Resulting Condition Code: When Bit 3 of the M_6 field is one, the code is set as follows:

0 All elements equal (All T results in Figure 24-5)
1 Mix of equal, and unequal or unordered elements (A mix of T and F results in Figure 24-5)
2 --
3 All elements not equal or unordered (All F results in Figure 24-5)

Otherwise, the code remains unchanged.

IEEE Exceptions:

- Invalid Operation

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

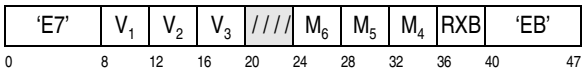
CXi: IEEE invalid-operation exception if the vector-enhancements facility 1 is installed and the SQ control in M_5 is one. The results shown are produced only when FPC 0.0 is zero.

Figure 24-5. Results: VECTOR FP COMPARE EQUAL

VECTOR FP COMPARE HIGH

VFCH V_1,V_2,V_3,M_4,M_5,M_6 [VRR-c]



The floating-point element or elements of the second operand are compared with each corresponding floating-point element or elements of the third operand. If the element in the second operand is greater than the element in the third operand, the bit positions of the corresponding element in the first operand are set to one. Otherwise, the bit positions in the corresponding element of the first operand are set to zeros. The size of the operand elements is determined by the floating-point-format control in the M_4 field. The second and third operand elements are treated as BFP numbers of the specified format.

If any of the elements in the second or third operands used in the comparison are SNaNs, an IEEE invalid-operation exception is recognized. If the vector-enhancements facility 1 is installed and the signal-if-QNaN (SQ) control is one and any of the elements in the second or third operands used in the comparison are QNaNs, an IEEE invalid-operation exception is also recognized.If the IEEE invalid-operation mask bit is one, a program interruption with a VXC indicating and IEEE invalid-operation and the corresponding element index occurs and the operation is suppressed. If the IEEE invalid-operation mask bit is zero, the bits of the corresponding element in the first operand are set to zeros and the IEEE invalid-operation flag bit is set in the FPC register.

See Figure 24-6 on page 24-13 for a detailed description of the results for each element.

The M_4 field specifies the floating-point format. The floating-point format determines the size of the elements within the vector register operands. If a reserved value is specified, a specification exception is recognized. If the vector-enhancements facility 1 is not installed the values 2 and 4 are reserved.

M_4	**Floating-Point Format**
0-1	Reserved

M_4	Floating-Point Format
2	Short format
3	Long format
4	Extended format
5-15	Reserved

The M_5 field has the following format:

The bits of the M_5 field are defined as follows:

- ***Single-Element-Control (S):*** If bit 0 is set to one, the operation takes place only on the zero-indexed element in the vector. In the absence of a trapping exception condition, the bit positions of all other elements in the first operand vector are unpredictable . The values of all other elements in the second and third operands are ignored. If bit 0 is set to zero, the operation occurs on all elements in the vector.
- ***Signal-on-QNaN (SQ):*** If bit 1 is set to one, a QNaN in any element of the second or third operands will signal an IEEE invalid-operation exception. If bit 1 is set to zero a QNaN will not signal an IEEE invalid-operation exception.
- ***Reserved:*** Bits 2, 3, and if the vector-enhancements facility 1 is not installed, bit 1 are reserved and must be zero. Otherwise, a specification exception is recognized.

The M_6 field has the following format:

The bits of the M_6 field are defined as follows:

- ***Reserved:*** Bits 0, 1, and 2 are reserved and must be zero. Otherwise, a specification exception is recognized.
- ***Condition Code Set (CS):*** If bit 3 is 0, the code remains unchanged. If the bit is one, the code is set as described below.

Resulting Condition Code: When Bit 3 of the M_6 field is one, the code is set as follows:

0 All elements greater than (All T results in Figure 24-6)
1 Mix of greater than, and non-greater than or unordered elements (A mix of T and F results in Figure 24-6)
2 --
3 All elements not greater than, or unordered (All F results in Figure 24-6)

Otherwise, the code remains unchanged.

IEEE Exceptions:

- Invalid operation

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

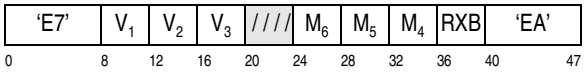
Figure 24-6. Results: VECTOR FP COMPARE HIGH

VECTOR FP COMPARE HIGH OR EQUAL

VFCHE V_1,V_2,V_3,M_4,M_5,M_6 [VRR-c]



The floating-point element or elements of the second operand are compared with each corresponding floating-point element or elements of the third operand. If the element in the second operand is greater than or equal to the element in the third operand, the bit positions of the corresponding element in the first operand are set to one. Otherwise the bit positions in the corresponding element of the first operand are set to zeros. The size of the operand elements is determined by the floating-point-format control in the M_4 field. The second and third operand elements are treated as BFP numbers of the specified format.

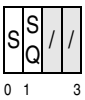
If any of the elements in the second or third operands used in the comparison are SNaNs, an IEEE invalid-operation exception is recognized. If the vector-enhancements facility 1 is installed and the signal-if-QNaN (SQ) control is one and any of the elements in the second or third operands used in the comparison are QNaNs, an IEEE invalid-operation exception is also recognized. If the IEEE invalid-operation mask bit is one, a program interruption with VXC set for IEEE invalid-operation and the corresponding element index occurs and the operation is suppressed. If the IEEE invalid-operation mask bit is zero, the bits of the corresponding element in the first operand are set to zeros and the IEEE invalid-operation flag bit is set in the FPC register.

See Figure 24-7 on page 24-15 for a detailed description of the results for each element.

The M_4 field specifies the floating-point format. The floating-point format determines the size of the elements within the vector register operands. If a reserved value is specified, a specification exception is recognized. If the vector-enhancements facility 1 is not installed the values 2 and 4 are reserved.

M_4	Floating-Point Format
0-1	Reserved
2	Short format
3	Long format
4	Extended format
5-15	Reserved

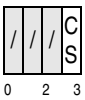
The M_5 field has the following format:



The bits of the M_5 field are defined as follows:

- ***Single-Element-Control (S):*** If bit 0 is set to one, the operation takes place only on the zero-indexed element in the vector. In the absence of a trapping exception condition, the bit positions of all other elements in the first operand vector are unpredictable . The values of all other elements in the second and third operands are ignored. If bit 0 is set to zero, the operation occurs on all elements in the vector.
- ***Signal-on-QNaN (SQ):*** If bit 1 is set to one, a QNaN in any element of the second or third operands will signal an IEEE invalid-operation exception. If bit 1 is set to zero a QNaN will not signal an IEEE invalid-operation exception.
- ***Reserved:*** Bits 2, 3, and if the vector-enhancements facility 1 is not installed, bit 1 are reserved and must be zero. Otherwise, a specification exception is recognized.

The M_6 field has the following format:



The bits of the M_6 field are defined as follows:

- ***Reserved:*** Bits 0, 1, and 2 are reserved and must be zero. Otherwise, a specification exception is recognized.
- ***Condition Code Set (CS):*** If bit 3 is 0, the code remains unchanged. If the bit is one, the code is set as described below.

Resulting Condition Code: When Bit 3 of the M_6 field is one, the code is set as follows:

0 All elements greater than or equal (All T results in Figure 24-7)

1 Mix of greater than or equal and less than or unordered elements (A mix of T and F results in Figure 24-7)

2 --

3 All elements less than or unordered (All F results in Figure 24-7)

Otherwise, the code remains unchanged.

IEEE Exceptions:

- Invalid operation

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

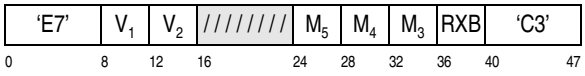
Figure 24-7. Results: VECTOR FP COMPARE HIGH OR EQUAL

VECTOR FP CONVERT FROM FIXED

VCFPS V_1,V_2,M_3,M_4,M_5 [VRR-a]
VCDG V_1,V_2,M_3,M_4,M_5 [VRR-a]

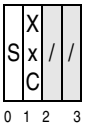


The signed binary integer element or elements of the second operand are converted to binary floating-point numbers. The results are placed in the corresponding element or elements of the first-operand location. The first operand elements are treated as BFP numbers.

The M_3 field specifies the floating-point format as well as the size of the binary integer. The floating-point format determines the size of the elements within the target vector register operand. If a reserved value is specified, a specification exception is recognized. If the vector-enhancements facility 2 is not installed, an M_3 field value of two is also invalid and a specification exception is recognized.

M_3	Floating-Point Format
0-1	Reserved
2	Word to BFP short format
3	Doubleword to BFP long format
4-15	Reserved

The M_4 field has the following format:



The bits of the M_4 field are defined as follows:

- ***Single-Element-Control (S):*** If bit 0 is set to one, the operation takes place only on the zero-indexed element in the vector and the result is placed in the zero-indexed element of the first operand. In the absence of a trapping exception condition, the bit positions of all other elements in the first operand vector are unpredictable . If bit 0 is set to zero, the operation occurs on all elements in the vector.

- ***IEEE-inexact-exception control (XxC):*** Bit 1 of the M_4 field is the XxC bit. If XxC is zero, recognition of IEEE-inexact exception is not suppressed; if XxC is one, recognition of IEEE-inexact exception is suppressed.
- ***Reserved:*** Bits 2 and 3 are reserved and must contain zeros otherwise a specification is recognized.

The converted result is rounded by the rounding method as specified by the modifier in the M_5 field:

M_5	Effective Rounding Method
0	According to current BFP rounding mode
1	Round to nearest with ties away from 0
3	Round to prepare for shorter precision
4	Round to nearest with ties to even
5	Round toward 0
6	Round toward +∞
7	Round toward -∞

An M_5 modifier other than 0, 1, or 3-7 is invalid. The M_5 field must designate a valid modifier; otherwise, a specification exception is recognized.

When the M_5 modifier field is zero, rounding is controlled by the current BFP rounding mode specified in the FPC register. When the field is not zero, rounding is performed as specified by the modifier, regardless of the current BFP rounding mode.

See Figure 24-8 on page 24-17 for a detailed description of the results for each element.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Inexact

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

VECTOR FP SQUARE ROOT	Xi: T(dNaN)	Xi: T(dNaN)	T(-0)	T(+0)	R($\sqrt{a}$)	T(+∞)	T(a)	Xi: T(a*)

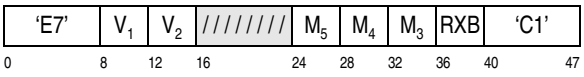
Explanation:

–	This situation cannot occur.
*	The SNaN is converted to the corresponding QNaN before it is placed at the target operand element location.
1	The operand element is extended to the longer format by appending zeros on the right before it is placed at the target operand element location.
2	The NaN is shortened to the target format by truncating the rightmost bits.
dNaN	Default NaN.
Fn	Finite nonzero number (includes both subnormal and normal).
R(v)	Rounding and range action is performed on the value v. See Figure 24-4 on page 24-6.
Rf(a)	The value a is converted to the precise intermediate value floating-point number v, and then action R(v) is performed.
T(x)	The value x is placed in the target operand element location if no trapping exceptions on other elements.
Xi:	IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.

Figure 24-8. Results: Single-Operand Instructions

VECTOR FP CONVERT FROM LOGICAL

VCFPL V_1,V_2,M_3,M_4,M_5 [VRR-a]
VCDLG V_1,V_2,M_3,M_4,M_5 [VRR-a]

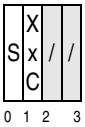


The unsigned binary integer element or elements in the second operand are converted to binary floating-point numbers. The results are placed in the corresponding element or elements of the first-operand location. The first operand elements are treated as BFP numbers.

The M_3 field specifies the floating-point format as well as the size of the binary integer. The floating-point format determines the size of the elements within the target vector register operand. If a reserved value is specified, a specification exception is recognized. If the vector-enhancements facility 2 is not installed, an M_3 field value of two is also invalid and a specification exception is recognized.

M_3	Floating-Point Format
0-1	Reserved
2	Word to BFP short format
3	Doubleword to BFP long format
4-15	Reserved

The M_4 field has the following format:



The bits of the M_4 field are defined as follows:

- ***Single-Element-Control (S):*** If bit 0 is set to one, the operation takes place only on the zero-

indexed element in the vector and the result is placed in the zero-indexed element of the first operand. In the absence of a trapping exception condition, the bit positions of all other elements in the first operand vector are unpredictable . If bit 0 is set to zero, the operation occurs on all elements in the vector.

- ***IEEE-inexact-exception control (XxC):*** Bit 1 of the M_4 field is the XxC bit. If XxC is zero, recognition of IEEE-inexact exception is not suppressed; if XxC is one, recognition of IEEE-inexact exception is suppressed.
- ***Reserved:*** Bits 2 and 3 are reserved and must contain zeros otherwise a specification is recognized.

The converted result is rounded by the rounding method as specified by the modifier in the M_5 field:

M_5	Effective Rounding Method
0	According to current BFP rounding mode
1	Round to nearest with ties away from 0
3	Round to prepare for shorter precision
4	Round to nearest with ties to even
5	Round toward 0
6	Round toward +∞
7	Round toward -∞

An M_5 modifier other than 0, 1, or 3-7 is invalid. The M_5 field must designate a valid modifier; otherwise, a specification exception is recognized.

When the M_5 modifier field is zero, rounding is controlled by the current BFP rounding mode specified in the FPC register. When the field is not zero, rounding is performed as specified by the modifier, regardless of the current BFP rounding mode.

See Figure 24-8 on page 24-17 for a detailed description of the results for each element.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Inexact

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

Extended Mnemonics:

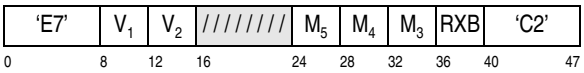
VECTOR FP CONVERT TO FIXED

VCSFP V_1,V_2,M_3,M_4,M_5 [VRR-a]
VCGD V_1,V_2,M_3,M_4,M_5 [VRR-a]



The BFP floating-point element or elements of the second operand are rounded to an integer value and then converted to the fixed-point format. The signed binary integer result is placed in the corresponding element of the first-operand location. The second operand elements are treated as BFP numbers.

If the second operand element is a finite number, it is rounded to an integer value by the rounding method as specified by the modifier in the M_5 field:

M_5	Effective Rounding Method
0	According to current BFP rounding mode
1	Round to nearest with ties away from 0
3	Round to prepare for shorter precision
4	Round to nearest with ties to even
5	Round toward 0
6	Round toward +∞
7	Round toward -∞

An M_5 modifier other than 0, 1, or 3-7 is invalid. The M_5 field must designate a valid modifier; otherwise, a specification exception is recognized.

When the M_5 modifier field is zero, rounding is controlled by the current BFP rounding mode specified in the FPC register. When the field is not zero, rounding is performed as specified by the modifier, regardless of the current BFP rounding mode.

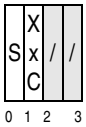
The sign of the result is the sign of the second operand element, except that a zero result has a plus sign.

See Figure 24-9 on page 24-19 for a detailed description of the results for each element.

The M_3 field specifies the floating-point format as well as the size of the binary integer. The floating-point format determines the size of the elements within the target vector register operand. If a reserved value is specified, a specification exception is recognized. If the vector-enhancements facility 2 is not installed, an M_3 field value of two is also invalid and a specification exception is recognized.

M_3	Floating-Point Format
0-1	Reserved
2	BFP short format to word
3	BFP long format to doubleword
4-15	Reserved

The M_4 field has the following format:



The bits of the M_4 field are defined as follows:

- ***Single-Element-Control (S):*** If bit 0 of the M_4 field is set to one, the operation takes place only on the zero-indexed element in the vector and the result is placed in the zero-indexed element of the first operand. In the absence of a trapping exception condition, the bit positions of all other elements in the first operand vector are unpredictable . If bit 0 is set to zero, the operation occurs on all elements in the vector.
- ***IEEE-inexact-exception control (XxC):*** Bit 1 of the M_4 field is the XxC bit. If XxC is zero, recognition of IEEE-inexact exception is not suppressed; if XxC is one, recognition of IEEE-inexact exception is suppressed.
- ***Reserved:*** Bits 2 and 3 are reserved and must contain zeros otherwise a specification is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Inexact
- Invalid operation

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

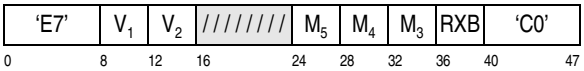
VECTOR FP CONVERT TO LOGICAL

VCLFP V_1,V_2,M_3,M_4,M_5 [VRR-a]
VCLGD V_1,V_2,M_3,M_4,M_5 [VRR-a]



The BFP floating-point element or elements of the second operand are rounded to an integer value and then converted to the fixed-point format. The unsigned binary integer result is placed in the corresponding element of the first-operand location. The second operand elements are treated as BFP numbers.

If the second operand element is a finite number, it is rounded to an integer value by the rounding method as specified by the modifier in the M_5 field:

M_5	Effective Rounding Method
0	According to current BFP rounding mode
1	Round to nearest with ties away from 0
3	Round to prepare for shorter precision
4	Round to nearest with ties to even

5 Round toward 0
6 Round toward +∞
7 Round toward -∞

An M_5 modifier other than 0, 1, or 3-7 is invalid. The M_5 field must designate a valid modifier; otherwise, a specification exception is recognized.

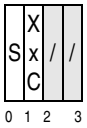
When the M_5 modifier field is zero, rounding is controlled by the current BFP rounding mode specified in the FPC register. When the field is not zero, rounding is performed as specified by the modifier, regardless of the current BFP rounding mode.

See Figure 24-10 on page 24-22 for a detailed description of the results for each element.

The M_3 field specifies the floating-point format as well as the size of the binary integer. The floating-point format determines the size of the elements within the target vector register operand. If a reserved value is specified, a specification exception is recognized. If the vector-enhancements facility 2 is not installed, an M_3 field value of 2 is also invalid and a specification exception is recognized.

M_3	Floating-Point Format
0-1	Reserved
2	BFP short format to word
3	BFP long format to doubleword
4-15	Reserved

The M_4 field has the following format:



The bits of the M_4 field are defined as follows:

- ***Single-Element-Control (S):*** If bit 0 is set to one, the operation takes place only on the zero-indexed element in the vector and the result is placed in the zero-indexed element of the first operand. In the absence of a trapping exception condition, the bit positions of all other elements in the first operand vector are unpredictable . If bit 0 is set to zero, the operation occurs on all elements in the vector.
- ***IEEE-inexact-exception control (XxC):*** Bit 1 of the M_4 field is the XxC bit. If XxC is zero, recognition of IEEE-inexact exception is not suppressed; if XxC is one, recognition of IEEE-inexact exception is suppressed.
- ***Reserved:*** Bits 2 and 3 are reserved and must contain zeros otherwise a specification is recognized.

Condition Code: The code remains unchanged.

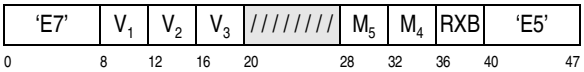
Figure 24-10. Results: VECTOR FP CONVERT TO LOGICAL 64-BIT

VECTOR FP DIVIDE

VFD V_1,V_2,V_3,M_4,M_5 [VRR-c]



The floating-point element or elements of the second operand (the dividend) are divided by the corresponding floating-point element or elements in the third operand (the divisor), and the quotient or quotients are placed at the corresponding elements in first-operand location. No remainder is preserved.

The operand elements are all treated as BFP numbers of the specified format.

If the divisor is nonzero and both the dividend and divisor are finite numbers, the second operand element is divided by the third operand element to form an intermediate quotient. The intermediate quotient, if nonzero, is rounded to the target format according to the current BFP rounding mode.

When the dividend is a finite number and the divisor is infinity, the result is zero.

The sign of the quotient, if the quotient is numeric, is the exclusive or of the corresponding operand element signs. This includes the sign of a zero or infinite quotient.

If the divisor is zero but the dividend is a finite number, an IEEE-division-by-zero exception is recognized. If the dividend and divisor are both zero, or if both are infinity, regardless of sign, an IEEE-invalid-operation exception is recognized.

See Figure 24-11 on page 24-24 for a detailed description of the results of each element.

The M_4 field specifies the floating-point format. The floating-point format determines the size of the elements within the vector register operands. If a reserved value is specified, a specification exception is recognized. If the vector-enhancements facility 1 is not installed the values 2 and 4 are reserved.

M_4	Floating-Point Format
0-1	Reserved
2	Short format
3	Long format
4	Extended format
5-15	Reserved

The M_5 field has the following format:

The bits of the M_5 field are defined as follows:

- ***Single-Element-Control (S):*** If bit 0 is set to one, the operation takes place only on the zero-indexed element in the vector. In the absence of a trapping exception condition, the bit positions of all other elements in the first operand vector are unpredictable . If bit 0 is set to zero, the operation occurs on all elements in the vector.
- ***Reserved:*** Bits 1 to 3 are reserved and must be zero. Otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Invalid operation
- Division by zero
- Overflow
- Underflow
- Inexact

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

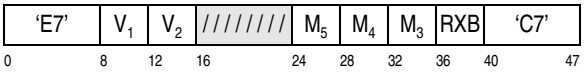
Explanation:

*	The SNaN is converted to the corresponding QNaN before it is placed at the target operand location.
Fn	Finite nonzero number (includes both subnormal and normal).
R(v)	Rounding and range action is performed on the value v. See Figure 24-4 on page 24-6.
T(x)	The value x is placed at the target operand element location if no trapping exceptions on other elements.
Xi:	IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.
Xz:	IEEE division-by-zero exception. The results shown are produced only when FPC 0.1 is zero.

Figure 24-11. Results: DIVIDE

VECTOR LOAD FP INTEGER

VFI V_1,V_2,M_3,M_4,M_5 [VRR-a]



The floating-point element or elements of the second operand are rounded to integer values in the same floating-point format, and the results are placed in the corresponding elements of the first-operand. The size of the operand elements is determined by the floating-point-format control in the M_3 field. The first and second operands are treated as BFP numbers.

The second operand elements, if finite numbers, are rounded to an integer value by the rounding method specified by the modifier in the M_5 field:

M_5	Effective Rounding Method
0	According to current BFP rounding mode
1	Round to nearest with ties away from 0
3	Round to prepare for shorter precision
4	Round to nearest with ties to even
5	Round toward 0
6	Round toward +∞
7	Round toward -∞

is recognized. If the vector-enhancements facility 1 is

An M_5 modifier other than 0, 1, or 3-7 is invalid. The M_5 field must designate a valid modifier; otherwise, a specification exception is recognized.

When the M_5 modifier field is zero, rounding is controlled by the current BFP rounding mode in the FPC register. When the field is not zero, rounding is performed as specified by the modifier, regardless of the current BFP rounding mode.

In the absence of an interruption, if the second operand element is an infinity or a QNaN, the result is that operand element; if the second operand element is an SNaN, the result is the corresponding QNaN.

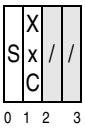
The sign of the result is the sign of the second operand element, even when the result is zero.

The M_3 field specifies the floating-point format. The floating-point format determines the size of the elements within the vector register operands. If a reserved value is specified, a specification exception

not installed the values 2 and 4 are reserved.

M_3	Floating-Point Format
0-1	Reserved
2	Short format
3	Long format
4	Extended format
5-15	Reserved

The M_4 field has the following format:



The bits of the M_4 field are defined as follows:

- ***Single-Element-Control (S):*** If bit 0 is set to one, the operation takes place only on the zero-indexed element in the vector. In the absence of a trapping exception condition, the bit positions of all other elements in the first operand vector are unpredictable . If bit 0 is set to zero, the operation occurs on all elements in the vector.
- ***IEEE-inexact-exception control (XxC):*** Bit 1 of the M_4 field is the XxC bit. If XxC is zero, recognition of IEEE-inexact exception is not suppressed; if XxC is one, recognition of IEEE-inexact exception is suppressed.
- ***Reserved:*** Bits 2 and 3 are reserved and must contain zeros otherwise a specification is recognized.

See Figure 24-12 on page 24-26 for a detailed description of the results for each element.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Invalid operation
- Inexact

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

Programming Notes:

1. VECTOR LOAD FP INTEGER rounds BFP numbers to an integer values. These integers, which remain in the BFP format, should not be confused with binary integers, which have a fixed-point format.
2. If the BFP operand element is a finite number with a large enough exponent so that it is already an integer, the result value remains the same.

SFx IEEE inexact flag, FPC 1.4.

T(x) The value x is placed at the target operand element location if no trapping exceptions on other elements.

Figure 24-12. Results: VECTOR LOAD FP INTEGER

VECTOR FP LOAD LENGTHENED

VFLL V_1,V_2,M_3,M_4 [VRR-a]

The even indexed floating-point element or elements of the second operand are converted to the next largest format floating point numbers, and the results are placed in the even-odd pair of elements in the first operand. The operand elements are all treated as BFP numbers of the specified format.

When the second operand element is numeric, the value of the second operand element is placed in the target format.

If the second operand element is an SNaN, an IEEE-invalid-operation exception is recognized; if there is no interruption, the result is the corresponding QNaN with the fraction extended.

The sign of the result is the same as the sign of the source.

See Figure 24-8 on page 24-17 for a detailed description of the results for each element.

The M_3 field specifies the floating-point format. The floating-point format determines the size of the elements within the second operand. If a reserved value is specified, a specification exception is recognized. If the vector-enhancements facility 1 is not installed the value 3 is reserved.

M_3	Floating-Point Format
0-1	Reserved
2	Short format
3	Long format
4-15	Reserved

The M_4 field has the following format:

The bits of the M_4 field are defined as follows:

- ***Single-Element-Control (S):*** If bit 0 is set to one, the operation takes place only on the zero-indexed element in the vector. In the absence of a trapping exception condition, the bit positions of all other elements in the first operand vector are unpredictable . If bit 0 is set to zero, the operation occurs on all elements in the vector.
- ***Reserved:*** Bits 1 to 3 are reserved and must be zero. Otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Invalid operation

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

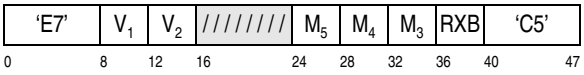
Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
VLDE	V_1,V_2,M_3,M_4	VFLL	V_1,V_2,M_3,M_4
VLDEB	V_1,V_2	VFLL	$V_1,V_2,2,0$
WLDEB	V_1,V_2	VFLL	$V_1,V_2,2,8$
VFLLS	V_1,V_2	VFLL	$V_1,V_2,2,0$
WFLLS	V_1,V_2	VFLL	$V_1,V_2,2,8$
WFLLD	V_1,V_2	VFLL	$V_1,V_2,3,8$

Programming Note: If a trapping IEEE exception is encountered during execution of VECTOR LOAD LENGTHENED it is model dependent if the VIX in the VXC field is the index of the source or target element unless the vector-enhancements facility 1 is installed in which case it is always the index of the source element.

VECTOR FP LOAD ROUNDED

VFLR V_1,V_2,M_3,M_4,M_5 [VRR-a]



The floating-point element or elements of the second operand, are rounded to the precision of the next smallest element size, and the result is placed at the corresponding even elements in the first-operand location. The data in the odd elements of the first operand is unpredictable. The size of the second operand elements is determined by the floating-point-format control in the M_3 field. The operand elements are all treated as BFP numbers.

The sign of the resulting element or elements is the same as the corresponding element of the second operand.

The second operand element, if a finite number, is rounded by the rounding method as specified by the modifier in the M_5 field:

M_5	Effective Rounding Method
0	According to current BFP rounding mode
1	Round to nearest with ties away from 0
3	Round to prepare for shorter precision
4	Round to nearest with ties to even
5	Round toward 0
6	Round toward $+\infty$
7	Round toward $-\infty$

An M_5 modifier other than 0, 1, or 3-7 is invalid. The M_5 field must designate a valid modifier; otherwise, a specification exception is recognized.

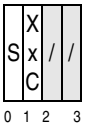
When the M_5 modifier field is zero, rounding is controlled by the current BFP rounding mode specified in the FPC register. When the field is not zero, rounding is performed as specified by the modifier, regardless of the current BFP rounding mode.

See Figure 24-8 on page 24-17 for a detailed description of the results for each element.

The M_3 field specifies the floating-point format. The floating-point format determines the size of the elements within the second operand. If a reserved value is specified, a specification exception is recognized. If the vector-enhancements facility 1 is not installed the value 4 is reserved.

M_3	Floating-Point Format
0-2	Reserved
3	Long format
4	Extended format
5-15	Reserved

The M_4 field has the following format:



The bits of the M_4 field are defined as follows:

- ***Single-Element-Control (S):*** If bit 0 is set to one, the operation takes place only on the zero-indexed element in the vector. In the absence of a trapping exception condition, the bit positions of all other elements in the first operand vector are unpredictable . If bit 0 is set to zero, the operation occurs on all elements in the vector.
- ***IEEE-inexact-exception control (XxC):*** Bit 1 of the M_4 field is the XxC bit. If XxC is zero, recognition of IEEE-inexact exception is not suppressed; if XxC is one, recognition of IEEE-inexact exception is suppressed.
- ***Reserved:*** Bits 2 and 3 are reserved and must contain zeros otherwise a specification is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Invalid operation
- Overflow
- Underflow
- Inexact

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

Programming Note: The sign of the rounded result is the same as the sign of the operand element, even when the result is zero.

VECTOR FP MAXIMUM

VFMAX V_1,V_2,V_3,M_4,M_5,M_6 [VRR-c]

The floating point element or elements of the second operand are compared to the corresponding floating-point element or elements of the third operand. The greater of the two values is placed in the corresponding element of the first operand. The operand elements are all treated as BFP numbers of the specified format.

Depending on the maximum function performed, if any of the floating-point elements in the second or third operand are NaNs, an IEEE invalid-operation exception may be recognized as specified in the action figures. If the IEEE invalid-operation mask bit is one, a program interruption with VXC set for IEEE invalid-operation and the corresponding element index occurs and the operation is suppressed.

The M_6 field specifies the handling of special cases for the comparison, see Figure 24-13 to Figure 24-22 for detailed descriptions of the results for each element. If a reserved value is specified, a specification exception is recognized.

M_6	Maximum Function Performed
0	IEEE MaxNum
1	Java Math.Max()
2	C-Style Max Macro
3	C++ Algorithm.max()
4	fmax()
5-7	Reserved
8	IEEE MaxNumMag
9	Java Math.Max() of absolute values
10	C-Style Max Macro of absolute values
11	C++ Algorithm.max() of absolute values
12	fmax() of absolute values
13-15	Reserved

The M_4 field specifies the floating-point format. The floating-point format determines the size of the elements within the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_4	Floating-Point Format
0-1	Reserved
2	Short format
3	Long format
4	Extended format
5-15	Reserved

The M_5 field has the following format:

The bits of the M_5 field are defined as follows:

- ***Single-Element-Control (S):*** If bit 0 is set to one, the operation takes place only on the zero-indexed element in the vector. In the absence of a trapping exception condition, the bit positions of all other elements in the first operand vector are unpredictable . The values of all other elements in the second and third operands are ignored. If bit 0 is set to zero, the operation occurs on all elements in the vector.
- ***Reserved:*** Bits 1, 2, and 3 are reserved and must be zero. Otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Invalid operation

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector-enhancements facility 1 is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

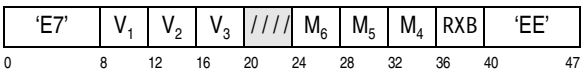
VECTOR FP MINIMUM

VFMIN V_1,V_2,V_3,M_4,M_5,M_6 [VRR-c]



The floating-point element or elements of the second operand are compared to the corresponding floating-point element or elements of the third operand. The lesser of the two values is placed in the corresponding element of the first operand. The operand elements are all treated as BFP numbers of the specified format.

Depending on the minimum function performed, if any of the floating-point elements in the second or third operand are NaNs, an IEEE invalid-operation exception may be recognized as specified in the action figures. If the IEEE invalid-operation mask bit is one, a program interruption with VXC set for IEEE invalid-operation and the corresponding element index occurs and the operation is suppressed.

The M_6 field specifies the handling of special cases for the comparison, see Figure 24-23 to Figure 24-32 for detailed descriptions of the results for each ele-

ment. If a reserved value is specified, a specification exception is recognized.

M_6	Minimum Function Performed
0	IEEE MinNum
1	Java Math.Min()
2	C-Style Min Macro
3	C++ algorithm.min()
4	fmin()
5-7	Reserved
8	IEEE MinNum of absolute values
9	Java Math.Min() of absolute values
10	C-Style Min Macro of absolute values
11	C++ algorithm.min() of absolute values
12	fmin() of absolute values
13-15	Reserved

The M_4 field specifies the floating-point format. The floating-point format determines the size of the elements within the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_4	Floating-Point Format
0-1	Reserved
2	Short format
3	Long format
4	Extended format
5-15	Reserved

The M_5 field has the following format:

The bits of the M_5 field are defined as follows:

- ***Single-Element-Control (S):*** If bit 0 is set to one, the operation takes place only on the zero-indexed element in the vector. In the absence of a trapping exception condition, the bit positions of all other elements in the first operand vector are unpredictable . The values of all other elements in the second and third operands are ignored. If bit 0 is set to zero, the operation occurs on all elements in the vector.
- ***Reserved:*** Bits 1, 2, and 3 are reserved and must be zero. Otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Invalid operation

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector-enhancements facility 1 is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

Extended Mnemonics:

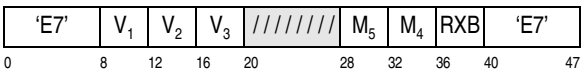
Figure 24-32. Results: VECTOR FP MINIMUM with M_6=12 ("fmin() of absolute values")

VECTOR FP MULTIPLY

VFM V_1,V_2,V_3,M_4,M_5 [VRR-c]



The product of the floating-point element or elements of the second operand (the multiplier) and the corresponding floating-point element or elements of the third operand (the multiplicand) are placed in the corresponding element or elements of the first-operand.

The size of the operand elements is determined by the floating-point-format control in the M_4 field. The operand elements are all treated as BFP numbers.

The two corresponding operand elements, if finite numbers, are multiplied, forming an intermediate product. The result is rounded to the operand format according to the current BFP rounding mode.

The sign of the product, if the product is numeric, is the exclusive OR of the operand element signs. This includes the sign of a zero or infinite product.

If one operand element is a zero and the other an infinity, an IEEE-invalid-operation exception is recognized.

See Figure 24-33 on page 24-42 for a detailed description of the results for each element.

The M_4 field specifies the floating-point format. The floating-point format determines the size of the elements within the vector register operands. If a reserved value is specified, a specification exception is recognized. If the vector-enhancements facility 1 is not installed the values 2 and 4 are reserved.

M_4	Floating-Point Format
0-1	Reserved
2	Short format
3	Long format
4	Extended format
5-15	Reserved

The M_5 field has the following format:

The bits of the M_5 field are defined as follows:

- ***Single-Element-Control (S):*** If bit 0 is set to one, the operation takes place only on the zero-indexed element in the vector. In the absence of a trapping exception condition, the bit positions of all other elements in the first operand vector are unpredictable . If bit 0 is set to zero, the operation occurs on all elements in the vector.
- ***Reserved:*** Bits 1 to 3 are reserved and must be zero. Otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Invalid operation
- Overflow
- Underflow
- Inexact

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
VFMSB	V_1,V_2,V_3	VFM	$V_1,V_2,V_3,2,0$
VFMDB	V_1,V_2,V_3	VFM	$V_1,V_2,V_3,3,0$
WFMSB	V_1,V_2,V_3	VFM	$V_1,V_2,V_3,2,8$
WFMDB	V_1,V_2,V_3	VFM	$V_1,V_2,V_3,3,8$
WFMXB	V_1,V_2,V_3	VFM	$V_1,V_2,V_3,4,8$

Programming Note: Interchanging the two operand elements in a BFP multiplication does not affect the value of the product when the result is numeric. This is not true, however, when both operand elements are QNaNs, in which case the result is the second operand element; or when both operand elements are SNaNs and the IEEE-invalid-operation mask bit in the FPC register is zero, in which case the result is the QNaN derived from the second operand element.

Second Operand Element (a) Is	Results for VECTOR FP MULTIPLY (a•b) when Third Operand Element (b) Is

SNaN	Xi: T(a*)	Xi: T(a*)	Xi: T(a*)	Xi: T(a*)	Xi: T(a*)	Xi: T(a*)	Xi: T(a*)	Xi: T(a*)

Explanation:

*	The SNaN is converted to the corresponding QNaN before it is placed at the target operand element location.
dNaN	Default NaN.
Fn	Finite nonzero number (includes both subnormal and normal).
R(v)	Rounding and range action is performed on the value v. See Figure 24-4 on page 24-6.
T(x)	The value x is placed at the target operand element location if no trapping exceptions on other elements.
Xi:	IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.

Figure 24-33. Results: VECTOR FP MULTIPLY

VECTOR FP MULTIPLY AND ADD

VFMA V_1,V_2,V_3,V_4,M_5,M_6 [VRR-e]

VECTOR FP MULTIPLY AND SUBTRACT

VFMS V_1,V_2,V_3,V_4,M_5,M_6 [VRR-e]

VECTOR FP NEGATIVE MULTIPLY AND ADD

VFNMA V_1,V_2,V_3,V_4,M_5,M_6 [VRR-e]

VECTOR FP NEGATIVE MULTIPLY AND SUBTRACT

VFNMS V_1,V_2,V_3,V_4,M_5,M_6 [VRR-e]

The floating-point element or elements of the third operand are multiplied by the corresponding floating-point element or elements of the second operand, and then the corresponding floating-point element or elements of the fourth operand are added to or subtracted from the products. The sum or differences are placed at the corresponding first-operand element locations.The size of the operand elements is determined by the floating-point-format control in the M_6 field. The operand elements are all treated as BFP numbers.

The VECTOR FP MULTIPLY AND ADD and VECTOR FP MULTIPLY AND SUBTRACT operations may be summarized below, where "(i)" represents the "i"th indexed element of the operand:

$$op_1(i) = op_3(i) \bullet op_2(i) \pm op_4(i)$$

The VECTOR FP NEGATIVE MULTIPLY AND ADD and VECTOR FP NEGATIVE MULTIPLY AND SUBTRACT operations may be summarized as below where "(i)" represents the "i"th indexed element of the operand:

$op_1(i) = -(op_3(i) \bullet op_2(i) \pm op_4(i))$

When all of the corresponding operand elements are finite numbers, the third and second BFP operand elements are multiplied, forming an intermediate product, and the corresponding fourth operand element is then added (or subtracted) algebraically to (or from) the intermediate product, forming an intermediate sum. The intermediate sum, if nonzero, is rounded to the operand format according to the current BFP rounding mode and then placed at the corresponding element of the first-operand location. The exponent and fraction of the intermediate product are maintained exactly; rounding and range checking occur only on the intermediate sum.

See Figure 24-34 for a detailed description of the results for each element of VECTOR FP MULTIPLY AND ADD. The results for each element of VECTOR FP MULTIPLY AND SUBTRACT are the same, except that the fourth operand element, if numeric, participates in the operation with its sign bit inverted. When the fourth operand element is a NaN, it participates in the operation with its sign bit unchanged.

The results for each element of VECTOR FP NEGATIVE MULTIPLY AND ADD and VECTOR FP NEGATIVE MULTIPLY AND SUBTRACT are the same as for VECTOR FP MULTIPLY AND ADD and VECTOR FP MULTIPLY AND SUBTRACT, respectively, except the sign bit of numeric results are inverted. When the result is a NaN its sign bit is unchanged.

The M_6 field specifies the floating-point format. The floating-point format determines the size of the elements within the vector register operands. If a reserved value is specified, a specification exception is recognized. For VECTOR FP MULTIPLY AND ADD and VECTOR FP MULTIPLY AND SUBTRACT, if the vector-enhancements facility 1 is not installed the values 2 and 4 are reserved.

M_6	Floating-Point Format
0-1	Reserved
2	Short format
3	Long format
4	Extended format
5-15	Reserved

The M_5 field has the following format:

The bits of the M_5 field are defined as follows:

- ***Single-Element-Control (S):*** If bit 0 is set to one, the operation takes place only on the zero-indexed element in the vector. In the absence of a trapping exception condition, the bit positions of all other elements in the first operand vector are unpredictable . If bit 0 is set to zero, the operation occurs on all elements in the vector.
- ***Reserved:*** Bits 1 to 3 are reserved and must be zero. Otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Invalid operation
- Overflow
- Underflow
- Inexact

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (VFMA and VFMS, if the vector facility for z/Architecture is not installed; VFNMA and VFNMS, if the vector-enhancements facility 1 is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

Programming Note: VECTOR FP MULTIPLY AND ADD, VECTOR FP MULTIPLY AND SUBTRACT, VECTOR FP NEGATIVE MULTIPLY AND ADD, and VECTOR NEGATIVE MULTIPLY AND SUBTRACT produce a precise intermediate value, and a single rounding operation is performed after the addition or subtraction. This definition is consistent with the Power architecture, and, in certain applications, can be used to great advantage, especially in algorithms used in math libraries.

Third Operand Element (a) Is	Results, Part 1, for MULTIPLY AND ADD (a•b+c) when Second Operand Element (b) Is

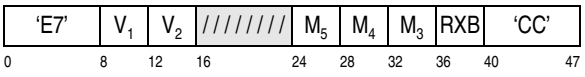
Explanation:

*	The SNaN is converted to the corresponding QNaN before it is placed at the target operand element location.
dNaN	Default NaN.
Fn	Finite nonzero number (includes both subnormal and normal).
P(x)	The value x is passed to Part 2 of this figure.
R(v)	Rounding and range action is performed on the value v. See Figure 24-4 on page 24-6.
Rezd	Exact zero-difference result. See Figure 24-4 on page 24-6.
T(x)	The value x is placed at the target operand element location if no trapping exceptions on other elements.
Xi:	IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.

Figure 24-34. Results: VECTOR FP MULTIPLY AND ADD (Part 2 of 2)

VECTOR FP PERFORM SIGN OPERATION

VFPSO V_1,V_2,M_3,M_4,M_5 [VRR-a]



The sign of the floating-point element or elements of the second operand are modified in a manner specified by the value of the M_5 field. The modified sign bit and the rest of the unchanged second operand element are placed into the corresponding element in the first operand. The size of the operand elements is determined by the floating-point-format control in the M_3 field. The operand elements are all treated as BFP numbers.

The sign operation is performed even if the element contains zero. If the element contains a QNaN or SNaN, the sign is still set without causing an IEEE exception.

The M_5 field indicates the operation to perform on the sign bit.

M_5	Sign Operation Performed
0	The sign bit is inverted (complement)
1	The sign bit is set to one (negative)
2	The sign bit is set to zero (positive)

If any other M_5 values are specified, a specification exception is recognized.

The M_3 field specifies the floating-point format. The floating-point format determines the size of the elements within the vector register operands. If a reserved value is specified, a specification exception is recognized. If the vector-enhancements facility 1 is not installed the values 2 and 4 are reserved.

M_3	Floating-Point Format
0-1	Reserved
2	Short format
3	Long format
4	Extended format
5-15	Reserved

The M_4 field has the following format:

The bits of the M_4 field are defined as follows:

- ***Single-Element-Control (S):*** If bit 0 is set to one, the operation takes place only on the zero-indexed element in the vector. The bit positions of all other elements in the first operand vector are unpredictable . If bit 0 is set to zero, the operation occurs on all elements in the vector.
- ***Reserved:*** Bits 1 to 3 are reserved and must be zero. Otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions: None

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

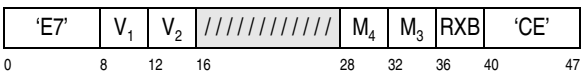
VECTOR FP SQUARE ROOT

VFSQ V_1,V_2,M_3,M_4 [VRR-a]



The square roots of the floating-point element or elements of the second operand are placed in the corre-

sponding elements of the first-operand location. The size of the operand elements is determined by the floating-point-format control in the M_3 field. The operand elements are all treated as BFP numbers.

The result rounded according to the current BFP rounding mode is placed at the first operand element location.

If the second operand element is a positive finite number, the result is the square root of that number with a plus sign. If the operand element is a zero of either sign, the result is a zero of the same sign. If the operand element is $+\infty$, the result is $+\infty$.

If the second operand element is less than zero, an IEEE-invalid-operation exception is recognized.

See Figure 24-8 on page 24-17 for a detailed description of the results for each element.

The M_3 field specifies the floating-point format. The floating-point format determines the size of the elements within the vector register operands. If a reserved value is specified, a specification exception is recognized. If the vector-enhancements facility 1 is not installed the values 2 and 4 are reserved.

M_3	Floating-Point Format
0-1	Reserved
2	Short format
3	Long format
4	Extended format
5-15	Reserved

The M_4 field has the following format:

The bits of the M_4 field are defined as follows:

- ***Single-Element-Control (S):*** If bit 0 is set to one, the operation takes place only on the zero-indexed element in the vector. In the absence of a trapping exception condition, the bit positions of all other elements in the first operand vector are unpredictable . If bit 0 is set to zero, the operation occurs on all elements in the vector.
- ***Reserved:*** Bits 1 to 3 are reserved and must be zero. Otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Invalid operation
- Inexact

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

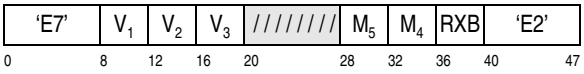
VECTOR FP SUBTRACT

VFS V_1,V_2,V_3,M_4,M_5 [VRR-c]



The floating-point element or elements in the third operand are subtracted from the floating-point element or elements of the second operand, and the difference is placed in the floating-point element or elements at the first-operand location. The size of the operand elements is determined by the floating-point-format control in the M_4 field. The operand elements are all treated as BFP numbers.

The execution of VECTOR FP SUBTRACT is identical to that of VECTOR FP ADD, except that the third operand element, if numeric, participates in the operation with its sign bit inverted. When the third operand contains an element that is a NaN, it participates in the operation with its sign bit unchanged. See Figure 24-3 on page 24-5 for the detailed results for each element of VECTOR FP ADD.

The M_4 field specifies the floating-point format. The floating-point format determines the size of the ele-

ments within the vector register operands. If a reserved value is specified, a specification exception is recognized. If the vector-enhancements facility 1 is not installed the values 2 and 4 are reserved.

M_4	Floating-Point Format
0-1	Reserved
2	Short format
3	Long format
4	Extended format
5-15	Reserved

The M_5 field has the following format:

The bits of the M_5 field are defined as follows:

- ***Single-Element-Control (S):*** If bit 0 is set to one, the operation takes place only on the zero-indexed element in the vector. In the absence of a trapping exception condition, the bit positions of all other elements in the first operand vector are unpredictable . If bit 0 is set to zero, the operation occurs on all elements in the vector.
- ***Reserved:*** Bits 1 to 3 are reserved and must be zero. Otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Invalid operation
- Overflow
- Underflow
- Inexact

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

Operand elements, including SNaNs and QNaNs, are examined without causing an IEEE exception.

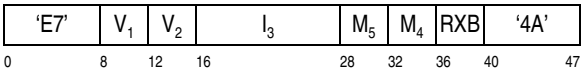
VECTOR FP TEST DATA CLASS IMMEDIATE

VFTCI V_1,V_2,I_3,M_4,M_5 [VRI-e]



The class and sign of the floating-point element or elements of the second operand are examined to select one bit from the third-operand. If the selected bit is set, all bit positions of the corresponding element in the first operand are set to ones, otherwise they are set to zero. The size of the operand elements is determined by the floating-point-format control in the M_4 field. The second operand elements are treated as BFP numbers.

The 12 bits of the third operand, bits 16-27 of the instruction text, are used to specify 12 combinations of BFP data class and sign.

As shown in Figure 24-35, BFP operand elements are divided into six classes: zero, normal number, subnormal number, infinity, quiet NaN, and signaling NaN.

BFP Element Class	Bit Used when Sign Is +	Bit Used when Sign Is -
Zero	0	1
Normal number	2	3
Subnormal number	4	5
Infinity	6	7
Quiet NaN	8	9
Signaling NaN	10	11

Figure 24-35. Third-Operand Bits for VECTOR FP TEST DATA CLASS

One or more of the third-operand bits may be set to one.

The M_4 field specifies the floating-point format. The floating-point format determines the size of the elements within the vector register operands. If a reserved value is specified, a specification exception is recognized. If the vector-enhancements facility 1 is not installed the values 2 and 4 are reserved.

M_4	Floating-Point Format
0-1	Reserved
2	Short format
3	Long format
4	Extended format
5-15	Reserved

The M_5 field has the following format:

The bits of the M_5 field are defined as follows:

- ***Single-Element-Control (S):*** If bit 0 is set to one, the operation takes place only on the zero-indexed element in the vector. The bit positions of all other elements in the first operand vector are unpredictable . If bit 0 is set to zero, the operation occurs on all elements in the vector.
- ***Reserved:*** Bits 1 to 3 are reserved and must be zero. Otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Selected bit is 1 for all elements (match)
1 Selected bit is 1 for at least one but not all elements (when S-bit is zero)
2 --
3 Selected bit is 0 for all elements (no match)

IEEE Exceptions: None.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Vector-Packed-Decimal Facility

The vector-packed-decimal facility provides instructions to operate on signed-packed-decimal format data in register operands. Decimal numbers and decimal instructions are introduced in Chapter 8, “Decimal Instructions.” The decimal-arithmetic instructions described in Chapter 8 operate on decimal data in storage operands. Since the delay between instructions encountered to ensure sequential order of operand accesses is likely less between register accesses than between storage accesses, a sequence of vector decimal instructions referencing operands in registers may achieve better performance than a comparable sequence of decimal instructions referencing operands in storage. Additionally, a program performing sign manipulation can use the force operand positive controls of the vector decimal-arithmetic instructions described in this chapter to reduce the program instruction count.

Vector Decimal Control

The vector decimal instructions described in this chapter are available to use when the vector-packed-decimal facility for z/Architecture is installed (which requires the vector facility for z/Architecture to also be installed), the vector enablement control (bit 46) in control register zero is one, and the AFP-register control (bit 45) in control register zero is one. If the vector-packed-decimal facility for z/Architecture is not installed and a vector decimal instruction is executed, then an operation exception is recognized. If the vector-packed-decimal facility for z/Architecture is installed, the vector enablement control (bit 46) in control register zero is zero, and a vector decimal instruction is executed, a data exception with DXC FE hex is recognized. When the vector-packed-decimal facility for z/Architecture is installed, and the AFP-register control (bit 45) in control register zero is zero, and a vector decimal instruction is executed, it is unpredictable whether a data exception is recognized.

Vector Decimal Registers

The vector-packed-decimal facility uses the same 32 vector registers as the vector facility. When a decimal operand occupies a vector register, the operand is in the signed-packed-decimal format and occupies all 16 bytes (31 digits and a sign), as illustrated in Figure 25-1 on page 25-2. Decimal numbers with fewer than 31 significant digits are right-aligned with

© Copyright IBM Corp. 2000, 2025

zeros supplied in the remaining leftmost digits. Several vector decimal-arithmetic instructions described in this chapter provide a result digits count (RDC) control to specify the number of rightmost digits of an operation to place in the result register.

The vector registers are used by the vector-packed-decimal facility to support decimal operand lengths up to 16 bytes. The vector-packed-decimal facility does not support multiple elements within a vector register for the purpose of parallel processing.

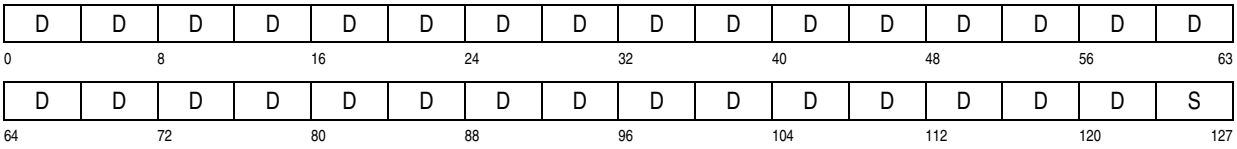

Figure 25-1. Signed-Packed-Decimal Format Number in Vector Registers

Decimal Digits and Signs

Decimal digits 0-9 have codes 0000-1001 binary.

The preferred positive sign has code 1100 binary (C hex). The preferred negative sign has code 1101 binary (D hex). The vector decimal-arithmetic instructions and VECTOR CONVERT TO DECIMAL instructions generate a preferred sign code when the force operand 1 positive control (P1) is zero and generate alternate positive sign code 1111 binary (F hex) when the P1 control is one. VECTOR LOAD IMMEDIATE generates a preferred sign code. The VECTOR PACK ZONED and VECTOR UNPACK ZONED instructions move the source sign to the result sign unchanged.

The vector decimal-arithmetic instructions provide the option to treat source sign codes as positive and ignore source sign codes during operation and validity checks. The force operand positive (P) controls enable this option.

The vector decimal-arithmetic instructions and VECTOR CONVERT TO DECIMAL instructions generate a positive sign when the resulting magnitude is zero. VECTOR LOAD IMMEDIATE can produce a zero magnitude with a negative sign code. The VECTOR PACK ZONED and VECTOR UNPACK ZONED instructions move the source sign to the result sign unchanged.

General-Operand Data Exception

The vector decimal instructions recognize general-operand data exceptions for invalid decimal codes as described in “General-Operand Data Exception” on page 8-5 which are subject to additional control fields in the instruction that can mask reporting. Decimal zone codes are never checked for validity in zone format. Decimal digit codes are always checked for validity unless a no validity (NV) control is enabled for the instruction. Decimal sign codes are checked for validity unless the corresponding force operand positive (P) control is enabled for the source operand (P1, P2, or P3, corresponding to operand 1, 2, and 3), or no validation (NV) control is enabled, or no sign validation (NSV) control is enabled for the instruction. If an invalid digit or sign code is detected and not masked by controls mentioned above, then a general-operand data exception is recognized.

Instructions

The vector decimal-arithmetic instructions perform addition, subtraction, multiplication, division, comparison and shifting. The set of vector decimal instructions includes the vector decimal-arithmetic instructions, VECTOR CONVERT TO BINARY, VECTOR CONVERT TO DECIMAL, VECTOR PACK ZONED, VECTOR UNPACK ZONED, VECTOR LOAD IMMEDIATE DECIMAL, and VECTOR TEST DECIMAL instructions.

Programming Notes:

1. The vector-packed-decimal-enhancement facility 1 provides the following enhancements:
   - Support for negative zero and digit code validity check for VECTOR PERFORM SIGN OPERATION DECIMAL (VPSOP).
   - Support on the following instructions to suppress a decimal overflow exception: VECTOR ADD DECIMAL (VAP), VECTOR

CONVERT TO BINARY (VCVB, VCVBG), VECTOR CONVERT TO DECIMAL (VCVD, VCVDG), VECTOR [SHIFT AND] DIVIDE DECIMAL (VDP, VSDP), VECTOR MULTIPLY [AND SHIFT] DECIMAL (VMSP, VMP), VECTOR REMAINDER DECIMAL (VRP), VECTOR SHIFT AND ROUND DECIMAL (VSRP), VECTOR SUBTRACT DECIMAL (VSP).

2. The vector-packed-decimal-enhancement facility 2 provides the following enhancements:
   - Support for conversion instructions between hexadecimal-floating-point format (HFP) and signed-packed-decimal format data in vector registers: DECIMAL SCALE AND CONVERT TO HFP (VSCHP), DECIMAL SCALE AND CONVERT AND SPLIT TO HFP (VSCSHP), and VECTOR CONVERT HFP TO SCALED DECIMAL (VCSPH).
   - Support for counting rightmost nibbles with VECTOR COUNT LEADING ZERO DIGITS (VCLZDP).
   - Support for converting between signed-packed-decimal format data in vector registers and zoned-packed-decimal format data in vector registers: VECTOR PACK ZONED REGISTER (VPKZR), VECTOR UNPACK ZONED HIGH (VUPKZH), and VECTOR UNPACK ZONED LOW (VUPKZL).
   - Support for signed-packed-decimal format data in vector register shifted and rounded: VECTOR SHIFT AND ROUND REGISTER (VSRPR).
3. The following instructions are available when the vector-packed-decimal-enhancement facility 3 is installed:
   - VECTOR CONVERT TO BINARY (VCVBQ)
   - VECTOR CONVERT TO DECIMAL (VCVDQ)
   - VECTOR TEST ZONED (VTZ)

Figure 25-2. Summary of Vector Decimal Instructions (Part 2 of 2)

DECIMAL SCALE AND CONVERT AND SPLIT TO HFP

VSCSHP V_1,V_2,V_3 [VRR-b]

The second operand is a signed-packed-decimal number and is scaled by the unsigned binary integer in byte element seven of the third operand and converted to a hexadecimal floating-point number. Byte element seven of the third operand is treated as an unsigned binary integer and must have a value less than 8 otherwise the result is unpredictable. The second operand is multiplied by the scale factor which is equal to 10 to the power of byte element seven of the third operand. Since the second operand is a signed-packed-decimal number, scaling by a power of 10 is equivalent to shifting the digits left. The intermediate result is converted and split to two hexadecimal floating-point operands, using normalization and truncation. The intermediate result is first normalized and truncated to hexadecimal floating-point short format, called the high result. Then the original intermediate result minus the short truncated result is normalized then truncated to hexadecimal long format. These two results are called the high and low result, respectively. If the low result is equal to zero, then it is forced to true zero.

The high and low results are placed into the first operand register. The high hexadecimal floating-point short format result is converted to hexadecimal long format by placing the high short result in the vector register bits 0 to 31 and bits 32 to 63 are set to zeros. The low result in hexadecimal floating-point long for-

mat is placed in bits 64 to 127 of the same vector register.

The sign of the high result is equal to the sign code of the second operand except when the second operand is a negative zero then the high result is set equal to a zero with a positive sign. The sign of the low result also equals the sign of the high result, except when the low result is forced to a true zero and the high result is non-zero and negative.

All digits and sign of the second operand are checked for validity. If the validity check fails, a general-operand data exception is recognized.

Overflow is not possible.

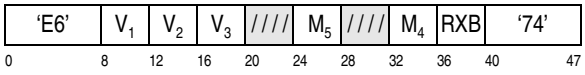
Resulting Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, vector instruction
- Data with DXC 00, general operand
- Operation (if the vector-packed-decimal-enhancement facility 2 is not installed)
- Transaction constraint

DECIMAL SCALE AND CONVERT TO HFP

VSCHP V_1,V_2,V_3,M_4,M_5 [VRR-b]



The second operand is a signed-packed-decimal number and is scaled by the unsigned binary integer in byte element seven of the third operand and converted to a hexadecimal floating-point number. Byte element seven of the third operand is limited to values less than 8 otherwise results are unpredictable. The second operand is multiplied by a scale factor equal to 10 to the power of byte element seven of the third operand. Since the second operand is a signed-packed-decimal number, scaling by a power of 10 is equivalent to shifting the digits left. The intermediate result is converted to hexadecimal floating-point format. The size of the first operand is selected by the floating-point-format control in the M_4 field. The normalized intermediate result is rounded using the rounding method specified in the M_5 field.

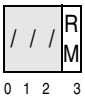
The sign of the result is equal to the sign code of the second operand except when the second operand is zero then the result is forced to be a positive true zero. A true zero is an HFP number with a zero characteristic and zero fraction.

All digits and sign of the second operand are checked for validity. If the validity check fails, a general-operand data exception is recognized.

The M_4 field specifies the hexadecimal floating-point format for operand one. If a reserved value of the M_4 field is specified, a specification exception is recognized.

M_4	Floating-Point Format
0-1	Reserved
2	Short format
3	Long format
4	Extended format
5-15	Reserved

The scaled and converted intermediate result is rounded by the rounding method as specified by the RM modifier in the M_5 field which has the following format:



The bits of the M_5 field are:

- ***Reserved:*** Bits 0-2 are ignored but should contain zeros; otherwise, the program may not operate compatibly in the future.
- ***Rounding Mode (RM):*** When bit 3 is zero, the normalized intermediate result is truncated to form the result. When bit 3 is one, the normalized intermediate result is rounded to nearest with ties away from zero. A normalized intermediate result consists of the 29, 15, or 7 most significant hexadecimal digits of the scaled and converted result for extended, long, and short format, respectively; which includes one guard digit on the right. A one is added to the leftmost bit of the guard digit of the intermediate result, any carry is propagated to the left, and the guard digit is dropped to produce the result fraction.

The result is placed in the entire vector register specified by the first operand, for all formats, placing the

result in the zero-indexed element in the vector and placing zeros in any other elements.

Overflow is not possible.

Resulting Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, vector instruction
- Data with DXC 00, general operand
- Operation (if the vector-packed-decimal-enhancement facility 2 is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

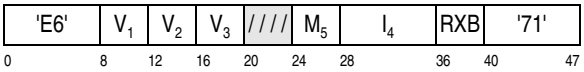
Extended Mnemonic		Base Mnemonic	
VSCHSP	V_1,V_2,V_3,M_5	VSCHP	$V_1,V_2,V_3,2,M_5$
VSCHDP	V_1,V_2,V_3,M_5	VSCHP	$V_1,V_2,V_3,3,M_5$
VSCHXP	V_1,V_2,V_3,M_5	VSCHP	$V_1,V_2,V_3,4,M_5$

Programming Notes:

1. Use of VR0-15 is recommended for short and long HFP formats since instructions in Chapter 18, "Hexadecimal-Floating-Point Instructions" only operate on FPRs which map to the leftmost 64 bits of these registers.
2. If this instruction is used to create HFP extended format result in a vector register, this format can be efficiently transformed into an FPR pair by using the VECTOR PERMUTE DOUBLEWORD IMMEDIATE instruction. This is needed if the result is to be subsequently utilized as extended input to HFP format instructions of Chapter 18, "Hexadecimal-Floating-Point Instructions."

VECTOR ADD DECIMAL

VAP V_1,V_2,V_3,I_4,M_5 [VRI-f]



The second operand is added to the third operand. The sign and specified number of rightmost digits of the sum are placed in the first operand location with other digits set to zero. The operands are in the signed-packed-decimal format.

The sign codes of the second and third operands may be modified for use in the add operation by the force operand two positive (P2) and force operand three positive (P3) controls respectively.

Addition is algebraic, taking into account the signs and all digits of the second and third operands.

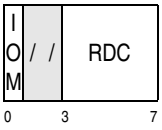
All digit codes are checked for validity. The sign codes are checked for validity unless overridden by the force operand two positive (P2) or force operand three positive (P3) controls.

If the result digits count (RDC) control does not specify enough digits to contain all leftmost nonzero digits of the sum, decimal overflow occurs. The operation is completed. The result is obtained by ignoring the overflow digits, and if the condition code set (CS) control is one, condition code 3 is set. If the decimal-overflow mask in the PSW is one and the instruction-overflow mask (IOM) is zero, a program interruption for decimal overflow occurs.

If the RDC control specifies less than thirty one digits, zeros are placed in the remaining leftmost digits of the first operand.

When the result, after the RDC control is applied, is nonzero and the force operand one positive (P1) control is zero, rules of algebra determine the sign of the result and a preferred sign code is used. When the result, after the RDC control is applied, is zero and the P1 control is zero, the sign of the result is made positive with preferred sign code 1100. When the P1 control is one, the sign of the result is made positive with sign code 1111.

The I_4 field has the following format:



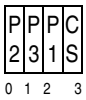
The bits of the I_4 field are defined as follows:

- ***Instruction-Overflow Mask (IOM):*** When the vector-packed-decimal-enhancement facility 1 is not installed, bit 0 is reserved and must contain zero; otherwise, a specification exception is rec-

ognized. When the vector-packed-decimal-enhancement facility 1 is installed, bit 0 is the instruction-overflow mask. When the instruction-overflow mask is one, recognition of a decimal overflow program interrupt is suppressed.

- ***Reserved:*** Bits 1-2 are reserved and must contain zeros. Otherwise, a specification exception is recognized.
- ***Result Digits Count (RDC):*** Bits 3-7 contain an unsigned binary number specifying the number of rightmost digits of the sum to be placed in the first operand. If the magnitude of the sum is larger than the largest decimal number that can be represented with the specified number of digits, decimal overflow occurs, and if the decimal-overflow mask is one, a program interruption for decimal overflow occurs. If the RDC field is zero, a specification exception is recognized.

The M_5 field has the following format:



The bits of the M_5 field are:

- ***Force Operand 2 Positive (P2):*** When bit 0 is one, the second operand sign is treated as a positive sign and is not checked for validity. When bit 0 is zero, the second operand sign is used in the operation and is checked for validity.
- ***Force Operand 3 Positive (P3):*** When bit 1 is one, the third operand sign is treated as a positive sign and is not checked for validity. When bit 1 is zero, the third operand sign is used in the operation and is checked for validity.
- ***Force Operand 1 Positive (P1):*** When bit 2 is one, the sign of the result placed in the first operand is forced to positive and a sign code of 1111 is used. When bit 2 is zero, the sign of the result placed in the first operand is the preferred sign code for the sign of the sum.
- ***Condition Code Set (CS):*** When bit 3 is zero, the condition code is not set and remains unchanged. When bit 3 is one, the condition code is set as specified in the resulting condition code section below.

Resulting Condition Code:

When the CS bit is one, the condition code is set as follows:

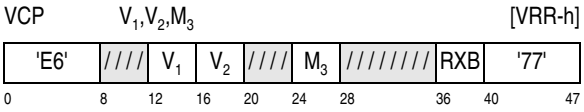
0 Result zero; no overflow
1 Result less than zero; no overflow
2 Result greater than zero; no overflow
3 Overflow

When the CS bit is zero, the condition code remains unchanged.

Program Exceptions:

- Data with DXC FE, vector instruction
- Data with DXC 00, general operand
- Decimal overflow
- Operation (if the vector-packed-decimal facility for z/Architecture is not installed)
- Specification
- Transaction constraint

VECTOR COMPARE DECIMAL



The first operand is compared with the second operand, and the result is indicated in the condition code. The operands are in the signed-packed-decimal format.

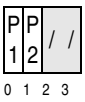
The sign codes of the first and second operands may be modified for use in the compare operation by the force operand one positive (P1) and force operand two positive (P2) controls respectively.

Comparison is algebraic and follows the procedure for decimal subtraction with operand two subtracted from operand one. When the difference is zero the operands are equal. When a nonzero difference is positive or negative, the first operand is high or low, respectively.

All digit codes are checked for validity. The sign codes are checked for validity unless overridden by the force operand one positive (P1) or force operand two positive (P2) controls.

Overflow cannot occur because the difference is discarded.

The M_3 field has the following format:



The bits of the M_3 field are defined as follows:

- ***Force Operand 1 Positive (P1):*** When bit 0 is one, the first operand sign is treated as a positive sign and is not checked for validity. When bit 0 is zero, the first operand sign is used in the operation and is checked for validity.
- ***Force Operand 2 Positive (P2):*** When bit 1 is one, the second operand sign is treated as a positive sign and is not checked for validity. When bit 1 is zero, the second operand sign is used in the operation and is checked for validity.
- ***Reserved:*** Bits 2-3 are ignored but should contain zeros; otherwise, the program may not operate compatibly in the future.

Resulting Condition Code:

The condition code is set as follows:

0 Operands equal
1 First operand low
2 First operand high
3 --

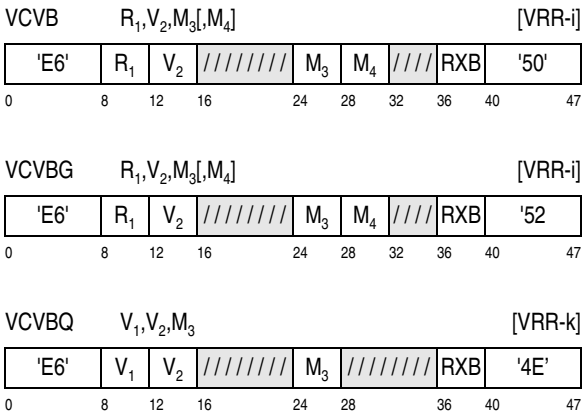
Program Exceptions:

- Data with DXC FE, vector instruction
- Data with DXC 00, general operand
- Operation (if the vector-packed-decimal facility for z/Architecture is not installed)
- Transaction constraint

Programming Notes:

1. The preferred and alternate sign codes for a particular sign are treated as equivalent for comparison purposes.
2. A negative zero and positive zero compare equal.

VECTOR CONVERT TO BINARY



The second operand is changed from decimal to binary, and the result is placed at the first-operand location. The second operand is in a vector register. For VECTOR CONVERT TO BINARY (VCVB and VCVBG), the first operand is in a general register. For VECTOR CONVERT TO BINARY (VCVBQ), the first operand is in a vector register.

The second operand has the format of signed-packed-decimal data. The sign of the second operand may be modified for use before conversion by the force operand 2 positive (P2) control or the logical binary (LB) control. All digit codes of the second operand are checked for validity. The sign code of the second operand is checked for validity unless overridden by the force operand 2 positive (P2) control.

For VECTOR CONVERT TO BINARY (VCVB), the following applies:

- When the LB control is zero, the result of the conversion is a 32-bit signed binary integer, which is placed in bit positions 32-63 of general register R_1. Bits 0-31 of general register R_1 remain unchanged. The maximum positive number that can be converted and still be contained in 32 bit positions is 2,147,483,647; the maximum negative number (the negative number with the greatest absolute value) that can be converted is -2,147,483,648.
- When the LB control is one, the second operand sign is treated as a positive sign, and the result of the conversion is a 32-bit unsigned binary integer, which is placed in bit positions 32-63 of general register R_1. Bits 0-31 of general register R_1 remain unchanged. The maximum number that

can be converted and still be contained in 32 bit positions is 4,294,967,295.

For VECTOR CONVERT TO BINARY (VCVBG), the following applies:

- When the LB control is zero, the result of the conversion is a 64-bit signed binary integer, which is placed in bit positions 0-63 of general register R_1. The maximum positive number that can be converted and still be contained in a 64-bit register is 9,223,372,036,854,775,807; the maximum negative number (the negative number with the greatest absolute value) that can be converted is -9,223,372,036,854,775,808.
- When the LB control is one, the second operand sign is treated as a positive sign, and the result of the conversion is a 64-bit unsigned binary integer, which is placed in bit positions 0-63 of general register R_1. The maximum positive number that can be converted and still be contained in a 64-bit register is 18,446,744,073,709,551,615.

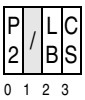
For VECTOR CONVERT TO BINARY (VCVBQ), the following applies:

- When the LB control is zero, the result of the conversion is a 128-bit signed binary integer, which is placed in bit positions 0-127 of vector register V_1.
- When the LB control is one, the second operand sign is treated as a positive sign, and the result of the conversion is a 128-bit unsigned binary integer, which is placed in bit positions 0-127 of vector register V_1.
- Every decimal number in the signed-packed-decimal format can be converted and contained in a 128-bit register. That is, overflow does not occur for VCVBQ.

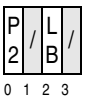
For any decimal number outside the maximum ranges (overflow case) defined for VCVB and VCVBG, the following occurs:

- When the vector-packed-decimal-enhancement facility 3 is not installed or the overflow-result control is zero, the rightmost 32 bits of the binary result are placed in bit positions 32-63 of general register R_1 for VCVB, and the rightmost 64 bits of the binary result are placed in bit positions 0-63 of general register R_1 for VCVBG.
- When the vector-packed-decimal-enhancement facility 3 is installed and the overflow-result control is one, zeros are placed in bit positions 32-63 of general register R_1 for VCVB, and zeros are placed in bit positions 0-63 of general register R_1 for VCVBG.
- Condition code three is optionally set depending on the value of the condition code set (CS) control.
- If the fixed-point-overflow mask is one and the instruction-overflow mask (IOM) is zero a program interruption for fixed-point overflow occurs.

For VECTOR CONVERT TO BINARY (VCVB and VCVBG), the M_3 field has the following format:



For VECTOR CONVERT TO BINARY (VCVBQ), the M_3 field has the following format:



The bits of the M_3 field are defined as follows:

- ***Force Operand 2 Positive (P2):*** When bit 0 is one, the second operand sign is treated as a positive sign and is not checked for validity. When bit 0 is zero, the second operand sign code is checked for validity, and is used in the operation if the LB control is zero.
- ***Reserved:*** Bit 1 is ignored but should contain zero; otherwise, the program may not operate compatibly in the future. For VCVBQ, bit 3 is also ignored but should contain zero; otherwise, the program may not operate compatibly in the future.
- ***Logical Binary (LB):*** When bit 2 is one, the first operand result is an unsigned binary integer, which is considered positive. When bit 2 is zero, the first operand result is a signed binary integer. When the LB control is one and the P2 control is zero, the sign code of the second operand is checked for validity but is treated as a positive sign code in the conversion.

- ***Condition Code Set (CS):*** For VCVB and VCVBG, when bit 3 is zero, the condition code is not set and remains unchanged. When bit 3 is one, the condition code is set as specified in the resulting condition code section below.

For VECTOR CONVERT TO BINARY (VCVB and VCVBG), the M_4 field has the following format:

The bits of the M_4 field are defined as follows:

- ***Instruction-Overflow Mask (IOM):*** When the vector-packed-decimal-enhancement facility 1 is not installed, bit 0 is reserved and should be zero; otherwise the program may not operate compatibly in the future. When the vector-packed-decimal-enhancement facility 1 is installed, bit 0 is the instruction-overflow mask. When the instruction-overflow mask is one, recognition of a fixed-point overflow program interrupt is suppressed.
- ***Overflow-Result Control (ORC):*** When the vector-packed-decimal-enhancement facility 3 is not installed, bit 1 is reserved and should be zero; otherwise the program may not operate compatibly in the future. When the vector-packed-decimal-enhancement facility 3 is installed, bit 1 is the overflow-result control. When overflow occurs and the overflow-result control is zero, the rightmost 32 bits of the binary result for VCVB, and the rightmost 64 bits of the binary result for VCVBG are placed in the appropriate bit positions of general register R_1. When overflow occurs and the overflow-result control is one, zeros are placed in the appropriate bit positions of general register R_1.
- ***Reserved:*** Bits 2-3 are ignored but should contain zeros; otherwise, the program may not operate compatibly in the future.

Resulting Condition Code:

For VCVB and VCVBG, when the CS bit is one, the condition code is set as follows:

0 No overflow
1 --
2 --
3 Overflow

For VCVB and VCVBG, when the CS bit is zero, the condition code remains unchanged.

For VCVBQ, the code remains unchanged.

Program Exceptions:

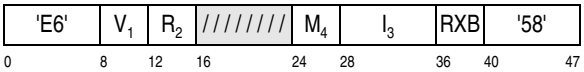
- Data with DXC FE, vector instruction
- Data with DXC 00, general operand
- Fixed-point overflow
- Operation (VCVB and VCVBG, if the vector-packed-decimal facility for z/Architecture is not installed; VCVBQ, if the vector-packed-decimal-enhancement facility 3 is not installed)
- Transaction constraint

Programming Notes:

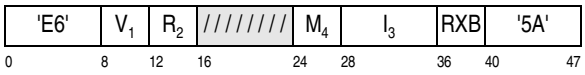
1. When the second operand is negative and the LB bit is zero, the result is in two's-complement notation.
2. VECTOR CONVERT TO BINARY (VCVB, VCVBG) differs from CONVERT TO BINARY (CVB, CVBY, CVBG) when the converted value is larger than the first operand can represent. For VECTOR CONVERT TO BINARY, in the overflow case, the operation is completed and results in a program interrupt for fixed-point-overflow if the fixed-point-overflow mask is one. For CONVERT TO BINARY, in the overflow case, the operation is suppressed and results in a program interrupt for fixed-point-divide.
3. For programs which do not examine the result placed in general register R_1 subsequent to overflow occurring, it is recommended the program set the overflow-result control to one. This can result in improved instruction performance on models which provide the vector-packed-decimal-enhancement facility 3.

VECTOR CONVERT TO DECIMAL

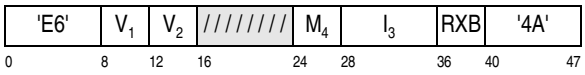
VCVD V_1,R_2,I_3,M_4 [VRI-i]



VCVDG V_1,R_2,I_3,M_4 [VRI-i]



VCVDQ V_1,V_2,I_3,M_4 [VRI-j]



The second operand is changed from binary to decimal, and the result is placed at the first-operand location. The first operand is in a vector register. For VECTOR CONVERT TO DECIMAL (VCVD and VCVDG), the second operand is in a general register. For VECTOR CONVERT TO DECIMAL (VCVDQ), the second operand is in a vector register.

For VECTOR CONVERT TO DECIMAL (VCVD), the second operand is treated as a 32-bit binary integer that is either signed or unsigned depending on the logical binary (LB) control. For VECTOR CONVERT TO DECIMAL (VCVDG), the second operand is treated as a 64-bit binary integer that is either signed or unsigned depending on the logical binary (LB) control. For VECTOR CONVERT TO DECIMAL (VCVDQ), the second operand is treated as a 128-bit binary integer that is either signed or unsigned depending on the logical binary (LB) control.

The result is in the format for signed-packed-decimal data, as described in Chapter 8, “Decimal Instructions.” The number of rightmost digits of the conversion, as specified by the result digits count (RDC) control, is placed in the first-operand location.

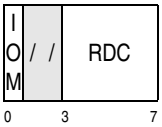
If the result digits count (RDC) control does not specify enough digits to contain all leftmost nonzero digits of the conversion, decimal overflow occurs. The operation is completed, the specified number of digits are placed in the first-operand location, and if the condition code set (CS) control is one, condition code 3 is set. If the decimal-overflow mask in the PSW is one and the instruction-overflow mask (IOM) is zero, a program interruption for decimal overflow occurs.

Note: For VECTOR CONVERT TO DECIMAL (VCVDQ), if the magnitude of the binary integer is greater than 9,999,999,999,999,999,999,999,999,999,999,999, then decimal overflow occurs, regardless of the value specified by the RDC control.

If the RDC control specifies less than thirty one digits, zeros are placed in the remaining leftmost digits of the first operand.

The rightmost four bits of the result represent the sign. When the result, after the RDC control is applied, is nonzero and the force operand one positive (P1) control is zero, the sign of the result is the preferred sign code corresponding to the sign of the second operand. When the result, after the RDC control is applied, is zero and the P1 control is zero, the sign of the result is made positive with preferred sign code 1100. When the P1 control is one, the sign of the result is made positive with sign code 1111.

The I_3 field has the following format:



The bits of the I_3 field are defined as follows:

- ***Instruction-Overflow Mask (IOM):*** When the vector-packed-decimal-enhancement facility 1 is not installed, bit 0 is reserved and must contain zero; otherwise, a specification exception is recognized. When the vector-packed-decimal-enhancement facility 1 is installed, bit 0 is the instruction-overflow mask. When the instruction-overflow mask is one, recognition of a decimal overflow program interrupt is suppressed.
- ***Reserved:*** Bits 1-2 are reserved and must contain zeros. Otherwise, a specification exception is recognized.
- ***Result Digits Count (RDC):*** Bits 3-7 contain an unsigned binary integer specifying the number of rightmost digits of the conversion to be placed in the first operand. If the magnitude of the conversion is larger than the largest decimal number that can be represented with the specified number of digits decimal overflow occurs, and if the decimal-overflow mask is one, a program interruption for decimal overflow occurs. If the RDC field is zero, a specification exception is recognized.

The M_4 field has the following format:

The bits of the M_4 field are defined as follows:

- ***Logical Binary (LB):*** When bit 0 is one, the second operand contains an unsigned binary integer. When bit 0 is zero, the second operand contains a signed binary integer.
- ***Reserved:*** Bit 1 is ignored but should contain zero; otherwise, the program may not operate compatibly in the future.
- ***Force Operand 1 Positive (P1):*** When bit 2 is one, the sign of the result placed in the first operand is forced to positive and a sign code of 1111 is used. When bit 2 is zero, the sign of the result placed in the first operand is the preferred sign code for the sign of the conversion.
- ***Condition Code Set (CS):*** When bit 3 is zero, the condition code is not set and remains unchanged. When bit 3 is one, the condition code is set as specified in the resulting condition code section below.

Resulting Condition Code:

When the CS bit is one, the condition code is set as follows:

0 No overflow
1 --
2 --
3 Overflow

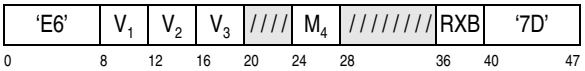
When the CS bit is zero, the condition code remains unchanged.

Program Exceptions:

- Data with DXC FE, vector instruction
- Decimal overflow
- Operation (VCVD and VCVDG, if the vector-packed-decimal facility for z/Architecture is not installed; VCVDQ, if the vector-packed-decimal-enhancement facility 3 is not installed)
- Specification
- Transaction constraint

VECTOR CONVERT HFP TO SCALED DECIMAL

VCSPH V_1,V_2,V_3,M_4 [VRR-j]



The second operand is an extended-precision hexadecimal floating-point number located in vector register V_2 and is converted to a binary coded decimal number and then scaled by the unsigned binary integer in byte element seven of the third operand and the intermediate result is rounded to a binary coded decimal integer. Byte element seven of the third operand is treated as unsigned binary integer and must be less than 32 otherwise the result is unpredictable. The second operand converted to decimal is multiplied by a scaling factor equal to 10 to the power of byte element seven of the third operand which is simply a shift operation. The intermediate result is then rounded to a decimal integer, using rounding mode specified by the M_4 field. The rightmost 31 decimal digits of integer are taken as the result and any overflow is ignored and the result is placed at the first-operand location.

The sign of the result is equal to the sign of the second operand even when the second operand is negative zero.

The converted and scaled intermediate result is rounded by the rounding method as specified by the modifier in the M_4 field. The M_4 field has the following format:

The bits of the M_4 field are:

- ***Reserved:*** Bits 0-2 are ignored but should contain zeros; otherwise, the program may not operate compatibly in the future.
- ***Rounding Mode (RM):*** When bit 3 is zero, the intermediate result is truncated to form the result. When bit 3 is one, the intermediate result is rounded to nearest with ties away from zero.

Resulting Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, vector instruction
- Operation (if the vector-packed-decimal-enhancement facility 2 is not installed)
- Transaction constraint

VECTOR COUNT LEADING ZERO DIGITS

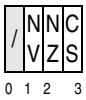
VCLZDP V_1,V_2,M_3 [VRR-k]

The number of leftmost zero digits in the second operand, which is in the signed-packed-decimal format, are counted and placed in byte seven of the first operand; all other bytes of the first operand are set to zero. A second operand with all zero digits and sign, results in a count of 31 digits which is the number of decimal digits in signed-packed-decimal format.

When the no-validation (NV) control is zero or the condition-code-set (CS) control is one, all digit and sign codes of the second operand are checked for validity. When the validity check fails, if the NV control is zero a general-operand data exception is recognized; otherwise, the condition code is set to three.

The interpretation of the sign of the second operand is a function of the negative zero (NZ) control and this affects the condition code.

The M_3 field has the following format:



The bits of the M_3 field are:

- ***Reserved:*** Bit 0 is ignored but should contain zero; otherwise, the program may not operate compatibly in the future.
- ***No Validation (NV):*** When bit 1 is zero, the second operand digits and sign are checked for validity. If the validity check fails, a general-operand data exception is recognized. When bit 1 is one, no general-operand data exception is reported, though validity checking may still be performed for condition code setting.
- ***Negative Zero (NZ):*** Bit 2 only applies when bit 3 is one. When bit 2 is zero, both positive and negative zero values result in condition code zero being set. When bit 2 is one, a positive zero results in condition code zero being set and a negative zero results in condition code one being set.
- ***Condition Code Set (CS):*** When bit 3 is zero, the condition code is not set and remains unchanged. When bit 3 is one, the condition code is set as specified in the resulting condition code section below.

Resulting Condition Code:

When the CS bit is one, the condition code is set as follows:

0 All digits and sign are valid and the source operand is equal to zero, except when NZ=1 and the sign is negative.
1 All digits and sign are valid and the source operand is negative, or when NZ=1 and the sign is negative and source operand is equal to zero.
2 All digits and sign are valid, the source operand is not equal to zero, and the sign is positive.
3 A digit or sign is invalid

When the CS bit is zero, the condition code remains unchanged.

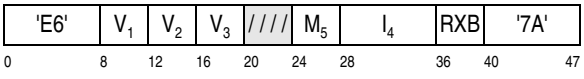
The operation is suppressed when a data exception is recognized.

Program Exceptions:

- Data with DXC FE, vector instruction
- Data with DXC 00, general operand
- Operation (if the vector-packed-decimal-enhancement facility 2 is not installed)
- Transaction constraint

VECTOR DIVIDE DECIMAL

VDP V_1,V_2,V_3,I_4,M_5 [VRI-f]



The second operand (the dividend) is divided by the third operand (the divisor). The sign and specified number of rightmost digits of the quotient are placed in the first-operand location with other digits set to zero. The operands and result are in the signed-packed-decimal format.

The sign codes of the second and third operands may be modified for use in the operation by the force operand two positive (P2) and force operand three positive (P3) controls respectively.

All digit codes are checked for validity. The sign codes are checked for validity unless overridden by the force operand two positive (P2) or force operand three positive (P3) controls.

When the result, after the result digits count (RDC) control is applied, is nonzero and the force operand one positive (P1) control is zero, rules of algebra determine the sign of the result and a preferred sign code is used. When the result, after the RDC control is applied, is zero and the P1 control is zero, the sign of the result is made positive with preferred sign code 1100. When the P1 control is one, the sign of the result is made positive with sign code 1111.

If the divisor is zero and the divisor sign code used is valid, a decimal-divide exception is recognized. This includes the case of division of zero by zero. The divisor sign code used is the third operand sign code when the force operand 3 positive (P3) bit is zero, and is a positive sign code when the force operand 3 positive (P3) bit is one.

If the RDC control does not specify enough digits to contain all leftmost nonzero digits of the quotient, decimal overflow occurs. The operation is completed. The result is obtained by ignoring the overflow digits, and if the condition code set (CS) control is one, condition code 3 is set. If the decimal-overflow mask in the PSW is one and the instruction-overflow mask (IOM) is zero, a program interruption for decimal overflow occurs.

If the RDC control specifies less than thirty one digits, zeros are placed in the remaining leftmost digits of the first operand.

The I_4 field has the following format:

The bits of the I_4 field are defined as follows:

- ***Instruction-Overflow Mask (IOM):*** When the vector-packed-decimal-enhancement facility 1 is not installed, bit 0 is reserved and must contain zero; otherwise, a specification exception is recognized. When the vector-packed-decimal-enhancement facility 1 is installed, bit 0 is the instruction-overflow mask. When the instruction-overflow mask is one, recognition of a decimal overflow program interrupt is suppressed.
- ***Reserved:*** Bits 1-2 are reserved and must contain zeros. Otherwise, a specification exception is recognized.
- ***Result Digits Count (RDC):*** Bits 3-7 contain an unsigned binary number specifying the number of rightmost digits of the quotient to be placed in the first operand. If the magnitude of the quotient is larger than the largest decimal number that can be represented with the specified number of digits, decimal overflow occurs, and if the decimal-overflow mask is one, a program interruption for decimal overflow occurs. If the RDC field is zero, a specification exception is recognized.

The M_5 field has the following format:

The bits of the M_5 field are:

- ***Force Operand 2 Positive (P2):*** When bit 0 is one, the second operand sign is treated as a positive sign and is not checked for validity. When bit 0 is zero, the second operand sign is used in the operation and is checked for validity.
- ***Force Operand 3 Positive (P3):*** When bit 1 is one, the third operand sign is treated as a positive sign and is not checked for validity. When bit 1 is zero, the third operand sign is used in the operation and is checked for validity.

- ***Force Operand 1 Positive (P1):*** When bit 2 is one, the sign of the result placed in the first operand is forced to positive and a sign code of 1111 is used. When bit 2 is zero, the sign of the result placed in the first operand is the preferred sign code for the sign of the quotient.
- ***Condition Code Set (CS):*** When bit 3 is zero, the condition code is not set and remains unchanged. When bit 3 is one, the condition code is set as specified in the resulting condition code section below.

Resulting Condition Code:

When the CS bit is one, the condition code is set as follows:

0 Result zero; no overflow
1 Result less than zero; no overflow
2 Result greater than zero; no overflow
3 Overflow

When the CS bit is zero, the condition code remains unchanged.

Program Exceptions:

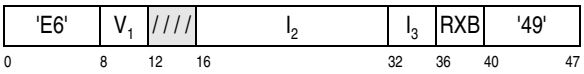
- Data with DXC FE, vector instruction
- Data with DXC 00, general operand
- Decimal divide
- Decimal overflow
- Operation (if the vector-packed-decimal facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. Unlike DIVIDE DECIMAL, VECTOR DIVIDE DECIMAL will recognize a decimal-overflow exception instead of a decimal-divide exception if the first operand is too short to contain all of the quotient digits.
2. VECTOR DIVIDE DECIMAL may recognize a decimal-divide exception when the divisor is zero, depending on the divisor sign code used, unlike DIVIDE DECIMAL, which may recognize a decimal-divide exception when the divisor is zero, depending on all sign and digit codes of both divisor and dividend. Also note, if the divisor is zero, all divisor digits are valid.

VECTOR LOAD IMMEDIATE DECIMAL

VLIP V_1,I_2,I_3 [VRI-h]



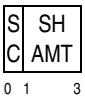
The four decimal digits of the second operand, shifted left by the specified number of digits, and concatenated on the right with the specified sign form a signed-packed-decimal format number placed at the first-operand location.

The four digit second operand is shifted left the number of digit positions specified by the shift amount (SHAMT) control. Zeros are supplied for vacated digit positions. The shifted value is placed in the magnitude of the signed-packed-decimal format first operand. Zeros are placed in the remaining leftmost digits of the first operand.

The sign code of the result placed at the first-operand is determined by the sign control (SC) bit.

All digits of the second operand are checked for validity.

The I_3 field has the following format:



The bits of the I_3 field are:

- ***Sign Control (SC):*** When bit 0 is zero, the result is positive with a sign code of 1100. When bit 0 is one, the result is negative with a sign code of 1101.
- ***Shift Amount (SHAMT):*** Bits 1-3 specify a three bit unsigned binary number specifying the number of digits to shift the second operand left.

Condition Code: The code remains unchanged.

Program Exceptions:

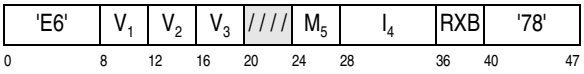
- Data with DXC FE, vector instruction
- Data with DXC 00, general operand

- Operation (if the vector-packed-decimal facility for z/Architecture is not installed)
- Transaction constraint

Programming Note: VECTOR LOAD IMMEDIATE DECIMAL can produce a negative zero, a zero value with a negative sign, which is a valid operand.

VECTOR MULTIPLY DECIMAL

VMP V_1,V_2,V_3,I_4,M_5 [VRI-f]



The second operand (the multiplicand) is multiplied by the third operand (the multiplier). The sign and specified number of rightmost digits of the product are placed in the first-operand location with other digits set to zero. The operands and result are in the signed-packed-decimal format.

The sign codes of the second and third operands may be modified for use in the operation by the force operand two positive (P2) and force operand three positive (P3) controls respectively.

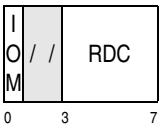
All digit codes are checked for validity. The sign codes are checked for validity unless overridden by the force operand two positive (P2) or force operand three positive (P3) controls.

When the result, after the result digits count (RDC) control is applied, is nonzero and the force operand one positive (P1) control is zero, rules of algebra from the multiplier and multiplicand signs determine the sign of the result and a preferred sign code is used. When the result, after the RDC control is applied, is zero and the P1 control is zero, the sign of the result is made positive with preferred sign code 1100. When the P1 control is one, the sign of the result is made positive with sign code 1111.

If the RDC control does not specify enough digits to contain all leftmost nonzero digits of the product, decimal overflow occurs. The operation is completed. The result is obtained by ignoring the overflow digits, and if the condition code set (CS) flag is one, condition code 3 is set. If the decimal-overflow mask in the PSW is one and the instruction-overflow mask (IOM) is zero, a program interruption for decimal overflow occurs.

If the RDC control specifies less than thirty one digits, zeros are placed in the remaining leftmost digits of the first operand.

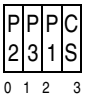
The I_4 field has the following format



The bits of the I_4 field are defined as follows:

- ***Instruction-Overflow Mask (IOM):*** When the vector-packed-decimal-enhancement facility 1 is not installed, bit 0 is reserved and must contain zero; otherwise, a specification exception is recognized. When the vector-packed-decimal-enhancement facility 1 is installed, bit 0 is the instruction-overflow mask. When the instruction-overflow mask is one, recognition of a decimal overflow program interrupt is suppressed.
- ***Reserved:*** Bits 1-2 are reserved and must contain zeros. Otherwise, a specification exception is recognized.
- ***Result Digits Count (RDC):*** Bits 3-7 contain an unsigned binary number specifying the number of rightmost digits of the product to be placed in the first operand. If the magnitude of the product is larger than the largest decimal number that can be represented with the specified number of digits, decimal overflow occurs, and if the decimal-overflow mask is one, a program interruption for decimal overflow occurs. If the RDC field is zero, a specification exception is recognized.

The M_5 field has the following format:



The bits of the M_5 field are:

- ***Force Operand 2 Positive (P2):*** When bit 0 is one, the second operand sign is treated as a positive sign and is not checked for validity. When bit 0 is zero, the second operand sign is used in the operation and is checked for validity.
- ***Force Operand 3 Positive (P3):*** When bit 1 is one, the third operand sign is treated as a posi-

tive sign and is not checked for validity. When bit 1 is zero, the third operand sign is used in the operation and is checked for validity.

- ***Force Operand 1 Positive (P1):*** When bit 2 is one, the sign of the result placed in the first operand is forced to positive and a sign code of 1111 is used. When bit 2 is zero, the sign of the result placed in the first operand is the preferred sign code for the sign of the product.
- ***Condition Code Set (CS):*** When bit 3 is zero, the condition code is not set and remains unchanged. When bit 3 is one, the condition code is set as specified in the resulting condition code section below.

Resulting Condition Code:

When the CS bit is one, the condition code is set as follows:

0 Result zero; no overflow
1 Result less than zero; no overflow
2 Result greater than zero; no overflow
3 Overflow

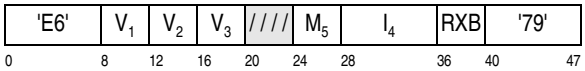
When the CS bit is zero, the condition code remains unchanged.

Program Exceptions:

- Data with DXC FE, vector instruction
- Data with DXC 00, general operand
- Decimal overflow
- Operation (if the vector-packed-decimal facility for z/Architecture is not installed)
- Specification
- Transaction constraint

VECTOR MULTIPLY AND SHIFT DECIMAL

VMSP V_1,V_2,V_3,I_4,M_5 [VRI-f]



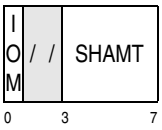
The product of the second operand (the multiplicand) and the third operand (the multiplier) is shifted right by the number of digits specified in the fourth operand and is placed at the first-operand location. The operands and result are in the signed-packed-decimal format.

The sign codes of the second and third operands may be modified for use in the operation by the force operand two positive (P2) and force operand three positive (P3) controls respectively.

All digit codes are checked for validity, including digits with no effect on the result due to the shift amount. The sign codes are checked for validity unless overridden by the force operand two positive (P2) or force operand three positive (P3) controls.

When the result, after being shifted, is nonzero and the force operand one positive (P1) control is zero, rules of algebra from the multiplier and multiplicand signs determine the sign of the result and a preferred sign code is used. When the result, after being shifted, is zero and the P1 control is zero, the sign of the result is made positive with preferred sign code 1100. When the P1 control is one, the sign of the result is made positive with sign code 1111.

The I_4 field has the following format:

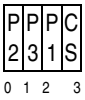


The bits of the I_4 field are defined as follows:

- ***Instruction-Overflow Mask (IOM):*** When the vector-packed-decimal-enhancement facility 1 is not installed, bit 0 is reserved and must contain zero; otherwise, a specification exception is recognized. When the vector-packed-decimal-enhancement facility 1 is installed, bit 0 is the instruction-overflow mask. When the instruction-overflow mask is one, recognition of a decimal overflow program interrupt is suppressed.
- ***Reserved:*** Bits 1-2 are reserved and must contain zeros. Otherwise, a specification exception is recognized.
- ***Shift Amount (SHAMT):*** Bits 3-7 contain an unsigned binary number specifying the number of digits the product is shifted right before the rightmost thirty one digits are placed in the first operand. The sign position does not participate in the shift.

If the first operand does not contain all leftmost non-zero digits of the shifted product, decimal overflow occurs. The operation is completed. Condition code 3 is set if the Condition Code Set (CS) bit is one. If the decimal-overflow mask in the PSW is one and the instruction-overflow mask (IOM) is zero, a program interrupt for decimal overflow occurs.

The M_5 field has the following format:



The bits of the M_5 field are:

- ***Force Operand 2 Positive (P2):*** When bit 0 is one, the second operand sign is treated as a positive sign and is not checked for validity. When bit 0 is zero, the second operand sign is used in the operation and is checked for validity.
- ***Force Operand 3 Positive (P3):*** When bit 1 is one, the third operand sign is treated as a positive sign and is not checked for validity. When bit 1 is zero, the third operand sign is used in the operation and is checked for validity.
- ***Force Operand 1 Positive (P1):*** When bit 2 is one, the sign of the result placed in the first operand is forced to positive and a sign code of 1111 is used. When bit 2 is zero, the sign of the result placed in the first operand is the preferred sign code for the sign of the product.
- ***Condition Code Set (CS):*** When bit 3 is zero, the condition code is not set and remains unchanged. When bit 3 is one, the condition code is set as specified in the resulting condition code section below.

Resulting Condition Code:

When the CS bit is one, the condition code is set as follows:

0 Result zero; no overflow
1 Result less than zero; no overflow
2 Result greater than zero; no overflow
3 Overflow

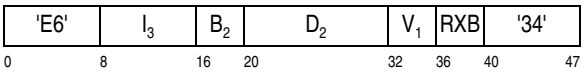
When the CS bit is zero, the condition code remains unchanged.

Program Exceptions:

- Data with DXC FE, vector instruction
- Data with DXC 00, general operand
- Decimal overflow
- Operation (if the vector-packed-decimal facility for z/Architecture is not installed)
- Specification
- Transaction constraint

VECTOR PACK ZONED

VPKZ $V_1,D_2(B_2),I_3$ [VSI]

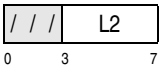


The format of the second operand is changed from the zoned format to the signed-packed-decimal format and placed in the first operand. The zoned and signed-packed-decimal formats are described in Chapter 8, “Decimal Instructions.”

The second operand is treated as having the zoned format. The numeric bits of each byte are treated as a digit. The zone bits are ignored, except the zone bits in the rightmost byte, which are treated as a sign.

The sign and digits are moved unchanged to the first operand and are not checked for valid codes. The sign is placed in the rightmost four bit positions of the first operand, and the digits are placed adjacent to the sign and to each other in the remainder of the result field. The number of bytes the second operand occupies in storage is specified by the operand 2 length code (L2) control. When necessary, the second operand is considered to be extended on the left with zeros.

The I_3 field has the following format:



The bits of the I_3 field are defined as follows:

- ***Reserved:*** Bits 0-2 are reserved and must contain zeros. Otherwise, a specification exception is recognized.
- ***Operand 2 Length Code (L2):*** Bits 3-7 contain the length code of the second-operand. The length of the second-operand is 1-31 bytes, cor-

responding to a length code in L2 of 0-30. The second-operand length must not exceed 31 bytes (L2 must be less than or equal to 30); otherwise, a specification exception is recognized.

Special Conditions:

If the L2 field is larger than 30 a specification exception is recognized.

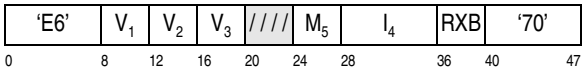
Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Data with DXC FE, vector instruction
- Operation (if the vector-packed-decimal facility for z/Architecture is not installed)
- Specification
- Transaction constraint

VECTOR PACK ZONED REGISTER

VPKZR V_1,V_2,V_3,I_4,M_5 [VRI-f]



An intermediate source vector is formed from the concatenation of the second operand followed by the third operand to form a 32-byte zoned-decimal number with 32 digits and sign, which is converted to signed-packed-decimal format which has 31 digits and a sign and placed in the first-operand location.

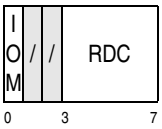
All digit codes of the source vector are checked for validity to determine if there is a general-operand data exception unless no validation (NV) control is one. The sign code of the source vector is checked for validity to determine if there is a general-operand data exception unless the no sign validation (NSV) control is one or the no validation (NV) control is one. See Figure 25-2 for details. The zone digits are not checked for validity and the intermediate source vector only has one sign digit located in the zone field of the rightmost byte.

The condition code setting (CS) control is independent of the control of general-operand data exception, and when equal to one, all digit and the sign code of the source vector are checked for validity to determine the condition code setting.

The determination of general-operand data exception is prior to decimal overflow detection and has precedence over it.

If the RDC control specifies less than thirty one digits, zeros are placed in the remaining leftmost digits of the first operand. Decimal overflow occurs if either the leftmost digit of the source vector is non-zero, or if the RDC field specifies less digits than the source vector contains. Decimal overflow is suppressed when either the decimal-overflow mask is a zero or the IOM field in the fourth operand is a one.

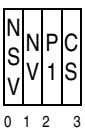
The I_4 field has the following format:



The bits of the I_4 field are defined as follows:

- ***Instruction Overflow Mask (IOM):*** Bit 0 is the instruction-overflow mask. When the instruction-overflow mask is one, or when the decimal-overflow mask (PSW bit 21) is zero, decimal-overflow exception is suppressed.
- ***Reserved:*** Bits 1-2 are reserved and must contain zeros. Otherwise, a specification exception is recognized.
- ***Result Digits Count (RDC):*** Bits 3-7 contain an unsigned binary number specifying the number of rightmost digits of the source vector to be placed in the first operand. If the magnitude of the source vector is larger than the largest decimal number that can be represented with the specified number of digits, decimal overflow occurs, and if the decimal-overflow mask (PSW bit 21) is one and IOM is zero a program interruption for decimal overflow occurs. If the RDC field is zero, a specification exception is reported

The M_5 field has the following format:



The bits of the M_5 field are:

- ***No Sign Validation (NSV):*** When bit 0 is zero and the NV control bit is zero, the source vector sign code is checked for validity to determine if there is a general-operand data exception. When bit 0 is one, or the NV control bit is one, the source vector sign code is only checked for validity for setting the condition code.
- ***No Validation (NV):*** When bit 1 is zero, the source vector digits are checked for validity for general-operand data exceptions; if the NSV control bit is zero, then the source vector sign code is also checked for validity. When bit 1 is one, then the source vector digits and sign code validities are only used for condition code setting and general-operand data exception is not reported.
- ***Force Operand 1 Positive (P1):*** When bit 2 is one, the sign of the result placed in the first operand is forced to positive and a sign code of 1111 binary is used. When bit 2 is zero, the sign of the result placed in the first operand maintains the sign code from the source vector.
- ***Condition Code Set (CS):*** When bit 3 is zero, the condition code is not set and remains unchanged. When bit 3 is one, the condition code is set as specified in the resulting condition code section below.

The following table shows the combination NV, NSV and CS fields and whether the sign of digits are checked for a general-operand data exception (GDE), which is independent of the value of P1, and whether condition code is set based on validity:

NV	NSV	CS	Sign Check for GDE	Digit Check for GDE	Condition Code Set
0	0	0	yes	yes	no
0	0	1	yes	yes	yes
0	1	0	no	yes	no
0	1	1	no	yes	yes
1	0	0	no	no	no
1	0	1	no	no	yes
1	1	0	no	no	no
1	1	1	no	no	yes

Figure 25-3. Sign and Digit Checking

If NV or NSV are equal to one, the sign code is not checked for validity and an invalid sign code of the source operand is propagated to the result if P1 is zero.

Resulting Condition Code:

When the CS bit is one, the condition code is set as follows:

0 The result is equal to zero and all digits and sign are valid, and no overflow.
1 The result is not equal to zero and the sign is negative and all digits and sign are valid, and no overflow.
2 The result is not equal to zero and the sign is positive and all digits and sign are valid, and no overflow.
3 Overflow or invalid digits or invalid sign.

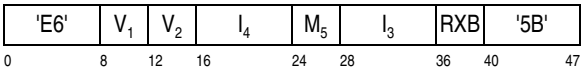
When the CS bit is zero, the condition code remains unchanged.

Program Exceptions:

- Data with DXC FE, vector instruction
- Data with DXC 00, general operand
- Decimal Overflow
- Operation (if the vector-packed-decimal-enhancement facility 2 is not installed)
- Specification
- Transaction constraint

VECTOR PERFORM SIGN OPERATION DECIMAL

VPSOP V_1,V_2,I_3,I_4,M_5 [VRI-g]



The modified sign and specified number of rightmost digits of the second operand are placed in the first operand location with other digits set to zero. The second operand and result are in the signed-packed-decimal format.

All digit codes of the second operand are checked for validity, unless the operand 2 no validation (NV) control is one. The sign code of the second operand is checked for validity based on the SO control, the operand 2 sign validation (SV) control, and the operand 2 no validation (NV) control, as specified in Figure 25-4.

The result sign code is a function of the SO control, the second operand sign, the second operand digits, the result digits count (RDC) control, the preserve sign (PS) control, the positive sign code (PC) control, and the negative zero (NZ) control, as specified in Figure 25-4.

Sign Operation (SO)	Result Magnitude (after RDC applied)	V_2 Sign	Preserve Sign (PS)	Positive Sign Code (PC)	Negative Zero (NZ)	V_2 Sign Code Validity Check	V_2 Digit Code Validity Check perform if...	Result Sign Code (hex)	CC[d]
00 (maintain)	nonzero[a]	positive	0	0	–	NV=0	NV=0	C positive	2
00 (maintain)	nonzero[a]	positive	0	1	–	NV=0	NV=0	F positive	2
00 (maintain)	nonzero[a]	negative	0	–	–	NV=0	NV=0	D negative	1
00 (maintain)	nonzero[a]	invalid[b]	0	–	–	NV=0	NV=0	2nd operand sign	2
00 (maintain)	zero[a]	positive	0	0	–	NV=0	NV=0	C positive	0
00 (maintain)	zero[a]	positive	0	1	–	NV=0	NV=0	F positive	0
00 (maintain)	zero[a]	negative	0	0	0	NV=0	NV=0	C positive	0
00 (maintain)	zero[a]	negative	0	1	0	NV=0	NV=0	F positive	0
00 (maintain)	zero[a]	negative	0	–	1	NV=0	NV=0	D negative	0
00 (maintain)	zero[a]	invalid[b]	0	–	–	NV=0	NV=0	2nd operand sign	0
00 (maintain)	nonzero[a]	positive	1	–	–	NV=0	NV=0	2nd operand sign	2
00 (maintain)	nonzero[a]	negative	1	–	–	NV=0	NV=0	2nd operand sign	1
00 (maintain)	nonzero[a]	invalid[b]	1	–	–	NV=0	NV=0	2nd operand sign	2
00 (maintain)	zero[a]	–	1	–	–	NV=0	NV=0	2nd operand sign	0
01 (complement)	nonzero[a]	positive	–	–	–	always	NV=0	D negative	1
01 (complement)	nonzero[a]	negative	–	0	–	always	NV=0	C positive	2
01 (complement)	nonzero[a]	negative	–	1	–	always	NV=0	F positive	2
01 (complement)	–	invalid[b]	–	–	–	always	NV=0	–[c]	–[c]
01 (complement)	zero[a]	positive	–	0	0	always	NV=0	C positive	0
01 (complement)	zero[a]	positive	–	1	0	always	NV=0	F positive	0
01 (complement)	zero[a]	positive	–	–	1	always	NV=0	D negative	0
01 (complement)	zero[a]	negative	–	0	–	always	NV=0	C positive	0
01 (complement)	zero[a]	negative	–	1	–	always	NV=0	F positive	0
10 (force positive)	nonzero[a]	–	–	0	–	SV=1	NV=0	C positive	2
10 (force positive)	nonzero[a]	–	–	1	–	SV=1	NV=0	F positive	2
10 (force positive)	zero[a]	–	–	0	–	SV=1	NV=0	C positive	0
10 (force positive)	zero[a]	–	–	1	–	SV=1	NV=0	F positive	0
11 (force negative)	nonzero[a]	–	–	–	–	SV=1	NV=0	D negative	1
11 (force negative)	zero[a]	–	–	0	0	SV=1	NV=0	C positive	0
11 (force negative)	zero[a]	–	–	1	0	SV=1	NV=0	F positive	0
11 (force negative)	zero[a]	–	–	–	1	SV=1	NV=0	D negative	0

Explanation:

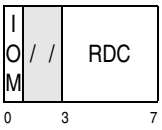
–	Results do not depend on this value
a	A result magnitude is considered nonzero if any bits of the result are nonzero
b	Sign codes 0-9 are considered invalid
c	Produces a suppressing data exception
CC	Resulting condition code when CS is one
d	Table is showing the condition code for the non-overflow case. Overflow case will deliver a CC3.

Figure 25-4. Operation of VECTOR PERFORM SIGN OPERATION DECIMAL

If the RDC control does not specify enough digits to contain all leftmost nonzero digits of the second operand, decimal overflow occurs. The operation is completed. The result is obtained by ignoring the overflow digits, and if the condition code set (CS) flag is one, condition code 3 is set. If the decimal-overflow mask in the PSW is one and the instruction-overflow mask (IOM) is zero, a program interruption for decimal overflow occurs.

If the RDC control specifies less than thirty one digits, zeros are placed in the remaining leftmost digits of the first operand.

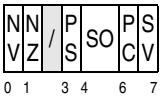
The I_3 field has the following format:



The bits of the I_3 field are defined as follows:

- ***Instruction-Overflow Mask (IOM):*** When the vector-packed-decimal-enhancement facility 1 is not installed, bit 0 is reserved and must contain zero; otherwise, a specification exception is recognized. When the vector-packed-decimal-enhancement facility 1 is installed, bit 0 is the instruction-overflow mask. When the instruction-overflow mask is one, recognition of a decimal overflow program interrupt is suppressed.
- ***Reserved:*** Bits 1-2 are reserved and must contain zeros. Otherwise, a specification exception is recognized.
- ***Result Digits Count (RDC):*** Bits 3-7 contain an unsigned binary integer specifying the number of rightmost digits of the second operand to be placed in the first operand. If the magnitude of the second operand is larger than the largest decimal number that can be represented with the specified number of digits, decimal overflow occurs, and if the decimal-overflow mask is one, a program interruption for decimal overflow occurs. If the RDC field is zero, a specification exception is recognized.

The I_4 field has the following format:

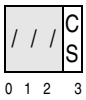


The bits of the I_4 field are defined as follows:

- ***No Validation (NV):*** When bit 0 is zero or the vector-packed-decimal-enhancement facility 1 is not installed, the second operand digits are checked for validity; if the SO control specifies maintain sign, then the second operand sign code is also checked for validity. Sign code validity is always checked when the SO control specifies complement sign and dependent on SV control if the SO control specifies force positive or force negative. If the validity check fails, a data exception is recognized. If bit 0 is one and the vector-packed-decimal-enhancement facility 1 is installed, then the second operand digits are not checked for validity; and if the SO control specifies maintain sign, then the second operand sign code is also not checked.
- ***Negative Zero (NZ):*** When the vector-packed-decimal-enhancement facility 1 is installed and bit 1 is one, the program specifies a negative-zero result is permitted; otherwise the sign for a zero result will be positive. When the magnitude of the result is zero, the result sign is a function of the sign code of the second operand, the SO, PC, NZ, and PS controls, as specified in Figure 25-4 on page 25-21.
- ***Reserved:*** Bit 2 is ignored but should contain zeros; otherwise, the program may not operate compatibly in the future.
- ***Preserve Sign (PS):*** When the vector-packed-decimal-enhancement facility 3 is installed, the operation specified by the SO control is maintain, and bit 3 is one, the sign code of the second operand is placed unmodified into the sign position of the first operand, regardless of the values specified in the PC and NZ controls. When the vector-packed-decimal-enhancement facility 3 is not installed, the value in the SO field is nonzero, or bit 3 is zero, the sign code placed in the first operand is a function of the sign code of the second operand, result magnitude, SO, PC, and NZ controls.
- ***Sign Operation (SO):*** Bits 4-5 specify the sign operation used in determining the result sign code. The result sign code is a function of the SO control, the second operand sign, the second operand digits, the RDC control, the PC, NZ, and PS bits, as specified in Figure 25-4.
- ***Positive Sign Code (PC):*** Bit 6 applies when the result sign is generated by means other than directly placing the sign code of the second operand into the result. That is, bit 6 applies when SO is nonzero or when PS is zero and the sign code of the second operand is valid. When bit 6 applies and is one, sign code 1111 is used for a positive result. When bit 6 applies and is zero, sign code 1100 is used for a positive result.

- ***Operand 2 Sign Validation (SV):*** If bit 7 is one and the SO control specifies force positive or force negative, then the second operand sign code is checked for validity. If bit 7 is zero and the SO control specifies force positive or force negative, then the second operand sign code is not checked for validity. When the SO control specifies maintain or complement sign, the second operand sign code is checked for validity, based on the NV bit value. If the validity check fails, a data exception is recognized.

The M_5 field has the following format:



The bits of the M_5 field are:

- ***Reserved:*** Bits 0-2 are ignored but should contain zeros; otherwise, the program may not operate compatibly in the future.
- ***Condition Code Set (CS):*** When bit 3 is zero, the condition code is not set and remains unchanged. When bit 3 is one, the condition code is set as specified in the resulting condition code section below.

Resulting Condition Code:

When the CS bit is one, the condition code is set as follows:

0 Result zero; no overflow
1 Result less than zero; no overflow
2 Result greater than zero, or nonzero result and invalid sign code; no overflow
3 Overflow

When the CS bit is zero, the condition code remains unchanged.

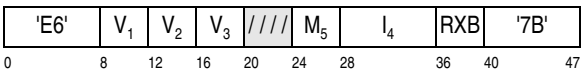
Program Exceptions:

- Data with DXC FE, vector instruction
- Data with DXC 00, general operand
- Decimal overflow
- Operation (if the vector-packed-decimal facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Programming Note: When there is no overflow, the CS bit is one, and the result is zero after applying the RDC, condition code 0 is set, regardless of the result sign code.

VECTOR REMAINDER DECIMAL

VRP V_1,V_2,V_3,I_4,M_5 [VRI-f]



The second operand (the dividend) is divided by the third operand (the divisor). The sign and specified number of rightmost digits of the remainder are placed in the first-operand location with other digits set to zero. The operands and result are in the signed-packed-decimal format.

The sign codes of the second and third operands may be modified for use in the operation by the force operand two positive (P2) and force operand three positive (P3) controls respectively.

All digit codes are checked for validity. The sign codes are checked for validity unless overridden by the force operand two positive (P2) or force operand three positive (P3) controls.

When the result, after the result digits count (RDC) control is applied, is nonzero and the force operand one positive (P1) control is zero, the sign of the dividend after P2 is applied is the sign of the result and a preferred sign code is used. When the result, after the RDC control is applied, is zero and the P1 control is zero, the sign of the result is made positive with preferred sign code 1100. When the P1 control is one, the sign of the result is made positive with sign code 1111.

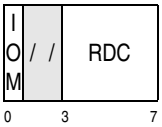
If the divisor is zero and the divisor sign code used is valid, a decimal-divide exception is recognized. This includes the case of division of zero by zero. The divisor sign code used is the third operand sign code when the force operand 3 positive (P3) bit is zero, and is a positive sign code when the force operand 3 positive (P3) bit is one.

If the RDC control does not specify enough digits to contain all leftmost nonzero digits of the remainder, decimal overflow occurs. The operation is completed. The result is obtained by ignoring the overflow digits, and if the condition code set (CS) flag is one, condi-

tion code 3 is set. If the decimal-overflow mask in the PSW is one and the instruction-overflow mask (IOM) is zero, a program interruption for decimal overflow occurs.

If the RDC control specifies less than thirty one digits, zeros are placed in the remaining leftmost digits of the first operand.

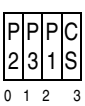
The I_4 field has the following format:



The bits of the I_4 field are defined as follows:

- ***Instruction-Overflow Mask (IOM):*** When the vector-packed-decimal-enhancement facility 1 is not installed, bit 0 is reserved and must contain zero; otherwise, a specification exception is recognized. When the vector-packed-decimal-enhancement facility 1 is installed, bit 0 is the instruction-overflow mask. When the instruction-overflow mask is one, recognition of a decimal overflow program interrupt is suppressed.
- ***Reserved:*** Bits 1-2 are reserved and must contain zeros. Otherwise, a specification exception is recognized.
- ***Result Digits Count (RDC):*** Bits 3-7 contain an unsigned binary number specifying the number of rightmost digits of the remainder to be placed in the first operand. If the magnitude of the remainder is larger than the largest decimal number that can be represented with the specified number of digits, decimal overflow occurs, and if the decimal-overflow mask is one, a program interruption for decimal overflow occurs. If the RDC field is zero, a specification exception is recognized.

The M_5 field has the following format:



The bits of the M_5 field are:

- ***Force Operand 2 Positive (P2):*** When bit 0 is one, the second operand sign is treated as a positive sign and is not checked for validity. When bit 0 is zero, the second operand sign is used in the operation and is checked for validity.
- ***Force Operand 3 Positive (P3):*** When bit 1 is one, the third operand sign is treated as a positive sign and is not checked for validity. When bit 1 is zero, the third operand sign is used in the operation and is checked for validity.
- ***Force Operand 1 Positive (P1):*** When bit 2 is one, the sign of the result placed in the first operand is forced to positive and a sign code of 1111 is used. When bit 2 is zero, the sign of the result placed in the first operand is the preferred sign code for the sign of the remainder.
- ***Condition Code Set (CS):*** When bit 3 is zero, the condition code is not set and remains unchanged. When bit 3 is one, the condition code is set as specified in the resulting condition code section below.

Resulting Condition Code:

When the CS bit is one, the condition code is set as follows:

0 Result zero; no overflow
1 Result less than zero; no overflow
2 Result greater than zero; no overflow
3 Overflow

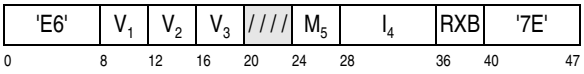
When the CS bit is zero, the condition code remains unchanged.

Program Exceptions:

- Data with DXC FE, vector instruction
- Data with DXC 00, general operand
- Decimal divide
- Decimal overflow
- Operation (if the vector-packed-decimal facility for z/Architecture is not installed)
- Specification
- Transaction constraint

VECTOR SHIFT AND DIVIDE DECIMAL

VSDP V_1,V_2,V_3,I_4,M_5 [VRI-f]



The second operand, shifted left (the dividend) by the number of digits specified in the fourth operand, is divided by the third operand (the divisor), and the rightmost thirty one digits of the quotient are placed in the first-operand location. The operands and result are in the signed-packed-decimal format.

The sign codes of the second and third operands may be modified for use in the operation by the force operand two positive (P2) and force operand three positive (P3) controls respectively.

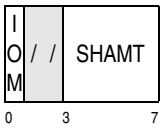
All digit codes are checked for validity. The sign codes are checked for validity unless overridden by the force operand two positive (P2) or force operand three positive (P3) controls.

If the first operand can not contain all leftmost nonzero digits of the quotient, decimal overflow occurs. The operation is completed. The result is obtained by ignoring the overflow digits, and if the condition code set (CS) flag is one, condition code 3 is set. If the decimal-overflow mask in the PSW is one and the instruction-overflow mask (IOM) is zero, a program interrupt for decimal overflow occurs.

When the rightmost thirty one digits of the quotient are nonzero and the force operand one positive (P1) control is zero, rules of algebra from the dividend and divisor signs determine the sign of the result and a preferred sign code is used. When the rightmost thirty one digits of the quotient are zero and the P1 control is zero, the sign of the result is made positive with preferred sign code 1100. When the P1 control is one, the sign of the result is made positive with sign code 1111.

If the divisor is zero and the divisor sign code used is valid, a decimal-divide exception is recognized. This includes the case of division of zero by zero. The divisor sign code used is the third operand sign code when the force operand 3 positive (P3) bit is zero, and is a positive sign code when the force operand 3 positive (P3) bit is one.

The I_4 field has the following format:



The bits of the I_4 field are defined as follows:

- ***Instruction-Overflow Mask (IOM):*** When the vector-packed-decimal-enhancement facility 1 is not installed, bit 0 is reserved and must contain zero; otherwise, a specification exception is recognized. When the vector-packed-decimal-enhancement facility 1 is installed, bit 0 is the instruction-overflow mask. When the instruction-overflow mask is one, recognition of a decimal overflow program interrupt is suppressed.
- ***Reserved:*** Bits 1-2 are reserved and must contain zeros. Otherwise, a specification exception is recognized.
- ***Shift Amount (SHAMT):*** Bits 3-7 contain an unsigned binary number specifying the number of digits the second operand is shifted left to form the dividend. The second operand sign position does not participate in the shift. Zeros are supplied for the vacated digit positions.

The M_5 field has the following format:

The bits of the M_5 field are:

- ***Force Operand 2 Positive (P2):*** When bit 0 is one, the second operand sign is treated as a positive sign and is not checked for validity. When bit 0 is zero, the second operand sign is used in the operation and is checked for validity.
- ***Force Operand 3 Positive (P3):*** When bit 1 is one, the third operand sign is treated as a positive sign and is not checked for validity. When bit 1 is zero, the third operand sign is used in the operation and is checked for validity.
- ***Force Operand 1 Positive (P1):*** When bit 2 is one, the sign of the result placed in the first operand is forced to positive and a sign code of 1111 is used. When bit 2 is zero, the sign of the result placed in the first operand is the preferred sign code for the sign of the quotient.
- ***Condition Code Set (CS):*** When bit 3 is zero, the condition code is not set and remains unchanged. When bit 3 is one, the condition code is set as specified in the resulting condition code section below.

Resulting Condition Code:

When the CS bit is one, the condition code is set as follows:

0 Result zero; no overflow
1 Result less than zero; no overflow
2 Result greater than zero; no overflow
3 Overflow

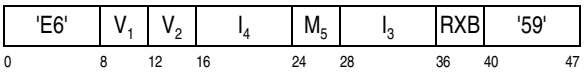
When the CS bit is zero, the condition code remains unchanged.

Program Exceptions:

- Data with DXC FE, vector instruction
- Data with DXC 00, general operand
- Decimal divide
- Decimal overflow
- Operation (if the vector-packed-decimal facility for z/Architecture is not installed)
- Specification
- Transaction constraint

VECTOR SHIFT AND ROUND DECIMAL

VSRP V_1,V_2,I_3,I_4,M_5 [VRI-g]



The second operand is shifted in the direction and for the number of decimal-digit positions specified by the fourth operand, and, when shifting to the right is specified, the absolute value of the second operand is rounded by the rounding digit, and the result is placed at the first-operand location. The first and second operands are in the signed-packed-decimal format.

The sign code of the second operand may be modified for use in the operation by the force operand two positive control (P2).

All digit codes are checked for validity, including digits with no effect on the result due to the shift amount. The sign code is checked for validity unless overridden by the force operand two positive control (P2).

Only the digit portion of the second operand is shifted; the sign position does not participate in the shifting. Zeros are supplied for the vacated digit positions. The result is stored in the first operand.

The shift amount (SHAMT) control specifies a 7-bit signed binary integer, indicating the direction and number of decimal-digit positions to be shifted. Positive shift values specify shifting to the left. Negative shift values, which are represented in two's complement notation, specify shifting to the right. The following are examples of the interpretation of shift values:

SHAMT (binary)	amount and direction
0011111	31 digits to the left
0000001	1 digit to the left
0000000	No shift
1111111	1 digit to the right
1100000	32 digits to the right

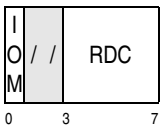
For a right shift, the second operand is rounded by treating the second operand as positive, regardless of the sign, and decimally adding the rounding digit, as specified by the decimal rounding digit control (DRD), to the leftmost of the digits to be shifted out and by propagating the carry, if any, to the left. The sum is then shifted to the right. Except for validity checking and participation in rounding, the digits shifted out of the rightmost decimal-digit position are ignored and are lost.

If one or more nonzero digits are shifted out during a left shift, or if the result digits count (RDC) control does not specify enough digits to contain all leftmost nonzero digits of the shifted value, decimal overflow occurs. The operation is completed. The result is obtained by ignoring the overflow digits, and if the condition code set (CS) flag is one condition code 3 is set. If the decimal-overflow mask in the PSW is one and the instruction-overflow mask (IOM) is zero, a program interruption for a decimal overflow occurs.

When the result, after the RDC control is applied, is nonzero and the force operand one positive (P1) control is zero, the sign of the second operand after P2 is applied determines the sign of the result and a preferred sign code is used. When the result, after being shifted, is zero and the P1 control is zero, the sign of the result is made positive with preferred sign code 1100. When the P1 control is one, the sign of the result is made positive with sign code 1111.

If the RDC control specifies less than thirty one digits, zeros are placed in the remaining leftmost digits of the first operand.

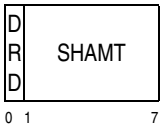
The I_3 field has the following format:



The bits of the I_3 field are defined as follows:

- ***Instruction-Overflow Mask (IOM):*** When the vector-packed-decimal-enhancement facility 1 is not installed, bit 0 is reserved and must contain zero; otherwise, a specification exception is recognized. When the vector-packed-decimal-enhancement facility 1 is installed, bit 0 is the instruction-overflow mask. When the instruction-overflow mask is one, recognition of a decimal overflow program interrupt is suppressed.
- ***Reserved:*** Bits 1-2 are reserved and must contain zeros. Otherwise, a specification exception is recognized.
- ***Result Digits Count (RDC):*** Bits 3-7 contain an unsigned binary number specifying the number of rightmost digits of the shifted value to be placed in the first operand. If the magnitude of the shifted value is larger than the largest decimal number that can be represented with the specified number of digits, decimal overflow occurs. If the RDC field is zero, a specification exception is recognized.

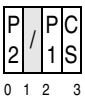
The I_4 field has the following format:



The bits of the I_4 field are defined as follows:

- ***Decimal Rounding Digit (DRD):*** When bit 0 is zero, the rounding digit is zero, when bit 0 is one, the rounding digit is 5.
- ***Shift Amount: (SHAMT):*** Bits 1-7 specify a signed binary integer representing the shift amount and direction. Bit 1 must equal bit 2 or results are unpredictable.

The M_5 field has the following format:



The bits of the M_5 field are:

- ***Force Operand 2 Positive (P2):*** When bit 0 is one, the second operand sign is treated as a positive sign and is not checked for validity. When bit 0 is zero, the second operand sign is used in the operation and is checked for validity.
- ***Reserved:*** Bit 1 is ignored but should contain zero; otherwise, the program may not operate compatibly in the future.
- ***Force Operand 1 Positive (P1):*** When bit 2 is one, the sign of the result placed in the first operand is forced to positive and a sign code of 1111 is used. When bit 2 is zero, the sign of the result placed in the first operand is the preferred sign code for the sign of the shifted value.
- ***Condition Code Set (CS):*** When bit 3 is zero, the condition code is not set and remains unchanged. When bit 3 is one, the condition code is set as specified in the resulting condition code section below.

Resulting Condition Code:

When the CS bit is one, the condition code is set as follows:

0 Result zero; no overflow
1 Result less than zero; no overflow
2 Result greater than zero; no overflow
3 Overflow

When the CS bit is zero, the condition code remains unchanged.

Program Exceptions:

- Data with DXC FE, vector instruction
- Data with DXC 00, general operand
- Decimal overflow
- Operation (if the vector-packed-decimal facility for z/Architecture is not installed)
- Specification
- Transaction constraint

VECTOR SHIFT AND ROUND DECIMAL REGISTER

VSRPR V_1,V_2,V_3,I_4,M_5 [VRI-f]

The second operand is shifted in the direction and for the number of decimal-digit positions specified by the third operand, and, when shifting to the right is specified, the absolute value of the second operand is rounded by the rounding digit, and the result is placed at the first-operand location. The first and second operands are in the signed-packed-decimal format.

The sign code of the result may be forced positive by the force operand one positive control (P1) or the force operand two positive control (P2).

All digit codes are checked for validity, including digits with no effect on the result due to the shift amount. The sign code is checked for validity unless overridden by the force operand two positive control (P2).

Only the digit portion of the second operand is shifted; the sign position does not participate in the shifting. Zeros are supplied for the vacated digit positions. The result is stored in the first operand.

The shift amount (SHAMT) control specifies an 8-bit signed binary integer, indicating the direction and number of decimal-digit positions to be shifted. SHAMT is located in byte element seven of the third operand. Positive shift values specify shifting to the left. Negative shift values, which are represented in two's complement notation, specify shifting to the right. Shift amounts greater than or equal to 31 are equivalent to shifting left 31 digits and shift amounts less than or equal to -32 are equivalent to shifting right 32 digits. The following are examples of the interpretation of shift values:

SHAMT (binary)	SHAMT (decimal)	amount and direction
01111111	+127	31 digits to the left
01000000	+64	31 digits to the left
00011111	+31	31 digits to the left
00000001	+1	1 digit to the left
00000000	0	No shift
11111111	-1	1 digit to the right
11100000	-32	32 digits to the right
10111111	-65	32 digits to the right
10000000	-128	32 digits to the right

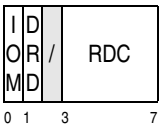
For a right shift, the second operand is rounded by treating the second operand as positive, regardless of the sign, and decimally adding the rounding digit, as specified by the decimal rounding digit control (DRD), to the leftmost of the digits to be shifted out and by propagating the carry, if any, to the left. The sum is then shifted to the right. Except for validity checking and participation in rounding, the digits shifted out of the rightmost decimal-digit position are ignored and are lost.

If one or more nonzero digits are shifted out during a left shift, or if the result digits count (RDC) control does not specify enough digits to contain all leftmost nonzero digits of the shifted value, decimal overflow occurs. The operation is completed. The result is obtained by ignoring the overflow digits, and if the condition code set (CS) flag is one condition code 3 is set. If the decimal-overflow mask in the PSW is one and the instruction overflow mask (IOM) is zero, a program interruption for a decimal overflow occurs.

When the result, after the RDC control is applied, is nonzero and the force operand one positive (P1) control is zero, the sign of the second operand after P2 is applied determines the sign of the result and a preferred sign code is used. When the result, after being shifted, is zero and the P1 control is zero, the sign of the result is made positive with preferred sign code 1100. When the P1 control is one, the sign of the result is made positive with sign code 1111.

If the RDC control specifies less than thirty one digits, zeros are placed in the remaining leftmost digits of the first operand.

The I_4 field has the following format:



The bits of the I_4 field are defined as follows:

- ***Instruction Overflow Mask (IOM):*** Bit 0 is the instruction-overflow mask. When the instruction-overflow mask is one or when the decimal-over-

flow mask (PSW bit 21) is zero, recognition of a decimal overflow program interrupt is suppressed.

- ***Decimal Rounding Digit (DRD):*** When bit 1 is zero, the rounding digit is zero, when bit 1 is one, the rounding digit is 5.
- ***Reserved:*** Bit 2 is reserved and must contain zero. Otherwise, a specification exception is recognized.
- ***Result Digits Count (RDC):*** Bits 3-7 contain an unsigned binary number specifying the number of rightmost digits of the shifted value to be placed in the first operand. If the magnitude of the shifted value is larger than the largest decimal number that can be represented with the specified number of digits, decimal overflow occurs, if the decimal-overflow mask (PSW bit 21) is a one and the IOM is zero a program interrupt for decimal overflow occurs. If the RDC field is zero, a specification exception is recognized.

The M_5 field has the following format:

The bits of the M_5 field are:

- ***Force Operand 2 Positive (P2):*** When bit 0 is one, the second operand sign is treated as a positive sign with a sign code of 1100 binary and is not checked for validity. When bit 0 is zero, the second operand sign is used in the operation and is checked for validity.
- ***Reserved:*** Bit 1 is ignored but should contain zero; otherwise, the program may not operate compatibly in the future.
- ***Force Operand 1 Positive (P1):*** When bit 2 is one, the sign of the result placed in the first operand is forced to positive and a sign code of 1111 binary is used. When bit 2 is zero, the sign of the result placed in the first operand is the preferred sign code for the sign of the shifted value.
- ***Condition Code Set (CS):*** When bit 3 is zero, the condition code is not set and remains unchanged. When bit 3 is one, the condition code is set as specified in the resulting condition code section below.

Note that if both P1 and P2 are ones the positive sign code of 1111 binary is used.

Resulting Condition Code:

When the CS bit is one, the condition code is set as follows:

0 Result zero; no overflow
1 Result less than zero; no overflow
2 Result greater than zero; no overflow
3 Overflow

When the CS bit is zero, the condition code remains unchanged.

Program Exceptions:

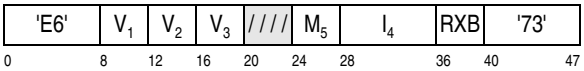
- Data with DXC FE, vector instruction
- Data with DXC 00, general operand
- Decimal overflow
- Operation (if the vector-packed-decimal-enhancement facility 2 is not installed)
- Specification
- Transaction constraint

Programming Note: VECTOR SHIFT AND ROUND DECIMAL REGISTER (VSRPR) and VECTOR SHIFT AND ROUND DECIMAL (VSRP) are the same except for 2 differences.

1. The shift amount is located in a vector register (VSRPR) instead of in an immediate field (VSRP). VSRP only has a 7 bit signed binary integer shift amount where the most significant bit must equal the next most significant bit. VSRPR allows 8 bit signed binary integer values and gives predictable results for the full range.
2. The DRD field was moved from an immediate field next to the shift amount (VSRP) to be in the other immediate field next to the IOM bit (VSRPR).

VECTOR SUBTRACT DECIMAL

VSP V_1,V_2,V_3,I_4,M_5 [VRI-f]



The third operand is subtracted from the second operand. The sign and specified number of rightmost

digits of the difference are placed in the first operand location with other digits set to zero. The operands and result are in the signed-packed-decimal format.

VECTOR SUBTRACT DECIMAL is executed the same as VECTOR ADD DECIMAL, except that the third operand is considered to have a sign opposite to the sign in the potentially modified operand.

The sign codes of the second and third operands may be modified for use in the operation by the force operand two positive (P2) and force operand three positive (P3) controls respectively.

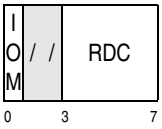
All digit codes are checked for validity. The sign codes are checked for validity unless overridden by the force operand two positive (P2) or force operand three positive (P3) controls.

When the result, after the result digits count (RDC) control is applied, is nonzero and the force operand one positive (P1) control is zero, rules of algebra determine the sign of the result and a preferred sign code is used. When the result, after the RDC control is applied, is zero and the P1 control is zero, the sign of the result is made positive with preferred sign code 1100. When the P1 control is one, the sign of the result is made positive with sign code 1111.

If the RDC control does not specify enough digits to contain all leftmost nonzero digits of the difference, decimal overflow occurs. The operation is completed. The result is obtained by ignoring the overflow digits, and if the condition code set (CS) control is one, condition code 3 is set. If the decimal-overflow mask in the PSW is one and the instruction-overflow mask (IOM) is zero, a program interruption for decimal overflow occurs.

If the RDC control specifies less than thirty one digits, zeros are placed in the remaining leftmost digits of the first operand.

The I_4 field has the following format:



The bits of the I_4 field are defined as follows:

- ***Instruction-Overflow Mask (IOM):*** When the vector-packed-decimal-enhancement facility 1 is not installed, bit 0 is reserved and must contain zero; otherwise, a specification exception is recognized. When the vector-packed-decimal-enhancement facility 1 is installed, bit 0 is the instruction-overflow mask. When the instruction-overflow mask is one, recognition of a decimal overflow program interrupt is suppressed.
- ***Reserved:*** Bits 1-2 are reserved and must contain zeros. Otherwise, a specification exception is recognized.
- ***Result Digits Count (RDC):*** Bits 3-7 contain an unsigned binary number specifying the number of rightmost digits of the difference to be placed in the first operand. If the magnitude of the difference is larger than the largest decimal number that can be represented with the specified number of digits, decimal overflow occurs, and if the decimal-overflow mask is one, a program interruption for decimal overflow occurs. If the RDC field is zero, a specification exception is recognized.

The M_5 field has the following format:

The bits of the M_5 field are:

- ***Force Operand 2 Positive (P2):*** When bit 0 is one, the second operand sign is treated as a positive sign and is not checked for validity. When bit 0 is zero, the second operand sign is used in the operation and is checked for validity.
- ***Force Operand 3 Positive (P3):*** When bit 1 is one, the third operand sign is treated as a positive sign and is not checked for validity. When bit 1 is zero, the third operand sign is used in the operation and is checked for validity.
- ***Force Operand 1 Positive (P1):*** When bit 2 is one, the sign of the result placed in the first operand is forced to positive and a sign code of 1111 is used. When bit 2 is zero, the sign of the result placed in the first operand is the preferred sign code for the sign of the difference.
- ***Condition Code Set (CS):*** When bit 3 is zero, the condition code is not set and remains

unchanged. When bit 3 is one, the condition code is set as specified in the resulting condition code section below.

Resulting Condition Code:

When the CS bit is one, the condition code is set as follows:

0 Result zero; no overflow
1 Result less than zero; no overflow
2 Result greater than zero; no overflow
3 Overflow

When the CS bit is zero, the condition code remains unchanged.

Program Exceptions:

- Data with DXC FE, vector instruction
- Data with DXC 00, general operand
- Decimal overflow

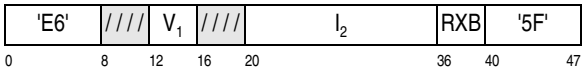
- Specification
- Transaction constraint

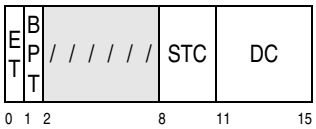
VECTOR TEST DECIMAL

VTP $V_1[,I_2]$ [VRR-g]



The first operand is tested for valid decimal digits and a valid sign code. The controls specified in the I_2 field are used to determine which codes are considered valid for each test. The result is indicated in the condition code. The operand is in the signed-packed-decimal format.

The I_2 field has the following format:



The bits of the I_2 field are defined as follows:

- ***Enhanced Testing (ET):*** When the vector-packed-decimal-enhancement facility 3 is not installed or bit 0 is zero, the sign-test control (STC), the digits count (DC), and the byte-padding test (BPT) control are not used during the operation. When the vector-packed-decimal-enhancement facility 3 is installed and bit 0 is one, the STC, DC, and BPT controls are used during the operation.
- ***Byte-Padding Test (BPT):*** When the vector-packed-decimal-enhancement facility 3 is installed and the enhanced-testing control is one, bit 1 specifies whether the digit position immediately to the left of the rightmost number (N) of digits specified by the digits count (DC) is tested for the value of zero. BPT only applies when N is even. Refer to Figure 25-6 on page 25-32 for a comprehensive list of cases.
- ***Sign-Test Control (STC):*** When the vector-packed-decimal-enhancement facility 3 is installed and the enhanced-testing control is one, bits 8-10 specify which codes are considered valid sign codes, as specified in Figure 25-5 on page 25-32.
- ***Digits Count (DC):*** When the vector-packed-decimal-enhancement facility 3 is installed and the enhanced-testing control is one, bits 11-15 specify the number (N) of rightmost digit positions to be tested to contain any of the valid decimal digit codes 0-9. Refer to Figure 25-6 on page 25-32 for a comprehensive list of cases.
- ***Reserved:*** Bits 2-7 are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.

Resulting Condition Code:

0 All digit codes and the sign considered valid
1 All digit codes considered valid and sign considered invalid
2 At least one digit code considered invalid and sign considered valid
3 At least one digit code considered invalid and sign considered invalid

Program Exceptions:

- Data with DXC FE, vector instruction
- Operation (if the vector-packed-decimal facility for z/Architecture is not installed)
- Transaction constraint

Enhanced Testing (ET)	Sign-Test Control (STC) (binary)	All N digits are zeros[1]	Sign codes considered valid	Sign codes considered invalid
0	–	–	A-F	0-9
1	000	–	A-F	0-9
1	001	no or N=0	A-F	0-9
1	001	yes and N>0	A,C,E,F	0-9,B,D
1	010	–	C,D	0-B,E-F
1	011	no or N=0	C,D	0-B,E-F
1	011	yes and N>0	C	0-B,D-F
1	100	–	F	0-E
1	101	–	F	0-E
1	110	–	C,D,F	0-B,E
1	111	no or N=0	C,D,F	0-B,E
1	111	yes and N>0	C,F	0-B,D-E

Explanation:

– Results do not depend on this value.
1 Invalid digits are considered to be nonzero digits.
N The number (N) of rightmost digit positions specified by the DC control to be tested.

Figure 25-5. Sign code testing for VECTOR TEST DECIMAL

Enhanced Testing (ET)	Digits Count (DC) (N)	Byte-Padding Test (BPT)	Meaning
0	–	–	Codes 0-9 are considered valid in all digit positions.
1	N=0	–	Codes 0-F are considered valid in all digit positions (that is, none of the digit positions are tested for validity and only the sign is tested).
1	N>0 and odd	–	Codes 0-9 are considered valid in the rightmost N digit positions. Codes 0-F are considered valid in the remaining leftmost digit positions (that is, the remaining leftmost digit positions are not tested for validity).
1	N>0 and even	0	Codes 0-9 are considered valid in the rightmost N digit positions. Codes 0-F are considered valid in the remaining leftmost digit positions (that is, the remaining leftmost digit positions are not tested for validity).
1	N>0 and even	1	Codes 0-9 are considered valid in the rightmost N digit positions. Code 0 is considered valid in the digit position immediately to the left of the rightmost N digit positions. Codes 0-F are considered valid in the remaining leftmost digit positions (that is, the remaining leftmost digit positions are not tested for validity).

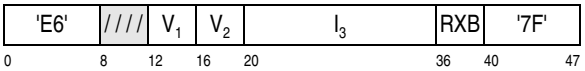
Explanation:

– Results do not depend on this value.
N The number (N) of rightmost digit positions specified by the DC control to be tested.

Figure 25-6. Digit code testing for VECTOR TEST DECIMAL

VECTOR TEST ZONED

VTZ V_1,V_2,I_3 [VRI-I]

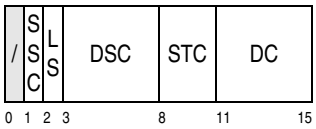


VECTOR TEST ZONED tests whether the decimal number in the source adheres to a specified variation of the zoned format. The result is indicated in the condition code.

One variation of the zoned format is described in Chapter 8, “Decimal Instructions.” Other variations of the zoned format are described in the definition for this instruction.

The source is formed from the concatenation of the first operand followed by the second operand and contains a decimal number in the zoned format with a length of 1-32 bytes. The decimal number is right justified in the source. The leftmost bytes of the source which are not part of the decimal number are ignored.

The I_3 field has the following format:



The bits of the I_3 field are defined as follows:

- ***Reserved:*** Bit 0 is reserved and should contain zero; otherwise, the program may not operate compatibly in the future.
- ***Separate-Sign Control: (SSC):*** When bit 1 is one, the decimal number in the source includes a byte designating the sign which is separate from, and to the left or right of, the bytes containing digits. When bit 1 is zero, the leftmost or rightmost byte containing a digit also contains the sign.
- ***Leading Sign: (LS):*** When bit 2 is one, the leftmost byte of the decimal number in the source includes the sign. When bit 2 is zero, the rightmost byte of the decimal number includes the sign.
- ***Disallowed-Spaces Count: (DSC):*** Bits 3-7 contain an unsigned binary integer specifying the number of rightmost bytes of the decimal number in the source which should not contain characters representing spaces. DSC only applies when SSC and LS are zeros. When DSC does apply and is zero or is greater than DC, results are unpredictable.
- ***Sign-Test Control (STC):*** Bits 8-10 specify which codes are considered valid sign codes in the source. When the sign is in a byte having the SD-byte format, STC values 0-7 apply. When the sign is in a byte having the SS-byte format, STC values 2-3 apply and other STC values are reserved for possible future extensions and should not be specified; otherwise, the program may not operate compatibly in the future. Figure 25-8 on page 25-35 details how the values specified in the STC field control the sign-code test.
- ***Digits Count (DC):*** Bits 11-15 contain an unsigned binary integer specifying the number of bytes in the decimal number which contain a digit. If the DC field is zero, a specification exception is recognized. When the decimal number includes characters representing spaces, the digits count includes the number of spaces.

The values in the separate-sign control (SSC), leading sign (LS), and disallowed-spaces count (DSC) controls specify one of five variations of the zoned format to be used during the test operation. The five types of variations of the zoned format are as follows:

ETS-type-zoned format (embedded trailing sign):
The decimal number in the source is tested to comply with this format when SSC is zero, LS is zero, and the value in the DSC control equals the value in the DC control. A decimal number in this format has a sign embedded in the rightmost byte of the number. The digits count (DC) field specifies the number of bytes in the decimal number which contain a digit. The rightmost byte has the SD-byte format. All other bytes have the ZD-byte format.

SETS-type-zoned format (spaced embedded trailing sign):
The decimal number in the source is tested to comply with this format when SSC is zero, LS is zero, and the value in the DSC control is less than the value in the DC control. A decimal number in this format has a sign embedded in the rightmost byte of the number. The digits count (DC) field specifies the number of bytes in the decimal number which contain a digit or a space character. The rightmost byte has the SD-byte format. The value in the DSC control is subtracted from the value in the DC control and the difference specifies the number of leftmost bytes of the decimal number which may have either the SP-byte format or the ZD-byte format. The only valid value for a byte having the SP-byte format is 40 hex, which is

the EBCDIC code for a space character. Space characters are considered nonzero digits. All other bytes have the ZD-byte format.

ELS-type-zoned format (embedded leading sign):
The decimal number in the source is tested to comply with this format when SSC is zero and LS is one. A decimal number in this format has a sign embedded in the leftmost byte of the number. The digits count (DC) field specifies the number of bytes in the decimal number which contain a digit. The leftmost byte has the SD-byte format. All other bytes have the ZD-byte format.

STS-type-zoned format (separate trailing sign):
The decimal number in the source is tested to comply with this format when SSC is one and LS is zero. A decimal number in this format has a separate sign in the rightmost byte of the number. The rightmost byte has the SS-byte format. The only valid values for a byte having the SS-byte format are 4E hex and 60 hex, which are the EBCDIC codes for positive and negative, respectively. All other bytes have the ZD-byte format. The digits count (DC) field specifies the number of bytes in the decimal number which contain a digit. The number of bytes in the decimal number is one more than the number of bytes containing digits.

SLS-type-zoned format (separate leading sign):
The decimal number in the source is tested to comply with this format when SSC is one and LS is one. A decimal number in this format has a separate sign in the leftmost byte of the number. The leftmost byte has the SS-byte format. The only valid values for a byte having the SS-byte format are 4E hex and 60 hex, which are the EBCDIC codes for positive and negative, respectively. All other bytes have the ZD-byte format. The digits count (DC) field specifies the number of bytes in the decimal number which contain a digit. The number of bytes in the decimal number is one more than the number of bytes containing digits.

Figure 25-7 on page 25-34 summarizes the five types of variations of the zoned format which may be specified for use during the execution of VECTOR TEST ZONED.

Controls			Specified	Examples of decimal numbers in the source							
SSC	LS	DSC	variation	DC	DSC	Rightmost 6 bytes of the source					
0	0	DSC=DC	ETS-type-zoned format	5	5	/ /	ZD	ZD	ZD	ZD	SD
0	0	DSC<DC	SETS-type-zoned format	5	3	/ /	SP	SP	ZD	ZD	SD
				5	3	/ /	ZD	SP	ZD	ZD	SD
				5	3	/ /	SP	ZD	ZD	ZD	SD
				5	3	/ /	ZD	ZD	ZD	ZD	SD
0	1	–	ELS-type-zoned format	4	–	/ /	/ /	SD	ZD	ZD	ZD
1	0	–	STS-type-zoned format	4	–	/ /	ZD	ZD	ZD	ZD	SS
1	1	–	SLS-type-zoned format	4	–	/ /	SS	ZD	ZD	ZD	ZD

Explanation:

–	Not applicable.
/ /	Source byte contents ignored.
DC	Digits count.
DSC	Disallowed-spaces count.
LS	Leading sign.
SD	SD-byte format.
SP	SP-byte format.
SS	SS-byte format.
SSC	Separate-sign control.
ZD	ZD-byte format.

Figure 25-7. Variations of the zoned format for VECTOR TEST ZONED

The types of byte formats described are as follows:

SD-byte format (sign and digit):
Bytes designated to have this format consist of a sign code (S) in the leftmost 4 bits and a digit code (D) in the rightmost 4 bits. Values A-F hex may be valid sign codes, depending on the specified sign-test control (STC). Values 0-9 are invalid sign codes. Values 0-9 are valid digit codes. Values A-F hex are invalid digit codes.

ZD-byte format (zone and digit):
Bytes designated to have this format consist of a zone code (Z) in the leftmost 4 bits and a digit code (D) in the rightmost 4 bits. If the zone code is F hex, then values 0-9 are valid digit codes and values A-F hex are invalid digit codes. If the zone code is not F hex, then any value is considered to be an invalid digit code in the rightmost 4 bits.

SP-byte format (space):
Bytes designated to have this format consist of an 8-bit character considered to represent one digit. Value 40 hex, which is the EBCDIC code for a space, is the only valid value for the digit in this byte. All other values in bytes having this format are considered as invalid digits.

SS-byte format (separate sign):
Bytes designated to have this format consist of an 8-bit character representing the sign. Value 4E hex and depending on the sign-test control (STC), value 60 hex, which are the EBCDIC codes for positive and negative, respectively are valid values to represent the sign. All other values in a byte having this format are considered to be an invalid sign.

Figure 25-8 on page 25-35 summarizes the sign code testing for VECTOR TEST ZONED and Figure 25-9 on page 25-35 summarizes the digit code testing for VECTOR TEST ZONED.

Source byte format	Digit codes considered valid (hex)
SD-byte format	0-9[1]
ZD-byte format	F0-F9[2]
SP-byte format	40[2]

Explanation:

1 Only the rightmost 4 bits of bytes having this format participate in the digit code testing.
2 All 8 bits of bytes having this format participate in the digit code testing.

Figure 25-9. Digit code testing for VECTOR TEST ZONED

Resulting Condition Code:

0 All digit codes and the sign considered valid
1 All digit codes considered valid and sign considered invalid
2 At least one digit code considered invalid and sign considered valid
3 At least one digit code considered invalid and sign considered invalid

Source byte format	STC	All N digits are zeros[3]	Sign codes considered valid (hex)
SD-byte format	000	–	A-F[1]
	001	no	A-F[1]
	001	yes	A,C,E,F[1]
	010	–	C,D[1]
	011	no	C,D[1]
	011	yes	C[1]
	100	–	F[1]
	101	–	F[1]
	110	–	C,D,F[1]
	111	no	C,D,F[1]
	111	yes	C,F[1]
SS-byte format	010	–	4E,60[2]
	011	no	4E,60[2]
	011	yes	4E[2]

Explanation:

1 Only the leftmost 4 bits of bytes having this format participate in the sign code testing.
2 All 8 bits of bytes having this format participate in the sign code testing.
3 Space characters and invalid digits are considered to be nonzero digits.
– Results do not depend on this value.
N The number (N) of digit positions specified by the DC control to be tested. This number includes characters representing spaces, which are considered to be nonzero digits.
STC Sign-test control.

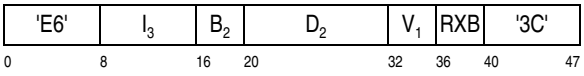
Figure 25-8. Sign code testing for VECTOR TEST ZONED

Program Exceptions:

- Data with DXC FE, vector instruction
- Operation (if the vector-packed-decimal-enhancement facility 3 not installed)
- Specification
- Transaction constraint

VECTOR UNPACK ZONED

VUPKZ $V_1,D_2(B_2),I_3$ [VSI]

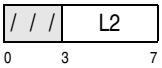


The format of the first operand is changed from the signed-packed-decimal format to the zoned format and placed in the second-operand location. The signed-packed-decimal and zoned formats are described in Chapter 8, “Decimal Instructions.”

The first operand is treated as having the signed-packed-decimal format. Its digits and sign are placed unchanged in the second-operand location, using the zoned format. Zone bits with coding of 1111 binary are supplied for all bytes except the rightmost byte, the zone of which receives the sign of the first operand. The sign and digits are not checked for valid codes.

The number of bytes the second operand occupies in storage is specified by the operand 2 length code (L2) control. If the second-operand field is too short to contain all digits of the first operand, the remaining leftmost portion of the first operand is ignored.

The I_3 field has the following format:



The bits of the I_3 field are defined as follows:

- ***Reserved:*** Bits 0-2 are reserved and must contain zeros. Otherwise, a specification exception is recognized.
- ***Operand 2 Length Code (L2):*** Bits 3-7 contain the length code of the second-operand. The length of the second-operand is 1-31 bytes, corresponding to a length code in L2 of 0-30. The second-operand length must not exceed 31 bytes (L2 must be less than or equal to 30); otherwise, a specification exception is recognized.

Special Conditions:

If the L2 field is larger than 30 a specification exception is recognized.

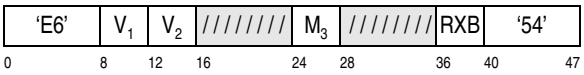
Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)
- Data with DXC FE, vector instruction
- Operation (if the vector-packed-decimal facility for z/Architecture is not installed)
- Specification
- Transaction constraint

VECTOR UNPACK ZONED HIGH

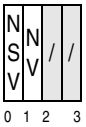
VUPKZH V_1,V_2,M_3 [VRR-k]



The second operand is in signed-packed-decimal format which has 31 digits and a sign and the leftmost 15 digits are converted to the zoned format and placed in the rightmost 15 bytes of the first-operand. The most significant digit is set equal to zero.

Zone bits with coding of 1111 binary are supplied for all bytes and the sign digit is not expanded into result. All 31 digits of the second operand are checked for valid codes if the no validation control (NV) bit is 0 and the sign is also checked if the no sign validation control (NSV) bit is zero.

The M_3 field has the following format:



The bits of the M_3 field are:

- ***No Sign Validation (NSV):*** if bit 0 is zero and the NV control is zero, then the second operand sign code is checked for validity to determine if there is a general-operand data exception. If bit 0 is one or the NV control bit is one then the second operand sign code is not checked for validity.
- ***No Validation (NV):*** if bit 1 is zero then the second operand digits are checked for validity; if the NSV control bit is also zero, then the second operand sign code is checked for validity. If bit 1 is one, then the second operand digits and sign code are not checked for validity. See Figure 25-3 for details.
- ***Reserved:*** Bits 2 and 3 are reserved and should contain zeros. Otherwise, the program may not operate compatibly in the future.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, vector instruction
- Data with DXC 00, general operand

- Operation (if the vector-packed-decimal-enhancement facility 2 is not installed)
- Transaction constraint

Programming Note: VECTOR UNPACK ZONED HIGH and VECTOR UNPACK ZONED LOW can be used together to unpack a signed-packed-decimal format operand in a vector register into zoned-decimal format operand in two vector registers with the high data unsigned and the low data signed. Either or both instructions can check the validity of the digits and sign code of the signed-packed-decimal format source.

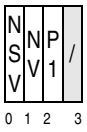
VECTOR UNPACK ZONED LOW

VUPKZL V_1,V_2,M_3 [VRR-k]

The second operand is in signed-packed-decimal format which has 31 digits and a sign and the rightmost 16 digits and sign are converted to the zoned format and placed in the first-operand location.

Zone bits with coding of 1111 binary are supplied for all bytes except the rightmost byte, the zone of which receives the sign of the first operand. All 31 digits of the second operand are checked for valid codes if the no validation control (NV) bit is 0 and the sign is also checked if the no sign validation control (NSV) is zero.

The M_3 field has the following format:



The bits of the M_4 field are:

- ***No Sign Validation (NSV):*** if bit 0 is zero and the NV control bit is zero, then the second operand sign code is checked for validity to determine if there is a general-operand data exception. If bit 0 is one or the NV control bit is one then the second operand sign code is not checked for validity.
- ***No Validation (NV):*** if bit 1 is zero then the second operand digits are checked for validity; if the NSV control bit is zero, then the second operand sign code is also checked for validity. If bit 1 is one, then the second operand digits and sign code are not checked for validity. See Figure 25-3 for details.
- ***Force Operand 1 Positive (P1):*** When bit 2 is one, the sign of the result placed in the first operand is forced to positive and a sign code of 1111 binary is used. When bit 2 is zero, the sign of the result placed in the first operand maintains the sign code from the second operand. Note this field is only applied if there is no general-operand data exception.
- ***Reserved:*** Bit 3 is reserved and should contain zero. Otherwise, the program may not operate compatibly in the future.

If NV or NSV are equal to one, the sign code is not checked for validity and an invalid sign code of the source operand is propagated to the result if P1 is zero.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, vector instruction
- Data with DXC 00, general operand
- Operation (if the vector-packed-decimal-enhancement facility 2 is not installed)
- Transaction constraint

Programming Note: VECTOR UNPACK ZONED HIGH and VECTOR UNPACK ZONED LOW can be used together to unpack a signed-packed-decimal format operand in a vector register into zoned-decimal format operand in two vector registers with the high data unsigned and the low data signed. Either or both instructions can check the validity of the digits and sign code of the signed-packed-decimal format source.

Chapter 26. Specialized-Function-Assist Instructions

Neural Network Processing Data 26-1
NNP-Data-Type-1 Format 26-1
8-Bit Signed Binary Integer Data Format. . . . 26-1

DEFLATE CONVERSION CALL 26-18
NEURAL NETWORK PROCESSING ASSIST 26-62
SORT LISTS 26-119
VECTOR FP CONVERT AND LENGTHEN FROM NNP HIGH. 26-144
VECTOR FP CONVERT AND LENGTHEN FROM NNP LOW 26-145
VECTOR FP CONVERT AND ROUND TO NNP 26-146
VECTOR FP CONVERT FROM NNP. 26-146
VECTOR FP CONVERT TO NNP 26-147

The specialized-function-assist instructions described in this chapter are intended to provide performance improvements for specific operations used in software libraries, utilities, and operating system services. The facilities and instructions described in this chapter may be replaced or removed in the future. As a result, it is recommended that when a software library, utility, or operating system service provides an implementation using one or more of the specialized-function-assist instructions in this chapter, the software library also provides an alternate implementation which does not rely on any specialized-function-assist instruction in case the corresponding facility is not available to the program. It is also recommended that application programs use provided software libraries, utilities, or operating system services rather than use specialized-function-assist instructions directly.

The description for each instruction in this chapter specifies whether the instruction is a privileged or unprivileged instruction.

Neural Network Processing Data

The NEURAL NETWORK PROCESSOR ASSIST (NNPA) instruction, as well as the related convert instructions described in this chapter, perform operations on model-dependent data types.

NNP-Data-Type-1 Format

NNP-data-type-1 format represents a 16-bit signed floating-point number in a proprietary format with a range and precision tailored toward neural-network processing. Other models may use other data formats.

Programming Note: The following instructions are available for converting between the binary-floating-point (BFP) format and the NNP-data-type-1 format:

- VECTOR FP CONVERT AND LENGTHEN FROM NNP HIGH
- VECTOR FP CONVERT AND LENGTHEN FROM NNP LOW
- VECTOR FP CONVERT AND ROUND TO NNP
- VECTOR FP CONVERT FROM NNP
- VECTOR FP CONVERT FROM NNP

8-Bit Signed Binary Integer Data Format

Certain NNPA functions use the 8-bit signed binary integer data format having a range of –128 to +127. Arithmetic operations that result in an 8-bit signed binary integer are saturating; that is, if the result is less than -128, it is set to -128, and if the result is greater than +127, it is set to +127.

Instructions

The instructions described in this chapter are summarized in Figure 26-1 on page 26-2. The figure lists each instruction and indicates the instruction name, mnemonic, operation code, format, and other noteworthy characteristics.

COMPUTE DIGITAL SIGNATURE AUTHENTICATION

KDSA R_1, R_2 [RRE]

A function specified by the function code in general register 0 is performed.

Bits 16-23 of the instruction and the R_1 field are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.

General register 0 contains various controls affecting the operation of the instruction, as follows:

Function Code (FC): Bit positions 57-63 of general register 0 contain the function code. Figure 26-2 shows the assigned function codes for COMPUTE DIGITAL SIGNATURE AUTHENTICATION. When the message-security-assist extension 13 is installed, function code 127 is valid for COMPUTE DIGITAL SIGNATURE AUTHENTICATION. All other function codes are unassigned. A specification exception is recognized if an unassigned or uninstalled function code is specified.

Code	Function	Param. Block Size (bytes)	Data Block Size (bytes)

V Variable parameter block size. See each format-x parameter block for the exact size of that parameter block.

Figure 26-2. Function Codes for COMPUTE DIGITAL SIGNATURE AUTHENTICATION

Deterministic (D): Bit position 56 of general register 0 contains the deterministic bit which affects the KDSA-ECDSA-Sign-P256, KDSA-ECDSA-Sign-

P384, and KDSA-ECDSA-Sign-P521 function codes. When the deterministic bit is equal to zero the source random number is used to generate a secret random number within the execution of the instruction, hidden to the user. This adds security to the signature process and the signature will vary with each execution. When the deterministic bit is equal to a one the source random number is used directly and will provide the same signature for each execution with the same input. Other function codes are unaffected by the deterministic bit.

Bits 0-31 of general register 0 are ignored. Bits 32-55 of general register 0 are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.

General register 1 contains the logical address of the leftmost byte of the parameter block in storage. In the 24-bit addressing mode, the contents of bit positions 40-63 of general register 1 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of general register 1 constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register 1 constitute the address.

Figure 26-3 on page 26-4 shows the contents of the general registers just described.

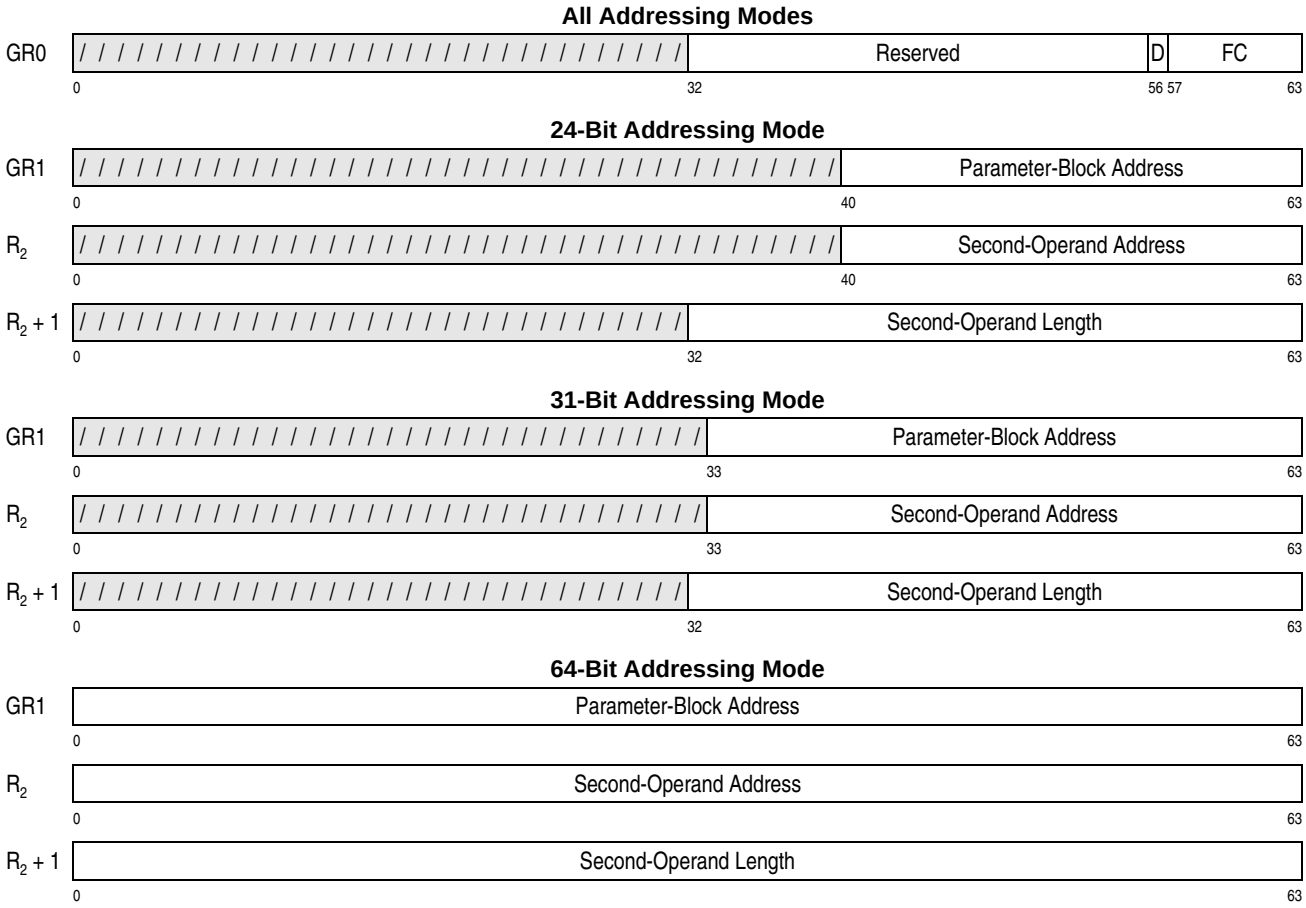

Figure 26-3. General Register Assignment for COMPUTE DIGITAL SIGNATURE AUTHENTICATION

In the access-register mode, access register 1 specifies the address space containing the parameter block.

The query function provides the means of indicating the availability of the other functions. The contents of general registers R_2 and $R_2 + 1$ are ignored for the query function.

The query-authentication-information function provides the information that can be used by the program to authenticate the running instruction's firmware code level (IFCL) currently installed on the model. The contents of general registers R_2, and $R_2 + 1$ are ignored for the query-authentication-information function.

The verify functions check the validity of the signature of the hashed message and reports whether the credentials are valid via the condition code. The sign functions create a signature for the hashed message.

Note: The description of the COMPUTE DIGITAL SIGNATURE AUTHENTICATION (KDSA) instruction assumes that the reader is familiar with the Elliptic Curve Digital Signal Algorithm (ECDSA) described in Reference [24.] on page xxxii and in the Edwards-curve Digital Signature Algorithm (EdDSA) described in Reference [25.] on page xxxii.

In the case of ECDSA, three Weierstrass curves over prime fields are supported: NIST P256, P384, and P521. In Reference [24.] on page xxxii these curves are actually referred to as P-256, P-384, and P-521, respectively. In Reference [32.] on page xxxiii and Reference [33.] on page xxxiii they are referred to as secp256r1, secp384r1, and secp521r1, respectively. Also see Reference [27.] on page xxxii section 5.4 p.17-18 for algorithm details and see D.1.2.3-5 in Reference [24.] on page xxxii p.100 for the curve parameter values including the prime modulus, the order, the coefficient, the base point x coordinate, and the base point y coordinate used by these function codes. Two other prime fields are supported which use the EdDSA algorithm in Reference [25.] on page xxxii and Reference [26.] on page xxxii referred to as Ed25519 and Ed448 though they use the curve Curve255-19 and Curve448, respectively. Also see Reference [25.] on page xxxii for algorithm details and curve parameter values, section 5.1.7 and 5.2.7 describe the verify function and 5.1 and 5.2 describe the curve parameters for Ed25519 and Ed448 respectively which are used by these function codes. The following is the definition of the moduli of these fields:

- $P256 = 2^{256} - 2^{224} + 2^{192} + 2^{96} - 1$
- $P384 = 2^{384} - 2^{128} - 2^{96} + 2^{32} - 1$
- $P521 = 2^{521} - 1$
- $Ed25519 = 2^{255} - 19$
- $Ed448 = 2^{448} - 2^{224} - 1$

The sign and verify function codes (1, 2, 3, 9, 10, 11, 17, 18, and 19), which use the ECDSA algorithm on NIST curves, ignore the contents of general registers R_2 and $R_2 + 1$. These functions utilize a hashed message of fixed size which is contained in the parameter block.

The Edwards curve functions: KDSA-EdDSA-Verify, KDSA-EdDSA-Sign, and KDSA-Encrypted-EdDSA-Sign (function codes 32, 36, 40, 44, 48, and 52), use the EdDSA algorithm, and the message is not prehashed Reference [25.] on page xxxii. The second operand is the message. The PureEdDSA variant is supported for the curves Ed25519 and Ed448. Other variants such as the HashEdDSA variants Ed25519ph and Ed448ph and the context variant Ed25519ctx are not supported. The context is assumed to be null and the prehash function is the identity function and the flag is 0.

The R_2 field designates an even-odd pair of general registers and must designate an even-numbered register other than general register 0; otherwise, a specification exception is recognized.

The location of the leftmost byte of the second operand is specified by the contents of the R_2 general register. The number of bytes in the second-operand location is specified in general register $R_2 + 1$. Note the second-operand can have a length of zero bytes.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general register R_2 constitute the address of the second operand, and the contents of bit positions 0-39 are ignored; bits 40-63 of the updated address replace the corresponding bits in general register R_2, carries out of bit position 40 of the updated address are ignored, and the contents of bit positions 32-39 of general register R_2 are set to zeros. In the 31-bit addressing mode, the contents of bit positions 33-63 of general register R_2 constitute the address of the second operand, and the contents of bit positions 0-32 are ignored; bits 33-63 of the updated address replace the corresponding bits in general register R_2, carries out of bit position 33 of the updated address are ignored, and the content of bit position 32 of general register R_2 is set to zero. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register R_2 constitute the address of the second operand; bits 0-63 of the updated address replace the contents of general register R_2 and carries out of bit position 0 are ignored.

In both the 24-bit and the 31-bit addressing modes, the contents of bit positions 32-63 of general register $R_2 + 1$ form a 32-bit unsigned binary integer which specifies the number of bytes in the second operand; and the updated value replaces the contents of bit positions 32-63 of general register $R_2 + 1$. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register $R_2 + 1$ form a 64-bit unsigned binary integer which specifies the number of bytes in the second operand; and the updated value replaces the contents of general register $R_2 + 1$.

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers R_2 and $R_2 + 1$, always remain unchanged. In the access register mode, access register R_2 specifies the address space for the second operand.

These functions will be described in more detail along with their parameter blocks.

KDSA-Query (Function Code 0)

The location of the operands and addresses used by the instruction are shown in Figure 26-3 on page 26-4.

The parameter block used for the function has the following format shown in Figure 26-4:

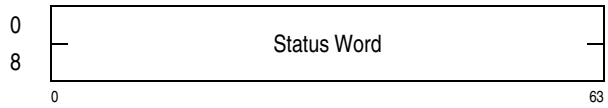

Figure 26-4. Parameter Block for KDSA-Query

A 128-bit status word is stored in the parameter block. Bits 0-127 of this field correspond to function codes 0-127, respectively, of the COMPUTE DIGITAL SIGNATURE AUTHENTICATION instruction. When a bit is one, the corresponding function is installed; otherwise, the function is not installed.

Condition code 0 is set when execution of the KDSA-Query function completes; condition codes 1, 2, and 3 are not applicable to this function.

KDSA-ECDSA-Verify Functions

This section describes the function codes for three KDSA-ECDSA-Verify functions for Weierstrass curves with NIST primes:

- KDSA-ECDSA-Verify-P256 (function code 1)
- KDSA-ECDSA-Verify-P384 (function code 2)
- KDSA-ECDSA-Verify-P521 (function code 3)

The locations of the operands and addresses used by each of these functions are as shown in Figure 26-3 on page 26-4. The parameter block contains the operands used by the KDSA-ECDSA-Verify functions and is addressed by general register 1.

The KDSA-ECDSA-Verify function checks the validity of a signed message. The originator of the message has a public key that can be used to see if the signature matches the hashed message. The signature consists of two integers in the prime field designated by R and S. The originator and receiver agree on a hashing scheme for creating the signature. The KDSA-ECDSA-Verify function operates on the already hashed message represented as H(msg) in the parameter block. The hashed message is reduced to be less than the order of the curve by modulo reduction by the order of the curve. The originator's public key is represented by K. An elliptic curve public key is actually a point on the curve and has X and Y coordinates (represented by Xk and Yk) within the prime field making it twice as big as other parameters. These operands are supplied to the function in the parameter block. The operation results in a true or false validity indication which is represented by a condition code equal to zero versus two respectively.

The parameter block used for KDSA-ECDSA-Verify-P256 function has the format as shown in Figure 26-5, below.

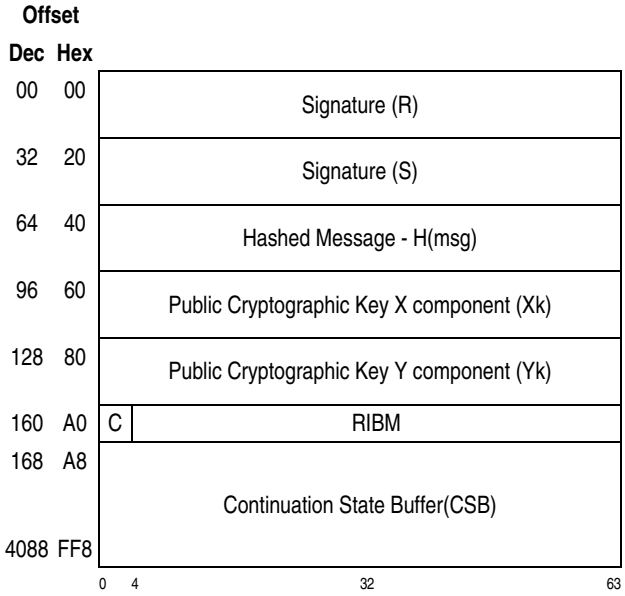

Figure 26-5. Parameter Block for KDSA-ECDSA-Verify-P256 Function

The parameter block for KDSA-ECDSA-Verify-P384 is shown in Figure 26-6, below. Each field is 48 bytes

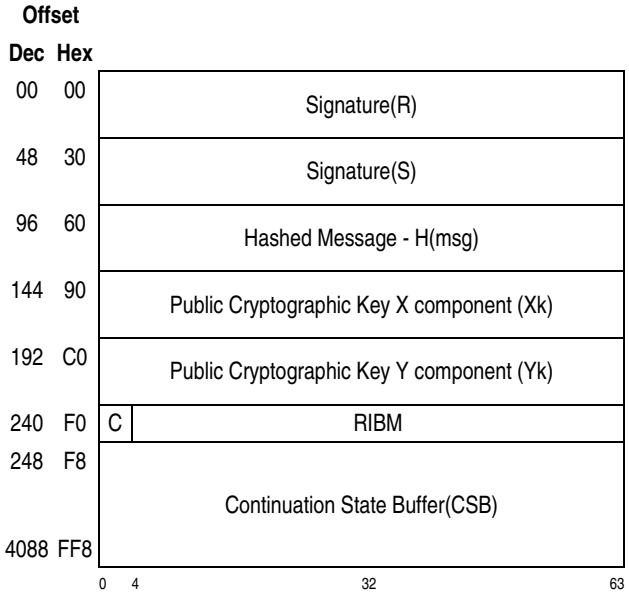

Figure 26-6. Parameter Block for KDSA-ECDSA-Verify-P384 Function

or 384 bits wide.

The parameter block for KDSA-ECDSA-Verify-P521 is shown in Figure 26-7, below. The NIST standard

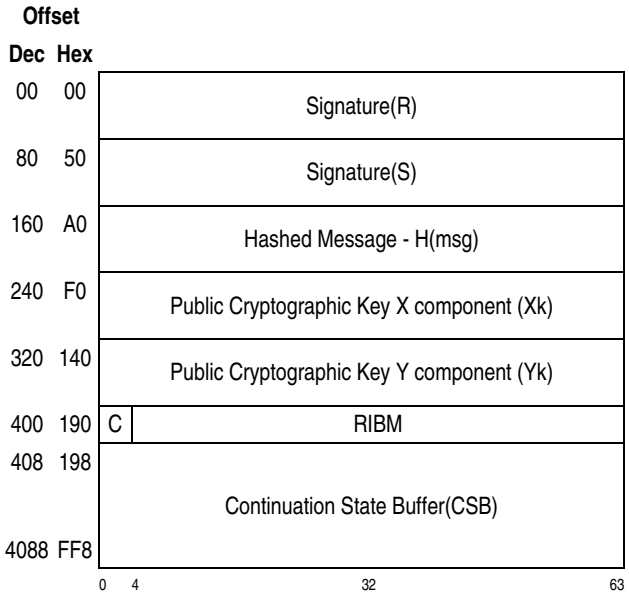

Figure 26-7. Parameter Block for KDSA-ECDSA-Verify-P521 Function

defines data to be passed in “octets” which are 8 bits wide. 521-bit operands need to be padded on the leftmost significant bits with 7 zeros to form 528 bits or 66 bytes (octets). Each parameter is 66 bytes which is right-aligned in the 80-byte field. The 14 remaining bytes are ignored and not updated. The hashed message is 66 bytes wide and upper bits can be non-zero which may require the function to perform modulo reduction by the order of the curve.

The reserved for IBM use (RIBM) field is 60 bits and the information code (C) is 4 bits for a total of 8 bytes, and must be initialized to zero prior to the first invocation of the instruction for each message; otherwise results are unpredictable. The RIBM holds status and control information and the continuation state buffer (CSB) is provided to hold intermediate results for partial completion reported by setting the condition code equal to 3. The parameter block should not be altered by the program after partial completion and before reexecution of the instruction for the purpose of resuming the operation; otherwise results are unpredictable. Corruption of the CSB is handled by the CPU clearing the intermediate results and status in the CSB and ending in partial completion which will allow a clean re-execution of the instruction. Also the CSB is cleared by the CPU of any intermediate state if the KDSA instruction ends with neither a condition code 3 nor an access exception. The information code is utilized by the KDSA Encrypted Sign

functions to distinguish between different condition code one cases and is reserved for future use on other function codes.

Condition code 1 is set when the public key is invalid due to a coordinate not being greater than or equal to zero and less than the prime modulus of the curve, or the point not on the curve. Condition code 2 is set if the signature is invalid, and condition code 0 is set if the signature is valid. Condition code 3 is set if the operation ends in partial completion.

KDSA-ECDSA-Sign Functions

Note: The description of the KDSA-ECDSA-Sign function assumes that the reader is familiar with the Elliptic Curve Digital Signal Algorithm (ECDSA) described in Reference [24.] on page xxxii.

This section illustrates the operation for three KDSA-ECDSA-Sign and three KDSA-Encrypted-ECDSA-Sign functions:

- KDSA-ECDSA-Sign-P256 (function code 9)
- KDSA-ECDSA-Sign-P384 (function code 10)
- KDSA-ECDSA-Sign-P521 (function code 11)
- KDSA-Encrypted-ECDSA-Sign-P256 (function code 17)
- KDSA-Encrypted-ECDSA-Sign-P384 (function code 18)
- KDSA-Encrypted-ECDSA-Sign-P521 (function code 19)

The KDSA-ECDSA-Sign function uses a cryptographic key (K) that is a plain text key for the author's private key. The KDSA-Encrypted-ECDSA-Sign function uses an encrypted key to hold the author's private key and has a corresponding Wrapping Key Verification Pattern (WK_eVP) to test the key.

The ECDSA algorithm uses a random number to randomize the signature. KDSA-ECDSA-Sign and KDSA-Encrypted-ECDSA-Sign functions for NIST curves (P256, P384, and P521) utilize a user specified random number, RN, in the parameter block. For KDSA-ECDSA-Sign with the deterministic bit equal to zero and for KDSA-Encrypted-ECDSA-Sign, the specified random number is hashed with a CPU-generated random number that varies on each invocation. For KDSA-ECDSA-Sign with the deterministic bit equal to one the user specified random number is used directly, which makes every execution with the same input produce the same signature. The EdDSA algorithm does not use a random number.

The result of the sign function is a signature represented by two integers, R and S, which is stored in the designated location in the parameter block. When the deterministic bit is zero, R and S are greater than zero and less than the order of the curve for the particular function. When the deterministic bit is one, R and S are greater than or equal to zero and less than the order of the curve for the particular function.

The parameter block for KDSA-ECDSA-Sign-P256 function with plain text key is shown in Figure 26-8, below.

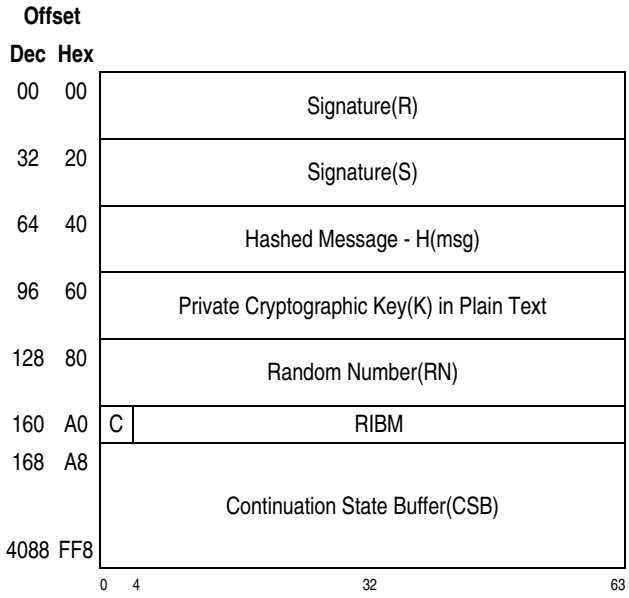

Figure 26-8. Parameter Block for KDSA-ECDSA-Sign-P256 Function

The parameter block for KDSA-ECDSA-Sign-P384 function with plain text key is shown in Figure 26-9, below.

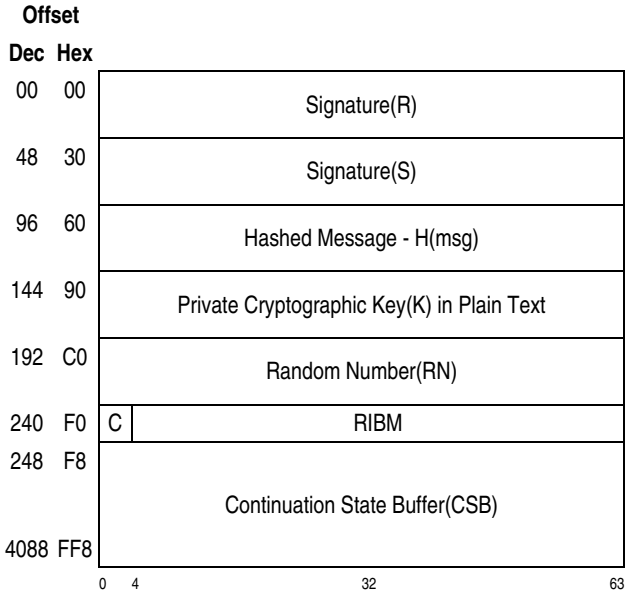

Figure 26-9. Parameter Block for KDSA-ECDSA-Sign-P384 Function

The parameter block for KDSA-ECDSA-Sign-P521 function for with plain text key is shown in Figure 26-10. The NIST standard defines data to be passed in "octets" which are 8 bits wide. 521-bit operands need to be padded on the leftmost significant bits with 7 zeros to form 528 bits or 66 bytes (octets). Each parameter is 66 bytes which is right-aligned in the 80-byte field. The 14 remaining bytes are ignored and not updated. The hashed message is 66 bytes wide and leftmost bits can be non-zero which may require the function to perform modulo reduction by the order of the curve.

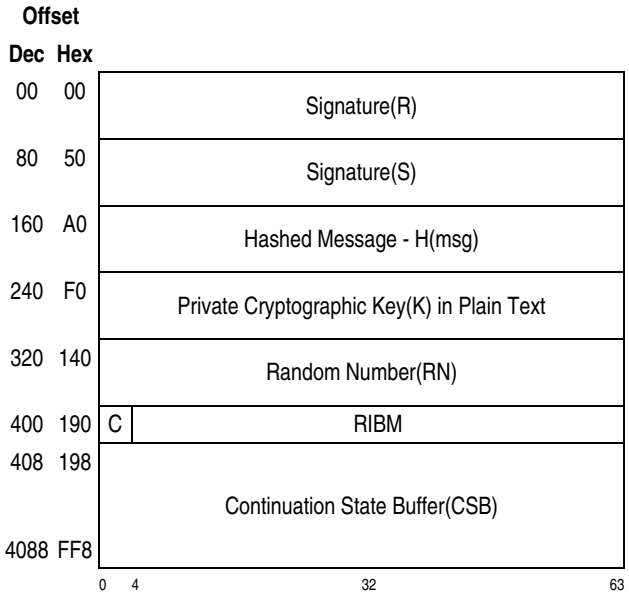

Figure 26-10. Parameter Block for KDSA-ECDSA-Sign-P521 Function

The parameter block for KDSA-Encrypted-ECDSA-Sign-P256 which uses an encrypted key is shown in Figure 26-11, below.

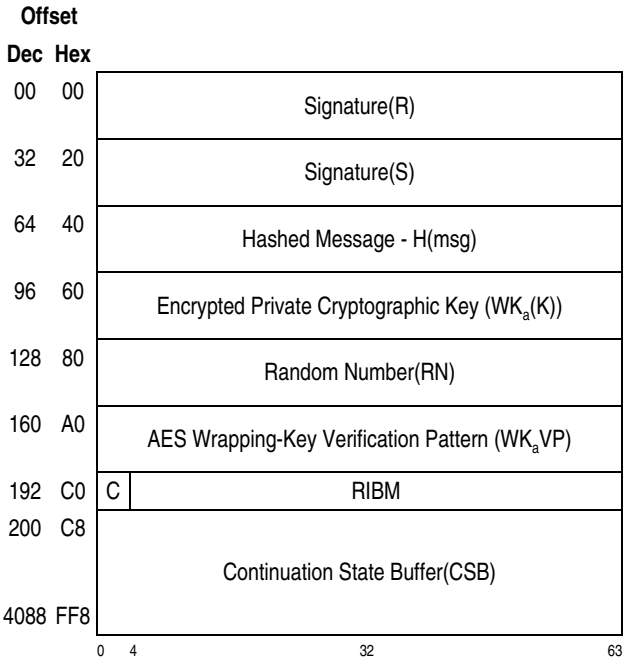

Figure 26-11. Parameter Block for KDSA-Encrypted-ECDSA-Sign-P256 Function

The parameter block for KDSA-Encrypted-ECDSA-Sign-P384 function is shown in Figure 26-12, below.

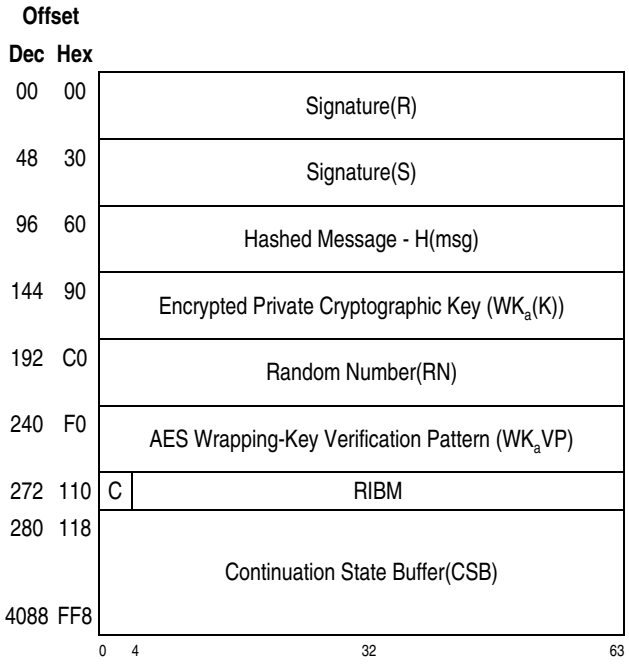

Figure 26-12. Parameter Block for KDSA-Encrypted-ECDSA-Sign-P384 Function

The parameter block for KDSA-Encrypted-ECDSA-Sign-P521 function is shown in Figure 26-13, below.

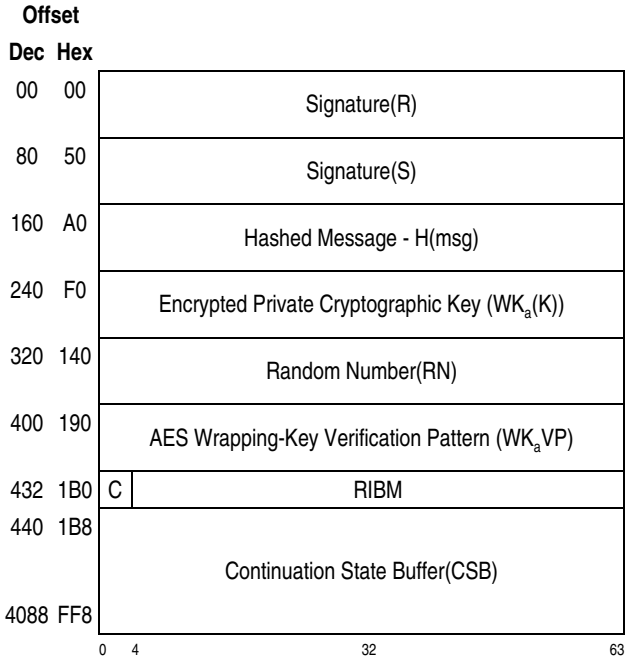

Figure 26-13. Parameter Block for KDSA-Encrypted-ECDSA-Sign-P521 Function

P521 format has 521 bits with an additional most significant 7 bits of zeros for R, S, and operands for 66 bytes which are right aligned within the 80 byte field. The remaining 14 bytes of the R and S fields are unchanged. The hashed message is the width of the whole 80-byte field.

Condition code 1 is set and C is set to 0001 binary if the verification pattern mismatches. The condition code is set to 1 and C is set to 0000 binary if the private key is zero or greater than or equal to the order of the curve. Condition code 2 is set if the random number is not invertible for ECDSA-Sign with the deterministic bit set to one but not when the deterministic bit is zero or for Encrypted-ECDSA-Sign. For ECDSA-Sign with the deterministic bit set to zero and for Encrypted-ECDSA-Sign the CPU generated random number will be invertible. Condition code 0 is set if signature generation is successful. Condition code 3 is set if the operation ends in partial completion.

KDSA-EdDSA-Verify Functions

This section illustrates the operation for two KDSA-EdDSA-Verify functions for Edwards curves:

- KDSA-EdDSA-Verify-Ed25519 (function code 32)
- KDSA-EdDSA-Verify-Ed448 (function code 36)

The locations of the operands and addresses used by each of these functions are as shown in Figure 26-3 on page 26-4. The parameter block contains the operands used by the KDSA-EdDSA-Verify functions and is addressed by general register 1.

Note that EdDSA is defined in RFC-8032 Reference [25.] on page xxxii to have integers encoded in little-endian form as opposed to most cryptographic algorithms. Transformation from little-endian to big-endian can be accomplished by a MOVE INVERSE (MVCIN) instruction and KDSA is assumed to have operands in big-endian form.

For Ed25519 the most significant bit of the most significant byte is not needed for 255 bit format though the standard requires this bit to be a zero. For compressed points the y-coordinate is placed in the 255 least significant bits and the x-coordinate least significant bit is placed in the remaining most significant bit. Ed448 encodes a compressed point with the 56 byte y-coordinate in the least significant 56 bytes of the 57 bytes and the x-coordinate least significant bit

is placed in the most significant bit of the most significant byte and the remaining bits of the byte are filled with zeros. Note that the integer representation of a compressed point can not take on all values, and there are some values which are invalid and can not be decompressed. In the case of input that can not be decompressed, such as the signature R or the public key, a condition code is produced indicating the input is invalid.

The KDSA-EdDSA-Verify function checks the validity of a signed message. The originator of the message has a public key that can be used to see if the signature matches the hashed message. The signature consists of two integers in the prime field designated by R and S. The originator and receiver agree on a hashing scheme for creating the signature. The KDSA-EdDSA-Verify function operates on full message which is addressed by operand 2. The originator's public key is represented by K in the parameter block and it is in compressed format where the least significant bit of the x coordinate is concatenated to all the bits of the y coordinate. Therefore the public key is slightly wider than the prime of the curve taking 57 bytes for the Ed448 curve. The operation results in a true or false validity indication in the condition code represented by condition code equal to zero or two respectively.

Note the public key and signature R are compressed points that are represented in big-endian form in the parameter block, though the RFC-8032 algorithm Reference [25.] on page xxxii requires these compressed points to be hashed in little-endian format in compressed format. This requires byte reversing the public key and signature R.

The parameter block used for KDSA-EdDSA-Verify-Ed25519 function has the format as shown in Figure 26-14, below. R, S, and K are represented as

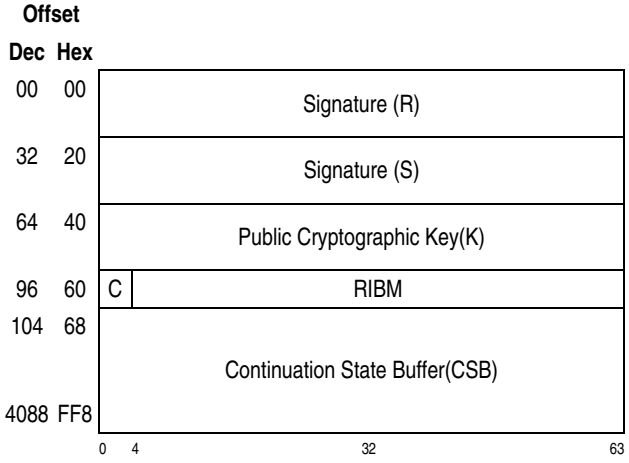

Figure 26-14. Parameter Block for KDSA-EdDSA-Verify-Ed25519 Function

32 bytes or 256 bits wide.

The parameter block for KDSA-EdDSA-Verify-Ed448 is shown in Figure 26-15, below. R, S, and K fields

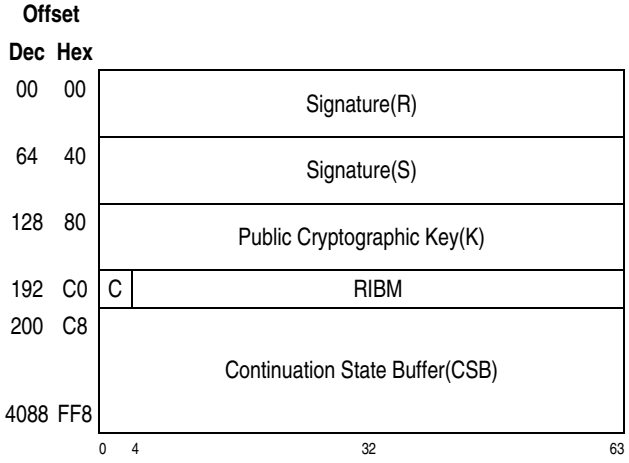

Figure 26-15. Parameter Block for KDSA-EdDSA-Verify-Ed448 Function

are 64 bytes or 512 bits wide. The S parameter is represented by the rightmost 456 bits of the 512 bit field and the R and K field which are compressed points are represented by the rightmost 456 bits of the 512 bit field.

The second operand address in general register R_2 and the second operand length in general register R_2+1 are not updated as the message is processed.

Condition code 1 is set when the public key is invalid due to the compressed point not being decompressable or the Y coordinate not being greater than or

equal to zero and less than the prime of the curve, or the point not on the curve. Condition code 2 is set if the signature is invalid and condition code 0 is set if the signature is valid. There are several cases of the signature being invalid such as the compressed point R not being decompressable or its resulting Y coordinate not greater than zero and less than the prime or the signature S not being greater than zero and less than the prime or the signature not matching. Note for Ed448 S is 57 bytes and the most significant byte must be zero otherwise condition code 2 is set. Condition code 3 is set if the operation ends with partial completion.

KDSA-EdDSA-Sign Functions

Note: The description of the KDSA-EdDSA-Sign function assumes that the reader is familiar with the Edwards-curve Digital Signature Algorithm (EdDSA) described in Reference [25.] on page xxxii.

This section illustrates the operation for two KDSA-EdDSA-Sign functions and the two KDSA-Encrypted-EdDSA-Sign functions:

- KDSA-EdDSA-Sign-Ed25519 (function code 40)
- KDSA-EdDSA-Sign-Ed448 (function code 44)
- KDSA-Encrypted-EdDSA-Sign-Ed25519 (function code 48)
- KDSA-Encrypted-EdDSA-Sign-Ed448 (function code 52)

The KDSA-EdDSA-Sign function uses a cryptographic key (K) that is a plain text key for the author's private key. This key must be protected by software. The KDSA-Encrypted-EdDSA-Sign function uses an encrypted key to hold the author's private key and has a corresponding Wrapping Key Verification Pattern (WK_aVP) to test the key.

The EdDSA algorithm does not use a random number and therefore none is specified for KDSA-EdDSA-Sign functions.

The result of the KDSA-EdDSA-Sign function is a signature which is represented by two integers, R and S, where S is greater than zero and less than the order of the curve for the particular function and is stored in the designated location in the parameter block.

Note that for EdDSA the private key is not checked for range since it is directly hashed and does not need to be in a certain range.

Note the public key and signature R are compressed points that are created internal to the sign operation in big-endian form, though the RFC-8032 algorithm Reference [25.] on page xxxii requires these compressed points to be hashed in little-endian format in compressed format. This requires byte reversing the public key and signature R.

The parameter block for KDSA-EdDSA-Sign-Ed25519 with plain text key is shown in Figure 26-16, below. The R, S, and K parameters are 32 byte

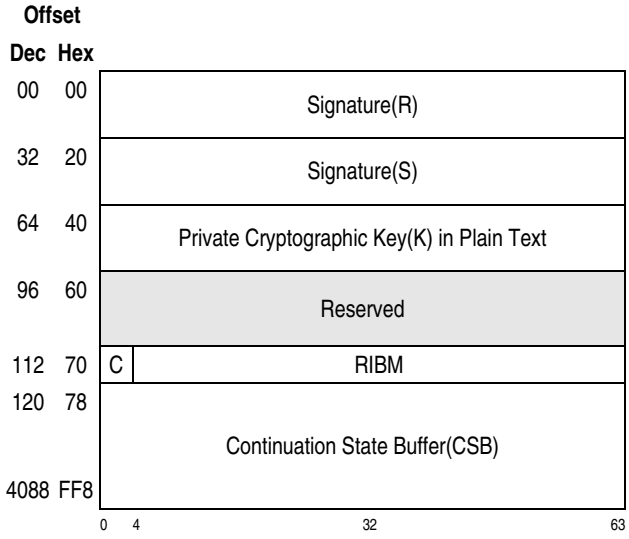

Figure 26-16. Parameter Block for KDSA-EdDSA-Sign-Ed25519 Functions

fields. Note that the S parameter has the most significant bit of the field forced to zero. No random number is specified since EdDSA algorithm does not require one.

The parameter block for KDSA-EdDSA-Sign-Ed448 function with plain text key is shown in Figure 26-17,

below. The R, S, and the K parameters are 456 bits

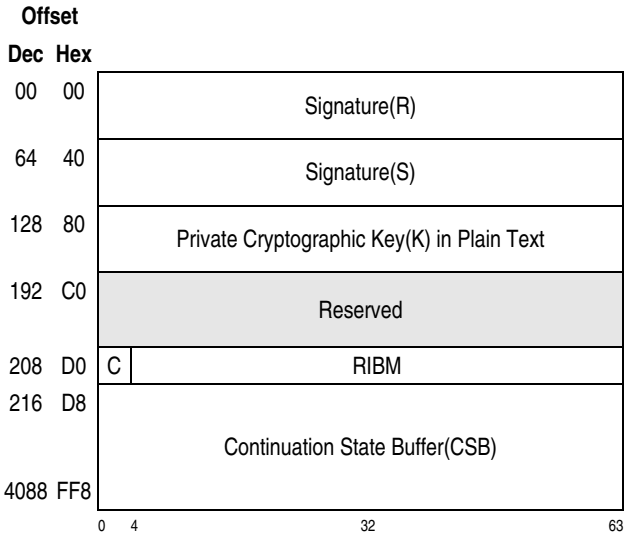

Figure 26-17. Parameter Block for KDSA-EdDSA-Sign-Ed448 Function

or 57 bytes and are right aligned. The remaining bytes of the R and S fields are unchanged. The Ed448 format also uses the EdDSA algorithm which does not utilize a random number.

The reserved for IBM use (RIBM) field is 60 bits and the information code (C) is 4 bits for a total of 8 bytes, and must be initialized to zero prior to the first invocation of the instruction for each message; otherwise results are unpredictable. The RIBM field holds status and control information and the continuation state buffer (CSB) is provided to hold intermediate results for partial completion reported by setting the condition code equal to 3. The parameter block should not be altered by the program after partial completion and before reexecution of the instruction for the purpose of resuming the operation; otherwise results are unpredictable. Corruption of the CSB is handled by the CPU clearing the intermediate results and status in the CSB and ending in partial completion which will allow a clean re-execution of the instruction. Also the CSB is cleared by the CPU of any intermediate state if the KDSA instruction ends with neither a condition code 3 nor an access exception. The information code is utilized by the KDSA Encrypted Sign functions to distinguish between different condition code one cases and is reserved for future use on other function codes.

The parameter block for KDSA-Encrypted-ECDSA-Sign-Ed25519 for encrypted key is shown in Figure 26-18, below. Note the Ed25519 format uti-

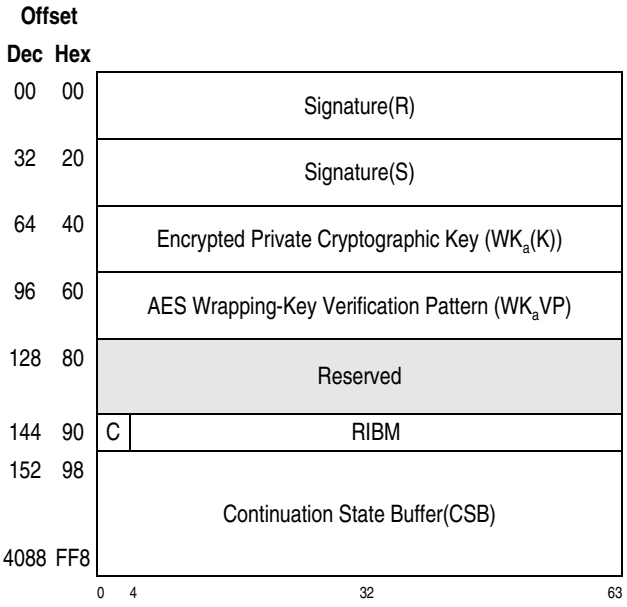

Figure 26-18. Parameter Block for KDSA-Encrypted-EdDSA-Sign-Ed25519 Function

lizes 32 bytes for each parameter including the S field which has a zero for the most significant bit.

The parameter block for KDSA-Encrypted-EdDSA-Sign-Ed448 is shown in Figure 26-19, below. The R

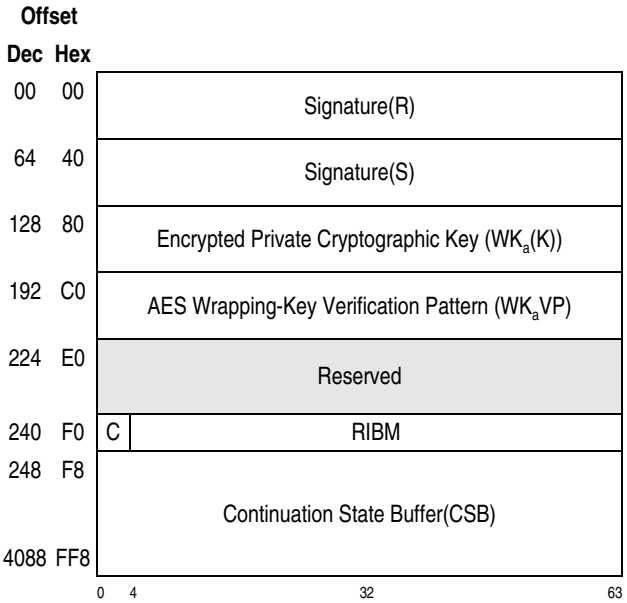

Figure 26-19. Parameter Block for KDSA-EdDSA-Sign-Ed448 Function

and S parameters require 456 bits or 57 bytes and they are right aligned within the 64 byte fields.

The second operand address in general register R_2 and the second operand length in general register $R_2 + 1$ are not updated as the message is processed which is twice for the KDSA-EdDSA-Sign and KDSA-Encrypted-EdDSA-Sign functions.

Condition code 1 is set and C is set to 0001 binary, if the verification pattern mismatches. Condition code 0 is set if signature generation is successful. Condition code 3 is set if the operation ends with partial completion.

Operand Field Description

The fields of the parameter block for all KDSA-Verify and KDSA-Sign functions are as follows where each parameter is right aligned in the field and extracted to byte boundaries (P521 parameters are 66 bytes or 528 bits with the most significant 7 bits equal to zeros, except for the hashed message which allows these 7 bits to be non-zero):

Signature (R): The first part of the signature is represented by R. For ECDSA, R is an unsigned integer which is greater than zero and less than the order of the curve, otherwise it is considered an invalid signature and for the ECDSA Verify function results in a condition code equal to 2. For EdDSA functions, R is a compressed point where the least significant bit of X is concatenated with the Y. R must be decompressable or the condition code is set to 2. For Ed25519, R is 256 bits consisting of 1 bit of X concatenated on the left of 255 bits of Y and for Ed448 an extra byte is added on the left with 1 bit X concatenated with 7 zeros, followed by 448 bits of Y. The Y coordinate must be greater than or equal to zero and less than the prime otherwise it is considered an invalid signature resulting in a condition code equal to 2.

Signature (S): The second part of the signature is represented by S. S is an unsigned integer for both ECDSA and EdDSA functions and is greater than zero and less than the order of the curve, otherwise for the Verify functions it is considered an invalid signature resulting in a condition code equal to 2.

Hashed Message - H(msg): The sign and verify operation utilize a hashed version of the author's message for ECDSA curves. Hashing for ECDSA is performed prior to the KDSA instruction to allow greater flexibility in supported encryption. The hashed message is an unsigned integer and can be any value including zero or greater than the prime. The hashed message is reduced by the function modulo the order of the curve to be greater than or equal to zero and less than the order of the curve. This parameter is not available on EdDSA curves, since they do not prehash the message, and instead operand 2 addresses the encrypted message.

Cryptographic Key (K): The cryptographic key used in the sign and verify operations begins at various bytes of the parameter block. The size of the key field and its offset in the parameter block are dependent on the function code, as shown in Figure 26-20.

Function Code	Function	Key Length (bytes)	Key Offset (bytes)
1	KDSA-ECDSA-Verify-P256	32x2	96-159
2	KDSA-ECDSA-Verify-P384	48x2	144-239
3	KDSA-ECDSA-Verify-P521	66x2	254-319, 334-399
9	KDSA-ECDSA-Sign-P256	32	96-127
10	KDSA-ECDSA-Sign-P384	48	144-191
11	KDSA-ECDSA-Sign-P521	66	254-319
17	KDSA-Encrypted-ECDSA-Sign-P256	32	96-127

Figure 26-20. Summary of Key Lengths and Offsets for KDSA Functions

The key used for KDSA-EdDSA-Verify functions is a compressed point whereas the other functions use an integer key. If the compressed point public key can not be decompressed or if the Y coordinate is greater than or equal to the prime the condition code is set to 1. Note that Ed25519 requires 255 least significant bits of the 256-bit, 32-byte field. The KDSA-Sign for P521 and Ed448 require different key widths for encrypted key and plain text functions. The encrypted key is encoded into blocks of 128 bits. The P521 plain text key for sign and for verify are 521 bits which is 65 bytes and 1 bit, which is aligned in the rightmost bits of the 66 byte key and the 66 byte key

is aligned in the rightmost bytes of the 80 byte field in the parameter block.

For KDSA-ECDSA-Sign the key must be greater than zero and less than the order of the curve or the condition code is set to 1. For KDSA-ECDSA-Verify the public key point has to be on the curve and the coordinates must be less than the order of the curve or the condition code is set to 1.

AES Wrapping-Key Verification Pattern (WK_aVP): For the KDSA-Encrypted-Sign functions (codes 17-19, 48, and 52), the 32 bytes immediately following the key in the parameter block contain the AES wrapping-key verification pattern (WK_aVP).

For the KDSA-Verify functions and the plain text key KDSA-Sign functions, the WK_aVP field is not present in the parameter block.

Wrapping-Key Verification: For the KDSA-Sign with encrypted key functions (function codes 17-19, 48, and 52), the contents of the 32-byte WK_aVP field are compared with the contents of the AES wrapping-key verification-pattern register. If they mismatch, the parameter-block location remains unchanged, and the operation is completed by setting condition code 1. If they match, the contents of the key field of the parameter block are deciphered using the AES wrapping key to obtain the cryptographic key, K. (See the “Protection of Cryptographic Keys” on page 7-490 for details.) Note encrypted ECC keys are protected by AES-256 encryption.

For the KDSA functions that do not use encrypted keys, wrapping-key verification is not performed.

Random Number (RN): The KDSA-ECDSA-Sign and KDSA-Encrypted-Sign functions have an input random number. For KDSA-ECDSA-Sign functions with the deterministic bit set equal to one, the random number must be greater than zero and less than the order of the curve; otherwise the operation completes with setting condition code 2. In this case, the parameter block is unchanged, except for the RIBM and CSB fields, which may be updated. The random number must be invertible by the order of curve; otherwise the operation completes with setting condition code 2. In this case, the parameter block is unchanged, except for the RIBM and CSB fields, which may be updated..

For KDSA-ECDSA-Sign with the deterministic bit equal to zero and for KDSA-Encrypted-ECDSA-Sign functions the random number can be any value including zero, since it is not used directly but instead is used as a seed to create an invertible, hidden, random number.

RIBM, C, and Continuation State Buffer (CSB):

The RIBM and C must be initialized to zero prior to the first invocation of the instruction for each message; otherwise results are unpredictable. This reserved area and continuation state buffer (CSB) are provided to hold intermediate results for partial completion reported by setting the condition code equal to 3. The parameter block should not be altered by the program after partial completion and before reexecution of the instruction for the purpose of resuming the operation; otherwise results are unpredictable. If corruption is detected in the RIBM and CSB the CPU clears the CSB intermediate state and status and ends the instruction in partial completion which will allow a clean reexecution of the instruction. Also, the CSB is cleared by the CPU of any intermediate state when the instruction ends in neither partial completion nor an access exception. The C field is an information code field defined for the KDSA Encrypted Sign functions to distinguish the condition code one cases of private key not in range, C=0000 binary, and the WKVP mismatch, C=0001 binary and is reserved for other functions.

Reserved: As an input to an operation, reserved fields should contain zeros; otherwise, the program may not operate compatibly in the future. When an operation ends, reserved fields may be stored as zeros or may remain unchanged.

KDSA-Query-Authentication-Information (Function Code 127)

The locations of the operands and addresses used by the instruction are as shown in Figure 26-3 on page 26-4.

The KDSA-query-authentication-information function stores the information that can be used by the program to authenticate the running instruction’s firmware code level (IFCL) currently installed on the model into the format-0 parameter block for KDSA-query-authentication-information. Condition code 0 is set when execution of the KDSA-query-authentication-information function completes; condition codes 1, 2, and 3 are not applicable to this function.

The format-0 parameter block used for the KDSA-query-authentication-information function has the following format:

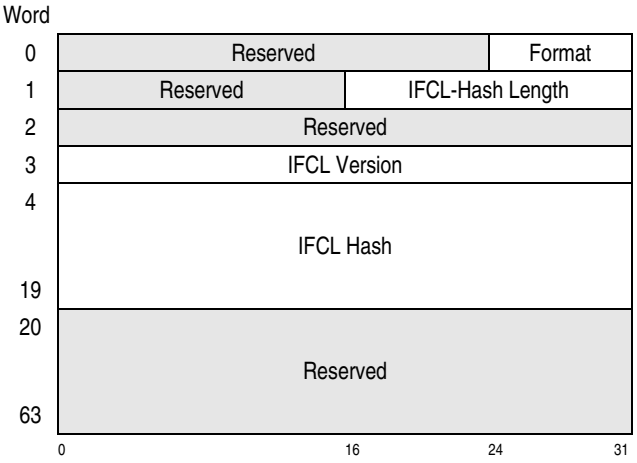

Figure 26-21. Format-0 Parameter Block for KDSA-Query-Authentication-Information

The format-0 parameter block contains the following fields:

Reserved: Bytes 0-2 of word 0, bytes 0-1 of word 1, word 2, and words 20-63 are reserved and stored as zeros.

Format: Byte 3 of word 0 contains an 8-bit unsigned binary integer whose value specifies the format of the parameter block. A format value of zero indicates a format-0 parameter block. When a format-0 parameter block is stored, the value of this field is set to zero.

IFCL-Hash Length: Bytes 2-3 of word 1 contain a 16-bit unsigned binary integer specifying the number of bytes of the IFCL hash stored in the IFCL hash field. When the IFCL hash is less than or equal to 64 bytes, the IFCL-hash length field is set to the actual length of the IFCL hash. When the IFCL hash is larger than 64 bytes, the IFCL-hash length field is set to 64.

IFCL Version: Word 3 contains a 32-bit unsigned binary integer specifying the version number of the IFCL.

IFCL Hash: Words 4-19 contain the hash value of the IFCL. The IFCL-hash length field specifies the number of bytes that are in the IFCL hash field. The IFCL hash value is left aligned. When the IFCL hash is less than 64 bytes, it is padded with zeros on the right. When the IFCL hash is larger than 64 bytes, only the leftmost 64 bytes of the IFCL hash are stored.

Common Operation

When the entire parameter block overlaps the PER storage-area designation, a PER storage-alteration event is recognized, when applicable, for the parameter block. When only a portion of the parameter block overlaps the PER storage-area designation, it is model-dependent which of the following occurs:

- A PER storage-alteration event is recognized, when applicable, for the entire parameter block.
- A PER storage-alteration event is recognized, when applicable, for the portion of the parameter block that is stored.

A PER zero-address-detection event is recognized, when applicable, for the second-operand location and for the parameter block.

For functions that perform a comparison of the wrapping-key verification pattern field in the parameter block with the wrapping-key verification-pattern register, it is unpredictable whether access exceptions and PER zero-address-detection events are recognized for the second operand when the comparison results in a mismatch.

When the contents of general register R_2 are zero, multiple PER zero-address-detection events will be detected if the instruction ends in partial completion.

Access exceptions may be reported for a larger portion of an operand than is processed in a single execution of the instruction; however, access exceptions are not recognized for locations beyond the length of an operand nor for locations more than 4 K-bytes beyond the current location being processed. The entire parameter block may be tested for store-type accesses even though part of it may not be stored. All KDSA function codes may test for store-type accesses including KDSA-Verify since it could store to the RIBM and CSB fields on partial completion.

If the CPU is enabled to update counters in the cryptography-counter set, then the following apply for all functions other than KDSA-Query and KDSA-Query-Authentication-Information:

- The appropriate counter has been updated when the instruction ends with condition code 0 set.

- For the verify functions, the appropriate counter has been updated when the instruction ends with condition code 2 set.
- Access exceptions for the appropriate counter may be recognized even though the function may be completed without updating the appropriate counter. That is, the appropriate counter may be tested for accessibility prior to determining whether a verify function may end with setting condition code 1 or prior to determining whether a sign function may end with setting condition code 1 or 2.

Special Conditions for KDSA

If the second operand overlaps the parameter block, results are unpredictable.

A specification exception is recognized and no other action is taken if any of the following occurs:

1. Bits 57-63 of general register 0 specify an unassigned or uninstalled function code.
2. The R_2 field designates an odd-numbered register or general register 0.

Resulting Condition Code:

0 Query: function completes; Verify: signature verified for function; Sign: normal completion.
1 Verify: public key not on curve, or not decompressable, or coordinate greater than the prime of the curve; Sign: key verification-pattern mismatch, or for ECDSA-Sign the private key is equal to zero or greater than the prime of the curve.
2 Verify: signature is incorrect, or for EdDSA R not decompressable, or for non-Encrypted ECDSA sign with D=1: random number not invertible or out of range (0 < RN < order of curve).
3 Partial completion

Program Exceptions:

- Access (fetch, parameter block fields, operand 2 (EdDSA functions only); store, parameter block fields; fetch and store, cryptography counter)
- Operation (if the message-security-assist extension 9 is not installed)
- Specification
- Transaction constraint

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B	Operation exception.
7.C	Transaction constraint.
8.	Specification exception due to invalid function code or invalid register number.
9.A.1	Access exceptions for an access to the parameter block.
9.A.2	Sign function with condition code 1 due to verification-pattern mismatch, or ECDSA private key equal to zero or greater than the order of the curve. Verification function for ECDSA with condition code 1 due to the public key not on the curve or one or more of the coordinates greater than or equal to the order. Verification function for EdDSA with condition code 1 due to the public key not decompressable, or one or more of the coordinates greater than or equal to the prime.
9.A.3	ECDSA Sign (non-encrypted) function and D = 1 with condition code 2 due to a non-invertible random number or out of range (0 < RN < order of curve). Verification function for ECDSA with condition code 2 due to the signature equal to zero, or signature greater than or equal to the prime of the curve, and CPU not enabled to update counters or appropriate counter is accessible. Verification function for EdDSA with condition code 2 due to the signature S equal to zero, or signature S greater than or equal to the order of the curve, or signature R not decompressable, or the Y coordinate greater than or equal to the prime, and CPU not enabled to update counters or appropriate counter is accessible.
9.B	Access exceptions for an access to the second operand.
9.C	Access exceptions for an access to a cryptography counter.

Figure 26-22. Priority of Execution: KDSA

10.	Condition code 3 due to partial processing.
11.	Condition code 0 due to normal completion, condition code 0 designating a valid signature for a verify function, or condition code 2 designating an invalid signature for a verify function.

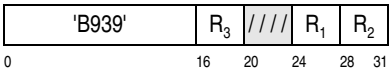
Figure 26-22. Priority of Execution: KDSA (Continued)

Programming Notes:

1. The performance of the query function (code 0) may be significantly slower than that of simply examining a location in storage. If the program needs to frequently test for the availability of a function, it should perform the query function once during initialization; subsequently it should examine the stored results of the query function in memory with an instruction such as TEST UNDER MASK.
2. When condition code 3 is set, the general registers containing the operand addresses and lengths, and the parameter block, are updated such that the program can simply branch back to the instruction to continue the operation.
3. The R_1 field is not used by this instruction for any function codes.
4. Software should clear fields in the parameter block that are sensitive such as the Private Key and the Random Number to limit the time exposed in storage. The CPU will zero out the CSB upon restart of the instruction and full completion.
5. The reserved field should be initialized to zero otherwise the program may not operate compatibly in the future.

DEFLATE CONVERSION CALL

DFLTCC R_1,R_2,R_3 [RRF-a]



DEFLATE CONVERSION CALL performs functions related to transforming the state of data between the original (uncompressed) form of the data, and a compressed representation of the data, as specified by the standard described in Reference [23.] on page xxxii. The uncompressed data is a sequence of bytes. The compressed representation of the data includes symbols. Symbols represent an individual byte of uncompressed data, referred to as a literal byte, or represent a reoccurring sequence of bytes of uncompressed data, referred to as a duplicate string. A Huffman table specifies the encoding and decoding between compressed-data symbols and uncompressed data. There are two types of Huffman tables. A fixed-Huffman table (FHT) is a predetermined specification which includes all possible codings. A dynamic-Huffman table (DHT) is a set of codings created specifically for the data to be compressed, which may be a subset of all possible codings. A compressed representation of data generated with a DHT is typically smaller than a compressed representation of the same data generated with an FHT. A portion of the most recently processed uncompressed data, referred to as history, is maintained for encoding and decoding compressed-data symbols representing duplicate strings. The history is the reference source for duplicate strings. The history is updated as data is processed during an operation.

The definition of DEFLATE CONVERSION CALL assumes knowledge of the DEFLATE compressed data format, which is described in Reference [23.] on page xxxii. Noteworthy attributes of the DEFLATE standard which apply to DEFLATE CONVERSION CALL are as follows:

- A compressed-data set consists of a series of blocks. There are three types of blocks. One type consists of a 3-bit header followed by length information and uncompressed data. Two types of blocks consists of a 3-bit header followed by compressed-data elements.
- Compressed-data elements may include a compressed representation of a dynamic-Huffman table, compressed-data symbols, and an end-of-block (EOB) symbol.
- Compressed-data elements have various bit lengths.
- Compressed-data elements may begin or end between byte boundaries in storage.
- Compressed-data elements are loaded into bytes in order from the rightmost bit position to the leftmost bit position.

Refer to “Descriptions for Compressed-data Blocks” on page 26-45 for details on boundaries and orderings for bytes and bits of the various blocks encountered in a compressed-data set.

When a compressed-data element occupies part of, and not all of, a byte in storage, the entire byte in

storage is accessed. Storage-operand lengths specify the number of addressable bytes, which may specify more bits than the compressed-data occupies.

DEFLATE CONVERSION CALL is an unprivileged instruction. It may be executed when the CPU is in the problem or supervisor state.

Bits 20-23 of the instruction are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.

A function specified by the function code in bit positions 57-63 of general register 0 is performed. Figure 26-23 shows the assigned function codes for DEFLATE CONVERSION CALL. All other function codes are unassigned. When the specified function is DFLTCC-CMPR or DFLTCC-XPND, bit 56 of general register 0 specifies the history-buffer type (HBT) used during the operation. When HBT is zero, the history buffer is called an in-line history buffer. When using an in-line history buffer, the history is immediately to the left of the second operand when DFLTCC-CMPR is specified, and is immediately to the left of the first operand when DFLTCC-XPND is specified. When HBT is one, the history-buffer is called a circular history buffer. When using a circular history buffer, the history is a portion of, or all of, the third operand when either DFLTCC-CMPR or DFLTCC-XPND is specified. When the DFLTCC-QAF or DFLTCC-GDHT function is specified, bit 56 of general register 0 is ignored. Bit positions 0-31 of general register 0 are ignored. Bit positions 32-55 of general register 0 are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.

Code	Function	Parameter Block Size (bytes)
0	DFLTCC-QAF	32
1	DFLTCC-GDHT	384
2	DFLTCC-CMPR	1536
4	DFLTCC-XPND	1536

Figure 26-23. Function Codes for DEFLATE COMPRESSION CALL

When bits 57-63 of general register 0 designate an unassigned or uninstalled function code, a specification exception is recognized.

The contents of general register 1 specify the logical address of the leftmost byte of the parameter block in storage. The parameter block must be designated on a doubleword boundary; otherwise a specification exception is recognized.

When the specified function is DFLTCC-CMPR or DFLTCC-XPND, the contents of general register R_1 specify the logical address of the leftmost byte of the first operand. When the specified function is DFLTCC-CMPR, the contents of general register $R_1 + 1$, in conjunction with the values of the NT and SBB fields of the parameter block, specify the length of the first operand. Figure 26-24 on page 26-19 provides examples which demonstrate the length of the first operand for the DFLTCC-CMPR function as a function of the contents of general register $R_1 + 1$, the NT field, and the SBB field. When the specified function is DFLTCC-XPND, the contents of general register $R_1 + 1$ specify the length of the first operand. When the specified function is DFLTCC-CMPR or DFLTCC-XPND the results of compressing or uncompressing data are stored at the first-operand location. When the DFLTCC-QAF or DFLTCC-GDHT function is specified, the contents of general registers R_1 and $R_1 + 1$ are ignored. For all functions, the R_1 field designates an even-odd pair of general registers. For all functions, the R_1 field must not designate general register 0 and must designate an even-numbered register; otherwise, a specification exception is recognized.

contents of GR R1 + 1 (hex)	NT	SBB (binary)	length of first operand
00000000 00000002	0	001	15 bits
00000000 00000001	1	---	8 bits
00000000 00000001	0	000	8 bits
00000000 00000001	0	011	5 bits
00000000 00000001	0	111	1 bit
00000000 00000000	-	---	0 bits

Figure 26-24. Examples Illustrating how NT and SBB Apply to the length of the first operand for the DFLTCC-CMPR function

When the specified function is DFLTCC-GDHT, DFLTCC-CMPR, or DFLTCC-XPND, the contents of general register R_2 specify the logical address of the leftmost byte of the second operand. When the spec-

ified function is DFLTCC-CMPR or DFLTCC-GDHT, the contents of general register $R_2 + 1$ specify the length of the second operand. When the specified function is DFLTCC-XPND, the contents of general register $R_2 + 1$, in conjunction with the values of the NT and SBB fields of the parameter block, specify the length of the second operand. When the second-operand length is referenced and has a non-zero value at the beginning of the execution of the instruction, data is fetched from the second-operand location. When the second-operand length is referenced, has a value of zero at the beginning of the execution of the instruction, and the continuation flag (CF) field of the parameter block is one at the beginning of the execution of the instruction, the second operand is not accessed. Refer to page 26-52 and page 26-59 for additional details. When the DFLTCC-QAF function is specified, the contents of general registers R_2 and $R_2 + 1$ are ignored. When the DFLTCC-GDHT function is specified and the contents of general register $R_2 + 1$ specify a length equal to zero, a specification exception is recognized and the second operand is not accessed. When the DFLTCC-CMPR or DFLTCC-XPND function is specified, the continuation flag (CF) field of the parameter block is zero at the beginning of the execution of the instruction, and the contents of general register $R_2 + 1$ specify a length equal to zero, a specification exception is recognized and the second operand is not accessed. For all functions, the R_2 field designates an even-odd pair of general registers. For all functions, the R_2 field must not designate general register 0 and must designate an even-numbered register; otherwise, a specification exception is recognized.

When the specified function is DFLTCC-CMPR or DFLTCC-XPND and the history-buffer type (HBT) is circular, the contents of general register R_3 specify the logical address of the leftmost byte of the third operand, and must designate a 4 K-byte boundary; otherwise a specification exception is recognized. The circular history buffer is a 32 K-byte buffer located at the third-operand location. When the specified function is DFLTCC-CMPR or DFLTCC-XPND and the HBT is zero, the contents of general register R_3 are ignored. When the DFLTCC-QAF or DFLTCC-GDHT function is specified, the contents of general register R_3 are ignored. For all functions, the R_3 field must not designate general register 0 or general register 1; otherwise, a specification exception is recognized.

As part of the operation when the specified function is DFLTCC-CMPR, the address in general register R_1 is incremented by the number of bytes processed of the first operand that included processing bit position 0, and the length in general register $R_1 + 1$ is decremented by the same number; the address in general register R_2 is incremented by the number of bytes processed of the second operand, and the length in general register $R_2 + 1$ is decremented by the same number. The number of bytes processed of the first operand that included processing bit position 0 is the integer quotient resulting from an integer division with the dividend being the sum of the number of output bits processed and the original value of the SBB, and the divisor being a value of eight. The formation and updating of the addresses and lengths are dependent on the addressing mode.

As part of the operation when the specified function is DFLTCC-XPND, the address in general register R_1 is incremented by the number of bytes processed of the first operand, and the length in general register $R_1 + 1$ is decremented by the same number; the address in general register R_2 is incremented by the number of bytes processed of the second operand that included processing bit position 0, and the length in general register $R_2 + 1$ is decremented by the same number. The number of bytes processed of the second operand that included processing bit position 0 is the integer quotient resulting from an integer division with the dividend being the sum of the number of input bits processed and the original value of the SBB, and the divisor being a value of eight. The formation and updating of the addresses and lengths are dependent on the addressing mode.

For all functions, the contents of general registers 0, 1, and R_3 are not modified.

In the 24-bit addressing mode, the following apply:

- The contents of bit positions 40-63 of general registers 1, R_1, R_2, and R_3 constitute the addresses of the parameter block, first operand, second operand, and circular history buffer, respectively, and the contents of bit positions 0-39 are ignored.
- Bits 40-63 of the updated first-operand and second-operand addresses replace the corresponding bits in general registers R_1 and R_2, respectively. Carries out of bit position 40 of the updated addresses are ignored, and the contents of bit positions 32-39 of general registers R_1 and R_2 are set to zeros. The contents of bit positions 0-31 of general registers R_1 and R_2 remain unchanged. When the instruction ends

with partial or normal completion, and an updated operand address equals the operand address at the beginning of the execution of the instruction, bit positions 32-39 of the corresponding general register are set to zeros.
- The contents of bit positions 32-63 of general registers $R_1 + 1$ and $R_2 + 1$ form 32-bit unsigned binary integers which specify the number of bytes in the first and second operands, respectively. The contents of bit positions 0-31 of general registers $R_1 + 1$ and $R_2 + 1$ are ignored.
- Bits 32-63 of the updated first-operand and second-operand lengths replace the corresponding bits in general registers $R_1 + 1$ and $R_2 + 1$, respectively. The contents of bit positions 0-31 of general registers $R_1 + 1$ and $R_2 + 1$ remain unchanged.

In the 31-bit addressing mode, the following apply:

- The contents of bit positions 33-63 of general registers 1, R_1, R_2, and R_3 constitute the addresses of the parameter block, first operand, second operand, and circular history buffer, respectively, and the contents of bit positions 0-32 are ignored.
- Bits 33-63 of the updated first-operand and second-operand addresses replace the corresponding bits in general registers R_1 and R_2, respectively. Carries out of bit position 33 of the updated addresses are ignored, and the content of bit position 32 of general registers R_1 and R_2 is set to zero. The contents of bit positions 0-31 of general registers R_1 and R_2 remain unchanged. When the instruction ends with partial or normal completion, and an updated operand address equals the operand address at the beginning of the execution of the instruction, bit position 32 of the corresponding general register is set to zero.
- The contents of bit positions 32-63 of general registers $R_1 + 1$ and $R_2 + 1$ form 32-bit unsigned binary integers which specify the number of bytes in the first and second operands, respectively. The contents of bit positions 0-31 of general registers $R_1 + 1$ and $R_2 + 1$ are ignored.
- Bits 32-63 of the updated first-operand and second-operand lengths replace the corresponding bits in general registers $R_1 + 1$ and $R_2 + 1$, respectively. The contents of bit positions 0-31 of general registers $R_1 + 1$ and $R_2 + 1$ remain unchanged.

In the 64-bit addressing mode, the following apply:

- The contents of bit positions 0-63 of general registers 1, R_1, R_2, and R_3 constitute the addresses of the parameter block, first operand, second operand, and circular history buffer, respectively.
- Bits 0-63 of the updated first-operand and second-operand addresses replace the corresponding bits in general registers R_1 and R_2, respectively. Carries out of bit position 0 of the updated addresses are ignored.
- The contents of bit positions 0-63 of general registers $R_1 + 1$ and $R_2 + 1$ form 64-bit unsigned binary integers which specify the number of bytes in the first and second operands, respectively.
- Bits 0-63 of the updated first-operand and second-operand lengths replace the corresponding bits in general registers $R_1 + 1$ and $R_2 + 1$, respectively.

In the access-register mode, access registers 1, R_1, R_2, and R_3 specify the address spaces containing the parameter block, first operand, second operand, and circular history buffer, respectively. When DFTCC-CMPR with an in-line history buffer is specified in the access-register mode, access register R_2 specifies the address space containing the in-line history. When DFTCC-XPND with an in-line history buffer is specified in the access-register mode, access register R_1 specifies the address space containing the in-line history.

Figure 26-25 on page 26-21 shows the contents of the general registers just described.

All Addressing Modes

Explanation:

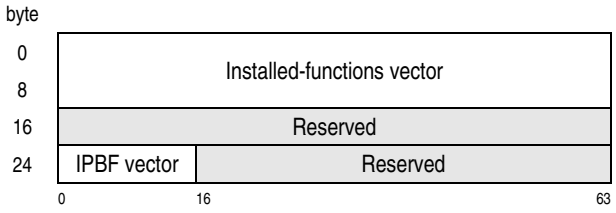
FC Function code
HBT History buffer type

Figure 26-25. General Register Assignment for DFLTCC (Part 2 of 2)

Function Code 0: DFLTCC-QAF (Query Available Functions)

The DFLTCC-QAF (query) function provides the means of indicating the availability of all installed functions and installed parameter block formats.

The parameter block for the query function has the following format:



Explanation

IPBF Installed-parameter-block-formats

Figure 26-26. Parameter Block for DFLTCC-QAF

An installed-functions vector and an installed-parameter-block-formats vector are stored to bytes 0-15 and bytes 24-25, respectively, of the parameter block, as illustrated in Figure 26-26.

Bits 0-127 of the installed-functions vector correspond to function codes 0-127, respectively, of the DEFLATE CONVERSION CALL instruction. When a bit is one, the corresponding function is installed; otherwise, the function is not installed.

Bits 0-15 of the installed-parameter-block-formats vector correspond to parameter-block formats 0-15, respectively, for the DFLTCC-GDHT, DFLTCC-CMPR, and DFLTCC-XPND functions. When a bit is one, the corresponding parameter-block format is installed; otherwise, the parameter-block format is not installed.

Zeros are stored to reserved bytes 16-23 and 26-31 of the parameter block.

The contents of general registers R_1, $R_1 + 1$, R_2, $R_2 + 1$, and R_3 are ignored when the DFLTCC-QAF function is specified.

A PER storage-alteration event is recognized, when applicable, for the parameter block. A PER zero-address-detection event is recognized, when applicable, for the parameter block.

Condition code 0 is set when execution of the DFLTCC-QAF function completes; condition codes 1, 2, and 3 are not applicable to the query function.

Function Code 1: DFLTCC-GDHT (Generate Dynamic-Huffman Table)

When the DFLTCC-GDHT function is specified, the second operand is used as a source to generate a compressed representation of a dynamic-Huffman table (DHT), as specified by the DEFLATE standard. Aspects of DHT generation are specified by the program to the machine using the DHTGC field of the parameter block. It is intended that the source contains uncompressed data and subsequent to completing the operation, the generated result is specified with the DFLTCC-CMPR function to compress the same source.

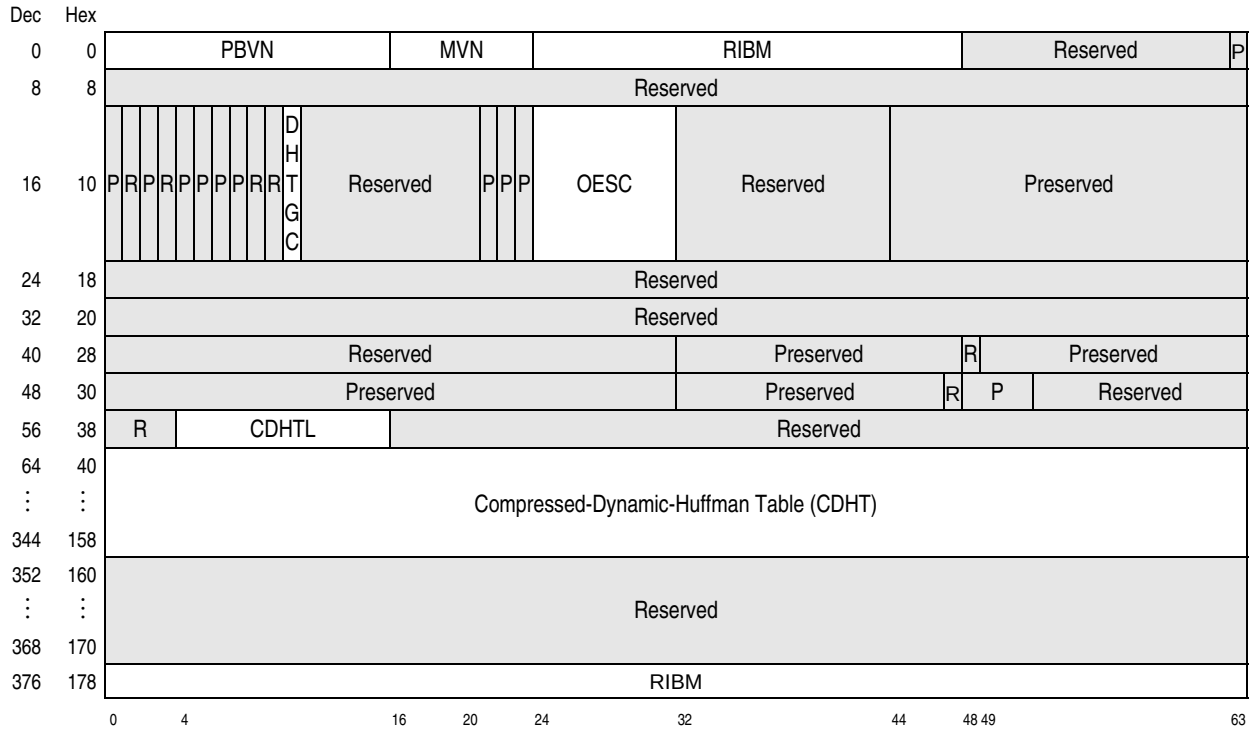
There is no history to reference from prior operations while processing the current operation.

When the contents of general register $R_2 + 1$ specify a length greater than 32 K-bytes, the following applies:

- Only the first 32 K-bytes of the second operand are used to generate the DHT.
- Access exceptions are not recognized for locations beyond the first 32 K-bytes of the second operand.

When the contents of general register $R_2 + 1$ specify a length equal to zero, a specification exception is recognized and the second operand is not accessed.

The parameter block for the DFLTCC-GDHT function is shown in Figure 26-27 on page 26-24. The fields of the parameter block are described in section ”Parameter Block for Data Conversion” on page 26-35. Fields of the parameter block designated as preserved are not modified by the DFLTCC-GDHT function. Preserved fields are distinguished from reserved fields to enable a program to initialize a single storage location, use that storage location for the parameter block of a DFLTCC-GDHT function, and subsequently use the same storage location for the parameter block of a DFLTCC-CMPR function.



Explanation:

CDHTL	Compressed-Dynamic-Huffman Table Length
DHTGC	Dynamic-Huffman-Table Generation Control
MVN	Model-Version Number
OESC	Operation-Ending-Supplemental Code
P	Preserved
PBVN	Parameter-Block-Version Number
R	Reserved
RIBM	Reserved for IBM use

Figure 26-27. Parameter Block (format 0 hex) for the DFLTCC-GDHT function

An invalid-input condition exists when the DFLTCC-GDHT function is specified and the following occurs:

- The format of the parameter block, as specified by the parameter-block-version number, is not supported by the model.

When an invalid-input condition is encountered, a dynamic-Huffman table (DHT) is not generated, the operation ends, and the following occurs:

- A model-dependent value is stored to the model-version number (MVN) field of the parameter block.
- The operation-ending-supplemental code (OESC) field of the parameter block is set to 01 hex.
- Condition code 2 is set.

Normal completion occurs when a dynamic-Huffman table (DHT) is generated. When the operation ends due to normal completion, the following occurs:

- A model-dependent value is stored to the model-version number (MVN) field of the parameter block.
- A compressed format of the generated DHT is stored to the CDHT field of the parameter block. The resulting compressed format of the DHT includes a Huffman code representing an end-of-block (EOB) symbol.
- The length of the compressed format of the generated DHT is stored to the CDHTL field of the parameter block.

- The operation-ending-supplemental code (OESC) field of the parameter block is set to 00 hex.
- Condition code 0 is set.

Condition codes 1 and 3 are not applicable to the DFLTCC-GDHT function.

General registers R_2 and $R_2 + 1$ are not modified by the operation.

The contents of general registers R_1, $R_1 + 1$, and R_3 are ignored when the DFLTCC-GDHT function is specified.

When the entire parameter block overlaps the PER storage-area designation, a PER storage-alteration event is recognized, when applicable, for the parameter block. When only a portion of the parameter block overlaps the PER storage-area designation, it is model-dependent which of the following occurs:

- A PER storage-alteration event is recognized, when applicable, for the entire parameter block.
- A PER storage-alteration event is recognized, when applicable, for the portion of the parameter block that is stored.

A PER zero-address-detection event is recognized, when applicable, for the second-operand location and for the parameter block.

Function Code 2: DFLTCC-CMPR (Compress)

When the DFLTCC-CMPR function is specified, a compressing operation is performed. The operation consists of encoding data from the second-operand location into compressed-data symbols, which are stored to the first-operand location.

The operation proceeds as described in section “Compressing Data” on page 26-51.

Normal completion occurs when the entire second operand is compressed and stored to the first-operand location. When the operation ends due to normal completion, the following occurs:

- A model-dependent value is stored to the model-version number (MVN) field of the parameter block.
- The continuation flag (CF) field of the parameter block is set to zero.
- The sub-byte boundary (SBB) field of the parameter block is updated.
- The operation-ending-supplemental code (OESC) field of the parameter block is set to zeros.
- The history length (HL) field of the parameter block is updated.
- The history offset (HO) field of the parameter block is updated, when applicable.
- The check value field of the parameter block is updated.
- The end-of-block length (EOBL) and end-of-block symbol (EOBS) fields of the parameter block are updated.
- The address in general register R_1 is incremented by the number of bytes processed of the first operand that included processing bit 0, and the length in general register $R_1 + 1$ is decremented by the same number. The number of bytes processed of the first operand that included processing bit 0 is the integer quotient resulting from an integer division with the dividend being the sum of the number of output bits processed and the original value of the SBB, and the divisor being a value of eight.
- The address in general register R_2 is incremented by the number of source bytes processed, and the length in general register $R_2 + 1$ is decremented by the same number.
- Condition code 0 is set.

The formation and updating of the addresses and lengths are dependent on the addressing mode.

When normal completion occurs, the NT and CSB fields of the parameter block are undefined, but may be modified.

When a CPU-determined number of bytes have been processed and an invalid-input condition, as defined on page 26-27, has not been encountered, the operation ends and the following occurs:

- A model-dependent value is stored to the model-version number (MVN) field of the parameter block.
- The continuation flag (CF) bit in the parameter block is set to one.
- The new task (NT) field of the parameter block is set to zero when the CPU-determined number of bytes processed is greater than zero.
- The sub-byte boundary (SBB) field of the parameter block is updated.

- The operation-ending-supplemental code (OESC) field of the parameter block is set to zeros.
- The history length (HL) field of the parameter block is updated.
- The history offset (HO) field of the parameter block is updated, when applicable.
- The check value field of the parameter block is updated.
- The end-of-block length (EOBL) and end-of-block symbol (EOBS) fields of the parameter block are updated.
- The continuation-state buffer (CSB) field in the parameter block is updated.
- The address in general register R_1 is incremented by the number of bytes processed of the first operand that included processing bit 0, and the length in general register $R_1 + 1$ is decremented by the same number. The number of bytes processed of the first operand that included processing bit 0 is the integer quotient resulting from an integer division with the dividend being the sum of the number of output bits processed and the original value of the SBB, and the divisor being a value of eight.
- The address in general register R_2 is incremented by the number of source bytes processed, and the length in general register $R_2 + 1$ is decremented by the same number.
- Condition code 3 is set.

The formation and updating of the addresses and lengths are dependent on the addressing mode.

The CPU-determined number of bytes depends on the model, and may be a different number each time the instruction is executed.

Subsequent to the instruction ending with condition code 3 set, it is expected the program does not modify any input or output specification for the instruction and branches back to reexecute the instruction to resume the operation.

In certain unusual situations, despite ending the instruction with condition code 3 set, the parameter block and general registers are not updated. These situations may occur when the CPU performs a quiescing operation or CPU retry while executing DEFLATE CONVERSION CALL. In these cases, the CPU-determined number of bytes processed is zero, data may have been stored to the first-operand location, data may have been stored to the third-operand location, when applicable, and corresponding change bits have been set.

The first-operand length is insufficient to complete the operation when any of the following conditions apply:

- The first-operand length, as specified by the contents of general register $R_1 + 1$, is zero at the beginning of the execution of the instruction.
- The first-operand length becomes equal to zero during the execution of the instruction and normal completion does not occur.

Note: The first-operand length is zero when the content of general register $R_1 + 1$ is zero, regardless of the values in the NT and SBB fields of the parameter block.

When the first-operand length becomes equal to zero during the execution of the instruction and an invalid-input condition, as defined on page 26-27, has not been encountered, the operation ends and the following occurs:

- A model-dependent value is stored to the model-version number (MVN) field of the parameter block.
- The continuation flag (CF) bit in the parameter block is set to one.
- The new task (NT) field of the parameter block is set to zero.
- The sub-byte boundary (SBB) field of the parameter block is updated.
- The operation-ending-supplemental code (OESC) field of the parameter block is set to zeros.
- The history length (HL) field of the parameter block is updated.
- The history offset (HO) field of the parameter block is updated, when applicable.
- The check value field of the parameter block is updated.
- The end-of-block length (EOBL) and end-of-block symbol (EOBS) fields of the parameter block are updated.
- The continuation-state buffer (CSB) field in the parameter block is updated.
- The address in general register R_1 is incremented by the number of bytes processed of the first operand that included processing bit 0, and the length in general register $R_1 + 1$ is decremented by the same number. The number of bytes processed of the first operand that

included processing bit 0 is the integer quotient resulting from an integer division with the dividend being the sum of the number of output bits processed and the original value of the SBB, and the divisor being a value of eight.
- The address in general register R_2 is incremented by the number of source bytes processed, and the length in general register $R_2 + 1$ is decremented by the same number.
- Condition code 1 is set.

The formation and updating of the addresses and lengths are dependent on the addressing mode.

When the first-operand length is zero at the beginning of the execution of the instruction and an invalid-input condition, as defined on page 26-27, has not been encountered, the operation ends and the following occurs:

- Condition code 1 is set.

Subsequent to the instruction ending with condition code 1 set, it is expected the program modifies the first-operand length, first-operand address, or both and reexecute the instruction to resume the operation.

An invalid-input condition exists when the DFLTCC-CMPR function is specified and any of the following occurs:

1. The format of the parameter block, as specified by the parameter-block-version number, is not supported by the model.
2. NT is zero and HL is greater than 32,768.
3. The HTT is one and the CDHTL is less than 42 or greater than 2283.
4. The HTT is one and the CDHTL does not equal the length of the compressed format of the DHT specified in the CDHT field.
5. The HTT is one and the HLIT sub-element of the compressed format of the DHT is greater than 29 (invalid DHT).
6. The HTT is one and the HDIST sub-element of the compressed format of the DHT is greater than 29 (invalid DHT).
7. The HTT is one and the compressed format of the DHT (contents of the CDHT field) specifies a code which is in the sequence of codes specifying the bit lengths for the 19 possible code lengths defined for a compressed DHT, and is less than the length required by the Huffman algorithm to specify a functional Huffman tree (invalid DHT).
8. The HTT is one and the compressed format of the DHT (contents of the CDHT field) specifies code length 16 (copy previous code length) as the first code length for the set of elements consisting of literal bytes, an EOB symbol, and duplicate-string lengths (invalid DHT).
9. The HTT is one and the compressed format of the DHT (contents of the CDHT field) specifies a code which is in the sequence of codes specifying code lengths for literal bytes, and the code does not match any of the codes determined to represent the set of referenced code lengths, as specified earlier in the compressed DHT (invalid DHT).
10. The HTT is one and the compressed format of the DHT (contents of the CDHT field) specifies a code which assigns code length 0 (CL0) to the EOB symbol. In this case, the corresponding DHT does not specify a Huffman code to represent an EOB symbol (invalid DHT).
11. The HTT is one and the compressed format of the DHT (contents of the CDHT field) specifies a code which is in the sequence of codes specifying code lengths for duplicate-string lengths and pointer distances, and the code does not match any of the codes determined to represent the set of referenced code lengths, as specified earlier in the compressed DHT (invalid DHT).
12. The HTT is one and the compressed format of the DHT (contents of the CDHT field) specifies a number of code lengths which is greater than the number of Huffman codes in the DHT, as specified by the sum of the values in the HLIT field, the HDIST field, and 258. This is possible with an improper uses of code lengths 16, 17, and 18 (invalid DHT).
13. The HTT is one and the compressed format of the DHT (contents of the CDHT field) specifies a code length for the set of literal bytes, EOB symbol, and duplicate-string lengths, which is less than the length required by the Huffman algorithm to specify a functional Huffman tree. (invalid DHT).

14. The HTT is one and the compressed format of the DHT (contents of the CDHT field) specifies a code length for the set of duplicate-string pointer distances, which is less than the length required by the Huffman algorithm to specify a functional Huffman tree. (invalid DHT).

15. The HTT is one and the CPU attempts to generate a compressed-data symbol to represent a literal byte in the second operand, and the DHT derived from the contents of the CDHT field is non-universal and does not specify a Huffman code corresponding to that literal byte.

16. The HTT is one and the CPU attempts to generate a compressed-data symbol to represent a duplicate-string in the second operand, and the DHT derived from the contents of the CDHT field is non-universal and does not specify a Huffman code corresponding to that duplicate-string length or pointer distance.

When an invalid-input condition is encountered while attempting to generate a compressed-data symbol to represent a literal byte or duplicate-string in the second operand, no results associated with that literal byte or duplicate-string are generated, and the length of the second operand is not reduced by the size of that literal byte or duplicate-string.

When an invalid-input condition is encountered and neither the first-operand length (specified by the contents of general register $R_1 + 1$, NT, and SBB) nor the second-operand length is reduced, during the execution of the instruction, the operation ends, and the following occurs:

- A model-dependent value is stored to the model-version number (MVN) field of the parameter block.
- A nonzero value is stored to the operation-ending-supplemental code (OESC) field of the parameter block.
- Condition code 2 is set.

When an invalid-input condition is encountered and the first-operand length (specified by the contents of general register $R_1 + 1$, NT, and SBB) or second-operand length is reduced during the execution of the instruction, the operation ends, and the following occurs:

- A model-dependent value is stored to the model-version number (MVN) field of the parameter block.
- The continuation flag (CF) bit in the parameter block is set to one.
- The new task (NT) field of the parameter block is set to zero.
- The sub-byte boundary (SBB) field of the parameter block is updated.
- A nonzero value is stored to the operation-ending-supplemental code (OESC) field of the parameter block.
- The history length (HL) field of the parameter block is updated.
- The history offset (HO) field of the parameter block is updated, when applicable.
- The check value field of the parameter block is updated.
- The end-of-block length (EOBL) and end-of-block symbol (EOBS) fields of the parameter block are updated.
- The continuation-state buffer (CSB) field in the parameter block is updated.
- The address in general register R_1 is incremented by the number of bytes processed of the first operand that included processing bit 0, and the length in general register $R_1 + 1$ is decremented by the same number. The number of bytes processed of the first operand that included processing bit 0 is the integer quotient resulting from an integer division with the dividend being the sum of the number of output bits processed and the original value of the SBB, and the divisor being a value of eight.
- The address in general register R_2 is incremented by the number of source bytes which are successfully encoded to compressed-data symbols, and the length in general register $R_2 + 1$ is decremented by the same number. Source bytes causing the invalid-input condition cannot be encoded and do not contribute to the update of general registers R_2 and $R_2 + 1$.
- Condition code 2 is set.

The formation and updating of the addresses and lengths are dependent on the addressing mode.

Subsequent to processing any portion of the first or second operand, and invalid-input condition 15 or 16 is due to be recognized, the result is that either the invalid-data condition is recognized, or the operation ends with partial completion and condition code 3 is set. If condition code 3 is set, the invalid-data condi-

tion will be recognized when the instruction is executed again, to continue processing the same operands, and the invalid-data condition still exists.

A PER storage-alteration event is recognized, when applicable, for the following:

- Stores to the parameter block, as described below.
- Stores to the first-operand location.
- Stores to the third-operand location, which only occur when the history-buffer type (HBT) is one (circular).

When the entire parameter block overlaps the PER storage-area designation, a PER storage-alteration event is recognized, when applicable, for the parameter block. When only a portion of the parameter block overlaps the PER storage-area designation, it is model-dependent which of the following occurs:

- A PER storage-alteration event is recognized, when applicable, for the entire parameter block.
- A PER storage-alteration event is recognized, when applicable, for the portion of the parameter block that is stored.

A PER zero-address-detection event is recognized, when applicable, for the parameter block, first-operand location, second-operand location, and third-operand location when the HBT is one (circular).

When the instruction ends with a nonzero condition code set, input data referenced from the second-operand location may be completely, or only partially, processed. When input data is only partially processed, results in the first-operand location, first-operand address, first-operand length, and SBB field of the parameter block do not represent a state consistent with the updated second-operand address and length. In these cases, partially processed data and internal-state information may be placed in the CSB field of the parameter block. The amount of partially processed data depends on conditions existing at the time the operation ends and the model. Although some data may only be partially processed, results stored to the left of the location designated by the updated first-operand address are complete and will not be modified when the operation resumes. Furthermore, when the instruction ends with condition code 1 or 3 set, it is expected the program subsequently reexecutes the instruction to resume the operation, at which time the contents of the CSB field are referenced prior to resuming the operation. When the instruction ends with condition code 0 set, all data is completely processed and all results associated with input and output data represent a consistent state.

Subsequent to the instruction ending with a nonzero condition code set, and without encountering an invalid-input condition, and prior to reexecuting the instruction for the purpose of resuming the operation, the program should not modify any fields of the parameter block; otherwise results are unpredictable.

Function Code 4: DFLTCC-XPND (Expand)

When the DFLTCC-XPND function is specified, an uncompressing operation is performed. The operation consists of decoding compressed-data symbols from the second-operand location into uncompressed data, which is stored to the first-operand location.

The operation proceeds as described in section “Uncompressing Data” on page 26-56.

Normal completion occurs when all elements of the final block of the compressed-data set in the second operand are decoded and all uncompressed data is stored to the first-operand location. The last block of the compressed-data set is identified when the BFINAL bit of the block header is one. When the operation ends due to normal completion, the following occurs:

- A model-dependent value is stored to the model-version number (MVN) field of the parameter block.
- The continuation flag (CF) field of the parameter block is set to zero.
- The sub-byte boundary (SBB) field of the parameter block is updated.
- The operation-ending-supplemental code (OESC) field of the parameter block is set to zeros.
- The incomplete-function status (IFS) field of the parameter block is set to zeros.
- The incomplete-function length (IFL) field of the parameter block is updated, when applicable.
- The history length (HL) field of the parameter block is updated.
- The history offset (HO) field of the parameter block is updated, when applicable.
- The check value field of the parameter block is updated.

- The compressed dynamic-Huffman table (CDHT) and compressed dynamic-Huffman-table length (CDHTL) fields of the parameter block are set to zeros.
- The address in general register R_1 is incremented by the number of bytes stored at the first-operand location, and the length in general register $R_1 + 1$ is decremented by the same number.
- The address in general register R_2 is incremented by the number of bytes processed of the second operand that included processing bit 0, and the length in general register $R_2 + 1$ is decremented by the same number. The number of bytes processed of the second operand that included processing bit 0 is the integer quotient resulting from an integer division with the dividend being the sum of the number of input bits processed and the original value of the SBB, and the divisor being a value of eight.
- Condition code 0 is set.

The formation and updating of the addresses and lengths are dependent on the addressing mode.

When normal completion occurs, the NT and CSB fields of the parameter block are undefined, but may be modified.

When a CPU-determined amount of data has been processed and an invalid-input condition, as defined on page 26-32, has not been encountered, the operation ends and the following occurs:

- A model-dependent value is stored to the model-version number (MVN) field of the parameter block.
- The continuation flag (CF) bit in the parameter block is set to one.
- The new task (NT) field of the parameter block is set to zero when the CPU-determined amount of data processed is greater than zero.
- The sub-byte boundary (SBB) field of the parameter block is updated.
- The operation-ending-supplemental code (OESC) field of the parameter block is set to zeros.
- The incomplete-function status (IFS) field of the parameter block is updated.
- The incomplete-function length (IFL) field of the parameter block is updated, when applicable.
- The history length (HL) field of the parameter block is updated.
- The history offset (HO) field of the parameter block is updated, when applicable.
- The check value field of the parameter block is updated.
- The compressed dynamic-Huffman table (CDHT) and compressed dynamic-Huffman-table length (CDHTL) fields of the parameter block are updated. When partial completion occurs while processing a block with BTYPE value of 10 binary, the bytes of the CDHT field not required to represent the table are stored as zeros. When partial completion occurs while processing a block with BTYPE value of 00 or 01 binary, zeros are stored to the CDHT and CDHTL fields.
- The continuation-state buffer (CSB) field in the parameter block is updated.
- The address in general register R_1 is incremented by the number of bytes stored at the first-operand location, and the length in general register $R_1 + 1$ is decremented by the same number.
- The address in general register R_2 is incremented by the number of bytes processed of the second operand that included processing bit 0, and the length in general register $R_2 + 1$ is decremented by the same number. The number of bytes processed of the second operand that included processing bit 0 is the integer quotient resulting from an integer division with the dividend being the sum of the number of input bits processed and the original value of the SBB, and the divisor being a value of eight.
- Condition code 3 is set.

The formation and updating of the addresses and lengths are dependent on the addressing mode.

The CPU-determined amount of data depends on the model, and may be a different number each time the instruction is executed.

Subsequent to the instruction ending with condition code 3 set, it is expected the program does not modify any input or output specification for the instruction and branches back to reexecute the instruction to resume the operation.

In certain unusual situations, despite ending the instruction with condition code 3 set, the parameter block and general registers are not updated. These situations may occur when the CPU performs a quiescing operation or CPU retry while executing DEFLATE CONVERSION CALL. In these cases, the CPU-determined amount of data processed is zero, data may have been stored to the first-operand location, data may have been stored to the third-operand

location, when applicable, and corresponding change bits have been set.

The second-operand length is insufficient to complete the operation when the following applies:

- The last element of a compressed-data block with BFINAL equal to one has not been decoded during the operation, and the number of bits in the second operand, as designated by the second-operand length and SBB, is less than the number of bits of the next element to decode, and all results from decoding data from the second-operand location have been placed at the first-operand location.

When the second-operand length is insufficient to complete the operation, the operation has been partially completed, and an invalid-input condition, as defined on page 26-32, has not been encountered, the operation ends, and the following occurs:

- A model-dependent value is stored to the model-version number (MVN) field of the parameter block.
- The continuation flag (CF) bit in the parameter block is set to one.
- The new task (NT) field of the parameter block is set to zero.
- The sub-byte boundary (SBB) field of the parameter block is updated.
- The operation-ending-supplemental code (OESC) field of the parameter block is set to zeros.
- The incomplete-function status (IFS) field of the parameter block is updated.
- The incomplete-function length (IFL) field of the parameter block is updated, when applicable.
- The history length (HL) field of the parameter block is updated.
- The history offset (HO) field of the parameter block is updated, when applicable.
- The check value field of the parameter block is updated.
- The compressed dynamic-Huffman table (CDHT) and compressed dynamic-Huffman-table length (CDHTL) fields of the parameter block are updated. When partial completion occurs while processing a block with BTYPE value of 10 binary, the bytes of the CDHT field not required to represent the table are stored as zeros. When partial completion occurs while processing a block with BTYPE value of 00 or 01 binary, zeros are stored to the CDHT and CDHTL fields.
- The continuation-state buffer (CSB) field in the parameter block is updated.
- The address in general register R_1 is incremented by the number of bytes stored at the first-operand location, and the length in general register $R_1 + 1$ is decremented by the same number.
- The address in general register R_2 is incremented by the number of bytes processed of the second operand that included processing bit 0, and the length in general register $R_2 + 1$ is decremented by the same number. The number of bytes processed of the second operand that included processing bit 0 is the integer quotient resulting from an integer division with the dividend being the sum of the number of input bits processed and the original value of the SBB, and the divisor being a value of eight.
- Condition code 2 is set.

The formation and updating of the addresses and lengths are dependent on the addressing mode.

Subsequent to the instruction ending with condition code 2 set and the OESC field of the parameter block set to zeros, it is expected the program modifies the second-operand length, second-operand address, or both and reexecute the instruction to resume the operation.

The first-operand length is insufficient to complete the operation when the following applies:

- Results from decoding data from the second-operand location can not be placed at the first-operand location due to the first-operand length being equal to zero.

Note: Since decoding data from the second-operand location may not generate result data to place at the first-operand location, an updated first-operand length being equal to zero is not the only criteria which defines when condition code 1 is set. It is possible for some operations to proceed with a first-operand length being equal to zero.

When the first-operand length is insufficient to complete the operation, the operation has been partially completed, and an invalid-input condition, as defined on page 26-32, has not been encountered, the operation ends, and the following occurs:

- A model-dependent value is stored to the model-version number (MVN) field of the parameter block.

- The continuation flag (CF) bit in the parameter block is set to one.
- The new task (NT) field of the parameter block is set to zero.
- The sub-byte boundary (SBB) field of the parameter block is updated.
- The operation-ending-supplemental code (OESC) field of the parameter block is set to zeros.
- The incomplete-function status (IFS) field of the parameter block is updated.
- The incomplete-function length (IFL) field of the parameter block is updated, when applicable.
- The history length (HL) field of the parameter block is updated.
- The history offset (HO) field of the parameter block is updated, when applicable.
- The check value field of the parameter block is updated.
- The compressed dynamic-Huffman table (CDHT) and compressed dynamic-Huffman-table length (CDHTL) fields of the parameter block are updated. When partial completion occurs while processing a block with BTYPE value of 10 binary, the bytes of the CDHT field not required to represent the table are stored as zeros. When partial completion occurs while processing a block with BTYPE value of 00 or 01 binary, zeros are stored to the CDHT and CDHTL fields.
- The continuation-state buffer (CSB) field in the parameter block is updated.
- The address in general register R_1 is incremented by the number of bytes stored at the first-operand location, and the length in general register $R_1 + 1$ is decremented by the same number.
- The address in general register R_2 is incremented by the number of bytes processed of the second operand that included processing bit 0, and the length in general register $R_2 + 1$ is decremented by the same number. The number of bytes processed of the second operand that included processing bit 0 is the integer quotient resulting from an integer division with the dividend being the sum of the number of input bits processed and the original value of the SBB, and the divisor being a value of eight.
- Condition code 1 is set.

The formation and updating of the addresses and lengths are dependent on the addressing mode.

Subsequent to the instruction ending with condition code 1 set, it is expected the program modifies the first-operand length, first-operand address, or both and reexecute the instruction to resume the operation.

An invalid-input condition exists when the DFLTCC-XPND function is specified and any of the following occurs:

1. The format of the parameter block, as specified by the parameter-block-version number, is not supported by the model.
2. NT is zero and HL is greater than 32,768.
3. A compressed-data block with BTYPE equal 11 binary is encountered.
4. A compressed-data block with BTYPE equal 00 binary and NLEN not equal to the one's complement of LEN is encountered.
5. A compressed format of a DHT (contents of a compressed-data block with BTYPE equal 10 binary) is encountered and the HLIT sub-element of the compressed DHT is greater than 29 (invalid DHT).
6. A compressed format of a DHT (contents of a compressed-data block with BTYPE equal 10 binary) is encountered and the HDIST sub-element of the compressed DHT is greater than 29 (invalid DHT).
7. A compressed format of a DHT (contents of a compressed-data block with BTYPE equal 10 binary) is encountered which specifies a code which is in the sequence of codes specifying the bit lengths for the 19 possible code lengths defined for a compressed DHT, and is less than the length required by the Huffman algorithm to specify a functional Huffman tree (invalid DHT).
8. A compressed format of a DHT (contents of a compressed-data block with BTYPE equal 10 binary) is encountered which specifies code length 16 (copy previous code length) as the first code length for the set of elements consisting of literal bytes, an EOB symbol, and duplicate-string lengths (invalid DHT).
9. A compressed format of a DHT (contents of a compressed-data block with BTYPE equal 10 binary) is encountered which specifies a code which is in the sequence of codes specifying code lengths for literal bytes, and the code does not match any of the codes determined to represent the set of referenced code lengths, as spec-

ified earlier in the compressed DHT (invalid DHT).

10. A compressed format of a DHT (contents of a compressed-data block with BTYPE equal 10 binary) is encountered which specifies a code which assigns code length 0 (CL0) to the EOB symbol. In this case, the corresponding DHT does not specify a Huffman code to represent an EOB symbol (invalid DHT).

11. A compressed format of a DHT (contents of a compressed-data block with BTYPE equal 10 binary) is encountered which specifies a code which is in the sequence of codes specifying code lengths for duplicate-string lengths and pointer distances, and the code does not match any of the codes determined to represent the set of referenced code lengths, as specified earlier in the compressed DHT (invalid DHT).

12. A compressed format of a DHT (contents of a compressed-data block with BTYPE equal 10 binary) is encountered which specifies a number of code lengths which is greater than the number of Huffman codes in the DHT, as specified by the sum of the values in the HLIT field, the HDIST field, and 258. This is possible with an improper uses of code lengths 16, 17, and 18 (invalid DHT).

13. A compressed format of a DHT (contents of a compressed-data block with BTYPE equal 10 binary) is encountered which specifies a code length for the set of literal bytes, EOB symbol, and duplicate-string lengths, which is less than the length required by the Huffman algorithm to specify a functional Huffman tree. (invalid DHT).

14. A compressed format of a DHT (contents of a compressed-data block with BTYPE equal 10 binary) is encountered which specifies a code length for the set of duplicate-string pointer distances, which is less than the length required by the Huffman algorithm to specify a functional Huffman tree. (invalid DHT).

15. A compressed-data symbol, which is encountered in a compressed-data block with BTYPE equal 10 binary, specifies a Huffman code which is not defined by the non-universal DHT derived from the compressed format of the DHT in the same block. In this case, the number of bits of the second operand which must be available to process, for the purpose of recognizing the invalid-input condition, is model-dependent. More specifically, a model attempting to decode an undefined code may process 15 bits prior to recognizing the exception, even though the exception could be determined after processing less bits.

16. A compressed-data symbol is encountered which is a duplicate-string pointer and specifies a distance greater than the length of history available at the point of processing the symbol.

17. A compressed-data symbol, which is encountered in a compressed-data block with BTYPE equal 01 binary, specifies an invalid code (a code of 11000110 or 11000111 binary for a duplicate-string length, or a code of 11110 or 11111 binary for a duplicate-string-pointer distance). In this case, the number of bits of the second operand which must be available to process, for the purpose of recognizing the invalid-input condition, is model-dependent. More specifically, a model attempting to decode an invalid code may process 8 bits, in the case of a duplicate-string length, or 5 bits, in the case of a duplicate-string-pointer distance, prior to recognizing the exception, even though the exception could be determined after processing less bits.

When an invalid-input condition is encountered while attempting to decode an element of a compressed-data block, no results associated with that element are generated, and the length of the second operand (specified by the contents of general register $R_2 + 1$, NT, and SBB) is not reduced by the size of that element. However, it is possible a prior execution of the instruction ended with partially processing only a fraction of an element of input data. In that case, during the prior execution of the instruction, it had not yet been determined as to whether or not an invalid-input condition may exist with that element and the length of the second operand was reduced by the fraction of that element.

When an invalid-input condition is encountered and neither the first-operand length nor the second-operand length (specified by the contents of general register $R_2 + 1$, NT, and SBB) is reduced, during the execution of the instruction, the operation ends, and the following occurs:

- A model-dependent value is stored to the model-version number (MVN) field of the parameter block.

- A nonzero value is stored to the operation-ending-supplemental code (OESC) field of the parameter block.
- Condition code 2 is set.

When an invalid-input condition is encountered and the first-operand length or the second-operand length (specified by the contents of general register $R_2 + 1$, NT, and SBB) is reduced, during the execution of the instruction, the operation ends, and the following occurs:

- A model-dependent value is stored to the model-version number (MVN) field of the parameter block.
- The continuation flag (CF) bit in the parameter block is set to one.
- The new task (NT) field of the parameter block is set to zero.
- The sub-byte boundary (SBB) field of the parameter block is updated.
- A nonzero value is stored to the operation-ending-supplemental code (OESC) field of the parameter block.
- The incomplete-function status (IFS) field of the parameter block is updated.
- The incomplete-function length (IFL) field of the parameter block is updated, when applicable.
- The history length (HL) field of the parameter block is updated.
- The history offset (HO) field of the parameter block is updated, when applicable.
- The check value field of the parameter block is updated.
- The compressed dynamic-Huffman table (CDHT) and compressed dynamic-Huffman-table length (CDHTL) fields of the parameter block are updated. When partial completion occurs while processing a block with BTYPE value of 10 binary, the bytes of the CDHT field not required to represent the table are stored as zeros. When partial completion occurs while processing a block with BTYPE value of 00 or 01 binary, zeros are stored to the CDHT and CDHTL fields. An invalid DHT is not successfully processed and does not get placed into the CDHT field.
- The continuation-state buffer (CSB) field in the parameter block is updated.
- The address in general register R_1 is incremented by the number of bytes stored at the first-operand location, and the length in general register $R_1 + 1$ is decremented by the same number.
- The address in general register R_2 is incremented by the number of bytes of the second operand that were successfully processed (decoded) and included processing bit 0, and the length in general register $R_2 + 1$ is decremented by the same number. The number of bytes processed of the second operand that included processing bit 0 is the integer quotient resulting from an integer division with the dividend being the sum of the number of input bits processed and the original value of the SBB, and the divisor being a value of eight. Source data causing the invalid-input condition cannot be decoded successfully and does not contribute to the update of general registers R_2 and $R_2 + 1$.
- Condition code 2 is set.

The formation and updating of the addresses and lengths are dependent on the addressing mode.

Subsequent to processing any portion of the first or second operand, and any of the invalid-input conditions 3-17 is due to be recognized, the result is that either the invalid-data condition is recognized, or the operation ends with partial completion and condition code 3 is set. If condition code 3 is set, the invalid-data condition will be recognized when the instruction is executed again, to continue processing the same operands, and the invalid-data condition still exists.

A PER storage-alteration event is recognized, when applicable, for the following:

- Stores to the parameter block, as described below.
- Stores to the first-operand location.
- Stores to the third-operand location, which only occur when the history-buffer type (HBT) is one (circular).

When the entire parameter block overlaps the PER storage-area designation, a PER storage-alteration event is recognized, when applicable, for the parameter block. When only a portion of the parameter block overlaps the PER storage-area designation, it is model-dependent which of the following occurs:

- A PER storage-alteration event is recognized, when applicable, for the entire parameter block.
- A PER storage-alteration event is recognized, when applicable, for the portion of the parameter block that is stored.

A PER zero-address-detection event is recognized, when applicable, for the parameter block, first-oper-

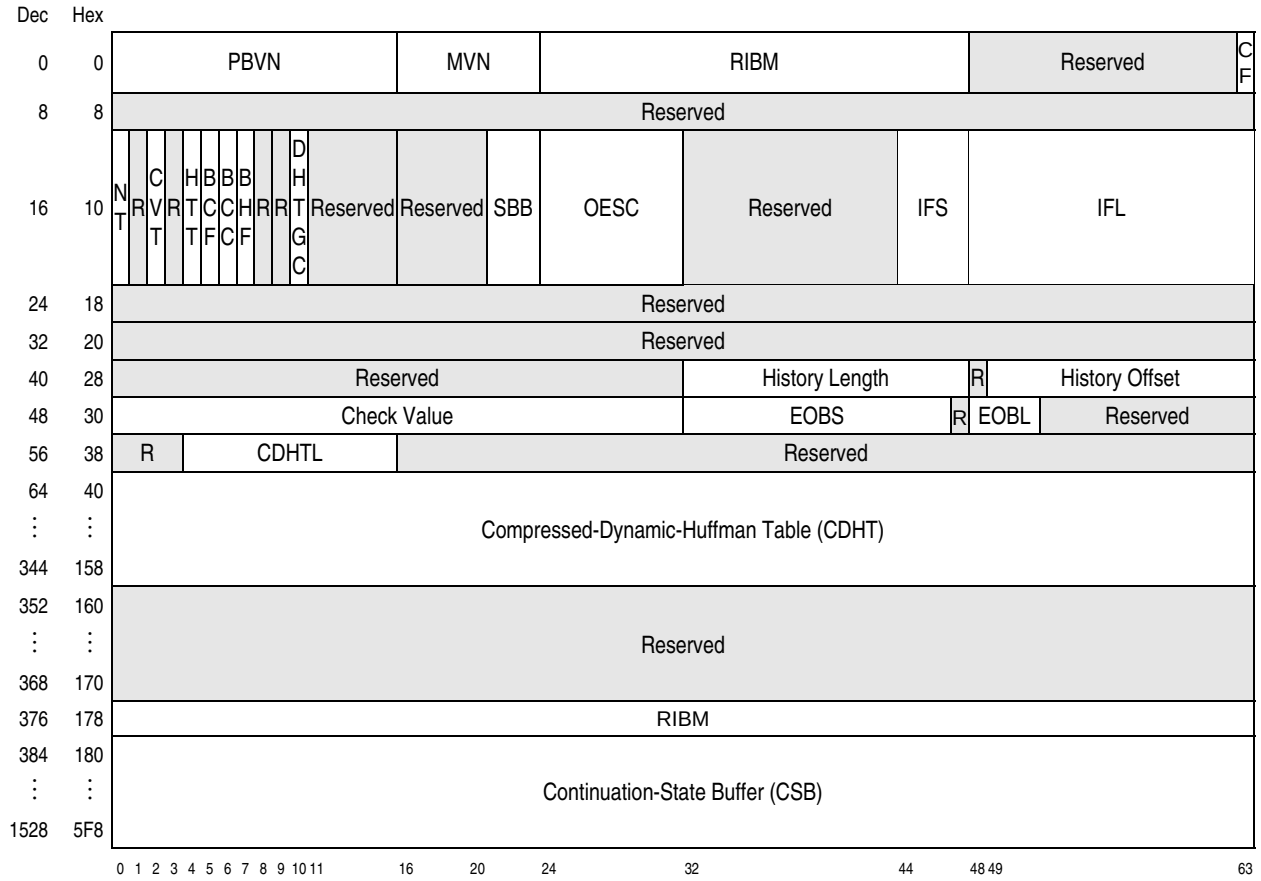
and location, second-operand location, and third-operand location when the HBT is one (circular).

When the instruction ends with a nonzero condition code set, input data referenced from the second-operand location may be completely, or only partially, processed. When input data is only partially processed, results in the first-operand location, first-operand address, first-operand length, SBB field of the parameter block, check value field of the parameter block, HL field of the parameter block, IFS field of the parameter block, and when applicable, the third-operand location and HO field of the parameter block, do not represent a state consistent with the updated second-operand address and length. In these cases, partially processed data and internal-state information may be placed in the CSB field of the parameter block. The amount of partially processed data depends on conditions existing at the time the operation ends and the model. Although some data may only be partially processed, results stored to the left of the location designated by the updated first-operand address are complete and will not be modified when the operation resumes. Furthermore, when the instruction ends with a nonzero condition code set and without encountering an invalid-input condition, it is expected the program subsequently reexecutes the instruction to resume the operation, at which time the contents of the CSB field are referenced prior to resuming the operation. When the operation ends with condition code 0 set, all data is completely processed and all results associated with input and output data represent a consistent state.

Subsequent to the instruction ending with a nonzero condition code set, and without encountering an invalid-input condition, and prior to reexecuting the instruction for the purpose of resuming the operation, the program should not modify any fields of the parameter block; otherwise results are unpredictable.

Parameter Block for Data Conversion

The parameter block with format 0 hex for the DFLTCC-CMPR and DFLTCC-XPND functions is shown in Figure 26-28 on page 26-36.



Explanation:

BCC	Block-Closing Control
BCF	Block-Continuation Flag
BHF	Block-Header Final bit
CDHTL	Compressed-Dynamic-Huffman Table Length
CF	Continuation Flag
CVT	Check Value Type
DHTGC	Dynamic-Huffman Table Generation Control
EOBL	End-of-block Length
EOBS	End-of-block Symbol
HTT	Huffman-Table Type
IFL	Incomplete-Function Length
IFS	Incomplete-Function Status
MVN	Model-Version Number
NT	New Task
OESC	Operation-Ending-Supplemental Code
PBVN	Parameter-Block-Version Number
R	Reserved
RIBM	Reserved for IBM use
SBB	Sub-Byte Boundary

Figure 26-28. Parameter Block (format 0 hex) for the DFLTCC-CMPR and DFLTCC-XPND functions

The fields of the parameter block are defined as follows:

Reserved: As an input to an operation, reserved fields should contain zeros; otherwise, the program may not operate compatibly in the future. When an operation ends, reserved fields may be stored as zeros or may remain unchanged.

Parameter-Block-Version Number (PBVN): Bytes 0-1 of the parameter block specify the version of the parameter block. Bits 0-11 of the PBVN are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future. Bits 12-15 of the PBVN contain an unsigned binary integer specifying the format of the parameter block. The DFLTCC-QAF function provides the means of indicating the parameter block formats available. When the format of the parameter block specified is not supported by the model, an invalid-input condition is recognized (condition code 2 is set and a nonzero value is stored to the OESC field). The PBVN is specified by the program and is not modified during the execution of the instruction.

Model-Version Number (MVN): Byte 2 of the parameter block is an unsigned binary integer identifying the model which executed the instruction. The program is not required to initialize the MVN. The MVN is updated during the execution of the instruction. The value stored in the MVN is model-dependent.

When the continuation flag (CF) is one, the MVN may be an input to the operation for the purpose of interpreting the contents of the CSB field of the parameter block to resume the operation.

Reserved for IBM use (RIBM): Bytes 3-5 and 376-383 of the parameter block are reserved for IBM use and must contain zeros; otherwise results are unpredictable. The RIBM field is not modified during the execution of the instruction.

Continuation Flag (CF): Bit 63 of the parameter block, when one, indicates the operation is partially complete and the contents of the continuation-state buffer may be used to resume the operation. It is required for the program to initialize the continuation flag (CF) to zero and not modify CF in the event the instruction is to be reexecuted for the purpose of resuming the operation; otherwise results are unpredictable.

New Task (NT): Bit 0 of byte 16 of the parameter block, when one, indicates the operation applies to the beginning of a compressed-data set. Therefore, no history and no check value from a prior operation applies to the current operation. When NT is one at the beginning of the operation, and the operation ends after partial completion, zero is stored to the NT field. When NT is zero, history and a check value from a prior operation apply to the current operation.

When the specified function is DFLTCC-CMPR, the meaning for each combination of values of the NT and CF fields is as follows:

NT	CF	meaning
1	0	Generate an individual block of a compressed-data set, which is the first block of the set.
0	0	Generate an individual block of a compressed-data set, which is not the first block of the set.
0	1	Continue to generate a block which is currently partially generated.
1	1	Invalid combination.

Check Value Type (CVT): Bit 2 of byte 16 of the parameter block specifies the type of check value contained in the check value field of the parameter block. When CVT is zero, the check value type is a 32-bit cyclic-redundancy-check (CRC-32). When CVT is one, the check value type is a 32-bit Adler checksum (Adler-32). The CVT bit is not modified during the execution of the instruction.

Huffman-Table Type (HTT): Bit 4 of byte 16 of the parameter block, when zero, specifies a table containing fixed-Huffman codes (FHT), as defined by the DEFLATE standard, is used during a compression operation. When the HTT is one, a table containing dynamic-Huffman codes (DHT), as specified in the CDHT field of the parameter block, is used during a compression operation. The HTT does not apply to uncompressing operations. The HTT bit is not modified during the execution of the instruction.

Block-Continuation Flag (BCF): Bit 5 of byte 16 of the parameter block applies when the DFLTCC-CMPR function is specified. When zero, a 3-bit block header, and when applicable, the compressed format of a dynamic-Huffman table, as specified in the CDHT field of the parameter block, is stored to the

first-operand location prior to storing any compressed-data elements. When one, neither a block header nor a compressed format of a DHT is stored to the first-operand location. When NT is one, BCF is treated as equal to zero. The BCF bit is not modified during the execution of the instruction.

Block Closing Control (BCC): Bit 6 of byte 16 of the parameter block applies when the DFLTCC-CMPR function is specified. When one, subsequent to storing all compressed-data symbols, an end-of-block (EOB) symbol is stored to the first-operand location. When the HTT specifies using an FHT, Huffman code 0000000 binary (which corresponds to the intermediate integer representation of 256 in the table specifying codes for literal bytes, an EOB symbol, and duplicate-string lengths) is used for the EOB symbol. When the HTT specifies using a DHT, the Huffman code for the EOB symbol is specified in the DHT. When the BCC bit is zero, an EOB symbol is not stored to the first-operand location.

The BCC bit is not modified during the execution of the instruction.

Block Header Final (BHF): Bit 7 of byte 16 of the parameter block applies when the DFLTCC-CMPR function is specified and either BCF is zero or NT is one; otherwise the BHF does not apply. When applicable and one, the first bit of the block header (BFINAL) is set to one before storing the block header to the first-operand location. When applicable and zero, the first bit of the block header (BFINAL) is set to zero before storing the block header to the first-operand location. The BHF bit is not modified during the execution of the instruction.

DHT Generation Control (DHTGC): Bit 2 of byte 17 of the parameter block applies to generating a dynamic-Huffman table (DHT). The DHT specifies Huffman codes for symbols representing literal bytes, duplicate-string lengths, an EOB symbol, and duplicate-string-pointer distances. The value of a Huffman code for a particular symbol is a function of the count of occurrences for the entity, which the symbol represents, in the uncompressed form of the data. When the count for a symbol is zero, there is no Huffman code in the DHT for the symbol. The DHTGC specifies counts equal to zero will be treated as follows:

DHTGC	meaning
0	Treat counts of literal bytes, duplicate-string lengths, and pointer distances equal to zero as equal to one (generate a universal DHT).
1	Treat counts of duplicate-string lengths and pointer distances equal to zero as equal to one.

A DHT which specifies a Huffman code for every possible value of literal bytes, an EOB symbol, duplicate-string lengths, and duplicate-string-pointer distances is called a universal DHT. A DHT which does not specify Huffman codes for values of literal bytes, duplicate-string lengths, or duplicate-string-pointer distances which do not occur in the uncompressed form of the data is called a non-universal DHT.

For all values of the DHTGC, the resulting DHT specifies Huffman codes for all possible duplicate-string lengths and pointer distances, as defined by the DEFLATE standard. Therefore, the HLIT and HDIST sub-elements of the resulting compressed form of the DHT each contain the value of 29. For definitions of the HLIT and HDIST sub-elements, refer to section “Descriptions for Compressed-data Blocks”, beginning on page 26-45.

The DHTGC is an input to the operation when the DFLTCC-GDHT function is specified. The DHTGC does not apply to the operation when the DFLTCC-CMPR or DFLTCC-XPND function is specified. The DHTGC is not modified during the execution of the instruction.

Sub-Byte Boundary (SBB): Bits 5-7 of byte 18 of the parameter block contain an unsigned binary integer specifying the boundary between processed and unprocessed bits within a byte of the compressed-data stream. The byte of the stream referenced is the last byte referenced, meaning the rightmost byte, when an operation ends, and is the first byte to be referenced, meaning the leftmost byte, when an operation begins or resumes. When the DFLTCC-CMPR function is specified, the SBB applies to the byte designated by the first-operand address. When the DFLTCC-XPND function is specified, the SBB applies to the byte designated by the second-operand address. The SBB specifies the number of rightmost bits that have been processed. The SBB is an input to the operation and an output of the operation. Figure 26-29 on page 26-44 illustrates a com-

pressed-data stream when SBB has the value of 011 binary. Figure 26-30 on page 26-44 provides examples which demonstrate how the SBB applies to the DFLTCC-CMPR function. When NT is one, SBB is treated as equal to 000 binary.

Operation-Ending-Supplemental Code (OESC): When execution of DEFLATE CONVERSION CALL ends, a code is stored to byte 19 of the parameter block. The code conveys information about invalid-input conditions encountered during execution. When an invalid-input condition is not encountered, zeros are stored to the OESC field. When an invalid-input condition is encountered, a nonzero value is stored to the OESC field, which indicates the cause of the invalid-input condition recognized during execution. The codes stored to the OESC field are defined as follows:

OESC (hex)	meaning
00	An invalid-input condition was not encountered.
01	The format of the parameter block, as specified by the parameter-block-version number, is not supported by the model.
02	The DFLTCC-CMPR or DFLTCC-XPND function is specified, the history length field is greater than 32,768, and the new task field is zero.
11	A compressed-data block with BTYPE equal to 11 binary is encountered.
12	A compressed-data block with BTYPE equal to 00 binary and NLEN not equal to the one's complement of LEN is encountered.
21	The CDHTL field applies and is less than 42 or greater than 2283.
22	The HLIT sub-element of a compressed DHT used during the operation is greater than 29 (invalid DHT).
23	The HDIST sub-element of a compressed DHT used during the operation is greater than 29 (invalid DHT).
24	A compressed DHT used during the operation specifies a code which is in the sequence of codes specifying the bit lengths for the 19 possible code lengths defined for a compressed DHT, and is less than the length required by the Huffman algorithm to specify a functional Huffman tree (invalid DHT).
26	A compressed DHT used during the operation specifies code length 16 (copy previous code length) as the first code length for the set of elements consisting of literal bytes, an EOB symbol, and duplicate-string lengths (invalid DHT).
27	A compressed DHT used during the operation specifies a code which is in the sequence of codes specifying code lengths for literal bytes, and the code does not match any of the codes determined to represent the set of referenced code lengths, as specified earlier in the compressed DHT (invalid DHT).
28	A compressed DHT used during the operation specifies a code which assigns code length 0 (CL0) to the EOB symbol. In this case, the corresponding DHT does not specify a Huffman code to represent an EOB symbol (invalid DHT).
29	A compressed DHT used during the operation specifies a code which is in the sequence of codes specifying code lengths for duplicate-string lengths and pointer distances, and the code does not match any of the codes determined to represent the set of referenced code lengths, as specified earlier in the compressed DHT (invalid DHT).
2A	A compressed DHT used during the operation specifies a number of code lengths which is greater than the number of Huffman codes in the DHT, as specified by the sum of the values in the HLIT field, the HDIST field, and 258. This is possible with an improper uses of code lengths 16, 17, and 18. (invalid DHT).
2B	A compressed DHT used during the operation specifies a code length for the set of literal bytes, EOB symbol, and duplicate-string lengths, which is less than the length required by the Huffman algorithm to specify a functional Huffman tree. (invalid DHT).
2D	A compressed DHT used during the operation specifies a code length for the set of duplicate-string pointer distances, which is less than the length required by the Huffman algorithm to specify a functional Huffman tree. (invalid DHT).
2F	The CDHTL field applies and does not equal the length of the compressed DHT in the CDHT field used during the operation.

OESC (hex)	meaning
31	A compressed DHT used during the operation does not specify a Huffman code corresponding to a literal byte or a duplicate-string length processed during the operation (deficient non-universal DHT), or the DFLTCC-XPND function is specified and a compressed-data symbol, which is encountered in a compressed-data block with BTYPE equal 01 binary, specifies an invalid code for a duplicate-string length (11000110 or 11000111 binary).
32	A compressed DHT used during the operation does not specify a Huffman code corresponding to a duplicate-string-pointer distance processed during the operation (deficient non-universal DHT), or the DFLTCC-XPND function is specified and a compressed-data symbol, which is encountered in a compressed-data block with BTYPE equal 01 binary, specifies an invalid code for a duplicate-string-pointer distance (11110 or 11111 binary).
40	A compressed-data symbol is encountered which is a duplicate-string pointer and specifies a distance greater than the length of history available at the point of processing the symbol.
FF	No additional information is provided.

Support for codes other than zero and FF hex is model-dependent. When multiple invalid-input conditions exist, it is model-dependent which code is reported in the OESC field.

Incomplete-Function Status (IFS): Bits 4-7 of byte 21 of the parameter block contain status information when certain operations end. When an uncompressing operation ends, the IFS conveys information about the second operand as follows:

IFS (binary)	meaning
0000	The operation ended after decoding the last element of a block with BFINAL equal to one.
1000	The operation ended after decoding an element, other than the last element, of a block with BTYPE equal 00 binary and BFINAL equal to zero.
1001	The operation ended after decoding an element, other than the last element, of a block with BTYPE equal 00 binary and BFINAL equal to one.
1010	The operation ended after decoding an element, other than the last element, of a block with BTYPE equal 01 binary and BFINAL equal to zero.
1011	The operation ended after decoding an element, other than the last element, of a block with BTYPE equal 01 binary and BFINAL equal to one.
1100	The operation ended after decoding an element, other than the last element, of a block with BTYPE equal 10 binary and BFINAL equal to zero.
1101	The operation ended after decoding an element, other than the last element, of a block with BTYPE equal 10 binary and BFINAL equal to one.
1110	The operation ended at a block boundary, the last element of a block with BFINAL equal to one has not been decoded, and the first element of the subsequent block has not yet been processed.

Note: An uncompressing operation may end with IFS equal 0000 binary and not satisfy normal completion. In such cases, the operation ends with condition code 1 or 3 set.

When a compressing operation ends, the IFS field is undefined, but may be modified.

The IFS is not an input to the operation.

Incomplete-Function Length (IFL): Bytes 22-23 of the parameter block contain length information when certain operations end. For an uncompressing operation, the IFL applies to the second operand. When an uncompressing operation ends after decoding some, but not all of a block with BTYPE equal 00 binary, the IFL contains an unsigned binary integer

specifying the number of bytes of the block in the second operand, which have not yet been processed. Bytes 22-23 contain the IFL in big-endian byte order, unlike the LEN field of a block with BTYPE equal 00 binary, which is in little-endian byte order.

When an uncompressing operation ends after decoding a complete block with BTYPE equal 00 binary and BFINAL equal to one, zeros are stored to the IFL field. When an uncompressing operation ends after decoding some, but not all of a block with a non-zero BTYPE, or ends at a block boundary, the IFL field is undefined, but may be modified.

When a compressing operation ends, the IFL field is undefined, but may be modified.

The IFL is not an input to the operation.

History Length (HL): Bytes 44-45 of the parameter block contain an unsigned binary integer specifying the number of bytes of history in the history buffer which can be referenced during an operation. The HL applies to in-line and circular history buffers. When new task (NT) equals one, no history applies to the beginning of the operation and the history length is treated as zero as an input to the operation.

An invalid-input condition is recognized (condition code 2 is set and a nonzero value is stored to the OESC field) when the history length is greater than 32,768 and NT equals zero.

The history length is modified during compressing and uncompressing operations. When the sum of the original HL and the number of uncompressed data bytes processed during the operation is less than, or equal to 32,768, the updated HL is equal to the sum of the original HL and the number of uncompressed data bytes processed during the operation; otherwise the updated HL is equal to the value of 32,768.

History Offset (HO): Fifteen bits, starting with bit 1 of byte 46, through bit 7 of byte 47, of the parameter block, contain an unsigned binary integer specifying an offset in the third operand when the history-buffer type is circular. The sum of the contents of R_3 and the history offset designates the location of the first byte of history within the circular-history buffer, which is the least recently processed byte of uncompressed data in the buffer. When the history-buffer type is circular, history offset is an input to the operation and is updated at the end of the operation. When the sum of the original HL and the number of uncompressed data bytes processed during the operation is less than, or equal to 32,768, the updated HO is equal to the original HO; otherwise, the updated HO is equal to the sum of the original HO, the original HL, and the number of uncompressed data bytes processed during the operation, modulo 32,768.

When the history-buffer type is in-line, the HO field of the parameter block is undefined, but may be modified.

Check Value: Bytes 48-51 of the parameter block contain a check value. As part of the operation, a check value is generated. The check value applies to the uncompressed data operand. That is, the check value applies to the second operand for the DFLTCC-CMPR function and applies to the first operand for the DFLTCC-XPND function. When the CVT bit is zero, a 32-bit cyclic-redundancy-check check value (CRC-32) is generated. When the CVT bit is one, a 32-bit Adler checksum check value (Adler-32) is generated.

The inputs to generating a check value are a 4 byte base and the uncompressed data processed during the operation. The base input provides the means to compute a single and consistent check value for a set of compressed-data blocks, regardless of the number of times the DFLTCC instruction is executed to process the complete set of compressed-data blocks. When the NT bit is zero, the original value in the check value field is used for the base input in generating a check value.

When an Adler-32 check value is generated, the following apply:

- When the NT bit is one, a value of one is used for the 4 byte base input.
- The sums defined in the Adler-32 check value generation are modulo 65,521.
- The result is stored to the check value field in big-endian byte order. That is, the most significant byte of the check value is located in byte 48 and the least significant byte of the check value is located in byte 51.

When a CRC-32 check value is generated, the following apply:

- When the NT bit is one, a value of zero is used for the 4 byte base input.
- The polynomial used as the divisor in generating a CRC-32 check value is

$x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x^1 + x^0$, which is represented as 104C11DB7 hex. In this representation, the left-most bit corresponds to the most significant bit.

- The first and final stages of generating the check value are computing the one's complement of the base input and computing the one's complement of the result, prior to storing the result, respectively.
- The result is stored to the check value field in little-endian byte order. That is, the least significant byte of the check value is located in byte 48 and the most significant byte of the check value is located in byte 51.

The check value is only meaningful to the program when the operation ends with condition code 0 set; otherwise, the check value is only an intermediate result and only meaningful to resume the operation. When the DFLTCC-CMPR function is specified and the operation ends with condition code 1, 2, or 3 set, some bytes to the left of the byte designated by the second-operand address may not be included in the computation of the resulting check value. When the DFLTCC-XPND function is specified and the operation ends with condition code 1, 2, or 3 set, some result bytes not yet stored to the right of the byte designated by the first-operand address may already be included in the computation of the resulting check value.

End-Of-Block Symbol (EOBS): Fifteen bits, starting with bit 0 of byte 52, through bit 6 of byte 53, of the parameter block, contain an end-of-block (EOB) symbol. The EOBL field of the parameter block specifies the length of the EOB symbol in the EOBS field. The EOB symbol is left justified in the EOBS field. Bits of the EOBS field not occupied by the EOB symbol are stored as zeros. The EOBS field is an output of the operation when compressing data, regardless which type of Huffman table applies. The EOBS field is not used as an input to the operation.

Bit 0 of byte 52 contains the most significant bit of the EOB symbol. When the length of the EOB symbol is 7 bits, bit 6 of byte 52 contains the least significant bit of the EOB symbol. When the length of the EOB symbol is 15 bits, bit 6 of byte 53 contains the least significant bit of the EOB symbol.

For blocks using a FHT, the EOB symbol is 0000000 binary, as defined by the DEFLATE standard. For blocks using a DHT, the EOB symbol is defined by the DHT. The EOB symbol is conveyed in order to provide the capability for the program to close a block.

The EOBS field is undefined when the DFLTCC-XPND function is specified, but may be modified.

End-Of-Block Length (EOBL): Bits 0-3 of byte 54 of the parameter block contain an unsigned binary integer specifying the length of the end-of-block (EOB) symbol in the EOBS field of the parameter block. The length specifies the number of bits which the EOB symbol occupies in the EOBS field. The EOBL field is an output of the operation when compressing data, regardless which type of Huffman table applies. The EOBL field is not used as an input to the operation.

The EOBL field is undefined when the DFLTCC-XPND function is specified, but may be modified.

Compressed Dynamic-Huffman-Table Length (CDHTL): Twelve bits, starting with bit 4 of byte 56, through bit 7 of byte 57, of the parameter block contain an unsigned binary integer which specifies the length, as a bit count, of the compressed format of the DHT in the CDHT field of the parameter block.

The CDHTL is an output from the operation when the DFLTCC-GDHT function is specified.

The CDHTL is an input to the operation when the DFLTCC-CMPR function is specified and HTT is one. When the CDHTL does not specify an appropriate length for the CDHT, an invalid-input condition is recognized (condition code 2 is set and a nonzero value is stored to the OESC field). The CDHTL is not modified when the DFLTCC-CMPR function is specified.

When the DFLTCC-XPND function is specified and the operation ends after decoding only a portion of a block with BTYPE 10 binary, the length of the compressed representation of the DHT in the block is stored to this field. When the DFLTCC-XPND function is specified and the operation ends at a block boundary or after decoding only a portion of a block with BTYPE 00 or 01 binary, zeros are stored to this field. When an uncompressing operation is resumed within a block with BTYPE 10 binary (that is when CF equals one and IFS equals C or D hex), this field is an input to the operation.

Compressed Dynamic-Huffman Table (CDHT): Bytes 64-351 of the parameter block contain a compressed format of a dynamic-Huffman table (DHT).

The DHT specifies Huffman codes (bit sequences) to represent two sets of elements. The elements for one set include literal bytes, an EOB symbol, and duplicate-string lengths. The elements for the other set include duplicate-string pointer distances. The compressed representation of the DHT defines a set of code lengths and specifies a code length (CL) for each element of each set. The Huffman code for an element expected to be referenced during an operation is derived from the CL specified for that element and the number of elements in the same set with the same specified CL. Specifically, the compressed representation of the DHT includes the following:

- An HLIT field to specify the number of Huffman codes representing literal bytes, an EOB symbol, and duplicate-string lengths.
- An HDIST field to specify the number of Huffman codes representing and duplicate-string pointer distances.
- An HCLEN field to specify the number of Huffman codes representing code lengths.
- A sequence of codes specifying a bit length for each of the 19 code lengths defined for the compressed DHT.
- A sequence of codes specifying a code length for each of the elements of the set consisting of literal bytes, an EOB symbol, and duplicate-string lengths.
- A sequence of codes specifying a code length for each of the elements of the set consisting of duplicate-string pointer distances.

Refer to the description of a compressed-data block with block type 10 binary, starting on page 26-47 for a detailed description of the compressed representation of a DHT.

The compressed representation of the DHT is left justified in the CDHT field. That is, the rightmost bit of byte 64 contains the least-significant bit of the HLIT sub-element of the compressed representation of the DHT.

The compressed representation of a DHT is an output from the operation when the DFLTCC-GDHT function is specified.

The compressed representation of a DHT is an input to the operation when the DFLTCC-CMPR function is specified and HTT is one. The CDHT field is not modified by the DFLTCC-CMPR function.

When the DFLTCC-XPND function is specified and the operation ends after decoding only a portion of a block with BTYPE 10 binary, the compressed representation of the DHT in the block is stored to this field. When the DFLTCC-XPND function is specified and the operation ends at a block boundary or after decoding only a portion of a block with BTYPE 00 or 01 binary, zeros are stored to this field. When an uncompressing operation is resumed within a block with BTYPE 10 binary (that is when CF equals one and IFS equals C or D hex), this field is an input to the operation.

When the CDHT is modified, bits of the field not required to represent the compressed representation of the DHT are stored as zeros.

Continuation-State Buffer (CSB): When conditions cause a value of one to be stored in the CF field, internal-state data is stored to bytes 384-1535 of the parameter block; otherwise bytes 384-1535 of the parameter block are undefined and may be modified. The internal-state data stored is model-dependent and may be used subsequently to resume the operation. It is expected, but not required, for the program to initialize the continuation-state buffer to contain all zeros. Subsequent to the instruction ending with a nonzero condition code set, and prior to reexecuting the instruction for the purpose of resuming the operation, the program should not modify the continuation-state buffer; otherwise results are unpredictable.

Sub-byte boundary (SBB) value of 011 binary:

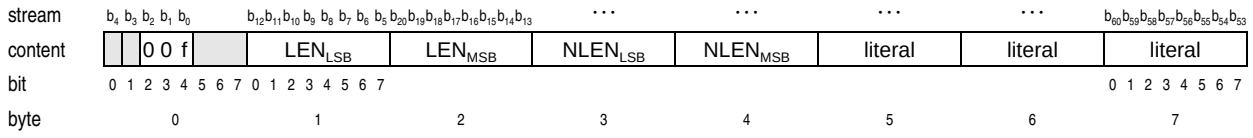
Descriptions for Compressed-data Blocks

The bytes of a compressed-data block in storage are processed from left to right. Compressed-data blocks are not required to start or end on byte boundaries. A compressed-data block is a bit stream. Elements of the block are loaded into storage one bit at a time. The bit stream is loaded from right to left within each byte of storage and in byte order from left to right. When the element is a Huffman code, the bits are stored in order from most significant bit to least significant bit of the element. When the element is not a Huffman code, the bits are stored in order from least significant bit to most significant bit of the element.



Explanation:

b	Bits of the stream processed in order of subscripts, starting with b_0
f	Block header final bit (BFINAL)
LEN	Number of bytes in the block with literal data
NLEN	The one's complement of LEN
LSB	Least Significant Byte
MSB	Most Significant Byte
literal	uncompressed byte of data

Figure 26-31. Block Type 00 (no compression) Example

Figure 26-31 illustrates an example of a block with block type 00 binary, which contains no compressed-data symbols. The following applies to this example:

- The compressed-data block consists of a bit stream which begins with bit 4 of byte 0, identified as b_0, and ends with bit 0 of byte 7, identified as b_{60}.
- The first element encountered in the bit stream is BFINAL in bit 4 of byte 0.
- The second element encountered in the bit stream is BTYPE in bits 2-3 of byte 0. In this example, the BTYPE is 00 binary.
- Bits to the left of the BTYPE and to the right of a byte boundary are ignored when the BTYPE is 00 binary, which is bits 0-1 of byte 0 in this example.
- The third element encountered in the bit stream is the least significant byte of the LEN field, which is followed by the most significant byte of the LEN field. Bytes 1-2 contain the LEN field in little-endian byte order. The LEN field specifies the number of bytes in the block with literal data. Literal data is uncompressed data. The bytes with literal data follow the NLEN field in the bit stream.
- The elements encountered in the bit stream following the LEN field are the least significant byte of the NLEN field, followed by the most significant byte of the NLEN field, respectively. Bytes 3-4 contain the NLEN field in little-endian byte order. The NLEN field is the one's complement of the LEN field.
- Elements encountered in the bit stream following the NLEN field are uncompressed data, identified as literal bytes. Bytes 5-7 contain uncompressed data, which is unchanged from the source data used to generate this block.
- None of the elements contained in this block are Huffman codes. Every element in this block is stored to the bit stream order in order from least significant bit to most significant bit of the element, as defined by the DEFLATE standard. Since the LEN, NLEN, and literal elements are each an integral number of bytes aligned on byte boundaries, these elements may be processed as units of bytes, and not necessarily as units of bits.

Figure 26-32 on page 26-46 illustrates an example of a block with block type 01 binary, which contains compressed-data symbols generated using a fixed-Huffman table (FHT). The following applies to this example:

- The compressed-data block consists of a bit stream which begins with bit 4 of byte 0, identi-

fied as b_0, and ends with bit 3 of byte 11, identified as b_{89}.

- The first element encountered in the bit stream is BFINAL in bit 4 of byte 0.
- The second element encountered in the bit stream is BTYPE in bits 2-3 of byte 0. In this example, the BTYPE is 01 binary.
- The fixed-Huffman table (FHT) is not a component of the block.
- The third element encountered in the bit stream is the first compressed-data symbol, which begins in bit 1 of byte 0. A compressed-data symbol consists of the following sub-elements, which are encountered in the bit stream in the order which they are listed:

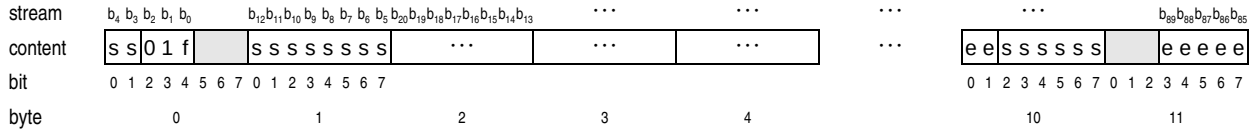
  1. A Huffman code of variable length. The most significant bits of the code designate the length of the code. The code is encountered in the bit stream starting with the most significant bit of the code and ending with the least significant bit of the code. When the code represents a literal value or the end-of-block symbol, the code is the only sub-element of the compressed-data symbol. When the code represents a length of a pointer to the history buffer, the code is followed by subsequent sub-elements of the compressed-data symbol.

  2. When applicable, as specified by the DEFLATE standard, extra length bits may follow the Huffman code representing a pointer length. Extra length bits are encountered in the bit stream starting with the least significant bit and ending with the most significant bit of the extra length bits.

  3. The next sub-element encountered in the bit stream is a 5-bit distance code of a pointer to the history buffer. The distance code is encountered in the bit stream starting with the most significant bit of the code and ending with the least significant bit of the distance code.

  4. When applicable, as specified by the DEFLATE standard, extra distance bits may follow the distance code. Extra distance bits are encountered in the bit stream starting with the least significant bit and ending with the most significant bit of the extra distance bits.

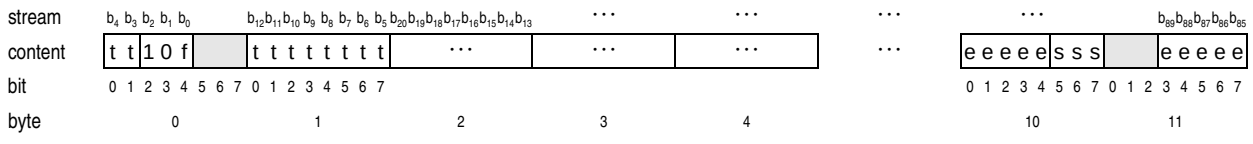
- Bits 0-1 of byte 0, all bits of bytes 1 through 9, and bits 2-7 of byte 10 contain bits of compressed-data symbols.
- The last element encountered in the bit stream is a compressed-data symbol containing a single sub-element, which is the Huffman code representing the end-of-block (EOB) symbol. The EOB symbol for a block with BTYPE 01 binary is 0000000 binary. In this example, bit 1 of byte 10 contains the most significant bit of the EOB symbol and bit 3 of byte 11 contains the least significant bit of the EOB symbol.
- Bit 3 of byte 11 contains the last bit of the bit stream, which is the last bit of the compressed-data block.



Explanation:

b	Bits of the stream processed in order of subscripts, starting with b_0
f	Block header final bit (BFINAL)
s	A bit of a compressed-data symbol
e	A bit of the end-of-block (EOB) symbol

Figure 26-32. Block Type 01 (compressed data using FHT) Example



Explanation:

b	Bits of the stream processed in order of subscripts, starting with b_0
f	Block header final bit (BFINAL)
s	A bit of a compressed-data symbol
e	A bit of the end-of-block (EOB) symbol
t	A bit of the compressed dynamic-Huffman table

Figure 26-33. Block Type 10 (compressed data using DHT) Example

Figure 26-33 on page 26-47 illustrates an example of a block with block type 10 binary, which contains compressed-data symbols generated using a dynamic-Huffman table (DHT). The following applies to this example:

- The compressed-data block consists of a bit stream which begins with bit 4 of byte 0, identified as b_0, and ends with bit 3 of byte 11, identified as b_{89}.
- The first element encountered in the bit stream is BFINAL in bit 4 of byte 0.
- The second element encountered in the bit stream is BTYPE in bits 2-3 of byte 0. In this example, the BTYPE is 10 binary.
- The third element encountered in the bit stream is the compressed representation of the dynamic-Huffman table (DHT), which begins in bit 1 of byte 0. The compressed representation of the DHT consists of the following sub-elements, which are encountered in the bit stream in the order which they are listed:

    1. HLIT: The sum of the 5-bit HLIT sub-element and 257 specifies the number of Huffman codes representing literal bytes, an EOB symbol, and duplicate-string lengths. Valid values of HLIT range from 0 to 29. HLIT bits are encountered in the bit stream starting with the least significant bit and ending with the most significant bit of the HLIT sub-element. In this example, bit 1 of byte 0, identified as b_3 is the least significant bit of the HLIT sub-element.

    2. HDIST: The sum of the 5-bit HDIST sub-element and 1 specifies the number of Huffman codes representing duplicate-string pointer distances. Valid values of HDIST range from 0 to 29. HDIST bits are encountered in the bit stream starting with the least significant bit and ending with the most significant bit of the HDIST sub-element.

    3. HCLEN: The sum of the 4-bit HCLEN sub-element and 4 specifies the number of Huffman codes representing code lengths. Valid values of HCLEN range from 0 to 15. HCLEN bits are encountered in the bit stream starting with the least significant bit and ending with the most significant bit of the HCLEN sub-element.

    4. A sequence of codes specifying a bit length for each of the code lengths defined for the compressed DHT. The number of codes is equal to the sum of HCLEN and 4. Each code is 3 bits.

    5. A sequence of codes specifying a code length for each of the elements of the set consisting of literal bytes, an EOB symbol, and duplicate-string lengths. The number of code lengths specified is equal to the sum of HLIT and 257.

       When the last code length (CL) for the set of literal bytes, an EOB symbol, and duplicate-string lengths is 16, 17, or 18, and the extra bits following the CL specify repeating the CL for more elements than are defined for the set, the code length also applies to the set of duplicate-string pointer distances. The sequence of codes specifying code lengths for the set of literal bytes, an EOB symbol, and duplicate-string lengths, followed by the sequence of codes specifying code lengths

for duplicate-string pointer distances is a contiguous sequence for both sets.

6. A sequence of codes specifying a code length for each of the elements of the set consisting of duplicate-string pointer distances. The number of code lengths specified is equal to the sum of HDIST and 1.

- The fourth element encountered in the bit stream is the first compressed-data symbol. A compressed-data symbol consists of the following sub-elements, which are encountered in the bit stream in the order which they are listed:

  1. A Huffman code of variable length. The most significant bits of the code designate the length of the code. The code is encountered in the bit stream starting with the most significant bit of the code and ending with the least significant bit of the code. When the code represents a literal value or the end-of-block symbol, the code is the only sub-element of the compressed-data symbol. When the code represents a length of a pointer to the history buffer, the code is followed by subsequent sub-elements of the compressed-data symbol.

  2. When applicable, as specified by the DEFLATE standard, extra length bits may follow the Huffman code representing a pointer length. Extra length bits are encountered in the bit stream starting with the least significant bit and ending with the most significant bit of the extra length bits.

  3. The next sub-element encountered in the bit stream is a 5-bit distance code of a pointer to the history buffer. The distance code is encountered in the bit stream starting with the most significant bit of the code and ending with the least significant bit of the distance code.

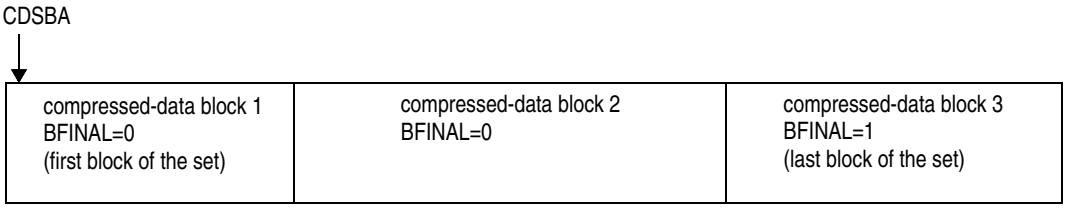
  4. When applicable, as specified by the DEFLATE standard, extra distance bits may follow the distance code. Extra distance bits are encountered in the bit stream starting with the least significant bit and ending with the most significant bit of the extra distance bits.

- Subsequent bits encountered in the bit stream, up to and including bit 5 of byte 10, contain bits of compressed-data symbols.
- The last element encountered in the bit stream is a compressed-data symbol containing a single sub-element, which is the Huffman code representing the end-of-block (EOB) symbol. In this example, bit 4 of byte 10 contains the most significant bit of the EOB symbol and bit 3 of byte 11 contains the least significant bit of the EOB symbol.
- Bit 3 of byte 11 contains the last bit of the bit stream, which is the last bit of the compressed-data block.

Processing a Compressed-Data Set

This section describes examples of processing a compressed-data set to illustrate intended uses of DEFLATE CONVERSION CALL and augment the descriptions of various fields of the parameter block. The examples are simplistic and do not describe all possible scenarios, requirements, and capabilities.

The following examples and descriptions apply to a compressed-data set in storage, as illustrated in Figure 26-34 on page 26-49.



Explanation:
CDSBA: Compressed-Data Set Begin Address
BFINAL: The BFINAL element of each compressed-data block

Figure 26-34. An Example of a Compressed-Data Set in Storage.

For the examples in this section, it is intended for a program processing the compressed-data set to consider the following:

- A single parameter block may be defined and referenced by multiple usages of DEFLATE CONVERSION CALL to process the entire compressed-data set. The check value and check value type fields of the parameter block shall apply to all compressed-data blocks in the compressed-data set. The sub-byte boundary field of the parameter block shall apply to transitions between individual blocks. The history length and history offset may apply to multiple blocks. The remaining fields of the parameter block only apply to the individual compressed-data block being processed by a specific execution of a DEFLATE CONVERSION CALL instruction.
- An individual check value applies to all of the uncompressed data represented by the compressed-data set.
- There is no history for the first compressed-data symbol in block 1 to reference. Subsequent symbols in block 1 may reference history corresponding to previously encountered symbols in block 1. Symbols in block 2 may reference history corresponding to previously encountered symbols in blocks 2 and 1. Symbols in block 3 may references history corresponding to previously encountered symbols in blocks 3, 2, and 1.

Figure 26-35 on page 26-49 lists a portion of a sample program used to compress data into the compressed-data set described in Figure 26-34. Figure 26-36 lists the values for certain fields of the parameter block used during the execution of the DFLTCC instruction located at the instruction address labeled IABLK1. Figure 26-37 lists the values for certain fields of the parameter block used during the execution of the DFLTCC instruction located at the instruction address labeled IABLK2. These figures demonstrate some of the details associated with using DEFLATE CONVERSION CALL multiple times to process an entire compressed-data set.

```
                L       1,PBLKADDR      Load parameter block address into GR1.

```

Figure 26-38. Sample of a Program Uncompressing Data from a Compressed-Data Set

Compressing Data

The process of compressing data includes generating one or more compressed-data blocks. The compress function of DEFLATE CONVERSION CALL is used to construct a portion of an individual block. The portion may be the entire block. This function generates portions of a block with block type (BTYPE) 01 or 10 binary, and not 00 binary. When the new task bit (NT) of the parameter block is one, the first block of compressed data is generated and there is no history to reference from previously performed compressing operations.

An individual block contains the following elements in the order which they are listed:

1. Final block indication (BFINAL).
2. Block type (BTYPE).
3. Compressed format of a Dynamic-Huffman Table, when applicable.
4. Compressed-data symbols.
5. End-of-block (EOB) symbol.

The compression operation generates the elements specified in the order defined for a block. The elements may begin or end between byte boundaries in storage. The sub-byte boundary (SBB) applies to storing of the first element to the first-operand location. A compressed-data block is a bit stream. Components of the block are loaded into storage one bit at a time. The bit stream is loaded from right to left within each byte of storage and in byte order from left to right.

When the SBB is nonzero, the reference to the first byte at the first-operand location is an update reference.

Uncompressed data from the second-operand location is compressed and stored as compressed-data symbols to the first-operand location.

When the first-operand length is zero at the beginning of the execution of the instruction, the first operand is not accessed, and the first-operand address

and first-operand length in general registers R_1 and $R_1 + 1$, respectively, are not changed. This applies when the value of the CF field is zero or one at the beginning of the execution of the instruction.

When the second-operand length is zero at the beginning of the execution of the instruction, the second operand is not accessed, and the second-operand address and second-operand length in general registers R_2 and $R_2 + 1$, respectively, are not changed. The second-operand length is zero at the beginning of the execution of the instruction for the following case:

- The instruction is being reexecuted to resume the operation (the CF field of the parameter block is one at the beginning of the execution of the instruction) and completing the operation can be performed with references to the CSB field of the parameter block, and without references to the second operand.

Note: The program can not use DEFLATE CONVERSION CALL to perform the following operations:

- Generate an empty compressed-data block. An empty compressed data block consists of a block header, a compressed format of a DHT when applicable, and an EOB symbol.
- Close an open compressed-data block. That is, only store an EOB symbol to the end of the compressed-data block.

The compression algorithm includes searching an updated history of recently compressed data for a string of bytes which matches data currently being compressed from the second-operand location. Before the compression operation begins or resumes, the following applies:

- When new task (NT) is one, there is no initial history available to reference.
- When NT is zero, and bit 56 of general register 0 (HBT) is zero (in-line), the initial history available to reference is located to the left of, and adjacent to, the leftmost byte of the second operand, and the length of the initial history is specified by the history length (HL) field of the parameter block.
- When NT is zero, and bit 56 of general register 0 (HBT) is one (circular), the initial history available to reference is located in the third-operand location, as specified by the history offset (HO) and history length (HL) fields of the parameter block.

During the compression operation, fetch-type references to the entire history may be made, regardless which bytes of history are required to perform the operation. Furthermore, when the history-buffer type is circular, fetch-type references to the entire 32 K-byte history buffer may be made, regardless which bytes of history are required to perform the operation.

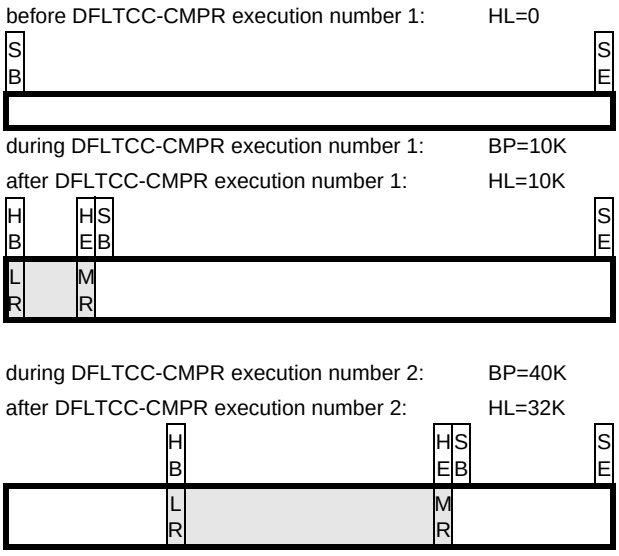
During the compression operation, history is updated. Subsequent to encoding one or more bytes of source data into a compressed-data symbol without encountering an invalid-input condition, the source bytes are concatenated to the end of the history. The most recently processed bytes of source data, up to a maximum of 32 K-bytes, constitute the updated history available to reference while processing subsequent bytes of source data.

When the compression operation ends, the following applies to the resulting history available to subsequently resume the operation, or begin another operation:

- When the HBT is in-line, storage updates to the second-operand location are not required when the history is updated. The updated second-operand address and updated HL specify the updated location and updated length of the resulting history.
- When the HBT is circular, storage updates to the third-operand location are required when the history is updated. The third-operand address, updated HO, and updated HL specify the updated location and updated length of the resulting history.

Figure 26-39 on page 26-53 illustrates the location of in-line history with respect to the second operand before and after multiple executions of a DEFLATE CONVERSION CALL instruction with DFLTCC-

CMPR function and an in-line history specified, when each execution ends with partial completion.



Explanation:

shaded areas: bytes of history

HE	history-end address: location specified by $R_2 - 1$
LR	least recently processed byte in history
MR	most recently processed byte in history
BP	bytes of uncompressed data processed
HL	history length

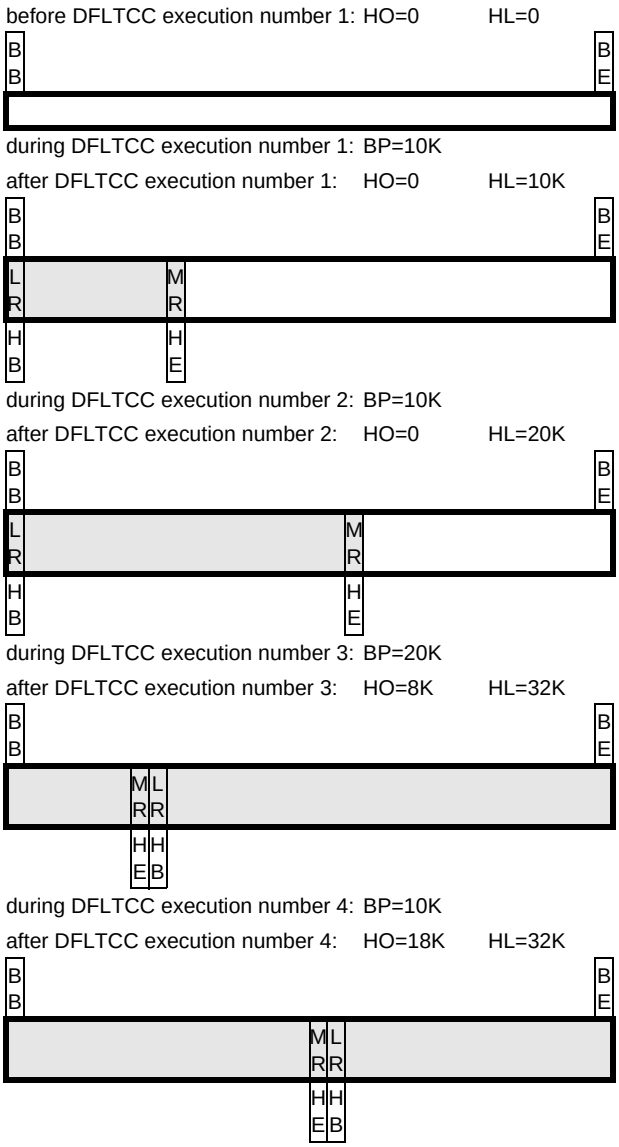
Figure 26-39. In-line History before and after executing DFLTCC-CMPR multiple times

When the HBT specified by bit 56 of general register 0 is circular, the history is maintained in a 32 K-byte buffer located at the third-operand location. The location of the first byte of history within the buffer (HB) is designated by the sum of the contents of general register R_3 and the history offset (HO). The first byte of history is the least recently processed byte of uncompressed data in the buffer. The location of the last byte of history within the buffer (HE) is designated by the following equation:

$$HE = R_3 + \text{modulo32K}(HO + HL - 1)$$

The last byte of history is the most recently processed byte of uncompressed data in the buffer. When the sum of the history offset (HO) and history length (HL) exceeds the size of the third operand (32 K-bytes), the history wraps from the end of the third operand to the beginning of the third operand. Figure 26-40 on page 26-54 illustrates the location of the history within a circular history buffer before and after multiple executions of a DEFLATE CONVERSION CALL instruction with DFLTCC-CMPR function

and a circular history buffer specified, when each execution ends with partial completion.



Explanation:

shaded areas: bytes of history within the circular history buffer

HO	history offset
HL	history length

Figure 26-40. Circular History Buffer before and after executing DFLTCC multiple times

When the HBT is circular and the number of bytes processed from the second-operand location is less than 32,768, the following applies:

- Stores are made to a range of bytes in the third-operand location. The range of bytes includes and starts with the location designated by:

  R_3 + modulo32K(HOO + HLO)

  The range of bytes includes and ends with the location designated by:

  R_3 + modulo32K(HOO + HLO + BP -1)

  The definitions of the variables in the previous equations are:

  HOO: The history offset before the instruction executes.

  HLO: The history length before the instruction executes.

  BP: The number of bytes processed from the second-operand location during the execution of the instruction.

  Stores made to the range of bytes just described are subject to store-type access exceptions, PER storage-alteration events, and setting change bits.

- Stores which do not modify the contents of storage locations and are not necessary, may be made to bytes in the third-operand location which are not included in the range just described. Stores to such locations are also subject to store-type access exceptions, PER storage-alteration events, and setting change bits.

When the HBT is circular and the number of bytes processed from the second-operand location is more than, or equal to 32,768, stores are made to all bytes of the third-operand location and subject to store-type access exceptions, PER storage-alteration events, and setting change bits.

When the block-continuation flag (BCF) is zero, a 3-bit block header, consisting of BFINAL followed by BTYPE, is stored to the first-operand location. The BFINAL bit of the block header is set equal to the block header final bit (BHF) of the parameter block. When the Huffman-table type (HTT) is zero, the BTYPE field of the block header is set to 01 binary and when the HTT is one, BTYPE field of the block header is set to 10 binary. When a block header is stored, the BFINAL bit is stored to the bit specified by the SBB in the first byte of the first operand. Subse-

quently, the BTYPE is stored to the first-operand location. Refer to section “Descriptions for Compressed-data Blocks” on page 26-45 for details on ordering of bits, as elements of a block are stored. When the BCF is one, a block header is not stored.

When the Huffman-table type (HTT) is one, the compressed format of the dynamic-Huffman table (DHT) specified in the parameter block is examined for invalid-input conditions. When an invalid-input condition exists for the specified compressed format of the DHT, the compressed DHT is referred to as invalid and can not be used to compress data. Refer to page 26-27 for a list of invalid-input conditions which may occur when the DFLTCC-CMPR function is specified. When the compressed format of the DHT specifies a bit length for a code length, or a code length for a literal byte, the EOB symbol, a duplicate-string length, or a duplicate-string pointer distance, which is greater than the length required by the Huffman algorithm to specify a proper and functional Huffman tree, the compressed DHT is still used to derive a functional DHT and compress data. When the block-continuation flag (BCF) is zero and the HTT is one, the compressed format of the DHT, as specified in the CDHT field of the parameter block is stored to the first-operand location.

During the compression operation, source data from the second-operand location is encoded into compressed-data symbols. As part of the encoding, source data is compared to the history. When no match is found, the intermediate representation of the source data is literal bytes, which is the same as the source data. When a match is found, the intermediate representation of the source data is a pointer to a location within the history which contains a duplicate copy of the source data. A pointer consists of a length and a distance. The length is the number of source data bytes which match a string in the history. The distance is the number of bytes from the end of the history to the beginning of the string which matches the source data. Two Huffman code trees from the Huffman table are used to encode the intermediate representation of the source data into compressed-data symbols. When the Huffman-table type (HTT) is zero, a fixed-Huffman table (FHT), as described by the DEFLATE standard, specifies the two Huffman code trees used for encoding intermediate results. When the HTT is one, the dynamic-Huffman table (DHT), which is derived from the compressed representation of the DHT, specified in the CDHT field of the parameter block, specifies the two Huffman code trees used for encoding intermediate results. The encoding is performed as described by the DEFLATE standard. When a non-universal DHT is used which does not specify a Huffman code required to encode the intermediate representation of the source data, an invalid-input condition is recognized. The bits of the resulting compressed-data symbol are arranged in the order specified by the DEFLATE standard before storing the result to the first-operand location.

Note: Duplicate-string lengths range from 3 to 258 bytes, as defined in Reference [23.] on page xxxii.

Prior to processing further source data, the history is updated as described previously.

The process is repeated until all source bytes have been processed.

After all source bytes have been processed and the block closing control (BCC) is one, an end-of-block (EOB) symbol is stored to the first-operand location. When a fixed-Huffman table is used, Huffman code 0000000 binary is used for the EOB symbol. When a dynamic-Huffman table (DHT) is used, the Huffman code used for the EOB symbol is specified by the DHT. The bits of the EOB symbol are arranged in the order specified by the DEFLATE standard before storing the EOB symbol to the first-operand location.

When the last compressed-data symbol of the operation (including the EOB symbol), only occupies a portion of the last byte to store, the bits that do not contain a portion of the last symbol are stored as zeros.

Subsequent to processing the last compressed-data symbol, the following occurs:

- A model-dependent value is stored to the model-version number (MVN) field of the parameter block.
- The sub-byte boundary (SBB) field of the parameter block is updated.
- The end-of-block length (EOBL) and end-of-block symbol (EOBS) fields of the parameter block are updated.
- The address in general register R_1 is incremented by the number of bytes processed of the first operand that included processing bit 0, and the length in general register $R_1 + 1$ is decremented by the same number. The number of bytes processed of the first operand that included processing bit 0 is the integer quotient

resulting from an integer division with the dividend being the sum of the number of output bits processed and the original value of the SBB, and the divisor being a value of eight.
- The address in general register R_2 is incremented by the number of source bytes processed, and the length in general register $R_2 + 1$ is decremented by the same number.

The formation and updating of the addresses and lengths are dependent on the addressing mode.

Coincident with compressing the source data, the source data is an input to generating a 32-bit check value. Refer to “Check Value” on page 26-41 for details on generating a check value. The resulting check value is stored to the check value field of the parameter block.

Uncompressing Data

The expand function of DEFLATE CONVERSION CALL is used to decode a compressed-data set into uncompressed data. The compressed-data set in the second-operand location consists of one or more consecutive compressed-data blocks. The blocks of the compressed-data set are processed from left to right. The bytes of a block are processed from left to right. The blocks are not required to start or end on byte boundaries. Each block is decoded independent of other blocks in the compressed-data set. General register R_2 specifies the logical address of the leftmost byte of the first block in the compressed-data set. The last block in the compressed-data set is the block encountered during processing with the BFINAL bit equal to one. There are three types of blocks to process. The method of decoding the contents of a block is a function of the block type (BTYPE).

When the operation begins (when the continuation flag field of the parameter block is zero), the bit designated by general register R_2, the new task (NT) field, and the sub-byte boundary (SBB) field is interpreted as the first bit of a compressed-data block (the BFINAL bit of a block header).

The expand function includes referencing an updated history of recently decoded uncompressed data. Before the uncompressing operation begins or resumes, the following applies:

- When new task (NT) is one, there is no initial history available to reference.
- When NT is zero, and bit 56 of general register 0 (HBT) is zero (in-line), the initial history available to reference is located to the left of, and adjacent to, the leftmost byte of the first operand, and the length of the initial history is specified by the history length (HL) field of the parameter block.
- When NT is zero, and bit 56 of general register 0 (HBT) is one (circular), the initial history available to reference is located in the third-operand location, as specified by the history offset (HO) and history length (HL) fields of the parameter block.

During the operation, fetch-type references to the entire history may be made, regardless which bytes of history are required to perform the operation. Furthermore, when the history-buffer type is circular, fetch-type references to the entire 32 K-byte history buffer may be made, regardless which bytes of history are required to perform the operation.

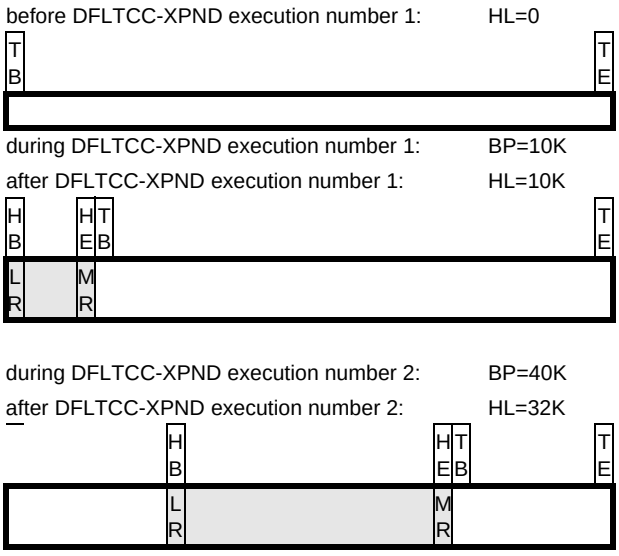
During the uncompressing operation, history is updated. Subsequent to decoding source data without encountering an invalid-input condition, the resulting bytes of uncompressed data are concatenated to the end of the history. The most recently decoded bytes of uncompressed data, up to a maximum of 32 K-bytes, constitute the updated history available to reference while processing subsequent source data.

When the uncompressing operation ends, the following applies to the resulting history available to subsequently resume the operation, or begin another operation:

- When the HBT is in-line, storage updates to the first-operand location also constitute updates to the resulting history. The updated first-operand address and updated HL specify the updated location and updated length of the resulting history.
- When the HBT is circular, storage updates to the third-operand location are required when the history is updated. The third-operand address, updated HO, and updated HL specify the updated location and updated length of the resulting history.

Figure 26-41 on page 26-57 illustrates the location of in-line history with respect to the first operand before and after multiple executions of a DEFLATE CONVERSION CALL instruction with DFLTCC-XPND function and an in-line history specified, when each

execution ends with partial completion. The history length (HL) is modified during the operation.



Explanation:

shaded areas: bytes of history

HB	history-begin address: location specified by R_1 - HL
HE	history-end address: location specified by R_1 - 1
LR	least recently processed byte in history
MR	most recently processed byte in history
BP	bytes of uncompressed data processed
HL	history length

Figure 26-41. In-line History before and after executing DFLTCC-XPND multiple times

When bit 56 of general register 0 specifies a circular history buffer, the history is maintained in a 32 K-byte buffer located at the third-operand location. The location of the first byte of history within the buffer (HB) is designated by the sum of the contents of general register R_3 and the history offset (HO). The first byte of history is the least recently processed byte of uncompressed data in the buffer. The location of the last byte of history within the buffer (HE) is designated by the following equation:

$$HE = R_3 + \text{modulo32K}(HO + HL - 1)$$

The last byte of history is the most recently processed byte of uncompressed data in the buffer. When the sum of the history offset (HO) and history length (HL) exceeds the size of the third operand (32 K-bytes), the history wraps from the end of the third operand to the beginning of the third operand. Figure 26-40 on page 26-54 illustrates the location of the history within a circular history buffer before and after multiple executions of a DEFLATE CONVERSION CALL instruction with DFLTCC-XPND function and a circular history buffer specified, when each execution ends with partial completion.

When the HBT is circular and the number of bytes stored to the first-operand location is less than 32,768, the following applies:

- Stores are made to a range of bytes in the third-operand location. The range of bytes includes and starts with the location designated by:

  R_3 + modulo32K(HOO + HLO)

  The range of bytes includes and ends with the location designated by:

  R_3 + modulo32K(HOO + HLO + BP -1)

  The definitions of the variables in the previous equations are:

  HOO: The history offset before the instruction executes.

  HLO: The history length before the instruction executes.

  BP: The number of bytes stored to the first-operand location during the execution of the instruction.

  Stores made to the range of bytes just described are subject to store-type access exceptions, PER storage-alteration events, and setting change bits.

- Stores which do not modify the contents of storage locations and are not necessary, may be made to bytes in the third-operand location which are not included in the range just described. Stores to such locations are also subject to store-type access exceptions, PER storage-alteration events, and setting change bits.

When the HBT is circular and the number of bytes stored to the first-operand location is more than, or equal to 32,768, stores are made to all bytes of the third-operand location and subject to store-type access exceptions, PER storage-alteration events, and setting change bits.

When the BTYPE is 00 binary, the block does not contain compressed data. Figure 26-31 on page 26-45 illustrates a block with BTYPE equal 00

binary. The LEN field specifies the number of literal bytes in the block. The byte order of the LEN field is little-endian. The LEN field may specify zero literal bytes. The literal bytes of the block are placed at the first-operand location. The history is also updated, as previously described, with each literal byte of the block.

When the BTYPE is 01 binary, the block contains compressed-data symbols that were generated using a fixed-Huffman table (FHT). The FHT is defined by the DEFLATE standard and is not part of the block. Figure 26-32 on page 26-46 illustrates a block with BTYPE equal 01 binary. Subsequent to interpreting the block header, compressed-data symbols are decoded in the order in which they appear in the block. Bytes of the block are processed from left to right. Bits within each byte of the block are processed from right to left. Each symbol is completely processed prior to processing the next symbol in the block. Each symbol which is not the end-of-block (EOB) symbol represents a literal value or a pointer to a substring previously decoded in the history buffer. A previously decoded substring is also referred to as a duplicate string. A pointer consists of codes representing the substring length and the distance from the end of the history to the beginning of the substring. When a symbol represents a substring in the history, the substring is referenced from the history buffer. The uncompressed data resulting from decoding a symbol is placed at the first-operand location.

Note: Duplicate-string lengths range from 3 to 258 bytes, as defined in Reference [23.] on page xxxii.

Prior to processing further source data, the history is updated as previously described.

The updated history applies to decoding the next symbol of the block. When the EOB symbol is encountered, processing of the block is complete.

When the BTYPE is 10 binary, the block contains compressed-data symbols that were generated using a dynamic-Huffman table (DHT). A compressed format of the DHT used is an element of the compressed-data block. Figure 26-33 on page 26-47 illustrates a block with BTYPE equal 10 binary. Subsequent to interpreting the block header, the compressed format of the DHT provided within the compressed-data block is examined for invalid-input conditions. When an invalid-input condition exists for the provided compressed format of the DHT, the compressed format of the DHT is referred to as invalid and can not be used to uncompress data. Refer to page 26-32 for a list of invalid-input conditions which may occur when the DFLTCC-XPND function is specified. When the compressed format of the DHT specifies a bit length for a code length, or a code length for a literal byte, the EOB symbol, a duplicate-string length, or a duplicate-string pointer distance, which is greater than the length required by the Huffman algorithm to specify a proper and functional Huffman tree, the compressed DHT is still used to derive a functional DHT and compress data. Subsequent to examining the compressed format of the DHT, compressed-data symbols are decoded in the order in which they appear in the block. Bytes of the block are processed from left to right. Bits within each byte of the block are processed from right to left. Each symbol is completely processed prior to processing the next symbol in the block. The processing of symbols in a block with BTYPE 10 binary is the same as previously described for processing symbols in a block with BTYPE 01, except the former uses the DHT provided to decode symbols, and the latter uses the FHT to decode symbols. When a non-universal DHT is provided which does not specify a Huffman code required to decode a compressed-data symbol, an invalid-input condition is recognized.

Coincident with uncompressing the second operand, the uncompressed data is an input to generating a 32-bit check value. Refer to “Check Value” on page 26-41 for details on generating a check value. The resulting check value is stored to the check value field of the parameter block.

Subsequent to processing the last block of the compressed-data set, the following occurs:

- A model-dependent value is stored to the model-version number (MVN) field of the parameter block.
- The sub-byte boundary (SBB) field of the parameter block is updated.
- The address in general register R_1 is incremented by the number of bytes stored at the first-operand location, and the length in general register $R_1 + 1$ is decremented by the same number.
- The address in general register R_2 is incremented by the number of bytes processed of the second operand that included processing bit 0, and the length in general register $R_2 + 1$ is decremented by the same number. The number of bytes processed of the second operand that included processing bit 0 is the integer quotient resulting from an integer division with the divi-

dend being the sum of the number of input bits processed and the original value of the SBB, and the divisor being a value of eight.

The formation and updating of the addresses and lengths are dependent on the addressing mode.

When the first-operand length is zero at the beginning of the execution of the instruction, the first operand is not accessed, and the first-operand address and first-operand length in general registers R_1 and $R_1 + 1$, respectively, are not changed. Although the first-operand address is not changed, in the 24-bit addressing mode, bit positions 32-39 of the corresponding general register may be set to zeros, and in the 31-bit addressing mode, bit position 32 of the corresponding general register may be set to zero, as described starting on page 26-20. This applies when the value of the CF field is zero or one at the beginning of the execution of the instruction.

When the second-operand length is zero at the beginning of the execution of the instruction, the second operand is not accessed, and the second-operand address and second-operand length in general registers R_2 and $R_2 + 1$, respectively, are not changed. Although the second-operand address is not changed, in the 24-bit addressing mode, bit positions 32-39 of the corresponding general register may be set to zeros, and in the 31-bit addressing mode, bit position 32 of the corresponding general register may be set to zero, as described starting on page 26-20. The second-operand length is zero at the beginning of the execution of the instruction for the following case:

- The instruction is being reexecuted (the CF field of the parameter block is one at the beginning of the execution of the instruction) and the entire second operand was processed when the instruction was previously executed.

The uncompressing operation may end without storing any results to the first-operand location, even though data was processed from the second-operand location. This occurs when the data processed from the second-operand location only contains any of the following compressed-data block elements:

- A block header.
- The LEN field of a block with block type 00 binary.
- The NLEN field of a block with block type 00 binary.
- A compressed format of a dynamic-Huffman table.
- An end-of-block (EOB) symbol.

Other Conditions

When the DFLTCC-CMPR or DFLTCC-XPND function is specified, execution of the instruction ends after processing a CPU-determined amount of data. This permits interruptions to occur. When the instruction ends with partial completion, the addresses in general registers R_1 and R_2, the lengths in general registers $R_1 + 1$ and $R_2 + 1$, and specific fields of the parameter block are updated, so that the instruction, when reexecuted, resumes the operation at the point it was suspended.

When a DFLTCC-CMPR or DFLTCC-XPND function is being executed and an access exception is due to be recognized for the first or second operand, the result is that either the exception is recognized, or the operation ends with partial completion and condition code 3 is set. If condition code 3 is set, the exception will be recognized when the instruction is executed again to continue processing the same operands and the exception condition still exists.

As observed by this CPU, other CPUs, and channel programs, references to the parameter block, first, second, and third operands may be multiple-access references, accesses to these storage locations are not necessarily block-concurrent, and the sequence of these accesses or references is undefined.

Results are unpredictable if the DFLTCC-CMPR or DFLTCC-XPND function is specified and any of the following apply:

- The parameter block overlaps the first or second operand.
- The first operand overlaps the second operand.
- The specified history-buffer type (HBT) is circular and the third operand overlaps the first operand, the second operand, or the parameter block.
- The specified history-buffer type (HBT) is in-line, the DFLTCC-CMPR function is specified, and the history overlaps the first operand or the parameter block.
- The specified history-buffer type (HBT) is in-line, the DFLTCC-XPND function is specified, and the history overlaps the second operand or the parameter block.

In certain unusual situations, despite ending the execution of DEFLATE CONVERSION CALL with a

CPU-determined amount of data processed being zero, data may have been stored to the first-operand location, data may have been stored to the third-operand location, when applicable, and corresponding change bits have been set, when applicable. In these cases, the contents of the parameter block and general registers have not been modified from original values. These situations may occur when the CPU performs a quiescing operation or CPU retry while executing DEFLATE CONVERSION CALL.

Resulting Condition Code:

0 Normal completion
1 The first-operand length is insufficient to complete the operation
2 The second-operand length is insufficient to complete the operation (DFLTCC-XPND) or invalid-input condition
3 CPU-determined amount of data processed

Program Exceptions:

- Access (fetch, operand 2, in-line history; fetch and store, parameter block, operand 1, operand 3)
- Operation (if the DEFLATE-conversion facility is not installed)
- Specification
- Transaction constraint

The priority of execution for the DEFLATE CONVERSON CALL instruction is shown in Figure 26-42 on page 26-60.

Prior to usage, the compressed format of a DHT is examined for the existence of invalid-input conditions. When the length of the compressed format of a DHT is not precisely defined due to an invalid-input condition, the interpreted length may depend on the condition, be model dependent, and does not exceed 286 bytes. As a result, when the DFLTCC-XPND function is specified, the current second-operand length is 287, or less bytes, and a compressed format of a DHT with an invalid-input condition is encountered in the second operand, it is model dependent whether the invalid-input condition (priority 14.A) or insufficient second-operand length (condition code 2 - priority 14.B) is recognized.

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B	Operation exception.
7.C	Transaction constraint.
8.A	Specification exception due to invalid function code or invalid register number.
8.B	Specification exception due to parameter block not designated on doubleword boundary.
8.C	Specification exception due to circular history buffer not designated on 4 K-byte boundary.
9.	Access exceptions for an access to the parameter block.
10.	Condition code 2 due to specified format of the parameter block is not supported by the model.
11.	Specification exception due to second-operand length equal to zero and CF equal to zero at the beginning of the execution of the instruction.
12.	Condition code 1 due to first-operand length equal to zero at the beginning of the execution of the instruction and DFLTCC-CMPR is specified.
13.A	Condition code 2 due to the history length field greater than 32,768 and the new task field is zero when DFLTCC-CMPR or DFLTCC-XPND is specified.
13.B	Access exceptions for an access to the first operand and the first-operand length is nonzero.
13.C	Access exceptions for an access to the second operand and the second-operand length is nonzero.
13.D	Access exceptions for an access to in-line history specified at the beginning of the execution of the instruction.
13.E	Access exceptions for an access to the third operand.
14.A	Condition code 2 due to invalid-input conditions other than those included in items 10 and 13.A above.

Figure 26-42. Priority of Execution: DFLTCC (Part 1 of 2)

14.B	Condition codes 1, 2, or 3 due to conditions other than those included in items 10, 12, 13.A, and 14.A above.
15.	Condition code 0.

Figure 26-42. Priority of Execution: DFLTCC (Part 2 of 2)

Programming Notes:

1. There is no partial completion for the DFLTCC-GDHT function. To complete the function, all pages designated by the second operand must be accessible.

2. When the program references the end-of-block (EOB) symbol in the parameter block to close a compressed-data block, the program is responsible for reversing the bit order of the EOB symbol, which is a Huffman code.

3. When compressing or uncompressing data, it may be significantly more efficient overall when the operation can be performed with the minimum number of times DEFLATE CONVERSION CALL (DFTLCC) is executed. In other words, executing DFLTCC with a large operand may be significantly more efficient than executing DFLTCC with small operands multiple times.

4. For the compressing and uncompressing operations, when condition code 3 is set, the general registers used by the instruction and the parameter block have been updated such that the program can simply branch back to the instruction to continue the operation.

5. When the program anticipates referencing the first or second operand of DEFLATE CONVERSION CALL (DFLTCC), subsequent to executing the instruction, there may be a performance advantage associated with the subsequent reference when DFLTCC is immediately preceded by NEXT INSTRUCTION ACCESS INTENT (NIAI) specifying an access intent corresponding to the operand of interest with an access intent code value of one or two.

6. When DFLTCC-XPND is specified and the instruction ends with condition code 2 set, the value stored to the OESC field of the parameter block distinguishes between ending due to an insufficient second-operand length (zero stored to OESC field) and ending due to an invalid-input condition (nonzero value stored to OESC field).

7. The Huffman codes of a non-universal DHT may be shorter than the Huffman codes of a universal DHT generated from the same data. As a result, compressed-data symbols generated when using a non-universal DHT may occupy less bits than those generated when using a universal DHT.

8. A program may encounter an invalid-input condition (condition code 2 set with a nonzero value stored to the OESC field of the parameter block) when using a non-universal DHT to compress data which was not the same data used as an input to generating the non-universal DHT.

9. Different compressed representations may be generated from the same uncompressed input. However, all compressed representations comply with the cited DEFLATE standard and can be decoded to the original (uncompressed) form of the data by any decoder which complies to the same standard. Varying results may be observed on the same model and between different models. Generated results may depend on the following:

   - Variations of boundaries in storage for the input data.
   - Variations of the CPU-determined amount of data processed during the execution of the instruction.
   - Variations of the algorithms implementing the functions.

   Differences to compressed-data symbols primarily include, but are not limited to, representations of duplicate strings.

10. A compressing operation may end with: the location of the last byte stored being equal to the location of first byte of the PER storage-area designation, a nonzero value in the sub-byte boundary (SBB) field of the parameter block, and a PER storage-alteration event being recognized. In this case, the address in general register R_1 is equal to the starting address of the PER storage-area designation.

11. Performance may be significantly degraded when the CPU is enabled to recognize PER storage-alteration events and the PER storage-area designation overlaps with the first-operand location or the third-operand location.

12. When the DFLTCC-CMPR function is specified and the operation ends with a nonzero value in

the sub-byte boundary (SBB) field of the parameter block, the operation included storing to the byte designated by the resulting first-operand address. When the DFLTCC-XPND function is specified and the operation ends with a nonzero value in the SBB, the operation included fetching the byte designated by the resulting second-operand address.

13. When the operation ends with a nonzero condition code set and the OESC field contains zeros, the CSB field of the parameter block may contain partially processed data, and it is expected the program reexecutes the instruction to resume the operation.

14. Subsequent to an operation ending with a nonzero condition code set, and prior to reexecuting the instruction for the purpose of resuming the operation, the program should not modify any fields of the parameter block; otherwise results are unpredictable.

15. When the DFLTCC-GDHT function is specified, the compressed representation of a DHT generated describes three proper-full Huffman code trees, according to the Huffman algorithm. That is, no under-full Huffman code trees are described. An under-full Huffman code tree is derived from a compressed representation of a DHT which specifies a code length for an element which is greater than the length required by the Huffman algorithm to specify a proper and functional Huffman tree.

    When the DFLTCC-CMPR function is specified, HTT is one, and the compressed representation of the DHT includes a description of an under-full Huffman code tree, the compressed-data results can be transformed to the original uncompressed data by using the DFLTCC-XPND function, but not all decoders, which comply to the DEFLATE standard may be able to transform the results to the original uncompressed data. This may occur when the compressed representation of a DHT, specified by the program, for the DFLTCC-CMPR function was not generated as a result of performing the DFLTCC-GDHT function.

16. When the DFLTCC-CMPR function ends with condition code 1 set, the result stored to the sub-byte boundary (SBB) field of the parameter block is 000 binary. Recognizing this scenario may be relevant to a program allocating output buffers for use with DEFLATE CONVERSION CALL.

17. When the DFLTCC-XPND function is specified with a circular history buffer and two different logical addresses in the first operand translate to the same absolute address, the results stored to the circular history buffer are unpredictable. Depending on the model, the implementation for updating the circular history buffer may include fetching decoded data stored to the first-operand location.

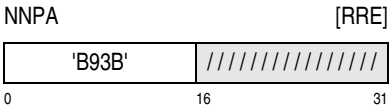
18. Athough not explicitly stated in Reference [23.] on page xxxii, two representations for the duplicate-string length of 258 bytes are possible, which are as follows:

    - Symbol code with value 284 followed by 5 extra bits with value 11111 binary.
    - Symbol code with value 285, which is the preferred representation, since it may occur frequently.

    When uncompressing data, both representations are successfully decoded.

BCG: text up to next BCG tag is new/replacement

NEURAL NETWORK PROCESSING ASSIST



NEURAL NETWORK PROCESSING ASSIST performs functions related to tensor computation.

A function specified by the function code in general register 0 is performed.

Bits 16-31 of the instruction are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.

General register 0 contains a function code that determines the function to be performed by the instruction. Upon completion of the instruction, general register 0 contains status flags and a response code that may be updated under certain conditions. The content of general register 0 is as follows:

Function Code (FC): Bit positions 56-63 of general register 0 contain the function code. Figure 26-43 shows the assigned function codes for

NEURAL NETWORK PROCESSING ASSIST. All other function codes are unassigned. If an unassigned or uninstalled function code is specified, a response code of 0002 hex and condition code 1 are set in general register 0. This field is not modified during execution.

Code (Dec)	Code (Hex)	Function	Parameter Block Size (bytes)
0	0	NNPA-QAF	256
16	10	NNPA-ADD	4096
17	11	NNPA-SUB	4096

Figure 26-43. Function Codes for NEURAL NETWORK PROCESSING ASSIST

Programming Note: Defined and installed function codes are model-dependent, and with the exclusion of the NNPA-QAF, their availability may change in future models.

Status Flags (SF): Bit positions 24-31 of general register 0 contain the status flags. If an exceptional condition is detected during the execution of the instruction, the corresponding status-flag bit will be set to one; otherwise, the bit remains unchanged. Reserved flags are stored as zero or unmodified. The flags stored to the SF field are defined as follows:

SF (bit)	Meaning
0	Range Violation: This flag is set to one when a nonnumeric value was either detected in an input tensor or stored to an output tensor. This flag is only valid when the instruction completes with condition code 0.
1-7	Reserved

Programming Note: The SF should be initialized to zero prior to the beginning of a sequence of NNPA operations to accumulate the status across all operations of the sequence.

Response Code (RC): Bit positions 0-15 of general register 0 contain the response code. When an invalid-input condition is encountered, a nonzero value is stored to the RC field, which indicates the cause of the invalid-input condition recognized during execution of the NEURAL NETWORK PROCESSING ASSIST, and condition code 1 is set. The response code is not altered in other cases. Response codes less than F000 hex apply to all NNPA functions unless the function description states otherwise. The codes stored to the RC field are defined as follows:

RC (hex)	Meaning
0001	The format of the parameter block, as specified by the parameter-block-version number, is not supported by the model or by the specified function.
0002	The specified function is not defined or installed on the machine.
0010	A specified tensor data-layout format is not supported.
0011	A specified tensor-data type is not supported.

RC (hex)	Meaning
0012	A specified dimension-index size for a tensor is greater than the maximum size supported for that dimension. When the format-1 parameter block is not installed, the maximum size is the MDIS value. When the format-1 parameter block is installed, the maximum size is the corresponding MDnIS value.
0013	The size of a specified tensor is greater than the maximum-tensor size (MTS).
0014	The specified tensor address is not aligned on a 4 K-byte boundary.
0015	The function-specific-save-area address is not aligned on a 4 K-byte boundary.
F000-FFFF	Function specific response codes: These response codes are defined for certain functions. See the description of the specified function code for details.

Figure 26-97 on page 26-118 lists the priority at which normal and exceptional conditions are recognized by the NNPA instruction. For cases where multiple response codes may be applicable (particularly, rows labeled 12.A and 13.A in the figure), it is model dependent which response code is indicated.

Bits 16-23 and 32-55 of general register 0 are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.

The contents of general register 1 specify the logical address of the leftmost byte of the parameter block in storage. The parameter block must be designated on a doubleword boundary; otherwise, a specification exception is recognized.

For all functions, the contents of general register 1 are not modified.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general register 1 constitutes the address of the parameter block, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of general register 1 constitutes the address of the parameter block, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register 1 constitutes the address of the parameter block.

In the access-register mode, access register 1 specifies the address space containing the parameter block, all input tensors, output tensors, and the function-specific-save area.

Figure 26-44 on page 26-64 shows the contents of the general registers just described.

RC Response Code
SF Status Flags

Figure 26-44. General Register Assignments for NNPA

Programming Note: Supported NNPA function codes, parameters and parameter ranges may vary from model to model. This can lead to an NNPA instruction finishing unexpectedly with condition code

1 on a particular model, for example, after a live-guest relocation. The program must be designed to be able to recover from this state and may need to restart the entire AI operation from the beginning after querying, again, the supported capabilities and functions via the NNPA-QAF function.

Symbols Used in Function Descriptions

The following symbols are used in the subsequent descriptions of function codes for the NEURAL NETWORK PROCESSING ASSIST instruction.

Figure 26-45 shows the symbol representing the NNPA-ADD function (see “Function Code 16: NNPA-ADD” on page 26-83), where A is input-tensor 1, B is input-tensor 2, and C is the output tensor.

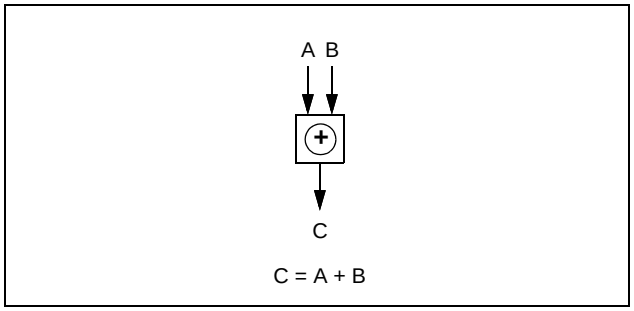

Figure 26-45. NNPA-ADD

Figure 26-47 shows the symbol representing the NNPA-SUB function (see “Function Code 17: NNPA-SUB” on page 26-83), where A, the minuend, is input-tensor 1, B, the subtrahend, is input-tensor 2, and C is the output tensor.

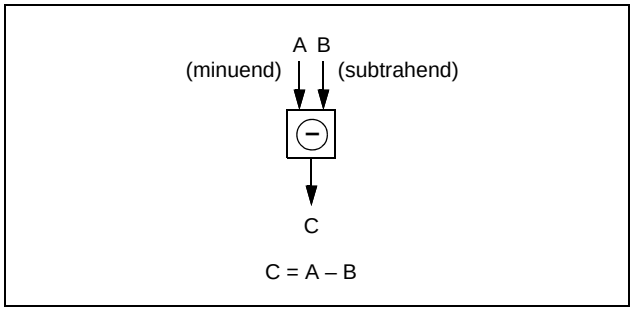

Figure 26-46. NNPA-SUB

Figure 26-47 shows the symbol representing the NNPA-MUL function (see “Function Code 18: NNPA-MUL” on page 26-83), where A, the multiplicand, is input-tensor 1, B, the multiplier, is input-tensor 2, and C is the output tensor.

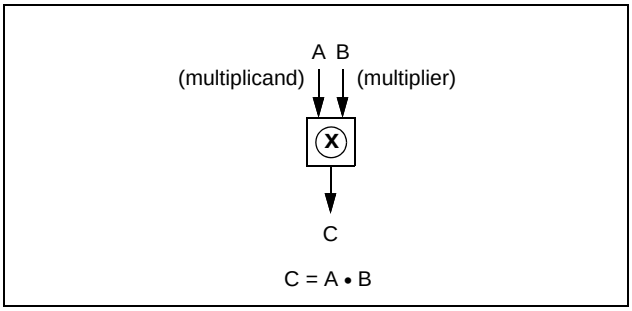

Figure 26-47. NNPA-MUL

Figure 26-48 shows the symbol representing the NNPA-DIV function (see “Function Code 19: NNPA-DIV” on page 26-830 , where A, the dividend, is input-tensor 1, B, the divisor, is input-tensor 2, and C is the output tensor.

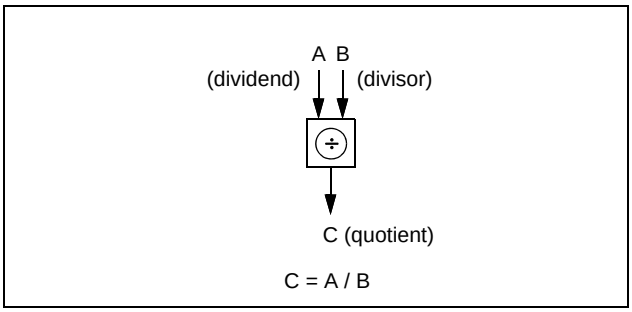

Figure 26-48. NNPA-DIV

Figure 26-49 shows the symbol representing the NNPA-SIGMOID function (see “Function Code 51: NNPA-SIGMOID” on page 26-87) , where A is input-tensor 1, and B is the output tensor.

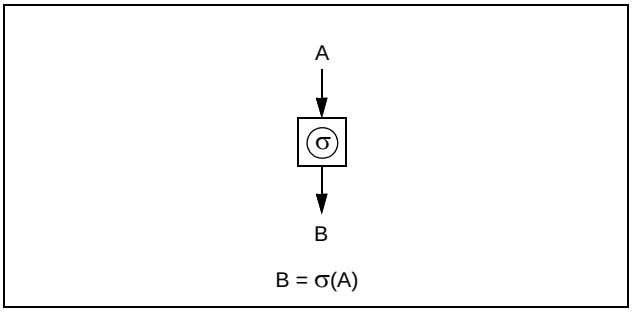

Figure 26-49. NNPA-SIGMOID

Figure 26-50 shows the symbol representing the NNPA-TANH function (see “Function Code 50:

NNPA-TANH" on page 26-87) , where A is input-tensor 1, and B is the output tensor.

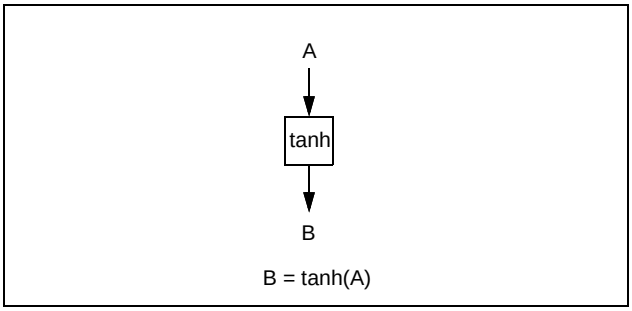

Figure 26-50. NNPA-TANH

Figure 26-51 shows the symbol representing a fused multiply add operation that is equivalent to the operation performed to generate an output element by the NNPA-BATCHNORM function (see "Function Code 64: NNPA-BATCHNORM" on page 26-89) , where A, the multiplicand, is input-tensor 1, B, the multiplier, is input-tensor 2, C, the addend, is input-tensor 3, and D is the output tensor.

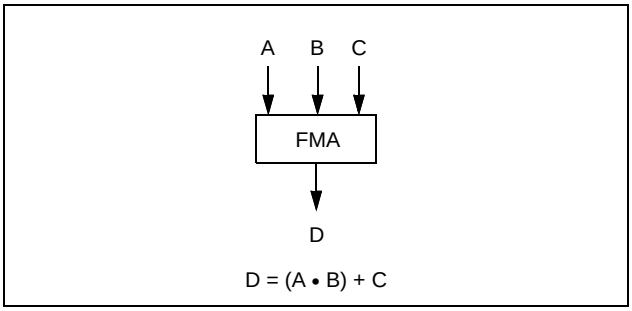

Figure 26-51. NNPA-BATCHNORM

Figure 26-52 shows the symbol representing the square-root operation used in the NNPA-LAYER-NORM function, where the output B represents the square root of the input A.

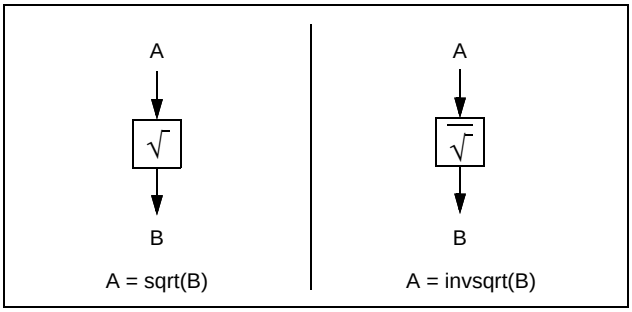

Figure 26-52. Square-Root and Inverse-Square-Root Operations

Symbols Explanation:

The following symbols are used in the subsequent descriptions of NNPA functions:

I_xD_yIS	Dimension-*y*-index size of the input-tensor *x* defined in tensor-descriptor *x*.
O_xD_yIS	Dimension-*y*-index size of the output-tensor *x* defined in tensor-descriptor *x*.
D_2S	Dimension-2 stride.
D_3S	Dimension-3 stride.
D_2WS	Dimension-2-window size.
D_3WS	Dimension-3-window size.
I_xD_yI	Dimension-*y* index of the input-tensor *x* defined in tensor-descriptor *x*. The value of I_xD_yI goes from zero to I_xD_yIS minus one.
$\lceil X \rceil$	The smallest signed-integer value greater than or equal to X.
$\lfloor X \rfloor$	The largest signed-integer value less than or equal to X.
x MOD y	Remainder of the integer division of x by y where both x and y are unsigned integers.

Function Code 0: NNPA-QAF (Query Available Functions)

The NNPA-QAF (query) function provides the means of indicating the availability of all installed functions, installed parameter-block formats, installed data types, installed data-layout formats, maximum-dimension-index size, and maximum-tensor size.

Condition code 0 is set when execution of the NNPA-QAF function completes; condition codes 1, 2, and 3 are not applicable to the query function.

The parameter block for the NNPA-QAF has the following format:

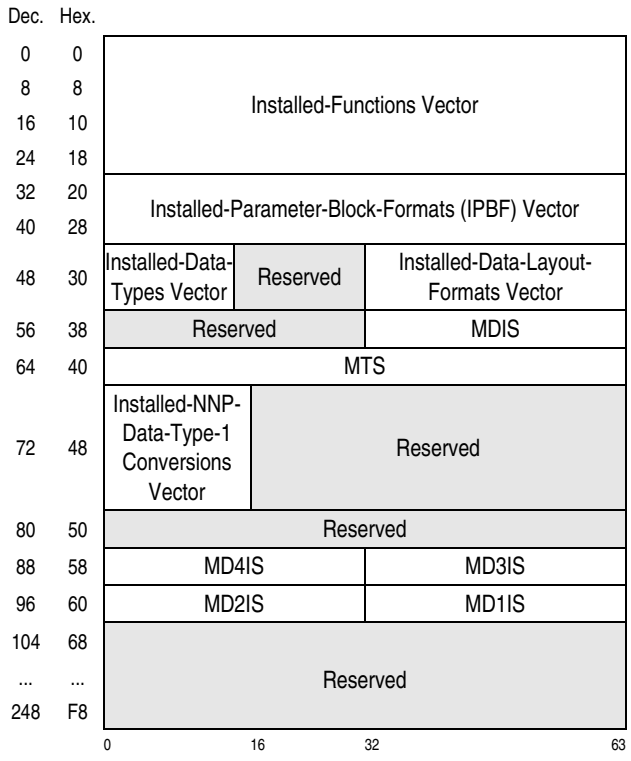

Figure 26-53. Parameter Block for NNPA-QAF

Reserved: When the operation ends, zeros will be stored to all reserved fields.

Installed-Functions Vector: Bytes 0-31 of the parameter block contain the installed-functions vector. Bits 0-255 of the installed-functions vector correspond to function codes 0-255, respectively, of the NEURAL NETWORK PROCESSING ASSIST instruction. When a bit is one, the corresponding function is installed; otherwise, the function is not installed.

Installed-Parameter-Block-Formats (IPBF) Vector: Bytes 32-47 of the parameter block contain the installed-parameter-block-formats vector. Bits 0-127 of the IPBF vector correspond to parameter-block formats 0-127 for all functions of NEURAL NETWORK PROCESSING ASSIST other than NNPA-QAF. When a bit is one, the corresponding parameter-block format is installed; otherwise, the parameter-block format is not installed.

Programming Note: For functions other than NNPA-QAF, the value of the parameter-block-version number (PBVN, specified in the NNPA parameter block) corresponds directly to a bit position in the IPBF vector. If the PBVN specifies a bit position in the IPBF vector that is zero, then that parameter-block format is not supported, response code 0001 hex is set in general register 0, and the instruction completes with condition code 1.

Functions that are part of the original neural-network-processing-assist facility all support parameter-block-format 0, and the description of the function does not mention the PBVN. When a function's behavior has been enhanced or modified based on changes to parameter-block fields, the function's description will include any dependencies on a PBVN value.

Installed-Data-Types Vector: Bytes 48-49 of the parameter block contain the installed-data-types vector. Bits 0-15 of the installed-data-types vector correspond to a data type being installed. When a bit is one, the corresponding data type is installed; otherwise, the data type is not installed.

Bit	Data Type
0	NNP-Data-Type 1 (16-bit)
1-5	Reserved
6	32-bit binary-floating-point (BFP short) format
7	Reserved
8	8-bit signed or unsigned binary integer
9	Reserved
10	32-bit signed or unsigned binary integer
11-15	Reserved

Programming Notes:

1. Not all installed-data types are available to all NNPA functions. See the function description for details of which data types are supported by the function for inputs and outputs.

2. An installed-data type does not distinguish between whether the data type is signed or unsigned. See the function description to determine the actual usage.

Installed-Data-Layout-Formats Vector: Bytes 52-55 of the parameter block contain the Installed-data-layout-formats vector. Bits 0-31 of the installed-data-layout-formats vector correspond to data-layout for-

mat being installed. When a bit is one, the corresponding data-layout format is installed; otherwise, the data-layout format is not installed.

Bit	Data-Layout Format
0	4D-feature tensor
1	4D-kernel tensor
2	4D-weights tensor
3-30	Reserved
31	4D-generic tensor

Programming Note: Not all installed data-layout formats are available to all NNPA functions. See the function description for details of which data-layout formats are supported by a function.

Maximum-Dimension-Index Size (MDIS): Bytes 60-63 of the parameter block contain a 32-bit unsigned binary integer that specifies the maximum number of elements in one or more dimension-index sizes for any specified tensor.

When the format-1 parameter block is not installed, the MDIS value applies to all dimension-index sizes. When the format-1 parameter block is installed, the MDnIS values apply to individual dimension-index sizes and the MDIS value is equal to the minimum of the MDnIS values.

Programming Note: Some NNPA functions restrict the size of a tensor's dimension to a value less than MDIS.

Maximum-Tensor Size (MTS): Bytes 64-71 of the parameter block contain a 64-bit unsigned binary integer that specifies the maximum number of bytes in any specified tensor including any pad bytes required by the tensor format.

Installed-NNP-Data-Type-1-Conversions Vector: Bytes 72-73 of the parameter block contain the installed-NNP-data-type-1-conversions vector. Bits 0-15 of the installed-NNP-data-type-1-conversions vector correspond to installed data type conversions between binary-floating-point (BFP) and NNP-Data-Type-1 formats. When a bit is one, the corresponding conversion is installed; otherwise, the conversion is not installed.

Bit	Data Type
0	Reserved
1	BFP tiny format (16 bit)
2	BFP short format (32 bit)
3-15	Reserved

Programming Note: The installed-NNP-data-type-1-conversions vector indicates the types of binary-floating-point formats that are supported by the following instructions:

- VECTOR FP CONVERT AND LENGTHEN FROM NNP HIGH
- VECTOR FP CONVERT AND LENGTHEN FROM NNP LOW
- VECTOR FP CONVERT AND ROUND TO NNP
- VECTOR FP CONVERT FROM NNP
- VECTOR FP CONVERT FROM NNP

Maximum-Dimension-n-Index-Sizes (MDnIS): Bytes 88-103 of the parameter block contain four 4-byte unsigned integers that specify the maximum number of elements in each dimension of a tensor, as follows:

Field	Bytes	Contents
MD4IS	88-91	Maximum dimension-4 index size
MD3IS	92-95	Maximum dimension-3 index size
MD2IS	96-99	Maximum dimension-2 index size
MD1IS	100-103	Maximum dimension-1 index size

The MDnIS fields are stored and are applicable only when the format-1 parameter block is installed; otherwise, zeros are stored in bytes 88-103. When applicable, an individual MDnIS value will never be less than the MDIS value.

Tensor Specification

To operate efficiently the NNPA instruction needs input tensors provided in particular data-layout formats (see "Installed-Data-Layout-Formats Vector" on page 26-67 for supported formats).

The NNPA instruction operates with 4D-tensors, that is tensors with 4 dimensions. All non-transformed tensors (generic tensors) described here are in row-major format, that is when enumerating all tensor elements in increasing storage-address order, the inner dimension called E1 will be incremented first through all *E1-index-size* values starting with 0 through the

E1-index-size - 1, before the index of the E2 dimension will be increased and the stepping through the E1 dimension is repeated. The index of the outer dimension called E4 dimension is increased last.

Tensors that have lower number of dimensions (that is, 3D-, 2D, or 1D-tensors) will be represented as a 4D-tensor with the index size of the unused dimensions set to one.

An example of a non-transformed (generic) tensor is shown in Figure 26-54 where each element of the tensor is contiguous in storage.

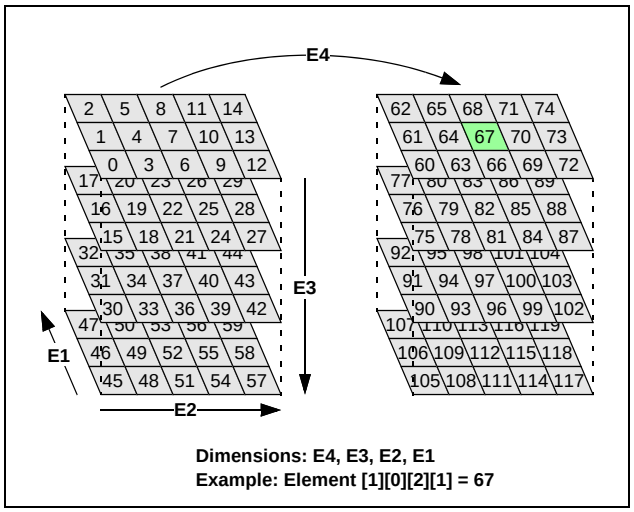

Figure 26-54. Example of a Generic 4D-Tensor with Dimensions 2,4,5,3

The row-format generic tensor is considered to be in data-layout-format 31. When installed, the NNPA-TRANSFORM function can be used to transform a data-layout-format-31 generic tensor to and from a data-layout-format-0 4D-feature tensor.

Sticks, Stickification, and Elements Per Stick (eps): Tensors that have been transformed into the NNP data layouts – that is, tensors that have been structured such that the E1 and E2 dimensions are optimally sized for processing by the NNPA instruction – are referred to as *stickified* tensors (in that their E1 dimensions are so-called *sticks* of a fixed size). Conversely, generic tensors that have not been transformed are referred to as *unstickified* tensors. For all current processor models, the size of a stick is 128 bytes.

In the specifications and figures for data-layout-formats 0 and 1 shown below, the maximum number of elements per stick (*eps*) is determined as follows:

eps = stick_size / element_size

The element size is derived from the data type. The elements per stick for the supported data types are shown in Figure 26-55.

Data Type			Elements Per Stick (eps)
Code	Name	Size (bytes)	
0	NNP Data-Type 1	2	64
6	32-bit BFP-short format	4	32
8	8-bit signed binary integer	1	128
10	32-bit binary integer	4	32

Figure 26-55. Elements Per 128-Byte Stick

The term *eps* is used extensively in the following descriptions and figures.

Data-Layout-Format-0 Specification

The transformation of a row-major generic 4D-tensor with dimensions E4, E3, E2, E1 (Figure 26-54 on page 26-69) into an NNPA data-layout-format-0 4D-feature tensor (Figure 26-56 on page 26-71) is illustrated in Figure 26-57 on page 26-72.

The resulting tensor can be represented as a 4D-tensor of eps-element vectors or a 5D-tensor with dimensions FE4, FE1, FE3, FE2, FE0 respectively equals to:

E4, ⌈E1 / eps⌉, E3, ⌈E2 / 32⌉ • 32, eps.

The total size, in elements of the resulting tensor, is the product of these five dimensions.

An element [e4][e3][e2][e1] of the generic tensor will be mapped to the following element of the resulting 5D-tensor:

[e4][⌊e1 / eps⌋][e3][e2][e1 MOD eps].

The resulting tensor may have more elements than the generic tensor. All elements of the resulting tensor with no corresponding elements in the generic tensor are called pad elements.

Consider the element [fe4][fe1][fe3][fe2][fe0] of an NNPA data-layout-format-0 4D-feature tensor of eps-element vectors or its equivalent representation as 5D-tensor of elements. This element is either a pad element or its corresponding element in the generic

4D tensor with dimensions E4, E3, E2, E1 can be determined with the following formula:

- if fe2 ≥ E2 then this is an E2-pad element
- else if fe1 • eps + fe0 ≥ E1 then this is a E1-pad element
- else the indices of the corresponding element in the generic 4D-tensor are:

  [fe4][fe3][fe2][fe1 • eps + fe0]

Alternatively, consider the element at offset *dlf0_off* of an NNPA data layout format 0 4D-feature tensor. This element is either a pad element or its corresponding element in the generic 4D-tensor with dimensions E4, E3, E2, E1 and can be determined as follow:

- if *dlf0_off* MOD (⌈E2/32⌉ • 32 • eps) ≥ E2 • eps then this is an E2-pad element
- else:
  - area3d = E3 • ⌈E2 / 32⌉ • 32 • ⌈E1 / eps⌉ • eps
  - rem3d = dlf0_off MOD area3d
  - if (⌊ rem3d / (E3 • ⌈E2 / 32⌉ • 32 • eps) ⌋ == ⌊ E1 / eps ⌋ AND rem3d MOD eps >= E1 MOD eps) then this is an E1-pad element
- else the corresponding element in the generic 4D-tensor is:

  [⌊*dlf0_off* / (⌈E1 / eps⌉ • E3 • ⌈E2 / 32⌉ • 32 • eps)⌋]
  [(⌊ *dlf0_off* / (⌈E2/32⌉ • 32 • eps) ⌋) MOD E3]
  [(⌊ (*dlf0_off* / eps) ⌋) MOD (⌈E2/32⌉ • 32)]
  [(⌊ *dlf0_off* / (E3 • ⌈E2/32⌉ • 32 • eps) ⌋ MOD ⌈E1 / eps⌉) • eps + (*dlf0_off* MOD eps)]

Pad elements are ignored for the input tensors and model dependent for output tensors. It is model dependent if PER storage-alteration is detected on pad elements of output tensors.

Programming Notes:

1. For convolutional neural-network based artificial-intelligence models, the meaning of the 4 dimensions of a feature tensor (data-layout-format 0) can generally be mapped to:
   - E4: N - Size of mini-batch
   - E3: H - Height of the 3D-tensor / image
   - E2: W - Width of the 3D-tensor / image
   - E1: C - Channels or classes of the 3D-tensor
2. For machine learning or recurrent neural-network based artificial-intelligence models, the meaning of the 4 dimensions of a 4D-feature tensors (data-layout-format 0) will generally be mapped to:
   - E4: T - Number of time steps or models
   - E3: Reserved, generally set to 1
   - E2: N_{mb} - Size of mini-batch
   - E1: L - Number of features
3. The NNPA data-layout-format 0 provides two-dimensional data locality within 4 K-byte blocks of data (pages) as well as 4 K-byte block data alignment for the outer dimensions of the generated tensor.

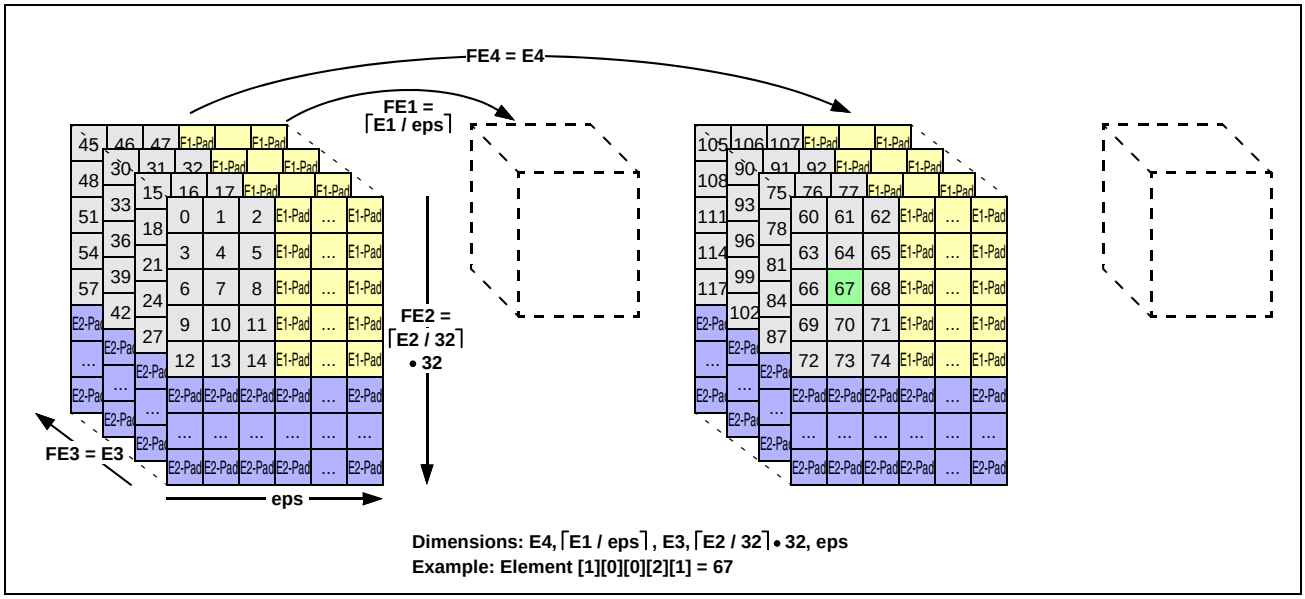

Figure 26-56. Example of a Transformed 4D-Tensor in Data-Layout-Format 0

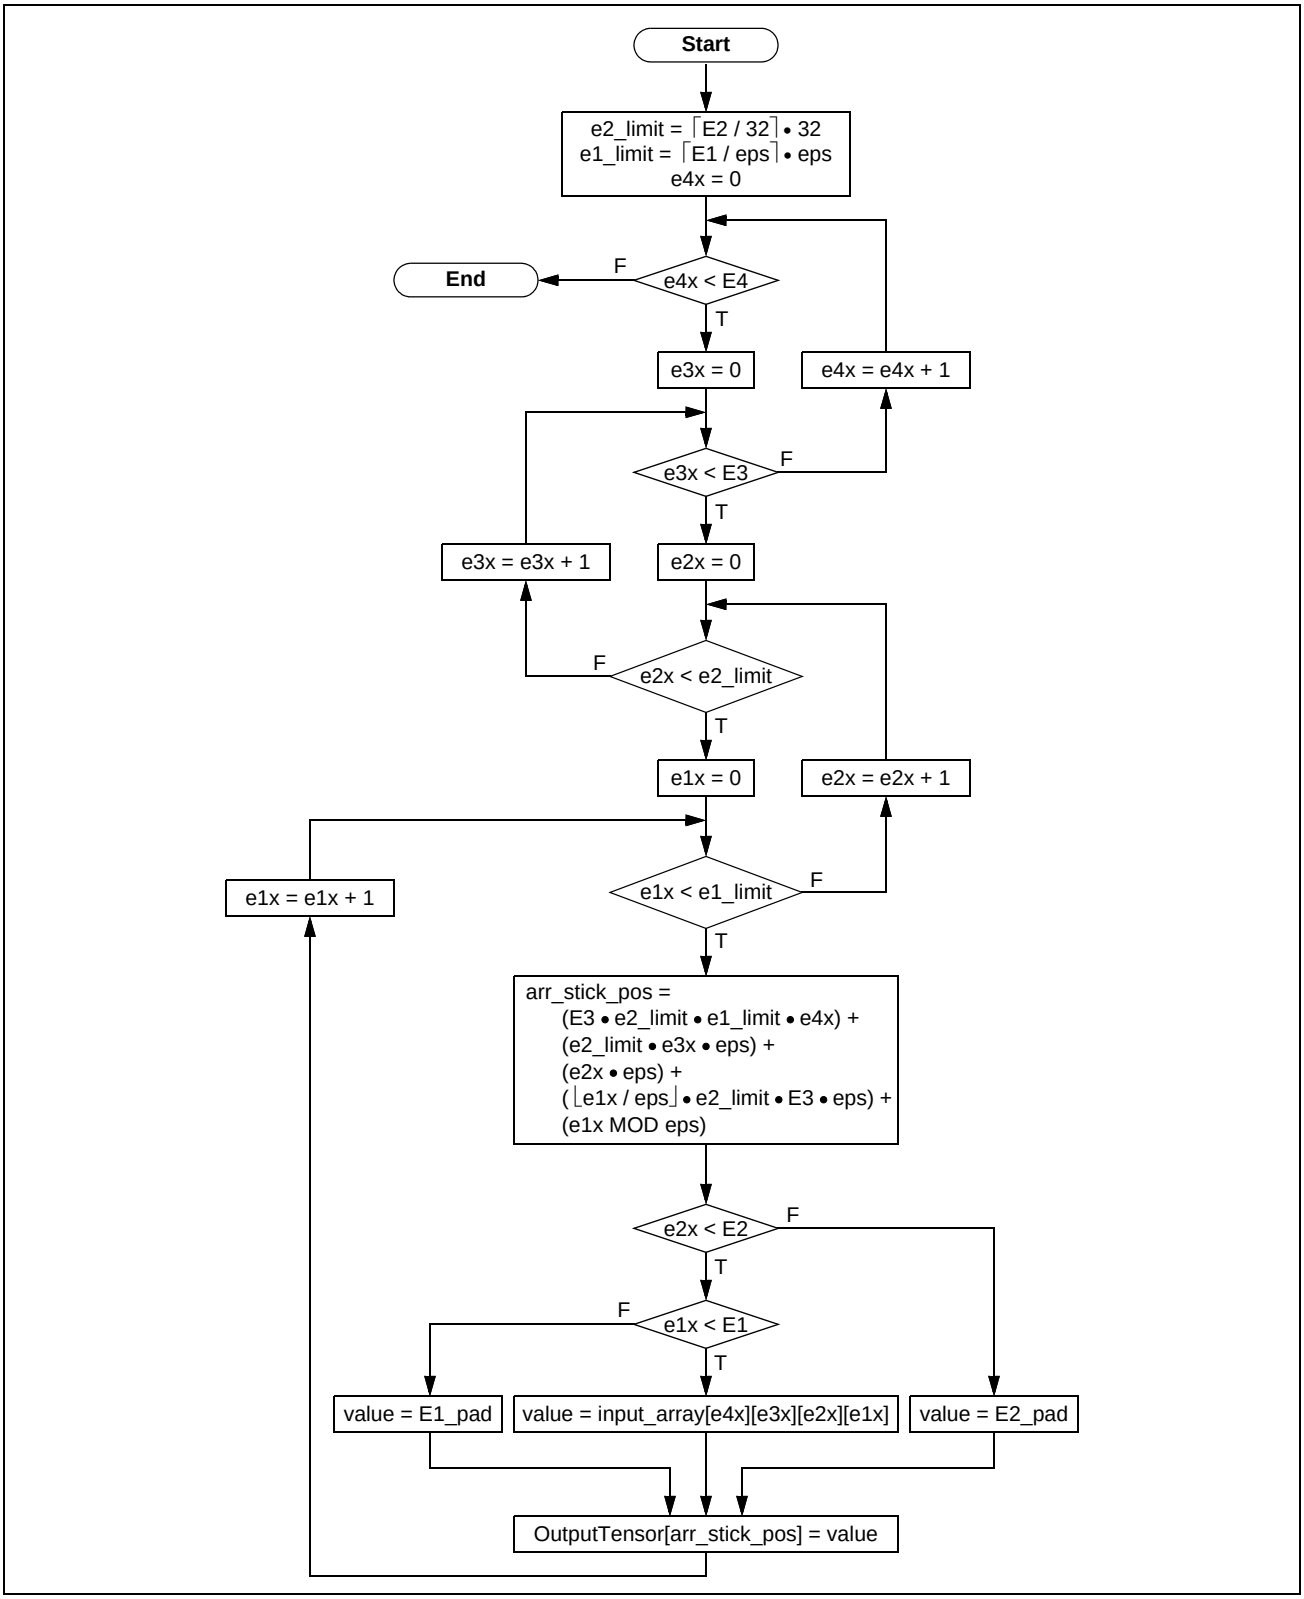

Figure 26-57. Transformation to Data-Layout-Format 0 (4D-Feature Tensor)

Data-Layout-Format-1 Specification

The transformation of a row-major generic 4D-tensor with dimensions E4, E3, E2, E1 (Figure 26-54 on page 26-69) into an NNPA data-layout-format 1 4D-kernel tensor (Figure 26-58 on page 26-74) is illustrated in Figure 26-59 on page 26-75.

The resulting tensor can be represented as a 4D-tensor of eps-element vectors or a 5D-tensor with dimensions FE1, FE4, FE3, FE2, FE0 respectively equals to:

⌈E1 / eps⌉, E4, E3, ⌈E2 / 32⌉ • 32, eps.

The total size, in elements of the resulting tensor, is the product of these five dimensions.

An element [e4][e3][e2][e1] of the generic tensor will be mapped to the following element of the resulting 5D-tensor:

[⌊e1 / eps⌋][e4][e3][e2][e1 MOD eps].

The resulting tensor may have more elements than the generic tensor. All elements of the resulting tensor with no corresponding elements in the generic tensor are called pad elements.

Consider the element [fe1][fe4][fe3][fe2][fe0] of an NNPA data-layout-format 1 4D-feature tensor of eps-element vectors or its equivalent representation as 5D-tensor of elements. This element is either a pad element or its corresponding element in the generic 4D-tensor with dimensions E4, E3, E2, E1 can be determined with the following formula:

- if fe2 ≥ E2 then this is an E2-pad element
- else if fe1 • eps + fe0 ≥ E1 then this is an E1-pad element
- else the indices of the corresponding element in the generic 4D-tensor are:

  [fe4][fe3][fe2][fe1 • eps + fe0]

Alternatively, consider the element at offset *dlf1_off* of an NNPA data-layout-format 1 4D-feature tensor. This element is either a pad element or its corresponding element in the generic 4D-tensor with dimensions E4, E3, E2, E1 and can be determined as follow:

- if *dlf1_off* MOD (⌈E2 / 32⌉ • 32 • eps) ≥ E2 • eps then this is an E2-pad element
- else:
  - area4d = E4 • E3 • ⌈E2 / 32⌉ • 32 • ⌈E1/eps⌉ • eps
  - rem4d = dlf0_off MOD area4d
  - if (⌊ rem3d / (E4 • E3 • ⌈E2 / 32⌉ • 32 • eps) ⌋ == ⌊ E1 / eps ⌋ AND rem3d MOD eps >= E1 MOD eps) then this is an E1-pad element
- else the corresponding element in the generic 4D-tensor is:

  [⌊*dlf1_off* / (E3 • ⌈E2/32⌉ • 32 • eps)⌋ MOD E4]
  [(⌊ *dlf1_off* / (⌈E2 / 32⌉ • 32 • eps) ⌋) MOD E3]
  [(⌊ (*dlf1_off* / eps) ⌋) MOD (⌈E2/32⌉ • 32)]
  [⌊ *dlf1_off* / (E4 • E3 • ⌈E2/32⌉ • 32 • eps) ⌋ • eps + (*dlf1_off* MOD eps)]

Pad elements are ignored for the input tensors and model dependent for output tensors. It is model dependent if PER storage-alteration is detected on pad elements of output tensors.

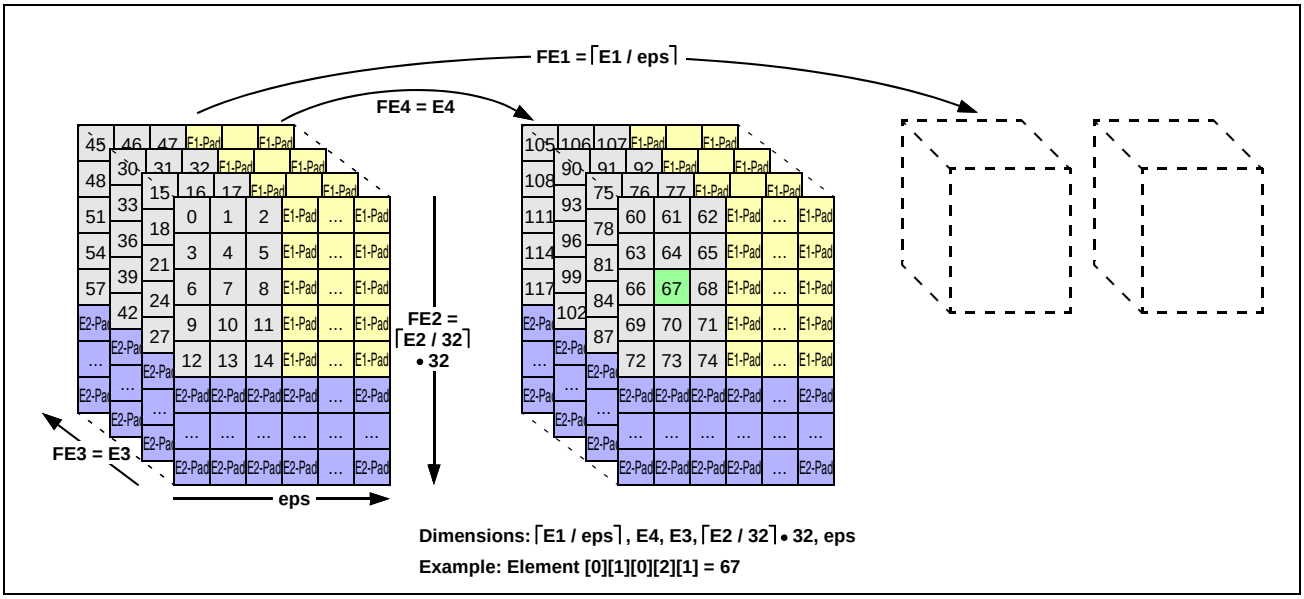

Figure 26-58. Example of a Transformed 4D-Tensor in Data-Layout-Format 1

Programming Notes:

1. For convolutional neural-network based artificial-intelligence models, the meaning of the 4 dimensions of a kernel tensor (data-layout-format 1) can generally be mapped to:
   - E4: H - Height of the 3D-tensor / image
   - E3: W - Width of the 3D-tensor / image
   - E2: C - Number of channels of the 3D-tensor
   - E1: K - Number of kernels
2. The NNPA data-layout-format 1 provides two dimensional kernel parallelism within 4 K-byte blocks of data (pages) as well as 4 K-byte block data alignment for the outer dimensions of the generated tensor for efficient processing.

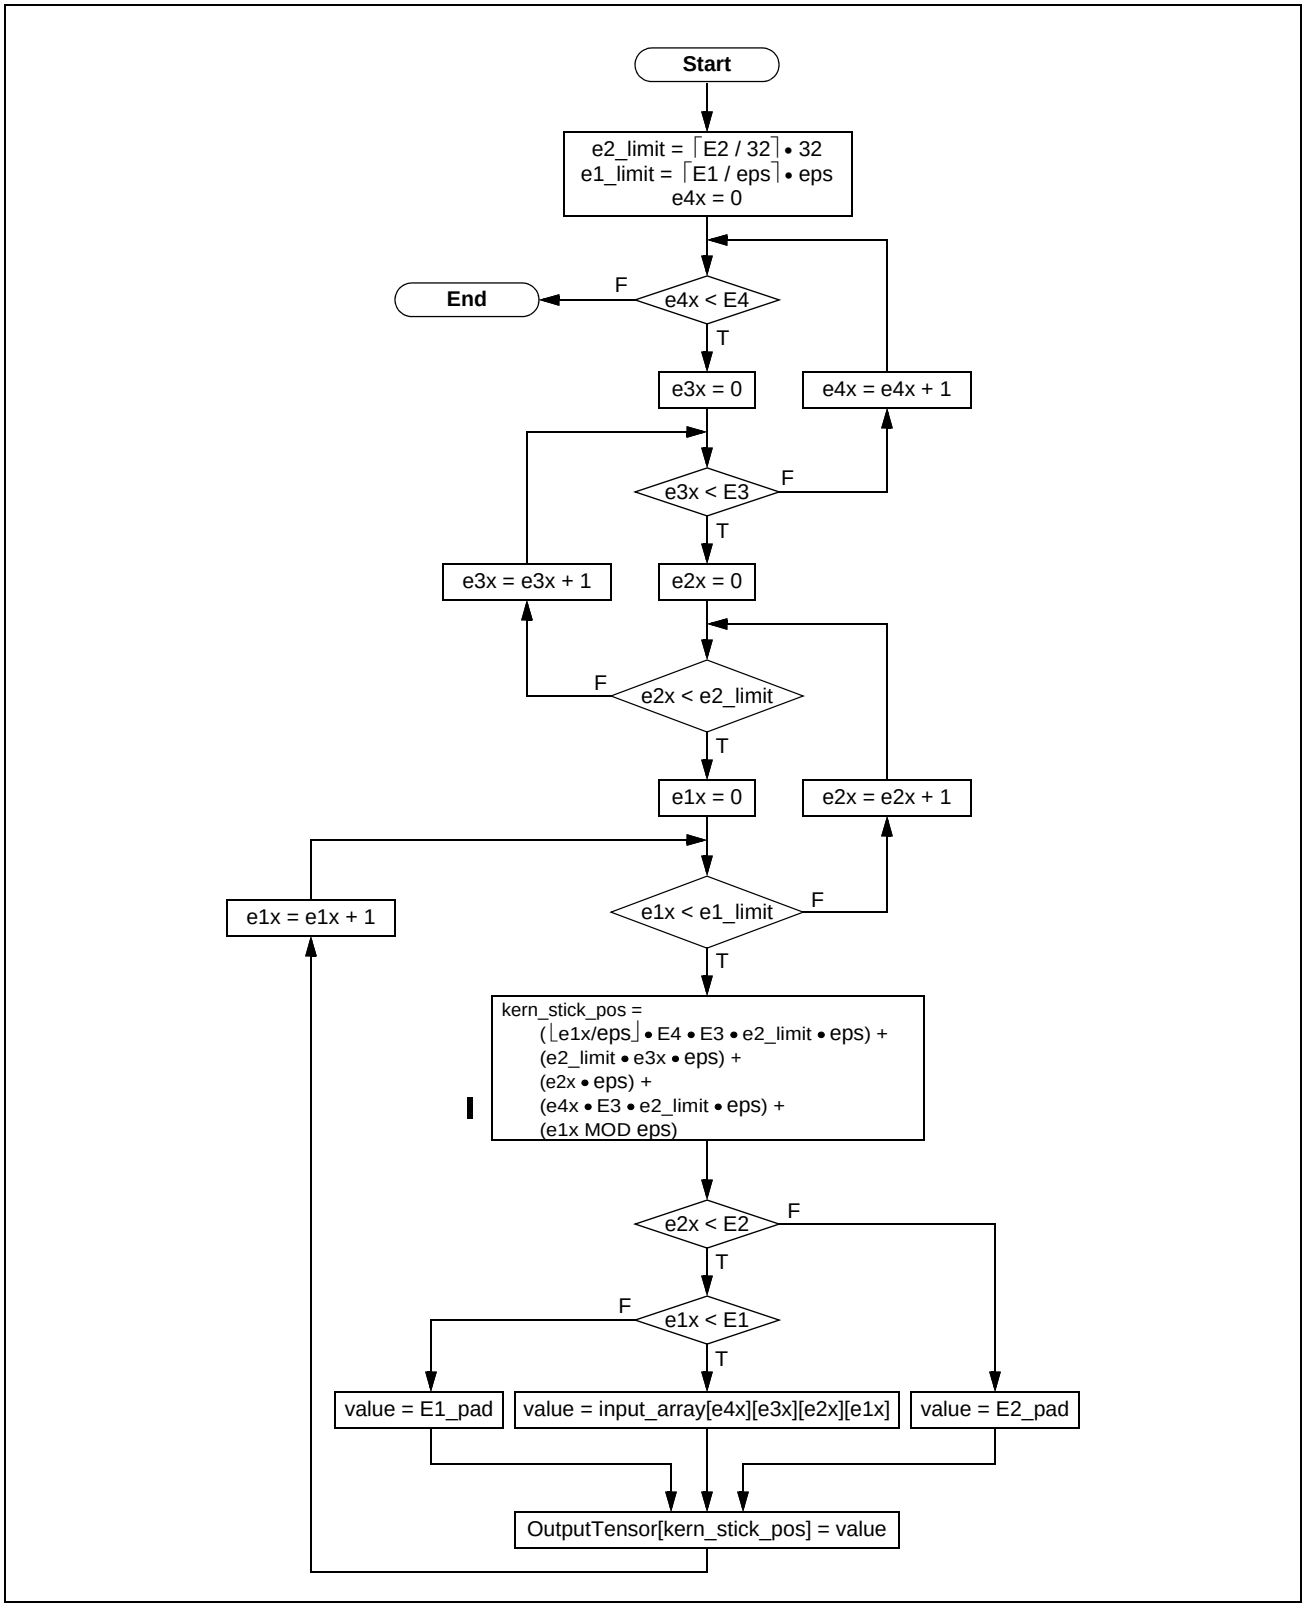

Figure 26-59. Transformation to Data Layout Format 1 (4D-Kernel Tensor)

Data-Layout-Format-2 Specification

In data-layout-format 2, the data type always specifies an element size of one byte, and the elements in even/odd rows are paired in storage. For example, elements in dimensions [E2,E1] appear in storage in the following order: [0,0], [1,0], [0,1], [1,1], [0,2], [1,2], and so forth.

The transformation of a row-major generic 4D-tensor with dimensions E4, E3, E2, E1 (Figure 26-54 on page 26-69) into an NNPA data-layout-format-2 4D-weights tensor (Figure 26-60 on page 26-77) is illustrated in Figure 26-61 on page 26-78.

The resulting tensor can be represented as a 4D-tensor of 64 element-pair vectors or a 6D-tensor with dimensions FE4, FE1, FE3, FE2, FE0, FEP respectively equal to:

$$E4, \lceil E1 / 64 \rceil, E3, \lceil E2 / 64 \rceil \bullet 32, 64, 2.$$

An element [e4][e3][e2][e1] of the generic tensor will be mapped to the following element of the resulting 6D-tensor:

$$[\, e4 \,][\, \lfloor e1 / 64 \rfloor \,][\, e3 \,][\, \lfloor e2 / 2 \rfloor \,][\, e1 \text{ MOD } 64 \,][\, e2 \text{ MOD } 2 \,].$$

The resulting tensor may have more elements than the generic tensor. All elements of the resulting tensor with no corresponding elements in the generic tensor are called pad elements.

Consider the element [fe4][fe1][fe3][fe2][fe0][fep] of a 6D representation of an NNPA data-layout-format-2 or -3 4D-weights tensor. This element is either a pad element or its corresponding element in the generic 4D tensor with dimensions E4, E3, E2, E1, and can be determined with the following formula:

- if $fe2 \bullet 2 + fep \geq \lfloor (E2 + 1) / 2 \rfloor \bullet 2$, then this is an E2-pad element
- else if $fe2 \bullet 2 + fep \geq E2$, or $fe1 \bullet 64 + fe0 \geq E1$, then this is a E1-pad element
- else the indices of the corresponding element in the generic 4D-tensor are:

$$[\, fe4 \,][\, fe3 \,][\, fe2 \bullet 2 + fep \,][\, fe1 \bullet 64 + fe0 \,]$$

Alternatively, consider the element at offset *dlf2_off* of an NNPA data-layout-format-2 or -3 4D-weights tensor. This element is either a pad element or its corresponding element in the generic 4D-tensor with dimensions E4, E3, E2, E1. To simplify the process of converting an offset of a 4D-weights tensor into the indices of a 4D-generic tensor, the prospective indices are first determined as follows:

- $e2\_limit = \lceil E2 / 64 \rceil \bullet 64$
- $e1\_limit = \lceil E1 / 64 \rceil \bullet 64$
- $area\_3d = E3 \bullet e2\_limit \bullet e1\_limit$
- $e4x = \lfloor dlf2\_off / area\_3d \rfloor$
- $e3x = \lfloor dlf2\_off / (e2\_limit \bullet 64) \rfloor \text{ MOD } E3$
- $e2x = \lfloor dlf2\_off / 128 \rfloor \text{ MOD } \lfloor e2\_limit / 2 \rfloor \bullet 2 + dlf2\_off \text{ MOD } 2$
- $e1x = \lfloor dlf2\_off / (E3 \bullet e2\_limit \bullet 64) \rfloor \text{ MOD } \lfloor e1\_limit / 64 \rfloor \bullet 64 + \lfloor dlf2\_off / 2 \rfloor \text{ MOD } 64$

The determination of whether an offset is a pad element or an element in the 4D-generic tensor is as follows:

- if e2x >= (E2 + 1) / 2 • 2, then this is an E2-pad element.
- if (e2x >= E2) OR (e1x >= E1), then this is an E1-pad element
- else the corresponding element in the generic 4D-tensor is [e4x] [e3x] [e2x] [e1x].

Pad elements are ignored for the input tensors and model dependent for output tensors. It is model dependent if PER storage-alteration is detected on pad elements of output tensors.

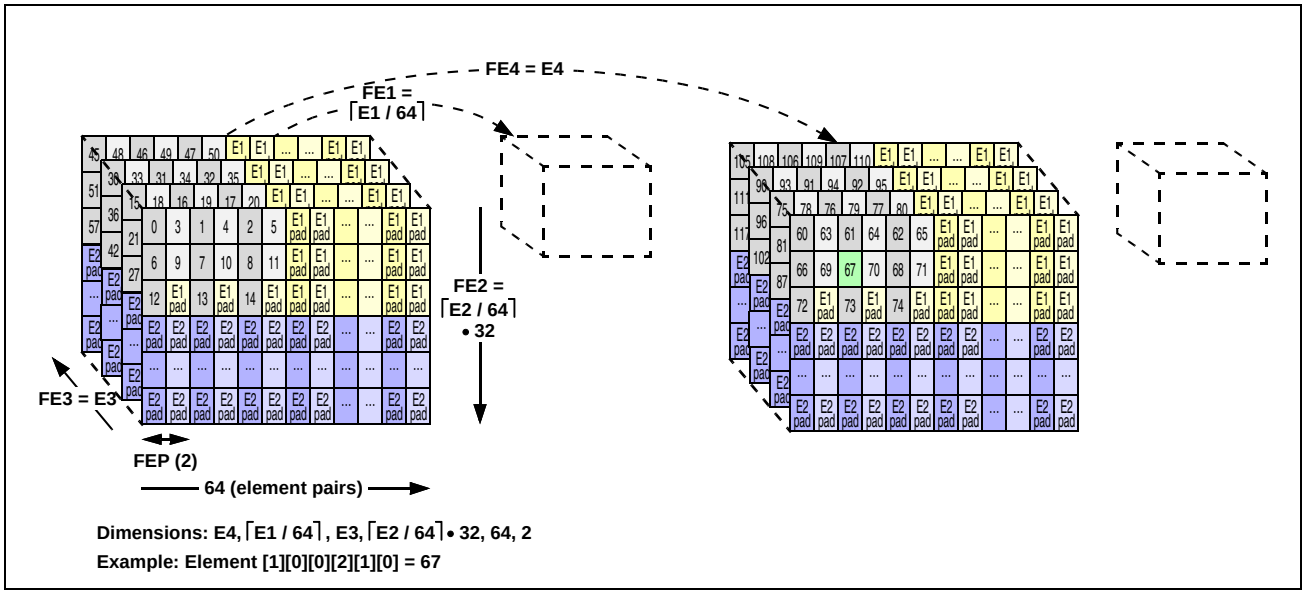

Figure 26-60. Example of a Transformed 4D-Tensor in Data-Layout-Format 2

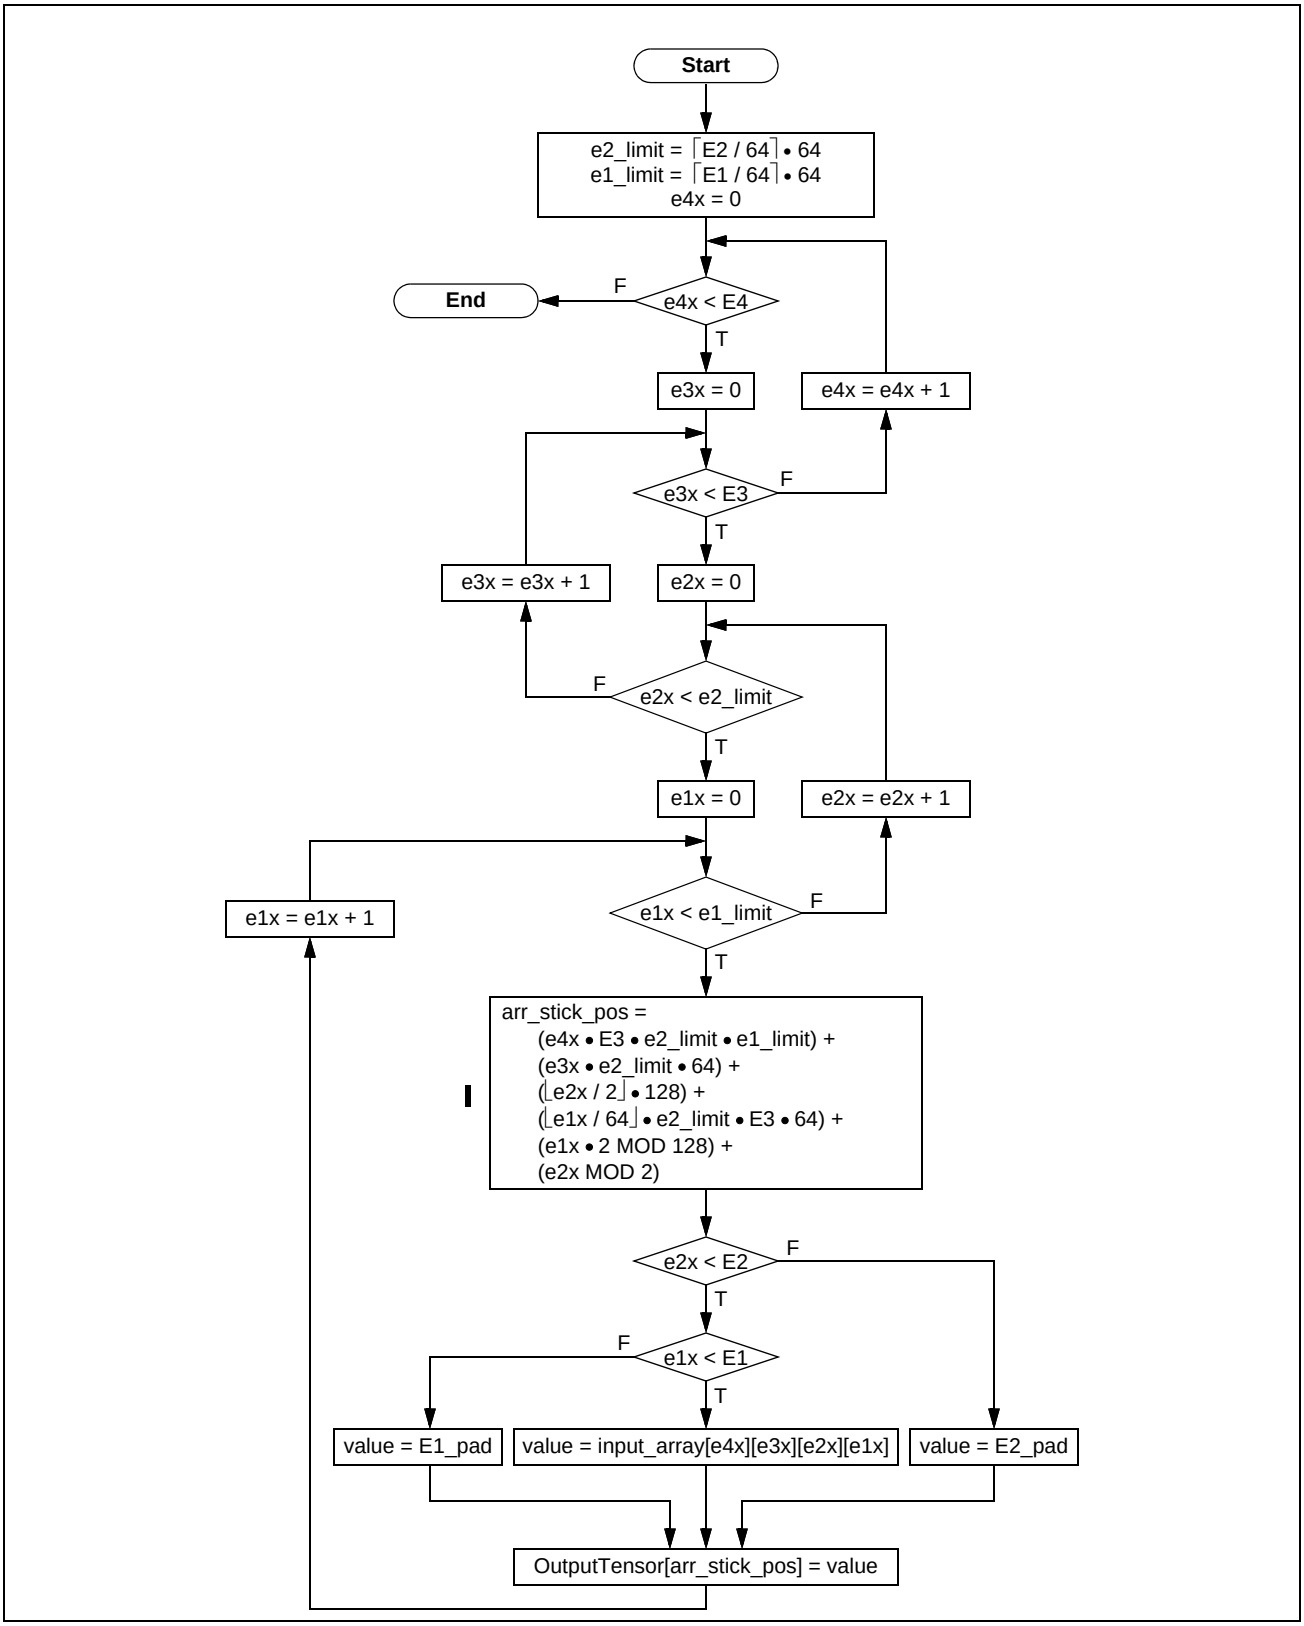

Figure 26-61. Transformation to Data Layout Format 2 (4D-Weights Tensor)

Data-Layout-Format-31 Specification

A data-layout-format-31 tensor is a row-format generic tensor, as described in "Tensor Specification" on page 26-68 (that is, an unstickified tensor without padding). When installed, the NNPA-TRANSFORM function can be used to transform a data-layout-format-31 tensor to and from a data-layout-format-0 4D-feature tensor.

Parameter Block: Tensor Descriptor

The format for each tensor-descriptor field in a format-0 or format-1 parameter block is shown in Figure 26-62 on page 26-79. If a tensor descriptor is not used by a function, it will be ignored.

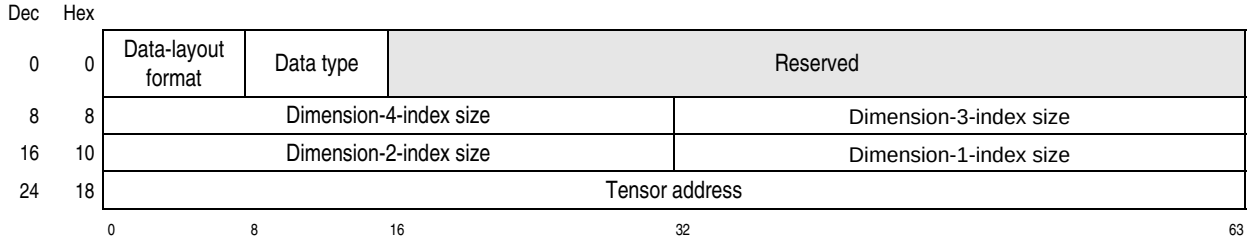

Figure 26-62. Tensor Descriptor for Format-0 and Format-1Parameter Block

Reserved: As an input to the operation, reserved fields should contain zeros; otherwise, the program may not operate compatibly in the future. When the operation ends, reserved fields may be stored as zeros or may remain unchanged. The behavior is model dependent.

Data-layout format: Byte 0 of the tensor descriptor contains an 8-bit unsigned binary integer specifying the data-layout format. The valid values for data-layout format are as follows:

Format	Description	Alignment (bytes)
0	4D-feature tensor	4096
1	4D-kernel tensor	4096
2	4D-weights tensor	4096
3-30	Reserved	—
31	4D-generic tensor	Based on data type
32-255	Reserved	—

When the alignment of a data-layout format is based on the data type, the alignment is an integral boundary based on the size in bytes of a data element. For example, for a 4D-generic tensor having a BFP-short-format data type, the alignment is four bytes.

If an unsupported or reserved data-layout format is specified, the response code of 0010 hex is set in general register 0, and the instruction completes by setting condition code 1.

Data-type: Byte 1 contains an 8-bit unsigned binary integer specifying the data type of the tensor. The assigned data types are described below:

Value	Data type	Data Size (bits)
0	NNP-data-type 1	16
1-5	Reserved	—
6	BFP short format	32
7	Reserved	—
8	Signed binary integer	8
9	Reserved	—
10	Signed or unsigned binary integer	32
11-255	Reserved	—

If an unsupported or reserved data type is specified, the response code of 0011 hex is set in general register 0, and the instruction completes by setting condition code 1.

Dimension 1-4 -index size: Collectively, dimensions index sizes one through four specify the *shape* of a 4D-tensor, each in the form of a 32-bit unsigned binary integer. Each dimension-index size of the original tensor must be greater than zero and less than or equal to the the maximum size supported for that

dimension (refer to the definitions for the MDIS and MDnIS fields in the parameter block stored by the NNPA-QAF function and definitions for the function specified in case the function defines a different maximum size); otherwise, response code 0012 hex is set in general register 0, and the instruction completes by setting condition code 1. The size of the transformed tensor (that is, in data-layout-format 0 or data-layout-format 1) must be less than or equal to the maximum-tensor size (MTS); otherwise, response code 0013 hex is set in general register 0, and the instruction completes by setting condition code 1.

Tensor Address: Bytes 24-31 of the tensor descriptor contain the logical address of the leftmost byte of the tensor. If the tensor descriptor is used by the function, then:

- If the address is not aligned on the boundary of the associated data-layout format, response code of 0014 hex is set in general register 0, and the instruction completes by setting condition code 1.
- The address is subject to the current addressing mode.

NNPA: Parameter Block

The parameter block with format 0 or 1 hex for the NNPA functions is shown in Figure 26-63. Note that fields marked with an asterisk (*) exist only in a format-1 parameter block; these fields are reserved in a format-0 parameter block.

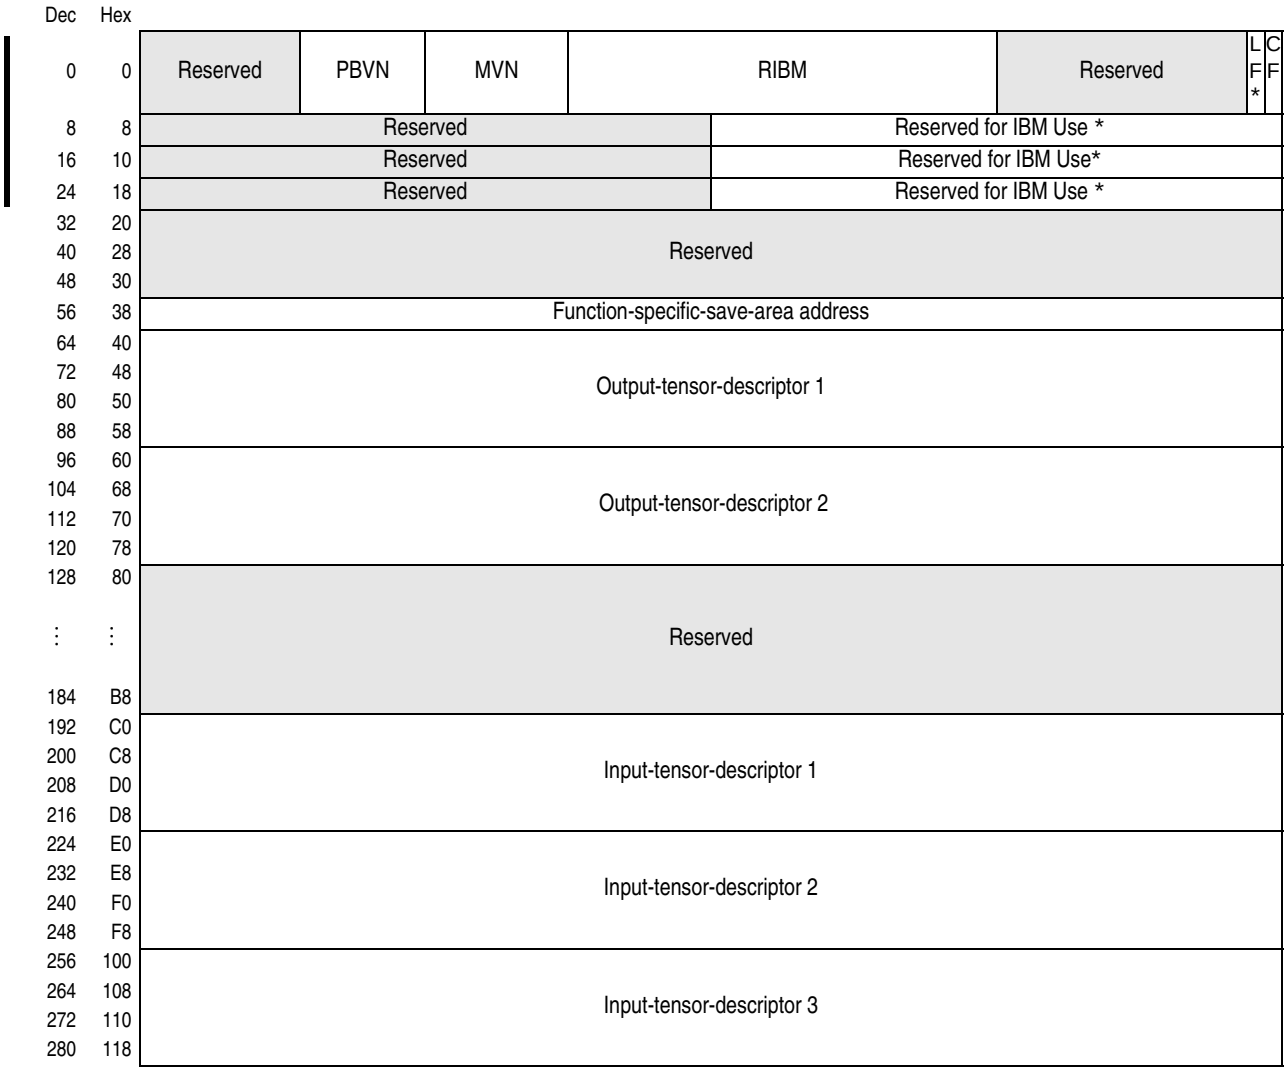

Figure 26-63. Parameter Block (formats 0 and 1) for the NNPA Functions (Part 1 of 2)

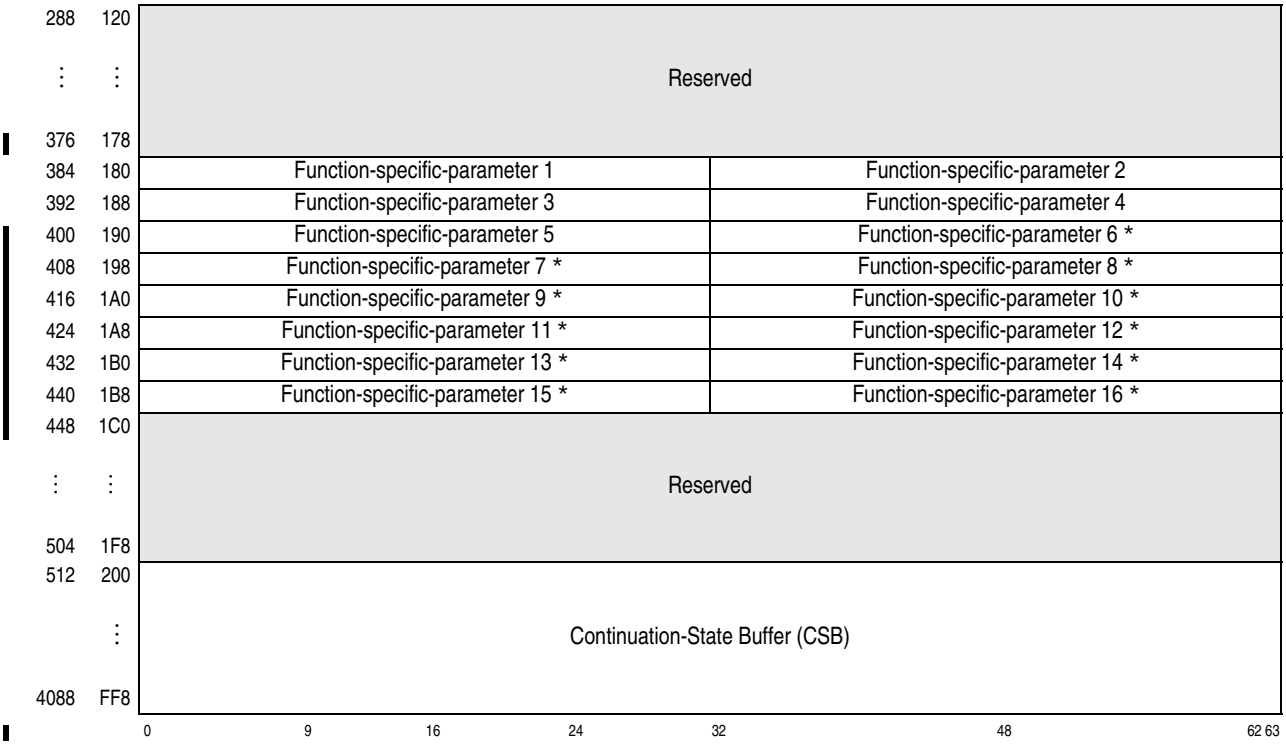

Explanation:

*	Field exists in the format-1 parameter block. In the format-0 parameter block, this field is reserved.
CF	Continuation Flag
MVN	Model-Version Number
PBVN	Parameter-Block-Version Number
RIBM	Reserved for IBM use

Figure 26-63. Parameter Block (formats 0 and 1) for the NNPA Functions (Part 2 of 2)

The fields of the format-0 and format-1 parameter blocks for the NNPA functions are defined as follows:

Reserved: As an input to the operation, reserved fields should contain zeros; otherwise, the program may not operate compatibly in the future. When the operation ends, reserved fields may be stored as zeros or may remain unchanged.

Parameter-Block-Version Number (PBVN): Bits 9-15 of the parameter block contain a 7-bit unsigned binary integer specifying the format of the parameter block. The NNPA-QAF function provides the means of indicating the parameter-block formats available. When the format of the parameter block specified is not supported by the model, the response code of 0001 hex is set in general register 0, and the instruction completes by setting condition code 1. The PBVN is specified by the program and is not modified during the execution of the instruction.

Model-Version Number (MVN): Byte 2 of the parameter block is an 8-bit unsigned binary integer identifying the model which executed the instruction. When the continuation flag (CF) is one, the MVN may be an input to the operation for the purpose of interpreting the content of the continuation-state buffer (CSB) of the parameter block to resume the operation.

Reserved for IBM use (RIBM): Bytes 3-5 of the parameter block are reserved for IBM use and must be initialized with all zeros; otherwise, results are unpredictable. The RIBM field may be modified during the execution of the instruction.

LF: Bit 62 is reserved for IBM use.

Continuation Flag (CF): Bit 63 of the parameter block, when one, indicates the operation is partially complete and the contents of the continuation-state buffer (CSB), may be used to resume the operation. It is required for the program to initialize the continua-

tion flag (CF) to zero and not modify CF in the event the instruction is to be re-executed for the purpose of resuming the operation; otherwise, results are unpredictable.

If the CF is one at the beginning of the operation and the contents of the parameter block have changed since the initial invocation, results are unpredictable and may include recognition of a general-operand data exception.

Function-specific-save-area address: Bytes 56-63 of the parameter block contain the logical address of the function-specific-save area. If the function-specific-save area is used by a function, then:

- The function-specific-save-area address must be aligned on a 4 K-byte boundary; otherwise, response code 0015 hex is set in general register 0, and the instruction completes with a condition code of 1.
- The address is subject to the current addressing mode.

The size of the function-specific-save area depends on the function.

Input/Output-Tensor Descriptors: Bytes 64-287 of the parameter block contain output-tensor and input-tensor descriptors, detailed in Section "Parameter Block: Tensor Descriptor" on page 26-79. Tensor descriptors not used by a function will be ignored. In the remain of this chapter, *input-tensor x* denotes the input tensor described by input-tensor-descriptor *x*; *output-tensor x* denotes the output tensor described by output-tensor-descriptor *x*.

Function-specific-parameter 1 to 16: Bytes 384-447 of the parameter block contain function-code-specific parameters. If a function does not need all function-specific-parameter fields, the unused fields should contain zeros; otherwise, the program may not operate compatibly in the future.

Continuation-State Buffer (CSB): Bytes 512-4095 of the parameter block are reserved for IBM use to hold intermediate results for partial completion reported by setting the condition code equal to 3.

When the entire function-specific-save area overlaps the PER storage-area designation, a PER storage-alteration event is recognized, when applicable, for the function-specific-save area. When only a portion of the function-specific-save area overlaps the PER storage-area designation, it is model dependent which of the following occurs:

- A PER storage-alteration event is recognized, when applicable, for the entire function-specific-save area.
- A PER storage-alteration event is recognized, when applicable, for the portion of the function-specific-save area that is stored.

When the entire parameter block overlaps the PER storage-area designation, a PER storage-alteration event is recognized, when applicable, for the parameter block. When only a portion of the parameter block overlaps the PER storage-area designation, it is model dependent which of the following occurs:

- A PER storage-alteration event is recognized, when applicable, for the entire parameter block.
- A PER storage-alteration event is recognized, when applicable, for the portion of the parameter block that is stored.

A PER zero-address-detection event is recognized, when applicable, for the parameter block. Zero address detection does not apply to the tensor addresses or the function-specific-save-area address.

Programming Notes:

1. The NNPA instruction indicates partial completion of a function by setting condition code 3. When condition code 3 is set, the program can simply branch back to the instruction to resume processing of the same function, until condition code 0 is set indicating successful completion. When condition code 3 is set, the machine sets intermediate results in the RIBM, CF, and CSB fields and any function-specific save area which is required for subsequent successful continuation of the function.

   Alteration of any of the parameter-block fields or, when applicable, the function-specific save area following partial completion and before subsequent execution of NNPA may produce unpredictable results.

2. Function-specific parameters 6-16 appear in parameter blocks having a parameter-block-version number greater than zero.

Function Code 16: NNPA-ADD

When the NNPA-ADD function is specified, each element of the input-tensor 1 is added to the corresponding element of the input-tensor 2, and the resulting sum is placed in the corresponding element of the output-tensor 1.

If the specified data-layout-format field in any of the specified tensor descriptors does not contain a value of zero (4D-feature tensor) or if the data-type field in any specified tensor descriptor does not contain a value of zero (NNP-data-type 1) response code 0010 hex or 0011 hex, respectively, is set in general register 0, and the instruction completes with condition code 1.

The shape, the data layout, and the data type of input-tensor 1, input-tensor 2, and the output-tensor 1 must be the same; otherwise, a general-operand data exception is recognized.

The output-tensor-descriptor 2, input-tensor-descriptor 3, all function-specific parameters, and function-specific-save-area-address fields are ignored.

Function Code 17: NNPA-SUB

When the NNPA-SUB function is specified, each element of the input-tensor 2 is subtracted from the corresponding element of the input-tensor 1, and the resulting difference is placed in the corresponding element of the output-tensor 1.

If the specified data-layout-format field in any of the specified tensor descriptors does not contain a value of zero (4D-feature tensor) or if the data-type field in any specified tensor descriptor does not contain a value of zero (NNP-data-type 1) response code 0010 hex or 0011 hex, respectively, is set in general register 0, and the instruction completes with condition code 1.

The shape, the data layout, and the data type of input-tensor 1, input-tensor 2, and the output-tensor 1 must be the same; otherwise, a general-operand data exception is recognized.

The output-tensor-descriptor 2, input-tensor-descriptor 3, all function-specific parameters, and function-specific-save-area-address fields are ignored.

Function Code 18: NNPA-MUL

When the NNPA-MUL function is specified, the product of each element of the input-tensor 1 (the multiplicand) and the corresponding element of the input-tensor 2 (the multiplier) is placed in the corresponding element of the output-tensor 1.

If the specified data-layout-format field in any of the specified tensor descriptors does not contain a value of zero (4D-feature tensor) or if the data-type field in any specified tensor descriptor does not contain a value of zero (NNP-data-type 1) response code 0010 hex or 0011 hex, respectively, is set in general register 0, and the instruction completes with condition code 1.

The shape, the data layout, and the data type of input-tensor 1, input-tensor 2, and the output-tensor 1 must be the same; otherwise, a general-operand data exception is recognized.

The output-tensor-descriptor 2, input-tensor-descriptor 3, all function-specific parameters, and function-specific-save-area-address fields are ignored.

Function Code 19: NNPA-DIV

When the NNPA-DIV function is specified, for each element of the input-tensor 1 (the dividend) is divided by the corresponding element of the input-tensor 2 (the divisor), and the quotient is placed in the corresponding element of the output-tensor 1.

If the specified data-layout-format field in any of the specified tensor descriptors does not contain a value of zero (4D-feature tensor) or if the data-type field in any specified tensor descriptor does not contain a value of zero (NNP-data-type 1) response code 0010 hex or 0011 hex, respectively, is set in general register 0, and the instruction completes with condition code 1.

The shape, the data layout, and the data type of input-tensor 1, input-tensor 2, and the output-tensor 1 must be the same; otherwise, a general-operand data exception is recognized.

The output-tensor-descriptor 2, input-tensor-descriptor 3, all function-specific parameters, and function-specific-save-area-address fields are ignored.

Function Code 20: NNPA-MIN

When the NNPA-MIN function is specified, each element of the input-tensor 1 is compared to the corresponding element of the input-tensor 2. The smaller of the two values is placed into the corresponding element of the output-tensor 1.

If the specified data-layout-format field in any of the specified tensor descriptors does not contain a value of zero (4D-feature tensor) or if the data-type field in any specified tensor descriptor does not contain a value of zero (NNP-data-type 1) response code 0010 hex or 0011 hex, respectively, is set in general register 0, and the instruction completes with condition code 1.

The shape, the data layout, and the data type of input-tensor 1, input-tensor 2, and the output-tensor 1 must be the same; otherwise, a general-operand data exception is recognized.

The output-tensor-descriptor 2, input-tensor-descriptor 3, all function-specific parameters, and function-specific-save-area-address fields are ignored.

Function Code 21: NNPA-MAX

When the NNPA-MAX function is specified, each element of the input-tensor 1 is compared to the corresponding element of the input-tensor 2. The greater of the two values is placed into the corresponding element of the output-tensor 1.

If the specified data-layout-format field in any of the specified tensor descriptors does not contain a value of zero (4D-feature tensor) or if the data-type field in any specified tensor descriptor does not contain a value of zero (NNP-data-type 1) response code 0010 hex or 0011 hex, respectively, is set in general register 0, and the instruction completes with condition code 1.

The shape, the data layout, and the data type of input-tensor 1, input-tensor 2, and the output-tensor 1 must be the same; otherwise, a general-operand data exception is recognized.

The output-tensor-descriptor 2, input-tensor-descriptor 3, all function-specific parameters, and function-specific-save-area-address fields are ignored.

Function Code 32: NNPA-LOG (Natural Logarithm)

When the NNPA-LOG function is specified, for each element of the input-tensor 1, if the element is greater than zero, then the natural logarithm of the element is placed in the corresponding element of output-tensor 1; otherwise, a model dependent value is placed in the corresponding element of output-tensor 1.

If the specified data-layout-format field in any of the specified tensor descriptors does not contain a value of zero (4D-feature tensor) or if the data-type field in any specified tensor descriptor does not contain a value of zero (NNP-data-type 1) response code 0010 hex or 0011 hex, respectively, is set in general register 0, and the instruction completes with condition code 1.

The shape, the data layout, and the data type of input-tensor 1 and the output-tensor 1 must be the same; otherwise, a general-operand data exception is recognized.

The output-tensor-descriptor 2, input-tensor-descriptor 2, input-tensor-descriptor 3, all function-specific parameters, and function-specific-save-area-address fields are ignored.

Function Code 33: NNPA-EXP (Exponential Function)

When the NNPA-EXP function is specified, for each element of the input-tensor 1, the exponential function (e^x) of the element is placed in the corresponding element of output-tensor 1.

If the specified data-layout-format field in any of the specified tensor descriptors does not contain a value of zero (4D-feature tensor) or if the data-type field in any specified tensor descriptor does not contain a value of zero (NNP-data-type 1) response code 0010 hex or 0011 hex, respectively, is set in general register 0, and the instruction completes with condition code 1.

The shape, the data layout, and the data type of input-tensor 1 and the output-tensor 1 must be the same; otherwise, a general-operand data exception is recognized.

The output-tensor-descriptor 2, input-tensor-descriptor 2, input-tensor-descriptor 3, all function-specific parameters, and function-specific-save-area address are ignored.

Function Code 34: NNPA-SQRT

When the NNPA-SQRT function is specified, the approximate value of the square root of each element of the input-tensor 1 is placed in the corresponding element of the output-tensor 1.

The NNPA-SQRT function is available when the parameter-block version number (PBVN) is greater than zero. If the PBVN is zero, response code 0001 hex is set in general register 0, and the instruction completes with condition code 1.

If the specified data-layout-format field in any of the specified tensor descriptors does not contain a value of zero (4D-feature tensor) or if the data-type field in any specified tensor descriptor does not contain a value of zero (NNP-data-type 1) response code 0010 hex or 0011 hex, respectively, is set in general register 0, and the instruction completes with condition code 1.

The shape, the data layout, and the data type of input-tensor 1 and the output-tensor 1 must be the same; otherwise, a general-operand data exception is recognized.

The output-tensor-descriptor 2, input-tensor-descriptors 2 and 3, all function-specific parameters, and function-specific-save-area-address fields are ignored.

Programming Note: The NNPA-SQRT function is not available on all models supporting the NNPA instruction.

Function Code 35: NNPA-INVSQRT

When the NNPA-INVSQRT function is specified, the approximate value of the inverse square root of the sum of each element of the input-tensor 1 plus the value epsilon (ε) is placed in the corresponding element of the output-tensor 1.

Bits 16-31 of function-specific-parameter 1 contain the value epsilon in the NNP-data-type 1 format.

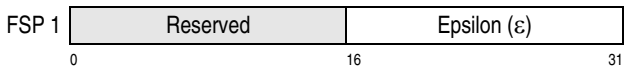

Figure 26-64. NNPA-INVSQRT Function-Specific-Parameter 1

The NNPA-SQRT-INV function is available when the parameter-block version number (PBVN) is greater than zero. If the PBVN is zero, response code 0001 hex is set in general register 0, and the instruction completes with condition code 1.

If the specified data-layout-format field in any of the specified tensor descriptors does not contain a value of zero (4D-feature tensor) or if the data-type field in any specified tensor descriptor does not contain a value of zero (NNP-data-type 1) response code 0010 hex or 0011 hex, respectively, is set in general register 0, and the instruction completes with condition code 1.

The shape, the data layout, and the data type of input-tensor 1 and the output-tensor 1 must be the same; otherwise, a general-operand data exception is recognized.

The output-tensor-descriptor 2, input-tensor-descriptors 2 and 3, function-specific-parameters 2 and above, and function-specific-save-area-address fields are ignored.

Programming Notes:

1. The inverse square root for an element with value *x* plus epsilon (ε) is calculated as follows:

$$\text{invsqrt}(x) = \frac{1}{\text{sqrt}(x + \varepsilon)}$$

Figure 26-65. NNPA-INVSQRT function

2. The NNPA-INVSQRT function is not available on all models supporting the NNPA instruction.
3. On some models, if either or both an element and epsilon are very large, the addition of the two may result in a nonnumeric value, the inverse square root of which will also be nonnumeric. This may occur even though the inverse square root of an unconstrained sum would easily fit in the data type of an output-tensor element.

Function Code 49: NNPA-RELU (Rectified Linear Unit)

When the NNPA-RELU function is specified, each element of input-tensor 1 is processed to produce a corresponding element in output-tensor 1, as follows:

- When the input element is less than or equal to zero, then processing is as follows:
  - When the parameter-block-version number is zero, a positive zero value is placed in the output element.
  - When the parameter-block version number is greater than zero, the value of the input element multiplied by an adjustment factor (AF) in function-specific-parameter 2, is placed in the output element.
- When the input element is greater than zero, then processing is as follows:
  - If the clipping value specified in function-specific-parameter 1 is zero, then the input element is placed unchanged in the output element.
  - If the clipping value is positive, then the minimum value of the input element and the clipping value is placed in the output element.

Clipping Value: Function-specific-parameter (FSP) 1 defines the clipping value for the RELU operation. If the clipping-value field contains only zeros, no clipping is performed. If a negative value (including –0) or a nonnumeric value of either sign is specified, a general operand data exception is recognized.

Adjustment Factor (AF): When the parameter-block-version number (PBVN) is greater than zero, FSP 2 contains the adjustment factor. In this case, a negative element from input-tensor 1 multiplied by the adjustment factor to produce the corresponding element in output-tensor 1. If a negative value (including –0), a nonnumeric value, or a value that is greater than 1.0 is specified, a general-operand data exception is recognized. When the PBVN is zero, FSP 2 is ignored.

Both FSPs 1 and 2 are in the NNP-data-type-1 format in bits 16-31; bits 0-15 of the FSPs are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.

Figure 26-66 illustrates the function-specific parameters of the NNPA-RELU function.

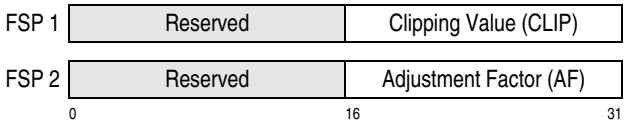

Figure 26-66. NNPA-RELU Function-Specific Parameters

Figure 26-67 illustrates the operation of the NNPA-RELU function.

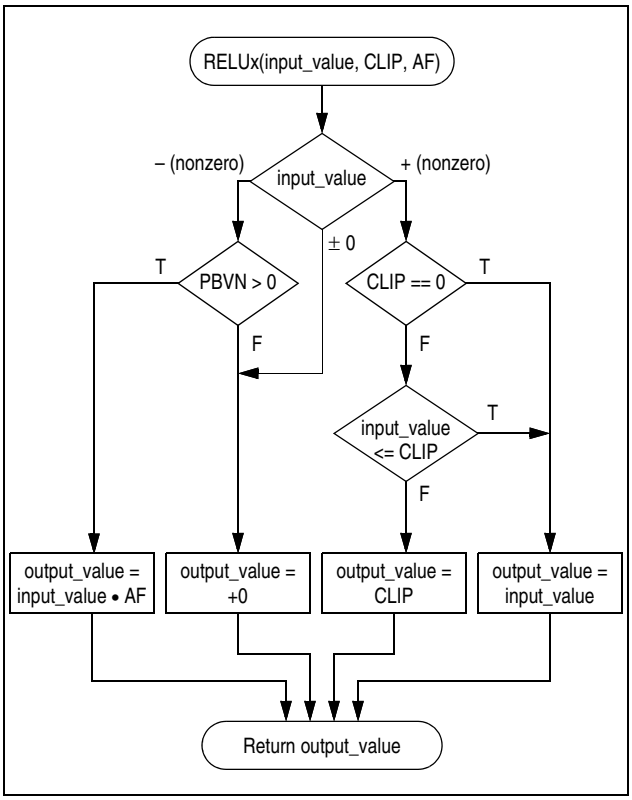

Figure 26-67. RELUx() operation

If the specified data-layout-format field in any of the specified tensor descriptors does not contain a value of zero (4D-feature tensor) or if the data-type field in any specified tensor descriptor does not contain a value of zero (NNP-data-type 1) response code 0010 hex or 0011 hex, respectively, is set in general register 0, and the instruction completes with condition code 1.

All of the following conditions must be true; otherwise, a general-operand data exception is recognized:

- The shape, the data layout, and the data type of input-tensor 1 and the output-tensor 1 must be the same.
- The clipping value in function-specific-parameter 1 must not be negative (including –0) or a nonnumeric value.
- When the parameter-block-version number is greater than zero, the adjustment factor (AF) in function-specific-parameter 2 must not be negative (including –0), a nonnumeric value, or a value greater than or equal to 1.0.

The output-tensor-descriptor 2, input-tensor-descriptor 2, input-tensor-descriptor 3, function-specific-parameters 3 and above, and function-specific-save-area-address fields are ignored.

Programming Notes:

1. The clipping value and adjustment factor (AF) in function-specific-parameters 1 and 2, respectively, can be obtained by use of the VCRNF instruction described on page 26-146.
2. When the parameter-block-version number (PBVN) is zero, or when the PBVN is greater than zero but the adjustment factor is zero, a negative input value causes an output element of positive zero to be stored.

   When the PBVN is greater than zero and the adjustment factor is not zero, the negative number is multiplied by the adjustment factor to produce an output value. Ideally, the adjustment factor should cause the input value to be scaled to a smaller value. This technique is sometimes referred to as *leaky RELU*.

Function Code 50: NNPA-TANH

When the NNPA-TANH function is specified, for each element of the input-tensor 1, the corresponding element in the output-tensor 1 is the hyperbolic tangent of that element. See Figure 26-68 for the mathematical equation for the hyperbolic tangent.

If the specified data-layout-format field in any of the specified tensor descriptors does not contain a value of zero (4D-feature tensor) or if the data-type field in any specified tensor descriptor does not contain a value of zero (NNP-data-type 1) response code 0010 hex or 0011 hex, respectively, is set in general register 0, and the instruction completes with condition code 1.

The shape, the data layout, and the data type of input-tensor 1 and the output-tensor 1 must be the same; otherwise, a general-operand data exception is recognized.

The output-tensor-descriptor 2, input-tensor-descriptor 2, input-tensor-descriptor 3, all function-specific parameters, and function-specific-save-area-address fields are ignored.

Programming Note: The hyperbolic tangent for an element with value *x* is calculated as follows:

$$\tanh(x) = \frac{e^{x} - e^{-x}}{e^{x} + e^{-x}}$$

Figure 26-68. NNPA-TANH function

Function Code 51: NNPA-SIGMOID

When the NNPA-SIGMOID function is specified, for each element of the input-tensor 1, the corresponding element in the output-tensor 1 is the sigmoid function of that element. See Figure 26-69 for the mathematical equation for the sigmoid function.

If the specified data-layout-format field in any of the specified tensor descriptors does not contain a value of zero (4D-feature tensor) or if the data-type field in any specified tensor descriptor does not contain a value of zero (NNP-data-type 1) response code 0010 hex or 0011 hex, respectively, is set in general register 0, and the instruction completes with condition code 1.

The shape, the data layout, and the data type of input-tensor 1 and the output-tensor 1 must be the same; otherwise, a general-operand data exception is recognized.

The output-tensor-descriptor 2, input-tensor-descriptor 2, input-tensor-descriptor 3, all function-specific parameters, and function-specific-save-area-address fields are ignored.

Programming Note: The sigmoid function for an element with value *x* is calculated as follows:

$$\text{sigmoid}(x) = \frac{1}{1 + e^{-x}}$$

Figure 26-69. NNPA-SIGMOID function

Function Code 52: NNPA-SOFTMAX

When the NNPA-SOFTMAX function is specified, for specified elements of each vector in dimension 1 of the input-tensor 1, the corresponding elements of the corresponding vector in the output-tensor 1 is computed as described below:

1. The maximum value of the vector is computed.
2. The summation of the exponentials of the difference between each element in dimension 1 of the vector and the maximum value computed in step 1 above is computed. If both the element in dimension 1 of the input vector and the maximum value computed in step one are numeric values, and the difference is nonnumeric, the result of the exponential for that element is forced to zero.
3. For each element in the vector an intermediate quotient is formed of the exponential of the difference between the element and the maximum value computed in step 1 divided by the summation computed in step 2 above. An optional activation function is applied to this intermediate quotient to form the corresponding element in the output vector.

This process is repeated for all dimension-4-index-size vectors, dimension-3-index-size vectors, and dimension-2-index-size vectors in dimension 1.

When the parameter-block-version number (PBVN) is zero, all of the elements of the dimension-1 vector are processed.

When the PBVN is greater than zero, function-specific-parameter 2 contains a 32-bit unsigned binary integer that specifies an element count that is processed as follows:

- When the element count is zero, all of the elements of the dimension-1 vector are processed.
- When the element count is nonzero and less than or equal to the dimension-1-index size, it specifies a count of dimension-1 elements to be processed, beginning with element zero.

  Dimension-1 elements in input-tensor 1 that have an index greater than or equal to the element count are ignored, and dimension-1 elements in output-tensor that have an index greater than or equal to the element count are set to zero.
- When the element count is greater than the dimension-1-index size, response code F002 hex is placed in general register 0, and the operation completes with condition code 1.

Figure 26-70 illustrates the function-specific parameters used by the NNPA-SOFTMAX function.

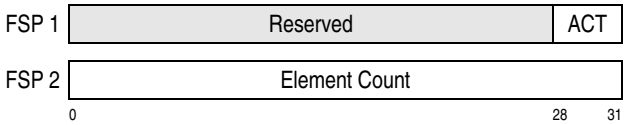

Figure 26-70. NNPA-SOFTMAX Function-Specific-Parameters

Function-specific-parameter 1 controls the activation function. The ACT field contains a 4-bit unsigned binary integer specifying the activation function, as follows:

ACT	Activation Function
0	No activation function performed
1	Natural logarithm
2-15	Reserved

If a reserved value is specified for the ACT field, response code of F001 hex is placed in general register 0, and the operation completes with condition code 1.

If the specified data-layout-format field in any of the specified tensor descriptors does not contain a value of zero (4D-feature tensor) or if the data-type field in any specified tensor descriptor does not contain a value of zero (NNP-data-type 1) response code 0010 hex or 0011 hex, respectively, is set in general register 0, and the instruction completes with condition code 1.

If the dimension-3-index size of input-tensor 1 is not equal to one, response code F000 hex is set in general register 0, and the instruction completes with condition code 1.

The shape, the data layout, and the data type of input-tensor 1 and the output-tensor 1 must be the same; otherwise, a general-operand data exception is recognized.

The output-tensor-descriptor 2, input-tensor-descriptor 2, and input-tensor-descriptor 3 are ignored.

When the PBVN is zero, function-specific-parameters 2 and above are ignored. When the PBVN is greater than zero, function-specific-parameters 3 and above are ignored.

An 8 K-byte function-specific-save area may be used by this function to save intermediate results.

Programming Note: If all elements of a dimension-1 vector of the input-tensor 1 contain the largest magnitude negative number representable in the specified data type, results may be less accurate.

Function Code 53: NNPA-GELU (Gaussian Error Linear Unit)

When the NNPA-GELU function is specified, for each element of input-tensor 1, the corresponding element of output-tensor 1 is the gelu function of that element, computed as follows:

$$gelu(x) = 0.5 \bullet x \bullet (1 + \tanh(x \bullet 0.7978845608 \bullet (1 + 0.044715 \bullet x \bullet x)))$$

The NNPA-GELU function is available when the parameter-block version number (PBVN) is greater than zero. If the PBVN is zero, response code 0001 hex is set in general register 0, and the instruction completes with condition code 1.

If the specified data-layout-format field in any of the specified tensor descriptors does not contain a value of zero (4D-feature tensor) or if the data-type field in any specified tensor descriptor does not contain a value of zero (NNP-data-type 1), response code 0010 hex or 0011 hex, respectively, is set in general register 0, and the instruction completes with condition code 1.

The shape, the data layout, and the data type of input-tensor 1 and output-tensor 1 must be the same; otherwise, a general-operand data exception is recognized.

- The dimension-1-index size of input-tensors 1, 2, 3 and the output-tensor 1 must be the same.

The output-tensor-descriptor 2, input-tensor-descriptors 2 and 3, all function-specific parameters, and function-specific-save-area-address fields are ignored.

Programming Notes:

1. The NNPA-GELU function is not available on all models supporting the NNPA instruction.
2. The range of certain input-element values may result in an error of greater than 1% in the output element, however the accuracy of properly conditioned models is not significantly degraded.

Function Code 64: NNPA-BATCHNORM

When the NNPA-BATCHNORM function is specified, for each vector in dimension 1 of the input-tensor 1 the corresponding vector in dimension 1 of the output-tensor 1 is computed by multiplying each element in the vector by the corresponding element in the dimension-1 vector that makes up the input-tensor 2. The full precision product is then added to the corresponding element in the dimension-1 vector that makes up the input-tensor 3 and then rounding to the precision of the specified data type of the output tensor. This process is repeated for all dimension-4-index-size vectors, dimension-3-index-size vectors, and dimension-2-index-size vectors in dimension 1 of input-tensor 1.

If the specified data-layout-format field in any of the specified tensor descriptors does not contain a value of zero (4D-feature tensor) or if the data-type field in any specified tensor descriptor does not contain a value of zero (NNP-data-type 1) response code 0010 hex or 0011 hex, respectively, is set in general register 0, and the instruction completes with condition code 1.

All of the following conditions must be true; otherwise, a general-operand data exception is recognized:

- The shape and the data layout of input-tensor 1 and the output-tensor 1 must be the same.
- The data type of the input tensors and the output-tensor 1 must be the same.

- The dimension-2-index size, dimension-3-index size, and dimension-4-index size of input-tensors 2 and 3 must be one.

The output-tensor-descriptor 2, all function-specific parameters, and function-specific-save-area-address fields are ignored.

Function Code 65: NNPA-MOMENTS

When the NNPA-MOMENTS function is specified, the arithmetic mean and variance of the elements in dimensions 1, 2, and 3 of each dimension-4 index of input-tensor 1 are computed. The arithmetic means are stored in the dimension-4 elements of output-tensor 1, and the variances are stored in the dimension-4 elements of output-tensor 2.

The product from the multiplication of the dimension-1-index size, dimension-2-index-size, and dimension-3-index size of input-tensor 1 is the number of elements (*L*) used in computing the mean and variance.

The arithmetic mean of the elements in each three-dimensional vectors corresponding to a dimension-4 index in input-tensor 1 is computed from the summation of their contents divided by *L*.

The variance of the elements in each three-dimensional vectors corresponding to a dimension-4 index in input-tensor 1 is computed from the sum of the squares of the difference of each element minus the mean, the sum then divided by either *L* or *L*–1.

Function-specific-parameter 1 contains a 32-bit unsigned binary integer called the Bessel correction (δ). The Bessel correction is subtracted from the number of elements in dimensions 1, 2, and 3 (that is, from the divisor *L*) when computing the variance. If function-specific-parameter 1 contains any value other than zero or one, a general-operand data exception is recognized. Figure 26-71 illustrates the contents of function-specific-parameter 1.

Figure 26-71. NNPA-MOMENTS Function-Specific-Parameter 1

The NNPA-MOMENTS function is available when the parameter-block version number (PBVN) is greater than zero. If the PBVN is zero, response code 0001 hex is set in general register 0, and the instruction completes with condition code 1.

If the data-layout-format field in any of the specified tensor descriptors does not contain a value of zero (4D-feature tensor), or if the data-type field in any specified tensor does not contain a value of zero (NNP-data-type 1), response code 0010 hex or 0011 hex, respectively, is set in general register 0, and the instruction completes with condition code 1.

All of the following conditions must be true; otherwise, a general-operand data exception is recognized:

- The data-layout format and data type of all specified tensors must be the same.
- The dimension-4-index size of all specified tensors must be the same.
- The dimension-1-index size, dimension-2-index size, and dimension-3-index size of output-tensors 1 and 2 must be one.
- The value of function-specific-parameter 1 must be either zero or one.
- When the value of function-specific-parameter 1 is one, the total number of elements in dimensions 1, 2, and 3 of input-tensor 1 (*L*) must be greater than one.

The input-tensor-descriptors 2 and 3, function-specific-parameters 2 and above, and function-specific-save-area address are ignored.

Programming Notes:

1. When computing variance, a Bessel correction of zero indicates variance for a population, and a one indicates variance for a sample.
2. The NNPA-MOMENTS function may be used in combination with the NNPA-LAYERNORM function to perform a normalization operation. See programming note 1 on page page 26-92 for details.
3. The NNPA-MOMENTS function is not available on all models supporting the NNPA instruction.

Function Code 66: NNPA-LAYERNORM

When the NNPA-LAYERNORM function is specified, for each element in dimensions 1, 2, and 3 corresponding to a dimension-4 index in input-tensor 1, the following processing occurs:

1. A corresponding element in dimension 4 of input-tensor 2 is subtracted to form a difference.
2. A corresponding element in dimension 4 of input-tensor 3 is added to the contents of function-specific-parameter 3 (epsilon) to form a sum.
3. The inverse square root of the sum from step 2 is computed.
4. The difference from step 1 is multiplied by the inverse square root of the sum from step 3 to form a first intermediate product.
5. The first intermediate product from step 4 is multiplied by the contents of function-specific parameter 2 (gamma) to form a second intermediate product.
6. The second intermediate product from step 5 is added to the contents of function-specific parameter 1 (beta) to form a result that is stored in the corresponding element of output-tensor 1.

Bit positions 16-31 of function-specific parameters (FSPs) 1-3 contain the values of beta, gamma, and epsilon, respectively, in the NNP-data-type-1 format. Bit positions 0-15 of function-specific parameters 1-3 are reserved and should contains zeros; otherwise, the program may not operate compatibly in the future. Figure 26-72 illustrates these function-specific parameters.

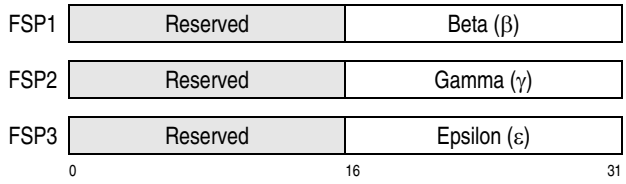

Figure 26-72. NNPA-LAYERNORM Function-Specific Parameters

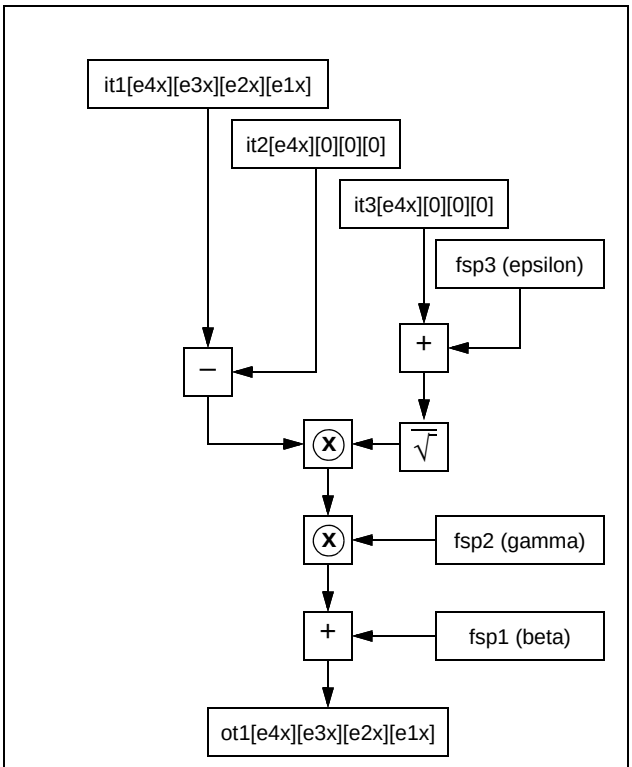
Processing of an element by NNPA-LAYERNORM is as follows:

$$\text{LayerNorm}(x) = (x - \overline{X}) \bullet \text{invsqrt}(\sigma + \varepsilon) \bullet \gamma + \beta$$

In this formula, $\overline{X}$ and σ are the corresponding elements from dimension 4 of input-tensors 2 and 3, respectively; and ε, γ, and β are the values in bits 16-31 of FSPs 3, 2, and 1, respectively.

Figure 26-73 illustrates the processing of elements in input-tensors 1-3, and the resulting element in output-tensor 1.



Explanation:

$\overline{\sqrt{\ }}$	Inverse square root.
–	Subtraction; minuend at top, subtrahend at right.
÷	Division; dividend at left, divisor at right.
beta	Addend in function-specific-parameter 1.
epsilon	Addend in function-specific-parameter 3.
e*n*x	Dimension *n* index of a tensor.
fsp*n*	Function-specific parameter *n*.
gamma	Multiplicand in function-specific-parameter 2.
it*n*	Input-tensor *n*.
ot1	Output-tensor 1.

Figure 26-73. NNPA-LAYERNORM Processing of a Single Element

The NNPA-LAYERNORM function is available when the parameter-block version number (PBVN) is greater than zero. If the PBVN is zero, response code 0001 hex is set in general register 0, and the instruction completes with condition code 1.

If the data-layout-format field in any of the specified tensor descriptors does not contain a value of zero (4D-feature tensor), or if the data-type field in any specified of the specified tensors does not contain a value of zero (NNP-data-type 1), response code 0010 hex or 0011 hex, respectively, is set in general register 0, and the instruction completes with condition code 1.

All of the following conditions must be true; otherwise, a general-operand data exception is recognized:

- The data-layout format and data type of all specified tensors must be the same.
- The dimension-4-index size of all specified tensors must be the same.
- The dimension-1-index size, dimension-2-index size, and dimension-3-index size of input tensor 1 must be the same as the corresponding index size in output tensor 1.
- The dimension-1-index size, dimension-2-index size, and dimension-3-index size of input-tensors 2 and 3 must be one.
- The contents of function-specific parameters 1 (beta), 2 (gamma), and 3 (epsilon) must all be numeric values.

Output-tensor-descriptor 2, function-specific-parameters 4 and above, and the function-specific-save-area address are ignored.

Programming Notes:

1. The NNPA-LAYERNORM function is intended to be used in combination with the NNPA-MOMENTS function to perform a normalization operation. The NNPA-MOMENTS function produces two output tensors containing the averages and variances, respectively, of the dimension-4-index elements of the input tensor.

   The original input tensor to NNPA-MOMENTS is also intended to be used as input-tensor 1 to NNPA-LAYERNORM. Output tensors 1 and 2 from NNPA-MOMENTS are used as input-tensors 2 and 3 to NNPA-LAYERNORM.

2. The beta and gamma values in function-specific parameters 1 and 2, respectively (also known as bias and gain in some publications), provide a means of providing a learned scale and offset. The epsilon value in function-specific parameter 3 is intended to be a small value (for example, 0.001) to provide numerical stability.

3. The NNPA-LAYERNORM function is not available on all models supporting the NNPA instruction.

Function Code 67: NNPA-NORM

When the NNPA-NORM function is specified, the following process is performed for each element of dimensions 2, 3, and 4 of input-tensors 1 and 2 and output-tensor 1:

1. Each element in dimension 1 of input-tensor 2 is subtracted from the corresponding element input-tensor 1, and the difference from this subtraction is squared. The sum of the squared differences for dimension 1 is computed.
2. The square root of the sum is placed in the first element of dimension 1 of output-tensor 1.

The NNPA-NORM function is available when the parameter-block version number (PBVN) is greater than zero. If the PBVN is zero, response code 0001 hex is set in general register 0, and the instruction completes with condition code 1.

If the data-layout-format field in any of the specified tensor descriptors does not contain a value of zero (4D-feature tensor), or if the data-type field in any of the specified tensors does not contain a value of zero (NNP-data-type 1), response code 0010 hex or 0011 hex, respectively, is set in general register 0, and the instruction completes with condition code 1.

If the dimension-3-index size of any specified tensor is not equal to one, response code F000 hex is set in general register 0, and the instruction completes with condition code 1.

All of the following conditions must be true; otherwise, a general-operand data exception is recognized:

- The data-layout format and data type of output-tensor 1, input-tensor 1, and input-tensor 2 must be the same.

- The dimension-4-index size of all specified tensors must be the same.
- The dimension-2-index size of all specified tensors must be the same.
- The dimension-1-index size of input-tensors 1 and 2 must be the same. The dimension-1-index size of output-tensor 1 must be one.

Output-tensor-descriptor 2, input-tensor-descriptor 3, all function-specific parameters, and the function-specific-save-area address are ignored.

Programming Note: The NNPA-NORM function is not available on all models supporting the NNPA instruction.

Function Code 80: NNPA-MAXPOOL2D

Function Code 81: NNPA-AVGPOOL2D

When either the NNPA-MAXPOOL2D or the NNPA-AVGPOOL2D functions are specified, input-tensor 1 is reduced by the specified operation to summarize windows of the input. The windows of the input are selected by moving a 2D sliding window over dimension-indices 2 and 3. The summary of the window is an element in the output-tensor 1. The sliding window dimensions are described by function-specific-parameter 4 and function-specific-parameter 5. The amount that the sliding window moves over the input-tensor 1 when computing adjacent output-tensor elements is called the stride. The sliding window stride is specified by function-specific-parameter 2 and function-specific-parameter 3. When the NNPA-MAXPOOL2D operation is specified, the MAX operation defined below is performed on the window to compute the maximum element value. When the NNPA-AVGPOOL2D operation is specified, the AVG operation defined below is performed on the window to compute the average value of all windows' elements. If the specified padding type is VALID all elements in the window are added to the collection used to compute the resulting output element. If the specified padding type is SAME, depending on the location of the window, only a subset of elements from the window may be added to the collection used to compute the resulting output-tensor 1 element.

See Figure 26-77 on page 26-96 for a more detailed description of how the window is defined and how the window slides over the input. The *CollectElements()* operation adds an element to the collection of elements and increments the number of elements in the collection, see part 2 of Figure 26-77 on page 26-96 for a detailed description of the *CollectElements()* operation. Each time the window start position moves, the collection is emptied. It is model dependent whether elements not required to perform the operation are accessed. This may differ on different models.

MAX Operation: The maximum of the collection of elements in the window is computed by comparing all elements in the collection to each other and returning the largest value.

AVG Operation: The average of the collection of elements in the window is computed as the summation of all elements in the collection divided by the number of elements in the collection.

Figure 26-74 illustrates the contents of the function-specific parameters for the NNPA-MAXPOOL2D and NNPA-AVGPOOL2D functions.

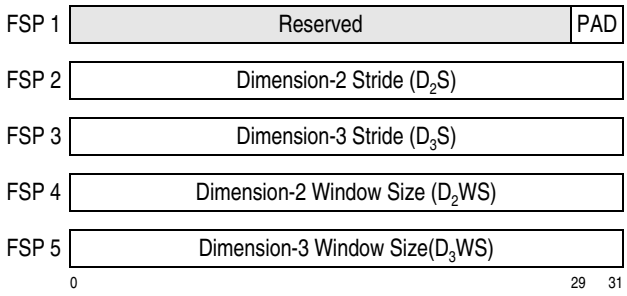


Figure 26-74. Function-Specific Parameters for NNPA-MAXPOOL2D & NNPA-AVGPOOL2D

The function-specific-parameter fields are allocated as follows:

- Bits 29-31 of function-specific-parameter 1 contain a 3-bit unsigned binary integer that controls padding type, as follows:

PAD	Padding Type
0	VALID
1	SAME
2-7	Reserved

If a reserved value is specified for the PAD field, a response code F000 hex is set in general regis-

ter 0, and the operation completes with condition code 1.

Bit positions 0-28 of the function-specific-parameter 1 are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.

- Function-specific-parameter 2 (FSP2) contains a 32-bit unsigned binary integer that specifies the dimension-2 stride (D_2S) which specifies the number of elements the sliding window moves in dimension 2.

- Function-specific-parameter 3 (FSP3) contains a 32-bit unsigned binary integer that specifies the dimension-3 stride (D_3S) which specifies the number of elements the sliding window moves in dimension 3.

- Function-specific-parameter 4 (FSP4) contains a 32-bit unsigned binary integer that specifies the dimension-2-window size (D_2WS) which specifies the number of elements in dimension 2 the sliding window contains.

- Function-specific-parameter 5 (FSP5) contains a 32-bit unsigned binary integer that specifies the dimension-3-window size (D_3WS) which specifies the number of elements in dimension 3 the sliding window contains.

All of the following conditions must be true; otherwise, response code 0012 hex is set in general register 0, and the operation completes with condition code 1:

- When the format-1 parameter block is not installed, the specified values in FSPs 2 through 5 must be less than or equal to the maximum-dimension-index size (MDIS).

  When the format-1 parameter block is not installed, the specified values in FSPs 2 and 4 must be less than or equal to the maximum-dimension-2-index size (MD2IS), and the specified values in FSPs 3 and 5 must be less than or equal to the maximum-dimension-3-index size (MD3IS).

- The specified values in function-specific-parameters 4 and 5 must be greater than zero.

If the dimension-2 stride (FSP2) and the dimension-3 stride (FSP3) are both zero and either the dimension-2-window size (FSP4) or the dimension-3-window size (FSP5) is greater than 1024, response code F001 hex is set in general register 0. If the dimension-2 stride (FSP2) and the dimension-3 stride (FSP3) are both greater than zero and either the dimension-2-window size (FSP4) or the dimension-3-window size (FSP5) is greater than 64, response code F002 hex is set in general register 0. If the dimension-2 stride (FSP2) and the dimension-3 stride (FSP3) are both greater than zero and either the dimension-2 stride (FSP2) or the dimension-3 stride (FSP3) is greater than 30, response code F003 hex is set in general register 0. If the dimension-2 stride (FSP2) and the dimension-3 stride (FSP3) are both greater than zero and either the input-tensor 1 dimension-2-index size or the input-tensor 1 dimension-3-index size is greater than 1024, response code F004 hex is set in general register 0. For all of the above conditions the instruction completes with condition code 1.

If the specified data-layout-format field in any of the specified tensor descriptors does not contain a value of zero (4D-feature tensor) or if the data-type field in any specified tensor descriptor does not contain a value of zero (NNP-data-type 1) response code 0010 hex or 0011 hex, respectively, is set in general register 0 and the instruction completes with condition code 1.

All of the following conditions must be true; otherwise, a general-operand data exception is recognized:

- The dimension-4-index size and dimension-1-index size of the input-tensor 1 and the output-tensor 1 must be the same.

- The data layout and the data type of the input-tensor 1 and the output-tensor 1 must be the same.

- If the dimension-2 stride (FSP2) and the dimension-3 stride (FSP3) are both zero, all of the following additional conditions must be true:

  – The input-tensor 1 dimension-2-index size must be equal to the dimension-2-window size (FSP4).

  – The input-tensor 1 dimension-3-index size must be equal to the dimension-3-window size (FSP5).

  - The dimension-2-index size and the dimension-3-index size of the output-tensor 1 must be one.
  - The specified padding must be VALID.

- If either the dimension-2 stride (FSP2) or the dimension-3 stride (FSP3) is non-zero, then both strides must be non-zero.
- If the dimension-2 stride (FSP2) and the dimension-3 stride (FSP3) are both greater than zero all of the following additional conditions must be true:
  - When the specified padding is VALID, and the dimension-2-window size (FSP4) must be less than or equal the dimension-2-index size of the input-tensor 1.
  - When the specified padding is VALID, and the dimension-3-window size (FSP5) must be less than or equal the dimension-3-index size of the input-tensor 1.
  - When the specified padding is SAME, the following relationship between the dimension-2-index size and dimension-3-index-size of the input-tensor 1 and output-tensor 1 must be satisfied:

$$O_1D_2IS = \left\lceil \frac{I_1D_2IS}{D_2S} \right\rceil$$

$$O_1D_3IS = \left\lceil \frac{I_1D_3IS}{D_3S} \right\rceil$$

Figure 26-75. Pooling with SAME padding specified

  - When the specified padding is VALID, the following relationship between the dimension-2-index size and dimension-3-index size of the input-tensor 1 and output-tensor 1 must be satisfied:

$$O_1D_2IS = \left\lceil \frac{I_1D_2IS - D_2WS + 1}{D_2S} \right\rceil$$

$$O_1D_3IS = \left\lceil \frac{I_1D_3IS - D_3WS + 1}{D_3S} \right\rceil$$

Figure 26-76. Pooling with VALID padding specified

The output-tensor-descriptor 2, input-tensor-descriptors 2 and 3, function-specific-parameters 6 and above, and function-specific-save-area-address field are ignored.

The order of the arithmetic operations for the NNPA-AVGPOOL2D function is model dependent and may lead to different results on different models.

Programming Note: When the NNPA-AVGPOOL2D function is performed, if the elements of input-tensor 1 are either very small or very large, accuracy may be reduced.

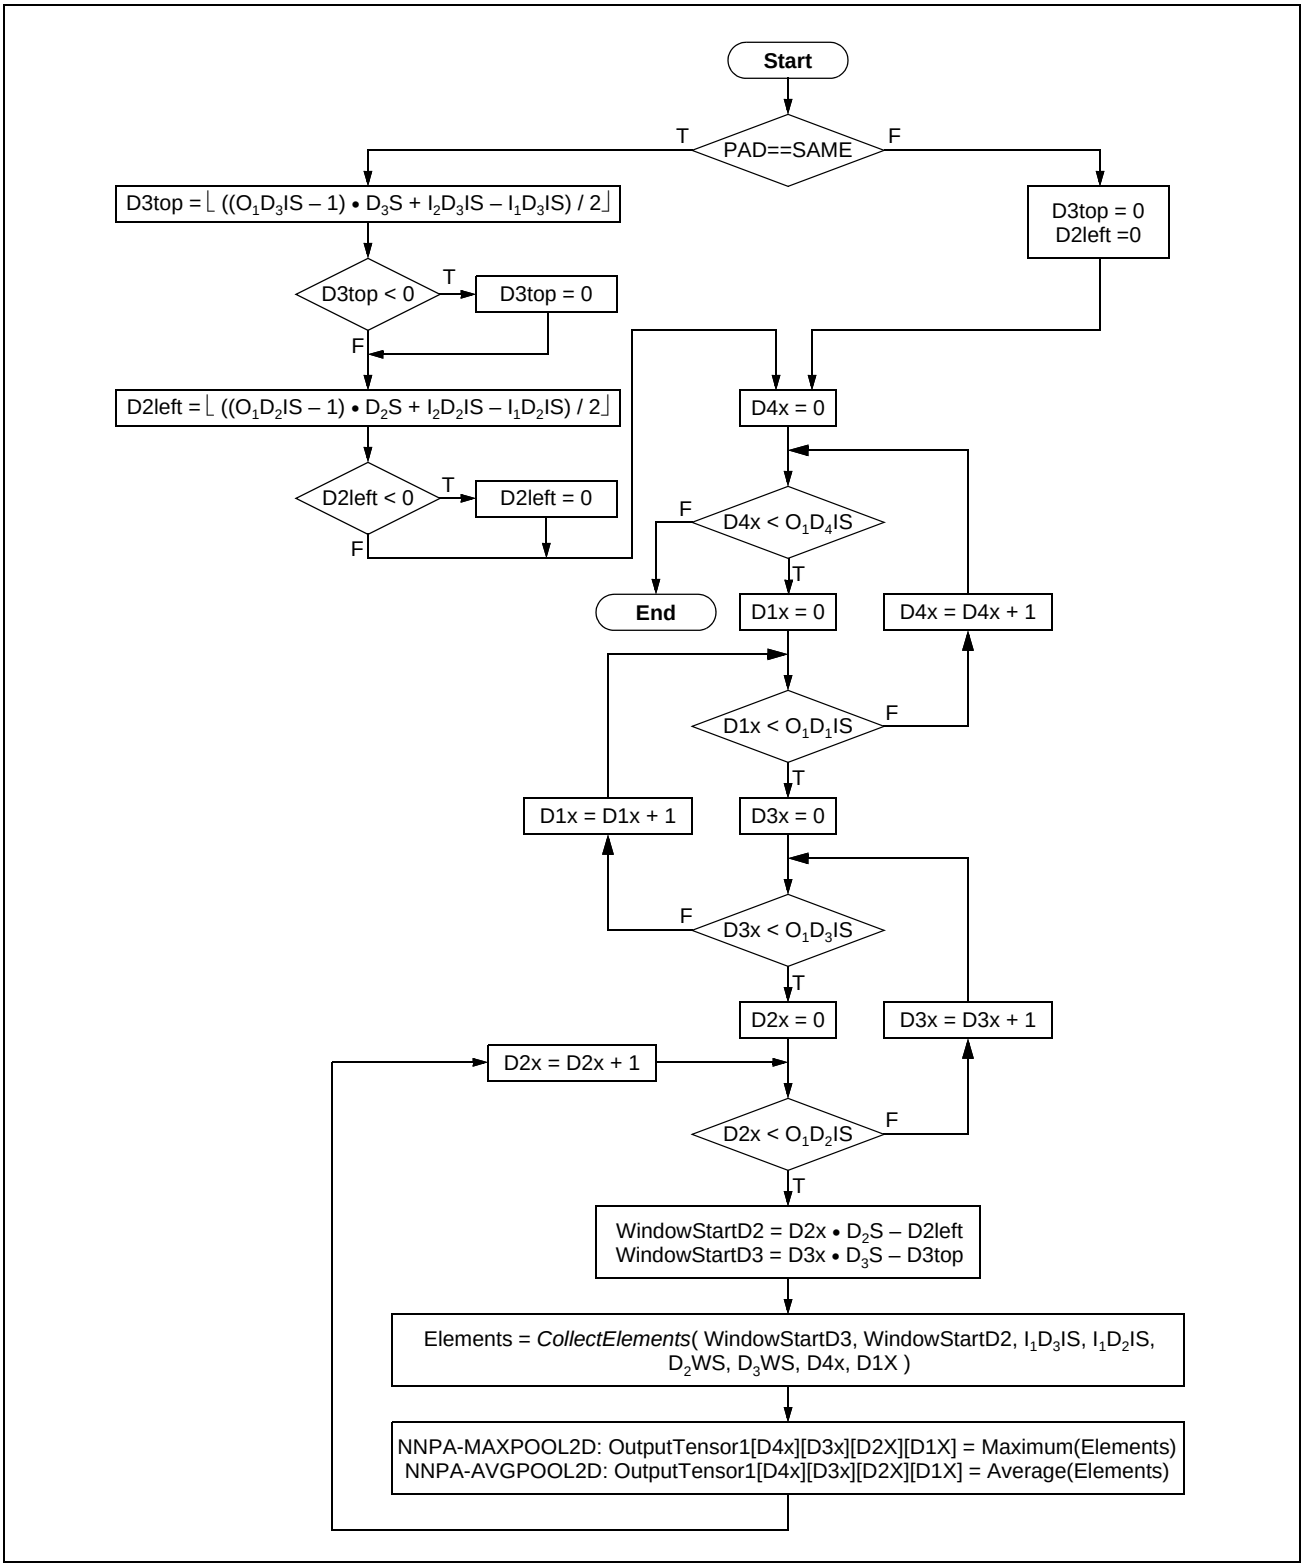

Figure 26-77. NNPA-MAXPOOL2D / NNPA-AVGPOOL2D (Part 1 of 2)

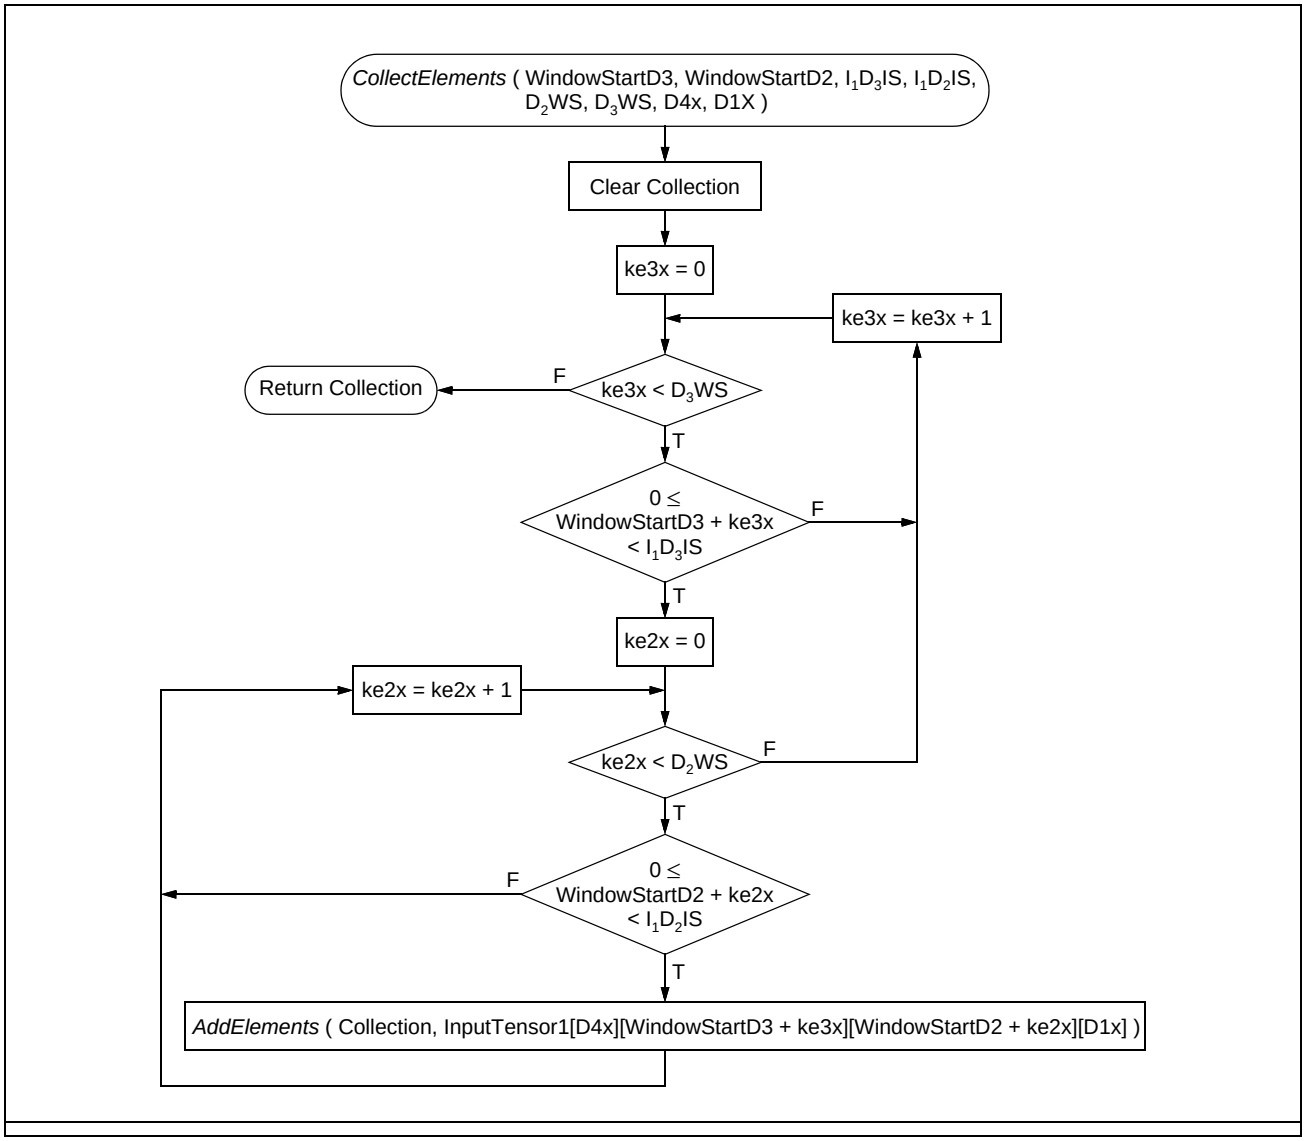

Figure 26-77. NNPA-MAXPOOL2D / NNPA-AVGPOOL2D (Part 2 of 2)

Function Code 96: NNPA-LSTMACT

When the NNPA-LSTMACT function is specified, input-tensor 1 split into four sub-tensors for each dimension-4-index value, along with input-tensor 2 split into four sub-tensors for each dimension-4-index value, and input-tensor 3 are the inputs to the LSTMACT operation shown in Figure 26-78 on page 26-98. At the end of the LSTMACT operation, results are written to output-tensor 1 and output-tensor 2.

If the specified data-layout-format field in any of the specified tensor descriptors does not contain a value of zero (4D-feature tensor) or if the data-type field in any specified tensor descriptor does not contain a value of zero (NNP-data-type 1) response code 0010 hex or 0011 hex, respectively, is set in general register 0, and the instruction completes with condition code 1.

All of the following conditions must be true; otherwise, a general-operand data exception is recognized:

- The dimension-4-index size for the input-tensor 3, and output-tensors 1 and 2 must be equal to one.
- The dimension-4-index size for the input-tensor 1 and input-tensor 2 must be equal to four.

- The dimension-3-index size for all input tensors and the two output tensors must be equal to one.
- The data layout and data type of all input tensors and the two output tensors must be the same.
- The dimension-1-index size of all input tensors and the two output tensors must be the same.
- The dimension-2-index size of all input tensors and the two output tensors must be the same.

The function-specific-save-area-address field is ignored. All function-specific parameters should contain zeros; otherwise, the program may not operate compatibly in the future.

The order of the arithmetic operations is model dependent and may lead to different results on different models.

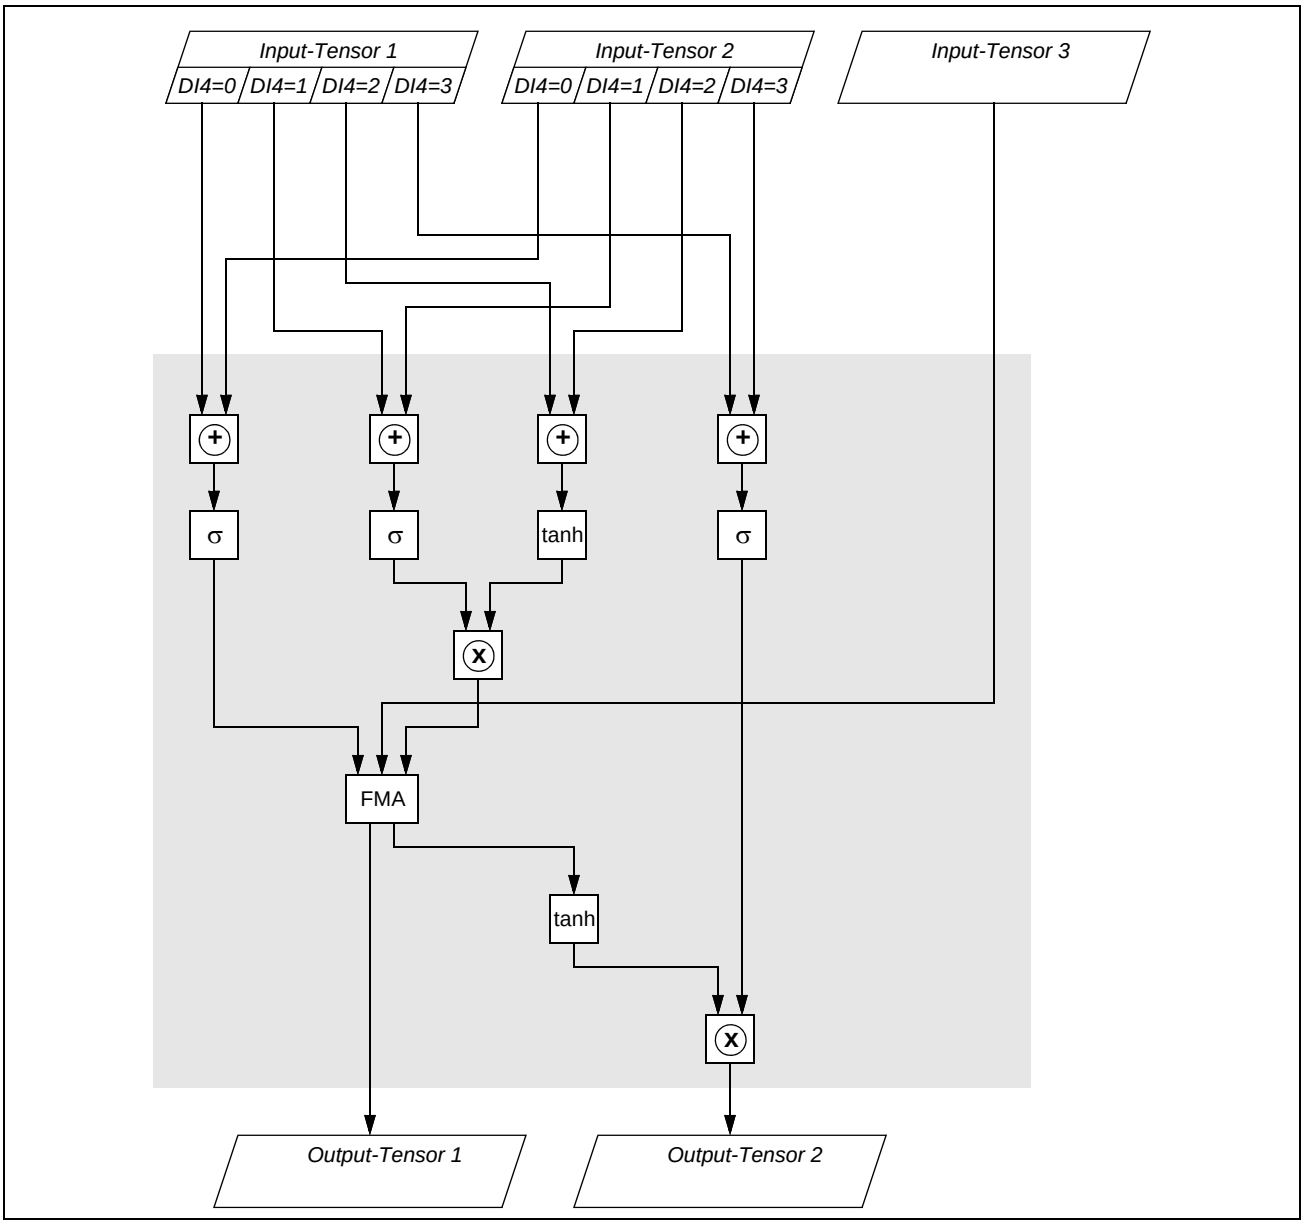

Figure 26-78. NNPA-LSTMACT Operation

Function Code 97: NNPA-GRUACT

When the NNPA-GRUACT function is specified, input-tensor 1 split into three sub-tensors for each dimension-4-index value, along with input-tensor 2 split into three sub-tensors for each dimension-4-index value, and input-tensor 3 are the inputs to the GRUACT operation shown in Figure 26-79 on page 26-100. At the end of the GRUACT operation, the output-tensor 1 is stored.

If the specified data-layout-format field in any of the specified tensor descriptors does not contain a value of zero (4D-feature tensor) or if the data-type field in any specified tensor descriptor does not contain a value of zero (NNP-data-type 1) response code 0010 hex or 0011 hex, respectively, is set in general register 0, and the instruction completes with condition code 1.

All of the following conditions must be true; otherwise, a general-operand data exception is recognized:

- The dimension-4-index size of output-tensor 1 and input-tensor 3 must be equal to one.
- The dimension-4-index size of input-tensor 1 and input-tensor 2 must be equal to three.
- The dimension-3-index size for all input tensors and the output-tensor 1 must be equal to one.
- The dimension-1-index size of all input tensors and the output-tensor 1 must be the same.
- The dimension-2-index size of all input tensors and the output-tensor 1 must be the same.
- The data layout and data type of all input tensors and the output-tensor 1 must be the same.

The output-tensor-descriptor 2, all function-specific parameters, and function-specific-save-area-address fields are ignored.

The order of the arithmetic operations is model dependent and may lead to different results on different models.

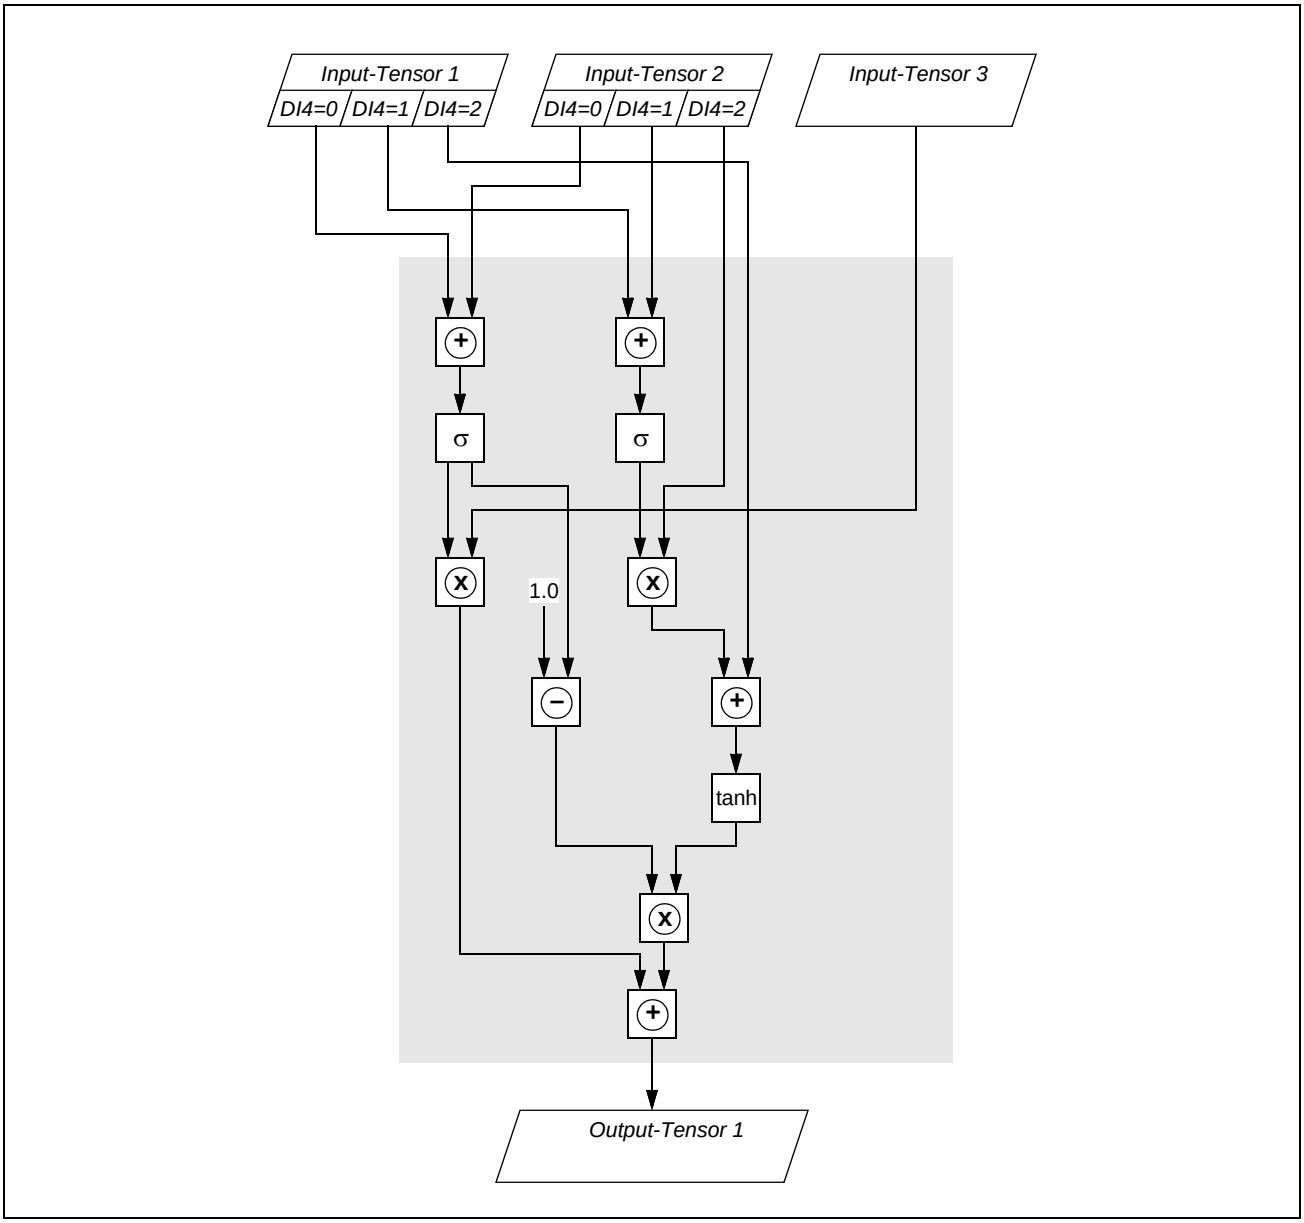

Figure 26-79. NNPA-GRUACT Operation

Function Code 112: NNPA-CONVOLUTION

When the NNPA-CONVOLUTION function is specified, for each output element in the output-tensor 1, a 3-dimensional input-1 window consisting of dimension indices 3, 2, and 1 is selected from input-tensor 1, described by the input-tensor 1 descriptor. A 3-dimensional input-2 window of the same size consisting of dimension indices 4, 3, and 2 is selected from input-tensor 2 (see Figure 26-80 on page 26-101 for correspondence). The elements in the input-1 window are multiplied by the corresponding elements in the input-2 window and all of the products are added together to create an initial summation. This initial summation is added to the corresponding element of input-tensor 3 to compute an intermediate summation value. The element of the output-tensor 1 is the result of the specified activation function performed on the intermediate summation. If no activation function is specified, the output element is equal to the intermediate summation.

If the specified padding type is VALID, all elements in the window are used to compute the resulting initial summation. If the specified padding type is SAME, depending on the location of the window, some elements of the input-1 window may be implied zero, when computing the resulting initial summation.

General AI usage	Input-tensor 1 (Feature tensor)	Input-tensor 2 (Kernel tensor)
Tensor count	Dimension 4	Dimension 1
Tensor height	Dimension 3	Dimension 4
Tensor width	Dimension 2	Dimension 3
Tensor channels	Dimension 1	Dimension 2

Figure 26-80. Tensor dimensions correspondence between feature and kernel tensors

It is model dependent whether the range violation is detected for the NNPA-CONVOLUTION function.

See Figure 26-84 on page 26-104 for a more detailed description of how the windows are defined and how the windows are selected based on the output element.

The *RELUx()* activation operation used in Figure 26-84 is detailed in Figure 26-67 on page 26-86, however the adjustment factor of the NNPA-RELU function is not used by NNPA-CONVOLUTION. It is model dependent whether elements not required to perform the operation are accessed. This may differ on different models.

The function-specific parameters used by the NNPA-CONVOLUTION function are illustrated in Figure 26-81 (below).

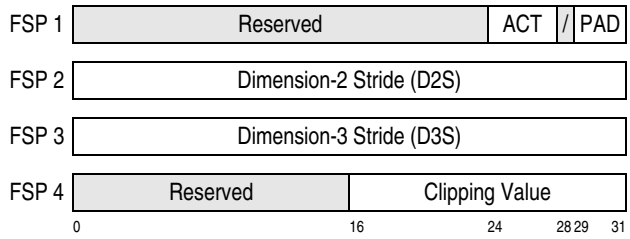

Figure 26-81. Function-Specific Parameters for NNPA-CONVOLUTION

- Function-specific-parameter 1 controls the padding type and the activation function.

  Bit positions 29-31 contain a 3-bit unsigned binary integer specifying the padding type (PAD).

PAD	Padding Type
0	VALID
1	SAME
2-7	Reserved

  Bit positions 24-27 contain a 4-bit unsigned binary integer specifying the activation function (ACT).

ACT	Activation Function
0	No activation function performed
1	RELU
2-15	Reserved

  If an activation function of RELU is specified, the resulting output element value is determined as follows: if the intermediate summation value is less than or equal to zero the corresponding element in the output-tensor 1 is zero; otherwise, the corresponding element in the output-tensor 1 is the minimum of the intermediate summation value and the clipping value specified in function-specific-parameter 4.

  If a reserved value is specified for the PAD field, response code of F000 hex is set in general register 0, and the operation completes with condition code 1. If a reserved value is specified for the ACT field, response code of F001 hex is set in general register 0, and the operation completes with condition code 1.

- Function-specific-parameter 2 (FSP2) contains a 32-bit unsigned binary integer that specifies the dimension-2 stride (D_2S) which specifies the number of elements the sliding window moves in dimension 2.

  When the format-1 parameter block is not installed, the specified value in FSP2 must be less than or equal to the maximum-dimension-index size (MDIS), and when the format-1 parameter block is installed, the specified value in FSP2 must be less than or equal to the maximum-dimension-2-index size (MD2IS); otherwise, response code 0012 hex is set in general register 0, and the operation completes with condition code 1.

- Function-specific-parameter 3 (FSP3) contains a 32-bit unsigned binary integer that specifies the dimension-3 stride (D_3S) which specifies the number of elements the sliding window moves in dimension 3.

  When the format-1 parameter block is not installed, the specified value in FSP3 must be less than or equal to the maximum-dimension-index size (MDIS), and when the format-1 parameter block is installed, the specified value in FSP3 must be less than or equal to the maximum-dimension-3-index size (MD3IS); otherwise, response code 0012 hex is set in general register 0, and the operation completes with condition code 1.

- Function-specific-parameter 4 defines the clipping value for the optional RELU activation operation. If the ACT field is zero, this field is ignored. If the ACT field specifies RELU, the clipping value is specified in NNP-data-type 1 format. A clipping-value field of zero means to use the maximum positive value; in other words, no clipping is performed. If a negative value, including negative zero or a nonnumeric value of either sign, is specified in NNP-data-type 1 format, a general-operand data exception is recognized.

If the specified data-layout-format field in any of the specified tensor descriptors except input-tensor 2 does not contain a value of zero (4D-feature tensor), or the specified data-layout-format field in input-tensor 2 does not contain a value of one (4D-kernel tensor), then response code 0010 hex is set in general register 0, and the instruction completes with condition code 1. If the data-type-field in any specified tensor descriptor does not contain a value of zero (NNP-data-type 1), then response code 0011 hex is set in general register 0, and the instruction completes with condition code 1.

If the dimension-2 stride (FSP2) and the dimension-3 stride (FSP3) are both zero and either the dimension-3-index size or the dimension-4-index size of input-tensor 2 is greater than 448, then response code F002 hex is set in general register 0. If dimension-2 stride (FSP2) and the dimension-3 stride (FSP3) are both greater than zero and either the dimension-3-index size or the dimension-4-index size of the input-tensor 2 is greater than 64, then response code F003 hex is set in general register 0, and the operation completes with condition code 1. If either the dimension-2 stride (FSP2) or the dimension-3 stride (FSP3) is greater than 13, then response code F004 hex is set in general register 0, and the operation completes with condition code 1.

All of the following conditions must be true; otherwise, a general-operand data exception is recognized:

- The data layout of input-tensor 1, input-tensor 3, and the output-tensor 1 must be the same.
- The data type of all input tensors and the output-tensor 1 must be the same.
- The dimension-2-index size, dimension-3-index size, and dimension-4-index size of the input-tensor 3 must be 1.
- The dimension-4-index size of the output-tensor 1 must be equal to the dimension-4-index size of the input-tensor 1.
- The dimension-1-index size of the output-tensor 1 must be equal to the dimension-1-index size of the input-tensor 2 and the dimension-1-index size of the input-tensor 3.
- The dimension-1-index size of the input-tensor 1 must be equal to the dimension-2-index size of the input-tensor 2.
- If the dimension-2 stride (FSP2) and the dimension-3 stride (FSP3) are both zero, then all of the following additional conditions must be true:
  - The input-tensor 1 dimension-2-index size must be equal to the dimension-3-index size of input-tensor 2.

- The input-tensor 1 dimension-3-index size of the input-tensor must be equal to the dimension-4-index size of input-tensor 2.
- The dimension-2-index size and the dimension-3-index size of the output-tensor 1 must be one.
- The specified padding must be VALID.

- If either the dimension-2 stride (FSP2) or the dimension-3 stride (FSP3) is non-zero, then both strides must be non-zero.
- If the dimension-2 stride (FSP2) and the dimension-3 stride (FSP3) are both greater than zero all of the following additional conditions must be true:
  - When the specified padding is VALID, the dimension-2-index size of the input-tensor 1 must be greater than or equal to the dimension-3-index size of input-tensor 2.
  - When the specified padding is VALID, the dimension-3-index size of the input-tensor 1 must be greater than or equal to the dimension-4-index size of the input-tensor 2.
  - When the specified padding is SAME, the following relationship between the dimension-2-index size and dimension-3-index size of the input-tensor 1 and output-tensor 1 must be satisfied:

$$O_1D_2IS = \left\lceil \frac{I_1D_2IS}{D_2S} \right\rceil$$

$$O_1D_3IS = \left\lceil \frac{I_1D_3IS}{D_3S} \right\rceil$$

Figure 26-82. Convolution with SAME padding specified

  - When the specified padding is VALID, the following relationship between the dimension-2-index size and dimension-3-index size of the input-tensor 1, dimension-3-index size and dimension-4-index size of the input-tensor 2 and output-tensor 1 must be satisfied:

$$O_1D_2IS = \left\lceil \frac{I_1D_2IS - I_2D_3IS + 1}{D_2S} \right\rceil$$

$$O_1D_3IS = \left\lceil \frac{I_1D_3IS - I_2D_4IS + 1}{D_3S} \right\rceil$$

Figure 26-83. Convolution with VALID padding specified

The output-tensor-descriptor 2, and the function-specific-save-area-address fields are ignored. Function-specific-parameters 5 and above should contain zeros; otherwise, the program may not operate compatibly in the future.

The order of the arithmetic operations is model dependent and may lead to different results on different models.

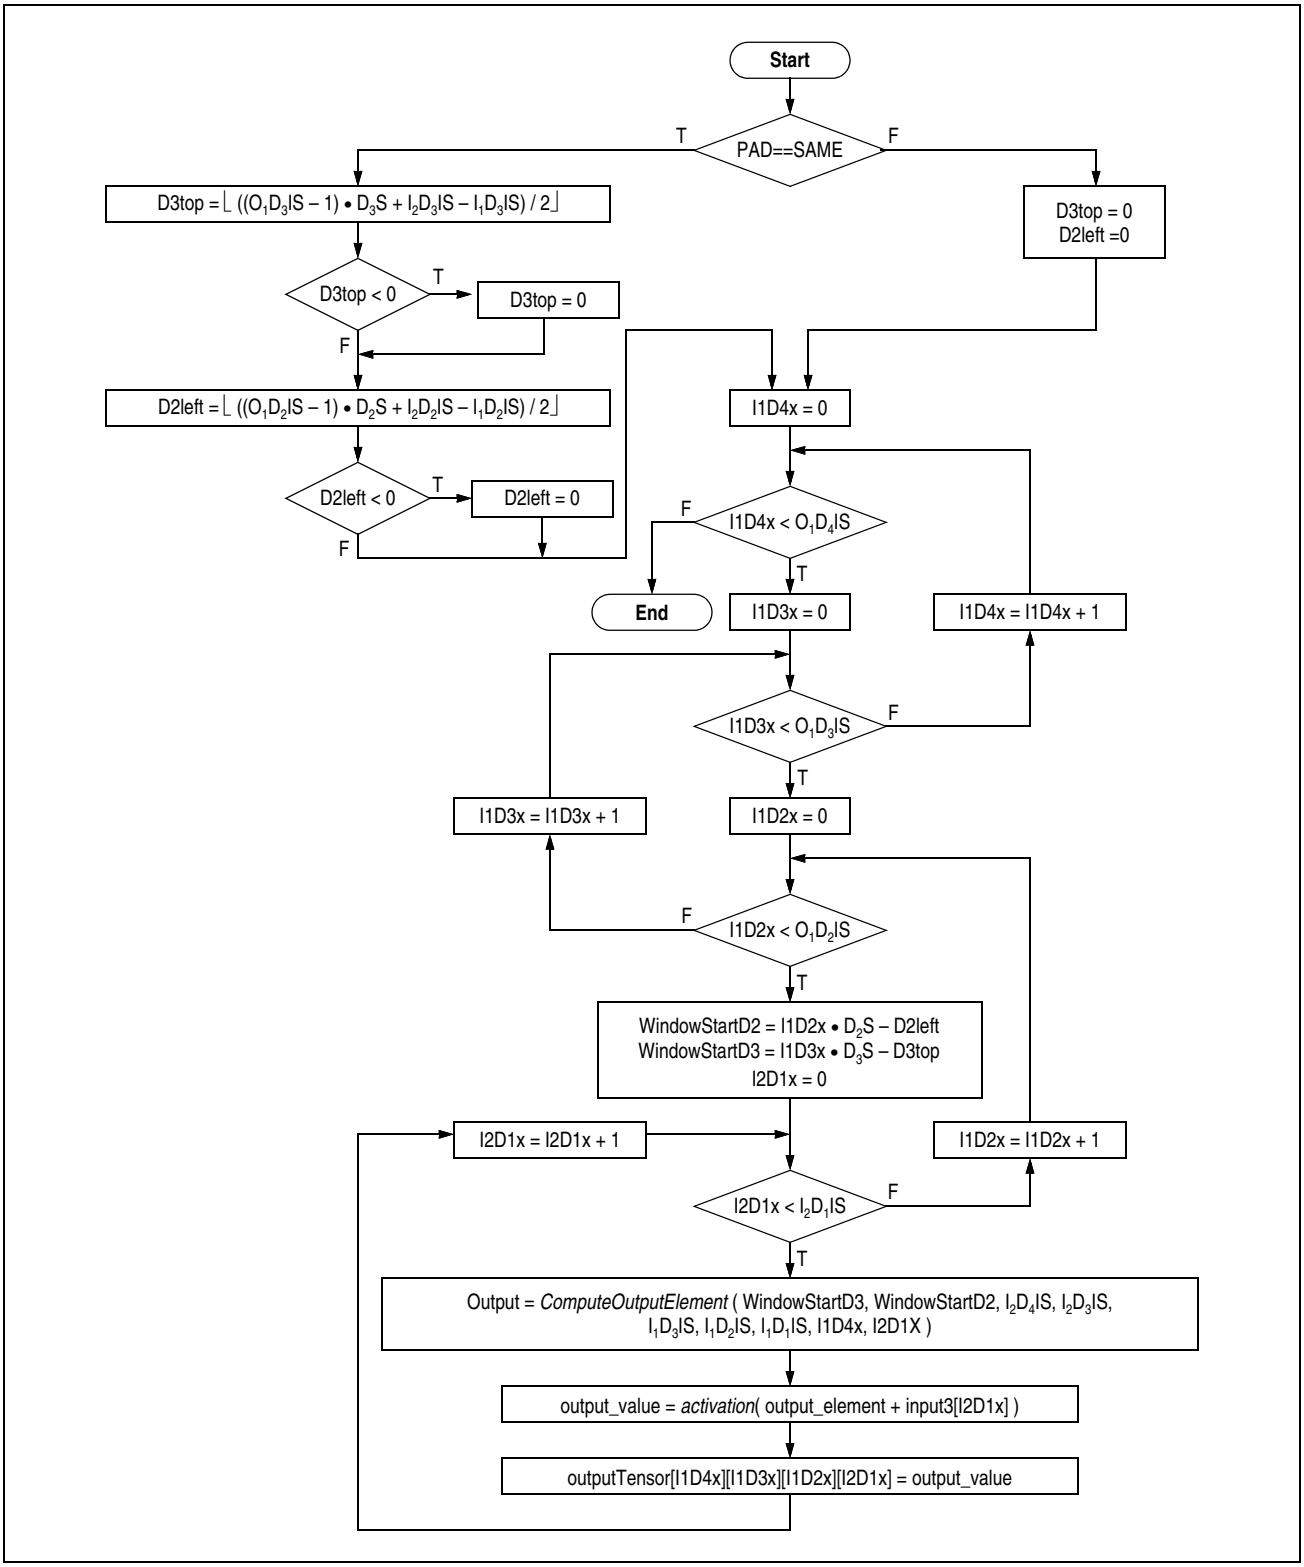

Figure 26-84. NNPA-CONVOLUTION (Part 1 of 2)

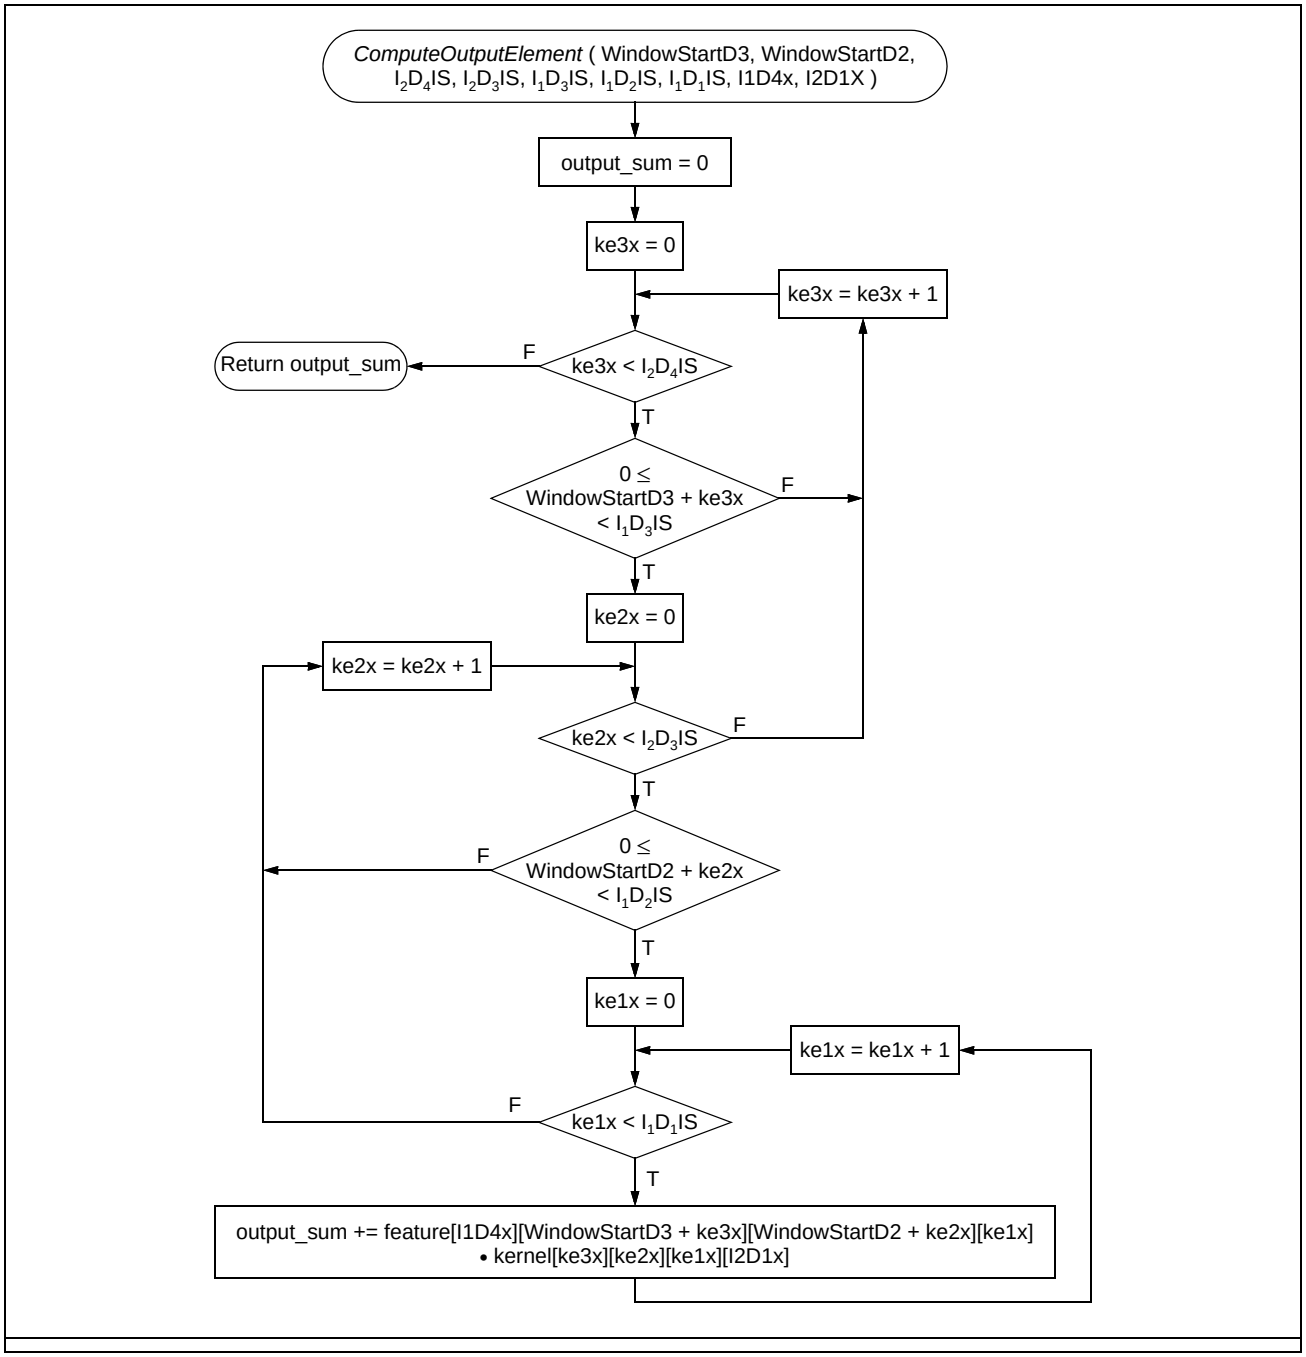

Figure 26-84. NNPA-CONVOLUTION (Part 2 of 2)

Function Code 113: NNPA-MATMUL-OP

Function Code 114: NNPA-MATMUL-OP-BCAST23

Function Code 115: NNPA-MATMUL-OP-BCAST1

Note: Text describing the common operation of the NNPA-MATMUL-OP, NNPA-MATMUL-OP-BCAST23, and NNPA-MATMUL-OP-BCAST1 functions is referred to as simply the *NNPA-MATMUL functions*. Text describing an operation that is unique to a particular function will mention the function by its full name.

When any of the NNPA-MATMUL functions are specified, each element in the output-tensor 1 is computed as described below:

1. A dimension-A vector is selected from the input-tensor 1 using the get-dimension-A-vector operation described on page 26-109.
2. A dimension-B vector is selected from the input-tensor 2 using the get-dimension-B-vector operation described on page 26-110.
3. An intermediate dot product of the dimension-A vector and the dimension-B vector is computed using the dot product operation. When function-specific parameters 3, 5, and 7 are applicable, the intermediate dot product is scaled by a factor *M*. The dot-product operation is described on page 26-108.
4. Processing of the intermediate dot product depends on the NNPA-MATMUL function specified, as described below. Where applicable, the fused operation is determined by function-specific parameter 1, as described on page 26-108.

   - NNPA-MATMUL-OP: A fused operation is performed on the intermediate dot product and the element of input-tensor 3 with the same dimension-index-4 value and dimension-index-1 value as output-tensor 1.
   - NNPA-MATMUL-OP-BCAST23: When the parameter-block-version number is zero, the element of input-tensor 3 with the same dimension-1-index value as output-tensor-1 element is added to the previously-computed intermediate dot product and stored in output-tensor 1.

     When the parameter-block-version number is greater than zero, a fused operation is performed on the intermediate dot product and the element of input-tensor 3 with the same dimension-1-index value as output-tensor 1.
   - NNPA-MATMUL-OP-BCAST1: When the parameter-block-version number is zero, the function is not available. In this case, response code 0001 hex is set in general register 0, and the instruction completes with condition code 1.

     When the parameter-block-version number is greater than zero, a fused operation is performed on the intermediate dot product and the element of input-tensor 3 with the same dimension-4-index value and dimension-1-index value as output-tensor 1.

   Regardless of the function, the resulting element is stored in output-tensor 1.

Each row of Figure 26-85 illustrates a valid combination of parameter-block-version number, data-layout format, data type, and applicable function-specific parameters (FSPs). A function-specific parameter is said to be *applicable* to the NNPA-MATMUL functions when its contents are used in the manipulation of an input tensor's elements (that is, when it is used to perform any of transposition, scaling, offsetting, or clipping). If the function-specific parameter is not applicable (as shown by a hyphen in a row of the figure), it has no effect on the contents of an input tensor's elements.

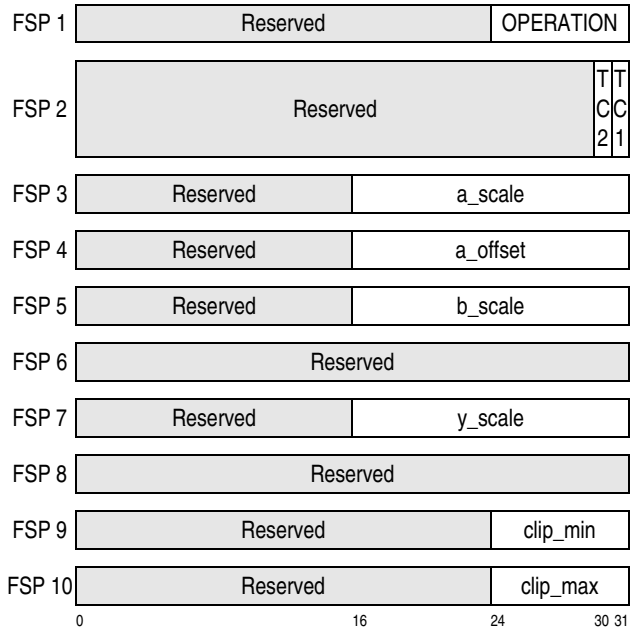
*_scale	See Figure 26-86.
a_offset	See Figure 26-86.
clip_max	See Figure 26-86.
clip_min	See Figure 26-86.
DLF	Data-layout format specified in the tensor descriptor (0=4D-feature tensor, 2=4D-weights tensor.
DT	Data type in specified the tensor descriptor (0=NNP-data-type 1, 8=8-bit signed binary integer).
IT_*n*	Input-tensor *n*.
OP	See Figure 26-86.
OT_1	Output-tensor 1.
PBVN	Parameter-block-version number specified in the parameter block.
TCs	See Figure 26-86.

Figure 26-85. NNPA-MATMUL Functions: Supported Data-Layout Formats, Data Types, and Applicable Function-Specific Parameters Based on the Parameter-Block-Version Number

Figure 26-86 provides additional details on the function-specific parameters for the NNPA-MATMUL functions.



Explanation:

a_offset When applicable, an NNPA-data-type-1 value in bits 16-31 of FSP 4, used by the get-dimension-A-vector operation.

a_scale When applicable, an NNPA-data-type-1 value in bits 16-31 of FSP 3, used by the get-dimension-A-vector and dot-product operations.

b_scale When applicable, an NNPA-data-type-1 value in bits 16-31 of FSP 5, used by the dot-product operation.

clip_max When applicable, an 8-bit signed binary integer in bits 24-31 of FSP 10, used by the dot-product operation.

clip_min When applicable, an 8-bit signed binary integer in bits 24-31 of FSP 9, used by the dot-product operation.

FSP 2-10: When the parameter-block-version number is greater than 0, one or more of FSPs 2-10 may be applicable, as indicated by a row in Figure 26-85.

OPERATION: An 8-bit unsigned binary integer in FSP 1, used by the fused operation. When the PBVN is 0, this field is not applicable to the NNPA-MATMUL-OP-BCAST23 function.

TC1 When applicable, a one-bit binary flag in bit 31 of FSP 2, used by the get-dimension-A-vector operation.

TC2 When applicable, a one-bit binary flag in bis 30 of FSP 2, used by the get-dimension-B-vector operation.

y_scale When applicable, an NNPA-data-type-1 value in bits 16-31 of FSP 7, used by the dot-product operation.

Figure 26-86. Function-Specific Parameters for NNPA-MATMUL Functions

Dot-Product Operation: The intermediate dot product of two vectors of the same size is computed as the summation of products of each element in the dimension-A vector and the corresponding element of the dimension-B vector. The two input vectors to the dot-product operation are the results of the get-dimension-A-vector operation (described on page 26-109) and the get-dimension-B-vector operation (described on page 26-110).

When function-specific parameters 3, 5, and 7 (a_scale, b_scale, and y_scale) are applicable, a scaling factor (M) is determined as follows:

$$M = y\_scale / (a\_scale \bullet b\_scale)$$

In this case, each element of the intermediate dot product is multiplied by the scaling factor M.

If the calculation of the scaling factor results in a value of M that is zero or a nonnumeric value of either sign, response code F002 hex is set in general register 0, and the instruction completes with condition code 1.

Fused Operation: Bits 24-31 of function-specific-parameter 1 contain an 8-bit unsigned binary integer that controls the operation performed on the intermediate dot product (scaled by M when applicable) and the corresponding element from input-tensor 3.

The OPERATION field, illustrated in Figure 26-86, specifies the operation performed.

OPERATION	Operation Type
0	Addition
1	Compare if dot product is high
2	Compare if dot product is not low
3	Compare if dot product and element are equal
4	Compare if dot product and element are not equal
5	Compare if dot product is not high
6	Compare if dot product is low
7-255	Reserved

All other values of the OPERATION field are reserved. If a reserved value is specified for the OPERATION field, response code of F000 hex is set in general register 0, and the operation completes with condition code 1. The OPERATION field is not applicable to the NNPA-MATMUL-OP-BCAST23

function when the parameter-block-version number is zero.

Depending on the operation, the value of an input-tensor-3 element is either added to or compared with the intermediate dot product (scaled if applicable), as follows:

- For an operation type of addition, the input-tensor-3 element is added to the intermediate dot product.
- For operation types of comparison, the intermediate dot product is compared to the input-tensor-3 element and if the comparison is true, the result is set to a value of +1; otherwise, it is set to a value of +0 in the data type specified for the output-tensor 1.

Programming Note: Care must be exercised when comparing NNP-data-type-1 values for equality or inequality since the order of operations and rounding may produce, what appear to be, slightly different values when they are essentially the same value.

Get-Dimension-A-Vector Operation: The get-dimension-A-vector operation returns a vector of elements from input-tensor 1 that is used by the dot-product operation. Processing of the get-dimension-A-vector operation depends on which NNPA-MATMUL function is being performed, as follows:

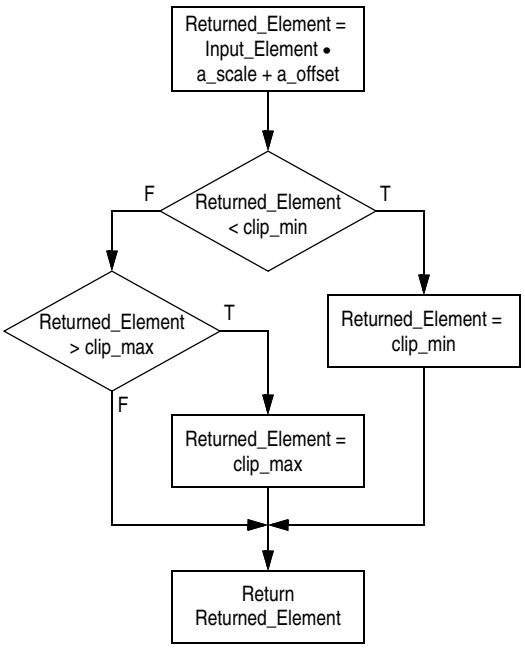
- NNPA-MATMUL-OP: For a specified output element, a dimension-A vector is selected from input-tensor 1 where the input dimension-4 index is the output dimension-4 index, and the input dimension-3 index is the output dimension-3 index.
- NNPA-MATMUL-OP-BCAST23: For a specified output element, a dimension-A vector is selected from input-tensor 1 where the input dimension-4 index is the output dimension-4 index, and the input dimension-3 index is the output dimension-3 index.
- NNPA-MATMUL-OP-BCAST1: For a specified output element, a dimension-A vector is selected from input-tensor 1 where the input-dimension-4 index is zero, and the input-dimension-3 index is zero.

When the transposition-control 1 (TC1) in bit 31 of function-specific parameter 2 is not applicable, or when TC1 is applicable and zero, the dimension-2 index of input-tensor 1 is the dimension-2 index of output-tensor 1, and dimension 1 of input-tensor 1 comprises the resulting dimension-A vector. When TC1 is applicable and one, the dimension-1 index of input-tensor 1 is the dimension-2 index of output-tensor 1, and dimension 2 of input-tensor 1 comprises the resulting dimension-A vector.

When the data type of input-tensor 1 is NNP-data-type 1 and the data type of input-tensor 2 is 8-bit signed-binary integer, the elements in the resulting dimension-A vector are further processed by the a_scale, a_offset, clip_min, and clip_max values in function-specific parameters 3, 4, 9, and 10, respectively. This processing is as follows:

returned_element = MIN(clip_max, MAX(clip_min, input_element • a_scale + a_offset))

The elements in input-tensor 1 are unchanged. Figure 26-87 illustrates the function-specific parameters that may be applicable to the get-dimension-A-vector operation.



Explanation:

a_offset	a_offset value in FSP 4
a_scale	a_scale value in FSP 3
clip_max	Maximum clip value in FSP 10.
clip_min	Minimum clip value in FSP 9.

Figure 26-87. Scaling, Offsetting, and Clipping in the Get-Dimension-A-Vector Operation

If an input element is nonnumeric, or if processing an input element with a_scale and a_offset results in a nonnumeric value, then the range-violation status flag is set and the resulting element value is unpredictable. If the value of a_offset is nonnumeric, a general-operand data exception is recognized. Returned elements are rounded to the nearest number in the target format.

Get-Dimension-B-Vector Operation: The get-dimension-B-vector operation returns a vector of elements from input-tensor 2 that is used by the dot-product operation. Processing of the get-dimension-B-vector operation depends on which NNPA-MATMUL function is being performed, as follows:

- NNPA-MATMUL-OP: For a specified output element, a dimension-B vector is selected from input-tensor 2 where the input dimension-4 index is the output dimension-4 index, and the input dimension-3 index is the output dimension-3 index.
- NNPA-MATMUL-OP-BCAST23: For a specified output element, a dimension-B vector is selected from input-tensor 2 where the input dimension-4 index is zero, and the input dimension-3 index is the output dimension-3 index.
- NNPA-MATMUL-OP-BCAST1: For a specified output element, a dimension-B vector is selected from input-tensor 2 where the input dimension-4 index is the output dimension-4 index, and the input dimension-3 index is zero.

When the transposition-control 2 (TC2) in bit 30 of function-specific parameter 2 is not applicable, or when TC2 is applicable and zero, the dimension-1 index of input-tensor 2 is the dimension-1 index of output-tensor 1, and dimension 2 of input-tensor 2 comprises the resulting dimension-B vector. When TC2 is applicable and one, the dimension-2 index of input-tensor 2 is the dimension-1 index of output-tensor 1, and dimension 1 of input-tensor 2 comprises the resulting dimension-B vector.

Programming Notes:

1. The input-vector dimension that is used to produce the results of the get-dimension-A-vector and get-dimension-B-vector operations is referred to as the *common* dimension. The elements from the common dimensions of input-tensors 1 and 2 form the input to the dot-product operation.
2. The a_scale, a_offset, clip_min, and clip_max values (in function-specific parameters 3, 4, 9, and 10, respectively) that may apply to the get-dimension-A-vector operation are not applicable to the get-dimension-B-vector operation.

When the parameter-block-version number is 0, and the specified data-layout-format field in any of the specified tensor descriptors does not contain a value of zero (4D-feature tensor) or if the data-type field in any specified tensor descriptor does not contain a value of zero (NNP-data-type 1) response code 0010 hex or 0011 hex, respectively, is set in general register 0, and the instruction completes with condition code 1. When the parameter-block-version number is 1, and the combination of parameter-block-version number, data-layout formats and data types of each specified tensor descriptor do not match those of an individual row in Figure 26-85 on page 26-107, then response code F001 hex is set in general register 0, and the instruction completes with condition code 1.

All of the following conditions must be true; otherwise, a general-operand data exception is recognized:

- The dimension-4-index size must meet the following function-dependent criteria:
  - NNPA-MATMUL-OP: The dimension-4-index size must be the same in all input tensors and in output-tensor 1.
  - NNPA-MATMUL-OP-BCAST23: The dimension-4-index size of input-tensor 1 output-tensor 1 must be equal, and the dimension-4-index size of input-tensor 2 and input-tensor 3 must be equal to one.
  - NNPA-MATMUL-OP-BCAST1: The dimension-4-index sizes of input-tensor 2, input-tensor 3, and output-tensor 1 must be the same, and the dimension-4-index size of input-tensor 1 must be equal to one.
- The dimension-3-index size of all input tensors and the output-tensor 1 must be equal to one.
- The dimension-2-index size of the input-tensor 3 must be equal to one.
- Dimension-1- and -2-index sizes of all tensors must meet the requirements specified in an

applicable row of Figure 26-88, the applicable row being determined by the transposition controls.

Transposition Control (TC)		Input-Tensor 1		Input-Tensor 2		Input-Tensor 3		Output-Tensor 1	
TC2	**TC1**	**E2**	**E1**	**E2**	**E1**	**E2**	**E1**	**E2**	**E1**
–	**–**	Y	C	C	X	1	X	Y	X
0	**0**	Y	C	C	X	1	X	Y	X
0	**1**	C	Y	C	X	1	X	Y	X
1	**0**	Y	C	X	C	1	X	Y	X
1	**1**	C	Y	X	C	1	X	Y	X

Explanation:

–	When transposition controls are not applicable, the row describes the dimension requirements.
C	The common dimension-index size (C) of input-tensors 1 and 2 must be equal.
E*n*	Dimension-*n*-index size of the specified input tensor.
TCn	When transposition controls are applicable, a row describes the dimension requirements for the combination of TC2 and TC1.
X	The dimension-index size of input-tensor 2 that is not the common dimension must be equal to the dimension-1-index sizes of input-tensor 3 and output-tensor 1.
Y	The dimension-index size of input-tensor 1 that is not the common dimension must be equal to the dimension-2 index size of output-tensor 1.
1	The dimension-2-index size of input-tensor 3 must be one.

Figure 26-88. NNPA-MATMUL Functions: Dimensions 1 and 2 Index-Size Requirements

- When the parameter-block-version number is zero, the data layout and data type of all input tensors and the output-tensor 1 must be the same.
- When function-specific-parameter 4 applies, the value of a_offset must be a numeric value.
- When function-specific-parameters 9 and 10 apply, the clip_min value must be less than the clip_max value.

The output-tensor-descriptor 2, and function-specific-save-area-address fields are ignored. Function-specific-parameters 11 and above and function-specific parameters that are not applicable should contain zeros; otherwise, the program may not operate compatibly in the future.

The order of the arithmetic operations is model dependent and may lead to different results on different models.

Programming Notes:

1. When the parameter-block-version number is zero, response codes F001 and F002 hex cannot occur. When the parameter-block-version number is greater than zero, response codes 0010 and 0011 hex cannot occur.
2. The NNPA-MATMUL-OP-BCAST1 function is not available on all models supporting the NNPA instruction.

Function Code 240: NNPA-TRANSFORM

When the NNPA-TRANSFORM function is specified, the content of input-tensor 1 is transformed into a different data-layout format and data type, and the result of the transformation is stored in output-tensor 1.

Bits 24-31 of function-specific parameter 1 (FSP1) contain an 8-bit unsigned binary integer transformation-operation code (TOC) specifying the type of transformation to be performed. Bit 0 of FSP1 contains a saturation control (SC) that is use by some of the transformation operations. Bits 1-23 of FSP1 are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.

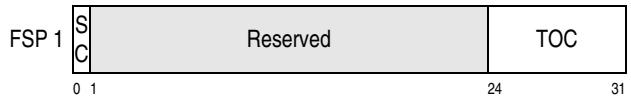


Figure 26-89. NNPA-TRANSFORM Transformation-Operation Code (TOC) and Saturation Control (SC)

Figure 26-90 illustrates each transformation-operation code, the corresponding data-layout format and data type for input-tensor 1, and the resulting data-layout format and data types in output-tensor 1.

TOC		Input Tensor		Output Tensor	
(Dec)	(Hex)	DLF	DT	DLF	DT
2	2	31 (4D-generic tensor)	6 (BFP short format)	0 (4D-feature tensor)	0 (NNP-data-type 1)
6	6	31 (4D-generic tensor)	6 (BFP short format)	0 (4D-feature tensor)	8 (8-bit signed binary integer)
129	81	0 (4D-feature tensor)	0 (NNP-data-type 1)	31 (4D-generic tensor)	6 (BFP short format)

Explanation:

DLF Data-layout format
DT Data type
TOC Transformation-operation code (in function-specific parameter 1)

Figure 26-90. NNPA-TRANSFORM Supported Input and Output Tensor Specifications

The NNPA-TRANSFORM function is available when the parameter-block version number (PBVN) is greater than zero. If the PBVN is zero, response code 0001 hex is set in general register 0, and the instruction completes with condition code 1.

If an unsupported transformation operation code is specified in function-specific parameter 1, then response code F000 hex is set in general register 0 and the instruction completes with condition code 1.

If the data-layout formats specified in the input- and output-tensor descriptors are not supported for the specified transformation operation, then response code 0010 hex is set in general register 0 and the instruction completes with condition code 1. If the data types specified in the input and output tensor descriptors are not supported for the specified transformation operation, then response code 0011 hex is set in general register 0 and the instruction completes with condition code 1.

The shape of input-tensor 1 and the output-tensor 1 must be the same; otherwise, a general-operand data exception is recognized.

The input-tensor-descriptor 2, input-tensor-descriptor 3, and output-tensor-descriptor 2 fields are ignored. For TOCs 2 and 129, function-specific-parameters (FSPs) 2 and above are ignored. For TOC 6, FSPs 6 and above are ignored. For TOCs 2 and 6, the function-specific-save-area-address field is ignored.

NNPA-TRANSFORM TOC 2 Processing: TOC 2 transforms BFP-short-format elements from the generic-format input-tensor 1 into NNP-data-type-1 elements in the data-layout-format-0 output-tensor 1.

When the transformation of an input-tensor-1 element results in a value that exceeds the smallest or largest value that can be represented in the NNP-data-type-1 format of output-tensor 1, the saturation control (SC) in bit position 0 of FSP 1 applies, as follows:

SC	Result
0	The resulting element is a nonnumeric value. The range-violation status flag is set to one.
1	The resulting element contains the smallest or largest value, as appropriate, in the NNP-data-type-1 format. The range-violation status flag is not set.

Regardless of the saturation control, any input-tensor 1 element that is nonnumeric or an infinity results in an output-tensor 1 element that is nonnumeric, and the range-violation status flag is set to one.

NNPA-TRANSFORM TOC 6 Processing: TOC 6 transforms BFP-short-format elements from the generic-format input-tensor 1 into 8-bit signed-binary-integer elements in the data-layout-format 0 output-tensor 1 and provides a means of applying scale, offset, and clip values when forming the resulting elements.

An input-tensor-1 element is first transformed from the BFP-short format into an intermediate value in the NNP-data-type-1 format that is then processed with a scale, offset, and clipping values (described below). When the transformation to the intermediate value results in a value that exceeds the smallest or largest value that can be represented in the NNP-data-type-1 format needed for scaling, the saturation control (SC) in bit position 0 of FSP 1 applies, as follows:

SC	Result
0	The resulting intermediate value is a nonnumeric value. The range-violation status flag is set to one.
1	The resulting intermediate value contains the smallest or largest value, as appropriate, in the NNP-data-type-1 format, and the range-violation status flag is not set based on intermediate computations.

Regardless of the saturation control, the range-violation flag is set to one in general register 0 if any input-tensor-1 element is nonnumeric or infinity; such values result in an intermediate value that is nonnumeric.

Bit positions 16-31 of FSPs 2 and 3 contain the scale and offset values in the NNP-data-type-1 format, and bit positions 24-31 of FSPs 4 and 5 contain the clip_min and clip_max values in the 8-bit signed binary integer format. Bit positions 0-15 of FSPs 2 and 3 and bit positions 0-23 of FSPs 4 and 5 are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future. Figure 26-91 illustrates these function-specific parameters.

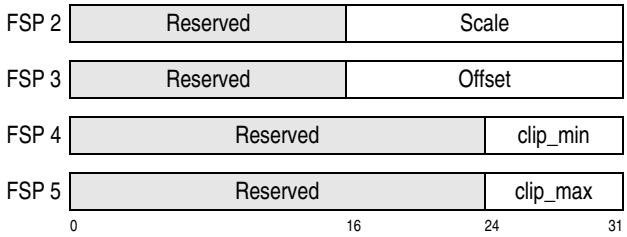

Figure 26-91. NNPA-TRANSFORM TOC 6 Function-Specific Parameters

Each intermediate value is processed according to the following formula, with the result being placed into the corresponding element of output-tensor 1:

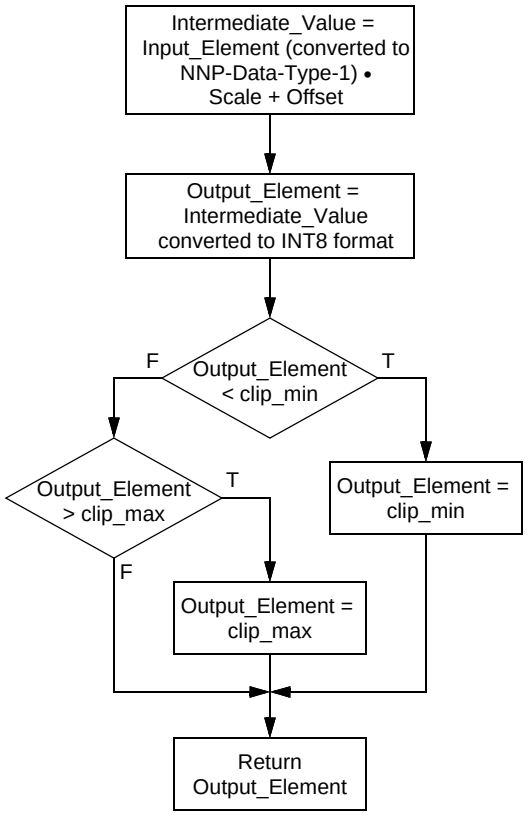
output_element = MIN(clip_max, MAX(intermediate_value • scale + offset, clip_min))

If a range violation is recognized when computing an output element, then the resulting element value is unpredictable.

When TOC 6 is specified, the minimum-clip value in FSP 4 must be less than the maximum-clip value in FSP 5; otherwise, a general-operand data exception is recognized.

When the scale value in FSP2 is zero or a nonnumeric value of either sign, or when the offset value in FSP3 is a nonnumeric value of either sign, response code F001 hex is set in general register 0, and the instruction completes with condition code 1.

Figure 26-92 illustrates the conceptual processing of elements when TOC 6 is specified.



Explanation:

clip_max	Maximum clip value in FSP 5 (INT8 format).
clip_min	Minimum clip value in FSP 4 (INT8 format).
INT8	8-bit signed binary integer.
Offset	Offset value in FSP 3 (NNP data-type-1 format).
Scale	Scaling factor from FSP 2 (NNP data-type-1 format).

Figure 26-92. Transformation of an Element Using TOC 6

Programming Notes:

1. The application of the scale and offset may result in a value that is nonnumeric. In this case, the range-violation status flag is set in general register 0 when the instruction completes with condition code 0.
2. The NNPA-TRANSFORM function is not available on all models supporting the NNPA instruction.

NNPA-TRANSFORM TOC 129 Operation: TOC 129 transforms NNP-data-type-1 elements from the data-layout-format-0 input-tensor 1 into BFP-short-format elements in the generic-format output-tensor 1.

When the transformation-operation code (TOC) is 129, the following applies:

- The saturation control does not apply. Bit position 0 of FSP 1 is reserved and should contain zero; otherwise, the program may not operate compatibly in the future.
- An 8 K-byte function-specific-save area (FSSA) may be used by this function to save intermediate results.
- The FSSA address in the parameter block must designate a 4 K-byte boundary; otherwise, response code 0015 hex is set in general register 0, and the instruction completes with condition code 1.

When the TOC is not 129, a function-specific-save area is not accessed, and no boundary exception condition is recognized.

Function Code 241: NNPA-REDUCE

When the NNPA-REDUCE function is specified, for each of dimensions 4, 3, and 2 of input-tensor 1, the corresponding dimension-1 vector of elements in the tensor are reduced to a single element. The resulting reduced values of a dimension-1 vectors are stored in dimension-1 element 0 of output-tensor 1 having the corresponding dimension 4, 3, and 2 indices as input-tensor 1.

Bits 24-31 of function-specific parameter 1 contain an 8-bit unsigned binary integer specifying which reduction operation (OPERATION) is to be performed, as illustrated in Figure 26-93. Bits 0-23 of function-specific parameter 1 are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.

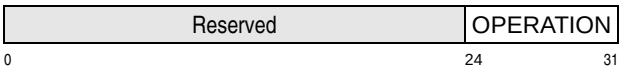


Figure 26-93. NNPA-REDUCE Function-Specific-Parameter 1

Valid OPERATION codes, the resulting reduced values, and resulting data types are illustrated in Figure 26-94.

OPERATION	Reduced Value from Dimension 1 of Input-Tensor 1	DT
0	The value of the minimum element	0
1	Index of the dimension-1 element having the minimum value	10
2	The value of the maximum element	0
3	Index of the dimension-1 element having the maximum value	10

Explanation:

DT	Resulting data type: 0=NNP-data-type-1, 10=32-bit unsigned binary integer.
OPERATION	Reduction operation code in bits 24-31 of function-specific-parameter 1.

Figure 26-94. NNPA-REDUCE OPERATION Codes and Resulting Values

Output-tensor 1 is of the data-layout-format 0, regardless of the OPERATION code. However, for OPERATION codes 0 and 2, the data type of output-tensor 1 is the NNP-data-type 1 (16-bit elements).

For OPERATION codes 1 and 3, the following applies:

- The resulting element indices in output-tensor 1 are 32-bit unsigned binary integers.
- If multiple numeric elements in a dimension-1 vector of input-tensor 1 meet the selection criteria, then the lowest-numbered index meeting the criteria is identified.
- If a nonnumeric element is encountered in a dimension-1 vector of input-tensor 1, then (a) the resulting element in dimension 1 of output-tensor is unpredictable, and (b) the range-violation status flag is set.

The NNPA-REDUCE function is available when the parameter-block version number (PBVN) is greater than zero. If the PBVN is zero, response code 0001 hex is set in general register 0, and the instruction completes with condition code 1.

A response code is set in general register 0, and the instruction completes with condition code 1 when any of the following conditions are true:

- The specified data-layout-format field in any of the specified tensor descriptors does not contain a value of zero (4D-feature tensor). In this case, response code 0010 hex is set.
- The specified data-type field in input-tensor-descriptor 1 does not contain a value of zero (NNP-data-type 1). In this case, response code 0011 hex is set.
- The OPERATION value is not one of those listed in Figure 26-94. In this case, response code F000 hex is set. This condition is tested before the following condition.
- The specified data-type of output-tensor 1 does not correspond to the operation being performed, in which case response code 0011 hex is set. The OPERATION values and corresponding data types are as follows:
  - When the OPERATION value is 0 or 2, the specified data-type field in output-tensor-descriptor 1 must contain a value of 0 (NNP-data-type 1).
  - When the OPERATION value is 1 or 3, the specified data-type field in output-tensor-descriptor 1 must contain a value of 10 (32-bit binary integer).

A general-operand data exception is recognized when any of the following conditions are true:

- The data-layout format of input-tensor 1 and output-tensor 1 are not equal.
- The specified dimension-4-index size, dimension-3-index size, and dimension-2-index size of input-tensor 1 are not the same as the corresponding index sizes of output-tensor 1.
- The specified dimension-1-index size of output-tensor 1 is not 1.

An 8 K-byte function-specific-save area may be used by this function to save intermediate results.

The output-tensor-descriptor 2, input-tensor-descriptor 2, input-tensor-descriptor 3, function-specific-parameters 2 and above are ignored.

Programming Notes:

1. The NNPA-REDUCE function is not available on all models supporting the NNPA instruction.

2. Consider a dimension-1 vector containing the following ten elements:

Value	-8	+0	38	-24	36	3	-14	38	-1	15
Index	0	1	2	3	4	5	6	7	8	9

Figure 26-95 shows the resulting reduced value of this vector for each valid OPERATION code.

OPERATION	Result
0 (minimum)	-24
1 (index to minimum)	3
2 (maximum)	38
3 (index to maximum)	2

Figure 26-95. NNPA-REDUCE Sample Results

NNPA Common Operation

If the CPU is enabled to update counters in the analytics-counter set, then the following apply for all functions other than NNPA-Query:

- Subsequent to completing all operations defined for the specified function code and prior to setting condition code 0, the CPU attempts to access and increment the appropriate counter or counters. Refer to the definition of each counter to determine which counters are due to be incremented.
- When the CPU attempts to increment the appropriate counters other than counter number 27, the AICB is accessible, and the appropriate counters are accessible, the appropriate counters are incremented by one and the instruction ends with setting condition code 0. In this case, multiple counters may be incremented, as appropriate.
- When instruction execution includes completion of processing all inputs defined for the specified function code and the activity-instrumentation-control block (AICB) or an appropriate counter is not accessible, the instruction ends in partial completion and condition code 3 is set.
- When none of the inputs defined for the specified function code require any processing at the beginning of the instruction and the activity-instrumentation-control block (AICB) or an appropriate counter is not accessible, an access exception is recognized for the control block or counter location. When the control block is not accessible, the counter location can not be determined.
- When the AICB is accessible, the analytics-counter block is accessible and attempted execution results in recognizing an access exception for any input tensor, any output tensor, or the function-specific-save area, attempted execution also results in incrementing the analytics-counter number 27 by one.

Refer to Figure 5-19 on page 5-115 for the definitions of analytics-counter numbers 1-21 and 28-36.

The definitions for analytics-counter numbers 22-27 are described below.

Analytics-counter numbers 22-26: The NNPA instruction completed with condition code 0. The analytics counter that is updated depends on the NNPA function, and either the size of an input tensor or the dimension-index sizes of an input or output tensor. Each row of Figure 26-96 designates an analytics counter, and each column illustrates the conditions under which the counter is updated for a particular NNPA function.

Depending on tensor sizes and dimensions, more than one analytics counter may be incremented when the NNPA instruction completes with condition code 0.

Analytics-counter number 27: Attempted execution of NNPA results in recognizing an access exception for any input tensor, any output tensor, or the function-specific-save area. If an access-exception condition also exists concurrently for the AICB or this counter, then the access exception for the input tensor, output tensor or function-specific-save area is recognized without incrementing this counter. If reexecuting the NNPA instruction multiple times is required to reach normal completion of an operation, then this counter can be incremented multiple times throughout the period of reexecuting the instruction

when access exceptions are recognized multiple times.

Analytics-Counter Number	NNPA Function																											
	16 – NNPA-ADD	17 – NNPA-SUB	18 – NNPA-MUL	19 – NNPA-DIV	20 – NNPA-MIN	21 – NNPA-MAX	32 – NNPA-LOG	33 – NNPA-EXP	34 – NNPA-SQRT	35 – NNPA-INVSQRT	49 – NNPA-RELU	50 – NNPA-TANH	51 – NNPA-SIGMOID	52 – NNPA-SOFTMAX	53 – NNPA-GELU	64 – NNPA-BATCHNORM	65 – NNPA-MOMENTS	66 – NNPA-LAYERNORM	67 – NNPA-NORM	80 – NNPA-MAXPOOL2D	81 – NNPA-AVGPOOL2D	96 – NNPA-LSTMACT	97 – NNPA-GRUACT	112 – NNPA-CONVOLUTION	113 – NNPA-MATMUL-OP	114 – NNPA-MATMUL-OP-BCAST23	115 – NNPA-MATMUL-OP-BCAST1	240 – NNPA-TRANSFORM	241 – NNPA-REDUCE
22	a	a	a	a	a	a	a	a	a	a	a	a	a	a	a	a	a	a	a	b	b	a	a	b	c	c	c	a	a
23	a	a	a	a	a	a	a	a	a	a	a	a	a	a	a	a	a	a	a	a	a	a	a	a,b	a,b	a,b	a,b	a	a
24	a	a	a	a	a	a	a	a	a	a	a	a	a	a	a	a	a	a	a	a	a	a	a	a	b	b	b	a	a
25	a	a	a	a	a	a	a	a	a	a	a	a	a	a	a	a	a	a	a	a	a	a	a	a	b	b	b	a	a
26	a	a	a	a	a	a	a	a	a	a	a	a	a	a	a	a	a	a	a	a	a	a	a	a	b	b	b	a	a

Explanation:

22.a Dimension-2-index size for input-tensor 1 is less than 32.
22.b Dimension-4-index size for input-tensor 1 is less than 32.
22.c Dimension-2-index size for output-tensor 1 is less than 32.

23.a When the format-1 parameter block is not installed, the dimension-1, 2, 3, or 4-index size for input-tensor 1 is greater than the quotient of the maximum-dimension index size (MDIS) divided by 4. When the format-1 parameter block is installed, any of dimension-1, 2, 3, or 4-index size for input-tensor 1 is greater than the quotient of the corresponding maximum-dimension-n-index size (MDnIS) value divided by 4. Note, if both 23.a and 23.b are present, then the counter is incremented only once.
23.b When the format-1 parameter block is not installed, the dimension-1 or 2-index size for input-tensor 2 is greater than the quotient of the MDIS divided by 4. When the format-1 parameter block is installed, either the dimension-1 or 2-index size for input-tensor 2 is greater than the quotient of the corresponding MDnIS value divided by 4.

24.a Input-tensor 1 size is less than or equal to 64 K-bytes.
24.b The sum of input-tensor 1 size and input-tensor 2 size is less than or equal to 64 K-bytes.

25.a Input-tensor 1 size is greater than 64 K-bytes and less than or equal to 1 M-byte
25.b The sum of input-tensor 1 size and input-tensor 2 size is greater than 64 K-bytes and less than or equal to 1 M-byte.

26.a Input-tensor 1 size is greater than 1 M-byte and less than or equal to 2 G-bytes
26.b The sum of input-tensor 1 size and input-tensor 2 size is greater than 1 M-byte and less than or equal to 2 G-bytes.

Figure 26-96. Analytics-Counter Numbers 22-26 for NNPA Functions Completing with CC0

Special Conditions

If any output tensor or the function-specific-save area overlaps with any input tensor, the function-specific-save area, or the parameter block, results are unpredictable.

A specification exception is recognized when execution of NEURAL NETWORK PROCESSING ASSIST is attempted and the parameter block is not designated on a doubleword boundary.

A general operand data exception is recognized when execution of NEURAL NETWORK PROCESSING ASSIST is attempted and any of the following applies:

- Tensor descriptors are inconsistent with the specified function.
- NNPA-AVGPOOL2D, NNPA-CONVOLUTION, and NNPA-MAXPOOL2D: The specified padding does not meet the criteria of the specified window size or stride.
- NNPA-CONVOLUTION: The RELU activation function is specified, and the clipping value is negative or a nonnumeric value of either sign.
- NNPA-MOMENTS: The Bessel correction value is one, and the number of elements in dimensions 1-3 is one.
- NNPA-MATMUL Functions: When applicable, the specified minimum clip value is not less than the specified maximum clip value.
- NNPA-RELU: The clip value or the adjustment factor is either negative or a nonnumeric value, or the adjustment factor greater than or equal to 1.0.
- NNPA-TRANSFORM: Transformation-operation code 6 is specified, and the minimum-clip value is not less than the maximum-clip value.

Resulting Condition Code:

0 Normal completion
1 Response code is set
2 --
3 CPU-determined amount of data processed

Program Exceptions:

- Access (fetch, input tensors, activity-instrumentation-control block; fetch and store, parameter block, function-specific-save area, output tensors, analytics counter)
- Data with DXC 0, general operand
- Operation (if the neural network processing assist facility is not installed)
- Specification
- Transaction constraint

The priority of execution for the NEURAL NETWORK PROCESSING ASSIST instruction is shown in Figure 26-42 on page 26-60.

1.-7.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
8.A	Condition code 1 due to an unassigned or uninstalled function code specified.
8.B	Specification exception due to parameter block not designated on doubleword boundary.
9.	Access exceptions for an access to the parameter block.
10.	Condition code 1 due to specified format of the parameter block not supported by the model or by the specified function.
11.	Condition code 1 due to an invalid transformation operation code in function-specific parameter 1 for NNPA-TRANSFORM.
12.A	Condition code 1 due to the specified tensor data layouts are not supported.
12.B	General-operand data exception due to differing data layouts between tensor descriptors.
13.A	Condition code 1 due to conditions other than those included in items 8.A, 10, 11, and 12.A above.
13.B	General-operand data exception due to conditions other than those included in item 12.B.
14.A	Access exceptions for an access to an output tensor.
14.B	Access exceptions for an access to an input tensor.
14.C	Access exceptions for an access to the function-specific-save area.
15.	Condition code 3 due to partial processing of any input defined for the function.
16.	Condition code 3 due to completion of processing all inputs defined for the function and access-exception condition detected for an access to an analytics counter.
17.	Access exceptions for an access to the AICB or an analytics counter and none of the inputs defined for the function require processing.
18.	Condition code 0.

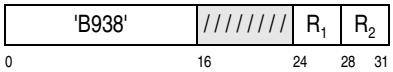
Figure 26-97. Priority of Execution: NNPA

Programming Notes:

1. The performance of the query function (code 0) may be significantly slower than that of simply examining a location in storage. If the program needs to frequently test for the availability of a function, it should perform the query function once during initialization; subsequently it should examine the stored results of the query function in storage with an instruction such as TEST UNDER MASK.
2. Bits 1-7 of the status flags are reserved for future extension and should be set to zero.
3. In-place NNPA operations where an output-tensor buffer and an input-tensor buffer have the same address can produce unpredictable results and must be avoided.

SORT LISTS

SORTL R_1,R_2 [RRE]



SORT LISTS performs functions related to sorting records of data.

SORT LISTS is an unprivileged instruction. It may be executed when the CPU is in the problem or supervisor state.

A function specified by the function code in general register 0 is performed.

Bits 16-23 of the instruction are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.

Bit positions 57-63 of general register 0 contain the function code. Figure 26-98 shows the assigned function codes for SORT LISTS. All other function codes are unassigned.

Code	Function	Parameter Block Size (bytes)
0	SORTL-QAF	32
1	SORTL-SFLR	$(576+16xN_{IS})^{F0}$
2	SORTL-SVLR	$(576+16xN_{IS})^{F0}$

Explanation

F0 Format-0 parameter block (the format is specified in the PBVN field)

N_{IS} Number of input lists, as specified by the Interface Size

Figure 26-98. Function Codes for SORT LISTS

When bits 57-63 of general register 0 designate an unassigned or uninstalled function code, a specification exception is recognized.

Bit 56 of general register 0 specifies a mode of operation (merge mode) which applies to the SORTL-SFLR and SORTL-SVLR functions. For a description of merge mode (MM), refer to section “Function Code 1: SORTL-SFLR (Sort Fixed-Length-Records)” beginning on page 26-123. Bit 56 of general register 0 is ignored when the specified function is SORTL-QAF.

Bit positions 0-31 of general register 0 are ignored. Bit positions 32-55 of general register 0 are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.

The contents of general register 1 specify the logical address of the leftmost byte of the parameter block in storage. The parameter block must be designated on a doubleword boundary; otherwise a specification exception is recognized.

For all functions, the contents of general registers 0 and 1 are not modified.

For all functions, the R_1 field designates an even-odd pair of general registers. For all functions, the R_1 field must not designate general register 0 and must designate an even-numbered register; otherwise, a specification exception is recognized. When the specified function is SORTL-SFLR or SORTL-SVLR, the contents of general register R_1 specify the logical address of the leftmost byte of the first operand and the contents of general register $R_1 + 1$ specify the length of the first operand in bytes. When the specified function is SORTL-SFLR or SORTL-SVLR, the first operand must be designated on a doubleword boundary; otherwise a specification exception is rec-

ognized. Data, in the form of records, is selected from a set of input lists and is stored at the first-operand location. When the SORTL-QAF function is specified, the contents of general registers R_1 and $R_1 + 1$ are ignored.

For all functions, the R_2 field designates an even-odd pair of general registers. For all functions, the R_2 field must not designate general register 0 and must designate an even-numbered register; otherwise, a specification exception is recognized. When the specified function is SORTL-SFLR or SORTL-SVLR, and merge mode (MM) is zero, the contents of general register R_2 specify the logical address of the leftmost byte of the second operand and the contents of general register $R_2 + 1$ specify the length of the second operand in bytes. When the specified function is SORTL-SFLR or SORTL-SVLR, and merge mode (MM) is zero, the second operand must be designated on a doubleword boundary; otherwise a specification exception is recognized. The starting address and length of each output list, referred to as output-list delineations (OLD), are stored at the second-operand location when MM is zero. When the SORTL-QAF function is specified, or MM is one, the contents of general registers R_2 and $R_2 + 1$ are ignored.

As part of the operation when the specified function is SORTL-SFLR or SORTL-SVLR, the following occurs:

- The address in general register R_1 is incremented by the number of bytes stored at the first-operand location, and the length in general register $R_1 + 1$ is decremented by the same number.
- When MM is zero, the address in general register R_2 is incremented by the number of bytes stored at the second-operand location, and the length in general register $R_2 + 1$ is decremented by the same number.

The formation and updating of the addresses and lengths are dependent on the addressing mode.

In the 24-bit addressing mode, the following apply:

- The contents of bit positions 40-63 of general registers 1, R_1, and R_2 constitute the addresses of the parameter block, first operand, and second operand, respectively, and the contents of bit positions 0-39 are ignored.
- Bits 40-63 of the updated first-operand and second-operand addresses replace the corresponding bits in general registers R_1 and R_2, respectively. Carries out of bit position 40 of the updated addresses are ignored, and the contents of bit positions 32-39 of general registers R_1 and R_2 are set to zeros. The contents of bit positions 0-31 of general registers R_1 and R_2 remain unchanged.
- The contents of bit positions 32-63 of general registers $R_1 + 1$ and $R_2 + 1$ form 32-bit unsigned binary integers which specify the number of bytes in the first and second operands, respectively. The contents of bit positions 0-31 of general registers $R_1 + 1$ and $R_2 + 1$ are ignored.
- Bits 32-63 of the updated first-operand and second-operand lengths replace the corresponding bits in general registers $R_1 + 1$ and $R_2 + 1$, respectively. The contents of bit positions 0-31 of general registers $R_1 + 1$ and $R_2 + 1$ remain unchanged.

In the 31-bit addressing mode, the following apply:

- The contents of bit positions 33-63 of general registers 1, R_1, and R_2 constitute the addresses of the parameter block, first operand, and second operand, respectively, and the contents of bit positions 0-32 are ignored.
- Bits 33-63 of the updated first-operand and second-operand addresses replace the corresponding bits in general registers R_1 and R_2, respectively. Carries out of bit position 33 of the updated addresses are ignored, and the content of bit position 32 of general registers R_1 and R_2 is set to zero. The contents of bit positions 0-31 of general registers R_1 and R_2 remain unchanged.
- The contents of bit positions 32-63 of general registers $R_1 + 1$ and $R_2 + 1$ form 32-bit unsigned binary integers which specify the number of bytes in the first and second operands, respectively. The contents of bit positions 0-31 of general registers $R_1 + 1$ and $R_2 + 1$ are ignored.
- Bits 32-63 of the updated first-operand and second-operand lengths replace the corresponding bits in general registers $R_1 + 1$ and $R_2 + 1$, respectively. The contents of bit positions 0-31 of general registers $R_1 + 1$ and $R_2 + 1$ remain unchanged.

In the 64-bit addressing mode, the following apply:

- The contents of bit positions 0-63 of general registers 1, R_1, and R_2 constitute the addresses of the parameter block, first operand, and second operand, respectively.
- Bits 0-63 of the updated first-operand and second-operand addresses replace the correspond-

ing bits in general registers R_1 and R_2, respectively. Carries out of bit position 0 of the updated addresses are ignored.

- The contents of bit positions 0-63 of general registers $R_1 + 1$ and $R_2 + 1$ form 64-bit unsigned binary integers which specify the number of bytes in the first and second operands, respectively.
- Bits 0-63 of the updated first-operand and second-operand lengths replace the corresponding bits in general registers $R_1 + 1$ and $R_2 + 1$, respectively.

In the access-register mode, access registers 1, R_1, and R_2 specify the address spaces containing the parameter block, first operand, and second operand, respectively.

Figure 26-99 on page 26-121 shows the contents of the general registers just described.

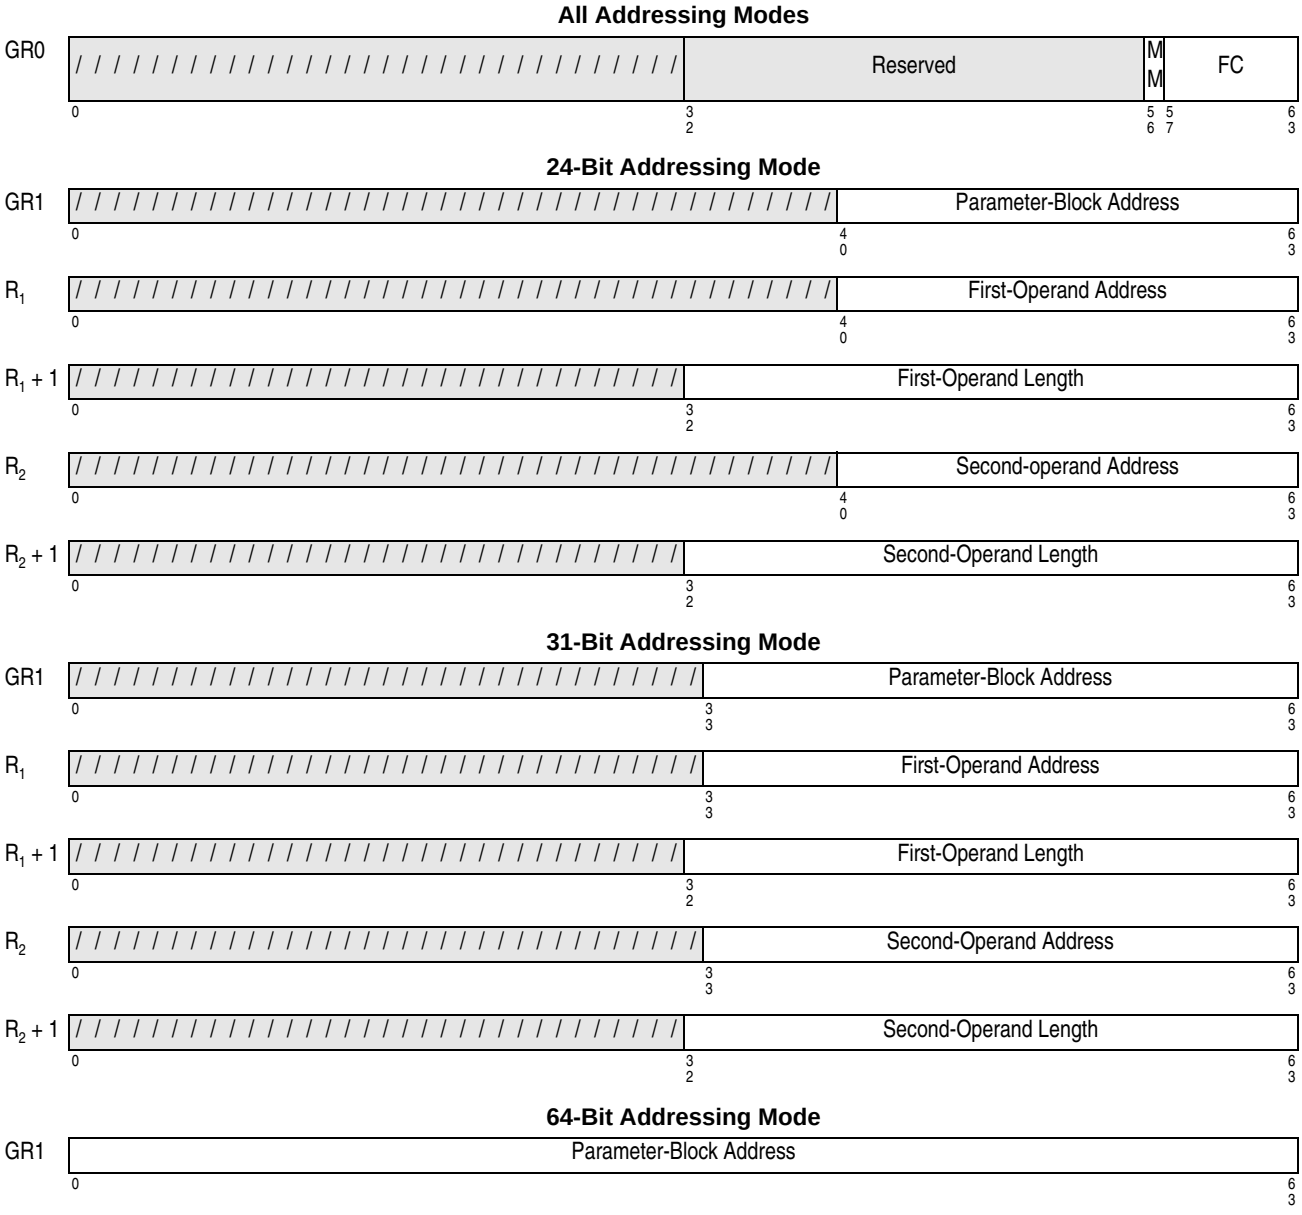


Figure 26-99. General Register Assignments for SORTL (Part 1 of 2)

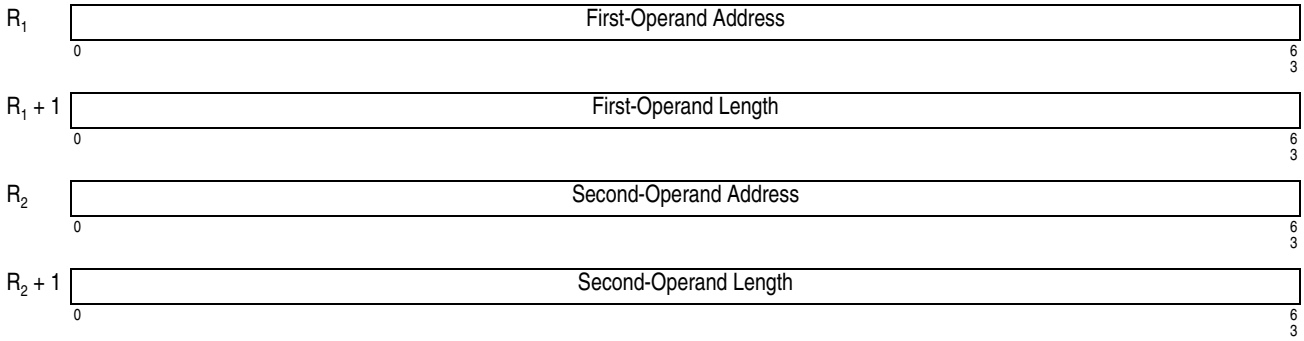


Explanation:

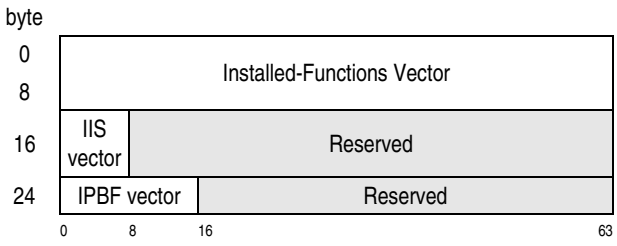
FC Function code.
MM Merge Mode.

Figure 26-99. General Register Assignments for SORTL (Part 2 of 2)

Function Code 0: SORTL-QAF (Query Available Functions)

The SORTL-QAF (query) function provides the means of indicating the availability of all installed functions, installed parameter block formats, and interface sizes available. An interface size is the number of input lists available to the program. The size of the parameter block for the SORT-SFLR and SORT-SVLR functions is proportional to the interface size specified by the program.

The parameter block for the SORTL-QAF function has the following format:



Explanation

IIS Installed-interface-sizes
IPBF Installed-parameter-block-formats

Figure 26-100. Parameter Block for SORTL-QAF

An installed-functions vector, an installed-interface-sizes vector, and an installed-parameter-block-formats vector are stored to bytes 0-15, byte 16, and bytes 24-25, respectively, of the parameter block, as illustrated in Figure 26-100.

Bits 0-127 of the installed-functions vector correspond to function codes 0-127, respectively, of the SORT LISTS instruction. When a bit is one, the corresponding function is installed; otherwise, the function is not installed.

Bits 0-7 of the installed-interface-sizes vector indicate the interface sizes available to the program. An interface size is the number of input lists to be specified by the program for the SORT-SFLR and SORTL-SVLR functions. Bits 0-7 of the installed-interface-sizes vector correspond to the following interface sizes:

bit	interface size
0	reserved
1	reserved
2	32 input lists
3	64 input lists
4	128 input lists
5	reserved
6	reserved
7	reserved

When a bit is one, the corresponding interface size is available to the program. One or more bits may be stored as ones. For example, a value of 00101000 binary indicates interfaces sizes of 32 and 128 input lists are available. Bits 0-1 and 5-7 are reserved and stored as zeros. The interface size of 32 input lists is always available when the enhanced-sort facility is installed. Therefore, bit 2 is always stored as one.

Bits 0-15 of the installed-parameter-block-formats vector correspond to parameter-block formats 0-15, respectively for the SORTL-SFLR and SORTL-SVLR functions. When a bit is one, the corresponding parameter-block format is installed; otherwise, the parameter-block format is not installed.

Zeros are stored to reserved bytes 17-23 and 26-31 of the parameter block.

The contents of general registers R_1, R_2, $R_1 + 1$, and $R_2 + 1$ are ignored by the SORT-QAF function.

A PER storage-alteration event is recognized, when applicable, for the parameter block. A PER zero-address-detection event is recognized, when applicable, for the parameter block.

Condition code 0 is set when execution of the SORTL-QAF function completes; condition codes 1, 2, and 3 are not applicable to the query function.

Function Code 1: SORTL-SFLR (Sort Fixed-Length-Records)

A set of input lists is sorted and stored as a set of output lists at the first-operand location. Each list is a set of records. Each record consists of a fixed-length key and a fixed-length payload, as shown in Figure 26-101 on page 26-123.

Figure 26-101. Fixed-Length-Record format

Records from the input lists are sorted based on the values of the keys. The records may be sorted in ascending, or descending order, as specified in the sort order (SO) field of the parameter block.

An input list is referred to as being presorted in ascending order when the key of each record of the input list is greater than, or equal to, the key of the adjacent record on the left in the same input list. An input list is referred to as being presorted in descending order when the key of each record of the input list is less than, or equal to, the key of the adjacent record on the left in the same input list.

The records of an output list may be sourced from multiple input lists, and are stored in sorted order. The number of output lists stored at the first-operand location depends on the input data. When every active input list is presorted in the same order as specified in the SO field, only one output list is produced.

Bit 56 of general register 0 specifies a mode of operation, referred to as merge mode (MM), which distinguishes whether or not more information related to the results stored at the first-operand location is provided. MM applies to the SORTL-SFLR function.

When merge mode is zero, no active input list is considered presorted. When MM is zero, for each output list stored at the first-operand location, a corresponding output-list delineation (OLD) is stored at the second-operand location. Each OLD consists of an 8-byte OLD-address, which designates the location of the first record in the corresponding output list, followed by an 8-byte OLD-length, which specifies the length, in bytes, of the corresponding output list.

When merge mode is one, every active input list is considered presorted in the same order as specified by the SO field of the parameter block.

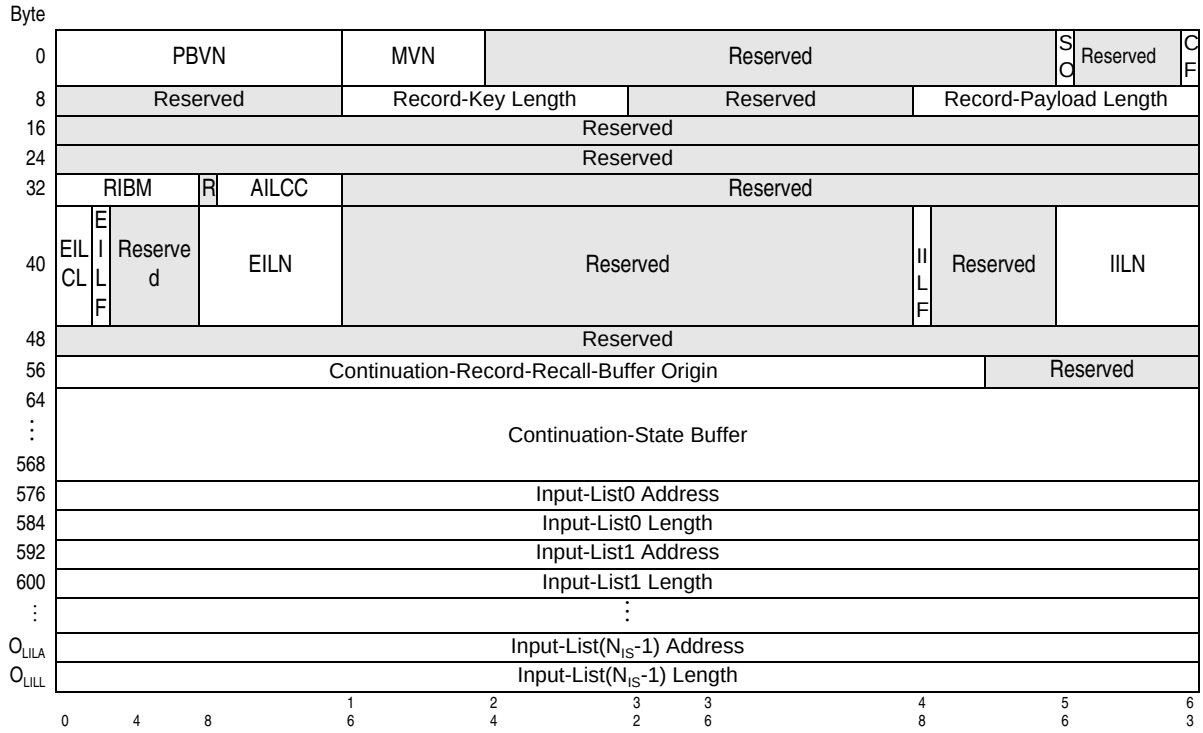
When merge mode is one and every active input list is presorted in the same order as specified by the SO field of the parameter block, the result stored at the first-operand location is a single output list of records in sorted order. When MM is one and any active input list is not presorted in the same order as specified by the SO field of the parameter block, results are unpredictable.

When merge mode is one, the contents of general registers R_2 and $R_2 + 1$ are ignored and no information is stored at the second-operand location. When MM is one, procedures required to distinguish separations between output lists may not be performed, thereby potentially improving the performance of the operation. When MM is one, data is not stored to the continuation-record-recall buffer.

The locations of the operands and addresses used by the SORTL-SFLR function are as shown in Figure 26-99 on page 26-121.

SORTL-SFLR: Parameter Block

The parameter block with format 0 hex for the SORTL-SFLR function is shown in Figure 26-102 on page 26-124. The format is specified in the PBVN field of the parameter block.



Explanation:

AILCC	Active-Input-Lists Count Code
CF	Continuation Flag
EILCL	Empty-Input-Lists Control
EILF	Empty-Input-List Flag
EILN	Empty-Input-List Number
IILF	Incomplete-Input-List Flag
IILN	Incomplete-Input-List Number
MVN	Model-Version Number
N_{IS}	Number of input lists, as specified by the Interface Size
O_{LILA}	Offset of the Last Input List Address: $O_{LILA} = 576 + 16x(N_{IS} - 1)$
O_{LILL}	Offset of the Last Input List Length: $O_{LILL} = 576 + 16x(N_{IS} - 1) + 8$
PBVN	Parameter-Block-Version Number
R	Reserved
RIBM	Reserved for IBM use
SO	Sort Order

Figure 26-102. Parameter Block (format 0 hex) for SORTL-SFLR and SORTL-SVLR

The fields of the format-0 parameter block for the SORTL-SFLR function are defined as follows:

Reserved: As an input to the operation, reserved fields should contain zeros; otherwise, the program may not operate compatibly in the future. When the operation ends, reserved fields may be stored as zeros or may remain unchanged.

Parameter-Block-Version Number (PBVN): Bytes 0-1 of the parameter block specify the version and size of the parameter block. Bits 0-7 of the PBVN have the same format and definition as bits 0-7 of the installed-interface-sizes vector (byte 16) of the parameter block for the SORTL-QAF (query) function. Bits 0-7 specify the number of input lists described in the parameter block, N_{IS}. The size of the format-0 parameter block, in bytes, is determined by evaluating the formula ($576 + 16xN_{IS}$). One and only one bit of bits 0-7 must have a value of one; otherwise a general-operand data exception is recognized. Bits 8-11 of the PBVN are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future. Bits 12-15 of the

PBVN contain an unsigned binary integer specifying the format of the parameter block. The SORTL-QAF function provides the means of indicating the parameter block formats available. When the size or format of the parameter block specified is not supported by the model, a general-operand data exception is recognized. The PBVN is specified by the program and is not modified during the execution of the instruction.

Model-Version Number (MVN): Byte 2 of the parameter block is an unsigned binary integer identifying the model which executed the instruction. The MVN is updated during the execution of the instruction. The value stored in the MVN is model-dependent.

When the continuation flag (CF) is one, the MVN is an input to the operation. When CF is one and the MVN identifies the same model as the model currently executing the instruction, data from the continuation-state buffer (CSB) may be used to resume the operation. When CF is one and the MVN identifies a different model than the model currently executing the instruction, part, or all of the CSB field may be ignored.

The program must not modify the MVN in the event the instruction is to be reexecuted for the purpose of resuming the operation; otherwise results are unpredictable.

Sort Order (SO): Bit 56 of the parameter block, when zero, specifies an ascending sort order, and when one, specifies a descending sort order. When ascending sort order is specified, each record of an output list contains a key that is greater than, or equal to, the key of the adjacent record on the left, in the same output list. When descending sort order is specified, each record of an output list contains a key that is less than, or equal to, the key of the adjacent record on the left, in the same output list. The SO is not updated during the execution of the instruction.

Continuation Flag (CF): Bit 63 of the parameter block, when one, indicates the operation is partially complete and the contents of the continuation-state buffer (CSB), and when merge mode (MM) is zero, the contents of the continuation-record-recall buffer, may be used to resume the operation. It is required for the program to initialize the continuation flag (CF) to zero and not modify CF in the event the instruction is to be reexecuted for the purpose of resuming the operation; otherwise results are unpredictable.

Record-Key Length: Bytes 10-11 of the parameter block contain an unsigned binary integer specifying the size, in bytes, of all keys, in all records processed during the operation. A general-operand data exception is recognized for any of the following conditions:

- A key size of zero bytes is specified.
- A key size which is not a multiple of 8 is specified.
- A key size larger than 4096 bytes is specified.

The record-key length is not updated during the execution of the instruction.

Record-Payload Length: When the SORTL-SFLR function is specified, bytes 14-15 of the parameter block contain an unsigned binary integer specifying the size, in bytes, of all payloads, in all records processed during the operation. A general-operand data exception is recognized for any of the following conditions:

- A payload size which is not a multiple of 8 is specified.
- The sum of the key and payload sizes specified is larger than 4096 bytes.

A payload size of zero is valid.

When the SORTL-SVLR function is specified, the record-payload length field of the parameter block is ignored. The record-payload length is not updated during the execution of the instruction.

Reserved for IBM use (RIBM): Byte 32 of the parameter block is reserved for IBM use and must contain zeros; otherwise results are unpredictable. The RIBM field is not modified during the execution of the instruction.

Active-Input-Lists Count Code (AILCC): Bits 1-7 of byte 33 of the parameter block are a 7-bit unsigned integer that specifies the number of the input list which denotes the boundary between active and inactive input lists. Input lists with list numbers less than or equal to the value of the AILCC field are in the active state. Input lists with list numbers greater than the value of the AILCC field are in the inactive state. The number of input lists in the active state is one more than the value in the AILCC field.

Input lists in the active state participate in the operation. Input lists in the inactive state do not participate in the operation.

When the value of the AILCC field plus one is greater than the number of input lists described in the parameter block, as specified by bits 0-7 of the PBVN field, a general-operand data exception is recognized.

The value specified in the AILCC field does not affect the size of the parameter block. Access exceptions apply to the entire parameter block, regardless of any input list being in the inactive state.

The AILCC is not updated during the execution of the instruction.

Empty-Input-Lists Control (EILCL): When bit 0 of byte 40 of the parameter block is one, the operation ends when the length of input list0 becomes zero during the operation. When bit 0 of byte 40 of the parameter block is zero, the operation continues to proceed when the length of input list0 becomes zero during the operation. When bit 1 of byte 40 of the parameter block is one, the operation ends when the length of an active input list, other than input list0, becomes zero during the operation. When bit 1 of byte 40 of the parameter block is zero, the operation continues to proceed when the length of an active input list, other than input list0, becomes zero during the operation. See programming note 1 for a description of the intended values and uses of the EILCL field.

When the length of an active input list is initially zero before execution of the instruction, the corresponding bit of the EILCL does not apply.

The EILCL is not updated during the execution of the instruction.

The program must not modify the EILCL in the event the instruction is to be reexecuted for the purpose of resuming the operation; otherwise results are unpredictable.

Empty-Input-List Flag (EILF): When the EILCL is 11 binary, and the operation ends due to the updated length of an active input list is equal to zero, and condition code 2 is set, the value of one is stored to bit 2, of byte 40, of the parameter block; otherwise the value of zero is stored to bit 2, of byte 40, of the parameter block. When the EILF contains a value of one, the input list number of the input list which became empty during the operation is placed in the EILN field of the parameter block.

The EILF may be referenced at the beginning of the execution of the instruction when the operation is being resumed. The program must not modify the EILF in the event the instruction is to be reexecuted for the purpose of resuming the operation; otherwise results are unpredictable.

Empty-Input-List Number (EILN): When conditions cause a value of one to be stored in the EILF field, the input list number of the input list which became empty during the operation is stored in byte 41 of the parameter block; otherwise the value of zero is stored in byte 41 of the parameter block.

The EILN is ignored at the beginning of the operation.

Incomplete-Input-List Flag (IILF): When the operation ends as a result of attempting to process an incomplete input list, the value of one is stored to bit 0, of byte 46, of the parameter block; otherwise the value of zero is stored to bit 0, of byte 46, of the parameter block. An active input list is considered to be incomplete when the corresponding input-list length is greater than zero and less than the number of bytes of the record designated by the input-list address. This condition may exist at the beginning of the operation, or may be encountered during the operation. When the IILF contains a value of one, the input list number, of the incomplete input list encountered, is placed in the IILN field of the parameter block.

When the operation ends with setting condition code 2 and the resulting value in the IILF field is zero, the operation ended due to an empty input list. When the operation ends with setting condition code 2 and the resulting value in the IILF field is one, the operation ended due to an incomplete input list.

The IILF may be referenced at the beginning of the execution of the instruction when the operation is being resumed. The program must not modify the IILF in the event the instruction is to be reexecuted for the purpose of resuming the operation; otherwise results are unpredictable.

Incomplete-Input-List Number (IILN): When conditions cause a value of one to be stored in the IILF field, the input list number, of the incomplete input list encountered, is stored in byte 47 of the parameter block; otherwise the value of zero is stored in byte 47 of the parameter block. When multiple input lists are

incomplete, it is model dependent which incomplete input list number is stored to the IILN field.

The IILN is ignored at the beginning of the operation.

Continuation-Record-Recall-Buffer Origin: A 4 K-byte buffer in storage, called the continuation-record-recall buffer, is provided by the program for the CPU to store and reference data between two executions of the same SORT LISTS instruction, in case an operation ends and may be resumed later. Bit 0 of byte 56 through bit 3 of byte 62 of the parameter block specify bits 0-51 of the continuation-record-recall-buffer origin, which is used in the formation of the continuation-record-recall address. The continuation-record-recall address is aligned on a 4 K-byte boundary and is the logical address of the leftmost byte of the continuation-record-recall buffer.

In the 24-bit addressing mode, bits 40-51 of the continuation-record-recall-buffer origin with 12 zeros appended to the right form the continuation-record-recall address. In the 31-bit addressing mode, bits 33-51 of the continuation-record-recall-buffer origin with 12 zeros appended to the right form the continuation-record-recall address. In the 64-bit addressing mode, bits 0-51 of the continuation-record-recall-buffer origin with 12 zeros appended to the right form the continuation-record-recall address.

In the access-register mode, access register 1 specifies the address space containing the continuation-record-recall buffer in storage.

When merge mode (MM) is zero and the operation ends after storing one or more records, the key of the last record stored to the first operand may also be stored to the continuation-record-recall buffer.

When MM is one, the continuation-record-recall-buffer origin is ignored.

The continuation-record-recall-buffer origin is not modified during the execution of the instruction.

The program must not modify the continuation-record-recall-buffer origin in the event the instruction is to be reexecuted for the purpose of resuming the operation; otherwise results are unpredictable.

Continuation-State Buffer (CSB): When conditions cause a value of one to be stored in the CF field, internal-state data is stored to bytes 64-575 of the parameter block; otherwise bytes 64-575 of the parameter block are undefined and may be modified. The internal-state data stored is model-dependent and may be used subsequently to resume the operation when the instruction is reexecuted. The program must not modify the continuation-state buffer in the event the instruction is to be reexecuted for the purpose of resuming the operation; otherwise results are unpredictable.

Input-ListN Address: The parameter block defines multiple input lists. The number of input lists defined in the parameter block, N_{IS}, is specified by bits 0-7 of the PBVN. The input lists are numbered from zero to (N_{IS}-1). For each input list, the parameter block specifies an 8 byte input-list address. For input list number N, the contents of bytes 576 + 16xN through 583 + 16xN, of the format-0 parameter block, specify the logical address of the leftmost byte of input list number N in storage.

Each input-list address corresponding to an input list in the active state, as specified by the AILCC field, is an input to the operation and is updated by the operation. Each input-list address corresponding to an input list in the inactive state, as specified by the AILCC field, is ignored by the operation.

When an input-list address is an input to the operation, the following applies:

- In 24-bit addressing mode, bits 40-63, of the input-list address, designate the location of the leftmost byte of the input list in storage, and the contents of bits 0-39, of the input-list address are treated as zeros.
- In 31-bit addressing mode, bits 33-63, of the input-list address, designate the location of the leftmost byte of the input list in storage, and the contents of bits 0-32, of the input-list address are treated as zeros.
- In 64-bit addressing mode, bits 0-63, of the input-list address, designate the location of the leftmost byte of the input list in storage.

In the access-register mode, access register 1 specifies the address space containing all active input lists in storage.

For all input lists in the active state, the corresponding input-list address must be designated on a doubleword boundary; otherwise, a general-operand data exception is recognized.

When an input-list address is updated by the operation, the following applies:

- When one or more records of the input list have been processed as part of the operation, the corresponding input-list address is incremented by the number of bytes which the processed records occupy in storage. The formation and updating of the input-list address are dependent on the addressing mode.
- In 24-bit addressing mode, bits 40-63 of the updated input-list address replace the corresponding bits in the input-list address field of the parameter block, a carry out of bit position 40 of the updated input-list address is ignored, and the contents of bit positions 0-39 of the input-list address field of the parameter block are set to zeros.
- In 31-bit addressing mode, bits 33-63 of the updated input-list address replace the corresponding bits in the input-list address field of the parameter block, a carry out of bit position 33 of the updated input-list address is ignored, and the contents of bit positions 0-32 of the input-list address field of the parameter block are set to zeros.
- In 64-bit addressing mode, bits 0-63 of the updated input-list address replace the corresponding bits in the input-list address field of the parameter block, and a carry out of bit position 0 of the updated input-list address is ignored.

In 24- and 31-bit addressing modes, when the execution of the instruction ends and the instruction is not suppressed, nullified, or terminated, each 64-bit input-list address corresponding to an active input list is updated, even when the address is not incremented.

Input-ListN Length: For each input list, the parameter block specifies an 8 byte input-list length. For input list number N, bytes 584 + 16xN through 591 + 16xN, of the parameter block, contain an unsigned integer which specifies the number of bytes in input list number N.

Each input-list length corresponding to an input list in the active state, as specified by the AILCC field, is an input to the operation and is updated by the operation. Each input-list length corresponding to an input list in the inactive state, as specified by the AILCC field, is ignored by the operation.

In all addressing modes, the contents of bit positions 0-63 of an input-list length field specify the length of the corresponding input list.

When one or more records of an input list have been processed as part of the operation, the corresponding input-list length is decremented by the number of bytes which the processed records occupy in storage. In all addressing modes, bits 0-63 of an updated input-list length replace bits 0-63 in the corresponding input-list length field of the parameter block.

SORTL-SFLR: Ending Conditions

Normal completion occurs when all records from all active input lists have been sorted and stored to the first operand.

When the operation ends due to normal completion, the following occurs:

- The address and length in general registers R_1 and $R_1 + 1$, respectively, are updated.
- The address and length in general registers R_2 and $R_2 + 1$, respectively, are updated when MM is zero.
- The input-listN address and input-listN length fields are updated for all input lists in the active state.
- The model-version number is set.
- The continuation flag is set to zero.
- The empty-input-list flag (EILF) is set to zero.
- The empty-input-list number is set to zero.
- The incomplete-input-list flag (IILF) is set to zero.
- The incomplete-input-list number is set to zero.
- Condition code 0 is set.

The formation and updating of the addresses and lengths are dependent on the addressing mode.

When normal completion occurs, the CSB field of the parameter block is undefined after the operation ends.

When a CPU-determined number of bytes have been processed, the operation ends and the following occurs:

- The address and length in general registers R_1 and $R_1 + 1$, respectively, are updated.
- The address and length in general registers R_2 and $R_2 + 1$, respectively, are updated when MM is zero.
- The input-listN address and input-listN length fields are updated for all input lists in the active state.
- The model-version number is set.
- The continuation flag is set to one.

- A key value is stored to the continuation-record-recall buffer when MM is zero and one or more records have been placed at the first-operand location during the execution of the instruction.
- The continuation-state buffer is updated.
- The empty-input-list flag (EILF) is set to zero.
- The empty-input-list number is set to zero.
- The incomplete-input-list flag (IILF) is set to zero.
- The incomplete-input-list number is set to zero.
- Condition code 3 is set.

The formation and updating of the addresses and lengths are dependent on the addressing mode.

The CPU-determined number of bytes depends on the model, and may be a different number each time the instruction is executed. The CPU-determined number of bytes is typically nonzero. Although this number may be zero and appear as a no-progress case, the CPU protects against endless recurrence of this no-progress case.

Subsequent to the instruction ending with condition code 3 set, it is expected the program does not modify any input or output specification for the instruction and branches back to reexecute the instruction to resume the operation.

When bit 0 of the empty-input-lists control (EILCL) is one and the length of input list0 becomes zero during the operation and normal completion does not apply, the operation ends and the following occurs:

- The address and length in general registers R_1 and $R_1 + 1$, respectively, are updated.
- The address and length in general registers R_2 and $R_2 + 1$, respectively, are updated when MM is zero.
- The input-listN address and input-listN length fields are updated for all input lists in the active state.
- The model-version number is set.
- The continuation flag is set to one.
- A key value may be stored to the continuation-record-recall buffer when EILCL is 10 binary and MM is zero. A key value is stored to the continuation-record-recall buffer when EILCL is 11 binary and MM is zero. In either case, one or more records have been placed at the first-operand location during the execution of the instruction.
- The continuation-state buffer is updated.
- The empty-input-list flag is set (refer to Figure 26-103).
- The empty-input-list number is set (refer to Figure 26-103).
- The incomplete-input-list flag is set to zero.
- The incomplete-input-list number is set to zero.
- Condition code 2 is set.

The formation and updating of the addresses and lengths are dependent on the addressing mode.

When bit 1 of the empty-input-lists control (EILCL) is one and the length of an active input list, other than input list0, becomes zero during the operation and normal completion does not apply, the operation ends and the following occurs:

- The address and length in general registers R_1 and $R_1 + 1$, respectively, are updated.
- The address and length in general registers R_2 and $R_2 + 1$, respectively, are updated when MM is zero.
- The input-listN address and input-listN length fields are updated for all input lists in the active state.
- The model-version number is set.
- The continuation flag is set to one.
- A key value may be stored to the continuation-record-recall buffer when EILCL is 01 binary and MM is zero. A key value is stored to the continuation-record-recall buffer when EILCL is 11 binary and MM is zero. In either case, one or more records have been placed at the first-operand location during the execution of the instruction.
- The continuation-state buffer is updated.
- The empty-input-list flag is set (refer to Figure 26-103).
- The empty-input-list number is set (refer to Figure 26-103).
- The incomplete-input-list flag is set to zero.
- The incomplete-input-list number is set to zero.
- Condition code 2 is set.

The formation and updating of the addresses and lengths are dependent on the addressing mode.

When an incomplete input list in the active state is encountered, the operation ends and the following occurs:

- The address and length in general registers R_1 and $R_1 + 1$, respectively, are updated.
- The address and length in general registers R_2 and $R_2 + 1$, respectively, are updated when MM is zero.

- The input-listN address and input-listN length fields are updated for all input lists in the active state.
- The model-version number is set.
- The continuation flag is set to one.
- A key value is stored to the continuation-record-recall buffer when MM is zero and one or more records have been placed at the first-operand location during the execution of the instruction.
- The continuation-state buffer is updated.
- The empty-input-list flag (EILF) is set to zero.
- The empty-input-list number is set to zero.
- The incomplete-input-list flag (IILF) is set to one.
- The input-list number of the incomplete input list encountered is placed in the incomplete-input-list number (IILN) field of the parameter block.
- Condition code 2 is set.

The formation and updating of the addresses and lengths are dependent on the addressing mode.

When the length of the first operand is insufficient to store another record, the operation ends and the following occurs:

- The address and length in general registers R_1 and $R_1 + 1$, respectively, are updated.
- The address and length in general registers R_2 and $R_2 + 1$, respectively, are updated when MM is zero.
- The input-listN address and input-listN length fields are updated for all input lists in the active state.
- The model-version number is set.
- The continuation flag is set to one.
- A key value may be stored to the continuation-record-recall buffer when MM is zero and one or more records have been placed at the first-operand location during the execution of the instruction.
- The continuation-state buffer is updated.
- The empty-input-list flag is set to zero.
- The empty-input-list number is set to zero.
- The incomplete-input-list flag is set to zero.
- The incomplete-input-list number is set to zero.
- Condition code 1 is set.

The formation and updating of the addresses and lengths are dependent on the addressing mode.

When merge mode (MM) is zero and the length of the second operand is less than 16, the operation ends and the following occurs:

- The address and length in general registers R_1 and $R_1 + 1$, respectively, are updated.
- The address and length in general registers R_2 and $R_2 + 1$, respectively, are updated.
- The input-listN address and input-listN length fields are updated for all input lists in the active state.
- The model-version number is set.
- The continuation flag is set to one.
- A key value may be stored to the continuation-record-recall buffer when one or more records have been placed at the first-operand location during the execution of the instruction.
- The continuation-state buffer is updated.
- The empty-input-list flag is set to zero.
- The empty-input-list number is set to zero.
- The incomplete-input-list flag is set to zero.
- The incomplete-input-list number is set to zero.
- Condition code 1 is set.

The formation and updating of the addresses and lengths are dependent on the addressing mode.

EILCL (binary)	condition causing operation to end	results				
		CC	IILF	IILN	EILF	EILN
—	normal completion	0	0	0	0	0
—	first or second operand length is insufficient	1	0	0	0	0
—	IL0 determined to be incomplete	2	1	0 (IL0)	0	0
—	ILN determined to be incomplete	2	1	N (ILN)	0	0
10	IL0 became empty (ILN may also be empty)	2	0	0	0	0
01	ILN became empty (IL0 may also be empty)	2	0	0	0	0
11	IL0 became empty (only one input list became empty)	2	0	0	1	0 (IL0)
11	ILN became empty (only one input list became empty)	2	0	0	1	N (ILN)
—	CPU-determined number of bytes processed	3	0	0	0	0

Explanation:

—	any value
IL0	input list with list number 0
ILN	input list with list number N, where N > 0

Figure 26-103. SORTL Parameter Block Fields IILF, IILN, EILF, and EILN when operation ends

The operation ending condition is called partial completion when the execution of the instruction ends in completion (does not end in suppression, nullification, or termination) and normal completion does not occur.

A PER storage-alteration event is recognized, when applicable, for the following:

- Stores to the parameter block, as described below.
- Stores to the first-operand location.
- Stores to the second-operand location.
- Stores to the continuation-record-recall buffer.

When the entire parameter block lies within the PER storage-area designation, a PER storage-alteration event is recognized, when applicable, for the parameter block. When only a portion of the parameter block lies within the PER storage-area designation, it is model-dependent which of the following occurs:

- A PER storage-alteration event is recognized, when applicable, for the entire parameter block.
- A PER storage-alteration event is recognized, when applicable, for the portion of the parameter block that is stored.

When a PER storage-alteration event is recognized, fewer than 4K additional bytes are stored to the operand location which lies within the designated PER storage-area, before the event is reported.

A PER zero-address-detection event is recognized, when applicable, for the parameter block, first-operand location, and second-operand location. Zero-address detection does not apply to the input list addresses and the continuation-record-recall-buffer origin, which are specified in the parameter block.

As part of the operation when merge mode is zero or one, the input-list addresses and lengths for all input lists in the active state are updated. For each input-list in the active state, the input-list address is incremented by the number of bytes of all records from the input list which were selected and placed at the first-operand location during the operation, and the input-list length is decremented by the same number. The formation and updating of the input-list addresses are dependent on the addressing mode.

As the operation proceeds, an incomplete input list may be encountered. An incomplete input list is recognized during a unit of operation which attempts to reference a record from an input list which is incomplete. Multiple units of operation may be completed prior to recognizing an incomplete input list. This applies when merge mode is zero or one.

As the operation proceeds, an access exception for an access to an active input list, the first operand, or the second operand, when applicable, may be encountered. An access exception is recognized during a unit of operation which attempts to access a storage location and an access exception exists for

that location. Multiple units of operation may be completed prior to recognizing an access exception. This applies when merge mode is zero or one. Refer to Figure 26-111 on page 26-142 to determine which access-exception condition is recognized when multiple conditions exist concurrently.

When the operation ends with partial completion, internal-state data, which may include a history of prior comparisons between records, is stored to the continuation-state buffer (CSB) field of the parameter block. Subsequently, when the instruction is reexecuted, for the purpose of resuming the operation, the contents of the CSB may be loaded into the CPU and the history may be referenced when the operation resumes. This applies when merge mode is zero or one.

Refer to section “Other Conditions”, beginning on page 26-140, for descriptions of other conditions that apply to the SORTL-SFLR function.

SORTL-SFLR: Processing

The SORTL-SFLR function consists of selecting records from a set of input lists, in the sort order specified, and placing the selected records at the first-operand location. As the operation proceeds, current values for the first-operand address and addresses for all active input lists are maintained. The function proceeds in units of operation. During each unit of operation, for each active input list, the key designated by the corresponding current input-list address is examined and one record is placed at the first-operand location.

The SORTL-SFLR function includes multiple comparisons between keys of records from different input lists. When comparing keys, the following applies:

- Keys are treated as unsigned-binary integers, also referred to as unstructured data.
- When comparing keys of equal value, the key from the input list with the highest input-list number is selected to be in sort order before other keys with the same value. In this case, the corresponding record from the input list with the highest input-list number is stored to the first operand before other records with the same key value. This applies for ascending and descending sort orders.

When merge mode (MM) is zero, the active input lists designate lists, each of which is treated as containing records, from left to right, in random order. When MM is zero, the records stored to the first-operand location constitute one or more output lists, and the starting address and length of each output list is stored to the second-operand location. When MM is zero, each unit of operation consists of the following steps, in the order specified:

1. Determine if the next record to store to the first-operand location may be included in the most recent output list (the output list which includes the record most recently stored to the first-operand location), as follows:

   - When the continuation flag (CF) is zero and the first unit of operation is being processed, no records have been stored to the first-operand location, and the next record to store will be the first record of an output list.
   - When CF is one, the prior execution of the instruction ended with condition code 1, and the first unit of operation is being processed for the current execution of the instruction, the next record to store will be the first record of an output list.
   - When CF is one, IILF is zero, EILF is zero, the prior execution of the instruction ended with condition code 2, and the first unit of operation is being processed for the current execution of the instruction, the next record to store will be the first record of an output list.
   - When CF is one, IILF or EILF is one, the prior execution of the instruction ended with condition code 2, and the first unit of operation is being processed for the current execution of the instruction, the next record to store may be included in the most recent output list.
   - When CF is one, the prior execution of the instruction ended with condition code 3, and the first unit of operation is being processed for the current execution of the instruction, the next record to store may be included in the most recent output list.
   - When the unit of operation being processed is not the first unit of operation for the current execution of the instruction, the next record to store may be included in the most recent output list.

   Note: The CPU stores the presence or absence of certain conditions to the continuation-state buffer when the execution of the instruction ends

with partially completing an operation. The CPU references this information when the operation is subsequently resumed.

2. When the next record to store may be included in the most recent output list, determine the set of records which qualify to be included in the most recent output list. For each input list which is active, not empty and not incomplete, compare the key of the record designated by the current input-list address (current input key) to the key of the record most recently stored to the first-operand location (previously stored key). For this purpose, the reference to the previously stored key is not a reference to the first-operand location. Instead, it is a reference to the input list from which the key was previously selected, or it is a reference to the continuation-record-recall buffer. It is a reference to the continuation-record-recall buffer when the operation is being resumed and the current execution of the instruction has not yet placed any records at the first-operand location.

   When the sort order is ascending and the value of the current input key is greater than or equal to the value of the previously stored key, consider the current input key as belonging to a set of keys qualifying for inclusion in the most recent output list. When the sort order is descending and the value of the current input key is less than or equal to the value of the previously stored key, consider the current input key as belonging to a set of keys qualifying for inclusion in the most recent output list. When the number of keys in the set of keys qualifying for inclusion in the most recent output list is zero, the next record to store will be the first record of an output list. When the number of keys in the set of keys qualifying for inclusion in the most recent output list is nonzero, the next record to store will be included in the most recent output list.

3. When the next record to store will be included in the most recent output list, compare all keys in the set of keys qualifying for inclusion in the most recent output list. When the sort order is ascending, select the smallest key value and corresponding record. When the sort order is descending, select the largest key value and corresponding record. Refer to page 26-132 for the result of comparing keys of equal value.

4. When the next record to store will be the first record of an output list, compare the keys of the records designated by all current input-list addresses corresponding to input lists which are active, not empty, and not incomplete. When the sort order is ascending, select the smallest key value and corresponding record. When the sort order is descending, select the largest key value and corresponding record.

5. The selected record is placed at the current first-operand location.

6. The current first-operand address is incremented by the number of bytes equal to the length of the selected record.

7. The current input-list address, corresponding to the input list containing the selected record, is incremented by the number of bytes equal to the length of the selected record.

As part of the operation when merge mode is zero, for each output list stored at the first-operand location, a corresponding output-list delineation (OLD) is stored at the second-operand location. Each OLD consists of an 8-byte OLD-address, which designates the location of the first record in the corresponding output list, followed by an 8-byte OLD-length, which specifies the length, in bytes, of the corresponding output list. When the operation ends with condition code 3, or condition code 2 and EILF equal to one, or condition code 2 and IILF equal to one, the most recent output list being processed at the end of the operation may be partially processed and not completely processed. That is, the number of records in the partially processed output list is an intermediate value and may be increased when the operation resumes. In this case, an output-list delineation (OLD), corresponding to the partially processed output list, is not placed at the second-operand location, until after the operation is resumed and the output list is completely processed.

When merge mode is zero and the operation ends after storing one or more records and normal completion does not occur, the key of the last record stored to the first-operand location is also stored to the continuation-record-recall buffer in the cases described in the definition of the continuation-record-recall-buffer origin on page 26-127.

When merge mode is zero and the operation ends due to normal completion, one or more output lists have been placed at the first-operand location and output-list delineations have been placed at the second-operand location. The program may use output-

list delineations as input-list address and length values in a parameter block for a subsequent SORTL operation.

Figure 26-104 on page 26-134 illustrates the first and second operands, before and after executing SORTL-SFLR with merge mode equal zero.

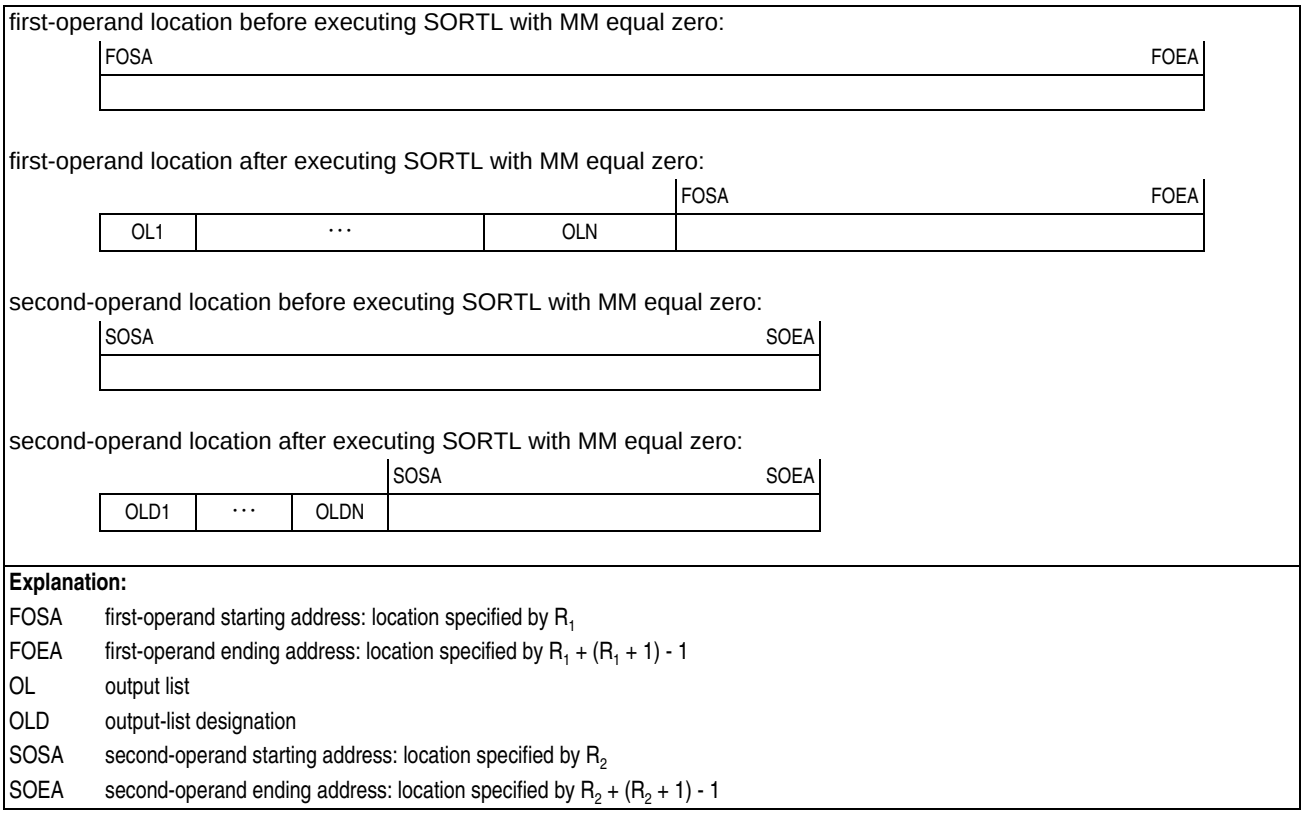


Figure 26-104. First and second operands before and after executing SORTL with MM equal zero

When merge mode (MM) is one, the active input lists designate lists, each of which is treated as containing records, from left to right, in the sorted order, as specified by the SO field of the parameter block. When MM is one, the records stored to the first-operand location constitute a single output list. When MM is one, each unit of operation consists of the following steps, in the order specified:

1. Compare the keys of the records designated by all current input-list addresses corresponding to input lists which are active, not empty, and not incomplete. When the sort order is ascending, select the smallest key value and corresponding record. When the sort order is descending, select the largest key value and corresponding record. Refer to page 26-132 for the result of comparing keys of equal value.
2. The selected record is placed at the current first-operand location.
3. The current first-operand address is incremented by the number of bytes equal to the length of the selected record.
4. The current input-list address, corresponding to the input list containing the selected record, is incremented by the number of bytes equal to the length of the selected record.

Figure 26-105 on page 26-135 illustrates the first operand, before and after executing SORTL-SFLR with merge mode equal one.

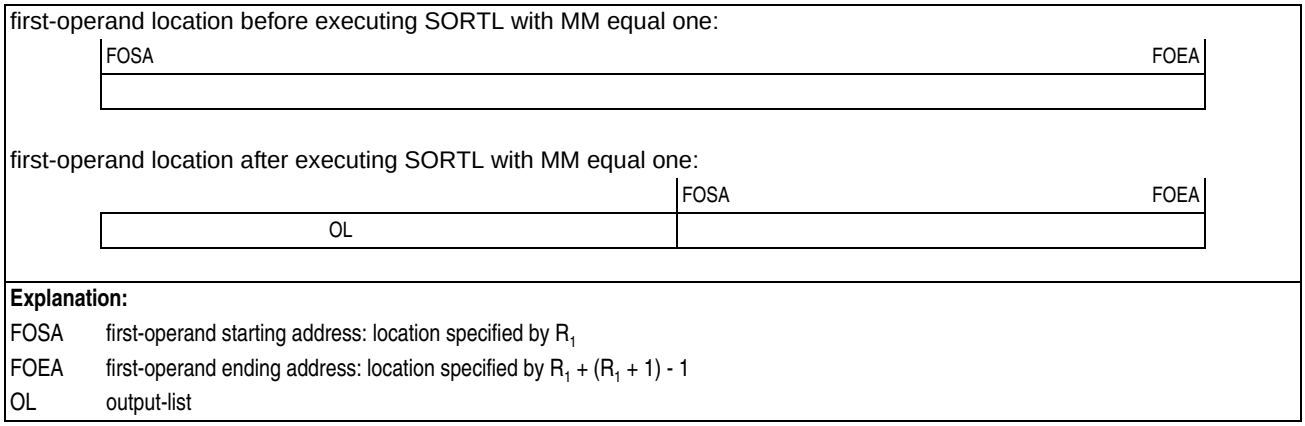

Figure 26-105. First operand before and after executing SORTL with MM equal one

SORTL-SFLR: Resuming an Operation

When the instruction ends with condition code 1, the program may modify the first-operand address, first-operand length, second-operand address, second-operand length, any active input-list address, and any active-input list length, as appropriate, and subsequently, resume the operation.

When the instruction ends with condition code 2, IILF equal zero, and EILF equal zero, the program may modify the first-operand address, first-operand length, second-operand address, second-operand length, any active input-list address, and any active-input list length, as appropriate, and subsequently, resume the operation.

When the instruction ends with condition code 2 and EILF equal one, the program may modify the input-list address and length for the input list specified by the EILN, as appropriate, and subsequently, resume the operation. In this case, the program may also modify the first-operand address and first-operand length when merge mode (MM) is one.

When the instruction ends with condition code 2 and IILF equal one, the program may modify the input-list address and length for the input list specified by the IILN, as appropriate, and subsequently, resume the operation. In this case, the program may also modify the first-operand address and first-operand length when merge mode (MM) is one.

When the instruction ends with condition code 3, and before reexecuting the instruction to resume the operation, if the program modifies any active input-list address or length, the first-operand address or length, or the second-operand address or length, results are unpredictable.

Figure 26-106 on page 26-136 summarizes the original and final values for inputs to a SORTL-SFLR function that ends in partial completion and which inputs may be modified by the program prior to resuming the operation. It is not required, and is not expected, for the program to modify the parameter block between ending the operation with condition code 3 set and branching back to the instruction, to reexecute the instruction, for the purpose of resuming the operation.

Input to SORTL-SFLR	Before the operation	After partially completing the operation (CC=1, 2, or 3)	Before resuming the operation	After completing the operation (CC=0)
parameter-block-version number	program's choice	unchanged	same as before BO	unchanged

2028	20

Explanation:

sort order	ascending
record-key length	8 bytes
record-payload length	0 bytes
00...37	8 bytes with most significant 7 bytes being zero and least significant byte containing value 37

Figure 26-108. SORTL-SFLR Example with 3 input lists

When two operations perform the same SORTL-SFLR function with merge mode equal zero on the same set of unsorted input records and the only difference between the two operations is the number of input lists used to specify the input data, the operation with the larger number of input lists typically results in a smaller number of output lists. Figure 26-109 on page 26-139 illustrates an example of using 6 input lists to operate on the same input data as the example in Figure 26-108 on page 26-138, which only uses 3 input lists.

Byte (hex)	input list0	input list1	input list2	input list3	input list4	input list5
0	00...05	00...10	00...99	00...17	00...02	00...88

00...37	8 bytes with most significant 7 bytes being zero and least significant byte containing value 37

Figure 26-109. SORTL-SFLR Example with 6 input lists

For a suggested procedure to generate a single list of records in sorted order from a set of records in random order, refer to programming note 1 on page 26-142.

Function Code 2: SORTL-SVLR (Sort Variable-Length-Records)

The SORTL-SVLR function operates the same as the SORTL-SFLR function, except for the following:

- All records consist of a fixed-length key, an 8-byte payload length, and a variable-length payload, as shown in Figure 26-110 on page 26-140. Therefore, all records have a variable length.
- Bytes 14-15 of the parameter block for the SORTL-SVLR function are ignored.
- The least significant 2 bytes of the payload-length field of each record contains an unsigned binary integer specifying the length, in bytes, of the payload in the same record. A payload length of zero is valid. The payload length must be a multiple of 8; otherwise a general-operand data exception is recognized. The most significant 6 bytes of the payload-length field are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future. The sum of the key length, eight, and the payload length must not be larger than 4096; otherwise a general-operand data exception is recognized. When a general-operand data exception is recognized as a result of an inappropriate payload length, the input-list address corresponding to the active input list encountering the exception specifies the logical address of the leftmost byte of the errant record. When a variable-length record is stored to the first-operand location, the reserved bytes of the payload-length field are not modified.
- An incomplete input list may not be recognized during a unit of operation which only attempts to reference the key of a record from an input list with an input-list length greater than the key size and less than the record size. In this case, the incomplete input list will be recognized when

attempting to store the record from the incomplete input list, to the first-operand location.

Explanation

PL Payload Length

Figure 26-110. Variable-Length-Record format

The parameter block for the SORTL-SVLR function is the same as the parameter block for the SORTL-SFLR function, except for bytes 14-15, as indicated above.

Refer to section “Other Conditions”, beginning on page 26-140, for descriptions of other conditions that apply to the SORTL-SVLR function.

Special Conditions

A specification exception is recognized when execution of SORT LISTS is attempted and any of the following applies:

- Bits 57-63 of general register 0 designate an unassigned or uninstalled function code.
- The R_1 field designates an odd-numbered register or general register 0.
- The R_2 field designates an odd-numbered register or general register 0. This applies when merge mode (MM) is zero or one.
- The parameter block is not designated on a doubleword boundary.
- The SORTL-SFLR function or the SORTL-SVLR function is specified and the first operand is not designated on a doubleword boundary.
- The SORTL-SFLR or SORTL-SVLR function is specified and the second operand is not designated on a doubleword boundary when MM is zero.

A general-operand data exception is recognized when execution of SORT LISTS is attempted and any of the following applies:

- The SORTL-SFLR or SORT-SVLR function is specified and no bits, or multiple bits, of bits 0-7 of the parameter-block-version number, contain a value of one.
- The SORTL-SFLR or SORTL-SVLR function is specified and the size or format of the parameter block, as specified by the parameter-block-version number, is not supported by the model.
- The SORTL-SFLR or SORTL-SVLR function is specified and the record-key length specifies a key size of zero, a key size which is not a multiple of 8, or a key size greater than 4096.
- The SORTL-SFLR function is specified and the record-payload length in the parameter block specifies a payload size which is not a multiple of 8, or a payload size, when added to the key size, is greater than 4096.
- The SORTL-SVLR function is specified and the record-payload length in the variable-length record specifies a payload size which is not a multiple of 8, or a payload size, when added to the key size, is greater than 4088, in which case it is model dependent whether the operation is suppressed or terminated.
- The SORTL-SFLR or SORTL-SVLR function is specified and the value of the active-input-lists count code (AILCC) plus one is greater than the number of input lists described by the parameter block.
- The SORTL-SFLR or SORTL-SVLR function is specified and an input-list address, corresponding to an active input list, is not designated on a doubleword boundary.

When a general-operand data exception is recognized, the operation is suppressed, except as described above.

Other Conditions

Execution of the instruction ends after processing a CPU-determined number of bytes. This permits interruptions to occur. When the instruction ends with partial completion, the addresses in general registers R_1 and R_2, the lengths in general registers $R_1 + 1$ and $R_2 + 1$, and specific fields of the parameter block are updated so that the instruction, when reexecuted, resumes the operation at the point it was suspended.

Access exceptions are not recognized for locations greater than 4 K-bytes to the right of the locations designated by the first and second-operand addresses. Access exceptions are not recognized for

locations greater than 4 K-bytes to the right of the location designated by an input-list address.

If an access exception is due to be recognized for the first operand, second operand, or any active input list, the result is that either the exception is recognized or condition code 3 is set. If condition code 3 is set, the exception will be recognized when the instruction is executed again to continue processing the same operands, assuming the exception condition still exists.

Access-exception conditions are not recognized for an inactive input list. Access-exception conditions are not recognized for an input list with an input-list length equal to zero at the beginning of the execution of the instruction.

When the key of a record crosses a page boundary and access-exception conditions exist for both pages, either access exception may be recognized.

When access-exception conditions exist for multiple keys being processed during a single unit of operation, any of these conditions may be recognized.

When the parameter block crosses a page boundary and access-exception conditions exist for both pages, the access exception for the leftmost page is recognized. Access exceptions apply to the entire parameter block, regardless of any input list being in the inactive state.

When the operation ends with partial completion, up to 4 K-bytes of data may have been stored at locations within the first operand which are at, or to the right of, the location designated by the updated first-operand address. Such stores result in setting change bits, when applicable, and recognizing PER storage-alteration events, when applicable. Storing to these locations will be repeated when the instruction is executed again to continue processing the same operands.

As observed by this CPU, other CPUs, and channel programs, references to the parameter block, the first operand, the output-lists-delineations buffer, and all input lists in the active state may be multiple-access references, accesses to these storage locations are not necessarily block-concurrent, and the sequence of these accesses or references is undefined.

Results are unpredictable when the specified function is SORTL-SFLR or SORTL-SVLR and any of the following apply:

- The parameter block overlaps any active input list or the first operand.
- Any active input list overlaps the first operand.
- Merge mode is zero and the parameter block overlaps the second operand or the continuation-record-recall buffer.
- Merge mode is zero and any active input list overlaps the second operand or the continuation-record-recall buffer.
- Merge mode is zero and the first operand overlaps the second operand or the continuation-record-recall buffer.
- Merge mode is zero and the second operand overlaps the continuation-record-recall buffer.
- Another CPU or channel program stores to a key of a record in an input list or the continuation-record-recall buffer.

Resulting Condition Code:

0 Normal completion
1 The length of the first operand is less than the size of a record, or merge mode is zero and the length of the second operand is less than 16
2 An incomplete input list was encountered (IILF=1), or the EILCL is nonzero and the length of an input list became equal to zero during the operation
3 CPU-determined amount of data processed

Program Exceptions:

- Access (fetch, input lists; fetch and store, parameter block and continuation-record-recall buffer; store, operands 1 and 2)
- Data with DXC 0, general operand
- Operation (if the enhanced-sort facility is not installed)
- Specification
- Transaction constraint

The priority of execution for the SORT LISTS instruction is shown in Figure 26-111 on page 26-142. When multiple conditions which have priority values beginning with 13 exist, the condition recognized is the one that is encountered first, as the operation proceeds. When the operation is being resumed (the continuation flag is one at the beginning of the execution of the instruction), a history of prior comparisons between keys may be used in place of initially accessing all input lists which are active and not

empty. As a result, an access exception for an access to a specific input list may not be encountered at the same point of processing, as compared to when no history of prior comparisons is used. When variable-length records are processed, conditions which are a function of a record length may be partially evaluated before the payload length is determined, and completely evaluated after the payload length is determined. As a result, the observed priority among such conditions may differ when a condition is determined to exist after only partially evaluating requirements, instead of after completely evaluating all requirements.

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B	Operation exception.
7.C	Transaction constraint.
8.A	Specification exception due to invalid function code or invalid register number.
8.B	Specification exception due to parameter block not designated on doubleword boundary.
8.C	Specification exception due to first operand not designated on doubleword boundary.
8.D	Specification exception due to second operand not designated on doubleword boundary and merge mode is zero.
9.	Access exceptions for an access to bytes 0-7 of the parameter block.
10.	General-operand data exception due to an unsupported value of the PBVN field in the parameter block.
11.	Access exceptions for an access to bytes of the parameter block other than bytes 0-7.
12.	General-operand data exception due to an invalid value of a field in the parameter block other than the PBVN.
13.A	Access exceptions for an access to an active input list.
13.B	Access exceptions for an access to the continuation-record-recall buffer when merge mode is zero.
13.C	Access exceptions for an access to the first operand.
13.D	Access exceptions for an access to the second operand when merge mode is zero.
13.E	Condition code 2 due to an incomplete input list.
13.F	Condition code 1 due to insufficient length of first operand.

13.G	Condition code 1 due to insufficient length of second operand when merge mode is zero.
13.H	General-operand data exception due to an invalid payload length of a variable-length record.
13.I	Condition code 2 due to an empty input list.
14.	Condition code 3.

Figure 26-111. Priority of Execution: SORTL (Part 2 of 2)

Programming Notes:

1. To generate a single list of records in sorted order from a set of records in random order, a program may perform the following procedure:

   a. Evenly partition the set of records among an initial set of lists, where each list contains records in random order. Execute the SORT LISTS instruction with the initial set of lists as input lists and merge mode equal to zero, to generate an intermediate set of lists (each of which contains records in sorted order), and the storage locations and lengths for each list of the intermediate set of lists.

   b. Perform one or more merge operations as required to generate a single list containing all records in sorted order. When the number of lists generated in the prior step is more than the maximum number of input lists for the SORLT instruction, multiple merge operations are required; otherwise, only a single merge operation is required. For each merge operation, execute the SORTL instruction with merge mode equal to one and as many lists from the intermediate set of lists as necessary and possible.

2. The intended values and uses of the empty-input-lists control (EILCL) field are as follows:

EILCL (binary)	**description**
00	Stop after all records from all active input lists are sorted.
10	Stop after input list0 (always active) becomes empty.
11	Stop after any active input list becomes empty. When the operation ends for this reason, EILF is set to one and EILN identifies the input list which became empty.

3. When the active-input-lists count code (AILCC) is zero, there is only one active input list and the

results stored at the first-operand location are the same as the data fetched from input list0.

4. The total execution time of the instruction is generally proportional to the size of the keys. Larger keys generally result in longer execution times. Total execution time of the instruction is also proportional to the size of the payloads.

5. Future models may only support a maximum number of input lists which is less than the maximum number supported by models currently available. The interface size of 32 input lists is always available on all models.

6. Models implementing separate instruction and data caches may use the instruction cache to perform storage-operand fetch references to data in active-input lists. When a program performs storage-operand store references to storage locations, and in a relatively-short period of time, executes SORT LISTS with those same storage locations being designated as active input lists, performance of the program may be affected due to transferring the data associated with those storage locations from the data cache to the instruction cache.

7. Special precautions should be taken if SORT LISTS is made the target of an execute-type instruction. See the programming note concerning interruptible instructions under EXECUTE.

8. When a program expects to invoke SORT LISTS multiple times with merge mode equal to zero, as part of processing a large amount of data, it is recommended the program utilize all input lists available and evenly partition records among the input lists. This reduces the number of times the data is accessed when sorting all of the data.

9. Subsequent to SORT LISTS with merge mode equal to zero ending with condition code 0 set and multiple output-list delineations (OLDs) in the second operand, a program intending to generate a single list of records in sorted order must invoke another SORT LISTS operation with input lists specified to be the resulting OLDs from the prior SORT LISTS invocation. In this case, it is recommended the second invocation of SORT LISTS specifies merge mode equal to one.

   Similarly, subsequent to invoking SORT LISTS with merge mode equal zero, for as many times as necessary, to generate a complete set of sorted lists from a large number of randomly ordered records, it is recommended to invoke SORT LISTS with merge mode equal one, for as many times as necessary, to generate a single sorted list.

10. To reduce the number of times each record is accessed when merging multiple sorted lists into a single list with ascending sort order (for example), it is recommended the program performs the following process:

    - Determine the maximum number, N, of input lists available for SORT LISTS.
    - Compare the keys of the first record of all sorted lists which have not yet been merged into the single list. Select the N lists which have the lowest first key values.
    - Execute SORT LISTS with merge mode (MM) equal one, empty-input-lists control (EILCL) equal 10 binary, input-list0 specifying only the first record of the list with the highest first key value of the selected N lists, and the remaining input lists specifying the other N-1 selected lists.
    - Subsequent to SORT LISTS ending with condition code 2, IILF equal zero, and EILF equal zero, repeat the process.

11. Subsequent to SORT LISTS ending with condition code 1 set, it is recommended the program perform the following actions prior to invoking SORT LISTS again, to resume the operation:

    - If the first-operand length is less than the largest record length of all records being processed, then the first-operand length or first-operand address and length should be updated, as appropriate.
    - If merge mode (MM) is zero and the second-operand length is less than 16, then the second-operand length or second-operand address and length should be updated, as appropriate.
    - If the length of any active input list equals zero, then the corresponding input-list address and length may be updated to designate another list of records to be included in the sorting operation.

12. Subsequent to SORT LISTS ending with condition code 2 set, it is recommended the program perform the following actions prior to invoking SORT LISTS again, to resume the operation:

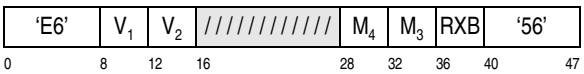
    - If the incomplete-input-list flag (IILF) is one, then the input-list length or input-list address

and length of the input list identified by the incomplete-input-list number (IILN) should be updated, as appropriate.
- If the empty-input-list flag (EILF) is one, then the input-list length or input-list address and length of the input list identified by the empty-input-list number (EILN) should be updated, as appropriate.
- If the IILF is zero, the EILF is zero, and the input-list0 length is zero, then the input-list0 length or input-list0 address and length should be updated, as appropriate. Furthermore, the input-list address and length for all active input lists may be updated, which may be the appropriate action if there was only one record designated by input-list0 originally, and the empty-input-lists control (EILCL) is 10 binary.
- If merge mode (MM) is one and the first-operand length is less than the largest record length of all records being processed, then the first-operand length or first-operand address and length should be updated, as appropriate.
- If MM is zero and either IILF is one, or EILF is one, then the first-operand address and length, and the second-operand address and length should not be updated.
- If MM is zero, IILF is zero, EILF is zero, and the first-operand length is less than the largest record length of all records being processed, then the first-operand length or first-operand address and length should be updated, as appropriate.
- If MM is zero, IILF is zero, EILF is zero, and the second-operand length is less than 16, then the second-operand length or second-operand address and length should be updated, as appropriate.

13. When the next-sequential instruction after NEXT INSTRUCTION ACCESS INTENT (NIAI) is SORT LISTS (SORTL), the execution of SORTL is not effected by NIAI.

VECTOR FP CONVERT AND LENGTHEN FROM NNP HIGH

VCLFNH V_1,V_2,M_3,M_4 [VRR-a]



The elements, from left-to-right, of the leftmost half of the vector-register second operand are converted and placed into double-sized elements in the first operand from left-to-right. The rightmost half of the second operand is ignored.

If the same register is used to designate the first operand as the second operand the original source value is used throughout the operation with no intermediate updates.

The format of the second operand elements is specified by the source-data type in the M_4 field. The format of the first operand elements is specified by the target-data type in the M_3 field.

The M_3 field specifies the target-data type.

M_3	Target-Data Type
0-1	Reserved
2	BFP short format
3-15	Reserved

If a reserved value is specified, an IEEE-inexact exception is recognized.

The M_4 field specifies the source-data type.

M_4	Source-Data Type
0	NNP-data-type 1
1-15	Reserved

If a reserved value is specified, an IEEE-inexact exception is recognized.

If the combination of valid M_3 and M_4 values is not supported by the model an IEEE-inexact exception is recognized. If an IEEE-inexact exception is recognized, the first operand is unpredictable.

An IEEE-inexact exception is not recognized during the conversion itself.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Invalid operation
- Inexact

Program Exceptions:

- Data with DXC FE, Vector Instruction

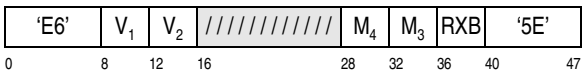
- Operation (if the neural network processing assist facility is not installed)
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

Programming Notes:

1. This instruction converts only the leftmost elements half of the second operand. See VECTOR FP CONVERT AND LENGTHEN FROM NNP LOW instruction to convert the other half of the second operand.
2. Supported data types may vary from model to model. This can lead to an unexpected IEEE-Inexact exception on a particular model, e.g. after a live-guest relocation. The program must be designed to be able to recover from this state and may need to restart the entire AI operation from the beginning after querying, again, the supported capacities and functions via the NNPA-QAF function.

VECTOR FP CONVERT AND LENGTHEN FROM NNP LOW

VCLFNL V_1,V_2,M_3,M_4 [VRR-a]



The elements, from left-to-right, of the rightmost half of the vector-register second operand are converted and placed into double-sized elements in the first operand from left-to-right. The leftmost half of the second operand is ignored.

If the same register is used to designate the first operand as the second operand the original source value is used throughout the operation with no intermediate updates.

The format of the second operand elements is specified by the source-data type in the M_4 field. The format of the first operand elements is specified by the target-data type in the M_3 field.

The M_3 field specifies the target-data type.

M_3	Target-Data Type
0-1	Reserved
2	BFP short format
3-15	Reserved

If a reserved value is specified, an IEEE-inexact exception is recognized.

The M_4 field specifies the source-data type.

M_4	Source-Data Type
0	NNP-data-type 1
1-15	Reserved

If a reserved value is specified, an IEEE-inexact exception is recognized.

If the combination of valid M_3 and M_4 values is not supported by the model an IEEE-inexact exception is recognized. If an IEEE-inexact exception is recognized the first operand is unpredictable.

An IEEE-inexact exception is not recognized during the conversion itself.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Invalid operation
- Inexact

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the neural network processing assist facility is not installed)
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

Programming Notes:

1. This instruction converts only the rightmost elements half of the second operand. See VECTOR FP CONVERT AND LENGTHEN FROM NNP HIGH instruction to convert the other half of the second operand.
2. Supported data types may vary from model to model. This can lead to an unexpected IEEE-

Inexact exception on a particular model, e.g. after a live-guest relocation. The program must be designed to be able to recover from this state and may need to restart the entire AI operation from the beginning after querying, again, the supported capacities and functions via the NNPA-QAF function.

VECTOR FP CONVERT AND ROUND TO NNP

VCRNF V_1,V_2,V_3,M_4,M_5 [VRR-c]

The elements, from left-to-right, of the vector-register second operand followed by the vector-register third operand are converted, rounded and placed into half-sized elements in the first operand from left-to-right.

If the same register is used to designate the first operand as the second or third operand the original source value is used throughout the operation with no intermediate updates.

The format of the second and third operand elements is specified by the source-data type in the M_5 field. The format of the first operand elements is specified by the target-data type in the M_4 field.

The M_4 field specifies the target-data type.

M_4	Target-Data Type
0	NNP-data-type 1
1-15	Reserved

If a reserved value is specified, an IEEE-inexact exception is recognized.

The M_5 field specifies the source-data type.

M_5	Source-Data Type
0-1	Reserved
2	BFP short format
3-15	Reserved

If a reserved value is specified, an IEEE-inexact exception is recognized.

If the combination of valid M_4 and M_5 values is not supported by the model an IEEE-inexact exception is recognized. If an IEEE-inexact exception is recognized the first operand is unpredictable.

An IEEE-inexact exception is not recognized during the conversion itself.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Invalid operation
- Overflow
- Underflow
- Inexact

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the neural network processing assist facility is not installed)
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

Programming Note: Supported data types may vary from model to model. This can lead to an unexpected IEEE-Inexact exception on a particular model, e.g. after a live-guest relocation. The program must be designed to be able to recover from this state and may need to restart the entire AI operation from the beginning after querying, again, the supported capacities and functions via the NNPA-QAF function.

VECTOR FP CONVERT FROM NNP

VCFN V_1,V_2,M_3,M_4 [VRR-a]

The elements, from left-to-right, of the vector-register second operand are converted, rounded and placed into elements in the first operand from left-to-right.

If the same register is used to designate the first operand as the second operand the original source value is used throughout the operation with no intermediate updates.

The format of the second operand elements is specified by the source-data type in the M_4 field. The format of the first operand elements is specified by the target-data type in the M_3 field.

The M_3 field specifies the target-data type.

M_3	Target-Data Type
0	Reserved
1	BFP tiny format
2-15	Reserved

If a reserved value is specified, an IEEE-inexact exception is recognized.

The M_4 field specifies the source-data type.

M_4	Source-Data Type
0	NNP-data-type 1
1-15	Reserved

If a reserved value is specified, an IEEE-inexact exception is recognized.

If the combination of valid M_3 and M_4 values is not supported by the model an IEEE-inexact exception is recognized. If an IEEE-inexact exception is recognized the first operand is unpredictable.

An IEEE-inexact exception is not recognized during the conversion itself.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Invalid operation
- Overflow
- Underflow
- Inexact

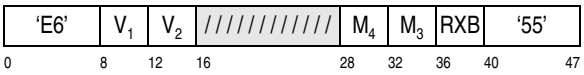
Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the neural network processing assist facility is not installed)
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

Programming Note: Supported data types may vary from model to model. This can lead to an unexpected IEEE-Inexact exception on a particular model, e.g. after a live-guest relocation. The program must be designed to be able to recover from this state and may need to restart the entire AI operation from the beginning after querying, again, the supported capacities and functions via the NNPA-QAF function.

VECTOR FP CONVERT TO NNP

VCNF V_1,V_2,M_3,M_4 [VRR-a]



The elements, from left-to-right, of the vector-register second operand are converted, rounded and placed into elements in the first operand from left-to-right.

If the same register is used to designate the first operand as the second operand the original source value is used throughout the operation with no intermediate updates.

The format of the second operand elements is specified by the source-data type in the M_4 field. The format of the first operand elements is specified by the target-data type in the M_3 field.

The M_3 field specifies the target-data type.

M_3	Target-Data Type
0	NNP-data-type 1
1-15	Reserved

If a reserved value is specified, an IEEE-inexact exception is recognized.

The M_4 field specifies the source-data type.

M_4	Source-Data Type
0	Reserved
1	BFP tiny format
2-15	Reserved

If a reserved value is specified, an IEEE-inexact exception is recognized.

If the combination of valid M_3 and M_4 values is not supported by the model an IEEE-inexact exception is recognized. If an IEEE-inexact exception is recognized the first operand is unpredictable.

An IEEE-inexact exception is not recognized during the conversion itself.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Invalid operation

- Overflow
- Inexact

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the neural network processing assist facility is not installed)
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

Programming Note: Supported data types may vary from model to model. This can lead to an unexpected IEEE-Inexact exception on a particular model, e.g. after a live-guest relocation. The program must be designed to be able to recover from this state and may need to restart the entire AI operation from the beginning after querying, again, the supported capacities and functions via the NNPA-QAF function.

This appendix (except for the examples for FIND LEFTMOST ONE, ROTATE THEN EXCLUSIVE OR SELECTED BITS, ROTATE THEN INSERT SELECTED BITS, ROTATE THEN OR SELECTED BITS, and changes in the terminology for signed-packed decimal and unsigned-packed decimal) is the same as in *Enterprise Systems Architecture/390 Principles of Operation*, SA22-7201; it has not been revised to show the enlargement of register sizes or the 64-bit addressing mode.

Number Representation

Binary Integers

Signed Binary Integers

Signed binary integers are most commonly represented as halfwords (16 bits) or words (32 bits). In both lengths, the leftmost bit (bit 0) is the sign of the number. The remaining bits (bits 1-15 for halfwords and 1-31 for words) are used to specify the magnitude of the number. Binary integers are also referred to as fixed-point numbers, because the radix point (binary point) is considered to be fixed at the right, and any scaling is done by the programmer.

Positive binary integers are in true binary notation with a zero sign bit. Negative binary integers are in two's-complement notation with a one bit in the sign position. In all cases, the bits between the sign bit and the leftmost significant bit of the integer are the same as the sign bit (that is, all zeros for positive numbers, all ones for negative numbers).

Negative binary integers are formed in two's-complement notation by inverting each bit of the positive binary integer and adding one. As an example using the halfword format, the binary number with the decimal value +26 is made negative (-26) in the following manner:

```
+26    0 000 0000 0001 1010
Invert 1 111 1111 1110 0101
Add 1                    1
       ____________________
-26     1 111 1111 1110 0110 (Two's complement
                              form)
(S is the sign bit.)
```

This is equivalent to subtracting the number:

```
        00000000 00011010
from
      1 00000000 00000000
```

Negative binary integers are changed to positive in the same manner.

The following addition examples illustrate two's-complement arithmetic and overflow conditions. Only eight bit positions are used.

```
1.  +57 = 0011 1001
    +35 = 0010 0011
    ---------------
    +92 = 0101 1100

2.  +57 = 0011 1001
    -35 = 1101 1101
    ---------------
    +22 = 0001 0110 No overflow – carry into
                    leftmost position and
                    carry out

3.  +35 = 0010 0011
    -57 = 1100 0111
    ---------------
    -22 = 1110 1010 Sign change only – no
                    carry into leftmost posi-
                    tion and no carry out

4.  -57 = 1100 0111
    -35 = 1101 1101
    ---------------
    -92 = 1010 0100 No overflow – carry into
                    leftmost position and
                    carry out

5.  +57 = 0011 1001
    +92 = 0101 1100
    ---------------
   +149 =*1001 0101 *Overflow – carry into
                    leftmost position, no
                    carry out

6.  -57 = 1100 0111
    -92 = 1010 0100
    ---------------
   -149 =*0110 1011 *Overflow – no carry into
                    leftmost position but carry
                    out
```

The presence or absence of an overflow condition may be recognized from the carries:

- There is no overflow:
  1. If there is no carry into the leftmost bit position and no carry out (examples 1 and 3).
  2. If there is a carry into the leftmost position and also a carry out (examples 2 and 4).
- There is an overflow:
  1. If there is a carry into the leftmost position but no carry out (example 5).
  2. If there is no carry into the leftmost position but there is a carry out (example 6).

The following are 16-bit signed binary integers. The first is the maximum positive 16-bit binary integer. The last is the maximum negative 16-bit binary integer (the negative 16-bit binary integer with the greatest absolute value).

```
 2^15-1=  32,767 = 0 111 1111 1111 1111
 2^0==        1 = 0 000 0000 0000 0001
 0  =        0 = 0 000 0000 0000 0000
-2^0 =       -1 = 1 111 1111 1111 1111
-2^15= -32,768 = 1 000 0000 0000 0000
```

Figure A-1 illustrates several 32-bit signed binary integers arranged in descending order. The first is the maximum positive binary integer that can be represented by 32 bits, and the last is the maximum negative binary integer that can be represented by 32 bits.

```
 2^31-1  =  2 147 483 647  = 0 111 1111 1111 1111 1111 1111 1111 1111
 2^16    =         65 536  = 0 000 0000 0000 0001 0000 0000 0000 0000
 2^0     =              1  = 0 000 0000 0000 0000 0000 0000 0000 0001
 0       =              0  = 0 000 0000 0000 0000 0000 0000 0000 0000
 -2^0    =             -1  = 1 111 1111 1111 1111 1111 1111 1111 1111
 -2^1    =             -2  = 1 111 1111 1111 1111 1111 1111 1111 1110
 -2^16   =        -65 536  = 1 111 1111 1111 1111 0000 0000 0000 0000
 -2^31+1 = -2 147 483 647  = 1 000 0000 0000 0000 0000 0000 0000 0001
 -2^31   = -2 147 483 648  = 1 000 0000 0000 0000 0000 0000 0000 0000
```

Figure A-1. 32-Bit Signed Binary Integers

Unsigned Binary Integers

Certain instructions, such as ADD LOGICAL, treat binary integers as unsigned rather than signed. Unsigned binary integers have the same format as

signed binary integers, except that the leftmost bit is interpreted as another numeric bit rather than a sign bit. There is no complement notation because all unsigned binary integers are considered positive.

The following examples illustrate the addition of unsigned binary integers. Only eight bit positions are used. The examples are numbered the same as the corresponding examples for signed binary integers.

```
1.   57 = 0011 1001
      35 = 0010 0011
     ──────────────────
      92 = 0101 1100

2.   57 = 0011 1001
     221 = 1101 1101
     ──────────────────
     278 =*0001 0110 *Carry out of leftmost
                      position

3.   35 = 0010 0011
     199 = 1100 0111
     ──────────────────
     234 = 1110 1010

4.  199 = 1100 0111
     221 = 1101 1101
     ──────────────────
     420 =*1010 0100 *Carry out of leftmost
                      position

5.   57 = 0011 1001
      92 = 0101 1100
     ──────────────────
     149 = 1001 0101

6.  199 = 1100 0111
     164 = 1010 0100
     ──────────────────
     363 =*0110 1011 *Carry out of leftmost
                      position
```

A carry out of the leftmost bit position may or may not imply an overflow, depending on the application.

Figure A-2 illustrates several 32-bit unsigned binary integers arranged in descending order.

```
2^32-1 = 4 294 967 295 = 1111 1111 1111 1111 1111 1111 1111 1111
2^31   = 2 147 483 648 = 1000 0000 0000 0000 0000 0000 0000 0000
2^31-1 = 2 147 483 647 = 0111 1111 1111 1111 1111 1111 1111 1111
2^16   =        65 536 = 0000 0000 0000 0001 0000 0000 0000 0000
2^0    =             1 = 0000 0000 0000 0000 0000 0000 0000 0001
0      =             0 = 0000 0000 0000 0000 0000 0000 0000 0000
```

Figure A-2. 32-Bit Unsigned Binary Integers

Decimal Integers

Decimal integers consist of one or more decimal digits and a sign. Each digit and the sign are represented by a 4-bit code. The decimal digits are in binary-coded decimal (BCD) form, with the values 0-9 encoded as 0000-1001. The sign is usually represented as 1100 (C hex) for plus and 1101 (D hex) for minus. These are the preferred sign codes, which are generated by the machine for the results of decimal-arithmetic operations. There are also several alternate sign codes (1010, 1110, and 1111 for plus; 1011 for minus). The alternate sign codes are accepted by the machine as valid in source operands but are not generated for results.

Decimal integers may have different lengths, from one to 16 bytes. Of the many decimal formats, only two will be considered here: signed-packed-decimal and zoned. In the signed-packed-decimal format, each byte contains two decimal digits, except for the rightmost byte, which contains the sign code in the right half. For decimal arithmetic, the number of decimal digits in the signed-packed-decimal format can vary from one to 31. Because decimal integers must consist of whole bytes and there must be a sign code on the right, the number of decimal digits in this format is always odd. If an even number of significant digits is desired, a leading zero must be inserted on the left.

In the zoned format, each byte consists of a decimal digit on the right and the zone code 1111 (F hex) on the left, except for the rightmost byte where the sign code replaces the zone code. Thus, a decimal integer in the zoned format can have from one to 16 digits. The zoned format may be used directly for input

and output in the extended binary-coded-decimal interchange code (EBCDIC), except that the sign must be separated from the rightmost digit and handled as a separate character. For positive (unsigned) numbers, however, the sign can simply be represented by the zone code of the rightmost digit because the zone code is one of the acceptable alternate codes for plus.

In either format, negative decimal integers are represented in true notation with a separate sign. As for binary integers, the radix point (decimal point) of decimal integers is considered to be fixed at the right, and any scaling is done by the programmer.

The following are some examples of decimal integers shown in hexadecimal notation:

Decimal Value	Signed Packed Format	Zoned Format
+123	12 3C or 12 3F	F1 F2 C3 or F1 F2 F3
-4321	04 32 1D	F4 F3 F2 D1
+000050	00 00 05 0C or 00 00 05 0F	F0 F0 F0 F0 F5 C0 or F0 F0 F0 F0 F5 F0
-7	7D	D7
00000	00 00 0C or 00 00 0F	F0 F0 F0 F0 C0 or F0 F0 F0 F0 F0

Under some circumstances, a zero with a minus sign (negative zero) is produced. For example, the multiplicand:

```
00 12 3D   (-123)
```

times the multiplier:

```
   0C      (+0)
```

generates the product:

```
00 00 0D   (-0)
```

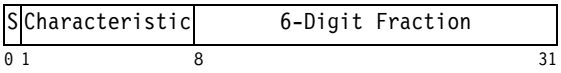
because the product sign follows the algebraic rule of signs even when the value is zero. A negative zero, however, is equivalent to a positive zero in that they compare equal in a decimal comparison.

Hexadecimal-Floating-Point Numbers

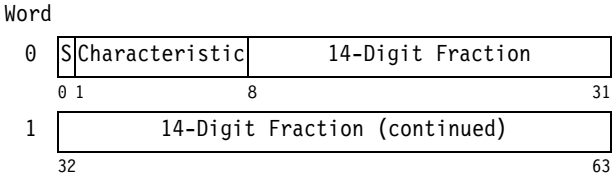
A hexadecimal-floating-point (HFP) number is expressed as a hexadecimal fraction multiplied by a separate power of 16. The term floating point indicates that the placement, of the radix (hexadecimal) point, or scaling, is automatically maintained by the machine.

The part of an HFP number which represents the significant digits of the number is called the fraction. A second part specifies the power (exponent) to which 16 is raised and indicates the location of the radix point of the number. The fraction and exponent may be represented by 32 bits (short format), 64 bits (long format), or 128 bits (extended format).

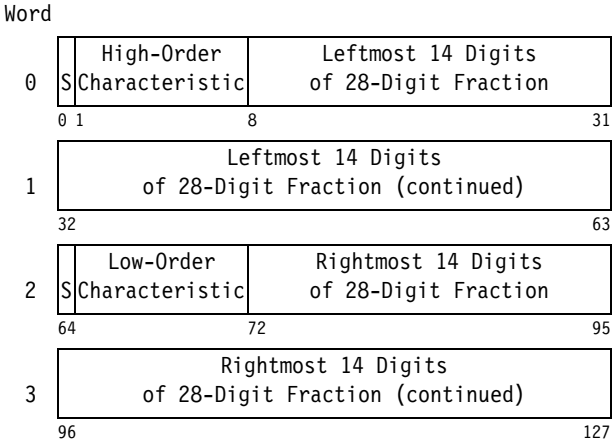
Short HFP Number



Long HFP Number



Extended HFP Number



An HFP number has two signs: one for the fraction and one for the exponent. The fraction sign, which is also the sign of the entire number, is the leftmost bit of each format (0 for plus, 1 for minus). The numeric part of the fraction is in true notation regardless of the sign. The numeric part is contained in bits 8-31 for the short format, in bits 8-63 for the long format, and in bits 8-63 followed by bits 72-127 for the extended format.

The exponent sign is obtained by expressing the exponent in excess-64 notation; that is, the exponent is added as a signed number to 64. The resulting number is called the characteristic. It is located in bits 1-7 for all formats. The characteristic can vary from 0 to 127, permitting the exponent to vary from -64 through 0 to +63. This provides a scale multiplier in the range of 16^{-64} to 16^{+63}. A nonzero fraction, if normalized, has a value less than one and greater than or equal to 1/16, so that the range covered by the magnitude M of a normalized floating-point number is:

$$16^{-65} \leq M < 16^{63}$$

In decimal terms:

16^{-65} is approximately 5.4×10^{-79}

16^{63} is approximately 7.2×10^{75}

More precisely,

In the short format:

$$16^{-65} \leq M \leq (1 - 16^{-6}) \times 16^{63}$$

In the long format:

$$16^{-65} \leq M \leq (1 - 16^{-14}) \times 16^{63}$$

In the extended format:

$$16^{-65} \leq M \leq (1 - 16^{-28}) \times 16^{63}$$

Within a given fraction length (6, 14, or 28 digits), an HFP operation will provide the greatest precision if the fraction is normalized. A fraction is normalized when the leftmost digit (bit positions 8, 9, 10, and 11) is nonzero. It is unnormalized if the leftmost digit contains all zeros.

If normalization of the operand is desired, the HFP instructions that provide automatic normalization are used. This automatic normalization is accomplished by left-shifting the fraction (four bits per shift) until a nonzero digit occupies the leftmost digit position. The characteristic is reduced by one for each digit shifted.

Figure A-3 illustrates sample normalized short HFP numbers. The last two numbers represent the smallest and the largest positive normalized numbers.

1.0	$= +1/16 \times 16^{1}$	$= 0\ 100\ 0001\ 0001\ 0000\ 0000\ 0000\ 0000\ 0000_2$
0.5	$= +8/16 \times 16^{0}$	$= 0\ 100\ 0000\ 1000\ 0000\ 0000\ 0000\ 0000\ 0000_2$
1/64	$= +4/16 \times 16^{-1}$	$= 0\ 011\ 1111\ 0100\ 0000\ 0000\ 0000\ 0000\ 0000_2$
0.0	$= +0 \times 16^{-64}$	$= 0\ 000\ 0000\ 0000\ 0000\ 0000\ 0000\ 0000\ 0000_2$
-15.0	$= -15/16 \times 16^{1}$	$= 1\ 100\ 0001\ 1111\ 0000\ 0000\ 0000\ 0000\ 0000_2$
5.4×10^{-79}	$\approx +1/16 \times 16^{-64}$	$= 0\ 000\ 0000\ 0001\ 0000\ 0000\ 0000\ 0000\ 0000_2$
7.2×10^{75}	$\approx (1-16^{-6}) \times 16^{63}$	$= 0\ 111\ 1111\ 1111\ 1111\ 1111\ 1111\ 1111\ 1111_2$

Figure A-3. Normalized Short Hexadecimal-Floating-Point Numbers

Conversion Example

Convert the decimal number 59.25 to a short HFP number. (In another appendix are tables for the conversion of hexadecimal and decimal integers and fractions.)

1. The number is separated into a decimal integer and a decimal fraction.

   59.25 = 59 plus 0.25

2. The decimal integer is converted to its hexadecimal representation.

   $59_{10} = 3B_{16}$

3. The decimal fraction is converted to its hexadecimal representation.

   $0.25_{10} = 0.4_{16}$

4. The integral and fractional parts are combined and expressed as a fraction times a power of 16 (exponent).

$3B.4_{16} = 0.3B4_{16} \times 16^2$

5. The characteristic is developed from the exponent and converted to binary.

```
base + exponent  = characteristic
64   + 2         = 66 = 1000010
```

6. The fraction is converted to binary and grouped hexadecimally.

$.3B4_{16} = .0011\ 1011\ 0100$

7. The characteristic and the fraction are stored in the short format. The sign position contains the sign of the fraction.

```
S Char      Fraction
0 1000010   0011 1011 0100 0000 0000 0000
```

Examples of instruction sequences that may be used to convert between signed binary integers and HFP numbers are shown in “Hexadecimal-Floating-Point-Number Conversion” on page A-44.

Instruction-Use Examples

The following examples illustrate the use of many of the unprivileged instructions. Before studying one of these examples, the reader should consult the instruction description.

The instruction-use examples are written principally for assembler-language programmers, to be used in conjunction with the appropriate assembler-language publications.

Most examples present one particular instruction, both as it is written in an assembler-language statement and as it appears when assembled in storage (machine format).

Machine Format

All machine-format values are given in hexadecimal notation unless otherwise specified. Storage addresses are also given in hexadecimal. Hexadecimal operands are shown converted into binary, decimal, or both if such conversion helps to clarify the example for the reader.

Assembler-Language Format

In assembler-language statements, registers and lengths are presented in decimal. Displacements, immediate operands, and masks may be shown in decimal, hexadecimal, or binary notation; for example, 12, X‘C’, and B‘1100’ represent the same value. Whenever the value in a register or storage location is referred to as “not significant,” this value is replaced during the execution of the instruction.

When SS-format instructions are written in the assembler language, lengths are given as the total number of bytes in the field. This differs from the machine definition, in which the length field specifies the number of bytes to be added to the field address to obtain the address of the last byte of the field. Thus, the machine length is one less than the assembler-language length. The assembler program automatically subtracts one from the length specified when the instruction is assembled.

In some of the examples, symbolic addresses are used in order to simplify the examples. In assembler-language statements, a symbolic address is represented as a mnemonic term written in all capitals, such as FLAGS, which may denote the address of a storage location containing data or program-control information. When symbolic addresses are used, the assembler supplies actual base and displacement values according to the programmer’s specifications. Therefore, the actual values for base and displacement are not shown in the assembler-language format or in the machine-language format. For assembler-language formats, in the labels that designate instruction fields, the letter “S” is used to indicate the combination of base and displacement fields for an operand address. (For example, S2 represents the combination of B2 and D2.) In the machine-language format, the base and displacement address components are shown as asterisks (****).

Addressing Mode in Examples

Except where otherwise specified, the examples assume the 24-bit addressing mode.

General Instructions

(See Chapter 7, “General Instructions” for a complete description of the general instructions.)

ADD HALFWORD (AH)

The ADD HALFWORD instruction algebraically adds the contents of a two-byte field in storage to the contents of a register. The storage operand is expanded to 32 bits after it is fetched and before it is used in the add operation. The expansion consists in propagating the leftmost (sign) bit 16 positions to the left. For example, assume that the contents of storage locations 2000-2001 are to be added to register 5. Initially:

Register 5 contains 00 00 00 19 = 25_{10}.

Storage locations 2000-2001 contain FF FE = -2_{10}.

Register 12 contains 00 00 18 00.

Register 13 contains 00 00 01 50.

The format of the required instruction is:

Machine Format

Op Code	R_1	X_2	B_2	D_2
4A	5	D	C	6B0

Assembler Format

```
Op Code  R1,D2(X2,B2)
-------------------------
   AH  5,X'6B0'(13,12)
```

After the instruction is executed, register 5 contains 00 00 00 17 = 23_{10}. Condition code 2 is set to indicate a result greater than zero.

AND (N, NC, NI, NR)

When the Boolean operator AND is applied to two bits, the result is one when both bits are one; otherwise, the result is zero. When two bytes are ANDed, each pair of bits is handled separately; there is no connection from one bit position to another. The following is an example of ANDing two bytes:

```
First-operand byte:    0011 0101₂
Second-operand byte:   0101 1100₂
-----------------------------------
Result byte:           0001 0100₂
```

NI Example

A frequent use of the AND instruction is to set a particular bit to zero. For example, assume that storage location 4891 contains 0100 0011_2. To set the rightmost bit of this byte to zero without affecting the other bits, the following instruction can be used (assume that register 8 contains 00 00 48 90):

Machine Format

Op Code	I_2	B_1	D_1
94	FE	8	001

Assembler Format

```
Op Code  D1(B1),I2
-------------------------
   NI    1(8),X'FE'
```

When this instruction is executed, the byte in storage is ANDed with the immediate byte (the I_2 field of the instruction):

```
Location 4891:    0100 0011₂
Immediate byte:   1111 1110₂
-----------------------------
Result:           0100 0010₂
```

The resulting byte, with bit 7 set to zero, is stored back in location 4891. Condition code 1 is set.

Linkage Instructions (BAL, BALR, BAS, BASR, BASSM, BSM)

Four unprivileged instructions (BRANCH AND LINK, BRANCH AND SAVE, BRANCH AND SAVE AND SET MODE, and BRANCH AND SET MODE) are available, together with the unconditional branch (BRANCH ON CONDITION with a mask of 15), to provide linkage between subroutines. BRANCH AND LINK (BAL or BALR) is provided primarily for compatibility with programs written for System/370; BRANCH AND SAVE (BAS or BASR) is recommended instead for programs which are to be executed using ESA/370. The instructions BRANCH AND SAVE AND SET MODE (BASSM) and BRANCH AND SET MODE (BSM) provide subroutine linkage together with switching between the 24-bit and the 31-bit addressing modes. The use of these instructions is discussed in a programming note at the end of the section “Subroutine Linkage without the Linkage Stack” on page 5-14 (See also

the semiprivileged instruction BRANCH AND STACK.)

The following example compares the operation of these instructions and of the unconditional-branch instruction BRANCH ON CONDITION (BC or BCR with a mask of 15). Assume that each instruction in turn is located at the current instruction address, ready to be executed next. For the first set of examples, the addressing-mode bit, PSW bit 32, is initially zero (24-bit addressing in effect). For the second set, PSW bit 32 is initially one (31-bit addressing). Assume also that general register 5 is to receive the linkage information, and that general register 6 contains the branch address.

The format of the BALR instruction is:

Machine Format

Op Code	R_1	R_2
05	5	6

Assembler Format

Op Code	R_1,R_2
BALR	5,6

The other linkage instructions in the RR format have the same format but different op codes:

```
BASR   0D
BASSM  0C
BSM    0B
```

For comparison with the RR-format instructions, the results of two RX-format instructions are also shown.

The format of the BAL instruction is:

Machine Format

Op Code	R_1	X_2	B_2	D_2
45	5	0	6	000

Assembler Format

Op Code	R_1,D_2(X_2,B_2)
BAL	5,0(0,6)

The BAS instruction has the same format, but the op code is 4D.

The BCR instruction specifies only one register:

Machine Format

Op Code	M_1	R_2
07	F	6

Assembler Format

Op Code	M_1,R_2
BCR	15,6

Assume that:

Register 5 contains BB BB BB BB.

Register 6 contains 82 46 8A CE.

PSW bits 32-63 contain

00 00 10 D6 (for 24-bit addressing).
80 00 10 D6 (for 31-bit addressing).

Condition code is 01_2.

Program mask is 1100_2.

The effect of executing each instruction in turn is as follows:

24-Bit Mode Initially

Instruction	Register 5	PSW (32-63)
Before	BB BB BB BB	00 00 10 D6
BCR 15,6	BB BB BB BB	00 46 8A CE
BAL 5,0(0,6)	9C 00 10 DA	00 46 8A CE
BAS 5,0(0,6)	00 00 10 DA	00 46 8A CE
BALR 5,6	5C 00 10 D8	00 46 8A CE
BASR 5,6	00 00 10 D8	00 46 8A CE
BASSM 5,6	00 00 10 D8	82 46 8A CE
BSM 5,6	3B BB BB BB	82 46 8A CE

31-Bit Mode Initially

Instruction	Register 5	PSW (32-63)
Before	BB BB BB BB	80 00 10 D6
BCR 15,6	BB BB BB BB	82 46 8A CE
BAL 5,0(0,6)	80 00 10 DA	82 46 8A CE
BAS 5,0(0,6)	80 00 10 DA	82 46 8A CE
BALR 5,6	80 00 10 D8	82 46 8A CE
BASR 5,6	80 00 10 D8	82 46 8A CE
BASSM 5,6	80 00 10 D8	82 46 8A CE
BSM 5,6	BB BB BB BB	82 46 8A CE

Note that a value of zero in the R_2 field of any of the RR-format instructions indicates that the branching function is not to be performed; it does not refer to

register 0. Likewise, a value of zero in the R_1 field of the BSM instruction indicates that the old value of PSW bit 32 is not to be saved and that register 0 is to be left unchanged. Register 0 can be designated by the R_1 field of instructions BAL, BALR, BAS, BASR, and BASSM, however. In the RX-format branch instructions, branching occurs independent of whether there is a value of zero in the B_2 field or X_2 field of the instruction. However, when the field is zero, instead of using the contents of general register 0, a value of zero is used for that component of address generation.

Programming Note: It should be noted that execution of BAL in the 24-bit addressing mode results in bit 0 of register 5 being set to one. This is because the ILC for an RX-format instruction is 10. This is the only case in which bit zero of the return register does not correctly reflect the addressing mode of the caller. Thus, BSM may be used to return for BALR, BAS, BASR, and BASSM in both the 24-bit and the 31-bit addressing modes, but it cannot be used to return if the program was called by using BAL in the 24-bit addressing mode.

Other BALR and BASR Examples

The BALR or BASR instruction with the R_2 field set to zero may be used to load a register for use as a base register. For example, in the assembler language, the two statements:

```
BALR    15,0
USING   *,15
```

or

```
BASR    15,0
USING   *,15
```

indicate that the address of the next sequential instruction following the BALR or BASR instruction will be placed in register 15, and that the assembler may use register 15 as a base register until otherwise instructed. (The USING statement is an “assembler instruction” and is thus not a part of the object program.)

BRANCH AND STACK (BAKR)

The semiprivileged BRANCH AND STACK instruction facilitates linkage between subroutines by saving status in a linkage-stack state entry (sometimes called a branch state entry to distinguish it from a program-call state entry). When BRANCH AND STACK has been used, the return from the called program is made by means of the PROGRAM RETURN instruction. PROGRAM RETURN restores access registers 2-14, general registers 2-14, and the PSW with values saved in the state entry, except that it leaves the PER mask unchanged. The use of BRANCH AND STACK is discussed in “Branching Using the Linkage Stack” on page 5-74.

BRANCH AND STACK can be used to perform a calling linkage, or it can be used at or near the entry point of the called program, depending on whether the R_1 field of the instruction is zero or nonzero, respectively. If the R_1 field is zero, bits 32-63 of the PSW saved in the state entry indicate the current addressing mode (24-bit or 31-bit) and the address of the next sequential instruction after the BRANCH AND STACK instruction or an EXECUTE instruction. If the R_1 field is nonzero, bits 32-63 of the PSW saved in the state entry are set with a value generated from the contents of general register R_1: bit 32 of the PSW is set equal to bit 0 of the register, and bits 1-31 of the PSW are set with an address generated from bits 1-31 of the register under the control of bit 0 of the register. Bits 32-63 of the PSW saved in the state entry are referred to in the following examples as the return value.

The branch address for the instruction is generated from the contents of general register R_2 under the control of the current addressing mode. Bit 0 of general register R_2 does not affect the operation. If the R_2 field of the instruction is zero, the operation is performed without branching.

In addition to saving a complete PSW (except with an unpredictable PER mask) in the state entry, BRANCH AND STACK saves the new value of bits 32-63 of the current PSW in the state entry. Bits 32-63 are referred to in the following examples as the branch value.

The following examples contain cases in which bit 32 of the current PSW is either zero or one (24-bit or 31-bit addressing) before BRANCH AND STACK is executed and in which bit 0 of the general register designated by a nonzero R_1 or R_2 field is either zero or one.

BAKR Example 1

This example shows BAKR used in a calling program. BAKR performs a branch, and the return is to be to the next sequential instruction.

The format of the BAKR instruction is:

Machine Format

Op Code		R_1	R_2
B240		0	6

Assembler Format

```
Op Code  R1,R2
──────────────
  BAKR   0,6
```

Assume four cases of initial values, as follows:

```
    PSW (32-63)    Register 6

1.  00 00 10 D6    02 46 8A CE
2.  00 00 10 D6    82 46 8A CE
3.  80 00 10 D6    02 46 8A CE
4.  80 00 10 D6    82 46 8A CE
```

The results in the four cases are as follows:

```
    Return         Branch Value
    Value          and PSW (32-63)

1.  00 00 10 DA    00 46 8A CE
2.  00 00 10 DA    00 46 8A CE
3.  80 00 10 DA    82 46 8A CE
4.  80 00 10 DA    82 46 8A CE
```

BAKR Example 2

This example shows BAKR used in a called program. BAKR does not perform a branch, and the return is to be as specified in general register R_1.

The format of the BAKR instruction is:

Machine Format

Op Code		R_1	R_2
B240		5	0

Assembler Format

```
Op Code  R1,R2
──────────────
  BAKR   5,0
```

Assume four cases of initial values, as follows:

```
    Register 5     PSW (32-63)

1.  04 00 10 D6    00 46 8A CE
2.  04 00 10 D6    82 46 8A CE
3.  84 00 10 D6    00 46 8A CE
4.  84 00 10 D6    82 46 8A CE
```

The results in the four cases are as follows:

```
    Return         Branch Value
    Value          and PSW (32-63)

1.  00 00 10 D6    00 46 8A D2
2.  00 00 10 D6    82 46 8A D2
3.  84 00 10 D6    00 46 8A D2
4.  84 00 10 D6    82 46 8A D2
```

BAKR Example 3

This example shows BAKR used in a called program. BAKR performs a branch, and the return is to be as specified in general register R_1.

The format of the BAKR instruction is:

Machine Format

Op Code		R_1	R_2
B240		5	6

Assembler Format

```
Op Code  R1,R2
──────────────
  BAKR   5,6
```

Assume eight cases of initial values, as follows:

```
    Register 5     Register 6     PSW (32-63)

1.  04 00 10 D6    06 99 99 00    00 46 8A CE
2.  04 00 10 D6    06 99 99 00    82 46 8A CE
3.  04 00 10 D6    86 99 99 00    00 46 8A CE
4.  04 00 10 D6    86 99 99 00    82 46 8A CE
5.  84 00 10 D6    06 99 99 00    00 46 8A CE
6.  84 00 10 D6    06 99 99 00    82 46 8A CE
7.  84 00 10 D6    86 99 99 00    00 46 8A CE
8.  84 00 10 D6    86 99 99 00    82 46 8A CE
```

The results in the eight cases are as follows:

```
    Return         Branch Value
    Value          and PSW (32-63)

1.  00 00 10 D6    00 99 99 00
2.  00 00 10 D6    86 99 99 00
3.  00 00 10 D6    00 99 99 00
4.  00 00 10 D6    86 99 99 00
```

```
5.  84 00 10 D6    00 99 99 00
6.  84 00 10 D6    86 99 99 00
7.  84 00 10 D6    00 99 99 00
8.  84 00 10 D6    86 99 99 00
```

BRANCH ON CONDITION (BC, BCR)

The BRANCH ON CONDITION instruction tests the condition code to see whether a branch should or should not occur. The branch occurs only if the current condition code corresponds to a one bit in a mask specified by the instruction.

Condition Code	Instruction (Mask) Bit	Mask Value
0	8	8
1	9	4
2	10	2
3	11	1

For example, assume that an ADD (A or AR) operation has been performed and that a branch to address 6050 is desired if the sum is zero or less (condition code is 0 or 1). Also assume:

Register 10 contains 00 00 50 00.

Register 11 contains 00 00 10 00.

The RX form of the instruction performs the required test (and branch if necessary) when written as:

Machine Format

Op Code	M_1	X_2	B_2	D_2
47	C	B	A	050

Assembler Format

```
Op Code  M1,D2(X2,B2)
_____________________
  BC     12,X'50'(11,10)
```

A mask of 12_{10} means that there are ones in instruction bits 8 and 9 and zeros in bits 10 and 11, so that branching takes place when the condition code is either 0 or 1.

A mask of 15 would indicate a branch on any condition (an unconditional branch). A mask of zero would indicate that no branch is to occur (a no-operation).

(See also “Linkage Instructions (BAL, BALR, BAS, BASR, BASSM, BSM)” on page A-8 for an example of the BCR instruction.)

BRANCH ON COUNT (BCT, BCTR)

The BRANCH ON COUNT instruction is often used to execute a program loop for a specified number of times. For example, assume that the following represents some lines of coding in an assembler-language program:

```
    ⋮
LUPE  AR   8,1
    ⋮
BACK  BCT  6,LUPE
    ⋮
```

where register 6 contains 00 00 00 03 and the address of LUPE is 6826. Assume that, in order to address this location, register 10 is used as a base register and contains 00 00 68 00.

The format of the BCT instruction is:

Machine Format

Op Code	R_1	X_2	B_2	D_2
46	6	0	A	026

Assembler Format

```
Op Code  R1,D2(X2,B2)
_____________________
  BCT    6,X'26'(0,10)
```

The effect of the coding is to execute three times the loop defined by the instructions labeled LUPE through BACK, while register 6 is decremented from three to zero.

BRANCH ON INDEX HIGH (BXH)

BXH Example 1

The BRANCH ON INDEX HIGH instruction is an index-incrementing and loop-controlling instruction that causes a branch whenever the sum of an index value and an increment value is greater than some compare value. For example, assume that:

Register 4 contains 00 00 00 8A = 138_{10} = the index.

Register 6 contains 00 00 00 02 = 2_{10} = the increment.

Register 7 contains 00 00 00 AA = 170_{10} = the compare value.

Register 10 contains 00 00 71 30 = the branch address.

The format of the BXH instruction is:

Machine Format

Op Code	R_1	R_3	B_2	D_2
86	4	6	A	000

Assembler Format

```
Op Code   R1,R3,D2(B2)
-------------------
  BXH     4,6,0(10)
```

When the instruction is executed, first the contents of register 6 are added to register 4, second the sum is compared with the contents of register 7, and third the decision whether to branch is made. After execution:

Register 4 contains 00 00 00 8C = 140_{10}.

Registers 6 and 7 are unchanged.

Since the new value in register 4 is not yet greater than the value in register 7, the branch to address 7130 is not taken. Repeated use of the instruction will eventually cause the branch to be taken when the value in register 4 reaches 172_{10}.

BXH Example 2

When the register used to contain the increment is odd, that register also becomes the compare-value register. The following assembler-language subroutine illustrates how this may be used to search a table.

Table	
2 Bytes	2 Bytes
ARG1	FUNCT1
ARG2	FUNCT2
ARG3	FUNCT3
ARG4	FUNCT4
ARG5	FUNCT5
ARG6	FUNCT6

Assume that:

Register 8 contains the search argument.

Register 9 contains the width of the table in bytes (00 00 00 04).

Register 10 contains the length of the table in bytes (00 00 00 18).

Register 11 contains the starting address of the table.

Register 14 contains the return address to the main program.

As the following subroutine is executed, the argument in register 8 is successively compared with the arguments in the table, starting with argument 6 and working backward to argument 1. If an equality is found, the corresponding function replaces the argument in register 8. If an equality is not found, zero replaces the argument in register 8.

```
SEARCH    LNR  9,9
NOTEQUAL  BXH  10,9,LOOP
NOTFOUND  SR   8,8
          BCR  15,14
LOOP      CH   8,0(10,11)
          BC   7,NOTEQUAL
          LH   8,2(10,11)
          BCR  15,14
```

The first instruction (LNR) causes the value in register 9 to be made negative. After execution of this instruction, register 9 contains FF FF FF FC = -4_{10}. Considering the case when no equality is found, the BXH instruction will be executed seven times. Each time BXH is executed, a value of -4 is added to register 10, thus reducing the value in register 10 by 4. The new value in register 10 is compared with the -4 value in register 9. The branch is taken each time until the value in register 10 is -4. Then the branch is not taken, and the SR instruction sets register 8 to zero.

BRANCH ON INDEX LOW OR EQUAL (BXLE)

The BRANCH ON INDEX LOW OR EQUAL instruction performs the same operation as BRANCH ON INDEX HIGH, except that branching occurs when the sum is lower than or equal to (instead of higher than) the compare value. As the instruction which increments and tests an index value in a program loop, BXLE is useful at the end of the loop and BXH at the

beginning. The following assembler-language routines illustrate loops with BXLE.

BXLE Example 1

Assume that a group of ten 32-bit signed binary integers are stored at consecutive locations, starting at location GROUP. The integers are to be added together, and the sum is to be stored at location SUM.

```
        SR   5,5         Set sum to zero
        LA   6,GROUP     Load first address
        SR   7,7         Set index to zero
        LA   8,4         Load increment 4
        LA   9,39        Load compare value
LOOP    A    5,0(7,6)    Add integer to sum
        BXLE 7,8,LOOP    Test end of loop
        ST   5,SUM       Store sum
```

The two-instruction loop contains an ADD (A) instruction which adds each integer to the contents of general register 5. The ADD instruction uses the contents of general register 7 as an index value to modify the starting address obtained from register 6. Next, BXLE increments the index value by 4, the increment previously loaded into register 8, and compares it with the compare value in register 9, the odd register of this even-odd pair. The compare value was previously set to 39, which is one less than the number of bytes in the data area; this is also the address, relative to the starting address, of the rightmost byte of the last integer to be added. When the last integer has been added, BXLE increments the index value to the next relative address (40), which is found to be greater than the compare value (39) so that no branching takes place.

BXLE Example 2

The technique illustrated in Example 1 is restricted to loops containing instructions in the RX instruction format. That format allows both a base register and an index register to be specified (double indexing).

For instructions in other formats, where an index register cannot be specified, the previous technique may be modified by having the address itself serve as the index value in a BXLE instruction and by using as the compare value the address of the last byte rather than its relative address. The base register then provides the address directly at each iteration of the loop, and it is not necessary to specify a second register to hold the index value (single indexing).

In the following example, an AND (NI) instruction in the SI instruction format sets to zero the rightmost bit of each of the same group of integers as in Example 1, thus making all of them even. The I_2 field of the NI instruction contains the byte X'FE', which consists of seven ones and a zero. That byte is ANDed into byte 3, the rightmost byte, of each of the integers in turn.

```
        LA   6,GROUP     Load first address
        LA   8,4         Load increment 4
        LA   9,GROUP+39  Load compare value
LOOP    NI   3(6),X'FE'  AND immediate
        BXLE 6,8,LOOP    Test end of loop
```

The technique shown in Example 2 does not work, however, on an ESA/370 system when it is in the 31-bit addressing mode and the data is located at the rightmost end of a 31-bit address space. In this case, the compare value would be set to 2^{31}-1, which is the largest possible 32-bit signed binary value. The reason the technique does not work is that the BXLE and BXH instructions treat their operands as 32-bit signed binary integers. When the address in general register 6 reaches the value 2^{31}-4, BXLE increments it to a value that is interpreted as -2^{31}, rather than 2^{31}, and the comparison remains low, which causes looping to continue indefinitely.

This situation can be avoided by not allowing data areas to extend to the rightmost location in a 31-bit address space or by using other techniques; these may include double indexing when possible, as in Example 1, or starting at the end and stepping downward through the data area with a negative increment.

COMPARE AND FORM CODEWORD (CFC)

See “Sorting Instructions” on page A-53.

COMPARE HALFWORD (CH)

The COMPARE HALFWORD instruction compares a 16-bit signed binary integer in storage with the contents of a register. For example, assume that:

Register 4 contains FF FF 80 00 = $-32{,}768_{10}$.

Register 13 contains 00 01 60 50.

Storage locations 16080-16081 contain 8000 = $-32{,}768_{10}$.

When the instruction:

Machine Format

Op Code	R_1	X_2	B_2	D_2
49	4	0	D	030

Assembler Format

```
Op Code  R1,D2(X2,B2)
CH       4,X'30'(0,13)
```

is executed, the contents of locations 16080-16081 are fetched, expanded to 32 bits (the sign bit is propagated to the left), and compared with the contents of register 4. Because the two numbers are equal, condition code 0 is set.

COMPARE LOGICAL (CL, CLC, CLI, CLR)

The COMPARE LOGICAL instruction differs from the signed-binary comparison instructions (C, CH, CR) in that all quantities are handled as unsigned binary integers or as unstructured data.

CLC Example

The COMPARE LOGICAL (CLC) instruction can be used to perform the byte-by-byte comparison of storage fields up to 256 bytes in length. For example, assume that the following two fields of data are in storage:

Field 1

1886											1891
D1	D6	C8	D5	E2	D6	D5	6B	C1	4B	C2	4B

Field 2

1900											190B
D1	D6	C8	D5	E2	D6	D5	6B	C1	4B	C3	4B

Also assume:

Register 9 contains 00 00 18 80.

Register 7 contains 00 00 19 00.

Execution of the instruction:

Machine Format

Op Code	L	B_1	D_1	B_2	D_2
D5	0B	9	006	7	000

Assembler Format

```
Op Code  D1(L,B1),D2(B2)
CLC      6(12,9),0(7)
```

sets condition code 1, indicating that the contents of field 1 are lower in value than the contents of field 2.

Because the collating sequence of the EBCDIC code is determined simply by a logical comparison of the bits in the code, the CLC instruction can be used to collate EBCDIC-coded fields. For example, in EBCDIC, the above two data fields are:

```
Field 1:  JOHNSON,A.B.
Field 2:  JOHNSON,A.C.
```

Condition code 1 indicates that JOHNSON,A.B. should precede JOHNSON,A.C. for the fields to be in alphabetic sequence.

CLI Example

The COMPARE LOGICAL (CLI) instruction compares a byte from the instruction stream with a byte from storage. For example, assume that:

Register 10 contains 00 00 17 00.

Storage location 1703 contains 7E.

Execution of the instruction:

Machine Format

Op Code	I_2	B_1	D_1
95	AF	A	003

Assembler Format

```
Op Code  D1(B1),I2
CLI      3(10),X'AF'
```

sets condition code 1, indicating that the first operand (the quantity in main storage) is lower than the second (immediate) operand.

CLR Example

Assume that:

Register 4 contains 00 00 00 01 = 1.

Register 7 contains FF FF FF FF = 2^{32} - 1.

Execution of the instruction:

Machine Format

Op Code	R_1	R_2
15	4	7

Assembler Format

```
Op Code  R1,R2
-------------
  CLR    4,7
```

sets condition code 1. Condition code 1 indicates that the first operand is lower than the second.

If, instead, the signed-binary comparison instruction COMPARE (CR) had been executed, the contents of register 4 would have been interpreted as +1 and the contents of register 7 as -1. Thus, the first operand would have been higher, so that condition code 2 would have been set.

COMPARE LOGICAL CHARACTERS UNDER MASK (CLM)

The COMPARE LOGICAL CHARACTERS UNDER MASK (CLM) instruction provides a means of comparing bytes selected from a general register to a contiguous field of bytes in storage. The M_3 field of the CLM instruction is a four-bit mask that selects zero to four bytes from a general register, each mask bit corresponding, left to right, to a register byte. In the comparison, the register bytes corresponding to ones in the mask are treated as a contiguous field. The operation proceeds left to right. For example, assume that:

Storage locations 10200-10202 contain F0 BC 7B.

Register 12 contains 00 01 00 00.

Register 6 contains F0 BC 5C 7B.

Execution of the instruction:

Machine Format

Op Code	R_1	M_3	B_2	D_2
BD	6	D	C	200

Assembler Format

```
Op Code  R1,M3,D2(B2)
--------------------------------
  CLM    6,B'1101',X'200'(12)
```

causes the following comparison:

```
Register 6:  F0   BC   5C   7B
   Mask M3:   1    1    0    1
              --   --        --

                F0   BC         7B
                |    |          |
                |    |    |     |
Storage         |    |    |     |
Locations       |    |    |     |
10200-10202:    |    |    |     |
                +----+----+-----+
                | F0 | BC | 7B  |
                +----+----+-----+
```

Because the selected bytes are equal, condition code 0 is set.

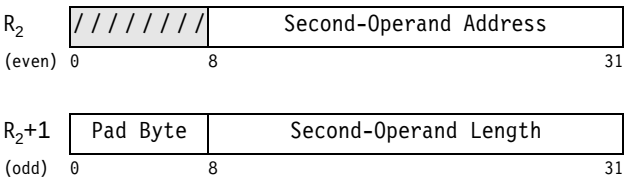
COMPARE LOGICAL LONG (CLCL)

The COMPARE LOGICAL LONG instruction is used to compare two operands in storage, byte by byte. Each operand can be of any length. Two even-odd pairs of general registers (four registers in all) are used to locate the operands and to control the execution of the CLCL instruction, as illustrated in the following diagram. The first register of each pair must be an even register, and it contains the storage address of an operand. The odd register of each pair contains the length of the operand it covers, and the leftmost byte of the second-operand odd register contains a padding byte which is used to extend the shorter operand, if any, to the same length as the longer operand.

The following illustrates the assignment of registers in the 24-bit addressing mode:

```
R1      +--------+-------------------------+
(even)  |////////|  First-Operand Address  |
        0        8                         31

R1+1    +--------+-------------------------+
(odd)   |////////|  First-Operand Length   |
        0        8                         31
```



In the 31-bit addressing mode, the operand addresses would be in bit positions 1-31 of the even registers shown above.

Since the CLCL instruction may be interrupted during execution, the interrupting program must preserve the contents of the four registers for use when the instruction is resumed.

The following instructions set up two register pairs to control a text-string comparison. For example, assume:

Operand 1
Address: 20800_{16}
Length: 100_{10}

Operand 2
Address: $20A00_{16}$
Length: 132_{10}

Padding Byte
Address: 20003_{16}
Length: 1
Value: 40_{16}

Register 12 contains 00 02 00 00.

The setup instructions are:

LA	4,X'800'(12)	Set register 4 to start of first operand
LA	5,100	Set register 5 to length of first operand
LA	8,X'A00'(12)	Set register 8 to start of second operand
LA	9,132	Set register 9 to length of second operand
ICM	9,B'1000',3(12)	Insert padding byte in leftmost byte position of register 9

Register pair 4,5 defines the first operand. Bits 8-31 of register 4 contain the storage address of the start of an EBCDIC text string, and bits 8-31 of register 5 contain the length of the string, in this case 100 bytes.

Register pair 8,9 defines the second operand, with bits 8-31 of register 8 containing the starting location of the second operand and bits 8-31 of register 9 containing the length of the second operand, in this case 132 bytes. Bits 0-7 of register 9 contain an EBCDIC blank character (X'40') to pad the shorter operand. In this example, the padding byte is used in the first operand, after the 100th byte, to compare with the remaining bytes in the second operand.

With the register pairs thus set up, the format of the CLCL instruction is:

Machine Format

Op Code	R_1	R_2
0F	4	8

Assembler Format

```
Op Code  R1,R2
---------------
  CLCL    4,8
```

When this instruction is executed, the comparison starts at the left end of each operand and proceeds to the right. The operation ends as soon as an inequality is detected or the end of the longer operand is reached.

If this CLCL instruction is interrupted after 60 bytes have compared equal, the operand lengths in registers 5 and 9 will have been decremented to 40 and 72, respectively. The operand addresses in registers 4 and 8 will have been incremented to X'2083C' and X'20A3C'; the leftmost byte of registers 4 and 8 will have been set to zero. The padding byte X'40' remains in register 9. When the CLCL instruction is reexecuted with these register contents, the comparison resumes at the point of interruption.

Now, assume that the instruction is interrupted after 110 bytes. That is, the first 100 bytes of the second operand have compared equal to the first operand, and the next 10 bytes of the second operand have compared equal to the padding byte (blank). The residual operand lengths in registers 5 and 9 are 0 and 22, respectively, and the operand addresses in registers 4 and 8 are X'20864' (the value when the first operand was exhausted) and X'20A6E' (the current value for the second operand).

When the comparison ends, the condition code is set to 0, 1, or 2, depending on whether the first operand

is equal to, less than, or greater than the second operand, respectively.

When the operands are unequal, the addresses in registers 4 and 8 indicate the bytes that caused the mismatch.

COMPARE LOGICAL STRING (CLST)

The COMPARE LOGICAL STRING instruction is used to compare a first operand designated by general register R_1 and a second operand designated by general register R_2. The comparison is made left to right, byte by byte, until unequal bytes are compared, an ending character specified in general register 0 is encountered in either operand, or a CPU-determined number of bytes have been compared. The condition code is set to 0 if the two operands are equal, to 1 if the first operand is low, to 2 if the second operand is low, or to 3 if a CPU-determined number of bytes have been compared. If the ending character is found in both operands simultaneously, the operands are equal. If it is found in only one operand, that operand is low.

When condition code 1 or 2 is set, the addresses of the last bytes processed in the first and second operands are placed in general registers R_1 and R_2, respectively. These are the addresses of unequal bytes in the two operands, or they are the address of an ending character in one operand and of the byte in the corresponding byte position in the other operand. When condition code 3 is set, the addresses of the next bytes to be processed are placed in the registers. When condition code 0 is set, the contents of the registers remain unchanged.

Following are examples of first and second operands beginning at decimal locations 1000 and 2000, respectively. The addresses in general registers R_1 and R_2 are 1000 and 2000, respectively. The ending character in general register 0 is 00 hex (as in the C programming language). The values of the operand bytes are shown in hex, and the resulting condition code and final contents of general registers R_1 and R_2 are shown.

Example 1

```
1000           2000
C1 C2 C3 00    C1 C2 C3 00

CC: 0; (R1): 1000; (R2): 2000
```

Example 2

```
1000           2000
40 40 40 C1    40 40 40 C2

CC: 1; (R1): 1003; (R2): 2003
```

Example 3

```
1000           2000
40 40 40 C2    40 40 40 C1

CC: 2; (R1): 1003; (R2): 2003
```

Example 4

```
1000           2000
C1 C2 C3 00    C1 C2 C3 C4

CC: 1; (R1): 1003; (R2): 2003
```

Example 5

```
1000           2000
C1 C2 C3 C4    C1 C2 C3 00

CC: 2; (R1): 1003; (R2): 2003
```

Example 6

Assuming that the CPU-determined number of bytes compared is 256:

```
1000     1256  2000     2256
40 .. 40 00    40 .. 40 00

CC: 3; (R1): 1256; (R2): 2256
```

Example 7

```
1000           2000
00 40 40 40    40 40 40 40

CC: 1; (R1): 1000; (R2): 2000
```

Example 8

```
1000           2000
40 40 40 40    00 40 40 40

CC: 2; (R1): 1000; (R2): 2000
```

Example 9

```
1000           2000
00 40 40 40    00 40 40 40

CC: 0; (R1): 1000; (R2): 2000
```

CONVERT TO BINARY (CVB)

The CONVERT TO BINARY instruction converts an eight-byte, signed-packed-decimal number into a signed binary integer and loads the result into a gen-

eral register. After the conversion operation is completed, the number is in the proper form for use as an operand in signed binary arithmetic. For example, assume:

Storage locations 7608-760F contain a decimal number in the signed-packed-decimal format: 00 00 00 00 00 25 59 4C (+25,594).

The contents of register 7 are not significant.

Register 13 contains 00 00 76 00.

The format of the conversion instruction is:

Machine Format

Op Code	R_1	X_2	B_2	D_2
4F	7	0	D	008

Assembler Format

Op Code	R_1,D_2(X_2,B_2)
CVB	7,8(0,13)

After the instruction is executed, register 7 contains 00 00 63 FA.

CONVERT TO DECIMAL (CVD)

The CONVERT TO DECIMAL instruction is the opposite of the CONVERT TO BINARY instruction. CVD converts a signed binary integer in a register to signed-packed-decimal number and stores the eight-byte result. For example, assume:

Register 1 contains the signed binary integer: 00 00 0F 0F.

Register 13 contains 00 00 76 00.

The format of the instruction is:

Machine Format

Op Code	R_1	X_2	B_2	D_2
4E	1	0	D	008

Assembler Format

Op Code	R_1,D_2(X_2,B_2)
CVD	1,8(0,13)

After the instruction is executed, storage locations 7608-760F contain 00 00 00 00 00 03 85 5C (+3855).

The plus sign generated is the preferred plus sign, 1100_2.

DIVIDE (D, DR)

The DIVIDE instruction divides the dividend in an even-odd register pair by the divisor in a register or in storage. Since the instruction assumes the dividend to be 64 bits long, it is important first to extend a 32-bit dividend on the left with bits equal to the sign bit. For example, assume that:

Storage locations 3550-3553 contain 00 00 08 DE = 2270_{10} (the dividend).

Storage locations 3554-3557 contain 00 00 00 32 = 50_{10} (the divisor).

The initial contents of registers 6 and 7 are not significant.

Register 8 contains 00 00 35 50.

The following assembler-language statements load the registers properly and perform the divide operation:

Statement	Comments
L 6,0(0,8)	Places 00 00 08 DE into register 6.
SRDA 6,32(0)	Shifts 00 00 08 DE into register 7. Register 6 is filled with zeros (sign bits).
D 6,4(0,8)	Performs the division.

The machine format of the above DIVIDE instruction is:

Machine Format

Op Code	R_1	X_2	B_2	D_2
5D	6	0	8	004

After the instructions listed above are executed:

Register 6 contains 00 00 00 14 = 20_{10} = the remainder.

Register 7 contains 00 00 00 2D = 45_{10} = the quotient.

Note that if the dividend had not been first placed in register 6 and shifted into register 7, register 6 might not have been filled with the proper dividend-sign bits (zeros in this example), and the DIVIDE instruction might not have given the expected results.

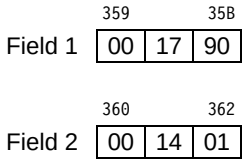
EXCLUSIVE OR (X, XC, XI, XR)

When the Boolean operator EXCLUSIVE OR is applied to two bits, the result is one when either, but not both, of the two bits is one; otherwise, the result is zero. When two bytes are EXCLUSIVE ORed, each pair of bits is handled separately; there is no connection from one bit position to another. The following is an example of the EXCLUSIVE OR of two bytes:

```
First-operand byte:    0011 0101₂
Second-operand byte:   0101 1100₂
-------------------------------------
Result byte:           0110 1001₂
```

XC Example

The EXCLUSIVE OR (XC) instruction can be used to exchange the contents of two areas in storage without the use of an intermediate storage area. For example, assume two three-byte fields in storage:



Execution of the instruction (assume that register 7 contains 00 00 03 58):

Machine Format

Op Code	L	B_1	D_1	B_2	D_2
D7	02	7	001	7	008

Assembler Format

Op Code	$D_1(L,B_1),D_2(B_2)$
XC	1(3,7),8(7)

Field 1 is EXCLUSIVE ORed with field 2 as follows:

```
Field 1:  00000000 00010111 10010000₂ = 00 17 90₁₆
Field 2:  00000000 00010100 00000001₂ = 00 14 01₁₆
-------------------------------------------------
Result:   00000000 00000011 10010001₂ = 00 03 91₁₆
```

The result replaces the former contents of field 1. Condition code 1 is set to indicate a nonzero result.

Now, execution of the instruction:

Machine Format

Op Code	L	B_1	D_1	B_2	D_2
D7	02	7	008	7	001

Assembler Format

Op Code	$D_1(L,B_1),D_2(B_2)$
XC	8(3,7),1(7)

produces the following result:

```
Field 1:  00000000 00000011 10010001₂ = 00 03 91₁₆
Field 2:  00000000 00010100 00000001₂ = 00 14 01₁₆
-------------------------------------------------
Result:   00000000 00010111 10010000₂ = 00 17 90₁₆
```

The result of this operation replaces the former contents of field 2. Field 2 now contains the original value of field 1. Condition code 1 is set to indicate a nonzero result.

Lastly, execution of the instruction:

Machine Format

Op Code	L	B_1	D_1	B_2	D_2
D7	02	7	001	7	008

Assembler Format

Op Code	$D_1(L,B_1),D_2(B_2)$
XC	1(3,7),8(7)

produces the following result:

```
Field 1:  00000000 00000011 10010001₂ = 00 03 91₁₆
Field 2:  00000000 00010111 10010000₂ = 00 17 90₁₆
-------------------------------------------------
Result:   00000000 00010100 00000001₂ = 00 14 01₁₆
```

The result of this operation replaces the former contents of field 1. Field 1 now contains the original value of field 2. Condition code 1 is set to indicate a nonzero result.

XI Example

A frequent use of the EXCLUSIVE OR (XI) instruction is to invert a bit (change a zero bit to a one or a one bit to a zero). For example, assume that storage location 8082 contains 0110 1001_2. To invert the leftmost and rightmost bits without affecting any of the other bits, the following instruction can be used (assume that register 9 contains 00 00 80 80):

Machine Format

Op Code	I_2	B_1	D_1
97	81	9	002

Assembler Format

```
Op Code  D1(B1),I2
-------------------
   XI    2(9),X'81'
```

When the instruction is executed, the byte in storage is EXCLUSIVE ORed with the immediate byte (the I_2 field of the instruction):

```
Location 8082:   0110 1001₂
Immediate byte:  1000 0001₂
---------------------------
Result:          1110 1000₂
```

The resulting byte is stored back in location 8082. Condition code 1 is set to indicate a nonzero result.

Notes:

1. With the XC instruction, fields up to 256 bytes in length can be exchanged.
2. With the XR instruction, the contents of two registers can be exchanged.
3. Because the X instruction operates storage to register only, an exchange cannot be made solely by the use of X.
4. A field EXCLUSIVE ORed with itself is cleared to zeros.
5. For additional examples of the use of EXCLUSIVE OR, see “Hexadecimal-Floating-Point-Number Conversion” on page A-44.

EXECUTE (EX)

The EXECUTE instruction causes one *target instruction* in main storage to be executed out of sequence without actually branching to the target instruction. Unless the R_1 field of the EXECUTE instruction is zero, bits 8-15 of the target instruction are ORed with bits 56-63 of the R_1 register before the target instruction is executed. Thus, EXECUTE may be used to supply the length field for an SS instruction without modifying the SS instruction in storage. For example, assume that a MOVE (MVC) instruction is the target that is located at address 3820, with a format as follows:

Machine Format

Op Code	L	B_1	D_1	B_2	D_2
D2	00	C	003	D	000

Assembler Format

```
Op Code  D1(L,B1),D2(B2)
------------------------
  MVC    3(1,12),0(13)
```

where register 12 contains 00 00 89 13 and register 13 contains 00 00 90 A0.

Further assume that at storage address 5000, the following EXECUTE instruction is located:

Machine Format

Op Code	R_1	X_2	B_2	D_2
44	1	0	A	000

Assembler Format

```
Op Code  R1,D2(X2,B2)
---------------------
   EX    1,0(0,10)
```

where register 10 contains 00 00 38 20 and register 1 contains 00 0F F0 03.

When the instruction at 5000 is executed, the rightmost byte of register 1 is ORed with the second byte of the target instruction:

```
Instruction byte:   0000 0000₂ = 00
Register byte:      0000 0011₂ = 03
-----------------------------------
Result:             0000 0011₂ = 03
```

causing the instruction at 3820 to be executed as if it originally were:

Machine Format

Op Code	L	B_1	D_1	B_2	D_2
D2	03	C	003	D	000

Assembler Format

```
Op Code  D1(L,B1),D2(B2)
-------------------------
  MVC    3(4,12),0(13)
```

However, after execution:

Register 1 is unchanged.

The instruction at 3820 is unchanged.

The contents of the four bytes starting at location 90A0 have been moved to the four bytes starting at location 8916.

The CPU next executes the instruction at address 5004 (PSW bits 104-127 contain 00 50 04).

FIND LEFTMOST ONE (FLOGR)

FIND LEFTMOST ONE may be used to locate free objects, the availability of which is tracked in a hierarchical bit map.

In the following example, the hierarchical bit map consists of multiple levels of bits, each level having 64 times the number of bits as the next lower-numbered level. This example shows four levels, mapping a total of 16M objects, however additional levels may be added to manage larger numbers of objects.

The highest-numbered bit map level (L3 in this illustration) represents the availability of individual objects, for example, records or pages. A one bit indicates that the object is available, and a zero bit means that the object is not available.

In lower-numbered bit map levels (L0, L1, and L2 in this illustration), a bit position corresponds to a doubleword in the next higher-numbered level. When a bit in a lower-numbered bit map level is one, at least one bit of the corresponding doubleword in the higher-level is one. When a bit in a lower-number bit map level is zero, no bits in the corresponding higher-level doubleword are one.

An example of using FIND LEFTMOST ONES to quickly locate the next available lowest-numbered object, as mapped by such a hierarchical bit map, is shown below. Upon completion, at the label “FOUND”, general register 15 contains the number of the located object. If no objects are available, the code branches to the label “NOTFND”.

```
       LA    15,0           Zero accumulator
       LA    9,OFFSET       Point to table
       LA    10,4           Load increment
       LA    11,ENDOFF-1    Load compare value
FIND   LGR   7,15           Copy accum. to R7
       ALGF  7,0(,9)        Add # DWs to bits
       SLLG  7,7,3          Get byte offset
       LG    1,BITS(7)      Get DW to test
       FLOGR 0,1            Find leftmost one
       BZ    NOTFND         No one bits found
       SLLG  15,15,6        Times # bits in DW
       AGR   15,0           Add bit just found
       BXLEG 9,10,FIND      Do for each level
FOUND  STG   1,BITS(7)      Update changed bit
       ...
NOTFND [Any instruction]

OFFSET DC    A((L0-BITS)/8) Offset to level 0
       DC    A((L1-BITS)/8) Offset to level 1
       DC    A((L2-BITS)/8) Offset to level 2
       DC    A((L3-BITS)/8) Offset to level 3
ENDOFF EQU   *              End of table

BITS   DS    0D             Start of bit map
L0     DS    FD             -L0 (64 objects)
L1     DS    64FD           -L1 (4K objects)
L2     DS    (64*64)FD      -L2 (256K objects)
L3     DS    (64*64*64)FD   -L3 (16M objects)
```

This code sequence shows the zeroing of the found bit with the STORE (STG) instruction at the label “FOUND”. Proper maintenance of such a hierarchical bit map requires that when all bits of a doubleword become zeros, the corresponding bit in the next lower-numbered level is set to zeros. Similarly, when adding a free object to the highest level, the corresponding bits in lower-numbered levels must be set to one. These maintenance functions are not shown.

Note, in a multiprocessing environment, access to the bit map is assumed to be serialized for the duration of the update process.

INSERT CHARACTERS UNDER MASK (ICM)

The INSERT CHARACTERS UNDER MASK (ICM) instruction may be used to replace all or selected bytes in a general register with bytes from storage and to set the condition code to indicate the value of the inserted field.

For example, if it is desired to insert a three-byte address from FIELDA into register 5 and leave the leftmost byte of the register unchanged, assume:

Machine Format

Op Code	R_1	M_3	S_2
BF	5	7	* * * *

Assembler Format

```
Op Code  R1,M3,S2
─────────────────────────
  ICM    5,B'0111',FIELDA

FIELDA:                   FE DC BA
Register 5 (before):      12 34 56 78
Register 5 (after):       12 FE DC BA
Condition code (after):   1 (leftmost bit of
                             inserted field
                             is one)
```

As another example:

Machine Format

Op Code	R_1	M_3	S_2
BF	6	9	* * * *

Assembler Format

```
Op Code  R1,M3,S2
─────────────────────────
  ICM    6,B'1001',FIELDB

FIELDB:                  12 34
Register 6 (before):     00 00 00 00
Register 6 (after):      12 00 00 34
Condition code (after): 2 (inserted field is
                           nonzero with left-
                           most zero bit)
```

When the mask field contains 1111, the ICM instruction produces the same result as LOAD (L) (provided that the indexing capability of the RX format is not needed), except that ICM also sets the condition code. The condition-code setting is useful when an all-zero field (condition code 0) or a leftmost one bit (condition code 1) is used as a flag.

LOAD (L, LR)

The LOAD instruction takes four bytes from storage or from a general register and place them unchanged into a general register. For example, assume that the four bytes starting with location 21003 are to be loaded into register 10. Initially:

Register 5 contains 00 02 00 00.

Register 6 contains 00 00 10 03.

The contents of register 10 are not significant.

Storage locations 21003-21006 contain 00 00 AB CD.

To load register 10, the RX form of the instruction can be used:

Machine Format

Op Code	R_1	X_2	B_2	D_2
58	A	5	6	000

Assembler Format

```
Op Code  R1,D2(X2,B2)
──────────────────────
   L     10,0(5,6)
```

After the instruction is executed, register 10 contains 00 00 AB CD.

LOAD ADDRESS (LA)

The LOAD ADDRESS instruction provides a convenient way to place a nonnegative binary integer up to 4095_{10} in a register without first defining a constant and then using it as an operand. For example, the following instruction places the number 2048_{10} in register 1:

Machine Format

Op Code	R_1	X_2	B_2	D_2
41	1	0	0	800

Assembler Format

Op Code	R_1,D_2(X_2,B_2)
LA	1,2048(0,0)

The LOAD ADDRESS instruction can also be used to increment a register by an amount up to 4095_{10} specified in the D_2 field. Depending on the addressing mode, only the rightmost 24 or 31 bits of the sum are retained, however. The leftmost bits of the 32-bit result are set to zeros. For example, assume that register 5 contains 00 12 34 56.

The instruction:

Machine Format

Op Code	R_1	X_2	B_2	D_2
41	5	0	5	00A

Assembler Format

Op Code	R_1,D_2(X_2,B_2)
LA	5,10(0,5)

adds 10 (decimal) to the contents of register 5 as follows:

```
Register 5 (old):  00 12 34 56
D2 field:          00 00 00 0A
-----------------------------
Register 5 (new):  00 12 34 60
```

The register may be specified as either B_2 or X_2. Thus, the instruction LA 5,10(5,0) produces the same result.

As the most general example, the instruction LA 6,10(5,4) forms the sum of three values: the contents of register 4, the contents of register 5, and a displacement of 10 and places the 24-bit or 31-bit sum with zeros appended on the left in register 6.

LOAD HALFWORD (LH)

The LOAD HALFWORD instruction places unchanged a halfword from storage into the right half of a register. The left half of the register is loaded with zeros or ones according to the sign (leftmost bit) of the halfword.

For example, assume that the two bytes in storage locations 1803-1804 are to be loaded into register 6. Also assume:

The contents of register 6 are not significant.

Register 14 contains 00 00 18 03.

Locations 1803-1804 contain 00 20.

The instruction required to load the register is:

Machine Format

Op Code	R_1	X_2	B_2	D_2
48	6	0	E	000

Assembler Format

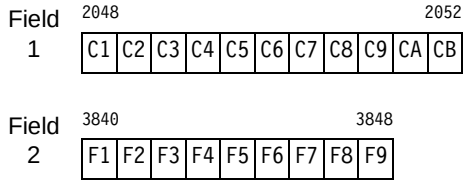
Op Code	R_1,D_2(X_2,B_2)
LH	6,0(0,14)

After the instruction is executed, register 6 contains 00 00 00 20. If locations 1803-1804 had contained a negative number, for example, A7 B6, a minus sign would have been propagated to the left, giving FF FF A7 B6 as the final result in register 6.

MOVE (MVC, MVI)

MVC Example

The MOVE (MVC) instruction can be used to move data from one storage location to another. For example, assume that the following two fields are in storage:



Also assume:

Register 1 contains 00 00 20 48.

Register 2 contains 00 00 38 40.

With the following instruction, the first eight bytes of field 2 replace the first eight bytes of field 1:

Machine Format

Op Code	L	B_1	D_1	B_2	D_2
D2	07	1	000	2	000

Assembler Format

```
Op Code  D1(L,B1),D2(B2)
MVC      0(8,1),0(2)
```

After the instruction is executed, field 1 becomes:

Field 1	2048										2052
	F1	F2	F3	F4	F5	F6	F7	F8	C9	CA	CB

Field 2 is unchanged.

MVC can also be used to propagate a byte through a field by starting the first-operand field one byte location to the right of the second-operand field. For example, suppose that an area in storage starting with address 358 contains the following data:

358								360
00	F1	F2	F3	F4	F5	F6	F7	F8

With the following MVC instruction, the zeros in location 358 can be propagated throughout the entire field (assume that register 11 contains 00 00 03 58):

Machine Format

Op Code L B_1 D_1 B_2 D_2

D2 07 B 001 B 000

Assembler Format

```
Op Code  D1(L,B1),D2(B2)
MVC      1(8,11),0(11)
```

Because MVC is executed as if one byte were processed at a time, the above instruction, in effect, takes the byte at address 358 and stores it at 359 (359 now contains 00), takes the byte at 359 and stores it at 35A, and so on, until the entire field is filled with zeros. Note that an MVI instruction could have been used originally to place the byte of zeros in location 358.

Notes:

1. Although the field occupying locations 358-360 contains nine bytes, the length coded in the assembler format is equal to the number of moves (one less than the field length).
2. The order of operands is important even though only one field is involved.

MVI Example

The MOVE (MVI) instruction places one byte of information from the instruction stream into storage. For example, the instruction:

Machine Format

Op Code	I_2	B_1	D_1
92	5B	1	000

Assembler Format

```
Op Code  D1(B1),I2
MVI      0(1),C'$'
```

may be used, in conjunction with the instruction EDIT AND MARK, to insert the EBCDIC code for a dollar symbol at the storage address contained in general register 1 (see also the example for EDIT AND MARK).

MOVE INVERSE (MVCIN)

The MOVE INVERSE (MVCIN) instruction can be used to move data from one storage location to another while reversing the order of the bytes within the field. For example, assume that the following two fields are in storage:

Field 1	2048										2052
	C1	C2	C3	C4	C5	C6	C7	C8	C9	CA	CB

Field 2	3840								3848
	F1	F2	F3	F4	F5	F6	F7	F8	F9

Also assume:

Register 1 contains 00 00 20 48.

Register 2 contains 00 00 38 40.

With the following instruction, the first eight bytes of field 2 replace the first eight bytes of field 1:

Machine Format

Op Code	L	B_1	D_1	B_2	D_2
E8	07	1	000	2	007

Assembler Format

```
Op Code  D1(L,B1),D2(B2)
MVCIN    0(8,1),7(2)
```

After the instruction is executed, field 1 becomes:

Field 1	2048										2052
	F8	F7	F6	F5	F4	F3	F2	F1	C9	CA	CB

2048 2052

Field 2 is unchanged.

Note: This example uses the same general registers, storage locations, and original values as the first example for MVC. For MVCIN, the second-operand address must designate the rightmost byte of the field to be moved, in this case location 3847. This is accomplished by means of the 7 in the D_2 field of the instruction.

MOVE LONG (MVCL)

The MOVE LONG (MVCL) instruction can be used for moving data in storage as in the first example of the MVC instruction, provided that the two operands do not overlap. MVCL differs from MVC in that the address and length of each operand are specified in an even-odd pair of general registers. Consequently, MVCL can be used to move more than 256 bytes of data with one instruction. As an example, assume:

Register 2 contains 00 0A 00 00.

Register 3 contains 00 00 08 00.

Register 8 contains 00 06 00 00.

Register 9 contains 00 00 08 00.

Execution of the instruction:

Machine Format

Op Code	R_1	R_2
0E	8	2

Assembler Format

```
Op Code  R1,R2
MVCL     8,2
```

moves $2{,}048_{10}$ bytes from locations A0000-A07FF to locations 60000-607FF. Assuming that the CPU is in the 24-bit addressing mode, bits 8-31 of registers 2 and 8 are incremented by 800_{16}, and bits 0-7 of registers 2 and 8 are set to zeros. Bits 8-31 of registers 3 and 9 are decremented to zero. Condition code 0 is set to indicate that the operand lengths are equal.

If register 3 had contained F0 00 04 00, only the $1{,}024_{10}$ bytes from locations A0000-A03FF would have been moved to locations 60000-603FF. The remaining locations 60400-607FF of the first operand would have been filled with 1,024 copies of the padding byte X'F0', as specified by the leftmost byte of register 3. Bits 8-31 of register 2 would have been incremented by 400_{16}, bits 8-31 of register 8 would have been incremented by 800_{16}, and bits 0-7 of registers 2 and 8 would have been set to zeros. Bits 8-31 of registers 3 and 9 would still have been decremented to zero. Condition code 2 would have been set to indicate that the first operand was longer than the second.

The technique for setting a field to zeros that is illustrated in the second example of MVC cannot be used with MVCL. If the registers were set up to attempt such an operation with MVCL, no data movement would take place and condition code 3 would indicate destructive overlap.

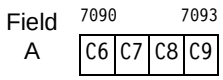
Instead, MVCL may be used to clear a storage area to zeros as follows. Assume register 8 and 9 are set up as before. Register 3 contains only zeros, specifying zero length for the second operand and a zero padding byte. Register 2 is not used to access storage, and its contents are not significant. Executing the instruction MVCL 8,2 causes locations 60000-607FF to be filled with zeros. Bits 8-31 of register 8 are incremented by 800_{16}, and bits 0-7 of registers 2 and 8 are set to zeros. Bits 8-31 of register 9 are decremented to zero, and condition code 2 is set to indicate that the first operand is longer than the second.

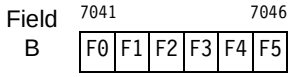
MOVE NUMERICS (MVN)

Two related instructions, MOVE NUMERICS and MOVE ZONES, may be used with decimal data in the zoned format to operate separately on the rightmost

four bits (the numeric bits) and the leftmost four bits (the zone bits) of each byte. Both are similar to MOVE (MVC), except that MOVE NUMERICS moves only the numeric bits and MOVE ZONES moves only the zone bits.

To illustrate the operation of the MOVE NUMERICS instruction, assume that the following two fields are in storage:





Also assume:

Register 14 contains 00 00 70 90.

Register 15 contains 00 00 70 40.

After the instruction:

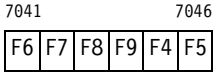
Machine Format

Op Code	L	B_1	D_1	B_2	D_2
D1	03	F	001	E	000

Assembler Format

```
Op Code  D1(L,B1),D2(B2)
-------------------------
  MVN    1(4,15),0(14)
```

is executed, field B becomes:



The numeric bits of the bytes at locations 7090-7093 have been stored in the numeric bits of the bytes at locations 7041-7044. The contents of locations 7090-7093 and 7045-7046 are unchanged.

MOVE STRING (MVST)

The MOVE STRING instruction is used to move a second operand designated by general register R_2 to a first-operand location designated by general register R_1. The movement is made left to right until an ending character specified in general register 0 has been moved or a CPU-determined number of bytes have been moved. The condition code is set to 1 if the ending character was moved or to 3 if a CPU-determined number of bytes were moved.

When condition code 1 is set, the address of the ending character in the first operand is placed in general register R_1, and the contents of general register R_2 remain unchanged. When condition code 3 is set, the address of the next byte to be processed in the first and second operands is placed in general registers R_1 and R_2, respectively.

Following is an example program that sets string A equal to the concatenation of string B followed by string C, where the length of each of strings B and C is unknown, and the end of each of strings B and C is indicated by an ending character of 00 hex (as in the C programming language). The program is not written for execution in the access-register mode.

```
         L      4,STRAADR
         L      5,STRBADR
         SR     0,0
LOOP1    MVST   4,5
         BC     1,LOOP1
         L      5,STRCADR
LOOP2    MVST   4,5
         BC     1,LOOP2
         [Any instruction]
```

MOVE WITH OFFSET (MVO)

MOVE WITH OFFSET may be used to shift a signed-packed-decimal number an odd number of digit positions or to concatenate a sign to an unsigned-packed-decimal number.

Assume that the three-byte unsigned-packed-decimal number in storage locations 4500-4502 is to be moved to locations 5600-5603 and given the sign of the signed-packed-decimal number ending at location 5603. Also assume:

Register 12 contains 00 00 56 00.

Register 15 contains 00 00 45 00.

Storage locations 5600-5603 contain 77 88 99 0C.

Storage locations 4500-4502 contain 12 34 56.

After the instruction:

Machine Format

Op Code	L_1	L_2	B_1	D_1	B_2	D_2
F1	3	2	C	000	F	000

Assembler Format

Op Code	$D_1(L_1,B_1),D_2(L_2,B_2)$
MVO	0(4,12),0(3,15)

is executed, the storage locations 5600-5603 contain 01 23 45 6C. Note that the second operand is extended on the left with one zero to fill out the first-operand field.

MOVE ZONES (MVZ)

The MOVE ZONES instruction can operate on overlapping or nonoverlapping fields, as can the instructions MOVE (MVC) and MOVE NUMERICS. When operating on nonoverlapping fields, MOVE ZONES works like the MOVE NUMERICS instruction (see its example), except that MOVE ZONES moves only the zone bits of each byte. To illustrate the use of MOVE ZONES with overlapping fields, assume that the following data field is in storage:

800					805
F1	C2	F3	C4	F5	C6

Also assume that register 15 contains 00 00 08 00. The instruction:

Machine Format

Op Code	L	B_1	D_1	B_2	D_2
D3	04	F	001	F	000

Assembler Format

Op Code	$D_1(L,B_1),D_2(B_2)$
MVZ	1(5,15),0(15)

propagates the zone bits from the byte at address 800 through the entire field, so that the field becomes:

800					805
F1	F2	F3	F4	F5	F6

MULTIPLY (M, MR)

Assume that a number in register 5 is to be multiplied by the contents of a four-byte field at address 3750. Initially:

The contents of register 4 are not significant.

Register 5 contains 00 00 00 9A = 154_{10} = the multiplicand.

Register 11 contains 00 00 06 00.

Register 12 contains 00 00 30 00.

Storage locations 3750-3753 contain 00 00 00 83 = 131_{10} = the multiplier.

The instruction required for performing the multiplication is:

Machine Format

Op Code	R_1	X_2	B_2	D_2
5C	4	B	C	150

Assembler Format

Op Code	$R_1,D_2(X_2,B_2)$
M	4,X'150'(11,12)

After the instruction is executed, the product is in the register pair 4 and 5:

Register 4 contains 00 00 00 00.

Register 5 contains 00 00 4E CE = $20{,}174_{10}$.

Storage locations 3750-3753 are unchanged.

The RR format of the instruction can be used to square the number in a register. Assume that register 7 contains 00 01 00 05. The contents of register 6 are not significant. The instruction:

Machine Format

Op Code	R_1	R_2
1C	6	7

Assembler Format

Op Code	R_1,R_2
MR	6,7

multiplies the number in register 7 by itself and places the result in the pair of registers 6 and 7:

Register 6 contains 00 00 00 01.

Register 7 contains 00 0A 00 19.

MULTIPLY HALFWORD (MH)

The MULTIPLY HALFWORD instruction is used to multiply the contents of a register by a two-byte field in storage. For example, assume that:

Register 11 contains 00 00 00 15 = 21_{10} = the multiplicand.

Register 14 contains 00 00 01 00.

Register 15 contains 00 00 20 00.

Storage locations 2102-2103 contain FF D9 = -39_{10} = the multiplier.

The instruction:

Machine Format

Op Code	R_1	X_2	B_2	D_2
4C	B	E	F	002

Assembler Format

Op Code	R_1,D_2(X_2,B_2)
MH	11,2(14,15)

multiplies the two numbers. The product, FF FF FC CD = -819_{10}, replaces the original contents of register 11.

Only the rightmost 32 bits of a product are stored in a register; any significant bits on the left are lost. No program interruption occurs on overflow.

OR (O, OC, OI, OR)

When the Boolean operator OR is applied to two bits, the result is one when either bit is one; otherwise, the result is zero. When two bytes are ORed, each pair of bits is handled separately; there is no connection from one bit position to another. The following is an example of ORing two bytes:

First-operand byte:	$0011\ 0101_2$
Second-operand byte:	$0101\ 1100_2$
Result byte:	$0111\ 1101_2$

OI Example

A frequent use of the OR instruction is to set a particular bit to one. For example, assume that storage location 4891 contains $0100\ 0010_2$. To set the rightmost bit of this byte to one without affecting the other bits, the following instruction can be used (assume that register 8 contains 00 00 48 90):

Machine Format

Op Code	I_2	B_1	D_1
96	01	8	001

Assembler Format

Op Code	D_1(B_1),I_2
OI	1(8),X'01'

When this instruction is executed, the byte in storage is ORed with the immediate byte (the I_2 field of the instruction):

Location 4891:	$0100\ 0010_2$
Immediate byte:	$0000\ 0001_2$
Result:	$0100\ 0011_2$

The resulting byte with bit 7 set to one is stored back in location 4891. Condition code 1 is set.

PACK (PACK)

Assume that storage locations 1000-1003 contain the following zoned-decimal number that is to be converted to a signed-packed-decimal number and left in the same location:

	1000			1003
Zoned number	F1	F2	F3	C4

Also assume that register 12 contains 00 00 10 00. After the instruction:

Machine Format

Op Code	L_1	L_2	B_1	D_1	B_2	D_2
F2	3	3	C	000	C	000

Assembler Format

Op Code	$D_1(L_1,B_1),D_2(L_2,B_2)$
PACK	0(4,12),0(4,12)

is executed, the result in locations 1000-1003 is in the signed-packed-decimal format:

	1000			1003
Signed-packed number	00	01	23	4C

Notes:

1. This example illustrates the operation of PACK when the first- and second-operand fields overlap completely.
2. During the operation, the second operand was extended on the left with zeros.

ROTATE THEN EXCLUSIVE OR SELECTED BITS

The following example illustrates the use of ROTATE THEN EXCLUSIVE OR SELECTED BITS to determine if the access-control bits of a page's storage-protection key match the key in the PSW. In this example, only the condition code is set; the result is not placed in the first-operand register.

```
LAY   9,BLOCK   Point to storage block.
IVSK  14,9      Insert key into bits 56-63.
EPSW  4,0       Extract PSW key (bits 40-43).
RXSBG 4,14,128+40,43,16 Compare keys.
```

On completion, the condition code will be set to zero if the PSW key matches the access-control bits in the storage key of page addressed by general register 9. Condition code 1 will be set if the keys do not match.

ROTATE THEN INSERT SELECTED BITS

1. The following example illustrates the use of ROTATE THEN INSERT SELECTED BITS to extract the various DAT-table indices of a virtual address contained in general register 8. This example shows the use of the zero-remaining-bits control to set the remaining bits of the result registers to zero.

   The virtual address in general register 8 is assumed to be 123456789ABCDEF0 hex.

   ```
   RISBG 1,8,53,128+63,11 Get reg. 1st index.
   RISBG 2,8,53,128+63,22 Get reg. 2nd index.
   RISBG 3,8,53,128+63,33 Get reg. 3rd index.
   RISBG 4,8,53,128+63,44 Get segment index.
   RISBG 5,8,56,128+63,52 Get page index.
   RISBG 6,8,52,128+63,0  Get byte index.
   ```

   The condition code following each RISBG is 2. On completion, general registers 1-6 contain the region-first index, region-second index, region-third index, segment index, page index, and byte index, respectively, as follows:

   ```
   GR1: 0000000000000091 (RFX)
   GR2: 0000000000000515 (RSX)
   GR3: 00000000000004F1 (RTX)
   GR4: 00000000000001AB (SX)
   GR5: 00000000000000CD (PX)
   GR6: 0000000000000EF0 (BX)
   ```

2. The following example illustrates shifting a 64-bit value to the left by *L* bits:

   ```
   RISBG R1,R2,0,X'80'+63-L,L
   ```

3. The following example illustrates shifting a 32-bit value to the right by *R* bits and setting the left-most 32 bits to zero:

   ```
   RISBG R1,R2,32+R,X'80'+63,-R
   ```

4. The following example illustrates zeroing bits *S* through *E* of general register 3.

   ```
   RISBG 3,3,mod64(E+1),128+mod64(S-1),0
   ```

   Mod64 represents a modulo function which effectively ANDs the value in parentheses with 3F hex.

ROTATE THEN OR SELECTED BITS

The following example illustrates the use of ROTATE THEN OR SELECTED BITS to rotate and combine selected bits of general registers 6 and 8.

```
LG    6,=X'004C487040CF4600'
LG    8,=X'C07FAF37FC968280'
ROSBG 6,8,8,54,32
```

On completion, condition code 1 is set, and general register 6 is as follows:

```
GR6: 00DECAF0C0FFEE00
```

Note that only bits 8-54 of the registers are ORed; bits 0-7 and 55-63 of general register 6 are not modified.

SEARCH STRING (SRST)

The SEARCH STRING instruction is used to search a second operand designated by general register R_2 for a character specified in general register 0. The length of the second operand is known — the address of the first byte after the second operand is in general register R_1.

When the specified character is found, condition code 1 is set, the address of the character is placed in general register R_1, and the contents of general register R_2 remain unchanged. When the address of the next second-operand byte to be examined equals the address in general register R_1, condition code 2 is set, and the contents of general register R_1 and R_2 remain unchanged. When a CPU-determined number of second-operand bytes have been examined, condition code 3 is set, the address of the next byte to be processed in the second operand is placed in general register R_2, and the contents of general register R_1 remain unchanged.

SRST Example 1

Following is an example program that determines the end of string A, as indicated by an ending character equal to 00 hex (as in the C programming language), and then determines the address of the first character equal to C1 hex in the string. The program is based on the assumption that the second operand does not begin at location 0 or wrap around in storage, and, therefore, condition code 2 will not be set by the first SEARCH STRING instruction because of the address in general register 0. The program is not written for execution in the access-register mode.

```
     L     5,STRAADR
     SR    0,0
LOOP1 SRST  0,5
     BC    1,LOOP1
     L     5,STRAADR
     LR    4,0
     LA    0,X'C1'
LOOP2 SRST  4,5
     BC    1,LOOP2
     BC    2,NOTFND
FOUND [Any instruction]
     ...
NOTFND [Any instruction]
```

SRST Example 2

Following is an example program that determines the address of the first character equal to C1 hex in the string A whose length is known. The program is not written for execution in the access-register mode.

```
     L     5,STRAADR
     L     4,STRALEN
     AR    4,5
     LA    0,X'C1'
LOOP1 SRST  4,5
     BC    1,LOOP1
     BC    2,NOTFND
FOUND [Any instruction]
     ...
NOTFND [Any instruction]
```

In this example, the value in STRALEN may be a length that either does or does not include an ending character at the end of the string, provided that the ending character is not the character for which the search is made.

SHIFT LEFT DOUBLE (SLDA)

The SHIFT LEFT DOUBLE instruction shifts the 63 numeric bits of an even-odd register pair to the left, leaving the sign bit unchanged. Thus, the instruction performs an algebraic left shift of a 64-bit signed binary integer.

For example, if the contents of registers 2 and 3 are:

```
00 7F 0A 72   FE DC BA 98 =
00000000 01111111 00001010 01110010
11111110 11011100 10111010 10011000₂
```

The instruction:

Machine Format

Op Code	R_1		B_2	D_2
8F	2	////	0	01F

Assembler Format

```
Op Code  R1,D2(B2)
-------------------
 SLDA    2,31(0)
```

results in registers 2 and 3 both being left-shifted 31 bit positions, so that their new contents are:

```
7F 6E 5D 4C   00 00 00 00 =
01111111 01101110 01011101 01001100
00000000 00000000 00000000 00000000(2)
```

Because significant bits are shifted out of bit position 1 of register 2, overflow is indicated by setting condition code 3, and, if the fixed-point-overflow mask bit in the PSW is one, a fixed-point-overflow program interruption occurs.

SHIFT LEFT SINGLE (SLA)

The SHIFT LEFT SINGLE instruction is similar to SHIFT LEFT DOUBLE, except that it shifts only the 31 numeric bits of a single register. Therefore, this instruction performs an algebraic left shift of a 32-bit signed binary integer.

For example, if the contents of register 2 are:

```
00 7F 0A 72 = 00000000 01111111 00001010 01110010(2)
```

The instruction:

Machine Format

Op Code	R_1		B_2	D_2
8B	2	////	0	008

Assembler Format

```
Op Code  R1,D2(B2)
-------------------
  SLA    2,8(0)
```

results in register 2 being shifted left eight bit positions so that its new contents are:

```
7F 0A 72 00 = 01111111 00001010 01110010 00000000(2)
```

Condition code 2 is set to indicate that the result is greater than zero.

If a left shift of nine places had been specified, a significant bit would have been shifted out of bit position 1. Condition code 3 would have been set to indicate this overflow and, if the fixed-point-overflow mask bit in the PSW were one, a fixed-point overflow interruption would have occurred.

STORE CHARACTERS UNDER MASK (STCM)

STORE CHARACTERS UNDER MASK (STCM) may be used to place selected bytes from a register into storage. For example, if it is desired to store a three-byte address from general register 8 into location FIELD3, assume:

Machine Format

Op Code	R_1	M_3	S_2
BE	8	7	* * * *

Register Format

```
Op Code  R1,M3,S2
-----------------------
 STCM    8,B'0111',FIELD3
```

```
Register 8:       12 34 56 78
FIELD3 (before):  not significant
FIELD3 (after):   34 56 78
```

As another example:

Machine Format

Op Code	R_1	M_3	S_2
BE	9	5	* * * *

Register Format

```
Op Code  R1,M3,S2
-----------------------
 STCM    9,B'0101',FIELD2
```

```
Register 9:      01 23 45 67
FIELD2 (before): not significant
FIELD2 (after):  23 67
```

STORE MULTIPLE (STM)

Assume that the contents of general registers 14, 15, 0, and 1 are to be stored in consecutive four-byte fields starting with location 4050 and that:

Register 14 contains 00 00 25 63.

Register 15 contains 00 01 27 36.

Register 0 contains 12 43 00 62.

Register 1 contains 73 26 12 57.

Register 6 contains 00 00 40 00.

The initial contents of locations 4050-405F are not significant.

The STORE MULTIPLE instruction allows the use of just one instruction to store the contents of the four registers:

Machine Format

Op Code	R_1	R_3	B_2	D_2
90	E	1	6	050

Assembler Format

Op Code	R_1,R_3,D_2(B_2)
STM	14,1,X'50'(6)

After the instruction is executed:

Locations 4050-4053 contain 00 00 25 63.

Locations 4054-4057 contain 00 01 27 36.

Locations 4058-405B contain 12 43 00 62.

Locations 405C-405F contain 73 26 12 57.

TEST UNDER MASK (TM)

The TEST UNDER MASK instruction examines selected bits of a byte and sets the condition code accordingly. For example, assume that:

Storage location 9999 contains FB.

Register 7 contains 00 00 99 90.

Assume the instruction to be:

Machine Format

Op Code	I_2	B_1	D_1
91	C3	7	009

Assembler Format

Op Code	D_1(B_1),I_2
TM	9(7),B'11000011'

The instruction tests only those bits of the byte in storage for which the mask bits are ones:

FB = $1111\ 1011_2$
Mask = $1100\ 0011_2$

Test = $11xx\ xx11_2$

Condition code 3 is set: all selected bits in the test result are ones. (The bits marked “x” are ignored.)

If location 9999 had contained B9, the test would have been:

B9 = $1011\ 1001_2$
Mask = $1100\ 0011_2$

Test = $10xx\ xx01_2$

Condition code 1 is set: the selected bits are both zeros and ones.

If location 9999 had contained 3C, the test would have been:

3C = $0011\ 1100_2$
Mask = $1100\ 0011_2$

Test = $00xx\ xx00_2$

Condition code 0 is set: all selected bits are zeros.

Note: Storage location 9999 remains unchanged.

TRANSLATE (TR)

The TRANSLATE instruction can be used to translate data from any character code to any other desired code, provided that each character code consists of eight bits or fewer. An appropriate translation table is required in storage.

In the following example, EBCDIC code is translated to ASCII code. The first step is to create a 256-byte table in storage locations 1000-10FF. This table contains the characters of the ASCII code in the sequence of the binary representation of the EBCDIC code; that is, the ASCII representation of a char-

acter is placed in storage at the starting address of the table plus the binary value of the EBCDIC representation of the same character.

For simplicity, the example shows only the part of the table containing the decimal digits:

10F0									10F9
30	31	32	33	34	35	36	37	38	39

Assume that the four-byte field at storage location 2100 contains the EBCDIC code for the digits 1984:

Locations 2100-2103 contain F1 F9 F8 F4.

Register 12 contains 00 00 21 00.

Register 15 contains 00 00 10 00.

As the instruction:

Machine Format

Op Code	L	B_1	D_1	B_2	D_2
DC	03	C	000	F	000

Assembler Format

```
Op Code  D1(L,B1),D2(B2)
--------------------------
   TR    0(4,12),0(15)
```

is executed, the binary value of each EBCDIC byte is added to the starting address of the table, and the resulting address is used to fetch an ASCII byte:

```
Table starting address:    1000
First EBCDIC byte:           F1
-------------------------------
Address of ASCII byte:     10F1
```

After execution of the instruction:

Locations 2100-2103 contain 31 39 38 34.

Thus, the ASCII code for the digits 1984 has replaced the EBCDIC code in the four-byte field at storage location 2100.

TRANSLATE AND TEST (TRT)

The TRANSLATE AND TEST instruction can be used to scan a data field for characters with a special meaning. To indicate which characters have a special meaning, a table similar to the one used for the TRANSLATE instruction is set up, except that zeros in the table indicate characters without any special meaning and nonzero values indicate characters with a special meaning.

Figure A-4 on page A-34 has been set up to distinguish alphameric characters (A to Z and 0 to 9) from blanks, certain special symbols, and all other characters which are considered invalid. EBCDIC coding is assumed. The 256-byte table is assumed stored at locations 2000-20FF.

	0	1	2	3	4	5	6	7	8	9	A	B	C	D	E	F
200_	40	40	40	40	40	40	40	40	40	40	40	40	40	40	40	40
201_	40	40	40	40	40	40	40	40	40	40	40	40	40	40	40	40
202_	40	40	40	40	40	40	40	40	40	40	40	40	40	40	40	40
203_	40	40	40	40	40	40	40	40	40	40	40	40	40	40	40	40
204_	04	40	40	40	40	40	40	40	40	40	40	08	40	0C	10	40
205_	14	40	40	40	40	40	40	40	40	40	40	18	1C	20	40	40
206_	24	28	40	40	40	40	40	40	40	40	40	2C	40	40	40	40
207_	40	40	40	40	40	40	40	40	40	40	40	30	34	38	3C	40
208_	40	40	40	40	40	40	40	40	40	40	40	40	40	40	40	40
209_	40	40	40	40	40	40	40	40	40	40	40	40	40	40	40	40
20A_	40	40	40	40	40	40	40	40	40	40	40	40	40	40	40	40
20B_	40	40	40	40	40	40	40	40	40	40	40	40	40	40	40	40
20C_	40	00	00	00	00	00	00	00	00	00	40	40	40	40	40	40
20D_	40	00	00	00	00	00	00	00	00	00	40	40	40	40	40	40
20E_	40	40	00	00	00	00	00	00	00	00	40	40	40	40	40	40
20F_	00	00	00	00	00	00	00	00	00	00	40	40	40	40	40	40

Note: If the character codes in the statement being translated occupy a range smaller than 00 through FF_{16}, a table of fewer than 256 bytes can be used.

Figure A-4. Translate and Test Table

The table entries for the alphameric characters in EBCDIC are 00; thus, the letter A (code C1) corresponds to byte location 20C1, which contains 00.

The 15 special symbols have nonzero entries from 04_{16} to $3C_{16}$ in increments of 4. Thus, the blank (code 40) has the entry 04_{16}, the period (code 4B) has the entry 08_{16}, and so on.

All other table positions have the entry 40_{16} to indicate an invalid character.

The table entries are chosen so that they may be used to select one of a list of 16 words containing

addresses of different routines to be entered for each special symbol or invalid character encountered during the scan.

Assume that this list of 16 branch addresses is stored at locations 3004-3043.

Starting at storage location CA80, there is the following sequence of 21_{10} EBCDIC characters, where “b” stands for a blank.

Locations CA80-CA94:
UNPKbPROUT(9),WORD(5)

Also assume:

Register 1 contains 00 00 CA 7F.

Register 2 contains 00 00 30 00.

Register 15 contains 00 00 20 00.

As the instruction:

Machine Format

Op Code	L	B_1	D_1	B_2	D_2
DD	14	1	001	F	000

Assembler Format

```
Op Code  D1(L,B1),D2(B2)
-------------------------
  TRT    1(21,1),0(15)
```

is executed, the value of the first source byte, the EBCDIC code for the letter U, is added to the starting address of the table to produce the address of the table entry to be examined:

```
Table starting address      2000
First source byte (U)         E4
-------------------------------
Address of table entry      20E4
```

Because zeros were placed in storage location 20E4, no special action occurs. The operation continues with the second and subsequent source bytes until it reaches the blank in location CA84. When this symbol is reached, its value is added to the starting address of the table, as usual:

```
Table starting address      2000
Source byte (blank)           40
-------------------------------
Address of table entry      2040
```

Because location 2040 contains a nonzero value, the following actions occur:

The address of the source byte, 00CA84, is placed in the rightmost 24 bits of register 1.

The table entry, 04, is placed in the rightmost eight bits of register 2, which now contains 00 00 30 04.

Condition code 1 is set (scan not completed).

The TRANSLATE AND TEST instruction may be followed by instructions to branch to the routine at the address found at location 3004, which corresponds to the blank character encountered in the scan. When this routine is completed, program control may return to the TRANSLATE AND TEST instruction to continue the scan, except that the length must first be adjusted for the characters already scanned.

For this purpose, the TRANSLATE AND TEST may be executed by the use of an EXECUTE instruction, which supplies the length specification from a general register. In this way, a complete statement scan can be performed with a single TRANSLATE AND TEST instruction used repeatedly by means of EXECUTE, and without modifying any instructions in storage. In the example, after the first execution of TRANSLATE AND TEST, register 1 contains the address of the last source byte translated. It is then a simple matter to subtract this address from the address of the last source byte (CA94) to produce a length specification. This length minus one is placed in the register that is referenced as the R_1 field of the EXECUTE instruction. (Note that the length code in the machine format is one less than the total number of bytes in the field.) The second-operand address of the EXECUTE instruction points to the TRANSLATE AND TEST instruction, which is the same as illustrated above, except for the length (L) which is set to zero.

UNPACK (UNPK)

Assume that storage locations 2501-2502 contain a signed-packed-decimal number that is to be unpacked and placed in storage locations 1000-1004. Also assume:

Register 12 contains 00 00 10 00.

Register 13 contains 00 00 25 00.

Storage locations 2501-2502 contain 12 3D.

The initial contents of storage locations 1000-1004 are not significant.

After the instruction:

Machine Format

Op Code	L_1	L_2	B_1	D_1	B_2	D_2
F3	4	1	C	000	D	001

Assembler Format

```
Op Code  D1(L1,B1),D2(L2,B2)
UNPK     0(5,12),1(2,13)
```

is executed, the storage locations 1000-1004 contain F0 F0 F1 F2 D3.

UPDATE TREE (UPT)

See “Sorting Instructions” on page A-53.

Decimal Instructions

(See Chapter 8, “Decimal Instructions” for a complete description of the decimal instructions.)

ADD DECIMAL (AP)

Assume that the signed-packed-decimal number at storage locations 500-503 is to be added to the signed-packed-decimal number at locations 2000-2002. Also assume:

Register 12 contains 00 00 20 00.

Register 13 contains 00 00 05 00.

Storage locations 2000-2002 contain 38 46 0D (a negative number).

Storage locations 500-503 contain 01 12 34 5C (a positive number).

After the instruction:

Machine Format

Op Code	L_1	L_2	B_1	D_1	B_2	D_2
FA	2	3	C	000	D	000

Assembler Format

```
Op Code  D1(L1,B1),D2(L2,B2)
AP       0(3,12),0(4,13)
```

is executed, the storage locations 2000-2002 contain 73 88 5C; condition code 2 is set to indicate that the result is greater than zero. Note that:

1. Because the two numbers had different signs, they were in effect subtracted.
2. Although the second operand is longer than the first operand, no overflow interruption occurs because the result can be entirely contained within the first operand.

COMPARE DECIMAL (CP)

Assume that the signed-packed-decimal contents of storage locations 700-703 are to be algebraically compared with the signed-packed-decimal contents of locations 500-502. Also assume:

Register 12 contains 00 00 06 00.

Register 13 contains 00 00 03 00.

Storage locations 700-703 contain 17 25 35 6D.

Storage locations 500-502 contain 72 14 2D.

After the instruction:

Machine Format

Op Code	L_1	L_2	B_1	D_1	B_2	D_2
F9	3	2	C	100	D	200

Assembler Format

```
Op Code  D1(L1,B1),D2(L2,B2)
CP  X'100'(4,12),X'200'(3,13)
```

is executed, condition code 1 is set, indicating that the first operand (the contents of locations 700-703) is less than the second.

DIVIDE DECIMAL (DP)

Assume that the signed-packed-decimal number at storage locations 2000-2004 (the dividend) is to be divided by the signed-packed-decimal number at locations 3000-3001 (the divisor). Also assume:

Register 12 contains 00 00 20 00.

Register 13 contains 00 00 30 00.

Storage locations 2000-2004 contain 01 23 45 67 8C.

Storage locations 3000-3001 contain 32 1D.

After the instruction:

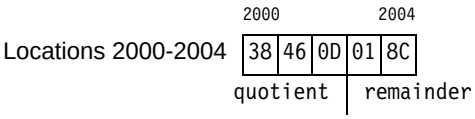
Machine Format

Op Code	L_1	L_2	B_1	D_1	B_2	D_2
FD	4	1	C	000	D	000

Assembler Format

```
Op Code  D1(L1,B1),D2(L2,B2)
DP       0(5,12),0(2,13)
```

is executed, the dividend is entirely replaced by the signed quotient and remainder, as follows:



Notes:

1. Because the dividend and divisor have different signs, the quotient receives a negative sign.
2. The remainder receives the sign of the dividend and the length of the divisor.
3. If an attempt were made to divide the dividend by the one-byte field at location 3001, the quotient would be too long to fit within the four bytes allotted to it. A decimal-divide exception would exist, causing a program interruption.

EDIT (ED)

Before data in the signed-packed-decimal or unsigned-packed-decimal format can be used in a printed report, digits and signs must be converted to printable characters. Moreover, punctuation marks, such as commas and decimal points, may have to be inserted in appropriate places. The highly flexible EDIT instruction performs these functions in a single instruction execution.

This example shows step-by-step one way that the EDIT instruction can be used. The field to be edited (the source) is four bytes long; it is edited against a pattern 13 bytes long. The following symbols are used:

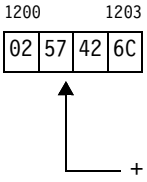
Symbol	Meaning
b (Hexadecimal 40)	Blank character
((Hexadecimal 21)	Significance starter
d (Hexadecimal 20)	Digit selector

Assume that register 12 contains:

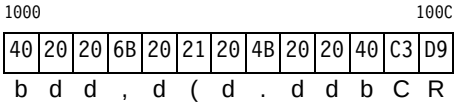
```
00 00 10 00
```

and that the source and pattern fields are:

Source



Pattern



Execution of the instruction:

Machine Format

Op Code	L	B_1	D_1	B_2	D_2
DE	0C	C	000	C	200

Assembler Format

```
Op Code  D1(L,B1),D2(B2)
ED       0(13,12),X'200'(12)
```

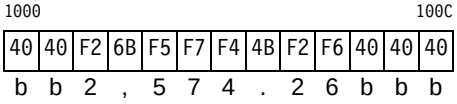
alters the pattern field as follows:

Pattern	Digit	Significance Indicator (Before/ After)	Rule	Location 1000-100C
b		off/off	leave(1)	bdd,d(d.ddbCR
d	0	off/off	fill	bbd,d(d.ddbCR
d	2	off/on(2)	digit	bb2,d(d.ddbCR
,		on/on	leave	same
d	5	on/on	digit	bb2,5(d.ddbCR
(	7	on/on	digit	bb2,57d.ddbCR
d	4	on/on	digit	bb2,574.ddbCR
.		on/on	leave	same
d	2	on/on	digit	bb2,574.2dbCR
d	6+	on/off(3)	digit	bb2,574.26bCR
b		off/off	fill	same
C		off/off	fill	bb2,574.26bbR
R		off/off	fill	bb2,574.26bbb

Notes:
1. This character is the fill byte.
2. First nonzero decimal source digit turns on significance indicator.
3. Plus sign in the four rightmost bits of the byte turns off significance indicator.

Thus, after the instruction is executed, the pattern field contains the result as follows:

Pattern



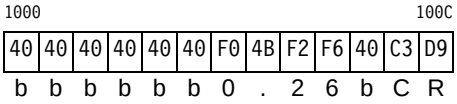
This pattern field prints as:

```
  2,574.26
```

The source field remains unchanged. Condition code 2 is set because the number was greater than zero.

If the number in the source field is changed to the negative number 00 00 02 6D and the original pattern is used, the edited result this time is:

Pattern



This pattern field prints as:

```
  0.26 CR
```

The significance starter forces the significance indicator to the on state and hence causes a leading zero and the decimal point to be preserved. Because the minus-sign code has no effect on the significance indicator, the characters CR are printed to show a negative (credit) amount.

Condition code 1 is set (number less than zero).

EDIT AND MARK (EDMK)

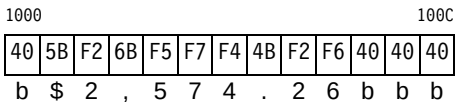
The EDIT AND MARK instruction may be used, in addition to the functions of EDIT, to insert a currency symbol, such as a dollar sign, at the appropriate position in the edited result. Assume the same source in storage locations 1200-1203, the same pattern in locations 1000-100C, and the same contents of general register 12 as for the EDIT instruction above. The previous contents of general register 1 (GR1) are not significant; a LOAD ADDRESS instruction is used to set up the first digit position that is forced to print if no significant digits occur to the left.

The instructions:

LA	1,6(0,12)	Load address of forced significant digit into GR1
EDMK	0(13,12),X‘200’(12)	Leave address of first significant digit in GR1
BCTR	1,0	Subtract 1 from address in GR1
MVI	0(1),C ‘$’	Store dollar sign at address in GR1

produce the following results for the two examples under EDIT:

Pattern



This pattern field prints as:

```
  $2,574.26
```

Condition code 2 is set to indicate that the number edited was greater than zero.

Pattern

1000											100C
40	40	40	40	40	5B	F0	4B	F2	F6	40	C3	D9
b	b	b	b	b	$	0	.	2	6	b	C	R

This pattern field prints as:

```
$0.26 CR
```

Condition code 1 is set because the number is less than zero.

MULTIPLY DECIMAL (MP)

Assume that the signed-packed-decimal number in storage locations 1202-1204 (the multiplicand) is to be multiplied by the signed-packed-decimal number in locations 500-501 (the multiplier).

	1202		1204
Multiplicand	38	46	0D

	500	501
Multiplier	32	1D

The multiplicand must first be extended to have at least two bytes of leftmost zeros, corresponding to the multiplier length, so as to avoid a data exception during the multiplication. ZERO AND ADD can be used to move the multiplicand into a longer field. Assume:

Register 4 contains 00 00 12 00.

Register 6 contains 00 00 05 00.

Then execution of the instruction:

```
ZAP X'100'(5,4),2(3,4)
```

sets up a new multiplicand in storage locations 1300-1304:

	1300				1304
Multiplicand (new)	00	00	38	46	0D

Now, after the instruction:

Machine Format

Op Code	L_1	L_2	B_1	D_1	B_2	D_2
FC	4	1	4	100	6	000

Assembler Format

```
Op Code  D1(L1,B1),D2(L2,B2)
MP  X'100'(5,4),0(2,6)
```

is executed, storage locations 1300-1304 contain the product: 01 23 45 66 0C.

SHIFT AND ROUND DECIMAL (SRP)

The SHIFT AND ROUND DECIMAL (SRP) instruction can be used for shifting decimal numbers in storage to the left or right. When a number is shifted right, rounding can also be done.

Decimal Left Shift

In this example, the contents of storage location FIELD1 are shifted three places to the left, effectively multiplying the contents of FIELD1 by 1000. FIELD1 is six bytes long. The following instruction performs the operation:

Machine Format

Op Code	L_1	I_3	S_1	B_2	D_2
F0	5	0	* * * *	0	003

Assembler Format

```
Op Code  S1(L1),S2,I3
  SRP    FIELD1(6),3,0

FIELD1 (before):  00 01 23 45 67 8C

FIELD1 (after):   12 34 56 78 00 0C
```

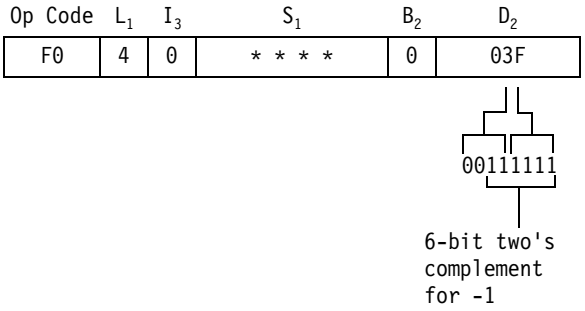
The second-operand address in this instruction specifies the shift amount (three places). The rounding digit, I_3, is not used in a left shift, but it must be a valid decimal digit. After execution, condition code 2 is set to show that the result is greater than zero.

Decimal Right Shift

In this example, the contents of storage location FIELD2 are shifted one place to the right, effectively

dividing the contents of FIELD2 by 10 and discarding the remainder. FIELD2 is five bytes in length. The following instruction performs this operation:

Machine Format



Assembler Format

```
Op Code  S1(L1),S2,I3
```

```
  SRP    FIELD2(5),64-1,0

FIELD 2 (before):  01 23 45 67 8C

FIELD 2 (after):   00 12 34 56 7C
```

In the SRP instruction, shifts to the right are specified in the second-operand address by negative shift values, which are represented as a six-bit value in two's complement form.

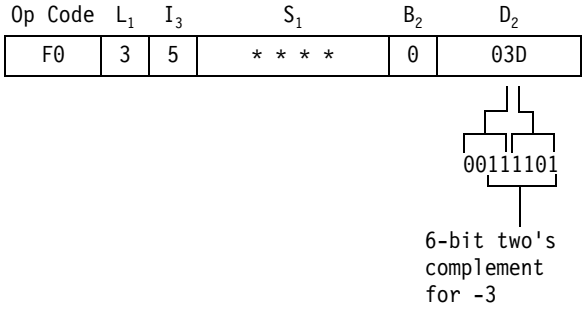
The six-bit two's complement of a number, n, can be specified as 64 - n. In this example, a right shift of one is represented as 64 - 1.

Condition code 2 is set.

Decimal Right Shift and Round

In this example, the contents of storage location FIELD3 are shifted three places to the right and rounded, in effect dividing by 1000 and rounding up. FIELD3 is four bytes in length.

Machine Format



Assembler Format

```
Op Code  S1(L1),S2,I3
```

```
  SRP    FIELD3(4),64-3,5

FIELD 3 (before):  12 39 60 0D

FIELD 3 (after):   00 01 24 0D
```

The shift amount (three places) is specified in the D_2 field. The I_3 field specifies a rounding digit of 5. The rounding digit is added to the last digit shifted out (which is a 6), and the carry is propagated to the left. The sign is ignored during the addition.

Condition code 1 is set because the result is less than zero.

Multiplying by a Variable Power of 10

Since the shift value specified by the SRP instruction specifies both the direction and amount of the shift, the operation is equivalent to multiplying the decimal first operand by 10 raised to the power specified by the shift value.

If the shift value is to be variable, it may be specified by the B_2 field instead of the displacement D_2 of the SRP instruction. The general register designated by B_2 should contain the shift value (power of 10) as a signed binary integer.

A fixed scale factor modifying the variable power of 10 may be specified by using both the B_2 field (variable part in a general register) and the D_2 field (fixed part in the displacement).

The SRP instruction uses only the rightmost six bits of the effective address $D_2(B_2)$ and interprets them as a six-bit signed binary integer to control the left or right shift as in the preceding shift examples.

ZERO AND ADD (ZAP)

Assume that the signed-packed-decimal number at storage locations 4500-4502 is to be moved to locations 4000-4004 with four leading zeros in the result field. Also assume:

Register 9 contains 00 00 40 00.

Storage locations 4000-4004 contain 12 34 56 78 90.

Storage locations 4500-4502 contain 38 46 0D.

After the instruction:

Machine Format

Op Code	L_1	L_2	B_1	D_1	B_2	D_2
F8	4	2	9	000	9	500

Assembler Format

```
Op Code  D1(L1,B1),D2(L2,B2)
ZAP      0(5,9),X'500'(3,9)
```

is executed, the storage locations 4000-4004 contain 00 00 38 46 0D; condition code 1 is set to indicate a negative result without overflow.

Note that, because the first operand is not checked for valid sign and digit codes, it may contain any combination of hexadecimal digits before the operation.

Hexadecimal-Floating-Point Instructions

(See Chapter 9, “Floating-Point Overview and Support Instructions” for a complete description of the hexadecimal-floating-point instructions.)

In this section, the abbreviations FPR0, FPR2, FPR4, and FPR6 stand for floating-point registers 0, 2, 4, and 6 respectively.

ADD NORMALIZED (AD, ADR, AE, AER, AXR)

The ADD NORMALIZED instruction performs the addition of two HFP numbers and places the normalized result in a floating-point register. Neither of the two numbers to be added must necessarily be in normalized form before addition occurs. For example, assume that:

FPR6 contains the unnormalized number C3 08 21 00 00 00 00 00 = $-82.1_{16} = -130.06_{10}$ approximately.

Storage locations 2000-2007 contain the normalized number 41 12 34 56 00 00 00 00 = $+1.23456_{16} = +1.14_{10}$ approximately.

Register 13 contains 00 00 20 00.

The instruction:

Machine Format

Op Code	R_1	X_2	B_2	D_2
7A	6	0	D	000

Assembler Format

```
Op Code  R1,D2(X2,B2)
AE       6,0(0,13)
```

performs the short-precision addition of the two operands, as follows.

The characteristics of the two numbers (43 and 41) are compared. Since the number in storage has a characteristic that is smaller by 2, it is right-shifted two hexadecimal digit positions. One guard digit is retained on the right. The fractions of the two numbers are then added algebraically:

```
                                    Fraction GD[1]
FPR6                              -43 08 21 00
Shifted number from storage       +43 00 12 34  5
-------------------------------------------------
Intermediate sum                  -43 08 0E CB  B
Left-shifted sum                  -42 80 EC BB
```

[1] Guard digit

Because the intermediate sum is unnormalized, it is left-shifted to form the normalized HFP number $-80.ECBB_{16} = -128.92_{10}$ approximately. Combining the sign with the characteristic, the result is C2 80 EC BB, which replaces the left half of FPR6. The right half of FPR6 and the contents of storage locations 2000-2007 are unchanged. Condition code 1 is set to indicate a result less than zero.

If the long-precision instruction AD were used, the result in FPR6 would be C2 80 EC BA A0 00 00 00. Note that use of the long-precision instruction would avoid a loss of precision in this example.

ADD UNNORMALIZED (AU, AUR, AW, AWR)

The ADD UNNORMALIZED instruction operates the same as the ADD NORMALIZED instruction, except that the final result is not normalized. For example, using the same operands as in the example for ADD NORMALIZED, when the short-precision instruction:

Machine Format

Op Code	R_1	X_2	B_2	D_2
7E	6	0	D	000

Assembler Format

```
Op Code  R1,D2(X2,B2)
-------------------
   AU    6,0(0,13)
```

is executed, the two numbers are added as follows:

```
                                Fraction GD[1]
FPR6                           -43 08 21 00
Shifted number from storage    +43 00 12 34  5
-------------------------------------------------
Intermediate sum               -43 08 0E CB  B
```

[1] Guard digit

The guard digit participates in the addition but is discarded. The unnormalized sum replaces the left half of FPR6. Condition code 1 is set because the result is less than zero.

The truncated result in FPR6 (C3 08 0E CB 00 00 00 00) shows a loss of a significant digit when compared to the result of short-precision normalized addition.

COMPARE (CD, CDR, CE, CER)

Assume that FPR4 contains 43 00 00 00 00 00 00 00 (zero), and FPR6 contains 35 12 34 56 78 9A BC DE (a positive number). The contents of the two registers are to be compared using a long-precision COMPARE instruction.

Machine Format

Op Code	R_1	R_2
29	4	6

Assembler Format

```
Op Code  R1,R2
-------------
   CDR   4,6
```

The number with the smaller characteristic, which is in register FPR6, is right-shifted 43 - 35 hex (67 - 53 decimal) or 14 digit positions, so that the two characteristics agree. The shifted number is 43 00 00 00 00 00 00 00, with a guard digit of one. Therefore, when the two numbers are compared, condition code 1 is set, indicating that operand 1 in FPR4 is less than operand 2 in FPR6.

If the example is changed to a second operand with a characteristic of 34 instead of 35, so that FPR6 contains 34 12 34 56 78 9A BC DE, the operand is right-shifted 15 positions, leaving all fraction digits and the guard digit as zeros. Condition code 0 is set, indicating equality. This example shows that two HFP numbers with different characteristics or fractions may compare equal if the numbers are unnormalized or zero.

As another example of comparing unnormalized HFP numbers, 41 00 12 34 56 78 9A BC compares equal to all numbers of the form 3F 12 34 56 78 9A BC 0X (X represents any hexadecimal digit). When the COMPARE instruction is executed, the two rightmost digits are shifted right two places, the 0 becomes the guard digit, and the X does not participate in the comparison.

However, when two normalized HFP numbers are compared, the relationship between numbers that compare equal is unique: each digit in one number must be the same as the corresponding digit in the other number.

DIVIDE (DD, DDR, DE, DER)

Assume that the first operand (the dividend) is in FPR2 and the second operand (the divisor) in FPR0. If the operands are in the short-precision format, the resulting quotient is returned to FPR2 by the instruction:

Machine Format

Op Code	R_1	R_2
3D	2	0

Assembler Format

```
Op Code   R1,R2
──────────────
  DER     2,0
```

Several examples of short-precision HFP division, with the dividend in FPR2 and the divisor in FPR0, are shown below. For case A, the result, which replaces the dividend, is obtained in the following steps.

```
                 7.2522F
        ┌──────────────
.123400 │.821000
         7F6C00
         ──────
          2A400 0
          24680 0
          ──────
           5D80 00
           5B04 00
           ───────
            27C 000
            246 800
            ───────
             35 8000
             24 6800
             ───────
             11 18000
             11 10C00
             ────────
                 7400
```

Case	FPR2 Before (Dividend)	FPR0 (Divisor)	FPR2 After (Quotient)
A	-43 082100	+43 001234	-42 72522F
B	+42 101010	+45 111111	+3D F0F0F0
C	+48 30000F	+41 400000	+47 C0003C
D	+48 30000F	+41 200000	+48 180007
E	+48 180007	+41 200000	+47 C00038

Case C shows a number being divided by 4.0. Case D divides the same number by 2.0, and case E divides the result of case D again by 2.0. The results of cases C and E differ in the rightmost hexadecimal digit position, which illustrates an effect of result truncation.

HALVE (HDR, HER)

HALVE produces the same result as HFP DIVIDE with a divisor of 2.0. Assume FPR2 contains the long-precision number +48 30 00 00 00 00 00 0F. The following HALVE instruction produces the result +48 18 00 00 00 00 00 07 in FPR2:

Machine Format

Op Code	R_1	R_2
24	2	2

Assembler Format

```
Op Code   R1,R2
──────────────
  HDR     2,2
```

MULTIPLY (MD, MDR, MDE, MDER, MXD, MXDR, MXR)

For this example, the following long-precision operands are in FPR0 and FPR2:

```
FPR0:  -33 606060 60606060
FPR2:  -5A 200000 20000020
```

A long-precision product is generated by the instruction:

Machine Format

Op Code	R_1	R_2
2C	0	2

Assembler Format

```
Op Code   R1,R2
──────────────
  MDR     0,2
```

If the operands were not already normalized, the instruction would first normalize them. It then generates an intermediate result consisting of the full 28-digit hexadecimal product fraction obtained by multiplying the 14-digit hexadecimal operand fractions, together with the appropriate sign and a characteristic that is the sum of the operand characteristics less 64 (40 hex):

The fraction multiplication is performed as follows:

```
                .60606060606060
                .20000020000020
                ---------------
                C0C0C0C0C0C0C00
          C0C0C0C0C0C0C0
    C0C0C0C0C0C0C0
-------------------------------
.0C0C0C1818182418181 80C0C0C00
```

Attaching the sign and characteristic to the fraction gives:

```
+4D 0C0C0C 18181824 1818180C 0C0C00
```

Because this intermediate product has a leading zero, it is then normalized. The truncated final result placed in FPR0 is:

```
+4C C0C0C1 81818241
```

Hexadecimal-Floating-Point-Number Conversion

The following examples illustrate one method of converting between binary fixed-point numbers (32-bit signed binary integers) and normalized HFP numbers. Conversion must provide for the different representations used with negative numbers: the two's-complement form for signed binary integers, and the signed-absolute-value form for the fractions of HFP numbers.

Fixed Point to Hexadecimal Floating Point

The method used here inverts the leftmost bit of the 32-bit signed binary integer, which is equivalent to adding 2^{31} to the number and considering the result to be positive. This changes the number from a signed integer in the range 2^{31} - 1 through -2^{31} to an unsigned integer in the range 2^{32} - 1 through 0. After conversion to the long HFP format, the value 2^{31} is subtracted again.

Assume that general register 9 (GR9) contains the integer -59 in two's-complement form:

```
GR9:     FF FF FF C5
```

Further, assume two eight-byte fields in storage: TEMP, for use as temporary storage, and TWO31, which contains the floating-point constant 2^{31} in the following format:

```
TWO31:   4E 00 00 00 80 00 00 00
```

This is an unnormalized long HFP number with the characteristic 4E, which corresponds to a radix point (hexadecimal point) to the right of the number.

The following instruction sequence performs the conversion:

		Result
X	9,TWO31+4	GR9: 7FFF FFC5
ST	9,TEMP+4	TEMP: xxxx xxxx 7FFF FFC5
MVC	TEMP(4),TWO31	TEMP: 4E00 0000 7FFF FFC5
LD	2,TEMP	FPR2: 4E00 0000 7FFF FFC5
SD	2,TWO31	FPR2: C23B 0000 0000 0000

The EXCLUSIVE OR (X) instruction inverts the leftmost bit in general register 9, using the right half of the constant as the source for a leftmost one bit. The next two instructions assemble the modified number in an unnormalized long HFP format, using the left half of the constant as the plus sign, the characteristic, and the leading zeros of the fraction. LOAD (LD) places the number unchanged in floating-point register 2. The SUBTRACT NORMALIZED (SD) instruction performs the final two steps by subtracting 2^{31} in HFP form and normalizing the result.

Hexadecimal Floating Point to Fixed Point

The procedure described here consists basically in reversing the steps of the previous procedure. Two additional considerations must be taken into account. First: the HFP number may not be an exact integer. Truncating the excess hexadecimal digits on the right requires shifting the number one digit position farther to the right than desired for the final result, so that the units digit occupies the position of the guard digit. Second: the HFP number may have to be tested as to whether it is outside the range of numbers representable as a 32-bit signed binary integer.

Assume that floating-point register 6 contains the number $59.25_{10} = 3B.4_{16}$ in normalized form:

```
FPR6:    42 3B 40 00 00 00 00 00
```

Further, assume three eight-byte fields in storage: TEMP, for use as temporary storage, and the constants 2^{32} (TWO32) and 2^{31} (TWO31R) in the following formats:

```
TWO32:    4E 00 00 01 00 00 00 00
TWO31R:   4F 00 00 00 08 00 00 00
```

The constant TWO31R is shifted right one more position than the constant TWO31 of the previous example, so as to force the units digit into the guard-digit position.

The following instruction sequence performs the integer truncation, range tests, and conversion to a signed binary integer in general register 8 (GR8):

		Result
SD	6,TWO31R	FPR6: C87F FFFF C500 0000
BC	11,OVERFLOW	Branch to overflow routine if result is greater than or equal to zero
AW	6,TWO32	FPR6: 4E00 0000 8000 003B
BC	4,OVERFLOW	Branch to overflow routine if result is less than zero
STD	6,TEMP	TEMP: 4E00 0000 8000 003B
XI	TEMP+4,X‘80’	TEMP: 4E00 0000 0000 003B
L	8,TEMP+4	GR8: 0000 003B

The SUBTRACT NORMALIZED (SD) instruction shifts the fraction of the number to the right until it lines up with TWO31R, which causes the fraction digit 4 to fall to the right of the guard digit and be lost; the result of subtracting 2^{31} from the remaining digits is renormalized. The result should be less than zero; if not, the original number was too large in the positive direction. The first BRANCH ON CONDITION (BC) performs this test.

The ADD UNNORMALIZED (AW) instruction adds 2^{32}: 2^{31} to correct for the previous subtraction and another 2^{31} to change to an all-positive range. The second BC tests for a result less than zero, showing that the original number was too large in the negative direction. The unnormalized result is placed in temporary storage by the STORE (STD) instruction. There the leftmost bit of the binary integer is inverted by the EXCLUSIVE OR (XI) instruction to subtract 2^{31} and thus convert the unsigned number to the signed format. The final result is loaded into GR8.

Multiprogramming and Multiprocessing Examples

When two or more programs sharing common storage locations are being executed concurrently in a multiprogramming or multiprocessing environment, one program may, for example, set a flag bit in the common-storage area for testing by another program. It should be noted that the instructions AND (NI, NIY, or NC), EXCLUSIVE OR (XI, XIY, or XC), and OR (OI, OIY, or OC) could be used to set flag bits in a multiprogramming environment; but when the interlocked-access facility 2 is not installed, the same instructions may cause program logic errors in a multiprocessing configuration where two or more CPUs can fetch, modify, and store data in the same storage locations simultaneously.

Example of a Program Failure Using OR Immediate

The following example assumes that the interlocked-access facility 2 is not installed.

Assume that two independent programs try to set different bits to one in a common byte in storage. The following example shows how the use of the instruction OR immediate (OI) can fail to accomplish this, if the programs are executed simultaneously on two different CPUs. One of the possible error situations is depicted.

Execution of instruction OI FLAGS,X’01’ on CPU A	FLAGS	Execution of instruction OI FLAGS,X’80’ on CPU B
	X’00’	Fetch FLAGS X’00’
Fetch FLAGS X’00’	X’00’	
	X’00’	OR X’80’ into X’00’
OR X’01’ into X’00’	X’00’	
	X’80’	Store X’80’ into FLAGS
Store X’01’ into FLAGS	X’01’	
FLAGS should have value of X’81’ following both updates when the programs do not execute simultaneously.		

The problem shown here is that the value stored by the OI instruction executed on CPU A overlays the value that was stored by CPU B. The initially-stored

value X'80' was overlaid by the subsequently-stored value X'01' because the fetch and store accesses for each instruction are a noninterlocked-update reference.

The COMPARE AND SWAP instruction has been provided to overcome this and similar problems.

When the interlocked-access facility 2 is installed, the update performed by OR (OI) instruction is an interlocked-update reference, and the problem illustrated here does not occur.

Conditional Swapping Instructions (CS, CDS)

The COMPARE AND SWAP (CS) and COMPARE DOUBLE AND SWAP (CDS) instructions can be used in multiprogramming or multiprocessing environments to serialize access to counters, flags, control words, and other common storage areas.

The following examples of the use of the COMPARE AND SWAP and COMPARE DOUBLE AND SWAP instructions illustrate the applications for which the instructions are intended. It is important to note that these are examples of functions that can be performed by programs while the CPU is enabled for interruption (multiprogramming) or by programs that are being executed in a multiprocessing configuration. That is, the routine allows a program to modify the contents of a storage location while the CPU is enabled, even though the routine may be interrupted by another program on the same CPU that will update the location, and even though the possibility exists that another CPU may simultaneously update the same location.

The COMPARE AND SWAP instruction first checks the value of a storage location and then modifies it only if the value is what the program expects; normally this would be a previously fetched value. If the value in storage is not what the program expects, then the location is not modified; instead, the current value of the location is loaded into a general register, in preparation for the program to loop back and try again. During the execution of COMPARE AND SWAP, no other CPU can perform a store access or interlocked-update access at the specified location.

To ensure successful updating of a common storage field by two or more CPUs, all updates must be done by means of an interlocked-update reference. See the programming notes of COMPARE AND SWAP for an example of how COMPARE AND SWAP can be unsuccessful due to an OR IMMEDIATE instruction executed by another CPU.

Setting a Single Bit

The following instruction sequence shows how the COMPARE AND SWAP instruction can be used to set a single bit in storage to one. Assume that the first byte of a word in storage called “WORD” contains eight flag bits.

```
      LA   6,X'80'   Put bit to be ORed into GR6
      SLL  6,24      Shift left 24 places to
                       align the byte to be ORed
                       with the location of the
                       flag bits within WORD
      L    7,WORD    Fetch current flag values
RETRY LR   8,7       Load flags into GR8
      OR   8,6       Set bit to one
      CS   7,8,WORD  Store new flags if current
                       flags unchanged, or re-
                       fetch current flag values
                       if changed
      BC   4,RETRY   If new flags are not stored,
                       try again
```

The format of the COMPARE AND SWAP instruction is:

Machine Format

Op Code	R_1	R_3	S_2
BA	7	8	* * * *

Assembler Format

```
Op Code  R1,R3,S2
_________________
   CS    7,8,WORD
```

The COMPARE AND SWAP instruction compares the first operand (general register 7 containing the current flag values) to the second operand in storage (WORD) while no CPU other than the one executing the COMPARE AND SWAP instruction is permitted to perform a store access or interlocked-update access at the specified storage location.

If the comparison is successful, indicating that the flag bits have not been changed since they were fetched, the modified copy in general register 8 is stored into WORD. If the flags have been changed,

the compare will not be successful, and their new values are loaded into general register 7.

The conditional branch (BC) instruction tests the condition code and reexecutes the flag-modifying instructions if the COMPARE AND SWAP instruction indicated an unsuccessful comparison (condition code 1). When the COMPARE AND SWAP instruction is successful (condition code 0), the flags contain valid data, and the program exits from the loop.

The branch to RETRY will be taken only if some other program modifies the contents of WORD. This type of a loop differs from the typical “bit-spin” loop. In a bit-spin loop, the program continues to loop until the bit changes. In this example, the program continues to loop only if the value does change during each iteration. If a number of CPUs simultaneously attempt to modify a single location by using the sample instruction sequence, one CPU will fall through on the first try, another will loop once, and so on until all CPUs have succeeded.

Updating Counters

In this example, a 32-bit counter is updated by a program using the COMPARE AND SWAP instruction to ensure that the counter will be correctly updated. The original value of the counter is obtained by loading the word containing the counter into general register 7. This value is moved into general register 8 to provide a modifiable copy, and general register 6 (containing an increment to the counter) is added to the modifiable copy to provide the updated counter value. The COMPARE AND SWAP instruction is used to ensure valid storing of the counter.

The program updating the counter checks the result by examining the condition code. The condition code 0 indicates a successful update, and the program can proceed. If the counter had been changed between the time that the program loaded its original value and the time that it executed the COMPARE AND SWAP instruction, the execution would have loaded the new counter value into general register 7 and set the condition code to 1, indicating an unsuccessful update. The program must then repeat the update sequence until the execution of the COMPARE AND SWAP instruction results in a successful update.

The following instruction sequence performs the above procedure:

```
     LA  6,1      Put increment (1) into GR6
     L   7,CNTR   Put original counter value
                    into GR7
LOOP LR  8,7      Set up copy in GR8 to modify
     AR  8,6      Increment copy
     CS  7,8,CNTR Update counter in storage
     BC  4,LOOP   If original value had
                    changed, update new value
```

The following shows two CPUs, A and B, executing this instruction sequence simultaneously: both CPUs attempt to add one to CNTR.

CPU A			CPU B		
GR7	GR8	CNTR	GR7	GR8	Comments
		16			
16	16				CPU A loads GR7 and GR8 from CNTR
			16	16	CPU B loads GR7 and GR8 from CNTR
				17	CPU B adds one to GR8
	17				CPU A adds one to GR8
		17			CPU A executes CS; successful match, store
			17		CPU B executes CS; no match, GR7 changed to CNTR value
				18	CPU B loads GR8 from GR7, adds one to GR8
		18			CPU B executes CS; successful match, store

Bypassing Post and Wait

See the *MVS Programming: Authorized Assembler Services Guide* (SA22-7608) for details on bypassing the z/OS WAIT and POST routines.

Lock/Unlock

When a common storage area larger than a doubleword is to be updated, it is usually necessary to provide special interlocks to ensure that a single program at a time updates the common area. Such an area is called a serially reusable resource (SRR).

In general, updating a list, or even scanning a list, cannot be safely accomplished without first “freezing” the list. However, the COMPARE AND SWAP and COMPARE DOUBLE AND SWAP instructions can be used in certain restricted situations to perform queuing and list manipulation. Of prime importance is the capability to perform the lock/unlock functions and to

provide sufficient queuing to resolve contentions, either in a LIFO or FIFO manner. The lock/unlock functions can then be used as the interlock mechanism for updating an SRR of any complexity.

The lock/unlock functions are based on the use of a "header" associated with the SRR. The header is the common starting point for determining the states of the SRR, either free or in use, and also is used for queuing requests when contentions occur. Contentions are resolved using WAIT and POST. The general programming technique requires that the program that encounters a "locked" SRR must "leave a mark on the wall" indicating the address of an ECB on which it will WAIT. The "unlocking" program sees the mark and posts the ECB, thus permitting the waiting program to continue. In the two examples given, all programs using a particular SRR must use either the LIFO queuing scheme or the FIFO scheme; the two cannot be mixed. When more complex queuing is required, it is suggested that the queue for the SRR be locked using one of the two methods shown.

Lock/Unlock with LIFO Queuing for Contentions

The header consists of a word, that is, a four-byte field aligned on a word boundary. The word can contain zero, a positive value, or a negative value.

- A zero value indicates that the serially reusable resource (SRR) is free.
- A negative value indicates that the SRR is in use but no additional programs are waiting for the SRR.
- A positive value indicates that the SRR is in use and that one or more additional programs are waiting for the SRR. Each waiting program is identified by an element in a chained list. The positive value in the header is the address of the element most recently added to the list.

Each element consists of two words. The first word is used as an ECB; the second word is used as a pointer to the next element in the list. A negative value in a pointer indicates that the element is the last element in the list. The element is required only if the program finds the SRR locked and desires to be placed in the list.

The following chart describes the action taken for LIFO LOCK and LIFO UNLOCK routines. The routines following the chart allow enabled code to perform the actions described in the chart.

Function	Action		
	Header Contains Zero	Header Contains Positive Value	Header Contains Negative Value
LIFO LOCK (the incoming element is at location A)	SRR is free. Set the header to a negative value. Use the SRR.	SRR is in use. Store the contents of the header into location A+4. Store address A into the header. WAIT; the ECB is at location A.	
LIFO UNLOCK	Error	Some program is waiting for the SRR. Move the pointer from the "last in" element into the header. POST; the ECB is in the "last in" element.	The list is empty. Store zeros into the header. The SRR is free.

LIFO LOCK Routine:

Initial Conditions:

- GR1 contains the address of the incoming element.
- GR2 contains the address of the header.

```
LLOCK  SR     3,3       GR3 = 0
       ST     3,0(1)    Initialize the ECB
       LNR    0,1       GR0 = a negative value
TRYAGN CS     3,0,0(2)  Set the header to a
                          negative value if the
                          header contains zeros
       BC     8,USE     Did the header contain
                          zeros?
       ST     3,4(1)    No, store the value of
                          the header into the
                          pointer in the in-
                          coming element
       CS     3,1,0(2)  Store the address of
                          the incoming element
                          into the header
       LA     3,0(0)    GR3 = 0
       BC     7,TRYAGN  Did the header get up-
                          dated?
       WAIT   ECB=(1)   Yes, wait for the re-
                          source; the ECB is in
                          the incoming element
USE    [Any instruction]
```

LIFO UNLOCK Routine:

Initial Conditions:

- GR2 contains the address of the header.

```
LUNLK L    1,0(2)    GR1 = the contents of
                       the header
A     LTR  1,1       Does the header contain
      BC   4,B         a negative value?
      L    0,4(1)    No, load the pointer
      CS   1,0,0(2)    from the 'last in'
                       element and store it in
                       the header
      BC   7,A       Did the header get
                       updated?
      POST (1)       Yes, post the 'last in'
                       element
      BC   15,EXIT   Continue
B     SR   0,0       The header contains a
      CS   1,0,0(2)    negative value; free
      BC   7,A         the header and continue
EXIT  [Any instruction]
```

Note that the LOAD instruction L 1,0(2) at location LUNLK would have to be CS 1,1,0(2) if it were not for the rule concerning storage-operand consistency. This rule requires the LOAD instruction to fetch a four-byte operand aligned on a word boundary such that, if another CPU changes the word being fetched by an operation which is also at least word-consistent, either the entire new or the entire old value of the word is obtained, and not a combination of the two. (See “Storage-Operand Consistency” on page 5-133.)

Lock/Unlock with FIFO Queuing for Contentions

The header always contains the address of the most recently entered element. The header is originally initialized to contain the address of a posted ECB. Each program using the serially reusable resource (SRR) must provide an element regardless of whether contention occurs. Each program then enters the address of the element which it has provided into the header, while simultaneously it removes the address previously contained in the header. Thus, associated with any particular program attempting to use the SRR are two elements, called the “entered element” and the “removed element” The “entered element” of one program becomes the “removed element” for the immediately following program. Each program then waits on the removed element, uses the SRR, and then posts the entered element.

When no contention occurs, that is, when the second program does not attempt to use the SRR until after the first program is finished, then the POST of the first program occurs before the WAIT of the second program. In this case, the bypass-post and bypass-wait routines described in the preceding section are applicable. For simplicity, these two routines are shown only by name rather than as individual instructions.

In the example, the element need be only a single word, that is, an ECB. However, in actual practice, the element could be made larger to include a pointer to the previous element, along with a program identification. Such information would be useful in an error situation to permit starting with the header and chaining through the list of elements to find the program currently holding the SRR.

It should be noted that the element provided by the program remains pointed to by the header until the next program attempts to lock. Thus, in general, the entered element cannot be reused by the program. However, the removed element is available, so each program gives up one element and gains a new one. It is expected that the element removed by a particular program during one use of the SRR would then be used by that program as the entry element for the next request to the SRR.

It should be noted that, since the elements are exchanged from one program to the next, the elements cannot be allocated from storage that would be freed and reused when the program ends. It is expected that a program would obtain its first element and release its last element by means of the routines described in “Free-Pool Manipulation”.

The following chart describes the action taken for FIFO LOCK and FIFO UNLOCK.

Function	Action
FIFO LOCK (the incoming element is at location A)	Store address A into the header. WAIT; the ECB is at the location addressed by the old contents of the header.
FIFO UNLOCK	POST; the ECB is at location A.

The following routines allow enabled code to perform the actions described in the previous chart.

FIFO Lock Routine:

Initial conditions:

- GR3 contains the address of the header.
- GR4 contains the address, A, of the element currently owned by this program. This element becomes the entered element.

```
FLOCK  LR   2,4       GR2 now contains
                        address of element to
                        be entered
       SR   1,1       GR1 = 0
       ST   1,0(2)    Initialize the ECB
       L    1,0(3)    GR1 = contents of the
                        header
TRYAGN CS   1,2,0(3)  Enter address A into
                        header while remember-
       BC   7,TRYAGN    ing old contents of
                        header into GR1; GR1
                        now contains address
                        of removed element
       LR   4,1       Removed element becomes
                        new currently owned
                        element
       HSWAIT         Perform bypass-wait
                        routine; if ECB
                        already posted, con-
                        tinue; if not, wait;
                        GR1 contains the
                        address of the ECB
USE    [Any instruction]
```

FIFO Unlock Routine:

Initial conditions:

- GR2 contains the address of the removed element, obtained during the FLOCK routine.
- GR5 contains 40 00 00 00_{16}

```
FUNLK  LR  1,2  Place address of entered
                  element in GR1; GR1 = ad-
                  dress of ECB to be posted
       SR  0,0  GR0 = 0; GR0 has a post code
                  of zero
       OR  0,5  Set bit 1 of GR0 to one
       HSPOST   Perform bypass-post routine;
                  if ECB has not been waited
                  on, then mark posted and
                  continue; if it has been
                  waited on, then post
CONTINUE [Any instruction]
```

Free-Pool Manipulation

It is anticipated that a program will need to add and delete items from a free list without using the lock/unlock routines. This is especially likely since the lock/unlock routines require storage elements for queuing and may require working storage. The lock/unlock routines discussed previously allow simultaneous lock routines but permit only one unlock routine at a time. In such a situation, multiple additions and a single deletion to the list may all occur simultaneously, but multiple deletions cannot occur at the same time. In the case of a chain of pointers containing free storage buffers, multiple deletions along with additions can occur simultaneously. In this case, the removal cannot be done using the COMPARE AND SWAP instruction without a certain degree of exposure.

Consider a chained list of the type used in the example in section “Lock/Unlock with LIFO Queuing for Contentions” on page A-48. Assume that the first two elements are at locations A and B, respectively. If one program attempted to remove the first element and was interrupted between the fourth and fifth instructions of the LUNLK routine, the list could be changed so that elements A and C are the first two elements when the interrupted program resumes execution. The COMPARE AND SWAP instruction would then succeed in storing the value B into the header, thereby destroying the list.

The probability of the occurrence of such list destruction can be reduced to *near* zero by appending to the header a counter that indicates the number of times elements have been added to the list. The use of a 32-bit counter guarantees that the list will not be destroyed unless the following events occur, in the exact sequence:

1. An unlock routine is interrupted between the fetch of the pointer from the first element and the update of the header.
2. The list is manipulated, including the deletion of the element referenced in 1, and exactly 2^{32} (or an integer multiple of 2^{32}) additions to the list are performed. Note that this takes on the order of days to perform in any practical situation.
3. The element referenced in 1 is added to the list.
4. The unlock routine interrupted in 1 resumes execution.

The following routines use such a counter in order to allow multiple, simultaneous additions and removals at the head of a chain of pointers.

The list consists of a doubleword header and a chain of elements. The first word of the header contains a pointer to the first element in the list. The second word of the header contains a 32-bit counter indicating the number of additions that have been made to the list. Each element contains a pointer to the next element in the list. A zero value indicates the end of the list.

The following chart describes the free-pool-list manipulation.

Function	Action	
	Header = 0,Count	Header = A,Count
ADD TO LIST (the incoming element is at location A)	Store the first word of the header into location A. Store the address A into the first word of the header. Decrement the second word of the header by one.	
DELETE FROM LIST	The list is empty.	Set the first word of the header to the value of the contents of location A. Use element A.

The following routines allow enabled code to perform the free-pool-list manipulation described in the above chart.

ADD TO FREE LIST Routine:

Initial Conditions:

- GR2 contains the address of the element to be added.
- GR4 contains the address of the header.

```
ADDQ   LM   0,1,0(4) GR0,GR1 = contents of
                       the header
TRYAGN ST   0,4(2)   Point the new element to
                       the top of the list
       LR   3,1      Move the count to GR3
       ALFI  3,1      Increment the count
       CDS  0,2,0(4) Update the header
       BC   7,TRYAGN
```

DELETE FROM FREE LIST Routine:

Initial conditions:

- GR4 contains the address of the header.

```
DELETQ LM   2,3,0(4)    GR2,GR3 = contents
                          of the header
TRYAGN LTR  2,2         Is the list empty?
       BC   8,EMPTY     Yes, get help
       L    0,4(2)      No, GR0 = the pointer
                          from the first
                          element
       LR   1,3         Move the count to GR1
       CDS  2,0,0(4)    Update the header
       BC   7,TRYAGN
USE    [Any instruction] The address of the re-
                          moved element is in
                          GR2
```

Notes:

1. The LM (LOAD MULTIPLE) instructions at locations ADDQ and DELETQ would have to be CDS (COMPARE DOUBLE AND SWAP) instructions if it were not for the rule concerning storage-operand consistency. This rule requires the LOAD MULTIPLE instructions to fetch an eight-byte operand aligned on a doubleword boundary such that, if another CPU changes the doubleword being fetched by an operation which is also at least doubleword-consistent, either the entire new or the entire old value of the doubleword is obtained, and not a combination of the two. (See “Storage-Operand Consistency” on page 5-133.)
2. The add-to-free-list and delete-from-free-list examples shown above assume that the pointer to the next element in the list is in the second word of the element, as described “Lock/Unlock with LIFO Queuing for Contentions” on page A-48.

PERFORM LOCKED OPERATION (PLO)

The PERFORM LOCKED OPERATION instruction can be used in a multiprogramming or multiprocessing environment to perform compare, load, compare-and-swap, and store operations on two or more discontiguous locations that can be words, doublewords, quadwords, or octowords. The operations are performed as an atomic set of operations. When the PLO-extension facility is not installed, the operations are performed under the control of a lock that is held only for the duration of the execution of a single PERFORM LOCKED OPERATION instruction, as opposed to across the execution of multiple instructions. Since lock contention is resolved by the CPU

and is very brief, the program need not include a method for dealing with the case when the lock to be used is held by a program being executed by another CPU. Also, there need be no concern that the program may be interrupted while it holds a lock, since PERFORM LOCKED OPERATION will complete its operation and release its lock before an interruption can occur. When the PLO-extension facility is installed, the operations are performed under control of other means.

PERFORM LOCKED OPERATION can be thought of as performing concurrent interlocked updates of multiple operands. However, when the PLO-extension facility is not installed, the instruction does not actually perform any interlocked update, and a serially reusable resource cannot be updated predictably through the use of both PERFORM LOCKED OPERATION and conditional-swapping instructions (CS and CDS).

Following is an example of how PERFORM LOCKED OPERATION can be used to add an element at the beginning of a queue. Some of the details described in this example only apply when the PLO-extension facility is not installed, but the use of PERFORM LOCKED OPERATION in this example also applies when the PLO-extension facility is installed.

Assume the following variables associated with the queue: S, which is a sequence number that is incremented anytime the queue is changed; H (for head), which is the address of the first element on the queue; and C, which is a count of the number of elements on the queue. Assume a queue element contains a variable, F (for forward), which is the address of the next element on the queue. If a new element, N, is to be enqueued at the head of the queue, that can be done by setting F in N to H and then performing the following atomic set of operations:

S+1 → S
A(N) → H
C+1 → C

where A(N) is the address of N.

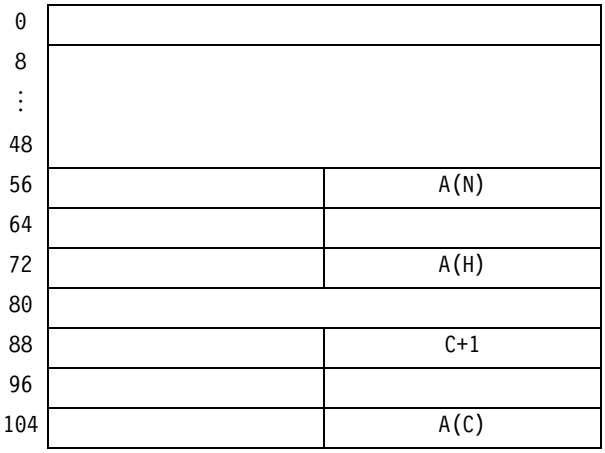
The enqueueing of N can be done by means of the following steps:

1. Obtain consistent values of S, H, and C, meaning obtain S and obtain the H and C that are consistent with that value of S.
2. Store H in N.F.
3. By means of PLO.CSDST (PERFORM LOCKED OPERATION performing compare and swap and double store), with S as the swap variable and H and C as the store variables, add one to S, set H to A(N), and add one to C, provided that S still has the value obtained in step 1. If S has already been changed, go back to step 1.

Consistent values of S, H, and C cannot necessarily be obtained simply by using three LOAD instructions because a PERFORM LOCKED OPERATION instruction being executed by another CPU may have completed an update of S but not yet of H or C. In this case, the three LOAD instructions will obtain the new S but the old H or C. However, as will be described, it may be possible to use three LOAD instructions.

If S is obtained while holding the lock, meaning by means of PERFORM LOCKED OPERATION, then H and C can be obtained by LOAD instructions since no other CPU can subsequently change H or C without changing S, as observed when the lock is held.

The parameter list used by the PLO.csdst is as follows, assuming the access-register mode is not used:



The program is as follows:

```
LA    RT,H        Initialize addresses in
                   PL (T = temp)
ST    RT,PL+76    Op4 address (address of
                   H)
LA    RT,C
ST    RT,PL+108   Op6 address (address of
                   C)
```

```
      LA    RN,N      Address of N
      ST    RN,PL+60  Initialize op3 in PL
                        (address of N)
      LA    R1,S      PLT address = address
                        of S
-------------------------------------------
      SR    RS,RS     Dummy S.  CC1 will
                        probably be set
      SR    R0,R0     Function code 0
                        (compare and load)
      PLO   RS,S,RS,S Obtain S while holding
                        lock
-------------------------------------------
      LA    R0,16     Function code 16 (csdst)
LOOP  L     RT,H      Consistent H
      ST    RT,OFSTF(,RN)  OFSTF = offset of
                             F in N
      L     RT,C      Consistent C
      LA    RT,1(,RT) C+1
      ST    RT,PL+92  Initialize op5 in PL
                        (C+1)
      LA    RSP,1(,RS) RS/RSP = even-odd pair.
                        S+1 in RSP
      PLO   RS,S,0,PL
      BNZ   LOOP      Br if S changed (if CC
                        not 0)
```

Note the following about the first PERFORM LOCKED OPERATION instruction (PLO.CL). If S is not zero (which is probably true), S (the second operand, op2) is loaded into RS (the first-operand comparison value, op1c). If S is zero, S (the fourth operand, op4) is loaded into RS (the third operand, op3). Either of these loads occurs while the lock is held. It is unnecessary to test the condition code to determine which load occurred.

The above program may be a simplification. If the queue has associated with it a variable, T (for tail), that is the address of the last element on the queue, and the queue is currently empty, T also must be set when N is added to the queue. This would require a different program using a compare-and-swap-and-triple-store operation.

If the queue is added to, deleted from, and rearranged by means of PERFORM LOCKED OPERATION instructions in which the sequence number, S, is always the second operand, then, since the definition of PERFORM LOCKED OPERATION specifies that the second operand is always stored last, the first PERFORM LOCKED OPERATION instruction in the above program can be replaced by a LOAD instruction. The three instructions within the dashed lines would be replaced by L RS,S.

Sorting Instructions

Tree Format

Two instructions, COMPARE AND FORM CODEWORD and UPDATE TREE, refer to a tree — a data structure with a specific format. A tree consists of some number (always odd) of consecutively numbered nodes. Node 1 is the root of the tree. Every node except the root has one parent node in the same tree. Every parent node has two son nodes. Every even-numbered node is the *leftson* of its parent node, and every odd-numbered node (except node 1) is the *rightson* of its parent node. Division by two (ignoring remainder) of the node number gives the parent node number. Nodes with sons are also called internal nodes, and nodes without sons are called terminal nodes. Figure A-5 on page A-54 illustrates schematically a 21-node tree with arrows drawn from each parent node to each son node.

A tree is used for merging several sorted sequences of records into a single merged sequence of records. At each step in the merging process, there exists the initial part of the merged sequence and the remaining parts of each of the sorted sequences that are being merged. Each step consists in selecting the lowest record (the record with the lowest key when sorting in ascending sequence) from all of the as yet unmerged parts of the sorted sequences and adding it to the merged sequence. Each terminal node in the tree represents one of the sorted sequences. The number of internal nodes in the tree is one less than the number of sorted sequences. Each internal node conceptually contains one record from each of the sorted sequences but one; these are the lowest records, from all but one of the sorted sequences, that have not yet been added to the merged sequence. In addition, there is the lowest record from the one remaining sorted sequence. This additional record is compared and interchanged with nodes of the tree to select the record to be added next to the merged sequence. This processing begins with the parent of the terminal node that represents the one remaining sorted sequence, and it continues from that node along the path to the root of the tree. The selected record emerges from the root of the tree.

The tree may perhaps be most easily explained by considering each node to represent a comparison operation in an “elimination tournament” to find the lowest record. After the tournament has been completed, each node has an associated “loser” record which had a higher key in the comparison represented by that node. Besides a loser record at each node, there is one record (the “winner”) which is not associated with any node since it never compared high. The next step would be to introduce a new record from the same sorted sequence from which the winner record originated and replay the tournament with the new record in place of the former winner. It can be seen that it is unnecessary to do all the comparisons represented by all the nodes in the tree — most of them are unaffected by the new record replacing the former winner. In fact, it is sufficient to redo only those node comparisons in which the former winner record participated. Each new record is inserted into the tree at the terminal node that represents the sorted sequence containing the record. The use of the tree assumes that programming provides a method of remembering at which terminal node each winning record originated. The instruction UPDATE TREE allows for a new record to be inserted at a terminal node and the tree to be updated so that a new winner record is left in the general registers.

Rather than comparing the actual keys of records, much of the merge logic can be performed using “codewords” to represent a record key rather than referring to actual keys. The value of a codeword at a node in the tree depends not only on the record’s key but also on the key of the winning record in the last comparison at that node. The codeword consists of two parts:

1. Bits 16-31 contain the one’s complement of the first halfword in which the record key differs from that of the node’s winning record.
2. Bits 0-15 specify the byte offset of the halfword in this record’s key just beyond the halfword value (complemented) in bit positions 16-31.

When comparing records in the path of the last winner record, if the new record is also represented by a codeword resulting from a comparison with the last winner, all codewords in the update path are with respect to the same winner. When comparing such codewords, a high codeword represents a low key and vice versa. Thus, when codewords are unequal, a node entry with a high codeword (representing a low actual key) should move up the tree.

In the case of a tie value of codewords, it is necessary to refer to the actual keys. This is done by the instruction COMPARE AND FORM CODEWORD, which resolves the ambiguity and computes a new codeword for the high-key (loser) record.

The eight bytes at each node of a tree consist of (1) a codeword for this record, computed with respect to the last record which compared low against this record and (2) a parameter usable to locate this record, for example, a direct or indirect address.

The instruction UPDATE TREE is so defined that tree updating stops after equal codewords are detected and the tie-breaking instruction COMPARE AND FORM CODEWORD can be used, after which UPDATE TREE can resume tree updating at the point where equal codewords were previously found.

COMPARE AND FORM CODEWORD may alternatively be used for merging in descending sequence. In that case, bits 16-31 of the codeword at a node contain the true value of the first halfword in which the record key differs from that of the node’s winning record. When the descending option of COMPARE AND FORM CODEWORD is used, the higher of two codewords represents the higher key.

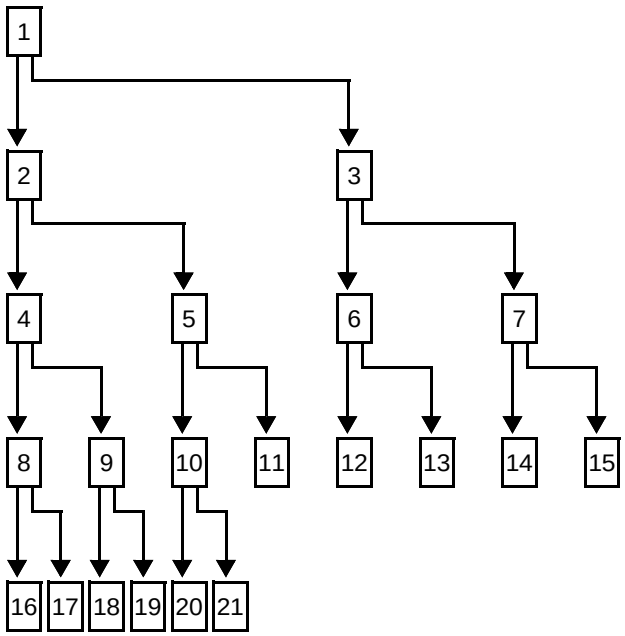


Figure A-5. Schematic Diagram of Merge Control Tree with 21 Nodes

Example of Use of Sort Instructions

An example illustrates how the instructions UPDATE TREE and COMPARE AND FORM CODEWORD may be used in the merge operation within a sort program. A five-way merge requires a tree data structure with four internal nodes and five terminal-node positions. The schematic diagram shown later in this section illustrates such a tree, containing four internal nodes (not counting the dummy node) and five input sequences for a merge, one sequence at each terminal-node position. Each record in an input sequence in the diagram is indicated by its address. The actual record contents are shown in Figure A-7 on page A-58. Each record contains 16 bytes, consisting of the following fields:

Byte Offset (hexadecimal)	Field
0-5	Six-byte record key.
6-7	Halfword node index specifying the input sequence of the next record of this input sequence.
8-B	Address of the next record in the same input sequence.
C-F	This chaining field is initially zero. At the completion of the merge, this field is to contain the address of the next record in the merged sequence.

The merge process forms a single sorted sequence from five input sequences, each of which is in sorted order. This process can be subdivided into three steps:

1. A priming step takes the first record from each of the five input sequences and places them in the tree data structure. For each record to be introduced into the tree, first its codeword value is computed with respect to the lowest possible key value of all zeros. This codeword, with a second word which contains the address of the actual record, forms a doubleword node value that can be placed at the appropriate node. After priming, the node values, one each from each of the five input sequences, will have been placed in the tree so that each of the four internal nodes contains one node value and the node value for a winner record has emerged from the root of the tree.

2. After each winner emerges from the tree, the main merge process is performed repeatedly. Each iteration introduces the node value for one new record into the tree and produces a node value for a new winner record. The tree plus the winner must at all times contain precisely one node value from each input sequence being merged. Therefore, the new node value that is introduced into the tree on each iteration must come from the same input sequence from which the winner node value in the preceding iteration originated.

3. When the node value for the last record of an input sequence emerges as a winner, there is no successor record from that input sequence to be introduced into the tree on the next iteration. Hence, the order of the merge must be reduced by one for each such occurrence. This runout process will consist of one or more iterations for each of a four-way, three-way, two-way, and one-way merge. The onset of runout occurs in the example when it is found that the next input record from a sequence is lower than its predecessor (a sequence break).

The priming process is discussed next, and the state of the tree is shown after priming is complete. Then, a short program that uses the instructions UPDATE TREE and COMPARE AND FORM CODEWORD to perform the main merge is described. An abbreviated trace is then presented to show the status of the tree and certain general registers for 16 iterations of the main merge. The runout process is not discussed in this example.

Priming begins by forming the node value for the first record of each input sequence. The first word of the node value is the codeword formed by executing COMPARE AND FORM CODEWORD on a record key containing all binary zeros. The second word of the node value is the address of the record represented by that node value. The node values for the first record of each input sequence are:

```
Sequence Index          Node Values

      28          0006 FFFC 0000 1030
      30          0006 FFFB 0000 1040
      38          0006 FFFA 0000 1050
      40          0004 FFFE 0000 1080
      48          0006 FFF0 0000 1060
```

In the example, the tree data structure is assumed to have base address X‘1000’, which is kept in general register 4 (to match the expected use in UPDATE TREE). Similarly, internal-node index values and

input-sequence index values are always used from general register 5.

Although the tree-priming program is not part of this example, the UPDATE TREE instruction is used in creating it as follows. First, the codeword position for each internal node of the tree is initialized to all ones (X'FFFF FFFF'). This artifice fills the tree with dummy low records. Then, for each record in the table, (1) the sequence index is loaded into general register 5, (2) the node value is loaded into general registers 0 and 1, and (3) UPDATE TREE is executed. At the completion of this priming process, the tree-node contents in the example are as shown on line 0 of Figure A-9 on page A-60. The contents of the general registers are as shown on the first line of Figure A-8 on page A-59.

The figure illustrating the program for the main merge is divided into three groups of columns, containing the absolute program, the general-register trace, and the symbolic program. The first part of the program extends from symbolic locations L1 through L2; it introduces a new record into the tree and executes an UPDATE TREE instruction. If no tied codewords are encountered in UPDATE TREE, then the BRANCH ON CONDITION instruction following UPDATE TREE loops back to L1 to introduce the next record into the tree. This BRANCH ON CONDITION instruction is suitable for use when UPDATE TREE operates in accordance with either its method 1 (setting condition code 1) or its method 2 (setting condition code 3). (The preceding sentence applies to 370-XA. In ESA/370 and ESA/390, UPDATE TREE operates in accordance with only method 2, which is not to say that it cannot set condition code 1. Method 2, but not method 1, tests for the condition that sets condition code 3.)

If UPDATE TREE encounters tied codewords, then the UPDATE TREE instruction is completed, the subsequent BRANCH ON CONDITION instruction does not branch, and control falls through to the second part of the program, which handles entries with tied codewords. This part then branches back to UPDATE TREE at L2, which resumes the tree updating. It is possible for tied codewords to be encountered at any level in the tree (or indeed at all levels), so that the tied-codeword part of the program may be entered up to three times for each record introduced.

The general-register trace for the first part of the main merge shows the contents of the first seven general registers after each instruction is executed during the first iteration. Note that the merged-chain field (at 1140) serves as the anchor for the merged-chain address chain through the records. The trace shows only the lower half of certain general registers, whose upper half is always zero.

Figure A-9 on page A-60 gives an abbreviated trace of the entire main merge of 16 records. For each record introduced into the tree, there are one or more lines (always an odd number) given in the figure to show the tree updating, which results finally in a winner in GR0 and GR1. The first line for each record shows the values of GR5, GR2, and GR3 before the first or only execution of UPDATE TREE. For the even-numbered lines, the storage updating by UPDATE TREE of tree nodes is shown (read left to right to follow the order of swapping). For example, consider line 10 and the corresponding UPDATE TREE: since GR5 contains 28, the first storage node examined is 1010 (refer to the schematic diagram). Since the codeword in GR0 is 0004 FFFE (same as for GR2), which is less than that of the word at 1010 (0006 FFF0), the doubleword at 1010 is swapped with that in GR0 and GR1. A second comparison at 1008 in the same execution of UPDATE TREE causes another register-storage doubleword swap, which leaves the winner (record 1040) in GR1 at the completion of UPDATE TREE (see the column at the far right of Figure A-9 on page A-60).

When a codeword comparison is made which does not result in a tie or a swap (that is, when the storage-codeword value is low), an asterisk appears in the trace for that storage entry.

When equal codewords are found, the execution of UPDATE TREE is completed. The following line in each such case shows the result of the tied-codeword routine, which always stores a new codeword and may also store a new record address before branching back to L2 to execute UPDATE TREE again. In this line, the notation “loses” or “wins” means that the node loses or wins, respectively.

The tie-break trace part of Figure A-8 on page A-59 shows the treatment of the third record (that is, the first record for which UPDATE TREE encounters a tied codeword). This corresponds to line 31 in Figure A-9 on page A-60.

The following is a summary of the steps that are needed to use this example for verification purposes:

1. Initialize storage as follows:

a. 1008 through 102F from line 0 of Figure A-9 on page A-60

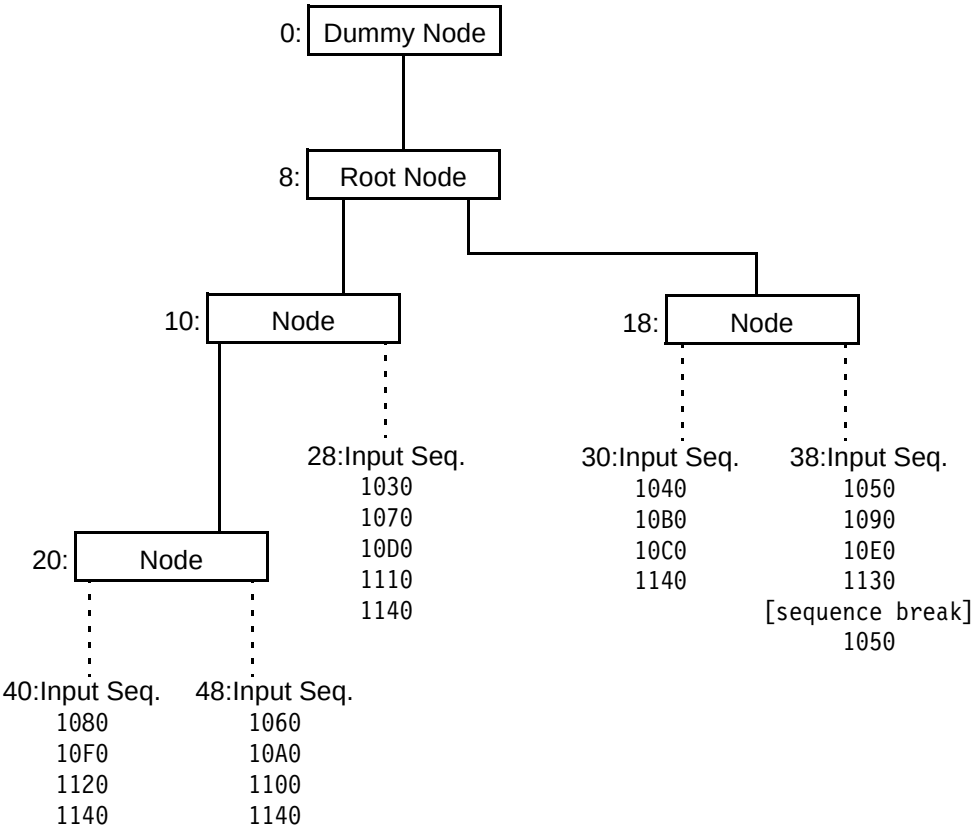
b. 1030 through 114F from Figure A-7 on page A-58

c. 1150 through 1189 from Figure A-8 on page A-59

2. Initialize GRs per first line in Figure A-8 and trace first record per Figure A-8.

3. Trace to completion of each UPT or BC 15,L2 (once for each line of Figure A-9). A detailed trace of the GRs for the tied-codeword part of line 31 of Figure A-9 is given in the lower part of Figure A-8.

4. Verify that addresses in the chain beginning at 103C and continuing through 114C are as shown in the right-hand column of Figure A-7.



Note: Each node and input sequence is identified by a number which is the hexadecimal node index. Each input sequence is given as a list of record addresses (also in hexadecimal).

Explanation:

[1] Line 0 shows the values in the tree after it is primed.

* Means no swap.

** Means no swap if UPDATE TREE method 1 is used or no examination if UPDATE TREE method 2 is used. Only method 2 is included in ESA/370 and ESA/390.

CC = 0 UPDATE TREE finds a tie and sets condition code 0.

Loses The tied-codeword routine finds that the node loses.

Wins The tied-codeword routine finds that the node wins.

Equal The tied-codeword routine finds that the keys are equal.

Branch Branches to terminate at 118A on sequence break.

No compNo compare.

Figure A-9. Abbreviated Trace of Main Merge Processing

Appendix B. Lists of Instructions

The following figures list instructions by name, mnemonic, and operation code. Some models may offer instructions that do not appear in the figures, such as those provided for assists or as part of special or custom features.

The operation code for the interpretive execution facility is not included in this appendix. See the publication *IBM System/370 Extended Architecture Interpretive Execution*, SA22-7095, for the operation code associated with that facility.

The operation code 00 hex with a two-byte instruction format is allocated for use by the program when an indication of an invalid operation is required. Operation code 00 hex will never be assigned to an instruction implemented in the CPU.

Explanation of Symbols in "Characteristics" Columns:

- $ — Causes serialization.
- ¢ — Causes serialization and checkpoint synchronization.
- £ — Causes specific-operand serialization.
- ¢[1] — Causes serialization and checkpoint synchronization when the M_1 and R_2 fields contain 1111 binary and 0000 binary, respectively. Causes only serialization when the fast-BCR-serialization facility is installed, and the M_1 and R_2 fields contain 1110 binary and 0000 binary, respectively.
- £[1] — Causes specific-operand serialization when the interlocked-access facility 1 is installed and the storage operand is aligned on an integral boundary corresponding to its size.
- ¤[1] — Restricted from transactional execution.
- ¢[2] — Causes serialization and checkpoint synchronization when the state entry to be unstacked is a program-call state entry.
- £[2] — Causes specific-operand serialization when the interlocked-access facility 2 is installed.
- ¤[2] — Restricted from transactional execution when R_2 nonzero and branch tracing is enabled.
- ¢[3] — Causes serialization and checkpoint synchronization when the set-key control is one.
- ¤[3] — Restricted from transactional execution when mode tracing is enabled.
- ¢[4] — Causes serialization and checkpoint synchronization when the KFC value is 4 or 5.
- ¤[4] — Restricted from transactional execution when a monitor-event condition occurs.
- ¢[5] — Causes serialization when write through MIO storage address referenced and checkpoint synchronization.
- ¤[5] — Model dependent whether the instruction is restricted from transactional execution.
- ¤[6] — Restricted from transactional execution when the effective allow-AR-modification control is zero.
- ¤[7] — Restricted from transactional execution when the effective allow-floating-point-operation control is zero.
- ¤[8] — May be restricted from transactional execution depending on machine conditions.
- ¤[9] — Restricted in the constrained transactional-execution mode; a transaction-constraint program exception may be recognized. For STCMH, the instruction is restricted only when the M_3 field is zero.
- ¤[10] — Restricted to forward branches in the constrained transactional-execution mode.
- ¤[11] — For PFD and PFDRL, it is model dependent whether the instruction is restricted from transactional execution when the code in the M_1 field is 6 or 7; for STCMH, it is model dependent whether the instruction is restricted when the M_3 field is zero and the code in the R_1 field is 6 or 7.
- ¤[12] — Restricted from transactional execution when a guarded-storage event is recognized. When in the transactional-execution mode, the transaction is aborted, and the guarded-storage event is processed.
- A* — Access exceptions for logical addresses. The optional asterisk indicates that a PER ZAD event is not recognized.
- A[1]* — Access exceptions; not all access exceptions may occur; see instruction description for details. The optional asterisk indicates that a PER ZAD event is not recognized.
- AI — Access exceptions for instruction address.
- B — PER branch event. (For LGG and LLGFSG, the PER branch event is only recognized coincident with a guarded-storage event.)

B† B_1 field designates an access register when bit 47 of GR0 is zero, and bits 16-17 of the current PSW are 01 binary; or when bit 47 of GR0 is one, and bits 40-41 of GR0 are 01 binary.

B‡ B_2 field designates an access register when bit 63 of GR0 is zero, and bits 16-17 of the current PSW are 01 binary; or when bit 63 of GR0 is one, and bits 56-57 of GR0 are 01 binary.

B_1 B_1 field designates an access register in the access-register mode.

B_2 B_2 field designates an access register in the access-register mode.

B_4 B_4 field designates an access register in the access-register mode.

BE BEAR-enhancement facility.

BP B_2 field designates an access register when PSW bits 16 and 17 have the value 01.

C Condition code is set.

C* Condition code is optionally set.

C^1 Condition code is set when the conditional-SSKE facility is installed, and either or both of the MR and MC bits are one.

CF Concurrent-functions facility.

CS Compare-and-swap-and-store facility.

CT Configuration-topology facility.

CX Constrained transactional-execution facility.

D2 DAT-enhancement facility 2.

Da AFP-register data exception.

Db BFP-instruction data exception.

Dc Compare-and-trap data exception.

DE DAT-enhancement facility 1.

DF Decimal-overflow exception.

DF* Decimal-overflow exception conditionally recognized.

Dg General-operand data exception.

DK Decimal-divide exception.

DM Depending on the model, DIAGNOSE may generate various program exceptions and may change the condition code.

DO Distinct-operands facility.

DP Reset-DAP-protection facility.

Dt DFP-instruction data exception.

Dv Vector-instruction data exception.

E E instruction format.

E2 Extended-translation facility 2.

E3 Extended-translation facility 3.

ED1 Enhanced-DAT facility 1.

ED2 Enhanced-DAT facility 2.

EH Execution-hint facility.

EI Extended-immediate facility.

EO HFP-exponent-overflow exception.

ES Expanded-storage facility.

ET Extract-CPU-time facility.

EU HFP-exponent-underflow exception.

EX Execute exception.

FC Designation of access registers depends on the function code of the instruction.

FG FPR-GR-transfer facility.

FK HFP-divide exception.

FL Store-facility-list-extended facility.

FS Floating-point-support-sign-handling facility.

G0 Instruction execution includes the implied use of general register 0.

G1 Instruction execution includes the implied use of general register 1.

G2 Instruction execution includes the implied use of general register 2.

G4 Instruction execution includes the implied use of general register 4.

GE General-instructions-extension facility.

GF Guarded-storage facility.

GM Instruction execution includes the implied use of multiple general registers.

GS Instruction execution includes the implied use of general register 1 as the subsystem-identification word.

GZ DEFLATE-conversion facility.

HM HFP-multiply-add/subtract facility.

HW High-word facility.

I I instruction format.

I1 Access register 1 is implicitly designated in the access-register mode.

I4 Access register 4 is implicitly designated in the access-register mode.

IA Interlocked-access facility.

IC Condition code alternative to interruptible instruction.

IE IE instruction format.

IF Fixed-point-overflow exception.

IF* Fixed-point-overflow exception conditionally recognized.

II Interruptible instruction.

IK Fixed-point-divide exception.

IM Insert-reference-bits-multiple facility

IS Interruptible instruction and special-operation exception.

K PER storage-key-alteration event.

L New condition code is loaded.

L1 Load/store-on-condition facility 1.

L2 Load/store-on-condition facility 2.

LD Long-displacement facility.

LS HFP-significance exception.

LT Load-and-trap facility.

LZ Load-and-zero-rightmost-byte facility.

M3 Message-security assist extension 3.

M4 Message-security assist extension 4.

M5 Message-security assist extension 5.

M8 Message-security assist extension 8.

M9 Message-security assist extension 9.

MD Designation of access registers in the access-register mode is model-dependent.

ME Monitor event.

MI1 Miscellaneous-instruction-extensions facility 1.

MI2 Miscellaneous-instruction-extensions facility 2.

MI3 Miscellaneous-instruction-extensions facility 3.

MI4 Miscellaneous-instruction-extensions facility 4.

MII MII instruction format.

MO Move-with-optional-specifications facility.

MS Message-security assist.

N Instruction is new in z/Architecture as compared to ESA/390.

N3 Instruction is new in z/Architecture and has been added to ESA/390.

NN Neural-network-processing-assist facility.

OP Operand exception.

P Privileged-operation exception; also, restricted from transactional execution.

PA Processor-assist facility.

PC DFP packed-conversion facility.

PE Parsing-enhancement facility.

PF PFPO facility.

PI Processor-activity-instrumentation facility

PK Population-count facility.

Q Privileged-operation exception for semiprivileged instructions; also, restricted from transactional execution.

R_1 R_1 field designates an access register in the access-register mode.

R_2 R_2 field designates an access register in the access-register mode.

R_3 R_3 field designates an access register in the access-register mode.

RA Reusable-ASN-and-LX facility.

RB Reset-reference-bits-multiple facility.

RI RI instruction format.

RIE RIE instruction format.

RIL RIL instruction format.

RIS RIS instruction format.

RM R_1 field designates an access register in the access-register mode, and access-register 1 also is used in the access-register mode.

RR RR instruction format.

RRD RRD instruction format.

RRE RRE instruction format.

RRF RRF instruction format.

RRS RRS instruction format.

RS RS instruction format.

RSI RSI instruction format.

RSL RSL instruction format.

RSY RSY instruction format.

RX RX instruction format.

RXE RXE instruction format.

RXF RXF instruction format.

RXY RXY instruction format.

S S instruction format.

SC Store-clock-fast facility.

SE Special operation, stack-empty, stack-specification, and stack-type exceptions.

SF Special-operation, stack-full, and stack-specification exceptions.

SI SI instruction format.

SIL SIL instruction format.

SIY SIY instruction format.

SL Enhanced-sort facility.

SMI SMI instruction format.

SO Special-operation exception.

SP Specification exception.

SQ HFP-square-root exception.

SS SS instruction format.

SSE SSE instruction format.

SSF SSF instruction format.

ST PER storage-alteration event. (For LGG and LLGFSG, the PER storage-alteration event is only recognized coincident with a guarded-storage event.)

SU PER store-using-real-address event.

SW Special-operation exception and space-switch event.

T Trace exceptions (which include trace table, addressing, and low-address protection).

TE Test-pending-external-interruption facility.

TF Decimal-floating-point facility.

TR Decimal-floating-point-rounding facility.

TS TOD-clock-steering facility.

TX Transactional-execution facility.

U Condition code is unpredictable.

U_1 R_1 field designates an access register unconditionally.

U_2 R_2 field designates an access register unconditionally.

UB R_1 and R_3 fields designate access registers unconditionally, and B_2 field designates an access register in the access-register mode.

UE HFP unnormalized-extensions facility.

V1 Vector-enhancements facility 1.

V2 Vector-enhancements facility 2.

V3 Vector-enhancements facility 3.

VD Vector packed-decimal facility.

VD2 Vector-packed-decimal-enhancement facility 2.

VD3 Vector-packed-decimal-enhancement facility 3.

VF Vector facility for z/Architecture.

VRI VRI instruction format.

VRR VRR instruction format.

VRS VRS instruction format.

VRV VRV instruction format.

VRX VRX instruction format.

VSI VSI instruction format.

WE Space-switch event.

Xd Integer divide vector-processing exception.

XF IEEE-exception-simulation facility.

Xg Simulated IEEE exception.

Xi IEEE invalid-operation data or vector-processing exception.

Xo IEEE overflow data or vector-processing exception.

Xq Quantum data exception (if the floating-point extension facility is installed).

Xu IEEE underflow data or vector-processing exception.

XX Execute-extension facility.

Xx IEEE inexact data or vector-processing exception.

Xz IEEE division-by-zero data or vector-processing exception.

Z^1 Additional exceptions and events for PROGRAM CALL (which include ASX-translation, EX-translation, LX-translation, PC-translation-specification, special-operation, stack-full, and stack-specification exceptions and space-switch event).

Z^2 Additional exceptions and events for PROGRAM TRANSFER (which include AFX-translation, ASX-translation, primary-authority, and special-operation exceptions and space-switch event).

Z^3 Additional exceptions for SET SECONDARY ASN (which include AFX translation, ASX translation, secondary authority, and special operation).

Z^4 Additional exceptions and events for PROGRAM RETURN (which include AFX-translation, ASX-translation, secondary-authority, special-operation, stack-empty, stack-operation, stack-specification, and stack-type exceptions and space-switch event).

Z^5 Additional exceptions for BRANCH AND STACK (which include special operation, stack full, and stack specification).

Z^6 Additional exceptions and events for PROGRAM TRANSFER WITH INSTANCE (which include AFX-translation, ASTE-instance, ASX-translation, primary-authority, special-operation, and subspace-replacement exceptions and space-switch event).

Z^7 Additional exceptions for SET SECONDARY ASN WITH INSTANCE (which include AFX translation, ASTE instance, ASX translation, secondary authority, special operation, and subspace replacement).

ZF Decimal-floating-point-zoned-conversion facility.

Appendix C. Condition-Code Settings

This appendix lists the condition-code setting for instructions in z/Architecture which set the condition code. In addition to those instructions listed which set the condition code, the condition code may be changed by DIAGNOSE and the target of EXECUTE. The condition code is loaded by LOAD PSW, LOAD PSW EXTENDED, PROGRAM RETURN, RESUME PROGRAM, and SET PROGRAM MASK and by an interruption. The condition code is set to zero by initial CPU reset and is loaded by the successful conclusion of the initial-program-loading sequence.

Some models may offer instructions which set the condition code and do not appear in this document, such as those provided for assists or as part of special or custom features.

Instruction	Condition Code			
	0	1	2	3
ADD (BFP, DFP)	Zero	< zero	> zero	NaN
ADD (general)	Zero	< zero	> zero	Overflow
ADD DECIMAL	Zero	< zero	> zero	Overflow
ADD HALFWORD	Zero	< zero	> zero	Overflow
ADD HALFWORD IMMEDIATE	Zero	< zero	> zero	Overflow
ADD HIGH	Zero	< zero	> zero	Overflow
ADD IMMEDIATE	Zero	< zero	> zero	Overflow
ADD IMMEDIATE HIGH	Zero	< zero	> zero	Overflow
ADD LOGICAL	Zero, no carry	Not zero, no carry	Zero, carry	Not zero, carry
ADD LOGICAL HIGH	Zero, no carry	Not zero, no carry	Zero, carry	Not zero, carry
ADD LOGICAL IMMEDIATE	Zero, no carry	Not zero, no carry	Zero, carry	Not zero, carry
ADD LOGICAL WITH CARRY	Zero, no carry	Not zero, no carry	Zero, carry	Not zero, carry
ADD LOGICAL WITH SIGNED IMMEDIATE	Zero, no carry	Not zero, no carry	Zero, carry	Not zero, carry
ADD LOGICAL WITH SIGNED IMMEDIATE HIGH	Zero, no carry	Not zero, no carry	Zero, carry	Not zero, carry
ADD NORMALIZED	Zero	< zero	> zero	—
ADD UNNORMALIZED	Zero	< zero	> zero	—
AND	Zero	Not zero	—	—
AND IMMEDIATE	Zero	Not zero	—	—
AND WITH COMPLEMENT	Zero	Not zero	—	—
CANCEL SUBCHANNEL	Function initiated	—	—	Not operational
CHECKSUM	Checksum complete	—	—	CPU-determined completion
CIPHER MESSAGE	Normal completion	Verification mismatch	—	Partial completion
CIPHER MESSAGE WITH AUTHENTICATION	Normal completion	Verification mismatch	Partial completion (LAAD or LPC zero)	Partial completion (time out)
CIPHER MESSAGE WITH CHAINING	Normal completion	Verification mismatch	—	Partial completion
CIPHER MESSAGE WITH CIPHER FEEDBACK	Normal completion	Verification mismatch	—	Partial completion
CIPHER MESSAGE WITH COUNTER	Normal completion	Verification mismatch	—	Partial completion
CIPHER MESSAGE WITH OUTPUT FEEDBACK	Normal completion	Verification mismatch	—	Partial completion
CLEAR SUBCHANNEL	Function initiated	—	—	Not operational
COMPARE (BFP, DFP)	Equal	Low	High	Unordered
COMPARE (general, HFP)	Equal	Low	High	—
COMPARE AND FORM CODEWORD	Equal	OCB=0: low OCB=1: high	OCB=0: high OCB=1: low	—
COMPARE AND LOAD	Equal	Not equal	—	—

Instruction	Condition Code			
	0	1	2	3
COMPARE AND REPLACE DAT TABLE ENTRY	Equal	Not equal	—	—
COMPARE AND SIGNAL	Equal	Low	High	Unordered
COMPARE AND SWAP	Equal	Not equal	—	—
COMPARE AND SWAP AND PURGE	Equal	Not equal	—	—
COMPARE AND SWAP AND STORE	Equal	Not equal	—	—
COMPARE BIASED EXPONENT	Equal	Low	High	Unordered
COMPARE DECIMAL	Equal	Low	High	—
COMPARE DOUBLE AND SWAP	Equal	Not equal	—	—
COMPARE HALFWORD	Equal	Low	High	—
COMPARE HALFWORD IMMEDIATE	Equal	Low	High	—
COMPARE HALFWORD RELATIVE LONG	Equal	Low	High	—
COMPARE HIGH	Equal	Low	High	—
COMPARE IMMEDIATE	Equal	Low	High	—
COMPARE IMMEDIATE HIGH	Equal	Low	High	—
COMPARE LOGICAL	Equal	Low	High	—
COMPARE LOGICAL CHARACTERS UNDER MASK	Equal	Low	High	—
COMPARE LOGICAL HIGH	Equal	Low	High	—
COMPARE LOGICAL IMMEDIATE	Equal	Low	High	—
COMPARE LOGICAL IMMEDIATE HIGH	Equal	Low	High	—
COMPARE LOGICAL LONG	Equal	Low	High	—
COMPARE LOGICAL LONG EXTENDED	Equal	Low	High	CPU-determined completion
COMPARE LOGICAL LONG UNICODE	Equal	Low	High	CPU-determined completion
COMPARE LOGICAL RELATIVE LONG	Equal	Low	High	—
COMPARE LOGICAL STRING	Equal	Low	High	CPU-determined completion
COMPARE RELATIVE LONG	Equal	Low	High	—
COMPARE UNTIL SUBSTRING EQUAL	Equal substrings	Last bytes equal	Last bytes unequal	CPU-determined completion
COMPRESSION CALL	Op2 processed	Op1 full and op2 not processed	—	CPU-determined completion
COMPUTE DIGITAL SIGNATURE AUTHENTICATION	Verify: Signature verified; Sign: Normal Completion	Verify: public key not on curve; Sign: key verification-pattern mismatch; Sign & Verify: reserved area	Verify: signature is incorrect or invalid; Sign: random number is not invertible if deterministic	Partial completion
COMPUTE INTERMEDIATE MESSAGE DIGEST	Normal completion	—	—	Partial completion
COMPUTE LAST MESSAGE DIGEST	Normal completion	—	—	Partial completion
COMPUTE MESSAGE AUTHENTICATION CODE	Normal completion	Verification mismatch	—	Partial completion
CONVERT BFP TO HFP	Zero	< zero	> zero	Special case
CONVERT HFP TO BFP	Zero	< zero	> zero	Special case
CONVERT TO FIXED	Zero	< zero	> zero	Special case
CONVERT TO LOGICAL	Zero	< zero	> zero	Special case
CONVERT TO PACKED	Source is zero	Source is less than zero	Source is greater than zero	Infinity, QNaN, SNaN, Partial result

Figure C-1. Summary of Condition-Code Settings (Part 2 of 8)

Instruction	Condition Code			
	0	1	2	3
CONVERT TO ZONED	Source is zero	Source is less than zero	Source is greater than zero	Infinity, QNaN, SNaN, Partial result
CONVERT UTF-16 TO UTF-32	Data processed	Op1 full	Invalid low surrogate	CPU-determined completion
CONVERT UTF-16 TO UTF-8	Data processed	Op1 full	Invalid low surrogate	CPU-determined completion
CONVERT UTF-32 TO UTF-16	Data processed	Op1 full	Invalid UTF-32 character	CPU-determined completion
CONVERT UTF-32 TO UTF-8	Data processed	Op1 full	Invalid UTF-32 character	CPU-determined completion
CONVERT UTF-8 TO UTF-16	Data processed	Op1 full	Invalid UTF-8 character	CPU-determined completion
CONVERT UTF-8 TO UTF-32	Data processed	Op1 full	Invalid UTF-8 character	CPU-determined completion
DEFLATE CONVERSION CALL	Normal Completion	op1 length insufficient	op2 length insufficient (DFLTCC-XPND) or invalid input	CPU-determined completion
DIAGNOSE[1]	See note	See note	See note	See note
DIVIDE TO INTEGER	Remainder complete; normal quotient	Remainder complete; quotient overflow or NaN	Remainder incomplete; normal quotient	Remainder incomplete; quotient overflow or NaN
EDIT	Zero	< zero	> zero	—
EDIT AND MARK	Zero	< zero	> zero	—
EXCLUSIVE OR	Zero	Not zero	—	—
EXCLUSIVE OR IMMEDIATE	Zero	Not zero	—	—
EXTRACT STACKED STATE	Branch state entry	Program-call state entry	—	—
FIND LEFTMOST ONE	No one bit found	—	One bit found	—
HALT SUBCHANNEL	Function initiated	Status-pending with other than intermediate status	Busy	Not operational
INSERT ADDRESS SPACE CONTROL	Primary-space mode	Secondary-space mode	Access-register mode	Home-space mode
INSERT CHARACTERS UNDER MASK	All zeros	First bit one	First bit zero	—
LOAD ADDRESS SPACE PARAMETERS	Parameters loaded	Primary ASN not available	Secondary ASN not available or not authorized	Space-switch event
LOAD AND TEST (BFP, DFP)	Zero	< zero	> zero	NaN
LOAD AND TEST (general, HFP)	Zero	< zero	> zero	—
LOAD COMPLEMENT (BFP)	Zero	< zero	> zero	NaN
LOAD COMPLEMENT (gen)	Zero	< zero	> zero	Overflow
LOAD COMPLEMENT (HFP)	Zero	< zero	> zero	—
LOAD COUNT TO BLOCK BOUNDARY	Operand 1 = 16	—	—	Operand 1 < 16
LOAD NEGATIVE (BFP)	Zero	< zero	—	NaN
LOAD NEGATIVE (gen, HFP)	Zero	< zero	—	—
LOAD PAGE TABLE ENTRY ADDRESS	Translation, STE.P = 0	Translation, STE.P = 1	I bit on in RTE or STE, or enhanced-DAT applies and STE.FC=1	Exception condition exists

Figure C-1. Summary of Condition-Code Settings (Part 3 of 8)

Instruction	Condition Code			
	0	1	2	3
LOAD POSITIVE (BFP)	Zero	—	> zero	NaN
LOAD POSITIVE (gen)	Zero	—	> zero	Overflow
LOAD POSITIVE (HFP)	Zero	—	> zero	—
LOAD PSW[3] / LOAD PSW EXTENDED[3]	See note	See note	See note	See note
LOAD REAL ADDRESS [2]	Translation available	ST entry invalid	PT entry invalid	ASCE or entry not available or length violation
MODIFY SUBCHANNEL	SCHIB information placed in subchannel	Status-pending	Busy	Not operational
MOVE LONG	Length equal	Length low	Length high	Destructive overlap
MOVE LONG EXTENDED	Length equal	Length low	Length high	CPU-determined completion
MOVE LONG UNICODE	Length equal	Length low	Length high	CPU-determined completion
MOVE PAGE	Data moved	Operand 1 invalid, both valid in ES, locked, or ES error	Operand 2 invalid	—
MOVE STRING	—	Data moved	—	CPU-determined completion
MOVE TO PRIMARY	Length $\leq$ 256	—	—	Length > 256
MOVE TO SECONDARY	Length $\leq$ 256	—	—	Length > 256
MOVE WITH KEY	Length $\leq$ 256	—	—	Length > 256
MOVE WITH OPTIONAL SPECIFICATIONS	Length $\leq$ 4,096	—	—	Length > 4,096
NAND	Zero	Not zero	—	—
NEURAL NETWORK PROCESSING ASSIST	Normal Completion	Response code stored	—	CPU-determined completion
NOR	Zero	Not zero	—	—
NOT EXCLUSIVE OR	Zero	Not zero	—	—
OR	Zero	Not zero	—	—
OR IMMEDIATE	Zero	Not zero	—	—
OR WITH COMPLEMENT	Zero	Not zero	—	—
PAGE IN	Page-in operation completed	Expanded-storage data error	—	Expanded-storage block not available
PAGE OUT	Page-out operation completed	Expanded-storage data error	—	Expanded-storage block not available
PERFORM CRYPTOGRAPHIC COMPUTATION	Normal completion	Verification mismatch; Scalar-Multiply: source not on curve or out of range, d out of range	Invalid index or length; Scalar-Multiply: d is zero which yields result of infinity	Partial completion
PERFORM FLOATING-POINT OPERATION (test bit one)	Function code valid	—	—	Function code invalid
PERFORM FLOATING-POINT OPERATION (test bit zero)	Normal result	Nontrap exception	Trap exception with alternate action	—
PERFORM LOCKED OPERATION (test bit one)	Function code valid	—	—	Function code invalid

Figure C-1. Summary of Condition-Code Settings (Part 4 of 8)

Instruction	Condition Code			
	0	1	2	3
PERFORM LOCKED OPERATION (test bit zero)	All comparisons equal (function codes 0-37)	First comparison not equal (function codes 0-29)	Second comparison not equal (function codes 8-11 and 26); any comparison not equal (function codes 30-37)	—
PERFORM RANDOM NUMBER OPERATION	Normal completion	—	—	Partial completion
PERFORM TIMING FACILITY FUNCTION	Function performed	—	—	Function not available
PERFORM TOPOLOGY FUNCTION (FC 0 or 1)	Change initiated	—	Request rejected	—
PERFORM TOPOLOGY FUNCTION (FC 2)	Report not pending	Report pending	—	—
POPULATION COUNT	Zero	Not zero	—	—
PROGRAM RETURN	See note	See note	See note	See note
QUERY PROCESSOR ACTIVITY COUNTER INFORMATION	Complete information stored	—	—	Incomplete information stored
RESET CHANNEL PATH	Function initiated	—	Busy	Not operational
RESET REFERENCE BIT EXTENDED	R bit zero, C bit zero	R bit zero, C bit one	R bit one, C bit zero	R bit one, C bit one
RESUME PROGRAM[3]	See note	See note	See note	See note
RESUME SUBCHANNEL	Function initiated	Status pending	Function not applicable	Not operational
ROTATE THEN AND SELECTED BITS	Zero	Not zero	—	—
ROTATE THEN EXCLUSIVE OR SELECTED BITS	Zero	Not zero	—	—
ROTATE THEN INSERT SELECTED BITS	Zero	< zero	> zero	—
ROTATE THEN OR SELECTED BITS	Zero	Not zero	—	—
SEARCH STRING	—	Found	Not found	CPU-determined completion
SEARCH STRING UNICODE	—	Found	Not found	CPU-determined completion
SET CLOCK	Set	Secure	—	Not operational
SET PROGRAM MASK[4]	See note	See note	See note	See note
SET STORAGE KEY EXTENDED	Storage key not set	Entire storage key set	Partial storage key set	Entire storage key set; bits 48-55 of GR R_1 unpredictable
SHIFT AND ROUND DECIMAL	Zero	< zero	> zero	Overflow
SHIFT LEFT (DOUBLE/SINGLE)	Zero	< zero	> zero	Overflow
SHIFT RIGHT (DOUBLE/SINGLE)	Zero	< zero	> zero	—
SIGNAL PROCESSOR	Order accepted	Status stored	Busy	Not operational
SORT LISTS	Normal Completion	First or second operand length is insufficient to continue	Incomplete or empty input list encountered	CPU-determined completion
START SUBCHANNEL	Function initiated	Status-pending	Busy	Not operational
STORE CHANNEL REPORT WORD	CRW stored	Zeros stored	—	—
STORE CLOCK	Set	Not set	Error	Stopped or not operational
STORE CLOCK EXTENDED	Set	Not set	Error	Stopped or not operational
STORE CLOCK FAST	Set	Not set	Error	Stopped or not operational

Figure C-1. Summary of Condition-Code Settings (Part 5 of 8)

Instruction	Condition Code			
	0	1	2	3
STORE FACILITY LIST EXTENDED	Complete facility list stored	—	—	Incomplete facility list stored
STORE SUBCHANNEL	SCHIB stored	—	—	Not operational
STORE SYSTEM INFORMATION	Information provided	—	—	Information not available
SUBTRACT (BFP, DFP)	Zero	< zero	> zero	NaN
SUBTRACT (general)	Zero	< zero	> zero	Overflow
SUBTRACT DECIMAL	Zero	< zero	> zero	Overflow
SUBTRACT HALFWORD	Zero	< zero	> zero	Overflow
SUBTRACT HIGH	Zero	< zero	> zero	Overflow
SUBTRACT LOGICAL	—	Not zero, borrow	Zero, no borrow	Not zero, no borrow
SUBTRACT LOGICAL HIGH	—	Not zero, borrow	Zero, no borrow	Not zero, no borrow
SUBTRACT LOGICAL IMMEDIATE	—	Not zero, borrow	Zero, no borrow	Not zero, no borrow
SUBTRACT LOGICAL WITH BORROW	Zero, borrow	Not zero, borrow	Zero, no borrow	Not zero, no borrow
SUBTRACT NORMALIZED (HFP)	Zero	< zero	> zero	—
SUBTRACT UNNORMALIZED (HFP)	Zero	< zero	> zero	—
TEST ACCESS	ALET 0	DU access list, no exceptions	PS access list, no exceptions	ALET 1 or exceptions
TEST ADDRESSING MODE	Twenty-four bit mode	Thirty-one bit mode	—	Sixty-four bit mode
TEST AND SET	Left bit zero	Left bit one	—	—
TEST BLOCK	Usable	Not usable	—	—
TEST DATA CLASS	Zero (no match)	One (match)	—	—
TEST DATA GROUP	Zero (no match)	One (match)	—	—
TEST DECIMAL	Digits and sign valid	Sign invalid	Digit invalid	Sign and digit invalid
TEST PENDING EXTERNAL INTERRUPTION	None pending	One or more pending	—	—
TEST PENDING INTERRUPTION	Interruption code not stored	Interruption code stored	—	—
TEST PROTECTION	Can fetch, can store	Can fetch, cannot store	Cannot fetch, cannot store	Translation not available
TEST SUBCHANNEL	IRB stored; subchannel status-pending	IRB stored; subchannel not status-pending	—	Not operational
TEST UNDER MASK	All zeros	Mixed	—	All ones
TEST UNDER MASK (HIGH/LOW)	All zeros	Mixed, left bit zero	Mixed, left bit one	All ones
TRANSACTION BEGIN	Initiated successfully	—	—	—
TRANSACTION END	CPU in transactional-execution mode at start of instruction	—	CPU not in trans.-execution mode at start of instruction	—
TRANSLATE AND TEST	All zeros	Incomplete	Complete	—
TRANSLATE AND TEST EXTENDED	All zeros	Nonzero code selected	—	CPU-determined completion
TRANSLATE AND TEST REVERSE	All zeros	Incomplete	Complete	—
TRANSLATE AND TEST REVERSE EXTENDED	All zeros	Nonzero code selected	—	CPU-determined completion
TRANSLATE EXTENDED	Data processed	Op1 byte equal test byte	—	CPU-determined completion
TRANSLATE ONE TO ONE, ONE TO TWO, TWO TO ONE, TWO TO TWO	Character equal test character not found	Character equal test character found	—	CPU-determined completion

Figure C-1. Summary of Condition-Code Settings (Part 6 of 8)

Instruction	Condition Code			
	0	1	2	3
UNPACK ASCII	Sign plus	Sign minus	—	Sign invalid
UNPACK UNICODE	Sign plus	Sign minus	—	Sign invalid
UPDATE TREE	Equal	Not equal or no comparison	—	GR5 nonzero, GR0 negative
VECTOR ADD DECIMAL[5]	Zero	< zero	> zero	Overflow
VECTOR COMPARE DECIMAL	Equal	Low	High	—
VECTOR COMPARE EQUAL[5]	All elements equal	Some elements equal	—	No element equal
VECTOR COMPARE HIGH LOGICAL[5]	All elements high	Some elements high	—	No element high
VECTOR COMPARE HIGH[5]	All elements high	Some elements high	—	No element high
VECTOR CONVERT TO BINARY[5]	No overflow	—	—	Overflow
VECTOR CONVERT TO DECIMAL[5]	No overflow	—	—	Overflow
VECTOR COUNT LEADING ZERO DIGITS[5]	Zero	< zero	> zero	Invalid digit or sign
VECTOR DIVIDE DECIMAL[5]	Zero	< zero	> zero	Overflow
VECTOR ELEMENT COMPARE	Equal	Low	High	—
VECTOR ELEMENT COMPARE LOGICAL	Equal	Low	High	—
VECTOR FIND ANY ELEMENT EQUAL[5]	None equal, zero found	Equal element found, no zeros if ZS=1	Equal element found and zero found	No equal elements, no zeros
VECTOR FIND ELEMENT EQUAL[5]	Zero found	Equal element found, no zeros	Equal element found, and zero	Not equal, no zeros
VECTOR FIND ELEMENT NOT EQUAL[5]	Zero found	Not equal element found, less than	Not equal found, greater than	Equal, no zero
VECTOR FP COMPARE AND SIGNAL SCALAR	Elements equal	First element low	First element high	Elements unordered
VECTOR FP COMPARE EQUAL[5]	All elements equal	Mix of equal and unequal (or unordered) elements	—	All elements not equal (or unordered)
VECTOR FP COMPARE HIGH OR EQUAL[5]	All elements ≥	Mix of ≥ and <	—	All elements < (or unordered)
VECTOR FP COMPARE HIGH[5]	All elements >	Mix of > and ≤	—	All elements ≤ (or unordered)
VECTOR FP COMPARE SCALAR	Elements equal	First element low	First element high	Elements unordered
VECTOR FP TEST DATA CLASS IMMEDIATE	Match	Selected bit 1 for some (but not all) elements	—	No match
VECTOR ISOLATE STRING[5]	Zero element found	—	—	All elements nonzero
VECTOR MULTIPLY AND SHIFT DECIMAL[5]	Zero	< zero	> zero	Overflow
VECTOR MULTIPLY DECIMAL[5]	Zero	< zero	> zero	Overflow
VECTOR PACK LOGICAL SATURATE[5]	No saturation	Some saturated		All saturated
VECTOR PACK SATURATE[5]	No saturation	Some saturated		All saturated
VECTOR PACK ZONED REGISTER[5]	Zero	< zero	> zero	Overflow or invalid digit or sign
VECTOR PERFORM SIGN OPERATION DECIMAL[5]	Zero	< zero	> zero	Overflow
VECTOR REMAINDER DECIMAL[5]	Zero	< zero	> zero	Overflow
VECTOR SHIFT AND DIVIDE DECIMAL[5]	Zero	< zero	> zero	Overflow
VECTOR SHIFT AND ROUND DECIMAL[5]	Zero	< zero	> zero	Overflow
VECTOR SHIFT AND ROUND DECIMAL REGISTER[5]	Zero	< zero	> zero	Overflow
VECTOR STRING RANGE COMPARE[5]	Zero found	At least one in ranges, no zero	At least one in ranges, zero found	No ranges match, no zeros

Figure C-1. Summary of Condition-Code Settings (Part 7 of 8)

Instruction	Condition Code			
	0	1	2	3
VECTOR STRING SEARCH	no match found[6]	no match found[6]	full match found	partial match found
VECTOR SUBTRACT DECIMAL[5]	Zero	< zero	> zero	Overflow
VECTOR TEST DECIMAL	Digits and sign valid	Sign invalid	Digit invalid	Sign and digit invalid
VECTOR TEST UNDER MASK	All zeros or mask zero	Mixed	—	All ones
VECTOR TEST ZONED	Digits and sign valid	Sign invalid	Digit invalid	Sign and digit invalid
ZERO AND ADD	Zero	< zero	> zero	Overflow

Explanation and Notes:

— Code is not set by the instruction.

1 For DIAGNOSE, the resulting condition code is model-dependent.

2 For LOAD REAL ADDRESS, the following applies:
Condition code 1 is set if segment-table entry is invalid for LRAG, or for LRA and LRAY in 64-bit addressing mode, or for LRA and LRAY in 24-bit or 31-bit addressing mode and bits 0-32 of the entry address are all zeros.
Condition code 2 is set if page-table entry is invalid for LRAG, or for LRA and LRAY in 64-bit addressing mode, or for LRA and LRAY in 24-bit or 31-bit addressing mode and bits 0-32 of the entry address are all zeros.
Condition code 3 is set if address-space-control element not available, region-table entry outside table or invalid, segment-table entry outside table, or, for LRA in 24- or 31-bit mode when bits 0-32 of entry address not all zeros, segment- or page-table entry invalid.

3 For LOAD PSW, LOAD PSW EXTENDED, and RESUME PROGRAM, the condition code is loaded from the condition-code field of the second operand.

4 For SET PROGRAM MASK, the condition code is loaded from bit positions 2 and 3 of the first operand.

5 For various vector-facility instructions, the condition code is optionally set based on the CS control (in a mask field of the instruction)

6 For VECTOR STRING SEARCH, refer to the instruction description for the distinction between condition codes 0 and 1.

Introduction to Compression Call Facility

The compression call facility consists of the COMPRESSION CALL (CMPSC) instruction, which compresses or expands data as specified by a bit in general register 0. COMPRESSION CALL is primarily intended to operate on randomly accessed DB2* data, typically 80-byte records, so that the data can be kept on DASD in compressed form, thus saving DASD space. However, COMPRESSION CALL can also be used to compress any randomly or sequentially accessed data, provided that there is some degree of repetition of character strings (which may be actual characters or bytes of numeric or graphic data) in the data. COMPRESSION CALL also has an option, named the symbol-translation option and the order-preservation option, that allows the instruction to be used to compress VTAM* network data and DB2 keys, respectively.

In the following material, COMPRESSION CALL is first described for the case in which the symbol translation and order preservation options are not used, and then the differences due to the options are described.

Compression and Expansion Dictionaries

COMPRESSION CALL uses two static dictionaries that must be prepared by the program, before the compression operation, by scanning data that is typical of that to be compressed. One of these dictionaries is named the compression dictionary and is used only during compression. The other dictionary is named the expansion dictionary, is used during expansion, and may, depending on an option, be used slightly during compression. During expansion, the beginning of the expansion dictionary is designated by an address in general register 1. During compression, this same address designates the beginning of the compression dictionary, and the expansion dictionary, if used, immediately follows the compression dictionary.

Each of the compression and expansion dictionaries contains 512, 1K, 2K, 4K, or 8K doubleword entries, as determined by bits in general register 0. An entry in either of the dictionaries is identified or designated by means of the *index* to its position in that dictionary. That is, the first entry in a dictionary is identified or designated by index 0, the next by index 1, and so forth. The two entries at the same index position in each of the two dictionaries correspond to each other in that they both represent the same character string, which string is called a *symbol*.

Compression-Dictionary Entries

The entries in the compression dictionary correspond approximately to a Ziv-Lempel tree. There are 256 *alphabet* entries corresponding to the 256 possible values of a single-byte character, and these are the topmost entries in the tree (which is upside down). The alphabet entries may be *parent* entries that point to *child* entries. The child entries may in turn be par-

© Copyright IBM Corp. 2000, 2025

ent entries that point to their child entries. Each of the alphabet entries and the child entries is called a *character entry*. A character entry represents one or more *extension characters*. An alphabet entry represents one extension character. (The character represented by an alphabet entry is the *first* character of a character symbol, which term is defined in the next paragraph. The character is an extension to a null character represented by a physically non-existing null root entry that conceptually is the parent of the 256 alphabet entries.) A lower-level character entry represents from one to five extension characters. (In a pure Ziv-Lempel tree, each node represents only one extension character.)

In addition to representing one or more extension characters, a compression-dictionary entry represents a *character symbol* that is the extension characters of the entry preceded by the extension characters of all of the entry's ancestor entries, up to an alphabet entry.

The alphabet entries are the first entries in a dictionary and have the indexes 0-255. If an entry is a parent, it contains the index, called a *child pointer*, of its first child. Its other children, if any, follow the first child contiguously in the dictionary (and thus in storage).

Compression Process

Compression occurs as follows. The first character of the string to be compressed is used as an index to locate the alphabet entry that represents the first character. If the alphabet entry has children, the children are processed in the left-to-right order of the children, and the extension characters represented by each child are compared to the next characters of the string until a match is found or all children have been examined. If a match is found, the process is repeated using the children of that child and the next characters of the string. When the last match has been found, which might be just the match on the alphabet entry, the index of the last matching entry is output as the compressed data. This index is called an *index symbol*. The length in bits of an index symbol is the power of 2 that defines the number of entries in the dictionary. Thus, the length is nine, 10, 11, 12, or 13 bits depending on whether the number of entries is 512, 1K, 2K, 4K, or 8K, respectively.

There is an exception to the above that is described below in the section “Restriction on Identical Child and Sibling Characters.”

The unqualified term “symbol” can mean either a character symbol or an index symbol. The first meaning applies when discussing the uncompressed data or the dictionary entries. The second meaning applies when discussing the compressed data.

Child and Sibling Characters

It is a fundamental goal of the compression call facility to minimize the number of storage references required when processing dictionary entries to find matches. To this end, a character entry never contains its own first extension character and always contains the first extension characters of some number of its children, if any. These first extension characters of the children are named *child characters*. The positional number of a child character in a parent along with the pointer to the first child locates the child. If an entry represents more than one extension character, the characters after the first are in the entry and are called *additional extension characters.*

If a parent has more children than the number of bytes available in the parent to contain child characters, the first extension characters of the additional children are in a *sibling-descriptor* dictionary entry that follows the last child entry able to be represented by means of its child character in the parent. These first extension characters in a sibling descriptor are named *sibling characters*. COMPRESSION CALL provides the option of having either format-0 or format-1 sibling descriptors. A format-0 sibling descriptor is one doubleword, contains up to seven sibling characters, and resides entirely within the compression dictionary. It resides at an index position that would otherwise be used by a character entry. A format-1 sibling descriptor is two doublewords, contains up to 14 sibling characters, and has its first doubleword at an index position in the compression dictionary and its second doubleword at the same index position in the expansion dictionary. This position in the expansion dictionary would otherwise be wasted. This partial residence of sibling descriptors in the expansion dictionary is the only way the expansion dictionary is used during compression.

A sibling descriptor contains from one to seven or 14 sibling characters that correspond to the additional children of the parent. The additional child entries follow the sibling descriptor in the dictionary. If there are more than seven or 14 additional children, another sibling descriptor follows the seventh or fourteenth additional child. This following of seven or 14 children

by another sibling descriptor can be repeated again and again. However, a parent must have no more than 260 children; otherwise, a data exception may be recognized when an attempt is made to find a match on a child after the 260th child.

Child and Extension-Character Combinations

The compression dictionary contains only two types of entries: character entries and sibling descriptors. However, the character entries have different formats depending on how many additional extension characters an entry represents and on whether an entry has zero, one, or more than one children. Only the following combinations are allowed:

- If an entry has zero children, it can have from zero to four additional extension characters.
- If an entry has one chid, it can have from zero to four additional extension characters.
- If an entry has more than one child it can have only zero or one additional extension character.

Character entries and sibling descriptors contain count fields whose contents specify the numbers of additional extension characters, child characters, or sibling characters in the entries and also whether a sibling descriptor follows a child. Character entries and sibling descriptors also contain *examine-child* bits that specify whether child entries, whether designated from a parent or a sibling descriptor, need to be examined. A child entry need not be examined if the entry represents only one extension character and has no children. Conversely, if the entry represents (contains) one or more additional extension characters or has children, the entry must be examined in order to continue the matching process.

Restriction on Identical Child and Sibling Characters

The compression process is described above with some lack of detail, which detail is provided here. However, this section, including its programming notes, does not apply if the order-preservation option is used.

After a match has been found on a parent entry, and if the parent has children, the next character of the string is compared against the child characters in the parent and the sibling characters in the sibling descriptors that are among the children of the parent until a match is found or all child and sibling characters have been processed. If a match is found, the next characters of the string are compared against the additional extension characters, if any, in the child designated by means of the matched child or sibling character. If the additional extension characters match, or if there are no additional extension characters, the matching process is repeated using the matched child as the next parent. If there are additional extension characters that do not match the next characters of the string, then, except in one case, it is model-dependent whether the matching process is ended, with the match on the current parent being the last match, or whether the matching process is continued by attempting to match on a remaining child of the current parent. The one exceptional case is when the designated child and also the next child are in a set of children designated by means of consecutive identical child characters (not sibling characters) beginning with the first child character in the parent. In this case, an attempt is made to match on the following children in the set until either a match is found or all such children have been processed.

The effect of the detailed operation just described is that it is assured that it is useful for two or more identical characters to appear as child characters in a parent or sibling characters in a sibling descriptor under a parent only when the characters are all consecutive child characters beginning with the first child character in the parent. In any case where the identical characters are not consecutive child characters beginning with the first child character in the parent, the second character and any subsequent identical child or sibling character may be wasted since, depending on the model, they may never be compared against a string character equal to them.

Programming Notes:

1. When an examine-child bit indicates that the corresponding child need not be examined, it does not necessarily cause the child not to be examined. Therefore, the count fields in the child must contain all zeros as they correctly should; otherwise, there may be a match on one or more false additional extension characters or a false child character in the child. Since the expansion dictionary will not have been built to recreate the falsely matched character or characters, the

expanded data will not be equal to the original uncompressed data.

2. The restriction against identical child or sibling characters may improve performance because it generally allows the matching process to be ended immediately after a match on a child or sibling character followed by a failure to match on additional extension characters in the designated child. On the other hand, the provision that attempted matching continues in the case of identical consecutive leading child characters improves performance in the case of compressing strings, of many different lengths, of the same repeated character. For example, consider the following two different sets of compression-dictionary entries that might be used for compressing strings, of lengths 1-15, of the character A. (Strings of binary zeros or of blanks are a more important case, but those two characters are unprintable and, therefore, cannot be shown in this example.)

   In the first set of entries (Set 1), each parent has only one child, and there are no additional extension characters -- each child represents only one more character than its parent. Set 1 is shown abstractly as follows:

Set 1

Entry Number	Character Symbol Represented by Entry
1	A
2	AA
3	AAA
4	AAAA
5	AAAAA
6	AAAAAA
7	AAAAAAA
8	AAAAAAAA
9	AAAAAAAAA
10	AAAAAAAAAA
11	AAAAAAAAAAA
12	AAAAAAAAAAAA
13	AAAAAAAAAAAAA
14	AAAAAAAAAAAAAA
15	AAAAAAAAAAAAAAA

   The entries in Set 1 are shown with the first and only child of a parent immediately beneath the parent except indented one character position to the right. Part of the abstraction is that the entries are numbered 1-15 even though, in an actual dictionary, entries 0-255 must be alphabet entries. Note that the number of A's represented by an entry is equal to the number of the entry.

   The number of storage references made to the dictionary during compression may be an important determinant of performance, depending on the model. Using Set 1, the number of dictionary storage references needed to compress a string of 1-15 A's is equal to the number of A's in the string.

   In the second set of entries (Set 2), each parent has two children, the first child has one additional extension character, and the second child has no additional extension character -- the first child represents two more characters than its parent, and the second child represents one more character than its parent. Set 2 is shown abstractly as follows. The following also explicitly shows the number of A's represented by each entry and the number of storage references needed to match on each entry.:

Set 2

Entry Number	Character Symbol Represented by Entry	Stg. A's	Stg. Refs
1	A	1	1
2	AAA	3	2
4	AAAAA	5	3
6	AAAAAAA	7	4
8	AAAAAAAAA	9	5
10	AAAAAAAAAAA	11	6
12	AAAAAAAAAAAAA	13	7
14	AAAAAAAAAAAAAAA	15	8
15	AAAAAAAAAAAAAA	14	9
13	AAAAAAAAAAAA	12	8
11	AAAAAAAAAA	10	7
9	AAAAAAAA	8	6
7	AAAAAA	6	5
5	AAAA	4	4
3	AA	2	3

   The entries in Set 2 are shown with the first child of a parent immediately beneath the parent, except indented one character position to the right, and with the other child of the same parent aligned vertically with the first child. For example, entry 1 (A) has the children 2 (AAA) and 3 (AA), and entry 2 (AAA) has the children 4 (AAAAA) and 5 (AAAA). Entries 3 (AA) and 5 (AAAA) do

not have a child. The entries are numbered as they are because the children of a parent must be numbered consecutively.

It can be seen that except for entries 5 and 3 of Set 2, the number of storage references needed to match on a Set-2 entry is always less than the number of storage references needed to match on the Set-1 entry representing the same number of A's.

A dictionary might contain entries in the style of either Set 1 or Set 2 that would allow compression of a string of up to 260 repeated characters as a single index symbol. Using entries in the style of Set 2, instead of the style of Set 1, reduces the number of required storage references by approximately 50%. (Matching a string of 101 A's would require 101 references using the Set-1 style but only 51 references using the Set-2 style.)

3. Long strings of a repeated character can be compressed with even fewer storage references if entries in the style of Set 3, shown below, are used. Using entries in the style of Set 3, instead of the style of Set 1, reduces the number of required storage references by approximately 67%.

Set 3

Entry Number	Character Symbol Represented by Entry	Stg. A's	Stg. Refs
1	A	1	1
2	AAAAAA	6	2
7	AAAAAAA	7	3
8	AAAAAAAAAAAA	12	4
13	AAAAAAAAAAAAA	13	5
14	AAAAAAAAAAAAAAAAA	18	6
15	AAAAAAAAAAAAAAAA	17	7
16	AAAAAAAAAAAAAAAA	16	8
17	AAAAAAAAAAAAAAA	15	9
18	AAAAAAAAAAAAAA	14	10
9	AAAAAAAAAAA	11	5
10	AAAAAAAAAA	10	6
11	AAAAAAAAA	9	7
12	AAAAAAAA	8	8
3	AAAAA	5	3
4	AAAA	4	4
5	AAA	3	5
6	AA	2	6

In Set 3, an odd-level parent has no additional extension character and five children, and the children, in order, have four, three, two, one, and zero additional extension characters -- the children represent from five to one more characters than their parent. An even-level parent, which is the first child of an odd-level parent, has four additional extension characters and one child, which is the next odd-level parent. The second through fifth children of an oddlevel parent do not have a child. Specifically in Set 3, entry 1 (A) has the children 2 (AAAAAA), 3 (AAAAA), 4 (AAAA), 5 (AAA), and 6 (AA); entry 2 (AAAAAA) has the child 7 (AAAAAAA); entry 7 has the children 8-12; entry 8 has the child 13, and entry 13 has the children 14-18. Entries 3-6, 9-12, and 15-18 do not have a child. Entry 14 might have a child to continue the pattern.

Matching a string of 18 A's requires six storage references, which is 33% of the number required when using the Set-1 style.

Entries should not be arranged as in the following examples.

Set 4 (Erroneous)

Entry Number	Character Symbol Represented by Entry
1	A
2	AA
3	AAA

Entry 3 in Set 4 is useless because if the string to be matched is AAA, a match of the AA at the beginning of the string will be found on entry 2, and entry 3 will not be examined. (This would be true also if the string to be matched were AAB and entry 3 represented AAB.)

Set 5 (Erroneous)

Entry Number	Character Symbol Represented by Entry
1	A
2	AAA
3	AB
4	AA

Entry 4 in Set 5 may be useless because if the string to be matched is AAX, the matching process may end, depending on the model, after the failure to match the AAX to entry 2. (Entries 2 and 4 are designated by identical child charac-

ters in entry 1, and the first of these child characters is the first child character in entry A, but the two child characters are not consecutive.)

Set 5 (Erroneous)

Entry Number	Character Symbol Represented by Entry
1	A
2	AB
3	AAA
4	AA

Entry 4 in Set 6 may be useless because if the string to be matched is AAX, the matching process may end, depending on the model, after the failure to match the AAX to entry 3. (Entries 3 and 4 are designated by identical consecutive child characters in entry 1, but the first of these child characters is not the first child character in entry A.)

Expansion-Dictionary Entries

The expansion dictionary contains three types of entries: *unpreceded character entries*, *preceded character entries*, and the second halves of the format-1 sibling descriptors that begin in the compression dictionary. An unpreceded character entry represents a character symbol by containing all of the characters of the symbol -- these are the extension characters represented by the corresponding entry in the compression dictionary and the extension characters represented by all the ancestors of that compression-dictionary entry. An unpreceded character entry can contain from one to seven characters. A preceded character entry represents a character symbol by containing from one to five of the rightmost characters of the symbol and also a pointer, called a *predecessor pointer*, to another expansion-dictionary character entry that contains some or all of the next lefthand characters of the character symbol. That is, the predecessor pointer in a preceded character entry can point to either an unpreceded or a preceded character entry.

A predecessor pointer is not necessarily a parent pointer, which term has no role in this definition. That is, a predecessor pointer may designate a higher-level entry that is more remote than simply a parent.

An unpreceded character entry contains a complete-symbol-length field whose contents specify the number of characters in the entry. A preceded character entry contains a partial-symbol-length field whose contents specify the number of characters in the entry, and it also contains an offset that may be used to position the leftmost character of the entry in the expanded-data operand.

Expansion Process

Expansion of an index symbol occurs in a way that depends on whether the value of the symbol is in the range 0-255 or is 256 or larger. If the value of the index symbol is in the range 0-255, a byte containing the value of the symbol is simply stored as the next byte of expanded data, and no reference is made to the expansion dictionary. That is, the index symbol is assumed to designate an expansion-dictionary entry that represents the same character symbol as does the alphabet entry that is designated by the index symbol in the compression dictionary -- the index symbol can be said to designate an alphabet entry in the expansion dictionary. If the value of the index symbol is 256 or larger, expansion occurs by using the value as an index to locate the corresponding expansion-dictionary character entry and then (1) outputting the characters in the entry, and (2) if the entry is a preceded entry, proceeding up the chain of preceded entries and outputting the characters in each of them on the left of the characters already output, until finally an unpreceded entry has been encountered. Following is a more detailed description of the case when the value of the index symbol is 256 or larger.

1. The rightmost byte of the first preceded character entry obtained during the expansion of an index symbol contains the byte offset from the current location in the expanded-data operand to where the first extension character represented by the character entry is to be placed. (All preceded character entries contain an offset since any entry can be the first one obtained during an expansion.) The address of the current location is named the current origin address. At the end of the operation, the current origin address is updated in accordance with one of two methods, and which method is used is unpredictable. When the first method is used, the current origin address is updated by adding to it the sum of the partial symbol length and the offset in the first-obtained preceded entry. When the second method is used, the current origin address is updated by adding to it the number of characters

placed in the first operand location due to the expansion of the index symbol. If the expansion-dictionary entries processed specify a logically correct operation, the results are the same regardless of which method is used. The entries are considered to specify a logically correct operation if they together contain n characters and cause placement of those n characters, without overlaps or spaces, in the n character positions beginning at the original current origin address and ending at the address that is one less than the updated current origin address. The machine does not check in any way that the operation is logically correct.

2. If the first character entry obtained during expansion of an index symbol is an unpreceded entry, the characters in the entry are placed at the current origin address, and then the current origin address is updated by adding to it the complete symbol length in the unpreceded entry.

3. When the first character entry obtained during expansion of an index symbol is a preceded entry, the processing of the preceding entries, which may include additional preceded entries, is in accordance with one of two methods, and which method is used is unpredictable. When the first method is used, the processing is the same as in items 1 and 2; that is, the characters in a preceded entry are placed as determined by the offset in the entry, and the characters in an unpreceded entry are placed at the current origin address. When the second method is used, the characters in each preceding entry are placed immediately to the left of the characters resulting from the previously processed preceded entry. Either the same or different methods may be used for each of preceded and unpreceded entries and for each of multiple preceded entries. If the entries processed specify a logically correct operation, the results are the same regardless of which method is used. The updated current origin address is determined as specified in item 1. If the operation is logically incorrect and leaves spaces in the n character positions beginning at the original current origin address, the contents of those spaces are unpredictable.

   When method 1 is used, storing may be specified to occur at or to the right of the updated current origin address because either the offset in a subsequent preceded entry is larger than the offset in the first one or because the offset in the first one is too small, considering the complete symbol length in the unpreceded entry. (The preceding is incomplete because it does not deal with partial symbol lengths, but the point should be clear.) When method 2 is used, storing may be specified to occur to the left of the original current origin address because the offset in the first preceded entry is too small. In the method-1 or method-2 case, such storing may be within or outside the first-operand location. It may cause a data exception to be recognized, or it may be attempted. If it is attempted, it may cause an access exception to be recognized and the operation to be nullified or suppressed, depending on the exception. If an access exception is recognized, the results may not be true nullification or suppression because storing may have occurred in a location for which no access exception was recognized. Recognition of an access exception may cause condition code 3 to be set instead of being treated as a program-interruption condition.

4. When entropy-encoding is not enabled and the value of a predecessor pointer is in the range 0-255, either the pointer may be used to reference a dictionary entry as already described, or the value may simply be stored as the next byte of expanded data. When entropy-encoding is enabled and the value of a predecessor pointer is in the range 0-255 the pointer is always used to reference a dictionary entry as already described.

Programming Note: If no predecessor pointer designates one of the entries 0-255 in the expansion dictionary, those entries need not actually be provided, and the storage that would be occupied by the entries can be used for other purposes. However, the storage must exist and have the correct storage key since the CPU may pretest the entire expansion dictionary, including entries 0-255, for access exceptions.

Compressed-Data Symbol Size

The bits in general register 0 that specify the number of bits in an index symbol and the size in entries and bytes of a dictionary are named the compressed-data symbol size (CDSS).

Symbol Translation

During compression, symbol translation can be specified by means of a bit in general register 0; this bit is ignored during expansion. When symbol translation is specified, the index symbols generated by the compression process are used to locate two-byte entries in a symbol-translation table (STT), and *interchange symbols* are taken from the STT entries and placed in the compressed-data operand. The beginning of the STT is designated by the address and an offset in general register 1.

When symbol-translation is specified, the CDSS does not specify either the number of bits in an index symbol or the size of the compression dictionary; the CDSS specifies the number of bits in an interchange symbol, the compression dictionary is considered to extend to the beginning of the STT, and the size of the STT in bytes is considered to be one fourth that of the compression dictionary.

Symbol translation is not performed during (before) expansion because the expansion dictionary can be formed to directly expand interchange symbols, that is, during expansion, interchange symbols and index symbols are considered to be identical, and only the term index symbol is used.

Symbol translation and format-1 sibling descriptors must not both be specified; otherwise, the results are unpredictable.

Programming Note: Symbol translation is for use by VTAM. During compression, VTAM will form an adaptive dictionary until compression becomes good, and VTAM will then freeze its dictionary and transform it to the architected form used by COMPRESSION CALL. VTAM will also signal the other end of the session to freeze its dictionary also, but the other end will then continue to use its frozen adaptive dictionary. Since the architected dictionary must contain some entries that are sibling-descriptor entries while the adaptive dictionary has no similar requirement (all of its entries are character entries), most of the entries in the architected dictionary cannot have the same indexes as the logically corresponding entries in the adaptive dictionary, and symbol translation must be used to generate the correct interchange symbols.

Order Preservation

During compression, order preservation can be specified by means of a bit in general register 0. When order preservation is specified, the symbol-translation bit in the register is ignored, but a modified form of symbol translation occurs.

When an appropriate compression dictionary and symbol-translation table are used, order preservation causes, for successive units of uncompressed data that are in collating-sequence order, production of corresponding successive units of compressed data that also are in collating-sequence order.

The compression process used in the basic compression operation uses what is referred to here as the *unordered* comparison algorithm: the children of a parent are not considered to be in any particular order, and the next characters from the string being compressed are compared against the extension characters represented by the children in the left-to-right order of the children until either a match is found or all of the children have been processed. The result of the compression process is the index symbol that designates the last matched entry, which is the parent entry if no match was found on any child or there are no children.

The order-preservation option causes the compression process to use an *ordered* comparison algorithm: the children of a parent are considered to be ordered such that the string of one or more extension characters represented by any child is always earlier in the collating sequence than the string of one or more extension characters represented by the next child of the same parent, that is, the children are considered to be in collating-sequence order. The next characters from the string being compressed are compared against the extension characters represented by the children in the left-to-right order of the children until any of the following is true: (1) a match is found on an entry without children, or a match is found on an entry with children but there is not another character in the string; (2) the next characters from the string have a collating-sequence value less than that of the extension characters represented by a child of the last matched parent; or (3) the next characters from the string have a collating-sequence value greater than that of the extension characters represented by the last child of the last matched parent. The result of the compression process in each of the three cases is as follows:

1. If the process ends because of a match on an entry without children or because of a match on an entry when there is not another character in the string, the result is the index symbol that designates the entry.

2. If the process ends because the next characters of the string have a value less than that of the characters represented by a child, the result is the index symbol that designates the child.

3. If the process ends because the next characters of the string have a value greater than that of the characters represented by the last child, the result is the index symbol that designates the last child.

Note that Case 2 includes the case when the next character of the string match the leftmost extension characters represented by a child but there are not as many next characters remaining in the string as there are additional extension characters represented in the child.

The index symbol produced by the compression process is used to locate a symbol-translation-table entry containing an interchange symbol just as when the symbol-translation option is specified. The resulting interchange symbol that is placed in the compressed-data operand is then as follows:

1. In Case 1, the interchange symbol in the entry.

2. In Case 2, the interchange symbol in the entry, minus one; that is, one is subtracted from the value of the interchange symbol that is in the entry to form the interchange symbol that is stored.

3. In Case 3, the interchange symbol in the entry, plus one; that is, one is added to the value of the interchange symbol that is in the entry to form the interchange symbol that is stored.

Although the order-preservation option does not affect the expansion process, the expansion dictionary must be formed so that the interchange symbols produced by compression are properly expanded when they are treated as index symbols during expansion. During expansion, an index symbol equal to an interchange symbol produced during compression must designate a dictionary entry that represents the same character symbol as did the last entry that was matched during the compression. In Case 2 or 3, the last matched entry is the parent of the entry that caused the Case 2 or Case 3 condition to be satisfied.

Programming Note: The assumption that an index symbol in the range 0-255 designates an alphabet entry in the expansion dictionary requires that interchange symbols be assigned as follows when the order-preservation option is used. If n is the number of the lowest-numbered alphabet entry in the compression dictionary having a child, then the interchange symbols 0-n must be assigned to alphabet entries 0-n, the interchange symbol 256 must be assigned to the first epsilon entry or child under entry n, and the interchange symbols (n+1)-255 must not be assigned.

Entropy Encoding

Entropy encoding can be specified by means of a bit in general register 0. When entropy encoding is specified, a higher degree of compression may be obtained due to using shorter codewords for more frequent symbols.

The compressed operand does not contain index symbols, instead it contains codewords. The codewords may vary from 1-16 bits in length. Each codeword represents an index symbol. The most frequent index symbols will have codewords with fewer bits, and less frequent index symbols will have codewords with more bits.

The mapping of index symbols to codewords is handled differently for compression and expansion. However, the entropy descriptor is common. The entropy descriptor describes the valid codewords from most frequent to least frequent. The entropy descriptor consists of sixteen halfword entries each of which contain a count of the number of entries of the corresponding bit length from one to sixteen.

The mapping of index symbols to codewords is done by generating a prefix tree for all index symbols. The prefix tree is formed using the frequency that each index symbol is seen when compressing data. The codewords are grouped by their information content and enumerated in descending order. This is sometimes called a cannonical Huffman code or an Shannon-Fano code. Since all of the codewords are ordered, it is possible to describe the tree by enumerating the number of entries of each codeword length. The maximum codeword size supported is 16-bits. The entropy descriptor must fully represent a valid

tree. The sum of all of the entries in the entropy descriptor must add up to the number of dictionary entries plus one; otherwise, a general-operand data exception is recognized. Also there cannot be any underflow or overflow when computing the lower and upper bound codewords for each bit length otherwise a general-operand data exception is recognized.

The entropy descriptor is located immediately after the compression or expansion dictionary and is pointed to by the offset field in general register 1. During compression a symbol translation table is located immediately after the entropy descriptor. The symbol translation table is one fourth the size of the compression dictionary.

During compression index symbols which are formed during compression are used to index into the symbol translation table. Each halfword in the symbol translation table contains the codeword which maps to the index symbol left aligned in the halfword. Any unused bits in the symbol translation table entry must contain zeros; otherwise, a general-operand data exception is recognized. The number of bits from the symbol translation table entry to be copied to the first operand location is computed for each symbol translation table entry.

During expansion the bits of the second operand are broken into codewords using the information in the entropy description. The codewords are converted to sequence numbers and used to index directly into the expansion dictionary. Indices 0-255 have no special meaning in the expansion dictionary when the entropy encoding option is specified. Since the entries in the expansion dictionary are indexed by sequence numbers they must be ordered by likelihood. The sequence number is the number of codewords with a higher probability than the current input codeword.

Results of Dictionary Errors

The following may be truncated on the left to eliminate bits not needed because of the dictionary size, or they may always be treated as 13 bits regardless of the dictionary size: child pointers, predecessor pointers, and index symbols that are used to locate entries in a symbol-translation table. If the pointers or symbols are not truncated and a child pointer specifies an entry beyond the end of the compression dictionary, a predecessor pointer specifies an entry beyond the end of the expansion dictionary, or an index symbol specifies an entry beyond the end of the symbol-translation table, any of the following may occur: in the case of a child pointer and a zero examine-child bit, an index symbol containing too many bits may be generated and stored in the first-operand location (possibly overlaying a rightmost bit or bits of the previous index symbol); the contents at the improper location may be used in the normal way as a dictionary or table entry; or a data exception may be recognized. If the contents are to be used in the normal way, an access exception can be recognized for the improper location even after a store has occurred in the first-operand location. Such an access exception does not result in true nullification or suppression, except that the instruction address in the PSW is correct for the type of exception recognized. When order-preservation is specified, the results when dictionary entries are not in collating-sequence order are unpredictable and may include recognition of a data exception.

Dictionary Formats

Notation

(m-n) Value allowed in the field

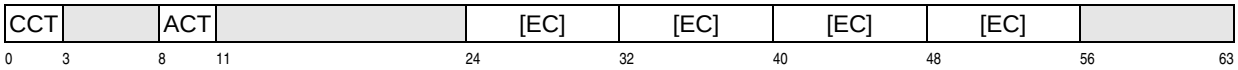
[EC] Extension character may be present

Three periods (...) means the preceding field may be repeated.

Compression Dictionary

Character Entry

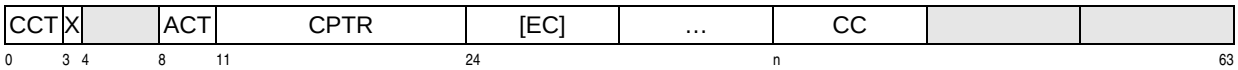
When CCT = 0



ACT Additional-extension-character count (0-4); number of ECs in entry. if ACT is 5, 6, or 7, it may be treated as 4, may cause data exception, or may cause comparison to mod(ACT,4) additional entries that are obtained from unpredictable locations in the current entry or from storage locations immediately following the current entry; see Note 1

EC Additional extension character

When CCT = 1



X examine-child bit; child has one or more additional extension characters or has children; see Note 2

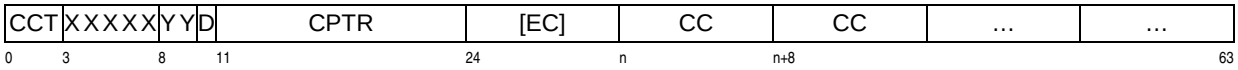
ACT Additional-extension-character count (0-4). if ACT is 5, 6, or 7, it may be treated as 4, may cause data exception, or may cause comparison to mod(ACT,4) additional entries that are obtained from unpredictable locations in the current entry or from storage locations immediately following the current entry.

CPTR Index of first child

EC Additional extension character(s)

CC Child character

When CCT >1



CCT Child count (2-6 if D=0, 2-5 if D=1). If D=0 and CCT=6, sibling descriptor follows 5th child (CCT = 7 may be treated as 6 or it may cause a data exception). If D=1 and CCT=5, sibling descriptor follows 4th child ACT (CCT = 6 or 7 may be treated as 5 or it may cause a data exception)

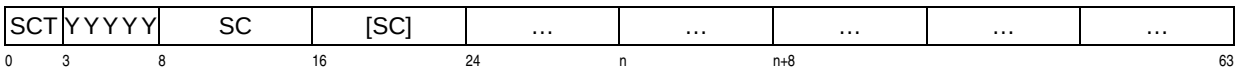
XXXXX Examine-child bits for children 1-5 (D=0) or 1-4 (D=1). Bit(s) ignored if respective child does not exist.

YY Examine child bits for 6th & 7th siblings designated by first format-0 sibling descriptor for children of this entry; or examine-child-bits for 13th and 14th siblings designated by first format-1 sibling descriptor for children of this entry. Bit(s) ignored if sibling does not exist.

EC Additional extension character(s)

CC Child character

Format-0 Sibling Descriptor

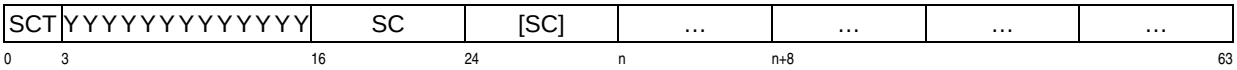


SCT Sibling Count (0-7); zero is treated as 7 and indicates another SD follows 7th sibling

YYY… Examine-child bits for siblings 1-5; bit is ignored if sibling does not exist; if this is the first sibling descriptor under parent, bits for siblings 6 and 7 are in parent — otherwise, 6th and 7th siblings must be examined since bits for them are not provided.

SC Sibling character

Format-1 Sibling Descriptor



SCT Sibling Count (1-15); 15 is treated as 14 and indicates another SD follows 14th sibling. 0 may be treated as 15 or cause a data exception)

YYY… Examine-child bits for siblings 1-12; bit is ignored if sibling does not exist; if this is the first sibling descriptor under parent, bits for siblings 13 and 14 are in parent — otherwise, 1‘3th and 14th siblings must be examined since bits for them are not provided.

SC Sibling character

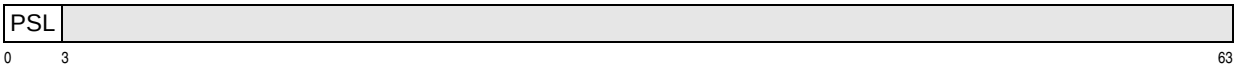
Notes:

1. If ACT or D is nonzero in alphabet entry, any of the following may result:
   - ACT or D is treated as zero.
   - ACT or D does not cause comparison to additional extension characters but does determine the position of the first child character.
   - ACT or D is treated the same as in a nonalphabet entry except that, if this causes a mismatch on the next characters to be compressed, a data exception is recognized.
2. A child may be examined even if its examine-child bit (X or Y) is zero. If an examine-child bit (X or Y) is one and the corresponding child or sibling exists, but it is not true that the child or sibling either has one or more additional extension characters or has children, a data exception may be recognized.

Expansion Dictionary

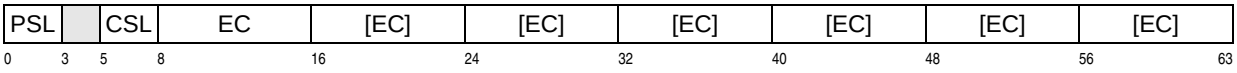
Character Entry

Generic Form



PSL Partial-symbol length (0-5); number of ECs in entry; 0 indicates an unpreceded entry; 6 and 7 may be treated as 5, may cause a data exception, or may cause movement to the first operand location of one or two, respectively, additional ECs that are obtained from unpredictable locations in the current entry or from the storage locations immediately following the current entry.

If PSL=0 (Unpreceded Entry)

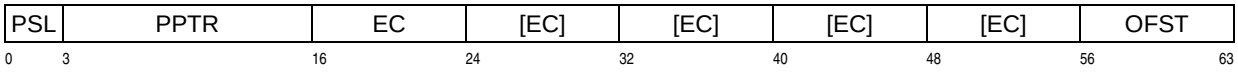


CSL Complete-symbol length (1-7); number of ECs in the entry; 0 may cause a data exception or may cause movement to the first operand location of up to 256 ECs that are obtained from unpredictable locations in the current entry or from storage locations immediately following the current entry

EC Extension character

Bits 3 and 4 of the entry should be zeros; otherwise, any of the following may occur: the bits may be ignored, they may cause a data exception, or they may cause movement to the first operand location of up to 24 additional ECs that are obtained from unpredictable locations in the current entry or from the storage locations immediately following the current entry.

If PSL>0 (Preceded Entry)



PSL Partial-symbol length (1-5); number of ECs in the entry; 0 indicates an unpreceded entry; 6 and 7 may be treated as 5, may cause a data exception, or may cause movement to the first operand location of one or two, respectively, additional ECs that are obtained from unpredictable locations in the current entry or from the storage locations immediately following the current entry.

PPTR Predecessor pointer; index of preceding entry that should contain the next left-hand characters of the character symbol represented by this entry

OFST Offset (0-255) from the current position in the output area to where first EC in this entry is placed; however, for preceded entries after the first one, either method 1 or method 2 may be used -- see the text

When expansion is completed, the output pointer is advanced either by the sum of the PSL and OFST in the first-encountered preceded entry or by the number of characters placed in the first-operand location due to expansion of the index symbol. If the first method is used and PSL is 6 or 7, either 5 or the actual value of PSL may be used.

There is no checking for logical correctness of the operation.

Format-1 Sibling Descriptor

The expansion dictionary contains bits 64-127 of the format-1 sibling descriptors that begin in the compression dictionary.

Figure G-1. Powers of 2

Appendix H. Hexadecimal Tables

The following tables aid in converting hexadecimal values to decimal values, or the reverse.

Direct Conversion Table

This table provides direct conversion of decimal and hexadecimal numbers in these ranges:

Hexadecimal	Decimal
000 to FFF	0000 to 4095

To convert numbers outside these ranges, and to convert fractions, use the hexadecimal and decimal conversion tables that follow the direct conversion table in this appendix.

TO CONVERT HEXADECIMAL TO DECIMAL

1. Locate the column of the decimal numbers corresponding to the leftmost digit or letter of the hexadecimal; select from this column and record the number that corresponds to the position of the hexadecimal digit or letter.
2. Repeat step 1 for the next (second from the left) position.
3. Repeat step 1 for the units (third from the left) position.
4. Add the numbers selected from the table to form the decimal number.

EXAMPLE

Conversion of Hexadecimal Value	D34
1. D	3328
2. 3	48
3. 4	+ 4
4. Decimal	3380

To convert integer numbers greater than the capacity of the table, use the techniques below:

HEXADECIMAL TO DECIMAL

Successive cumulative multiplication from left to right, adding units position.

Example: $D34_{16} = 3380_{10}$

D = 13
x 16
208
3 = + 3
211
x 16
3376
4 = + 4
3380

TO CONVERT DECIMAL TO HEXADECIMAL

1. (a) Select from the table the highest decimal number that is equal to or less than the number to be converted.
   (b) Record the hexadecimal of the column containing the selected number.
   (c) Subtract the selected decimal from the number to be converted.
2. Using the remainder from step 1(c), repeat all of step 1 to develop the second position of the hexadecimal (and a remainder)
3. Using the remainder from step 2, repeat all of step 1 to develop the units position of the hexadecimal.
4. Combine the terms to form the hexadecimal number.

EXAMPLE

Conversion of Decimal Value	3380
1. D	-3328
	52
2. 3	- 48
	4
3. 4	- 4
4. Hexadecimal	D34

DECIMAL TO HEXADECIMAL

Divide and collect the remainder in reverse order

Example: $3380_{10} = X_{16}$

		Remainder
16	3380 →	4
16	211 →	3
16	13 →	D

$3380_{10} = D34_{16}$

POWERS OF 16 TABLE

Example: $268,435,456_{10} = (2.68435456 \times 10^8)_{10} = 1000\ 0000_{16} = (10^7)_{16}$

16^n	n
1	0
16	1
256	2
4 096	3
65 536	4
1 048 576	5
16 777 216	6
268 435 456	7
4 294 967 296	8
68 719 476 736	9
1 099 511 627 776	10 = A
17 592 186 044 416	11 = B
281 474 976 710 656	12 = C
4 503 599 627 370 496	13 = D
72 057 594 037 927 936	14 = E
1 152 921 504 606 846 976	15 = F

TO CONVERT .ABC HEXADECIMAL TO DECIMAL

Find .A in position 1 .6250

Find .0B in position 2 .0429 6825

Find .00C in position 3 + .0029 2968 7500

.ABC is equal to .6708 9843 7500

TO CONVERT .13 DECIMAL TO HEXADECIMAL

1. Find .1250 next lowest to .1300
   subtract – .1250 = .2 Hex
2. Find .0039 0625 next lowest to .0050 0000
   – .0039 0625 = .01
3. Find .0009 7656 2500 .0010 9375 0000
   – .0009 7656 2500 = .004
4. Find .0001 0681 1523 4375 .0001 1718 7500 0000
   – .0001 0681 1523 4375 = .0007
   .0000 1037 5976 5625 = .2147 Hex
5. .13 Decimal is approximately equal to

To convert fractions beyond the capacity of the table, use techniques below:

HEXADECIMAL TO FRACTION DECIMAL

Convert the hexadecimal fraction to its decimal equivalent using the same technique as for integer numbers. Divide the results by 16n (n is the number of fraction positions).

Example: $.8A7 = .540771_{10}$

$8A7_{16} = 2215_{10}$ .540771

$16^3 = 4096$ 4096 | 2215.000000

DECIMAL FRACTION TO HEXADECIMAL

Collect integer parts of product in the order of calculation.

Example: $.5408_{10} = .8A7_{16}$

.5408
× 16
8 ← 8. 6528
× 16
A ← 10. 4448
× 16
7 ← 7. 1168

Hexadecimal Addition and Subtraction Table

Example: 6 + 2 = 8, 8 - 2 = 6, and 8 - 6 = 2

Appendix J. List of Extended Mnemonics

In place of specifying the architected assembler syntax for an instruction, referred to as the base-mnemonic syntax, a program may specify an alternative assembler syntax, referred to as the extended-mnemonic syntax. The extended-mnemonic syntax consists of an extended mnemonic and in most cases, a subset of the instruction fields. An extended mnemonic correlates to a particular instruction mnemonic. In most cases, the extended mnemonic also correlates to particular values in one or more fields of the instruction. The purpose of providing extended mnemonics for specialized usages of certain instructions is to simplify assembler-language programming.

The following figure provides a list of recommended extended mnemonics and syntax for various instructions. For a comprehensive list of extended mnemonics supported by a specific assembler, refer to the appropriate assembler-language publication.

Instruction Name	Extended-Mnemonic Syntax		Base-Mnemonic Syntax		Comments	Page

A

A (ADD) binary instruction 7-26
abort
  transactional execution 5-91
aborted-transaction-instruction-address
  in the transaction diagnostic block 5-96
absolute address 3-4
absolute storage 3-5
access-control bits
  in segment-table entry 3-47, 3-50
access-control bits in storage key 3-9
access-exception-fetch/store-indication facility
  facility indication 4-103
access exceptions 6-49, 6-56
  priority of 6-56
  recognition of 6-49
access key 3-11
  for channel-program execution 3-11, 15-25, 15-30
  for channel-subsystem monitoring 3-11
  for CPU 3-11
access list 5-57
  See also access-list entry
  accessing capability, revocation of 5-52
  allocation and invalidation of entries in 5-50
  authorizing the use of entries in 5-51
  concepts 5-48
  designation (ALD) 5-57
  length (ALL) 5-57
  origin (ALO) 5-57
access-list-controlled protection 3-13
  exception for 6-35
access-list designation 5-57
access-list entry (ALE) 5-57
  authorization index (ALEAX) 5-58
  number
    See ALEN
  sequence exception 6-22
    as an access exception 6-49
  sequence number (ALESN)
    in ALE 5-57
    in ALET 5-55
  token
    See ALET
access-register mode 3-41
access-register translation (ART) 5-54
  as part of LOAD REAL ADDRESS, STORE REAL ADDRESS, TEST ACCESS, and TEST PROTECTION 5-60
  introduction to 5-48
  lookaside buffer
    See ALB
  sequence of table fetches 5-127
access-register-translation (ART) tables 5-56
access registers 2-6
  designation of 5-48
  functions of 5-47
  instructions for use of 5-53
  machine-check save area for 3-89
  save areas for 3-84
  store-status save area for 3-89
  validity bit for 11-21
access to storage 5-120

ADD LOGICAL WITH SIGNED IMMEDIATE instructions 7-32
ADD NORMALIZED HFP instructions 18-8
example A-41
ADD UNNORMALIZED HFP instructions 18-9
example A-42
additional floating-point (AFP) registers 9-9
address 3-2
24-bit, 31-bit, and 64-bit 3-6
in branch-address generation 5-13
in operand address generation 5-12
absolute 3-4
AR-specified virtual
See AR-specified
arithmetic 3-6, 5-11
unsigned binary 7-6
backward stack-entry 5-81
base
See base address
branch
See branch address
comparison 12-1
controls for 12-1
effect on CPU state 4-2
CPU
See CPU address
effective
See effective address
format 3-3
forward-section header 5-82
generation 5-10
for storage addressing 3-7
home virtual
See home virtual address
I/O 13-5
instruction
See instruction address
invalid 6-20
logical
See logical address
numbering of for byte locations 3-2
PER
See PER address
prefixing
See prefix
primary virtual
See primary virtual address
real 3-5
secondary virtual
See secondary virtual address
size of
controlled by addressing mode 5-10
storage 3-2
summary information 3-71
translation
See dynamic address translation, prefix
types 3-4
virtual 3-5
wraparound
See wraparound
address-limit checking (I/O)
effect of I/O-system reset on 17-15
limit mode (bits in PMCW) 15-3
address-limit-checking control (I/O) 15-27, 16-12
used for IPL 17-17
address of] 15-35
address space 3-23
AR-specified 5-47
changing of 3-24
control bits
control bit 5-77
in the PSW 4-7
use in address translation 3-41
created by DAT 3-39
number
See ASN
address-space-control element (ASCE) 3-43
effective 3-54
home 3-46
in AST entry 3-33
used for access-register translation 5-59
used for subspace groups 5-70
primary 3-43
secondary 3-45
type exception 6-23
addressing
trimodal 7-8
address-and-translation-mode identification (ATMID) 4-31
addressing exception 6-20
as an access exception 6-49, 6-56
addressing mode 5-10
bit in linkage-stack state entry 5-84
bit in the PSW 4-7
effect on address size 3-7
effect on operand-address generation 5-12
effect on sequential instruction-address generation 5-10
effect on wraparound 3-7
in branch-address generation 5-13
in examples A-7
in operand address generation 5-12
set by BRANCH AND SAVE AND SET MODE instruction 7-38
set by BRANCH AND SET MODE instruction 7-39
set by SET ADDRESSING MODE instruction 7-436

use of 5-18
ADR (ADD NORMALIZED) HFP instruction 18-8
ADTR (ADD) DFP instruction 20-19
AE (ADD NORMALIZED) HFP instruction 18-8
example A-41
AEB (ADD) BFP instruction 19-15
AEBR (ADD) BFP instruction 19-15
AER (ADD NORMALIZED) HFP instruction 18-8
AFI (ADD IMMEDIATE) instruction 7-27, 7-29
AFP (additional floating-point) registers 9-9
AFP-register data exception 6-26
AFT (ASN first table) 3-31
AFTE (ASN-first-table entry) 3-31
AFTO (ASN-first-table origin) 3-31
AFX (ASN-first-table index) 3-31
invalid bit 3-32
translation exception 6-22
AG (ADD) binary instruction 7-26
AGF (ADD) binary instruction 7-27
AGFI (ADD IMMEDIATE) instruction 7-27
AGFR (ADD) binary instruction 7-26
AGH (ADD HALFWORD) instruction 7-28
AGHI (ADD HALFWORD IMMEDIATE) instruction 7-28
AGHIK (ADD IMMEDIATE) instruction 7-27
AGR (ADD) binary instruction 7-26
AGRK (ADD) binary instruction 7-26
AGSI (ADD IMMEDIATE) instruction 7-27
AH (ADD HALFWORD) instruction 7-28
example A-8
AHHHR (ADD HIGH) binary instruction 7-29
AHI (ADD HALFWORD IMMEDIATE) instruction 7-28
AHIK (ADD IMMEDIATE) instruction 7-27
AHY (ADD HALFWORD) instruction 7-28
AIH (ADD IMMEDIATE HIGH) binary instruction 7-29
AKM (authorization key mask) 5-38
AL (ADD LOGICAL) instruction 7-30
ALB (ART-lookaside buffer) 5-65
entry
clearing of 5-67
effect of translation changes on 5-67
usable state 5-66
ALC (ADD LOGICAL WITH CARRY) instruction 7-31
ALCG (ADD LOGICAL WITH CARRY) instruction 7-31
ALCGR (ADD LOGICAL WITH CARRY) instruction 7-31
ALCR (ADD LOGICAL WITH CARRY) instruction 7-31
ALD (access-list designation) 5-57
ALE
See access-list entry
ALEAX (access-list-entry authorization index) 5-58
ALEN (access-list-entry number) 5-55
invalid bit 5-57
translation exception 6-22
as an access exception 6-49
alert (class of machine-check condition) 11-10
alert interruption condition (I/O) 16-5
alert-status bit (I/O) 16-17
ALESN (access-list-entry sequence number)
in ALE 5-57
in ALET 5-55
ALET (access-list-entry token) 5-50, 5-55
specification exception 6-23
as an access exception 6-49
ALFI (ADD LOGICAL IMMEDIATE) instruction 7-30
ALG (ADD LOGICAL) instruction 7-30
ALGF (ADD LOGICAL) instruction 7-30
ALGFI (ADD LOGICAL IMMEDIATE) instruction 7-30
ALGFR (ADD LOGICAL) instruction 7-30
ALGHSIK (ADD LOGICAL WITH SIGNED IMMEDIATE) instruction 7-32
ALGR (ADD LOGICAL) instruction 7-30
ALGRK (ADD) binary instruction 7-30
ALGSI (ADD LOGICAL WITH SIGNED IMMEDIATE) instruction 7-32
ALHHHR (ADD LOGICAL HIGH) binary instruction 7-31
ALHSIK (ADD LOGICAL WITH SIGNED IMMEDIATE) instruction 7-32
alignment 3-3
ALL (access-list length) 5-57
allegiance
active 15-13
channel-path 15-12
dedicated 15-13
effect on CLEAR SUBCHANNEL of 15-12
working 15-12
allowed interruptions 6-6
ALO (access-list origin) 5-57
ALR (ADD LOGICAL) instruction 7-30
ALRK (ADD) binary instruction 7-30
ALSI (ADD LOGICAL WITH SIGNED IMMEDIATE) instruction 7-32
ALSIH (ADD LOGICAL WITH SIGNED IMMEDIATE HIGH) instruction 7-33
ALSIHN (ADD LOGICAL WITH SIGNED IMMEDIATE HIGH) binary instruction 7-33
alter-and-display controls 12-2
alteration
storage (PER event) 4-37
ALY (ADD LOGICAL) instruction 7-30
ancillary-report bit
in channel-report word 17-31
in machine-check-interruption code 11-18

in subchannel logout 16-49
AND IMMEDIATE instructions 7-34
AND instructions 7-33
examples A-8
AND WITH COMPLEMENT instructions 7-35
AP (ADD DECIMAL) instruction 8-6
example A-36
AR (ADD) binary instruction 7-26
AR-specified (access-register-specified) 3-5, 3-24
address space 3-24, 5-47
virtual address 3-5
AR-specified (access-register-specified) virtual address
effective address-space-control element for 3-54

true zero (HFP number) 18-1
TS (TEST AND SET) instruction 7-459
TSB (transport-status block) 15-48
address of 15-35
contents of 15-49, 15-56
TSCH (TEST SUBCHANNEL) instruction 14-21
two's complement binary notation 7-4
examples A-2
type of PROGRAM CALL 5-39

U

UIB
See UTC information block 4-59
ulp (unit in the last place) 9-7, 9-8, 19-3
ultravisor-call facility
facility indication 4-103
unit check (device status)
in establishing dedicated allegiance 15-13
unit of operation 5-24
unlock A-47
example with FIFO queuing A-50
example with LIFO queuing A-49
unnormalized floating-point number 18-2
HFP data only 9-4
unordered (comparison to a NaN) 9-24
UNPACK ASCII instruction 7-483
UNPACK instruction 7-483
example A-35
UNPACK UNICODE instruction 7-484
UNPK (UNPACK) instruction 7-483
example A-35
UNPKA (PACK ASCII) instruction 7-483
UNPKU (PACK UNICODE) instruction 7-484
unprivileged instructions 4-6, 7-4
unsigned binary
arithmetic 7-6

integer 7-4
examples A-3
in address generation 5-11
unsigned binary integer
conversion to floating point 19-21
unsigned-packed-decimal format 8-2
used in DFP formatting instructions 20-8
unsigned scaling exponent (α) 9-12
unsolicited interruption condition (I/O) 16-3
unstack-suppression bit 5-80
unstacking process 5-88
update reference 5-131
UPDATE TREE instruction 7-485
example A-53
UPT (UPDATE TREE) instruction 7-485
example A-53
usable ALB entry 5-66
UTC (Coordinated Universal Time) used in TOD epoch 4-53
UTC information block (UIB) 4-59

V

VA (VECTOR ADD) vector instruction 22-4
VAC (VECTOR ADD WITH CARRY) vector instruction 22-5
VACC (VECTOR ADD COMPUTE CARRY) vector instruction 22-5
VACCC (VECTOR ADD WITH CARRY COMPUTE CARRY) vector instruction 22-6
valid ART-table entry 5-66
valid CBC 11-2
valid floating-point-register numbers 9-9
valid region-table, segment-table, or page-table entry 3-65
validation 11-6
of registers 11-9
of storage 11-7
of storage key 11-7
of TOD clock 11-9
validity bit for backward stack-entry address 5-81
validity bit for forward-section-header address 5-82
validity bits
in machine-check-interruption code 11-20
in subchannel logout 16-49
VAP (VECTOR ADD DECIMAL) instruction 25-6
variable-length field 3-3
VAVG (VECTOR AVERAGE) vector instruction 22-7
VAVGL (VECTOR AVERAGE LOGICAL) vector instruction 22-7
VBLEND (VECTOR BLEND) vector instruction 21-5
VBPERM (VECTOR BIT PERMUTE) vector instruction 21-5, 21-7
VCDG (VECTOR FP CONVERT FROM FIXED 64-BIT) vector instruction 24-15
VCDLG (VECTOR FP CONVERT FROM LOGICAL 64-BIT) vector instruction 24-17
VCEQ (VECTOR COMPARE EQUAL) vector instruction 22-9
VCFN (VECTOR FP CONVERT FROM NNP) vector instruction 26-146
VCFPS (VECTOR FP CONVERT FROM FIXED) vector instruction 24-15
VCGD (VECTOR FP CONVERT TO FIXED 64-BIT) vector instruction 24-18
VCH (VECTOR COMPARE HIGH) vector instruction 22-9
VCHL (VECTOR COMPARE HIGH LOGICAL) vector instruction 22-10
VCKSM (VECTOR CHECKSUM) vector instruction 22-7
VCLFNH (VECTOR FP CONVERT AND LENGTHEN FROM NNP HIGH) vector instruction 26-144
VCLFNL (VECTOR FP CONVERT AND LENGTHEN FROM NNP LOW) vector instruction 26-145
VCLFP (VECTOR FP CONVERT TO LOGICAL) vector instruction 24-20
VCLGD (VECTOR FP CONVERT TO LOGICAL 64-BIT) vector instruction 24-20
VCLZ (VECTOR COUNT LEADING ZEROS) vector instruction 22-11
VCLZDP (VECTOR COUNT LEADING ZERO DIGITS) instruction 25-13
VCNF (VECTOR FP CONVERT TO NNP) vector instruction 26-147
VCP (VECTOR COMPARE DECIMAL) instruction 25-7
VCRNF (VECTOR FP CONVERT AND ROUND TO NNP) vector instruction 26-146
VCSFP (VECTOR FP CONVERT TO FIXED) vector instruction 24-18
VCSPH (VECTOR CONVERT HFP TO SCALED DECIMAL) instruction 25-12
VCTZ (VECTOR COUNT TRAILING ZEROS) vector instruction 22-12
VCVB (VECTOR CONVERT TO BINARY) instruction 25-8
VCVBG (VECTOR CONVERT TO BINARY) instruction 25-8
VCVBQ (VECTOR CONVERT TO BINARY) instruction 25-8
VCVD (VECTOR CONVERT TO DECIMAL) instruction 25-10
VCVDG (VECTOR CONVERT TO DECIMAL) instruction 25-11
VCVDQ (VECTOR CONVERT TO DECIMAL) instruction 25-11

VD (VECTOR DIVIDE) instruction 22-12
VDL (VECTOR DIVIDE LOGICAL) instruction 22-12
VDP (VECTOR DIVIDE DECIMAL) instruction 25-13
VEC (VECTOR ELEMENT COMPARE) vector instruction 22-8
VECL (VECTOR ELEMENT COMPARE LOGICAL) vector instruction 22-8
vector
  registers 2-5
    validity bit for 11-21, 11-22
VECTOR ADD COMPUTE CARRY vector instruction 22-5
VECTOR ADD DECIMAL instruction 25-6
VECTOR ADD vector instruction 22-4
VECTOR ADD WITH CARRY COMPUTE CARRY vector instruction 22-6
VECTOR ADD WITH CARRY vector instruction 22-5
VECTOR AND vector instruction 22-6
VECTOR AND WITH COMPLEMENT vector instruction 22-6
VECTOR AVERAGE LOGICAL vector instruction 22-7
VECTOR AVERAGE vector instruction 22-7
VECTOR BIT PERMUTE vector instruction 21-5
VECTOR BLEND 21-5
VECTOR CHECKSUM vector instruction 22-7
VECTOR COMPARE DECIMAL instruction 25-7
VECTOR COMPARE EQUAL vector instruction 22-9
VECTOR COMPARE HIGH LOGICAL vector instruction 22-10
VECTOR COMPARE HIGH vector instruction 22-9
VECTOR CONVERT HRP TO SCALED DECIMAL instruction 25-12
VECTOR CONVERT TO BINARY instructions 25-8
VECTOR CONVERT TO DECIMAL instructions 25-10
VECTOR COUNT LEADING ZERO DIGITS instruction 25-13
VECTOR COUNT LEADING ZEROS vector instruction 22-11
VECTOR COUNT TRAILING ZEROS vector instruction 22-12
VECTOR DIVIDE DECIMAL instruction 25-13
VECTOR DIVIDE instruction 22-12
VECTOR DIVIDE LOGICAL instruction 22-12
VECTOR ELEMENT COMPARE LOGICAL vector instruction 22-8
VECTOR ELEMENT COMPARE vector instruction 22-8
VECTOR ELEMENT ROTATE AND INSERT UNDER MASK vector instruction 22-28
VECTOR ELEMENT ROTATE LEFT LOGICAL vector instruction 22-27
VECTOR ELEMENT SHIFT LEFT vector instruction 22-29
VECTOR ELEMENT SHIFT RIGHT ARITHMETIC vector instruction 22-30
VECTOR ELEMENT SHIFT RIGHT LOGICAL vector instruction 22-30
vector-enhancements facility 2 1-31
VECTOR EVALUATE instruction 22-13
vector-exception code (VXC) 6-20
VECTOR EXCLUSIVE OR vector instruction 22-14
vector facility for z/Architecture
  facility indication 4-103
vector facility for z/architecture 1-32
VECTOR FIND ANY ELEMENT EQUAL vector instruction 23-2
VECTOR FIND ELEMENT EQUAL vector instruction 23-3
VECTOR FIND ELEMENT NOT EQUAL vector instruction 23-4
VECTOR FP ADD vector instruction 24-4
VECTOR FP COMPARE AND SIGNAL SCALAR vector instruction 24-8
VECTOR FP COMPARE EQUAL vector instruction 24-9
VECTOR FP COMPARE HIGH OR EQUAL vector instruction 24-13
VECTOR FP COMPARE HIGH vector instruction 24-11
VECTOR FP COMPARE SCALAR vector instruction 24-7
VECTOR FP CONVERT AND LENGTHEN FROM NNP HIGH vector instruction 26-144
VECTOR FP CONVERT AND LENGTHEN FROM NNP LOW vector instruction 26-145
VECTOR FP CONVERT AND ROUND TO NNP vector instruction 26-146
VECTOR FP CONVERT FROM FIXED 64-BIT vector instruction 24-15
VECTOR FP CONVERT FROM LOGICAL 64-BIT vector instruction 24-17
VECTOR FP CONVERT FROM NNP vector instruction 26-146
VECTOR FP CONVERT TO FIXED 64-BIT vector instruction 24-18
VECTOR FP CONVERT TO LOGICAL 64-BIT vector instruction 24-20
VECTOR FP CONVERT TO NNP vector instruction 26-147
VECTOR FP DIVIDE vector instruction 24-22
VECTOR FP LOAD LENGTHENED vector instruction 24-26
VECTOR FP LOAD ROUNDED vector instruction 24-27
VECTOR FP MAXIMUM vector instruction 24-28

VECTOR FP MINIMUM vector instruction 24-34
VECTOR FP MULTIPLY AND ADD vector instruction 24-42
VECTOR FP MULTIPLY AND SUBTRACT vector instruction 24-42
VECTOR FP MULTIPLY vector instruction 24-40
VECTOR FP NEGATIVE MULTIPLY AND ADD vector instruction 24-42
VECTOR FP NEGATIVE MULTIPLY AND SUBTRACT vector instruction 24-42
VECTOR FP PERFORM SIGN OPERATION vector instruction 24-44
VECTOR FP SQUARE ROOT vector instruction 24-45
VECTOR FP SUBTRACT vector instruction 24-46
VECTOR FP TEST DATA CLASS IMMEDIATE vector instruction 24-47
VECTOR GALOIS FIELD MULTIPLY SUM AND ACCUMULATE vector instruction 22-16
VECTOR GALOIS FIELD MULTIPLY SUM vector instruction 22-16
VECTOR GATHER ELEMENT vector instruction 21-6
VECTOR GENERATE BYTE MASK vector instruction 21-6
VECTOR GENERATE ELEMENT MASKS 21-7
VECTOR GENERATE MASK vector instruction 21-7
VECTOR ISOLATE STRING vector instruction 23-5
VECTOR LOAD AND REPLICATE vector instruction 21-8
VECTOR LOAD COMPLEMENT vector instruction 22-17
VECTOR LOAD ELEMENT IMMEDIATE vector instruction 21-12
VECTOR LOAD ELEMENT vector instruction 21-11
VECTOR LOAD FP INTEGER vector instruction 24-24
VECTOR LOAD GR FROM VR ELEMENT vector instruction 21-13
VECTOR LOAD IMMEDIATE DECIMAL instruction 25-15
VECTOR LOAD LOGICAL ELEMENT AND ZERO vector instruction 21-13
VECTOR LOAD MULTIPLE vector instruction 21-14
VECTOR LOAD POSITIVE vector instruction 22-17
VECTOR LOAD RIGHTMOST WITH LENGTH instruction 21-15
VECTOR LOAD TO BLOCK BOUNDARY vector instruction 21-15
VECTOR LOAD vector instruction 21-8
VECTOR LOAD VR ELEMENT FROM GR vector instruction 21-16
VECTOR LOAD VR FROM GRS DISJOINT vector instruction 21-16
VECTOR LOAD WITH LENGTH vector instruction 21-17
VECTOR MAXIMUM LOGICAL vector instruction 22-18
VECTOR MAXIMUM vector instruction 22-18
VECTOR MERGE HIGH vector instruction 21-17
VECTOR MERGE LOW vector instruction 21-17
VECTOR MINIMUM LOGICAL vector instruction 22-18
VECTOR MINIMUM vector instruction 22-18
VECTOR MULTIPLY AND ADD EVEN vector instruction 22-20
VECTOR MULTIPLY AND ADD HIGH vector instruction 22-19
VECTOR MULTIPLY AND ADD LOGICAL EVEN vector instruction 22-20
VECTOR MULTIPLY AND ADD LOGICAL HIGH vector instruction 22-19
VECTOR MULTIPLY AND ADD LOGICAL ODD vector instruction 22-21
VECTOR MULTIPLY AND ADD LOW vector instruction 22-19
VECTOR MULTIPLY AND ADD ODD vector instruction 22-21
VECTOR MULTIPLY AND SHIFT DECIMAL instruction 25-16
VECTOR MULTIPLY DECIMAL instruction 25-16
VECTOR MULTIPLY EVEN vector instruction 22-23
VECTOR MULTIPLY HIGH vector instruction 22-21
VECTOR MULTIPLY LOGICAL EVEN vector instruction 22-23
VECTOR MULTIPLY LOGICAL HIGH vector instruction 22-21
VECTOR MULTIPLY LOGICAL ODD vector instruction 22-23
VECTOR MULTIPLY LOW vector instruction 22-22
VECTOR MULTIPLY ODD vector instruction 22-23
VECTOR NAND vector instruction 22-25
VECTOR NOR vector instruction 22-24
VECTOR NOT EXCLUSIVE OR vector instruction 22-25
VECTOR OR vector instruction 22-26
VECTOR OR WITH COMPLEMENT vector instruction 22-26
VECTOR PACK LOGICAL SATURATE vector instruction 21-19
VECTOR PACK SATURATE vector instruction 21-18
VECTOR PACK vector instruction 21-18
VECTOR PACK ZONED instruction 25-18
VECTOR PACK ZONED REGISTER instruction 25-19
vector-packed-decimal facility 1-31, 1-33
  facility indication 4-103

VECTOR PERFORM SIGN OPERATION DECIMAL instruction 25-20
VECTOR PERMUTE DOUBLEWORD IMMEDIATE vector instruction 21-20
VECTOR PERMUTE vector instruction 21-20
VECTOR POPULATION COUNT vector instruction 22-26
VECTOR REMAINDER DECIMAL instruction 25-23
VECTOR REMAINDER instruction 22-27
VECTOR REMAINDER LOGICAL instruction 22-27
VECTOR REPLICATE IMMEDIATE vector instruction 21-21
VECTOR REPLICATE vector instruction 21-21
VECTOR SCATTER ELEMENT vector instruction 21-22

X field of instruction 5-10
XC (EXCLUSIVE OR) instruction 7-292
  examples A-20
XG (EXCLUSIVE OR) instruction 7-292
XGR (EXCLUSIVE OR) instruction 7-292
XI (EXCLUSIVE OR) instruction 7-292
  example A-21
XIHF (EXCLUSIVE OR IMMEDIATE) instruction 7-293
XILF (EXCLUSIVE OR IMMEDIATE) instruction 7-293
XIY (EXCLUSIVE OR) instruction 7-292
XR (EXCLUSIVE OR) instruction 7-292
XRK (EXCLUSIVE OR) binary instruction 7-292
XSCH (CANCEL SUBCHANNEL) instruction 14-3
XY (EXCLUSIVE OR) instruction 7-292

Z

Z bit (zero condition-code bit) 16-12
  as cause of intermediate interruption condition 16-18
z/Architecture architecture
  additions to 1-2, 1-7
  original highlights of 1-2
ZAP (ZERO AND ADD) instruction 8-14
  example A-41
zero
  instruction-length code 6-7
  normal meaning for byte value xxxi
  setting floating-point register to 9-35
  true (HFP number) 18-1
zero-address-detection PER event
  mask for 4-27
ZERO AND ADD instruction 8-14
  example A-41
zero condition code (Z bit in SCSW) 16-12
zero-padding control 7-188
zone bits 8-1
  moving of 7-345
zoned decimal numbers 8-1
zoned-decimal numbers
  examples A-4

Communicating Your Comments to IBM

Title: z/Architecture Principles of Operation

Publication No: SA22-7832-14

If you especially like or dislike anything about this book, please provide your feedback to IBM.

At the time this document was created, the means to provide feedback were as follows:

- Visit the IBM website which provides this publication.
- Somewhere on the website (in the past, at the top right) find the “Was this topic helpful?” text followed by a thumbs up, “positive feedback” icon and a thumbs down, “negative feedback” icon.
- If either icon is selected, a “Rate this content” pop-up menu is presented. Add your feedback in the comment portion of this pop-up menu and use the “Submit” button on the menu. Feel free to comment on specific errors or omissions, accuracy, organization, subject matter, or completeness of this book. Include your name and email address in your comments if you would like a reply.

When you send comments to IBM, you grant IBM a nonexclusive right to use or distribute your comments in any way it believes appropriate without incurring any obligation to you.

Your feedback helps improve the content provided and is appreciated.
