWDT

If **tail-chaining** prevents a derived exception on exception return, the derived exception might instead be generated on the return from the last tail-chained exception.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R\_PXVB

When the Background state is Secure state, if **tail-chaining** causes a change of Security state from Secure to Non-secure, additional context is saved on taking the Non-secure exception if it has not already been saved as indicated by **EXC\_RETURN.DCRS**:

In a PE without the Floating-point Extension:

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - **S**.

I<sub>TKLM</sub>

When multiple exceptions are **tail-chained**, **EXC\_RETURN.DCRS** keeps track of whether the additional context is stacked. The following figure is an example:

a In a PE with the Floating-point Extension, floating-point context and additional floating-point context is also stacked if **CONTROL.FPCA** is 1.

Applies to an implementation of the architecture *Armv8.0-M* onward.

I<sub>TMVF</sub>

When multiple exceptions are **tail-chaining**, a Secure tail-chained exception after a Non-secure exception cannot rely on any registers containing the values they had when no exception was active.

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - **S**.

I<sub>LNPQ</sub>

Arm recommends that **FPCCR.CLRONRET** is set to 1, to ensure hardware automatically clears the Floating-point context registers to zero on exception return.

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - **FP**.

R<sub>JMHS</sub>

If the PE recognizes a new asynchronous exception while it is **tail-chaining**, and the new asynchronous exception has a higher priority than the next tailed-chained exception, the PE can, instead, take the new asynchronous exception, using late-arrival preemption.

This rule is true even if the next tail-chained exception is a derived exception on exception return. The PE can, instead, take the new asynchronous exception. If it does, the derived exception becomes pending.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>P</sub>LBN

Before entering a [tail-chained](#) exception handler during an exception return, the banked [FPCCR.LSPACT](#) field associated with the background Security state, as indicated by the [EXC\\_RETURN.S](#) bit, must be set to one if it was one before the exception return.

*Applies to an implementation of the architecture Armv8.0-M onward.*

## B3.27 Exceptions, instruction resume, or instruction restart

### B3.27.1 Basic definitions

|            |                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $R_{PGRC}$ | The PE can take an exception during execution of a Load Multiple or Store Multiple instruction, effectively halting the instruction, and resume execution of the instruction after returning from the exception. This is called <i>instruction resume</i> .<br><br><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">M</a>.</i> |
| $I_{FFGR}$ | Instruction resume is an OPTIONAL optimisation.<br><br><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">M</a>.</i>                                                                                                                                                                                                             |
| $R_{KRLL}$ | The PE can abandon execution of a Load Multiple or Store Multiple instruction to take an exception, and after returning from the exception, restart the Load Multiple or Store Multiple instruction again from the start of the instruction. This is called <i>instruction restart</i> .<br><br><i>Applies to an implementation of the architecture Armv8.0-M onward.</i>                        |
| $I_{NDQT}$ | Load multiple or Store multiple instructions that support instruction resume are called <i>interrupt-continuable instructions</i> .<br><br><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">M</a>.</i>                                                                                                                         |

### B3.27.2 Instruction restart behavior

|            |                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $R_{KCMD}$ | To support <i>instruction restart</i> , singleword load instructions do not update the destination register when the PE takes an exception during execution.<br><br><i>Applies to an implementation of the architecture Armv8.0-M onward.</i>                                                                                                                                                                            |
| $R_{VFBX}$ | Where a fault is taken during the execution of a <a href="#">VLLDM</a> instruction the PE abandons the stacking of the Secure floating-point register contents and saves the state so that on return from the fault the instruction can be restarted.<br><br><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">S</a> &amp;&amp; <a href="#">FP</a>.</i> |
| $I_{JJQX}$ | If the PE is using instruction restart, Arm recommends that Load Multiple or Store Multiple instructions are not used with data in Device memory.<br><br><i>Applies to an implementation of the architecture Armv8.0-M onward.</i>                                                                                                                                                                                       |

### B3.27.3 Interrupt-continuable instructions

|            |                                                                                                                                                                                                                                                                                                                                                                      |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $R_{LGPO}$ | The interrupt-continuable instructions are <a href="#">LDM</a> , <a href="#">LDMDB</a> , <a href="#">STM</a> , <a href="#">STMDB</a> , <a href="#">POP</a> (multiple registers), and <a href="#">Push</a> (multiple registers).<br><br><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">M</a>.</i> |
| $R_{RDHK}$ | In a PE with the Floating-point Extension, the floating-point interrupt-continuable instructions are <a href="#">VLDM</a> , <a href="#">VSTM</a> , <a href="#">VPOP</a> , and <a href="#">VPUSH</a> .<br><br><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">FP</a>.</i>                          |
| $R_{HKPV}$ | The <a href="#">VLLDM</a> and <a href="#">VLSTM</a> instructions are not interrupt-continuable.<br><br><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">M</a>.</i>                                                                                                                                 |
| $I_{HMDB}$ | It is IMPLEMENTATION DEFINED whether the <a href="#">CLRM</a> instruction is interrupt-continuable.<br><br><i>Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - <a href="#">M</a>.</i>                                                                                                                             |

I\_CVLR

It is IMPLEMENTATION DEFINED whether the [VSCCLRM](#) instruction is interrupt-continuable.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [M](#).*

R\_SXPP

It is IMPLEMENTATION DEFINED whether, if there is an asynchronous exception, Floating-point or MVE instruction execution can be interrupted after triggering lazy Floating-point state preservation, but before updating the ownership of the Floating-point context.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [FP](#) || [MVE](#). Note, *S* is required for updating ownership of FP context. MVE is only available in an Armv8.1-M implementation.*

R\_ZSZM

It is IMPLEMENTATION DEFINED whether [VLLDM](#) and [VLSTM](#) instructions abort or complete when an interrupt occurs.

When executing the [VLLDM](#) instruction, and when [FPCCR.LSPACT](#) is zero, if the instruction does not raise a NOCP UsageFault, nor an UNALIGNED UsageFault, and is either interrupted or aborted due to a memory fault, then any registers that would be loaded by this instruction must be cleared.

If no registers have been updated as a result of the interrupted [VLLDM](#) instruction the registers are permitted to retain their former values.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [M](#).*

R\_QVFC

When the PE is using instruction resume, [EPSR.ICI](#) is set to a nonzero value that is the continuation state of the interrupt-continuable instruction:

- For [LDM](#), [LDMDB](#), [STM](#), [STMDB](#), [POP \(multiple registers\)](#), and [PUSH \(multiple registers\)](#) instructions, [EPSR.ICI](#) contains the number of the first register in the register list that is to be loaded or stored after instruction resume.
- For the floating-point instructions [VLDM](#), [VSTM](#), [VPOP](#), and [VPUSH](#), [EPSR.ICI](#) contains the number of the lowest numbered doubleword Floating-point Extension register that was not loaded or stored before the PE took the exception.

The [EPSR.ICI](#) values shown in the following table are valid [EPSR.ICI](#) values:

| <a href="#">EPSR</a> [26:25]     | <a href="#">EPSR</a> [15:12]        | <a href="#">EPSR</a> [11:10]     |
|----------------------------------|-------------------------------------|----------------------------------|
| <a href="#">ICI</a> [7:6] = 0b00 | <a href="#">ICI</a> [5:2] = reg_num | <a href="#">ICI</a> [1:0] = 0b00 |
| <a href="#">ICI</a> [7:6] = 0b00 | <a href="#">ICI</a> [5:2] = 0b0000  | <a href="#">ICI</a> [1:0] = 0b00 |

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [M](#). Note, some instructions listed require FP.*

R\_PCZR

If [EPSR.ICI](#) contains a valid [ICI](#) nonzero value and the register number that it contains is either:

- Not in the register list of the interrupt-continuable instructions.
- The first register in the register list of the interrupt-continuable instructions.

Then, when an interrupt-continuable instruction is executed, behavior is a CONSTRAINED UNPREDICTABLE choice between the following:

- The instruction generates an INVSTATE UsageFault.
- The instruction completes execution.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [M](#).*

R\_LRGK

The PE generates an INVSTATE UsageFault if [EPSR.ICI](#) contains a valid nonzero value and the instruction being executed is not an instruction which supports interrupt-continuation. A fault is not generated if the instruction is a [BKPT](#) instruction.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [M](#).*

### B3.27.4 Behavior of interrupt-continuable instructions

- R<sub>ZLVP</sub>** If the **VSCCLRM** instruction supports resuming from a nonzero **EPSR.ICI** value, then the ICI value will correspond to the Floating-point registers in the register list and not the **VPR** register. When the last Floating-point register in the register list is cleared, the **VPR** register must also be cleared and the instruction must be completed.
- Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **S** && (**MVE** || **FP**).*
- R<sub>KLPL</sub>** The PE does not generate an INVSTATE UsageFault if the **VSCCLRM** instruction does not support instruction resume from a nonzero **EPSR.ICI** value. If an attempt is made to resume this instruction from a nonzero **EPSR.ICI** value, then the nonzero **EPSR.ICI** value is ignored and the instruction is restarted.
- Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **S** && (**MVE** || **FP**).*
- R<sub>SNRJ</sub>** In an implementation that includes MVE, the PE does not generate an INVSTATE UsageFault on exception return if **EPSR.ECI** contains a valid ECI value and the instruction is a beat-wise MVE instruction.
- Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **MVE**.*
- R<sub>JXKQ</sub>** If the PE uses instruction resume during an interrupt-continuable instruction, other than a Store Multiple instruction, then after the exception return, the values of all registers in the register list are UNKNOWN, except for the following:
- Registers that are marked by **EPSR.ICI** as already loaded.
  - The base register.
  - The **PC**.
- Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **M**.*

### B3.27.5 Exceptions during Load Multiple and Store Multiple instructions

- R<sub>RNRM</sub>** When the PE uses instruction restart to restart a Load Multiple instruction with the **PC** in its register list, the PE must, if the **PC** was loaded before generation of the exception, restore the **PC** before taking the exception.
- Applies to an implementation of the architecture Armv8.0-M onward.*
- R<sub>PQRT</sub>** When the PE uses instruction resume to resume a Load Multiple instruction with the **PC** in its register list, the PE must, if the **PC** was loaded before generation of the exception, restore the **PC** before taking the exception.
- Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **M**.*
- R<sub>LSCQ</sub>** In a PE without the Main Extension, if the PE takes any exception during any Load Multiple or Store Multiple instruction, including **PUSH (multiple registers)** and **POP (multiple registers)**, the PE uses instruction restart and the **Base register** is restored to the original value.
- Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **!M**.*
- R<sub>QRRX</sub>** In a PE with the Main Extension that does not implement **EPSR.ICI**, or when a fault is taken during any Load Multiple or Store Multiple instruction, including **PUSH (multiple registers)** and **POP (multiple registers)**, the PE uses instruction restart and the **Base register** is restored to the original value.
- Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **M**.*
- R<sub>QLTD</sub>** If the PE takes an interrupt during any Load Multiple or Store Multiple instruction which is not in an IT block, including **PUSH (multiple registers)** and **POP (multiple registers)**, then if the instruction is using **SP** as the base register, and the instruction performs write-back of **SP**:
- If the **SP** presented to the exception entry sequence is lower than any element pushed by an **STM**, or not yet popped by an **LDM**, then the **SP** is set to the lowest value in the list and the instruction resumes following the exception return using the continuation state held in **EPSR.ICI**.
  - Otherwise, the **SP** is restored to the original value and the instruction restarts on exception return.
- Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **M**.*

| I <sub>GXDN</sub> | <p>The following is a trivial <code>memcpy</code> example which uses the T1 variant of the LE instruction. The T1 variant uses <b>LR</b>:</p> <pre> 1      memcpy: 2          PUSH    {R0, LR} 3          WLS     LR, R2, loopEnd    //R2=size 4      loopStart: 5          LDRSB   R3, [R1], #1      // R1 = srcPtr, R3 = temp reg 6          STRB    R3, [R0], #1      // R0 = destPtr 7          LE      LR, loopStart 8 9      loopEnd: 10         POP     {R0, PC} </pre>                                                                                                                              |

The **WLS** and **LE** instructions cause the loop body to be executed  $n$  times, where  $n$  is specified by the value of R2. In this example, the low overhead loop instructions operate as follows:

- If the iteration count that is passed to the **WLS** instruction is nonzero, the loop iteration count is copied to **LR**. If the iteration count is zero, the **WLS** instruction jumps to the end of the loop.

- If additional iterations of the loop are required when the [LE](#) instruction is executed (as indicated by the value in [LR](#)), the iteration count decrements [LR](#) and branches back to the start of the loop. The [LE](#) instruction also caches the loop branch information in [LO\\_BRANCH\\_INFO](#). Subsequent iterations might not be required to re-execute the [LE](#) instruction.
- If [LR](#) indicates that no further iterations are required, the PE branches over the [LE](#) instruction when execution reaches the last instruction in the body of the loop.

The [LE](#) T2 variant of the [LE](#) instruction does not include [LR](#) as an argument and can be used where the number of iterations is not known in advance.

*Applies to an implementation of the architecture [Armv8.1-M](#) onward. The extension requirements are - [LOB](#).*

I<sub>CRKM</sub>

The T3 variant of the [LE](#) instruction is [LETP](#), which is a tail predicated loop. Tail predicated loops can be used if the iteration count is not known in advance. A trivial `memcpy` example of the [LETP](#) instruction is shown here:

```

1      memcpy:
2          PUSH    {R0, LR}
3          WLSTP.8    LR, R2, vectLoopEnd    //R2 = element / byte count
4
5      vectLoopStart:
6          VLDRB.8    Q0, [R1], #16    // R1 = srcPtr
7          VSTRB.8    Q0, [R0], #16    // R0 = destPtr
8          LETP      LR, vectLoopStart
9
10     vectLoopEnd:
11         POP      {R0, PC}

```

*Applies to an implementation of the architecture [Armv8.1-M](#) onward. The extension requirements are - [LOB](#) && [MVE](#).*

R<sub>FZXX</sub>

The [LE](#), [LETP](#) instruction caches the loop branch information in [LO\\_BRANCH\\_INFO](#).

*Applies to an implementation of the architecture [Armv8.1-M](#) onward. The extension requirements are - [LOB](#).*

R<sub>NMGH</sub>

When executing a [LE](#) instruction, [LR](#) decrements by one on each iteration of the loop.

*Applies to an implementation of the architecture [Armv8.1-M](#) onward. The extension requirements are - [LOB](#).*

R<sub>HSNB</sub>

An `INVSTATE UsageFault` is raised if a [LE](#) instruction is executed and [FPSCR.LTPSIZE](#) does not read as four.

*Applies to an implementation of the architecture [Armv8.1-M](#) onward. The extension requirements are - [LOB](#).*

R<sub>CCRF</sub>

Executing an [LETP](#) instruction when [FPSCR.LTPSIZE](#) is between zero and four inclusive will not generate an `INVSTATE UsageFault`.

*Applies to an implementation of the architecture [Armv8.1-M](#) onward. The extension requirements are - [LOB](#) && [MVE](#).*

R<sub>VRQV</sub>

For low overhead loop instructions, [LR](#) stores the loop iteration count. For a tail predicated low overhead loop instruction, [LR](#) stores the number of vector elements to be processed.

*Applies to an implementation of the architecture [Armv8.1-M](#) onward. The extension requirements are - [LOB](#). Note, [MVE](#) required for tail predication.*

R<sub>HNLf</sub>

When executing a [LETP](#) instruction, [LR](#) decrements by the element width indicated in [FPSCR.LTPSIZE](#). When [FPSCR.LTPSIZE](#) is not set to four tail predication is applied according to the value in [LR](#). The number of elements is calculated by dividing the vector width, 128, by the element width in [FPSCR.LTPSIZE](#).

*Applies to an implementation of the architecture [Armv8.1-M](#) onward. The extension requirements are - [LOB](#) && [MVE](#).*

R<sub>ZWFJ</sub>

The following events update the low overhead loop flags, as indicated by [LO\\_BRANCH\\_INFO.VALID](#) bit.

Applies to an implementation of the architecture *Armv8.1-M* onward. The extension requirements are - [LOB](#). Note, some rows require *S*.

I<sub>SWHC</sub>

If the debugger expects predictable control flow, then Arm recommends that the implicit branches are disabled and that the associated cache is cleared.

Applies to an implementation of the architecture *Armv8.1-M* onward. The extension requirements are - [LOB](#).

R<sub>GHQJ</sub>

For implementations that include [MVE](#), the architecture permits the architecturally overlapping execution of a vector instruction at the end of the loop with an instruction at the start of the next iteration of the loop, except when:

- The vector instructions at the end of the loop write to [LR](#).
- The instruction at the start of the loop reads or writes to [LR](#).
- Data dependencies between vector instructions are violated.

Applies to an implementation of the architecture *Armv8.1-M* onward. The extension requirements are - [LOB](#) && [MVE](#).

R<sub>XZJF</sub>

When a new floating-point context is created and [FPCCR.ASPEN](#) is set to one the PE automatically initializes [FPSCR.LTPSIZE](#) to four.

Applies to an implementation of the architecture *Armv8.1-M* onward. The extension requirements are - [LOB](#) && ([MVE](#) || [FP](#)).

I<sub>JLJL</sub>

When a new floating-point context is created and [FPCCR.ASPEN](#) is set to zero it is the responsibility of software to correctly initialize [FPSCR.LTPSIZE](#).

Applies to an implementation of the architecture *Armv8.1-M* onward. The extension requirements are - [LOB](#) && ([MVE](#) || [FP](#)).

I<sub>RRPL</sub>

When a [WLSTP](#) or a [DLSTP](#) instruction is used to initialize a loop, the loop end instruction must be an [LETP](#) instruction. If an [LE](#) instruction is used in this scenario, the predication applied might be incorrect.

Applies to an implementation of the architecture *Armv8.1-M* onward. The extension requirements are - [LOB](#) && [MVE](#).

I<sub>TPKG</sub>

When a [WLS](#) or a [DLS](#) instruction is used to initialize a loop, the loop end instruction must be an [LE](#) instruction.

Applies to an implementation of the architecture *Armv8.1-M* onward. The extension requirements are - [LOB](#).

R<sub>RKZN</sub>

The execution of an implicit or explicit [LE](#), [LETP](#) instruction is CONSTRAINED UNPREDICTABLE anywhere within an IT block. When the instruction is committed for execution, one of the following occurs:

- An UNDEFINED exception is taken.
- ITSTATE is cleared to 0.

- The instructions are executed as if they had passed the condition code check and the ITSTATE is advanced.
- The instructions execute as NOPs, as if they had failed the condition code check and the ITSTATE is not advanced.

*Applies to an implementation of the architecture **Armv8.1-M** onward. The extension requirements are - **LOB**.*

[LTPSIZE](#).

## B3.29 Branch future

**I<sub>TBQH</sub>** The Armv8.1-M architecture supports branch future instructions (BF instructions). The BF instruction and its variants are requests to the PE to perform a branch in the future. The variants of the branch future instruction are BF, BFX, BFL, BFLX, and BFCSEL.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - LOB.*

**I<sub>VCGC</sub>** An example of a BF branch point is as follows:

```
1 start:
2     BFX b_label, LR          // Set up BF at b_label
3     ADD r0, r0, r1
4     ADD r0, r0, r2
5     ADD r0, r0, r3
6     // This is the BF branch point
7 b_label:
8     BX LR                   // Executed if LO_BRANCH_INFO invalid
```

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - LOB.*

**R<sub>SVXL</sub>** If the last instruction immediately before the BF branch point writes to LR, and a BFL or BFLX set up the BF branch point, then LR is set to the return address, and not to the value that is generated by the instruction at the BF branch point.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - LOB.*

**R<sub>FZVC</sub>** BF initializes the LO\_BRANCH\_INFO register to cause a low overhead branch just before execution reaches the specified label, that is the branch point.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - LOB.*

**R<sub>JTGY</sub>** When BF causes a branch, this branch occurs at the branch point. The instruction after the branch point is not executed if the branch is taken.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - LOB.*

**R<sub>JVJF</sub>** Inserting the BF branch point in the middle of a T32 instruction results in one of the following CONSTRAINED UNPREDICTABLE behaviors:

- It executes as a NOP.
- It raises an UNDEFINED instruction fault.
- It executes normally and the branch that is associated with the BF instruction is taken.
- It executes normally and the branch that is associated with the BF instruction is not taken.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - LOB.*

**R<sub>VGJR</sub>** If the BF branch point is in an IT block, and it does not immediately precede the last instruction in the IT block, then the following CONSTRAINED UNPREDICTABLE behaviors can result:

- The instruction executes normally and the branch that is associated with the BF instruction is not taken. The BF instruction can be treated as a NOP.
- The instruction before the BF branch point raises an UNDEFINED instruction fault.
- ITSTATE is cleared to 0.
- Taking the branch that is associated with the BF instruction causes ITSTATE to become UNKNOWN.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - LOB.*

**R<sub>HLVZ</sub>** If a BF branch point is within an IT block, the branch that was created by the BF instruction is not affected by the IT condition.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - LOB.*

$R_{JFHP}$  When executing in Handler mode, [BF](#) instructions that attempt to cause a branch to [EXC\\_RETURN](#) behave as NOPs.

*Applies to an implementation of the architecture [Armv8.1-M](#) onward. The extension requirements are - [LOB](#).*

$R_{BGSF}$  In an implementation that includes the Security Extension, [BF](#) instructions that attempt to cause a branch to [FNC\\_RETURN](#) behave as NOPs.

*Applies to an implementation of the architecture [Armv8.1-M](#) onward. The extension requirements are - [LOB](#) && [S](#).*

$R_{MCKJ}$  Taking a branch that is created by the BF instruction clears ITSTATE to 0.

*Applies to an implementation of the architecture [Armv8.1-M](#) onward. The extension requirements are - [LOB](#).*

## B3.30 Vector tables

R<sub>NWFF</sub>

In a PE with the Security Extension, two vector tables are implemented, the Secure Vector table and the Non-secure Vector table, and it is IMPLEMENTATION DEFINED which of the following is true:

- The PE supports configurability of each vector table base, and two Vector Table Offset Registers, [VTOR\\_S](#) and [VTOR\\_NS](#), are provided for this purpose.
- The PE does not support configurability of either vector table base, and [VTOR\\_S](#) and [VTOR\\_NS](#) are WI.

If the PE supports configurability of each vector table base:

- Exceptions that target Secure state use [VTOR\\_S](#) to determine the base address of the Secure vector table.
- Exceptions that target Non-secure state use [VTOR\\_NS](#) to determine the base address of the Non-secure vector table.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [S](#).*

R<sub>GTJQ</sub>

In a PE without the Security Extension, a single vector table is implemented, and it is IMPLEMENTATION DEFINED which of the following is true:

- The PE supports configurability of the vector table base, and a single Vector Table Offset Register, [VTOR](#), is provided for this purpose.
- The PE does not support configurability of the vector table base, and [VTOR](#) is WI.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [!S](#).*

I<sub>WFGX</sub>

Arm recommends that [VTOR\\_S](#) points to memory that is Secure and not Non-secure callable.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [S](#).*

R<sub>WPRT</sub>

A vector table contains both:

- The initialization value for the main stack pointer on reset.
- The start address of each exception handler.

The *exception number* defines the order of entries.

| Word offset in vector table | Value that is held at offset                                     |
|-----------------------------|------------------------------------------------------------------|
| 0                           | Initial value for the main stack pointer on reset.               |
| 1                           | Start address for the reset handler.                             |
| Exception number            | Start address for the handler for the exception with that number |
| .                           | .                                                                |
| .                           | .                                                                |
| .                           | .                                                                |
| Exception number            | Start address for the handler for the exception with that number |

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>LFDL</sub>

In a PE with a configurable vector table base, the vector table is naturally-aligned to a power of two, with an alignment value that is:

- A minimum of 128 bytes.
- Greater than or equal to (Number of Exceptions supported x4).

*Applies to an implementation of the architecture Armv8.0-M onward.*

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| R <sub>VDPD</sub>  | <p>Vector fetches for entries beyond the natural alignment of the associated <a href="#">VTOR</a> occur from an UNKNOWN entry within the vector table.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward.</i></p>                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| I <sub>P LSB</sub> | <p>Arm recommends that it is ensured that the vector table and <a href="#">VTOR</a> are aligned so that the entry for the highest taken exception falls within the natural alignment of the table, and at a minimum that the vector table is 128 byte aligned. A PE might impose further restrictions on the <a href="#">VTOR</a>.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward.</i></p>                                                                                                                                                                                                                                                                |

## B3.31 Hardware-controlled priority escalation to HardFault

**R<sub>GNVS</sub>** If a synchronous exception with an equal or lower priority to execution is pending, the PE hardware escalates it to become a HardFault. This rule applies to all synchronous exceptions and DebugMonitor exceptions that are caused by the [BKPT](#) instruction. This rule does not apply to asynchronous exceptions and all other DebugMonitor exceptions. If the HardFault cannot be taken the PE enters [Lockup](#).

*Applies to an implementation of the architecture Armv8.0-M onward. Note, DebugMonitor exception requires M.*

**R<sub>HPLM</sub>** [FPCCR](#).\*RDY (not the current execution priority) determines the escalation of synchronous exceptions generated because of lazy floating-point state preservation. This means that an asynchronous exception might be pended.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>TKCW</sub>** When the execution priority is less than HardFault and a disabled configurable-priority exception occurs, the PE escalates the configurable-priority fault to HardFault.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [M](#).*

**R<sub>DQRR</sub>** A fault that has been escalated to a HardFault, and not pended, retains the return address behavior of the original fault and sets [HFSR.FORCED](#) to 1.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**I<sub>NHFZ</sub>** When [AIRCR.IESB](#) is one, a detected asynchronous BusFault will be handled synchronously.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [RAS](#).*

## B3.32 Special-purpose mask registers, PRIMASK, BASEPRI, FAULTMASK, for configurable priority boosting

I\_BNJJG

In a PE with the Main Extension, the [PRIMASK](#), [FAULTMASK](#), and [BASEPRI](#) registers can be used as follows. A PE without the Main Extension implements [PRIMASK](#), but does not implement [FAULTMASK](#) and [BASEPRI](#).

### PRIMASK

In a PE without the Security Extension:

- Setting this bit to one boosts the current execution priority to 0, masking all exceptions with an equal or lower priority.

In a PE with the Security Extension:

- Setting [PRIMASK\\_S](#) to one boosts the current execution priority to 0.
- If [AIRCR.PRIS](#) is:

0:

Setting [PRIMASK\\_NS](#) to one boosts the current execution priority to 0.

1:

Setting [PRIMASK\\_NS](#) to one boosts the current execution priority to  $0 \times 80$ .

In a PE with the Security Extension, when the current execution priority is boosted to a particular value, all exceptions with an equal or lower priority are masked.

### FAULTMASK

In a PE without the Security Extension:

- Setting this bit to one boosts the current execution priority to -1, masking all exceptions with an equal or lower priority.

In a PE with the Security Extension, if [AIRCR.BFHFNMINS](#) is:

0:

Setting [FAULTMASK\\_S](#) to one boosts the current execution priority to -1.

If [AIRCR.PRIS](#) is:

0: Setting [FAULTMASK\\_NS](#) to one boosts the current execution priority to 0.

1: Setting [FAULTMASK\\_NS](#) to one boosts the current execution priority to  $0 \times 80$ .

1:

Setting [FAULTMASK\\_S](#) to one boosts the current execution priority to -3.

Setting [FAULTMASK\\_NS](#) to one boosts the current execution priority to -1.

In a PE with the Security Extension, when the current execution priority is boosted to a particular value, all exceptions with an equal or lower priority are masked.

### BASEPRI

In a PE without the Security Extension:

- This field can be set to a priority number between 1 and the maximum supported priority number. This boosts the current execution priority to that number, masking all exceptions with an equal or lower priority.

In a PE with the Security Extension:

- [BASEPRI\\_S](#) can be set to a priority number between 1 and the maximum supported priority number.

- If AIRCR.PRIS is:

- 0: BASEPRI\_NS can be set to a priority number between 1 and the maximum supported priority number.
- 1: BASEPRI\_NS can be set to a priority number between 1 and the maximum supported priority number. The value in BASEPRI\_NS is then mapped to the bottom half of the priority range, so that the current execution priority is boosted to the mapped-to value in the bottom half of the priority range, that is from 0x80 to the supported maximum.

In a PE with the Security Extension, when the current execution priority is boosted to a particular value, all exceptions with an equal or lower priority are masked.

*Applies to an implementation of the architecture Armv8.0-M onward. Note, FAULTMASK and BASEPRI require M.*

R\_FHMC

The PRIMASK, FAULTMASK, and BASEPRI priority boosting mechanisms only boost the group priority, not the subpriority.

*Applies to an implementation of the architecture Armv8.0-M onward. Note, FAULTMASK and BASEPRI require M.*

R\_SKBJ

Without the Security Extension:

- An exception return sets FAULTMASK to 0.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - !S && M.*

R\_HRTM

With the Security Extension:

- An exception return sets FAULTMASK to 0 if the raw execution priority is greater than or equal to 0. EXC\_RETURN.ES indicates which banked instance of FAULTMASK is set to 0.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - S && M.*

I\_LSXJ

The raw execution priority is:

- The execution priority minus the effects of any configurable PRIMASK, FAULTMASK, or BASEPRI priority boosting.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - M.*

I\_GBVL

The requested execution priority for a Security state is negative when any of the following are true:

- The banked FAULTMASK bit is 1, including when AIRCR.PRIS is also 1.
- A HardFault is active.
- An NMI is active and targets the Security state for which the requested execution priority is being calculated.

*Applies to an implementation of the architecture Armv8.0-M onward. Note, FAULTMASK requires M.*

R\_QZWN

The PRIMASK and FAULTMASK values can be set by the execution of a CPS instruction. The effects of the instruction are guaranteed to be visible when either of the following conditions apply:

- If the CPSID variant is executed, the PE serializes the change so that it is visible to instructions appearing in program order after completion of CPSID instruction.
- If the CPSIE variant is executed, the effects of the instruction are only guaranteed to be visible after a Context synchronization event.

*Applies to an implementation of the architecture Armv8.0-M onward. Note, FAULTMASK requires M.*

## B3.33 Lockup

**I<sub>RKJB</sub>** *Lockup* is a PE state where the PE stops executing instructions in response to an error for which escalation to an appropriate HardFault handler is not possible because of the current execution priority. An example is a synchronous exception that escalates to a Secure HardFault, but cannot escalate to a Secure HardFault because a Secure HardFault is already active.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**I<sub>FSFR</sub>** Arm recommends that an implementation provides a **LOCKUP** signal that, when the PE is in *lockup*, signals to the external system that the PE is in *lockup*.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>MBTM</sub>** When the PE is in *lockup*:

- **DHCSR.S\_LOCKUP** reads as 1.
- The **PC** reads as 0xEFFFFFFE. This is an XN address.
- The PE stops fetching and executing instructions.
- If the implementation provides an external **LOCKUP** signal, **LOCKUP** is asserted HIGH.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>JRJC</sub>** Exit from *lockup* is only by one of the following:

- A Cold reset.
- A Warm reset.
- Entry to Debug state.
- Preemption by another exception.

*Applies to an implementation of the architecture Armv8.0-M onward. Note, entry to Debug state requires Halting debug.*

**R<sub>HJNP</sub>** Exit from *lockup* causes both **DHCSR.S\_LOCKUP** and, if implemented, the external **LOCKUP** signal, to be deasserted.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>SPPN</sub>** On an exit from *lockup* by entry to Debug state, or by preemption by another exception, the return address is 0xEFFFFFFE.

*Applies to an implementation of the architecture Armv8.0-M onward. Note, entry to Debug state requires Halting debug.*

**I<sub>CRHJ</sub>** After exit from *lockup* by entry to Debug state, or by preemption by another exception, a subsequent return from Debug state or that exception without modifying the return address attempts to execute from 0xEFFFFFFE. Execution from this address is guaranteed to generate an IACCVIOL MemManage fault, causing the PE to reenter *lockup* if the execution priority has not been modified. Modification of the return address would enable execution to be resumed, however Arm recommends treating entry to *lockup* as fatal and requiring the PE to be reset.

*Applies to an implementation of the architecture Armv8.0-M onward. Note, entry to Debug state requires Halting debug.*

### B3.33.1 Instruction-related lockup behavior

#### Instruction execution

R<sub>VGMR</sub>

A synchronous exception results in **lockup** when:

- The synchronous exception would otherwise escalate to a Secure HardFault and any of the following is true:
  - Secure HardFault is already active.
  - NMI is active and **AIRCR.BFHFNMINS** is 0.
  - **FAULTMASK\_S.FM** is 1.
  - Non-secure HardFault is active and **AIRCR.BFHFNMINS** is 0.
- The synchronous exception would otherwise escalate to a Non-secure HardFault and any of the following is true:
  - Non-secure HardFault or Secure HardFault is already active.
  - NMI is active.
  - **FAULTMASK\_NS.FM** or **FAULTMASK\_S.FM** is 1.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **S**. Note, **FAULTMASK** requires **M**.*

R<sub>QMMB</sub>

If the Security Extension is not implemented, a synchronous exception results in **lockup** when:

- The synchronous exception would otherwise escalate to HardFault and any of the following is true:
  - HardFault is already active.
  - NMI is active.
  - **FAULTMASK** is always 1.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **!S**.*

R<sub>VGNW</sub>

Entry to **lockup** from an exception causes:

- Any Fault Status Registers associated with the exception to be updated.
- No update to the pending exception state or to the active exception state.
- The **PC** to be set to 0xEFFFFFFE.
- **EPSR.IT** to be become UNKNOWN.

In addition, **HFSR.FORCED** is not changed.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>DWKP</sub>

Asynchronous BusFaults do not cause **lockup**.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>KTQM</sub>

When a BusFault does not cause **lockup**, the value that is read or written to the location that generated the BusFault is UNKNOWN.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>HTVD</sub>

ITSTATE does not advance when the PE is in **lockup**.

*Applies to an implementation of the architecture Armv8.0-M onward.*

## Floating-point lazy Floating-point context preservation

R<sub>RNKB</sub>

When **FPCCR.LSPACT** is 1, a NOCP UsageFault, **AU** violation, **MPU** violation, or synchronous BusFault during lazy Floating-point context preservation causes **lockup** if any of the following is true:

- **FPCCR.HFRDY** is 0, the \*RDY bit associated with the original exception is 0, and the current execution priority is high enough to prevent preemption.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **FP**. Note, an MPU violation requires **MPU**, an SAU violation requires **S**.*

R<sub>MMBJ</sub>

When **FPCCR.LSPEN** is 0, any faults that are caused by floating-point register reads or writes during exception entry or exception return are handled as faults on stacking or unstacking respectively.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **FP**.*

## B3.33.2 Exception-related lockup behavior

### Vector or stack pointer error on reset

R<sub>BHVG</sub>

On reset, if reading the vector table to obtain either the vector for the reset handler or the initialization value for the main stack pointer causes a BusFault, the PE enters **lockup** in HardFault with the following behavior:

- **HFSR.VECTTBL** is set to 1.
- In a PE with the Security Extension, Secure HardFault is made active. That is, **SHCSR.S.HARDFFAULTACT** is set to 1.
- In a PE without the Security Extension, HardFault is made active. That is, **SHCSR.HARDFFAULTACT** is set to 1.
- An UNKNOWN value is loaded into the main stack pointer.
- The **IPSR** is set to 0.
- **EPSR.T** is UNKNOWN.
- **EPSR.IT** is set to zero.
- The **PC** is set to 0xEFFFFFFE.

*Applies to an implementation of the architecture Armv8.0-M onward. Note, a Secure HardFault requires S.*

### Errors on preemption and stacking for exception entry

R<sub>VKTX</sub>

An **AU** violation, **MPU** violation, NOCP UsageFault, STKOF UsageFault, LSERR SecureFault, or synchronous BusFault during context stacking causes **lockup** when:

- The exception would escalate to a Secure HardFault if any of the following is true:
  - Secure HardFault is already active.
  - NMI is active and **AIRCR.BFHFNMINs** is 0.
  - **FAULTMASK.S.FM** is 1.
  - Non-secure HardFault is active and **AIRCR.BFHFNMINs** is 0.
- The exception would escalate to a Non-secure HardFault if any of the following is true:
  - Non-secure HardFault or Secure HardFault is already active.
  - NMI is active.
  - **FAULTMASK.NS.FM** or **FAULTMASK.S.FM** is 1.

In these cases, the point of PE **lockup** is when, after the exception to be taken has been chosen, the handler for that exception is entered. These cases do not in themselves cause any additional exception to become pending.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **S**. Note, an AU violation requires S, an MPU violation requires MPU, a UsageFault requires M, a SecureFault requires S.*

R<sub>QSSB</sub>

When an **AU** violation, **MPU** violation, NOCP UsageFault, STKOF UsageFault, LSERR SecureFault, or synchronous BusFault occurs during context stacking, it is IMPLEMENTATION DEFINED whether the PE continues to stack any of the remaining context.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **S**. Note, an AU violation requires S, an MPU violation requires MPU, a UsageFault requires M, a SecureFault requires S, LSERR requires FP.*

R<sub>GJJG</sub>

At the point of encountering an [AU](#) violation, [MPU](#) violation, NOCP UsageFault, STKOF UsageFault, LSERR SecureFault, or synchronous bus error during context stacking, the PE:

- Updates any Fault Status Registers associated with the error.
- Does not change [HFSR.FORCED](#).

At the point of [lockup](#):

- All state, including the [LR](#), [IPSR](#), and active and pending bits, is modified as though the fault on context stacking had never occurred, other than the following:
  - [EPSR.T](#) becomes UNKNOWN.
  - [EPSR.IT](#) is set to zero.
  - The [PC](#) is set to 0xEFFFFFFE.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are -S. Note, an AU violation requires S, an MPU violation requires MPU, a UsageFault requires M, a SecureFault requires S, LSERR requires FP.*

## Vector read error on NMI or HardFault entry

R<sub>CTKP</sub>

On entry to an NMI or HardFault, if reading the vector table to obtain the vector for the NMI or HardFault handler causes a bus error, the PE enters [lockup](#) with the following behavior:

- [HFSR.VECTTBL](#) is set to 1.
- The [IPSR](#) is updated to hold the exception number of the exception taken.
- The active bit of the exception that is taken is set to 1.
- The pending bit of the exception that is taken is cleared to 0.
- [EPSR.T](#) is UNKNOWN.
- [EPSR.IT](#) is set to zero.
- The [LR](#) is set to the [EXC\\_RETURN](#) value that would have been used had the fault not occurred.
- The [PC](#) is set to 0xEFFFFFFE.

*Applies to an implementation of the architecture Armv8.0-M onward.*

I<sub>NMRW</sub>

Because [AU](#) violations on vector reads are required to be treated as late-arriving, they cannot cause [lockup](#), and instead result in a higher priority exception being taken. Vector reads always use the system address map and cannot generate [MPU](#) violations.

*Applies to an implementation of the architecture Armv8.0-M onward.*

## Integrity checks on exception return

R<sub>TRFJ</sub>

A fault that is generated by a failed *integrity check on exception return* is generated after either the active bit for the returning exception, or the active bit for NMI or HardFault, has been cleared to 0, and if applicable, after [FAULTMASK](#) has also been cleared to 0. A fault that is generated by a failed integrity check on exception return causes [lockup](#) when:

- The exception would escalate to a Secure HardFault and any of the following is true:
  - Secure HardFault is already active.
  - NMI is active and [AIRCR.BFHFNMINS](#) is 0.
  - [FAULTMASK\\_S.FM](#) is 1.
  - Non-secure HardFault is active and [AIRCR.BFHFNMINS](#) is 0.
- The exception would escalate to a Non-secure HardFault and any of the following is true:
  - Non-secure HardFault or Secure HardFault is already active.
  - NMI is active.
  - [FAULTMASK\\_NS.FM](#) or [FAULTMASK\\_S.FM](#) is 1.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - S.*

R<sub>DFKP</sub>

When the PE enters **lockup** because of a fault that is generated by a failed integrity check, the PE:

- Updates any Fault Status Registers associated with the error.
- Sets **IPSR** to 0, if **EXC\_RETURN** for the returning exception indicated a return to Thread mode.
- Sets **IPSR** to 3, if **EXC\_RETURN** for the returning exception indicated a return to Handler mode.
- Sets the stack pointer that is used for unstacking to the value it would have had if the fault had not occurred.
  - If the **XPSR** load faults, the SP is 64-bit aligned.
- Updates **CONTROL.FPCA**, based on **EXC\_RETURN.FType**.
- **CONTROL.SFPA** becomes UNKNOWN.
- Sets the **PC** to 0xEEFFFFFFE.

In addition, the **APSR**, **EPSR**, **FPSCR**, R0-R12, **LR**, and S0-S31 are UNKNOWN.

*Applies to an implementation of the architecture Armv8.0-M onward. Note, **CONTROL.FPCA** and **SFPA**, **FPSCR** and S0-S31 require FP || MVE. MVE is only available in an Armv8.1-M implementation.*

R<sub>XNZJ</sub>

When the PE enters **lockup** because of a fault that is generated by a failed integrity check, and MVE is implemented, **VPR** is UNKNOWN.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - MVE.*

## Errors when unstacking state on exception return

R<sub>WKSJ</sub>

Context unstacking is performed after any clearing of exception active bits or **FAULTMASK**, that is required by the exception return, has been made visible. A synchronous exception during context unstacking causes **lockup** when:

- The exception would escalate to a Secure HardFault and any of the following is true:
  - Secure HardFault is already active.
  - **FAULTMASK.S.FM** is 1.
  - Non-secure HardFault is active and **AIRCR.BFHFNMINS** is 0.
- The exception would escalate to a Non-secure HardFault and any of the following is true:
  - Non-secure HardFault or Secure HardFault is already active.
  - NMI is active.
  - **FAULTMASK.NS.FM** or **FAULTMASK.S.FM** is 1.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - S.*

R<sub>XFCQ</sub>

When a synchronous exception during context unstacking causes **lockup**, the PE:

- Updates any Fault Status Registers associated with the error.
- Sets **IPSR** to 0, if **EXC\_RETURN** for the returning exception indicated a return to Thread mode.
- Sets **IPSR** to 3, if **EXC\_RETURN** for the returning exception indicated a return to Handler mode.
- Sets the stack pointer that is used for unstacking to the value it would have had if the fault had not occurred.
  - If the **XPSR** load faults, the **SP** is 64-bit aligned.
- Updates **CONTROL.FPCA**, based on **EXC\_RETURN**.
- Sets the **PC** to 0xEEFFFFFFE.

In addition, the **APSR**, **EPSR**, **FPSCR**, R0-R12, **LR**, and S0-S31 are UNKNOWN.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>WZFG</sub>

When the PE enters [lockup](#) because of an [AU](#) violation, [MPU](#) violation, or synchronous BusFault during context unstacking, and MVE is implemented, [VPR](#) is UNKNOWN.

*Applies to an implementation of the architecture **Armv8.1-M** onward. The extension requirements are - [MVE](#).*

## B3.37 The Custom Datapath Extension

### B3.37.1 Overview of the Custom Datapath Extension

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| I <sub>QNBG</sub> | <p>CDE introduces three classes of two instructions in the co-processor instruction space:</p> <ul style="list-style-type: none"> <li>• Three classes operate on the general-purpose register file, including the condition code flags APSR_nzcv.</li> <li>• Three classes operate on the Floating-point or SIMD register file only.</li> </ul> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <b>CDE</b>. Note, (FP    MVE) required for Floating-point register file. MVE is only available in an Armv8.1-M implementation.</i></p>                                                                                |
| I <sub>JWBF</sub> | <p>A Custom Datapath instruction operating on the Floating-point or SIMD register files uses one of:</p> <ul style="list-style-type: none"> <li>• 32-bit S registers.</li> <li>• 64-bit D registers.</li> <li>• 128-bit Q registers.</li> </ul> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <b>CDE</b> &amp;&amp; (FP    MVE). Note, Q registers require MVE, MVE is only available in an Armv8.1-M implementation.</i></p>                                                                                                                                                                                       |
| I <sub>RBLJ</sub> | <p>The three classes of CDE instructions are defined by the following patterns:</p> <ul style="list-style-type: none"> <li>• &lt;operation code&gt; &lt;destination register&gt;.</li> <li>• &lt;operation code&gt; &lt;destination register&gt;, &lt;source register&gt;.</li> <li>• &lt;operation code&gt; &lt;destination register&gt;, &lt;source register 1&gt;, &lt;source register 2&gt;.</li> </ul> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <b>CDE</b>.</i></p>                                                                                                                                       |
| I <sub>FZRZ</sub> | <p>The destination register of a Custom Datapath instruction might be optionally read, as well as written.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <b>CDE</b>.</i></p>                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| I <sub>BXBG</sub> | <p>The operation code can be split between a true operation code in the custom datapath and an immediate value used in the custom datapath. The architecture does not prescribe any split.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <b>CDE</b>.</i></p>                                                                                                                                                                                                                                                                                                                                                    |
| I <sub>NFMB</sub> | <p>Immediate consequences of the above are:</p> <ul style="list-style-type: none"> <li>• No operations on the Floating-point or SIMD registers can set condition codes.</li> <li>• There are no instructions that support the use of all of, or any combination of the following: <ul style="list-style-type: none"> <li>– S registers.</li> <li>– D registers.</li> <li>– Q registers.</li> <li>– The general-purpose register file.</li> </ul> </li> </ul> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <b>CDE</b>. Note, Q registers require MVE, MVE is only available in an Armv8.1-M implementation.</i></p> |
| I <sub>TVRP</sub> | <p>Operations on the general-purpose register file operate on 32-bit registers, or a dual-register consisting of a 64-bit value constructed from an even numbered general-purpose register and its immediately following odd numbered pair.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <b>CDE</b>.</i></p>                                                                                                                                                                                                                                                                                                   |

### B3.37.2 Enabling CDE instructions

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| I <sub>CXBC</sub> | <p>Custom Datapath instructions can be found within, and are associated with, the existing coprocessor encoding and numbering spaces.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - CDE.</i></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| R <sub>XLTS</sub> | <p>Custom Datapath instructions fall into encoding spaces associated with a <i>coprocessor</i> number in the range 0 to 7 inclusive.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - CDE.</i></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| I <sub>WWNQ</sub> | <p>Enabling the coprocessor space in which the Custom Datapath Extension is implemented is the same as other IMPLEMENTATION DEFINED coprocessors. The function <code>IsCPEEnabled()</code> describes this.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - CDE. Note, S required for Secure state.</i></p>                                                                                                                                                                                                                                                                                                                                        |
| R <sub>VSVW</sub> | <p>If a coprocessor is associated with the Custom Datapath Extension, that coprocessor cannot execute the following instructions:</p> <ul style="list-style-type: none"> <li>• CDP, CDP2.</li> <li>• LDC, LDC2 (immediate).</li> <li>• LDC, LDC2 (literal).</li> <li>• MCR, MCR2.</li> <li>• MCRR, MCRR2.</li> <li>• MRC, MRC2.</li> <li>• MRRC, MRRC2.</li> <li>• STC, STC2.</li> </ul> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - CDE.</i></p>                                                                                                                                                                                                 |
| R <sub>SKRX</sub> | <p>Execution of a Custom Datapath instruction that accesses the Floating-point or SIMD register file causes <i>Lazy Floating-point stacking</i> as specified by the architecture.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - CDE &amp;&amp; (FP    MVE). Note, MVE is only available in an Armv8.1-M implementation.</i></p>                                                                                                                                                                                                                                                                                                                 |
| R <sub>LQTN</sub> | <p>When executing a CDE instruction the PE checks that the coprocessor associated with CDE is enabled. If access to another coprocessor is required, for example the Floating-point Extension or MVE, a second coprocessor check is carried out.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - CDE &amp;&amp; (FP    MVE). Note, MVE is only available in an Armv8.1-M implementation.</i></p>                                                                                                                                                                                                                                                  |
| R <sub>GNRV</sub> | <p>The order in which the PE carries out the <code>ExecuteFPCheck()</code> function and <code>Coproc_Accepted()</code> function for execution, that is after decoding the instruction, of CDE instructions accessing the S, D or Q register files is IMPLEMENTATION DEFINED.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - CDE &amp;&amp; (FP    MVE). ## Chapter B4

# Floating-point Support

This chapter specifies the Armv8-M Floating-point support rules. It contains the following sections:

- B4.1 The optional Floating-point Extension, Fpv5.*
- B4.2 About the Floating-point Status and Control Registers.*
- B4.3 Registers for Floating-point data processing, S0-S31, or D0-D15.*
- B4.4 Floating-point standards and terminology.*
- B4.5 Floating-point data representable.*
- B4.6 Floating-point encoding formats, half-precision, single-precision, and double-precision.*
- B4.7 The IEEE 754 Floating-point exceptions.*
- B4.8 The Flush-to-zero mode.*
- B4.9 The Default NaN mode, and NaN handling.*
- B4.10 The Default NaN.*
- B4.11 Combinations of Floating-point exceptions.*
- B4.12 Priority of Floating-point exceptions relative to other Floating-point exceptions.*

## B4.1 The optional Floating-point Extension, FPUv5

I<sub>VBNH</sub>

The optional Floating-point Extension defines a *Floating Point Unit* (FPU). Coprocessors 10 and 11 support the Extension.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **FP**.*

I<sub>WPHK</sub>

The scalar Floating-point Extension can be implemented with or without **MVE-F**.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **FP**.*

I<sub>RXQX</sub>

Floating-point is sometimes abbreviated to FP.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **FP**.*

R<sub>GQBM</sub>

The version of Floating-point Extension that is supported is FPUv5.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **FP**.*

I<sub>FGSG</sub>

FPUv5 provides all of the following:

- Single-precision arithmetic operations.
- Optional double-precision arithmetic operations.
- Conversions between integer, double-precision, single-precision, and half-precision formats.
- Registers for Floating-point processing S0-S31, or D0-D15.
- Data transfers, between Arm general-purpose registers and FPUv5 Extension registers S0-S31, or D0-D15, of single-precision and double-precision values.
- A **Flush-to-zero mode** that software can enable or disable.
- An optional *alternative half-precision* interpretation of the IEEE 754 half-precision encoding format.

FPUv5 adds the following System registers:

- The **FPSCR**, to the CP10 and CP11 System register space.
- The **FPCAR**, **FPCCR**, **FPDSCR**, **MVFR0**, **MVFR1**, and **MVFR2**, to the *System Control Block* (SCB).

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **FP** || **MVE**. Note, MVE only available in an Armv8.1-M implementation.*

I<sub>TVZF</sub>

From Armv8.1-M onwards, FPUv5 provides Half-precision arithmetic operations.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **FP**.*

I<sub>PVBQ</sub>

When the Floating-point Extension is implemented, some software tools might require the following information:

| Extension | Single-precision arithmetic operations only | Single and double-precision arithmetic operations |
|-----------|---------------------------------------------|---------------------------------------------------|
| FPUv5     | FPUv5-SP-D16-M                              | FPUv5-D16-M                                       |

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **FP**.*

I<sub>FTDS</sub>

When the Floating-point Extension is implemented, software can interrogate **MVFR0**, **MVFR1**, and **MVFR2** to discover the Floating-point features that are implemented.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **FP**.*

I<sub>JDJQ</sub>

To use the Floating-point Extension, software must enable access to CP10, by writing to **CPACR.CP10**.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **FP**.*

R<sub>PDMM</sub>

The value of **CPACR.CP11** is UNKNOWN if it is not programmed to the same value as **CPACR.CP10**.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **FP**.*

## B4.2 About the Floating-point Status and Control Registers

**I<sub>FQTM</sub>** For implementations of the Armv8.1-M architecture, [FPCXT](#) and [VPR](#) provide additional controls.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [FP](#).*

**R<sub>HCJS</sub>** The register map of the coprocessor System register space is as follows.

| Location | Register                           | Information     |
|----------|------------------------------------|-----------------|
| 0b0001   | <a href="#">FPSCR.{N, Z, C, V}</a> | Access to flags |

All locations that are not explicitly listed in this table are reserved, and accesses to these locations result in UNPREDICTABLE behavior.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [FP](#).*

**R<sub>KHDZ</sub>** The register map of the coprocessor System register space is as follows.

| Location | Register                               | Information                                    |
|----------|----------------------------------------|------------------------------------------------|
| 0b0001   | <a href="#">FPSCR.{N, Z, C, V}</a>     | Access to flags                                |
| 0b0010   | <a href="#">FPSCR.{N, Z, C, V, QC}</a> | Access to flags, including MVE saturation flag |
| 0b1100   | <a href="#">VPR</a>                    | Privileged access to this register only        |
| 0b1101   | <a href="#">VPR.P0</a>                 | Access to P0 field                             |
| 0b1110   | <a href="#">FPCXT_NS</a>               | Saves and restores the Non-secure FP context   |
| 0b1111   | <a href="#">FPCXT_S</a>                | Saves and restores the Secure FP context       |

All locations that are not explicitly listed in this table are reserved, and accesses to these locations result in UNPREDICTABLE behavior.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [FP](#) || [MVE](#).*

**I<sub>GJWP</sub>** Software can use [VMRS](#) and [VMSR](#) instructions to access the Floating-point Status and Control registers.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [FP](#).*

**I<sub>DSSS</sub>** Software can use [VMRS](#), [VMSR](#), [VLDR \(System Register\)](#), and [VSTR \(System Register\)](#) instructions to access [FPCXT](#), [VPR](#), and the Floating-point Status and Control registers.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [FP](#) || [MVE](#).*

**R<sub>RRTZ</sub>** Accesses to the [FPCXT](#) will behave as NOPs unless at least one of MVE or the Floating-point Extension is implemented.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [FP](#) || [MVE](#).*

**R<sub>WXZV</sub>** Accesses to the [FPCXT](#) are UNDEFINED from the Non-secure state.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - ([FP](#) || [MVE](#)) && [S](#).*

**R<sub>FXBJ</sub>** Execution of Floating-point instructions that generate Floating-point exceptions update the appropriate status fields of [FPSCR](#).

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [FP](#).*

*FPSCR, Floating Point Status and Control Register.*

## B4.3 Registers for Floating-point data processing, S0-S31, or D0-D15

R<sub>TWCB</sub>

The registers that Fpv5 adds for Floating-point processing are visible as either:

- 32 single-precision registers, S0-S31.
- 16 double-precision registers, D0-D15.

These map as follows:

| S0-S31 |  | D0-D15 |  |
|--------|--|--------|--|
| S0     |  | D0     |  |
| S1     |  |        |  |
| S2     |  | D1     |  |
| S3     |  |        |  |
| S4     |  | D2     |  |
| S5     |  |        |  |
| S6     |  | D3     |  |
| S7     |  |        |  |
| ⋮      |  | ⋮      |  |
| S28    |  | D14    |  |
| S29    |  |        |  |
| S30    |  | D15    |  |
| S31    |  |        |  |

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - **FP** || **MVE**. Note, *MVE* only available in an *Armv8.1-M* implementation.

R<sub>XWJQ</sub>

After a Warm reset, the values of S0-S31 or D0-D15 are UNKNOWN.

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - **FP** || **MVE**. Note, *MVE* only available in an *Armv8.1-M* implementation.

R<sub>WGFL</sub>

If a **VLDM** indexes S and D registers outside of the range defined by **VFPSmallRegisterBank()** the instruction will behave as a NOP in respect of the unimplemented S or D registers.

Applies to an implementation of the architecture *Armv8.1-M* onward. The extension requirements are - **FP** || **MVE**.

R<sub>RDCQ</sub>

If a **VSTM** indexes S and D registers outside of the range defined by **VFPSmallRegisterBank()** the behavior is as follows:

- For unimplemented S registers the instructions behaves as NOP and no writes to memory occur.
- For unimplemented D registers the instruction behaves either as a NOP or it is permissible for some writes to the addresses specified by the instruction to occur but the values written will be UNKNOWN.

Applies to an implementation of the architecture *Armv8.1-M* onward. The extension requirements are - **FP** || **MVE**.

R<sub>DLNJ</sub>

If a **VSCCLRM** indexes S and D registers outside of the range defined by **VFPSmallRegisterBank()** the instruction will behave as a NOP in respect of the unimplemented S or D registers.

Applies to an implementation of the architecture *Armv8.1-M* onward. The extension requirements are - **FP** || **MVE**.

[B4.1 The optional Floating-point Extension, Fpv5.](#)

[B3.18 Exception handling.](#)

## B4.4 Floating-point standards and terminology

I<sub>XNMN</sub>

There are two editions of the IEEE 754 standard:

- IEEE 754-1985.
- IEEE 754-2008.

In this manual, references to IEEE 754 that do not include the year apply to either edition.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **FP**.*

I<sub>MQFS</sub>

The Floating-point terminology that this manual uses differs from that used in IEEE 754-2008 as follows:

| This manual                        | IEEE 754-2008                |
|------------------------------------|------------------------------|
| Normalized                         | Normal                       |
| Denormal, or denormalized          | Subnormal                    |
| Round towards Minus Infinity (RM)  | roundTowardNegative          |
| Round towards Plus Infinity (RP)   | roundTowardPositive          |
| Round towards Zero (RZ)            | roundTowardZero              |
| Round to Nearest (RN)              | roundTiesToEven              |
| Round to Nearest with Ties to Away | roundTiesToAway              |
| Rounding mode                      | Rounding-direction attribute |

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **FP**.*

I<sub>BGNP</sub>

The following is called *Arm standard Floating-point operation*:

- IEEE 754-2008 plus the following configuration:
  - Flush-to-zero mode enabled.
  - Default NaN mode enabled.
  - Round to Nearest mode selected.
  - Alternative half-precision interpretation not selected.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **FP**.*

See also:

*IEEE 754-2008, IEEE Standard for Floating-point Arithmetic, August 2008.*

[B4.8 The Flush-to-zero mode.](#)

[B4.9 The Default NaN mode, and NaN handling.](#)

[B4.6 Floating-point encoding formats, half-precision, single-precision, and double-precision.](#)

## B4.5 Floating-point data representable

R<sub>FWXC</sub>

FPv5 supports the following, as defined by IEEE 754:

- Normalized numbers.
- Denormalized numbers.
- Zeros, +0 and -0.
- Infinities,  $+\infty$  and  $-\infty$ .
- NaNs, signaling NaNs and quiet NaN.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **FP**.*

See also:

[B4.4 Floating-point standards and terminology.](#)

*IEEE 754-2008, IEEE Standard for Floating-point Arithmetic, August 2008.*

[B4.6 Floating-point encoding formats, half-precision, single-precision, and double-precision.](#)

**R<sub>RHKS</sub>** The half-precision, single-precision, and double-precision encoding formats are those defined by IEEE 754-2008, in addition to an alternative half-precision format.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are -FP.*

$I_{LGTJ}$  The half-precision encoding format is:

*Applies to an implementation of the architecture **Armv8.0-M** onward. The extension requirements are - **FP**.*

$I_{\text{CWBP}}$  The single-precision encoding format is:

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are -FP.*

$\mathbb{I}_{\text{FVWV}}$  The double-precision encoding format is:

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are -FP.*

$R_{RWRW}$  The interpretations of the half-precision, single-precision, and double-precision encoding formats are as follows.

### Half-precision

There are two interpretations of the half-precision encoding formats:

- The interpretation that is defined by IEEE 754-2008.
- An alternative half-precision interpretation, indicated by [FPSCR.AHP](#).

## Single-precision

The interpretation that is defined by IEEE 754-2008.

## Double-precision

The interpretation that is defined by IEEE 754-2008. See the following table:

| <b>E</b><br><b>(biased</b><br><b>exponent)</b>                      | <b>T</b><br><b>(trailing</b><br><b>significand)</b> | <b>S</b><br><b>(sign bit)</b> | <b>T</b><br><b>[51]</b> | <b>Value</b>           |
|---------------------------------------------------------------------|-----------------------------------------------------|-------------------------------|-------------------------|------------------------|
| Zero for all formats.                                               | Nonzero                                             | -                             | -                       | A denormalized number. |
| -                                                                   | Zero                                                | 0                             | -                       | Zero, +0               |
| -                                                                   | -                                                   | 1                             | -                       | Zero, -0               |
| Zero < E < 0x1F, if one of the half precision formats.              | -                                                   | -                             | -                       | A normalized number.   |
| Zero < E < 0xFF, if single-precision format.                        | -                                                   | -                             | -                       | -                      |
| Zero < E < 0x7FF, if double-precision format.                       | -                                                   | -                             | -                       | -                      |
| 0x1F, if half-precision format, IEEE interpretation.                | Nonzero                                             | -                             | 0                       | A signaling NaN        |
| 0xFF, if single-precision format.                                   | -                                                   | -                             | 1                       | A quiet NaN            |
| 0x7FF, if double-precision format.                                  | Zero                                                | 0                             | -                       | Infinity, +∞           |

| 0x1F, if half-precision, alternative half-precision interpretation. | -                                                   | -                             | -                       | A normalized number.   |

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - **FP**.

R<sub>DPHH</sub>

The value of a normalized number is equal to:

**Half-precision:**  $(-1)^S \times 2^{(E-15)} \times (1.T)$

**Single-precision:**  $(-1)^S \times 2^{(E-127)} \times (1.T)$

**Double-precision:**  $(-1)^S \times 2^{(E-1023)} \times (1.T)$

The value of a denormalized number is equal to:

**Half-precision:**  $(-1)^S \times 2^{-14} \times (0.T)$

**Single-precision:**  $(-1)^S \times 2^{-126} \times (0.T)$

**Double-precision:**  $(-1)^S \times 2^{-1022} \times (0.T)$

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - **FP**.

R<sub>PKXD</sub>

Denormalized numbers can be flushed to zero. FPUv5 provides a **Flush-to-zero mode**.

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - **FP**.

## B4.7 The IEEE 754 Floating-point exceptions

R<sub>BCCl</sub>

The IEEE 754 Floating-point exceptions are:

**Invalid Operation:** This exception is as IEEE 754-2008 (7.2) describes.

**Division by zero:** This exception is as IEEE 754-2008 (7.3) describes, with the following assumption:

- For the reciprocal and reciprocal square root estimate functions the dividend is assumed to be +1.0.

**Overflow:** This exception is as IEEE 754-2008 (7.4) describes.

**Underflow:** This exception is as IEEE 754-2008 (7.5) describes, with the additional clarification that:

- Assessing whether a result is tiny and nonzero is done before rounding.

**Inexact:** This exception is as IEEE 754-2008 (7.6) describes.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **FP**.*

I<sub>JCWS</sub>

The criteria for the Underflow exception to be generated are different in [Flush-to-zero mode](#).

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **FP**.*

I<sub>NFHK</sub>

The corresponding status flags for the IEEE 754 Floating-point exceptions are FPSCR.{IOC, DZC, OFC, UFC, IXC}.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **FP**.*

## B4.10 The Default NaN

R\_FQFG

The Default NaN is:

| Field | Half-precision,<br>IEEE 754-2008 interpretation | Single-precision              | Double-precision              |
|-------|-------------------------------------------------|-------------------------------|-------------------------------|
| S     | 0                                               | 0                             | 0                             |
| E     | 0x1F                                            | 0xFF                          | 0x7FF                         |
| T     | bit[9] == 1, bits[8:0] == 0                     | bit[22] == 1, bits[21:0] == 0 | bit[51] == 1, bits[50:0] == 0 |

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - **FP**.

See also:

[B4.6 Floating-point encoding formats, half-precision, single-precision, and double-precision.](#)

[B4.9 The Default NaN mode, and NaN handling.](#)

## B4.11 Combinations of Floating-point exceptions

$I_{BTTH}$

In compliance with IEEE 754:

- An Inexact Floating-point exception can occur with an Overflow Floating-point exception.
- An Inexact Floating-point exception can occur with an Underflow Floating-point exception.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **FP**.*

$R_{LEFH}$

An Input Denormal exception can occur with other Floating-point exceptions.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **FP**.*

See also:

[B4.7 The IEEE 754 Floating-point exceptions.](#)

[B4.8 The Flush-to-zero mode.](#)

## B4.12 Priority of Floating-point exceptions relative to other Floating-point exceptions

R<sub>PLHJ</sub>

Some Floating-point instructions specify more than one Floating-point operation. In these cases, an exception on one operation is higher priority than an exception on another operation when generation of the second exception depends on the result of the first operation. Otherwise, it is UNPREDICTABLE which exception is higher priority.

*Applies to an implementation of the architecture **Armv8.0-M** onward. The extension requirements are - **FP**.*

See also:

[B4.7 The IEEE 754 Floating-point exceptions.](#)

## Chapter B5

# Vector Extension

This chapter specifies the optional Armv8.1-M Vector Extension rules. It contains the following sections:

*B5.1 Vector Extension operation.*

*B5.2 Vector register file.*

*B5.3 Lanes.*

*B5.4 Beats.*

*B5.5 Exception state.*

*B5.6 Predication/conditional execution.*

*B5.7 MVE interleaving/de-interleaving loads and stores.*

*Applies to an implementation of the architecture **Armv8.1-M** onward.*

## B5.1 Vector Extension operation

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## B5.2 Vector register file

R<sub>BBYH</sub>

**MVE** defines eight vector registers that alias onto the Floating-point Extension register file.

```
1 Q[0][127:96] = S3, Q[0][95:64] = S2, Q[0][63:32] = S1, Q[0][31:0] = S0
2 Q[1][127:96] = S7, Q[1][95:64] = S6, Q[1][63:32] = S5, Q[1][31:0] = S4
3 ...
4 Q[7][127:96] = S31, Q[7][95:64] = S30, Q[7][63:32] = S29, Q[7][31:0] = S28
```

These registers map as follows:

Applies to an implementation of the architecture *Armv8.1-M* onward. The extension requirements are - **MVE**.

R<sub>PPPV</sub>

If CP10 is enabled, access to vector register 0-7 is permitted, unless otherwise stated in the individual instruction descriptions.

Applies to an implementation of the architecture *Armv8.1-M* onward. The extension requirements are - **MVE**.

I<sub>MFLD</sub>

To reduce pressure on the vector register file, many vector instructions can use scalar arguments from the general-purpose register file.

Applies to an implementation of the architecture *Armv8.1-M* onward.

I<sub>WWPZ</sub>

After a Warm reset, the values of Q0-Q7 are UNKNOWN.

Applies to an implementation of the architecture *Armv8.1-M* onward.

[C1.4 Instruction set encoding information.](#)

## B5.3 Lanes

$R_{DWVD}$  The lane width of the operation to be performed is specified by the instruction that is being executed.

*Applies to an implementation of the architecture **Armv8.1-M** onward. The extension requirements are - **MVE**.*

$R_{QSBC}$  The permitted lane widths, and lane operations per beat, are:

- For a 64-bit lane size, a beat performs half of the lane operation.
- For a 32-bit lane size, a beat performs a one lane operation.
- For a 16-bit lane size, a beat performs a two lane operations.
- For an 8-bit lane size, a beat performs a four lane operations.

| Bit positions | 127 | 96 | 95 | 64 | 63 | 32 | 31 | 0 |   |   |   |   |   |   |   |   |
|---------------|-----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|
| A)            | 15  | 14 | 13 | 12 | 11 | 10 | 9  | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| B)            | 7   |    | 6  |    | 5  |    | 4  |   | 3 |   | 2 |   | 1 |   | 0 |   |
| C)            | 3   |    |    |    | 2  |    |    |   | 1 |   |   |   | 0 |   |   |   |
| D)            | 1   |    |    |    |    |    |    |   | 0 |   |   |   |   |   |   |   |

- A) 8-bit lane numbers  
B) 16-bit lane numbers  
C) 32-bit lane numbers  
D) 64-bit lane numbers

*Applies to an implementation of the architecture **Armv8.1-M** onward. The extension requirements are - **MVE**.*

[Chapter C2, Instruction specification](#)

## B5.4 Beats

$I_{YYZD}$  A vector instruction executes beats sequentially, from beat 0-3.

|              |     |    |    |    |    |    |    |   |
|--------------|-----|----|----|----|----|----|----|---|
| Bit position | 127 | 96 | 95 | 64 | 63 | 32 | 31 | 0 |
| Beat number  | 3   |    |    | 2  |    | 1  |    | 0 |

*Applies to an implementation of the architecture Armv8.1-M onward.*

$I_{PCBB}$  The number of beats for each tick describes how much of the architectural state is updated for each [Architecture tick](#) in the common case. In a trivial implementation, an [Architecture tick](#) might be one clock cycle:

- In a single-beat system, one beat might occur for each tick.
- In a dual-beat system, two beats might occur for each tick.
- In a quad-beat system, four beats might complete for each tick.

*Applies to an implementation of the architecture Armv8.1-M onward.*

$R_{XTZH}$  It is IMPLEMENTATION DEFINED how many beats are executed for each [Architecture tick](#).

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - MVE.*

$I_{MWSJ}$  The number of beats per tick might change at runtime and is not required to be constant.

*Applies to an implementation of the architecture Armv8.1-M onward.*

$R_{QJJP}$  Multiple faults might occur within a single [Architecture tick](#). In this case, only one fault is raised. The fault that is generated is determined using the following priorities:

- The fault from the oldest instruction takes priority.
- If multiple faults are associated with the oldest faulting instruction, the fault that was generated by the lowest numbered [Beat](#) takes priority.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - MVE.*

$I_{LHXJ}$  An exception can be taken on any beat of a vector instruction. [RETPSR.ECI](#) in the exception stack frame stores information about how many beats of the instruction at the return address and how many beats of the subsequent instruction have been executed.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - MVE.*

$R_{VVVG}$  When the execution of a beat-wise instruction raises a MemManage, BusFault, or SecureFault as a result of SAU or IDAU permission violations, the Fault Address Register associated with the exception is permitted to report any address associated with any lane of the instruction, including lanes predicated false, if all of the following are true:

- The lane associated with the address being reported belongs to the same beat as the lane that caused the fault.
- The address being reported is in the same 32-byte naturally-aligned address range as the lane that caused the fault.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - MVE.*

$R_{FXDM}$  If multiple lanes of a beat-wise instruction raise a MemManage, BusFault, or SecureFault as a result of SAU or IDAU permission violations within a single [Architecture tick](#), it is IMPLEMENTATION DEFINED which lane's fault is raised.

Regardless of which lane's fault is raised, a valid ECI value must be generated, and the ECI value must be consistent with the updates made to other architecture state, for example the Q or R register values.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - MVE.*

**I<sub>ZBKX</sub>** A dual-beat overlap system implies that the last two beats of a vector instruction can overlap with the first two beats of the next vector instruction.

*Applies to an implementation of the architecture Armv8.1-M onward.*

**I<sub>GNLS</sub>** The following is an example of a dual-beat system where two beats are executed per [Architecture tick](#). The figure labels are:

**Tick** [Architecture tick](#).

**A0-A3** Beats of the `VLDWR` instruction.

**B0-B3** Beats of the `VMUL` instruction.

**C0-C3** Beats of the `VSHR` instruction.

#### Vector instructions not overlapping

```
VLDWR.U32 Q1, [R0], #16
VMUL.I32  Q0, Q1,  Q2
VSHR.U32  Q0, Q0,  #1
```

#### Vector instructions overlapping

```
VLDWR.U32 Q1, [R0], #16
VMUL.I32  Q0, Q1,  Q2
VSHR.U32  Q0, Q0,  #1
```

[EPSR.ECI](#) explains how beats are captured in the ECI field.

*Applies to an implementation of the architecture Armv8.1-M onward.*

**R<sub>VWBD</sub>** The PE can resume execution of an [exception continuable instruction](#) from any valid ECI value, even if the PE cannot generate all the ECI values.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [MVE](#).*

**R<sub>KRNF</sub>** Instructions that are subject to beat-wise execution can only overlap if they are consecutive in the execution order.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [MVE](#).*

**R<sub>FKCG</sub>** The architecturally visible overlap of instructions is only permitted for instructions subject to beat-wise execution if:

- The overlap does not violate data dependencies between instruction beats.
- The overlap is not between two instructions subject to beat-wise execution that both access memory.
- In a low overhead loop, the overlap does not violate [LR hazard](#).
- The overlap is not between an instruction before a [BF branch point](#) and the instruction at the target of the BF.
- An implicit [LE](#), [LETP](#) instruction is executed at the end of a loop body when [LO\\_BRANCH\\_INFO](#) is valid and the instruction after the implicit [LE](#), [LETP](#) instruction in execution order is subject to beat-wise execution.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [MVE](#).*

**I<sub>NQKF</sub>** Vector instructions are permitted to overlap if the data dependency is at beat granularity and not at instruction granularity.

*Applies to an implementation of the architecture Armv8.1-M onward.*

R<sub>PRSG</sub>

After each [Architecture tick](#), the architectural instruction overlap is representable by a valid [EPSR.ECI](#) value.

*Applies to an implementation of the architecture **Armv8.1-M** onward. The extension requirements are - [MVE](#).*

*Applies to an implementation of the architecture Armv8.1-M onward.*

Applies to an implementation of the architecture *Armv8.1-M* onward.

I<sub>ZPTT</sub>

In **EPSR**, **XPSR**, and **RETPSR**, the ECI and ICI fields, and ITSTATE overlap.

Applies to an implementation of the architecture *Armv8.1-M* onward.

R<sub>KFZJ</sub>

The PE does not generate an INVSTATE Usage fault if a nonzero value in **EPSR.ICI** corresponds to a valid value in **EPSR.ECI**, and the instruction that is being executed is:

- A vector instruction that is subject to beat-wise execution.
- An **LE**, **LETP** instruction.
- An FPB generated **breakpoint** or a **BKPT** instruction.

The execution of the **breakpoint** or LE instruction does not advance any of the register fields that are used for instruction beat execution tracking.

Applies to an implementation of the architecture *Armv8.1-M* onward. The extension requirements are - **MVE**. Note, FPB requires FPB.

I<sub>GRFW</sub>

The architecture tracks the completion of beats within vector instructions. Because the **Element** size can be smaller than the beat size, it is possible that an exception might be generated for a beat that has only partially completed.

Applies to an implementation of the architecture *Armv8.1-M* onward.

R<sub>QDSP</sub>

If execution of a beat is abandoned, then:

- [RETPSR.ECI](#) only indicates that a beat is completed if all the [Elements](#) that are associated with the beat have been completed.
- If the destination register is not the same as the source register for an instruction that is abandoned because of an exception, the parts of a vector destination register that are associated with an abandoned beat, and all subsequent beats of the abandoned instruction, are set to an UNKNOWN value if the parts of the destination register would have been written to had the abandoned instruction been completed. It must not be possible for some parts of the destination register to become UNKNOWN that would otherwise retain their previous values.
- Any scalar destination registers, the [VPR](#) state, and the [FPSCR.QC](#) flag record all the architecture state updates that are associated with the fully completed beats. Updates that are associated with the abandoned beat and all subsequent beats of the instruction are not recorded.

Partial stores to locations that might be accessed by the abandoned beat and all subsequent beats might be observed. Loads to locations of the abandoned beats and all subsequent beats might be observed.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [MVE](#).*

R<sub>DDNC</sub>

The return address for the instruction fetch fault, an UNDEFINSTR Fault, or a NOCP Usage fault is always the address of the instruction that triggered the fault. The fault is taken after all the preceding instructions have completed.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [MVE](#).*

R<sub>ZLFY</sub>

If an exception is taken during the execution of overlapping beat-wise executable instructions, this might become architecturally visible.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [MVE](#).*

R<sub>KDNH</sub>

Architecture state updates that are associated with an [Architecture tick](#) are observed as one of the following:

- All updates to the architecture state are observable.
- Partial updates to the architecture states (both to the registers and to memory) are permitted for instructions that were terminated by an exception and can be restarted without data corruption. In other words, an instruction that is capable of instruction resume or restart and there is a valid [EPSR.ECI](#) value.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [MVE](#).*

I<sub>GRDV</sub>

Vector load or store instructions, that might be abandoned and subsequently restart the execution of a beat, might cause multiple accesses to the same memory location to be performed.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [MVE](#).*

## B5.6 Predication/conditional execution

**R<sub>RSLP</sub>** **MVE** includes predication that enables the independent masking of each lane within a vector operation. It supports the following predication mechanisms:

- Loop tail predication. This eliminates the requirement for special vector tail handling code after loops where the number of **Elements** to be processed is not a multiple of the number of **Elements** in the vector.
- VPT predication. This enables data-dependent conditions that are based on data value comparisons to mask each vector lane separately.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **MVE**.*

**R<sub>QGLY</sub>** Loop tail predication and VPT predication operate separately. The resulting predication flags from each mechanism are ANDed together so that a lane of a vector operation is only active if both the loop tail predication and the VPT predication conditions are true.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **MVE**.*

### B5.6.1 Loop tail predication

**R<sub>DCZN</sub>** Low overhead loops can be used with vector instructions, for example with a word-based memory copy instruction. The number of words to copy might not be a multiple of the vector length, therefore loop tail predication can eliminate any additional tail handling steps.

**MVE** includes special loop tail predication instructions, **WLSTP**, **DLSTP**, **LETP**, and **LCTP**, that operate as follows:

- The source register of the loop start instruction contains the number of vector **Elements** that are to be processed, instead of the iteration count.
- The loop start instruction sets **FPSCR.LTPSIZE** to the requested **Element** size. This alters the amount by which the **Element** count in LR is decremented at the end of each loop iteration.
- On the last iteration of the loop, the values in LR and **FPSCR.LTPSIZE** determines the number of vector lanes that are to be masked.
- After the last instruction of the last loop iteration has been executed, tail predication is disabled by setting **FPSCR.LTPSIZE** to 0b100.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **MVE**.*

**I<sub>RBP</sub>** The active floating-point state is defined by `ActiveFPState()`.

*Applies to an implementation of the architecture Armv8.1-M onward.*

**R<sub>GQSH</sub>** To prevent the inadvertent creation of floating-point contexts and the predication of vector operation outside of a loop, **FPSCR.LTPSIZE** behaves as follows:

- **FPSCR.LTPSIZE** reads as 0b100 if there is no active floating-point state.
- **FPSCR.LTPSIZE** is set to 0b100 if any of the following events occur:
  - On the last iteration of a loop by either the execution of an **LETP** instruction, or by execution reaching the end of the loop body when **LO\_BRANCH\_INFO** is valid and the floating-point context is active.
  - An **LCTP** instruction is executed.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **MVE**.*

| R <sub>ZFLV</sub> | Comparison-based predication is supported by vector predication blocks.<br><i>Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - <a href="#">MVE</a>.</i>                                                                                                                                                                                                                                                                                                                                                                                                                              |
| R <sub>CVTC</sub> | A vector predication block is called a VPT block. A VPT block is defined as the <i>n</i> instructions following a <a href="#">VPT</a> or <a href="#">VPST</a> instruction, where <i>n</i> is the number of instructions that the <a href="#">VPT</a> or <a href="#">VPST</a> instruction defines as being subject to predication conditions. The predication conditions are stored in the VPR register. <i>n</i> is less than or equal to 4.<br><i>Applies to an implementation of the architecture Armv8.1-M onward.</i>                                                                                                               |
| R <sub>BVPG</sub> | The instructions in a VPT block can be subject to either the condition or to the inverse of the condition.<br><i>Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - <a href="#">MVE</a>.</i>                                                                                                                                                                                                                                                                                                                                                                                           |
| I <sub>RVJJ</sub> | A <a href="#">VCMP (vector)</a> or a <a href="#">VCMP (floating-point)</a> instruction can be placed inside a VPT block. <a href="#">VCMP</a> instructions update the predication flag on completion, therefore affecting the subsequent instructions in the VPT block. The subsequent instructions in the VPT block are subject to the predicates of the VPT block and the updates caused by the <a href="#">VCMP</a> instructions. The execution of successive <a href="#">VCMP</a> instructions permits the creation of complex predication conditions.<br><i>Applies to an implementation of the architecture Armv8.1-M onward.</i> |
| I <sub>PHJP</sub> | Allowing instructions to be subject to either the condition or the inverse of the condition enables the instructions in both the THEN (T decorator) and the ELSE (E decorator) parts of an IF statement to be predicated with a single VPT instruction.<br><i>Applies to an implementation of the architecture Armv8.1-M onward.</i>                                                                                                                                                                                                                                                                                                    |

R<sub>VWGT</sub>

The following table shows the [VPT](#) instruction variants, mask field encodings, and the associated decorators that are placed on the subsequent instructions.

| Instruction name | Mask value | Number of subsequent instructions to be predicated | <v> instruction decorator |        |       |        |
|------------------|------------|----------------------------------------------------|---------------------------|--------|-------|--------|
|                  |            |                                                    | First                     | Second | Third | Fourth |
| VPT              | 0b1000     | 1                                                  | T                         | -      | -     | -      |
| VPTT             | 0b0100     | 2                                                  | T                         | T      | -     | -      |

| VPTTET           | 0b0111     | 4                                                  | T                         | T      | E     | T      |
| VPTEEE           | 0b1001     | 4                                                  | T                         | E      | E     | E      |
| VPTEET           | 0b1011     | 4                                                  | T                         | E      | E     | T      |
| VPTETT           | 0b1101     | 4                                                  | T                         | E      | T     | T      |
| VPTETE           | 0b1111     | 4                                                  | T                         | E      | T     | E      |

The same encoding format is used for [VPST](#).

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [MVE](#).*

R<sub>LKXQ</sub>

[VPR](#) contains a MASK field for each pair of beats of a vector instruction. This permits beat-wise overlapping of the [VPT](#) or [VPST](#) instructions with the surrounding vector instructions.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [MVE](#).*

R<sub>KHCV</sub>

The state of [VPR](#) is UNKNOWN when use of a VPT block results in CONSTRAINED UNPREDICTABLE behavior.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [MVE](#).*

R<sub>XHQ</sub>

The following conditions result in CONSTRAINED UNPREDICTABLE behavior when they apply to a VPT block:

- The presence of a non-VPT compatible instruction in a VPT block. This includes:
  - All instructions that are not part of [MVE](#), with the exception of [BKPT](#).
  - [MVE](#) instructions that are marked as not being VPT compatible.
- A [BF branch point](#) within a VPT block.
- Branching into a VPT block.
- Exception return or returns from Debug state if [VPR.{MASK23, MASK01}](#) is not consistent with the position returned to in the VPT block.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [MVE](#). Note, Debug state requires Halting Debug.*

R<sub>DZWZ</sub>

The CONSTRAINED UNPREDICTABLE behavior for a VPT block is one of the following:

- The VPT or VPST instruction generates an UNDEFINED Instruction fault.
- The instruction that causes the CONSTRAINED UNPREDICTABLE behavior does one of the following:
  - It raises an UNDEFINED Instruction fault.
  - It executes normally.
  - It has UNKNOWN predication applied.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - MVE.*

R<sub>HXSZ</sub>

In a VPT block, the VPR state is only advanced after the completion of a pair of beats within a VPT compatible instruction that is subject to beat-wise execution.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - MVE.*

R<sub>XXKG</sub>

The CONSTRAINED UNPREDICTABLE behavior for a VPT compatible instruction executed outside a VPT block when the VPR mask is nonzero is one of the following:

- It raises an UNDEFINED Instruction fault.
- It executes normally.
- It has UNKNOWN predication applied.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - MVE.*

R<sub>LQDR</sub>

Outside of a VPT block, when VPR.{MASK32, MASK01} is nonzero, the execution of a non-VPT compatible instruction is not UNPREDICTABLE and does not advance VPT state.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - MVE.*

R<sub>XXMHZ</sub>

In the case of an exception return or a return from Debug state, the instruction that exhibits the CONSTRAINED UNPREDICTABLE behavior is defined as the instruction that is being returned to.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - MVE. Note, Debug state requires Halting debug.*

R<sub>MBQX</sub>

For a BF branch point within a VPT block, the instruction that exhibits the CONSTRAINED UNPREDICTABLE behavior can be one of the following:

- The instruction before the BF branch point.
- The instruction after the BF branch point.
- The instruction at the BF branch target address.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - MVE.*

R<sub>SZQK</sub>

For the purposes of the CONSTRAINED UNPREDICTABLE behavior described in this section, a memory location is considered to be in VPT block until:

- The VPT or VPST instruction has been removed.
- All the addresses that are covered by the VPT block have been invalidated in the instruction cache (if implemented).
- A subsequent Context synchronization event has occurred.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - MVE.*

I<sub>KKNH</sub>

There are similarities between VPT/VPR and IT/ITSTATE, but there are also some important differences as follows:

- Unlike IT, the VPT instruction performs the actual comparison in addition to applying the result to the subsequent instructions. As such, VPT can be considered as the vectorized combination of CMP and IT.
- There are multiple MASK fields in VPR that handle partial instruction execution caused by exceptions during the overlapping of instructions.
- The MASK fields are similar to ITSTATE[3:0] and encode both the number of instructions outstanding in the current VPT block, and whether these instructions are subject to the THEN or the ELSE condition.

*Applies to an implementation of the architecture Armv8.1-M onward.*

**R<sub>HJGT</sub>** **VPR.P0** contains one predication bit per 8-bit lane. The **VPR** mask bits cause the VPR predication bits to be inverted if the corresponding mask bit is set to 1. The mask bits that are shifted out toggle the current predication condition and are not part of the predication condition. The value of **VPR.MASK01** affects bits[7:0] of **VPR.P0** and the value of **VPR.MASK23** affects bits [15:8] of **VPR.P0**.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **MVE**.*

**R<sub>PXMY</sub>** The **VPR** predication bits are not inverted after executing the last instruction in a VPT block.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **MVE**.*

**I<sub>LRVJ</sub>** The state in the **VPR** register can be accessed directly using **VMRS**, **VMSR**, **VLDR** (System Register), and **VSTR** (System Register) instructions. Setting **VPR** using a **VMSR** or **VLDR** (System Register) instruction does not make the instructions that follow **VMSR** or **VLDR** (System Register) part of a VPT block.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **MVE**.*

**R<sub>MPTV</sub>** Execution of a VPT compatible instruction outside of a VPT block with a nonzero value in **VPR.{MASK23, MASK01}** results in CONSTRAINED UNPREDICTABLE behavior and does one of the following:

- It raises an UNDEFINED Instruction fault.
- It executes normally.
- It has UNKNOWN predication applied.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **MVE**.*

See also:

[Chapter C1 Instruction Set Overview](#).

### B5.6.3 Effects of predication

**I<sub>TZPD</sub>** The exact effects of a false predication value are defined in the instruction pseudocode.

*Applies to an implementation of the architecture Armv8.1-M onward.*

**R<sub>SYDC</sub>** Vector predication has no effect on scalar instructions.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **MVE**.*

**R<sub>ZLSJ</sub>** For non-load instructions for vector register file writes, predication is always performed at byte level granularity, regardless of the **Element** size that is specified by the vector instruction.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **MVE**.*

**R<sub>VHSN</sub>** For non-load instructions, the predicate flags determine if the destination register byte is updated with the new value or if the previous value is preserved. For load instructions, where lanes are predicated false, the corresponding parts of the destination register are set to 0.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **MVE**.*

**R<sub>LYPK</sub>** For base pointer write-back, vector predication does not affect address write-back in load and store instructions. This applies both when the address is in a scalar register, and when it is in a vector register.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **MVE**.*

**R<sub>LNDR</sub>** The predication flag determines whether a lane operation is performed. For **Element** sizes of more than 8 bits for the types of instruction listed here, the LSB of the corresponding group of predicate flags determines:

- For vector operations that perform reduction across the vector and produce a scalar result, whether the value is accumulated or not.

- For vector store instructions, whether the store occurs or not.
- For vector load instructions, whether the value that is loaded or whether zeros are written to that element of the destination register.
- The setting of the [FPSCR.QC](#) saturation flags.

For predication, 64-bit vector memory load/store operations are treated as if they were a pair of 32-bit operations.

*Applies to an implementation of the architecture [Armv8.1-M](#) onward. The extension requirements are - [MVE](#).*

$I_{CJRK}$

The relation between lane width and bits in [VPR.P0](#) is as follows:

| Lane width | Bits in <a href="#">VPR.P0</a> |
|------------|--------------------------------|
| 32 bits    | [12, 8, 4, 0]                  |
| 16 bits    | [14, 12, 10, 8, 6, 4, 2, 0]    |
| 8 bits     | [15:0]                         |

*Applies to an implementation of the architecture [Armv8.1-M](#) onward.*

See also:

[B5.6.1 Loop tail predication.](#)

[B5.6.2 VPT predication.](#)

## B5.6.4 IT block

$R_{PZDX}$

Instructions that are subject to beat-wise execution are not permitted in IT blocks. For the exceptions to this rule, see the decode pseudocode in the individual instruction descriptions. In these exceptional cases, beat-wise execution is not performed and the instruction does not overlap with other instructions.

*Applies to an implementation of the architecture [Armv8.1-M](#) onward. The extension requirements are - [MVE](#).*

## B5.7 MVE interleaving/de-interleaving loads and stores

**I<sub>VWWN</sub>** For implementations that include [MVE](#), data streams can be interleaved and de-interleaved with strides of 2 and 4, using `VLD2/VLD4` and `VST2/VST4`.

*Applies to an implementation of the architecture **Armv8.1-M** onward.*

**R<sub>CMZP</sub>** The interleaving and de-interleaving instructions always operate on 128 bits of data at a time.

*Applies to an implementation of the architecture **Armv8.1-M** onward. The extension requirements are - [MVE](#).*

**I<sub>XGTN</sub>** When using `VLD4`, each of the four instructions loads 128 bits of data, and partially updates the four destination vector registers. The memory offsets and destination register sections that are accessed are arranged so that when all four instructions have been executed, the de-interleaving operation has been performed.

|                                      |    |                          |                          |                          |                          |
|--------------------------------------|----|--------------------------|--------------------------|--------------------------|--------------------------|
| <code>VLD40.32 {Q0-Q3}, [Rn]</code>  | Q3 | <code>S15=Mem[60]</code> | <code>S14=Mem[44]</code> | <code>S13=Mem[28]</code> | <code>S12=Mem[12]</code> |
| <code>VLD41.32 {Q0-Q3}, [Rn]</code>  | Q2 | <code>S11=Mem[56]</code> | <code>S10=Mem[40]</code> | <code>S9=Mem[24]</code>  | <code>S8=Mem[8]</code>   |
| <code>VLD42.32 {Q0-Q3}, [Rn]</code>  | Q1 | <code>S7=Mem[52]</code>  | <code>S6=Mem[36]</code>  | <code>S5=Mem[20]</code>  | <code>S4=Mem[4]</code>   |
| <code>VLD43.32 {Q0-Q3}, [Rn]!</code> | Q0 | <code>S3=Mem[48]</code>  | <code>S2=Mem[32]</code>  | <code>S1=Mem[16]</code>  | <code>S0=Mem[0]</code>   |

*Applies to an implementation of the architecture **Armv8.1-M** onward.*

**R<sub>NSFK</sub>** The assembly syntax for `VLD2/VLD4` and `VST2/VST4` lists the range of vector registers to be accessed. Only the lowest numbered register is encoded in the opcode. If this register number plus the number of registers to be accessed is greater than 7 (the highest numbered vector register) behavior is a CONSTRAINED UNPREDICTABLE choice of the following:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- One or more of the vector registers become UNKNOWN. If the instruction specifies write-back, the base register becomes UNKNOWN. No other general-purpose registers are affected.

*Applies to an implementation of the architecture **Armv8.1-M** onward. The extension requirements are - [MVE](#).*

## Chapter B6

# Pointer authentication and branch target identification Extension

This chapter specifies the optional Armv8.1-M Pointer Authentication Extension and Branch Target Identification Extension rules. It contains the following sections:

*B6.1 Implementing PAC and BTI.*

*B6.1.1 Pointer authentication.*

*B6.1.2 Branch target identification.*

*Applies to an implementation of the architecture Armv8.1-M onward.*

| I <sub>VRBT</sub> | <p>The <b>PAC</b> and <b>BTI</b> features can be independently enabled or disabled for every Security state and privilege level.</p> <p><i>Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - <b>PACBTI</b>. Note, The Security extension is required for Secure access.</i></p> |

## B6.1.1 Pointer authentication

R<sub>WRRP</sub>

PAC can be enabled or disabled as follows:

- [CONTROL.PAC\\_EN](#) for current Security state and privileged mode.
- [CONTROL.UPAC\\_EN](#) for current Security state and unprivileged mode.
- [CONTROL\\_S.PAC\\_EN](#) for Secure state and privileged mode.
- [CONTROL\\_S.UPAC\\_EN](#) for Secure state and unprivileged mode.
- [CONTROL\\_NS.PAC\\_EN](#) for Non-secure state and privileged mode.
- [CONTROL\\_NS.UPAC\\_EN](#) for Non-secure state and unprivileged mode.

The pseudocode function [PACEnabled\(\)](#) describes this.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PACBTI](#). Note, The Security extension is required for access to Secure register variants.*

R<sub>KRKP</sub>

In privileged mode [CONTROL.PAC\\_EN](#) and [CONTROL.UPAC\\_EN](#) can be accessed using [MSR](#) and [MRS](#) instructions.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PACBTI](#).*

R<sub>VCCY</sub>

In unprivileged mode [CONTROL.UPAC\\_EN](#) can be read using the [MRS](#) instruction.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PACBTI](#).*

R<sub>VLRL</sub>

For pointer authentication, there are four 128-bit keys:

|              | Non-secure state             | Secure state                |
|--------------|------------------------------|-----------------------------|
| Privileged   | <a href="#">PAC_KEY_P_NS</a> | <a href="#">PAC_KEY_P_S</a> |
| Unprivileged | <a href="#">PAC_KEY_U_NS</a> | <a href="#">PAC_KEY_U_S</a> |

The keys can be accessed by privileged software through the [MSR](#) and [MRS](#) instructions where:

- The register values [PAC\\_KEY\\_P\\_3](#) : [PAC\\_KEY\\_P\\_2](#) : [PAC\\_KEY\\_P\\_1](#) : [PAC\\_KEY\\_P\\_0](#) are concatenated to form [PAC\\_KEY\\_P](#).
- The register values [PAC\\_KEY\\_U\\_3](#) : [PAC\\_KEY\\_U\\_2](#) : [PAC\\_KEY\\_U\\_1](#) : [PAC\\_KEY\\_U\\_0](#) are concatenated to form [PAC\\_KEY\\_U](#).

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PACBTI](#). Note, The Security extension is required for access to Secure register variants.*

R<sub>LPQW</sub>

For the Pointer authentication instructions, it is IMPLEMENTATION DEFINED whether the encrypted value is generated using:

- The 5-round variant of the QARMA algorithm, known as QARMA5, as described in *The QARMA Block Cipher Family, Roberto Avanzi, Qualcomm Product Security Initiative*, when the value of [ID\\_ISAR5.PACBTI](#) is 0b0001.
- An IMPLEMENTATION DEFINED algorithm when the value of [ID\\_ISAR5.PACBTI](#) is 0b0010.
- The 3-round variant of the QARMA algorithm, known as QARMA3, as described in *The QARMA Block Cipher Family, Roberto Avanzi, Qualcomm Product Security Initiative*, when the value of [ID\\_ISAR5.PACBTI](#) is 0b0100.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PACBTI](#).*

R<sub>LDRC</sub>

When an IMPLEMENTATION DEFINED algorithm is used, the following applies:

- The algorithm must use the same input arguments as the [ComputePAC\(\)](#) function.
- The algorithm must provide the same result when:
  - The same arguments are passed to the algorithm (values in the registers and keys).

- The PE is executing at the same Security and privilege level.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **PACBTI**.*

**I<sub>KRZP</sub>** The IMPLEMENTATION DEFINED algorithm is permitted to apply further cryptographic rounds based on the Security and privilege level of the PE. Using the same input arguments and key values at different Security and privilege levels might produce different results.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **PACBTI**.*

**I<sub>KRXB</sub>** The following functions describe the QARMA algorithms supported by the **PACBTI** Extension:

- **ComputePAC()**
- **PACCellInvShuffle()**
- **PACCellShuffle()**
- **PACInvSub()**
- **PACMult()**
- **PACSubQ3()**
- **PACSubQ5()**
- **RotCell()**
- **TweakCellInvRot()**
- **TweakCellRot()**
- **TweakInvShuffle()**
- **TweakShuffle()**

Arm recommends that the QARMA family of algorithms should be used for pointer authentication.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **PACBTI**.*

**I<sub>NPTP</sub>** The **PAC** is generated by **PACBTI**, **PAC**, and **PACG** instructions.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **PACBTI**.*

**I<sub>PRJQ</sub>** The input arguments of the pseudocode function **ComputePAC()** are:

- Most significant bits of the 32-bit pointer/address/data are zero extended to 64 bits.
- Most significant bits of the 32-bit modifier are zero extended to 64 bits.
- The 128-bit cryptographic key.

The pseudocode function **CreatePAC()** describes this.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **PACBTI**.*

**R<sub>TRZN</sub>** If a **PAC** authentication instruction fails to validate the **PAC** an INVSTATE UsageFault is generated. The fault will be generated if any of the input arguments used for generating the **PAC** are modified before validating the **PAC**, any of the three general-purpose registers or the cryptographic key. Instructions **AUT**, **BXAUT**, and **AUTG** authenticate **PAC**.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **PACBTI**.*

**R<sub>XZVW</sub>** When **PACEnabled()** is FALSE:

- **PAC** generating instructions do not create the **PAC** and do not update any registers. Any other functionality provided by the instructions is unaffected.
- **PAC** authentication instructions do not validate the **PAC** and do not generate the INVSTATE UsageFault. Any other functionality provided by the instructions is unaffected.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **PACBTI**.*

**I<sub>PLRN</sub>** The output of the cryptographic algorithm is a 32-bit **PAC**, so it is possible for different combinations of input arguments and cryptographic keys to produce an identical **PAC**. This type of cryptographic collision cannot be detected by the **PAC** authentication instructions and an INVSTATE UsageFault will not be generated.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **PACBTI**.*

**I<sub>KFDR</sub>** The **PACBTI** Extension does not distinguish between privileged Thread mode execution and Handler mode execution. For example, a pointer authenticated in Handler mode can be validated in privileged Thread mode without generating an INVSTATE UsageFault.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **PACBTI**.*

**I<sub>ZGXX</sub>** There is no architectural restriction on the number of instructions that can be executed between:

- An instruction that generates **PAC** and an instruction that validates **PAC**. For example, **PAC** and **AUT**.
- An instruction that validates **PAC** and the return instruction. For example, **AUT** and **BX**.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **PACBTI**.*

**I<sub>FRLR</sub>** Arm recommends that between the authentication of a pointer and any subsequent reference to that pointer, the unprotected pointer should not be saved and restored from memory.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **PACBTI**.*

**I<sub>PLRM</sub>** The IT state is not advanced if a **PAC** validation instruction which is permitted in an IT block fails the pointer comparison and generates an INVSTATE UsageFault.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **PACBTI**.*

**I<sub>BRTY</sub>** Examples of using **PAC** are shown below.

```

1   LDR      R4, =func1      // Load function address.
2   BLX      R4              // Call function which is protected by PAC-AUT.
3 ret1:
4   MOV      R1, #AA         // #AA value stored in R1 register.
5   MOV      R2, #BB         // #BB value stored in R2 register.
6   LDR      R4, =func2
7   BLX      R4              // Call function which is protected by PAC-AUT.
8 ret2:
9   AUTG     R0, R1, R2      // Validate R0, R1, and R2 registers. If any of the
10                                // values or the secret key have changed, then an
11                                // INVSTATE UsageFault is generated.
12                                // Not supported on legacy implementations.
13   ...
14 func1:
15   PAC      R12, LR, SP     // Computes the cryptographic code using LR, SP, and
16                                // a secret key, then stores it in R12.
17                                // This instruction works on legacy implementations.
18   PUSH     {R4-R6, R12, LR} // Stack LR if it needs to be used before the AUT.
19   ...
20   POP      {R4-R6, R12, LR} // Restore the value of LR before authenticating.
21   AUT      R12, LR, SP     // Computes PAC using LR, SP, and a secret key, and
22                                // then compares it against the value in R12.
23                                // If the two values match then the LR is validated,
24                                // otherwise an INVSTATE UsageFault is generated.
25                                // This instruction works on legacy implementations.
26   BX       LR              // Return to 'ret1'.
27 func2:
28   PAC      R12, LR, SP     // Calculate PAC for LR.
29   ...
30   PACG     R0, R1, R2      // Calculate PAC where desired value is in R1 (#AA).
31                                // The modifier value is in R2 (#BB).
32                                // Computed PAC is stored in R0 register.
33                                // Not supported on legacy implementations.
34   ...
35   BXAUT    R12, LR, SP     // Validate LR and branch to LR ('ret2').
36                                // Not supported on legacy implementations.
```

*Chapter B6. Pointer authentication and branch target identification Extension*  
*B6.1. Implementing PAC and BTI*

*Applies to an implementation of the architecture **Armv8.1-M** onward. The extension requirements are - **PACBTI**.*

## B6.1.2 Branch target identification

R<sub>JKHH</sub>

BTI can be enabled or disabled as follows:

- [CONTROL.BTI\\_EN](#) for current Security state and privileged mode.
- [CONTROL.UBTI\\_EN](#) for current Security state and unprivileged mode.
- [CONTROL\\_S.BTI\\_EN](#) for Secure state and privileged mode.
- [CONTROL\\_S.UBTI\\_EN](#) for Secure state and unprivileged mode.
- [CONTROL\\_NS.BTI\\_EN](#) for Non-secure state and privileged mode.
- [CONTROL\\_NS.UBTI\\_EN](#) for Non-secure state and unprivileged mode.

The pseudocode function [BTIEnabled\(\)](#) describes this.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PACBTI](#). Note, The Security extension is required for access to Secure register variants.*

R<sub>LVTR</sub>

In privileged mode [CONTROL.BTI\\_EN](#) and [CONTROL.UBTI\\_EN](#) can be accessed using [MSR](#) and [MRS](#) instructions.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PACBTI](#).*

R<sub>PCZX</sub>

In unprivileged mode [CONTROL.UBTI\\_EN](#) can be read using the [MRS](#) instruction.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PACBTI](#).*

R<sub>FDGT</sub>

When BTI is enabled for the target Security and privilege state then any instruction that sets [EPSR.B](#) or [LO\\_BRANCH\\_INFO.BTI](#) to one is referred to as a [BTI setting](#) instruction. [BTIEnabled\(\)](#) describes this.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PACBTI](#).*

R<sub>KRRX</sub>

Any instruction that clears [EPSR.B](#) to zero is referred to as a [BTI clearing](#) instruction.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PACBTI](#).*

R<sub>HRRL</sub>

[EPSR.B](#) is automatically stacked and cleared to zero on exception entry and restored on exception return.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PACBTI](#).*

I<sub>LVMN</sub>

[EPSR.B](#) is not stacked and cleared to zero as a part of the [FNC\\_RETURN](#) stack frame.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PACBTI](#).*

R<sub>DFGH</sub>

If BTI is enabled then [EPSR.B](#) is set to one when any of the following [BTI setting](#) instructions are executed:

- [BLX](#).
- [BLXNS](#).
- When the register holding the branch address is not the [LR](#):
  - [BX](#).
  - [BXNS](#).
- When the address is loaded into the [PC](#):
  - [LDR \(register\)](#).
  - [LDR \(literal\)](#).
- When the address is loaded into the [PC](#) and the base address register is either not the [SP](#) or the [SP](#) and write-back of the [SP](#) does not occur:
  - [LDR \(immediate\)](#).
  - [LDM](#), [LDMIA](#), [LDMFD](#).
  - [LDMDB](#), [LDMEA](#).

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PACBTI](#).*

R<sub>DDFR</sub>

The [LO\\_BRANCH\\_INFO.BTI](#) bit is set to one when any of the following [BTI setting](#) instructions are executed:

- [BFLX](#).
- When the register holding the branch address is not the [LR](#):

– BFX.

Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **PACBTI**.

**R<sub>HJGG</sub>** When the **BTI setting** Branch Future branch is taken, **EPSR.B** is set to one when all of the following are true:

- **BTIEnabled()** is TRUE.
- **LO\_BRANCH\_INFO.BTI** is set to one.
- **LO\_BRANCH\_INFO.VALID** is set to one.

Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **PACBTI**.

**I<sub>PRKZ</sub>** The pseudocode functions **HandleLO()**, **GetInstrExecState()**, and **InstructionAdvance()** show how a **BTI setting** Branch Future instruction sets **EPSR.B** to one.

Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **PACBTI**.

**R<sub>TVHG</sub>** Any instruction that is not **BTI setting** and sets the **LO\_BRANCH\_INFO.VALID** bit to one must also clear the **LO\_BRANCH\_INFO.BTI** bit to zero. For example, the **LE** and **LETP** instructions.

Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **PACBTI**.

**I<sub>HLLR</sub>** The **BXAUT** instruction is not a **BTI setting** instruction regardless of which register is used as the branch target. Equivalent behavior with **BTI setting** can be achieved through an **AUT** or **AUTG** instruction followed by a **BX** instruction.

Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **PACBTI**.

**I<sub>LPCT</sub>** The **POP (single register)**, which is an alias of **LDR (immediate)**, and **POP (multiple registers)**, which is an alias of **LDM**, **LDMIA**, **LDMFD**, are not **BTI setting** instructions.

Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **PACBTI**.

**I<sub>CLFR</sub>** For transitions from Non-secure to Secure state, if the **SG** instruction is targeted by a **BTI setting** branch then the **CONTROL.BTI\_EN** and **CONTROL.UBTI\_EN** bits associated with the Security state of that branch determine whether the **EPSR.B** is set.

The **SG** instruction is **BTI clearing**, so if **EPSR.B** is set, it will be cleared even if **BTI** is not enabled.

Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **PACBTI** && **S**.

**I<sub>DFRT</sub>** For transitions from Secure to Non-secure state, if the transition is caused by a **BTI setting** branch, for example **BXNS**, then the **CONTROL\_NS.BTI\_EN** and **CONTROL\_NS.UBTI\_EN** bits will be checked to determine whether the **EPSR.B** is set.

Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **PACBTI** && **S**.

**R<sub>XZCV</sub>** The following instructions are **BTI clearing**:

- **BTI**.
- **SG**.
- **PACBTI**.

If the **EPSR.B** is set, the **BTI clearing** instructions will clear it to zero even if **BTI** is not enabled.

Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **PACBTI**.

**I<sub>ZLLP</sub>** When **PAC** functionality is required but creating a **landing pad** using **PACBTI** is undesirable then either a **PAC** or **PACG** instruction can be used.

Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **PACBTI**.

**R<sub>KJDW</sub>** When the **BKPT** instruction is executed and **EPSR.B** is one then **EPSR.B** is not cleared to zero and an **INVSTATE UsageFault** is not generated.

Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **PACBTI**.

I<sub>YYZG</sub>

Examples of using BTI are shown below.

```

1 // Current Security state is Non-secure
2   LDR    R4, =testBti // Load function address.
3   LDR    R3, =ret1
4   BLX    R4           // BTI is enabled for Non-secure state, set EPSR.B.
5 ret1:
6   BTI                    // BTI clearing instruction.
7   LDR    R4, =funcTestBti
8   BLX    R4           // Set EPSR.B.
9 ret2:
10  LDR    R4, =nscBti
11  BLX    R4           // Target address is in NSC region, set EPSR.B.
12 end:
13  ...
14 // Function in Non-secure state.
15 testBti:
16  BTI                    // BTI clearing instruction, valid entry point.
17  ...                  // LR not used for return, so PAC-AUT is not required.
18  ...                  // But using LR would be recommended in this scenario.
19  BX     R3             // Branch to 'ret1'. LR is not used, so the branch
20                      // target must be a BTI clearing instruction.
21 // Function in Non-secure state.
22 funcTestBti:
23  PACBTI R12, LR, SP    // BTI clearing instruction, valid entry point.
24  ...                  // Stacking and unstacking R12, LR, and SP is safe
25  ...                  // as any corruption will be detected by BXAUT.
26  BXAUT  R12, LR, SP    // Validate LR and return to 'ret2', address in LR.
27                      // The combined authenticate and branch instruction
28                      // is not backwards compatible with legacy software.
29 // Function in Non-secure state.
30 leafFunc:
31  BTI                    // Since BTI is enabled, a BTI clearing instruction
32  ...                  // is required.
33  BX     leafRet         // Does not set BTI, uses FNC_RETURN.
34  ...
35 // Non-secure Callable region.
36 nscBti:
37  SG                    // Clear BTI, regardless of the Secure BTI settings.
38  B      secure         // Call Secure function.
39  ...
40 // Function in Secure state.
41 secure:
42  PAC     R12, LR, SP    // BTI clearing PAC is not required.
43  ...
44  LDR     R6, =leafFunc
45  BLXNS   R6             // Call Non-secure function.
46                      // Instruction implicitly checks BTI settings for the
47                      // current privilege state in CONTROL_NS.
48 leafRet:
49  ...                  // BTI clearing instruction not required.
50  AUT     R12, LR, SP    // Validate LR.
51  ...                  // Stacking and unstacking LR and SP is not safe.
52  ...                  // Corruption of the registers will not be detected.
53  BXNS    LR             // Branch to 'end'. Does not set BTI.

```

Applies to an implementation of the architecture *Armv8.1-M* onward. The extension requirements are - **PACBTI**.

## Chapter B7

# Memory Model

This chapter specifies the Armv8-M memory model architecture rules. It contains the following sections:

- B7.1 Definition of the Armv8 memory model.*
- B7.2 Atomicity.*
- B7.3 Memory accesses.*
- B7.4 Address space.*
- B7.5 Endianness.*
- B7.6 Alignment behavior.*
- B7.7 Concurrent modification and execution of instructions.*
- B7.8 Access rights.*
- B7.9 Normal memory.*
- B7.10 Cacheability attributes.*
- B7.11 Device memory.*
- B7.12 Device memory attributes.*
- B7.13 Shareability attributes.*
- B7.14 Shareability domains.*
- B7.15 Memory access restrictions.*
- B7.16 Mismatched memory attributes.*
- B7.17 Load-Exclusive and Store-Exclusive accesses to Normal memory.*

*B7.18 Load-Acquire and Store-Release accesses to memory.*

*B7.19 Caches.*

*B7.20 Cache identification.*

*B7.21 Cache visibility.*

*B7.22 Cache coherency.*

*B7.23 Cache enabling and disabling.*

*B7.24 Cache behavior at reset.*

*B7.25 Behavior of Preload Data (PLD) and Preload Instruction (PLI) instructions with caches.*

*B7.26 Branch predictors.*

*B7.27 Cache maintenance operations.*

*B7.28 Ordering of cache maintenance operations.*

*B7.29 Branch predictor maintenance operations.*

## B7.1 Definition of the Armv8 memory model

I<sub>JRPK</sub>

This section describes observation and ordering in the Armv8 memory model. It contains the following subsections:

- [B7.1.1 Locations.](#)
- [B7.2.3 Ordering and observability.](#)
- [B7.2.5 Ordering constraints.](#)
- [B7.2.7 External ordering constraints.](#)
- [B7.2.6 Completion and endpoint ordering.](#)
- [B7.2.9 Memory barriers.](#)

*Applies to an implementation of the architecture Armv8.0-M onward.*

### B7.1.1 Locations

I<sub>CKCT</sub>

The Armv8 memory model provides a set of definitions that are used to constrain the permitted sequences of accesses to memory. The Armv8 memory model defines:

- The ordering of observation of memory accesses between different Observers.
- The ordering of arrival of memory accesses arriving at an endpoint.
- The mechanisms to control the ordering of observation of memory accesses and the arrival of memory accesses at an endpoint.

*Applies to an implementation of the architecture Armv8.0-M onward.*

## Locations, memory effects, and observers

### Location

R<sub>GZWZ</sub>

A *Location* is a single byte that is associated with an address in the physical address space.

*Applies to an implementation of the architecture Armv8.0-M onward.*

I<sub>LDTD</sub>

As part of its execution, an instruction might generate [memory effects](#). Observers in the system might observe the [memory effects](#) of that instruction on a Location.

*Applies to an implementation of the architecture Armv8.0-M onward.*

### Effects

R<sub>KFVX</sub>

The Effects of an instruction can be:

- Register effects.
- Memory effects.
- Barrier effects.
- Branching effects.

The effects of an instruction  $I_1$  are said to appear in program order before the effects of an instruction  $I_2$  if and only if  $I_1$  occurs before  $I_2$  in the order specified by the program. Each effect generated by an instruction has a unique identifier, which characterizes it among the events generated by the same instruction.

*Applies to an implementation of the architecture Armv8.0-M onward.*

## Register effects

R<sub>CLDD</sub>

The *Register effects* of an instruction are register reads or register writes of that instruction.

*Applies to an implementation of the architecture Armv8.0-M onward.*

I<sub>PTMD</sub>

For an instruction that accesses registers, a register read effect is generated for each register read by the instruction and a register write effect is generated for each register written by the instruction. An instruction may generate both read and write Register effects.

*Applies to an implementation of the architecture Armv8.0-M onward.*

## Memory effects

R<sub>JXFX</sub>

The *memory effects* of an instruction are the read, write, or barrier effects of that instruction.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>ZRCJ</sub>

For an instruction that accesses memory:

- A read effect is generated for each [Location](#) that is read by the instruction.
- A write effect is generated for each [Location](#) that is written by the instruction.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>VJRP</sub>

An instruction can generate both read and write effects.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>MTJR</sub>

The [memory effects](#) of an instruction I<sub>1</sub> are said to appear in program order before the [memory effects](#) of instruction I<sub>2</sub> if and only if I<sub>1</sub> occurs before I<sub>2</sub> in program order.

*Applies to an implementation of the architecture Armv8.0-M onward.*

I<sub>WDFL</sub>

For the purposes of describing the Armv8 memory model, all read and write effects access only Normal memory [Locations](#) in a common Shareability domain. Where this section refers to a read, write, or memory barrier without any qualification, then it is referring to the corresponding [memory effect](#).

*Applies to an implementation of the architecture Armv8.0-M onward.*

## Branching effects

R<sub>DHWH</sub>

The *Branching effects* of an instruction are effects which correspond to a branching decision being taken.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>JXQC</sub>

Conditional and compare-and-swap instructions do not create Branching effects.

*Applies to an implementation of the architecture Armv8.0-M onward.*

## Intrinsic order

R<sub>DBQB</sub>

There is a per-instruction *Intrinsic order* relation that provides a partial order over the effects of that instruction, according to the operation of that instruction.

*Applies to an implementation of the architecture Armv8.0-M onward.*

## Observer

R<sub>KWHH</sub>

An *Observer* refers to either a PE, or some other memory accessing agent that can generate reads from or writes to memory.

*Applies to an implementation of the architecture Armv8.0-M onward.*

## Common Shareability domain

$R_{RZFF}$

A *common Shareability domain* for a program is the smallest Shareability domain that contains all of the active Observers of the [memory effects](#) generated by a program.

*Applies to an implementation of the architecture **Armv8.0-M** onward.*

## B7.2 Atomicity

### B7.2.1 Single-copy atomicity

R<sub>SGSJ</sub>

For explicit memory accesses the following rules apply:

- A read that is generated by a load instruction that loads a single general-purpose register and is aligned to the size of the read in the instruction is single-copy atomic.
- A write that is generated by a store instruction that stores a single general-purpose register and is aligned to the size of the write in the instruction is single-copy atomic.
- Reads that are generated by a Load Pair instruction that loads two general-purpose registers and is aligned to the size of the load to each register are treated as two single-copy atomic reads, one for each register being loaded.
- Writes that are generated by a Store Pair instruction that stores two general-purpose registers and are aligned to the size of the store of each register are treated as two single-atomic writes, one for each register being stored.
- Load-Exclusive Pair instructions of two 32-bit quantities and Store-Exclusive Pair instructions of two 32-bit quantities are single-copy atomic.
- Reads to SIMD and floating-point registers of a single 32-bit or smaller quantity that is aligned to the size of the quantity being read are treated as single-copy atomic.
- Writes from SIMD and floating-point registers of a single 32-bit or smaller quantity that is aligned to the size of the quantity being stored are treated as single-copy atomic.

*Applies to an implementation of the architecture Armv8.0-M onward. Note, FP required for Floating-point register file, S0-S31 and D0-D16. SIMD instructions require DSP.*

R<sub>KDVX</sub>

If MVE is implemented, the following rules apply for explicit memory accesses:

- Element reads to SIMD and floating-point registers of 64-bit or smaller elements, where each element is aligned to the size of the quantity being loaded, have each element treated as a single-copy atomic read.
- Element writes from SIMD and floating-point registers of 64-bit or smaller elements, where each element is aligned to the size of the quantity being stored, have each element treated as a single-copy atomic store.
- Reads to SIMD and floating-point registers of a 128-bit value that is 64-bit aligned in memory are treated as a pair of single-copy atomic 64-bit reads.
- Writes from SIMD and floating-point registers of a 128-bit value that is 64-bit aligned in memory are treated as a pair of single-copy atomic 64-bit writes.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - MVE.*

R<sub>XDKD</sub>

All accesses to a single byte are single-copy atomic.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>DFJD</sub>

All other memory accesses are treated as streams of accesses to bytes, and no atomicity between accesses to bytes is ensured by the architecture.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>KBCZ</sub>

A beat-wise memory access instruction that is single-copy atomic has the following properties:

1. For a pair of overlapping single-copy atomic store instructions, all of the overlapping writes generated by one of the stores is **coherence-after** the corresponding overlapping writes generated by the other store.

2. For a single-copy atomic load instruction  $L_1$  that overlaps a single-copy atomic store  $S_2$ , if one of the overlapping reads generated by  $L_1$  [reads-from](#) one of the overlapping writes generated by  $S_2$ , then none of the overlapping writes generated by  $S_2$  are [coherence-after](#) the corresponding overlapping reads generated by  $L_1$ .

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [MVE](#).*

R<sub>GQXM</sub>

If, according to these rules, an instruction is executed as a series of accesses exceptions, including interrupts, can be taken during that sequence, regardless of the memory type being accessed. If any of these exceptions are returned from using their preferred return address, the instruction that generated the sequence of accesses is re-executed, and so any access performed before the exception was taken is repeated.

*Applies to an implementation of the architecture Armv8.0-M onward.*

## B7.2.2 Multi-copy atomicity

I<sub>BCHK</sub>

In a multiprocessing environment, writes to memory are *multi-copy atomic* if and only if all of the following are true:

- All writes to the same location are observed in the same order by all Observers, although some of the Observers might not observe all of the writes.
- A read of a location does not return the value of a write to that location until all Observers have observed that write.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>GJGP</sub>

Writes to Normal memory are not required to multi-copy atomic.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>LBGB</sub>

Writes to Device memory with the Gathering attribute are not required to be multi-copy atomic.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>WHJR</sub>

Writes to Device memory with the non-Gathering attribute that is single-copy atomic are also multi-copy atomic.

*Applies to an implementation of the architecture Armv8.0-M onward.*

[B7.6 Alignment behavior.](#)

[B7.2.5 Ordering constraints.](#)

## B7.2.3 Ordering and observability

I<sub>JLGR</sub>

The Armv8 memory model permits reordering of memory accesses. This description defines the constraints on the reordering of memory accesses using:

- Register value dependencies to establish order between instructions on a PE.
- Ordering constraints to establish order between accesses to a [Location](#).

*Applies to an implementation of the architecture Armv8.0-M onward.*

## Register value dependencies

$I_{DNJX}$

The Armv8 memory model defines the following dependencies between instructions:

- Dependency through registers.
- Address dependency.
- Data dependency.
- Control dependency.

*Applies to an implementation of the architecture Armv8.0-M onward.*

### Dependency through registers

$R_{LNLD}$

A *Dependency through registers* from first effect  $E_1$  to a second effect  $E_2$  exists with a PE if and only if at least one of the following applies:

- $E_1$  is a register write,  $W_1$ , which has been generated by a Store Exclusive,  $E_2$  is a register read  $R_2$  and  $R_2$  [reads-from-register](#)  $W_1$ .
- $E_1$  and  $E_2$  have been generated by the same instruction and  $E_1$  is before  $E_2$  in the Intrinsic Order of that instruction.
- There is a Dependency through registers from  $E_1$  to a third effect  $E_3$ , and there is a Dependency through registers from  $E_3$  to  $E_2$ .

*Applies to an implementation of the architecture Armv8.0-M onward.*

### Address dependency

$R_{NPWZ}$

An *address dependency* from a memory read  $R_1$  to a [Memory effect](#),  $RW_2$ , exists if and only if there is a Dependency through registers from  $R_1$  to a Register effect,  $E_3$  generated by  $RW_2$ , and  $E_3$  affects the address part of  $RW_2$ , and either:

- $RW_2$  is a memory write effect  $W_2$ .
- $RW_2$  is a memory read effect,  $R_2$ , and there is no [branching effect](#) on  $D_4$  such that there is a Dependency through registers from  $R_1$  to  $D_4$  and from  $D_4$  to  $R_2$ .

*Applies to an implementation of the architecture Armv8.0-M onward.*

### Data dependency

$R_{FNSF}$

A *data dependency* from a read  $R_1$  to a subsequent write  $W_2$  exists if and only if there is a register dependency from the data value returned by  $R_1$  to the data value written by  $W_2$ .

*Applies to an implementation of the architecture Armv8.0-M onward.*

### Control dependency

$R_{KFXC}$

A *Control dependency* from a memory read  $R_1$  to a [Memory effect](#)  $RW_2$  exists if and only if either:

- There is a Dependency through registers from  $R_1$  to a [branching effect](#)  $B_2$  and  $B_3$  is in program order before  $RW_2$ .
- There is a Dependency through registers from  $R_1$  to the determination of a synchronous exception on an instruction generating an effect  $RW_3$ , and  $RW_2$  appears in program order after  $RW_3$ .

*Applies to an implementation of the architecture Armv8.0-M onward.*

## B7.2.4 Ordering and observability at a Location

$I_{XQBW}$

Memory effects on a [Location](#) have the following relations:

- Reads-from-register.
- Reads-from.
- Local-read-successor.
- Local write successor.
- Data dependency.
- Coherence order.
- Coherence-after.
- Completion.
- Global completion.
- Overlapping accesses.
- Observed-by.
- DMB

*Applies to an implementation of the architecture Armv8.0-M onward.*

### Reads-from-register

$R_{ZQXF}$

The *reads-from-register* relation couples reads and writes to the same register such that each register read is paired with exactly one register write in the execution of a program. A read  $R_2$  Reads-from-register a write  $W_1$  to the same register if and only if  $R_2$  takes its data from  $W_1$ . By construction  $W_1$  must be in program order before  $R_2$  and there must be no intervening write to the same register in program order between  $W_1$  and  $R_2$ .

*Applies to an implementation of the architecture Armv8.0-M onward.*

### Reads-from

$R_{CMSK}$

A *reads-from* relation that couples reads and writes to the same [Location](#) so that each read is paired with a single write in the program. A read  $R_2$  of a [Location](#) reads-from a write  $W_1$  to the same [Location](#) if and only if  $R_2$  takes its data from  $W_1$ .

*Applies to an implementation of the architecture Armv8.0-M onward.*

$I_{MHCW}$

The reads-from relation represents a read being satisfied by a write and then returning the written data.

*Applies to an implementation of the architecture Armv8.0-M onward.*

### Local-read-successor

$R_{SZNB}$

A read from  $R_2$  of a [Location](#) is the *Local-read-successor* of a write from  $W_1$  from the same Observer to the same [Location](#) if and only if  $W_1$  appears in program order before  $R_2$  and there is not a write from  $W_3$  from the same Observer to the same [Location](#) appearing in program order between  $W_1$  and  $R_2$ .

*Applies to an implementation of the architecture Armv8.0-M onward.*

### Local write successor

$R_{FRJQ}$

A write  $W_2$  of a [Location](#) is the *Local write successor* of a write  $W_1$  from the same Observer to the same [Location](#) if and only if  $W_1$  appears in program order before  $W_2$ .

*Applies to an implementation of the architecture Armv8.0-M onward.*

## Data dependency

$R_{HHFZ}$  A *Data dependency* from a memory read,  $R_1$ , to a memory write,  $W_2$ , exists if and only if there is a dependency through registers from  $R_1$  to a [register effect](#),  $E_3$ , generated by  $W_2$  and  $E_3$  affects the data part of  $W_2$ .

*Applies to an implementation of the architecture Armv8.0-M onward.*

## Coherence order

$R_{XLMs}$  A *coherence order* relation for each [Location](#) in the program that provides a total order on all writes from all coherent Observers to that [Location](#), starting with a notional write of the initial value.

*Applies to an implementation of the architecture Armv8.0-M onward.*

$I_{HGfQ}$  The coherence order of a [Location](#) represents the order in which writes to the [Location](#) arrive at memory.

*Applies to an implementation of the architecture Armv8.0-M onward.*

## Coherence-after

$R_{VSMJ}$  A write  $W_2$  to a [Location](#) is *Coherence-after* another write  $W_1$  to the same [Location](#) if and only if  $W_2$  is sequenced after  $W_1$  in the coherence order of the [Location](#).

*Applies to an implementation of the architecture Armv8.0-M onward.*

$R_{WJVX}$  A write  $W_2$  to a [Location](#) is *Coherence-after* a read  $R_1$  of the same [Location](#) if and only if  $R_1$  [reads-from](#) a write  $W_3$  to the same [Location](#) and  $W_2$  is *Coherence-after*  $W_3$ .

*Applies to an implementation of the architecture Armv8.0-M onward.*

## Completion

$R_{LHTR}$  A read  $R_1$  of a [Location](#) by an Observer is *Complete* when a write to the same [Location](#) by a different Observer is [Coherence-after](#)  $R_1$ .

*Applies to an implementation of the architecture Armv8.0-M onward.*

$R_{RQRH}$  A write  $W_1$  to a [Location](#) by an Observer is *Complete* when both:

1. A write to the same [Location](#) by a different Observer will be [Coherence-after](#)  $W_1$ .
2. A read to the same [Location](#) by a different Observer will be [Read-from](#) a write that is [Coherence-after](#)  $W_1$ .

*Applies to an implementation of the architecture Armv8.0-M onward.*

## Global completion

$R_{HNRN}$  A [reads-from](#)  $R_1$  of a [Location](#) by an Observer is *Globally complete* if it is [Complete](#) and the write that it [reads-from](#) is also [Complete](#).

*Applies to an implementation of the architecture Armv8.0-M onward.*

$R_{SWKN}$  A write  $W_1$  to a [Location](#) by an Observer is *Globally complete* if it is [Complete](#).

*Applies to an implementation of the architecture Armv8.0-M onward.*

## Overlapping accesses

$R_{QBJR}$  Two memory effects overlap if and only if they access the same [Location](#). Two instructions overlap if and only if one or more of their generated memory effects overlap.

*Applies to an implementation of the architecture Armv8.0-M onward.*

## Observed-by

- $R_{MSFX}$  A read or a write  $RW_1$  from an **Observer** is *Observed-by* a write  $W_2$  from a different **Observer** if and only if  $W_2$  is **coherence-after**  $RW_1$ .  
*Applies to an implementation of the architecture Armv8.0-M onward.*
- $R_{DLDS}$  A write  $W_1$  from an **Observer** is observed-by a read  $R_2$  from a different **Observer** if and only if  $R_2$  **reads-from**  $W_1$ .  
*Applies to an implementation of the architecture Armv8.0-M onward.*
- $I_{WHVK}$  The observed-by relation only relates accesses generated by different **Observers**.  
*Applies to an implementation of the architecture Armv8.0-M onward.*

## DMB SY

- $R_{JTHS}$  Unless a specific Shareability domain is defined, a **DMB SY** applies to the Common shareability domain.  
*Applies to an implementation of the architecture Armv8.0-M onward.*
- $R_{FNCH}$  All properties that apply to **DMB SY** also apply to the corresponding **DSB**.  
*Applies to an implementation of the architecture Armv8.0-M onward.*

## Context synchronization instruction

- $R_{FGWN}$  A *Context synchronization instruction* is one of the following:
- An **ISB** instruction.
  - An instruction that generates a synchronous exception.
- Applies to an implementation of the architecture Armv8.0-M onward.*

### B7.2.4.1 Ordering relations

- $I_{WPKC}$  In addition to the ordering relations for a single **Location**, the Armv8 memory model also provides ordering relations to describe the ordering of memory effects to multiple **Locations**.  
*Applies to an implementation of the architecture Armv8.0-M onward.*

## Dependency-ordered-before

- $R_{ZZLM}$  A dependency creates externally-visible order between a read and another **memory effect** generated by the same Observer. A read  $R_1$  is *dependency-ordered-before* a read or write  $RW_2$  from the same Observer if and only if  $R_1$  appears in program order before  $RW_2$  and any of the following cases apply:
- There is an address dependency or a **data dependency** from  $R_1$  to  $RW_2$ .
  - $RW_2$  is a write  $W_2$  and there is a **control dependency** from  $R_1$  to  $W_2$ .
  - $RW_2$  is a read  $R_2$  generated by an instruction appearing in program order after an instruction  $I_3$  that generates a **Context synchronization event**, and there is a **dependency through registers** from  $R_1$  to  $I_3$ .
  - $RW_2$  is a write  $W_2$  appearing in program order after a read or a write  $RW_3$  and there is an address dependency from  $R_1$  to  $RW_3$ .
  - $RW_2$  is a **local-read-successor**  $R_2$  of a write,  $W_3$ , and there is an address dependency or **data dependency** from  $R_1$  to  $W_3$ .
- Applies to an implementation of the architecture Armv8.0-M onward.*

## Atomic-ordered-before

R<sub>NXVW</sub>

Load-Exclusive and Store-Exclusive instructions provide some ordering guarantees, even in the absence of dependencies. A read or a write  $RW_1$  is *atomic-ordered-before* a read or a write  $RW_2$  from the same Observer if and only if  $RW_1$  appears in program order before  $RW_2$  and either of the following cases apply:

- $RW_1$  is a read  $R_1$  and  $RW_2$  is a write  $W_2$  so that  $R_1$  and  $W_2$  are generated by an atomic instruction or a successful Load-Exclusive/Store-Exclusive instruction pair to the same [Location](#).
- $RW_1$  is a write  $W_1$  generated by an atomic instruction or a successful Store-Exclusive instruction and  $RW_2$  is a read  $R_2$  generated by an instruction with Acquire or AcquirePC semantics so that  $R_2$  [reads-from](#)  $W_1$ .

*Applies to an implementation of the architecture Armv8.0-M onward.*

## Single-copy-atomic-ordered-before

R<sub>DFDV</sub>

A read  $R_1$  is *single-copy-atomic-ordered-before* another read  $R_2$  if and only if all of the following statements are true:

- $R_1$  and  $R_2$  are reads from the same instruction.
- $R_1$  is not a [local-read-successor](#) of a write.
- $R_2$  is a [local-read-successor](#) of a write.

*Applies to an implementation of the architecture Armv8.0-M onward.*

## Barrier-ordered-before

R<sub>PXPQ</sub>

Barrier instructions order prior [memory effects](#) before subsequent [memory effects](#) generated by the same [Observer](#). A read or a write  $RW_1$  is *barrier-ordered-before* a read or a write  $RW_2$  from the same Observer if and only if  $RW_1$  appears in program order before  $RW_2$  and any of the following cases apply:

- $RW_1$  appears in program order before a [DMB](#) that appears in program order before  $RW_2$ .
- $RW_1$  appears in program order before an atomic instruction with both Acquire and Release semantics that appears in program order before  $RW_2$ .
- $RW_1$  is a write  $W_1$  generated by an instruction with Release semantics and  $RW_2$  is a read  $R_2$  generated by an instruction with Acquire semantics.
- $RW_1$  is a read  $R_1$  and  $R_1$  is generated by an instruction with Acquire semantics.
- $RW_2$  is a write  $W_2$  and  $W_2$  is generated by an instruction with Release semantics.

*Applies to an implementation of the architecture Armv8.0-M onward.*

## Locally-ordered-before

R<sub>ZQLS</sub>

Dependencies, Local write successor, Load/Store-Exclusive, atomic, and barrier instructions can be composed with an Observer to create externally-visible order. A read or write  $RW_1$  is *locally-ordered-before* a read or write  $RW_2$  from the same Observer if and only if any of the following apply:

- $RW_1$  is a write,  $W_1$ , and  $RW_2$  is a write,  $W_2$ , that is equal to or generated by the same instruction as a [local-write-successor](#) of  $RW_1$ .
- $RW_1$  is [dependency-ordered-before](#)  $RW_2$ .
- $RW_1$  is [atomic-ordered-before](#)  $RW_2$ .
- $RW_1$  is [barrier-ordered-before](#)  $RW_2$ .
- $RW_1$  is locally-ordered-before  $RW_2$ .

*Applies to an implementation of the architecture Armv8.0-M onward.*

## Ordered-before

$R_{GZXJ}$  An arbitrary pair of [memory effects](#) is ordered if it can be linked by a chain of ordered accesses consistent with external observation. A read or a write  $RW_1$  is *ordered-before* a read or a write  $RW_2$  if and only if any of the following cases apply:

- $RW_1$  is observed-by  $RW_3$  which is generated by the same instruction as  $RW_2$ .
- $RW_1$  is locally-ordered-before  $RW_2$ .
- $RW_1$  is ordered-before a read or write that is ordered-before  $RW_2$ .

*Applies to an implementation of the architecture Armv8.0-M onward.*

$I_{VPCD}$  For a read or write,  $RW_1$ , from an [Observer](#) that is ordered before a read or a write,  $RW_2$  from a different [Observer](#), the External visibility requirement requires that  $RW_2$  is not Observed-by  $RW_1$ . This means that architecturally-well-formed execution must not exhibit a cycle in the Ordered-before relation.

*Applies to an implementation of the architecture Armv8.0-M onward.*

$I_{MFCK}$  Informally, if a [memory effect](#),  $M_1$ , from an [Observer](#) appears in program order before a [memory effect](#),  $M_2$ , from the same Observer, then  $M_1$  will be seen to occur before  $M_2$  by all Observers in the system.

*Applies to an implementation of the architecture Armv8.0-M onward.*

See also:

[Chapter B9 Synchronization and Semaphores](#)

## B7.2.5 Ordering constraints

### Other-multi-copy atomic

$R_{MXHD}$  In an *other-multi-copy atomic* system, it is required that a write from an [Observer](#), if observed by a different [Observer](#), is then observed by all other Observers that access the [Location](#) coherently. It is, however, permitted for an [Observer](#) to observe its own writes prior to making them visible to other Observers in the system.

*Applies to an implementation of the architecture Armv8.0-M onward.*

$R_{XCGK}$  The Armv8 memory model is described as being other-multi-copy atomic.

*Applies to an implementation of the architecture Armv8.0-M onward.*

$R_{QPKH}$  The other-multi-copy atomic property of the Armv8 memory model is enforced by placing constraints on the possible executions of a program. Those executions that meet the constraints given by the ordering model are said to be *architecturally well-formed*. An implementation that is executing a program is only permitted to exhibit behavior consistent with an architecturally well-formed execution.

*Applies to an implementation of the architecture Armv8.0-M onward.*

### Architecturally well-formed

$R_{KNXM}$  An architecturally well-formed execution must satisfy both of the following requirements:

- Internal visibility.
- External visibility.

*Applies to an implementation of the architecture Armv8.0-M onward.*

## Internal visibility requirement

**R<sub>RZDJ</sub>** For a read or a write  $RW_1$  that appears in program order before a read or a write  $RW_2$  to the same **Location**, the internal visibility requirement requires that exactly one of the following statements is true:

- $RW_2$  is a write  $W_2$  that is **Coherence-after**  $RW_1$ .
- $RW_1$  is a write  $W_1$  and  $RW_2$  is a read  $R_2$  such that either:
  - $R_2$  **reads-from**  $W_1$ .
  - $R_2$  **reads-from** another write that is **Coherence-after**  $W_1$ .
- $RW_1$  and  $RW_2$  are both reads  $R_1$  and  $R_2$  such that  $R_1$  **reads-from** a write  $W_3$  and either:
  - $R_2$  **reads-from**  $W_3$ .
  - $R_2$  **reads-from** another write that is **Coherence-after**  $W_3$ .

*Applies to an implementation of the architecture Armv8.0-M onward.*

**I<sub>JJBB</sub>** If a **memory effect**  $M_1$  from an **Observer** appears in program order before a **memory effect**  $M_2$  from the same **Observer**, then  $M_1$  will be seen to occur before  $M_2$  by that **Observer**.

*Applies to an implementation of the architecture Armv8.0-M onward.*

## External visibility requirement

**R<sub>DVLW</sub>** For a read or a write  $RW_1$  from an **Observer** that is **ordered-before** a read or a write  $RW_2$  from a different **Observer**, the external visibility constraint requires that  $RW_2$  is not observed-by  $RW_1$ . This means that an architecturally well-formed execution must not exhibit a cycle in the **ordered-before** relation.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**I<sub>XRFB</sub>** If a **memory effect**  $M_1$  from an **Observer** is ordered-before another **memory effect**  $M_2$ , from a different **Observer**, then  $M_1$  will be seen to occur before  $M_2$  by all **Observers** in the system.

*Applies to an implementation of the architecture Armv8.0-M onward.*

### B7.2.6 Completion and endpoint ordering

**I<sub>XSQR</sub>** Interaction between **Observers** in a system is not restricted to communication through shared variables in coherent memory. For example, an **Observer** could configure an interrupt controller to raise an interrupt on another **Observer** as a form of message passing. These interactions typically involve an additional agent, which defines the instruction sequence that is required to establish communication links between different **Observers**. When these forms of interaction are used together with shared variables, a **DSB** instruction can be used to enforce ordering between them.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>MNQT</sub>** A read,  $R_1$ , to a **Location** is complete for a Shareability domain when any write to the same **Location** by an **Observer** within the Shareability domain will be **Coherence-after**  $R_1$ .

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>DXPG</sub>** A write  $W_1$  to a **Location** is complete for a Shareability domain when all of the following are true:

- Any write to the same **Location** by an **Observer** within the Shareability domain will be **Coherence-after**  $W_1$ .
- Any read to the same **Location** by an **Observer** within the Shareability domain will either **reads-from**  $W_1$  or **reads-from** a write that is **Coherence-after**  $W_1$ .

*Applies to an implementation of the architecture Armv8.0-M onward.*

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| R <sub>TCDN</sub> | The <i>peripheral coherence order</i> of a memory-mapped peripheral is a total order on all reads and writes to that peripheral.<br><br><i>Applies to an implementation of the architecture Armv8.0-M onward.</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| I <sub>QHFV</sub> | The peripheral coherence order for a memory-mapped peripheral signifies the order in which accesses arrive at the endpoint.<br><br><i>Applies to an implementation of the architecture Armv8.0-M onward.</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| R <sub>JWMW</sub> | For a read or a write RW <sub>1</sub> and a read or a write RW <sub>2</sub> to the same peripheral, then RW <sub>1</sub> will appear in the peripheral coherence order for the peripheral before RW <sub>2</sub> if either of the following cases apply: <ul style="list-style-type: none"> <li>• RW<sub>1</sub> and RW<sub>2</sub> are accesses using <i>Non-cacheable</i> or <i>Device</i> attributes and RW<sub>1</sub> is <a href="#">ordered-before</a> RW<sub>2</sub>.</li> <li>• RW<sub>1</sub> and RW<sub>2</sub> are accesses using Device-nGnRE or Device-nGnRnE attributes and RW<sub>1</sub> appears in program order before RW<sub>2</sub>.</li> </ul> |

*Applies to an implementation of the architecture Armv8.0-M onward.*

## Out-of-band-ordered-before

$R_{CHWP}$  A read or a write  $RW_1$  is *out-of-band-ordered-before* a read or a write  $RW_2$  if and only if either of the following cases apply:

- $RW_1$  appears in program order before a [DSB](#) instruction that begins an IMPLEMENTATION DEFINED instruction sequence indirectly leading to the generation of  $RW_2$ .
- $RW_1$  is [ordered-before](#) a read or a write  $RW_1$  and  $RW_1$  is out-of-band-ordered-before  $RW_2$ .

*Applies to an implementation of the architecture Armv8.0-M onward.*

$R_{VSNV}$  If a [memory effect](#)  $M_1$  is out-of-band-ordered-before a read or a write  $M_2$ , then  $M_1$  is seen to occur before  $M_2$  by all [Observers](#).

*Applies to an implementation of the architecture Armv8.0-M onward.*

## B7.2.7 External ordering constraints

$I_{ZCPH}$  The Armv8 memory model provides the following three alternative representations of the external ordering constraint:

- External visibility requirement.
- External completion requirement.
- External global completion requirement.

*Applies to an implementation of the architecture Armv8.0-M onward.*

## Completes-before order

$R_{QNHS}$  The *Completes-before order* is a total order that corresponds to the order in which memory effects complete within the system. The following effects constitute a single entry in the completes-before order:

- Writes from the same instruction.
- Reads from the same instruction which read from external writes.
- Writes from the same instruction which read from the same internal write.

All other reads constitute distinct entries in the completes-before order.

*Applies to an implementation of the architecture Armv8.0-M onward.*

## Completes-before

$R_{JCKC}$  A read or write  $RW_1$  *completes-before* a read or write  $RW_2$  if and only if  $RW_1$  appears in the completes-before order before  $RW_2$ .

*Applies to an implementation of the architecture Armv8.0-M onward.*

## Deriving Reads-from and Coherence order from the Completes-before order

$I_{WPBF}$  The completes-before order can be used to resolve the [Reads-from](#) relation for every memory access in the system.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>LQJQ</sub>

For a read,  $R_1$ , of a **Location** by an **Observer**, then:

- If there is a write  $W_2$  to the same **Location** from the same **Observer**,  $R_1$  will read-from  $W_2$  if all of the following are true:
  - $W_2$  appears in program order before  $R_1$ .
  - $R_1$  completes-before  $W_2$ .
  - There are no writes to the same **Location** appearing in program order between  $W_2$  and  $R_1$ .
- If there is a write  $W_2$  to same **Location** from a different **Observer**,  $R_1$  will read-from  $W_2$  if all of the following are true:
  - $W_2$  completes-before  $R_1$ .
  - There are no writes to the **Location** appearing in program order or in the completes-before order between  $W_2$  and  $R_1$ .
- If no such write exists  $R_1$  **reads-from** the initial value of the **Location**.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>TCLS</sub>

The Coherence order of writes to a **Location** is the order in which those writes appear in the completes-before order. The final value of each **Location** is determined by the final write to each **Location** in the completes-before order. If no such write exists for a given **Location**, the final value of the **Location** is the initial value of the **Location**.

*Applies to an implementation of the architecture Armv8.0-M onward.*

## External completion requirement

R<sub>NLVB</sub>

A read or write,  $RW_1$ , *Globally-completes-before* a read or a write,  $RW_2$ , if and only if any of the following are true:

- $RW_1$  is **locally-ordered-before**  $RW_2$ .
- $RW_2$  is a read,  $R_2$ , and  $R_1$  is single-copy-ordered-before  $R_2$

*Applies to an implementation of the architecture Armv8.0-M onward.*

## B7.2.8 Globally-completes-before order

R<sub>ZPSM</sub>

The *globally-completes-before order* is a total order that corresponds to the order in which memory effects globally-complete with the system. The following effects constitute a single entry in the globally-completes-before order:

- Writes from the same instruction.
- Reads from the same instruction which read from external writes.
- Reads from the same instruction which read from the same internal write.

All other reads constitute distinct entries in the globally-completes-before order.

*Applies to an implementation of the architecture Armv8.0-M onward.*

## Globally-completes-before

R<sub>FDKZ</sub>

A read or write,  $RW_1$ , *globally-completes-before* a read or write,  $RW_2$ , if and only if  $RW_1$  appears in the globally-completes-before order before  $RW_2$ .

*Applies to an implementation of the architecture Armv8.0-M onward.*

## Deriving reads-from and coherence order from the globally-completes-before order

|            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| $R_{NBQC}$ | The Armv8-M architecture supports the following memory barriers: <ul style="list-style-type: none"><li>• <i>Instruction Synchronization Barrier</i> (<a href="#">ISB</a>).</li><li>• <i>Data Memory Barrier</i> (<a href="#">DMB</a>).</li><li>• <i>Data Synchronization Barrier</i> (<a href="#">DSB</a>).</li><li>• <i>Consumption of Speculative Data Barrier</i> (<a href="#">CSDB</a>).</li><li>• <i>Physical Speculative Store Bypass Barrier</i> (<a href="#">PSSBB</a>).</li><li>• <i>Speculative Store Bypass Barrier</i> (<a href="#">SSBB</a>).</li></ul><br><i>Applies to an implementation of the architecture Armv8.0-M onward.</i> |
| $R_{LQXF}$ | The <a href="#">DMB</a> and <a href="#">DSB</a> memory barriers affect reads and writes to the memory system that are generated by Load/Store instructions and data or unified cache maintenance operations that are executed by the PE. Instruction fetches are not explicit accesses.<br><br><i>Applies to an implementation of the architecture Armv8.0-M onward.</i>                                                                                                                                                                                                                                                                          |

## B7.2.10 Instruction Synchronization Barrier

**R<sub>STMG</sub>** An **ISB** ensures that all instructions that come after the **ISB** instruction in program order are fetched from the cache or memory after the **ISB** instruction has completed.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**I<sub>RZFB</sub>** Using an **ISB** ensures that the effects of context-changing operations executed before the **ISB** are visible to the instructions fetched after the **ISB**.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>VJKH</sub>** Any context-changing operations appearing in program order after the **ISB** instruction only take effect after the **ISB** has been executed.

*Applies to an implementation of the architecture Armv8.0-M onward.*

See also:

[InstructionSynchronizationBarrier\(\)](#).

[Context synchronization event](#)

## B7.2.11 Data Memory Barrier

**R<sub>MPSG</sub>** The required Shareability for a **DMB** is *Full system*, and applies to all observers in the Shareability domain.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>GVDL</sub>** A **DMB** only affects memory accesses and the operation of data cache and unified cache maintenance operations, and has no effect on the ordering of any other instructions.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>HFTX</sub>** A **DMB** that ensures the completion of cache maintenance instructions has an access type of both loads and stores.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**I<sub>CNSK</sub>** The principle of the **DMB** is to introduce order between memory accesses that are specified to be affected by the **DMB** supplied as arguments to the **DMB** instruction.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>RGHH</sub>** The **DMB** instruction ensures that all affected memory accesses by the PE executing the **DMB** instruction that appear in program order before the **DMB** instruction and those instructions which originate from a different PE, are observed-by each PE before any affected memory accesses that are in program order after the **DMB** are observed-by that PE.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**I<sub>CLHH</sub>** The use of the **DMB** instruction between the Memory effects of instructions are **barrier-ordered-before**.

*Applies to an implementation of the architecture Armv8.0-M onward.*

See also:

[DataMemoryBarrier\(\)](#).

[B7.14 Shareability domains](#).

## B7.2.12 Data Synchronization Barrier

**I<sub>BGJS</sub>** A **DSB** is a memory barrier that ensures that memory accesses that occur before the **DSB** instruction have completed before the completion of the **DSB** instruction. The **DSB** acts as a stronger barrier than a **DMB** instruction and all ordering that is created by a **DMB** is also generated by a **DSB**.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>NKJW</sub>** The required Shareability for a **DSB** is Full system and applies to all observers in the Shareability domain.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>KMGH</sub>** A **DSB** completes when all of the following conditions apply:

- All explicit memory accesses that are observed by PEE before the **DSB** is executed and are of the required access types, and are from observers in the same required Shareability domain as PEE, are complete for the set of observers in the required Shareability domain.
- If the required access types of the **DSB** is reads and writes, then all cache and branch predictor maintenance instructions that are issued by PEE before the **DSB** are complete for the required Shareability domain.
- All explicit accesses to the **System Control Space** that result in a context altering operation issued by PEE before the **DSB** are complete.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>KMBX</sub>** No instruction that appears in program order after the **DSB** instruction can execute until the **DSB** completes.

*Applies to an implementation of the architecture Armv8.0-M onward.*

See also:

[DataSynchronizationBarrier\(\)](#).

[B7.14 Shareability domains](#).

## B7.2.13 Consumption of Speculative Data Barrier

**R<sub>CTSR</sub>** The **CSDB** is a memory barrier that prevents instructions that appear in program order after the barrier completes from determining any part of the value of data derived from speculatively executed load instructions that appeared in program order before completion of the **CSDB** memory barrier.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **M**.*

**I<sub>LZDK</sub>** When a **CSDB** instruction is executed, but before the **CSDB** completes and there are three instructions:

1. A load instruction speculatively executed in program order before the barrier that might or might not be architecturally executed.
2. A Conditional Move instruction that has passed its condition code check and does not have an address dependency for an input register on the speculatively executed load.
3. A load, store, data, or instruction preload appearing in program order after the barrier, which has an address dependency on the Conditional Move instruction.

The speculative execution of the load, store, data, or instruction preload does not influence the allocation of cache entries to determine any part of the value of the speculatively executed load instruction by an evaluation of the cache entries which have been allocated or evicted.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **M**.*

**I<sub>DDTH</sub>** When a **CSDB** instruction is executed, but before the **CSDB** completes and there are three instructions:

1. A load instruction speculatively executed in program order before the barrier that might or might not be architecturally executed.

2. A Conditional Move instruction that has no dependency to pass the condition tests or for an input register on the speculatively executed load.
3. An indirect branch instruction, appearing in program order after the barrier, that is dependent on the Conditional Move instruction for the target address of the indirect branch.

The speculative execution of the indirect branch does not influence the allocation of cache entries to determine any part of the value of the speculatively executed load instruction by an evaluation of the cache entries which have been allocated or evicted.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [M](#).*

**R<sub>JWCV</sub>** A [CSDB](#) instruction cannot be executed speculatively.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [M](#).*

**I<sub>QZKB</sub>** A [CSDB](#) can be inserted speculatively and completed when it is known not to be speculative.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [M](#).*

**R<sub>WGCX</sub>** The [CSDB](#) instruction is not available in an implementation without the Main Extension.

*Applies to an implementation of the architecture Armv8.0-M onward. Note, ![M](#).*

**I<sub>PCSF</sub>** Arm recommends that a combination of [DSB](#) and an [ISB](#) is inserted to prevent consumption of speculative data.

*Applies to an implementation of the architecture Armv8.0-M onward. Note, ![M](#).*

### B7.2.14 Physical Speculative Store Bypass Barrier

**I<sub>CCNK</sub>** The [PSSBB](#) prevents speculative loads from:

- Returning data older than the most recent store to the same physical address appearing in program order before the load.
- Returning data from stores using the same physical address appearing in program order after the load.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [M](#).*

**R<sub>MDLZ</sub>** The [PSSBB](#) is not available in an implementation without the Main Extension.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - ![M](#).*

### B7.2.15 Speculative Store Bypass Barrier

**I<sub>HWND</sub>** The [SSBB](#) prevents speculative loads from:

- Returning data older than the most recent store to the same address appearing in program order before the load.
- Returning data from stores using the same address appearing in program order after the load.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [M](#).*

**R<sub>MGLH</sub>** The [SSBB](#) is not available in an implementation without the Main Extension.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - ![M](#).*

### B7.2.16 Synchronization requirements for System Control Space

**R<sub>SJQJ</sub>** A [DSB](#) guarantees that all writes to the System Control Space have been completed.

*Applies to an implementation of the architecture Armv8.0-M onward.*

$R_{NPDJ}$  The execution of a [DSB](#) alone does not guarantee that the side effects of writes to the [System Control Space](#) are visible. A Context synchronization event is required for side effects of a write to the [System Control Space](#) to be visible.

*Applies to an implementation of the architecture [Armv8.0-M](#) onward.*

$R_{HMNM}$  A Context synchronization event guarantees that the side effects of any completed writes to the System Control Space are visible after the Context synchronization event.

*Applies to an implementation of the architecture [Armv8.0-M](#) onward.*

## B7.5 Endianness

I<sub>CTVV</sub>

In memory:

The following figures show the relationship between:

- The word at address A.
- The halfwords at addresses A and A+2.
- The bytes at addresses A, A+1, A+2, and A+3.

Data arranged in a little-endian format

Data arranged in a big-endian format

Instruction alignment and byte ordering

a) Bits[15:0]: this is hw 1 for a T32 instruction with a 16-bit encoding

b) Bits[31:0]: this is hw1 and hw2 for a T32 instruction with a 32-bit encoding

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>JJQL</sub>

Instruction fetches are always little-endian, which means that the PE assumes a little-endian arrangement of instructions in memory.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>MNSB</sub>

All accesses to the Private Peripheral Bus (PPB) are always little-endian, which means that the PE assumes a little-endian arrangement of the PPB registers.

*Applies to an implementation of the architecture Armv8.0-M onward.*

$R_{TFKG}$  The endianness of data accesses is IMPLEMENTATION DEFINED, as indicated by [AIRC.R.ENDIANNESS](#).

*Applies to an implementation of the architecture Armv8.0-M onward.*

$R_{KPCF}$  [AIRC.R.ENDIANNESS](#) is either:

- Implemented with a static value.
- Configured by a hardware input on reset.

*Applies to an implementation of the architecture Armv8.0-M onward.*

$R_{XDJV}$  Instructions that cause a memory access that crosses the PPB boundary are CONSTRAINED UNPREDICTABLE if [AIRC.R.ENDIANNESS](#) is set to 1. The permitted behavior is one of the following:

- The instruction behaves as a NOP.
- The instruction raises an UNALIGNED UsageFault.
- If the instruction that crossed the PPB boundary was a load, the value of the destination register becomes UNKNOWN.
- If the instruction that crossed the PPB boundary was a store, the value of the memory locations accessed becomes UNKNOWN.

*Applies to an implementation of the architecture Armv8.0-M onward. Note, a UsageFault requires M.*

$R_{QHWC}$  For data accesses, the following table shows the data element size that endianness applies to, for endianness conversion purposes.

| Instruction class            | Instructions                                                                                                                                                                                                                                                                                                                                                                                                                              | Element size |

## B7.8 Access rights

$R_{K1HH}$  An instruction fetch or memory access is subject to the following checks in the following order:

1. Alignment.
2. SAU or IDAU, or both.
3. MPU.
4. BusFault (IBUSERR).

*Applies to an implementation of the architecture Armv8.0-M onward.*

$R_{TQJS}$  An exception is generated, instead of normal execution of the fetching and decoding process, if one of the following occurs.

| Priority | Fault type                                                                                                                     | Cause                 |
|----------|--------------------------------------------------------------------------------------------------------------------------------|-----------------------|
| Highest  | One of the following SecureFaults: <ul style="list-style-type: none"> <li>• INVEP</li> <li>• INVTRAN</li> </ul>                | AU violation          |
| ↓        | The following MemManage Fault: <ul style="list-style-type: none"> <li>• IACCVIOL</li> </ul>                                    | MPU violation         |
| ↓        | The following BusFault: <ul style="list-style-type: none"> <li>• IBUSERR</li> </ul>                                            | System fault          |
| ↓        | One of the following: <ul style="list-style-type: none"> <li>• DebugMonitor exception</li> <li>• Halted Debug Entry</li> </ul> | FPB hit               |
| ↓        | The following SecureFault: <ul style="list-style-type: none"> <li>• INVEP</li> </ul>                                           | SG check              |
| ↓        | The following UsageFault: <ul style="list-style-type: none"> <li>• INVSTATE</li> </ul>                                         | T32 state check       |
| ↓        | The following UsageFault: <ul style="list-style-type: none"> <li>• INVSTATE</li> </ul>                                         | BTI state check       |
| Lowest   | One of the following UsageFaults: <ul style="list-style-type: none"> <li>• UNDEFINSTR</li> <li>• NOCP</li> </ul>               | Undefined instruction |

*Applies to an implementation of the architecture Armv8.0-M onward. Note, a Secure fault requires S, a MemManage fault requires M & MPU, a Halted Debug Entry fault can only occur if Halting Debug is implemented, a DebugMonitor exception require DebugMonitor, UsageFault and BusFault require M, HardFault when !M.*

$R_{KPNQ}$  If a memory access fails its alignment check, the fetch is not observably presented to the SAU.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - S.*

|            |                                                                                                                                                                                                                                                                                                              |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $R_{SDMQ}$ | <p>If an instruction fetch or memory access fails its AU check, the fetch is not observably presented to the relevant MPU for comparison.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">S</a> &amp; <a href="#">MPU</a>.</i></p> |
| $R_{FLN}$  | <p>If an instruction fetch or memory access fails its MPU check, it is not observably issued to the memory system.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">MPU</a>.</i></p>                                                |
| $I_{KBPD}$ | <p>If the <a href="#">EPSR.T</a> is zero it is IMPLEMENTATION DEFINED whether the instruction opcode is treated as a halfword or word on instruction fetch, with respect to fetch faults.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward.</i></p>                               |

R\_JDSF

If non-idempotent memory locations are mapped with the Normal memory type, then:

- Speculative read accesses can cause accesses to the non-idempotent memory locations that would not occur as part of a simple sequential execution, so corrupting the state of the non-idempotent memory location.
- Writes to a non-idempotent memory locations might be merged or split meaning that the number and size of writes seen by the memory location might not be the number and size that occur as part of a simple sequential execution, so corrupting the state of the non-idempotent memory location.

*Applies to an implementation of the architecture **Armv8.0-M** onward.*

## B7.10 Cacheability attributes

**R<sub>KXJV</sub>** The architecture provides Cacheability attributes that are defined independently for each of two conceptual levels of cache:

- The Inner cache.
- The Outer cache.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>XRWS</sub>** The Cacheability attributes are:

- Non-cacheable.
- Write-Through Cacheable.
- Write-Back Cacheable.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>QXW</sub>** It is IMPLEMENTATION DEFINED whether Write-Through Cacheable and Write-Back Cacheable can have the additional attribute Transient or Non-transient.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**I<sub>LDXP</sub>** The Transient attribute is a [memory hint](#) that indicates that the benefit of caching is for a short period. The architecture does not define what is meant by a *short period*.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>CFKN</sub>** Cacheability attributes other than Non-cacheable can be complemented by the following cache allocation hints, which are independent for read and write accesses:

- Read-Allocate, Transient Read-Allocate, or No Read-Allocate.
- Write-Allocate, Transient Write-Allocate, or No Write-Allocate.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>DRTR</sub>** The architecture does not require an implementation to make any use of cache allocation hints.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>FQSS</sub>** Any cacheable Normal memory region is treated as Read-Allocate, No Write-Allocate unless it is explicitly assigned other cache allocation hints.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**I<sub>FRVF</sub>** A Cacheable [Location](#) with no Read-Allocate and no Write-Allocate hints is not the same as a Non-cacheable [Location](#). A Non-cacheable [Location](#) has coherency guarantees for all [Observers](#) within the system that do not apply to a [Location](#) that is Cacheable, no Read-Allocate, no Write-Allocate.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>FTKW</sub>** All data accesses to Non-cacheable Normal memory locations are data coherent to all [Observers](#).

*Applies to an implementation of the architecture Armv8.0-M onward.*

| R <sub>FSCD</sub> | <p>A write to a Device memory <a href="#">Location</a> reaches the endpoint for that <a href="#">Location</a> in the memory system in finite time.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward.</i></p>                                                                                                                                                                                                                       |
| R <sub>VDMB</sub> | <p>Two writes of Device memory type, to the same location might be merged before they reach the endpoint unless either of the following conditions apply:</p> <ul style="list-style-type: none"> <li>• Both writes have the non-Reordering attribute.</li> <li>• There is an ordered-before relationship between the two writes.</li> </ul> <p><i>Applies to an implementation of the architecture Armv8.0-M onward.</i></p>                                  |
| R <sub>GTQ</sub>  | <p>A completed write to a Device memory <a href="#">Location</a> is globally observed for the Shareability domain in finite time without the requirement for cache maintenance instructions or barriers.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward.</i></p>                                                                                                                                                                 |
| R <sub>XMCH</sub> | <p>If the content of a Device memory <a href="#">Location</a> changes without a direct write to the <a href="#">Location</a>, the change is observed for the Shareability domain in finite time.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward.</i></p>                                                                                                                                                                         |

**R<sub>KJHG</sub>** For an instruction fetch from Device memory, if a branch causes the Program Counter (**PC**) to point to an area of memory that is not marked as execute-never, the implementation can either:

- Treat the fetch as if it is to a **Location** in Normal Non-cacheable memory.
- Take an IACCVIOL MemManage fault.

*Applies to an implementation of the architecture Armv8.0-M onward. Note, a MemManage fault requires M.*

**R<sub>DFJX</sub>** There is no requirement for the memory system beyond the PE to be able to identify the size of the elements that are accessed, for instructions that load the following from Device memory:

- More than one general-purpose register.
- One or more registers from the floating-point register file.

*Applies to an implementation of the architecture Armv8.0-M onward. Note, FP or, from Armv8.1-M MVE required for floating-point register file.*

**R<sub>KVHT</sub>** For an LDM, STM, LDRD, or STRD instruction with a register list that includes the **PC**, the architecture does not define the order in which the registers are accessed.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>SFPK</sub>** For an LDM, STM, VLDM, VSTM, VPOP or VPUSH instruction with a register list that does not include the **PC**, all registers are accessed in the order that they appear in the register list, for Device memory with the non-Reordering attribute.

*Applies to an implementation of the architecture Armv8.0-M onward.*

See also:

[B7.3 Memory accesses.](#)

[B7.13 Shareability attributes.](#)

[B7.12 Device memory attributes.](#)

[B7.14 Shareability domains.](#)

## B7.12 Device memory attributes

R<sub>VNSJ</sub>

Each Device memory region is assigned a combination of Device memory attributes. The attributes are:

**Gathering, G and nG:** The *Gathering* and *non-Gathering* attributes.

**Reordering, R and nR:** The *Reordering* and *non-Reordering* attributes.

**Early Write Acknowledgement, E and nE:** The *Early Write Acknowledgement* and *no Early Write Acknowledgement* attributes.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>CFFC</sub>

Each Device memory region is assigned one of the combinations in the following table:

| Memory Ordering | Name          | nG | nR | nE | G | R | E |
|-----------------|---------------|----|----|----|---|---|---|
| Strong          | Device-nGnRnE | Y  | Y  | Y  | - | - | - |
| ↓               | Device-nGnRE  | Y  | Y  | -  | - | - | Y |
| ↓               | Device-nGRE   | Y  | -  | -  | - | Y | Y |
| Weak            | Device-GRE    | -  | -  | -  | Y | Y | Y |

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>LJKD</sub>

Weaker memory can be accessed according to the rules specified for stronger memory:

- Memory with the:
  - G attribute can be accessed according to the rules specified for the nG attribute.
  - nG attribute cannot be accessed according to the rules specified for the G attribute.
- Memory with the:
  - R attribute can be accessed according to the rules specified for the nR attribute.
  - nR attribute cannot be accessed according to the rules specified for the R attribute.

Because the nE attribute is a hint:

- An implementation is permitted to perform an access with the E attribute in a manner consistent with the requirements specified by the nE attribute.
- An implementation is permitted to perform an access with the nE attribute in a manner consistent with the relaxations allowed by the E attribute.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>FJXX</sub>

For Device-GRE and Device-nGRE memory, the use of barriers is required to order accesses.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>PVCY</sub>

Memory accesses that are generated by vector instructions that target any type of Device memory operate as if the access had targeted a Device-GRE region.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [MVE](#).*

See also:

[B7.12.1 Gathering and non-Gathering Device memory attributes.](#)

[B7.12.2 Reordering and non-Reordering Device memory attributes.](#)

[B7.12.3 Early Write Acknowledgement and no Early Write Acknowledgement Device memory attributes.](#)

[B7.11 Device memory.](#)

## B7.12.1 Gathering and non-Gathering Device memory attributes

### G attribute

R<sub>DBSX</sub>

If multiple accesses of the same type, read or write, are to:

- The same location, with the G attribute, they can be merged into a single transaction.
- Different locations, all with the G attribute, they can be merged into a single transaction.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>KCMX</sub>

Gathering of accesses that are separated by a memory barrier is not permitted.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>JSRD</sub>

Gathering of accesses that are generated by a Load-Acquire/Store-Release is not permitted.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>MGKJ</sub>

A read can come from intermediate buffering of a previous write if:

- The accesses are not separated by a [DMB](#) or [DSB](#) barrier.
- The accesses are not separated by any other ordering construction that requires that the accesses are in order, for example a combination of Load-Acquire and Store-Release.
- The accesses are not generated by a Store-Release instruction.

*Applies to an implementation of the architecture Armv8.0-M onward.*

I<sub>SRDS</sub>

The architecture only defines programmer visible behavior. Therefore, if a programmer cannot tell whether Gathering has occurred, Gathering can be performed.

*Applies to an implementation of the architecture Armv8.0-M onward.*

### nG attribute

R<sub>GVTf</sub>

Multiple accesses to a [Location](#) with the nG attribute cannot be merged into a single transaction.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>BTWD</sub>

A read of a [Location](#) with the nG attribute cannot come from a cache or a buffer, but comes from the endpoint for that address in the memory system.

*Applies to an implementation of the architecture Armv8.0-M onward.*

See also:

[B7.18 Load-Acquire and Store-Release accesses to memory.](#)

## B7.12.2 Reordering and non-Reordering Device memory attributes

### R attribute

R<sub>RPTB</sub>

This attribute imposes no restrictions or relaxations.

*Applies to an implementation of the architecture Armv8.0-M onward.*

## nR attribute

R<sub>DFXL</sub>

If the access is to a:

- Peripheral, it arrives at the peripheral in program order. If there is a mixture of accesses to Device nGnRE and Device-nGnRnE in the same peripheral, these accesses occur in program order.
- Non-peripheral, this attribute imposes no restrictions or relaxations.

*Applies to an implementation of the architecture Armv8.0-M onward.*

I<sub>BDWB</sub>

The IMPLEMENTATION DEFINED size of the [single peripheral](#) is the same as applies for the ordering guarantee that is provided by the [DMB](#) instruction.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>NDHC</sub>

The non-Reordering attribute does not require any additional ordering, other than the ordering that applies to Normal memory, between:

- Accesses with the non-Reordering attribute and accesses with the Reordering attribute.
- Accesses with the non-Reordering attribute and accesses to Normal memory.
- Accesses with the non-Reordering attribute and accesses to different peripherals of IMPLEMENTATION DEFINED size.

*Applies to an implementation of the architecture Armv8.0-M onward.*

## B7.12.3 Early Write Acknowledgement and no Early Write Acknowledgement Device memory attributes

### E attribute

R<sub>PVSH</sub>

The E attribute imposes no restrictions or relaxations.

*Applies to an implementation of the architecture Armv8.0-M onward.*

### nE attribute

R<sub>FWFR</sub>

Assigning the nE attribute recommends that only the endpoint of the write access returns a write acknowledgment of the access, and that no earlier point in the memory system returns a write acknowledgment.

*Applies to an implementation of the architecture Armv8.0-M onward.*

I<sub>FQWQ</sub>

The E attribute is treated as a hint. Arm strongly recommends that this hint is not ignored by a PE, but is made available for use by the system.

*Applies to an implementation of the architecture Armv8.0-M onward.*

See also:

[B7.2.9 Memory barriers.](#)

## B7.13 Shareability attributes

R<sub>CJRF</sub>

Each Normal cacheable memory region is assigned one of the following Shareability attributes:

- *Non-shareable.*
- *Inner-shareable.*
- *Outer-shareable.*

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>PDVV</sub>

For Non-shareable memory, hardware is not required to make data accesses by different observers, other than the Debug Access Port, coherent. If a number of observers share the memory, cache maintenance instructions, in addition to the barrier operations that are required to ensure memory ordering, can ensure that the presence of caches does not lead to coherency issues.

*Applies to an implementation of the architecture Armv8.0-M onward.*

See also:

[B7.3 Memory accesses.](#)

[B7.9 Normal memory.](#)

[B7.11 Device memory.](#)

[B7.14 Shareability domains.](#)

[B7.27 Cache maintenance operations.](#)

## B7.14 Shareability domains

$R_{JMHL}$  There are two conceptual Shareability domains:

- The Inner Shareability domain.
- The Outer Shareability domain.

*Applies to an implementation of the architecture Armv8.0-M onward.*

$I_{XQWM}$  The following diagram shows the Shareability domains:

*Applies to an implementation of the architecture Armv8.0-M onward.*

$R_{MCPS}$  All observers in an Inner Shareability domain are data coherent for data accesses to memory that has the *Inner-shareable Shareability attribute*.

*Applies to an implementation of the architecture Armv8.0-M onward.*

$R_{SVCR}$  All observers in an Outer Shareability domain are data coherent for data accesses to memory that has the *Outer-shareable Shareability attribute*.

*Applies to an implementation of the architecture Armv8.0-M onward.*

$R_{JMFS}$  Each observer is a member of only a single Inner Shareability domain.

*Applies to an implementation of the architecture Armv8.0-M onward.*

$R_{BNWH}$  Each observer is a member of only a single Outer Shareability domain.

*Applies to an implementation of the architecture Armv8.0-M onward.*

$R_{FVBG}$  All members of the same Inner Shareability domain are always members of the same Outer Shareability domain.

*Applies to an implementation of the architecture Armv8.0-M onward.*

$R_{WFMV}$  Accesses to a shareable [Location](#) are coherent within the Shareability domain of that [Location](#).

*Applies to an implementation of the architecture Armv8.0-M onward.*

$I_{DHJF}$  An Inner Shareability domain is a subset of an Outer Shareability domain, although it is not required to be a proper subset.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>XHJL</sub>

Hardware is required to ensure coherency and ordering within the Shareability domain if all of the following apply:

- Before writing to a [Location](#) not using the Write-Back attribute, a [Location](#) in the caches that might have been written with the Write-Back attribute by an agent has been invalidated or cleaned.
- After writing the [Location](#) with the Write-Back attribute, the [Location](#) has been cleaned from the caches to make the write visible to external memory.
- Before reading the [Location](#) with a cacheable attribute, the cache [Location](#) has been invalidated, or cleaned and invalidated.
- A [DMB](#) barrier instruction has been executed, with a scope that applies to the common Shareability of the accesses, between any accesses to the same [Location](#) that use different attributes.

*Applies to an implementation of the architecture [Armv8.0-M](#) onward.*

See also:

[B7.2.3 Ordering and observability.](#)

[B7.13 Shareability attributes.](#)

## B7.15 Memory access restrictions

- $R_{QOCP}$  For accesses to any two bytes that are accessed by the same instruction, the two bytes have the same memory type and Shareability attributes, otherwise behavior is a CONSTRAINED UNPREDICTABLE choice of the following:
- Each memory access that is generated by the instruction uses the memory type and Shareability attribute that is associated with its own address.
  - The instruction executes as a NOP.
  - The instruction generates an alignment fault caused by the memory type.

*Applies to an implementation of the architecture Armv8.0-M onward.*

- $I_{WRBT}$  Except for possible differences in cache allocation hints, Arm deprecates having different Cacheability attributes for accesses to any two bytes that are generated by the same instruction.

*Applies to an implementation of the architecture Armv8.0-M onward.*

- $R_{BFKS}$  If the accesses of an instruction that cause multiple accesses to any type of Device memory cross the boundary of a memory region then the behavior is a CONSTRAINED UNPREDICTABLE choice of the following:
- All memory accesses that are generated by the instruction are performed as if the presence of the boundary had no effect on memory accesses.
  - All memory accesses that are generated by the instruction are performed as if the presence of the boundary had no effect on memory accesses, except that there is no guarantee of ordering between memory accesses.
  - The instruction executes as a NOP.
  - The instruction generates an alignment fault caused by the memory type.

*Applies to an implementation of the architecture Armv8.0-M onward.*

See also:

[B7.3 Memory accesses.](#)

## B7.16 Mismatched memory attributes

$R_{XHTK}$  Memory locations are accessed with *mismatched attributes* if all accesses to the [Location](#) do not use a common definition of all the following memory attributes of that [Location](#):

- Memory type - Device or Normal.
- Shareability.
- Cacheability, for the same level of the Inner or Outer cache, but excluding any cache allocation hints.

*Applies to an implementation of the architecture Armv8.0-M onward.*

$R_{VKHJ}$  When a memory [Location](#) is accessed with mismatched attributes, the only permitted effects are one or more of the following:

- Uniprocessor semantics for reads and writes to that memory [Location](#) might be lost. This means:
  - A read of the memory [Location](#) by one agent might not return the value that was most recently written to that memory [Location](#) by the same agent.
  - Multiple writes to the memory [Location](#) by one agent with different memory attributes might not be ordered in program order.
- There might be a loss of coherency when multiple agents attempt to access a memory [Location](#).
- There might be a loss of the properties that are derived from the memory type.
- If all Load-Exclusive/Store-Exclusive instructions that are executed across all threads to access a given memory [Location](#) do not use consistent memory attributes, the exclusive monitor state becomes UNKNOWN.
- Bytes that are written without the Write-Back cacheable attribute and that are within the same Write-Back granule as bytes that are written with the Write-Back cacheable attribute might have their values reverted to the old values as a result of cache Write-Back.

*Applies to an implementation of the architecture Armv8.0-M onward.*

$R_{NJLB}$  The loss of the properties that are associated with mismatched memory type attributes refers only to the following properties of Device memory that are additional to the properties of Normal memory:

- Prohibition of speculative read accesses.
- Prohibition on Gathering.
- Prohibition on Reordering.

*Applies to an implementation of the architecture Armv8.0-M onward.*

$R_{HCCD}$  Any agent that reads a memory [Location](#) with mismatched attributes using the same common definition of the Shareability and Cacheability attributes is guaranteed to access it coherently, to the extent required by that common definition of the memory attributes, only if all the following conditions are met:

- All aliases to the memory [Location](#) with write permission both use a common definition of the Shareability and Cacheability attributes for the memory [Location](#), and have the Inner Cacheability attribute the same as the Outer Cacheability attribute.
- All aliases to a memory [Location](#) use a definition of the Shareability attributes that encompasses all the agents with permission to access the [Location](#).

*Applies to an implementation of the architecture Armv8.0-M onward.*

$R_{GBKH}$  The possible permitted effects that are caused by mismatched attributes for a memory [Location](#) are defined more precisely if all the mismatched attributes define the memory [Location](#) as one of:

- Any Device memory type.
- Normal Inner Non-cacheable, Outer Non-cacheable memory.

In these cases, the only permitted software-visible effects of the mismatched attributes are one or more of the following:

- Possible loss of properties that are derived from the memory type when multiple agents attempt to access the memory [Location](#).
- Possible reordering of memory transactions to the same memory [Location](#) with different memory attributes, potentially leading to a loss of coherency or uniprocessor semantics. Any possible loss of coherency or uniprocessor semantics can be avoided by inserting [DMB](#) barrier instructions between accesses to the same memory [Location](#) that might use different attributes.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>VVBS</sub>

If the mismatched attributes for a [Location](#) mean that multiple cacheable accesses to the [Location](#) might be made with different Shareability attributes, then ordering and coherency are guaranteed only if:

- Each PE that accesses the [Location](#) with a cacheable attribute performs a clean and invalidate of the [Location](#) before and after accessing that [Location](#).
- A [DMB](#) barrier with scope that covers the full Shareability of the accesses is placed between any accesses to the same memory [Location](#) that use different attributes.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>VCXW</sub>

If multiple agents attempt to use Load-Exclusive or Store-Exclusive instructions to access a [Location](#), and the accesses from the different agents have different memory attributes associated with the [Location](#), the exclusive monitor state becomes UNKNOWN.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>ZKKV</sub>

All cache maintenance instructions and memory transactions must be completed, or ordered by the use of barrier operations, if they are not naturally ordered by the use of a common address.

*Applies to an implementation of the architecture Armv8.0-M onward.*

I<sub>TPWG</sub>

Arm strongly recommends that software does not use mismatched attributes for aliases of the same [Location](#). An implementation might not optimize the performance of a system that uses mismatched aliases.

*Applies to an implementation of the architecture Armv8.0-M onward.*

[Chapter B10 The Armv8-M Protected Memory System Architecture.](#)

[B7.14 Shareability domains.](#)

[B7.10 Cacheability attributes.](#)

[B7.11 Device memory.](#)

[B7.9 Normal memory.](#)

[B7.17 Load-Exclusive and Store-Exclusive accesses to Normal memory.](#)

## B7.17 Load-Exclusive and Store-Exclusive accesses to Normal memory

R<sub>KDWC</sub>

For Normal memory that is:

- Non-shareable, it is IMPLEMENTATION DEFINED whether Load-Exclusive and Store-Exclusive instructions take account of the possibility of accesses by more than one [Observer](#).
- Shareable, Load-Exclusive, and Store-Exclusive instructions take account of the possibility of accesses by more than one [Observer](#).

*Applies to an implementation of the architecture Armv8.0-M onward.*

See also:

[B7.9 Normal memory](#).

[B7.3 Memory accesses](#).

## B7.18 Load-Acquire and Store-Release accesses to memory

I<sub>VXGZ</sub>

The principle of a Load-Acquire instruction is to introduce order between the memory access generated by the Load-Acquire instruction and the memory accesses appearing in program order after the Load-Acquire instruction, ensuring that the memory access generated by the Load-Acquire instruction is all of the following:

- Observed-by each PE.
- Observed before any of the memory accesses appearing in program order after the Load-Acquire instruction are observed by that PE.
- Observed to the extent that each PE is required to observe the access coherently.

The Load-Acquire instructions create order between the Memory effects of instructions as described in the definition of [barrier-ordered-before](#).

*Applies to an implementation of the architecture Armv8.0-M onward.*

I<sub>ZDWZ</sub>

The principle of a Store-Release instruction is to introduce order between the memory accesses generated by the PE, PEe, executing the Store-Release instruction, together with those that originate from a different PE, to the extent that PEe is required to observe them coherently, Observed-by the PEe before executing the Store-release.

The use of Store-Release instructions create order between the Memory effects of instructions as described in the definition of [barrier-ordered-before](#).

*Applies to an implementation of the architecture Armv8.0-M onward.*

I<sub>VVTX</sub>

The following table summarizes the Load-Acquire/Store-Release instructions:

| Data type       | Load-Acquire | Store-Release | Load-Acquire Exclusive | Store-Release Exclusive |
|-----------------|--------------|---------------|------------------------|-------------------------|
| 32-bit word     | LDA          | STL           | LDAEX                  | STLEX                   |
| 16-bit halfword | LDAH         | STLH          | LDAEXH                 | STLEXH                  |
| 8-bit byte      | LDAB         | STLB          | LDAEXB                 | STELXB                  |

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>XBRM</sub>

A Store-Release followed by a Load-Acquire is observed in program order by each [Observer](#) within the Shareability domain of the memory address being accessed by the Store-Release and the memory address being accessed by the Load-Acquire.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>RRFK</sub>

For a Load-Acquire, observers in the Shareability domain of the address that is accessed by the Load-Acquire observe accesses in the following order:

1. The read caused by the Load-Acquire.
2. Reads and writes caused by loads and stores that appear in program order after the Load-Acquire for which the Shareability of the address that is accessed by the load or store requires that the [Observer](#) observes the access.

There are no other ordering requirements on loads or stores that appear before the Load-Acquire.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>WLWT</sub>

For a Store-Release, observers in the Shareability domain of the address that is accessed by the Store-Release observe accesses in the following order:

1. All of the following for which the Shareability of the address that is accessed requires that the [Observer](#) observes the access:
  - Reads and writes caused by loads and stores that appear in program order before the Store-Release.
  - Writes that were observed by the PE executing the Store-Release before it executed the Store-Release.

2. The write caused by the Store-Release.

There are no other ordering requirements on loads or stores that appear in program order after the Store-Release.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>HCKC</sub>** All Store-Release instructions are multi-copy atomic when they are observed with Load-Acquire instructions.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>DGXR</sub>** A Load-Acquire to an address in a memory-mapped peripheral of an arbitrary system-defined size that is defined as any type of Device memory access ensures that all memory accesses using Device memory types to the same memory-mapped peripheral that are architecturally required to be observed after the Load-Acquire will arrive at the memory-mapped peripheral after the memory access of the Load-Acquire.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>CKRC</sub>** A Store-Release to an address in a memory-mapped peripheral of an arbitrary system-defined size that is defined as any type of Device memory access ensures that all memory accesses using Device memory types to the same memory-mapped peripheral that are architecturally required to be observed before the Store-Release will arrive at the memory-mapped peripheral before the memory access of the Store-Release.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>GJHK</sub>** If a Load-Acquire to a memory address in a memory-mapped peripheral of an arbitrary system-defined size that is defined as any type of Device memory access has observed the value that is stored to that address by a Store-Release, then any memory access to the memory-mapped peripheral that is architecturally required to be ordered before the memory access of the Store-Release will arrive at the memory-mapped peripheral before any memory access to the same peripheral that is architecturally required to be ordered after the memory access of the Load-Acquire.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>WRLC</sub>** Load-Acquire and Store-Release access only a single data element.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>KCTN</sub>** Load-Acquire and Store-Release accesses are single-copy atomic.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>BXRP</sub>** If a Load-Acquire or Store-Release instruction accesses an address that is not aligned to the size of the data element being accessed, the access generates an alignment fault.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>NVRJ</sub>** A Store-Release Exclusive instruction only has the release semantics if the store is successful.

*Applies to an implementation of the architecture Armv8.0-M onward.*

## B7.20 Cache identification

R<sub>WBGH</sub>

A PE controls the implemented caches using:

- A single Cache Type Register, [CTR](#).
- A single Cache Level ID Register, [CLIDR](#).
- A single Cache Size Selection Register, [CSSELR](#).
- For each implemented cache, across all levels of caching, a Cache Size Identification Register, [CCSIDR](#).

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>XJTL</sub>

The number of levels of cache is IMPLEMENTATION DEFINED and can be determined from the Cache Level ID Register.

*Applies to an implementation of the architecture Armv8.0-M onward.*

I<sub>PPSB</sub>

[Cache sets](#) and [Cache ways](#) are numbered from 0. Usually the set number is an IMPLEMENTATION DEFINED function of an address.

*Applies to an implementation of the architecture Armv8.0-M onward.*

## B7.21 Cache visibility

$R_{QLVB}$  A completed write to a memory [Location](#) that is Non-cacheable or [Location](#) Write-Through Cacheable for a level of cache made by an [Observer](#) accessing the memory system inside the level of cache is visible to all observers accessing the memory system outside the level of cache without the need of explicit cache maintenance.

*Applies to an implementation of the architecture Armv8.0-M onward.*

$R_{RCHC}$  A completed write to a memory [Location](#) that is Non-cacheable for a level of cache made by an [Observer](#) accessing the memory system outside the level of cache is visible to all observers accessing the memory system inside the level of cache without the need of explicit cache maintenance.

*Applies to an implementation of the architecture Armv8.0-M onward.*

See also:

[B7.10 Cacheability attributes](#).

## B7.22 Cache coherency

R<sub>NNDJ</sub>

Data coherency of caches is ensured:

- When caches are not used.
- As a result of cache maintenance operations.
- By the use of hardware coherency mechanisms to ensure coherency of data accesses to memory for cacheable locations by observers in different Shareability domains.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>CPGW</sub>

Hardware is not required to ensure coherency between instruction caches and memory, even for regions of memory with the Shareability attribute.

*Applies to an implementation of the architecture Armv8.0-M onward.*

## B7.27 Cache maintenance operations

|                   |                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| I <sub>MRMG</sub> | Cache maintenance operations act on particular memory <a href="#">Locations</a> .<br><i>Applies to an implementation of the architecture Armv8.0-M onward.</i>                                                                                                                                                                                                                            |
| R <sub>JJLL</sub> | Following a Clean operation, updates made by an <a href="#">Observer</a> that controls the cache are made visible to other Observers that can access memory at the point to which the operation is performed.<br><i>Applies to an implementation of the architecture Armv8.0-M onward.</i>                                                                                                |
| R <sub>VRBP</sub> | The cleaning of a cache entry from a cache can overwrite memory that has been written by another <a href="#">Observer</a> only if the entry contains a <a href="#">Location</a> that has been written to by an <a href="#">Observer</a> in the Shareability domain of that memory <a href="#">Location</a> .<br><i>Applies to an implementation of the architecture Armv8.0-M onward.</i> |
| R <sub>SJFS</sub> | Following an invalidate operation, updates made visible by observers that access memory at the point to which the invalidate is defined are made visible to an <a href="#">Observer</a> that controls the cache.<br><i>Applies to an implementation of the architecture Armv8.0-M onward.</i>                                                                                             |
| R <sub>PGXK</sub> | An invalidate operation might result in the loss of updates to the <a href="#">Locations</a> affected by the operation that have been written by observers that access the cache.<br><i>Applies to an implementation of the architecture Armv8.0-M onward.</i>                                                                                                                            |
| R <sub>TKBD</sub> | If the address of an entry on which the invalidate operates does not have a Normal cacheable attribute, or if the cache is disabled, then an invalidate operation ensures that this address is not present in the cache.<br><i>Applies to an implementation of the architecture Armv8.0-M onward.</i>                                                                                     |
| R <sub>JTXK</sub> | If the address of an entry on which the invalidate operates has the Normal cacheable attribute, the cache invalidate operation cannot ensure that the address is not present in an enabled cache.<br><i>Applies to an implementation of the architecture Armv8.0-M onward.</i>                                                                                                            |
| R <sub>SDVP</sub> | A clean and invalidate operation behaves as the execution of a clean operation followed immediately by an invalidate operation. Both operations are performed to the same <a href="#">Location</a> .<br><i>Applies to an implementation of the architecture Armv8.0-M onward.</i>                                                                                                         |
| R <sub>VKSN</sub> | The clean operation cleans from the level of cache that is specified through at least the next level of cache away from the PE.<br><i>Applies to an implementation of the architecture Armv8.0-M onward.</i>                                                                                                                                                                              |
| R <sub>GFXB</sub> | The invalidate operation invalidates only at the level specified.<br><i>Applies to an implementation of the architecture Armv8.0-M onward.</i>                                                                                                                                                                                                                                            |
| R <sub>KVSM</sub> | For set/way operations and for All (entire cache) operations, the cache maintenance operation is to the next level of caching.<br><i>Applies to an implementation of the architecture Armv8.0-M onward.</i>                                                                                                                                                                               |
| R <sub>JTWT</sub> | For address operations, the cache maintenance operation is to the point of coherency (PoC) or to the point of unification (PoU) depending on the settings in <a href="#">CLIDR.{LoC, LOUU}</a> .<br><i>Applies to an implementation of the architecture Armv8.0-M onward.</i>                                                                                                             |
| R <sub>XLHX</sub> | Data cache maintenance operations affect data caches and unified caches.<br><i>Applies to an implementation of the architecture Armv8.0-M onward.</i>                                                                                                                                                                                                                                     |

- R<sub>QKMF</sub>** Instruction cache maintenance operations only affect instruction caches.  
*Applies to an implementation of the architecture Armv8.0-M onward.*
- R<sub>RSVL</sub>** Cache maintenance operations are memory mapped, 32-bit write-only operations.  
*Applies to an implementation of the architecture Armv8.0-M onward.*
- R<sub>NSHH</sub>** Cache maintenance operations can have one of the following side effects:
- Any **Location** in the cache might be cleaned.
  - Any unlocked **Location** in the cache might be cleaned and invalidated.
- Applies to an implementation of the architecture Armv8.0-M onward.*
- R<sub>DWMR</sub>** The ICIMVAU, DCIMVAC, DCCMVAU, DCCMVAC, and DCCIMVAC operations require the physical address in the memory map but it does not have to be cache-line aligned.  
*Applies to an implementation of the architecture Armv8.0-M onward.*
- R<sub>HCTC</sub>** For DCISW, DCCSW, and DCCISW, the STR operation identifies the **cache line** to which it applies by specifying the following:
- The cache set the line belongs to.
  - The way number of the line in the set.
  - The **cache level**.

The format of the register data for a set/way operation is:

Where:

**A** =  $\text{Log}_2(\text{ASSOCIATIVITY})$ , rounded up to the next integer if necessary.

**B** = (L + S).

**L** =  $\text{Log}_2(\text{LINELEN})$ .

**S** =  $\text{Log}_2(\text{NSETS})$ , rounded up to the next integer if necessary. ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on.

The values of A and S are rounded up to the next integer.

**Level** = ((Cache level to operate on) - 1). For example, this field is 0 for operations on an L1 cache, or 1 for operations on an L2 cache.

**Set** = The number of the set to operate on.

**Way** = The number of the way to operate on.

- If L == 4 then there is no SBZ field between the set and level fields in the register.
- If A == 0 there is no way field in the register, and register bits[31:B] are SBZ.
- If the level, set, or way field in the register is larger than the size implemented in the cache, then the effect of the operation is UNPREDICTABLE.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>RSBX</sub>** After the completion of an instruction cache maintenance operation, a [Context synchronization event](#) guarantees that the effects of the cache maintenance operation are visible to all instruction fetches that follow the [Context synchronization event](#).

*Applies to an implementation of the architecture Armv8.0-M onward.*

**I<sub>DHJQ</sub>** Arm recommends that, wherever possible, all caches that require maintenance to ensure coherency are included in the caches affected by the architecturally-defined cache maintenance operations.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>LRGS</sub>** It is IMPLEMENTATION DEFINED whether the DCIMVAC and DCISW operations, when performed from Non-secure state either:

- Clean any data that might be Secure data before invalidating it.
- Do not invalidate Secure data.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - S.*

**R<sub>VKDF</sub>** ICIALLU, ICIMVAU, DCCMVAU, DCCMVAC, DCCSW, DCCIMVAC, DCCISW, and BPIALL operations on Secure data might be ignored if the operation was performed from Non-secure state.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - S.*

**I<sub>MLLC</sub>** The following is the sequence of cache cleaning operations for a line of self-modifying code:

```

1 ; Enter this code with <Rx> containing the new 32-bit instruction and <Ry>;
2 containing the address of the instruction.
3 ; Use STRH in the first line instead of STR for a 16-bit instruction.
4 STR <Rx>, [<Ry>] ; Write instruction to memory
5 DSB ; Ensure write is visible
6 MOV <Rt>, 0xE000E000 ; Create pointer to base of System Control Space
7 STR <Ry>, [<Rt>,#0xF64] ; Clean data cache by address to point of unification
8 DSB ; Ensure visibility of the data cleaned from the cache
9 STR <Ry>, [<Rt>,#0xF58] ; Invalidate instruction cache by address to PoU
10 STR <Ry>, [<Rt>,#0xF78] ; Invalidate branch predictor
11 DSB ; Ensure completion of the invalidations
12 ISB ; Synchronize fetched instruction stream

```

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>HXMM</sub>** If the Security attribution of memory is changed, it is IMPLEMENTATION DEFINED whether cache maintenance operations are required to keep the system state valid.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - S.*

**R<sub>JFGF</sub>** In the cache maintenance instructions that operate by Set/Way, if any index argument is larger than the value supported by the implementation, then the behavior is CONSTRAINED UNPREDICTABLE and one of the following occurs:

- The instruction generates a BusFault.
- The instruction performs cache maintenance on one of the following:
  - No [cache lines](#).
  - A single arbitrary [cache line](#).
  - Multiple arbitrary [cache lines](#).

*Applies to an implementation of the architecture Armv8.0-M onward. Note, a BusFault requires M.*

[Cache Maintenance Operations](#).

[Cache Maintenance Operations \(NS alias\)](#).

[B7.2.3 Ordering and observability](#).

*B7.10 Cacheability attributes.*

## B7.28 Ordering of cache maintenance operations

**R<sub>GCNB</sub>** All cache and branch predictor maintenance operations that do not specify an address execute, relative to each other, in program order.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>GXNL</sub>** All cache maintenance operations that specify an address:

- Execute in program order relative to all cache operations that do not specify an address.
- Execute in program order relative to all cache maintenance operations that specify the same address.
- Can execute in any order relative to cache maintenance operations that specify a different address.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>RTJG</sub>** There is no restriction on the ordering of data or unified cache maintenance operation by address relative to any explicit load or store.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>MJPP</sub>** There is no restriction on the ordering of a data or unified cache maintenance operation by set/way relative to any explicit load or store.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**I<sub>VXXZ</sub>** A DSB instruction can be inserted to enforce ordering as required.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>SWBG</sub>** For the ICIALLU operation, the value in the register specified by the STR instruction that performs the operation is ignored.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**I<sub>ZQQZ</sub>** In a PE with the Security Extension, if cache maintenance operations are required when the security attribution of memory is changed, the following sequence of steps can be followed:

1. Execute a DSB instruction.
2. Clean the affected lines in data or unified caches using the DCC\* instruction.
3. Execute a DSB instruction.
4. Change the security attribution of the address range.
5. Execute a DSB instruction.
6. Invalidate the affected lines in all caches using the DCI\* and ICI\* instructions.
7. Execute a Context synchronization event.

*Applies to an implementation of the architecture Armv8.0-M onward.*

## Chapter B8

# The System Address Map

This chapter specifies the Armv8-M system address map rules. It contains the following sections:

*B8.1 System address map.*

*B8.2 The System region of the system address map.*

*B8.3 The System Control Space (SCS).*

## B8.1 System address map

R<sub>FQSD</sub>

The address space is divided into the following regions:

| Address                    | Region            | Memory type   | XN? | Cache   | Shareability  | Example usage                                                                                                         |
|----------------------------|-------------------|---------------|-----|---------|---------------|-----------------------------------------------------------------------------------------------------------------------|
| 0x00000000 -<br>0x1FFFFFFF | Code              | Normal        | -   | WT RA   | Non-shareable | Typically ROM or flash memory.                                                                                        |
| 0x20000000 -<br>0x3FFFFFFF | SRAM              | Normal        | -   | WBWA RA | Non-shareable | SRAM region typically used for on-chip RAM.                                                                           |
| 0x40000000 -<br>0x5FFFFFFF | Peripheral        | Device, nGnRE | XN  | -       | -             | On-chip peripheral address space.                                                                                     |
| 0x60000000 -<br>0x7FFFFFFF | RAM               | Normal        | -   | WBWA RA | Non-shareable | Memory with write-back, write allocate cache attribute for L2 and L3 cache support.                                   |
| 0x80000000 -<br>0x9FFFFFFF | RAM               | Normal        | -   | WT RA   | Non-shareable | Memory with Write-Through cache attribute.                                                                            |
| 0xA0000000 -<br>0xBFFFFFFF | Device            | Device, nGnRE | XN  | -       | -             | Peripherals accessible to all Requesters.                                                                             |
| 0xC0000000 -<br>0xDFFFFFFF | Device            | Device, nGnRE | XN  | -       | -             | Peripherals accessible only to the PE.                                                                                |
| 0xE0000000 -<br>0xE00FFFFF | System PPB        | Device, nGnRE | XN  | -       | -             | 1 MB region reserved as the PPB. This supports key resources, including the System Control Space, and debug features. |
| 0xE0100000 -<br>0xFFFFFFFF | System Vendor_SYS | Device, nGnRE | XN  | -       | -             | Vendor System Region.                                                                                                 |

WT - Write-Through.

RA - Read-allocate.

WBWA - Write-back, write-allocate.

XN - Memory with the execute-never memory attribute.

*Applies to an implementation of the architecture Armv8.0-M onward.*

I<sub>XXGQ</sub>

The term boundary is used to indicate the divide between memory regions stated in the system address map.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>MBRB</sub>

An access that crosses a boundary is UNPREDICTABLE. This rule also applies to the 0xFFFFFFFF - 0x00000000 boundary.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>DNBD</sub>

An unaligned or multi-word access that crosses a 0.5GB memory region boundary is UNPREDICTABLE.

*Applies to an implementation of the architecture Armv8.0-M onward.*

See also:

[B8.2 The System region of the system address map.](#)

[B7.4 Address space.](#)

[B7.3 Memory accesses.](#)

[B7.19 Caches.](#)

## B8.2 The System region of the system address map

R<sub>MHGM</sub>

The system region of the system address map is as follows:

Applies to an implementation of the architecture *Armv8.0-M* onward. Note, The *IMPDEF S & NS Address Space* and *IMPDEF NS Address space* are only available in an *Armv8.1-M* implementation.

R<sub>MXRW</sub>

In a PE without the Security Extension, the Non-secure SCS is RAZ/WI and any unprivileged access to the Non-secure SCS results in a BusFault.

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - *M* && *!S*. Note, if *!M* a HardFault is generated.

I<sub>FWLM</sub>

Arm recommends that Vendor\_SYS is divided as follows:

- 0xE0100000-0xFFFFFFFF is reserved.

- Vendor resources start at 0xF0000000.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**I<sub>MSFV</sub>** Arm strongly recommends that the IMPLEMENTATION DEFINED Secure and Non-secure Address space, 0x00000000 - 0xE001E000, and the IMPLEMENTATION DEFINED Non-secure alias Address space, 0xE003E000 - 0xE003FFFF, are implemented symmetrically.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - S. Note, The IMPDEF S & NS Address Space and IMPDEF NS Address space are only available in an Armv8.1-M implementation.*

**R<sub>RTKK</sub>** Any access to the PPB that results in a BusFault will be reported synchronously.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>GLNG</sub>** Privileged accesses to unimplemented registers are RES0.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>NDML</sub>** Unprivileged accesses to unimplemented registers will generate a synchronous BusFault unless otherwise stated.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - M.*

**R<sub>DQQS</sub>** Unprivileged accesses can be enabled to the Software Trigger Interrupt Register, STIR in the System Control Space by programming a control bit in the Configuration and Control Register, CCR.USERSETMPEND.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>NSWG</sub>** If a write to a PPB register triggers a BusFault the PPB register targeted by the write must not be updated. This applies regardless of whether the BusFault is subsequently ignored due to CCR.BFHFNMIGN.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - M.*

**R<sub>RJHJ</sub>** If the exception entry context stacking, exception return context unstacking, lazy floating-point state preservation, or the stacking or unstacking of a FNC\_RETURN stack frame, results in an access to an address within the PPB space the behavior of the access is CONSTRAINED UNPREDICTABLE and is one of the following:

- Generates a BusFault.
- Perform the specified access to the PPB space.

This does not apply to the VLSTM instruction.

*Applies to an implementation of the architecture Armv8.0-M onward.*

## Chapter B9

# Synchronization and Semaphores

This chapter specifies the Armv8-M architecture rules for exclusive access instructions and non-blocking synchronization of shared memory. It contains the following sections:

*B9.1 Exclusive access instructions.*

*B9.2 The local monitors.*

*B9.3 The global monitor.*

*B9.4 Exclusive access instructions and the monitors.*

*B9.5 Load-Exclusive and Store-Exclusive instruction constraints.*

## B9.1 Exclusive access instructions

$R_{LQDX}$  Armv8 provides non-blocking synchronization of shared memory, using synchronization primitives for accesses to both Normal and Device memory.

*Applies to an implementation of the architecture Armv8.0-M onward.*

$R_{RGCP}$  The synchronization primitives and associated instructions are as follows:

| Function        | T32 instruction                |
|-----------------|--------------------------------|
| Load-Exclusive  |                                |
| Byte            | <a href="#">LDREXB, LDAEXB</a> |
| Halfword        | <a href="#">LDREXH, LDAEXH</a> |
| Word            | <a href="#">LDREX, LDAEX</a>   |
| Store-Exclusive |                                |
| Byte            | <a href="#">STREXB, STLEXB</a> |
| Halfword        | <a href="#">STREXH, STLEXH</a> |
| Word            | <a href="#">STREX, STLEX</a>   |
| Clear-Exclusive |                                |
|                 | <a href="#">CLREX</a>          |

*Applies to an implementation of the architecture Armv8.0-M onward.*

$R_{MWFP}$  A Load-Exclusive instruction performs a load from memory, and:

- The executing PE marks the memory address for exclusive access.
- The local monitor of the executing PE transitions to the Exclusive Access state.

*Applies to an implementation of the architecture Armv8.0-M onward.*

$R_{JHMH}$  The size of the marked memory block is called the *Exclusives reservation granule* (ERG), and is an IMPLEMENTATION DEFINED value that is of a power of 2 size, in the range 4 - 512 words.

*Applies to an implementation of the architecture Armv8.0-M onward.*

$R_{MTTN}$  A marked block of the ERG is created by ignoring the least significant bits of the memory address. A marked address is any address within this marked block.

*Applies to an implementation of the architecture Armv8.0-M onward.*

$R_{FMXK}$  In some implementations the [CTR](#) identifies the Exclusives reservation granule. Where this is not the case, the Exclusives reservation granule is treated as having the maximum of 512 words.

*Applies to an implementation of the architecture Armv8.0-M onward.*

See also:

[B9.2 The local monitors.](#)

[B9.3 The global monitor.](#)

[B9.4 Exclusive access instructions and the monitors.](#)

[B9.5 Load-Exclusive and Store-Exclusive instruction constraints.](#)

## B9.2 The local monitors

**R<sub>QTFP</sub>** Any non-aborted attempt by the same PE to use a Store-Exclusive instruction to modify any address is guaranteed to clear the marking.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>NJWC</sub>** When a PE writes using any instruction other than a Store-Exclusive instruction:

- If the write is to a physical address that is not marked as Exclusive Access by its local monitor and that local monitor is in the Exclusive Access state, it is IMPLEMENTATION DEFINED whether the write affects the state of the local monitor.
- If the write is to a physical address that is marked as Exclusive Access by its local monitor, it is IMPLEMENTATION DEFINED whether the write affects the state of the local monitor.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>PFFT</sub>** It is IMPLEMENTATION DEFINED whether a store to a marked physical address causes a mark in the local monitor to be cleared if that store is by an observer other than the one that caused the physical address to be marked.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>KXNM</sub>** The state machine for the local monitor is shown here.

Operations marked \* are possible alternative IMPLEMENTATION DEFINED options.

In the diagram: `LoadExc1` represents any Load-Exclusive instruction

`StoreExc1` represents any Store-Exclusive instruction

`Store` represents any other store instruction.

Any `LoadExc1` operation updates the marked address to the most significant bits of the address `x` used for the operation.

The local monitor only transitions to the Exclusive Access state as the result of the architectural execution of one of the operations shown in the diagram.

Any transition of the local monitor to the Open Access state that is not caused by the architectural execution of an operation shown here does not indefinitely delay forward progress of execution.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>WTHJ</sub>** The local monitor does not hold any physical address, but instead treats any access as matching the address of the previous Load-Exclusive instruction.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>JWQS</sub>** A local monitor implementation can be unaware of Load-Exclusive and Store-Exclusive instructions from other PEs.

*Applies to an implementation of the architecture Armv8.0-M onward.*

|                   |                                                                                                                                                                                                                                                                               |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| R <sub>KJQW</sub> | <p>The architecture does not require a load instruction by another PE that is not a Load-Exclusive instruction to have any effect on the local monitor.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward.</i></p>                                  |
| R <sub>XMML</sub> | <p>It is IMPLEMENTATION DEFINED whether the transition from Exclusive Access to Open Access state occurs when the <code>Store</code> or <code>StoreExcl</code> is from another observer.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward.</i></p> |
| R <sub>MRS</sub>  | <p>The architecture permits a local monitor to transition to the Open Access state as a result of speculation, or from some other cause.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward.</i></p>                                                 |
| R <sub>HRHC</sub> | <p>An exception return clears the local monitor.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward.</i></p>                                                                                                                                         |

## B9.3 The global monitor

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| R <sub>FKFB</sub> | <p>For each PE in the system, the global monitor:</p> <ul style="list-style-type: none"><li>• Can hold at least one marked block.</li><li>• Maintains a state machine for each marked block it can hold.</li></ul> <p><i>Applies to an implementation of the architecture Armv8.0-M onward.</i></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| R <sub>VDLP</sub> | <p>For each PE, the architecture only requires global monitor support for a single marked address. Any situation that might benefit from the use of multiple marked addresses on a single PE is CONSTRAINED UNPREDICTABLE.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward.</i></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| R <sub>NNDC</sub> | <p>The global monitor can either reside in a block that is part of the hardware on which the PE executes or exist as a secondary monitor at the memory interfaces.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward.</i></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| I <sub>XTLH</sub> | <p>The IMPLEMENTATION DEFINED aspects of the monitors mean that the global monitor and the local monitor can be combined into a single unit, provided that the unit performs the global monitor and the local monitor functions defined in this manual.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward.</i></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| I <sub>KDWM</sub> | <p>For shareable memory locations, in some implementations and for some memory types, the properties of the global monitor require functionality outside the PE. Some system implementations might not implement this functionality for all locations of memory. In particular, this can apply to:</p> <ul style="list-style-type: none"><li>• Any type of memory in the system implementation that does not support hardware cache coherency.</li><li>• Non-cacheable memory, or memory treated as Non-cacheable, in an implementation that does support hardware cache coherency.</li></ul> <p>In such a system, it is defined by the system:</p> <ul style="list-style-type: none"><li>• Whether the global monitor is implemented.</li><li>• If the global monitor is implemented, which address ranges or memory types it monitors.</li></ul> <p><i>Applies to an implementation of the architecture Armv8.0-M onward.</i></p> |
| I <sub>QJNL</sub> | <p>The only memory types for which it is architecturally guaranteed that a global exclusive monitor is implemented are:</p> <ul style="list-style-type: none"><li>• Inner Shareable, Inner Write-Back, Outer Write-Back Normal memory with Read allocation hint and Write allocation hint and not transient.</li><li>• Outer Shareable, Inner Write-Back, Outer Write-Back Normal memory with Read allocation hint and Write allocation hints and not transient.</li></ul> <p><i>Applies to an implementation of the architecture Armv8.0-M onward.</i></p>                                                                                                                                                                                                                                                                                                                                                                         |
| R <sub>HBJJ</sub> | <p>The set of memory types that support atomic instructions includes all of the memory types for which a global monitor is implemented.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward.</i></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| R <sub>HLHS</sub> | <p>If the global monitor is not implemented for an address range or memory type, then performing a Load-Exclusive/Store-Exclusive instruction to such a location, in the absence of any other fault, has one or more of the following effects:</p> <ul style="list-style-type: none"><li>• The instruction generates BusFault.</li><li>• The instruction generates a DACCVIOL MemManage fault.</li><li>• The instruction is treated as a NOP.</li><li>• The Load-Exclusive instruction is treated as if it were accessing a Non-shareable location, but the state of the local monitor becomes UNKNOWN.</li></ul>                                                                                                                                                                                                                                                                                                                   |

- The Store-Exclusive instruction is treated as if it were accessing a Non-shareable location, but the state of the local monitor becomes UNKNOWN.
- The value held in the result register of the Store-Exclusive instruction becomes UNKNOWN.

*Applies to an implementation of the architecture Armv8.0-M onward. Note, a MemManage Fault requires M && MPU, a BusFault requires M.*

R<sub>FQRT</sub>

For write transactions generated by non-PE observers that do not implement exclusive accesses or other atomic access mechanisms, the effect that writes have on the global monitor and the local monitor that are used by an Arm PE is IMPLEMENTATION DEFINED. The writes might not clear the global monitors of other PEs for:

- Some address ranges.
- Some memory types.

*Applies to an implementation of the architecture Armv8.0-M onward.*

### B9.3.1 Load-Exclusive and Store-Exclusive

R<sub>RXVB</sub>

The global monitor only supports a single outstanding exclusive access to shareable memory for each PE.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>GXLf</sub>

The architecture does not require a load instruction by another PE, that is not a Load-Exclusive instruction, to have any effect on the global monitor.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>MPKM</sub>

A Load-Exclusive instruction by one PE has no effect on the global monitor state for any other PE.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>MFGC</sub>

A Store-Exclusive instruction performs a conditional store to memory:

- The store is guaranteed to succeed only if the physical address accessed is marked as exclusive access for the requesting PE and both the local monitor and the global monitor state machines for the requesting PE are in the Exclusive Access state. In this case:
  - A status value of 0 is returned to a register to acknowledge the successful store.
  - The final state of the global monitor state machine for the requesting PE is IMPLEMENTATION DEFINED.
  - If the address accessed is marked for exclusive access in the global monitor state machine for any other PE then that state machine transitions to Open Access state.
- If no address is marked as exclusive access for the requesting PE, the store does not succeed:
  - A status value of 1 is returned to a register to indicate that the store failed.
  - The global monitor is not affected and remains in Open Access state for the requesting PE.
- If a different physical address is marked as exclusive access for the requesting PE, it is IMPLEMENTATION DEFINED whether the store succeeds or not:
  - If the store succeeds a status value of 0 is returned to a register, otherwise a value of 1 is returned.
  - If the global monitor state machine for the PE was in the Exclusive Access state before the Store-Exclusive instruction it is IMPLEMENTATION DEFINED whether that state machine transitions to the Open Access state.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>NNMG</sub>

In a shared memory system, the global monitor implements a separate state machine for each PE in the system. The state machine for accesses to shareable memory by PE(n) can respond to all the shareable memory accesses visible to it.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>WKPJ</sub>** In a shared memory system, the global monitor implements a separate state machine for each observer that can generate a Load-Exclusive or a Store-Exclusive instruction in the system.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>NWWH</sub>** Whenever the global monitor state for a PE changes from Exclusive access to Open access, an event is generated and held in the Event register for that PE. This register is used by the Wait for Event mechanism.

*Applies to an implementation of the architecture Armv8.0-M onward.*

### B9.3.2 Load-Exclusive and Store-Exclusive in Shareable memory

**R<sub>HKQT</sub>** A Load-Exclusive instruction from shareable memory performs a load from memory, and causes the physical address of the access to be marked as exclusive access for the requesting PE. This access can also cause the exclusive access mark to be removed from any other physical address that has been marked by the requesting PE.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>GDMD</sub>** The state machine for PE(n) in a global monitor is as follows.

Any LoadExc1 operation updates the marked address to the most significant bits of the address x used for the operation.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>RGFK</sub>** Whether a Store-Exclusive instruction successfully updates memory or not depends on whether the address accessed matches the marked shareable memory address for the PE issuing the Store-Exclusive instruction, and whether the local monitor and the global monitor are in the exclusive state.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>QVWF</sub>** When the global monitor is in the Exclusive Access state, it is IMPLEMENTATION DEFINED whether a CLREX instruction causes the global monitor to transition from Exclusive Access to Open Access state.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>DLMP</sub>** A Load-Exclusive instruction can only update the marked shareable memory address for the PE issuing the Load-Exclusive instruction.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>BSGB</sub>

It is IMPLEMENTATION DEFINED:

- Whether a modification to a Non-shareable memory location can cause a global monitor to transition from Exclusive Access to Open Access state.
- Whether a Load-Exclusive instruction to a Non-shareable memory location can cause a global monitor to transition from Open Access to Exclusive Access state.

*Applies to an implementation of the architecture Armv8.0-M onward.*

## B9.4 Exclusive access instructions and the monitors

$R_{VXWN}$  The Store-Exclusive instruction defines the register to which the status value of the monitors is returned.

*Applies to an implementation of the architecture Armv8.0-M onward.*

$R_{DTRN}$  A Store-Exclusive instruction performs a conditional store to memory that depends on the state of the local monitor:

- **If the local monitor is in the Exclusive Access state:**
  - If the address of the Store-Exclusive instruction is the same as the address that has been marked in the monitor by an earlier Load-Exclusive instruction, then the store occurs. Otherwise, it is IMPLEMENTATION DEFINED whether the store occurs.
  - A status value is returned to a register:
    - \* If the store took place the status value is 0.
    - \* Otherwise, the status value is 1.
  - The local monitor of the executing PE transitions to the Open Access state.
- **If the local monitor is in the Open Access state:**
  - No store takes place.
  - A status value of 1 is returned to a register.
  - The local monitor remains in the Open Access state.

*Applies to an implementation of the architecture Armv8.0-M onward.*

$R_{DFNB}$  A Store-Exclusive instruction performs a store to Shareable memory that depends on the state of both the local monitor and the global monitor:

- **If both the local monitor and the global monitor are in the Exclusive Access state:**
  - If the address of the Store-Exclusive instruction is the same as the address that has been marked in the monitor by an earlier Load-Exclusive instruction, then the store occurs. Otherwise, it is IMPLEMENTATION DEFINED whether the store occurs.
  - A status value is returned to a register:
    - \* If the store took place the status value is 0.
    - \* Otherwise, the status value is 1.
  - The local monitor of the executing PE transitions to the Open Access state.
- **If either the local monitor or the global monitor is in the Open Access state:**
  - No store takes place.
  - A status value of 1 is returned to a register.
  - The local monitor of the executing PE transitions to the Open Access state.
  - The global monitor that is associated with the executing PE transitions to the Open Access state.

*Applies to an implementation of the architecture Armv8.0-M onward.*

For address-based maintenance instructions, this also applies to the monitors of other PEs in the same Shareability domain as the PE executing the cache maintenance instruction, as determined by the Shareability domain of the address being maintained.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward.</i></p> |
| I <sub>MDHL</sub> | <p>Arm strongly recommends that implementations ensure that the use of such maintenance instructions by a PE in the Non-secure state cannot cause a denial of service on a PE in the Secure state.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward.</i></p>                                                                                                                                                                                                                                                                                                                                                                                          |
| R <sub>RRTJ</sub> | <p>In the event of repeatedly-contending LoadExcl/StoreExcl instruction sequences from multiple PEs, an implementation ensures that forward progress is made by at least one PE.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward.</i></p>                                                                                                                                                                                                                                                                                                                                                                                                            |

## Chapter B10

# The Armv8-M Protected Memory System Architecture

This chapter specifies the Armv8-M *Protected Memory System Architecture* (PMSAv-8) rules, and in particular the rules for the optional *Memory Protection Unit* (MPU) and the optional *Security Attribution Unit* (SAU). It contains the following sections:

[B10.1 \*Memory Protection Unit\*.](#)

[B10.2 \*Security attribution\*.](#)

[B10.3 \*Security attribution unit \(SAU\)\*.](#)

[B10.4 \*IMPLEMENTATION DEFINED Attribution Unit \(IDAU\)\*.](#)

## B10.1 Memory Protection Unit

|                   |                                                                                                                                                                                                                                                                                                                                                      |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| R <sub>HPNK</sub> | <p>In an implementation that includes the Protected Memory System Architecture (PMSA), system address space is protected by a Memory Protection Unit (MPU).</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">MPU</a>.</i></p>                                               |
| R <sub>TBPJ</sub> | <p>PMSAv8-M only supports a unified memory model. All enabled regions support instruction and data accesses.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">MPU</a>.</i></p>                                                                                              |
| R <sub>HBNG</sub> | <p>Memory attributes are determined from the default system address map or by using an MPU.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">MPU</a>.</i></p>                                                                                                               |
| R <sub>BXCN</sub> | <p>MPU support in Armv8-M is optional.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">MPU</a>.</i></p>                                                                                                                                                                    |
| R <sub>MCCL</sub> | <p>The system address map can be configured to provide a background region for privileged accesses.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">MPU</a>.</i></p>                                                                                                       |
| R <sub>JVJC</sub> | <p>When the MPU is disabled or not present, accesses use memory attributes from the default system address map.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">!MPU</a>.</i></p>                                                                                          |
| R <sub>KLHL</sub> | <p>If the MPU is enabled, attributes for memory accesses that hit in a single region are provided by the hit region.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">MPU</a>.</i></p>                                                                                      |
| R <sub>DBBM</sub> | <p>The MPU divides the memory into regions.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">MPU</a>.</i></p>                                                                                                                                                               |
| R <sub>JVCN</sub> | <p>An individual MPU region is defined by:</p> <p>Address &gt;= MPU_RBAR.BASE:'00000' &amp;&amp; Address &lt;= MPU_RLAR.LIMIT:'11111'</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">MPU</a>.</i></p>                                                                     |
| R <sub>MNDS</sub> | <p>The number of supported MPU regions is IMPLEMENTATION DEFINED.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">MPU</a>.</i></p>                                                                                                                                         |
| I <sub>WTCL</sub> | <p>Because the <a href="#">MPU_TYPE</a> register is banked, an implementation can have a different number of MPU regions, including no MPU regions, for each Security state.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">S</a> &amp;&amp; <a href="#">MPU</a>.</i></p> |
| R <sub>XGFK</sub> | <p>All MPU regions are aligned to a multiple of 32 bytes.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">MPU</a>.</i></p>                                                                                                                                                 |
| R <sub>BPGB</sub> | <p>The PE can fetch and execute instructions from each MPU region according to the value of <a href="#">MPU_RBAR.XN</a>.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">MPU</a>.</i></p>                                                                                  |
| R <sub>ZLHD</sub> | <p>Unless otherwise stated, all load, store, and instruction fetch transactions are subject to an MPU check.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">MPU</a>.</i></p>                                                                                              |
| R <sub>DNXT</sub> | <p>If <a href="#">MPU_CTRL.ENABLE</a> is zero, MPU checks are carried out against the default system address map and not against any defined MPU regions.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">MPU</a>.</i></p>                                                 |

Chapter B10. The Armv8-M Protected Memory System Architecture  
B10.1. Memory Protection Unit

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| I <sub>HSCD</sub> | <p>The MPU check is one of a number of checks carried out on any load, store or instruction fetch transaction including alignment, security attribution checks, and a check for any BusFaults.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - MPU.</i></p>                                                                                                                                                                                                                                                                                                                                                                                                                      |
| R <sub>VHHL</sub> | <p>Exception vector reads from the Vector Address Table always use the default system address map and are not subject to an MPU check.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - MPU.</i></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| R <sub>VWXJ</sub> | <p>If MPU_CTRL.HFNMIENA is set to 0, any load, store or instruction fetch transaction where the requested execution priority is negative will use the Default Address Map for MPU checks.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - MPU.</i></p>                                                                                                                                                                                                                                                                                                                                                                                                                           |
| R <sub>VPJQ</sub> | <p>For the purposes of MPU checks, any change in the current execution priority resulting from a MSR or CPS requires a Context synchronization event to guarantee visibility.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - MPU.</i></p>                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| R <sub>TGQD</sub> | <p>Any load, store or instruction fetch transactions to the PPB, within the range 0xE0000000-0xE00FFFFFF, are not subject to an MPU check but are checked against the default system address map. Instruction fetches to this region generate an IACCVIOL MemManage fault.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. Note, MPU required for MPU checks.</i></p>                                                                                                                                                                                                                                                                                                                                             |
| R <sub>LLLL</sub> | <p>Any MPU region lookup performed for a load, store or instruction fetch transaction will generate a precise MemManage Fault if any of the following is true:</p> <ul style="list-style-type: none"> <li>• The address accessed by the load, store or instruction fetch transaction matches more than one MPU region.</li> <li>• The load, store or instruction fetch transaction does not match all of the access conditions for the MPU region being accessed.</li> <li>• The load, store or instruction fetch transaction only matches the system address map and the system address map is not enabled.</li> </ul> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - MPU.</i></p> |
| R <sub>KDJG</sub> | <p>The MPU is restricted in how it can change the system address map attributes associated with System space, that is, for addresses in the region 0xE0100000-0xFFFFFFFF. Unless otherwise stated, system space is always XN (Execute-never) and it is always Device-nGnR. If the MPU maps this to a type other than Device-nGnRnE, it is UNKNOWN whether the region is treated as Device-nGnRE or as Device-nGnRnE.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - MPU.</i></p>                                                                                                                                                                                                |
| R <sub>KMTF</sub> | <p>Unless otherwise stated for data accesses, the MPU memory attribution and privilege checking uses the configuration registers that correspond to the current Security state of the PE.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. | R <sub>LDTN</sub> | <p>The behavior of the following address ranges is fixed, so they are exempt from memory attribution by both the SAU and IDAU:</p>                                                                                                                                                                                                                                                                                                                       |

### Ranges exempt from checking security violation

The following address ranges are marked with the Security state indicated by NS-Req, that is, the current state of the PE for non-debug accesses. This marking sets the NS-Attr to NS-Req:

0xE0000000 - 0xE0003FFF: ITM, DWT, FPB, PMU.

0xE0005000 - 0xE0005FFF: RAS error record registers.

0xE000E000 - 0xE000EFFF: SCS Secure and Non-secure range.

0xE002E000 - 0xE002EFFF: SCS Non-secure alias range.

0xE0040000 - 0xE0041FFF: TPIU, ETM.

0xE00FF000 - 0xE00FFFFFFF: ROM table.

0xE0000000 - 0xFFFFFFFF: for instruction fetch only.

Additional address ranges specified by the IDAU.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - S. Note, some address ranges require DB. RAS and PMU are only available in an Armv8.1-M implementation.*

$R_{FGDW}$  The behavior of the following address range is fixed:

**0xF0000000 – 0xFFFFFFFF**

If the PE implements the Security Extension, this memory range is always marked as Secure and not Non-secure callable for instruction fetches.

If the Security Extension is not present, this range is marked as Non-secure.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - S.*

$R_{HFMG}$  Speculative fetches are not permitted to a Security attribution exempt address if either of the following hold true:

- The Secure MPU region check reports the address as execute-never.
- The Non-secure MPU region check reports the address as execute-never.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - S && MPU.*

$I_{VPWL}$  The Security attribution and MPU check sequence, for all data accesses which are not instruction fetches and accesses for instruction fetches are shown in the following diagrams.

If the memory transaction is lazy state preservation then NS-req is determined by [FPCCR.S](#). If the memory transaction is an exception vector fetch access NS-Req is set to the Security state of the exception. Unless otherwise specified, in all other cases it is the current Security state.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [S](#).*

R\_FTR

If the memory access is caused by the execution of an [SG](#) instruction the load from the stack is undertaken with the NS-Req set to Secure even though the [SG](#) instruction was executed from the Non-secure state.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [S](#).*

[B10.4 IMPLEMENTATION DEFINED Attribution Unit \(IDAU\).](#)

## B10.3 Security attribution unit (SAU)

**R<sub>VFLR</sub>** The SAU configuration defines an IMPLEMENTATION DEFINED number of memory regions. The number of regions is indicated by [SAU\\_TYPE.SREGION](#).

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - S.*

**I<sub>PPLK</sub>** The memory regions defined by the SAU configuration are referred to as SAU\_REGIONn, where n is a number from 0 - ([SAU\\_TYPE.SREGION](#)-1).

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - S.*

**R<sub>RVFP</sub>** The SAU region configuration fields can only be accessed indirectly using the window registers, [SAU\\_RNR](#) shown in the following table.

| SAU region configuration field | Associated window register field |
|--------------------------------|----------------------------------|
| SAU_REGIONn.ENABLE             | <a href="#">SAU_RLAR.ENABLE</a>  |
| SAU_REGIONn.NSC                | <a href="#">SAU_RLAR.NSC</a>     |
| SAU_REGIONn.BADDR              | <a href="#">SAU_RBAR.BADDR</a>   |
| SAU_REGIONn.LADDR              | <a href="#">SAU_RLAR.LADDR</a>   |

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - S.*

**R<sub>KRSC</sub>** When the SAU is enabled, an address is defined as matching a region in the SAU if the following is true:  
Address >= SAU\_REGIONn.BADDR: '00000' && Address <= SAU\_REGIONn.LADDR: '11111'

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - S.*

**R<sub>MPJC</sub>** Memory is marked as Secure by default. However, if the address matches a region with SAU\_REGIONn.ENABLE set to 1 and SAU\_REGIONn.NSC set to 0, then memory is marked as Non-secure.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - S.*

**R<sub>WGDK</sub>** An address that matches multiple SAU regions is marked as Secure and not Not-secure callable regardless of the attributes specified by the regions that matched the address.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - S.*

**R<sub>GVFQ</sub>** When the SAU is not enabled:

- Addresses are not checked against the SAU regions.
- The attribution of the address space is determined by the [SAU\\_CTRL.ALLNS](#) field.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - S.*

**R<sub>MBJN</sub>** To permit lockdown of the SAU configuration, it is IMPLEMENTATION DEFINED whether [SAU\\_RLAR](#), [SAU\\_RBAR](#), [SAU\\_CTRL](#), and [SAU\\_RNR](#) are writable.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - S.*

**R<sub>BBCT</sub>** Setting the [SAU\\_RNR.REGION](#) field to a value that does not correspond to an implemented memory region is CONSTRAINED UNPREDICTABLE as follows:

- Any subsequent read of [SAU\\_RNR.REGION](#) returns an UNKNOWN value.
- Any read of a register that is in an unimplemented region returns an UNKNOWN value.
- Any write to a register indirected by [SAU\\_RNR.REGION](#) causes all state that is indirected by that register to become UNKNOWN.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - S.*

## B10.4 IMPLEMENTATION DEFINED Attribution Unit (IDAU)

R<sub>MVCM</sub>

The IDAU can provide the following Security attribution information for an address:

- Security attribution exempt. This specifies that the address is exempt from security attribution. This information is combined with the address ranges that are architecturally required to be exempt from attribution.
- Non-secure. This specifies if the address is Secure or Non-secure.
- Non-secure callable. This specifies if code at the address can be called from Non-secure state. This attribute is only valid if the address is marked as Secure.
- Region number. This is the region number that matches the address, and is only used by the [TT](#) instruction.
- Region number valid. This specifies that the region number is valid. This field has no effect on the attribution of the address, and is only used by the [TT](#) instruction.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [S](#).*

[TT](#), [TTT](#), [TTA](#), [TTAT](#).

[B10.2 Security attribution](#).

## Chapter B11

# The System Timer, SysTick

This chapter specifies the Armv8-M system timer rules. It contains the following section:

[B11.1 \*The system timer, SysTick.\*](#)

## B11.1 The system timer, SysTick

R<sub>BQRG</sub>

In a PE without the Main Extension and without the Security Extensions, either:

- No system timers are implemented.
- One system timer, SysTick, is implemented.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - !M && !S.*

R<sub>PDDL</sub>

In a PE without the Main Extension but with the Security Extension, one of the following is true:

- No system timers are implemented.
- One system timer, SysTick, is implemented. ICSR.STTNS determines which Security state owns the SysTick.
- Two system timers are implemented:
  - SysTick, Secure instance.
  - SysTick, Non-secure instance.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - !M && S.*

R<sub>CNTG</sub>

In a PE with the Main Extension but without the Security Extension, one system timer, SysTick, is implemented.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - M && ST && !S.*

R<sub>XPCW</sub>

In a PE with the Main and Security Extensions, two system timers are implemented:

- SysTick, Secure instance.
- SysTick, Non-secure instance.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - M && S && ST.*

I<sub>DXSQ</sub>

There are the following SysTick registers:

- SysTick Control and Status Register (SYST\_CSR).
- SysTick Reload Value Register (SYST\_RVR).
- SysTick Current Value Register (SYST\_CVR).
- SysTick Calibration Value Register (SYST\_CALIB).

In a PE with the Security Extension and a SysTick instance dedicated to each Security state, these registers are banked.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - ST.*

I<sub>VHDT</sub>

Each implemented SysTick is a 24-bit decrementing, wrap-on-zero, clear-on-write counter:

- When enabled, the counter counts down from the value in SYST\_CVR. When it reaches zero, SYST\_CVR is reloaded with the value held in SYST\_RVR on the next clock edge.
- Reading SYST\_CVR returns the value of the counter at the time of the read access.
- When the counter reaches zero, it sets SYST\_CSR.COUNTFLAG to 1. Reading SYST\_CSR.COUNTFLAG clears it to 0.
- A write to SYST\_CVR clears both SYST\_CVR and SYST\_CSR.COUNTFLAG to 0. SYST\_CVR is then reloaded with the value held in SYST\_RVR on the next clock edge.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - ST.*

R<sub>TLGK</sub>

Writing the value zero to SYST\_RVR disables the SysTick on the next wrap-on-zero. The value zero is held by the counter after the wrap. This is true even when SYST\_CSR.ENABLE is 1.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - ST.*

R<sub>TTFT</sub>

A write to SYST\_CVR does not cause a SysTick exception.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - ST.*

| I <sub>RWFQ</sub> | <p>Each implemented SysTick is clocked by a reference clock, either the PE clock or an external system clock. It is IMPLEMENTATION DEFINED which clock is used as the external reference clock. Arm recommends that if an external system clock is used, the relationship between the PE clock and the external clock is documented, so that system timings can be calculated taking into account metastability, clock skew, and jitter.</p> <p><i>Applies to an implementation of the architecture <b>Armv8.0-M</b> onward. The extension requirements are - <a href="#">ST</a>.</i></p> |

## Chapter B12

# Nested Vectored Interrupt Controller

This chapter specifies the Armv8-M *Nested Vectored Interrupt Controller* (NVIC) rules. It contains the following sections:

[B12.1 \*NVIC definition.\*](#)

[B12.2 \*NVIC operation.\*](#)

## B12.1 NVIC definition

R<sub>XJJQ</sub> An Armv8-M PE includes an integral interrupt controller.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>WQHG</sub> The Interrupt Controller Type Register ([ICTR](#)) defines the number of external interrupt lines that are supported.

*Applies to an implementation of the architecture Armv8.0-M onward.*

See also:

[ICTR, Interrupt Controller Type Register.](#)

## B12.2 NVIC operation

## Chapter B13

### Debug

This chapter specifies the Armv8-M debug rules. It contains the following sections:

[B13.1 \*Debug feature overview.\*](#)

[B13.2 \*Accessing debug features.\*](#)

[B13.3 \*Debug authentication interface.\*](#)

[B13.4 \*Debug event behavior.\*](#)

[B13.5 \*Debug state.\*](#)

[B13.6 \*Exiting Debug state.\*](#)

[B13.7 \*Multiprocessor support.\*](#)

## B13.1 Debug feature overview

R<sub>WXRJ</sub> The debug configuration of an implementation is IMPLEMENTATION DEFINED.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>VTGP</sub> The following table describes the features of the Armv8-M debug architecture.

| Feature                                      | Main Extension                       | Baseline Implementation       |
|----------------------------------------------|--------------------------------------|-------------------------------|
| <b>DebugMonitor exception</b>                | Always implemented                   | Never implemented             |
| <b>Halting debug</b>                         | Optional                             | Optional                      |
| <b>EDBGRQ</b><br><i>External Halt signal</i> | Optional, requires Halting debug     | Requires Halting debug        |
| <b>Flash Patch and Breakpoint unit - FPB</b> | Optional, requires Halting debug     | Requires Halting debug        |
| <b>Data Watchpoint and Trace Unit - DWT</b>  |                                      |                               |
| <i>Debug functionality - DWT-D</i>           | Optional, requires Halting debug     | Requires Halting debug        |
| <i>Trace functionality - DWT-T</i>           | Requires ITM and Debug functionality | Never implemented             |
| <b>Instrumentation Trace Macrocell - ITM</b> | Optional, requires Halting debug     | Never implemented             |
| <b>Cross Trigger Interface - CTI</b>         | Requires ETM or Halting Debug        | Requires ETM or Halting Debug |
| <b>Trace Port Interface Unit - TPIU</b>      | Requires ITM or ETM                  | Requires ETM                  |
| <b>Embedded Trace Macrocell - ETM</b>        | Optional, requires Halting debug     | Optional                      |
| <b>Performance Monitors Unit - PMU</b>       | Optional, requires Halting debug     | Never implemented             |
| <b>Unprivileged Debug Extension - UDE</b>    | Optional, requires Halting debug     | Never implemented             |
| <b>DSP Debug Extension - DSPDE</b>           | Optional, requires Halting debug     | Never implemented             |

*Applies to an implementation of the architecture Armv8.0-M onward. Note, CTI requires Halting debug or ETM. PMU & UDE are only available in an Armv8.1-M implementation.*

R<sub>FHRN</sub> The following optional debug components are not part of the Armv8-M architecture:

- The *Cross-Trigger Interface (CTI)*.
- The CoreSight basic trace router (MTB).
- The Embedded Trace Macrocell (ETM).

*Applies to an implementation of the architecture Armv8.0-M onward. Note, CTI requires Halting debug or ETM.*

I<sub>ZNHD</sub> The recommended Debug implementation levels are:

- Minimum.
- Basic.
- Comprehensive.
- Program trace.

### Minimum

In an implementation that includes the Main Extension, the minimum level contains support for the DebugMonitor exception, including:

- The [BKPT](#) instruction.
- [DEMCR](#) Monitor debug features.
- Monitor entry from External debug requests.

- [DFSR](#).

[DHCSR](#), [DCRSR](#), [DCRDR](#), and the Halting debug features in [DFSR](#) and [DEMCR](#) are RES0.

[ID\\_DFR0](#) is RAZ.

In an implementation that does not include the Main Extension there is no debug support.

[DFSR](#), [DHCSR](#), [DCRSR](#), [DCRDR](#), and [DEMCR](#) are RES0.

[ID\\_DFR0](#) is RAZ.

### Basic

In an implementation that includes the Main Extension, the basic level adds support for Halting debug with:

- A Debug Access Port and ROM table.
- [DHCSR](#), [DCRSR](#), [DCRDR](#), and the Halting debug features in [DEMCR](#) are implemented.
- FPB with at least two breakpoints.
- DWT with at least:
  - One watchpoint that supports instruction, data address, and data value matching.
  - [DWT\\_PCSR](#).
- Optional support for a CTI in a multiprocessor system.

Support for the basic implementation is identified by [ID\\_DFR0](#).

In an implementation that includes Armv8.1-M, the DSP Debug Extension adds support for DSPDE. Support for the DSP Debug Extension is part of the basic level of debug.

In an implementation that does not include Armv8.1-M, there is no support for the DSP Debug Extension.

In an implementation that does not include the Main Extension, the basic level adds support for Halting debug with:

- A Debug Access Port and ROM table.
- [SHCSR](#), [DFSR](#), [DHCSR](#), [DCRSR](#), [DCRDR](#), and [DEMCR](#) are implemented. Access for the PE is IMPLEMENTATION DEFINED.
- FPB with at least two breakpoints.
- DWT with at least:
  - One watchpoint that supports instruction, data address, and data value matching.
  - [DWT\\_PCSR](#).
- Optional support for a CTI in a multiprocessor system.

Support for the basic implementation is identified by [ID\\_DFR0](#). In an Armv8.0 implementation [ID\\_DFR0](#) is RAZ, unless Halting debug is implemented.

### Comprehensive

In an implementation that includes the Main Extension, the comprehensive level adds basic trace support with:

- An ITM.
- DWT with:

- Trace support.
- Profiling support.
- Cycle counter.
- TPIU.

In an implementation that does not include the Main Extension, there is no support for the comprehensive level.

### **Program trace**

In an implementation that includes the Main Extension, Program trace adds support for ETMs.

In an implementation that does not include the Main Extension, Program trace adds supports for ETMs and TPIUs.

An Armv8.1-M implementation introduces further optional debug extensions:

### **Performance Monitoring**

In an implementation that includes Armv8.1-M, Performance Monitoring adds support for PMU. Support for the Performance Monitors extension is part of the comprehensive level of debug.

In an implementation that does not include Armv8.1-M, there is no support for Performance Monitoring.

### **Unprivileged Debug Extension**

In an implementation that does not include Armv8.1-M, there is no support for the Unprivileged Debug Extension. Support for the Unprivileged Debug Extension is part of the basic level of debug.

*Applies to an implementation of the architecture **Armv8.0-M** onward. The extension requirements are - **DB**. Note, UDE && PMU are only available in an 8.1-M implementation.*

## B13.1.1 Debug mechanisms

**R<sub>HWCH</sub>** Armv8-M supports a range of invasive and non-invasive debug mechanisms. The *invasive debug mechanisms* are:

- The ability to halt the PE. This provides a run-stop debug model.
- Debugging code using the DebugMonitor exception. This provides less intrusive debug than halting the PE.

The *non-invasive debug techniques* are:

- Generating application trace by writing to the *Instrumentation Trace Macrocell* (ITM), causing a low level of intrusion.
- Non-intrusive program trace and profiling.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **DB**. Note, M is required for the DebugMonitor exception and ITM.*

**I<sub>LBLF</sub>** When the PE is halted, it is in *Debug state*.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **Halting debug**.*

**I<sub>SXVR</sub>** When the PE is not halted, it is in *Non-debug state*.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **Halting debug**.*

**I<sub>HWPQ</sub>** Non-invasive debug components do not guarantee that they do not make any changes to the behavior or performance of the PE. Any changes that do occur must not be severe however, as this will reduce the usefulness of event counters for performance measurement and profiling. This does not include any change to program behavior that results from the same program being instrumented to use a Non-invasive debug feature, for example the Performance Monitors, or from some other performance monitoring process being run concurrently with the process being profiled. As such, a reasonable variation in performance is permissible.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**I<sub>DMQP</sub>** The *Unprivileged Debug Extension*, UDE, allows for a finer-grained control of debug access to the PE. UDE allows conditional debug capabilities when the PE is in an unprivileged mode, including support for the DebugMonitor exception and the optional Halting debug and non-invasive debug.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **UDE**.*

See also:

[B13.2 Accessing debug features.](#)

## B13.1.2 Debug resources

**R<sub>TZVG</sub>** In the system address map, debug resources are in the *Private Peripheral Bus* (PPB) region.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>FBHD</sub>** Except for the resources in the SCS, each debug component occupies a fixed 4KB address region.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **DB**.*

**R<sub>WXTK</sub>** The debug resources in the SCS are:

- The *Debug Control Block* (DCB).
- Debug controls in the *System Control Block* (SCB).

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **DB**.*

Chapter B13. Debug  
B13.1. Debug feature overview

**I<sub>KKBT</sub>** If the Main Extension is implemented, then support for DebugMonitor is implemented. If the Main Extension is not implemented, then DebugMonitor is not supported.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **DB**. Note, M is required for DebugMonitor exception.*

**R<sub>VMGD</sub>** ROM table entries identify which optional debug components are implemented.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **DB**.*

**R<sub>RRLF</sub>** The addresses of the debug resources are:

| Address range          | Debug Resource                                                                                        |
|------------------------|-------------------------------------------------------------------------------------------------------|
| 0xE0000000-0xE0000FFF  | Instrumentation Trace Macrocell (ITM)                                                                 |
| 0xE0001000-0xE0001FFF  | Data Watchpoint and Trace Unit (DWT)                                                                  |
| 0xE0002000-0xE0002FFF  | Flashpatch and Breakpoint Unit (FPB)                                                                  |
| 0xE0003000-0xE0003FFF  | Performance Monitor Unit (PMU)                                                                        |
| 0xE000E000-0xE000EFFF  | Secure SCS                                                                                            |

## Chapter B13. Debug

### B13.2. Accessing debug features

|                   |                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| I <sub>FWPG</sub> | <p>The ROM table indicates the implemented debug components, and the position of those components in the memory map. See the <i>Arm® Debug Interface v5 Architecture Specification</i> for the format of a ROM table entry.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">DB</a>.</i></p>                           |
| I <sub>PHJJ</sub> | <p>For an Armv8-M ROM table, all entry offsets are negative. The ROM table entry points to the top of a 4KB page, the offset points to the bottom of that page that contains the Peripheral and Component ID registers.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">DB</a>.</i></p>                               |
| R <sub>GPPX</sub> | <p>The ROM table is implemented if any other debug component is implemented or a Debug Access Port is implemented.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">DB</a>.</i></p>                                                                                                                                    |
| R <sub>BQSP</sub> | <p>Bit[0] of the ROM table entries indicates whether the corresponding debug component is implemented and is accessible through the PPB at the indicated address. If the corresponding debug component is not implemented, this bit has a value of 0.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">DB</a>.</i></p> |
| R <sub>NDQW</sub> | <p>If a debug component is implemented, debug registers can provide additional information about the implemented features of that debug component.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">DB</a>.</i></p>                                                                                                    |
| R <sub>ZZGJ</sub> | <p>The format of the ROM table is:</p>                                                                                                                                                                                                                                                                                                                                                          |

Chapter B13. Debug  
B13.2. Accessing debug features

| Offset           | Value                         | Name     | Description                                                                                                                                                                                       |
|------------------|-------------------------------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0x000            | 0xFFFF0F003                   | ROMSCS   | Points to the SCS at 0xE000E000                                                                                                                                                                   |
| 0x004            | 0xFFFF02002 or<br>0xFFFF02003 | ROMDWT   | Points to the Data Watchpoint and Trace unit at 0xE0001000                                                                                                                                        |
| 0x008            | 0xFFFF03002 or<br>0xFFFF03003 | ROMFPB   | Points to the Flash Patch and Breakpoint unit at 0xE0002000                                                                                                                                       |
| 0x00C            | 0xFFFF01002 or<br>0xFFFF01003 | ROMITM   | Points to Instrumentation Trace unit at 0xE0000000.                                                                                                                                               |
| 0x010            | 0xFFFF41002 or<br>0xFFFF41003 | ROMTPIU  | Points to the Trace Port Interface Unit.                                                                                                                                                          |
| 0x014            | 0xFFFF42002 or<br>0xFFFF42003 | ROMETM   | Points to the Embedded Trace Macrocell.                                                                                                                                                           |
| 0x018            | 0xFFFF42002 or<br>0xFFFF42003 | ROMPMU   | Points to the Performance Monitoring Unit.                                                                                                                                                        |
| -                | 0x00000000                    | End      | End of table marker. It is IMPDEF whether the table is extended with pointers to other system debug resources.<br>The table entries always terminate with a null entry.                           |
| 0x020 -<br>0xEFC | -                             | Not used | Reserved for additional ROM table entries.                                                                                                                                                        |
| 0xF00 -<br>0xFC8 | -                             | Reserved | Reserved, not used for ROM table entries.                                                                                                                                                         |
| 0xFCC            | 0x00000001                    | MEMTYPE  | Bit [0] is set to 1 to indicate that resources other than those listed in the ROM table are accessible in the same 32-bit address space, using the DAP.Bits [31:1] of the MEMTYPE entry are RES0. |
| 0xFD0            | IMP DEF                       | PIDR4    | CIDRx values are fully defined for the ROM table, and are CorseSight compliant.                                                                                                                   |
| 0xFD4            | 0                             | PIDR5    | PIDRx values are CoreSight compliant or RAZ.                                                                                                                                                      |

| 0xFEC            | IMP DEF                       | PIDR3    |                                                                                                                                                                                                   |
| 0xFF0            | 0x0000000D                    | CIDR0    |                                                                                                                                                                                                   |
| 0xFF4            | 0x00000010                    | CIDR1    |                                                                                                                                                                                                   |
| 0xFF8            | 0x00000005                    | CIDR2    |                                                                                                                                                                                                   |
| 0xFFC            | 0x000000B1                    | CIDR3    |                                                                                                                                                                                                   |

Accesses to the ROMITM cannot cause a non-existent memory exception.

It is IMPLEMENTATION DEFINED whether the ETM and TPIU are a shared resource and whether the resource is managed by the local PE or a different resource.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **DB** and those indicated in the table. Note, PMU is only available in an Armv8.1-M implementation.*

RJDGV

If a PMU is implemented, the end-of-table marker is 0x1C and has a value of 0x00000000. It is IMPLEMENTATION DEFINED whether the table is extended with pointers to other System debug resources.

Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **DB** & **PMU**.

[B13.2.3 CoreSight and identification registers.](#)

## B13.2.2 Debug System registers

R<sub>RHDW</sub>

The debug provision in the *System Control Block* (SCB) comprises:

- Two handler-related flag bits, **ICSR.ISRPREEMPT** and **ICSR.ISRPENDING**.
- The **DFSR**.

Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **DB**.

See also:

[Part D Register and Payload Specification.](#)

[Debug Control Block.](#)

## B13.2.3 CoreSight and identification registers

I<sub>CMLH</sub>

Arm recommends that CoreSight-compliant ID registers are implemented to allow identification and discovery of the components to a debugger.

Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **DB**.

R<sub>QCWD</sub>

The address spaces that are reserved in each of the debug components for IMPLEMENTATION DEFINED ID registers and CoreSight compliance are:

| Debug Component | Space reserved for ID registers | Space reserved for CoreSight compliance |
|-----------------|---------------------------------|-----------------------------------------|
| ITM             | 0xE0000FD0-0xE0000FFC           | 0xE0000FA0-0xE0000FCC                   |
| DWT             | 0xE0001FD0-0xE0001FFC           | 0xE0001FA0-0xE0001FCC                   |
| FPB             | 0xE0002FD0-0xE0002FFC           | 0xE0002FA0-0xE0002FCC                   |
| PMU             | 0xE0003FD0-0xE0003FFC           | 0xE0003FA0-0xE0003FCC                   |
| SCS             | 0xE000EFD0-0xE000EFFC           | 0xE000EFA0-0xE000EFCC                   |
| TPIU            | 0xE0040FD0-0xE0040FFC           | 0xE0040FA0-0xE0040FCC                   |
| ETM             | 0xE0041FD0-0xE0041FFC           | 0xE0041FA0-0xE0041FCC                   |
| ROM table       | 0xE00FFFD0-0xE00FFFFC           | 0xE00FFFA0-0xE00FFFCC                   |

Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **DB**. Note, PMU available only in an Armv8.1-M implementation.

R<sub>VWSX</sub>

For the ROM table, the ID register space is used for a set of CoreSight-compliant ID registers.

Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **DB**.

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## B13.3 Debug authentication interface

**R<sub>GWTN</sub>** The following pseudocode functions provide an abstracted description of the authentication interface:

- `ExternalInvasiveDebugEnabled()`.
- `ExternalSecureInvasiveDebugEnabled()`.
- `ExternalNoninvasiveDebugEnabled()`.
- `ExternalSecureNoninvasiveDebugEnabled()`.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **DB**.*

**R<sub>SWWT</sub>** For an implementation using the CoreSight signals **DBGEN**, **NIDEN**, **SPIDEN**, and **SPNIDEN**:

- `ExternalInvasiveDebugEnabled()` returns TRUE if **DBGEN** is asserted.
- `ExternalSecureInvasiveDebugEnabled()` returns TRUE if both **DBGEN** and **SPIDEN** are asserted.
- `ExternalNoninvasiveDebugEnabled()` returns TRUE if either **NIDEN** or **DBGEN** is asserted.
- `ExternalSecureNoninvasiveDebugEnabled()` returns TRUE if both of the following conditions apply:
  - Either **NIDEN** or **DBGEN** is asserted.
  - Either **SPNIDEN** or **SPIDEN** is asserted.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **DB**.*

**I<sub>FPCPK</sub>** The unprivileged debug capabilities enabled by `DAUTHCTRL.UIDEN` being set to 1 are available regardless of the state of the following:

- `DAUTHCTRL.INTSPNIDEN`.
- `DAUTHCTRL.SPNIDENSEL`.
- `DAUTHCTRL.INTSPIDEN`.
- `DAUTHCTRL.SPIDENSEL`.
- **DBGEN**.
- **SPIDEN**.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **Halting debug** && **UDE**. Note, S is required for Secure Behavior.*

**R<sub>HVGN</sub>** For any implementation of the authentication interface, if `ExternalInvasiveDebugEnabled()` is FALSE, then `ExternalSecureInvasiveDebugEnabled()` is FALSE.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **DB**.*

**R<sub>JWCS</sub>** For any implementation of the authentication interface, if `ExternalNoninvasiveDebugEnabled()` is FALSE, then `ExternalSecureNoninvasiveDebugEnabled()` is FALSE.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **DB**.*

**R<sub>XCMD</sub>** For any implementation of the authentication interface, if `ExternalInvasiveDebugEnabled()` is TRUE, then `ExternalNoninvasiveDebugEnabled()` is TRUE.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **DB**.*

**R<sub>LCHH</sub>** For any implementation of the authentication interface, if `ExternalSecureInvasiveDebugEnabled()` is TRUE, then `ExternalSecureNoninvasiveDebugEnabled()` is TRUE.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **DB**.*

**I<sub>MSRG</sub>** Secure self-hosted debug is controlled by the authentication interface. The pseudocode function [ExternalSecureSelfHostedDebugEnabled\(\)](#) provides an abstracted description of this authentication interface.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **DB**.*

**R<sub>GLWM</sub>** Between a change to the debug authentication interface and a following [Context synchronization event](#), it is UNPREDICTABLE whether the PE uses the old or the new values.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **DB**.*

### B13.3.1 Halting debug authentication

**I<sub>DMFG</sub>** Halting debug authentication is controlled by the IMPLEMENTATION DEFINED authentication interface function [ExternalInvasiveDebugEnabled\(\)](#), and if the Security Extension is implemented, the IMPLEMENTATION DEFINED authentication interface function [ExternalSecureInvasiveDebugEnabled\(\)](#).

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **Halting debug**. Note, External Secure invasive debug requires **S**.*

**R<sub>PHWV</sub>** Halting is prohibited in privileged mode in all states if the function [ExternalInvasiveDebugEnabled\(\)](#) returns FALSE. If UDE is not implemented this rule applies to all privilege modes.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **Halting debug** && **UDE**.*

**R<sub>JXTX</sub>** When the PE is halted, the PE behaves as if [ExternalInvasiveDebugEnabled\(\)](#) is TRUE. The pseudocode function [HaltingDebugAllowed\(\)](#) describes this.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **Halting debug**.*

**I<sub>BCZM</sub>** If the Security Extension is not implemented, there are two Halting debug authentication modes:

| <a href="#">ExternalInvasiveDebugEnabled()</a> | <b>DHCSR.S_HALT</b> | <b>Halting debug authentication mode</b> |
|------------------------------------------------|---------------------|------------------------------------------|
| FALSE                                          | 0                   | Halting is prohibited.                   |
| FALSE                                          | 1                   | Halting is allowed.                      |
| TRUE                                           | X                   | Halting is allowed.                      |

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **Halting debug** && **!S** && **!UDE**.*

**R<sub>BMRJ</sub>** Halting is prohibited in privileged modes in Secure state if any of the following conditions are TRUE:

- The IMPLEMENTATION DEFINED [ExternalInvasiveDebugEnabled\(\)](#) returns FALSE.
- **DAUTHCTRL.SPIDENSEL** is set to 1 and **DAUTHCTRL.S.INTSPIDEN** is set to 0.
- **DAUTHCTRL.SPIDENSEL** is set to 0 and [ExternalSecureInvasiveDebugEnabled\(\)](#) returns FALSE.

The pseudocode function `SecureHaltingDebugEnabled` describes this.

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - **Halting debug** && **S**.

I<sub>XKFR</sub>

If the Security Extension is not implemented and the Unprivileged Debug Extension is implemented, Halting debug has the following authentication modes:

| <code>HaltingDebugEnabled()</code> | <code>DAUTHCTRL.UIDEN</code> | Halting debug authentication mode                                                     |
|------------------------------------|------------------------------|---------------------------------------------------------------------------------------|
| FALSE                              | 0                            | Halting is prohibited in all modes.                                                   |
| FALSE                              | 1                            | Halting is allowed in unprivileged mode.<br>Halting is prohibited in privileged mode. |
| TRUE                               | X                            | Halting is allowed in all modes.                                                      |

Applies to an implementation of the architecture *Armv8.1-M* onward. The extension requirements are - **Halting debug** && **!S** && **UDE**.

R<sub>BDNX</sub>

Halting in unprivileged modes is prohibited in Secure state if either of:

- `SecureHaltingDebugEnabled()` returns FALSE.
- `DAUTHCTRL.S.UIDEN` is set to 0.

Applies to an implementation of the architecture *Armv8.1-M* onward. The extension requirements are - **UDE** && **Halting debug** && **S**.

R<sub>XFKR</sub>

Halting in unprivileged modes is prohibited in Non-secure state if all of the following are true:

- `HaltingDebugEnabled()` returns FALSE.
- `DAUTHCTRL.S.UIDEN` is set to 0.
- `DAUTHCTRL.NS.UIDEN` is set to 0.

Applies to an implementation of the architecture *Armv8.1-M* onward. The extension requirements are - **UDE** && **Halting debug** && **S**.

I<sub>VKHZ</sub>

`DAUTHCTRL.NS.UIDEN` controls whether debug request can be raised from unprivileged mode in Non-secure state. `DAUTHCTRL.S.UIDEN` controls whether debug requests can be raised from Secure or Non-secure state. When `DAUTHCTRL.S.UIDEN` is set to 1 `DAUTHCTRL.NS.UIDEN` has an **Effective value** of 1.

Applies to an implementation of the architecture *Armv8.1-M* onward. The extension requirements are - **Halting debug** && **UDE**. Note, **S** is required for Secure behavior.

R<sub>VQJZ</sub>

The value of `DHCSR.S_SDE`, `DHCSR.S_SUIDE` and `DHCSR.S_NSUIDE` are updated when the PE is not halted as described by the function `UpdateDebugEnabled()`.

Applies to an implementation of the architecture *Armv8.1-M* onward. The extension requirements are - **Halting debug**. Note, **S** is required for Secure behavior. **UDE** is required for Unprivileged Debug.

R<sub>KBKM</sub>

If the PE is in Non-debug state the following condition is true:

- `DHCSR.S_SDE` reads as one if the following is true, and reads as zero otherwise:
  - `SecureHaltingDebugEnabled()` returns TRUE.

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - **Halting debug** && **!UDE**. Note, **S** is required for Secure behavior.

R<sub>CVKR</sub>

If the PE is in Non-debug state the following conditions are true:

- `DHCSR.S_SDE` reads as one if any one of the following are true, and reads as zero otherwise:
  - `SecureHaltingDebugEnabled()` returns TRUE.
  - `UnprivHaltingDebugEnabled(TRUE)` returns TRUE.
- `DHCSR.S_SUIDE` reads as one if all of the following are true and reads as zero otherwise:

- `SecureHaltingDebugEnabled()` returns FALSE.
- `UnprivHaltingDebugEnabled(TRUE)` returns TRUE.
- **DHCSR.S\_NSUIDE** reads as one if both of the following are true and reads as zero otherwise:
  - `HaltingDebugEnabled()` returns FALSE.
  - `UnprivHaltingDebugEnabled(FALSE)` returns TRUE.

Applies to an implementation of the architecture *Armv8.1-M* onward. The extension requirements are - **Halting debug** && **UDE**. Note, *S* is required for Secure behavior.

R\_KMXG

If the PE is in Debug state:

- **DHCSR.S\_SDE** reads as one if either of the following is true, and reads as zero otherwise:
  - The PE entered Debug state from Secure state.
  - The PE entered Debug state from Non-secure state when `SecureHaltingDebugEnabled()` returned TRUE.

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - **Halting debug** && **!UDE**. Note, *S* is required for Secure behavior.

R\_TNMM

If the PE is in Debug state:

- **DHCSR.S\_SDE** reads as one if any one of the following is true, and reads as zero otherwise:
  - The PE entered Debug state from Secure state.
  - The PE entered Debug state from Non-secure state when `SecureHaltingDebugEnabled()` returned TRUE.
  - The PE entered Debug state from Non-secure state when `UnprivHaltingDebugEnabled(TRUE)` returned TRUE.
- **DHCSR.S\_SUIDE** reads as one if when the PE entered Debug state both of the following were true, and reads as zero otherwise:
  - `SecureHaltingDebugEnabled()` returned FALSE.
  - `UnprivHaltingDebugEnabled(TRUE)` returned TRUE.
- **DHCSR.S\_NSUIDE** reads as one if when the PE entered Debug state both the following were true, and reads as zero otherwise:
  - `HaltingDebugEnabled()` returned FALSE.
  - `UnprivHaltingDebugEnabled(FALSE)` returned TRUE.

Applies to an implementation of the architecture *Armv8.1-M* onward. The extension requirements are - **Halting debug** && **UDE**. Note, *S* is required for Secure behavior.

I\_LDTR

If the Security Extension is implemented, there are three Halting debug authentication modes:

| <b>HaltingDebugEnabled()</b> | <b>DHCSR.S_SDE</b> | <b>Halting debug authentication mode</b>                                          |
|------------------------------|--------------------|-----------------------------------------------------------------------------------|
| FALSE                        | X                  | Halting is prohibited.                                                            |
| TRUE                         | 0                  | Halting is allowed in Non-secure state.<br>Halting is prohibited in Secure state. |
|                              | 1                  | Halting is allowed.                                                               |

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - **Halting debug** && **S** && **!UDE**.

I<sub>LQVH</sub>

In an Armv8.1-M PE, unprivileged debug is authentication is as follows:

| Halting<br>DebugAllowed() | SecureHalting<br>DebugAllowed() | DAUTHCTRL_S.<br>UIDEN | DAUTHCTRL_NS.<br>UIDEN | Halting debug<br>authentication mode                                                                                                                                                                                              |
|---------------------------|---------------------------------|-----------------------|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FALSE                     | FALSE                           | 0                     | 0                      | Halting is prohibited.                                                                                                                                                                                                            |
| FALSE                     | FALSE                           | 0                     | 1                      | Halting is allowed in<br>Non-secure unprivileged mode.<br>Halting is prohibited in<br>Secure unprivileged mode.<br>Halting is prohibited in<br>Non-secure privileged mode.<br>Halting is prohibited in<br>Secure privileged mode. |

Applies to an implementation of the architecture *Armv8.1-M* onward. The extension requirements are - **Halting debug** && **UDE**. Note, S required for Secure state.

R<sub>FXCB</sub>

When **DHCSR.C\_DEBUGEN** == 0 or the PE is in a state in which Halting is prohibited, the PE does not enter Debug state.

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - **Halting debug**. Note, S is required for Secure behavior.

[CanHaltOnEvent\(\)](#).

## B13.3.2 Non-invasive debug authentication

R<sub>GFTG</sub>

Non-invasive authentication is controlled by the IMPLEMENTATION DEFINED function:

[ExternalNoninvasiveDebugEnabled\(\)](#).

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - **DB** && **!S**.

R<sub>HXQD</sub>

Secure Non-invasive authentication is controlled by the IMPLEMENTATION DEFINED functions:

- [ExternalSecureNoninvasiveDebugEnabled\(\)](#).
- [ExternalNoninvasiveDebugEnabled\(\)](#).

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - **DB** && **S**.

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

### B13.3.3 DebugMonitor exception authentication

|                   |                                                                                                                                                                                                                                  |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| R <sub>MXTM</sub> | <p>DebugMonitor exception authentication is only available if the Main Extension is implemented.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <b>M</b>.</i></p> |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

**R<sub>LQCN</sub>** DebugMonitor exception authentication is controlled by the IMPLEMENTATION DEFINED authentication interface function `ExternalSecureSelfHostedDebugEnabled()`.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **M** && **S**.*

**R<sub>GTSQ</sub>** Unless otherwise stated DebugMonitor exceptions are never generated for Secure privileged operations if all of the following conditions are true:

- **DAUTHCTRL.FSDMA** is set to 0.
- Any of the following conditions are true:
  - **DAUTHCTRL.SPIDENSEL** is set to 1 and **DAUTHCTRL.INTSPIDEN** is set to 0.
  - **DAUTHCTRL.SPIDENSEL** is set to 0 and `ExternalSecureSelfHostedDebugEnabled()` returns FALSE.

The pseudocode function `SecureDebugMonitorAllowed()` describes this.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **M** && **S**. Note, **DAUTHCTRL.FSDMA** is only available in an Armv8.1-M implementation.*

**I<sub>PWJZ</sub>** If UDE is implemented **DAUTHCTRL.FSDMA** allows the Secure DebugMonitor exception to be enabled independently of Halting debug and `ExternalSecureSelfHostedDebugEnabled()`. This field does not control the DebugMonitor exception permissions directly, instead **DAUTHCTRL.FSDMA** is used as an input into **DEMCR.SDME**, as described by `UpdateDebugEnabled()` and `SecureDebugMonitorAllowed()`.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **M** && **S** && **UDE**.*

**R<sub>WXMG</sub>** When a DebugMonitor exception is not pending and is not active:

- **DEMCR.SDME** is set to 1 if `SecureDebugMonitorAllowed()` is TRUE.
- **DEMCR.SDME** is zero otherwise.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **M**.*

**R<sub>CPPN</sub>** If `SecureDebugMonitorAllowed()` returned TRUE when a DebugMonitor exception is pending or active:

- **DEMCR.SDME** is set to 1 when the DebugMonitor exception became pending or active.
- **DEMCR.SDME** is zero otherwise.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **M**.*

**R<sub>YFPK</sub>** If **DEMCR.SDME** == 1, **SHPR3.PRI\_12** behaves as RAZ/WI when accessed from Non-secure state.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **M** && **S**.*

**I<sub>HNGD</sub>** When set to 1, **DEMCR.MON\_PEND** remains set to 1 until one of the following occurs:

- The DebugMonitor exception is taken
- A write to **DEMCR** sets the **DEMCR.MON\_PEND** to 0.
- The PE is reset.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **M**.*

**R<sub>SCZH</sub>** DebugMonitor exceptions are never generated for unprivileged operations if all of the following conditions are true:

- **DEMCR.MON\_EN** is 0.
- **DEMCR.UMON\_EN** is 0.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **UDE** && **M**.*

**R<sub>CKPB</sub>** DebugMonitor exceptions are never generated for Secure unprivileged operations when all of the following are true:

- `SecureDebugMonitorAllowed()` returns FALSE.
- **DEMCR.UMON\_EN** is 0 and **DEMCR.MON\_EN** is 0.

Applies to an implementation of the architecture *Armv8.1-M* onward. The extension requirements are - **M** && **S** && **UDE**.

`ExternalSecureSelfHostedDebugEnabled()`.

`SecureDebugMonitorAllowed()`.

`CanPendMonitorOnEvent()`.

`UpdateDebugEnabled()`.

### B13.3.4 DAP access permissions

**R<sub>BFSB</sub>** When `HaltingDebugEnabled()` is TRUE the external debugger can issue requests to the entire physical address space through the DAP. When the DAP accesses a System register the response to the DAP is defined by the access permissions of the register being accessed.

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - **DB**.

**R<sub>FFPN</sub>** The external debugger is capable of requesting Secure and Non-secure accesses through the DAP.

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - **DB** && **S**.

**R<sub>VDPK</sub>** The external debugger is capable of requesting Privileged and Unprivileged accesses through the DAP.

Applies to an implementation of the architecture *Armv8.1-M* onward. The extension requirements are - **DB** && **UDE**.

**I<sub>XNTP</sub>** **DAUTHCTRL.UIDAPEN** indicates software intent to allow the external debugger unprivileged access through the DAP to selected PPB registers.

Applies to an implementation of the architecture *Armv8.1-M* onward. The extension requirements are - **DB**. Note, **DAUTHCTRL.UIDAPEN** requires **UDE**.

**R<sub>TRLZ</sub>** When either **DAUTHCTRL.S.UIDAPEN** or **DAUTHCTRL.NS.UIDAPEN** is set, and no other debug authorization is active, the PE permits the external debugger to request unprivileged access through the DAP to the System PPB space. If the external debugger makes a privileged request, when **DAUTHCTRL.UIDAPEN** is set in either Security state the PE demotes the request to an unprivileged request. An unprivileged access will return an error to the DAP unless otherwise specified by the register description.

Applies to an implementation of the architecture *Armv8.1-M* onward. The extension requirements are - **DB**. Note, **DAUTHCTRL.UIDAPEN** requires **UDE**.

**R<sub>TXZB</sub>** If `HaltingDebugEnabled()` is FALSE, then:

- Unless otherwise stated, external debugger accesses through the DAP to addresses in the range 0x00000000 to 0xFFFFFFFF return an error to the DAP.
- If either bank of **DAUTHCTRL.UIDAPEN** is one, external debugger accesses through the DAP to addresses outside the range 0xE0000000 to 0xE00FFFFF return an error to the DAP.
- If neither bank of **DAUTHCTRL.UIDAPEN** is one, external debugger accesses are permitted as detailed in the table below:

| Address Range             | Component or description                        | NoninvasiveDebugAllowed() |           |
|---------------------------|-------------------------------------------------|---------------------------|-----------|
|                           |                                                 | FALSE                     | TRUE      |
| 0x00000000 – 0xDFFFFFFF   | Rest of Memory                                  | DAP error                 | DAP error |
| 0xE0000000 – 0xE00FFFFFFF | PPB                                             |                           |           |
| 0xE00xxFB0 – 0xE00xxFB7   | CoreSight Software Lock registers               | DAP error                 | RW        |
| 0xE00xxFD0 – 0xE00xxFFF   | CoreSight peripheral and component ID registers | RO                        | RO        |
| 0xE0000000 – 0xE0000FCF   | ITM                                             | DAP error                 | RW        |
| 0xE0001000 – 0xE0001FCF   | DWT                                             | DAP error                 | RW        |
| 0xE0003000 – 0xE0003FCF   | PMU                                             | DAP error                 | RW        |
| 0xE0040000 – 0xE0040FFF   | TPIU                                            | RW                        | RW        |
| 0xE0041000 – 0xE0041FFF   | ETM                                             | RW                        | RW        |
| 0xE0042000 – 0xE00FEFFF   | IMPDEF                                          | IMPDEF                    | IMPDEF    |
| 0xE00FF000 – 0xE00FFFFFFF | ROM table                                       | RO                        | RO        |
|                           | All other PPB regions                           | DAP error                 | DAP error |
| 0xE0100000 – 0xFFFFFFFF   | Vendor_SYS                                      | DAP error                 | RW        |

Applies to an implementation of the architecture **Armv8.0-M** onward. The extension requirements are - **DB**. Note, **DAUTHC-TRL.UIDAPEN** requires **UDE**. **UDE** and **PMU** are only available in an **Armv8.1-M** implementation.

**I<sub>LGXS</sub>** Where this rule does not prevent an external debugger access to a register through the DAP, the access permissions are defined by the register. The access permissions are set out in the Usage Constraints section of each register description.

Applies to an implementation of the architecture **Armv8.0-M** onward. The extension requirements are - **DB**.

**R<sub>KBQZ</sub>** A DAP memory access calls **MemD\_with\_priv\_security()** and **DAPCheck()**.

Applies to an implementation of the architecture **Armv8.1-M** onward. The extension requirements are - **DB**. Note, Secure accesses require **S** and unprivileged accesses require **UDE**.

**I<sub>DKCB</sub>** The architecture does not describe how a DAP requests Secure or Non-secure memory accesses. In the recommended **ADIV5** Memory Access Port (MEM-AP), Arm recommends that, when **CSW.DEVICEEN** is set to one:

- **CSW[30]**, **CSW.Prot[6]**, selects a Secure or Non-secure access:
  - **0**: Request a Secure access.
  - **1**: Request a Non-secure access.
- **CSW[23]**, **CSW.SPIDEN**, must be one. This is because the DAP can always request a Secure access.

When **CSW.DEVICEEN** is zero the MEM-AP is incapable of requesting any accesses. In **ADIV6** **CSW[23]** is **SDeviceEN**, but the behavior remains the same.

Applies to an implementation of the architecture **Armv8.0-M** onward. The extension requirements are - **DB** && **S**.

**I<sub>RVWM</sub>** The architecture does not describe how a DAP requests Privileged or Unprivileged memory accesses. In the recommended **ADIV5** or higher Memory Access Port (MEM-AP), Arm recommends that the **IMPLEMENTATION DEFINED** field **CSW[27:24]**, **PROT**, flags are used to define Privileged or Unprivileged accesses.

Applies to an implementation of the architecture **Armv8.1-M** onward. The extension requirements are - **DB** && **UDE**.

**I<sub>MRMX</sub>** In a CoreSight DAP, the **SPIDEN** input to the **Armv8-M** MEM-AP is independent of the **SPIDEN** input of the PE, and must be tied HIGH when **CSW.DEVICEEN** is one. When **CSW.DEVICEEN** is zero the MEM-AP is disabled and is incapable of making any requests for memory accesses.

Applies to an implementation of the architecture **Armv8.0-M** onward. The extension requirements are - **DB** && **S**.

- R<sub>JHBC</sub>** If **DHCSR.S\_SDE** == 1, and the DAP requests a Secure access, NS-Req is set to Secure.  
*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **DB** && **S**.*
- R<sub>LVBG</sub>** If either **DHCSR.S\_SDE** == 0 or the DAP requests a Non-secure access, NS-Req set to Non-secure.  
*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **DB** && **S**.*
- R<sub>WMRR</sub>** DAP accesses are checked by the IDAU and the SAU, if applicable. That is, if NS-Req on a DAP access specifies Non-secure access, and the IDAU or SAU prohibits Non-secure access to the address, an error response is returned to the DAP.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **DB** && **S**.*

- R<sub>VTTN</sub>** Unless otherwise stated DAP accesses are not checked by the MPU.  
*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **DB** && **MPU**.*
- R<sub>TYBC</sub>** The DAP NS-Req signal is ignored for accesses to the SCS registers. Instead, NS-Req is derived from the **DSCSR.SBRSELEN** and **DSCSR.SBRSEL**. The derived NS-Req is used for all permissions checks, including the privilege checks and demotions.  
*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **DB** && **S**.*
- R<sub>WBNK</sub>** DAP accesses to SCS registers in the range 0xE000E000-0xE000EFFF are affected by the values of **DSCSR.SBRSELEN**, and **DSCSR.SBRSEL**, as well as by the current Security state of the PE. The following table shows the effect of these factors on the register being viewed.

|  | DSCSR.SBRSELEN | DSCSR.SBRSEL | Current Security state<br>of the PE | View of register<br>accessed |
|--|----------------|--------------|-------------------------------------|------------------------------|
|  | 1              | 0            | X                                   | Non-secure.                  |
|  | 1              | 1            | X                                   | Secure.                      |
|  | 0              | X            | Non-secure.                         | Non-secure.                  |
|  | 0              | X            | Secure.                             | Secure.                      |

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - **DB** && **S**.

**I<sub>KLPQ</sub>** When **DHCSR.S\_SDE** == 0, then **DSCSR.SBRSELEN** reads as 1 and **DSCSR.SBRSEL** reads as 0, which selects the Non-secure bank of registers.

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - **DB** && **S**.

**R<sub>PMNV</sub>** Permitted DAP accesses to the region 0xE002E000-0xE002EFFF are RAZ/WI if the access is privileged or unprivileged. Privileged accesses never return a DAP error, and it is IMPLEMENTATION DEFINED whether an unprivileged access returns a DAP error.

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - **DB**. Note, This rule also applies to unprivileged accesses via *Armv8.1-M* UDE.

**I<sub>HBGQ</sub>** An *Armv8.1-M* PE with UDE extends the existing DAP access regime for the Main Extension.

Applies to an implementation of the architecture *Armv8.1-M* onward. The extension requirements are - **DB** && **UDE**.

**R<sub>RXKV</sub>** When **DAUTHCTRL.UIDAPEN** is set, unprivileged debugger accesses to reserved locations within the PPB are treated as RES0 and do not return a DAP error.

Applies to an implementation of the architecture *Armv8.1-M* onward. The extension requirements are - **UDE**.

**R<sub>MRPC</sub>** A privileged DAP request through the Unprivileged Debug Extension mechanism is demoted to an unprivileged access and is subject to MPU checks. Both privileged and unprivileged requests are subject to MPU checks.

Applies to an implementation of the architecture *Armv8.1-M* onward. The extension requirements are - **UDE** && **MPU**.

R<sub>WSQR</sub>

The DAP access process is extended when the Unprivileged Debug Extension is implemented, and `HaltingDebugAllowed()` returns FALSE, as shown in the following diagram.

Applies to an implementation of the architecture *Armv8.1-M* onward. The extension requirements are - **UDE** && **MPU**.

I<sub>LBGV</sub>

When `HaltingDebugAllowed()` returns TRUE, DAP accesses follow the behavior specified by R<sub>WMRR</sub>.

Applies to an implementation of the architecture *Armv8.1-M* onward. The extension requirements are - **UDE** && **MPU**.

## B13.4 Debug event behavior

### B13.4.1 About debug events

$I_{CBWT}$

An event that is triggered for debug reasons is known as a *debug event*.

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - **DB**.

$R_{PQKW}$

A debug event that is not ignored causes one of the following to occur:

- If Halting debug is implemented and enabled, entry to Debug state.
- A HardFault exception.
- Lockup.

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - **DB**. Note, entry to Debug state requires Halting Debug.

$R_{QLTQ}$

A debug event that is not ignored, can cause a DebugMonitor exception to occur.

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - **M**.

$R_{MNKP}$

The HardFault exceptions or Lockup that are caused by debug events are generated by:

- A **BKPT** instruction that is executed when the PE can neither halt nor generate a DebugMonitor exception.
- In some circumstances, the FPB.

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - **M**. Note, an FPB requires FPB.

$R_{WCPW}$

The debug events are as follows.

| Debug event  | Actions                                     |
|--------------|---------------------------------------------|
| Step         | Halt or DebugMonitor exception.             |
| Halt Request | Halt                                        |
| Breakpoint   | Halt, DebugMonitor exception, or Hardfault. |
| Watchpoint   | Halt or DebugMonitor exception.             |
| Vector catch | Halt only                                   |
| PMU Overflow | Halt or DebugMonitor exception              |
| External     | Halt or DebugMonitor exception.             |

Applies to an implementation of the architecture *Armv8.0-M* onward. Note, a DebugMonitor exception requires **M**. Halt requires Halting Debug. PMU is only available in an *Armv8.1-M* implementation.

$R_{LDRZ}$

The **DFSR** contains status bits for each debug event. These bits are set to 1 when a debug event causes the PE to halt or generate a DebugMonitor exception, and are then write-one-to-clear.

The following table shows which bit is set for each debug event.

| Event cause  | DFSR bit |
|--------------|----------|
| Step         | HALTED   |
| Halt request | HALTED   |
| Breakpoint   | BKPT     |
| Watchpoint   | DWTTRAP  |
| Vector catch | VCATCH   |
| PMU Overflow | PMU      |
| External     | EXTERNAL |

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - **M** || **Halting debug**. Note, PMU is only available in an *Armv8.1-M* implementation.

**R<sub>HNRV</sub>** It is IMPLEMENTATION DEFINED whether the **DFSR** debug event bits are updated when an event is ignored or the debug event is escalated to a HardFault.

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - **DB**.

**I<sub>KLLX</sub>** In an implementation of the *Armv8.1-M* architecture Arm recommends that the **DFSR** debug event bits are updated when an event is ignored. For example, when a DebugMonitor event is not taken or is escalated to a HardFault.

Applies to an implementation of the architecture *Armv8.1-M* onward. The extension requirements are - **DB**.

**I<sub>MCZX</sub>** Arm recommends that any **BKPT** executed should set **DFSR.BKPT** regardless of any authentication for halting, DebugMonitor or HardFault or Lockup behavior.

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - **DB**.

**R<sub>DVCR</sub>** If a **BKPT** instruction cannot halt and cannot generate a DebugMonitor exception then escalation to HardFault occurs.

The effect of **DEMCR.SDME** on the target Security state of an escalated Hardfault is an IMPLEMENTATION DEFINED choice, so that the target Security state of any escalated HardFault will be either:

- Non-secure state when the current Security state is Non-secure and **AIRCR.BFHFNMINs** is 1 and **DEMCR.SDME** is ignored.
- Secure state when any of the following are true:
  - The current Security state is Secure.
  - **AIRCR.BFHFNMINs** is 0.
  - **DEMCR.SDME** is 1 and is not ignored.

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - **DB** && **M**. Note, *S* required for Secure state.

**R<sub>TBWL</sub>** If a **BKPT** instruction that cannot halt and cannot generate a DebugMonitor exception then escalation to HardFault occurs. The target Security state of the generated Hardfault is the Secure state if any of the following are true:

- **DEMCR.SDME** is set to one.
- **AIRCR.BFHFNMINs** is zero.
- The current Security state is Secure.

Applies to an implementation of the architecture *Armv8.1-M* onward. The extension requirements are - **DB** && **S**. Note, *M* is always implemented in an *Armv8.1* implementation.

**I<sub>ZFKK</sub>** When escalating a DebugMonitor exception to HardFault **DEMCR.SDME** should be checked regardless of the value of **DEMCR.MON\_EN**.

Applies to an implementation of the architecture *Armv8.1-M* onward. The extension requirements are - **DB**. Note, *S* required for Secure state.

Chapter B13. Debug  
B13.4. Debug event behavior

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| R <sub>TKRS</sub> | <p>The asynchronous debug events are:</p> <ul style="list-style-type: none"> <li>• Watchpoint debug events caused by a match in the DWT, including instruction address match watchpoints.</li> <li>• Halt request debug events, where either: <ul style="list-style-type: none"> <li>– A debugger write that has set DHCSR.C_HALT to 1 and DHCSR.C_DEBUGEN set to 1.</li> <li>– A software write that sets DHCSR.C_HALT to 1 when DHCSR.C_DEBUGEN was set to 1.</li> </ul> </li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

- External debug request debug events caused by assertion of an IMPLEMENTATION DEFINED external debug request.
- PMU Overflow caused by an overflow of a PMU counter that is configured to generate an interrupt.

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - **DB**. Note, PMU is only available in an *Armv8.1-M* implementation.

R<sub>MPMC</sub>

When **DHCSR.C\_DEBUGEN** == 0 or the PE is in a state in which halting is prohibited, **DHCSR.C\_HALT** and **DHCSR.C\_STEP** are ignored, and these bits have an **Effective value** of 0.

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - **Halting debug**.

Applies to an implementation of the architecture *Armv8.1-M* onward.

[GenerateDebugEventResponse\(\)](#).

## Halting debug

R<sub>WLCF</sub>

Setting the **DHCSR.C\_DEBUGEN** bit to 1 enables Halting debug.

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - **Halting debug**.

R<sub>JXMW</sub>

Setting the **DAUTHCTRL.UIDEN** bit to 1, enables halting debug in unprivileged state. Setting the Secure instance of this bit enables unprivileged debug in both Secure and Non-secure state.

Applies to an implementation of the architecture *Armv8.1-M* onward. The extension requirements are - **Halting debug** && **UDE**.

R<sub>RZTG</sub>

A debug event sets **DHCSR.C\_HALT** to 1 if all of the following conditions apply:

- The debug event supports generating entry to Debug state.
- **DHCSR.C\_DEBUGEN** == 1.
- Unless otherwise stated, halting is allowed.

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - **Halting debug**.

R<sub>THLS</sub>

If **DHCSR.C\_HALT** has a value of 1 and halting is allowed, the PE halts and enters Debug state.

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - **Halting debug**.

R<sub>FKWB</sub>

A debug event that sets **DHCSR.C\_HALT** to 1 pends entry to Debug state.

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - **Halting debug**.

I<sub>VBXN</sub>

A debug event might set **DHCSR.C\_HALT** and remain pending through execution in a mode or state where Halting debug is prohibited, which might not be a finite time.

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - **Halting debug**.

R<sub>HQTX</sub>

When [SecureHaltingDebugEnabled\(\)](#) returns FALSE and [HaltingDebugEnabled\(\)](#) returns TRUE, a Debug event that sets **DHCSR.C\_HALT** to 1 will cause all of the following:

- The PE to halt on transition from Secure state to Non-secure state for any of the following reasons:
  - Exception entry.

- Exception return.
- Non-secure function call.
- Function return.

- The PE will halt and enter Debug state before completing the first instruction in Non-secure state.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **Halting debug**.*

R\_VDMZ When **UnprivHaltingDebugEnabled(FALSE)** returns TRUE a debug event that sets **DHCSR.C\_HALT** to 1 will cause the PE to halt and enter Debug state on transition from a privileged mode to an unprivileged mode before completing the first instruction in unprivileged mode.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **UDE** && **Halting debug**.*

R\_XSRJ If **DHCSR.C\_HALT** has a value of 1 or **EDBGRQ** is asserted before a **Context synchronization event**, and halting is allowed after the **Context synchronization event**, then the PE halts and enters Debug state before the first instruction following the Context synchronization event completes its execution.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **Halting debug** || **EDBGRQ**.*

R\_JXQF **DFSR** is updated at the same time as the PE sets **DHCSR.C\_HALT** to 1.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **Halting debug**.*

R\_TXWB If an instruction that is being stepped or an instruction that generates a debug event reads **DFSR** or **DHCSR**, the value that is read for the relevant **DFSR** bit or for **DHCSR.C\_HALT** is UNKNOWN.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **Halting debug**.*

R\_FRJC For asynchronous debug events, if halting is allowed, the PE enters Debug state in finite time.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **Halting debug**.*

R\_VJKX Entering Debug state has no architecturally defined effect on the Event Register and exclusive monitors.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **Halting debug**.*

I\_JNGH **DHCSR.C\_SNAPSTALL** might allow imprecise entry into the Debug state, for example by forcing any stalled load or store instructions to be abandoned.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **Halting debug**.*

R\_BTBJ If **DHCSR.C\_DEBUGEN** == 0 or **HaltingDebugEnabled()** == FALSE, **DHCSR.C\_SNAPSTALL** is ignored and has an **Effective value** of 0.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **Halting debug**.*

R\_HLNF If **DHCSR.S\_SDE** == 0, **DHCSR.C\_SNAPSTALL** ignores writes from the debugger.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **Halting debug** && **S**.*

R\_CBLC If **UDE** is implemented and **DHCSR.S\_SUIDE** == 1, debugger writes to **DHCSR.C\_SNAPSTALL** are ignored.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **Halting debug** && **UDE** && **S**.*

R\_RKBK When the PE is in a state in which halting is prohibited, if **DHCSR.C\_HALT** == 1 and **DHCSR.C\_DEBUGEN** == 1, then **DHCSR.C\_HALT** remains set unless it is cleared by a direct write to **DHCSR**. If the PE enters a state in which halting is allowed while **DHCSR.C\_HALT** is set to 1, then the PE enters Debug state.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **Halting debug**.*

## Chapter B13. Debug

### B13.4. Debug event behavior

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| R <sub>VFLQ</sub> | For asynchronous debug events, if taken as a DebugMonitor exception, and if the current priority is lower than the DebugMonitor exception group priority, a DebugMonitor exception is taken in finite time.<br><br><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">M</a>.</i>                                                                                             |
| R <sub>JVSC</sub> | A direct write to <a href="#">DEMCR</a> can set <a href="#">DEMCR.MON_PEND</a> to 1 at any time to make the DebugMonitor exception pending or can set <a href="#">DEMCR.MON_PEND</a> to 0 to remove a pending DebugMonitor exception.<br><br><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">M</a>.</i>                                                                   |
| R <sub>XPBN</sub> | When <a href="#">DEMCR.MON_PEND</a> == 1, the PE takes the DebugMonitor exception according to the exception prioritization rules, regardless of the value of <a href="#">DEMCR.SDME</a> and <a href="#">DEMCR.MON_EN</a> .<br><br><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">M</a>.</i>                                                                             |
| R <sub>NVQT</sub> | From Armv8.1 when <a href="#">DEMCR.MON_PEND</a> == 1, the PE takes the DebugMonitor exception according to the exception prioritization rules, regardless of the value of <a href="#">DEMCR.SDME</a> , <a href="#">DEMCR.MON_EN</a> and <a href="#">DEMCR.UMON_EN</a> .<br><br><i>Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - <a href="#">M</a> &amp;&amp; <a href="#">UDE</a>.</i> |
| R <sub>QZHW</sub> | Unless otherwise stated, synchronous and asynchronous DebugMonitor exceptions can only cause preemption at instruction boundaries.<br><br><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">M</a>.</i>                                                                                                                                                                      |
| R <sub>TMNT</sub> | For beat-wise executable instructions, synchronous and asynchronous DebugMonitor exceptions can cause preemption at either beat or instruction boundaries.<br><br><i>Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - <a href="#">MVE</a>.</i>                                                                                                                                            |
| I <sub>PJJJ</sub> | DebugMonitor exceptions on their own cannot cause instruction resume or instruction restart. However, if another exception preempts an execution-continuable instruction, then the PE might take that exception along with DebugMonitor exception as a tail-chained or late-arriving exception.<br><br><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">M</a>.</i>         |

### B13.4.2 Debug stepping

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| R <sub>HMCN</sub> | The Armv8-M architecture supports debug stepping in both Halting debug and for the DebugMonitor exception.<br><br><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">Halting debug</a>    <a href="#">M</a>.<br/>Note, might require the DebugMonitor exception.</i>                                                                                                                                                                                               |
| R <sub>THTG</sub> | It is IMPLEMENTATION DEFINED whether stepping a <a href="#">WFE</a> or <a href="#">WFI</a> instruction causes the <a href="#">WFE</a> or <a href="#">WFI</a> instruction to: <ul style="list-style-type: none"><li>• Retire and take the debug event.</li><li>• Go into a sleep state and take the debug event only when another wake up event occurs.</li></ul><br><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">Halting debug</a>    <a href="#">M</a>.</i> |
| R <sub>LLVC</sub> | If a debug event wakes a <a href="#">WFE</a> or <a href="#">WFI</a> instruction, then on taking the debug event, the instruction has retired.<br><br><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">Halting debug</a>    <a href="#">M</a>.</i>                                                                                                                                                                                                                |

**I<sub>ZLPK</sub>** If the PE exits from a sleep state due to an asynchronous debug event the PE will perform all of the following before halting the PE:

- Complete the exception return, including the consumption of the Stack frame.
- Clear the exclusive monitor state.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **Halting debug** || **M**.*

**I<sub>CMYW</sub>** The debug architecture includes support for stepping over vector instructions.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **MVE**.*

See also:

[Halting debug stepping.](#)

[Debug monitor stepping.](#)

## Halting debug stepping

**I<sub>QMXC</sub>** A debugger can use Halting debug stepping to exit from Debug state, execute a single instruction, and then reenter Debug state.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **Halting debug**.*

**R<sub>SWKC</sub>** Halting debug stepping is active when all of the following apply:

- **DHCSR.C\_DEBUGEN** is set to 1, Halting debug is enabled, and halting is allowed.
- **DHCSR.C\_STEP** is set to 1, halting stepping is enabled.
- The PE is in Non-debug state.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **Halting debug**.*

**R<sub>ZVKS</sub>** When the PE exits Debug state and Halting debug stepping becomes active, the PE performs a Halting debug step as follows:

1. Performs one of the following:
  - Completes the next instruction without generating any exception.
  - Takes any pending exception entry of sufficient priority, without completing the next instruction. The PE performs an exception entry sequence that stacks the next instruction context. This context might include instruction continuation bits if the next instruction was partly executed and supports instruction resume. The exception might be a pending exception, or an exception generated by the execution of the next instruction. Taking a pending exception might include entry to [Lockup](#).
  - Completes the execution of the next instruction, and then takes any pending exception of sufficient priority. The PE performs an exception entry sequence that stacks the following instruction context. Taking an exception might include entry to [Lockup](#).
  - If the next instruction is an exception return instruction, completes the next instruction, tail-chaining to enter a new exception handler. In each case where the PE performs an exception entry sequence it does so according to the exception priority and late-arrival rules, meaning derived and late-arriving exceptions might preempt the exception entry sequence. If the PE enters [Lockup](#) as a consequence of step one the PE will resolve the Lockup signal before halting the PE. The exception behavior is not recursive. Only a single [PushStack\(\)](#) update can occur in a step sequence.
2. Sets **DFSR.HALTED** and **DHCSR.C\_HALT** to 1. A read of the **DFSR.HALTED** or the **DHCSR.C\_HALT** bit performed by the stepped instruction returns an UNKNOWN value.
3. After the Halting debug step, before executing the following instruction, because **DHCSR.C\_HALT** is set the PE will halt and enter Debug state if halting is still allowed. However, if halting is prohibited after the Halting debug step then the PE does not enter Debug state and **DHCSR.C\_HALT** remains set.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **Halting debug**.*

R<sub>LJJB</sub>

If the implementation includes the Armv8.1-M profile Vector Extension, a Halting debug step has the following additional possible actions when stepping over vector instructions. The PE:

- Attempts to complete the execution of all in-flight vector instructions, does not execute any new instructions, and generates a synchronous exception that is taken.
- Completes the execution of all in-flight vector instructions, does not start the execution of new instructions, and does not generate an exception.
- Completely executes the next vector instruction, without overlapping execution, and does not generate an exception.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **Halting debug** && **MVE**.*

I<sub>LTRX</sub>

The debugger can optionally set **DHCSR.C\_MASKINTS** to 1 to prevent PENDSV, SysTick, and external interrupts from being taken. If a permitted exception becomes active, the PE steps into the exception handler and halts before executing the first instruction of the associated exception handler.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **Halting debug**.*

R<sub>NSMR</sub>

**DHCSR.C\_MASKINTS** is ignored and has an **Effective value** of 0 if any of the following are true:

- **HaltingDebugEnabled()** returns FALSE.
- **DHCSR.C\_DEBUGEN** is 0.
- The exception is Secure and **DHCSR.S\_SDE** is 0.
- UDE is implemented, the exception is Secure and **DHCSR.S\_SUIDE** is 1.
- UDE is implemented and **DHCSR.S\_NSUIDE** is 1.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **Halting debug**. Note, S is required for Secure state, and UDE is only available in an Armv8.1-M implementation.*

R<sub>MBCB</sub>

**DHCSR**.{C\_HALT, C\_STEP, C\_MASKINTS} can be written in a single write to **DHCSR**, as follows:

| <b>DHCSR write</b>                                                                                                        |               |                   |                                                                                                                                                                                                     |
|---------------------------------------------------------------------------------------------------------------------------|---------------|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| assumes that <b>DHCSR.C_DEBUGEN</b> and <b>DHCSR.S_HALT</b> are both set to 1 when the write occurs and the PE is halted. |               |                   |                                                                                                                                                                                                     |
| <b>C_HALT</b>                                                                                                             | <b>C_STEP</b> | <b>C_MASKINTS</b> | <b>Effect</b>                                                                                                                                                                                       |
| 0                                                                                                                         | 0             | 0                 | Exit Debug state and start instruction execution.<br>Exceptions can become active and prioritized according to the priority rules and the configuration of exceptions.                              |
| 0                                                                                                                         | 0             | 1                 | Exit Debug state and start instruction execution.<br>PendSV, SysTick and, external interrupts are disabled, otherwise exceptions can become active and prioritized according to the priority rules. |
| 0                                                                                                                         | 1             | 0                 | Exit Debug state, step an instruction and halt.<br>Exceptions can become active and prioritized according to the priority rules.                                                                    |
| 0                                                                                                                         | 1             | 1                 | Exit Debug state, step an instruction and halt.<br>PendSV, SysTick and, external interrupts are disabled, otherwise exceptions can become active and prioritized according to the priority rules.   |
| 1                                                                                                                         | X             | X                 | Remain in Debug state.                                                                                                                                                                              |

The write to **DHCSR** assumes that the PE is halted when the write occurs and the write is not UNPREDICTABLE.

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - **Halting debug**.

## Debug monitor stepping

I<sub>DXCT</sub>

A debugger can use debug monitor stepping to return from the DebugMonitor exception handler, execute a single instruction, and then reenter the DebugMonitor exception handler.

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - **DebugMonitor exception**.

R<sub>MLRM</sub>

Debug monitor stepping is active when all of the following apply:

- **DHCSR.C\_DEBUGEN** is set to 0 or the PE is in a state in which halting is prohibited.
- **DEMCR.MON\_EN** is set to 1, that is Monitor debug is enabled.
- **DEMCR.MON\_STEP** is set to 1, that is monitor stepping is enabled.
- **DEMCR.SDME** == 1 or the PE is in Non-secure state.
- Execution priority is below the priority of the DebugMonitor exception.

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - **M**.

R<sub>MJCF</sub>

From Armv8.1-M Debug monitor stepping is active when all of the following apply:

- **DHCSR.C\_DEBUGEN** is set to 0 or the PE is in a state in which halting is prohibited.
- **DEMCR.MON\_EN** is set to 1, or **DEMCR.UMON\_EN** is set to 1 and the instruction is executed in unprivileged mode, that is Monitor debug is enabled.
- **DEMCR.MON\_STEP** is set to 1, that is monitor stepping is enabled.
- **DEMCR.SDME** == 1 or the PE is in Non-secure state.
- Execution priority is below the priority of the DebugMonitor exception.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - M && UDE.*

R<sub>MWFT</sub>

When DebugMonitor stepping becomes active, the PE performs a DebugMonitor step as follows:

1. It performs one of the following:

- It completes the next instruction without generating any exception.
- It takes any pending exception of sufficient priority. The PE performs an exception entry sequence that stacks the next instruction context. The exception might be a pending exception, or it might be an exception generated by the execution of the next instruction. Taking a pending exception might include entry to [Lockup](#).
- If the next instruction is an exception return instruction, the PE completes the next instruction, tail-chaining to enter a new exception handler according to the normal exception priority and late-arrival rules.

If the PE performs an exception entry sequence as part of step 1, the PE stacks the next instruction context. This context might include instruction continuation bits if the next instruction was partly executed and supports instruction resume.

If the PE enters [Lockup](#) as a consequence of step one the PE will resolve the Lockup signal before entering the DebugMonitor exception if the DebugMonitor exception has sufficient priority to pre-empt execution after Lockup has been resolved.

2. If the execution priority is below the priority of the DebugMonitor exception after step 1, the PE sets [DEMCR.MON\\_PEND](#) and [DFSR.HALTED](#) to 1. A read of [DEMCR.MON\\_PEND](#) or [DFSR.HALTED](#) by the stepped instruction returns an UNKNOWN value.

3. Before executing the following instruction, the PE takes any pending exception with sufficient priority.

If step 2 set [DEMCR.MON\\_PEND](#) to 1, then the DebugMonitor exception is pending. However, it is UNPREDICTABLE whether the PE uses the new value or the old value of [DEMCR.MON\\_PEND](#) in determining the highest priority exception. This means that:

- Another exception might preempt execution before the DebugMonitor exception is taken, and the exception might be lower priority than the DebugMonitor exception. However, this is a [Context synchronization event](#) and the PE uses the new value of [DEMCR.MON\\_PEND](#) to determine the highest priority exception before executing the next instruction. This includes entry into [Lockup](#).
- If no other exceptions are pending, the PE takes the DebugMonitor exception.

Derived and late-arriving exceptions might preempt the exception entry sequence.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - M.*

R<sub>JKJM</sub>

If the implementation includes the Armv8.1-M profile Vector Extension, a Debug monitor step has the following additional possible actions when stepping over vector instructions. The PE:

- Attempts to complete the execution of all in-flight vector instructions, does not execute any new instructions, and generates a synchronous exception that is taken.
- Completes the execution of all in-flight vector instructions, does not start the execution of new instructions, and does not generate an exception.
- Completely executes the next vector instruction, without overlapping execution, and does not generate an exception.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - M && MVE.*

I<sub>GPSX</sub>

In all other cases, the DebugMonitor exception preempting execution returns control to the DebugMonitor exception handler. Unless that handler clears [DEMCR.MON\\_STEP](#) to 0, returning from the handler performs the next debug monitor step.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - M.*

**I<sub>KPKX</sub>** If, after the debug monitor stepping process, the taking of an exception means that the execution priority is no longer below that of the DebugMonitor exception, the values of **DEMCR.MON\_STEP** and **DEMCR.MON\_PEND** mean that debug monitor stepping process continues when execution priority falls back below the priority of the DebugMonitor exception.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **M**.*

See also:

**DHCSR**.

### B13.4.3 Vector catch

**I<sub>TVRX</sub>** Vector catch is the mechanism for generating a debug event and entering Debug state on entry to a particular exception handler or reset.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **M**.*

**R<sub>JCXR</sub>** Vector catching is only supported by Halting debug.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **Halting debug**.*

**R<sub>PBVX</sub>** The conditions for a vector catch, other than reset vector catch, are:

- **DHCSR.C\_DEBUGEN** == 1 and halting is allowed for the Security state the exception is targeting.
- The associated exception enable bit is set.
- The associated active bit is set.
- The associated vector catch enable bit.
- An exception is taken to the relevant exception handler. The associated fault status register status bit is set to 1.

When these conditions are met, the PE sets **DHCSR.C\_HALT** to 1 and enters Debug state before executing the first instruction of the exception handler.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **Halting debug**. Note, If the Main Extension is not implemented only bits [24],[10] and [0] of **DEMCR** are implemented with Halting debug functionality. SecureFault requires S.*

**I<sub>XDGP</sub>** Late arrival and derived exceptions might occur, preempting the exception targeted by the vector catch and postponing when the PE halts.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **Halting debug**.*

**R<sub>XKMH</sub>** The following table defines the exception, Fault status bit, and Vector catch bit.

| Exception       | Fault status bit | Vector catch bit<br>DEMCR |
|-----------------|------------------|---------------------------|
| HardFault       | HFSR.VECTTBL     | VC_INTERR                 |
|                 | HFSR.FORCED      | VC_HARDERR                |
|                 | HFSR.DEBUGEVT    | VC_HARDERR                |
| BusFault        | BFSR.IBUSERR     | VC_BUSERR                 |
|                 | BFSR.PRECISERR   | VC_BUSERR                 |
|                 | BFSR.IMPRESISERR | VC_BUSERR                 |
|                 | BFSR.UNSTKERR    | VC_INTERR                 |
|                 | BFSR.STKERR      | VC_INTERR                 |
|                 | BFSR.LSPERR      | VC_INTERR                 |
| DebugMonitor    | HFSR.DEBUGEVT    | -                         |
| MemManage fault | MMFSR.IACCVIOL   | VC_MMERR                  |
|                 | MMFSR.DACCVIOL   | VC_MMERR                  |
|                 | MMFSR.MUNSTKERR  | VC_INTERR                 |
|                 | MMFSR.MSTKERR    | VC_INTERR                 |
|                 | MMFSR.MLSPERR    | VC_INTERR                 |
| NMI             | -                | -                         |
| PENDSV          | -                | -                         |
| UsageFault      | UFSR.UNDEFINSTR  | VC_STATERR                |
|                 | UFSR.INVSTATE    | VC_STATERR                |
|                 | UFSR.INVPC       | VC_STATERR                |
|                 | UFSR.NOCP        | VC_NOCPERR                |
|                 | UFSR.STKOF       | VC_INTERR                 |
|                 | UFSR.UNALIGNED   | VC_CHKERR                 |
|                 | UFSR.DIVBYZERO   | VC_CHKERR                 |
| SecureFault     | SFSR.INVEP       | VC_SFERR                  |
|                 | SFSR.INVIS       | VC_SFERR                  |
|                 | SFSR.INVER       | VC_SFERR                  |
|                 | SFSR.AUVIOL      | VC_SFERR                  |
|                 | SFSR.INVTRAN     | VC_SFERR                  |
|                 | SFSR.LSPERR      | VC_SFERR                  |
|                 | SFSR.LSERR       | VC_SFERR                  |
| SVCall          | -                | -                         |
| SysTick         | -                | -                         |

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - *M*.

**R<sub>LKNL</sub>** When **DHCSR.C\_DEBUGEN** == 0 or the PE is in a state in which halting is prohibited, all **DEMCR.VC\_** bits, other than **DEMCR.VC\_CORERESET**, are ignored.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **Halting debug** && **S**.*

**R<sub>VZDB</sub>** If the PE resets into Secure state when both of:

- **DHCSR.C\_DEBUGEN** == 1
- **DEMCR.VC\_CORERESET** == 1

The PE will pend a Halt request and will halt and enter into Debug state when halting is permitted, setting **DFSR.VCATCH** to 1.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **Halting debug** && **S**.*

**R<sub>WRMQ</sub>** The PE pends a Vector catch event when all of the following is true:

- The PE has reset into Secure state.
- **DHCSR.C\_DEBUGEN** == 1.
- **DEMCR.VC\_CORERESET** == 1.
- Halting debug is not allowed in Secure state.

The PE does not halt until either it enters Non-secure state or debug is allowed in Secure state.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **Halting debug** && **S**.*

**R<sub>MSWM</sub>** If UDE is implemented and all of the following are true:

- **DHCSR.C\_DEBUGEN** == 1,
- **DEMCR.VC\_CORERESET** == 1,
- **UnprivHaltingDebugEnabled(FALSE)** returns TRUE,
- The PE resets into Secure state,

The PE will pend a Vector Catch debug event, if debug is prohibited in Secure state, and does not halt until either the PE enters Non-secure state or debug is permitted in Secure state.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **Halting debug** && **UDE**.*

## B13.4.4 Breakpoint instructions

**R<sub>CRJG</sub>** When **DHCSR.C\_DEBUGEN** == 0 or when the PE is in a state in which halting is prohibited, the **BKPT** instruction does not generate an entry to Debug state. If no DebugMonitor exception is generated, the **BKPT** instruction generates a HardFault exception or enters Lockup state.

*Applies to an implementation of the architecture Armv8.0-M onward.*

- R<sub>NXTW</sub>** A **BKPT** instruction halts the PE if either of the following cases are true:
1. **HaltingDebugAllowed()** returns TRUE and the following are true:
    - **DHCSR.C\_DEBUGEN** is set to 1.
    - The PE is not halted.
    - If the Security extension is implemented and the PE is executing in Secure state all of the following are true:
      - **DHCSR.S\_SDE** is set to 1.
      - UDE is not implemented or **DHCSR.S\_SUIDE** is set to 0.
  2. **HaltingDebugAllowed()** returns FALSE and all of the following are true:
    - UDE is implemented and the PE is executing Non-secure state and unprivileged mode and **DHCSR.S\_NSUIDE** is set to 1.
    - UDE is implemented and the PE is executing in Secure state and unprivileged mode and **DHCSR.S\_SUIDE** is set to 1.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **Halting debug** && **UDE**.*

- R<sub>ZJLD</sub>** A **BKPT** instruction generates a DebugMonitor exception if it does not halt the PE and all of the following conditions apply:
- The DebugMonitor exception priority is greater than the current execution priority.
  - The Security Extension is not implemented, the instruction is executed in Non-secure state, or **DEMCR.SDME** == 1.
  - One of the following conditions apply:
    - **DEMCR.MON\_EN** == 1
    - The Unprivileged Debug Extension is implemented, **DEMCR.UMON\_EN** == 1, and the instruction is executed in unprivileged mode.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **M** && **UDE**.*

## B13.4.5 External debug request

- R<sub>XZCP</sub>** When the PE is in Non-debug state, an external agent can signal an external debug request.
- Applies to an implementation of the architecture Armv8.0-M onward.*
- R<sub>GTGX</sub>** An external debug request can cause a debug event, that causes either:
- Entry to Debug state.
  - If the Main Extension is implemented, a DebugMonitor exception.
- Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **M** || **Halting debug**.*
- R<sub>FGCV</sub>** The PE ignores external debug requests when it is in Debug state.
- Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **Halting debug**.*
- R<sub>BXRD</sub>** When **DHCSR.C\_DEBUGEN** == 0 or the PE is in a state in which halting is prohibited, an External debug request does not generate an entry to Debug state and is ignored if no DebugMonitor exception is generated.
- Applies to an implementation of the architecture Armv8.0-M onward.*
- R<sub>BNBR</sub>** An External debug request that does not halt the PE will set **DEMCR.MON\_PEND** to 1 if all of the following are true:
- The DebugMonitor exception is enabled. That is if either or the following are true:

- DEMCR.MON\_EN is set to 1.
- DEMCR.UMON\_EN is set to 1 and the PE is executing in unprivileged mode.

- The priority of the DebugMonitor exception is sufficient to preempt the current execution priority.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - M && UDE.*

$I_{FSTF}$  R<sub>BNBR</sub> describes the conditions in which DEMCR.MON\_PEND will be set on the assertion of an External debug request. R<sub>KQTP</sub> and R<sub>RVXG</sub> set the bounds of the timing for when DEMCR.MON\_PEND will be set, so that privileged software can update DEMCR.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - M.*

R<sub>KQTP</sub> In the absence of a Context synchronization event an External debug request that does not cause the PE to halt will set DEMCR.MON\_PEND to 1 in finite time.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - M.*

R<sub>RVXG</sub> A Context synchronization event is sufficient to ensure that an External debug request has set DEMCR.MON\_PEND for the context being switched away from.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - M.*

## B13.5 Debug state

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| R <sub>RMKS</sub> | <p>In Halting debug, debug events allow an external debugger to halt the PE. The PE then enters Debug state. When the PE is in Debug state:</p> <ul style="list-style-type: none"> <li>• The PE stops executing instructions from the location indicated by the PC, and is instead controlled by the external debug interface.</li> <li>• The PE cannot service any interrupts.</li> </ul> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <b>Halting debug</b>.</i></p>                                                                                                                                                                                                                                                                 |
| R <sub>QDCP</sub> | <p>In Debug state, the PE clears the <b>DHCSR.S_REGRDY</b> bit to 0 when the debugger writes to <b>DCRSR</b> and the PE then sets the bit to 1 when the transfer between the <b>DCRDR</b> and R0-R12 (<b>Rn</b>), Special-purpose register, Floating-point Extension register, or DebugReturnAddress completes.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <b>Halting debug</b>. Note, Floating-point registers are RES0 if FP is not implemented.</i></p>                                                                                                                                                                                                                                                                      |
| I <sub>FKSM</sub> | <p>To transfer a word to a general-purpose register, to a Special-purpose register, to a Floating-point Extension register, or to DebugReturnAddress, a debugger:</p> <ol style="list-style-type: none"> <li>1. Writes the required word to <b>DCRDR</b>.</li> <li>2. Writes to the <b>DCRSR</b>, with the REGSEL value indicating the required register, and the REGWnR bit set to 1 to indicate a write access. This clears the <b>DHCSR.S_REGRDY</b> bit to 0.</li> <li>3. If required, polls <b>DHCSR</b> until <b>DHCSR.S_REGRDY</b> reads-as-one. This shows that the PE has transferred the <b>DCRDR</b> value to the selected register.</li> </ol> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <b>Halting debug</b>.</i></p> |
| I <sub>CMBB</sub> | <p>To transfer a word from a general-purpose register, from a Special-purpose register, from a Floating-point Extension register, or from DebugReturnAddress, a debugger:</p> <ol style="list-style-type: none"> <li>1. Writes to <b>DCRSR</b>, with the REGSEL value indicating the required register, and the REGWnR bit as 0 to indicate a read access. This clears the <b>DHCSR.S_REGRDY</b> bit to 0.</li> <li>2. Polls <b>DHCSR</b> until <b>DHCSR.S_REGRDY</b> reads-as-one. This shows that the PE has transferred the value of the selected register to <b>DCRDR</b>.</li> <li>3. Reads the required value from <b>DCRDR</b>.</li> </ol> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <b>Halting debug</b>.</i></p>          |
| R <sub>VLVD</sub> | <p>In Debug state, following a write to <b>DCRSR</b> that clears the <b>DHCSR.S_REGRDY</b> bit to 0, the behavior is UNPREDICTABLE if any of the following occur before the PE sets <b>DHCSR.S_REGRDY</b> to 1:</p> <ul style="list-style-type: none"> <li>• The PE exits Debug state, other than because of a Warm reset.</li> <li>• The debugger writes to <b>DCRDR</b> or <b>DCRSR</b>.</li> </ul> <p>If the <b>DCRSR.REGWnR</b> bit was set to 0 and the debugger reads from <b>DCRDR</b> before the PE sets <b>DHCSR.S_REGRDY</b> to 1, then the read returns an UNKNOWN value.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <b>Halting debug</b>.</i></p>                                                                   |
| R <sub>JKBB</sub> | <p>When using the <b>DCRDR</b>, <b>DCRSR</b> and <b>DHCSR.S_REGRDY</b> mechanism to write to <b>XPSR</b>, all bits of the <b>XPSR</b> are fully accessible. The effect of writing an illegal value is UNPREDICTABLE.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <b>Halting debug</b>.</i></p>                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| I <sub>RXQB</sub> | <p>The <b>DCRDR</b>, <b>DCRSR</b> and <b>DHCSR.S_REGRDY</b> mechanism differs from the behavior of <b>MSR</b> or <b>MRS</b> instruction accesses to the <b>XPSR</b>, where some bits are ignored on writes.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <b>Halting debug</b>.</i></p>                                                                                                                                                                                                                                                                                                                                                                                                                                            |

Applies to an implementation of the architecture *Armv8.1-M* onward. The extension requirements are - *PACBTI* && *Halting debug* && *UDE* && *S*.

See also:

*DCRDR*, Debug Core Register Data Register.

*DCRSR*, Debug Core Data Select Register.

`DebugRegisterTransfer()`

Applies to an implementation of the architecture *Armv8.1-M* onward.

## B13.6 Exiting Debug state

R<sub>BFGT</sub>

The PE exits Debug state:

- When the debugger writes 0 to [DHCSR.C\\_HALT](#).
- On receipt of an external restart request.
- On Warm reset.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [Halting debug](#).*

R<sub>GGMJ</sub>

For synchronous debug events DebugReturnAddress is:

| Synchronous debug event                                      | DebugReturnAddress                                                                                                                                                                                                                 |
|--------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Breakpoint debug events ( <a href="#">BKPT</a> or FPB Match) | Address of the breakpointed instruction.                                                                                                                                                                                           |
| Vector Catch debug events                                    | Address of the first instruction of the exception handler.                                                                                                                                                                         |
| Step debug events                                            | Address of the next instruction to be executed in simple sequential execution order following the instruction that was stepped. If an exception was taken during stepping, this is the first instruction of the exception handler. |

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [Halting debug](#).*

R<sub>XCCB</sub>

Bit[0] of a DebugReturnAddress value is RAZ/SBZ. When writing a DebugReturnAddress, writing bit [0] of the address does not affect the [EPSR.T](#) bit.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [Halting debug](#).*

R<sub>HNKB</sub>

Exiting Debug state has no architecturally defined effect on the Event Register and exclusive monitors.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [Halting debug](#).*

R<sub>WKSD</sub>

If software clears [DHCSR.C\\_HALT](#) to 0 when the PE is in Debug state, a subsequent read of the [DHCSR](#) that returns 1 for both [DHCSR.C\\_HALT](#) and [DHCSR.S\\_HALT](#) indicates that the PE has reentered Debug state because it has detected a new debug event.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [Halting debug](#).*

R<sub>FKXH</sub>

Before leaving Debug state caused by an imprecise entry into Debug state the system is reset.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [Halting debug](#).*

[B13.5 Debug state](#)

## B13.7 Multiprocessor support

**R<sub>QXLS</sub>** Systems that support debug of more than one PE, either within a single device or as heterogeneous PEs in a more complex system, require each PE to support all of the following to enable cross-triggering of debug events between PEs:

- An external debug request.
- A cross-halt event.
- An external restart request.

Support for these features is OPTIONAL in other systems.

*Applies to an implementation of the architecture Armv8.0-M onward.*

### B13.7.1 Cross-halt event

**R<sub>DLCV</sub>** When the PE enters Debug state, it signals to an external agent that it is entering Debug state.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [Halting debug](#).*

### B13.7.2 External restart request

**R<sub>ZKVV</sub>** When the PE is in Debug state, an external agent can signal an external restart request that causes the PE to exit Debug state.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [Halting debug](#).*

**R<sub>WJST</sub>** An external restart request is not ordered with respect to accesses to memory-mapped registers. It is UNPREDICTABLE whether an access to a memory-mapped register from a DAP completes before an external restart request.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [Halting debug](#).*

**I<sub>VNDK</sub>** A debugger ensures that any read or write of a memory-mapped register by the DAP completes before issuing an external restart request.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [DB](#).*

**R<sub>NJQN</sub>** The PE ignores external restart requests when it is in Non-debug state.

*Applies to an implementation of the architecture Armv8.0-M onward.*

## Chapter B14

# Debug and Trace Components

This chapter specifies the Armv8-M debug and trace component rules. It contains the following sections:

*B14.1 Instrumentation Trace Macrocell.*

*B14.2 Data Watchpoint and Trace unit.*

*B14.3 Embedded Trace Macrocell.*

*B14.4 Trace Port Interface Unit.*

*B14.5 Flash Patch and Breakpoint unit.*

## B14.1 Instrumentation Trace Macrocell

### B14.1.1 About the ITM

**R<sub>GDNG</sub>** The *Instrumentation Trace Macrocell* (ITM) provides a memory-mapped register interface that applications can use to generate Instrumentation packets.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **ITM**.*

**I<sub>BXWJ</sub>** The ITM is only available if the Main Extension is implemented.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **ITM**.*

**R<sub>LMXS</sub>** The ITM generates Instrumentation packets, Synchronization packets, and the following protocol packets:

- Overflow packets.
- Local timestamp packets.
- Global timestamp packets.
- Extension packets.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **ITM**.*

**R<sub>XQRX</sub>** The ITM combines the following packets into a single trace stream:

- Instrumentation packets.
- Synchronization packets.
- Protocol packets.
- Hardware source packets that are generated by the DWT.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **ITM**.*

**R<sub>MXMN</sub>** If the implementation includes the PMU, the PMU Hardware source packets are included in the single trace stream.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **ITM** && **PMU**.*

**I<sub>FQLR</sub>** The following figure shows how the ITM relates to other debug components.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **ITM**.*

**R<sub>BWJJ</sub>** When multiple sources are generating data at the same time, the ITM arbitrates using the following priorities:

**Synchronization, when required:** Priority level -1, highest.

**Instrumentation:** Priority level 0.

**Hardware source:** Priority level 1.

**Local timestamps:** Priority level 2.

**Global timestamp 1:** Priority level 3.

**Global timestamp 2:** Priority level 4.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [ITM](#).*

[ITM and DWT Packet Protocol Specification.](#)

## B14.1.2 ITM operation

R<sub>NKSC</sub>

The ITM consists of:

- Up to 256 stimulus port registers, [ITM\\_STIMn](#).
- Up to eight enable registers, [ITM\\_TERN](#).
- An access control register, [ITM\\_TPR](#).
- A general control register, [ITM\\_TCR](#).

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [ITM](#).*

R<sub>MFDV</sub>

The number of [ITM\\_STIMn](#) registers is an IMPLEMENTATION DEFINED multiple of eight. Software can discover the number of supported stimulus ports by writing all ones to the [ITM\\_TPR](#), and then reading how many bits are set to 1.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [ITM](#).*

R<sub>CGVD</sub>

If the ITM is disabled or not implemented, any Secure or Non-secure write to [ITM\\_STIMn](#) is ignored.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [ITM](#) && [S](#).*

R<sub>NJTR</sub>

Unprivileged and privileged software can always read all ITM registers.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [ITM](#).*

R<sub>FFXF</sub>

If the ITM is not implemented, the ITM registers are RAZ/WI.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [ITM](#).*

R<sub>CSFV</sub>

The [ITM\\_TPR](#) defines whether each group of eight [ITM\\_STIMn](#) registers, and their corresponding [ITM\\_TERN](#) bits, can be written by an unprivileged access.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [ITM](#).*

R<sub>PTXV</sub>

[ITM\\_STIMn](#) registers are 32-bit registers that support the following word-aligned accesses:

- Byte accesses, to access register bits[7:0].
- Halfword accesses, to access register bits[15:0].
- Word accesses, to access register bits[31:0].

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [ITM](#).*

R<sub>LNMW</sub>

Non-word-aligned accesses are UNPREDICTABLE.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [ITM](#).*

R<sub>NQVK</sub>

[ITM\\_TCR.ITMENA](#) is a global enable bit for the ITM. A Cold reset clears this bit to 0, disabling the ITM.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [ITM](#).*

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| R <sub>VRGP</sub> | <p>The <b>ITM_TERN</b> registers provide an enable bit for each stimulus port.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <b>ITM</b>.</i></p>                                                                                                                                                                                                                                                                                     |
| R <sub>NTCR</sub> | <p>When software writes to an enabled <b>ITM_STIMn</b> register, the ITM combines the identity of the port, the size of the write access, and the data that is written, into an Instrumentation packet that it writes to a stimulus port output buffer. The ITM transmits packets from the output buffer to a trace sink.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <b>ITM</b>.</i></p>                                          |
| R <sub>XPRK</sub> | <p>If an ITM implementation supports more than 32 stimulus ports, paging is used to indicate the stimulus port number. The stimulus port number is defined by the A field of the Instrumentation packet, byte 0 bits [7:3].</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <b>ITM</b>.</i></p>                                                                                                                                        |
| R <sub>QBCH</sub> | <p>An Extension packet is issued to define the page number, 0 to 7, with each subsequent Instrumentation packet.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <b>ITM</b>.</i></p>                                                                                                                                                                                                                                                   |
| R <sub>HWBQ</sub> | <p>Whenever a debugger receives an Instrumentation packet, it uses the the page number from the last Extension packet received, or a page number of 0 if the debugger has not received an Extension packet since the debugger last received a Synchronization packet.</p> <p><i>Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - <b>ITM</b>.</i></p>                                                                                              |
| R <sub>LBSR</sub> | <p>The ITM does not generate trace if <b>DEMCR.TRCENA</b> == 0 and either of the following are true:</p> <ul style="list-style-type: none"> <li>• <b>NoninvasiveDebugEnabled()</b> == FALSE and the PE is in Non-secure state.</li> <li>• <b>SecureNoninvasiveDebugEnabled()</b> == FALSE and the PE is in Secure state.</li> </ul> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <b>ITM</b>. Note, S required for Secure state.</i></p> |

The extension requirements are - <a href="#">ITM</a>.</i></p>                                                                                                                                                                                                                                                                                                                                                                                                                |
| R <sub>TSXR</sub> | <p>If periodic flushing is required, the ITM flushes trace data:</p> <ul style="list-style-type: none"> <li>• When a Synchronization packet is generated.</li> <li>• When trace is disabled, meaning that either <a href="#">DEMCR.TRCENA</a> is cleared to 0 or one or more of <a href="#">ITM_TCR.{TXENA, SYNCENA, TSENA, SYNCENA}</a> is cleared to 0, and the buffered trace includes at least one corresponding packet type.</li> <li>• In response to other IMPLEMENTATION DEFINED flush requests from the system.</li> </ul> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">ITM</a>.</i></p> |

**R<sub>MKFS</sub>** If a system supports multiple trace streams, the debugger writes a unique nonzero trace ID value to the **ITM\_TCR.TraceBusID** field. The system uses this value to identify the individual trace streams. To avoid trace stream corruption, before modifying the **ITM\_TCR.TraceBusID** a debugger does the following:

- It clears the **ITM\_TCR.ITMENA** bit to 0, to disable the ITM.
- It polls the **ITM\_TCR.BUSY** bit until it returns to 0, indicating that the ITM is inactive.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **ITM**.*

### B14.1.3 Timestamp support

**R<sub>RVL</sub>** Timestamps provide information on the timing of event generation regarding their visibility at a trace output port.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **ITM**.*

**R<sub>TFDG</sub>** An Armv8-M PE can implement either or both of the following types of timestamp:

- Local timestamps.
- Global timestamps.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **ITM**.*

#### Local timestamping

**R<sub>RMX</sub>** Local timestamps provide delta timestamp values, meaning each local timestamp indicates the elapsed time since generating the previous local timestamp.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **ITM**.*

**R<sub>WBG</sub>** The ITM generates the local timestamps from the timestamp counter in the ITM unit.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **ITM**.*

**R<sub>XLBH</sub>** The timestamp counter size is an IMPLEMENTATION DEFINED value that is less than or equal to 28 bits.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **ITM**.*

**R<sub>GPXT</sub>** It is IMPLEMENTATION DEFINED whether the ITM supports synchronous clocking of the timestamp counter mode.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **ITM**.*

**R<sub>SRJH</sub>** It is IMPLEMENTATION DEFINED whether the ITM and TPIU support asynchronous clocking of the timestamp counter mode.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **ITM**.*

**R<sub>GHP</sub>** **ITM\_TCR.TSENA** enables Local timestamp packet generation.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **ITM**.*

**R<sub>FSWG</sub>** When local timestamping is enabled and the DWT or ITM transfers a Hardware source or instrumentation trace packet to the appropriate output FIFO, and the timestamp counter is nonzero, the ITM:

- Generates a Local timestamp packet.
- Resets the timestamp counter to zero.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **ITM**.*

**R<sub>BRL</sub>** If the timestamp counter overflows, it continues counting from zero and the ITM generates an Overflow packet and transmits an associated Local timestamp packet at the earliest opportunity. If higher priority trace packets delay transmission of this Local timestamp packet, the timestamp packet has the appropriate nonzero local timestamp value.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **ITM**.*

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| R <sub>RMTN</sub> | If the implementation supports division of the incoming asynchronous clock signal, <a href="#">ITM_TCR.TSPrescale</a> sets the prescaler divide value.<br><br><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">ITM</a>.</i>                                                                                                                                                  |
| R <sub>SKCP</sub> | Software only selects asynchronous clocking when the TPIU is configured to use an output mode that supports asynchronous clocking.<br><br><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">ITM</a> &amp; <a href="#">TPIU</a>.</i>                                                                                                                                           |

**R<sub>JGCF</sub>** When software selects asynchronous clocking and the TPIU asynchronous interface is idle, the ITM holds the timestamp counter at zero. This means that the ITM does not generate a local timestamp on the first packet after an idle on the asynchronous interface.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [ITM](#) && [TPIU](#).*

See also:

[B14.4 Trace Port Interface Unit](#).

## Global timestamping

**I<sub>DKSD</sub>** Global timestamps provide absolute timestamp values, which are based on a system global timestamp clock. They provide synchronization between different trace sources in the system.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [ITM](#).*

**R<sub>HBWD</sub>** If an implementation includes Global timestamping, the ITM generates *Global timestamp* (GTS) packets, which are based on a global timestamp clock.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [ITM](#).*

**R<sub>KWQJ</sub>** The size of the global timestamp is either 48 bits or 64 bits. The choice between these two options is IMPLEMENTATION DEFINED.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [ITM](#).*

**R<sub>SRDF</sub>** To transfer the global timestamp, two formats of Global timestamp packets are defined:

- The first packet format, Global timestamp 1 packet, holds the value of the least significant timestamp bits[25:0], and wrap and clock change indicators.
- The second packet format, Global timestamp 2 packet, holds the value of the high-order timestamp bits:
  - Bits[47:26], if a 48-bit global timestamp is supported.
  - Bits[63:26], if a 64-bit global timestamp is supported.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [ITM](#).*

**R<sub>VGBT</sub>** The ITM generates a full Global timestamp packet, consisting of Global timestamp 1 packet Global timestamp 2 packet, in the following circumstances:

- When software first enables global timestamps, by changing the value of the [ITM\\_TCR.GTSFREQ](#) field from zero to a nonzero value.
- When the system asserts the clock ratio change signal in the external ITM timestamp interface.
- In response to a Synchronization packet request, even if [ITM\\_TCR.SYNCENA](#) == 0.
- When the ITM has to generate a global timestamp, and the ITM detects that the value of the high-order bits of the global timestamp have changed since the Global timestamp 2 packet was last generated.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [ITM](#).*

**R<sub>XQWL</sub>** If the global timestamp generated by the ITM does not have to be a full global timestamp, the ITM generates only a single Global timestamp 1 packet.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [ITM](#).*

**R<sub>DJLN</sub>** When the ITM generates a global timestamp, it does so after a non-delayed Instrumentation or Hardware Source packet. The Global Timestamp 1 packet is always associated with the most recently output non-delayed Instrumentation or Hardware Source packet.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [ITM](#).*

R<sub>WDCX</sub>

When the ITM generates a full global timestamp:

1. The ITM first generates the Global timestamp 1 packet with timestamp bits[25:0], with the applicable bit of the Wrap and ClockCh bits in that packet set to 1 to indicate that the high-order bits of the timestamp will also be output. This is the packet that the ITM outputs immediately after a non-delayed trace packet.
2. Because of packet prioritization, the ITM might have to transmit other trace packets before it can output the Global timestamp 2 packet that contains the high-order bits of the timestamp. It might also have to transmit another Global timestamp packet. If so, it outputs the Global timestamp 1 packet with timestamp bits[25:0] and the Wrap bit set to 1.
3. The ITM later generates the Global timestamp 2 packet with the high-order timestamp bits for the most recently transmitted Global timestamp 1 packet.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [ITM](#).*

[ITM and DWT Packet Protocol Specification](#).

## B14.1.4 Synchronization support

I<sub>LRJT</sub>

An external debugger uses Synchronization Packets to recover bit-to-byte alignment information in a serial data stream.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [ITM](#).*

I<sub>LVGD</sub>

Synchronization packets are independent of timestamp packets.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [ITM](#).*

R<sub>QRFL</sub>

If the ITM connects to a parallel trace port interface, it must generate periodic Synchronization packets. An ITM connected to an asynchronous serial trace port interface can generate Synchronization packets

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [ITM](#).*

I<sub>JNJV</sub>

Arm recommends that software disables Synchronization packets when using an asynchronous serial trace port, to reduce the data stream bandwidth.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [ITM](#).*

R<sub>RMND</sub>

If [ITM\\_TCR.SYNCENA](#) == 1, the ITM outputs a Synchronization packet:

- When it is first enabled.
- If [DWT\\_CYCCNT](#) is implemented and [DWT\\_CTRL.SYNCTAP](#) is nonzero, in response to a Synchronization packet request from the DWT unit.
- If [TPIU\\_PSCR](#) is implemented, in response to a Synchronization packet request from the TPIU:
  - If [DWT\\_CYCCNT](#) is not implemented, [TPIU\\_PSCR](#) is implemented.
  - If [DWT\\_CYCCNT](#) is implemented, it is IMPLEMENTATION DEFINED whether [TPIU\\_PSCR](#) is implemented.
- In response to other IMPLEMENTATION DEFINED Synchronization packet requests from the system.
- On exit from Debug state.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [ITM](#). Note, might require additional extensions as described in the rule.*

**R<sub>NXLD</sub>** When the ITM issues a Synchronization packet the ITM clears the value of the Page register to 0.  
*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - ITM. Note, When the ITM supports more than 32 Stimulus ports.*

See also:

[DWT\\_CTRL.SYNCTAP](#).

### B14.1.5 Continuation bits

**I<sub>BFMX</sub>** A Synchronization packet consists of a bit stream of at least 47 zero bits followed by a one bit. The final bit is the byte alignment marker, and therefore bit[7] of the last byte of a Synchronization packet is always one.  
*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - ITM.*

**R<sub>JNVH</sub>** The longest Extension packet is always 5 bytes. In an Extension packet, bit[7] of each byte, including the header byte, but not including the last byte of a 5-byte packet, is a continuation bit, C. Bit[7] of the last byte of a 5-byte Extension packet is part of the extension field. Bit[7] of the last byte of a fewer-than-5-byte Extension packet is always zero.  
*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - ITM.*

**R<sub>XFTL</sub>** For all other protocol packets, bit[7] of each byte, including the header byte, but not including the last byte of a 7-byte packet, is a continuation bit, C. Bit[7] of the last byte of a packet is always zero.  
*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - ITM.*

**R<sub>BBSF</sub>** Each packet type defines its maximum packet length. Except for Global timestamp 2 and Synchronization packets, the longest defined packet is 5 bytes.  
*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - ITM.*

**R<sub>DPJG</sub>** The continuation bit, C, is defined as:  
**0:** This is the last byte of the packet.  
**1:** This is not the last byte of the packet.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - ITM.*

## B14.2 Data Watchpoint and Trace unit

### B14.2.1 About the DWT

R<sub>QQLQ</sub>

The *Data Watchpoint and Trace* (DWT) unit provides the following features:

- Comparators that support:
  - Use as a single comparator for instruction address matching or data address matching.
  - Use in linked pairs for instruction address range matching or data address range matching.
- Generation, on a comparator match, of:
  - A debug event that causes the PE either to enter Debug state or, if the Main Extension is implemented, to take a DebugMonitor exception.
  - Signaling a match to an ETM, if implemented.
  - Signaling a match to another external resource.
- External instruction address sampling using an instruction address sample register.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T && (Debug-Monitor exception || Halting debug). Note, some comparator matches require ETM.*

R<sub>KBMX</sub>

If the Main Extension is implemented, the DWT provides the following features:

- An optional cycle counter.
- Comparators that support:
  - Use as a single comparator for cycle counter matching, if the cycle counter is implemented.
  - Use as a single comparator for data value matching.
  - Use in linked pairs for data value matching at a specific data address.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T && M.*

R<sub>DVJV</sub>

If the Main Extension and the ITM are implemented, the DWT provides the following trace generation features:

- Generating one or more trace packets on a comparator match.
- Generating periodic trace packets for software profiling.
- Exception trace.
- Performance event counters that generate trace.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T && M && ITM.*

R<sub>CPXJ</sub>

If `DWT_CTRL.NOTRCPKT` is 1, there is no DWT trace support.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.*

R<sub>FKFP</sub>

If `DWT_CTRL.NOCYCCNT` is 1, there is no cycle counter support.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.*

R<sub>BKGF</sub>

If `DWT_CTRL.NOPRFCNT` is 1, there is no event counter support.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.*

R<sub>HFTT</sub>

The `DWT_CTRL.NUMCOMP` field indicates the number of implemented DWT comparators, which is in the range 0-15.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.*

R<sub>BSKH</sub>

An *unprivileged match* is a match that is generated by one of the following:

- The hardware stacking or unstacking of registers, where the operation is unprivileged on any of:
  - Exception entry.
  - Stacking of additional context on tail-chaining.
  - Exception exit.
  - Function call entry.
  - Function return.
  - Lazy state preservation.
- An operation that is generated by an instruction that is executed in an unprivileged mode, including:
  - An instruction address match for an instruction that is executed in unprivileged mode.
  - A Data address or Data value match for a load or store that is generalized by an instruction that is executed in an unprivileged mode.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - DWT-T && S && UDE.*

R<sub>NDF</sub>

Privileged matches are prohibited if one or more of the following conditions apply:

- `DEMCR.TRCENA == 0` or `NoninvasiveDebugAllowed(TRUE) == FALSE`. If UDE is not implemented all matches will be prohibited.
- `DWT_FUNCTION.ACTION` specifies a debug event and all the following conditions apply:
  - `HaltingDebugAllowed() == FALSE` or `DHCSR.C_DEBUGEN == 0`.
  - The Main Extension is not implemented or `DEMCR.MON_EN == 0`.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.*

R<sub>FRGS</sub>

Unprivileged matches are prohibited if one or more of the following conditions apply:

- `DEMCR.TRCENA == 0`, or `NoninvasiveDebugAllowed(FALSE) == FALSE`.
- `DWT_FUNCTION.ACTION` specifies a debug event and all of the following are true:
  - `HaltingDebugAllowed() == FALSE` or `DHCSR.C_DEBUGEN == 0`.
  - UDE is not implemented or `UnprivHaltingDebugAllowed() == FALSE` or `DHCSR.C_DEBUGEN == 0`.
  - The Main extension is not implemented or `DEMCR.MON_EN == 0`.
  - UDE is not implemented or `DEMCR.UMON_EN == 0`.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.*

I<sub>JWHK</sub>

If UDE is not implemented, the `NoninvasiveDebugAllowed()` function ignores the privilege mode of the match and a match will be generated if the function returns TRUE.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.*

R<sub>MJBG</sub>

Secure matches are prohibited if one or more of the following conditions applies:

- `DWT_FUNCTION.ACTION` specifies a trace or trigger event and `SecureNoninvasiveDebugAllowed(TRUE) == FALSE`.
- `DWT_FUNCTION.ACTION` specifies a debug event and all of the following conditions apply:
  - `DHCSR.S_SDE == 0`.
  - The Main Extension is not implemented or `DEMCR.SDME == 0`.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - DWT-T && S. Note, M required if `DEMCR.SDME == 1`.*

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| R <sub>FTBG</sub> | When the DWT generates a match, then a Data trace match packet is generated, if all of the following conditions apply: <ul style="list-style-type: none"> <li>• <code>SecureNoninvasiveDebugAllowed()</code> == FALSE.</li> <li>• <code>DWT_FUNCTION.ACTION</code> specifies generating a Data trace PC value packet.</li> <li>• The instruction address that would be included in the packet refers to an instruction that was executed in Secure state.</li> </ul> <p>Otherwise, the type of trace packet that is specified by <code>DWT_FUNCTION.ACTION</code> is generated.</p> <i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T &amp;&amp; M &amp;&amp; S &amp;&amp; !UDE.</i>                                                                                                                                                                                                                                                                                                                                                                          |
| R <sub>RGWF</sub> | When the DWT generates a match and <code>DWT_FUNCTION.ACTION</code> specifies generating a Data trace PC value packet, then the type of trace packet that is specified by <code>DWT_FUNCTION.ACTION</code> is ignored and a Data trace match packet is generated in its place, if one or more of the following conditions apply for the instruction, that is the subject of the match, referred to by the instruction address that would otherwise be included in the Data trace PC value packet:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

- The Unprivileged Debug Extension is implemented, `NoninvasiveDebugAllowed(TRUE)` returns FALSE, and the instruction was executed in a privileged mode.
- The Security Extension and the Unprivileged Debug Extension are implemented, the instruction was executed in a Secure privileged mode, and `SecureNoninvasiveDebugAllowed(TRUE)` returns FALSE.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - DWT-T && M && S && UDE.*

**R\_FNDW** An access that results in a MemManage fault or SecureFault exception because of the alignment, SAU, IDAU, or MPU checks, is not observed by the DWT, and cannot generate a match.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T && (S || M && MPU).*

**R\_PGJB** The DWT treats hardware accesses to the stack as data accesses:

- For registers pushed to the stack by hardware as part of an exception entry or lazy state preservation.
- For registers popped from the stack by hardware as part of an exception return.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.*

**R\_NQNR** The DWT treats hardware accesses to the stack as data accesses:

- For registers pushed to the stack by hardware as part of a Non-secure function call.
- For registers popped from the stack by hardware as part of a Non-secure function return.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T && S.*

**R\_SFSC** Where a hardware access to the stack generates a Data trace PC value packet, the PC value in the packet will be as follows:

- On exception entry or a function call, the PC value will be the return address for the exception or function call.
- On lazy state preservation the PC value is the address of the instruction that triggered the lazy state preservation.
- On exception return or Non-secure function return the PC value is either:
  - The address of the instruction that caused the exception return or the Non-secure function return.
  - The `EXC_RETURN` or `FNC_RETURN` payload value used in the exception return or the Non-secure function return.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.*

**R\_YZLM** Watchpoints that occur as a result of DWT Unit events will be taken when all in-flight instructions have completed. However, under rare circumstances, the architecturally-visible overlap of instructions might be observable.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - DWT-T && MVE.*

**I\_BPHG** If a higher priority exception preempts the generated watchpoint, then the in-flight instruction might be visible when the PE enters Debug state or a DebugMonitor exception is subsequently taken. The debugger and software can observe the stacked value of `EPSR.ECI` to determine the overlap status.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - DWT-T && MVE && Halting debug || DebugMonitor exception.*

**R\_HKDY** Watchpoints can be triggered from a number of comparators based on configurable events. If triggered from an instruction address comparator, the watchpoint is triggered whenever the instruction attempts to execute. Predication has no effect on the watchpoint address comparator.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - DWT-T && MVE.*

| Data address with value | 0b11xx (not<br>0b1111)    | 0b10   | -           | -            | -                     | -                   | Yes               |
|                         |                           | 0b11   | -           | -            | Yes                   | -                   | Yes               |

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - *DWT-T*. Note, Cycle counter, Data value and Data address with value are only available if *M* is implemented.

## Instruction address range

R<sub>DKHG</sub>

To match an instruction that is in an instruction address range, the following conditions are met:

- The first comparator, <*n-1*>, is programmed for *Instruction address*.
- The second comparator, <*n*>, is programmed for *Instruction address limit*.

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - *DWT-T*.

R<sub>LNQD</sub>

The valid combinations of [DWT\\_FUNCTION.MATCH](#) and [DWT\\_FUNCTION.ACTION](#) for an instruction address range, and the events and data trace packets that matching a single access can generate, are specified in the following table.

In the table:

-: means that the packet or event is not generated.

**First:** means that the packet or event is generated by the first comparator match.

**Second:** means that the packet or event is generated by the second comparator match.

| MATCH  |        | ACTION |      | Data Trace  |              |                 |                     |                   |
|--------|--------|--------|------|-------------|--------------|-----------------|---------------------|-------------------|
| <n-1>  | <n>    | <n-1>  | <n>  | Debug Event | Match packet | PC Value packet | Data Address packet | Data Value packet |
| 0b0000 | 0b0011 | 0bxx   | 0bxx | -           | -            | -               | -                   | -                 |
| 0b0010 | 0b0011 | 0b00   | 0b00 | -           | -            | -               | -                   | -                 |
|        |        | 0b00   | 0b11 | -           | -            | Second          | -                   | -                 |
|        |        | 0b01   | 0b00 | First       | -            | -               | -                   | -                 |
|        |        | 0b10   | 0b00 | -           | First        | -               | -                   | -                 |

Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T && M.

R\_VDRJ

If the Main Extension is not implemented the valid combinations of [DWT\\_FUNCTION.MATCH](#) and [DWT\\_FUNCTION.ACTION](#) for an instruction address range, and the events and data trace packets that matching a single access can generate, are specified in the following table.

In the table:

-: means that the packet or event is not generated.

**First:** means that the packet or event is generated by the first comparator match.

**Second:** means that the packet or event is generated by the second comparator match.

| MATCH  |        | ACTION |      | Data Trace  |              |                 |                     |                   |
|--------|--------|--------|------|-------------|--------------|-----------------|---------------------|-------------------|
| <n-1>  | <n>    | <n-1>  | <n>  | Debug Event | Match packet | PC Value packet | Data Address packet | Data Value packet |
| 0b0000 | 0b0011 | 0bxx   | 0bxx | -           | -            | -               | -                   | -                 |
| 0b0010 | 0b0011 | 0b00   | 0b00 | -           | -            | -               | -                   | -                 |
|        |        | 0b01   | 0b00 | First       | -            | -               | -                   | -                 |

Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T && !M.

## Data address range

R\_LDGR

To match a data access in a data address range, the following conditions are met:

- The first comparator, <n-1>, is programmed for either *Data address* or *Data address with value*.
- The second comparator, <n>, is programmed for *Data address limit*.

Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T && M.

R\_PSBJ

The valid combinations of [DWT\\_FUNCTION.MATCH](#) and [DWT\\_FUNCTION.ACTION](#) for a data address range, and the events and data trace packets that matching a single access can generate, are specified in the following table.

In the table:

-: means that the packet or event is not generated.

**First:** means that the packet or event is generated by the first comparator match.

**Second:** means that the packet or event is generated by the second comparator match.

| MATCH           |        | ACTION |      | Data Trace  |              |                 |                     |                   |
|-----------------|--------|--------|------|-------------|--------------|-----------------|---------------------|-------------------|
| <n-1>           | <n>    | <n-1>  | <n>  | Debug Event | Match packet | PC Value packet | Data Address packet | Data Value packet |
| 0b0000          | 0b0111 | 0bxx   | 0bxx | -           | -            | -               | -                   | -                 |
| 0b01xx          | 0b0111 | 0b00   | 0b00 | -           | -            | -               | -                   | -                 |
| (not<br>0b0111) |        | 0b00   | 0b11 | -           | -            | -               | Second              | -                 |
|                 |        | 0b01   | 0b00 | First       | -            | -               | -                   | -                 |
|                 |        | 0b10   | 0b00 | -           | First        | -               | -                   | -                 |
|                 |        | 0b11   | 0b00 | -           | -            | First           | -                   | -                 |
| (not<br>0b1111) |        | 0b11   | 0b11 | -           | -            | First           | Second              | -                 |
|                 |        | 0b10   | 0b00 | -           | -            | -               | -                   | First             |
|                 |        | 0b10   | 0b11 | -           | -            | -               | Second              | First             |
|                 |        | 0b11   | 0b00 | -           | -            | First           | -                   | First             |
|                 |        | 0b11   | 0b11 | -           | -            | First           | Second              | First             |

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - *DWT-T*.

R<sub>HDMX</sub>

If the Main Extension is not implemented the valid combinations of and for a data address range, and the events and data trace packets that matching a single access can generate, are specified in the following table.

In the table:

-: means that the packet or event is not generated.

**First:** means that the packet or event is generated by the first comparator match.

**Second:** means that the packet or event is generated by the second comparator match.

| MATCH           |        | ACTION |      | Data Trace  |              |                 |                     |                   |
|-----------------|--------|--------|------|-------------|--------------|-----------------|---------------------|-------------------|
| <n-1>           | <n>    | <n-1>  | <n>  | Debug Event | Match packet | PC Value packet | Data Address packet | Data Value packet |
| 0b0000          | 0b0111 | 0bxx   | 0bxx | -           | -            | -               | -                   | -                 |
| 0b01xx          | 0b0111 | 0b00   | 0b00 | -           | -            | -               | -                   | -                 |
| (not<br>0b0111) |        | 0b00   | 0b11 | -           | -            | -               | Second              | -                 |
|                 |        | 0b01   | 0b00 | First       | -            | -               | -                   | -                 |

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - *DWT-T* & *!M*.

## Data value at specific address

R<sub>KFHV</sub>

Matching data values at specific data addresses is possible only if the Main Extension is implemented.

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - *DWT-T*.

R<sub>NNXD</sub>

To match a data value at a specific data address, the following conditions are met:

- The first comparator, <n-1>, is programmed for either *Data address* or *Data address with value*.
- The second comparator, <n>, is programmed for *Linked data value*.

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - *DWT-T*.

**R<sub>JKGJ</sub>** The first comparator matches any access that matches the address. The second matches only accesses that match the address and the data value.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.*

**R<sub>NTSD</sub>** The valid combinations of **DWT\_FUNCTION.MATCH** and **DWT\_FUNCTION.ACTION** for a linked data value, and the events and data trace packets that matching a single access can generate, are specified in the following table.

In the table:

**-:** means that the packet or event is not generated.

**First:** means that the packet or event is generated by the first comparator match.

**Second:** means that the packet or event is generated by the second comparator match.

**Both:** means that a first packet is generated by a first comparator match, even if the Linked data value comparator does not match, and a second packet is generated by the second comparator match, if both comparators match.

| MATCH           |        | ACTION |      | Data Trace  |              |                 |                     |                   |
|-----------------|--------|--------|------|-------------|--------------|-----------------|---------------------|-------------------|
| <n-1>           | <n>    | <n-1>  | <n>  | Debug Event | Match packet | PC Value packet | Data Address packet | Data Value packet |
| 0b0000          | 0b1011 | 0bxx   | 0bxx | -           | -            | -               | -                   | -                 |
| 0b01xx          | 0b1011 | 0b00   | 0b00 | -           | -            | -               | -                   | -                 |
| (not<br>0b0111) |        | 0b00   | 0b01 | Second      | -            | -               | -                   | -                 |
|                 |        | 0b00   | 0b10 | -           | Second       | -               | -                   | -                 |
|                 |        | 0b01   | 0b00 | First       | -            | -               | -                   | -                 |

| R <sub>TMZX</sub> | If an ETM is not implemented, the effect of <b>CMPMATCH</b> is IMPLEMENTATION DEFINED, including whether the trigger event has any observable effect or whether observable effects are visible to other components in the system.<br><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.</i>             |
| R <sub>XXKM</sub> | For all enabled watchpoints, if <b>DWT_FUNCTION<sub>n</sub></b> is not programmed as an Instruction address limit comparator and is not programmed as a Data address limit comparator, <b>CMPMATCH[n]</b> is triggered on a comparator match.<br><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.</i> |
| R <sub>GVHS</sub> | For all enabled watchpoints, if <b>DWT_FUNCTION<sub>n</sub></b> is programmed as an Instruction address limit or Data address limit comparator, it is UNPREDICTABLE whether <b>CMPMATCH[n]</b> is triggered on a comparator match.<br><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.</i>            |

## B14.2.5 Matching in detail

### Instruction address matching in detail

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| R <sub>GNVB</sub> | The DWT checks all instructions that are executed by a simple sequential execution of the program and do not generate any exception for an instruction address match, including conditional instructions that fail their condition code check.<br><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.</i>                                                                                                                               |
| R <sub>NQGR</sub> | An instruction might be checked by the DWT for an instruction address match if it either: <ul style="list-style-type: none"> <li>• Is executed by a simple sequential execution of the program and generates a synchronous exception.</li> <li>• Would be executed by the sequential execution of the program but is abandoned because of an asynchronous exception.</li> </ul> <i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.</i> |
| R <sub>KJJC</sub> | Speculative instruction prefetches, other than those that would be executed by the sequential execution of the program but that are abandoned because of asynchronous exceptions, do not generate matches.<br><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.</i>                                                                                                                                                                   |
| R <sub>DSDT</sub> | For all instruction address matches, if bit[0] of the comparator address has a value of 1, it is UNPREDICTABLE whether a match is generated when the other address bits match.<br><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.</i>                                                                                                                                                                                               |
| R <sub>KLXM</sub> | For single instruction address matches, an instruction matches if the address of the first byte of the instruction matches the comparator address.<br><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.</i>                                                                                                                                                                                                                           |
| R <sub>FXFM</sub> | For single address matches, if the instruction at address A is a 4-byte T32 instruction, and the address A+2 matches but the address A does not match, it is UNPREDICTABLE whether a match is generated.<br><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.</i>                                                                                                                                                                     |

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| R <sub>DNKD</sub> | For instruction address range matches, an instruction at address A matches if the address A lies between the lower comparator address, which is specified by comparator <n-1>, and the limit comparator address, which is specified by comparator <n>. Both addresses are inclusive to the range.<br><br><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.</i> |
| R <sub>JNXZ</sub> | For instruction address range matches, if the instruction at address A is a 4-byte T32 instruction, and the address A+2 lies in the range but the address A does not lie in the range, it is UNPREDICTABLE whether a match is generated.<br><br><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.</i>                                                          |
| R <sub>MLMQ</sub> | For instruction address range matches, if so configured, a Data trace PC value packet or Data trace match packet is generated for the first instruction that is executed in the range.<br><br><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.</i>                                                                                                            |
| I <sub>VHHW</sub> | For instruction address range matches, if so configured, a branch or sequential execution that stays within the range does not necessarily generate a new packet.<br><br><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.</i>                                                                                                                                 |
| R <sub>HMNx</sub> | For instruction address range matches, if so configured, <b>CMPMATCH</b> [n-1] is triggered for each instruction that is executed inside the range, where n-1 is the lower of the two comparators that configure the range.<br><br><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.</i>                                                                       |

## Data address matching in detail

|                   |                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| R <sub>BPWC</sub> | For all Data Address matches, all bits of the comparator address are considered.<br><br><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.</i>                                                                                                                                                                                             |
| R <sub>GSLX</sub> | Speculative reads might generate data address matches.<br><br><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.</i>                                                                                                                                                                                                                       |
| R <sub>WBBH</sub> | Speculative writes do not generate data address matches.<br><br><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.</i>                                                                                                                                                                                                                     |
| R <sub>VJFB</sub> | Prefetches into a cache do not generate data address matches.<br><br><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.</i>                                                                                                                                                                                                                |
| R <sub>CMRP</sub> | For single data address matches, an access matches if any accessed byte lies between the comparator address and a limit that is defined by <a href="#">DWT_FUNCTION.DATASIZE</a> .<br><br><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.</i>                                                                                           |
| R <sub>KHRF</sub> | For single data address matches, the comparator address is naturally-aligned to <a href="#">DWT_FUNCTION.DATASIZE</a> otherwise generation of watchpoint events is UNPREDICTABLE.<br><br><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.</i>                                                                                            |
| R <sub>KKRJ</sub> | For data address range matches, an access matches if any accessed byte lies between the lower comparator address, which is specified by comparator <n-1>, and the limit comparator address, which is specified by comparator <n>. | R <sub>ZDPM</sub> | For unlinked data value matches, an access matches if all bytes of any naturally-aligned subset, the size of which is specified by <a href="#">DWT_FUNCTION.DATAVSIZE</a> , of the access match the data value in <a href="#">DWT_COMPn</a> .<br><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.</i>                                                                                                                   |
| R <sub>ZHXP</sub> | The data value in <a href="#">DWT_COMPn</a> is in little-endian order with respect to memory.<br><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.</i>                                                                                                                                                                                                                                                                   |
| I <sub>HMMS</sub> | If the access is unaligned then this might generate a higher priority alignment fault, depending on the instruction type, profile, and configuration. In these cases no match is generated.<br><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.</i>                                                                                                                                                                     |
| R <sub>SQKS</sub> | For unlinked data value matches, if an access is unaligned, it is IMPLEMENTATION DEFINED whether it either treated as: <ul style="list-style-type: none"> <li>• A sequence of byte accesses.</li> <li>• A sequence of naturally-aligned accesses covering the accessed bytes. For a read, this access might access more bytes than the original access.</li> </ul> <i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.</i> |
| R <sub>QRPW</sub> | For linked data value matching, if an access is larger than <a href="#">DWT_FUNCTION.DATAVSIZE</a> , then only the naturally-aligned subset of the access of size <a href="#">DWT_FUNCTION.DATAVSIZE</a> at the matching address is compared for a match.<br><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.</i>                                                                                                       |
| R <sub>QVRK</sub> | For linked data value matching, the data address comparator address is naturally-aligned to <a href="#">DWT_FUNCTION.DATAVSIZE</a> , and the <a href="#">DWT_FUNCTION.DATAVSIZE</a> values for both comparators are the same.<br><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.</i>                                                                                                                                   |
| R <sub>KRCV</sub> | A Data value comparator that is linked to a Data address comparator does not change the behavior of the address comparator.<br><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.</i>                                                                                                                                                                                                                                     |
| R <sub>KQJB</sub> | For each comparator <i>n</i> that is configured to Data Value or Linked Data Value matching it is UNPREDICTABLE whether comparator <i>n</i> generates a match when for bit <i>m</i> =31-0, if any of the following are true: <ul style="list-style-type: none"> <li>• <a href="#">DWT_FUNCTION&lt;n&gt;.DATAVSIZE</a> specifies halfword or byte comparison and <a href="#">DWT_COMPn</a>[31:16] is not equal to <a href="#">DWT_COMPn</a>[15:0].</li> </ul>                         |

- `DWT_FUNCTION<n>.DATAVSIZE` specifies byte comparison and `DWT_COMPn[15:8]` is not equal to `DWT_COMPn[7:0]`.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.*

**R<sub>ZKRZ</sub>** For each comparator *n* that is configured to Data Value or Linked Data Value matching the value matches if, for each bit[*m*] any of the following are true:

- Bit[*m*] of the value is equal to `DWT_COMPn[m]`.
- `DWT_VMASKn` is implemented, `DWT_COMPn[m]` is set to 0, and `DWT_VMASKn[m]` is set to 1.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - DSPDE.*

**R<sub>BVLK</sub>** For each comparator *n* that is configured for Data Value or Linked Value matching, if `DWT_VMASKn` is implemented, then it is UNPREDICTABLE whether comparator *n* generates a match when, for bit *m* = 0-31, all of the following are true:

- `DWT_VMASKn[m]` is set to 1.
- `DWT_COMPn[m]` is not set to 0.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - DSPDE.*

**R<sub>HRTJ</sub>** For each comparator *n* that is configured for Data Value or Linked Value matching, if `DWT_VMASKn` is implemented, then it is UNPREDICTABLE whether comparator *n* generates a match if any of the following are true:

- `DWT_FUNCTION<n>.DATAVSIZE` specifies halfword or byte comparison and `DWT_VMASKn[31:16]` is not equal to `DWT_VMASKn[15:0]`.
- `DWT_FUNCTION<n>.DATAVSIZE` specifies byte comparison and `DWT_VMASKn[15:8]` is not equal to `DWT_VMASKn[7:0]`.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - DSPDE.*

**R<sub>SMHR</sub>** For each comparator *n* that is configured for neither Data Value nor Linked Data Value matching, `DWT_VMASKn` is ignored if it is implemented.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - DSPDE.*

| R <sub>FRHP</sub> | <p>DWT matches are generated asynchronously.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.</i></p>                                                                                                                                                                                                                                                                                                                                                                                                    |

$R_{THHR}$  A [DSB](#) barrier guarantees that the effect of a DWT match is visible to a subsequent read of [DWT\\_FUNCTION.-MATCHED](#), [DHCSR](#), or [DEMCR](#). In the absence of a [DSB](#) barrier, the effect is only guaranteed to be visible in finite time.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.*

$R_{HPGH}$  The effects of a DWT match never affect instructions appearing in program order before the operation that generates the match.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.*

See also:

[B3.26 Tail-chaining](#).

## B14.2.7 DWT trace restrictions and relaxations

$R_{PGCS}$  If a single instruction makes multiple single-copy atomic accesses, such as the multiple-byte accesses from an unaligned access or a predicated vector load/store operation, the DWT might gather a sequence of consecutive bytes from the multiple accesses, and trace it as a single access.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.*

$R_{HDKK}$  Where a single instruction or operation, or multiple instructions, generate multiple accesses that each generate one or more trace packets, then if the architecture guarantees the order in which a pair of these accesses is observed by the PE, the first trace packets that are generated for each of those accesses appear in the trace output in the same order.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.*

$R_{WSKK}$  Where a single instruction or operation, or multiple instructions, generate multiple accesses that each generate one or more trace packets, then if the architecture does not guarantee the order of the accesses, the order of the trace packets in the trace output is not defined.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.*

$R_{XCNB}$  If a single instruction or operation makes multiple or unaligned data accesses, then, if so configured, only the first access is guaranteed to generate a Data trace PC value packet, Data trace data address packet, or Data trace match packet. If the architecture does not guarantee the order of the accesses, the first access might be any of the accesses.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.*

$R_{XVBT}$  If a single instruction or operation makes multiple or unaligned data accesses, then, if so configured, a Data trace data value packet is generated for each matching access.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.*

$R_{QSCF}$  If a single instruction or operation makes unaligned data accesses, it is UNPREDICTABLE how many Data trace data value packets are generated for each unaligned matching access. An implementation might overread, meaning that more data outside the access might be traced.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.*

$R_{KXBL}$  If a single instruction or operation makes multiple or unaligned data accesses, then, if so configured, for a matching data access that generates a Data trace data value packet, at least that part of the value that is guaranteed to be single-copy atomic is traced.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.*

$R_{QWQS}$  Duplicate Data trace PC value packets, Data trace data address packets, and Data trace data value packets from a single access are not generated for a single access.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.*

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| R <sub>XDVS</sub> | <p>The cycle counter, DWT_CYCCNT, and the POSTCNT counter are disabled when <a href="#">DEMCR.TRCENA</a> == 0, but are not otherwise affected by debug authentication.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.</i></p>                 |
| R <sub>RTJR</sub> | <p>The cycle counter does not count in Secure state when <a href="#">DWT_CTRL.CYCDISS</a> is set to 1. This is independent of Secure debug authentication.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T &amp;&amp; S.</i></p>                |
| R <sub>KRFP</sub> | <p>When implemented and enabled, CYCCNT increments on each cycle of the PE clock, using the same definition of cycle as the Event counters when counting cycles in power-saving modes.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.</i></p> |
| R <sub>NFJW</sub> | <p>When the counter overflows it transparently wraps to zero.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.</i></p>                                                                                                                          |

R<sub>GXJK</sub> **DWT\_CTRL.CYCCNTENA** enables the CYCCNT counter.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.*

R<sub>BKCG</sub> POSTCNT is a 4-bit countdown counter derived from CYCCNT, that acts as a timer for the periodic generation of Periodic PC sample packets or Event counter packets, when these packets are enabled.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.*

I<sub>MGGL</sub> Periodic PC sample packets are not the same as the Data trace PC value packets that are generated by the DWT comparators.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.*

R<sub>DKGR</sub> The DWT does not support the generation of Periodic PC sample packets or Event packets if it does not implement the CYCCNT timer and **DWT\_CTRL.NOTRCPKT** is RAO.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.*

R<sub>RNTV</sub> The **DWT\_CTRL.CYCTAP** bit selects the CYCCNT tap bit for POSTCNT.

| CYCTAP bit | CYCCNT tap at | POSTCNT clock rate |
|------------|---------------|--------------------|
| 0          | Bit[6]        | (PE clock)/64      |
| 1          | Bit[10]       | (PE clock)/1024    |

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.*

R<sub>SXKK</sub> A write to **DWT\_CTRL** will initialize POSTCNT to the previous value of **DWT\_CTRL.POSTINIT** if all of the following are true:

- **DWT\_CTRL.PCSAMPLENA** was set to 0 prior to the write.
- **DWT\_CTRL.CYCEVTENA** was set to 0 prior to the write.
- The write sets either **DWT\_CTRL.PCSAMPLENA** or **DWT\_CTRL.CYCEVTENA** to 1.

It is UNPREDICTABLE whether any other write to **DWT\_CTRL** that alters the value of **DWT\_CTRL.PCSAMPLENA** and **DWT\_CTRL.CYCEVTENA** sets POSTCNT to **DWT\_CTRL.POSTINIT** or leaves POSTCNT unchanged.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.*

R<sub>XFRM</sub> When either **DWT\_CTRL.PCSAMPLENA** or **DWT\_CTRL.CYCEVTENA** is set to 1, and the CYCCNT tap bit transitions, either from 0 to 1 or from 1 to 0:

- If POSTCNT is nonzero, POSTCNT decrements by 1.
- If POSTCNT is 0, the DWT:
  - Reloads POSTCNT from **DWT\_CTRL.POSTPRESET**.
  - Generates a Periodic PC Sample packets if **DWT\_CTRL.PCSAMPLENA** is set to 1.
  - Generates an Event Counter packet with the Cyc bit set to 1 if **DWT\_CTRL.CYCEVTENA** is set to 1.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.*

I<sub>PNNs</sub> The enable bit for the POSTCNT counter underflow event is **DWT\_CTRL.CYCEVTENA**. There is no overflow event for the CYCCNT counter. When CYCCNT overflows it wraps to zero transparently. Software cannot access the POSTCNT value directly, or change this value.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.*

I<sub>JRVV</sub> This means that, to initialize POSTCNT, software:

1. Ensures that **DWT\_CTRL.CYCEVTENA** and **DWT\_CTRL.PCSAMPLENA** are set to 0. This can be achieved with a single write to **DWT\_CTRL**. This is also the reset value of these bits.
2. Writes the required initial value of POSTCNT to the **DWT\_CTRL.POSTINIT** field, leaving **DWT\_CTRL.CYCEVTENA** and **DWT\_CTRL.PCSAMPLENA** set to 0.

3. Sets either `DWT_CTRL.CYCEVTENA` or `DWT_CTRL.PCSAMPLENA` to 1 to enable the POSTCNT counter.

Each of these are separate writes to `DWT_CTRL`.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.*

`R_KNHF` Disabling CYCCNT stops POSTCNT.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.*

`R_TMHN` Writes to `DWT_CTRL.POSTINIT` are ignored if either `DWT_CTRL.CYCEVTENA` was set to 1 or `DWT_CTRL.PCSAMPLENA` was set to 1 prior to the write.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.*

### B14.2.9 Profiling counter support

`I_HXPV` If the Main Extension is implemented event counter support is an optional Non-invasive debug feature.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T && M.*

`R_WHWR` If event counter support is implemented the DWT provides five 8-bit Event counters for software profiling:

- `DWT_FOLDCNT`.
- `DWT_LSUNCT`.
- `DWT_EXCCNT`.
- `DWT_SLEEP CNT`.
- `DWT_CPICNT`.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.*

`R_GLMJ` DWT event counters do not increment when the PE is halted.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.*

`R_BRGW` The Event counters provide broadly accurate and statistically useful count information. However, the architecture allows for a reasonable degree of inaccuracy in the counts.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.*

`R_WMNV` The Event counters and CYCCNT use the same definition of cycle in particular when counting cycles in power-saving modes.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T && M.*

`I_GNWQ` To keep the implementation and validation cost low, a reasonable degree of inaccuracy in the counts is acceptable. Arm does not define a reasonable degree of inaccuracy but recommends the following guidelines:

- Under normal operating conditions, the Event counters present an accurate value count.
- Entry to or exit from Debug state can be a source of inaccuracy.
- Under very unusual, non-repeating pathological cases, the counts can be inaccurate.

An implementation does not introduce inaccuracies that can be triggered systematically by the execution of normal pieces of software. As the Event counters include counters for measuring exception overhead, this includes the operation of exceptions.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.*

`I_CHKR` Arm strongly recommends that an implementation document any particular scenarios where significant inaccuracies in the Event counters are expected.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.*

**I<sub>MWGO</sub>** At entry and exit from an exception or sleep state, the exact attribution of cycles to the exception and cycles to the sleep overhead counters is IMPLEMENTATION DEFINED. Arm recommends that the overhead cycles are attributed to the overhead counters.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.*

**I<sub>MPQN</sub>** The architecture does not define the point in a pipeline where the particular instruction increments an Event counter, relative to the point where the incremented counter can be read.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.*

**R<sub>LMPK</sub>** An Event counter overflows on every 256th event that is counted and then wraps to 0. If the appropriate counter overflow event is enabled in **DWT\_CTRL** the DWT outputs an Event counter packet with the appropriate counter flag set to 1.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.*

**R<sub>LHMB</sub>** Setting one of the enable bits to 1 clears the corresponding counter to 0.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.*

**I<sub>QRP</sub>** The following equation holds:

$$ICNT = CNT_{CYCLES} + CNT_{FOLD} - (CNT_{LSU} + CNT_{EXC} + CNT_{SLEEP} + CNT_{CPI})$$

Where:

**ICNT**: is the total number of instructions [Architecturally executed](#).

**CNT<sub>CYCLES</sub>**: is the number of cycles counted by **DWT\_CYCCNT**.

**CNT<sub>FOLD</sub>**: is the number of instructions counted by **DWT\_FOLDCNT**.

**CNT<sub>LSU</sub>**: is the number of cycles counted by **DWT\_LSUNCT**.

**CNT<sub>EXC</sub>**: is the number of cycles counted by **DWT\_EXCCNT**.

**CNT<sub>SLEEP</sub>**: is the number of cycles counted by **DWT\_SLEEPCNT**.

**CNT<sub>CPI</sub>**: is the number of cycles counted by **DWT\_CPICNT**.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.*

See also:

[B14.4 Trace Port Interface Unit](#).

## Generating Overflow packets from Event counters

**R<sub>KWDH</sub>** If an Event counter wraps to zero and the previous Event counter packet has been delayed and has not yet been output, and the counter flag in the previous Event counter packet is set to 0, then it is IMPLEMENTATION DEFINED whether:

- The DWT attempts to generate a second Event counter packet.
- The DWT updates the delayed Event counter packet to include the new wrap event.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.*

**R<sub>HKTL</sub>** If an Event counter wraps to zero and the previous Event counter packet has been delayed and has not yet been output, and the counter flag in the previous Event counter packet is set to 1, the DWT attempts to generate a second Event counter packet.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.*

**R<sub>VPXK</sub>** If the DWT unit attempts to generate a packet when its output buffer is full, an Overflow packet is output.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.*

**R<sub>SFFL</sub>** The size of the DWT output buffer is IMPLEMENTATION DEFINED.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.*

## B14.2.10 Program Counter sampling support

**R<sub>FXWL</sub>** Program Counter sampling is an optional component provided through [DWT\\_PCSR](#).

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.*

**I<sub>LNJL</sub>** Program Counter sampling is independent of PC sampling provided by:

- Periodic PC sample packets.
- Data trace PC value packets generated as a result of a DWT comparator match.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.*

**I<sub>KVFB</sub>** The architecture does not define the delay between an instruction being executed by the PE and its address being written to [DWT\\_PCSR](#).

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.*

**R<sub>NGNT</sub>** When [DWT\\_PCSR](#) returns a value other than 0xFFFFFFFF, the returned value is an instruction that has been committed for execution. It is IMPLEMENTATION DEFINED whether an instruction that failed its condition code check is considered as committed for execution. A read of [DWT\\_PCSR](#) does not return the address of an instruction that has been fetched but not committed for execution.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.*

**I<sub>TNVH</sub>** The following diagram describes when instructions are committed for execution:

*Applies to an implementation of the architecture Armv8.0-M onward.*

**I<sub>KCBH</sub>** Arm recommends that instructions that fail the condition code check are considered as committed instructions.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - DWT-T.*

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## B14.3 Embedded Trace Macrocell

**I<sub>LCCX</sub>** An *Embedded Trace Macrocell* (ETM) is an optional non-invasive debug feature of an Armv8-M implementation.  
*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [ETM](#).*

**R<sub>NGTT</sub>** An ETM implementation complies with one of the following versions of the ETM architecture:

|                 | Data trace | Security Extension          |                             |
|-----------------|------------|-----------------------------|-----------------------------|
|                 |            | Implemented                 | Not implemented             |
| Implemented     |            | ETMv3 not permitted         | ETMv3 not permitted         |
|                 |            | ETMv4, version 4.2 or later | ETMv4, version 4.0 or later |
| Not Implemented |            | ETMv3, version 3.5 or later | ETMv3, version 3.5          |
|                 |            | ETMv4, version 4.2 or later | ETMv4, version 4.0 or later |

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [ETM](#).*

**R<sub>QWRD</sub>** If Armv8.1-M is implemented and an ETM is implemented, ETMv4 version 4.5 is required. Data trace is not supported in ETMv4 version 4.5 and is not supported in Armv8.1-M.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [ETM](#).*

**R<sub>LPJM</sub>** If an ETM is implemented a trace sink is also implemented. If the trace sink that is implemented is the TPIU it is CoreSight compliant, and complies with the TPIU architecture for compatibility with Arm and other CoreSight-compatible debug solutions.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [ETM](#).*

**R<sub>NLNS</sub>** When an Armv8-M implementation includes an ETM, the **CMPMATCH[N]** signals from the DWT unit are available as control inputs to the ETM unit.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [ETM](#).*

**R<sub>NJDK</sub>** If the Main Extension is not implemented, it is IMPLEMENTATION DEFINED whether the ETM is accessible only to the debugger and is RES0 to software.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [ETM](#) && [!M](#).*

**R<sub>WPBN</sub>** If the ETMv3 is implemented the debugger programs the ETMTRACEIDR with a unique nonzero Trace ID for the ETM trace stream.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [ETM](#).*

**R<sub>TJSF</sub>** If the ETMv4 is implemented the debugger programs the TRCTRACEIDR with a unique nonzero Trace ID for the ETM trace stream.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [ETM](#).*

**R<sub>WSTB</sub>** The ETM is not directly affected by [DEMCR.TRCENA](#) being set to 0.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [ETM](#).*

## B14.4 Trace Port Interface Unit

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| I <sub>PWXP</sub> | <p>The <i>Trace Port Interface Unit</i> (TPIU) support for Armv8-M provides an output path for trace data from the DWT, ITM, and ETM. The TPIU is a trace sink.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">TPIU</a>.</i></p>                                                                                                                   |
| R <sub>CRTQ</sub> | <p>It is IMPLEMENTATION DEFINED whether the TPIU supports a parallel trace port output.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">TPIU</a>.</i></p>                                                                                                                                                                                           |
| R <sub>GTRP</sub> | <p>It is IMPLEMENTATION DEFINED whether the TPIU supports low-speed asynchronous serial port output using NRZ encoding. This operates as a traditional UART.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">TPIU</a>.</i></p>                                                                                                                      |
| R <sub>LKQT</sub> | <p>It is IMPLEMENTATION DEFINED whether the TPIU supports medium-speed asynchronous serial port output using Manchester encoding.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">TPIU</a>.</i></p>                                                                                                                                                 |
| I <sub>SDDK</sub> | <p>Arm recommends that the TPIU provides both parallel and asynchronous serial ports, for maximum flexibility with external capture devices.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">TPIU</a>.</i></p>                                                                                                                                      |
| R <sub>HJXK</sub> | <p>Whether the trace port clock is synchronous to the PE clock is IMPLEMENTATION DEFINED.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">TPIU</a>.</i></p>                                                                                                                                                                                         |
| R <sub>PKKS</sub> | <p>It is IMPLEMENTATION DEFINED whether the TPIU is reset by a Cold reset or has an independent Cold reset.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">TPIU</a>.</i></p>                                                                                                                                                                       |
| R <sub>JBKJ</sub> | <p>Software ensures that all trace is output and flushed to the trace sink before setting the <a href="#">DEMCR.TRCENA</a> bit to 0.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">TPIU</a>.</i></p>                                                                                                                                              |
| R <sub>STLV</sub> | <p>The TPIU is not directly affected by <a href="#">DEMCR.TRCENA</a> being set to 0 or <a href="#">NoninvasiveDebugAllowed()</a> being FALSE.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">TPIU</a>.</i></p>                                                                                                                                     |
| R <sub>JLCQ</sub> | <p>The output formatting modes that are supported by the TPIU are IMPLEMENTATION DEFINED. They are:</p> <ul style="list-style-type: none"><li>• Bypass.</li><li>• Continuous.</li></ul> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">TPIU</a>.</i></p>                                                                                               |
| R <sub>DMFP</sub> | <p>Bypass mode is only supported if a serial port output is supported.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">TPIU</a>.</i></p>                                                                                                                                                                                                            |
| R <sub>RRJP</sub> | <p>Continuous mode is supported if the parallel trace port is implemented. Continuous mode is selected when the parallel trace port is used.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">TPIU</a>.</i></p>                                                                                                                                      |
| R <sub>FCFT</sub> | <p>Continuous mode is supported if the ETM is implemented. Continuous mode is selected when the ETM is used.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">TPIU</a>.</i></p>                                                                                                                                                                      |
| R <sub>BRSK</sub> | <p>When <a href="#">ITM_TCR.SWOENA</a> is set to 1 and <a href="#">TPIU_SPPR.TXMODE</a> is either 0b01 or 0b10 a trace port clock signal from the TPIU drives the timestamp counter, through the configurable prescaler <a href="#">TPIU_ACPR</a>.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - <a href="#">TPIU</a> &amp;&amp; <a href="#">ITM</a>.</i></p> |

| R <sub>XPXS</sub> | Instruction address comparators match only on instruction fetches. The FPB treats hardware accesses to the stack as data accesses for registers that are: <ul style="list-style-type: none"><li>• Pushed to the stack by hardware as part of an exception entry or lazy state preservation.</li><li>• Popped from the stack by hardware as part of an exception return.</li><li>• Pushed to the stack by hardware as part of a Non-secure function return.</li><li>• Popped from the stack by hardware as part of a Non-secure function call.</li></ul> It is IMPLEMENTATION DEFINED whether the FPB treats a fetch from the exception vector table as part of an exception entry as a data access, or ignores these accesses, for the purposes of FPB address comparator matches. The fetch is never be treated as an instruction fetch.<br>The FPB does not match accesses from the DAP. |

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **FPB**.*

I<sub>CNBW</sub> Bit[0] of each instruction fetch address is always 0.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **FPB**.*

R<sub>CJJK</sub> When an Instruction address matching comparator is configured for breakpoint generation, a match on the address of a 32-bit instruction is configured to match the first halfword or both halfwords of the instruction.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **FPB**.*

R<sub>WSXN</sub> If a Breakpoint debug event is generated by the FPB on the second halfword of a 32-bit T32 instruction, it is UNPREDICTABLE whether the breakpoint generates a debug event.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **FPB**.*

R<sub>JNVD</sub> If the UDE is implemented an FPB match specifying a Breakpoint debug event generates a Breakpoint debug event that halts the PE in unprivileged mode if either of the following conditions are true:

- `HaltingDebugAllowed()` returns TRUE
- `UnprivHaltingDebugAllowed()` returns TRUE.

and the all of the following conditions are true:

- `DHCSR.S_HALT` == 0.
- The Security Extension is not implemented, the matching instruction is executed in Non-secure state, or `UnprivHaltingDebugAllowed(TRUE)` returns TRUE.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **FPB** && **UDE**.*

R<sub>HXMP</sub> An FPB match specifying a Breakpoint debug event generates a DebugMonitor exception if it does not halt the PE and all of the following conditions are true:

- `DEMCR.MON_EN` == 1.
- `DHCSR.S_HALT` == 0.
- The DebugMonitor exception group priority is greater than the current execution priority.
- The Security Extension is not implemented, the matching instruction is executed in Non-secure state, or `DEMCR.SDME` == 1.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **FPB**.*

R<sub>LTML</sub> An FPB match specifying a Breakpoint debug event generates a DebugMonitor exception if it does not halt the PE and either of the following conditions are true:

- `DEMCR.MON_EN` == 1.
- The Unprivileged Debug Extension is implemented, `DEMCR.UMON_EN` == 1 and the PE is executing in unprivileged mode.

and all of the following conditions apply:

- `DHCSR.S_HALT` == 0.
- The DebugMonitor exception group priority is greater than the current execution priority.
- The Security Extension is not implemented, the matching instruction is executed in Non-secure state, or `DEMCR.SDME` == 1.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **FPB** && **UDE**.*

R<sub>BFPK</sub> An FPB match that specifies a Breakpoint debug event might be ignored if it does not meet the conditions for generating either:

- A Breakpoint debug event that halts the PE.
- A DebugMonitor exception.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **FPB**.*

$R_{TKNR}$  Between a change to the debug authentication interface, [DHCSR](#), [DEMCR](#) or [DAUTHCTRL](#), that disables debug, and a following context synchronization event, it is UNPREDICTABLE whether any breakpoints generated by the FPB:

- Generate a Breakpoint debug event based on the old values and either:
  - If the Main Extension is implemented, generate a DebugMonitor exception.
  - Halts the PE.
- Are escalated to HardFault or [Lockup](#).
- Are ignored.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [FPB](#) && [UDE](#).*

$R_{DZWB}$  Breakpoints that occur as a result of FPB Unit events behave in the same way as a scalar [BKPT](#) instruction. All in-flight instructions are completed before halting.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [FPB](#) && [MVE](#).*

$I_{YVFX}$  Entry to debug state and debug monitor is delayed until all in-flight instructions have completed.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [FPB](#) && [MVE](#).*

## Chapter B15

# The Performance Monitors Extension

This chapter specifies the optional Armv8.1-M Performance Monitors Extension. It contains the following sections:

- [B15.1 Counters.](#)
- [B15.2 Accuracy of the performance counters.](#)
- [B15.3 Security, access, and modes.](#)
- [B15.4 Attributability.](#)
- [B15.5 Coexistence with the DWT Performance Monitors.](#)
- [B15.6 Interrupts and Debug events.](#)
- [B15.7 Performance Monitors and Debug state](#)
- [B15.8 List of supported architectural and microarchitectural events.](#)
- [B15.9 Generic architectural and microarchitectural events.](#)
- [B15.10 Common event descriptions.](#)
- [B15.11 Required PMU events.](#)
- [B15.12 IMPLEMENTATION DEFINED event numbers.](#)

*Applies to an implementation of the architecture Armv8.1-M onward.*

## B15.1 Counters

|        |                                                                                                                                                                                                                                                                                                                                                                                                                |

## B15.2 Accuracy of the performance counters

I<sub>RYDQ</sub>

The Performance Monitors provide broadly accurate and statistically useful count information. To keep the implementation and validation costs low, a reasonable degree of inaccuracy in the counts is acceptable.

Arm does not define a reasonable degree of inaccuracy, but recommends the following guidelines:

- Under normal operating conditions, the counters present an accurate value of the count.
- In exceptional circumstances, such as a change in Security state or other boundary condition, it is acceptable for the count to be inaccurate.
- Under very unusual, non-repeating, pathological cases, the counts can be inaccurate. These cases are likely to occur as a result of asynchronous exceptions, such as interrupts, where the chance of a systematic error in the count is very unlikely.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

R<sub>XCDG</sub>

A reasonable degree of inaccuracy in the PMU is permitted, if this does not create systematic inaccuracies in normal operating conditions.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

I<sub>JZGS</sub>

In normal operating conditions:

- Top level counters for a category of PMU events will reflect the orthogonal items in their sub-categories, when the sub-categories provide complete coverage. For example, a MEM\_ACCESS event will be the sum of events which count cache accesses.
- Where the sub-categories do not provide comprehensive coverage, the top level counters will count greater than or equal to the sum of the sub-categories.
- Architectural events will be consistently applied but allowance should be made for edge conditions when enabling or disabling counters.
- Arm recommends that barrier instructions are used when enabling or disabling the PMU or individual counters.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

## B15.4 Attributability

**R<sub>GBQN</sub>** An event that is caused by the PE that is counting the event is [Attributable](#). If an agent other than the PE that is counting the events causes an event, these events are [Unattributable](#).

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

**R<sub>XXLL</sub>** All architecturally defined events are [Attributable](#), unless otherwise stated in the PMU event list.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

**R<sub>XGRG</sub>** Events caused by the execution of an instruction are [Attributable](#) to the Security state and privilege mode the instruction was executed in.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#) && [S](#).*

**R<sub>LDGQ</sub>** Events are not counted if any of the following are true:

- The event is [Attributable](#) to Secure state and privileged mode and `SecureNoninvasiveDebugEnabled(TRUE) == FALSE`.
- The event is [Attributable](#) to Secure state and unprivileged mode and `SecureNoninvasiveDebugEnabled(FALSE) == FALSE`.
- The event is [Attributable](#) to Non-secure state and privileged mode and `NoninvasiveDebugEnabled(TRUE) == FALSE`.
- The event is [Attributable](#) to Non-secure state and unprivileged mode and `NoninvasiveDebugEnabled(FALSE) == FALSE`.

The event is [Attributable](#) to Secure state are not counted if `SecureNoninvasiveDebugEnabled() == FALSE`.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

**R<sub>WJDJ</sub>** [Attributable](#) Events caused by the following are [Attributable](#) to the NS-Req and privilege for the access:

- Vector fetches.
- The hardware stacking or unstacking of registers on any of:
  - Exception entry.
  - Exception exit.
  - Function call entry.
  - Function return.
  - Lazy state preservation.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#). Note, Secure state requires [S](#).*

**R<sub>VHLM</sub>** For each [Unattributable](#) event it is IMPLEMENTATION DEFINED whether the [Unattributable](#) event is counted when counting [Attributable](#) events is prohibited.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

## B15.5 Coexistence with the DWT Performance Monitors

**R<sub>NKCB</sub>** The PMU cycle counter **PMU\_CCNTR** is an alias of the **DWT\_CYCCNT** register. All derived PMU functions are available whenever the PMU enables the cycle counter. If both the PMU and the DWT are implemented, **DWT\_CTRL.NOCYCCNT** is RAZ.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **PMU** && **DWT-D**.*

**R<sub>ZBWD</sub>** When **PMU\_CTRL.E** == 1:

- A read of **DWT\_CPICNT**, **DWT\_EXCCNT**, **DWT\_FOLDCNT**, **DWT\_LSUCNT**, and **DWT\_SLEEPCNT** return an UNKNOWN value.
- **DWT\_CPICNT**, **DWT\_EXCCNT**, **DWT\_FOLDCNT**, **DWT\_LSUCNT**, and **DWT\_SLEEPCNT** might increment at random.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **PMU** && **DWT-T**.*

**R<sub>KDKT</sub>** When any of **DWT\_CTRL.FOLDEVTENA**, **LSUEVTENA**, **SLEEPEVTENA**, **EXCEVTENA**, **CPIEVTENA** == 1:

- A read of any **PMU\_EVCNTRn** counters returns an UNKNOWN value.
- A read of the PMU overflow flags in **PMU\_OVSSET** and **PMU\_OVSCLR** return UNKNOWN values.
- The **PMU\_EVCNTRn** counters might increment at random.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **PMU** && **DWT-T**.*

**R<sub>NDFK</sub>** When **PMU\_CTRL.E** == 1 and any of **DWT\_CTRL.CYCEVTENA**, **FOLDEVTENA**, **LSUEVTENA**, **SLEEPEVTENA**, **EXCEVTENA**, **CPIEVTENA** == 1:

- The generation of Event Counter packets by the DWT is UNPREDICTABLE.
- If any of the **PMU\_INTENSET.Pn** flags are set to 1, the generation of interrupts is UNPREDICTABLE.
- If **PMU\_CTRL.TRO** == 1 the generation of Event Counter packets by the PMU is UNPREDICTABLE.
- The PMU and DWT counters might increment at random.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **PMU** && **DWT-T**.*

**R<sub>KBZG</sub>** It is permissible for an implementation to allow the PMU or DWT to overwrite any packets held in the trace buffer on enabling the PMU and disabling the DWT or enabling the DWT and disabling the PMU without requiring software to flush output to the trace sink or TPIU.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **PMU** && **DWT-T**.*

**R<sub>RGQN</sub>** At any time:

- A write to any of **DWT\_CPICNT**, **DWT\_EXCCNT**, **DWT\_FOLDCNT**, **DWT\_LSUCNT**, or **DWT\_SLEEPCNT**, including the indirect write of 0 when writing 1 to any of **DWT\_CTRL.CYCEVTENA**, **FOLDEVTENA**, **LSUEVTENA**, **SLEEPEVTENA**, **EXCEVTENA**, **CPIEVTENA**, sets the **PMU\_EVCNTRn** to UNKNOWN values.
- A write of **PMU\_EVCNTRn**, including the indirect write of 0 when writing 1 to **PMU\_CTRL.P** to 1, sets **DWT\_CPICNT**, **DWT\_EXCCNT**, **DWT\_FOLDCNT**, **DWT\_LSUCNT**, and **DWT\_SLEEPCNT** to UNKNOWN values.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **PMU** && **DWT-T**.*

**I<sub>KLJG</sub>** It is permissible for PMU and DWT event counters to be aliased. Cycle counters **PMU\_CCNTR** and **DWT\_CYCCNT** are always aliased.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **PMU** && **DWT-T**.*

| I_PTHP | <p>In this section:</p> <p><b>Architecturally executed</b> Instruction architecturally executed is a class of event that counts for each instruction of the specified type. Architecturally executed means that the program flow is of the type that the counted instruction would be executed in a <a href="#">Simple sequential execution</a> of the program. Therefore an instruction that has been executed and retired is defined to be architecturally executed even if the PE discards the results of the speculative execution.</p> <p>If an instruction that would be executed in a <a href="#">Simple sequential execution</a> of the program that generates a synchronous exception, it is IMPLEMENTATION DEFINED whether the instruction is counted. Each architecturally executed instruction is counted once, even if the implementation splits the instruction into multiple operations. Instructions that have no visible effect on the architectural state of the PE are architecturally executed if they form part of the architecturally executed program flow. The point where such instructions are retired is IMPLEMENTATION DEFINED.</p> <p>Examples of instructions that have no visible effects are:</p> <ul style="list-style-type: none"> <li>• A <a href="#">NOP</a>.</li> <li>• A conditional instruction that fails its <a href="#">Condition code check</a>.</li> <li>• A Compare and Branch on Zero, <a href="#">CBZ</a>, instruction that does not branch.</li> <li>• A Compare and Branch on Nonzero, <a href="#">CBNZ</a>, instruction that does not branch.</li> </ul> <p>The point at which an event causes an event counter to be updated is not defined.</p> <p><b>Instruction architecturally executed, Condition code check pass</b> Instruction architecturally executed, Condition code check pass is a class of events that explicitly do not occur for:</p> <ul style="list-style-type: none"> <li>• A conditional instruction that fails its <a href="#">Condition code check</a>.</li> <li>• A Compare and Branch on Zero, <a href="#">CBZ</a>, instruction that does not branch.</li> <li>• A Compare and Branch on Nonzero, <a href="#">CBNZ</a>, instruction that does not branch.</li> <li>• A Store-Exclusive instruction that does not write to memory.</li> </ul> <p>Otherwise the definition of architecturally executed is the same as Instruction architecturally executed.</p> <p>A branch that is architecturally executed, with condition code check pass is also described as a branch taken.</p> |

**Instruction memory access** A PE acquires instructions for execution through instruction fetches. Instruction fetches might be due to:

- Fetching instructions that are architecturally executed.
- The result of the execution of a `PLI` instruction.
- Speculation that a particular instruction might be executed in the future.

The relationship between the fetch of an individual instruction and an instruction memory access is IMPLEMENTATION DEFINED. For example, an implementation might fetch many instructions including a non-integer number of instructions in a single instruction memory access.

**Memory-read operations** A PE accesses memory through memory-read operations and memory-write operations. A memory-read operation might be due to:

- The result of an architecturally executed memory-reading instruction.
- The result of a Speculatively executed memory-reading instruction.

For levels of cache hierarchy beyond the Level 1 caches, memory-read operations also include accesses made as part of a refill of another cache closer to the PE. Such refills might be due to any of the items in the following, non-exhaustive, list:

- Memory-read operations or Memory-write operations that miss in the cache.
- The execution of a preload data instruction.
- The execution of an instruction preload instruction on a unified cache.
- The execution of a cache maintenance operation. A preload instruction or cache maintenance operation is not, in itself, an access to that cache. However, as preload instruction or cache maintenance operation might generate cache refills which are then treated as memory-read operations beyond that cache.
- Speculation that a future instruction might access that memory location.
- Instruction memory accesses.

The relationship between memory-read instructions and memory-read operations is IMPLEMENTATION DEFINED.

**Memory-write operations** Memory-write operations might be due to:

- The result of an architecturally executed memory-writing instruction.
- The result of a Speculatively executed memory-writing instruction.

Speculatively executed memory-writing instructions that do not become architecturally executed must not alter the architecturally defined view of memory. They can, however, generate a memory-write operation that is later undone in some implementation-specific way.

For levels of cache hierarchy beyond the Level 1 caches, memory-write operations also include accesses made as part of a write-back from another cache closer to the PE. A write-back of this type might be due to any of the following non-exhaustive list:

- Evicting a dirty line from the cache, to allocate a cache line for a cache refill.
- The execution of a cache maintenance operation. A cache maintenance operation is not in itself an access to that cache. However, a cache maintenance operation might generate write-backs which are then treated as memory-write operations beyond that cache.
- The result of a coherency request from another PE.

The relationship between memory-writing instructions and memory-write operations is IMPLEMENTATION DEFINED.

The data written back from a cache that is shared with other PEs might not be the data that was written by the PE that performs the operation that leads to the write-back. Nevertheless, the event is counted as a write-back event for that PE.

**Microarchitectural operation** It is permissible for an implementation of a PE to break down instructions into separate, smaller, operations. The use of Microarchitectural operations (micro-ops) is IMPLEMENTATION DEFINED. An instruction might create one or more micro-ops at any point in the execution pipeline. For the

purpose of event counting, the micro-ops are counted. The definition of a micro-op is implementation-specific. An architecture instruction might create more than one micro-op for each instruction. Micro-ops might also be removed or merged in the execution stream, so an architecture instruction might create no micro-ops for an instruction. Any arbitrary translation of instructions to an equivalent sequence of micro-ops is permitted. The PE must strictly follow the architecturally visible behavior no matter the underlying division of an instruction into micro-ops.

The counting of operations can indicate the workload on the PE. However, there is no requirement for operations to represent similar amounts of work, and direct comparisons between different microarchitectures are not meaningful.

For example, an implementation might split an [LDM](#) instruction of six registers into six micro-ops, one for each load, and a seventh address-generation operation to determine the base address or write-back address. Therefore an instruction might be split into multiple countable events.

**Operations speculatively executed** There is no architecturally guaranteed relationship between a Speculatively executed micro-op and an architecturally executed instruction. The results of such an operation can also be discarded, if it transpires that the operation was not required, following a mispredicted branch. Therefore, Armv8-M defines these events as operations speculatively executed, where appropriate.

**Slot** An implementation of a PE might be able to execute multiple micro-ops in a single processor cycle. The maximum number of micro-ops that can be executed might vary at different points in the execution pipeline.

To allow profiling of the utilization of the resource of the PE, an implementation-specific point in the execution pipeline is chosen where the maximum number of micro-ops that can be executed is an IMPLEMENTATION DEFINED fixed value.

**Software change of the PC** Some events relate to instructions that cause a software change of the [PC](#). This includes all:

- Branch instructions.
- Memory-reading instructions that explicitly write to the [PC](#).
- Data-processing instructions that explicitly write to the [PC](#).
- Exception return instructions.

It is IMPLEMENTATION DEFINED whether any or all of the following are treated as software changes to the [PC](#):

- A [BKPT](#).
- An UNDEFINSTR Fault.
- Context synchronization barrier [ISB](#) instructions.

**Speculatively executed** Many events relate to speculatively executed operations. Here, speculatively executed means the PE did some work associated with one or more instructions but the instructions were not necessarily architecturally executed.

The definition of speculatively executed does not mean only those operations that are executed speculatively and later abandoned, for example due to a branch misprediction or fault. That is, speculatively executed operations must count operations on both false and correct execution paths.

Different groups of events can have different IMPLEMENTATION DEFINED definitions of speculatively executed. Such groups share a common base type, which the event name denotes. Each of the events in the previous example is of the base type, operation speculatively executed. For groups of events with a common base type, speculatively executed operations are all counted on the same basis, which normally means at the same point in the pipeline. It is possible to compare the counts and make meaningful observations about the program being profiled.

Within these groups, events are commonly defined with reference to a particular architecture instruction or group of instructions. In the case of speculatively executed operations this means operations with semantics that map to that type of instruction.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

| 0x4011       | uArch      | <a href="#">TRCEXTOUT1</a>             | ETM external output 1                                                                                    |
| 0x4012       | uArch      | <a href="#">TRCEXTOUT2</a>             | ETM external output 2                                                                                    |
| 0x4013       | uArch      | <a href="#">TRCEXTOUT3</a>             | ETM external output 3                                                                                    |
| 0x4018       | uArch      | <a href="#">CTI_TRIGOUT4</a>           | Cross-trigger Interface output trigger 4                                                                 |
| 0x4019       | uArch      | <a href="#">CTI_TRIGOUT5</a>           | Cross-trigger Interface output trigger 5                                                                 |
| 0x401A       | uArch      | <a href="#">CTI_TRIGOUT6</a>           | Cross-trigger Interface output trigger                                                                   |

| Event number | Event type | Event mnemonic | Description                            |
|--------------|------------|----------------|----------------------------------------|
|              |            |                | 6                                      |
| 0x401B       | uArch      | CTI_TRIGOUT7   | Cross-trigger Interface output trigger |
|              |            |                | 7                                      |

Applies to an implementation of the architecture *Armv8.1-M* onward. The extension requirements are - *PMU*.

## B15.9 Generic architectural and microarchitectural events

This section provides descriptions that apply to multiple events.

### B15.9.1 CTI\_TRIGOUT (Cross-trigger Interface output trigger , for = 4 to 7)

The counter counts for each event from CTI output trigger . Note: CTI output triggers are input events to the PMU and PE Trace Unit.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#) && [DSPDE](#).*

### B15.9.2 TRCEXTOUT (PE Trace Unit external output , for = 0 to 3)

The counter counts for each event signaled by the ETM external event .

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#) && [DSPDE](#).*

### B15.9.3 DWT\_CMPMATCH (DWT comparator match, for = 0 to 7)

The counter increments for each successful comparator match indicated by DWT comparator . The comparator does not increment if the comparator is not implemented or is disabled

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#) && [DSPDE](#).*

### B15.9.4 LI\_CACHE\_REFILL (Level instruction cache refill)

The counter counts each access that is counted by [L<n>I\\_CACHE](#) that returns instructions from beyond the Level instruction cache. Beyond in this context means a Level cache, where m>n, or memory.

The event indicates to software that the access missed in the Level instruction cache and might have a significant performance impact because of the additional latency, compared to an access that hits in the Level instruction cache.

The definition of Level cache is IMPLEMENTATION DEFINED, and does not necessarily correspond to the [cache levels](#) that are defined by the CLIDR mechanism. Instead, increasing values of correspond to increasing average additional latency.

The counter does not count:

- Accesses where the miss does not have a significant impact on performance.
- A miss that does not cause a new cache refill but is satisfied from a previous miss.

If the cache is shared, only accesses that are [Attributable](#) to this PE are counted.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### B15.9.5 LD\_CACHE\_REFILL (Level data cache refill)

The counter counts each access that is counted by [L<n>D\\_CACHE](#) that returns data from beyond the Level data cache. Beyond in this context means a Level cache, where m>n, or memory.

Each access to a [cache line](#) that causes a new linefill is counted, including those from instructions that generate multiple accesses, such as load or store multiples, and [PUSH](#) and [POP](#) instructions. In particular, the counter counts accesses to the Level cache that cause a refill. A refill includes any access that causes data to be fetched from outside the Level 1 to the Level cache, even if the data is ultimately not allocated into the Level cache.

The definition of Level cache is IMPLEMENTATION DEFINED, and does not necessarily correspond to the [cache levels](#) that are defined by the CLIDR mechanism. Instead, increasing values of correspond to increasing average additional latency.

The counter does not count:

- Accesses that do not cause a new Level cache refill but are satisfied by refilling data from a previous miss.
- Accesses to a [cache line](#) that generate a memory access but not a new linefill, such as Write-Through writes that hit in the cache.
- Cache maintenance instructions.
- A write that writes an entire line to the cache and does not fetch any data from outside the Level cache.
- A write that misses in the cache, and writes through the cache without allocating a line.

If the cache is shared, only accesses that are [Attributable](#) to this PE are counted.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### B15.9.6 LD\_CACHE\_MISS\_RD (Level data cache miss on read)

The counter counts each access that is counted by `L<n>D_CACHE_RD` that returns data from beyond the Level data or unified cache. Beyond in this context means a Level cache, where  $m > n$ , or memory.

The event indicates to software that the access missed in the Level data or unified cache and might have a significant performance impact because of the additional latency, compared to an access that hits in the Level data or unified cache.

The definition of Level cache is IMPLEMENTATION DEFINED, and does not necessarily correspond to the [cache levels](#) that are defined by the CLIDR mechanism. Instead, increasing values of correspond to increasing average additional latency.

The counter does not count:

- Accesses where the miss does not have a significant impact on performance.
- A miss that does not cause a new cache refill but is satisfied from a previous miss.

If the cache is shared, only accesses that are [Attributable](#) to this PE are counted.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### B15.9.7 LD\_CACHE\_WB (Level data cache write-back)

The counter counts every write-back of data from the Level data or unified cache.

The counter counts each write-back that causes data to be written from the Level cache to outside of the Level cache. For example, the counter counts the following cases:

- A write-back that causes data to be written to a Level<n+1> cache or memory.
- A write-back of a recently fetched [cache line](#) that has not been allocated to the Level cache.
- Transfers of data from the Level cache to outside of this cache that are made as a result of a coherency request. The conditions that determine which of these are counted for transfers to other Level caches within the same multiprocessor cluster are IMPLEMENTATION DEFINED.

Each write-back is counted one time, even if multiple accesses are required to complete the write-back.

Whether write-backs that are made as a result of cache maintenance instructions are counted is IMPLEMENTATION DEFINED. The counter does not count:

- The invalidation of a [cache line](#) without any write-back to a Level<n+1> cache or memory.
- Writes from the PE that write through the Level cache to outside of the Level cache.

An Unattributable write-back event occurs when a requestor outside the PE makes a coherency request that results in write-back. If the cache is shared, then an Unattributable write-back event is not counted. If the cache is not shared, then the event is counted. It is IMPLEMENTATION DEFINED whether a write of a whole [cache line](#) that is not the result of the eviction of a line from a cache, is counted.

If the cache is shared, only accesses that are [Attributable](#) to this PE are counted.

*Applies to an implementation of the architecture [Armv8.1-M](#) onward. The extension requirements are - [PMU](#).*

### B15.9.8 LI\_CACHE (Level instruction cache access)

The counter counts each [Attributable](#) access to at least the Level instruction cache. Each access to other Level instruction memory structures, such as refill buffers, is also counted.

*Applies to an implementation of the architecture [Armv8.1-M](#) onward. The extension requirements are - [PMU](#).*

### B15.9.9 LD\_CACHE (Level data cache access)

The counter counts each [Attributable](#) memory-read or [Attributable](#) memory-write access to at least the Level data or unified cache. Each access to a [cache line](#) is counted, including the multiple accesses of instructions, such as LDM or STM. Each access to other Level data or unified cache memory structures is also counted.

The counter does not count cache maintenance instructions.

*Applies to an implementation of the architecture [Armv8.1-M](#) onward. The extension requirements are - [PMU](#).*

### B15.9.10 LD\_CACHE\_RD (Level data cache access, read)

The counter operates the same way as [L<n>D\\_CACHE](#), with the one exception that the counter counts only memory-read accesses.

*Applies to an implementation of the architecture [Armv8.1-M](#) onward. The extension requirements are - [PMU](#).*

## B15.10 Common event descriptions

The common events that can be supported by the PMU counters are defined in this section. For the common features, the counters normally increment only one time for each event. The individual event descriptions include any exceptions to this. In the definitions, the term *Architecturally executed* means that the instruction flow is one where the counted instruction would have been executed in a simple sequential execution model.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - PMU.*

### SW\_INCR (0x0000, Architectural)

The counter increments on writes to the `PMU_SWINC` register. If the PE performs two *Architecturally executed* writes to the `PMU_SWINC` register without an intervening *Context synchronization event*, then the counter is incremented twice.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - PMU.*

### L1I\_CACHE\_REFILL (0x0001, Microarchitectural)

See `L<n>I_CACHE_REFILL`.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - PMU.*

### L1D\_CACHE\_REFILL (0x0003, Microarchitectural)

See `L<n>D_CACHE_REFILL`.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - PMU.*

### L1D\_CACHE (0x0004, Microarchitectural)

See `L<n>D_CACHE`.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - PMU.*

### LD\_RETIRED (0x0006, Architectural)

The counter increments for every executed memory-reading instruction.

`LD_RETIRED` does not count the return status value of a Store-Exclusive instruction. Whether the preload instructions `PLD`, `PLDW`, and `PLI`, count as memory-reading instructions is IMPLEMENTATION DEFINED. Arm recommends that if these instruction are not implemented as NOPs, then they are counted as memory-reading instructions.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - PMU.*

### ST\_RETIRED (0x0007, Architectural)

The counter increments for every executed memory-writing instruction. The counter does not increment for a Store-Exclusive instruction that fails.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - PMU.*

### INST\_RETIRE (0x0008, Architectural)

The counter increments for every [Architecturally executed](#) instruction.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### EXC\_TAKEN (0x0009, Architectural)

The counter increments on each exception entry. The counter does not further increment in the case of a late or derived exception, but it is incremented when [tail-chaining](#). This corresponds to calls to the [ActivateException\(\)](#) pseudocode function.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### EXC\_RETURN (0x000A, Architectural)

The counter increments on each exception return. This occurs when the PE is in Handler mode, and one of the following is executed and loads an [EXC\\_RETURN](#) value into the PC:

- A [POP](#) or LDM that includes loading the [PC](#).
- An LDR with the [PC](#) as a destination.
- A [BX](#) with any register.

This counter also increments on [tail-chaining](#).

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### PC\_WRITE\_RETIRE (0x000C, Architectural)

The counter increments for every software change of the [PC](#). This includes all of the following:

- Branch instructions.
- Loop start instructions.
- Loop end instructions.
- Memory-reading instructions that explicitly write to the [PC](#).
- Data-processing instructions that explicitly write to the [PC](#).

It is IMPLEMENTATION DEFINED whether the counter increments for any or all of:

- [BKPT](#) instructions.
- An exception generated because an instruction is UNDEFINED.
- The exception-generating instructions, [SVC](#), and [UDF](#).

It is IMPLEMENTATION DEFINED whether an [ISB](#) is counted as a software change of the [PC](#). The counter does not increment for exceptions other than those explicitly identified in these lists.

Conditional branches are only counted if the branch is taken.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### BR\_IMMED\_RETIRED (0x000D, Architectural)

The counter counts all immediate branch instructions that are [Architecturally executed](#), which includes the immediate variants of any B branch instruction or CBNZ instruction. Conditional branches are always counted, regardless of whether the branch is taken. If an [ISB](#) is counted as a software change of the PC instruction, then it is IMPLEMENTATION DEFINED whether an [ISB](#) is counted as an immediate branch instruction.

*Applies to an implementation of the architecture [Armv8.1-M](#) onward. The extension requirements are - [PMU](#).*

### BR\_RETURN\_RETIRED (0x000E, Architectural)

The counter counts function return instructions.

For example the following, non-exhaustive, list shows instructions that are counted:

- [BX](#) LR.
- [MOV](#) PC, LR.
- [POP](#) ..., PC.
- [LDR](#) PC, [SP], #offset.
- A [BXNS](#) with any register.
- Any indirect branch with [FNC\\_RETURN](#) as the target address.

The following is a non-exhaustive list of instructions that are not counted:

- [BX](#) with any register that is not [LR](#).
- Any [MOV](#) PC where the register being written to is not the [LR](#).
- [LDM](#) SP, ..., PC because write-back is not specified.
- [LDR](#) PC, [SP, #offset] because this specifies the wrong addressing mode.

*Applies to an implementation of the architecture [Armv8.1-M](#) onward. The extension requirements are - [PMU](#).*

### UNALIGNED\_LDST\_RETIRED (0x000F, Architectural)

The counter counts each memory-reading instruction or memory-writing instruction access that would generate an UNALIGNED UsageFault when [CCR.UNALIGN\\_TRP](#) is 1. It is IMPLEMENTATION DEFINED whether this event counts accesses that generate a fault, including accesses that do generate an UNALIGNED UsageFault.

*Applies to an implementation of the architecture [Armv8.1-M](#) onward. The extension requirements are - [PMU](#).*

### BR\_MIS\_PRED (0x0010, Microarchitectural)

The counter counts each correction to the predicted program flow that occurs because of a misprediction from, or no prediction from, the branch prediction resources, and that relates to instructions that the branch prediction resources are capable of predicting. If no program-flow prediction resources are implemented, Arm recommends that the counter counts all branches that are not taken.

*Applies to an implementation of the architecture [Armv8.1-M](#) onward. The extension requirements are - [PMU](#).*

## CPU\_CYCLES (0x0011, Microarchitectural)

The counter increments on every cycle.

All counters are subject to changes in clock frequency, including when a [WFI](#) or [WFE](#) instruction stops the clock. This means that it is **CONSTRAINED UNPREDICTABLE** whether or not CPU\_CYCLES continues to increment when the clocks are stopped by [WFI](#) and [WFE](#) instructions.

Unlike [PMU\\_CCNTR](#), this count is not affected by [PMU\\_CTRL.DP](#), or by [PMU\\_CTRL.C](#):

- The counter is not incremented in prohibited regions, and is not affected by [PMU\\_CTRL.DP](#).
- The counter is reset when event counters are reset by [PMU\\_CTRL.P](#), never by [PMU\\_CTRL.C](#).

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

## BR\_PRED (0x0012, Microarchitectural)

The counter counts every branch or other change in the program flow that the branch prediction resources are capable of predicting. If all branches are subject to prediction, then all branches are predictable branches. If branches are decoded before the branch predictor, so that the branch prediction logic dynamically predicts only some branches, for example conditional and indirect branches, then it is **IMPLEMENTATION DEFINED** whether other branches are counted as predictable branches. Arm recommends that all branches are counted.

An implementation might include other structures that predict branches, such as a loop buffer that predicts short backwards direct branches as taken. Each execution of such a branch is a predictable branch. Terminating the loop might generate a misprediction event that is counted by [BR\\_MIS\\_PRED](#). If no program-flow prediction resources are implemented, this event is optional, but Arm recommends that BR\_PRED counts all branches.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

## MEM\_ACCESS (0x0013, Microarchitectural)

The counter counts memory-read or memory-write operations that the PE made. The counter increments whether the access results in an access to a Level 1 data or unified cache, a Level 2 data or unified cache, or neither of these. The counter does not increment as a result of:

- Instruction memory accesses.
- Cache maintenance instructions.
- Write-back from any cache.
- Refilling of any cache.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

## L1I\_CACHE (0x0014, Microarchitectural)

See [L<n>I\\_CACHE](#).

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

## L1D\_CACHE\_WB (0x0015, Microarchitectural)

See [L<n>D\\_CACHE\\_WB](#).

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

## **L2D\_CACHE (0x0016, Microarchitectural)**

See [L<n>D\\_CACHE](#).

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

## **L2D\_CACHE\_REFILL (0x0017, Microarchitectural)**

See [L<n>D\\_CACHE\\_REFILL](#).

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

## **L2D\_CACHE\_WB (0x0018, Microarchitectural)**

See [L<n>D\\_CACHE\\_WB](#).

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

## **BUS\_ACCESS (0x0019, Microarchitectural)**

The counter counts memory-read or memory-write operations that access outside of the boundary of the PE and its closely-coupled caches. This counter does not include accesses to or from a TCM. Where this boundary lies with respect to any implemented caches is IMPLEMENTATION DEFINED.

The definition of a bus access is IMPLEMENTATION DEFINED but physically it is a single request rather than a burst, (that is, for each bus cycle for which the bus is active). Bus accesses include refills of, and write-backs from, data, instruction, and unified caches. Whether bus accesses include operations that do use the bus but that do not explicitly transfer data is IMPLEMENTATION DEFINED. An Unattributable bus access occurs when a requestor outside the PE makes a request that results in a bus access, for example, a coherency request.

If the bus is shared, then only [Attributable](#) bus accesses are counted. If the bus is not shared, then all bus accesses are counted.

Where an implementation has multiple buses at this boundary, this event counts the sum of accesses across all buses. If a bus supports multiple accesses per cycle, for example through multiple channels, the counter increments one time for each channel that is active on a cycle, and so it might increment by more than one in any given cycle. The maximum increment in any given cycle is IMPLEMENTATION DEFINED.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

## **MEMORY\_ERROR (0x001A, Microarchitectural)**

The counter counts every occurrence of a memory error that is signaled by memory closely coupled to this PE. The definition of local memories is IMPLEMENTATION DEFINED but includes caches and tightly-coupled memories. Memory error refers to a physical error that is detected by the hardware, such as a parity or ECC error. It includes errors that are correctable and those that are not. It does not include errors that are defined in the architecture, such as MPU or SAU faults.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### INST\_SPEC (0x001B, Microarchitectural)

The counter counts instructions that are speculatively executed by the PE. This includes instructions that are subsequently not architecturally executed. As a result, this event counts a larger number of instructions than the number of instructions [Architecturally executed](#). The definition of speculatively executed is IMPLEMENTATION DEFINED.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### BUS\_CYCLES (0x001D, Microarchitectural)

The counter increments on every cycle of the external memory interface of the PE.

If the implementation clocks the external memory interface at the same rate as the processor hardware, the counter counts every cycle.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### CHAIN (0x001E, Architectural)

Even-numbered counters never increment as a result of this event. This means the CHAIN event links the odd-numbered counter with the preceding even-numbered counter to provide a 32-bit counter.

The CHAIN event means a system can provide N 16-bit counters, N/2 32-bit counters, or a mixture of 16-bit counters and 32-bit counters. The increment of both counters is atomic with respect to software or external counter access.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### L1D\_CACHE\_ALLOCATE (0x001F, Microarchitectural)

The counter increments on every [Attributable](#) write that writes an entire line into the Level 1 cache without fetching from outside the Level 1 cache, for example a write from a coalescing buffer of a full cache line.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### L2D\_CACHE\_ALLOCATE (0x0020, Microarchitectural)

The counter increments on every [Attributable](#) write that writes an entire line into the Level 2 cache without fetching from outside the Level 1 or Level 2 caches, for example:

- A write-back from a Level 1 to a Level 2 cache.
- A write from a coalescing buffer of a full [cache line](#).

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

## BR\_RETIRE (0x0021, Architectural)

The counter counts all branches on the [Architecturally executed](#) path that would incur a cost if mispredicted:

- It counts at retirement:
  - All branch instructions.
  - All memory-reading instructions that explicitly write to the [PC](#).
  - All data-processing instructions that explicitly write to the [PC](#).
- It counts both:
  - Branches that are taken.
  - Branches that are not taken.
- It is IMPLEMENTATION DEFINED whether this includes each of:
  - Unconditional direct branch instructions.
  - Exception-generating instructions.
  - Exception return instructions.
  - Context synchronization instructions.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

## BR\_MIS\_PRED\_RETIRE (0x0022, Microarchitectural)

The counter counts all instructions counted by [BR\\_RETIRE](#) that were not correctly predicted. If no program-flow prediction resources are implemented, this event counts all retired not-taken branches.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

## STALL\_FRONTEND (0x0023, Microarchitectural)

The counter counts every cycle counted by the [CPU\\_CYCLES](#) event on which no operation was issued because there are no operations available to issue for this PE from the frontend. The division between frontend and backend is IMPLEMENTATION DEFINED. Frontend and backend events count at the same point in the pipeline.

For a simplified pipeline model of Fetch > Decode > Issue > Execute > Retire, Arm recommends that the events are counted when instructions are dispatched from Decode to Issue.

On a given cycle, both events might be counted if the backend is unable to accept any operations and there are no operations available to issue from the frontend.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

## STALL\_BACKEND (0x0024, Microarchitectural)

The counter counts every cycle counted by the [CPU\\_CYCLES](#) event on which no operation was issued because either:

- The backend is unable to accept any of the operations available for issue for this PE.
- The backend is unable to accept any operations.

For example, the back end might be unable to accept operations because of a resource conflict or non-availability. The division between frontend and backend is IMPLEMENTATION DEFINED. Frontend and backend events count at the same point in the pipeline.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### **L2I\_CACHE (0x0027, Microarchitectural)**

See [L<n>I\\_CACHE](#).

Applies to an implementation of the architecture *Armv8.1-M* onward. The extension requirements are - [PMU](#).

### **L2I\_CACHE\_REFILL (0x0028, Microarchitectural)**

See [L<n>I\\_CACHE\\_REFILL](#).

Applies to an implementation of the architecture *Armv8.1-M* onward. The extension requirements are - [PMU](#).

### **L3D\_CACHE\_ALLOCATE (0x0029, Microarchitectural)**

The counter increments on every [Attributable](#) write that writes an entire line into the Level 3 cache without fetching from outside the Level 1, Level 2, or Level 3 cache, for example:

- A write-back from a Level 2 to Level 3 cache.
- A write from a coalescing buffer of a full [cache line](#).

Applies to an implementation of the architecture *Armv8.1-M* onward. The extension requirements are - [PMU](#).

### **L3D\_CACHE\_REFILL (0x002A, Microarchitectural)**

See [L<n>D\\_CACHE\\_REFILL](#).

Applies to an implementation of the architecture *Armv8.1-M* onward. The extension requirements are - [PMU](#).

### **L3D\_CACHE (0x002B, Microarchitectural)**

See [L<n>D\\_CACHE](#).

Applies to an implementation of the architecture *Armv8.1-M* onward. The extension requirements are - [PMU](#).

### **L3D\_CACHE\_WB (0x002C, Microarchitectural)**

See [L<n>D\\_CACHE\\_WB](#).

Applies to an implementation of the architecture *Armv8.1-M* onward. The extension requirements are - [PMU](#).

### **LL\_CACHE\_RD (0x0036, Microarchitectural)**

See [L<n>D\\_CACHE\\_RD](#).

Applies to an implementation of the architecture *Armv8.1-M* onward. The extension requirements are - [PMU](#).

### **LL\_CACHE\_MISS\_RD (0x0037, Microarchitectural)**

See [L<n>D\\_CACHE\\_MISS\\_RD](#).

Applies to an implementation of the architecture *Armv8.1-M* onward. The extension requirements are - [PMU](#).

### L1D\_CACHE\_LMISS\_RD (0x0039, Microarchitectural)

See [L<n>D\\_CACHE\\_MISS\\_RD](#).

Applies to an implementation of the architecture *Armv8.1-M* onward. The extension requirements are - [PMU](#).

### OP\_RETIRED (0x003A, Microarchitectural)

The counter counts each operation counted by [OP\\_SPEC](#) that is later committed to the architectural state of this PE.

Applies to an implementation of the architecture *Armv8.1-M* onward. The extension requirements are - [PMU](#).

### OP\_SPEC (0x003B, Microarchitectural)

The counter counts the number of [Attributable](#) instructions or operations that are sent for execution by this PE, including those that are not committed to the architectural state of this PE.

This event might be an alias for [INST\\_SPEC](#).

Applies to an implementation of the architecture *Armv8.1-M* onward. The extension requirements are - [PMU](#).

### STALL (0x003C, Microarchitectural)

The counter counts every [Attributable](#) cycle on which no [Attributable](#) instruction operation was sent for execution for this PE.

The division between frontend and backend is IMPLEMENTATION DEFINED. [STALL](#), [STALL\\_FRONTEND](#) and [STALL\\_BACKEND](#) events count at the same point in the pipeline.

For a simplified pipeline model of Fetch, Decode, Issue, Execute, Retire, Arm recommends that the events are counted when instructions are dispatched from Decode to Issue.

Applies to an implementation of the architecture *Armv8.1-M* onward. The extension requirements are - [PMU](#).

### STALL\_SLOT\_BACKEND (0x003D, Microarchitectural)

Counts each slot counted by [STALL\\_SLOT](#) where no [Attributable](#) instruction or operation was sent for execution because either:

- The backend was unable to accept the instruction operation available for this PE on the slot.
- The backend is unable to accept any operations on the slot.

The division between frontend and backend is IMPLEMENTATION DEFINED. [STALL\\_SLOT](#), [STALL\\_SLOT\\_FRONTEND](#) and [STALL\\_SLOT\\_BACKEND](#) events count at the same point in the pipeline.

On a given cycle, both the [STALL\\_SLOT\\_FRONTEND](#) and the [STALL\\_SLOT\\_BACKEND](#) event might be counted if the backend is unable to accept any operations and there are no operations available to issue from the frontend.

Applies to an implementation of the architecture *Armv8.1-M* onward. The extension requirements are - [PMU](#).

### **STALL\_SLOT\_FRONTEND (0x003E, Microarchitectural)**

Counts each slot counted by [STALL\\_SLOT](#) where no [Attributable](#) instruction or operation was sent for execution because there was no [Attributable](#) instruction or operation available to issue for this PE from the frontend for the slot.

The division between frontend and backend is IMPLEMENTATION DEFINED. [STALL\\_SLOT](#), [STALL\\_SLOT\\_FRONTEND](#) and [STALL\\_SLOT\\_BACKEND](#) events count at the same point in the pipeline.

On a given cycle, both the [STALL\\_SLOT\\_FRONTEND](#) and the [STALL\\_SLOT\\_BACKEND](#) event might be counted if the backend is unable to accept any operations and there are no operations available to issue from the frontend.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### **STALL\_SLOT (0x003F, Microarchitectural)**

The counter counts on each [Attributable](#) cycle the number of instruction or operation slots that were not occupied by an instruction or operation [Attributable](#) to this PE.

The definition of a slot is IMPLEMENTATION DEFINED, but there is a fixed number of slots, WIDTH, that are available on each cycle, so that the formula  $\text{STALL\_SLOT} / (\text{CPU\_CYCLES} \times \text{WIDTH})$  gives the utilization of the slots of the processor by [Attributable](#) instruction or operations of this PE. Each slot can hold at most one instruction or operation each cycle.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### **L1D\_CACHE\_RD (0x0040, Microarchitectural)**

See [L<n>D\\_CACHE\\_RD](#).

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### **LE\_RETIRE (0x0100, Microarchitectural)**

The counter increments for every [Architecturally executed](#) loop end ([LE](#)) instruction, when that instruction registers an entry inside the [LO\\_BRANCH\\_INFO](#) cache.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### **LE\_SPEC (0x0101, Microarchitectural)**

The counter increments for every speculatively executed loop end ([LE](#)) instruction, when that instruction registers an entry inside the [LO\\_BRANCH\\_INFO](#) cache.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### **BF\_RETIRE (0x0104, Microarchitectural)**

The counter increments for every [Architecturally executed](#) branch future instruction, when that instruction registers an entry inside the [LO\\_BRANCH\\_INFO](#) cache.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### **BF\_SPEC (0x0105, Microarchitectural)**

The counter increments for every speculatively executed branch future instruction, when that instruction registers an entry inside the [LO\\_BRANCH\\_INFO](#) cache.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### **LE\_CANCEL (0x0108, Microarchitectural)**

The [LO\\_BRANCH\\_INFO](#) cache was cleared while it contained a valid loop entry as set up by a loop end instruction, and that did not coincide with the last iteration of the loop.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### **BF\_CANCEL (0x0109, Microarchitectural)**

The [LO\\_BRANCH\\_INFO](#) cache was cleared while it contained a valid branch entry as set up by a branch future instruction, and that did not coincide with a taken implicit branch.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### **SE\_CALL\_S (0x0114, Architectural)**

The counter increments for every [Architecturally executed SG](#) instruction that results in a Security state transition from Non-secure state to Secure state.

Arm recommends that this counter increments regardless of the Security state filters that are applied to the PMU.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### **SE\_CALL\_NS (0x0115, Architectural)**

The counter increments for every [Architecturally executed BLXNS](#) instruction that results in a Security state transition from Secure state to Non-secure state.

Arm recommends that this counter increments regardless of the Security state filters that are applied to the PMU.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### **DWT\_CMPMATCH0 (0x0118, Architectural)**

See [DWT\\_CMPMATCH<n>](#).

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#) && [DSPDE](#).*

### **DWT\_CMPMATCH1 (0x0119, Architectural)**

See [DWT\\_CMPMATCH<n>](#).

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#) && [DSPDE](#).*

### DWT\_CMPMATCH2 (0x011A, Architectural)

See [DWT\\_CMPMATCH<n>](#).

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#) && [DSPDE](#).*

### DWT\_CMPMATCH3 (0x011B, Architectural)

See [DWT\\_CMPMATCH<n>](#).

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#) && [DSPDE](#).*

### DWT\_CMPMATCH4 (0x011C, Architectural)

See [DWT\\_CMPMATCH<n>](#).

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#) && [DSPDE](#).*

### DWT\_CMPMATCH5 (0x011D, Architectural)

See [DWT\\_CMPMATCH<n>](#).

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#) && [DSPDE](#).*

### DWT\_CMPMATCH6 (0x011E, Architectural)

See [DWT\\_CMPMATCH<n>](#).

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#) && [DSPDE](#).*

### DWT\_CMPMATCH7 (0x011F, Architectural)

See [DWT\\_CMPMATCH<n>](#).

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#) && [DSPDE](#).*

### MVE\_INST\_RETIRED (0x0200, Architectural)

The counter increments for each [Architecturally executed MVE](#) instruction that is subject to beat-wise execution. This includes instructions that are partially or fully predicated, and instructions that resume execution after returning from an exception.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### MVE\_INST\_SPEC (0x0201, Microarchitectural)

The counter increments for each speculatively executed [MVE](#) instruction that is subject to beat-wise execution. This includes instructions that are subsequently not [Architecturally executed](#). As a result, this event might count a larger number of instructions than the number of instructions [Architecturally executed](#). The definition of speculatively executed is IMPLEMENTATION DEFINED.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### **MVE\_FP\_RETIRE**D (0x0204, Architectural)

The counter increments for each [Architecturally executed MVE](#) instruction, as counted by [MVE\\_INST\\_RETIRE](#)D, that operates on floating-point data. This includes [MVE](#) conversion instructions that convert to or from floating-point representation, as well as floating-point vector compare and vector predicate instructions.

*Applies to an implementation of the architecture [Armv8.1-M](#) onward. The extension requirements are - [PMU](#).*

### **MVE\_FP\_SPEC** (0x0205, Microarchitectural)

The counter increments for each speculatively executed [MVE](#) instruction, as counted by [MVE\\_INST\\_SPEC](#), that operates on floating-point data. This includes [MVE](#) conversion instructions that convert to or from floating-point representation, as well as floating-point vector compare and vector predicate instructions.

*Applies to an implementation of the architecture [Armv8.1-M](#) onward. The extension requirements are - [PMU](#).*

### **MVE\_FP\_HP\_RETIRE**D (0x0208, Architectural)

The counter increments for each [Architecturally executed MVE](#) floating-point instruction that operates on floating-point data, as counted by [MVE\\_FP\\_RETIRE](#)D, and which additionally operates on half-precision data. This includes [MVE](#) conversion instructions that convert to or from half-precision floating-point representation.

*Applies to an implementation of the architecture [Armv8.1-M](#) onward. The extension requirements are - [PMU](#).*

### **MVE\_FP\_HP\_SPEC** (0x0209, Microarchitectural)

The counter increments for each speculatively executed [MVE](#) floating-point instruction that operates on floating-point data, as counted by [MVE\\_FP\\_SPEC](#), and which additionally operates on half-precision data. This includes [MVE](#) conversion instructions that convert to or from half-precision floating-point representation.

*Applies to an implementation of the architecture [Armv8.1-M](#) onward. The extension requirements are - [PMU](#).*

### **MVE\_FP\_SP\_RETIRE**D (0x020C, Architectural)

The counter increments for each [Architecturally executed MVE](#) floating-point instruction that operates on floating-point data, as counted by [MVE\\_FP\\_RETIRE](#)D, and which additionally operates on single-precision data. This includes [MVE](#) conversion instructions that convert to or from single-precision floating-point representation.

*Applies to an implementation of the architecture [Armv8.1-M](#) onward. The extension requirements are - [PMU](#).*

### **MVE\_FP\_SP\_SPEC** (0x020D, Microarchitectural)

The counter increments for each speculatively executed [MVE](#) floating-point instruction that operates on floating-point data, as counted by [MVE\\_FP\\_SPEC](#), and which additionally operates on single-precision data. This does not include [MVE](#) conversion instructions that convert to or from single-precision floating-point representation.

*Applies to an implementation of the architecture [Armv8.1-M](#) onward. The extension requirements are - [PMU](#).*

### **MVE\_FP\_MAC\_RETIRED (0x0214, Architectural)**

The counter increments for each [Architecturally executed MVE](#) floating-point instruction that performs a multiply or multiply-accumulate operation. This includes instructions that perform fused multiply-accumulation.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### **MVE\_FP\_MAC\_SPEC (0x0215, Microarchitectural)**

The counter increments for each speculatively executed [MVE](#) floating-point instruction that performs a multiply or multiply-accumulate operation. This includes instructions that perform fused multiply-accumulation.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### **MVE\_INT\_RETIRED (0x0224, Architectural)**

The counter increments for each [Architecturally executed MVE](#) beat-wise integer or fixed-point instruction. This does not include any floating-point conversion instructions. This does include integer vector compare and vector predicate instructions.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### **MVE\_INT\_SPEC (0x0225, Microarchitectural)**

The counter increments for each speculatively executed [MVE](#) beat-wise integer or fixed-point instruction. This does not include any floating-point conversion instructions. This does include integer vector compare and vector predicate instructions.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### **MVE\_INT\_MAC\_RETIRED (0x0228, Architectural)**

The counter increments for each [Architecturally executed MVE](#) integer or fixed-point instruction, as counted by [MVE\\_INT\\_RETIRED](#), which additionally performs a multiply or multiply-accumulate operation. This includes reducing variants.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### **MVE\_INT\_MAC\_SPEC (0x0229, Microarchitectural)**

The counter increments for each speculatively executed [MVE](#) integer or fixed-point instruction, as counted by [MVE\\_INT\\_SPEC](#) which additionally performs a multiply or multiply-accumulate operation. This includes reducing variants.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### **MVE\_LDST\_RETIRED (0x0238, Architectural)**

The counter increments for each [Architecturally executed MVE](#) load instruction that writes data to a Q register or store instruction that sources data from a Q register.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### **MVE\_LDST\_SPEC (0x0239, Microarchitectural)**

The counter increments for each speculatively executed **MVE** load instruction that writes data to a Q register or store instruction that sources data from a Q register.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **PMU**.*

### **MVE\_LD\_RETIRED (0x023C, Architectural)**

The counter increments each time **MVE\_LDST\_RETIRED** increments as a result of a load operation.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **PMU**.*

### **MVE\_LD\_SPEC (0x023D, Microarchitectural)**

The counter increments each time **MVE\_LDST\_SPEC** increments as a result of a load operation.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **PMU**.*

### **MVE\_ST\_RETIRED (0x0240, Architectural)**

The counter increments each time **MVE\_LDST\_RETIRED** increments as a result of a store operation.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **PMU**.*

### **MVE\_ST\_SPEC (0x0241, Microarchitectural)**

The counter increments each time **MVE\_LDST\_SPEC** increments as a result of a store operation.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **PMU**.*

### **MVE\_LDST\_CONTIG\_RETIRED (0x0244, Microarchitectural)**

The counter increments each time a contiguous memory load or store instruction is **Architecturally executed**, and results in an optimal number of memory accesses. The counter increments for scatter-gather instructions that are promoted to contiguous accesses. The counter increments regardless of alignment.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **PMU**.*

### **MVE\_LDST\_CONTIG\_SPEC (0x0245, Microarchitectural)**

The counter increments each time a contiguous memory load or store instruction is speculatively executed, and results in an optimal number of memory accesses. The counter increments for scatter-gather instructions that are promoted to contiguous accesses. The counter increments regardless of alignment.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **PMU**.*

### **MVE\_LD\_CONTIG\_RETIRED (0x0248, Microarchitectural)**

The counter increments each time **MVE\_LDST\_CONTIG\_RETIRED** increments as a result of a load operation.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **PMU**.*

### **MVE\_LD\_CONTIG\_SPEC (0x0249, Microarchitectural)**

The counter increments each time [MVE\\_LDST\\_CONTIG\\_SPEC](#) increments as a result of a load operation.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### **MVE\_ST\_CONTIG\_RETIRED (0x024C, Microarchitectural)**

The counter increments each time [MVE\\_LDST\\_CONTIG\\_RETIRED](#) increments as a result of a store operation.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### **MVE\_ST\_CONTIG\_SPEC (0x024D, Microarchitectural)**

The counter increments each time [MVE\\_LDST\\_CONTIG\\_SPEC](#) increments as a result of a store operation.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### **MVE\_LDST\_NONCONTIG\_RETIRED (0x0250, Microarchitectural)**

The counter increments each time a non-contiguous memory load or store instruction is [Architecturally executed](#), and results in an increased number of accesses compared to a contiguous operation. The counter is incremented one time, regardless of the additional number of memory requests that are required to complete the execution of that instruction. The counter does not increment if a scatter-gather instruction is promoted to contiguous memory accesses.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### **MVE\_LDST\_NONCONTIG\_SPEC (0x0251, Microarchitectural)**

The counter increments each time a non-contiguous memory load or store instruction is speculatively executed, and results in an increased number of accesses compared to a contiguous operation. The counter is incremented one time, regardless of the additional number of memory requests that are required to complete the execution of that instruction. The counter does not increment if a scatter-gather instruction is promoted to contiguous memory accesses.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### **MVE\_LD\_NONCONTIG\_RETIRED (0x0254, Microarchitectural)**

The counter increments each time [MVE\\_LDST\\_NONCONTIG\\_RETIRED](#) increments as a result of a load operation.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### **MVE\_LD\_NONCONTIG\_SPEC (0x0255, Microarchitectural)**

The counter increments each time [MVE\\_LDST\\_NONCONTIG\\_SPEC](#) increments as a result of a load operation.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### **MVE\_ST\_NONCONTIG\_RETIRED (0x0258, Microarchitectural)**

The counter increments each time [MVE\\_LDST\\_NONCONTIG\\_RETIRED](#) increments as a result of a store operation.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### **MVE\_ST\_NONCONTIG\_SPEC (0x0259, Microarchitectural)**

The counter increments each time [MVE\\_LDST\\_NONCONTIG\\_SPEC](#) increments as a result of a store operation.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### **MVE\_LDST\_MULTI\_RETIRED (0x025C, Architectural)**

The counter increments whenever a VLD2x, VST2x, VLD4x, or VST4x instruction is [Architecturally executed](#).

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### **MVE\_LDST\_MULTI\_SPEC (0x025D, Microarchitectural)**

The counter increments whenever a VLD2x, VST2x, VLD4x, or VST4x instruction is speculatively executed.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### **MVE\_LD\_MULTI\_RETIRED (0x0260, Architectural)**

The counter increments whenever a VLD2x, or VLD4x instruction is [Architecturally executed](#).

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### **MVE\_LD\_MULTI\_SPEC (0x0261, Microarchitectural)**

The counter increments whenever a VLD2x, or VLD4x instruction is speculatively executed.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### **MVE\_ST\_MULTI\_RETIRED (0x0264, Architectural)**

The counter increments whenever a VST2x, or VST4x instruction is [Architecturally executed](#).

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### **MVE\_ST\_MULTI\_SPEC (0x0265, Microarchitectural)**

The counter increments whenever a VST2x, or VST4x instruction is speculatively executed.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### **MVE\_LDST\_UNALIGNED\_RETIRED (0x028C, Microarchitectural)**

The counter increments when [MVE\\_LDST\\_RETIRED](#) increments as a result of an instruction that requires one or more additional memory accesses because of misalignment.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### **MVE\_LDST\_UNALIGNED\_SPEC (0x028D, Microarchitectural)**

The counter increments when [MVE\\_LDST\\_SPEC](#) increments as a result of an instruction that requires one or more additional memory accesses because of misalignment.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### **MVE\_LD\_UNALIGNED\_RETIRED (0x0290, Microarchitectural)**

The counter increments when [MVE\\_LDST\\_UNALIGNED\\_RETIRED](#) increments as a result of a load operation.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### **MVE\_LD\_UNALIGNED\_SPEC (0x0291, Microarchitectural)**

The counter increments when [MVE\\_LDST\\_UNALIGNED\\_SPEC](#) increments as a result of a load operation.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### **MVE\_ST\_UNALIGNED\_RETIRED (0x0294, Microarchitectural)**

The counter increments when [MVE\\_LDST\\_UNALIGNED\\_RETIRED](#) increments as a result of a store operation.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### **MVE\_ST\_UNALIGNED\_SPEC (0x0295, Microarchitectural)**

The counter increments when [MVE\\_LDST\\_UNALIGNED\\_SPEC](#) increments as a result of a store operation.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### **MVE\_LDST\_UNALIGNED\_NONCONTIG\_RETIRED (0x0298, Microarchitectural)**

This counter increments whenever both [MVE\\_LDST\\_UNALIGNED\\_RETIRED](#) and [MVE\\_LDST\\_NONCONTIG\\_RETIRED](#) increment.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### **MVE\_LDST\_UNALIGNED\_NONCONTIG\_SPEC (0x0299, Microarchitectural)**

This counter increments whenever both [MVE\\_LDST\\_UNALIGNED\\_SPEC](#) and [MVE\\_LDST\\_NONCONTIG\\_SPEC](#) increment.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

### **MVE\_VREDUCE\_RETIRE** (0x02A0, Architectural)

The counter increments whenever an [MVE](#) instruction that operates on a vector to produce a scalar result that is stored in a general-purpose register is [Architecturally executed](#). This includes only instructions that have the ‘V’ suffix.

*Applies to an implementation of the architecture [Armv8.1-M](#) onward. The extension requirements are - [PMU](#).*

### **MVE\_VREDUCE\_SPEC** (0x02A1, Microarchitectural)

The counter increments whenever an [MVE](#) instruction that operates on a vector to produce a scalar result that is stored in a general-purpose register is speculatively executed. This includes only instructions that have the ‘V’ suffix.

*Applies to an implementation of the architecture [Armv8.1-M](#) onward. The extension requirements are - [PMU](#).*

### **MVE\_VREDUCE\_FP\_RETIRE** (0x02A4, Architectural)

The counter increments whenever both [MVE\\_VREDUCE\\_RETIRE](#) and [MVE\\_FP\\_RETIRE](#) increment.

*Applies to an implementation of the architecture [Armv8.1-M](#) onward. The extension requirements are - [PMU](#).*

### **MVE\_VREDUCE\_FP\_SPEC** (0x02A5, Microarchitectural)

The counter increments whenever both [MVE\\_VREDUCE\\_SPEC](#) and [MVE\\_FP\\_SPEC](#) increment.

*Applies to an implementation of the architecture [Armv8.1-M](#) onward. The extension requirements are - [PMU](#).*

### **MVE\_VREDUCE\_INT\_RETIRE** (0x02A8, Architectural)

The counter increments whenever both [MVE\\_VREDUCE\\_RETIRE](#) and [MVE\\_INT\\_RETIRE](#) increment.

*Applies to an implementation of the architecture [Armv8.1-M](#) onward. The extension requirements are - [PMU](#).*

### **MVE\_VREDUCE\_INT\_SPEC** (0x02A9, Microarchitectural)

The counter increments whenever both [MVE\\_VREDUCE\\_SPEC](#) and [MVE\\_INT\\_SPEC](#) increment.

*Applies to an implementation of the architecture [Armv8.1-M](#) onward. The extension requirements are - [PMU](#).*

### **MVE\_PRED** (0x02B8, Microarchitectural)

The counter increments on each [Architecture tick](#) where one or more beats of an [MVE](#) beat-wise instruction architecturally completes, and where one or more of these beats is partially or fully predicated false by VPR or loop-tail predication.

If a beat is interrupted by an exception and does not architecturally complete, or if the beat is masked by [EPSR.ECI](#) when resuming execution following an exception, Arm recommends that the counter does not increment.

The ratio  $(\text{MVE\_PRED} * \text{BEATS\_PER\_TICK}) / (4 * \text{MVE\_INST\_RETIRE})$  then offers an approximate insight into the proportion of [MVE](#) instructions affected by predication, where [BEATS\\_PER\\_TICK](#) is an IMPLEMENTATION DEFINED average number of beats, including from distinct overlapping instructions, executed per [Architecture tick](#).

*Applies to an implementation of the architecture [Armv8.1-M](#) onward. The extension requirements are - [PMU](#).*

### **MVE\_STALL (0x02CC, Microarchitectural)**

The counter counts every cycle counted by the [CPU\\_CYCLES](#) event on which no operation was issued as a direct result of an [MVE](#) instruction that is either currently executing or attempting to execute.

*Applies to an implementation of the architecture [Armv8.1-M](#) onward. The extension requirements are - [PMU](#).*

### **MVE\_STALL\_RESOURCE (0x02CD, Microarchitectural)**

The counter increments whenever [MVE\\_STALL](#) increments, and where the cause is attributable to an [MVE](#) instruction failing to execute because there are no available resources in the PE capable of executing that instruction.

*Applies to an implementation of the architecture [Armv8.1-M](#) onward. The extension requirements are - [PMU](#).*

### **MVE\_STALL\_RESOURCE\_MEM (0x02CE, Microarchitectural)**

The counter increments whenever [MVE\\_STALL](#) increments, and where the cause is attributable to an [MVE](#) instruction failing to execute because there are no available memory resources in the PE capable of executing that instruction.

*Applies to an implementation of the architecture [Armv8.1-M](#) onward. The extension requirements are - [PMU](#).*

### **MVE\_STALL\_RESOURCE\_FP (0x02CF, Microarchitectural)**

The counter increments whenever [MVE\\_STALL](#) increments, and where the cause is attributable to an [MVE](#) instruction failing to execute because there are no available floating-point resources in the PE capable of executing that instruction.

*Applies to an implementation of the architecture [Armv8.1-M](#) onward. The extension requirements are - [PMU](#).*

### **MVE\_STALL\_RESOURCE\_INT (0x02D0, Microarchitectural)**

The counter increments whenever [MVE\\_STALL](#) increments, and where the cause is attributable to an [MVE](#) instruction failing to execute because there are no available integer resources in the PE capable of executing that instruction.

*Applies to an implementation of the architecture [Armv8.1-M](#) onward. The extension requirements are - [PMU](#).*

### **MVE\_STALL\_BREAK (0x02D3, Microarchitectural)**

The counter increments whenever [MVE\\_STALL](#) increments, and where the cause is attributable to waiting for the completion of an in-flight [MVE](#) instruction. A possible example is when an [MVE](#) chainable instruction completes before executing a scalar instruction. Arm recommends that the counter increments only if no other specific attributable cause can be identified.

*Applies to an implementation of the architecture [Armv8.1-M](#) onward. The extension requirements are - [PMU](#).*

### **MVE\_STALL\_DEPENDENCY (0x02D4, Microarchitectural)**

The counter increments whenever [MVE\\_STALL](#) increments, and where the cause is attributable to the subsequent instruction being delayed to resolve a register RAW conflict.

*Applies to an implementation of the architecture [Armv8.1-M](#) onward. The extension requirements are - [PMU](#).*

### **ITCM\_ACCESS (0x4007, Microarchitectural)**

The counter counts memory read or memory write operations that the PE made to an instruction TCM.

*Applies to an implementation of the architecture [Armv8.1-M](#) onward. The extension requirements are - [PMU](#).*

### **DTCM\_ACCESS (0x4008, Microarchitectural)**

The counter counts memory read or memory write operations that the PE made to a data or unified TCM.

*Applies to an implementation of the architecture [Armv8.1-M](#) onward. The extension requirements are - [PMU](#).*

### **TRCEXTOUT0 (0x4010, Microarchitectural)**

See [TRCEXTOUT<n>](#).

*Applies to an implementation of the architecture [Armv8.1-M](#) onward. The extension requirements are - [PMU](#) && [DSPDE](#).*

### **TRCEXTOUT1 (0x4011, Microarchitectural)**

See [TRCEXTOUT<n>](#).

*Applies to an implementation of the architecture [Armv8.1-M](#) onward. The extension requirements are - [PMU](#) && [DSPDE](#).*

### **TRCEXTOUT2 (0x4012, Microarchitectural)**

See [TRCEXTOUT<n>](#).

*Applies to an implementation of the architecture [Armv8.1-M](#) onward. The extension requirements are - [PMU](#) && [DSPDE](#).*

### **TRCEXTOUT3 (0x4013, Microarchitectural)**

See [TRCEXTOUT<n>](#).

*Applies to an implementation of the architecture [Armv8.1-M](#) onward. The extension requirements are - [PMU](#) && [DSPDE](#).*

### **CTI\_TRIGOUT4 (0x4018, Microarchitectural)**

See [CTI\\_TRIGOUT<n>](#).

*Applies to an implementation of the architecture [Armv8.1-M](#) onward. The extension requirements are - [PMU](#) && [DSPDE](#).*

### **CTI\_TRIGOUT5 (0x4019, Microarchitectural)**

See [CTI\\_TRIGOUT<n>](#).

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#) && [DSPDE](#).*

### **CTI\_TRIGOUT6 (0x401A, Microarchitectural)**

See [CTI\\_TRIGOUT<n>](#).

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#) && [DSPDE](#).*

### **CTI\_TRIGOUT7 (0x401B, Microarchitectural)**

See [CTI\\_TRIGOUT<n>](#).

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#) && [DSPDE](#).*

## B15.11 Required PMU events

R\_FXXR

The architecture requires that the PMU supports at least the following common events:

- 0x0000 **SW\_INCR**: Instruction **Architecturally executed**, condition code check pass, software increment.
- 0x0003 **L1D\_CACHE\_REFILL**: **Attributable** Level 1 data cache refill.
  - This event is only required if the implementation includes a Level 1 data or unified cache.
- 0x0004 **L1D\_CACHE**: **Attributable** Level 1 data cache access.
  - This event is only required if the implementation includes a Level 1 data or unified cache.
- 0x0008 **INST\_RETIRED**: Instruction **Architecturally executed**.
- 0x0011 **CPU\_CYCLES**: Cycle.
- 0x0021 **BR\_RETIRED**: Instruction **Architecturally executed**, branch.
  - This event is only required if the implementation includes program flow prediction.
- 0x0022 **BR\_MIS\_PRED\_RETIRED**: Instruction **Architecturally executed**, mispredicted branch.
  - This event is only required if the implementation includes program flow prediction.
- 0x0023 **STALL\_FRONTEND**: No operation issued due to the frontend.
- 0x0024 **STALL\_BACKEND**: No operation issued due to the backend.
- 0x0200 **MVE\_INST\_RETIRED**: **MVE** instruction **Architecturally executed**.
  - This event is only required if the implementation includes **MVE**.
- 0x0238 **MVE\_LDST\_RETIRED**: **MVE** load or store instruction **Architecturally executed**.
  - This event is only required if the implementation includes **MVE**.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **PMU**.*

## B15.12 IMPLEMENTATION DEFINED event numbers

R<sub>ZJSZ</sub> For IMPLEMENTATION DEFINED event numbers, each counter is independently defined to either:

- Increment only one time for each event.
- Count the duration for which an event occurs.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

I<sub>LCNR</sub> Arm recommends that implementers establish a standardized numbering scheme for their IMPLEMENTATION DEFINED events, with common definitions and common count numbers applied to all of their implementations. In general, Arm recommends standardization across implementations with common features. However, Arm recognizes that attempting to standardize the encoding of microarchitectural features across too wide a range of implementations is not productive.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

I<sub>RKHN</sub> Arm strongly recommends that the IMPLEMENTATION DEFINED events allow the user to measure the utilization of any microarchitectural features that the implementation considers important for system performance, and any significant deviations from optimal performance.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [PMU](#).*

## Chapter B16

# Reliability, Availability, and Serviceability (RAS) Extension

This chapter specifies the Armv8.1-M Reliability, Availability, and Serviceability (RAS) Extension. A minimal implementation of this is mandatory for any implementation of the Armv8.1-M architecture, but any additional RAS features are optional.

This chapter contains the following sections:

[B16.1 Overview.](#)

[B16.2 Taxonomy of errors.](#)

[B16.3 Generating error exceptions.](#)

[B16.4 Error Synchronization Barrier \(ESB\).](#)

[B16.5 Implicit Error Synchronization \(IESB\).](#)

[B16.6 Fault handling.](#)

[B16.7 RAS error records.](#)

[B16.8 Multiple BusFault exceptions.](#)

[B16.9 Error Recovery reset](#)

[B16.10 Minimal RAS implementation.](#)

*Applies to an implementation of the architecture **Armv8.1-M** onward. The extension requirements are - **RAS**.*

## B16.1 Overview

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

[B16.10 Minimal RAS implementation.](#)

## B16.2 Taxonomy of errors

I<sub>GNNQ</sub>

The architecture does not specify techniques for:

- [Fault prevention](#).
- [Fault removal](#).
- [Fault injection](#).
- Testing.

These are IMPLEMENTATION DEFINED and are outside the scope of this architecture.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [RAS](#).*

See also:

- *Arm<sup>®</sup> Reliability, Availability, and Serviceability (RAS) Specification, Armv8, for the Armv8-A architecture profile.*

### B16.2.1 Architectural error propagation

R<sub>MVFK</sub>

For a PE, Error propagation applies to the propagation of detected errors between the general-purpose registers or the Floating-point Extension register file, and any program-visible architectural state of the PE, including:

- Other general-purpose registers and the Floating-point Extension register file.
- Memory-mapped registers.
- Special-purpose registers.
- Memory.

That is, the error is propagated by:

- A store of a corrupt value.
- A write of a corrupt value to a System register or a special-purpose register. Infecting a System register state might mean that the PE generates transactions that would not otherwise be permitted.
- Any operation that would not have been permitted to occur had the error not been activated, including:
  - A load or instruction fetch that would not have been permitted, including those from hardware speculation or prefetching.
  - A store to an incorrect address or a store that would not have been made or not permitted.
  - A direct or indirect write to a special-purpose or System register that would not have been made or not permitted.
  - Assertion of any signal, such as an interrupt, that would not have been asserted.
- Any operation not occurring that would have occurred had the error not been activated.
- Taking an asynchronous exception.
- The PE discarding data that it holds in a modified state.
- Any other loss of uniprocessor semantics, ordering or coherency.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [RAS](#).*

R<sub>RGPS</sub>

The propagated error is [silently propagated](#) if it is not signaled to a consumer as a [Detected](#) error.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [RAS](#).*

R<sub>JKVQ</sub>

The features that a PE includes to contain an error are IMPLEMENTATION DEFINED, and it is IMPLEMENTATION DEFINED whether an error can be signaled to the consumer as a [Detected](#) error.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [RAS](#).*

See also:

*Arm® Reliability, Availability, and Serviceability (RAS) Specification, Armv8, for the Armv8-A architecture profile.*

## B16.2.2 Architecturally infected, contained, and uncontained

$R_{VKZT}$  **Infected, Poisoned, Containable and Uncontainable** apply to all program-visible architectural state of the PE, including general-purpose registers, the Floating-point Extension register file, special purpose registers, System registers, and memory.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - RAS.*

$R_{ZPCB}$  An error is **Uncontainable** by the PE if the error is **silently propagated**, unless it is contained because all of the following are true:

- The corrupt value is in the general-purpose register or in the Floating-point Extension register file.
- The error has only been **silently propagated** by an instruction that occurs in program order after one of the following:
  - Taking a BusFault that is generated by the error.
  - An Error Synchronization Barrier operation that synchronizes the error.
- The error is not **silently propagated** in any other way.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - RAS.*

## B16.2.3 Architecturally consumed errors

$R_{RNNE}$  For a PE, an error is architecturally consumed if any of the following are true:

- An instruction commits the corruption into the visible state of the PE.
- The error is on an instruction fetch and the instruction is committed for execution.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - RAS.*

$R_{MKBF}$  The PE takes action for a detected, architecturally consumed error either by:

- Generating an error exception.
- Entering a failure mode.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - RAS.*

## B16.2.4 Other errors

$I_{TCZS}$  Errors from software faults are outside the scope of the RAS Extension error recovery architecture.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - RAS.*

$I_{KDJP}$  From within the PE itself, other errors might be detected. These are not errors that are detected by the architectural model of the PE and so are treated like errors that are detected by another component. Other components might report errors to a PE using error recovery interrupts. An example of this is when the cache, not the PE, detects a RAM error. Other components might report errors to a PE using error recovery interrupts.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - RAS.*

## B16.3 Generating error exceptions

I<sub>WZHQ</sub>

The following diagram shows the taxonomy of consumed errors.

Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **RAS**.

R<sub>PVJQ</sub>

An error exception is generated for all detected RAS errors that are neither **Corrected** nor **Deferred** errors. These error exceptions are signaled to, and consumed by, a PE and are not silently propagated.

Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **RAS**.

R<sub>RPFQ</sub>

A **Corrected** error is detected and corrected by the PE, and is not silently propagated.

Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **RAS**.

I<sub>NDMC</sub>

In normal circumstances a **Corrected** error no longer infects the node. In IMPLEMENTATION DEFINED circumstances, the **Corrected** error might remain latent in the node.

Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **RAS**.

I<sub>PSKL</sub>

For an **Uncontainable** error, if the error cannot be isolated to an application, the system must be shut down by software to avoid **Catastrophic failure**.

Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **RAS**.

I<sub>LFCG</sub>

For an **Unrecoverable** error, the application cannot continue and must be isolated by software methods.

Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **RAS**.

I<sub>PTXC</sub>

For a **Recoverable** error, if software cannot locate and repair the error, the application must be isolated by software methods.

Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **RAS**.

I<sub>RSJP</sub>

For a **Restartable** error, software might take action to locate and repair the error before it is consumed. The PE can be restarted by software without software taking any action to locate and repair the error.

Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **RAS**.

R<sub>SJKL</sub>

On each error exception, it is IMPLEMENTATION DEFINED whether the error has been contained or whether it is **Uncontainable**. If the error has been contained, it is further IMPLEMENTATION DEFINED whether the state of the PE on taking the error exception is **Unrecoverable**, **Recoverable**, or **Restartable**:

**Uncontainable error (UC)**: The error is **Uncontainable** if it has been, or might have been, **silently propagated**. This is also referred to as an Uncontained error.

**Unrecoverable error (UEU)**: The state of the PE is **Unrecoverable** if all of the following are true:

- The error has not been **silently propagated**.
- The PE cannot recover execution from the return address of the exception. This might be because of one of the following:
  - The error has been architecturally consumed by the PE and infected the state of the PE general-purpose registers, the Floating-point Extension register file, and System registers.
  - The exception is asynchronous.

**Recoverable error (UER)**: The state of the PE is **Recoverable** if all of the following are true:

- The error has not been **silently propagated**.
- The error has not been architecturally consumed by the PE (the architectural state of the PE is not infected).
- The exception is synchronous and the PE can recover execution from the return address of the exception.

The PE cannot make correct progress without either consuming the error or otherwise making the error **Unrecoverable**. The error remains latent in the system.

**Restartable error (UEO)**: The state of the PE is **Restartable** if all of the following are true:

- The error has not been **silently propagated**.
- The error has not been architecturally consumed by the PE (the architectural state of the PE is not infected).
- The exception is synchronous and the PE can recover execution from the return address of the exception.

The PE can make progress. However, the error might remain latent in the system.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **RAS**.*

R<sub>KZPT</sub>

The set of error types that can be reported by an implementation is IMPLEMENTATION DEFINED. An implementation can report:

- Any **Restartable** error as any of **Recoverable**, **Unrecoverable**, or **Uncontainable**.
- Any **Recoverable** error as either **Unrecoverable** or **Uncontainable**.
- Any **Unrecoverable** error as **Uncontainable**.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **RAS**.*

I<sub>XCSK</sub>

If the state of the PE is reported as **Recoverable**, this does not mean that the error can be recovered from. For example, because the error in memory might be one which does not allow software to recover the operation. Rather, software *might* be able to recover if it can repair the error and continue.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **RAS**.*

R<sub>SGHS</sub>

A bus error might be raised in response to:

- An architectural memory read, or reads from instruction fetches.
- An architectural write to memory, or cache maintenance operation.
- A read from memory because of hardware speculation, prefetching, or other non-architectural mechanisms.

The events that trigger bus errors are IMPLEMENTATION DEFINED.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **RAS**.*

R<sub>QLCQ</sub>

It is IMPLEMENTATION DEFINED whether a RAS error that is detected by the consumer of a write from a PE:

- Is deferred to the consumer.
- Is returned to the PE as a bus error.
- Generates an error recovery interrupt.

The behavior might vary by physical address or memory type.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - RAS.*

**R<sub>TFLL</sub>** The method by which the error is deferred depends on the component and is implementation-specific.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - RAS.*

**I<sub>RDQV</sub>** A common mechanism to defer the error is to create **Poisoned** state, which subsequently generates an error when that state is accessed.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - RAS.*

**R<sub>CXSW</sub>** The size of the **Protection granule** for any implemented error detection mechanism is IMPLEMENTATION DEFINED, and a system might implement multiple error detection mechanisms with different **Protection granule** sizes.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - RAS.*

**R<sub>GBDR</sub>** The mechanisms for clearing an error or poison from a **Protection granule** is IMPLEMENTATION DEFINED, and it is IMPLEMENTATION DEFINED whether any such mechanism exists.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - RAS.*

**R<sub>PXMR</sub>** **BFSR** is populated for every BusFault that is generated by a RAS error. **RFSR** is populated for every RAS BusFault exception, and it is IMPLEMENTATION DEFINED whether it is also updated for other asynchronous BusFault exceptions. If **RFSR** is updated, **RFSR.V** is set.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - RAS.*

**R<sub>FZKC</sub>** The severity of the error and the state of the PE are reported when the error exception is pended.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - RAS.*

**I<sub>ZKNJ</sub>** If an error exception occurs while the BusFault exception handler is handling a previous error exception, the existing exception nesting behaviors apply. This might cause the exception to escalate to a HardFault or Lockup.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - RAS.*

**R<sub>VWPS</sub>** A DAP request that causes a synchronous RAS error returns an error to the debugger, but does not update **RFSR**, **BFSR**, and **BFAR**.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - RAS.*

**R<sub>DCKC</sub>** A DAP access that causes an asynchronous RAS error does not return an error to the debugger, but for a read access UNKNOWN data is returned. A BusFault might be generated and update **RFSR**, **BFSR**, and **BFAR**.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - RAS.*

### B16.3.1 Error correction and deferment

**R<sub>WXZD</sub>** Hardware corrects or defers an error if it can do so. The error is logged, and a fault handling interrupt is generated for fault handling purposes if the node is configured to do so.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - RAS.*

## B16.4 Error Synchronization Barrier (ESB)

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

### B16.4.1 ESB and Unrecoverable errors

|                   |                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| R <sub>VDCF</sub> | <p>An <a href="#">ESB</a> acts as a barrier to all <a href="#">unrecoverable</a> (RAS-related and non-RAS related) bus errors and causes any <a href="#">Latent faults</a> to be recognized synchronously with the instruction.</p> <p><i>Applies to an implementation of the architecture <b>Armv8.1-M</b> onward. The extension requirements are - <a href="#">RAS</a>.</i></p> |
| I <sub>MSMM</sub> | <p>Depending on the current state of the PE, recognizing any latent bus errors might simply result in a BusFault being pending, or the BusFault might be taken or escalated.</p> <p><i>Applies to an implementation of the architecture <b>Armv8.1-M</b> onward. The extension requirements are - <a href="#">RAS</a>.</i></p>                                                    |
| I <sub>GCBZ</sub> | <p>The Error Synchronization Barrier operation contains the error for the current software context.</p> <p><i>Applies to an implementation of the architecture <b>Armv8.1-M</b> onward. The extension requirements are - <a href="#">RAS</a>.</i></p>                                                                                                                             |

### B16.4.2 ESB and other containable errors

- $I_{PHSB}$  For other types of [Containable](#) error:
- A [Recoverable](#) error has not yet been consumed by the PE.
  - [Restartable](#) and [Corrected](#) errors, and BusFault exceptions from reads by hardware speculation that do not corrupt the state of the PE, have not been consumed by the PE.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [RAS](#).*

- $R_{WKMP}$  An unconsumed RAS error might be taken at the [ESB](#).

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [RAS](#).*

### B16.4.3 ESB and other errors

- $R_{PHJW}$  Synchronous BusFault exceptions are not synchronized by an Error Synchronization Barrier.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [RAS](#).*

- $R_{TXBQ}$  Interrupts are not synchronized by an [ESB](#).

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [RAS](#).*

- $R_{VSDB}$  An [ESB](#) instruction will synchronize asynchronous BusFaults.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [RAS](#).*

- $R_{WRJG}$  An [ESB](#) always synchronizes [Containable](#) errors, but it is IMPLEMENTATION DEFINED whether IMPLEMENTATION DEFINED and uncategorized BusFault exceptions are [Uncontainable](#), and whether they can be synchronized by an Error Synchronization Barrier.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [RAS](#).*

- $I_{TZTR}$  [Uncontainable](#) errors might not have been contained, and Uncontainable BusFault exceptions might be asynchronous. An [Uncontainable](#) error might be taken at the [ESB](#) but this is not architecturally required.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [RAS](#).*

- $R_{TSGR}$  It is IMPLEMENTATION DEFINED whether IMPLEMENTATION DEFINED and uncategorized interrupts are [Containable](#) or [Uncontainable](#).

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [RAS](#).*

- $I_{HGSQ}$  An [Uncontainable](#) error might be taken at an Error Synchronization Barrier or recorded in [RFSR.IS](#) by an [ESB](#) instruction.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [RAS](#).*

- $R_{SBFD}$  When an [ESB](#) instruction is executed the return address from any taken BusFault exception is the [ESB](#) instruction.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [RAS](#).*

## B16.5 Implicit Error Synchronization (IESB)

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

R<sub>LZWF</sub>

When IESBs are enabled:

- An IESB occurs prior to stacking a lazy floating-point context, and any RAS errors are associated with foreground code.
- An IESB occurs after stacking a lazy floating-point context, and any RAS errors are associated with the register stacking.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [RAS](#).*

R<sub>JMXC</sub>

RAS faults set the first applicable syndrome information from the following list:

- [BFSR.LSPERR](#) if the error is attributable to lazy state preservation stacking.
- [BFSR.STKERR](#) if the error is attributable to exception register stacking.
- [BFSR.UNSTKERR](#) if the error is attributable to exception register unstacking.
- [BFSR.IBUSERR](#) if the error is caused by an instruction fetch or prefetch.
- [BFSR.PRECISERR](#) if the error occurred synchronously and is attributable to instruction execution.
- [BFSR.IMPRESERR](#) otherwise.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [RAS](#).*

## B16.6 Fault handling

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| I <sub>KLPK</sub> | <p>An example of a critical error is one where the <a href="#">node</a> has entered a failure mode, which means that the primary error recovery mechanisms cannot be used. For example, if a memory controller enters a failure mode and stops handling memory requests from application processors, and application processors host the primary error recovery software, then the error is signaled to a secondary error controller that has its own private resources to log the error. The RAS Extension allows for a dedicated interrupt, called the critical error interrupt, to be generated by a node when such an error occurs.</p> <p><i>Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - RAS.</i></p> |
| R <sub>FWDD</sub> | <p>For a given <a href="#">node</a>, the critical error interrupt is implemented if <a href="#">ERRFRn.CI</a> != 0b00.</p> <p><i>Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - RAS.</i></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

[Chapter B12 Nested Vectored Interrupt Controller](#).

## B16.7 RAS error records

**I<sub>ZFWK</sub>** On encountering an error, a **node** writes to the RAS **Error records**. These records can then be analyzed by software to determine whether there are any systematic problems to be dealt with.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **RAS**.*

**R<sub>QDZN</sub>** Each **node** provides at least one **Error record** to control error reporting and expose status.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **RAS**.*

**R<sub>FDFQ</sub>** A **node** can provide multiple **Error records** if it offers multiple, logically distinct functions.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **RAS**.*

**R<sub>STJR</sub>** If a **node** provides multiple **Error records**, these are serially indexed. Each record, other than the first record, has an **ERRFR<sub>n</sub>** register that is RAZ/WI and the **ERRCTRL<sub>n</sub>** register is RES0.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **RAS**.*

**I<sub>SDBZ</sub>** An example of a group containing four error records owned by three nodes is shown below:

In the diagram:

- Node<0> owns one error record: <0>.
- Node<1> owns two error records: <1> and <2>.
- Node<2> owns one error record: <3>.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **RAS**.*

**R<sub>JSWF</sub>** The standard **Error records** contain:

- Controls for common features, and an identification mechanism for these controls. For each **node** it is IMPLEMENTATION DEFINED whether the fault and error reporting mechanisms apply to both reads and writes, or whether they can be individually controlled for reads and writes.
- A status register for common status fields, such as the type and coarse characterization of the error.
- An address register, if applicable.
- IMPLEMENTATION DEFINED controls and identification registers.
- IMPLEMENTATION DEFINED status registers.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **RAS**.*

| R <sub>XPXH</sub> | <p>A counter for <a href="#">Corrected</a> errors is OPTIONAL.</p> <p><i>Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - <a href="#">RAS</a>.</i></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

R<sub>LJTP</sub>

The overwriting of errors depends on the type of the previous highest priority error and the type of the newly recorded error. This is shown in the table below. The table uses the following abbreviations:

- **CE:** [Corrected error](#).
- **CO:** Count and overflow. Keep the previous error syndrome and count the error. If counting the error causes an unsigned overflow of the counter set [ERRSTATUSn.OF](#) to 1.
- **CW:** Count and overwrite. Count CE if a counter is implemented and overwrite. If a counter is implemented and overflows, [ERRSTATUSn.OF](#) is set to an UNKNOWN value. Otherwise, it is IMPLEMENTATION DEFINED whether [ERRSTATUSn.OF](#) is set to 0 or unchanged.
- **CWO:** Count and overwrite or keep. The behavior is IMPLEMENTATION DEFINED and described by the value of [ERRFRn.CEO](#):
  - 0:** Count CE if a counter is implemented and keep the previous error syndrome.
  - 1:** Count CE. If [ERRSTATUSn.OF](#) == 1 before the CE is counted, keep the previous syndrome. Otherwise record the new error syndrome.

If the counter overflows or if no counter is implemented [ERRSTATUSn.OF](#) is set to 1.

- **DE:** [Detected error](#).
- **O:** Overflow. Keep the previous error syndrome and set [ERRSTATUSn.OF](#) to 1.
- **UEO:** [Restartable error](#).
- **UER:** [Recoverable error](#).
- **UEU:** [Unrecoverable error](#).
- **UC:** [Uncontainable error](#).
- **WO:** Overwrite and overflow. [ERRSTATUSn.OF](#) is set to 1.

If no counter is implemented, CW behaves the same as W, and CWO and CO behave the same as O.

| Previous error type | New detected error type |    |     |     |     |    |
|---------------------|-------------------------|----|-----|-----|-----|----|
|                     | CE                      | DE | UEO | UER | UEU | UC |
|                     | CW                      | W  | W   | W   | W   | W  |
| CE                  | CWO                     | WO | WO  | WO  | WO  | WO |
| DE                  | CO                      | O  | WO  | WO  | WO  | WO |
| UEO                 | CO                      | O  | O   | WO  | WO  | WO |
| UER                 | CO                      | O  | O   | O   | WO  | WO |
| UEU                 | CO                      | O  | O   | O   | O   | WO |
| UC                  | CO                      | O  | O   | O   | O   | O  |

## B16.10 Minimal RAS implementation

$I_{QJVV}$  The minimal RAS Extension is mandatory in an Armv8.1-M implementation. All additional RAS features are optional.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [RAS](#).*

$I_{NPMM}$  The RAS Extension is designed to provide a low implementation cost for devices that have limited RAS support.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [RAS](#).*

$I_{DHMH}$  The minimal implementation of the RAS Extension is:

- The [ESB](#) instruction. This might be implemented as a NOP for implementations that do not offer RAS-induced BusFaults.
- [RFSR](#). This might be implemented as RAZ/WI.
- [ERRDEVID](#). This might be implemented as RAZ/WI.
- [AIRC.RIESB](#) This might be implemented as RAZ/WI.
- [ID\\_PFR0.RAS](#) reads as a 0b0010.

This provides the necessary architectural support while offering no actual RAS reporting functionality.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [RAS](#).*

$I_{GRQK}$  [Error record](#) registers that are not implemented are RES0. In a minimal implementation, there might be no [Error records](#).

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - [RAS](#).*

## **Part C**

### **Armv8-M Instruction Set**

## Chapter C1

# Instruction Set Overview

This chapter provides a definition of the *instruction descriptions* contained in [Chapter C2 Instruction Specification](#). It contains the following sections:

- [C1.1 \*Instruction set.\*](#)
- [C1.2 \*Format of instruction descriptions.\*](#)
- [C1.3 \*Conditional execution.\*](#)
- [C1.4 \*Instruction set encoding information.\*](#)
- [C1.5 \*Modified immediate constants.\*](#)
- [C1.6 \*NOP-compatible hint instructions.\*](#)
- [C1.7 \*SBZ or SBO fields in instructions.\*](#)

## C1.1 Instruction set

R<sub>NPEK</sub>

There is one instruction set, called T32.

*Applies to an implementation of the architecture **Armv8.0-M** onward.*

See also:

[C1.4 Instruction set encoding information.](#)

[Chapter C2 Instruction Specification.](#)

## C1.2 Format of instruction descriptions

**I<sub>XQQV</sub>** Each instruction description in [Chapter C2 Instruction Specification](#) has the following content:

1. A title.
2. A short description.
3. The instruction encoding or encodings.
4. Any alias conditions, if applicable.
5. A list of the assembler symbols for the instruction.
6. Pseudocode describing how the instruction operates.
7. Notes, if applicable.

*Applies to an implementation of the architecture Armv8.0-M onward.*

### C1.2.1 The title

**I<sub>RFFL</sub>** The title of an instruction description includes the base mnemonic or mnemonics for the instruction. This is part of the assembler syntax, for example SUB.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**I<sub>BSWN</sub>** If different forms of an instruction use the same base mnemonic, each form has its own description. In this case, the title is the mnemonic followed by a short description of the instruction form in parentheses. This is most often used when an operand is an immediate value in one instruction form, but is a register in another form.

For example, in [Chapter C2 Instruction Specification](#) the Armv8-M Instruction Set there are the following titles for different forms of the ADD instruction:

- [ADD \(SP plus immediate\)](#)
- [ADD \(SP plus register\)](#)
- [ADD \(immediate\)](#)
- [ADD \(immediate to PC\)](#)
- [ADD \(register\)](#)

*Applies to an implementation of the architecture Armv8.0-M onward.*

**I<sub>RKXC</sub>** Where an instruction has more than one variant, the descriptions might be combined, for example for [CDP](#) and [CDP2](#).

*Applies to an implementation of the architecture Armv8.0-M onward.*

### C1.2.2 A short description

**I<sub>QNXW</sub>** This briefly describes the function of the instruction. The short description is not a complete description of the instruction and must be read in conjunction with the instruction encoding, mnemonic, alias conditions, assembler symbols, pseudocode and any applicable notes.

*Applies to an implementation of the architecture Armv8.0-M onward.*

### C1.2.3 The instruction encoding or encodings

**R<sub>LTJB</sub>** Instruction descriptions in this manual contain:

- An encoding section, containing one or more encoding diagrams, each followed by some decode pseudocode that:

1. Picks out any encoding-specific special cases.
  2. Translates the fields of the encoding into inputs for the common pseudocode of the instruction
- An operation section, containing common pseudocode that applies to all of the encodings being described. The Operation section pseudocode contains a call to the `EncodingSpecificOperations()` function which triggers the decode pseudocode, either at its start or only after a **Condition code check** performed by `if ConditionPassed() then`.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>BDDV</sub>

An encoding diagram specifies each bit of the instruction encoding as one of the following:

- A mandatory 0 or 1, represented in the diagram as 0 or 1. If the PE attempts to decode and execute the instruction and a bit does not have a mandatory value, the encoding corresponds to a different instruction.
- A *should be* 0 or *should be* 1, represented in the diagram as (0) or (1). If the PE attempts to decode and execute the instruction and a bit does not have the *should be* value, the instruction is CONSTRAINED UNPREDICTABLE.
- A named single bit or a bit in a named multi-bit field.

*Applies to an implementation of the architecture Armv8.0-M onward.*

I<sub>RTFM</sub>

In certain versions of the architecture some instruction encodings contain SBO or SBZ fields or bits. If these encoding fields or bits are changed to hard bits, 1 or 0, the field or bit in the diagram will be enclosed in square brackets. The architecture version being implemented will dictate whether or not the implementation follows hard encodings or SBZ or SBO rules.

For example in `MOV (register)` bit 15 of the second halfword of the T3 encoding has changed from SBZ in Armv8.0-M to 0 in Armv8.1-M, and is represented as [0].

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>BBZT</sub>

An encoding diagram matches an instruction if all mandatory bits are identical in the encoding diagram and the instruction.

*Applies to an implementation of the architecture Armv8.0-M onward.*

I<sub>DKWV</sub>

Between each encoding diagram and its T <n> heading, there is an italicized statement that describes which Armv8-M variant the encoding is present in. For example, *Armv8-M Main Extension only*.

*Applies to an implementation of the architecture Armv8.0-M onward.*

I<sub>JSBT</sub>

The instruction description shows the instruction encoding diagram, or, if the instruction has multiple encodings, shows all of the encoding diagrams. The heading for each encoding is the letter T followed by an arbitrary number, usually between 1 and 5.

*Applies to an implementation of the architecture Armv8.0-M onward.*

I<sub>FQDP</sub>

Below each encoding diagram is the *assembler syntax prototype* for that encoding, written in typewriter font. The assembler syntax prototype describes the syntax that can be used in the assembler to select this encoding, and also the syntax that is used when disassembling this encoding.

*Applies to an implementation of the architecture Armv8.0-M onward.*

I<sub>BLJR</sub>

In some cases an encoding has multiple variants of *assembler syntax prototype*, when the prototype differs depending on the value in one or more of the encoding fields. In these cases, the correct variant to use can be identified by either:

- Its subheading.
- An annotation to the syntax.

*Applies to an implementation of the architecture Armv8.0-M onward.*

See also:

[B7.5 Endianness](#).

*C1.2.6 Pseudocode describing how the instruction operates.*

## C1.2.4 Any alias conditions, if applicable

**I<sub>BMHC</sub>** Alias conditions are an optional part of an instruction description. If included, it describes the set of conditions for which an alternative mnemonic and its associated assembler syntax prototypes are preferred for disassembly by a disassembler. It includes a link to the alias instruction description that defines the alternative syntax. The alias syntax and the original syntax can be used interchangeably in the assembler source code.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**I<sub>RBCM</sub>** Arm recommends that if a disassembler outputs the alias syntax, it consistently outputs the alias syntax.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**I<sub>ZJKQ</sub>** Arm recommends that where possible, the alias is used.

*Applies to an implementation of the architecture Armv8.0-M onward.*

## C1.2.5 Standard assembler syntax fields

**I<sub>RHCC</sub>** This manual uses the Arm *Unified Assembler Language* (UAL). This assembly language syntax provides a canonical form for all T32 instructions.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**I<sub>LBNC</sub>** [UAL](#) describes the syntax for the mnemonic and the operands of each instruction. Operands can also be referred to as *Assembler symbols*. In addition, [UAL](#) assumes that instructions and data items can be given labels. It does not specify the syntax to be used for labels, see the assembler documentation for these details.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**I<sub>DPLM</sub>** The *Assembler symbols* subsection of an instruction description contains a list of the symbols that the assembler syntax prototype or prototypes use.

The following conventions are used:

< >: Angle brackets. Any symbol enclosed by these is mandatory. For each symbol, there is a description of what the symbol represents. The description usually also specifies which encoding field or fields encodes the symbol.

{ } : Brace brackets. Any symbol enclosed by these is optional. For each optional symbol, there is a description of what the symbol represents and how its presence or absence is encoded.

In some assembler syntax prototypes, some brace brackets are mandatory, for example if they surround a register list. When the use of brace brackets is mandatory, they are separated from other syntax items by one or more spaces.

# : Usually precedes a numeric constant. All uses of # are optional in assembler source code. Arm recommends that disassemblers output the # where the assembler syntax prototype includes it.

+/- : Indicates an optional + or - sign. If neither is coded, + is assumed.

! : Indicates that the result address is written back to the base register.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>MBQS</sub>** Single spaces are used for clarity, to separate syntax items. Where a space is mandatory, the assembler syntax prototype shows two or more consecutive spaces.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>SXWN</sub>** Any characters not shown in this conventions list must be coded exactly as shown in the assembler syntax prototype. Apart from brace brackets, these characters are used as part of a meta-language to define the architectural assembler syntax prototype for an instruction encoding, but have no architecturally defined significance in the input to an assembler or in the output from a disassembler.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>QZDB</sub>** **UAL** includes *instruction selection* rules that specify which instruction encoding is selected when more than one can provide the required functionality. The following assembler syntax prototype fields are standard across all or most instructions:

<c>: Specifies the condition under which the instruction is executed. If <c> is omitted, it defaults to *always* (AL).

<q>: Specifies one of the following optional assembler qualifiers on the instruction:

.N

Meaning narrow. The assembler must select a 16-bit encoding for the instruction. If this is not possible, an assembler error is produced.

.W

Meaning wide. The assembler must select a 32-bit encoding for the instruction. If this is not possible, an assembler error is produced.

If neither .W nor .N is specified, the assembler can select either a 16-bit or 32-bit encoding. If both encoding lengths are available, it must select a 16-bit encoding. In the few cases where more than one encoding of the same length is available for an instruction, the rules for selecting between them are instruction-specific and are part of the instruction description.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>HGFS</sub>** The following assembler syntax prototype field is standard across MVE instructions subject to VPT prediction:

<v>: Specifies a VPT predication block. This field is only available in implementations that include MVE, and it is only available inside a VPT block. Inside a VPT block, <v> can have one of the following values:

T

Indicates that the instruction is in the THEN section of a VPT block.

E

Indicates that the instruction is in the ELSE section of a VPT block.

<v> does not affect the encoding of the instruction, and only highlights to the programmer that some of the vector lanes might be masked because of VPT predication. The use of T or E outside a VPT block produces an assembler error.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **MVE**.*

**R<sub>BGFV</sub>** The <dt> field normally contains one data type specifier. Unless the assembler syntax description for the instruction indicates otherwise, <dt> indicates the data type contained in:

- The second operand, if any.
- The operand, if there is no second operand.
- The result, if there are no operand registers.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **FP** || **MVE**. Note, MVE requires an Armv8.1-M implementation.*

**R<sub>NKRJ</sub>** The <dt> field is usually specified as a single field. However, it can and might be specified as a concatenation of two or more fields.

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - **FP** || **MVE**. Note, MVE requires an Armv8.1-M implementation.*

R<sub>JSCH</sub>

There is some flexibility in the data type specifier syntax:

- Three data types can be specified, the results and both operands data types.  
`VMULL.P16.P8.P8, Q0, Q1, Q3` instead of `VMULL.P8, Q0, Q1, Q3`.
- Two data types can be specified, the data types of the two operands. In this case the result data type of the result is implied by the shape of the instruction.  
`VMULL.P8.P8, Q0, Q1, Q3` instead of `VMULL.P8, Q0, Q1, Q3`.
- Two data types can be specified, the data types of the single operand and the destination.  
`VMOVB.I16.I32 Q0, Q1` instead of `VMOVB.I32 Q0, Q1`
- Where an instruction does not specify a data type a data type can be specified for the instruction.
- A more specific data type can be used than the one specified by the instruction.
- The F32 data type can be abbreviated to F.
- The F64 data type can be abbreviated to D.

| Specified data type |      | Permitted more specific data types |          |      |            |
|---------------------|------|------------------------------------|----------|------|------------|
| None                |      | Any                                |          |      |            |
| .I<size>            | -    | .S<size>                           | .U<size> | -    | -          |
| .8                  | .I8  | .S8                                | .U8      | .P8  | -          |
| .16                 | .I16 | .S16                               | .U16     | .P16 | .F16       |
| .32                 | .I32 | .S32                               | .U32     | -    | .F32 or .F |
| .64                 | .I64 | .S64                               | .U64     | -    | .F64 or .D |

Applies to an implementation of the architecture *Armv8.0-M* onward. The extension requirements are - **FP** || **MVE**. Note, MVE requires an *Armv8.1-M* implementation.

I<sub>BWNR</sub>

Syntax options exist to override the normal instruction selection rules and ensure that a particular encoding is selected. These are useful when disassembling code, to ensure that subsequent assembly produces the original code, and in some other situations.

Applies to an implementation of the architecture *Armv8.0-M* onward.

## C1.2.6 Pseudocode describing how the instruction operates

I<sub>RTDZ</sub>

Each instruction description includes pseudocode that provides a precise description of what the instruction does.

Applies to an implementation of the architecture *Armv8.0-M* onward.

I<sub>LRFZ</sub>

In the instruction pseudocode, instruction fields are referred to by the names shown in the encoding diagram for the instruction.

Applies to an implementation of the architecture *Armv8.0-M* onward.

|            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $R_{NLPM}$ | Where the pseudocode describes UNPREDICTABLE behavior the constraints on that behavior are described in the Operation section.<br><br><i>Applies to an implementation of the architecture Armv8.0-M onward.</i>                                                                                                                                                                                                                                                                                |
| $I_{BNVW}$ | Pseudocode does not describe the ordering requirements when an instruction generates multiple memory accesses.<br><br><i>Applies to an implementation of the architecture Armv8.0-M onward.</i>                                                                                                                                                                                                                                                                                                |
| $R_{CRWM}$ | Pseudocode describes the exact rules when an UNDEFINED instruction fails its <a href="#">Condition code check</a> .<br><br>In such cases, the UNDEFINED pseudocode statement lies inside the if <code>ConditionPassed()</code> then ... structure, either directly or in the <code>EncodingSpecificOperations()</code> function call, and so the pseudocode indicates that the instruction executes as a NOP.<br><br><i>Applies to an implementation of the architecture Armv8.0-M onward.</i> |
| $I_{MZZK}$ | Pseudocode does not describe the exact ordering requirements when a single floating-point instruction generates more than one floating-point exception and one or more of those floating-point exceptions is trapped.<br><br><i>Applies to an implementation of the architecture Armv8.0-M onward.</i>                                                                                                                                                                                         |
| $I_{JMFJ}$ | An exception can be taken during execution of the pseudocode for an instruction, either explicitly as a result of the execution of a pseudocode function, or implicitly, for example if an interrupt is taken during execution of an <a href="#">LDM</a> instruction. If this happens, the pseudocode does not describe the extent to which the normal behavior of the instruction occurs.<br><br><i>Applies to an implementation of the architecture Armv8.0-M onward.</i>                    |

## C1.2.7 Use of labels in UAL instruction syntax

|            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $I_{BFJV}$ | The <a href="#">UAL</a> syntax for some instructions includes the label of an instruction or a literal data item that is at a fixed offset from the instruction being specified. The assembler must: <ol style="list-style-type: none"> <li>1. Calculate the <code>PC</code> or <code>Align(PC, 4)</code> value of the instruction. The <code>PC</code> value of an instruction is its address plus 4 for a T32 instruction. The <code>Align(PC, 4)</code> value of an instruction is its <code>PC</code> value ANDed with <code>0xFFFFF0</code> to force it to be word-aligned.</li> <li>2. Calculate the offset from the <code>PC</code> or <code>Align(PC, 4)</code> value of the instruction to the address of the labeled instruction or literal data item.</li> <li>3. Assemble a <i>PC-relative</i> encoding of the instruction, that is, one that reads its <code>PC</code> or <code>Align(PC, 4)</code> value and adds the calculated offset to form the required address.</li> </ol><br><i>Applies to an implementation of the architecture Armv8.0-M onward.</i> |
| $I_{TCVF}$ | For instructions that encode a subtraction operation, if the instruction cannot encode the calculated offset, but can encode minus the calculated offset, the instruction encoding specifies a subtraction of minus the calculated offset.<br><br><i>Applies to an implementation of the architecture Armv8.0-M onward.</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

R<sub>D</sub>LVP

The following instructions include a label:

- B and BL.
- CBNZ and CBZ.
- LDC, LDC2, LDR, LDRB, LDRD, LDRH, LDRSB, LDRSH, PLD, PLI, and VLDR:
  - When the assembler calculates an offset of 0 for the normal syntax of these instructions, it must assemble an encoding that adds 0 to the `Align(PC, 4)` value of the instruction. Encodings that subtract 0 from the `Align(PC, 4)` value cannot be specified by the normal syntax.
  - There is an alternative syntax for these instructions that specifies the addition or subtraction and the immediate offset explicitly. In this syntax, the label is replaced by `[PC, #+/-<imm>]`, where:
    - \* `+/-`: Is + or omitted to specify that the immediate offset is to be added to the `Align(PC, 4)` value, or - if it is to be subtracted.
    - \* `<imm>`: Is the immediate offset.
  - This alternative syntax makes it possible to assemble the encodings that subtract 0 from the `Align(PC, 4)` value, and to disassemble them to a syntax that can be re-assembled correctly.
- ADR:
  - When the assembler calculates an offset of 0 for the normal syntax of this instruction, it must assemble the encoding that adds 0 to the `Align(PC, 4)` value of the instruction. The encoding that subtracts from the `Align(PC, 4)` value cannot be specified by the normal syntax.
  - There is an alternative syntax for this instruction that specifies the addition or subtraction and the **immediate value** explicitly, by writing them as additions `ADD <Rd>, PC, #<imm>` or subtractions `SUB <Rd>, PC, #<imm>`. This alternative syntax makes it possible to assemble the encoding that subtracts 0 from the `Align(PC, 4)` value, and to disassemble it to a syntax that can be re-assembled correctly.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>K</sub>FSF

From Armv8.1-M the following instructions also include a label:

- BF, BFX, BFL, BFLX, BFCSEL.
- LE and LETP.
- WLS and WLSTP.

*Applies to an implementation of the architecture Armv8.1-M onward.*

## C1.2.8 Using syntax information

I<sub>B</sub>JGX

For a particular encoding:

- There is usually more than one assembler syntax prototype variant that assembles to it.
- The exact set of prototype variants that assemble to it usually depends on the operands to the instruction, for example the register numbers or immediate constants. As an example, for the **AND (register)** instruction, the syntax `AND R0, R0, R8` selects a 32-bit encoding, but `AND R0, R0, R1` selects a 16-bit encoding.

*Applies to an implementation of the architecture Armv8.0-M onward.*

I<sub>H</sub>QSS

For each instruction encoding that belongs to a target instruction set, an assembler can use the information in the encoding to determine whether it can use that particular encoding to encode the instruction requested by the **UAL** source. If multiple encodings can encode the instruction, then:

- If both a 16-bit encoding and a 32-bit encoding can encode the instruction, the architecturally preferred encoding is the 16-bit encoding. This means that the assembler must use the 16-bit encoding instead of the 32-bit encoding.

- If multiple encodings of the same width can encode the instruction, the assembler syntax indicates the preferred encoding, and how software can select other encodings if required. Each encoding also documents [UAL](#) syntax that selects it in preference to any other encoding. If no encodings of the target instruction set can encode the instruction requested by the [UAL](#) source, the assembler normally generates an error that indicates that the instruction is not available in that instruction set.

*Applies to an implementation of the architecture **Armv8.0-M** onward.*

## C1.3 Conditional execution

**I<sub>XDMQ</sub>** *Conditionally executed* means that the instruction only has its normal effect on the programmers' model operation, memory and coprocessors if the N, Z, C, and V flags in the [APSR](#) satisfy a condition specified in the instruction. If the flags do not satisfy this condition, the instruction acts as a NOP, that is, execution advances to the next instruction as normal, including any relevant checks for exceptions being taken, but has no other effect.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**I<sub>SPPQ</sub>** Most T32 instructions are unconditional. Conditional execution in T32 code can be achieved using any of the following instructions:

- A 16-bit conditional branch instruction, with a branch range of -256 to +254 bytes. See [B](#) for details.
- A 32-bit conditional branch instruction, with a branch range of approximately  $\pm 1\text{MB}$ . See [B](#) for details.
- 16-bit Compare and Branch on Zero and Compare and Branch on Nonzero instructions, with a branch range of +4 to +130 bytes. See [CBNZ](#), [CBZ](#) for details.
- A 16-bit If-Then instruction that makes up to four following instructions conditional. See [IT](#) for details. The instructions that are made conditional by an IT instruction are called its *IT block*. Instructions in an IT block must either all have the same condition, or some can have one condition, and others can have the inverse condition.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>FNBQ</sub>** In T32 instructions, the condition (if it is not [AL](#)) is encoded in a preceding IT instruction, other than [B](#), [CBNZ](#) and [CBZ](#). Some conditional branch instructions do not require a preceding IT instruction, and include a condition code in their encoding.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**I<sub>BDMC</sub>** The following table shows the conditions that are available for conditionally executed instructions.

| cond | Mnemonic<br>extension | Meaning, integer<br>arithmetic | Meaning, Floating-point<br>arithmetic | <a href="#">APSR</a> condition<br>flags |
|------|-----------------------|--------------------------------|---------------------------------------|-----------------------------------------|
| 0000 | EQ                    | Equal                          | Equal                                 | Z == 1                                  |
| 0001 | NE                    | Not equal                      | Not equal, or unordered               | Z == 0                                  |
| 0010 | CS                    | Carry set                      | Greater than, equal or unordered      | C == 1                                  |
| 0011 | CC                    | Carry clear                    | Less than                             | C == 0                                  |
| 0100 | MI                    | Minus, negative                | Less than                             | N == 1                                  |
| 0101 | PL                    | Plus, positive or zero         | Greater than, equal or unordered      | N == 0                                  |
| 0110 | VS                    | Overflow                       | Unordered                             | V == 1                                  |
| 0111 | VC                    | No overflow                    | Not unordered                         | V == 0                                  |
| 1000 | HI                    | Unsigned higher                | Greater than or unordered             | C == 1 and Z == 0                       |
| 1001 | LS                    | Unsigned lower or same         | Less than or equal                    | C == 0 or Z == 1                        |
| 1010 | GE                    | Signed greater than or equal   | Greater than or equal                 | N == V                                  |
| 1011 | LT                    | Signed less than               | Less than or unordered                | N != V                                  |
| 1100 | GT                    | Signed greater than            | Greater than                          | Z == 0 and N == V                       |
| 1101 | LE                    | Signed less than or equal      | Less than, equal or unordered         | Z == 1 and N != V                       |
| 1110 | None (AL)             | Always (unconditional)         | Always (unconditional)                | Any                                     |

Unordered means at least one NaN operand.

HS (unsigned higher or same) is a synonym for CS.

LO (unsigned lower) is a synonym for CC.

AL is an optional mnemonic extension for always, except in IT instructions. See IT for details.

*Applies to an implementation of the architecture Armv8.0-M onward.*

### C1.3.1 Conditional instructions

**R<sub>WRJS</sub>** The instructions that are made conditional by an IT instruction must be written with a condition after the mnemonic. These conditions must match the conditions imposed by the IT instruction.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**I<sub>WVXC</sub>** An example of R<sub>WRJS</sub> is:

```
1      ITTEE EQ
2      ADDEQ R0, R1
3      SUBEQ R2, R3
4      ADDNE R4, R5
5      SUBNE R6, R7
```

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>THGJ</sub>** Some instructions cannot be made conditional by an IT instruction. Some instructions can be conditional if they are the last instruction in the IT block, but not otherwise, see the individual instruction descriptions for details.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>TGXF</sub>** If the assembler syntax indicates a conditional branch that correctly matches a preceding IT instruction, it is assembled using a branch instruction encoding that does not include a condition field.

*Applies to an implementation of the architecture Armv8.0-M onward.*

See also

- IT instruction

### C1.3.2 Pseudocode details of conditional execution

**R<sub>NMVJ</sub>** The `CurrentCond()` pseudocode function prototype returns a 4-bit condition specifier as follows:

- For the T1 and T3 encodings of the Branch instruction, it returns the 4-bit `cond` field of the encoding.
- For all other T32 instructions:
  - If `ITSTATE.IT[3:0] != '0000'` it returns `ITSTATE.IT[7:4]`
  - If `ITSTATE.IT[7:0] == '00000000'` it returns `'1110'`
  - Otherwise, execution of the instruction is UNPREDICTABLE.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>LTPQ</sub>** The `ConditionPassed()` function calls the `ConditionHolds()` function to determine whether the instruction must be executed.

*Applies to an implementation of the architecture Armv8.0-M onward.*

See also

[C1.3.5 ITSTATE.](#)

[B.](#)

### C1.3.3 Conditional execution of undefined instructions

$R_{NPNF}$  The conditional execution applies to all instructions. This includes undefined instructions and other instructions that would cause entry to the UsageFault or the UNDEFINSTR UsageFault.

*Applies to an implementation of the architecture Armv8.0-M onward.*

$R_{PCJZ}$  If such an instruction fails its [condition code check](#) the instruction behaves as a NOP and does not cause an UsageFault.

*Applies to an implementation of the architecture Armv8.0-M onward.*

### C1.3.4 Interaction of undefined instruction behavior with UNPREDICTABLE or CONSTRAINED\_UNPREDICTABLE instruction behavior

$R_{NZWQ}$  If this manual describes an instruction as both:

- UNPREDICTABLE and UNDEFINED, then the instruction is UNPREDICTABLE.
- CONSTRAINED UNPREDICTABLE and UNDEFINED, then the instruction is CONSTRAINED UNPREDICTABLE.

*Applies to an implementation of the architecture Armv8.0-M onward.*

### C1.3.5 ITSTATE

$I_{RGFT}$  ITSTATE is held in [EPSR.IT](#).

This register holds the If-Then Execution state bits for the T32 [IT](#) instruction.

*Applies to an implementation of the architecture Armv8.0-M onward.*

$R_{QKPG}$  [EPSR.IT](#) and ITSTATE divide into two subfields:

IT[7:5]

Holds the *base condition* for the current IT block. The base condition is the top 3 bits of the condition specified by the IT instruction.

This subfield is 0b000 when no IT block is active.

IT[4:0]

Encodes:

- \* The size of the IT block. This is the number of instructions that are to be conditionally executed. The size of the block is indicated by the position of the least significant 1 in this field which is bit [4-size of the block].
- \* The value of the least significant bit, bit[0], of the condition code for each instruction in the block.
- \* Changing the value of the least significant bit of a condition code from 0 to 1 inverts the condition code. For example cond 0000 is EQ, and cond 0001 is NE.

This subfield is 0b00000 when no IT block is active.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>FPNH</sub>** When an IT instruction is executed, IT bits[7:0] are set according to the condition in the instruction, and the *Then* and *Else* (T and E) parameters in the instruction.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>XKGZ</sub>** An instruction in an IT block is conditional. The condition used is the current value of IT[7:4]. When an instruction in an IT block completes its execution normally, ITSTATE is advanced by shifting IT bits[4:0] left by 1 bit.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**I<sub>VQJM</sub>** For example:

|              | IT[7:5] | IT[4:0] |
|--------------|---------|---------|
| ITTEE EQ     | 000     | 00111   |
| ADDEQ R0, R1 | 000     | 01110   |
| SUBEQ R2, R3 | 000     | 11100   |
| ADDNE R4, R5 | 000     | 11000   |
| SUBNE R6, R7 | 000     | 00000   |

*Applies to an implementation of the architecture Armv8.0-M onward.*

**I<sub>KQBQ</sub>** Instructions that can complete their normal execution by branching are only permitted in an IT block as its last instruction, and so always result in ITSTATE advancing to normal execution.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**I<sub>FJLN</sub>** In the following table, *P* represents the base condition or the inverse of the base condition.

| IT Bits   |     |     |     |     |     |                                        |
|-----------|-----|-----|-----|-----|-----|----------------------------------------|
| [7:5]     | [4] | [3] | [2] | [1] | [0] |                                        |
| cond_base | P1  | P2  | P3  | P4  | 1   | Entry point for 4-instruction IT block |
| cond_base | P1  | P2  | P3  | 1   | 0   | Entry point for 3-instruction IT block |
| cond_base | P1  | P2  | 1   | 0   | 0   | Entry point for 2-instruction IT block |
| cond_base | P1  | 1   | 0   | 0   | 0   | Entry point for 1-instruction IT block |
| 000       | 0   | 0   | 0   | 0   | 0   | Normal execution, not in an IT block   |

Combinations of the IT bits not shown in this table are reserved.

*Applies to an implementation of the architecture Armv8.0-M onward.*

### C1.3.6 Pseudocode details of ITSTATE operation

**I<sub>JLKP</sub>** [ITAdvance\(\)](#) describes how ITSTATE advances after normal execution.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**I<sub>ZGZL</sub>** [InITBlock\(\)](#) and [LastInITBlock\(\)](#) test whether the current instruction is in an IT block, and whether it is the last instruction of an IT block.

*Applies to an implementation of the architecture Armv8.0-M onward.*

### C1.3.7 SVC and ITSTATE

**R<sub>TSWQ</sub>** The `ReturnAddress()` for an **SVC** instruction must point to the instruction after the **SVC** instruction and advance `ITSTATE`.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**I<sub>QWZW</sub>** When an **SVC** instruction is escalated to `HardFault` resulting in **lookup** the `ReturnAddress()` is `0xEFFFFFFE`.

*Applies to an implementation of the architecture Armv8.0-M onward.*

See also:

[B3.33 Lookup](#).

### C1.3.8 CONSTRAINED\_UNPREDICTABLE behavior and IT blocks

**R<sub>WWVX</sub>** Branching into an IT block, other than by way of exception return or exit from Debug state, leads to **CONSTRAINED UNPREDICTABLE** behavior. Execution starts from the address that is determined by the branch, but each instruction in the IT block is:

- Executed as if the instruction is not in an IT block, meaning that the instruction is executed unconditionally.
- Executed as if the instruction had passed its **Condition code check** within an IT block.
- Executed as a NOP. That is, the instruction **behaves as if** it had failed the Condition code check.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>CPDC</sub>** For exception returns or Debug state exits that cause **EPSR.IT** to be set to a reserved value with a nonzero value in **EPSR.IT**, the **EPSR.IT** bits are forced to `0b00000000`.

*Applies to an implementation of the architecture Armv8.0-M onward. Note, Debug state requires Halting debug.*

**R<sub>HVNS</sub>** Exception returns or Debug state exits that set **EPSR.IT** to a non-reserved value can occur when the flow of execution returns to a point:

- Outside an IT block, but with the **EPSR.IT** bits set to a value other than `0b00000000`.
- Inside an IT block, but with a different value of the **EPSR.IT** bits than if the IT block had been executed without an exception return or Debug state exit.

In this case the instructions at the target of the exception return or Debug state exit does one of the following:

- Execute as if they passed the Condition code check for the remaining iterations of the **EPSR.IT** state machine.
- Execute as NOPs. That is, they **behave as if** they failed the Condition code check for the remaining iterations of the **EPSR.IT** state machine.

*Applies to an implementation of the architecture Armv8.0-M onward. Note, Debug state requires Halting debug.*

**R<sub>LLDK</sub>** A number of instructions in the architecture are described as being **CONSTRAINED UNPREDICTABLE** either:

- Anywhere within an IT block.
- As an instruction within an IT block, other than the last instruction within an IT block.

Unless otherwise stated in this reference manual, when these instructions are committed for execution, one of the following occurs:

- An **UNDEFINED** exception is taken.
- The instructions are executed as if they had passed the **condition code check**.
- The instructions execute as NOPs, as if they had failed the **condition code check**.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**I<sub>NJKE</sub>** The behavior might in some implementations vary from instruction to instruction, or between different instances of the same instruction.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>BWMN</sub>** Branch instructions or other non-sequential instructions that change the **PC** are **CONSTRAINED UNPREDICTABLE** in an IT block. Where these instructions are not treated as **UNDEFINED** within an IT block, the remaining iterations of the **EPSR.IT** state machine is treated in one of the following ways:

- **EPSR.IT** is cleared to 0.
- **EPSR.IT** advances for either a sequential or a nonsequential change of the **PC** in the same way as it does for instructions that are not **CONSTRAINED UNPREDICTABLE** that cause a sequential change of the **PC**.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**I<sub>XHBL</sub>** This behavior does not apply to an instruction that is the last instruction in an IT block.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>TMWN</sub>** The instructions that are addressed by the updated **PC** does one of the following:

- Execute as if they had passed the **condition code check** for the remaining iterations of the **EPSR.IT** state machine.
- Execute as **NOPS**. That is, they behave as if they had failed the **condition code check** for the remaining iterations of the **EPSR.IT** state machine.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>KVXD</sub>** The remaining iterations of the **EPSR.IT** state machine behave in one of the following ways:

- The **EPSR.IT** state machine advances as if it were in an IT block.
- The **EPSR.IT** bits are ignored.
- The **EPSR.IT** bits are forced to 0b00000000.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>GZBX</sub>** Execution of an instruction inside an IT block with **ITSTATE** set to zero, an **ICI** value, or a value that is inconsistent with the IT block is **UNPREDICTABLE**.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>VBCG</sub>** In the **VIWDUP** and **VDWDUP** instructions the following conditions result in **CONSTRAINED UNPREDICTABLE** behavior:

- **Rn** is not a multiple of **imm**.
- **Rm** is not a multiple of **imm**.
- **Rn** >= **Rm**.

The **CONSTRAINED UNPREDICTABLE** behavior is that the resulting values of **Rn** and **Qd** become **UNKNOWN**.

*Applies to an implementation of the architecture Armv8.1-M onward. The extension requirements are - **MVE**.*

| I <sub>QVWL</sub> | <p>The choice between the behavior of the <b>PC</b> as a source or destination register might vary in some implementations from instruction to instruction, or between different instances of the same instruction.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward.</i></p>                                                                                                                                                                                                                                                                                                                                                                             |
| R <sub>LXPR</sub> | <p>For instructions that specify two destination registers and if one is specified as the <b>PC</b>, then the other destination register of the pair is UNKNOWN. The CONSTRAINED UNPREDICTABLE behavior for the write to the <b>PC</b> is either to ignore the write or to branch to an UNKNOWN location.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward.</i></p>                                                                                                                                                                                                                                                                                       |
| R <sub>DRSS</sub> | <p>An instruction that specifies the <b>PC</b> as a Base register and specifies a base register write-back is CONSTRAINED UNPREDICTABLE and behaves as if the <b>PC</b> is both the source and destination register.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward.</i></p>                                                                                                                                                                                                                                                                                                                                                                            |
| R <sub>XLVX</sub> | <p>For instructions that affect any or all of APSR.{N, Z, C, V} or APSR.GE when the register specifier is not the <b>PC</b>, any flags that are affected by an instruction that is CONSTRAINED UNPREDICTABLE become UNKNOWN.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward.</i></p>                                                                                                                                                                                                                                                                                                                                                                    |
| R <sub>JFGT</sub> | <p>For MRC instructions that use the <b>PC</b> as the destination register descriptor (and therefore target APSR.{N, Z, C, V}) and where these instructions are described as being CONSTRAINED UNPREDICTABLE the status of the flags becomes UNKNOWN.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward.</i></p>                                                                                                                                                                                                                                                                                                                                           |
| R <sub>XPBT</sub> | <p>Multi-access instructions that load the <b>PC</b> from Device memory are CONSTRAINED UNPREDICTABLE and one of the following behaviors occurs:</p> <ul style="list-style-type: none"> <li>• The instruction loads the <b>PC</b> from the memory location as if the memory location had the Normal Non-cacheable attribute</li> <li>• The instruction generates a IACCVIOL MemManage fault.</li> </ul> <p><i>Applies to an implementation of the architecture Armv8.0-M onward.</i></p>                                                                                                                                                                                             |
| I <sub>QXNP</sub> | <p>When a value of 0b1111 is permitted as a register specifier, as indicated in the individual instruction descriptions, a variety of meanings is possible. For register reads, these meanings are:</p> <ul style="list-style-type: none"> <li>• Read the <b>PC</b> value, that is, the address of the current instruction + 4. The base register of the table branch instructions TBB and TBH can be the <b>PC</b>. This enables branch tables to be placed in memory immediately after the instruction. (Some instructions read the <b>PC</b> value implicitly, without the use of a register specifier, for example the conditional branch instruction B&lt;cond&gt;.)</li> </ul> |

- Read the word-aligned **PC** value, that is, the address of the current instruction + 4, with bits [1:0] forced to zero. The base register of **LDC**, **LDR**, **LDRB**, **LDRD** (pre-indexed, no write-back), **LDRH**, **LDRSB**, and **LDRSH** instructions can be the word-aligned **PC**. This enables PC-relative data addressing. In addition, some encodings of the **ADD** and **SUB** instructions permit their source registers to be **0b1111** for the same purpose.
- Read zero. This is done in some cases when one instruction is a special case of another, more general instruction, but with one operand zero. In these cases, the instructions are listed on separate pages, with a special case in the pseudocode for the more general instruction cross-referencing the other page. An example of this is the descriptions of **MOV (register)** and **ORR (register)**.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**I<sub>KVHQ</sub>**

When a value of **0b1111** is permitted as a register specifier, as indicated in the individual instruction descriptions, a variety of meanings is possible. For register writes, these meanings are:

- The **PC** can be specified as the destination register of an **LDR** instruction. This is done by encoding **Rt** as **0b1111**. The loaded value is treated as an address, and the effect of execution is a branch to that address. bit[0] of the loaded value selects the Execution state after the branch and must have the value 1.
- Discard the result of a calculation. This is done in some cases when one instruction is a special case of another, more general instruction, but with the result discarded. In these cases, the instructions are listed on separate pages, with a special case in the pseudocode for the more general instruction cross-referencing the other page. An example of this is the descriptions of **TST (register)** and **AND (register)**.
- If the destination register specifier of an **LDRB**, **LDRH**, **LDRSB**, or **LDRSH** instruction is **0b1111**, the instruction is a memory hint instead of a load operation.
- If the destination register specifier of an **MRC** instruction is **0b1111**, bits[31:28] of the value transferred from the coprocessor are written to the **N**, **Z**, **C**, and **V** flags in the **APSR**, and bits[27:0] are discarded.

*Applies to an implementation of the architecture Armv8.0-M onward.*

## C1.4.4 Use of 0b1101 as a register specifier

### SP[1:0] definition

**R<sub>DSDB</sub>**

Bits [1:0] of **SP** must be treated as **SBZP** (Should Be Zero or Preserved). Writing a nonzero value to bits [1:0] results in UNPREDICTABLE behavior. Reading bits [1:0] returns zero.

*Applies to an implementation of the architecture Armv8.0-M onward.*

### 32-bit T32 instruction support for SP

**R<sub>SKNR</sub>**

Use of the **SP** in T32 instructions and 16-bit data processing instructions is restricted to the following cases:

- **SP** as the source or destination register of a **MOV** instruction. Only register to register transfers without shifts are supported, with no flag setting:

|   |            |               |
|---|------------|---------------|
| 1 | <b>MOV</b> | <b>SP, Rm</b> |
| 2 | <b>MOV</b> | <b>Rn, SP</b> |

- Adjusting **SP** up or down by a multiple of its alignment:

|   |               |                               |                                |
|---|---------------|-------------------------------|--------------------------------|
| 1 | <b>ADD{W}</b> | <b>SP, SP, #N</b>             | <b>; For N a multiple of 4</b> |
| 2 | <b>SUB{W}</b> | <b>SP, SP, #N</b>             | <b>; For N a multiple of 4</b> |
| 3 | <b>ADD</b>    | <b>SP, SP, Rm, LSL #shift</b> | <b>; For shift=0,1,2,3</b>     |
| 4 | <b>SUB</b>    | <b>SP, SP, Rm, LSL #shift</b> | <b>; For shift=0,1,2,3</b>     |

- **SP** as a base register, **Rn**, of any load or store instruction. This supports **SP**-based addressing for load, store, or memory hint instructions, with positive or negative offsets, with and without write-back.

- **SP** as the first operand, **Rn**, in any `ADD{S}`, `CMN`, `CMP`, or `SUB{S}` instruction. The add and subtract instructions support **SP**-based address generation, with the address going into a general-purpose register. `CMN` and `CMP` can check the stack pointer.
- **SP** as the transferred register, **Rt**, in any `LDR` or `STR` instruction.
- **SP** as the address in a `POP` or `PUSH` instruction.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>MRNT</sub>**

Where an instruction states that the **SP** is UNPREDICTABLE and **SP** is used:

- The value that is read or written from or to the **SP** is UNKNOWN.
- The instruction is permitted to be treated as UNDEFINED.
- If the **SP** is being written, it is UNKNOWN whether a stack limit check is applied.

*Applies to an implementation of the architecture Armv8.0-M onward.*

### C1.4.5 16-bit T32 instruction support for SP

**R<sub>STHZ</sub>**

Arm deprecates any other use of the **SP** in 16-bit T32 instructions. This affects the high register forms of `CMP` and `ADD`, where Arm deprecates the use of **SP** as **Rm**.

*Applies to an implementation of the architecture Armv8.0-M onward.*

### C1.4.6 Branching

**I<sub>PVGL</sub>**

Writing an address to the **PC** causes either a simple branch to that address or an *interworking* branch.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>TQSZ</sub>**

A simple branch is performed by `BranchTo()`.

*Applies to an implementation of the architecture Armv8.1-M onward.*

**R<sub>JTJJ</sub>**

An interworking branch is performed by `BranchReturn()`.

*Applies to an implementation of the architecture Armv8.1-M onward.*

**R<sub>CWSL</sub>**

Branching can occur in cases where `0b1111` is not a register specifier. In these cases, instructions write the **PC** either:

- Implicitly, for example, `b<cond>`.
- By using a register mask rather than a register specifier, for example `LDM`.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**I<sub>FLZZ</sub>**

The address to branch to can be:

- A loaded value, for example `LDM`.
- A register value, for example `BX`.
- The result of a calculation, for example `TBB` or `TBH`.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>WQBX</sub> The following table summarizes the branch instructions in the T32 instruction set.

| Instruction                                                  | See                                         | Range, T32    |
|--------------------------------------------------------------|---------------------------------------------|---------------|
| Branch to target address                                     | <a href="#">B</a>                           | ±16MB         |
| Compare and Branch on Nonzero,<br>Compare and Branch on Zero | <a href="#">CBNZ</a> , <a href="#">CBZ</a>  | 0-126 bytes   |
| Call a subroutine                                            | <a href="#">BL</a>                          | ±16MB         |
| Call a subroutine, optionally change Security state          | <a href="#">BLX</a> , <a href="#">BLXNS</a> | Any           |
| Branch to target address, change to Non-secure state         | <a href="#">BX</a> , <a href="#">BXNS</a>   | Any           |
| Table Branch (byte offsets)                                  | <a href="#">TBB</a> , <a href="#">TBH</a>   | 0-510 bytes   |
| Table Branch (halfword offsets)                              |                                             | 0-31070 bytes |

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>GJML</sub> Branches to loaded and calculated addresses can be performed by [LDR](#), [LDM](#) and data-processing instructions.

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>TPTF</sub> A load instruction that targets the [PC](#) behaves as a branch instruction.

*Applies to an implementation of the architecture Armv8.0-M onward.*

## C1.4.7 Instruction set, interworking and interstating support

R<sub>LBQC</sub> The following instructions are [Interworking](#) branches:

- [BX](#) and [BLX](#).
- [POP \(multiple registers\)](#)  
and all forms of [LDM](#), when the register list includes the [PC](#).
- [LDR \(immediate\)](#), [LDR \(literal\)](#), and [LDR \(register\)](#), with <Rt> equal to the [PC](#).

*Applies to an implementation of the architecture Armv8.0-M onward.*

R<sub>WRZR</sub> The value of bit[0] of an interworking branch instruction is not stored in the [PC](#). Bit[0] of an interworking branch instruction sets [EPSR.T](#). If [EPSR.T](#) is cleared to 0 an INVSTATE UsageFault or HardFault is generated on the next instruction the PE attempts to execute.

*Applies to an implementation of the architecture Armv8.0-M onward. Note, requires M for INVSTATE UsageFault.*

R<sub>GLPL</sub> The following instructions are *interstating branches*:

- [BXNS](#) and [BLXNS](#).

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [S](#).*

R<sub>GJMJ</sub> When an interstating branch is executed in Secure state, bit[0] of the target address indicates the target Security state:

- 0: The target Security state is Non-secure state.
- 1: The target Security state is Secure state.

The value of bit[0] of an interstating branch instruction is not stored in the [PC](#).

*Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - [S](#).*

R<sub>WNSX</sub>

Interstating branches are UNDEFINED when executing in Non-secure state.

*Applies to an implementation of the architecture **Armv8.0-M** onward. The extension requirements are - **S**.*

This table shows the immediate constant value in binary form, to relate `abcdefgh` to the encoding diagram. In assembly syntax, the **immediate value** is specified as a decimal integer by default.

The setting of the Carry flag will only apply if a logical operation with a modified immediate constant can set the flags.

Where i:imm3:a is 0001x, 0010x or 0011x the instruction will be UNPREDICTABLE if abcdefgh == 0b00000000.

*Applies to an implementation of the architecture Armv8.0-M onward.*

### C1.5.1 Operation of modified immediate constants

**T32ExpandImm()** and **T32T32ExpandImm C()** describe the operation of modified immediate constants.

*Applies to an implementation of the architecture Armv8.0-M onward.*

**R<sub>PHBG</sub>**      The operation of modified immediate constants are UNPREDICTABLE where both:

- `hw2[7:0] == 0b00000000.`

- $hw1[10] == 0$  and either:
  - $hw2[14:12] == 0b001.$
  - $hw2[14:12] == 0b010.$
  - $hw2[14:12] == 0b011.$

*Applies to an implementation of the architecture **Armv8.0-M** onward.*

## C1.6 NOP-compatible hint instructions

| R <sub>DJQL</sub> | <p>A PE with the Main Extension supports both the 16-bit and the 32-bit encodings of the Armv8-M NOP-compatible hint instructions.</p> <p><i>Applies to an implementation of the architecture Armv8.0-M onward. The extension requirements are - M.</i></p>                                         |

## C1.7 SBZ or SBO fields in instructions

$I_{PWBN}$  Many of the instructions have (0) or (1) in the instruction decode to indicate *Should-Be-Zero*, SBZ, or *Should-Be-One*, SBO.

*Applies to an implementation of the architecture Armv8.0-M onward.*

$R_{CKJK}$  If the instruction bit pattern of an instruction is executed with these fields not having the *should-be* values, one of the following must occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction operates as if the bit had the *should-be* value.
- Any destination registers of the instruction become UNKNOWN.

The exceptions to this rule are:

- LDM, LDMIA, LDMFD.
- LDMDB, LDMEA.
- POP (multiple registers).
- PUSH (multiple registers).
- SDIV.
- STM, STMIA, STMEA.
- STMDB, STMFD.
- UDIV.

*Applies to an implementation of the architecture Armv8.0-M onward.*

## Chapter C2

# Instruction Specification

This chapter specifies the Armv8-M instruction set. It contains the following sections:

[Top level T32 instruction set encoding](#)

[32-bit T32 instruction encoding](#)

[16-bit T32 instruction encoding](#)

[Alphabetical list of instructions](#)

## C2.1 Top level T32 instruction set encoding

The T32 instruction stream is a sequence of halfword-aligned halfwords. Each T32 instruction is either a single 16-bit halfword in that stream, or a 32-bit instruction consisting of two consecutive halfwords in that stream.

If the value of bits[15:11] of the halfword being decoded is one of the following, the halfword is the first halfword of a 32-bit instruction:

- 0b11101.
- 0b11110.
- 0b11111.

Otherwise, the halfword is a 16-bit instruction.

|     |    |    |    |    |     |   |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|-----|----|----|----|----|-----|---|---|---|---|---|---|---|---|---|---|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 15  | 14 | 13 | 12 | 11 | 10  | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| op0 |    |    |    |    | op1 |   |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

This table shows the decode field values and the associated subgroups:

| op0    | op1   | Subgroup                                        |
|--------|-------|-------------------------------------------------|
| != 111 | -     | <a href="#">16-bit T32 instruction encoding</a> |
| 111    | != 00 | <a href="#">32-bit T32 instruction encoding</a> |

This table shows the decode field values and the associated instructions:

| op0 | op1 | Instruction          |
|-----|-----|----------------------|
| 111 | 00  | <a href="#">B T2</a> |

## C2.2 16-bit T32 instruction encoding

This section describes the encoding of the 16-bit T32 instruction encoding. This section is decoded from [Top level T32 instruction set encoding](#).

This table shows the decode field values and the associated subgroups:

| op0    | Subgroup                                                            |
|--------|---------------------------------------------------------------------|
| 00xxxx | <a href="#">Shift (immediate), add, subtract, move, and compare</a> |
| 010000 | <a href="#">Data-processing (two low registers)</a>                 |
| 010001 | <a href="#">Special data instructions and branch and exchange</a>   |

| 011xxx | <a href="#">Load/store word/byte (immediate offset)</a>             |
| 1000xx | <a href="#">Load/store halfword (immediate offset)</a>              |
| 1001xx | <a href="#">Load/store (SP-relative)</a>                            |
| 1010xx | <a href="#">Add PC/SP (immediate)</a>                               |
| 1011xx | <a href="#">Miscellaneous 16-bit instructions</a>                   |
| 1100xx | <a href="#">Load/store multiple</a>                                 |
| 1101xx | <a href="#">Conditional branch, and Supervisor Call</a>             |

This table shows the decode field values and the associated instructions:

| op0    | Instruction                      |
|--------|----------------------------------|
| 01001x | <a href="#">LDR (literal) T1</a> |

### C2.2.1 Shift (immediate), add, subtract, move, and compare

This section describes the encoding of the Shift (immediate), add, subtract, move, and compare. This section is decoded from [16-bit T32 instruction encoding](#).

This table shows the decode field values and the associated subgroups:

| op0 | op1 | op2 | Subgroup                                                                      |
|-----|-----|-----|-------------------------------------------------------------------------------|
| 0   | 11  | 0   | <a href="#">Add, subtract (three low registers)</a>                           |
| 0   | 11  | 1   | <a href="#">Add, subtract (two low registers and immediate)</a>               |
| 1   | -   | -   | <a href="#">Add, subtract, compare, move (one low register and immediate)</a> |

This table shows the decode field values and the associated instructions:

| op0 | op1   | op2 | Instruction                         |
|-----|-------|-----|-------------------------------------|
|     | Alias |     | <a href="#">ASRS (immediate) T2</a> |
|     | Alias |     | <a href="#">ASR (immediate) T2</a>  |
|     | Alias |     | <a href="#">LSLS (immediate) T2</a> |
|     | Alias |     | <a href="#">LSL (immediate) T2</a>  |
|     | Alias |     | <a href="#">LSRS (immediate) T2</a> |
|     | Alias |     | <a href="#">LSR (immediate) T2</a>  |
| 0   | != 11 | -   | <a href="#">MOV (register) T2</a>   |

### C2.2.1.1 Add, subtract (three low registers)

This section describes the encoding of the Add, subtract (three low registers). This section is decoded from [Shift \(immediate\)](#), [add](#), [subtract](#), [move](#), and [compare](#).

|    |    |    |    |    |    |   |    |   |   |    |   |   |    |   |   |
|----|----|----|----|----|----|---|----|---|---|----|---|---|----|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8  | 7 | 6 | 5  | 4 | 3 | 2  | 1 | 0 |
| 0  | 0  | 0  | 1  | 1  | 0  | S | Rm |   |   | Rn |   |   | Rd |   |   |

This table shows the decode field values and the associated instructions:

| S | Instruction                       |
|---|-----------------------------------|
| 0 | <a href="#">ADD (register) T1</a> |
| 1 | <a href="#">SUB (register) T1</a> |

### C2.2.1.2 Add, subtract (two low registers and immediate)

This section describes the encoding of the Add, subtract (two low registers and immediate). This section is decoded from [Shift \(immediate\)](#), [add](#), [subtract](#), [move](#), and [compare](#).

|    |    |    |    |    |    |   |      |   |   |    |   |   |    |   |   |
|----|----|----|----|----|----|---|------|---|---|----|---|---|----|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8    | 7 | 6 | 5  | 4 | 3 | 2  | 1 | 0 |
| 0  | 0  | 0  | 1  | 1  | 1  | S | imm3 |   |   | Rn |   |   | Rd |   |   |

This table shows the decode field values and the associated instructions:

| S | Instruction                        |
|---|------------------------------------|
| 0 | <a href="#">ADD (immediate) T1</a> |
| 1 | <a href="#">SUB (immediate) T1</a> |

### C2.2.1.3 Add, subtract, compare, move (one low register and immediate)

This section describes the encoding of the Add, subtract, compare, move (one low register and immediate). This section is decoded from [Shift \(immediate\)](#), [add](#), [subtract](#), [move](#), and [compare](#).

|    |    |    |    |    |     |   |   |      |   |   |   |   |   |   |   |
|----|----|----|----|----|-----|---|---|------|---|---|---|---|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10  | 9 | 8 | 7    | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 0  | 0  | 1  | op |    | reg |   |   | imm8 |   |   |   |   |   |   |   |

This table shows the decode field values and the associated instructions:

| op | Instruction                        |
|----|------------------------------------|
| 00 | <a href="#">MOV (immediate) T1</a> |
| 01 | <a href="#">CMP (immediate) T1</a> |
| 10 | <a href="#">ADD (immediate) T2</a> |
| 11 | <a href="#">SUB (immediate) T2</a> |

## C2.2.2 Data-processing (two low registers)

This section describes the encoding of the Data-processing (two low registers). This section is decoded from [16-bit T32 instruction encoding](#).

|    |    |    |    |    |    |    |   |   |   |    |   |     |   |   |   |
|----|----|----|----|----|----|----|---|---|---|----|---|-----|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8 | 7 | 6 | 5  | 4 | 3   | 2 | 1 | 0 |
| 0  | 1  | 0  | 0  | 0  | 0  | op |   |   |   | Rs |   | reg |   |   |   |

This table shows the decode field values and the associated instructions:

| op    | Instruction                                              |
|-------|----------------------------------------------------------|
| 0000  | <a href="#">AND (register) T1</a>                        |
| 0001  | <a href="#">EOR (register) T1</a>                        |
| Alias | <a href="#">LSL (register) T1</a>                        |
| Alias | <a href="#">LSLS (register) T1</a>                       |
| Alias | <a href="#">LSR (register) T1</a>                        |
| Alias | <a href="#">LSRS (register) T1</a>                       |
| Alias | <a href="#">ASR (register) T1</a>                        |
| Alias | <a href="#">ASRS (register) T1</a>                       |
| 0101  | <a href="#">ADC (register) T1</a>                        |
| 0110  | <a href="#">SBC (register) T1</a>                        |
| Alias | <a href="#">ROR (register) T1</a>                        |
| Alias | <a href="#">RORS (register) T1</a>                       |
| 1000  | <a href="#">TST (register) T1</a>                        |

| 0011  |                                                          |
| 0100  |                                                          |
| 0111  |                                                          |

### C2.2.3 Special data instructions and branch and exchange

This section describes the encoding of the Special data instructions and branch and exchange. This section is decoded from [16-bit T32 instruction encoding](#).

|    |    |    |    |    |    |     |   |   |   |   |   |   |   |   |   |
|----|----|----|----|----|----|-----|---|---|---|---|---|---|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9   | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 0  | 1  | 0  | 0  | 0  | 1  | op0 |   |   |   |   |   |   |   |   |   |

This table shows the decode field values and the associated subgroups:

| op0   | Subgroup                                                          |
|-------|-------------------------------------------------------------------|
| 11    | <a href="#">Branch and exchange</a>                               |
| != 11 | <a href="#">Add, subtract, compare, move (two high registers)</a> |

#### C2.2.3.1 Branch and exchange

This section describes the encoding of the Branch and exchange. This section is decoded from [Special data instructions and branch and exchange](#).

|    |    |    |    |    |    |   |   |   |    |   |   |    |        |   |   |
|----|----|----|----|----|----|---|---|---|----|---|---|----|--------|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6  | 5 | 4 | 3  | 2      | 1 | 0 |
| 0  | 1  | 0  | 0  | 0  | 1  | 1 | 1 | L | Rm |   |   | NS | (0)(0) |   |   |

This table shows the decode field values and the associated instructions:

| L | Instruction                   |
|---|-------------------------------|
| 0 | <a href="#">BX, BXNS T1</a>   |
| 1 | <a href="#">BLX, BLXNS T1</a> |

#### C2.2.3.2 Add, subtract, compare, move (two high registers)

This section describes the encoding of the Add, subtract, compare, move (two high registers). This section is decoded from [Special data instructions and branch and exchange](#).

|    |    |    |    |    |    |    |   |   |    |   |   |    |   |   |   |
|----|----|----|----|----|----|----|---|---|----|---|---|----|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8 | 7 | 6  | 5 | 4 | 3  | 2 | 1 | 0 |
| 0  | 1  | 0  | 0  | 0  | 1  | op |   | D | Rs |   |   | Rd |   |   |   |

This table shows the decode field values and the associated instructions:

| D:Rd    | Rs      | op | Instruction                               |
|---------|---------|----|-------------------------------------------|
| != 1101 | != 1101 | 00 | <a href="#">ADD (register) T2</a>         |
| -       | 1101    | 00 | <a href="#">ADD (SP plus register) T1</a> |
| 1101    | != 1101 | 00 | <a href="#">ADD (SP plus register) T2</a> |
| -       | -       | 01 | <a href="#">CMP (register) T2</a>         |
| -       | -       | 10 | <a href="#">MOV (register) T1</a>         |

## C2.2.4 Load/store (register offset)

This section describes the encoding of the Load/store (register offset). This section is decoded from [16-bit T32 instruction encoding](#).

|    |    |    |    |    |    |   |    |   |   |    |   |   |    |   |   |
|----|----|----|----|----|----|---|----|---|---|----|---|---|----|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8  | 7 | 6 | 5  | 4 | 3 | 2  | 1 | 0 |
| 0  | 1  | 0  | 1  | L  | B  | H | Rm |   |   | Rn |   |   | Rt |   |   |

This table shows the decode field values and the associated instructions:

| B | H | L | Instruction                         |
|---|---|---|-------------------------------------|
| 0 | 0 | 0 | <a href="#">STR (register) T1</a>   |
| 0 | 1 | 0 | <a href="#">STRH (register) T1</a>  |
| 1 | 0 | 0 | <a href="#">STRB (register) T1</a>  |
| 1 | 1 | 0 | <a href="#">LDRSB (register) T1</a> |
| 0 | 0 | 1 | <a href="#">LDR (register) T1</a>   |
| 0 | 1 | 1 | <a href="#">LDRH (register) T1</a>  |
| 1 | 0 | 1 | <a href="#">LDRB (register) T1</a>  |
| 1 | 1 | 1 | <a href="#">LDRSH (register) T1</a> |

## C2.2.5 Load/store word/byte (immediate offset)

This section describes the encoding of the Load/store word/byte (immediate offset). This section is decoded from [16-bit T32 instruction encoding](#).

|    |    |    |    |    |      |   |   |   |   |    |   |   |    |   |   |
|----|----|----|----|----|------|---|---|---|---|----|---|---|----|---|---|
| 15 | 14 | 13 | 12 | 11 | 10   | 9 | 8 | 7 | 6 | 5  | 4 | 3 | 2  | 1 | 0 |
| 0  | 1  | 1  | B  | L  | imm5 |   |   |   |   | Rn |   |   | Rt |   |   |

This table shows the decode field values and the associated instructions:

| B | L | Instruction                         |
|---|---|-------------------------------------|
| 0 | 0 | <a href="#">STR (immediate) T1</a>  |
| 0 | 1 | <a href="#">LDR (immediate) T1</a>  |
| 1 | 0 | <a href="#">STRB (immediate) T1</a> |
| 1 | 1 | <a href="#">LDRB (immediate) T1</a> |

## C2.2.6 Load/store halfword (immediate offset)

This section describes the encoding of the Load/store halfword (immediate offset). This section is decoded from [16-bit T32 instruction encoding](#).

|    |    |    |    |    |      |   |   |   |   |    |   |   |    |   |   |
|----|----|----|----|----|------|---|---|---|---|----|---|---|----|---|---|
| 15 | 14 | 13 | 12 | 11 | 10   | 9 | 8 | 7 | 6 | 5  | 4 | 3 | 2  | 1 | 0 |
| 1  | 0  | 0  | 0  | L  | imm5 |   |   |   |   | Rn |   |   | Rt |   |   |

This table shows the decode field values and the associated instructions:

| L | Instruction                         |
|---|-------------------------------------|
| 0 | <a href="#">STRH (immediate) T1</a> |
| 1 | <a href="#">LDRH (immediate) T1</a> |

### C2.2.7 Load/store (SP-relative)

This section describes the encoding of the Load/store (SP-relative). This section is decoded from [16-bit T32 instruction encoding](#).

|    |    |    |    |    |    |   |   |      |   |   |   |   |   |   |   |
|----|----|----|----|----|----|---|---|------|---|---|---|---|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7    | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 1  | 0  | 0  | 1  | L  | Rt |   |   | imm8 |   |   |   |   |   |   |   |

This table shows the decode field values and the associated instructions:

| L | Instruction                        |
|---|------------------------------------|
| 0 | <a href="#">STR (immediate) T2</a> |
| 1 | <a href="#">LDR (immediate) T2</a> |

### C2.2.8 Add PC/SP (immediate)

This section describes the encoding of the Add PC/SP (immediate). This section is decoded from [16-bit T32 instruction encoding](#).

|    |    |    |    |    |    |   |   |      |   |   |   |   |   |   |   |
|----|----|----|----|----|----|---|---|------|---|---|---|---|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7    | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 1  | 0  | 1  | 0  | op | Rd |   |   | imm8 |   |   |   |   |   |   |   |

This table shows the decode field values and the associated instructions:

| op    | Instruction                                |
|-------|--------------------------------------------|
| Alias | <a href="#">ADD (immediate, to PC) T1</a>  |
| 0     | <a href="#">ADR T1</a>                     |
| 1     | <a href="#">ADD (SP plus immediate) T1</a> |

## C2.2.9 Miscellaneous 16-bit instructions

This section describes the encoding of the Miscellaneous 16-bit instructions. This section is decoded from [16-bit T32 instruction encoding](#).

| 15 | 14 | 13 | 12 | 11  | 10 | 9 | 8 | 7   | 6 | 5   | 4 | 3   | 2 | 1 | 0 |
|----|----|----|----|-----|----|---|---|-----|---|-----|---|-----|---|---|---|
| 1  | 0  | 1  | 1  | op0 |    |   |   | op1 |   | op2 |   | op3 |   |   |   |

This table shows the decode field values and the associated subgroups:

| op0  | op1   | op2 | op3  | Subgroup                              |
|------|-------|-----|------|---------------------------------------|
| 0000 | -     | -   | -    | <a href="#">Adjust SP (immediate)</a> |
| 0010 | -     | -   | -    | <a href="#">Extend</a>                |
| 1010 | != 10 | -   | -    | <a href="#">Reverse bytes</a>         |
| 1111 | -     | -   | 0000 | <a href="#">Hints</a>                 |
| x10x | -     | -   | -    | <a href="#">Push and Pop</a>          |

This table shows the decode field values and the associated instructions:

| op0  | op1 | op2 | op3     | Instruction                  |
|------|-----|-----|---------|------------------------------|
| 0110 | 01  | 1   | -       | <a href="#">CPS T1</a>       |
| 1110 | -   | -   | -       | <a href="#">BKPT T1</a>      |
| 1111 | -   | -   | != 0000 | <a href="#">IT T1</a>        |
| x0x1 | -   | -   | -       | <a href="#">CBNZ, CBZ T1</a> |

### C2.2.9.1 Adjust SP (immediate)

This section describes the encoding of the Adjust SP (immediate). This section is decoded from [Miscellaneous 16-bit instructions](#).

| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6    | 5 | 4 | 3 | 2 | 1 | 0 |
|----|----|----|----|----|----|---|---|---|------|---|---|---|---|---|---|
| 1  | 0  | 1  | 1  | 0  | 0  | 0 | 0 | S | imm7 |   |   |   |   |   |   |

This table shows the decode field values and the associated instructions:

| S | Instruction                                 |
|---|---------------------------------------------|
| 0 | <a href="#">ADD (SP plus immediate) T2</a>  |
| 1 | <a href="#">SUB (SP minus immediate) T1</a> |

### C2.2.9.2 Extend

This section describes the encoding of the Extend. This section is decoded from [Miscellaneous 16-bit instructions](#).

|    |    |    |    |    |    |   |   |   |   |    |   |   |    |   |   |
|----|----|----|----|----|----|---|---|---|---|----|---|---|----|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5  | 4 | 3 | 2  | 1 | 0 |
| 1  | 0  | 1  | 1  | 0  | 0  | 1 | 0 | U | B | Rm |   |   | Rd |   |   |

This table shows the decode field values and the associated instructions:

| B | U | Instruction             |
|---|---|-------------------------|
| 0 | 0 | <a href="#">SXTH T1</a> |
| 1 | 0 | <a href="#">SXTB T1</a> |
| 0 | 1 | <a href="#">UXTH T1</a> |
| 1 | 1 | <a href="#">UXTB T1</a> |

### C2.2.9.3 Reverse bytes

This section describes the encoding of the Reverse bytes. This section is decoded from [Miscellaneous 16-bit instructions](#).

|    |    |    |    |    |    |   |   |    |   |    |   |   |    |   |   |
|----|----|----|----|----|----|---|---|----|---|----|---|---|----|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7  | 6 | 5  | 4 | 3 | 2  | 1 | 0 |
| 1  | 0  | 1  | 1  | 1  | 0  | 1 | 0 | op |   | Rm |   |   | Rd |   |   |

This table shows the decode field values and the associated instructions:

| op | Instruction              |
|----|--------------------------|
| 00 | <a href="#">REV T1</a>   |
| 01 | <a href="#">REV16 T1</a> |
| 11 | <a href="#">REVSH T1</a> |

### C2.2.9.4 Hints

This section describes the encoding of the Hints. This section is decoded from [Miscellaneous 16-bit instructions](#).

|    |    |    |    |    |    |   |   |      |   |   |   |   |   |   |   |
|----|----|----|----|----|----|---|---|------|---|---|---|---|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7    | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 1  | 0  | 1  | 1  | 1  | 1  | 1 | 1 | hint |   |   |   | 0 | 0 | 0 | 0 |

This table shows the decode field values and the associated instructions:

| hint | Instruction                                   |
|------|-----------------------------------------------|
| 0000 | <a href="#">NOP T1</a>                        |
| 0001 | <a href="#">YIELD T1</a>                      |
| 0010 | <a href="#">WFE T1</a>                        |
| 0011 | <a href="#">WFI T1</a>                        |
| 0100 | <a href="#">SEV T1</a>                        |
| 0101 | Reserved hint, behaves as <a href="#">NOP</a> |
| 011x | Reserved hint, behaves as <a href="#">NOP</a> |
| 1xxx | Reserved hint, behaves as <a href="#">NOP</a> |

### C2.2.9.5 Push and Pop

This section describes the encoding of the Push and Pop. This section is decoded from [Miscellaneous 16-bit instructions](#).

| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7             | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----|----|----|----|----|----|---|---|---------------|---|---|---|---|---|---|---|
| 1  | 0  | 1  | 1  | L  | 1  | 0 | P | register_list |   |   |   |   |   |   |   |

This table shows the decode field values and the associated instructions:

| L     | Instruction                                  |
|-------|----------------------------------------------|
| 1     | <a href="#">LDM, LDMIA, LDMFD T3</a>         |
| Alias | <a href="#">POP (multiple registers) T3</a>  |
| Alias | <a href="#">PUSH (multiple registers) T2</a> |
| 0     | <a href="#">STMDB, STMFD T2</a>              |

### C2.2.10 Load/store multiple

This section describes the encoding of the Load/store multiple. This section is decoded from [16-bit T32 instruction encoding](#).

| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7             | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----|----|----|----|----|----|---|---|---------------|---|---|---|---|---|---|---|
| 1  | 1  | 0  | 0  | L  | Rn |   |   | register_list |   |   |   |   |   |   |   |

This table shows the decode field values and the associated instructions:

| L | Instruction                          |
|---|--------------------------------------|
| 1 | <a href="#">LDM, LDMIA, LDMFD T1</a> |
| 0 | <a href="#">STM, STMIA, STMEA T1</a> |

### C2.2.11 Conditional branch, and Supervisor Call

This section describes the encoding of the Conditional branch, and Supervisor Call. This section is decoded from [16-bit T32 instruction encoding](#).

| 15 | 14 | 13 | 12 | 11  | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----|----|----|----|-----|----|---|---|---|---|---|---|---|---|---|---|
| 1  | 1  | 0  | 1  | op0 |    |   |   |   |   |   |   |   |   |   |   |

This table shows the decode field values and the associated subgroups:

| op0 | Subgroup |
|-----|----------|
|-----|----------|

|      |                                      |
|------|--------------------------------------|
| 111x | <a href="#">Exception generation</a> |
|------|--------------------------------------|

This table shows the decode field values and the associated instructions:

| op0     | Instruction          |
|---------|----------------------|
| != 111x | <a href="#">B T1</a> |

### C2.2.11.1 Exception generation

This section describes the encoding of the Exception generation. This section is decoded from [Conditional branch](#), [and Supervisor Call](#).

|    |    |    |    |    |    |   |   |      |   |   |   |   |   |   |   |
|----|----|----|----|----|----|---|---|------|---|---|---|---|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7    | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 1  | 1  | 0  | 1  | 1  | 1  | 1 | S | imm8 |   |   |   |   |   |   |   |

This table shows the decode field values and the associated instructions:

| S | imm8 | Instruction            |
|---|------|------------------------|
| 0 | -    | <a href="#">UDF T1</a> |
| 1 | -    | <a href="#">SVC T1</a> |

## C2.3 32-bit T32 instruction encoding

This section describes the encoding of the 32-bit T32 instruction encoding. This section is decoded from [Top level T32 instruction set encoding](#).

|    |    |    |     |    |    |   |     |   |   |     |   |   |   |   |   |     |    |    |    |    |    |   |   |     |   |   |   |   |   |   |   |
|----|----|----|-----|----|----|---|-----|---|---|-----|---|---|---|---|---|-----|----|----|----|----|----|---|---|-----|---|---|---|---|---|---|---|
| 15 | 14 | 13 | 12  | 11 | 10 | 9 | 8   | 7 | 6 | 5   | 4 | 3 | 2 | 1 | 0 | 15  | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7   | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 1  | 1  | 1  | op0 |    |    |   | op1 |   |   | op2 |   |   |   |   |   | op3 |    |    |    |    |    |   |   | op4 |   |   |   |   |   |   |   |

This table shows the decode field values and the associated subgroups:

| op0  | op1 | op1:op2 | op2 | op3  | op4 | Subgroup                                                |
|------|-----|---------|-----|------|-----|---------------------------------------------------------|
| x11x | -   | -       | -   | -    | -   | Coprocessor, floating-point, and vector instructions    |
| 0100 | -   | -       | -   | -    | -   | Load/store (multiple, dual, exclusive, acquire-release) |
| 0101 | -   | -       | -   | -    | -   | Data-processing (shifted register)                      |
| 10xx | -   | -       | -   | 1xxx | -   | Branches and miscellaneous control                      |
| 10x0 | -   | -       | -   | 0xxx | -   | Data-processing (modified immediate)                    |
| 10x1 | -   | -       | 0   | 0xxx | -   | Data-processing (plain binary immediate)                |
| 1100 | -   | != 1x0  | -   | -    | -   | Load/store single                                       |
| 1101 | 0x  | -       | -   | 1111 | -   | Data-processing (register)                              |
| 1101 | 10  | -       | -   | -    | 00  | Multiply, multiply accumulate, and absolute difference  |
| 1101 | 11  | -       | -   | -    | -   | Long multiply and divide                                |

### C2.3.1 Coprocessor, floating-point, and vector instructions

This section describes the encoding of the Coprocessor, floating-point, and vector instructions. This section is decoded from [32-bit T32 instruction encoding](#).

|    |    |    |    |    |    |     |   |   |   |   |   |   |   |     |   |    |    |    |    |    |    |     |   |   |   |   |   |   |   |   |   |
|----|----|----|----|----|----|-----|---|---|---|---|---|---|---|-----|---|----|----|----|----|----|----|-----|---|---|---|---|---|---|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9   | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1   | 0 | 15 | 14 | 13 | 12 | 11 | 10 | 9   | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 1  | 1  | 1  |    | 1  | 1  | op0 |   |   |   |   |   |   |   | op1 |   |    |    |    |    |    |    | op2 |   |   |   |   |   |   |   |   |   |

This table shows the decode field values and the associated subgroups:

| op0 | op1 | op2 | Subgroup                                                                 |
|-----|-----|-----|--------------------------------------------------------------------------|
| 10  | -   | -   | Floating-point and vector miscellaneous instructions                     |
| 0x  | -   | -   | Floating-point and vector load/store, move, and coprocessor instructions |
| 11  | 0   | 1   | Miscellaneous vector arithmetic instructions                             |

#### C2.3.1.1 Floating-point and vector miscellaneous instructions

This section describes the encoding of the Floating-point and vector miscellaneous instructions. This section is decoded from [Coprocessor, floating-point, and vector instructions](#).

|    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |    |    |    |    |     |    |   |   |   |   |     |   |   |   |   |   |
|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|----|----|----|----|-----|----|---|---|---|---|-----|---|---|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | 15 | 14 | 13 | 12 | 11  | 10 | 9 | 8 | 7 | 6 | 5   | 4 | 3 | 2 | 1 | 0 |

#### Architected coprocessor load, store, and move instructions

This section describes the encoding of the Architected coprocessor load, store, and move instructions. This section is decoded from [Coprocessor load, store, and move instructions](#).

|    |    |    |     |    |    |   |   |   |   |   |     |     |     |   |   |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|----|----|----|-----|----|----|---|---|---|---|---|-----|-----|-----|---|---|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 15 | 14 | 13 | 12  | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4   | 3   | 2   | 1 | 0 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 1  | 1  | 1  | op0 | 1  | 1  | 0 |   |   |   |   | op1 | op2 | op3 |   |   |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

This table shows the decode field values and the associated instructions:

| op0 | op1     | op2 | op3     | Instruction                              |
|-----|---------|-----|---------|------------------------------------------|
| 0   | != 0010 | 1   | != 1111 | <a href="#">LDC, LDC2 (immediate) T1</a> |
| 1   | != 0010 | 1   | != 1111 | <a href="#">LDC, LDC2 (immediate) T2</a> |
| 0   | != 0010 | 1   | 1111    | <a href="#">LDC, LDC2 (literal) T1</a>   |
| 1   | != 0010 | 1   | 1111    | <a href="#">LDC, LDC2 (literal) T2</a>   |
| 0   | != 0010 | 0   | -       | <a href="#">STC, STC2 T1</a>             |
| 1   | != 0010 | 0   | -       | <a href="#">STC, STC2 T2</a>             |

|   |      |   |   |                                |
|---|------|---|---|--------------------------------|
| 0 | 0010 | 1 | - | <a href="#">MRRC, MRRC2 T1</a> |
| 1 | 0010 | 1 | - | <a href="#">MRRC, MRRC2 T2</a> |
| 0 | 0010 | 0 | - | <a href="#">MCRR, MCRR2 T1</a> |
| 1 | 0010 | 0 | - | <a href="#">MCRR, MCRR2 T2</a> |

### Custom Floating-point and vector instructions

This section describes the encoding of the Custom Floating-point and vector instructions. This section is decoded from [Coprorocessor load, store, and move instructions](#).

|    |    |    |    |    |    |   |   |     |   |     |   |   |   |   |   |    |    |    |    |    |        |   |   |     |   |   |   |   |   |   |   |
|----|----|----|----|----|----|---|---|-----|---|-----|---|---|---|---|---|----|----|----|----|----|--------|---|---|-----|---|---|---|---|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7   | 6 | 5   | 4 | 3 | 2 | 1 | 0 | 15 | 14 | 13 | 12 | 11 | 10     | 9 | 8 | 7   | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 1  | 1  | 1  | A  | 1  | 1  | 0 |   | op0 | D | op1 |   |   |   |   |   |    | Vd |    |    | 0  | coproc |   |   | op2 |   |   |   |   |   |   |   |

This table shows the decode field values and the associated instructions:

| op0 | op1 | op2 | Instruction                      |
|-----|-----|-----|----------------------------------|
| 0   | 10  | 1   | <a href="#">VCX1 (vector) T1</a> |
| 0   | 10  | 0   | <a href="#">VCX1 T1</a>          |
| 0   | 11  | 1   | <a href="#">VCX2 (vector) T1</a> |
| 0   | 11  | 0   | <a href="#">VCX2 T1</a>          |
| 1   | -   | 1   | <a href="#">VCX3 (vector) T1</a> |
| 1   | -   | 0   | <a href="#">VCX3 T1</a>          |

#### C2.3.1.2.2 Floating-point and vector load/store and, complex arithmetic instructions

This section describes the encoding of the Floating-point and vector load/store and, complex arithmetic instructions. This section is decoded from [Floating-point and vector load/store, move, and coprocessor instructions](#).

|    |    |    |     |    |    |   |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|----|----|----|-----|----|----|---|---|---|---|---|---|---|---|---|---|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 15 | 14 | 13 | 12  | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 1  | 1  | 1  | op0 | 1  | 1  |   |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

This table shows the decode field values and the associated subgroups:

| op0 | Subgroup                                                                  |
|-----|---------------------------------------------------------------------------|
| 1   | <a href="#">Floating-point and vector complex arithmetic instructions</a> |
| 0   | <a href="#">Floating-point and vector load/store instructions</a>         |

### Floating-point and vector complex arithmetic instructions

This section describes the encoding of the Floating-point and vector complex arithmetic instructions. This section is decoded from [Floating-point and vector load/store and, complex arithmetic instructions](#).

|    |    |    |    |    |    |   |   |     |   |     |   |   |    |     |   |    |    |    |     |    |    |   |     |   |     |   |     |   |    |     |   |
|----|----|----|----|----|----|---|---|-----|---|-----|---|---|----|-----|---|----|----|----|-----|----|----|---|-----|---|-----|---|-----|---|----|-----|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7   | 6 | 5   | 4 | 3 | 2  | 1   | 0 | 15 | 14 | 13 | 12  | 11 | 10 | 9 | 8   | 7 | 6   | 5 | 4   | 3 | 2  | 1   | 0 |
| 1  | 1  | 1  | 1  | 1  | 1  | 0 |   | op0 |   | op1 |   |   | Qn | op2 |   |    | Qd |    | op3 | 1  | 0  | 0 | op4 |   | op5 |   | op6 |   | Qm | op7 |   |

This table shows the decode field values and the associated instructions:

| op0 | op1 | op2 | op3 | op4 | op5 | op6 | op7 | Instruction               |
|-----|-----|-----|-----|-----|-----|-----|-----|---------------------------|
| 1   | 0   | 0   | 0   | 0   | 1   | 0   | 0   | VCADD (floating-point) T1 |
| -   | 1   | 0   | 0   | 0   | 1   | 0   | 0   | VCMLA (floating-point) T1 |

### Floating-point and vector load/store instructions

This section describes the encoding of the Floating-point and vector load/store instructions. This section is decoded from [Floating-point and vector load/store and, complex arithmetic instructions](#).

|    |    |    |    |    |    |   |     |   |   |     |   |   |    |   |   |    |    |    |    |    |    |     |   |   |   |   |   |   |   |   |   |
|----|----|----|----|----|----|---|-----|---|---|-----|---|---|----|---|---|----|----|----|----|----|----|-----|---|---|---|---|---|---|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8   | 7 | 6 | 5   | 4 | 3 | 2  | 1 | 0 | 15 | 14 | 13 | 12 | 11 | 10 | 9   | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 1  | 1  | 1  | 0  | 1  | 1  | 0 | op0 | U | D | op1 |   |   | Rn |   |   | Vd |    |    | 1  | 0  | 0  | op2 |   |   |   |   |   |   |   |   |   |

This table shows the decode field values and the associated instructions:

| op0 | op1 | op2 | Instruction |
|-----|-----|-----|-------------|
| 1   | 01  | 1   | VLDR T3     |
| 1   | 00  | 1   | VSTR T3     |

### C2.3.1.2.3 Coprocessor and Floating-point load/store, move, and security

This section describes the encoding of the Coprocessor and Floating-point load/store, move, and security. This section is decoded from [Floating-point and vector load/store, move, and coprocessor instructions](#).

|    |    |    |     |    |    |   |   |     |   |     |   |     |   |   |   |    |    |    |    |    |    |   |     |   |     |   |   |   |   |   |     |
|----|----|----|-----|----|----|---|---|-----|---|-----|---|-----|---|---|---|----|----|----|----|----|----|---|-----|---|-----|---|---|---|---|---|-----|
| 15 | 14 | 13 | 12  | 11 | 10 | 9 | 8 | 7   | 6 | 5   | 4 | 3   | 2 | 1 | 0 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8   | 7 | 6   | 5 | 4 | 3 | 2 | 1 | 0   |
| 1  | 1  | 1  | op0 | 1  | 1  | 0 |   | op1 |   | op2 |   | op3 |   |   |   |    |    |    |    |    |    |   | op4 |   | op5 |   |   |   |   |   | op6 |

This table shows the decode field values and the associated instructions:

| op0 | op1                  | op1:op3     | op2 | op3 | op4 | op5 | op6 | Instruction         |

| 0 | -       | 01   | STRH (register) T2      |
| 1 | != 1111 | 01   | LDRH (register) T2      |
| 0 | -       | 10   | STR (register) T2       |
| 1 | -       | 10   | LDR (register) T2       |

### C2.3.7.2 Load/store, unsigned (immediate, post-indexed)

This section describes the encoding of the Load/store, unsigned (immediate, post-indexed). This section is decoded from [Load/store single](#).

|    |    |    |    |    |    |   |   |   |      |   |   |   |   |   |   |    |    |    |    |    |    |   |   |      |   |   |   |   |   |   |   |
|----|----|----|----|----|----|---|---|---|------|---|---|---|---|---|---|----|----|----|----|----|----|---|---|------|---|---|---|---|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6    | 5 | 4 | 3 | 2 | 1 | 0 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7    | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 1  | 1  | 1  | 1  | 1  | 0  | 0 | 0 | 0 | size | L |   |   |   |   |   |    |    |    |    | 1  | P  | U | W |      |   |   |   |   |   |   |   |
|    |    |    |    |    |    |   |   |   |      |   |   |   |   |   |   | Rn |    |    |    | Rt |    |   |   | imm8 |   |   |   |   |   |   |   |

**This table shows the decode field values and the associated instructions:**

| <b>L</b> | <b>size</b> | <b>Instruction</b>        |
|----------|-------------|---------------------------|
| 0        | 00          | STRB (immediate) T3       |
| 1        | 00          | LDRB (immediate) T3       |
| 0        | 01          | STRH (immediate) T3       |
| 1        | 01          | LDRH (immediate) T3       |
| 0        | 10          | STR (immediate) T4        |
|          | Alias       | PUSH (single register) T4 |
| 1        | 10          | LDR (immediate) T4        |
|          | Alias       | POP (single register) T4  |

### C2.3.7.3 Load/store, unsigned (negative immediate)

This section describes the encoding of the Load/store, unsigned (negative immediate). This section is decoded from [Load/store single](#).

|    |    |    |    |    |    |   |   |   |      |   |   |   |    |   |   |    |    |    |    |    |    |   |   |   |   |   |   |   |      |   |   |
|----|----|----|----|----|----|---|---|---|------|---|---|---|----|---|---|----|----|----|----|----|----|---|---|---|---|---|---|---|------|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6    | 5 | 4 | 3 | 2  | 1 | 0 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2    | 1 | 0 |
| 1  | 1  | 1  | 1  | 1  | 0  | 0 | 0 | 0 | size | L |   |   | Rn |   |   |    |    |    | Rt |    |    | 1 | 1 | 0 | 0 |   |   |   | imm8 |   |   |

**This table shows the decode field values and the associated instructions:**

| L | Rt      | size | Instruction              |
|---|---------|------|--------------------------|
| 0 | -       | 00   | STRB (immediate) T3      |
| 1 | != 1111 | 00   | LDRB (immediate) T3      |
| 1 | 1111    | 0x   | PLD, PLDW (immediate) T2 |
| 0 | -       | 01   | STRH (immediate) T3      |
| 1 | != 1111 | 01   | LDRH (immediate) T3      |

|       |   |    |                           |
|-------|---|----|---------------------------|
| 0     | - | 10 | STR (immediate) T4        |
| Alias |   |    | PUSH (single register) T4 |
| 1     | - | 10 | LDR (immediate) T4        |
| Alias |   |    | POP (single register) T4  |

#### C2.3.7.4 Load/store, unsigned (unprivileged)

This section describes the encoding of the Load/store, unsigned (unprivileged). This section is decoded from [Load/store single](#).

|    |    |    |    |    |    |   |   |   |      |   |    |   |   |    |   |    |    |    |    |    |      |   |   |   |   |   |   |   |   |   |   |
|----|----|----|----|----|----|---|---|---|------|---|----|---|---|----|---|----|----|----|----|----|------|---|---|---|---|---|---|---|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6    | 5 | 4  | 3 | 2 | 1  | 0 | 15 | 14 | 13 | 12 | 11 | 10   | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 1  | 1  | 1  | 1  | 1  | 0  | 0 | 0 | 0 | size | L | Rn |   |   | Rt |   |    | 1  | 1  | 1  | 0  | imm8 |   |   |   |   |   |   |   |   |   |   |

This table shows the decode field values and the associated instructions:

| L | size | Instruction |
|---|------|-------------|
| 0 | 00   | STRBT T1    |
| 1 | 00   | LDRBT T1    |
| 0 | 01   | STRHT T1    |
| 1 | 01   | LDRHT T1    |
| 0 | 10   | STRT T1     |
| 1 | 10   | LDRT T1     |

#### C2.3.7.5 Load/store, unsigned (immediate, pre-indexed)

This section describes the encoding of the Load/store, unsigned (immediate, pre-indexed). This section is decoded from [Load/store single](#).

|    |    |    |    |    |    |   |   |   |      |   |    |   |   |    |   |    |    |    |    |    |      |   |   |   |   |   |   |   |   |   |   |
|----|----|----|----|----|----|---|---|---|------|---|----|---|---|----|---|----|----|----|----|----|------|---|---|---|---|---|---|---|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6    | 5 | 4  | 3 | 2 | 1  | 0 | 15 | 14 | 13 | 12 | 11 | 10   | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 1  | 1  | 1  | 1  | 1  | 0  | 0 | 0 | 0 | size | L | Rn |   |   | Rt |   |    | 1  | P  | U  | W  | imm8 |   |   |   |   |   |   |   |   |   |   |

This table shows the decode field values and the associated instructions:

| L     | size | Instruction               |
|-------|------|---------------------------|
| 0     | 00   | STRB (immediate) T3       |
| 1     | 00   | LDRB (immediate) T3       |
| 0     | 01   | STRH (immediate) T3       |
| 1     | 01   | LDRH (immediate) T3       |
| 0     | 10   | STR (immediate) T4        |
| Alias |      | PUSH (single register) T4 |
| 1     | 10   | LDR (immediate) T4        |
| Alias |      | POP (single register) T4  |

### C2.3.7.6 Load/store, unsigned (positive immediate)

This section describes the encoding of the Load/store, unsigned (positive immediate). This section is decoded from [Load/store single](#).

|    |    |    |    |    |    |   |   |   |      |   |   |   |   |   |   |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|----|----|----|----|----|----|---|---|---|------|---|---|---|---|---|---|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6    | 5 | 4 | 3 | 2 | 1 | 0 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 1  | 1  | 1  | 1  | 1  | 0  | 0 | 0 | 1 | size | L |   |   |   |   |   | Rt |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

This table shows the decode field values and the associated instructions:

| L | Rt      | size | Instruction                              |
|---|---------|------|------------------------------------------|
| 0 | -       | 00   | <a href="#">STRB (immediate) T2</a>      |
| 1 | != 1111 | 00   | <a href="#">LDRB (immediate) T2</a>      |

## C2.4 Alphabetical list of instructions

Every Armv8-M instruction is listed in this section. See [Instruction Set Overview](#) for the format of the instruction descriptions.

### C2.4.1 ADC (immediate)

Add with Carry (immediate). Add with Carry (immediate) adds an immediate value and the carry flag value to a register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

#### T1

Armv8-M Main Extension only

|    |    |    |    |    |    |   |   |   |   |   |   |    |   |   |   |    |      |    |    |    |    |   |   |   |      |   |   |   |   |   |   |  |
|----|----|----|----|----|----|---|---|---|---|---|---|----|---|---|---|----|------|----|----|----|----|---|---|---|------|---|---|---|---|---|---|--|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3  | 2 | 1 | 0 | 15 | 14   | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6    | 5 | 4 | 3 | 2 | 1 | 0 |  |
| 1  | 1  | 1  | 1  | 0  | i  | 0 | 1 | 0 | 1 | 0 | S | Rn |   |   |   | 0  | imm3 |    |    |    | Rd |   |   |   | imm8 |   |   |   |   |   |   |  |

#### ADC variant

Applies when **S** == 0.

ADC{<c>}{<q>} {<Rd>}, {<Rn>}, #<const>

#### ADCS variant

Applies when **S** == 1.

ADCS{<c>}{<q>} {<Rd>}, {<Rn>}, #<const>

#### Decode for this encoding

```
1 if !HaveMainExt() then UNDEFINED;
2 d = UInt(Rd); n = UInt(Rn); setflags = (S == '1'); imm32 = T32ExpandImm(i:imm3:imm8);
3 if d IN {13,15} || n IN {13,15} then UNPREDICTABLE;
```

#### Assembler symbols for all encodings

<c> See [C1.2.5 Standard assembler syntax fields](#).  
 <q> See [C1.2.5 Standard assembler syntax fields](#).  
 <Rd> Is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.  
 <Rn> Is the general-purpose source register, encoded in the "Rn" field.  
 <const> Is an immediate value derived from the 12-bit immediate that is encoded in the "i:imm3:imm8" field. See [C1.5 Modified immediate constants](#) for the range of values.

#### Operation for all encodings

```
1 if ConditionPassed() then
2   EncodingSpecificOperations();
3   (result, carry, overflow) = AddWithCarry(R[n], imm32, APSR.C);
4   R[d] = result;
5   if setflags then
6     APSR.N = result[31];
7     APSR.Z = IsZeroBit(result);
8     APSR.C = carry;
9     APSR.V = overflow;
```

#### Restricted behavior

##### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is independent of:

- The values of the data supplied in any of its registers.
  - The values of the N, Z, C, V flags.
- The point at which an asynchronous exception is taken does not vary based on any of the following:
  - The values of the data supplied in any the registers bwing used in this instruction.
  - The values of the N, Z, C, V flags.

## C2.4.2 ADC (register)

Add with Carry (register). Add with Carry (register) adds a register value, the carry flag value, and an optionally-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

### T1

Armv8-M

|    |    |    |    |    |    |   |   |   |   |    |   |   |     |   |   |
|----|----|----|----|----|----|---|---|---|---|----|---|---|-----|---|---|

sr\_type

#### ADC, rotate right with extend variant

Applies when **S == 0** && **imm3 == 000** && **imm2 == 00** && **sr\_type == 11**.

```
ADC{<c>}{<q>} {<Rd>, } <Rn>, <Rm>, RRX
```

#### ADC, shift or rotate by value variant

Applies when **S == 0** && **!(imm3 == 000 && imm2 == 00 && sr\_type == 11)**.

```
ADC<c>.W {<Rd>, } <Rn>, <Rm>
    // Inside IT block, and <Rd>, <Rn>, <Rm> can be represented in T1
ADC{<c>}{<q>} {<Rd>, } <Rn>, <Rm> {, <shift> #<amount>}
```

#### ADCS, rotate right with extend variant

Applies when **S == 1** && **imm3 == 000** && **imm2 == 00** && **sr\_type == 11**.

```
ADCS{<c>}{<q>} {<Rd>, } <Rn>, <Rm>, RRX
```

#### ADCS, shift or rotate by value variant

Applies when **S == 1** && **!(imm3 == 000 && imm2 == 00 && sr\_type == 11)**.

```
ADCS.W {<Rd>}, <Rn>, <Rm>
// Outside IT block, and <Rd>, <Rn>, <Rm> can be represented in T1
ADCS{<c>}{<q>} {<Rd>}, <Rn>, <Rm> {, <shift> #<amount>}
```

### Decode for this encoding

```
1 if !HaveMainExt() then UNDEFINED;
2 d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); setflags = (S == '1');
3 (shift_t, shift_n) = DecodeImmShift(sr_type, imm3:imm2);
4 if d IN {13,15} || n IN {13,15} || m IN {13,15} then UNPREDICTABLE;
```

### Assembler symbols for all encodings

|          |                                                                                                                                                                                                                                         |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <c>      | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                                                                                           |
| <q>      | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                                                                                           |
| <Rdn>    | Is the first general-purpose source register and the destination register, encoded in the "Rdn" field.                                                                                                                                  |
| <Rd>     | Is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.                                                                                                                  |
| <Rn>     | Is the first general-purpose source register, encoded in the "Rn" field.                                                                                                                                                                |
| <Rm>     | Is the second general-purpose source register, encoded in the "Rm" field.                                                                                                                                                               |
| <shift>  | Is the type of shift to be applied to the second source register, encoded in the "sr_type" field. It can have the following values:<br>LSL when sr_type = 00<br>LSR when sr_type = 01<br>ASR when sr_type = 10<br>ROR when sr_type = 11 |
| <amount> | Is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm3:imm2" field as <amount> modulo 32.                                                                    |

### Operation for all encodings

```
1 if ConditionPassed() then
2   EncodingSpecificOperations();
3   shifted = Shift(R[m], shift_t, shift_n, APSR.C);
4   (result, carry, overflow) = AddWithCarry(R[n], shifted, APSR.C);
5   R[d] = result;
6   if setflags then
7     APSR.N = result[31];
8     APSR.Z = IsZeroBit(result);
9     APSR.C = carry;
10    APSR.V = overflow;
```

### Restricted behavior

#### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the N, Z, C, V flags.
- The point at which an asynchronous exception is taken does not vary based on any of the following:
  - The values of the data supplied in any the registers bwing used in this instruction.
  - The values of the N, Z, C, V flags.

### C2.4.3 ADD (SP plus immediate)

Add to SP (immediate). ADD (SP plus immediate) adds an immediate value to the SP value, and writes the result to the destination register.

    // <imm12> cannot be represented in T1, T2, or T3
ADDW{<c>}{<q>} {<Rd>}, SP, #<imm12>
    // <imm12> can be represented in T1, T2, or T3

```

### Decode for this encoding

```

1 if !HaveMainExt() then UNDEFINED;
2 d = UInt(Rd); setflags = FALSE; imm32 = ZeroExtend(i:imm3:imm8, 32);
3 if d == 15 then UNPREDICTABLE;

```

### Assembler symbols for all encodings

|         |                                                                                                                                                                                                                                     |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <c>     | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                                                                                       |
| <q>     | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                                                                                       |
| <imm7>  | Is an unsigned immediate, a multiple of 4 in the range 0 to 508, encoded in the "imm7" field as <imm7>/4.                                                                                                                           |
| <Rd>    | For encoding T1: is the general-purpose destination register, encoded in the "Rd" field.<br>For encoding T3 and T4: is the general-purpose destination register, encoded in the "Rd" field.<br>If omitted, this register is the SP. |
| <imm8>  | Is an unsigned immediate, a multiple of 4, in the range 0 to 1020, encoded in the "imm8" field as <imm8>/4.                                                                                                                         |
| <imm12> | Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the "i:imm3:imm8" field.                                                                                                                                         |
| <const> | Is an immediate value derived from the 12-bit immediate that is encoded in the "i:imm3:imm8" field. See <a href="#">C1.5 Modified immediate constants</a> for the range of values.                                                  |

### Operation for all encodings

```

1 if ConditionPassed() then
2     EncodingSpecificOperations();
3     (result, carry, overflow) = AddWithCarry(SP, imm32, '0');
4     RSPCheck[d] = result;
5     if setflags then
6         APSR.N = result[31];
7         APSR.Z = IsZeroBit(result);
8         APSR.C = carry;
9         APSR.V = overflow;

```

### C2.4.4 ADD (SP plus register)

Add to SP (register). ADD (SP plus register) adds an optionally-shifted register value to the SP value, and writes the result to the destination register.

|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <c>      | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                                                                                                                                                                                                                                    |
| <q>      | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                                                                                                                                                                                                                                    |
| <Rdm>    | Is the general-purpose destination and second source register, encoded in the "Rdm" field. If omitted, this register is the SP. Arm deprecates using the PC as the destination register, but if the PC is used, the instruction is a simple branch to the address calculated by the operation.                                                                                   |
| <Rd>     | Is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP.                                                                                                                                                                                                                                                                     |
| <Rm>     | For encoding T2: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.                                                                                                                                                                                                                                           |
| <shift>  | For encoding T3: is the second general-purpose source register, encoded in the "Rm" field. Is the type of shift to be applied to the second source register, encoded in the "sr_type" field. It can have the following values:<br><div style="margin-left: 20px;"> LSL when sr_type = 00<br/> LSR when sr_type = 01<br/> ASR when sr_type = 10<br/> ROR when sr_type = 11 </div> |
| <amount> | Is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm3:imm2" field as <amount> modulo 32.                                                                                                                                                                                                             |

### Operation for all encodings

```
1 if ConditionPassed() then
2     EncodingSpecificOperations();
3     shifted = Shift(R[m], shift_t, shift_n, APSR.C);
4     (result, carry, overflow) = AddWithCarry(SP, shifted, '0');
5     if d == 15 then
6         BranchTo(result); // setflags is always FALSE here
7     else
8         RSPCheck[d] = result;
9         if setflags then
10             APSR.N = result[31];
11             APSR.Z = IsZeroBit(result);
12             APSR.C = carry;
13             APSR.V = overflow;
```

### C2.4.5 ADD (immediate)

Add (immediate). Add (immediate) adds an immediate value to a register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

### Assembler symbols for all encodings

|         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <c>     | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                                                                                                                                                                                                                                                                                                                         |
| <q>     | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                                                                                                                                                                                                                                                                                                                         |
| <Rdn>   | Is the general-purpose source and destination register, encoded in the "Rdn" field.                                                                                                                                                                                                                                                                                                                                                                                   |
| <imm8>  | Is an 8-bit unsigned immediate, in the range 0 to 255, encoded in the "imm8" field.                                                                                                                                                                                                                                                                                                                                                                                   |
| <Rd>    | Is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.                                                                                                                                                                                                                                                                                                                                                |
| <Rn>    | For encoding T1: is the general-purpose source register, encoded in the "Rn" field.<br>For encoding T3: is the general-purpose source register, encoded in the "Rn" field. If the SP is used, see <a href="#">C2.4.3 ADD (SP plus immediate)</a> .<br>For encoding T4: is the general-purpose source register, encoded in the "Rn" field. If the SP is used, see <a href="#">C2.4.3 ADD (SP plus immediate)</a> . If the PC is used, see <a href="#">C2.4.8 ADR</a> . |
| <imm3>  | Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "imm3" field.                                                                                                                                                                                                                                                                                                                                                                                      |
| <imm12> | Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the "i:imm3:imm8" field.                                                                                                                                                                                                                                                                                                                                                                           |
| <const> | Is an immediate value derived from the 12-bit immediate that is encoded in the "i:imm3:imm8" field. See <a href="#">C1.5 Modified immediate constants</a> for the range of values.                                                                                                                                                                                                                                                                                    |

### Operation for all encodings

```
1 if ConditionPassed() then
2   EncodingSpecificOperations();
```

```

3      (result, carry, overflow) = AddWithCarry(R[n], imm32, '0');
4      R[d] = result;
5      if setflags then
6          APSR.N = result[31];
7          APSR.Z = IsZeroBit(result);
8          APSR.C = carry;
9          APSR.V = overflow;

```

## Restricted behavior

### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the N, Z, C, V flags.
- The point at which an asynchronous exception is taken does not vary based on any of the following:
  - The values of the data supplied in any the registers bwing used in this instruction.
  - The values of the N, Z, C, V flags.

### C2.4.6 ADD (immediate, to PC)

Add to PC. Add to PC adds an immediate value to the Align(PC, 4) value to form a PC-relative address, and writes the result to the destination register. Arm recommends that, where possible, software avoids using this alias.

This instruction is a pseudo-instruction of the [ADR](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [ADR](#).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of [ADR](#) gives the operational pseudocode for this instruction.

#### T1

*Armv8-M*

|    |    |    |    |    |    |   |   |      |   |   |   |   |   |   |   |

#### T3 variant

ADDW{<c>}{<q>} <Rd>, PC, #<imm12>  
// <Rd>, <imm12> can be represented in T1

**is equivalent to**

ADR{<c>}{<q>} <Rd>, <label>

**and is never the preferred disassembly.**

#### T3 variant

ADD{<c>}{<q>} <Rd>, PC, #<imm12>

**is equivalent to**

ADR{<c>}{<q>} <Rd>, <label>

**and is never the preferred disassembly.**

### Assembler symbols for all encodings

<c> See [C1.2.5 Standard assembler syntax fields](#).  
 <q> See [C1.2.5 Standard assembler syntax fields](#).  
 <Rd> Is the general-purpose destination register, encoded in the "Rd" field.

|         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <label> | <p>For encoding T1: the label of an instruction or literal data item whose address is to be loaded into &lt;Rd&gt;. The assembler calculates the required value of the offset from the <a href="#">Align</a> (PC, 4) value of the ADR instruction to this label. Permitted values of the size of the offset are multiples of 4 in the range 0 to 1020.</p> <p>For encoding T2 and T3: the label of an instruction or literal data item whose address is to be loaded into &lt;Rd&gt;. The assembler calculates the required value of the offset from the <a href="#">Align</a> (PC, 4) value of the ADR instruction to this label. If the offset is zero or positive, encoding T3 is used, with <code>imm32</code> equal to the offset. If the offset is negative, encoding T2 is used, with <code>imm32</code> equal to the size of the offset. That is, the use of encoding T2 indicates that the required offset is minus the value of <code>imm32</code>. Permitted values of the size of the offset are 0-4095.</p> |
| <imm8>  | Is an unsigned immediate, a multiple of 4, in the range 0 to 1020, encoded in the "imm8" field as <imm8>/4.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <imm12> | Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the "i:imm3:imm8" field.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

### Operation for all encodings

The description of [ADR](#) gives the operational pseudocode for this instruction.

### C2.4.7 ADD (register)

Add (register). ADD (register) adds a register value and an optionally-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

#### T1

Armv8-M

#### ADD, rotate right with extend variant

Applies when S == 0 && imm3 == 000 && imm2 == 00 && sr\_type == 11.

```
ADD{<c>}{<q>} {<Rd>}, <Rn>, <Rm>, RRX
```

### ADD, shift or rotate by value variant

Applies when **S == 0 && !(imm3 == 000 && imm2 == 00 && sr\_type == 11).**

```
ADD<c>.W {<Rd>}, {<Rn>}, <Rm>
    // Inside IT block, and <Rd>, <Rn>, <Rm> can be represented in T1 or T2
ADD{<c>}{<q>} {<Rd>}, {<Rn>}, <Rm> {, <shift> #<amount>}
```

### ADDS, rotate right with extend variant

Applies when **S == 1 && imm3 == 000 && Rd != 1111 && imm2 == 00 && sr\_type == 11.**

```
ADDS{<c>}{<q>} {<Rd>}, {<Rn>}, <Rm>, RRX
```

### ADDS, shift or rotate by value variant

Applies when **S == 1 && !(imm3 == 000 && imm2 == 00 && sr\_type == 11) && Rd != 1111.**

```
ADDS.W {<Rd>}, {<Rn>}, <Rm>
    // Outside IT block, and <Rd>, <Rn>, <Rm> can be represented in T1 or T2
ADDS{<c>}{<q>} {<Rd>}, {<Rn>}, <Rm> {, <shift> #<amount>}
```

### Decode for this encoding

```
1 if Rd == '1111' && S == '1' then SEE "CMN (register)";
2 if Rn == '1101' then SEE "ADD (SP plus register)";
3 if !HaveMainExt() then UNDEFINED;
4 d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); setflags = (S == '1');
5 (shift_t, shift_n) = DecodeImmShift(sr_type, imm3:imm2);
6 if d == 13 || (d == 15 && S == '0') || n == 15 || m IN {13,15} then UNPREDICTABLE;
```

### Assembler symbols for all encodings

|         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <c>     | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <q>     | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <Rdn>   | Is the general-purpose source and destination register, encoded in the "DN:Rdn" field. If the PC is used, the instruction is a branch to the address calculated by the operation. This is a simple branch. The assembler language allows <Rdn> to be specified once or twice in the assembler syntax. When used inside an IT block, and <Rdn> and <Rm> are in the range R0 to R7, <Rdn> must be specified once so that encoding T2 is preferred to encoding T1. In all other cases there is no difference in behavior when <Rdn> is specified once or twice. |
| <Rd>    | For encoding T1: is the general-purpose destination register, encoded in the "Rd" field. When used inside an IT block, <Rd> must be specified. When used outside an IT block, <Rd> is optional, and: <ul style="list-style-type: none"> <li>- If omitted, this register is the same as &lt;Rn&gt;.</li> <li>- If present, encoding T1 is preferred to encoding T2.</li> </ul> For encoding T3: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.                                        |
| <Rn>    | For encoding T1: is the first general-purpose source register, encoded in the "Rn" field. For encoding T3: is the first general-purpose source register, encoded in the "Rn" field. If the SP is used, see <a href="#">C2.4.4 ADD (SP plus register)</a> .                                                                                                                                                                                                                                                                                                   |
| <Rm>    | For encoding T1 and T3: is the second general-purpose source register, encoded in the "Rm" field. For encoding T2: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used.                                                                                                                                                                                                                                                                                                                                             |
| <shift> | Is the type of shift to be applied to the second source register, encoded in the "sr_type" field. It can have the following values: <ul style="list-style-type: none"> <li>LSL when sr_type = 00</li> </ul>                                                                                                                                                                                                                                                                                                                                                  |

LSR when `sr_type = 01`  
 ASR when `sr_type = 10`  
 ROR when `sr_type = 11`  
 <amount> Is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm3:imm2" field as <amount> modulo 32.

### Operation for all encodings

```

1  if ConditionPassed() then
2      EncodingSpecificOperations();
3      shifted = Shift(R[m], shift_t, shift_n, APSR.C);
4      (result, carry, overflow) = AddWithCarry(R[n], shifted, '0');
5      if d == 15 then
6          BranchTo(result); // setflags is always FALSE here
7      else
8          R[d] = result;
9          if setflags then
10             APSR.N = result[31];
11             APSR.Z = IsZeroBit(result);
12             APSR.C = carry;
13             APSR.V = overflow;
```

### Restricted behavior

#### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the N, Z, C, V flags.
- The point at which an asynchronous exception is taken does not vary based on any of the following:
  - The values of the data supplied in any the registers bwing used in this instruction.
  - The values of the N, Z, C, V flags.

## C2.4.8 ADR

Form PC-relative address. Address to Register adds an immediate value to the PC value, and writes the result to the destination register.

This instruction is used by the pseudo-instructions [ADD \(immediate, to PC\)](#) and [SUB \(immediate, from PC\)](#).

### T1

| <code>&lt;Rd&gt;</code>    | Is the general-purpose destination register, encoded in the "Rd" field.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>&lt;label&gt;</code> | For encoding T1: the label of an instruction or literal data item whose address is to be loaded into <code>&lt;Rd&gt;</code> . The assembler calculates the required value of the offset from the <a href="#">Align</a> (PC, 4) value of the ADR instruction to this label. Permitted values of the size of the offset are multiples of 4 in the range 0 to 1020.<br>For encoding T2 and T3: the label of an instruction or literal data item whose address is to be loaded into <code>&lt;Rd&gt;</code> . The assembler calculates the required value of the offset from the <a href="#">Align</a> (PC, 4) value of the ADR instruction to this label. If the offset is zero or positive, encoding T3 is used, with <code>imm32</code> equal to the offset. If the offset is negative, encoding T2 is used, with <code>imm32</code> equal to the size of the offset. That is, the use of encoding T2 indicates that the required offset is minus the value of <code>imm32</code> . Permitted values of the size of the offset are 0-4095. |

### Operation for all encodings

```

1 if ConditionPassed() then
2     EncodingSpecificOperations();
3     result = if add then (Align(PC,4) + imm32) else (Align(PC,4) - imm32);
4     R[d] = result;
```

### C2.4.9 AND (immediate)

Bitwise AND (immediate). AND (immediate) performs a bitwise AND of a register value and an immediate value, and writes the result to the destination register.

| <Rd>    | Is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.                                                             |
| <Rn>    | Is the general-purpose source register, encoded in the "Rn" field.                                                                                                                 |
| <const> | Is an immediate value derived from the 12-bit immediate that is encoded in the "i:imm3:imm8" field. See <a href="#">C1.5 Modified immediate constants</a> for the range of values. |

#### Operation for all encodings

```

1 if ConditionPassed() then
2     EncodingSpecificOperations();
3     result = R[n] AND imm32;
4     R[d] = result;
5     if setflags then
6         APSR.N = result[31];
7         APSR.Z = IsZeroBit(result);
8         APSR.C = carry;
9         // APSR.V unchanged
```

#### Restricted behavior

##### Data Independent Timing behavior

If [AIRCR.DIT](#) is 1:

- The execution time of this instruction is independent of:

- The values of the data supplied in any of its registers.
  - The values of the N, Z, C, V flags.
- The point at which an asynchronous exception is taken does not vary based on any of the following:
  - The values of the data supplied in any the registers bwing used in this instruction.
  - The values of the N, Z, C, V flags.

## C2.4.10 AND (register)

Bitwise AND (register). AND (register) performs a bitwise AND of a register value and an optionally-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

#### AND, rotate right with extend variant

Applies when **S == 0 && imm3 == 000 && imm2 == 00 && sr\_type == 11**.

```
AND{<c>}{<q>} {<Rd>,<Rn>,<Rm>,<RRX>
```

#### AND, shift or rotate by value variant

Applies when **S == 0 && !(imm3 == 000 && imm2 == 00 && sr\_type == 11)**.

```
AND<c>.W {<Rd>,<Rn>,<Rm>
// Inside IT block, and <Rd>,<Rn>,<Rm> can be represented in T1
AND{<c>}{<q>} {<Rd>,<Rn>,<Rm> {,<shift> #<amount>}
```

#### ANDS, rotate right with extend variant

Applies when **S == 1 && imm3 == 000 && Rd != 1111 && imm2 == 00 && sr\_type == 11**.

```
ANDS{<c>}{<q>} {<Rd>,<Rn>,<Rm>,<RRX>
```

#### ANDS, shift or rotate by value variant

Applies when **S == 1 && !(imm3 == 000 && imm2 == 00 && sr\_type == 11) && Rd != 1111**.

```
ANDS.W {<Rd>,} <Rn>, <Rm>
// Outside IT block, and <Rd>, <Rn>, <Rm> can be represented in T1
ANDS{<c>}{<q>} {<Rd>,} <Rn>, <Rm> {, <shift> #<amount>}
```

### Decode for this encoding

```
1 if Rd == '1111' && S == '1' then SEE "TST (register)";
2 if !HaveMainExt() then UNDEFINED;
3 d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); setflags = (S == '1');
4 (shift_t, shift_n) = DecodeImmShift(sr_type, imm3:imm2);
5 if d == 13 || (d == 15 && S == '0') || n IN {13,15} || m IN {13,15} then UNPREDICTABLE;
```

### Assembler symbols for all encodings

| <Rdn>    | Is the first general-purpose source register and the destination register, encoded in the "Rdn" field.                                                                                                                                                                                |
| <Rd>     | Is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.                                                                                                                                                                |
| <Rn>     | Is the first general-purpose source register, encoded in the "Rn" field.                                                                                                                                                                                                              |
| <Rm>     | Is the second general-purpose source register, encoded in the "Rm" field.                                                                                                                                                                                                             |
| <shift>  | Is the type of shift to be applied to the second source register, encoded in the "sr_type" field. It can have the following values:<br><div style="margin-left: 20px;"> LSL when sr_type = 00<br/> LSR when sr_type = 01<br/> ASR when sr_type = 10<br/> ROR when sr_type = 11 </div> |
| <amount> | Is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm3:imm2" field as <amount> modulo 32.                                                                                                                  |

### Operation for all encodings

```
1 if ConditionPassed() then
2   EncodingSpecificOperations();
3   (shifted, carry) = Shift_C(R[m], shift_t, shift_n, APSR.C);
4   result = R[n] AND shifted;
5   R[d] = result;
6   if setflags then
7     APSR.N = result[31];
8     APSR.Z = IsZeroBit(result);
9     APSR.C = carry;
10    // APSR.V unchanged
```

### Restricted behavior

#### Data Independent Timing behavior

If [AIRCR.DIT](#) is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the N, Z, C, V flags.
- The point at which an asynchronous exception is taken does not vary based on any of the following:
  - The values of the data supplied in any the registers bwing used in this instruction.
  - The values of the N, Z, C, V flags.

### C2.4.11 ASR (immediate)

Arithmetic Shift Right (immediate). Arithmetic Shift Right (immediate) shifts a register value right by an immediate number of bits, shifting in copies of its sign bit, and writes the result to the destination register.

This instruction is an alias of the [MOV \(register\)](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [MOV \(register\)](#).
- The description of [MOV \(register\)](#) gives the operational pseudocode for this instruction.

#### T2

7   R[dal] = result[31:0];
```

#### Restricted behavior

##### Data Independent Timing behavior

If [AIRCR.DIT](#) is 1:

- The execution time of this instruction is insensitive to the value or values of the data subject to this instruction.
- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

### C2.4.14 ASRL (register)

Arithmetic Shift Right Long. Arithmetic shift right by 0 to 64 bits of a 64-bit value stored in two general-purpose registers. The shift amount is read in as the bottom byte of Rm. If the shift amount is negative, the shift direction is reversed.

#### T1

#### T1: ASRL variant

ASRL<c><q> RdaLo, RdaHi, Rm

#### Decode for this encoding

```

1 if RdaHi == '111' then SEE "SQRSHR (register)";
2 if !HaveMainExt() then UNDEFINED;
3 if !HasArchVersion(Armv8p1) then CONSTRAINED_UNPREDICTABLE;
4 if !HaveMve() then UNDEFINED;
5 dah = UInt(RdaHi:'1');
6 dal = UInt(RdaLo:'0');
7 m = UInt(Rm);
8 if RdaHi == '110' || Rm == '11x1' || Rm == RdaHi:'1' then CONSTRAINED_UNPREDICTABLE;
9 if Rm == RdaLo:'0' then CONSTRAINED_UNPREDICTABLE;
```

#### Assembler symbols for all encodings

<c, q> See C1.2.5 *Standard assembler syntax fields*.  
 <RdaLo> General-purpose register for the low-half of the 64-bit source and destination, containing the value to be shifted. This must be an even numbered register.  
 <RdaHi> General-purpose register for the high-half of the 64-bit source and destination, containing the value to be shifted. This must be an odd numbered register.  
 <Rm> General-purpose source register holding a shift amount in its bottom 8 bits.

#### Operation for all encodings

```

1 if ConditionPassed() then
2     EncodingSpecificOperations();
3
4     amount = SInt(R[m][7:0]);
5     opl = SInt(R[dah]:R[dal]);
6     result = (opl >> amount)[63:0];
7     R[dah] = result[63:32];
8     R[dal] = result[31:0];
```

#### Restricted behavior

##### Data Independent Timing behavior

If AIRCR.DIT is 1:

- The execution time of this instruction is insensitive to the value or values of the data subject to this instruction.
- The point at which an asynchronous exception is taken does not vary based on the value or values being used by this instruction.

### C2.4.15 ASRS (immediate)

Arithmetic Shift Right, Setting flags (immediate). Arithmetic Shift Right, Setting flags (immediate) shifts a register value right by an immediate number of bits, shifting in copies of its sign bit, writes the result to the destination register, and updates the condition flags based on the result.

This instruction is an alias of the [MOV \(register\)](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [MOV \(register\)](#).
- The description of [MOV \(register\)](#) gives the operational pseudocode for this instruction.

### Operation for all encodings

The description of [MOV \(register\)](#) gives the operational pseudocode for this instruction.

### Restricted behavior

#### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the N, Z, C, V flags.
- The point at which an asynchronous exception is taken does not vary based on any of the following:
  - The values of the data supplied in any the registers bwing used in this instruction.
  - The values of the N, Z, C, V flags.

## C2.4.16 ASRS (register)

Arithmetic Shift Right, Setting flags (register). Arithmetic Shift Right, Setting flags (register) shifts a register value right by a variable number of bits, shifting in copies of its sign bit, writes the result to the destination register, and updates the condition flags based on the result. The variable number of bits is read from the bottom byte of a register.

This instruction is an alias of the [MOV, MOVS \(register-shifted register\)](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [MOV, MOVS \(register-shifted register\)](#).
- The description of [MOV, MOVS \(register-shifted register\)](#) gives the operational pseudocode for this instruction.

| 1  | 1  | 1  | 1  | 0  | 0  | 1 | 1 | 1 | 0 | 1 | 0 | (1) | (1) | (1) | (1) | 1  | 0  | (0) | 0  | (0) | 0  | 0 | 0 | 0 | 0 | 1 | 0 | 1 | 1 | 0 | 1 |

### T1 variant

AUT R12, LR, SP

### Decode for this encoding

```
1 if !HaveMainExt() then UNDEFINED;
2 if InITBlock() then CONSTRAINED_UNPREDICTABLE;
```

### CONSTRAINED UNPREDICTABLE behavior

If InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes unconditionally.
- The instruction executes conditionally.

### Assembler symbols for all encodings

LR LR register, this instruction must always use this register.  
SP SP register, this instruction must always use this register.  
R12 R12 register, this instruction must always use this register.

### Operation for all encodings

```
1 EncodingSpecificOperations();
2
3 if PACEEnabled() then
4     if !ValidatePAC(LR, SP, R[12]) then
5         UFSR.INVSTATE = '1';
6         excInfo = CreateException(UsageFault);
7         HandleException(excInfo);
```

### Restricted behavior

#### Data Independent Timing behavior and the PACBTI extension

The timing of this instruction is insensitive to the value of the data being loaded or stored regardless of the value of AIRCR.DIT when accessing any of the following:

- PAC\_KEY\_P\_n.

- [PAC\\_KEY\\_U\\_n](#).
- The pointer value.
- The modifier value.
- The PAC value.

The point at which an asynchronous exception is taken does not vary based on any of the following:

- [PAC\\_KEY\\_P\\_n](#).
- [PAC\\_KEY\\_U\\_n](#).
- The pointer value.
- The modifier value.
- The PAC value.

## C2.4.18 AUTG

Authenticate general value, using key. This instruction computes a pointer authentication code using two input registers and a key. The computed PAC is compared against the PAC in the specified register. If the values do not match an INVSTATE UsageFault is generated.

## C2.4.19 B

Branch. Branch causes a branch to a target address.

### T1

*Armv8-M*

B<c>{<q>} <label>
// Not permitted in IT block
```

#### Decode for this encoding

```

1 if cond[3:1] == '111' then SEE "Related encodings";
2 if !HaveMainExt() then UNDEFINED;
3 imm32 = SignExtend(S:J2:J1:imm6:imm11:'0', 32);
4 if InitBlock() then UNPREDICTABLE;

```

## T4

Armv8-M

|    |    |    |    |    |    |       |   |   |   |   |   |   |   |   |   |    |    |    |    |    |       |   |   |   |   |   |   |   |   |   |   |
|----|----|----|----|----|----|-------|---|---|---|---|---|---|---|---|---|----|----|----|----|----|-------|---|---|---|---|---|---|---|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9     | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | 15 | 14 | 13 | 12 | 11 | 10    | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 1  | 1  | 1  | 1  | 0  | S  | imm10 |   |   |   |   |   |   |   |   |   | 1  | 0  | J1 | 1  | J2 | imm11 |   |   |   |   |   |   |   |   |   |   |

### T4 variant

B{<c>}.W <label>  
 // <label> can be represented in T2  
 B{<c>}{<q>} <label>

### Decode for this encoding

```

1 I1 = NOT(J1 EOR S); I2 = NOT(J2 EOR S); imm32 = SignExtend(S:I1:I2:imm10:imm11:'0', 32);
2 cond = CurrentCond();
3 if InitBlock() && !LastInitBlock() then UNPREDICTABLE;

```

### Assembler symbols for all encodings

<c> For encoding T1: see [C1.2.5 Standard assembler syntax fields](#). Must not be AL or omitted.  
 For encoding T2 and T4: see [C1.2.5 Standard assembler syntax fields](#).  
 For encoding T3: see [C1.2.5 Standard assembler syntax fields](#). <c> must not be AL or omitted.

<q> See [C1.2.5 Standard assembler syntax fields](#).

<label> For encoding T1: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the B instruction to this label, then selects an encoding that sets imm32 to that offset. Permitted offsets are even numbers in the range -256 to 254.  
 For encoding T2: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the B instruction to this label, then selects an encoding that sets imm32 to that offset. Permitted offsets are even numbers in the range -2048 to 2046.  
 For encoding T3: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the B instruction to this label, then selects an encoding that sets imm32 to that offset. Permitted offsets are even numbers in the range -1048576 to 1048574.  
 For encoding T4: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the B instruction to this label, then selects an encoding that sets imm32 to that offset. Permitted offsets are even numbers in the range -16777216 to 16777214.

### Operation for all encodings

```

1 if ConditionPassed(cond) then
2   EncodingSpecificOperations();
3   BranchTo(PC + imm32);

```

## C2.4.20 BF, BFX, BFL, BFLX, BFCSEL

Branch Future, Branch Future and Exchange, Branch Future with Link, Branch Future with Link and Exchange, Branch Future Conditional Select. These instructions notify the PE about an upcoming branch to `<label>`, so that the branch will be taken instead of fetching and executing the instruction at `<b_label>`. This allows the PE to reduce or eliminate any associated performance penalty that might have been caused by a branch that the PE was not notified about. It is IMPLEMENTATION DEFINED whether this instruction is treated as a NOP. To ensure correct program flow behavior in these cases, fallback code should be present at the point specified by `<b_label>`.

For the Branch Future with Link variant, the link register is updated when the branch is performed. The value written is offset from the branch point by 4 bytes, which corresponds to the length of the BL (immediate) instruction that would usually follow the branch point as part of the fallback code.

For the Branch Future with Link and Exchange variant, the link register is updated when the branch is performed. The value written is offset from the branch point by 2 bytes, which corresponds to the length of the BLX (register) instruction that would usually follow the branch point as part of the fallback code. If the PACBTI Extension is implemented this instruction will set LO\_BRANCH\_INFO.BTI to one (this bit will not be set if LR register is used as an argument in BFX). When the branch is taken and BTI is enabled then the EPSR.B is set to one.

The Branch Future Conditional Select variant creates a future branch to `<label>` if the condition code passes. If the explicit condition code fails, this variant does not behave as a NOP. Instead it creates a future branch to the instruction specified by `<ba_label>`, if there is no other active BF entry in the loop and branch cache.

| <Rd>    | Is the general-purpose destination register, encoded in the "Rd" field.                                         |
| <lsb>   | Is the least significant bit that is to be cleared, in the range 0 to 31, encoded in the "imm3:imm2" field.     |
| <width> | Is the number of bits to be cleared, in the range 1 to 32-<lsb>, encoded in the "msb" field as <lsb>+<width>-1. |

### Operation for all encodings

```
1 if ConditionPassed() then
2   EncodingSpecificOperations();
3   if msbit >= lsbit then
4     R[d][msbit:lsbit] = Replicate('0', msbit-lsbit+1);
5     // Other bits of R[d] are unchanged
6   else
7     R[d] = bits(32) UNKNOWN;
```

### Restricted behavior

#### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.

- The values of the N, Z, C, V flags.
- The point at which an asynchronous exception is taken does not vary based on any of the following:
  - The values of the data supplied in any the registers bwing used in this instruction.
  - The values of the N, Z, C, V flags.

## C2.4.22 BFI

Bit Field Insert. Bit Field Insert copies any number of low order bits from a register into the same number of adjacent bits at any position in the destination register.

### T1

Armv8-M Main Extension only

| <Rdn>    | Is the first general-purpose source register and the destination register, encoded in the "Rdn" field.                                                                                                                                                                                |
| <Rd>     | Is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.                                                                                                                                                                |
| <Rn>     | Is the first general-purpose source register, encoded in the "Rn" field.                                                                                                                                                                                                              |
| <Rm>     | Is the second general-purpose source register, encoded in the "Rm" field.                                                                                                                                                                                                             |
| <shift>  | Is the type of shift to be applied to the second source register, encoded in the "sr_type" field. It can have the following values:<br><div style="margin-left: 20px;"> LSL when sr_type = 00<br/> LSR when sr_type = 01<br/> ASR when sr_type = 10<br/> ROR when sr_type = 11 </div> |
| <amount> | Is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm3:imm2" field as <amount> modulo 32.                                                                                                                  |

### Operation for all encodings

```
1 if ConditionPassed() then
2   EncodingSpecificOperations();
3   (shifted, carry) = Shift_C(R[m], shift_t, shift_n, APSR.C);
4   result = R[n] AND NOT(shifted);
5   R[d] = result;
6   if setflags then
7     APSR.N = result[31];
8     APSR.Z = IsZeroBit(result);
9     APSR.C = carry;
10    // APSR.V unchanged
```

### Restricted behavior

#### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the N, Z, C, V flags.
- The point at which an asynchronous exception is taken does not vary based on any of the following:
  - The values of the data supplied in any the registers bwing used in this instruction.
  - The values of the N, Z, C, V flags.

## C2.4.25 BKPT

Breakpoint. Breakpoint causes a DebugMonitor exception or a debug halt to occur depending on the configuration of the debug support.

**BKPT** is an unconditional instruction and executes as such both inside and outside an **IT** instruction block.

### T1

Armv8-M

|    |    |    |    |    |    |   |   |      |   |   |   |   |   |   |   |

### T1 variant

BL{<c>}{<q>} <label>

### Decode for this encoding

```
1 I1 = NOT(J1 EOR S); I2 = NOT(J2 EOR S); imm32 = SignExtend(S:I1:I2:imm10:imm11:'0', 32);
2 if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

### Assembler symbols for all encodings

<c> See [C1.2.5 Standard assembler syntax fields](#).  
 <q> See [C1.2.5 Standard assembler syntax fields](#).  
 <label> The label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the BL instruction to this label, then selects an encoding with imm32 set to that offset. Permitted offsets are even numbers in the range -16777216 to 16777214.

### Operation for all encodings

```
1 if ConditionPassed() then
2   EncodingSpecificOperations();
3   LR = (ThisInstrAddr()[31:1] : '1') + ThisInstrLength();
4   BranchTo(PC + imm32);
```

## C2.4.27 BLX, BLXNS

Branch with Link and Exchange (Non-secure). Branch with Link and Exchange calls a subroutine at an address, with the address and instruction set specified by a register. Bit[0] complies with the Arm architecture interworking rules for switching between the A32 and T32 instruction sets. However, Armv8-M only supports the T32 instruction set, so bit[0] must be 1. If bit[0] is 0 the PE takes an INVSTATE UsageFault exception on the instruction at the target address.

Branch with Link and Exchange Non-secure calls a subroutine at an address specified by a register, and if bit[0] of the target address is 0 then the instruction causes a transition from Secure to Non-secure state. This variant of the instruction must only be used when the additional steps required to make such a transition safe have been taken.

BLXNS is UNDEFINED if executed in Non-secure state, or if the Security Extension is not implemented.

If the PACBTI Extension is implemented and BTI is enabled for the destination Security state and privilege mode then this instruction is a BTI setting instruction. When this instruction is executed it will set EPSR.B to one.

### T1

Armv8-M

|    |    |    |    |    |    |   |   |   |    |    |     |     |   |   |   |
|----|----|----|----|----|----|---|---|---|----|----|-----|-----|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6  | 5  | 4   | 3   | 2 | 1 | 0 |
| 0  | 1  | 0  | 0  | 0  | 1  | 1 | 1 | 1 | Rm | NS | (0) | (0) |   |   |   |

#### BLX variant

Applies when NS == 0.

BLX{<c>} {<q>} <Rm>

#### BLXNS variant

Applies when NS == 1.

BLXNS{<c>} {<q>} <Rm>

### Decode for this encoding

```

1 m = UInt(Rm); allowNonSecure = NS == '1';
2 if !IsSecure() && allowNonSecure then UNDEFINED;
3 if m IN {13,15} then UNPREDICTABLE;
4 if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

### Assembler symbols for all encodings

<c> See [C1.2.5 Standard assembler syntax fields](#).  
 <q> See [C1.2.5 Standard assembler syntax fields](#).  
 <Rm> Is the general-purpose register holding the address to be branched to, encoded in the "Rm" field.

### Operation for all encodings

```

1 if ConditionPassed() then
2   EncodingSpecificOperations();
3
4   target = R[m];
5   nextInstrAddr = (ThisInstrAddr()[31:1] : '1') + ThisInstrLength();
6
7   if allowNonSecure && (target[0] == '0') then
8     targetIsSecure = FALSE;
9     if !IsAligned(SP, 8) then UNPREDICTABLE;
10    address = SP - 8;
```

```
11     RETPSR_Type savedPSR = Zeros();
12     // EPSR.B is not preserved on the stack
13     savedPSR.Exception = IPSR.Exception;
14     savedPSR.SFPA = CONTROL_S.SFPA;
15     // Only the stack locations, not the store order, are architected
16     spName = LookUpSP();
17     mode = CurrentMode();
18     exc = Stack(address, 0, spName, mode, nextInstrAddr);
19     if exc.fault == NoFault then exc = Stack(address, 4, spName, mode, savedPSR);
20     HandleException(exc);
21     // Stack pointer update will raise a fault if limit violated
22     SP = address;
23     LR = 0xFFFFFFFF[31:0];
24     // If in handler mode, IPSR must be nonzero. To prevent revealing which
25     // Secure handler is calling Non-secure code, IPSR is set to an invalid but
26     // nonzero value (ie the reset exception number).
27     if mode == PEmode_Handler then
28         IPSR = 0x1[31:0];
29     else
30         targetIsSecure = IsSecure();
31         LR = nextInstrAddr;
32
33     setBti = BTIEnabled(targetIsSecure);
34     BranchCall(target, allowNonSecure, setBti);
```

### CONSTRAINED UNPREDICTABLE behavior

If !IsAligned(SP, 8), then one of the following behaviors must occur:

- The instruction uses the current value of the stack pointer.
- The instruction behaves as though bits[2:0] of the stack pointer are 0b000.

## C2.4.28 BTI

Branch target identification. When the PACBTI Extension is enabled this instruction is treated as a valid landing pad for jumps and calls and resets EPSR.B to zero.

This instruction is not permitted in an IT block.

This is a NOP-compatible hint.

### T1

Armv8.1-M PACBTI

|    |    |    |    |    |    |   |   |   |   |   |   |     |     |     |     |    |    |     |    |     |    |   |   |   |   |   |   |   |   |   |   |  |

### T1 variant

BTI

### Decode for this encoding

```
1 if !HaveMainExt() then UNDEFINED;
2 if InITBlock() then CONSTRAINED_UNPREDICTABLE;
```

### CONSTRAINED UNPREDICTABLE behavior

If InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes unconditionally.
- The instruction executes conditionally.

### Assembler symbols for all encodings

<none>

### Operation for all encodings

```
1 EncodingSpecificOperations();
2
3 // This instruction is an explicit BTI landing pad instruction.
4 // The EPSR.B bit is reset to zero.
5 EPSR.B = '0';
```

## C2.4.29 BX, BXNS

Branch and Exchange (Non-secure). Branch and Exchange causes a branch to an address, with the address and instruction set specified by a register. Bit[0] complies with the Arm architecture interworking rules for switching between the A32 and T32 instruction sets. However, Armv8-M only supports the T32 instruction set, so bit[0] must be 1. If bit[0] is 0 the PE takes an INVSTATE UsageFault exception on the instruction at the target address.

Branch and Exchange Non-secure causes a branch to an address specified by a register. If bit[0] of the target address is 0, and the target address is not FNC\_RETURN or EXC\_RETURN, then the instruction causes a transition from Secure to Non-secure state. This variant of the instruction must only be used when the additional steps required to make such a transition safe have been taken.

BX can also be used for an exception return.

BXNS is UNDEFINED if executed in Non-secure state, or if the Security Extension is not implemented.

If the PACBTI Extension is implemented, BTI is enabled for the destination security and privilege state, the operation is not a FNC\_RETURN or an EXC\_RETURN, and <Rm> is not LR, then this instruction is a BTI setting instruction, and when this instruction is executed it will set EPSR.B to one.

### T1

Armv8-M

| 0  | 1  | 0  | 0  | 0  | 1  | 1 | 1 | 0 | Rm |   |   | NS | (0) | (0) |   |

#### BX variant

Applies when NS == 0.

BX{<c>}{<q>} <Rm>

#### BXNS variant

Applies when NS == 1.

BXNS{<c>}{<q>} <Rm>

### Decode for this encoding

```
1 m = UInt(Rm); allowNonSecure = NS == '1';
2 if !IsSecure() && allowNonSecure then UNDEFINED;
3 if m IN {13,15} then UNPREDICTABLE;
4 if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

### Assembler symbols for all encodings

<c> See C1.2.5 Standard assembler syntax fields.  
 <q> See C1.2.5 Standard assembler syntax fields.  
 <Rm> Is the general-purpose register holding the address to be branched to, encoded in the "Rm" field.

### Operation for all encodings

```
1 if ConditionPassed() then
2   EncodingSpecificOperations();
3   // If BTI is enabled, this branch sets the EPSR.B flag to ensure that the target
4   // instruction is BTI clearing. If register LR is used, then a BTI clearing
5   // instruction is not required at the branch target.
6   target = R[m];
7   targetIsSecure = IsSecure() && !(allowNonSecure && target[0] == '0');
```

```
8      setBti      = BTIEnabled(targetIsSecure) && m != 14;
9      exc         = BranchReturn(target, allowNonSecure, setBti);
10     HandleException(exc);
```

### C2.4.30 BXAUT

Branch Exchange after Authenticating the address, using key. This instruction computes a pointer authentication code using the address, a modifier and, a key. The computed PAC is compared against the PAC in the specified register. If the values do not match an INVSTATE UsageFault is generated. Once the address has been authenticated the PE branches to that address.

Bit[0] complies with the Arm architecture interworking rules for switching between the A32 and T32 instruction sets. However, Armv8-M only supports the T32 instruction set, so bit[0] must be 1. If bit[0] is 0 the PE takes an INVSTATE UsageFault exception on the instruction at the target address.

BXAUT can be used for an exception return.

The instruction must be either outside any IT block, or the last instruction in an IT block.

| <c>  | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                                                  |
| <Rn> | Is the general-purpose source register containing the address to be encrypted, encoded in the "Rn" field.                                                                                      |
| <Rm> | Is the general-purpose source register containing the modifier to be used in the encryption operation, encoded in the "Rm" field.                                                              |
| <Ra> | Is the general-purpose register containing the encrypted value, encoded in the "Ra" field. The value in this register will be compared against the value produced by the encryption operation. |

#### Operation for all encodings

```

1 if ConditionPassed() then
2   EncodingSpecificOperations();
3   if PACEnabled() then
4     if !ValidatePAC(R[n], R[m], R[a]) then
```

```
5      UFSR.INVSTATE = '1';  
6      excInfo = CreateException(UsageFault);  
7      HandleException(excInfo);  
8      exc = BranchReturn(R[n], FALSE);  
9      HandleException(exc);
```

## Restricted behavior

### Data Independent Timing behavior and the PACBTI extension

The timing of this instruction is insensitive to the value of the data being loaded or stored regardless of the value of [AIRCR.DIT](#) when accessing any of the following:

- [PAC\\_KEY\\_P\\_n](#).
- [PAC\\_KEY\\_U\\_n](#).
- The pointer value.
- The modifier value.
- The PAC value.

The point at which an asynchronous exception is taken does not vary based on any of the following:

- [PAC\\_KEY\\_P\\_n](#).
- [PAC\\_KEY\\_U\\_n](#).
- The pointer value.
- The modifier value.
- The PAC value.

### C2.4.31 CBNZ, CBZ

Compare and Branch on Nonzero or Zero. Compare and Branch on Nonzero and Compare and Branch on Zero compare the value in a register with zero, and conditionally branch forward a constant value. They do not affect the condition flags.

#### T1

Armv8-M

|    |    |    |    |    |    |   |   |      |   |   |   |   |    |   |   |
|----|----|----|----|----|----|---|---|------|---|---|---|---|----|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7    | 6 | 5 | 4 | 3 | 2  | 1 | 0 |

| <q>     | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                        |
| <Rn>    | Is the general-purpose register to be tested, encoded in the "Rn" field.                                                                             |
| <label> | Is the program label to be conditionally branched to. Its offset from the PC, a multiple of 2 in the range 0 to 126, is encoded as "i:imm5" times 4. |

#### Operation for all encodings

```
1 EncodingSpecificOperations();
2 if nonzero != IsZero(R[n]) then
3     BranchTo(PC + imm32);
```

## C2.4.32 CDP, CDP2

Coprocessor Data Processing. Coprocessor Data Processing tells a coprocessor to perform an operation.

If no coprocessor can execute the instruction, a UsageFault exception is generated.

Arm reserves coprocessors CP8 to CP15, and this manual defines the valid instructions when coproc is in this range.

|          |                                                                                                             |
|----------|-------------------------------------------------------------------------------------------------------------|
| <c>      | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                               |
| <q>      | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                               |
| <coproc> | Is the name of the coprocessor, encoded in the "coproc" field. The generic coprocessor names are p0 to p15. |
| <opc1>   | Is a coprocessor-specific opcode, in the range 0 to 15, encoded in the "opc1" field.                        |
| <CRd>    | Is the destination coprocessor register, encoded in the "CRd" field.                                        |
| <CRn>    | Is the coprocessor register that contains the first operand, encoded in the "CRn" field.                    |
| <CRm>    | Is the coprocessor register that contains the second operand, encoded in the "CRm" field.                   |
| <opc2>   | Is a coprocessor-specific opcode in the range 0 to 7, defaulting to 0 and encoded in the "opc2" field.      |

### Operation for all encodings

```
1 if ConditionPassed() then  
2     EncodingSpecificOperations();  
3     ExecuteCPCheck(cp);  
4     if !Coprocc_Accepted(cp, ThisInstr()) then  
5         GenerateCoproccException();  
6     else  
7         Coproc_InternalOperation(cp, ThisInstr());
```

### C2.4.33 CINC

Conditional Increment. Returns, in the destination register, the value of the source register incremented by 1, if the condition is TRUE. Otherwise returns the value of the source register.

This is an alias of [CSINC](#) with the following condition satisfied:  $Rn == Rm \ \&\& \ Rn \neq 15$ .

This alias is the preferred disassembly.

#### T1

|    |    |    |    |    |    |   |   |   |   |   |   |    |   |   |   |    |     |    |    |    |    |   |   |       |   |   |   |    |   |   |   |
|----|----|----|----|----|----|---|---|---|---|---|---|----|---|---|---|----|-----|----|----|----|----|---|---|-------|---|---|---|----|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3  | 2 | 1 | 0 | 15 | 14  | 13 | 12 | 11 | 10 | 9 | 8 | 7     | 6 | 5 | 4 | 3  | 2 | 1 | 0 |

#### CINC variant

CINC<q> Rd, Rn, <fcond>

is equivalent to

CSINC<q> Rd, Rn, Rn, invert (<cond>)

and is the preferred disassembly when  $Rn == Rm \ \&\& \ Rn \neq 15$

#### Restricted behavior

##### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the N, Z, C, V flags.
- The point at which an asynchronous exception is taken does not vary based on any of the following:
  - The values of the data supplied in any the registers bwing used in this instruction.
  - The values of the N, Z, C, V flags.

## C2.4.34 CINV

Conditional Invert. Returns, in the destination register, the bitwise inversion of the value of the source register, if the condition is TRUE. Otherwise returns the value of the source register.

This is an alias of [CSINV](#) with the following condition satisfied:  $Rn == Rm \ \&\& \ Rn \neq 15$ .

This alias is the preferred disassembly.

### T1

|    |    |    |    |    |    |   |   |   |   |   |   |    |   |   |   |    |     |    |    |    |    |   |   |       |   |   |   |    |   |   |   |
|----|----|----|----|----|----|---|---|---|---|---|---|----|---|---|---|----|-----|----|----|----|----|---|---|-------|---|---|---|----|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3  | 2 | 1 | 0 | 15 | 14  | 13 | 12 | 11 | 10 | 9 | 8 | 7     | 6 | 5 | 4 | 3  | 2 | 1 | 0 |
| 1  | 1  | 1  | 0  | 1  | 0  | 1 | 0 | 0 | 1 | 0 | 1 | Rn |   |   |   | 1  | (0) | 1  | 0  | Rd |    |   |   | fcond |   |   |   | Rn |   |   |   |

### T1: CINV variant

CINV<q> Rd, Rn, <fcond>

is equivalent to

CSINV<q> Rd, Rn, Rn, invert (<cond>)

and is the preferred disassembly when  $Rn == Rm \ \&\& \ Rn \neq 15$

### Restricted behavior

#### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the N, Z, C, V flags.
- The point at which an asynchronous exception is taken does not vary based on any of the following:
  - The values of the data supplied in any the registers bwing used in this instruction.
  - The values of the N, Z, C, V flags.

## C2.4.35 CLREX

Clear Exclusive. Clear Exclusive clears the local record of the executing PE that an address has had a request for an exclusive access.

### T1

Armv8-M

|    |    |    |    |    |    |   |   |   |   |   |   |     |     |     |     |    |    |     |    |     |     |     |     |   |   |   |   |     |     |     |     |

### T1: CLRM variant

CLRM<c><q> <registers>

### Decode for this encoding

```

1 if !HaveMainExt() then UNDEFINED;
2 if !HasArchVersion(Armv8p1) then CONSTRAINED_UNPREDICTABLE;
3
4 registers = A:M:'0':register_list;
5 if BitCount(registers) < 1 then CONSTRAINED_UNPREDICTABLE;
```

### Assembler symbols for all encodings

<c, q> See [C1.2.5 Standard assembler syntax fields](#).  
 <registers> A list of the registers to clear, separated by commas and surrounded by { and }. The valid registers are APSR, LR/R14, and R12-R0, and are encoded as a bitmask in the A, M and register\_list fields.

### Operation for all encodings

```

1 if ConditionPassed() then
2   EncodingSpecificOperations();
3
4   for i = 0 to 14
5     if registers[i] == '1' then
6       R[i] = Zeros(32);
7
8   if registers[15] == '1' then
9     APSR = Zeros(32);
```

## C2.4.37 CLZ

Count Leading Zeros. Count Leading Zeros returns the number of binary zero bits before the first binary one bit in a value.

### T1

Armv8-M Main Extension only

|    |    |    |    |    |    |   |   |   |   |   |   |    |   |   |   |    |    |    |    |    |    |   |   |   |   |   |   |     |   |   |   |
|----|----|----|----|----|----|---|---|---|---|---|---|----|---|---|---|----|----|----|----|----|----|---|---|---|---|---|---|-----|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3  | 2 | 1 | 0 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3   | 2 | 1 | 0 |
| 1  | 1  | 1  | 1  | 1  | 0  | 1 | 0 | 1 | 0 | 1 | 1 | Rm |   |   |   | 1  | 1  | 1  | 1  | Rd |    |   |   | 1 | 0 | 0 | 0 | Rm2 |   |   |   |

### T1 variant

CLZ{<c>}{<q>} <Rd>, <Rm>

### Decode for this encoding

```

1 if !HaveMainExt() then UNDEFINED;
2 if Rm != Rm2 then UNPREDICTABLE;
3 d = UInt(Rd); m = UInt(Rm); m2 = UInt(Rm2);
4 if d IN {13,15} || m IN {13,15} || m2 IN {13,15} then UNPREDICTABLE;
```

### CONSTRAINED UNPREDICTABLE behavior

If  $Rm \neq Rm2$ , then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as described, with no change to its behavior and no additional side effects.
- The value in the destination register is UNKNOWN.

### Assembler symbols for all encodings

|      |                                                                                                      |
|------|------------------------------------------------------------------------------------------------------|
| <c>  | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                        |
| <q>  | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                        |
| <Rd> | Is the general-purpose destination register, encoded in the "Rd" field.                              |
| <Rm> | Is the general-purpose source register, encoded in the "Rm" field. Its number must be encoded twice. |

### Operation for all encodings

```

1 if ConditionPassed() then
2     EncodingSpecificOperations();
3     result = CountLeadingZeroBits(R[m]);
4     R[d] = result[31:0];
```

### Restricted behavior

#### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the N, Z, C, V flags.

- The point at which an asynchronous exception is taken does not vary based on any of the following:
  - The values of the data supplied in any the registers bwing used in this instruction.
  - The values of the N, Z, C, V flags.

### C2.4.38 CMN (immediate)

Compare Negative (immediate). Compare Negative (immediate) adds a register value and an immediate value. It updates the condition flags based on the result, and discards the result.

```

#### Assembler symbols for all encodings

<c> See [C1.2.5 Standard assembler syntax fields](#).  
 <q> See [C1.2.5 Standard assembler syntax fields](#).  
 <Rn> Is the general-purpose source register, encoded in the "Rn" field.  
 <const> Is an immediate value derived from the 12-bit immediate that is encoded in the "i:imm3:imm8" field. See [C1.5 Modified immediate constants](#) for the range of values.

#### Operation for all encodings

```
1 if ConditionPassed() then
2     EncodingSpecificOperations();
3     (result, carry, overflow) = AddWithCarry(R[n], imm32, '0');
4     APSR.N = result[31];
5     APSR.Z = IsZeroBit(result);
6     APSR.C = carry;
7     APSR.V = overflow;
```

#### Restricted behavior

##### Data Independent Timing behavior

If [AIRCR.DIT](#) is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the N, Z, C, V flags.
- The point at which an asynchronous exception is taken does not vary based on any of the following:
  - The values of the data supplied in any the registers bwing used in this instruction.
  - The values of the N, Z, C, V flags.

### C2.4.39 CMN (register)

Compare Negative (register). Compare Negative (register) adds a register value and an optionally-shifted register value. It updates the condition flags based on the result, and discards the result.

| <q>     | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                             |
| <Rn>    | Is the first general-purpose source register, encoded in the "Rn" field.                                                                                                  |
| <Rm>    | Is the second general-purpose source register, encoded in the "Rm" field.                                                                                                 |
| <shift> | Is the type of shift to be applied to the second source register, encoded in the "sr_type" field. It can have the following values:<br>LSL when <code>sr_type = 00</code> |

LSR   when sr\_type = 01  
ASR   when sr\_type = 10  
ROR   when sr\_type = 11  
<amount>   Is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm3:imm2" field as <amount> modulo 32.

### Operation for all encodings

```
1  if ConditionPassed() then
2      EncodingSpecificOperations();
3      shifted = Shift(R[m], shift_t, shift_n, APSR.C);
4      (result, carry, overflow) = AddWithCarry(R[n], shifted, '0');
5      APSR.N = result[31];
6      APSR.Z = IsZeroBit(result);
7      APSR.C = carry;
8      APSR.V = overflow;
```

### Restricted behavior

#### Data Independent Timing behavior

If [AIRCR.DIT](#) is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the N, Z, C, V flags.
- The point at which an asynchronous exception is taken does not vary based on any of the following:
  - The values of the data supplied in any the registers bwing used in this instruction.
  - The values of the N, Z, C, V flags.

## C2.4.40 CMP (immediate)

Compare (immediate). Compare (immediate) subtracts an immediate value from a register value. It updates the condition flags based on the result, and discards the result.

| <code>&lt;shift&gt;</code>  | Is the type of shift to be applied to the second source register, encoded in the "sr_type" field. It can have the following values:<br><div style="margin-left: 20px;"> <code>LSL</code> when <code>sr_type = 00</code><br/> <code>LSR</code> when <code>sr_type = 01</code><br/> <code>ASR</code> when <code>sr_type = 10</code><br/> <code>ROR</code> when <code>sr_type = 11</code> </div> |
| <code>&lt;amount&gt;</code> | Is the shift amount, in the range 1 to 31 (when <code>&lt;shift&gt; = LSL</code> or <code>ROR</code> ) or 1 to 32 (when <code>&lt;shift&gt; = LSR</code> or <code>ASR</code> ) encoded in the "imm3:imm2" field as <code>&lt;amount&gt;</code> modulo 32.                                                                                                                                     |

### Operation for all encodings

```
1 if ConditionPassed() then
2   EncodingSpecificOperations();
3   shifted = Shift(R[m], shift_t, shift_n, APSR.C);
4   (result, carry, overflow) = AddWithCarry(R[n], NOT(shifted), '1');
5   APSR.N = result[31];
6   APSR.Z = IsZeroBit(result);
7   APSR.C = carry;
8   APSR.V = overflow;
```

### Restricted behavior

#### Data Independent Timing behavior

If [AIRCR.DIT](#) is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the N, Z, C, V flags.
- The point at which an asynchronous exception is taken does not vary based on any of the following:
  - The values of the data supplied in any the registers bwing used in this instruction.

- The values of the N, Z, C, V flags.

## C2.4.42 CNEG

Conditional Negate. Returns, in the destination register, the negated value of the source register if the condition is TRUE, and otherwise returns the value of the source register.

This is an alias of [CSNEG](#) with the following condition satisfied:  $Rn == Rm$ .

This alias is the preferred disassembly.

### T1

|    |    |    |    |    |    |   |   |   |   |   |   |    |   |   |   |    |     |    |    |    |    |   |   |       |   |   |   |    |   |   |   |
|----|----|----|----|----|----|---|---|---|---|---|---|----|---|---|---|----|-----|----|----|----|----|---|---|-------|---|---|---|----|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3  | 2 | 1 | 0 | 15 | 14  | 13 | 12 | 11 | 10 | 9 | 8 | 7     | 6 | 5 | 4 | 3  | 2 | 1 | 0 |
| 1  | 1  | 1  | 0  | 1  | 0  | 1 | 0 | 0 | 1 | 0 | 1 | Rn |   |   |   | 1  | (0) | 1  | 1  | Rd |    |   |   | fcond |   |   |   | Rn |   |   |   |

### CNEG variant

CNEG<q> Rd, Rn, <fcond>

is equivalent to

CSNEG<q> Rd, Rn, Rn, invert (<cond>)

and is the preferred disassembly when  $Rn == Rm$

### Restricted behavior

#### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the N, Z, C, V flags.
- The point at which an asynchronous exception is taken does not vary based on any of the following:
  - The values of the data supplied in any the registers bwing used in this instruction.
  - The values of the N, Z, C, V flags.

### C2.4.43 CPS

Change PE State. Change PE State. The instruction modifies the PRIMASK and FAULTMASK special-purpose register values.

#### T1

Armv8-M

|    |    |    |    |    |    |   |   |   |   |   |    |     |     |   |   |
|----|----|----|----|----|----|---|---|---|---|---|----|-----|-----|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4  | 3   | 2   | 1 | 0 |
| 1  | 0  | 1  | 1  | 0  | 1  | 1 | 0 | 0 | 1 | 1 | im | (0) | (0) | I | F |

#### CPSID variant

Applies when **im** == 1.

CPSID{<q>} <iflags>

#### CPSIE variant

Applies when **im** == 0.

CPSIE{<q>} <iflags>

#### Decode for this encoding

```

1 enable = (im == '0');  disable = (im == '1');
2 if InITBlock() then UNPREDICTABLE;
3 if (I == '0' && F == '0') then UNPREDICTABLE;
4 affectPRI = (I == '1');  affectFAULT = (F == '1');
5 if !HaveMainExt() then
6     if (I == '0') then UNPREDICTABLE;
7     if (F == '1') then UNPREDICTABLE;
```

#### CONSTRAINED UNPREDICTABLE behavior

If **I** == '0' && **F** == '0', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

#### CONSTRAINED UNPREDICTABLE behavior

If !HaveMainExt() && (**I** == '0' || **F** == '1'), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

#### Assembler symbols for all encodings

<q>

See [C1.2.5 Standard assembler syntax fields](#).

<iflags>

Is a sequence of one or more of the following, specifying which interrupt mask bits are affected:

- f** FAULTMASK. When set to 1, raises the execution priority to -1, the same priority as HardFault. This is a 1-bit register, that can be updated only by privileged software. The register clears to 0 on return from any exception other than NMI.
- i** PRIMASK. When set to 1, raises the execution priority to 0. This is a 1-bit register, that can be updated only by privileged software.

### Operation for all encodings

```
1 EncodingSpecificOperations();
2 if CurrentModeIsPrivileged() then
3     if enable then
4         if affectPRI then
5             PRIMASK.PM = '0';
6         if affectFAULT then
7             FAULTMASK.FM = '0';
8     if disable then
9         if affectPRI then
10            PRIMASK.PM = '1';
11        if affectFAULT && ExecutionPriority() > -1 then
12            FAULTMASK.FM = '1';
```

## C2.4.44 CSDB

Consumption of Speculative Data Barrier. Consumption of Speculative Data Barrier is a memory barrier that controls speculative execution and data value prediction.

No instruction other than branch instructions and instructions that write to the PC appearing in program order after the CSDB can be speculatively executed using the results of any:

- Data value predictions of any instructions.
- APSR.N, Z, C, V predictions of any instructions other than conditional branch instructions and conditional instructions that write to the PC appearing in program order before the CSDB that have not been architecturally resolved.

APSR.N, Z, C, V is not considered a data value. This instruction permits:

- Control flow speculation before and after the CSDB.
- Speculative execution of conditional data processing instructions after the CSDB, unless they use the results of data value or APSR.N, Z, C, V predictions of instructions appearing in program order before the CSDB that have not been architecturally resolved.

This is a NOP-compatible hint.

5     result = RZ[n];  
6 else  
7     result = NOT(RZ[m]);  
8 R[d] = result;
```

## Restricted behavior

### Data Independent Timing behavior

If [AIRC.R.DIT](#) is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the N, Z, C, V flags.
- The point at which an asynchronous exception is taken does not vary based on any of the following:
  - The values of the data supplied in any the registers bwing used in this instruction.
  - The values of the N, Z, C, V flags.

## C2.4.50 CSNEG

Conditional Select Negation. Returns, in the destination register, the value of the first source register if the condition is TRUE, and otherwise returns the value of the second source register negated.

This instruction is not permitted in an IT block.

|    |    |    |    |    |    |   |   |   |   |     |   |   |    |   |   |    |    |    |    |    |    |        |   |   |     |   |   |     |   |   |   |
|----|----|----|----|----|----|---|---|---|---|-----|---|---|----|---|---|----|----|----|----|----|----|--------|---|---|-----|---|---|-----|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5   | 4 | 3 | 2  | 1 | 0 | 15 | 14 | 13 | 12 | 11 | 10 | 9      | 8 | 7 | 6   | 5 | 4 | 3   | 2 | 1 | 0 |
| 1  | 1  | 1  | A  | 1  | 1  | 1 | 0 | 0 | 1 | op1 |   |   | Rn |   |   | Rd |    |    | 0  |    |    | coproc |   |   | op2 |   | 1 | op3 |   |   |   |

#### Accumulator variant

Applies when **A == 1**

CX2DA<c>, <coproc>, <Rd>, <Rd+1>, <Rn>, #<imm>

#### Non-accumulator variant

Applies when **A == 0**

CX2D <coproc>, <Rd>, <Rd+1>, <Rn>, #<imm>

#### Decode for this encoding

```

1 if CoprocType(UInt(coproc)) != CP_CDEv1 then SEE "Coprocessor instructions";
2 if !HaveMainExt() then UNDEFINED;
3 cp = UInt(coproc);
4 d = UInt(Rd);
5 n = UInt(Rn);
6 imm = op1:op2:op3;
7 acc = (A == '1');
8 ExecuteCPCheck(cp);
9 // Register pairs containing SP or PC are UNPREDICTABLE.
10 if d > 10 then UNPREDICTABLE;
11 if n == 13 then UNPREDICTABLE;
12 if Rd[0] == '1' then UNPREDICTABLE;
13 if !acc && InITBlock() then UNPREDICTABLE;
```

#### CONSTRAINED UNPREDICTABLE behavior

If **d** is odd, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction returns and UNKNOWN value in **Rd**, **Rd + 1** and **Rd - 1**.
- The instruction executes as NOP.

#### CONSTRAINED UNPREDICTABLE behavior

If **d == 12**, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction returns and UNKNOWN value in **R12** and **SP**.

- The instruction executes as NOP.

#### CONSTRAINED UNPREDICTABLE behavior

If `d == 12 || d == 13`, then one of the following behaviors must occur:

- It is UNKNOWN whether a stack limit check is performed.

#### CONSTRAINED UNPREDICTABLE behavior

If `d == 14`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

#### CONSTRAINED UNPREDICTABLE behavior

If `n == 13`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The value in the destination register is UNKNOWN.
- The instruction executes as NOP.

#### CONSTRAINED UNPREDICTABLE behavior

If `!acc && InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP.

### Assembler symbols for all encodings

|                             |                                                                                                                                                                                                              |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;A&gt;</code>      | Accumulate with existing register contents. This parameter must be one of the following values:<br>– Encoded as <code>A = 0</code><br><code>A</code> Encoded as <code>A = 1</code>                           |
| <code>&lt;c&gt;</code>      | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                                                                |
| <code>&lt;coproc&gt;</code> | Is the name of the coprocessor, encoding in the "coproc" field. Valid names are p0 to p7 inclusive.                                                                                                          |
| <code>&lt;Rd&gt;</code>     | Is the general-purpose register R0 – R10 specifying the first of destination register pair, encoded in the "Rd" field. For accumulator variants, <code>&lt;Rd&gt;</code> also specifies the source register. |
| <code>&lt;Rn&gt;</code>     | Is the general-purpose R0 – R14 or APSR_nzcv source register, encoded in the "Rn" field. APSR_nzcv is encoded by the "Rn" field value 0b1111.                                                                |
| <code>&lt;imm&gt;</code>    | Is the immediate encoded in <code>op1:op2:op3</code> .                                                                                                                                                       |

### Operation for all encodings

```

1 if ConditionPassed() then
2     EncodingSpecificOperations();
3     if (!Coprocc_Accepted(cp, ThisInstr())) then
4         GenerateCoproccorException();
5     elseif acc then
6         RFD[d] = CX_op2(ThisInstr(), RFD[d], RF[n], 64);
7     else
8         RFD[d] = CX_op1(ThisInstr(), RF[n], 64);

```

## C2.4.55 CX3

Custom Instruction Class 3. Custom instruction class 3 computes a value based two source registers, an immediate and optionally the destination value, and writes the result to the destination register.

The source and destination registers can be either general-purpose registers or the Condition flags, specified by use of APSR\_nzcv.

|----|----|----|----|----|----|---|---|---|-----|---|---|---|----|---|---|----|----|----|----|----|----|--------|---|---|---|-----|---|-----|---|---|---|----|--|--|--|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6   | 5 | 4 | 3 | 2  | 1 | 0 | 15 | 14 | 13 | 12 | 11 | 10 | 9      | 8 | 7 | 6 | 5   | 4 | 3   | 2 | 1 | 0 |    |  |  |  |
| 1  | 1  | 1  | A  | 1  | 1  | 1 | 0 | 1 | op1 |   |   |   | Rn |   |   |    | Rm |    |    |    | 0  | coproc |   |   |   | op2 | 0 | op3 |   |   |   | Rd |  |  |  |

#### Accumulator variant

Applies when **A == 1**

CX3A<c>, <coproc>, <Rd>, <Rn>, <Rm>, #<imm>

#### Non-accumulator variant

Applies when **A == 0**

CX3 <coproc>, <Rd>, <Rn>, <Rm>, #<imm>

#### Decode for this encoding

```

1 if CoprocType(UInt(coproc)) != CP_CDEv1 then SEE "Coprocessor instructions";
2 if !HaveMainExt() then UNDEFINED;
3 cp = UInt(coproc);
4 d = UInt(Rd);
5 n = UInt(Rn);
6 m = UInt(Rm);
7 imm = op1:op2:op3;
8 acc = (A == '1');
9 ExecuteCPCheck(cp);
10 if d == 13 || n == 13 || m == 13 then UNPREDICTABLE;
11 if !acc && InITBlock() then UNPREDICTABLE;
```

#### CONSTRAINED UNPREDICTABLE behavior

If **d == 13**, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction returns an UNKNOWN value in SP and it is UNKNOWN whether a stack limit check is performed.
- The instruction executes as NOP.

#### CONSTRAINED UNPREDICTABLE behavior

If **n == 13 or m == 13**, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction returns an UNKNOWN value in SP.
- The instruction executes as NOP.

## CONSTRAINED UNPREDICTABLE behavior

If `!acc && InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP.

## Assembler symbols for all encodings

|          |                                                                                                                                                                                                                      |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <A>      | Accumulate with existing register contents. This parameter must be one of the following values: <ul style="list-style-type: none"> <li>– Encoded as A = 0</li> <li>A Encoded as A = 1</li> </ul>                     |
| <c>      | See <a href="#">C1.2.5 Standard assembler syntax fields</a> .                                                                                                                                                        |
| <coproc> | Is the name of the coprocessor, encoding in the "coproc" field. Valid names are p0 to p7 inclusive.                                                                                                                  |
| <Rd>     | Is the general-purpose R0 – R14 or APSR_nzcv destination register, encoded in the "Rd" field. For accumulator variants <Rd> also specifies the source register. APSR_nzcv is encoded by the "Rd" field value 0b1111. |
| <Rn>     | Is the general-purpose R0 – R14 or APSR_nzcv destination register, encoded in the "Rn" field. APSR_nzcv is encoded by the "Rn" field value 0b1111.                                                                   |
| <Rm>     | Is the general-purpose R0 – R14 or APSR_nzcv destination register, encoded in the "Rm" field. APSR_nzcv is encoded by the "Rm" field value 0b1111.                                                                   |
| <imm>    | Is the immediate encoded in op1:op2:op3.                                                                                                                                                                             |

## Operation for all encodings

```

1 if ConditionPassed() then
2     EncodingSpecificOperations();
3     if (!CoproccAccepted(cp, ThisInstr())) then
4         GenerateCoproccorException();
5     elseif acc then
6         RF[d] = CX_op3(ThisInstr(), RF[d], RF[n], RF[m], 32);
7     else
8         RF[d] = CX_op2(ThisInstr(), RF[n], RF[m], 32);

```

## C2.4.56 CX3D

Custom Instruction Class 3. Custom instruction class 3 dual computes a value based on two source registers, an immediate, and optionally the destination register pair value, and writes the result to the destination register pair.
