
Subject to the controls in the M_1 field, the CPU is provided with information about a branch or execute-type instruction designated by the second operand. The predicted target address of the designated instruction is specified by the third operand.

The contents of the RI_2 field are a signed binary integer specifying the number of halfwords that is added to the address of the current instruction to generate the address of a branch, or execute-type instruction. For BRANCH PREDICTION PRELOAD, the RI_2 field contains a signed 16-bit integer. For BRANCH PREDICTION RELATIVE PRELOAD, the RI_2 field contains a signed 12-bit integer.

When adding the number of halfwords specified in the RI_2 field to the address of the current instruction, the result is subject to the current addressing mode. That is, the result is treated as a 24-bit address in the 24-bit addressing mode, a 31-bit address in the 31-bit addressing mode, or a 64-bit address in the 64-bit addressing mode.

The M_1 field contains a 4-bit unsigned binary integer that is used as a code to signal the CPU attributes of the instruction designated by the second operand. The codes are as follows:

Code	Meaning
0	The instruction is a branch instruction that is 4 bytes in length. The branch instruction is not used for calling linkage or a returning linkage and there may be multiple potential targets of this branch instruction.
1-4	Reserved.
5	The instruction is a branch instruction that is 2 bytes in length. The branch instruction is used for calling linkage and there is only one target of this branch instruction.
6	The instruction is a branch instruction that is 2 bytes in length. The branch instruction is used for returning linkage.
7	The instruction is a branch instruction that is 2 bytes in length. The branch instruction is used for calling linkage and there may be multiple potential targets of this branch instruction.
8	The instruction is a branch instruction that is 4 bytes in length. The branch instruction is not used for calling linkage or returning linkage and there is only one target of this branch instruction.
9	The instruction is a branch instruction that is 4 bytes in length. The branch instruction is used for calling linkage and there is only one target of the branch instruction.
10	The instruction is a branch instruction that is 4 bytes in length. The branch instruction is used for returning linkage.
11	The instruction is a branch instruction that is 4 bytes in length. The branch instruction is used for calling linkage and there may be multiple potential targets of this branch instruction.
12	The instruction is a branch instruction that is 6 bytes in length. The branch instruction is not used for calling linkage or returning linkage and there is only one target of this branch instruction.
13	The instruction is a branch instruction that is 6 bytes in length. The branch instruction is used for calling linkage and there is only one target of this branch instruction.
14	The instruction is an EXECUTE instruction.
15	The instruction is an EXECUTE RELATIVE LONG instruction.

For BRANCH PREDICTION PRELOAD when the M_1 field specifies a branch instruction, the third operand address is the predicted branch-target address of the

instruction designated by the second operand. For BRANCH PREDICTION PRELOAD when the M_1 field specifies an execute-type instruction, the third operand address is the execute-target address of the instruction designated by the second operand.

For BRANCH PREDICTION RELATIVE PRELOAD, when the M_1 field specifies a branch instruction, the contents of the RI_3 field are a 24-bit signed binary integer specifying the number of halfwords that is added to the address of the BRANCH PREDICTION RELATIVE PRELOAD instruction to generate the branch-target address of the instruction designated by the second operand. For BRANCH PREDICTION RELATIVE PRELOAD, when the M_1 field specifies an execute-type instruction, the contents of the RI_3 field are a 24-bit signed binary integer specifying the number of halfwords that is added to the address of the BRANCH PREDICTION RELATIVE PRELOAD instruction to generate the execute-target address of the instruction designated by the second operand. When adding the number of halfwords specified by the RI_3 field to the address of the BRANCH PREDICTION RELATIVE PRELOAD instruction, the result is subject to the current addressing mode. That is, the result is treated as a 24-bit address in the 24-bit addressing mode, a 31-bit address in the 31-bit addressing mode, or a 64-bit address in the 64-bit addressing mode.

When the boundary of the third operand of BRANCH PREDICTION PRELOAD is not on a halfword boundary, it is model dependent whether the instruction acts as a no-operation.

Depending on the model, the CPU may not implement all of the branch-attribute codes. For codes that are not recognized by the CPU, and for reserved codes, the instruction acts as a no-operation.

The second and third operand addresses are instruction or effective addresses, not logical addresses. No access exceptions are recognized for the second or third operands. For BRANCH PREDICTION PRELOAD, there is no specification exception when the third operand specifies an odd address.

Condition Code: The code remains unchanged.

Program Exceptions:

- Operation (if the execution-hint facility is not installed)

Programming Notes:

1. In the absence of any branch-history information observed during program execution or provided by BPP or BPRP, current processor models that implement branch-prediction logic assume that the following operations represent conditional branches that are taken (that is, branches that update the PSW instruction address):

   - BAL, BAS, BCT, BCTG, BRAS, BRASL, BRCT, BRCTG, BRCTH, BRXLE, BRXLG, BXLE, and BXLEG
   - BALR, BASR, BCTGR, and BCTR, when the R_2 field is nonzero
   - BC, BIC, BRC, and BRCL, when the mask field is 1111 binary
   - BCR, when both the mask field is 1111 binary and the R_2 field is nonzero

   Similarly, for the purposes of branch prediction, the following operations are assumed to represent conditional branches that are not taken:

   - BC, BIC, BRC, and BRCL, when the mask field is between 0001 and 1110 binary, inclusive
   - BCR, when both the mask field is between 0001 and 1110 binary, inclusive, and the R_2 field is nonzero
   - BRXH, BRXHG, BXH, and BXHG
   - CGIB, CGIJ, CGRB, CGRJ, CIB, CIJ, CLGIB, CLGIJ, CLGRB, CLGRJ, CLIB, CLIJ, CLRB, CLRJ, CRB, and CRJ, when bits 0-2 of the mask field are between 001 and 110 binary

   Additionally, for the purposes of branch-prediction, the following operations are not considered to be branches.

   - BALR, BASR, BCTGR, and BCTR, when the R_2 field is zero
   - BC, BIC, BRC, and BRCL, when the mask field is 0000 binary
   - BCR, when either the mask field is 0000 binary or the R_2 field is zero

   The predictive behavior of conditional-branching operations not listed above is model dependent.

   The BPP and BPRP instructions provide a means by which the program can influence the branch-history logic, informing the CPU that the branching instruction designated by the second operand is expected to be a taken branch,

regardless of the assumed behavior described above.

2. BRANCH PREDICTION PRELOAD and BRANCH PREDICTION RELATIVE PRELOAD inform the CPU of a branch instruction and its predicted target, but this does not guarantee that the CPU will necessarily retain or use this branch-prediction information.

3. If a CPU retains the specified branch-prediction information, it is model dependent how long the information is retained.

4. Figure 7-3 shows the branch-prediction codes and their most-common usage. Refer to the definition of the codes on page 7-44 for a complete explanation of the codes and their respective meanings.

M_1 Code Value	IL	Corresponding Branch Instruction(s) by Mnemonic	Usage Type
0	4	BC[2]	Branch table
1		(none - code is reserved)	
2		(none - code is reserved)	
3		(none - code is reserved)	
4		(none - code is reserved)	
5	2	BALR[1], BASR[1], BCR[1,2]	Static calling linkage
6	2	BCR[1,2]	Returning linkage
7	2	BALR[1], BASR[1], BCR[1,2]	Dynamic calling linkage
8	4	BC[2], BCT, BRXH, BRXLE, BXH, BXLE, BRC[2], BRCT, BRCTG, BCTGR[1]	Conditional or unconditional branches
9	4	BAL, BAS, BRAS	Static calling linkage
10	4	BC[3]	unconditional returning linkage
11	4	BAL, BAS,	Dynamic calling linkage
12	6	BIC[2], BRCTH, BRCL[2], BCTG, BXHG, BXLEG, BRXHG, BRXLG, CGRJ[2], CLGRJ[2], CRJ[2], CLRJ[2], CGIJ[2], CLGIJ[2], CIJ[2], CLIJ[2], CGRB[2], CLGRB[2], CRB[2], CLRB[2], CGIB[2], CLGIB[2], CIB[2], CLIB[2]	Conditional or unconditional branches
13	6	BIC[2], BRASL	Static calling linkage
14	4	EX	
15	6	EXRL	

Figure 7-3. Branch-Prediction Codes and Most-Common Usage (Part 1 of 2)

M_1 Code Value	IL	Corresponding Branch Instruction(s) by Mnemonic	Usage Type

Explanation:

IL Instruction length
1 When the R_2 field is not zero.
2 When the mask field is not zero.
3 When the mask field is 1111 binary.

Notes:

1. A usage type of *branch table* indicates an instruction that is used to branch to a table of other instructions. An example is the "B BR_TBL(15)" instruction shown in programming note 3 for "TRANSLATE AND TEST EXTENDED" on page 7-470.
2. A usage type of *linkage* designates an instruction that calls or returns from a subroutine, as described in "Subroutine Linkage without the Linkage Stack" on page 5-14. Static calling linkage indicates a branch whose target location is a single location that is not changed by the program during execution. Dynamic calling linkage indicates a branch whose target location may be one of many locations that is determined by the program during execution.

Figure 7-3. Branch-Prediction Codes and Most-Common Usage (Part 2 of 2)

5. Performance degradation may occur for any of the following:

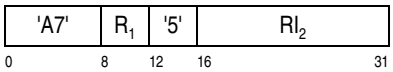
   - The RI_2 field is zero or the second operand designates an instruction that is not a branch instruction or execute-type instruction.
   - The RI_2 and M_1 fields designate a branch instruction and the branch is not taken.
   - The M_1 field designates a code specifying an incorrect length, instruction or usage type for the instruction designated by the second operand as shown by programming note 4.
   - The M_1 field designates a code specifying that the instruction designated by the second operand is a calling-linkage instruction, however there is no direct returning-linkage instruction. That is, the returning-linkage instruction is executed from a nested use of calling and returning subroutine linkage.
   - For BRANCH PREDICTION PRELOAD, the third operand specifies an odd address or designates an incorrect branch-target for the instruction designated by the second operand. For BRANCH PREDICTION RELATIVE PRELOAD, the RI_3 field designates an incorrect branch-target for the instruction designated by the RI_2 field.

- BRANCH PREDICTION PRELOAD or BRANCH PREDICTION RELATIVE PRELOAD are the target of an execute-type instruction.

6. Other than the performance implications described in the preceding note, the use of BPP or BPRP in a program does not change the execution sequence from that of a program that does not use BPP or BPRP.

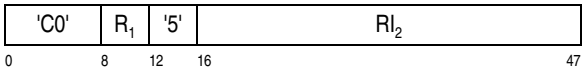
BRANCH RELATIVE AND SAVE

BRAS R_1,RI_2 [RI-b]



BRANCH RELATIVE AND SAVE LONG

BRASL R_1,RI_2 [RIL-b]



Information from the current PSW, including the updated instruction address, is saved as link information at the first-operand location. Subsequently, the instruction address in the PSW is replaced by the branch address.

In the 24-bit or 31-bit addressing mode, the link information is bits 32 and 97-127 of the PSW, consisting of the basic-addressing-mode bit and the rightmost 31 bits of the updated instruction address. The link information is placed in bit positions 32 and 33-63, respectively, of the first-operand location, and bits 0-31 of the location remain unchanged.

In the 64-bit addressing mode, the link information consists of the updated instruction address, placed in bit positions 0-63 of the first-operand location.

The contents of the RI_2 field are a signed binary integer specifying the number of halfwords that is added to the address of the instruction to generate the branch address.

Condition Code: The code remains unchanged.

Program Exceptions:

- Transaction constraint

Programming Notes:

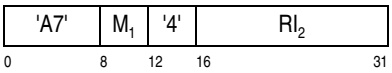
1. The operation is the same as that of the BRANCH AND SAVE (BAS) instruction except for the means of specifying the branch address. An example of the use of BRANCH AND SAVE is given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. The BRANCH RELATIVE AND SAVE and BRANCH RELATIVE AND SAVE LONG instructions, like the BRANCH AND SAVE instruction, are intended to be used for linkage to programs known to be in the same addressing mode as the caller. These instructions should be used in place of the BRANCH AND LINK instruction (BAL and BALR). See the programming notes on pages 5-15 and 5-18 in the section “Subroutine Linkage without the Linkage Stack” for a detailed discussion of these and other linkage instructions. See also the programming note under BRANCH AND LINK for a discussion of the advantages of the BRANCH RELATIVE AND SAVE, BRANCH RELATIVE AND SAVE LONG, and BRANCH AND SAVE instructions.

3. When the instruction is the target of an execute-type instruction, the branch is relative to the target address; see “Branch-Address Generation” on page 5-12.

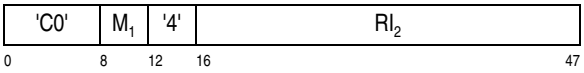
BRANCH RELATIVE ON CONDITION

BRC M_1,RI_2 [RI-c]



BRANCH RELATIVE ON CONDITION LONG

BRCL M_1,RI_2 [RIL-c]



The instruction address in the current PSW is replaced by the branch address if the condition code has one of the values specified by M_1; otherwise, nor-

mal instruction sequencing proceeds with the updated instruction address.

The contents of the RI_2 field are a signed binary integer specifying the number of halfwords that is added to the address of the instruction to generate the branch address.

The M_1 field is used as a four-bit mask. The four condition codes (0, 1, 2, and 3) correspond, left to right, with the four bits of the mask, as follows:

Condition Code	0	1	2	3
Instruction Bit Number of Mask	8	9	10	11
Mask Position Value	8	4	2	1

The current condition code is used to select the corresponding mask bit. If the mask bit selected by the condition code is one, the branch is successful. If the mask bit selected is zero, normal instruction sequencing proceeds with the next sequential instruction.

Condition Code: The code remains unchanged.

Program Exceptions:

- Transaction constraint

Programming Notes:

1. The operation is the same as that of the BRANCH ON CONDITION instruction except for the means of specifying the branch address. An example of the use of BRANCH ON CONDITION is given in Appendix A, “Number Representation and Instruction-Use Examples.”

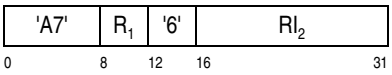
2. When a branch is to depend on more than one condition, the pertinent condition codes are specified in the mask as the sum of their mask position values. A mask of 12, for example, specifies that a branch is to be made when the condition code is 0 or 1.

3. When all four mask bits are zeros, the branch instruction is equivalent to a no-operation. When all four mask bits are ones, that is, the mask value is 15, the branch is unconditional.

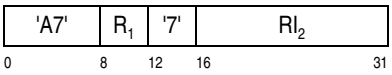
4. When the instruction is the target of an execute-type instruction, the branch is relative to the target address; see “Branch-Address Generation” on page 5-12.

BRANCH RELATIVE ON COUNT

BRCT R_1,RI_2 [RI-b]

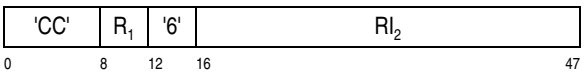


BRCTG R_1,RI_2 [RI-b]



BRANCH RELATIVE ON COUNT HIGH

BRCTH R_1,RI_2 [RIL-b]



A one is subtracted from the first operand, and the result is placed at the first-operand location. For BRANCH RELATIVE ON COUNT (BRCT), the first operand and result are treated as 32-bit binary integers in bits 32-63 of general register R_1, with overflow ignored; bits 0-31 of the register are unchanged. For BRANCH RELATIVE ON COUNT HIGH (BRCTH), the first operand and result are treated as 32-bit binary integers in bits 0-31 of general register R_1, with overflow ignored; bits 32-63 of the register are unchanged. For BRANCH RELATIVE ON COUNT (BRCTG), the first operand and result are treated as 64-bit binary integers, with overflow ignored. When the result is zero, normal instruction sequencing proceeds with the updated instruction address. When the result is not zero, the instruction address in the current PSW is replaced by the branch address.

The contents of the RI_2 field are a signed binary integer specifying the number of halfwords that is added to the address of the instruction to generate the branch address.

Condition Code: The code remains unchanged.

Program Exceptions:

- Operation (BRCTH, if the high-word facility is not installed)
- Transaction constraint

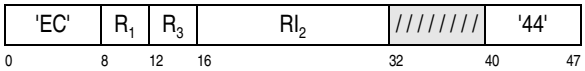
Programming Notes:

1. The operation is the same as that of the BRANCH ON COUNT instruction except for the means of specifying the branch address. An example of the use of BRANCH ON COUNT is given in Appendix A, “Number Representation and Instruction-Use Examples.”
2. The first operand and result can be considered as either signed or unsigned binary integers since the result of a binary subtraction is the same in both cases.
3. An initial count of one results in zero, and no branching takes place; an initial count of zero results in -1 and causes branching to be executed; an initial count of -1 results in -2 and causes branching to be executed; and so on. In a loop, branching takes place each time the instruction is executed until the result is again zero. Note that for BRCT, because of the number range, an initial count of -2^{31} results in a positive value of $2^{31} - 1$, or, for BRCTG, an initial count of -2^{63} results in a positive value of $2^{63} - 1$.
4. When the instruction is the target of an execute-type instruction, the branch is relative to the target address; see “Branch-Address Generation” on page 5-12.

BRANCH RELATIVE ON INDEX HIGH

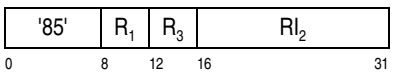
BRXH R_1,R_3,RI_2 [RSI]

BRXHG R_1,R_3,RI_2 [RIE-e]

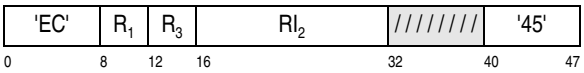


BRANCH RELATIVE ON INDEX LOW OR EQUAL

BRXLE R_1,R_3,RI_2 [RSI]



BRXLG R_1,R_3,RI_2 [RIE-e]



An increment is added to the first operand, and the sum is compared with a compare value. The result of the comparison determines whether branching occurs. Subsequently, the sum is placed at the first-operand location. The R_3 field designates registers containing the increment and the compare value.

The contents of the RI_2 field are a signed binary integer specifying the number of halfwords that is added to the address of the instruction to generate the branch address.

For BRANCH RELATIVE ON INDEX HIGH, when the sum is high, the instruction address in the current PSW is replaced by the branch address. When the sum is low or equal, normal instruction sequencing proceeds with the updated instruction address.

For BRANCH RELATIVE ON INDEX LOW OR EQUAL, when the sum is low or equal, the instruction address in the current PSW is replaced by the branch address. When the sum is high, normal instruction sequencing proceeds with the updated instruction address.

When the R_3 field is even, it designates a pair of registers; the contents of the even and odd registers of the pair are used as the increment and the compare value, respectively. When the R_3 field is odd, it designates a single register, the contents of which are used as both the increment and the compare value.

For purposes of the addition and comparison, all operands and results are treated as 32-bit signed binary integers for BRXH and BRXLE or as 64-bit signed binary integers for BRXHG and BRXLG. Overflow caused by the addition is ignored.

The original contents of the compare-value register are used as the compare value even when that register is also specified to be the first-operand location.

The sum is placed at the first-operand location, regardless of whether the branch is taken.

Condition Code: The code remains unchanged.

Program Exceptions:

- Transaction constraint

Programming Notes:

1. The operations are the same as those of the BRANCH ON INDEX HIGH and BRANCH ON INDEX LOW OR EQUAL instructions except for the means of specifying the branch address. Several examples of the use of BRANCH ON INDEX HIGH and BRANCH ON INDEX LOW OR EQUAL are given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. The word “index” in the names of these instructions indicates that one of the major purposes is the incrementing and testing of an index value. The increment, being a signed binary integer, may be used to increase or decrease the value in general register R_1 by an arbitrary amount.

3. Care must be taken in the 31-bit addressing mode when a data area in storage is at the rightmost end of an address space and a BRANCH RELATIVE ON INDEX HIGH (BRXH) or BRANCH RELATIVE ON INDEX LOW OR EQUAL (BRXLE) instruction is used to step upward through the data. Since the addition and comparison operations performed during the execution of these instructions treat the operands as 32-bit signed binary integers, the value following $2^{31} - 1$ is not 2^{31}, which cannot be represented in that format, but -2^{31}. The instruction does not provide an indication of such overflow. Consequently, some common looping techniques based on the use of these instructions do not work when a data area ends at address $2^{31} - 1$. This problem is illustrated in a BRANCH ON INDEX LOW OR EQUAL example in Appendix A, “Number Representation and Instruction-Use Examples.” A similar caution applies in the 64-bit addressing mode when data is at the end of a 64-bit address space and BRANCH RELATIVE ON INDEX HIGH (BRXHG) or BRANCH RELATIVE ON INDEX LOW OR EQUAL (BRXLG) is used.

4. When the instruction is the target of an execute-type instruction, the branch is relative to the target address; see “Branch-Address Generation” on page 5-12.

CHECKSUM

CKSM R_1,R_2 [RRE]

Successive four-byte elements of the second operand are added to the first operand in bit positions 32-63 of general register R_1 to form a 32-bit checksum in those bit positions. The first operand and the four-byte elements are treated as 32-bit unsigned binary integers. After each addition of an element, a carry out of bit position 32 of the first operand is added to bit position 63 of the first operand. Bits 0-31 of general register R_1 always remain unchanged. If the second operand is not a multiple of four bytes, its last one, two, or three bytes are treated as appended on the right with the number of all-zeros bytes needed to form a four-byte element. The four-byte elements are added to the first operand until either the entire second operand or a CPU-determined amount of the second operand has been processed. The result is indicated in the condition code.

The R_2 field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The location of the leftmost byte of the second operand is specified by the contents of the R_2 general register. The number of bytes in the second-operand location is specified by the 32-bit or 64-bit unsigned binary integer in the $R_2 + 1$ general register.

The handling of the address in general register R_2 and the length in general register $R_2 + 1$ is dependent on the addressing mode. In the 24-bit addressing mode, the contents of bit positions 40-63 of general register R_2 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the register constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 of the register constitute the address. In the 24-bit or 31-bit addressing mode, the length is a 32-bit unsigned binary integer in bit positions 32-63 of general register $R_2 + 1$, and the contents of bit positions 0-31 are ignored. In the 64-bit addressing mode, the length is a 64-bit unsigned binary integer in the register.

The addition of second-operand four-byte elements to the first operand proceeds left to right, four-byte element by four-byte element, and ends as soon as (1) the entire second operand has been processed or (2) a lesser CPU-determined amount of the second operand has been processed. In either case, the result in bit positions 32-63 of general register R_1 is a 32-bit checksum for the part of the second operand that has been processed. When the second operand is not a multiple of four bytes, the final second-operand bytes in excess of a multiple of four are conceptually appended on the right with an appropriate number of all-zeros bytes to form the final four-byte element.

If the operation ends because the entire second operand has been processed, the condition code is set to 0. If the operation ends because a lesser CPU-determined amount of the second operand has been processed, the condition code is set to 3. When the operation is to end with a setting of condition code 3, any carry out of bit position 32 of the first operand is added to bit position 63 of the first operand before the operation ends.

At the completion of the operation, the 32-bit or 64-bit operand-length field in the $R_2 + 1$ register is decremented by the number of actual second-operand bytes added to the first operand (not including any conceptually appended all-zeros bytes), and the address in the R_2 register is incremented by the same number. Thus, the 32-bit or 64-bit operand-length field contains a zero value if the condition code is set to 0, or it contains a nonzero value if the condition code is set to 3. In the 24-bit or 31-bit addressing mode, bits 0-31 of the $R_2 + 1$ register always remain unchanged.

When condition code 3 is set, the general registers used by the instruction have been set so that the remainder of the second operand can be processed by simply branching back to reexecute the instruction.

The amount of processing that results in the setting of condition code 3 is determined by the CPU on the basis of improving system performance, and it may be a different amount each time the instruction is executed. The minimum amount is four bytes or the number of bytes specified in the $R_2 + 1$ general register, whichever is smaller.

At the completion of the operation in the 24-bit or 31-bit addressing mode, the leftmost bits which are not part of the address in bit positions 32-63 of general register R_2 may be set to zeros or may remain unchanged, even when the initial length in register $R_2 + 1$ is zero. Bits 0-31 of general register R_2 remain unchanged.

When the R_1 register is the same register as the R_2 or $R_2 + 1$ register, the results are unpredictable.

Access exceptions for the portion of the second operand to the right of the last byte processed may or may not be recognized. For a second operand longer than 4K bytes, access exceptions are not recognized for locations more than 4K bytes beyond the last byte processed.

Access exceptions are not recognized if the R_2 field is odd. When the length of the second operand is zero, no access exceptions are recognized.

Resulting Condition Code:

0 Entire second operand processed
1 --
2 --
3 CPU-determined amount of the second operand processed

Program Exceptions:

- Access (fetch, operand 2)
- Specification
- Transaction constraint

Programming Notes:

1. The initial contents of bit positions 32-63 of the R_1 general register contribute to the 32-bit checksum. The program normally should set those contents to all zeros before issuing the CHECKSUM instruction.

2. A 16-bit checksum is used in, for example, the TCP/IP application. The following program can be executed after the CHECKSUM instruction to produce in bit positions 32-63 of general register R_2 a 16-bit checksum from the 32-bit checksum in bit positions 32-63 of general register R_1. The program is annotated to show the contents of bit positions 32-63 of the R_2 and $R_2 + 1$ registers after the execution of each instruction. The contents of bit positions 32-63 of the R_1 register are represented as A,B, meaning the value A in bit positions 32-47 and the value B in bit positions

48-63. The value C is a carry from A + B. Note that bit positions 32-63 of register $R_2 + 1$ are known to contain all zeros when CHECKSUM has set condition code 0.

Program		R_2 Bits 32-63	$R_2 + 1$ Bits 32-63
LR	R_2,R_1	A,B	0,0
SRDL	R_2,16	0,A	B,0
ALR	R_2,R_2+1	B,A	B,0
ALR	R_2,R_1	A+B+C,A+B	B,0
SRL	R_2,16	0,A+B+C	B,0

3. The CHECKSUM instruction may be used in computing hash values as illustrated in the following programming example. The variable KEY contains a string to be mapped into a slot in a hash table. The variable SIZE is a prime number designating the size of the hash table. The value of SIZE is determined by (a) the number of strings to be hashed into the table divided by the acceptable number of hash collisions, and (b) a value that is not too close to a power of two. Following the DIVIDE (D) instruction, the remainder in register 0 represents the resulting hash value.

```
        SR      1,1         Zero accumulator
        LA      2,KEY       Point to string
        LA      3,L'KEY     Load string length
LOOP    CKSM    1,2         Compute checksum
        BNZ     LOOP        Repeat if not done
        SR      0,0         Zero for divide
        D       0,SIZE      Compute hash value
        …
KEY     DS      CL64        String to be hashed
SIZE    DS      F           Size of hash table
```

4. In the access-register mode, access register 0 designates the primary address space regardless of the contents of access register 0.

5. The storage-operand references of CHECKSUM may be multiple-access references. (See “Storage-Operand Consistency” on page 5-133.)

6. Figure 7-4 on page 7-53 contains a summary of the operation.

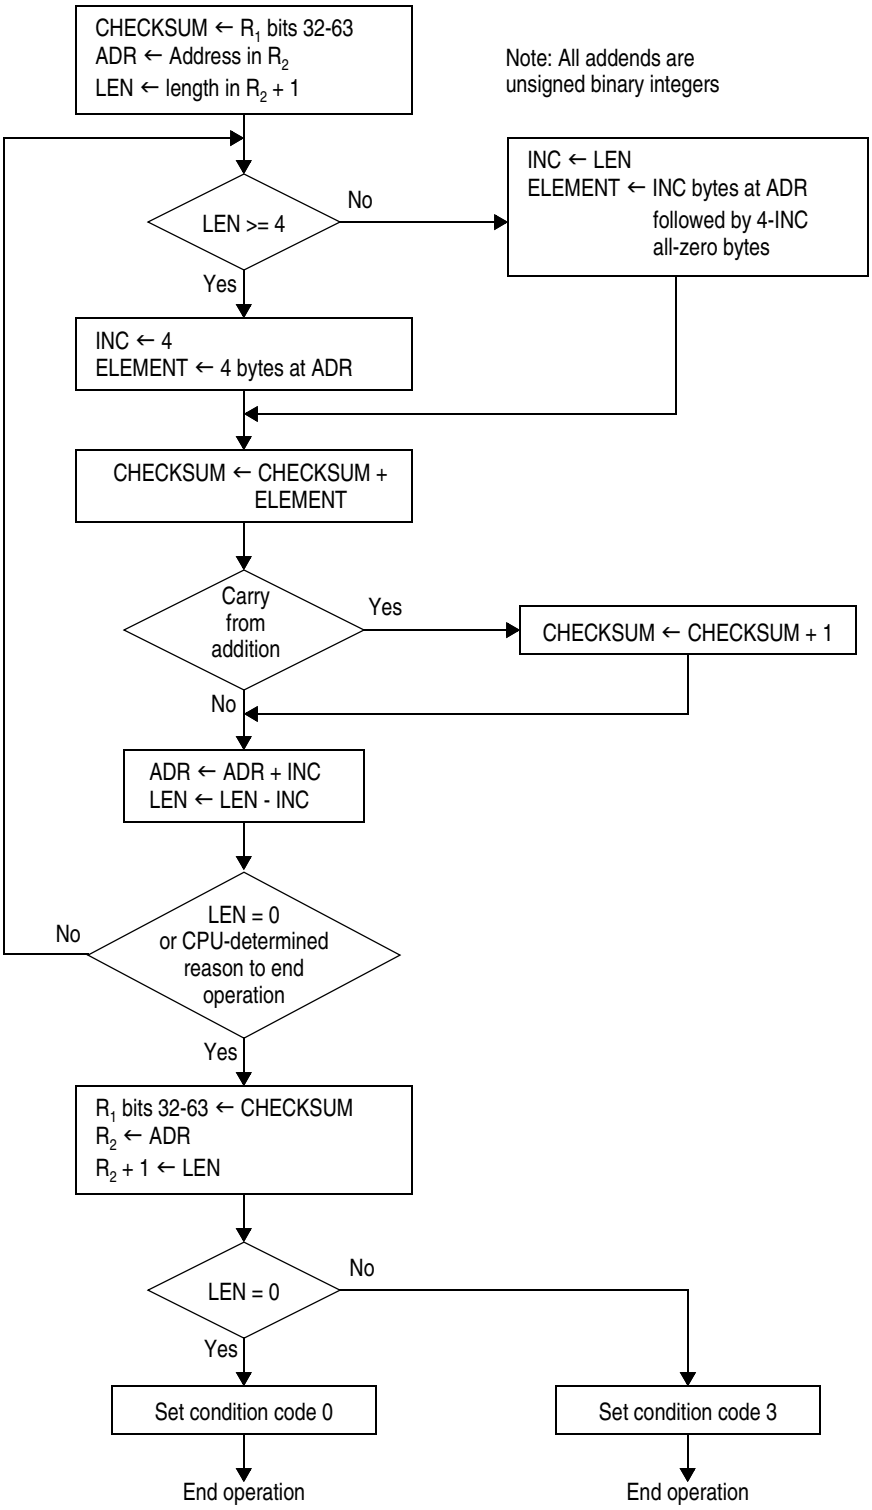


Figure 7-4. Execution of CHECKSUM

CIPHER MESSAGE

KM R_1,R_2 [RRE]

CIPHER MESSAGE WITH CHAINING

KMC R_1,R_2 [RRE]

A function specified by the function code in general register 0 is performed.

Bits 16-23 of the instruction are ignored.

Function Code (FC): Bit positions 57-63 of general register 0 contain the function code. Figure 7-5 and Figure 7-6 show the assigned function codes for CIPHER MESSAGE and CIPHER MESSAGE WITH CHAINING, respectively. When the message-security-assist extension 10 is installed, function codes 82, 84, 90, and 92 are valid for CIPHER MESSAGE. When the message-security-assist extension 13 is installed, function code 127 is valid for CIPHER MESSAGE and CIPHER MESSAGE WITH CHAINING.All other function codes are unassigned.

Modifier (M): When the function code in bit positions 57-63 of general register 0 is nonzero, bit position 56 of general register 0 contains a modifier bit indicating encryption or decryption is to be performed by the function. When the M bit is zero, the function performs encryption of the second operand; when the M bit is one, the function performs decryption of the second operand. The M bit is meaningful for cipher functions only; it is ignored for all other functions.

Bit positions 0-31 of general register 0 are ignored for all function codes. When the function code in bit positions 57-63 of general register 0 specifies function code 0-3, 9-11, 18-20, 26-28, 50, 52, 58, or 60 of CIPHER MESSAGE or function code 0-3, 9-11, 18-20, 26-28, or 67 of CIPHER MESSAGE WITH CHAINING, bit positions 32-55 of general register 0 are ignored. When the function code in bit positions 57-63 of general register 0 of CIPHER MESSAGE specifies a full XTS function (function code 82, 84, 90, or 94) and the specified full XTS function code is valid, bit positions 32-55 of general register 0 are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.

General register 1 contains the logical address of the leftmost byte of the parameter block in storage. In the 24-bit addressing mode, the contents of bit positions 40-63 of general register 1 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of general register 1 constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register 1 constitute the address.

The function codes for CIPHER MESSAGE are as follows.

Code	Function	Parm. Block Size (bytes)	Data Block Size (bytes)
0	KM-Query *	16	—
1	KM-DEA *	8	8
2	KM-TDEA-128 *	16	8
3	KM-TDEA-192 *	24	8

Code	Function	Parm. Block Size (bytes)	Data Block Size (bytes)
67	KMC-PRNG	32	8
127	KMC-Query-Authentication-Information	V	—

Explanation:

— Not applicable
* Function is also defined in the ESA/390 architectural mode and the ESA/390-compatibility mode. It is unpredictable whether other function codes are available in the ESA/390-compatibility mode.
V Variable parameter block size. See each format-x parameter block for the exact size of that parameter block.

Figure 7-6. Function Codes for CIPHER MESSAGE WITH CHAINING (Continued) (Part 2 of 2)

All other function codes are unassigned.

The query function provides the means of indicating the availability of the other functions. The contents of general registers R_1, R_2, and $R_2 + 1$ are ignored for the query function.

The query-authentication-information function provides the information that can be used by the program to authenticate the running instruction's firmware code level (IFCL) currently installed on the model. The contents of general registers R_1, R_2, and $R_2 + 1$ are ignored for the query-authentication-information function.

For all other functions, the second operand is ciphered as specified by the function code using a cryptographic key in the parameter block, and the result is placed in the first-operand location. For CIPHER MESSAGE WITH CHAINING, ciphering also uses an initial chaining value in the parameter block, and the chaining value is updated as part of the operation. For XTS functions, ciphering also uses either an XTS parameter or the next alpha power in the parameter block, and the XTS parameter is updated as part of the operation.

For KM-XTS functions, the XTS parameter in the parameter block is in little-endian format. For KM-full-XTS functions, the tweak value and the next alpha power in the parameter block are in little-endian format.

The R_1 field designates a general register and must designate an even-numbered register other than general register 0; otherwise, a specification exception is recognized. The R_2 field designates an even-odd pair of general registers and must designate an even-numbered register other than general register 0; otherwise, a specification exception is recognized.

The location of the leftmost byte of the first and second operands is specified by the contents of the R_1 and R_2 general registers, respectively. The number of bytes in the second-operand location is specified in general register $R_2 + 1$. The first operand is the same length as the second operand.

As part of the operation, the addresses in general registers R_1 and R_2 are incremented by the number of bytes processed, and the length in general register $R_2 + 1$ is decremented by the same number. The formation and updating of the addresses and length is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers R_1 and R_2 constitute the addresses of the first and second operands, respectively, and the contents of bit positions 0-39 are ignored; bits 40-63 of the updated addresses replace the corresponding bits in general registers R_1 and R_2, carries out of bit position 40 of the updated address are ignored, and the contents of bit positions 32-39 of general registers R_1 and R_2 are set to zeros. In the 31-bit addressing mode, the contents of bit positions 33-63 of general registers R_1 and R_2 constitute the addresses of the first and second operands, respectively, and the contents of bit positions 0-32 are ignored; bits 33-63 of the updated addresses replace the corresponding bits in general registers R_1 and R_2, carries out of bit position 33 of the updated address are ignored, and the content of bit position 32 of general registers R_1 and R_2 is set to zero. In the 64-bit addressing mode, the contents of bit positions 0-63 of general registers R_1 and R_2 constitute the addresses of the first and second operands, respectively; bits 0-63 of the updated addresses replace the contents of general registers R_1 and R_2, and carries out of bit position 0 are ignored.

In both the 24-bit and the 31-bit addressing modes, the contents of bit positions 32-63 of general register $R_2 + 1$ form a 32-bit unsigned binary integer which specifies the number of bytes in the first and second operands, and the contents of bit positions 0-31 are ignored; bits 32-63 of the updated value replace the corresponding bits in general register $R_2 + 1$. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register $R_2 + 1$ form a 64-bit unsigned binary integer which specifies the number of bytes in the first and second operands; and the updated value replaces the contents of general register $R_2 + 1$.

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers R_1, R_2, and $R_2 + 1$, always remain unchanged.

Figure 7-7 on page 7-56 shows the contents of the general registers just described.

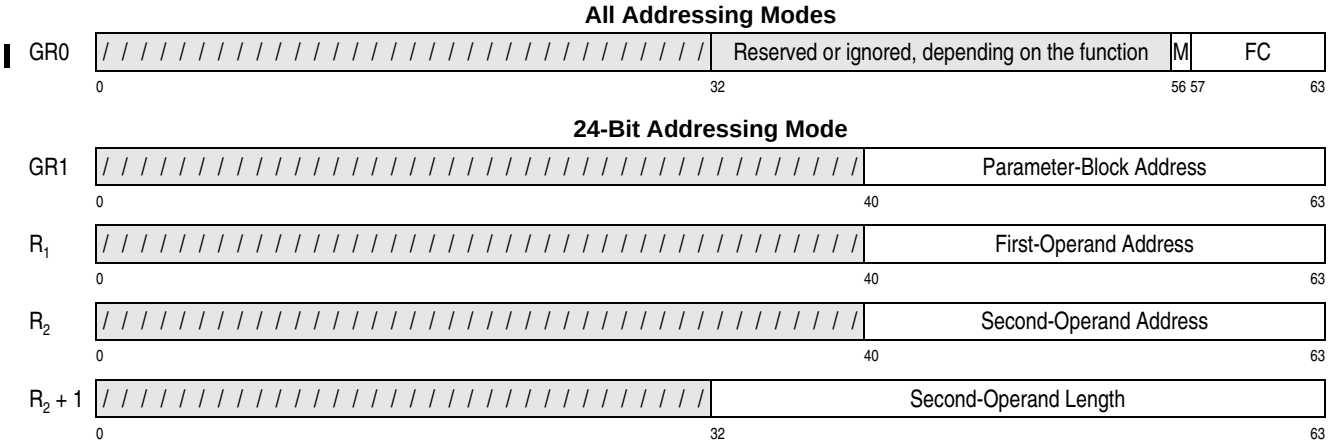

Figure 7-7. General Register Assignment for KM and KMC (Part 1 of 2)

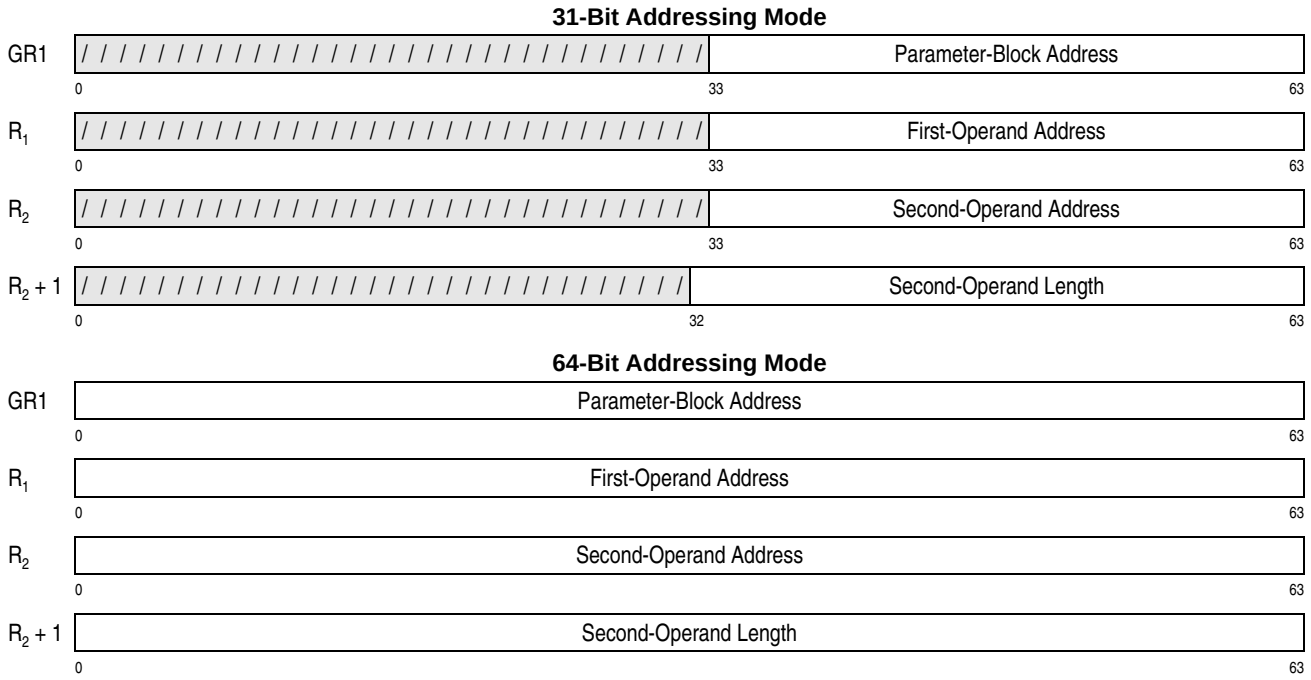

Figure 7-7. General Register Assignment for KM and KMC (Part 2 of 2)

In the access-register mode, access registers 1, R_1, and R_2 specify the address spaces containing the parameter block, first, and second operands, respectively.

The result is obtained as if processing starts at the left end of both the first and second operands and proceeds to the right, block by block. The cipher operation is ended when the number of bytes in the second operand as specified in general register $R_2 + 1$ have been processed and placed at the first-operand location or when a CPU-determined number of blocks that is less than the length of the second operand have been processed. The CPU-determined number of blocks depends on the model, and may be a different number each time the instruction is executed. The CPU-determined number of blocks is usually nonzero. In certain unusual situations, this number may be zero, and condition code 3 may be set with no progress. However, the CPU protects against endless reoccurrence of this no-progress case.

If the CPU is enabled to update counters in the cryptography-counter set, then subsequent to processing all bytes of the second operand, the appropriate counter is updated.

The results in the first-operand location, the chaining-value field, the XTS parameter field, or the next alpha power field are unpredictable if any of the following situations occur:

1. The cryptographic-key field or the encrypted cryptographic-key field overlaps any portion of the first operand.
2. The XTS parameter or next alpha power field overlaps any portion of the first operand or second operand.
3. The chaining-value field overlaps any portion of the first operand or the second operand.
4. The first and second operands overlap destructively. Operands are said to overlap destructively when the first-operand location would be used as a source after data would have been moved into it, assuming processing to be performed from left to right and one byte at a time.

Normal completion occurs when the cipher operation has ended and, when applicable, a counter in the cryptography-counter set has been updated. Partial completion occurs when a CPU-determined number of blocks that is less than the length of the second operand have been processed or when the CPU is enabled to update a counter in the cryptography-counter set and the appropriate counter has not yet been updated.

When the operation ends due to normal completion, condition code 0 is set and the resulting value in $R_2 + 1$ is zero. When the operation ends due to partial completion, condition code 3 is set. In this case, if the CPU is enabled to update counters in the cryptography-counter set, all of the second operand has been processed, and the appropriate counter is not accessible, then the resulting value placed in general register $R_2 + 1$ is zero; otherwise the resulting value placed in general register $R_2 + 1$ is nonzero.

A PER storage-alteration event may be recognized both for the first-operand location and for the portion of the parameter block that is stored. A PER zero-address-detection event may be recognized for the first- and second-operand locations and for the parameter block. When PER events are detected for one or more of these locations, it is unpredictable which location is identified in the PER access identification (PAID) and PER ASCE ID (AI).

When a storage-alteration PER event is recognized, fewer than 4K additional bytes are stored into the first-operand locations before the event is reported.

When the second-operand length is initially zero, the following occurs. The parameter block, first, and second operands are not accessed, and general registers R_1, R_2, and $R_2 + 1$ are not changed. If the CPU is not enabled to update counters in the cryptography-counter set, then condition code 0 is set. If the CPU is enabled to update counters in the cryptography-counter set, and the appropriate counter is accessible, then the appropriate counter is updated and condition code 0 is set. If the CPU is enabled to update counters in the cryptography-counter set, and the appropriate counter is not accessible, then the condition code remains unchanged and an access exception is recognized for the location of the appropriate counter.

When the contents of the R_1 and R_2 fields are the same, the contents of the designated registers are incremented only by the number of bytes processed, not by twice the number of bytes processed.

As observed by this CPU, other CPUs, and channel programs, references to the parameter block and storage operands may be multiple-access references, accesses to these storage locations are not necessarily block-concurrent, and the sequence of these accesses or references is undefined.

In certain unusual situations, instruction execution may complete by setting condition code 3 without updating the registers, the chaining value, and the XTS parameter to reflect the last unit of the first and second operands processed. The size of the unit processed in this case depends on the situation and the model, but is limited such that the portion of the first and second operands which have been processed and not reported do not overlap in storage. In all cases, change bits are set and PER storage-alteration events are reported, when applicable, for all first-operand locations processed.

For functions that perform a comparison of the wrapping-key verification pattern field in the parameter block with the wrapping-key verification-pattern register, it is unpredictable whether access exceptions and PER zero-address-detection events are recognized for the first and second operands when the comparison results in a mismatch.

Access exceptions may be reported for a larger portion of an operand than is processed in a single execution of the instruction; however, access exceptions are not recognized for locations beyond the length of an operand nor for locations more than 4 K-bytes beyond the current location being processed. For full XTS functions, the entire parameter block may be tested for store-type accesses even though part of it may not be stored. For all other functions, only the portion of the parameter block that is stored may be tested for store-type accesses.

Symbols Used in Function Descriptions

The following symbols are used in the subsequent description of the CIPHER MESSAGE and CIPHER MESSAGE WITH CHAINING functions. For data-encryption-algorithm (DEA) functions, the DEA-key-parity bit in each byte of the DEA key is ignored, and the operation proceeds normally, regardless of the DEA-key parity of the key.

The GCM (Galois/counter mode) multiplication operation may also be used instead of the XTS multiplication operation but it requires reinterpretation of the following inputs and outputs:

- The XTS parameter (initial XTSP) from the parameter block or TAU is treated as if it is already in little-endian format as input to the GCM multiplication operation. However, the 8 bits in each byte of the XTS parameter or TAU must be converted to bit-reversed format.

- The multiplier 2 must be converted to little-endian format and the 8 bits in each byte of the multiplier 2 must be converted to bit-reversed format. In other words, the multiplier input to the GCM multiplication operation is: 4000000000000000 0000000000000000 hex.
- The GCM multiplication operation is performed as described in Reference [17.] on page xxxii.
- The 8 bits in each byte of the product (output) of the GCM multiplication operation must be converted to bit-reversed format. This is the final result that yields the final XTS parameter (Output XTSP) or TAU.
- Figure 7-41 on page 7-68 shows an example of each field of the XTS multiplication operation mentioned above.

Further description of the data-encryption algorithm may be found in Reference [13.] on page xxxii. Further description of the AES standard may be found in Reference [14.] on page xxxii. Further description of the XTS multiplication operation over GF(2^{128}) may be found in Reference [43.] on page xxxiii. Further description of the GCM multiplication over GF(2^{128}) may be found in Reference [17.] on page xxxii.

KM-Query (KM Function Code 0)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-7 on page 7-56.

The parameter block used for the function has the following format:

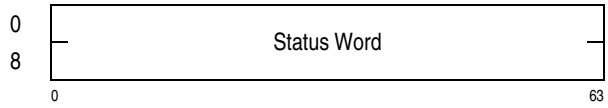

Figure 7-14. Parameter Block for KM-Query

A 128-bit status word is stored in the parameter block. Bits 0-127 of this field correspond to function codes 0-127, respectively, of the CIPHER MESSAGE instruction. When a bit is one, the corresponding function is installed; otherwise, the function is not installed.

Condition code 0 is set when execution of the KM-Query function completes; condition codes 1 and 3 are not applicable to this function.

KM-DEA (KM Function Code 1)

KM-Encrypted-DEA (KM Function Code 9)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-7 on page 7-56.

The parameter block used for the KM-DEA function has the following format:

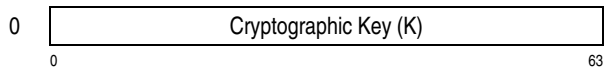

Figure 7-15. Parameter Block for KM-DEA

For the KM-DEA function, the cryptographic key is in byte offsets 0-7 of the parameter block.

The parameter block used for the KM-Encrypted-DEA function has the following format:

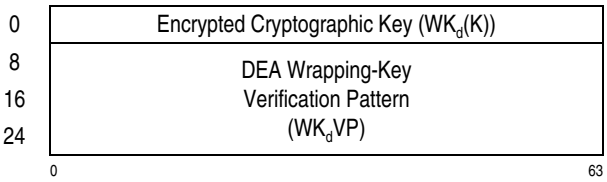

Figure 7-16. Parameter Block for KM-Encrypted-DEA

For the KM-Encrypted-DEA function, the contents of byte offsets 8-31 of the parameter block are compared with the contents of the DEA wrapping-key verification-pattern register. If they mismatch, the first-operand and parameter-block locations remain unchanged, and the operation is completed by setting condition code 1. If they match, the contents of byte offsets 0-7 of the parameter block are deciphered using the DEA wrapping key to obtain the 64-bit cryptographic key. (See the section, “Protection of Cryptographic Keys” on page 7-490, for details.)

The following description applies to both functions.

When the modifier bit in general register 0 is zero, an encipher operation is performed. The 8-byte plaintext blocks (P1, P2, …, Pn) in operand 2 are enciphered using the DEA algorithm with the 64-bit cryptographic key. Each plaintext block is independently enciphered; that is, the encipher operation is performed without chaining. The ciphertext blocks (C1, C2, …, Cn) are stored in operand 1. The operation is shown in Figure 7-17.

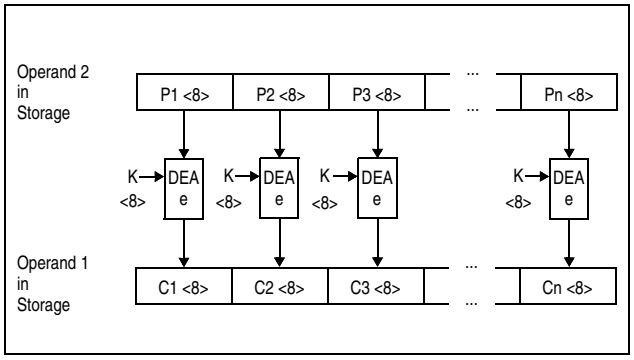

Figure 7-17. KM-DEA Encipher Operation Using 64-Bit Key

When the modifier bit in general register 0 is one, a decipher operation is performed. The 8-byte ciphertext blocks (C1, C2, …, Cn) in operand 2 are deciphered using the DEA algorithm with the 64-bit cryptographic key. Each ciphertext block is independently deciphered; that is, the decipher operation is performed without chaining. The plaintext blocks (P1, P2, …, Pn) are stored in operand 1. The operation is shown in Figure 7-18.

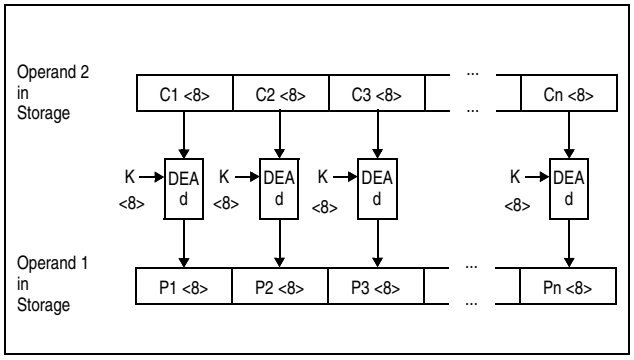

Figure 7-18. KM-DEA Decipher Operation Using 64-Bit Key

KM-TDEA-128 (KM Function Code 2)

KM-Encrypted-TDEA-128 (KM Function Code 10)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-7 on page 7-56.

The parameter block used for the KM-TDEA-128 function has the following format:

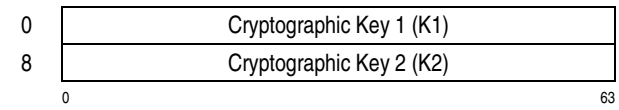

Figure 7-19. Parameter Block for KM-TDEA-128

For the KM-TDEA-128 function, the cryptographic key is in byte offsets 0-15 of the parameter block.

The parameter block used for the KM-Encrypted-TDEA-128 function has the following format:

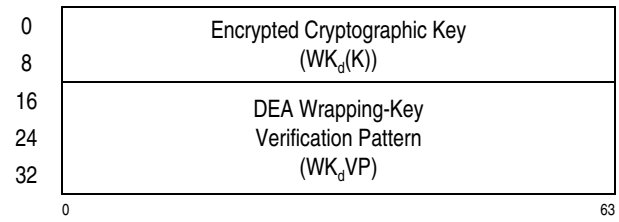

Figure 7-20. Parameter Block for KM-Encrypted-TDEA-128

For the KM-Encrypted-TDEA-128 function, the contents of byte offsets 16-39 of the parameter block are compared with the contents of the DEA wrapping-key verification-pattern register. If they mismatch, the first-operand and parameter-block locations remain unchanged, and the operation is completed by setting condition code 1. If they match, the contents of byte offsets 0-15 of the parameter block are deciphered using the DEA wrapping key to obtain the 128-bit cryptographic key, K = K1 || K2, where K1 is the leftmost 64 bits of K and K2 is the rightmost 64 bits of K. (See the section, “Protection of Cryptographic Keys” on page 7-490, for details.)

The following description applies to both functions.

When the modifier bit in general register 0 is zero, an encipher operation is performed. The 8-byte plaintext blocks (P1, P2, …, Pn) in operand 2 are enciphered using the TDEA (triple DEA) algorithm with the two 64-bit cryptographic keys. Each plaintext block is independently enciphered; that is, the encipher operation is performed without chaining. The ciphertext

blocks (C1, C2, …, Cn) are stored in operand 1. The operation is shown in Figure 7-21.

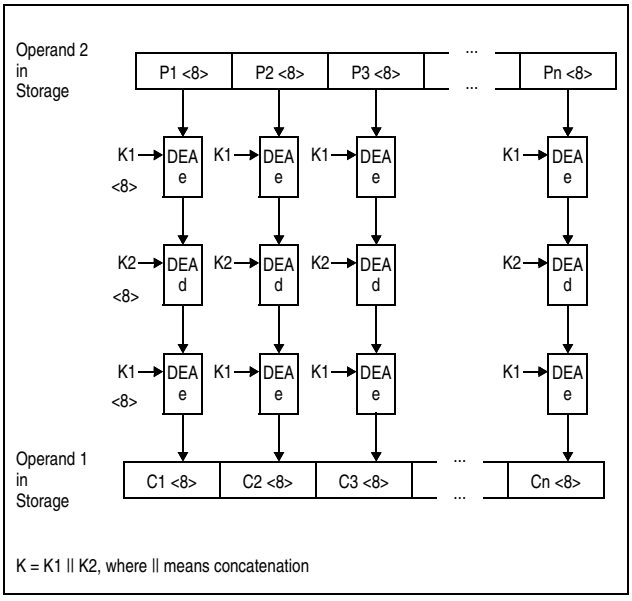

Figure 7-21. KM-TDEA Encipher Operation Using 128-Bit Key

When the modifier bit in general register 0 is one, a decipher operation is performed. The 8-byte ciphertext blocks (C1, C2, …, Cn) in operand 2 are deciphered using the TDEA algorithm with the two 64-bit cryptographic keys. Each ciphertext block is independently deciphered; that is, the decipher operation is performed without chaining. The plaintext blocks (P1, P2, …, Pn) are stored in operand 1. The operation is shown in Figure 7-22.

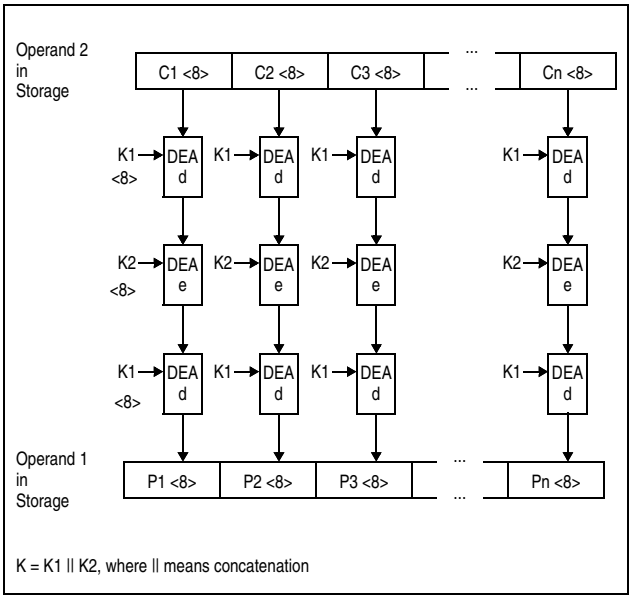

Figure 7-22. KM TDEA Decipher Operation Using 128-Bit Key

KM-TDEA-192 (KM Function Code 3)

KM-Encrypted-TDEA-192 (KM Function Code 11)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-7 on page 7-56.

The parameter block used for the KM-TDEA-192 function has the following format:

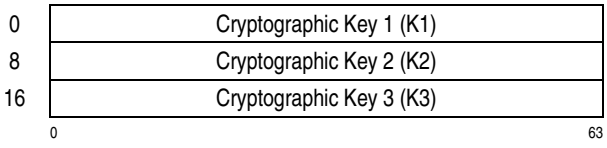

Figure 7-23. Parameter Block for KM-TDEA-192

For the KM-TDEA-192 function, the cryptographic key is in byte offsets 0-23 of the parameter block.

The parameter block used for the KM-Encrypted-TDEA-192 function has the following format:

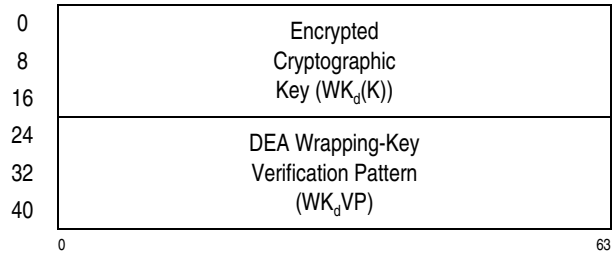

Figure 7-24. Parameter Block for KM-Encrypted-TDEA-192

For the KM-Encrypted-TDEA-192 function, the contents of byte offsets 24-47 of the parameter block are compared with the contents of the DEA wrapping-key verification-pattern register. If they mismatch, the first-operand and parameter-block locations remain unchanged, and the operation is completed by setting condition code 1. If they match, the contents of byte offsets 0-23 of the parameter block are deciphered using the DEA wrapping key to obtain the 192-bit cryptographic key, K = K1 || K2 || K3, where K1 is the leftmost 64 bits of K, K2 is the middle 64 bits of K, and K3 is the rightmost 64 bits of K. (See the section, “Protection of Cryptographic Keys” on page 7-490, for details.)

The following description applies to both functions.

When the modifier bit in general register 0 is zero, an encipher operation is performed. The 8-byte plaintext blocks (P1, P2, …, Pn) in operand 2 are enciphered using the TDEA algorithm with the three 64-bit cryptographic keys. Each plaintext block is independently enciphered; that is, the encipher operation is performed without chaining. The ciphertext blocks (C1, C2, …, Cn) are stored in operand 1. The operation is shown in Figure 7-25.

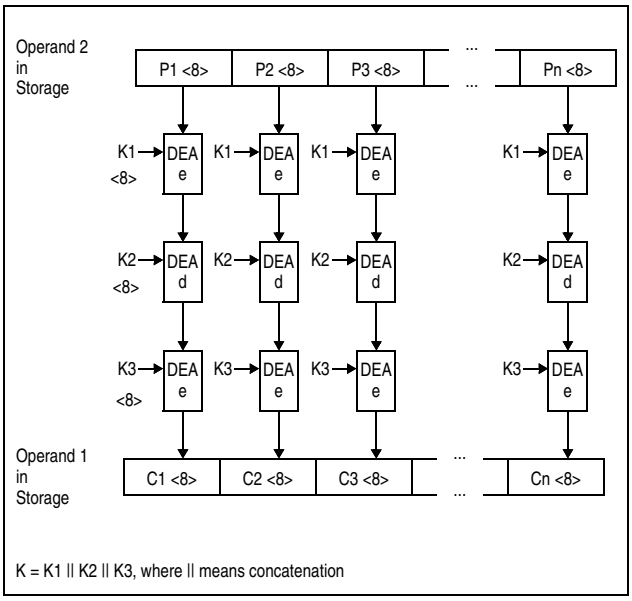

Figure 7-25. KM TDEA Encipher Operation Using 192-Bit Key

When the modifier bit in general register 0 is one, a decipher operation is performed. The 8-byte ciphertext blocks (C1, C2, …, Cn) in operand 2 are deciphered using the TDEA algorithm with the three 64-bit cryptographic keys. Each ciphertext block is independently deciphered; that is, the decipher operation is performed without chaining. The plaintext

blocks (P1, P2, …, Pn) are stored in operand 1. The operation is shown in Figure 7-26.

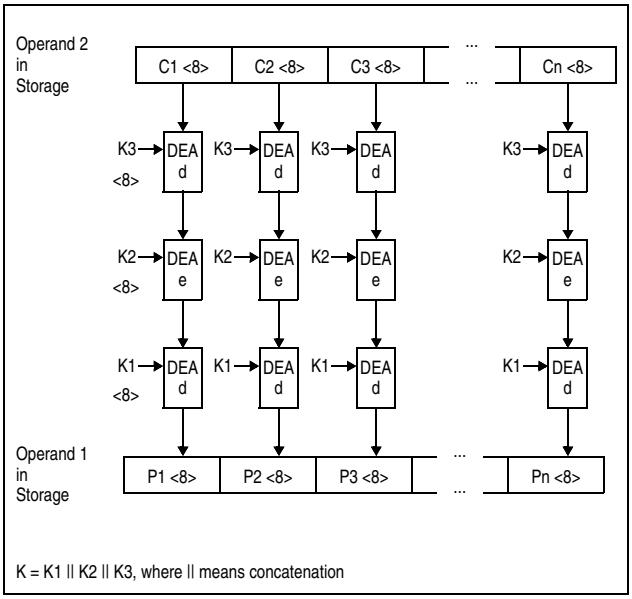

Figure 7-26. KM TDEA Decipher Operation Using 192-Bit Key

KM-AES-128 (KM Function Code 18)

KM-Encrypted-AES-128 (KM Function Code 26)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-7 on page 7-56.

The parameter block used for the KM-AES-128 function has the following format:

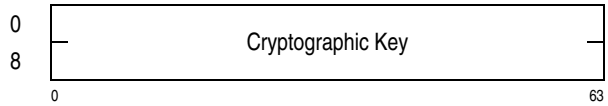

Figure 7-27. Parameter Block for KM-AES-128

For the KM-AES-128 function, the cryptographic key is in byte offsets 0-15 of the parameter block.

The parameter block used for the KM-encrypted-AES-128 function has the following format:

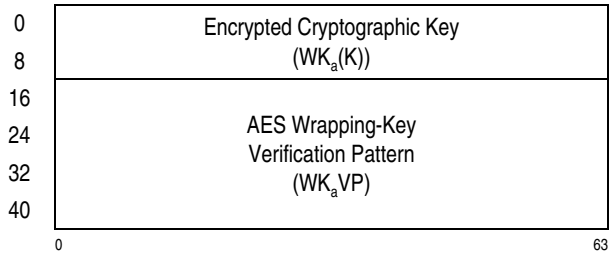

Figure 7-28. Parameter Block for KM-Encrypted-AES-128

For the KM-Encrypted-AES-128 function, the contents of byte offsets 16-47 of the parameter block are compared with the contents of the AES wrapping-key verification-pattern register. If they mismatch, the first-operand and parameter-block locations remain unchanged, and the operation is completed by setting condition code 1. If they match, the contents of byte offsets 0-15 of the parameter block are deciphered using the AES wrapping key to obtain the 128-bit cryptographic key, K. (See the section, “Protection of Cryptographic Keys” on page 7-490, for details.)

The following description applies to both functions.

When the modifier bit in general register 0 is zero, an encipher operation is performed. The 16-byte plaintext blocks (P1, P2, …, Pn) in operand 2 are enciphered using the AES algorithm with the 128-bit cryptographic key. Each plaintext block is independently enciphered; that is, the encipher operation is performed without chaining. The ciphertext blocks (C1, C2, …, Cn) are stored in operand 1. The operation is shown in Figure 7-29.

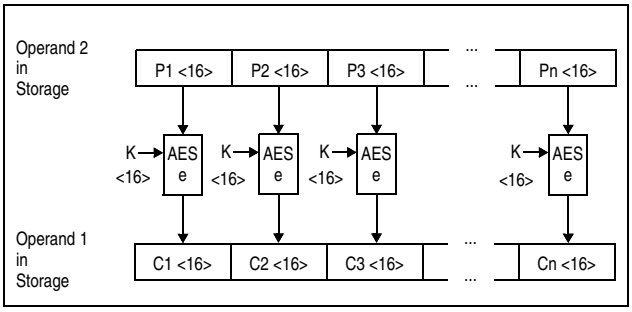

Figure 7-29. KM-AES Encipher Operation Using 128-Bit Key

When the modifier bit in general register 0 is one, a decipher operation is performed. The 16-byte ciphertext blocks (C1, C2, …, Cn) in operand 2 are deci-

phered using the AES algorithm with the 128-bit cryptographic key. Each ciphertext block is independently deciphered; that is, the decipher operation is performed without chaining. The plaintext blocks (P1, P2, …, Pn) are stored in operand 1. The operation is shown in Figure 7-30.

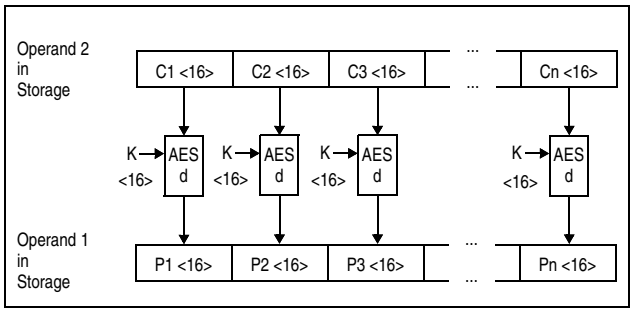

Figure 7-30. KM-AES Decipher Operation Using 128-Bit Key

KM-AES-192 (KM Function Code 19)

KM-Encrypted-AES-192 (KM Function Code 27)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-7 on page 7-56.

The parameter block used for the KM-AES-192 function has the following format:

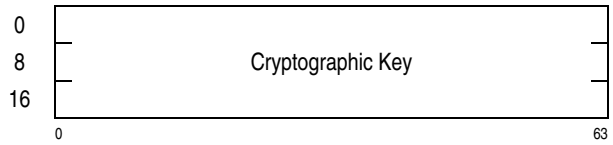

Figure 7-31. Parameter Block for KM-AES-192

For the KM-AES-192 function, the cryptographic key is in byte offsets 0-23 of the parameter block.

The parameter block used for the KM-Encrypted-AES-192 function has the following format:

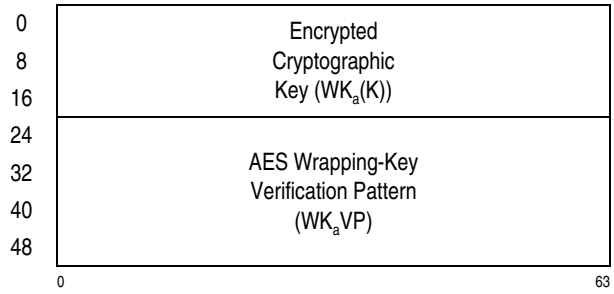

Figure 7-32. Parameter Block for KM-Encrypted-AES-192

For the KM-Encrypted-AES-192 function, the contents of byte offsets 24-55 of the parameter block are compared with the contents of the AES wrapping-key verification-pattern register. If they mismatch, the first-operand and parameter-block locations remain unchanged, and the operation is completed by setting condition code 1. If they match, the contents of byte offsets 0-23 of the parameter block are deciphered using the AES wrapping key to obtain the 192-bit cryptographic key, K. (See the section, “Protection of Cryptographic Keys” on page 7-490, for details.)

The following description applies to both functions.

When the modifier bit in general register 0 is zero, an encipher operation is performed. The 16-byte plaintext blocks (P1, P2, …, Pn) in operand 2 are enciphered using the AES algorithm with the 192-bit cryptographic key. Each plaintext block is independently enciphered; that is, the encipher operation is performed without chaining. The ciphertext blocks (C1, C2, …, Cn) are stored in operand 1. The operation is shown in Figure 7-33.

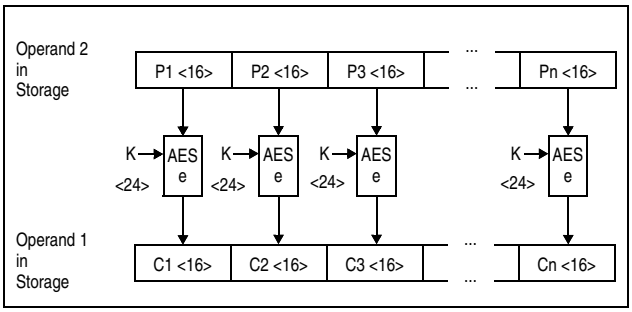

Figure 7-33. KM AES Encipher Operation Using 192-Bit Key

When the modifier bit in general register 0 is one, a decipher operation is performed. The 16-byte ciphertext blocks (C1, C2, …, Cn) in operand 2 are deciphered using the AES algorithm with the 192-bit cryptographic key. Each ciphertext block is independently deciphered; that is, the decipher operation is performed without chaining. The plaintext blocks (P1, P2, …, Pn) are stored in operand 1. The operation is shown Figure 7-34.

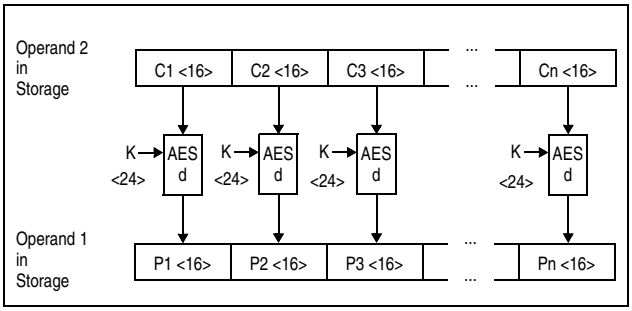

Figure 7-34. KM AES Decipher Operation Using 192-Bit Key

KM-AES-256 (KM Function Code 20)

KM-Encrypted-AES-256 (KM Function Code 28)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-7 on page 7-56.

The parameter block used for the KM-AES-256 function has the following format:

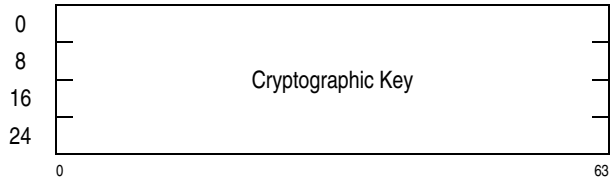

Figure 7-35. Parameter Block for KM-AES-256

For the KM-AES-256 function, the cryptographic key is in byte offsets 0-31 of the parameter block.

The parameter block used for the KM-Encrypted-AES-256 function has the following format:

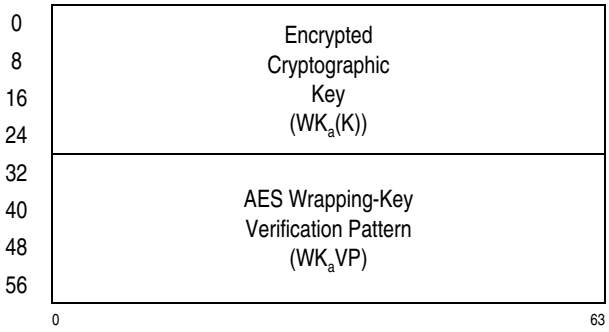

Figure 7-36. Parameter Block for KM-Encrypted-AES-256

For the KM-Encrypted-AES-256 function, the contents of byte offsets 32-63 of the parameter block are compared with the contents of the AES wrapping-key verification-pattern register. If they mismatch, the first-operand and parameter-block locations remain unchanged, and the operation is completed by setting condition code 1. If they match, the contents of byte offsets 0-31 of the parameter block are deciphered using the AES wrapping key to obtain the 256-bit cryptographic key, K. (See the section, “Protection of Cryptographic Keys” on page 7-490, for details.)

The following description applies to both functions.

When the modifier bit in general register 0 is zero, an encipher operation is performed. The 16-byte plaintext blocks (P1, P2, …, Pn) in operand 2 are enciphered using the AES algorithm with the 256-bit cryptographic key. Each plaintext block is independently enciphered; that is, the encipher operation is performed without chaining. The ciphertext blocks (C1, C2, …, Cn) are stored in operand 1. The operation is shown in Figure 7-37.

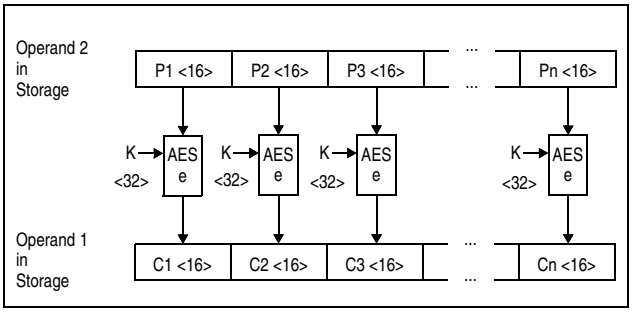

Figure 7-37. KM AES Encipher Operation Using 256-Bit Key

When the modifier bit in general register 0 is one, a decipher operation is performed. The 16-byte ciphertext blocks (C1, C2, …, Cn) in operand 2 are deciphered using the AES algorithm with the 256-bit cryptographic key. Each ciphertext block is independently deciphered; that is, the decipher operation is performed without chaining. The plaintext blocks (P1, P2, …, Pn) are stored in operand 1. The operation is shown in Figure 7-38.

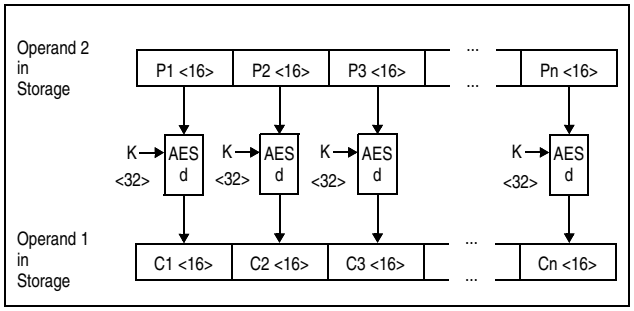

Figure 7-38. KM AES Decipher Operation Using 256-Bit Key

KM-XTS-AES-128 (KM Function Code 50)

KM-XTS-Encrypted-AES-128 (KM Function Code 58)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-7 on page 7-56.

The parameter block used for the KM-XTS-AES-128 function has the following format:

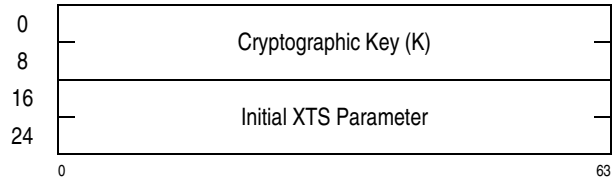

Figure 7-39. Parameter Block for KM-XTS-AES-128

For the KM-XTS-AES-128 function, the cryptographic key is in byte offsets 0-15 of the parameter block, and the initial XTS parameter is in bytes offsets 16-31 of the parameter block.

The parameter block used for the KM-XTS-encrypted-AES-128 function has the following format:

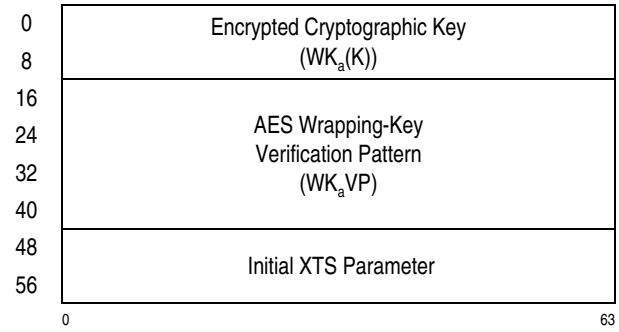

Figure 7-40. Parameter Block for KM-XTS-Encrypted-AES-128

For the KM-XTS-Encrypted-AES-128 function, the contents of byte offsets 16-47 of the parameter block are compared with the contents of the AES wrapping-key verification-pattern register. If they mismatch, the first-operand and parameter-block locations remain unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 48-63 of the parameter block contain the initial XTS parameter, and the contents of byte offsets 0-15 of the parameter block are deciphered using the AES wrapping key to obtain the 128-bit cryptographic key. (See the section “Protection of Cryptographic Keys” on page 7-490 for details.)

The following description applies to both functions.

When the modifier bit in general register 0 is zero, an encipher operation is performed. The 16-byte plaintext blocks (P1, P2, …, Pn) in operand 2 are enciphered using the AES-encryption algorithm with the 128-bit cryptographic key and the 128-bit initial XTS parameter.

Except for the first block, the XTS parameter used is the XTS parameter for the previous block multiplied by the value of 2 in GF(2^{128}). To encrypt the first block of plaintext, the initial XTS parameter is used.

The XTS parameter for each block is exclusive-ORed with the corresponding plaintext block. The result of the exclusive-OR operation is then encrypted using the AES-encryption algorithm with the 128-bit cryptographic key. The result of the encryption is then exclusive-ORed with the XTS parameter to produce the ciphertext block. The XTS parameter for this block is multiplied by the value of 2 in GF(2^{128}) to

obtain the XTS parameter for the next block. The operation is shown in Figure 7-41.

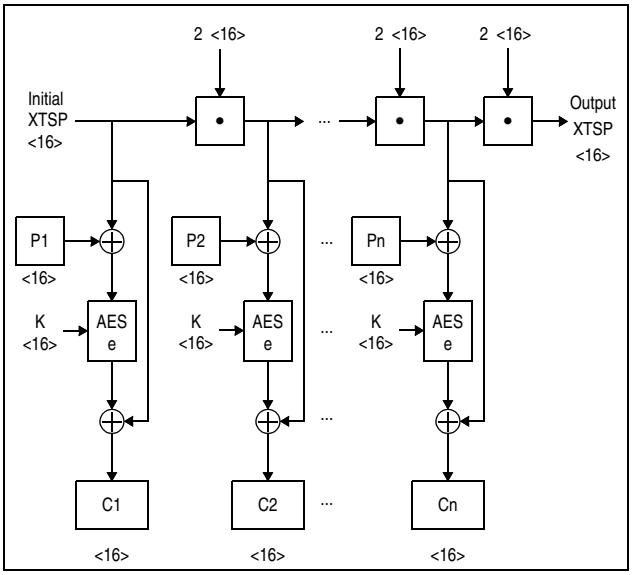

Figure 7-41. KM-XTS-AES-128 Encipher Operation

The ciphertext blocks (C1, C2, …, Cn) are stored in operand 1. The result of the final GCM multiplication, called the output XTS parameter (output XTSP), is stored into the initial XTS parameter field of the parameter block.

When the modifier bit in general register 0 is one, a decipher operation is performed. The 16-byte ciphertext blocks (C1, C2, …, Cn) in operand 2 are deciphered using the AES-decryption algorithm with the 128-bit cryptographic key and the 128-bit initial XTS parameter.

Except for the first block, the XTS parameter used is the XTS parameter for the previous block multiplied by the value of 2 in GF(2^{128}). To decrypt the first block of ciphertext, the initial XTS parameter is used.

The XTS parameter for each block is exclusive-ORed with the corresponding ciphertext block. The result of the exclusive-OR operation is then decrypted using the AES-decryption algorithm with the 128-bit cryptographic key. The result of the encryption is then exclusive-ORed with the XTS parameter to produce the plaintext block. The XTS parameter for this block is multiplied by the value of 2 in GF(2^{128}) to obtain the XTS parameter for the next block. The operation is shown in Figure 7-42.

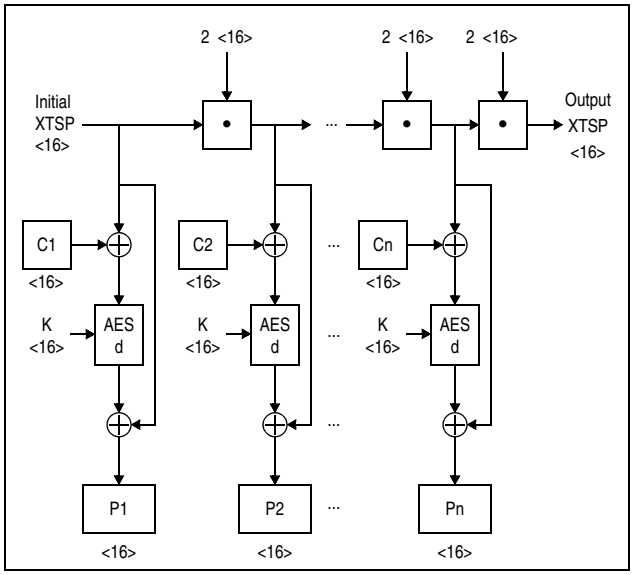

Figure 7-42. KM-XTS-AES-128 Decipher Operation

The plaintext blocks (P1, P2, …, Pn) are stored in operand 1. The result of the final GCM multiplication, called the output XTS parameter (output XTSP), is stored into the initial XTS parameter field of the parameter block.

KM-XTS-AES-256 (KM Function Code 52)

KM-XTS-Encrypted-AES-256 (KM Function Code 60)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-7 on page 7-56.

The parameter block used for the KM-XTS-AES-256 function has the following format:

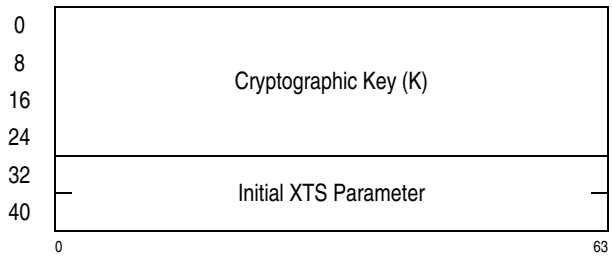

Figure 7-43. Parameter Block for KM-XTS-AES-256

For the KM-XTS-AES-256 function, the cryptographic key is in byte offsets 0-31 of the parameter block, and

the initial XTS parameter is in bytes offsets 32-47 of the parameter block.

The parameter block used for the KM-XTS-encrypted-AES-256 function has the following format:

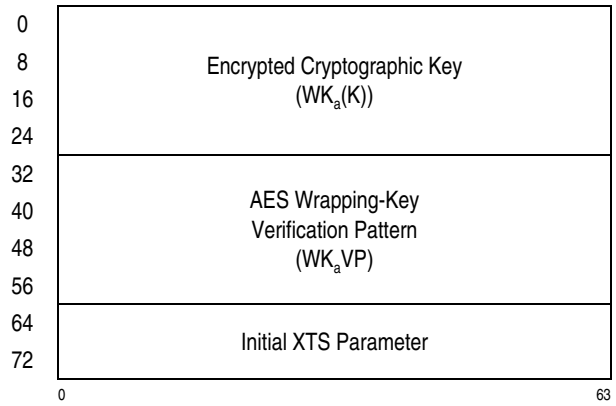

Figure 7-44. Parameter Block for KM-XTS-Encrypted-AES-256

For the KM-XTS-Encrypted-AES-256 function, the contents of byte offsets 32-63 of the parameter block are compared with the contents of the AES wrapping-key verification-pattern register. If they mismatch, the first-operand and parameter-block locations remain unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 64-79 of the parameter block contain the initial XTS parameter, and the contents of byte offsets 0-31 of the parameter block are deciphered using the AES wrapping key to obtain the 256-bit cryptographic key. (See the section "Protection of Cryptographic Keys" on page 7-490 for details.)

The following description applies to both functions.

When the modifier bit in general register 0 is zero, an encipher operation is performed. The 16-byte plaintext blocks (P1, P2, …, Pn) in operand 2 are enciphered using the AES-encryption algorithm with the 256-bit cryptographic key and the 128-bit initial XTS parameter.

Except for the first block, the XTS parameter used is the XTS parameter for the previous block multiplied by the value of 2 in GF(2^{128}). To encrypt the first block of plaintext, the initial XTS parameter is used.

The XTS parameter for each block is exclusive-ORed with the corresponding plaintext block. The result of the exclusive-OR operation is then encrypted using the AES-encryption algorithm with the 256-bit cryptographic key. The result of the encryption is then exclusive-ORed with the XTS parameter to produce the ciphertext block. The XTS parameter for this block is multiplied by the value of 2 in GF(2^{128}) to obtain the XTS parameter for the next block. The operation is shown in Figure 7-45.

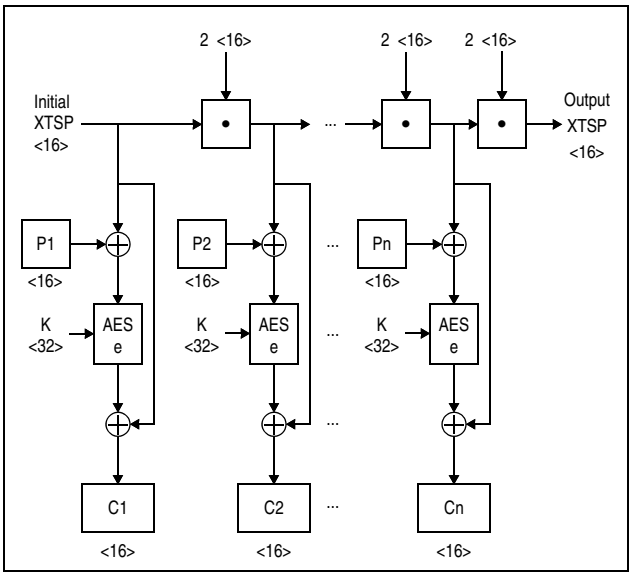

Figure 7-45. KM-XTS-AES-256 Encipher Operation

The ciphertext blocks (C1, C2, …, Cn) are stored in operand 1. The result of the final GCM multiplication, called the output XTS parameter (output XTSP), is stored into the initial XTS parameter field of the parameter block.

When the modifier bit in general register 0 is one, a decipher operation is performed. The 16-byte ciphertext blocks (C1, C2, …, Cn) in operand 2 are deciphered using the AES-decryption algorithm with the 256-bit cryptographic key and the 128-bit initial XTS parameter.

Except for the first block, the XTS parameter used is the XTS parameter for the previous block multiplied by the value of 2 in GF(2^{128}). To decrypt the first block of ciphertext, the initial XTS parameter is used.

The XTS parameter for each block is exclusive-ORed with the corresponding ciphertext block. The result of the exclusive-OR operation is then decrypted using the AES-decryption algorithm with the 256-bit cryptographic key. The result of the encryption is then exclusive-ORed with the XTS parameter to produce the plaintext block. The XTS parameter for this block is multiplied by the value of 2 in GF(2^{128}) to obtain the

XTS parameter for the next block. The operation is shown in Figure 7-46.

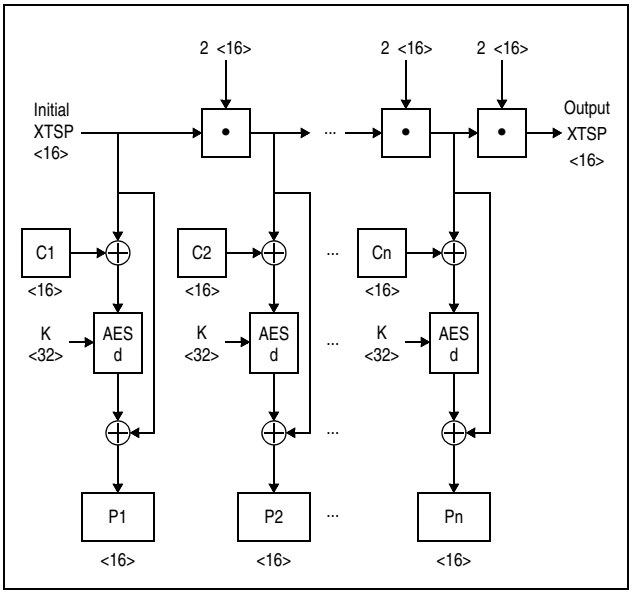

Figure 7-46. XTS-AES-256 Decipher Operation

The plaintext blocks (P1, P2, …, Pn) are stored in operand 1. The result of the final GCM multiplication, called the output XTS parameter (output XTSP), is stored into the initial XTS parameter field of the parameter block.

KM-Full-XTS-AES-128 (Function Code 82)

KM-Full-XTS-Encrypted-AES-128 (Function Code 90)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-7 on page 7-56.

The parameter block used for the KM-Full-XTS-AES-128 function has the following format:

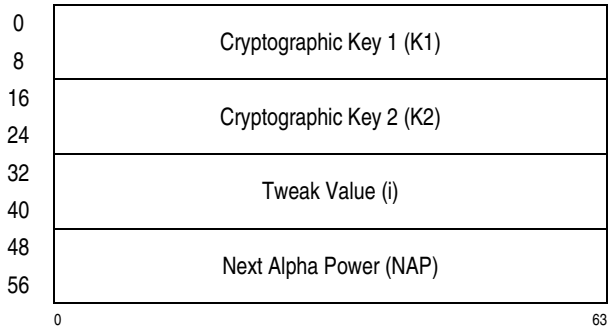

Figure 7-47. Parameter Block for KM-Full-XTS-AES-128

For the KM-Full-XTS-AES-128 function, the 128-bit cryptographic key 1 (K1), aka data key, and the 128-bit cryptographic key 2 (K2), aka tweak key, pair are in byte offsets 0-31 of the parameter block; the 128-bit tweak value (i) is in byte offsets 32-47 of the parameter block and the 128-bit next alpha power (NAP) is in byte offsets 48-63 of the parameter block.

The parameter block used for the KM-Full-XTS-Encrypted-AES-128 function has the following format:

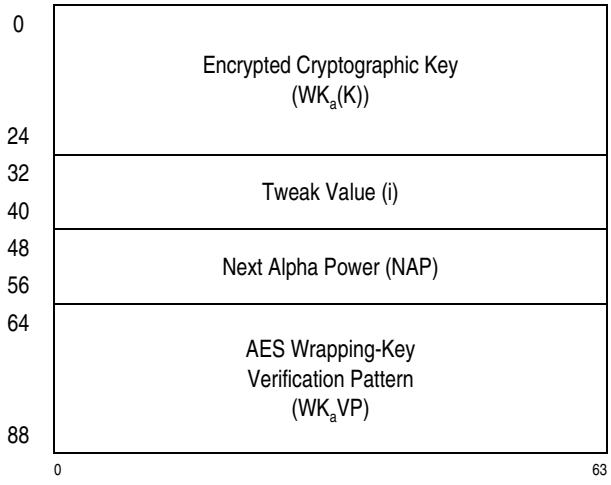

Figure 7-48. Parameter Block for KM-Full-XTS-Encrypted-AES-128

For the KM-Full-XTS-Encrypted-AES-128 function, the contents of byte offsets 64-95 of the parameter block are compared with the contents of the AES wrapping-key verification-pattern register. If they mismatch, the parameter-block location remains unchanged, and the operation is completed by setting condition code 1. If they match, the contents of

byte offsets 0-31 of the parameter block are deciphered using the AES wrapping key to obtain the 128-bit cryptographic key 1 (K1), aka data key (from the left-half), and the 128-bit cryptographic key 2 (K2), aka tweak key (from the right-half), pair. (See the section "Protection of Cryptographic Keys" on page 7-490 for details.) The 128-bit tweak value (i) is in byte offsets 32-47 of the parameter block and the 128-bit next alpha power (NAP) is in byte offsets 48-63 of the parameter block.

Programming Note: The PCKMO-Encrypt-AES-XTS-128-Double-Key function may be used to generate the encrypted cryptographic key for the KM-Full-XTS-Encrypted-AES-128 function.

The following description applies to both functions.

The 128-bit tweak value (i) is encrypted using the 128-bit tweak key (K2) and the AES encryption algorithm, and the result is multiplied by the NAP to produce the initial TAU. The multiplication operation is performed over GF(2^{128}). The operation is shown in Figure 7-49.

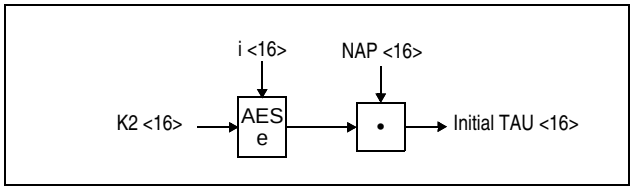

Figure 7-49. KM-Full-XTS-AES-128 Compute TAU Operation

When the modifier (M) bit in general register 0 is zero, an encipher operation is performed. The 16-byte plaintext blocks (P1, P2, …, Pn) in operand 2 are enciphered.

Except for the first block, the TAU used for the current block is the TAU from the previous block multiplied by the value of 2 in GF(2^{128}). To encrypt the first block of plaintext, the initial TAU is used.

Except for the first block, the NAP used for the current block is NAP from the previous block multiplied by the value of 2 in GF(2^{128}). For the first block of plaintext, the initial NAP from the parameter block is used.

The TAU for each block is exclusive-ORed with the corresponding plaintext block. The result of the exclusive-OR operation is then encrypted using the AES-encryption algorithm with the 128-bit data key (K1). The result of the encryption operation is exclusive-ORed with the TAU to produce the ciphertext block. The NAP for the current block is multiplied by the value of 2 in GF(2^{128}) to obtain the NAP for the next block. The operation is shown in Figure 7-50.

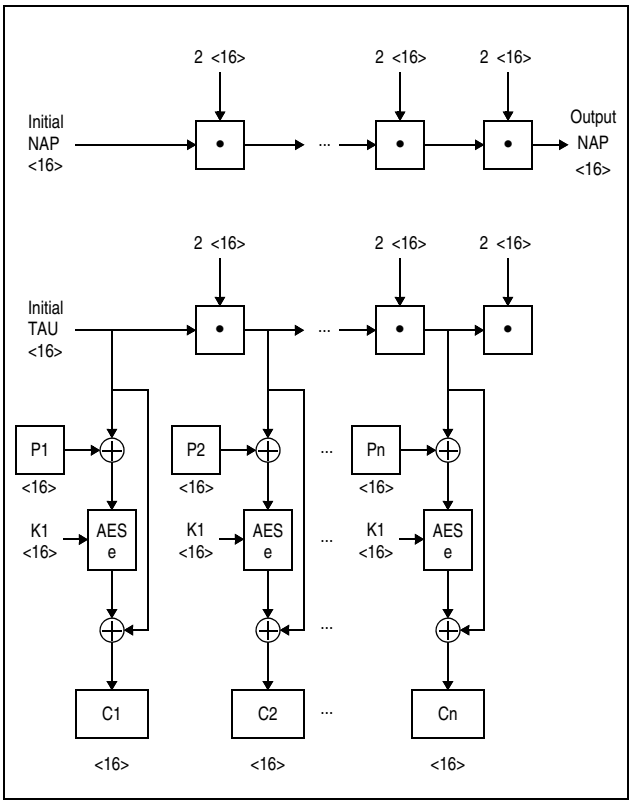

Figure 7-50. KM-Full-XTS-AES-128 Encipher Operation

The ciphertext blocks (C1, C2, …, Cn) are stored in operand 1.

When the modifier bit in general register 0 is one, a decipher operation is performed. The 16-byte ciphertext blocks (C1, C2, …, Cn) in operand 2 are deciphered.

Except for the first block, the TAU used for the current block is the TAU from the previous block multiplied by the value of 2 in GF(2^{128}). To decrypt the first block of ciphertext, the initial TAU is used.

Except for the first block, the NAP used for the current block is the NAP from the previous block multiplied by the value of 2 in GF(2^{128}). For the first block of ciphertext, the initial NAP from the parameter block is used.

The TAU for each block is exclusive-ORed with the corresponding ciphertext block. The result of the

exclusive-OR operation is then decrypted using the AES-decryption algorithm with the 128-bit data key (K1). The result of the decryption operation is exclusive-ORed with the TAU to produce the plaintext block. The NAP for this block is multiplied by the value of 2 in GF(2^{128}) to obtain the NAP for the next block. The operation is shown in Figure 7-51.

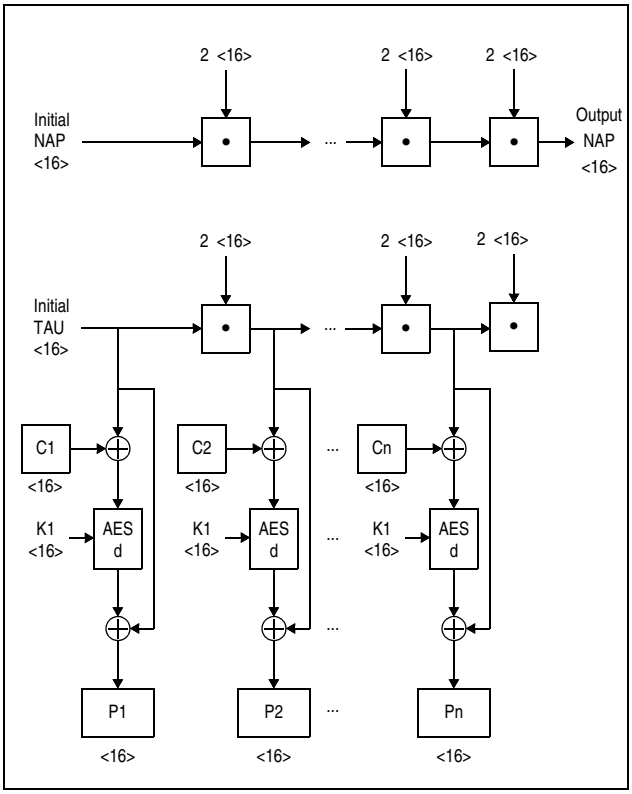

Figure 7-51. KM-Full-XTS-AES-128 Decipher Operation

The plaintext blocks (P1, P2, …, Pn) are stored in operand 1.

The processing of the function completes after the last input text block is ciphered and condition code 0 is set. When the operation ends due to partial completion, condition code 3 is set. For both cases, the result of the final NAP multiplication, called the output NAP, is stored into the next alpha power (NAP) field of the parameter block. Condition code 1 is not applicable to the KM-Full-XTS-AES-128 function.

KM-Full-XTS-AES-256 (Function Code 84)

KM-Full-XTS-Encrypted-AES-256 (Function Code 92)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-7 on page 7-56.

The parameter block used for the KM-Full-XTS-AES--256 function has the following format:

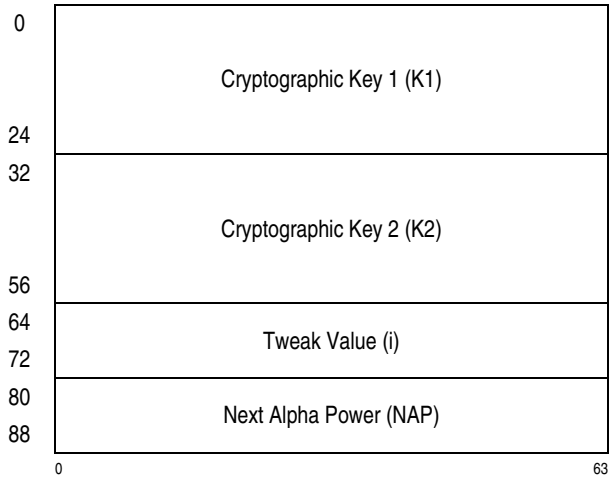

Figure 7-52. Parameter Block for KM-Full-XTS-AES-256

For the KM-Full-XTS-AES-256 function, the 256-bit cryptographic key 1 (K1), aka data key, and the 256-bit cryptographic key 2 (K2), aka tweak key, pair are in byte offsets 0-63 of the parameter block; the 128-bit tweak value (i) is in byte offsets 64-79 of the parameter block and the 128-bit next alpha power (NAP) is in byte offsets 80-95 of the parameter block.

The parameter block used for the KM-Full-XTS-Encrypted-AES-256 function has the following format:

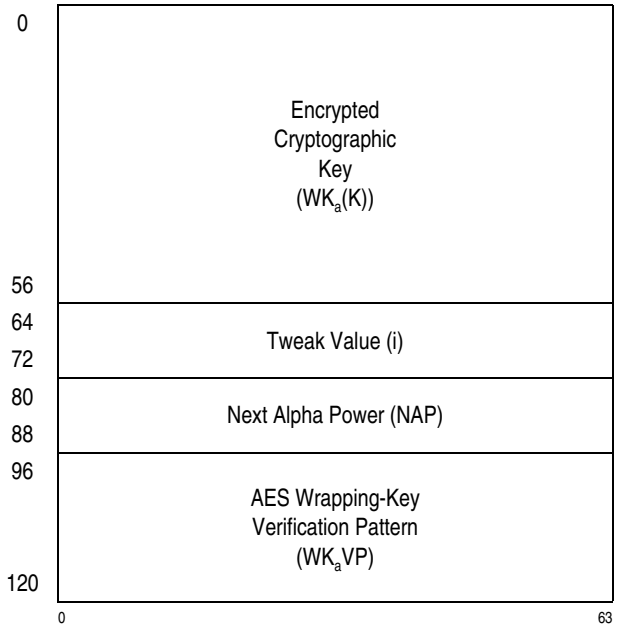

Figure 7-53. Parameter Block for KM-Full-XTS-Encrypted-AES-256

For the KM-Full-XTS-Encrypted-AES-256 function, the contents of byte offsets 96-127 of the parameter block are compared with the contents of the AES wrapping-key verification-pattern register. If they mismatch, the parameter-block location remains unchanged, and the operation is completed by setting condition code 1. If they match, the contents of byte offsets 0-63 of the parameter block are deciphered using the AES wrapping key to obtain the 256-bit cryptographic key 1 (K1), aka data key (from the left-half), and the 256-bit cryptographic key 2 (K2), aka tweak key (from the right-half), pair. (See the section “Protection of Cryptographic Keys” on page 7-490 for details.) The 128-bit tweak value (i) is in byte offsets 64-79 of the parameter block and the 128-bit next alpha power (NAP) is in byte offsets 80-95 of the parameter block.

Programming Note: The PCKMO-Encrypt-AES-XTS-256-Double-Key function may be used to generate the encrypted cryptographic key for the KM-Full-XTS-Encrypted-AES-256 function.

The following description applies to both functions.

The 128-bit tweak value (i) is encrypted using the 256-bit tweak key (K2) and the AES encryption algorithm, and the result is multiplied by the NAP to produce the initial TAU. The multiplication operations is performed over GF(2^{128}). The operation is shown in Figure 7-54.

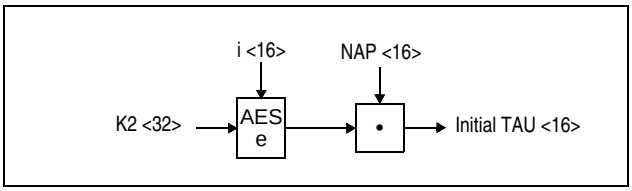

Figure 7-54. KM-Full-XTS-AES-256 Compute TAU Operation

When the modifier bit in general register 0 is zero, an encipher operation is performed. The 16-byte plaintext blocks (P1, P2, …, Pn) in operand 2 are enciphered.

Except for the first block, the TAU used for the current block is the TAU from the previous block multiplied by the value of 2 in GF(2^{128}). To encrypt the first block of plaintext, the initial TAU is used.

Except for the first block, the NAP used for the current block is NAP from the previous block multiplied by the value of 2 in GF(2^{128}). For the first block of plaintext, the initial NAP from the parameter block is used.

The TAU for each block is exclusive-ORed with the corresponding plaintext block. The result of the exclusive-OR operation is then encrypted using the AES-encryption algorithm with the 256-bit data key (K1). The result of the encryption operation is exclusive-ORed with the TAU to produce the ciphertext block. The NAP for the current block is multiplied by the

value of 2 in GF(2^{128}) to obtain the NAP for the next block. The operation is shown in Figure 7-55.

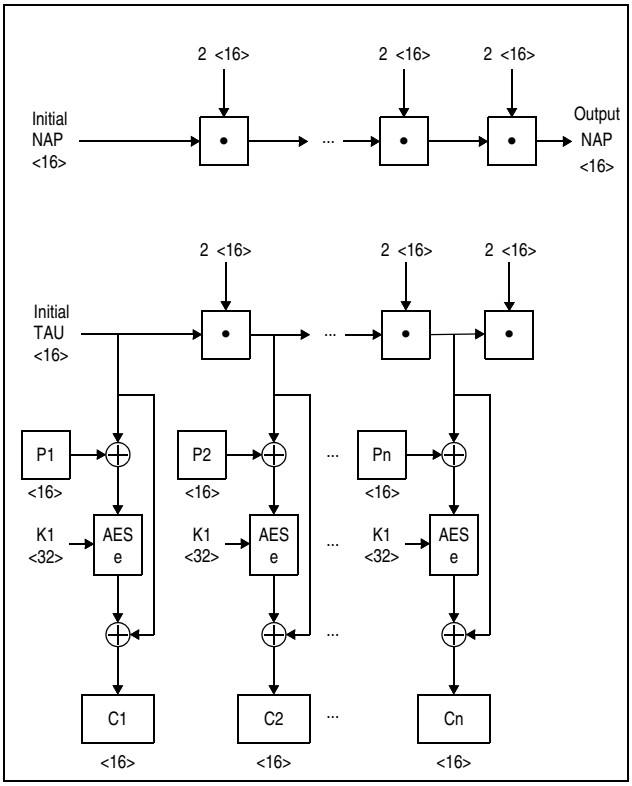

Figure 7-55. KM-Full-XTS-AES-256 Encipher Operation

The ciphertext blocks (C1, C2, …, Cn) are stored in operand 1.

When the modifier bit in general register 0 is one, a decipher operation is performed. The 16-byte ciphertext blocks (C1, C2, …, Cn) in operand 2 are deciphered.

Except for the first block, the TAU used for the current block is the TAU from the previous block multiplied by the value of 2 in GF(2^{128}). To decrypt the first block of ciphertext, the initial TAU is used.

Except for the first block, the NAP used for the current block is the NAP from the previous block multiplied by the value of 2 in GF(2^{128}). For the first block of ciphertext, the initial NAP from the parameter block is used.

The TAU for each block is exclusive-ORed with the corresponding ciphertext block. The result of the exclusive-OR operation is then decrypted using the AES-decryption algorithm with the 256-bit data key (K1). The result of the decryption operation is exclusive-ORed with the TAU to produce the plaintext block. The NAP for this block is multiplied by the value of 2 in GF(2^{128}) to obtain the NAP for the next block. The operation is shown in Figure 7-56.

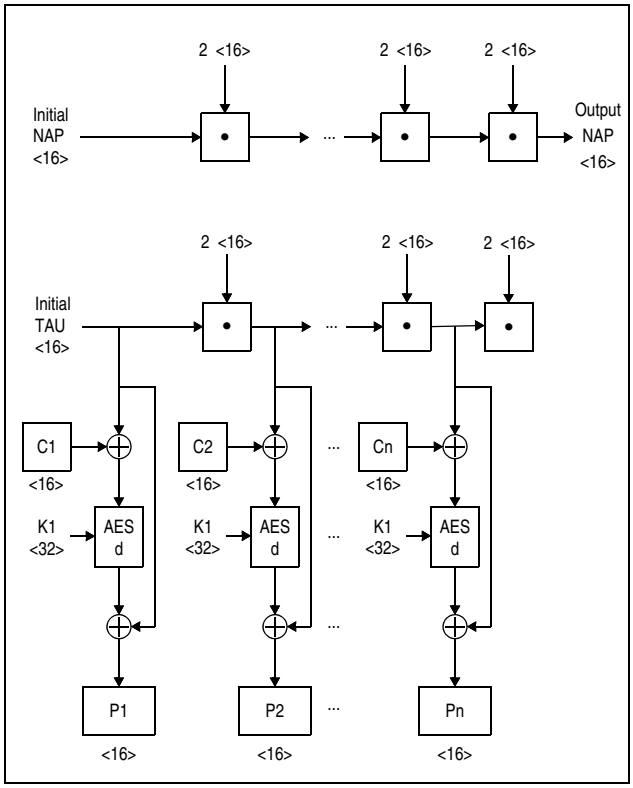

Figure 7-56. KM-Full-XTS-AES-256 Decipher Operation

The plaintext blocks (P1, P2, …, Pn) are stored in operand 1.

The processing of the function completes after the last input text block is ciphered and condition code 0 is set. When the operation ends due to partial completion, condition code 3 is set. For both cases, the result of the final NAP multiplication, called the output NAP, is stored into the next alpha power (NAP) field of the parameter block. Condition code 1 is not applicable to the KM-Full-XTS-AES-256 function.

KM-Query-Authentication-Information (Function Code 127)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-7 on page 7-56.

The KM-query-authentication-information function stores the information that can be used by the program to authenticate the running instruction's firmware code level (IFCL) currently installed on the

model into the format-0 parameter block for KM-query-authentication-information. Condition code 0 is set when execution of the KM-query-authentication-information function completes; condition codes 1 and 3 are not applicable to this function.

The format-0 parameter block used for the KM-query-authentication-information function has the following format:

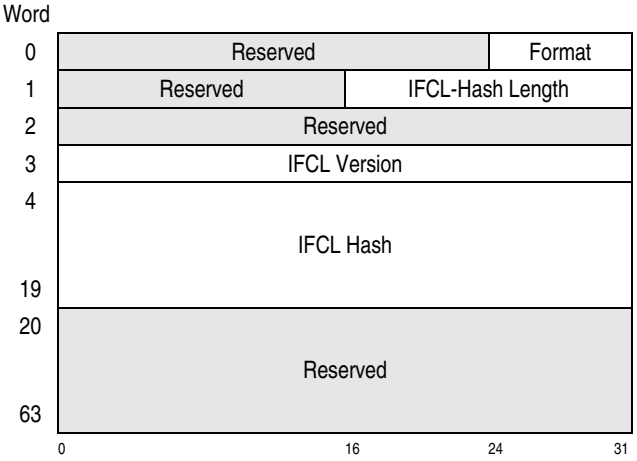

Figure 7-57. Format-0 Parameter Block for KM-Query-Authentication-Information

The format-0 parameter block contains the following fields:

Reserved: Bytes 0-2 of word 0, bytes 0-1 of word 1, word 2, and words 20-63 are reserved and stored as zeros.

Format: Byte 3 of word 0 contains an 8-bit unsigned binary integer whose value specifies the format of the parameter block. A format value of zero indicates a format-0 parameter block. When a format-0 parameter block is stored, the value of this field is set to zero.

IFCL-Hash Length: Bytes 2-3 of word 1 contain a 16-bit unsigned binary integer specifying the number of bytes of the IFCL hash stored in the IFCL hash field. When the IFCL hash is less than or equal to 64 bytes, the IFCL-hash length field is set to the actual length of the IFCL hash. When the IFCL hash is larger than 64 bytes, the IFCL-hash length field is set to 64.

IFCL Version: Word 3 contains a 32-bit unsigned binary integer specifying the version number of the IFCL.

IFCL Hash: Words 4-19 contain the hash value of the IFCL. The IFCL-hash length field specifies the number of bytes that are in the IFCL hash field. The IFCL hash value is left aligned. When the IFCL hash is less than 64 bytes, it is padded with zeros on the right. When the IFCL hash is larger than 64 bytes, only the leftmost 64 bytes of the IFCL hash are stored..

KMC-Query (KMC Function Code 0)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-7 on page 7-56.

The parameter block used for the function has the following format:

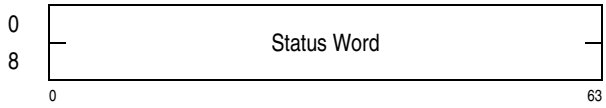

Figure 7-58. Parameter Block for KMC-Query

A 128-bit status word is stored in the parameter block. Bits 0-127 of this field correspond to function codes 0-127, respectively, of the CIPHER MESSAGE WITH CHAINING instruction. When a bit is one, the corresponding function is installed; otherwise, the function is not installed.

Condition code 0 is set when execution of the KMC-Query function completes; condition codes 1 and 3 are not applicable to this function.

KMC-DEA (KMC Function Code 1)

KMC-Encrypted-DEA (KMC Function Code 9)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-7 on page 7-56.

The parameter block used for the KMC-DEA function has the following format:

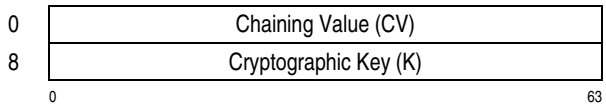

Figure 7-59. Parameter Block for KMC-DEA

For the KMC-DEA function, the chaining value is in byte offsets 0-7 of the parameter block and the cryptographic key is in byte offsets 8-15 of the parameter block.

The parameter block used for the KMC-Encrypted-DEA function has the following format:

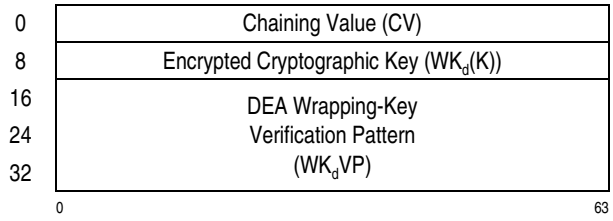

Figure 7-60. Parameter Block for KMC-Encrypted-DEA

For the KMC-Encrypted-DEA function, the contents of byte offsets 16-39 of the parameter block are compared with the contents of the DEA wrapping-key verification-pattern register. If they mismatch, the first-operand and parameter-block locations remain unchanged, and the operation is completed by setting condition code 1. If they match, the contents of byte offsets 8-15 of the parameter block are deciphered using the DEA wrapping key to obtain the 64-bit cryptographic key. (See the section, “Protection of Cryptographic Keys” on page 7-490, for details.) The chaining value is in byte offsets 0-7 of the parameter block.

The following description applies to both functions.

When the modifier bit in general register 0 is zero, an encipher operation is performed. The 8-byte plaintext blocks (P1, P2, …, Pn) in operand 2 are enciphered using the DEA algorithm with the 64-bit cryptographic key and the 64-bit chaining value.

The chaining value, called the initial chaining value (ICV), for deriving the first ciphertext block is the chaining value in the parameter block; the chaining value for deriving each subsequent ciphertext block is the corresponding previous ciphertext block. The ciphertext blocks (C1, C2, …, Cn) are stored in operand 1. The last ciphertext block is the output chaining value (OCV) and is stored into the chaining-value field of the parameter block. The operation is shown in Figure 7-61.

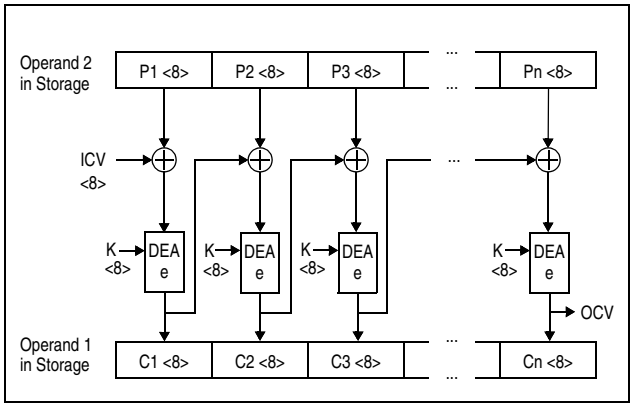

Figure 7-61. KMC DEA Encipher Operation Using 64-Bit Key

When the modifier bit in general register 0 is one, a decipher operation is performed. The 8-byte ciphertext blocks (C1, C2, …, Cn) in operand 2 are deciphered using the DEA algorithm with the 64-bit cryptographic key and the 64-bit chaining value.

The chaining value, called the initial chaining value (ICV), for deriving the first plaintext block is in the parameter block; the chaining value for deriving each subsequent plaintext block is the corresponding previous ciphertext block. The plaintext blocks (P1, P2, …, Pn) are stored in operand 1. The last ciphertext block is the output chaining value (OCV) and is stored into the chaining-value field in the parameter block. The operation is shown in Figure 7-62.

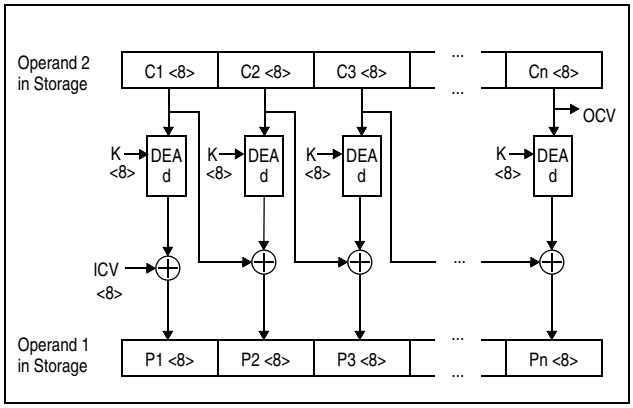

Figure 7-62. KMC DEA Decipher Operation Using 64-Bit Key

KMC-TDEA-128 (KMC Function Code 2)

KMC-Encrypted-TDEA-128 (KMC Function Code 10)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-7 on page 7-56.

The parameter block used for the KMC-TDEA-128 function has the following format:

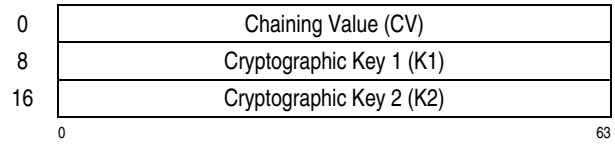

Figure 7-63. Parameter Block for KMC-TDEA-128

For the KMC-TDEA-128 function, the chaining value is in byte offsets 0-7 of the parameter block and the cryptographic key is in byte offsets 8-23 of the parameter block.

The parameter block used for the KMC-Encrypted-TDEA-128 function has the following format:

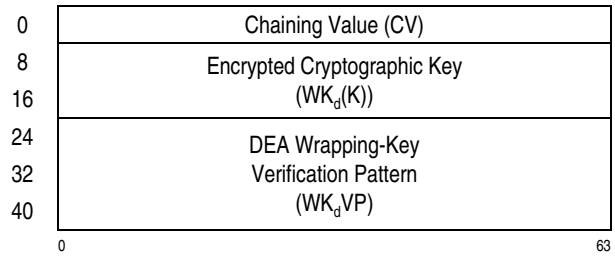

Figure 7-64. Parameter Block for KMC-Encrypted-TDEA-128

For the KMC-Encrypted-TDEA-128 function, the contents of byte offsets 24-47 of the parameter block are compared with the contents of the DEA wrapping-key verification-pattern register. If they mismatch, the first-operand and parameter-block locations remain unchanged, and the operation is completed by setting condition code 1. If they match, the contents of byte offsets 8-23 of the parameter block are deciphered using the DEA wrapping key to obtain the 128-bit cryptographic key. (See the section, “Protection of Cryptographic Keys” on page 7-490, for details.) The chaining value is in byte offsets 0-7 of the parameter block.

The following description applies to both functions.

When the modifier bit in general register 0 is zero, an encipher operation is performed. The 8-byte plaintext blocks (P1, P2, …, Pn) in operand 2 are enciphered using the TDEA algorithm with the two 64-bit cryptographic keys and the 64-bit chaining value.

The chaining value, called the initial chaining value (ICV), for deriving the first ciphertext block is the chaining value in the parameter block; the chaining value for deriving each subsequent ciphertext block is the corresponding previous ciphertext block. The ciphertext blocks (C1, C2, …, Cn) are stored in operand 1. The last ciphertext block is the output chaining value (OCV) and is stored into the chaining-value field of the parameter block. The operation is shown in Figure 7-65.

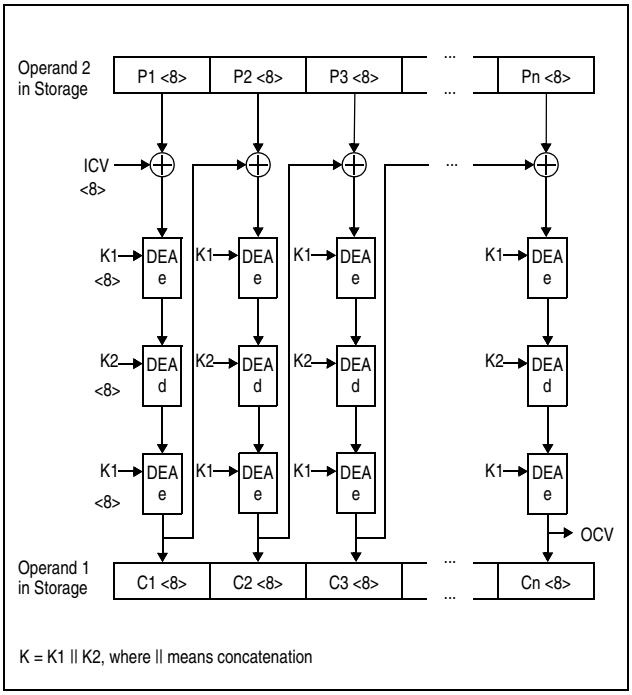

Figure 7-65. KMC TDEA Encipher Operation Using 128-Bit Key

When the modifier bit in general register 0 is one, a decipher operation is performed. The 8-byte ciphertext blocks (C1, C2, …, Cn) in operand 2 are deciphered using the TDEA algorithm with the two 64-bit cryptographic keys and the 64-bit chaining value.

The chaining value, called the initial chaining value (ICV), for deriving the first plaintext block is in the parameter block; the chaining value for deriving each subsequent plaintext block is the corresponding previous ciphertext block. The plaintext blocks (P1, P2, …, Pn) are stored in operand 1. The last ciphertext

block is the output chaining value (OCV) and is stored into the chaining-value field in the parameter block. The operation is shown in Figure 7-66.

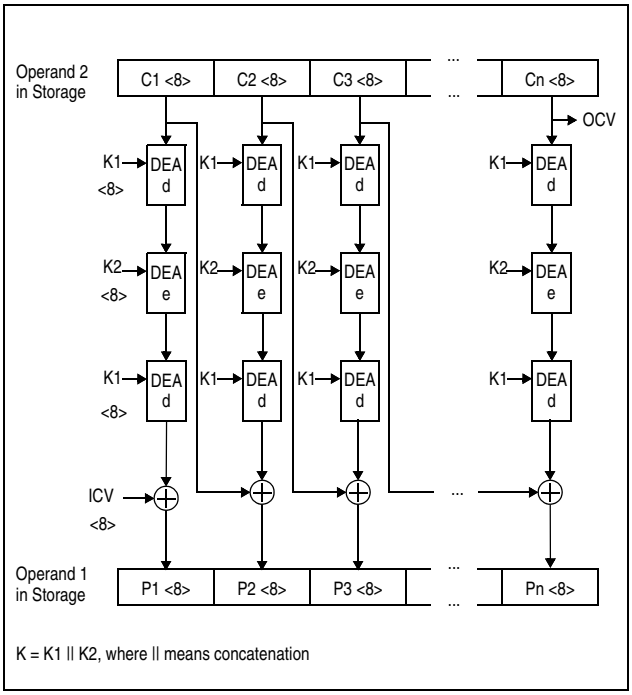

Figure 7-66. KMC TDEA Decipher Operation Using 128-Bit Key

KMC-TDEA-192 (KMC Function Code 3)

KMC-Encrypted-TDEA-192 (KMC Function Code 11)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-7 on page 7-56.

The parameter block used for the KMC-TDEA-192 function has the following format:

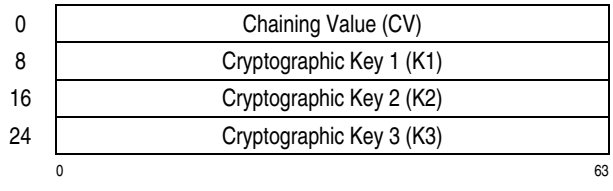

Figure 7-67. Parameter Block for KMC-TDEA-192

For the KMC-TDEA-192 function, the chaining value is in byte offsets 0-7 of the parameter block and the cryptographic key is in byte offsets 8-31of the parameter block.

The parameter block used for the KMC-Encrypted-TDEA-192 function has the following format:

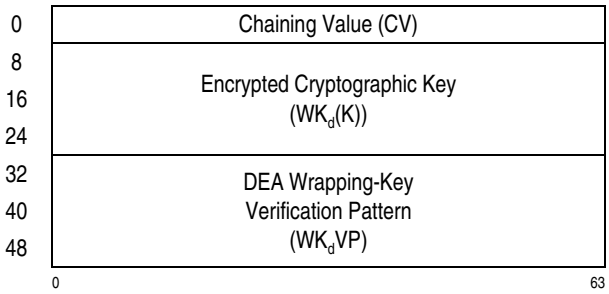

Figure 7-68. Parameter Block for KMC-Encrypted-TDEA-192

For the KMC-Encrypted-TDEA-192 function, the contents of byte offsets 32-55 of the parameter block are compared with the contents of the DEA wrapping-key verification-pattern register. If they mismatch, the first-operand and parameter-block locations remain unchanged, and the operation is completed by setting condition code 1. If they match, the contents of byte offsets 8-31 of the parameter block are deciphered using the DEA wrapping key to obtain the 192-bit cryptographic key. (See the section, “Protection of Cryptographic Keys” on page 7-490, for details.) The chaining value is in byte offsets 0-7 of the parameter block.

The following description applies to both functions.

When the modifier bit in general register 0 is zero, an encipher operation is performed. The 8-byte plaintext blocks (P1, P2, …, Pn) in operand 2 are enciphered using the TDEA algorithm with the three 64-bit cryptographic keys and the 64-bit chaining value.

The chaining value, called the initial chaining value (ICV), for deriving the first ciphertext block is the chaining value in the parameter block; the chaining value for deriving each subsequent ciphertext block is the corresponding previous ciphertext block. The ciphertext blocks (C1, C2, …, Cn) are stored in operand 1. The last ciphertext block is the output chaining value (OCV) and is stored into the chaining-value

field of the parameter block. The operation is shown in Figure 7-69.

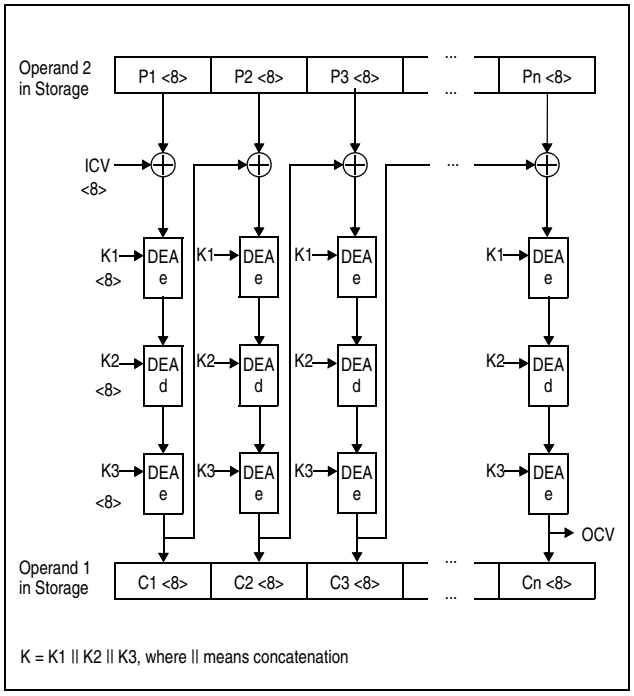

Figure 7-69. KMC TDEA Encipher Operation Using 192-Bit Key

When the modifier bit in general register 0 is one, a decipher operation is performed. The 8-byte ciphertext blocks (C1, C2, …, Cn) in operand 2 are deciphered using the TDEA algorithm with the three 64-bit cryptographic keys and the 64-bit chaining value.

The chaining value, called the initial chaining value (ICV), for deriving the first plaintext block is in the parameter block; the chaining value for deriving each subsequent plaintext block is the corresponding previous ciphertext block. The plaintext blocks (P1, P2, …, Pn) are stored in operand 1. The last ciphertext block is the output chaining value (OCV) and is stored into the chaining-value field in the parameter block. The operation is shown in Figure 7-70.

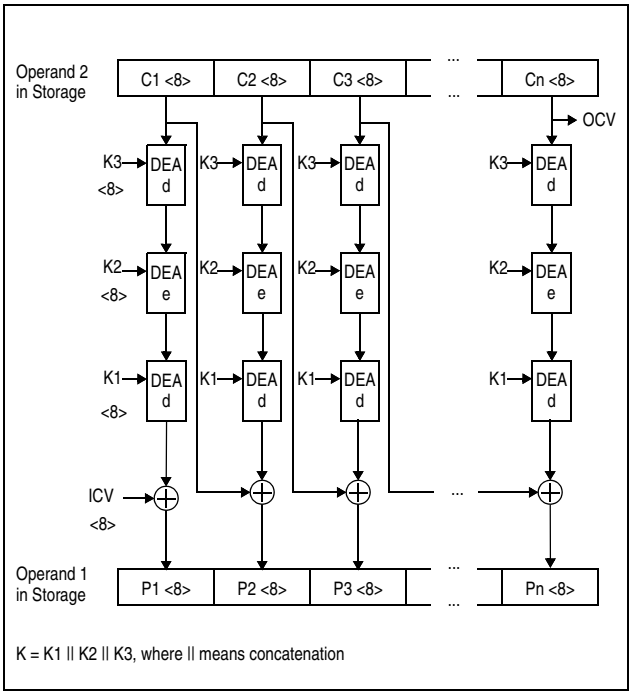

Figure 7-70. KMC TDEA Decipher Operation Using 192-Bit Key

KMC-AES-128 (KMC Function Code 18)

KMC-Encrypted-AES-128 (KMC Function Code 26)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-7 on page 7-56.

The parameter block used for the KMC-AES-128 function has the following format:

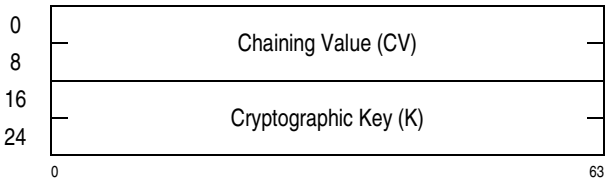

Figure 7-71. Parameter Block for KMC-AES-128

For the KMC-AES-128 function, the chaining value is in byte offsets 0-15 of the parameter block and the cryptographic key is in byte offsets 16-31 of the parameter block.

The parameter block used for the KMC-Encrypted-AES-128 function has the following format:

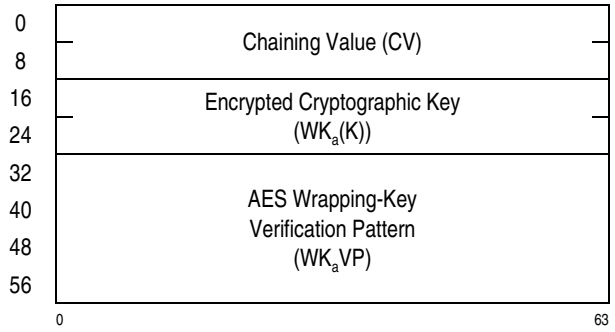

Figure 7-72. Parameter Block for KMC-Encrypted-AES-128

For the KMC-Encrypted-AES-128 function, the contents of byte offsets 32-63 of the parameter block are compared with the contents of the AES wrapping-key verification-pattern register. If they mismatch, the first-operand and parameter-block locations remain unchanged, and the operation is completed by setting condition code 1. If they match, the contents of byte offsets 16-31 of the parameter block are deciphered using the AES wrapping key to obtain the 128-bit cryptographic key, K. (See the section, "Protection of Cryptographic Keys" on page 7-490, for details.) The chaining value is in byte offsets 0-15 of the parameter block.

The following description applies to both functions.

When the modifier bit in general register 0 is zero, an encipher operation is performed. The 16-byte plaintext blocks (P1, P2, …, Pn) in operand 2 are enciphered using the AES algorithm with the 128-bit cryptographic key and the 128-bit chaining value.

The chaining value, called the initial chaining value (ICV), for deriving the first ciphertext block is the chaining value in the parameter block; the chaining value for deriving each subsequent ciphertext block is the corresponding previous ciphertext block. The ciphertext blocks (C1, C2, …, Cn) are stored in operand 1. The last ciphertext block is the output chaining value (OCV) and is stored into the chaining-value field of the parameter block. The operation is shown in Figure 7-73.

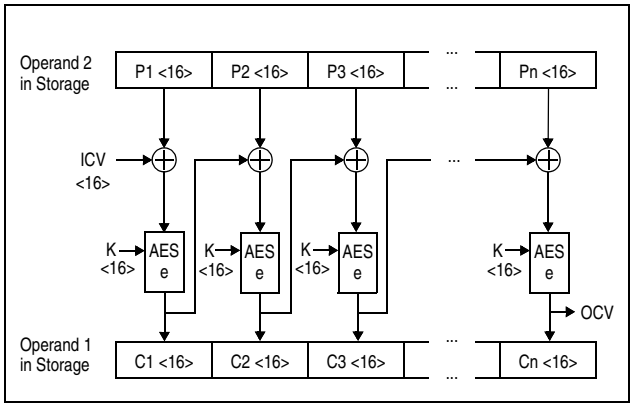

Figure 7-73. KMC AES Encipher Operation Using 128-Bit Key

When the modifier bit in general register 0 is one, a decipher operation is performed. The 16-byte ciphertext blocks (C1, C2, …, Cn) in operand 2 are deciphered using the AES algorithm with the 128-bit cryptographic key and the 128-bit chaining value.

The chaining value, called the initial chaining value (ICV), for deriving the first plaintext block is in the parameter block; the chaining value for deriving each subsequent plaintext block is the corresponding previous ciphertext block. The plaintext blocks (P1, P2, …, Pn) are stored in operand 1. The last ciphertext block is the output chaining value (OCV) and is stored into the chaining-value field in the parameter block. The operation is shown in Figure 7-74.

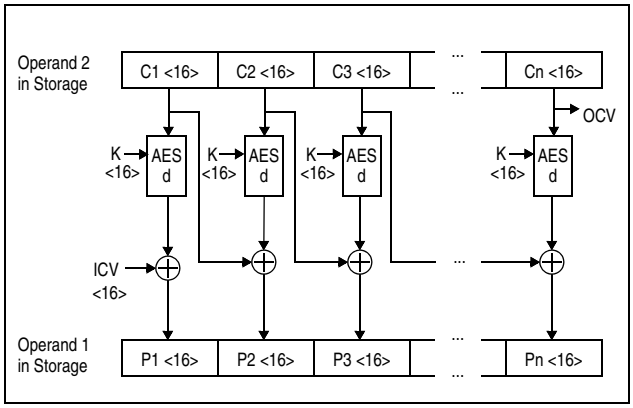

Figure 7-74. KMC AES Decipher Operation Using 128-Bit Key

KMC-AES-192 (KMC Function Code 19)

KMC-Encrypted-AES-192 (KMC Function Code 27)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-7 on page 7-56.

The parameter block used for the KMC-AES-192 function has the following format:

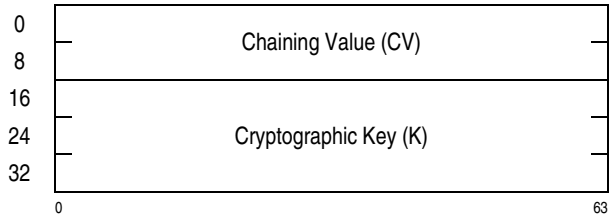

Figure 7-75. Parameter Block for KMC-AES-192

For the KMC-AES-192 function, the chaining value is in byte offsets 0-15 of the parameter block and the cryptographic key is in byte offsets 16-39 of the parameter block.

The parameter block used for the KMC-Encrypted-AES-192 function has the following format:

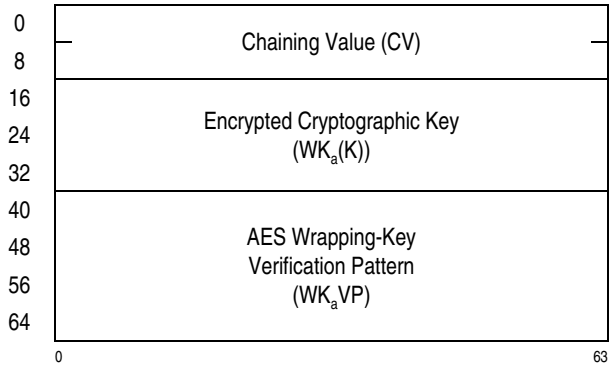

Figure 7-76. Parameter Block for KMC-Encrypted-AES-192

For the KMC-Encrypted-AES-192 function, the contents of byte offsets 40-71 of the parameter block are compared with the contents of the AES wrapping-key verification-pattern register. If they mismatch, the first-operand and parameter-block locations remain unchanged, and the operation is completed by setting condition code 1. If they match, the contents of byte offsets 16-39 of the parameter block are deciphered using the AES wrapping key to obtain the 192-bit cryptographic key, K. (See the section, "Protection of Cryptographic Keys" on page 7-490, for details.) The chaining value is in byte offsets 0-15 of the parameter block.

The following description applies to both functions.

When the modifier bit in general register 0 is zero, an encipher operation is performed. The 16-byte plaintext blocks (P1, P2, …, Pn) in operand 2 are enciphered using the AES algorithm with the 192-bit cryptographic key and the 128-bit chaining value.

The chaining value, called the initial chaining value (ICV), for deriving the first ciphertext block is the chaining value in the parameter block; the chaining value for deriving each subsequent ciphertext block is the corresponding previous ciphertext block. The ciphertext blocks (C1, C2, …, Cn) are stored in operand 1. The last ciphertext block is the output chaining value (OCV) and is stored into the chaining-value field of the parameter block. The operation is shown in Figure 7-77.

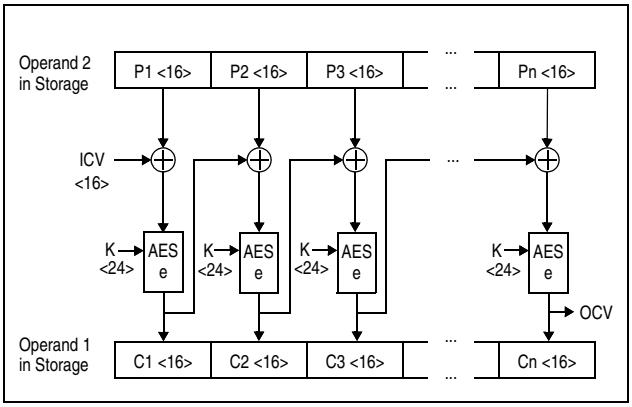

Figure 7-77. KMC AES Encipher Operation Using 192-Bit Key

When the modifier bit in general register 0 is one, a decipher operation is performed. The 16-byte ciphertext blocks (C1, C2, …, Cn) in operand 2 are deciphered using the AES algorithm with the 192-bit cryptographic key and the 128-bit chaining value.

The chaining value, called the initial chaining value (ICV), for deriving the first plaintext block is in the parameter block; the chaining value for deriving each subsequent plaintext block is the corresponding previous ciphertext block. The plaintext blocks (P1, P2, …, Pn) are stored in operand 1. The last ciphertext block is the output chaining value (OCV) and is

stored into the chaining-value field in the parameter block. The operation is shown in Figure 7-78.

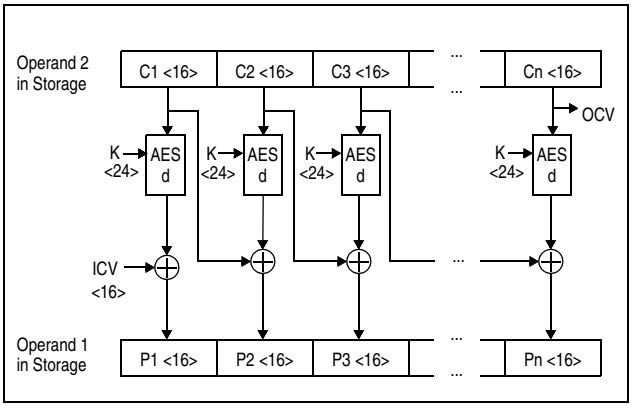

Figure 7-78. KMC AES Decipher Operation Using 192-Bit Key

KMC-AES-256 (KMC Function Code 20)

KMC-Encrypted-AES-256 (KMC Function Code 28)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-7 on page 7-56.

The parameter block used for the KMC-AES-256 function has the following format:

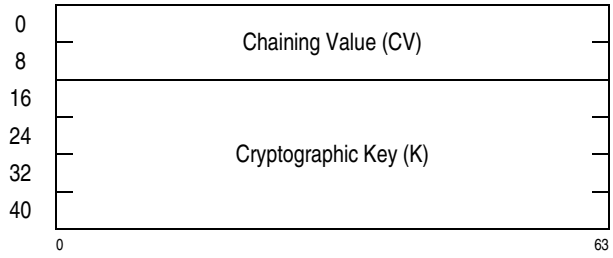

Figure 7-79. Parameter Block for KMC-AES-256

For the KMC-AES-256 function, the chaining value is in byte offsets 0-15 of the parameter block and the cryptographic key is in byte offsets 16-47 of the parameter block.

The parameter block used for the KMC-Encrypted-AES-256 function has the following format:

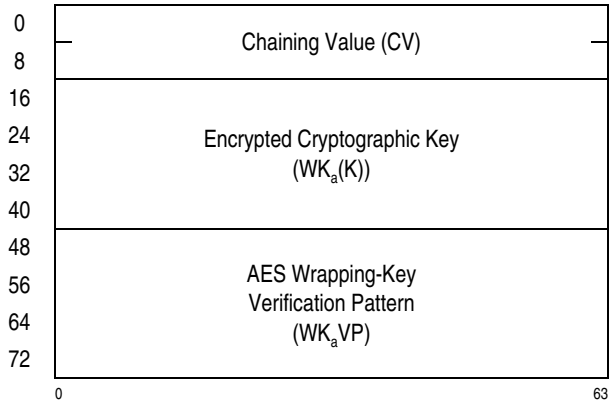

Figure 7-80. Parameter Block for KMC-Encrypted-AES-256

For the KMC-Encrypted-AES-256 function, the contents of byte offsets 48-79 of the parameter block are compared with the contents of the AES wrapping-key verification-pattern register. If they mismatch, the first-operand and parameter-block locations remain unchanged, and the operation is completed by setting condition code 1. If they match, the contents of byte offsets 16-47 of the parameter block are deciphered using the AES wrapping key to obtain the 256-bit cryptographic key, K. (See the section, “Protection of Cryptographic Keys” on page 7-490, for details.) The chaining value is in byte offsets 0-15 of the parameter block.

The following description applies to both functions.

When the modifier bit in general register 0 is zero, an encipher operation is performed. The 16-byte plaintext blocks (P1, P2, …, Pn) in operand 2 are enciphered using the AES algorithm with the 256-bit cryptographic key and the 128-bit chaining value.

The chaining value, called the initial chaining value (ICV), for deriving the first ciphertext block is the chaining value in the parameter block; the chaining value for deriving each subsequent ciphertext block is the corresponding previous ciphertext block. The ciphertext blocks (C1, C2, …, Cn) are stored in operand 1. The last ciphertext block is the output chaining value (OCV) and is stored into the chaining-value

field of the parameter block. The operation is shown in Figure 7-81.

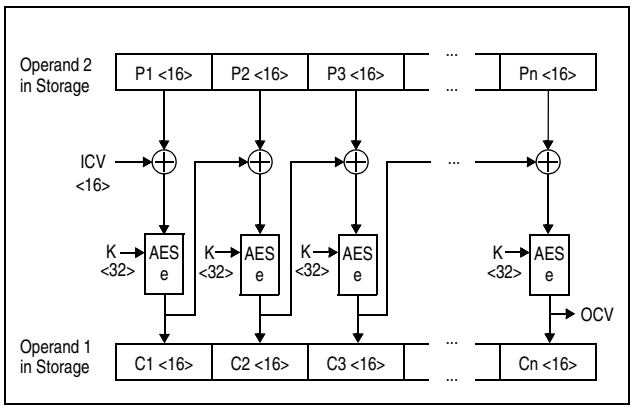

Figure 7-81. KMC AES Encipher Operation Using 256-Bit Key

When the modifier bit in general register 0 is one, a decipher operation is performed. The 16-byte ciphertext blocks (C1, C2, …, Cn) in operand 2 are deciphered using the AES algorithm with the 256-bit cryptographic key and the 128-bit chaining value.

The chaining value, called the initial chaining value (ICV), for deriving the first plaintext block is in the parameter block; the chaining value for deriving each subsequent plaintext block is the corresponding previous ciphertext block. The plaintext blocks (P1, P2, …, Pn) are stored in operand 1. The last ciphertext block is the output chaining value (OCV) and is stored into the chaining-value field in the parameter block. The operation is shown in Figure 7-82.

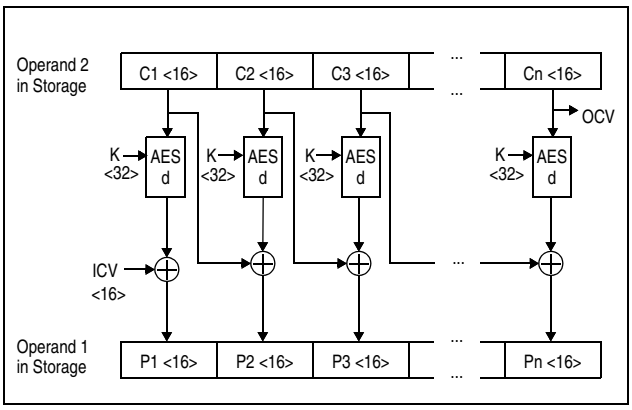

Figure 7-82. KMC AES Decipher Operation Using 256-Bit Key

KMC-PRNG (KMC Function Code 67)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-7 on page 7-56.

The parameter block used for the function has the following format:

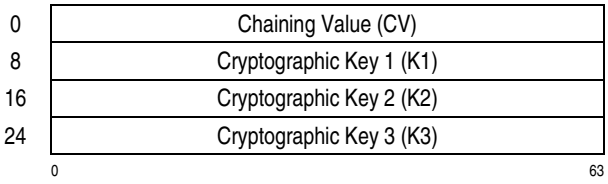

Figure 7-83. Parameter Block for KMC-PRNG

Regardless of the value of the modifier bit in general register 0, the 8-byte plaintext blocks in operand 2 are used to generate the 8-byte ciphertext blocks in operand 1 based on a pseudo-random-number-generation algorithm. The algorithm is based on TDEA using three 64-bit cryptographic keys and a 64-bit chaining value. The output chaining value (OCV) is

stored in the chaining-value field of the parameter block. The operation is shown in Figure 7-84.

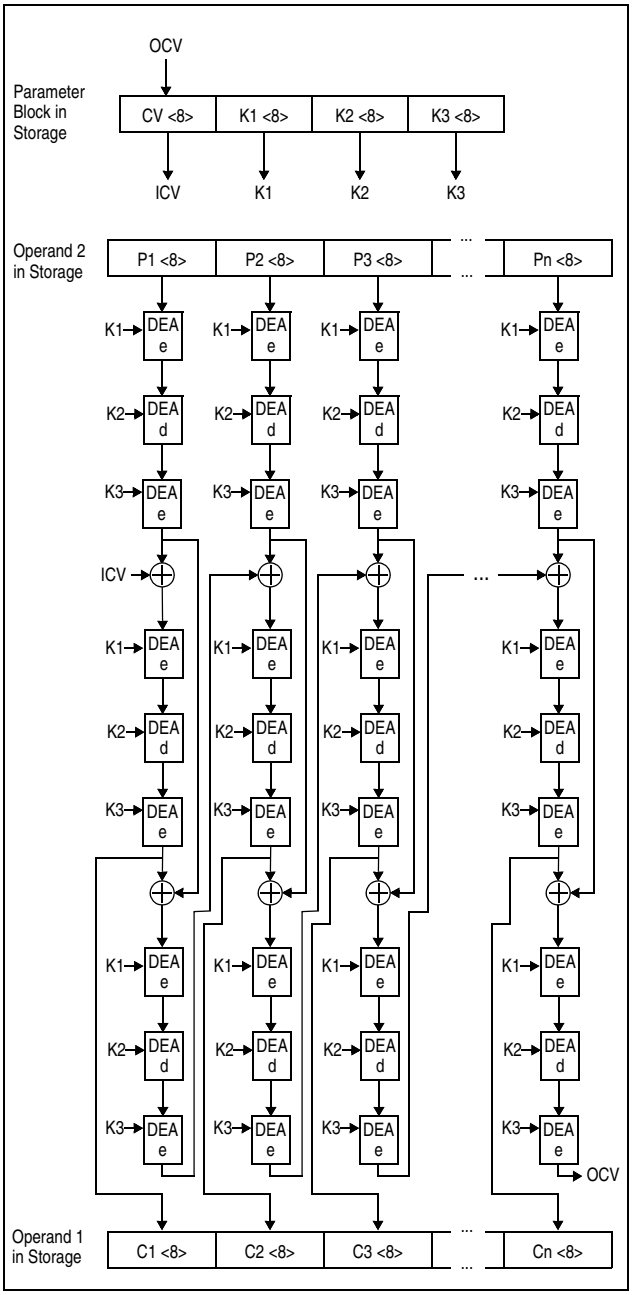

Figure 7-84. KMC-PRNG Operation

KMC-Query-Authentication-Information (Function Code 127)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-7 on page 7-56.

The KMC-query-authentication-information function stores the information that can be used by the program to authenticate the running instruction's firmware code level (IFCL) currently installed on the model into the format-0 parameter block for KMC-query-authentication-information. Condition code 0 is set when execution of the KMC-query-authentication-information function completes; condition codes 1 and 3 are not applicable to this function.

The format-0 parameter block used for the KMC-query-authentication-information function has the following format:

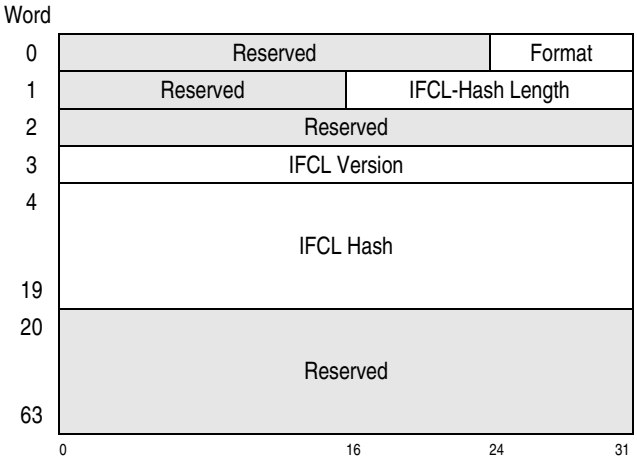

Figure 7-85. Format-0 Parameter Block for KMC-Query-Authentication-Information

The format-0 parameter block contains the following fields:

Reserved: Bytes 0-2 of word 0, bytes 0-1 of word 1, word 2, and words 20-63 are reserved and stored as zeros.

Format: Byte 3 of word 0 contains an 8-bit unsigned binary integer whose value specifies the format of the parameter block. A format value of zero indicates a format-0 parameter block. When a format-0 parameter block is stored, the value of this field is set to zero.

IFCL-Hash Length: Bytes 2-3 of word 1 contain a 16-bit unsigned binary integer specifying the number of bytes of the IFCL hash stored in the IFCL hash field. When the IFCL hash is less than or equal to 64 bytes, the IFCL-hash length field is set to the actual length of the IFCL hash. When the IFCL hash is larger than 64 bytes, the IFCL-hash length field is set to 64.

IFCL Version: Word 3 contains a 32-bit unsigned binary integer specifying the version number of the IFCL.

IFCL Hash: Words 4-19 contain the hash value of the IFCL. The IFCL-hash length field specifies the number of bytes that are in the IFCL hash field. The IFCL hash value is left aligned. When the IFCL hash is less than 64 bytes, it is padded with zeros on the right. When the IFCL hash is larger than 64 bytes, only the leftmost 64 bytes of the IFCL hash are stored.

Special Conditions for KM and KMC

A specification exception is recognized and no other action is taken if any of the following occurs:

1. Bits 57-63 of general register 0 specify an unassigned or uninstalled function code.
2. The R_1 or R_2 field designates an odd-numbered register or general register 0.
3. The second operand length is not a multiple of the data block size of the designated function (see Figure 7-5 on page 7-54 to determine the data block sizes for CIPHER MESSAGE functions; see Figure 7-6 on page 7-55 to determine the data block sizes for CIPHER MESSAGE WITH CHAINING functions). This specification-exception condition does not apply to the query functions.

Resulting Condition Code:

0 Normal completion
1 Verification-pattern mismatch
2 --
3 Partial completion

Program Exceptions:

- Access (fetch, operand 2, cryptographic key, cryptographic key 1, cryptographic key 2, wrapping-key verification pattern, and tweak value; store, operand 1, query parameter block, and query-authentication-information parameter block; fetch and store, chaining value, XTS parameter, next alpha power (NAP), and cryptography counter)
- Operation (if the message-security assist is not installed)
- Specification
- Transaction constraint

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B	Operation exception.
7.C	Transaction constraint
8.	Specification exception due to invalid function code or invalid register number.
9.	Specification exception due to invalid operand length.
10.	Access exceptions for an access to a cryptography counter and second-operand length originally zero.
11.	Condition code 0 due to second-operand length originally zero.
12.A.1	Access exceptions for an access to the parameter block.
12.A.2	Condition code 1 due to verification-pattern mismatch.
12.B	Access exceptions for an access to the first, or second operand.
13.	Condition code 3 due to partial completion (second-operand length still nonzero).
14.	Condition code 3 due to second-operand length stepped to zero and access-exception condition detected for an access to a cryptography counter.
15.	Condition code 0 due to normal completion (second-operand length originally nonzero, but stepped to zero).

Figure 7-86. Priority of Execution: KM and KMC

Programming Notes:

1. The performance of the query function (code 0) may be significantly slower than that of simply examining a location in storage. If the program needs to frequently test for the availability of a function, it should perform the query function once during initialization; subsequently it should examine the stored results of the query function in memory with an instruction such as TEST UNDER MASK.

2. When condition code 3 is set, the general registers containing the operand addresses and length, and the chaining value or the XTS parameter in the parameter block, are usually updated such that the program can simply branch back to the instruction to continue the operation.

   For unusual situations, the CPU protects against endless reoccurrence of the no-progress case and also protects against setting condition code 3 when the portion of the first and second operands to be reprocessed overlap in storage. Thus, the program can safely branch back to the instruction whenever condition code 3 is set with no exposure to an endless loop and no exposure to incorrectly retrying the instruction.

3. If the length of the second operand is nonzero initially and condition code 0 is set, the registers are updated in the same manner as for condition code 3. For CIPHER MESSAGE WITH CHAINING, the chaining value in this case is such that additional operands can be processed as if they were part of the same chain.

4. To save storage, the first and second operands may overlap exactly or the starting point of the first operand may be to the left of the starting point of the second operand. In either case, the overlap is not destructive.

5. For KM-XTS functions, the program must compute the initial XTS parameter by using the appropriate Compute-XTS-Parameter PCC functions before processing the first part of a message.

6. For KM-Full-XTS functions, the program must compute the next alpha power of the first message block designated by second operand and provide it as input in the next alpha power field of the parameter block. When the first message block designated by second operand is the very first message block, the next alpha power field of the parameter block is set to one to reflect using block sequential number zero.

7. The initial XTS parameter used in the KM-XTS-AES-128 (or the KM-XTS-Encrypted-AES-128) function is computed by using the AES encryption algorithm with a 128-bit cryptographic key, which shall be different from the 128-bit cryptographic key used in the KM-XTS-AES-128 (or the KM-XTS-Encrypted-AES-128) function.

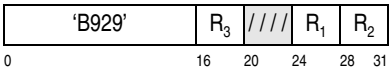
   Similarly, the initial XTS parameter used in the KM-XTS-AES-256 (or the KM-XTS-Encrypted-AES-256) function is computed by using the AES-encryption algorithm with a 256-bit cryptographic key, which shall be different from the 256- bit cryptographic key used in the KM-XTS-AES-256 (or the KM-XTS-Encrypted-AES-256) function.

8. For KM-Full-XTS functions, the cryptographic key 1 should be different from the cryptographic key 2. For the encrypted key functions, the cryptographic key 2 and the cryptographic key 1 must be concatenated together to form a single binding cryptographic key and then encrypt it as a single cryptographic key.

9. As observed by this CPU, other CPUs, and the I/O subsystem, inconsistent results may be briefly stored in the first-operand location. See the section “Effects of CPU Retry” on page 11-3 for further details.

CIPHER MESSAGE WITH AUTHENTICATION

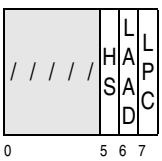
KMA R_1,R_3,R_2 [RRF-b]



A function specified by the function code in general register 0 is performed.

General register 0 contains various controls affecting the operation of the instruction, as follows:

Flags (F): Bit positions 48-55 of general register 0 contain an 8-bit flags field controlling the operation of the function. The flags field is meaningful only when the function code in bits 57-63 of general register 0 designates a ciphering function (that is, when the function code is nonzero). The format of the flags field is as follows:



The individual flag fields are as follows:

Reserved: Bits 0-4 of the flags field are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.

Hash-subkey-Supplied (HS) Flag: Bit 5 of the flags field indicates whether the hash-subkey (H) field in the parameter block contains a valid hash subkey. The HS flag is meaningful only when the function code is nonzero, and the function does not use an encrypted cryptographic key; the HS flag is ignored for functions that use an encrypted cryptographic key.

Last-AAD (LAAD) Flag: Bit 6 of the flags field qualifies the contents of the third operand. When the LAAD flag is one, it indicates that the third operand designates the last series of additional-authenticated-data (AAD) blocks. When the LAAD flag is zero, it indicates that the third operand does not designate the last series of AAD blocks.

Last-Plaintext / Ciphertext (LPC) Flag: Bit 7 of the flags field qualifies the contents of the second operand. When the LPC flag is one, it indicates that the second operand designates the last series of plaintext or ciphertext blocks. When the LPC flag is zero, it indicates that the second operand does not designate the last series of plaintext or ciphertext blocks.

A specification exception is recognized, and the operation is suppressed when the LPC flag is one, and the LAAD flag is zero.

Modifier (M): When the function code in bits 57-63 of general register 0 is nonzero, bit position 56 of general register 0 contains a modifier bit indicating encryption or decryption is to be performed by the function. When the M bit is zero, the function performs encryption of the second operand; when the M bit is one, the function performs decryption of the second operand. The M bit is ignored when the function code is zero.

Function Code (FC): Bit positions 57-63 of general register 0 contain the function code. Figure 7-87 shows the assigned function codes for CIPHER MESSAGE WITH AUTHENTICATION. When the message-security-assist extension 13 is installed, function code 127 is valid for CIPHER MESSAGE WITH AUTHENTICATION. All other function codes are unassigned.

Code	Function	Param. Block Size (bytes)	Data Block Size (bytes)
0	KMA-Query	16	—
18	KMA-GCM-AES-128	96	16
19	KMA-GCM-AES-192	104	16
20	KMA-GCM-AES-256	112	16
26	KMA-GCM-Encrypted-AES-128	128	16
27	KMA-GCM-Encrypted-AES-192	136	16
28	KMA-GCM-Encrypted-AES-256	144	16
127	KMA-Query-Authentication-Information	V	—

Explanation:

— Not applicable
V Variable parameter block size. See each format-x parameter block for the exact size of that parameter block.

Figure 7-87. Function Codes for CIPHER MESSAGE WITH AUTHENTICATION

Bits 0-31 of general register 0 are ignored. Bits 32-47 of general register 0 are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.

The query function provides the means of indicating the availability of the other functions. The contents of general registers R_1, R_2, $R_2 + 1$, R_3, and $R_3 + 1$ are ignored for the query function.

The query-authentication-information function provides the information that can be used by the program to authenticate the running instruction's firmware code level (IFCL) currently installed on the model. The contents of general registers R_1, R_2, $R_2 + 1$, R_3, and $R_3 + 1$ are ignored for the query-authentication-information function.

For all other functions, a message-authentication tag is formed from the contents of the third operand and from the contents of either the resulting first operand or the second operand, depending on whether the M bit is 0 or 1, respectively. Based on the M bit, the second operand is either encrypted or decrypted using a cryptographic key and counter values from the parameter block, and the result is placed in the first-operand location.

General register 1 contains the logical address of the leftmost byte of the parameter block in storage. In the 24-bit addressing mode, the contents of bit positions 40-63 of general register 1 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of general register 1 constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register 1 constitute the address.

The R_1 field designates a general register and must designate an even-numbered register other than general register 0; otherwise, a specification exception is recognized. The R_2 and R_3 fields each designate an even-odd pair of general registers and must designate even-numbered registers other than general register 0; otherwise, a specification exception is recognized. A specification exception is also recognized if the R_3 field designates the same register as either the R_1 or R_2 fields.

The location of the leftmost byte of the first, second, and third operands is specified by the contents of general registers R_1, R_2, and R_3, respectively. The number of bytes in the second-operand location is specified in general register $R_2 + 1$. The first operand is the same length as the second operand. The number of bytes in the third-operand location is specified in general register $R_3 + 1$.

As part of the operation, the address in general register R_3 is incremented by the number of third-operand bytes processed, and the length in general register $R_3 + 1$ is decremented by the same number; additionally, the addresses in general registers R_1 and R_2 are each incremented by the number of second-operand bytes processed, and the length in general register $R_2 + 1$ is decremented by the same number. The formation and updating of the addresses and length is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers R_1, R_2, and R_3 constitute the addresses of the first, second, and third operands, respectively, and the contents of bit positions 0-39 are ignored; bits 40-63 of the updated addresses replace the corresponding bits in general registers R_1, R_2, and R_3, carries out of bit position 40 of the updated address are ignored, and the contents of bit positions 32-39 of general registers R_1, R_2, and R_3 are set to zeros. In the 31-bit addressing mode, the contents of bit positions 33-63 of general registers R_1, R_2, and R_3 constitute the addresses of the first, second, and third operands, respectively, and the contents of bit positions 0-32 are ignored; bits 33-63 of the updated addresses replace the corresponding bits in general registers R_1, R_2, and R_3, carries out of bit position 33 of the updated address are ignored, and the content of bit position 32 of general registers R_1, R_2, and R_3 is set to zero. In the 64-bit addressing mode, the contents of bit positions 0-63 of general registers R_1, R_2, and R_3 constitute the addresses of the first, second, and third operands, respectively; bits 0-63 of the updated addresses replace the contents of general registers R_1, R_2, and R_3, and carries out of bit position 0 are ignored.

In both the 24-bit and the 31-bit addressing modes, the contents of bit positions 32-63 of general register $R_2 + 1$ form a 32-bit unsigned binary integer which specifies the number of bytes in the first and second operands, and the contents of bit positions 0-31 are ignored; bits 32-63 of the updated value replace the corresponding bits in general register $R_2 + 1$. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register $R_2 + 1$ form a 64-bit unsigned binary integer which specifies the number of bytes in the first and second operands; the updated value replaces the contents of general register $R_2 + 1$.

In both the 24-bit and the 31-bit addressing modes, the contents of bit positions 32-63 of general register $R_3 + 1$ form a 32-bit unsigned binary integer which specifies the number of bytes in the third operand, and the contents of bit positions 0-31 are ignored; bits 32-63 of the updated value replace the corresponding bits in general register $R_3 + 1$. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register $R_3 + 1$ form a 64-bit unsigned binary integer which specifies the number of bytes in the third operand; the updated value replaces the contents of general register $R_3 + 1$.

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers R_1, R_2, $R_2 + 1$, R_3, and $R_3 + 1$ always remain unchanged.

Figure 7-88 on page 7-89 shows the contents of the general registers just described.

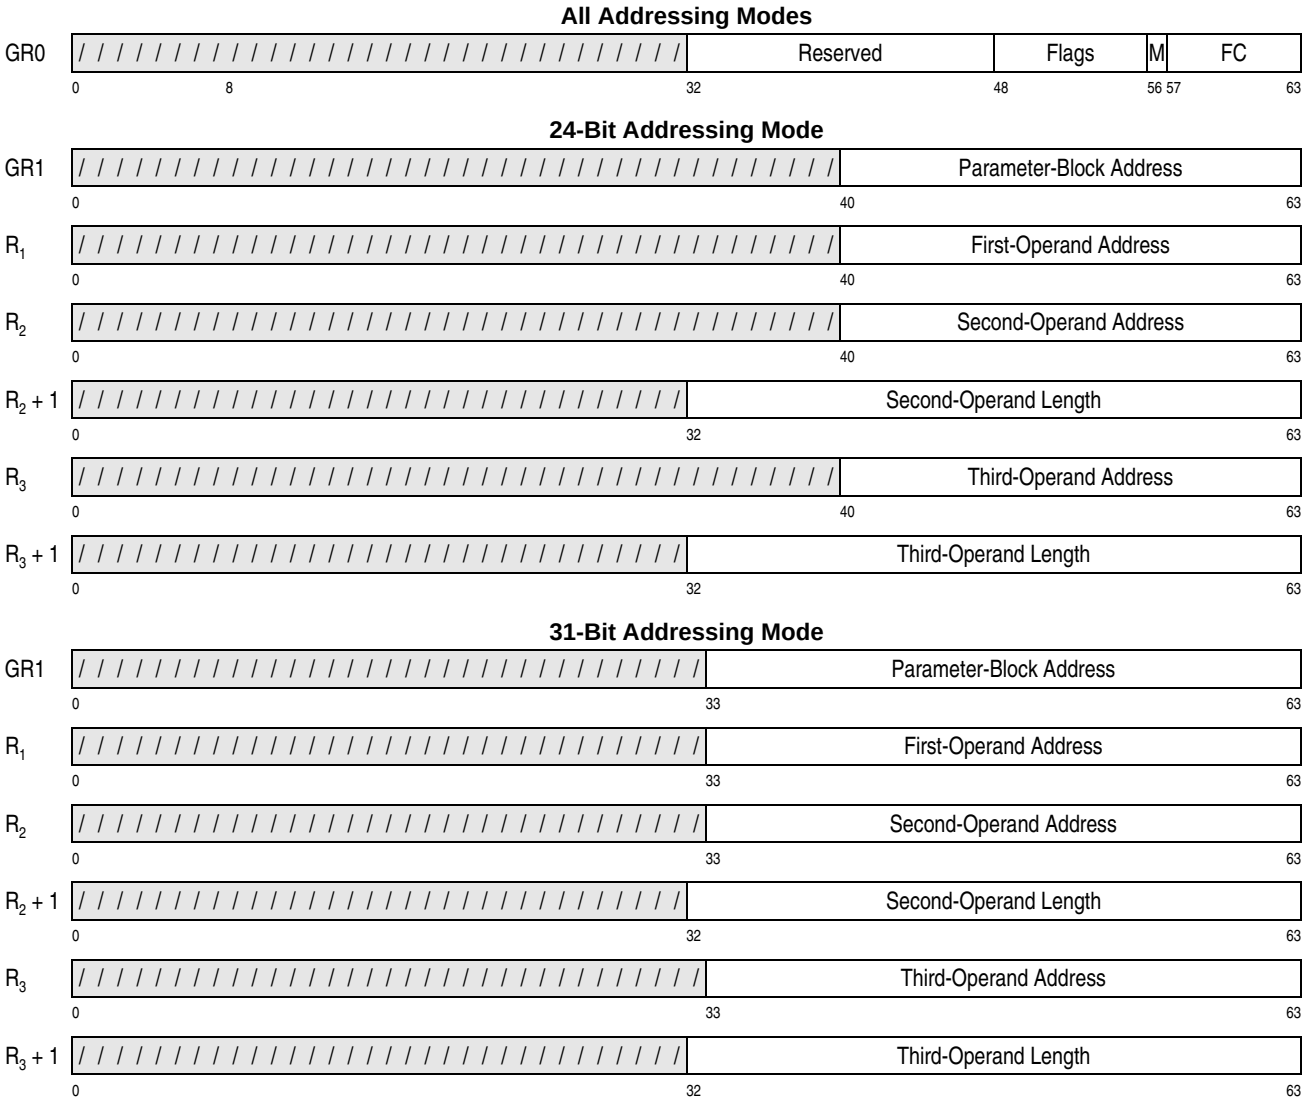


Figure 7-88. General Register Assignment for CIPHER MESSAGE WITH AUTHENTICATION (Part 1 of 2)

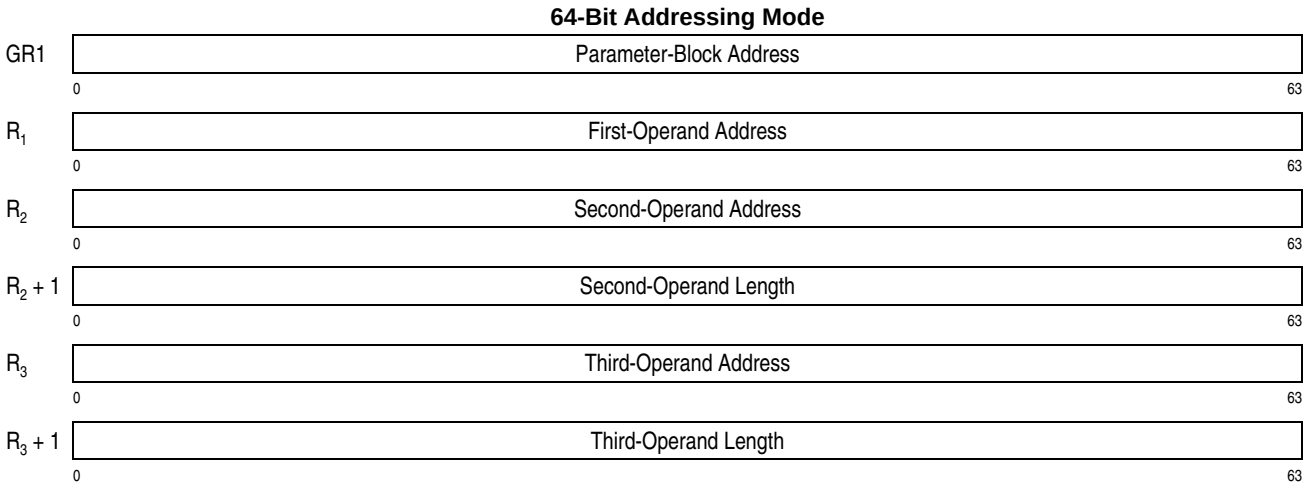

Figure 7-88. General Register Assignment for CIPHER MESSAGE WITH AUTHENTICATION (Part 2 of 2)

In the access-register mode, access registers 1, R_1, R_2, and R_3 specify the address spaces containing the parameter block, first, second, and third operands, respectively.

KMA-Query (Function Code 0)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-88 on page 7-89.

The parameter block used for the function has the following format:

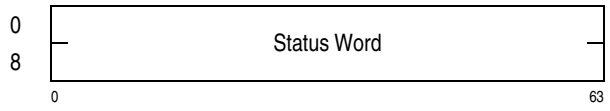

Figure 7-89. Parameter Block for KMA-Query

A 128-bit status word is stored in the parameter block. Bits 0-127 of this field correspond to function codes 0-127, respectively, of the CIPHER MESSAGE WITH AUTHENTICATION instruction. When a bit is one, the corresponding function is installed; otherwise, the function is not installed.

Condition code 0 is set when execution of the KMA-Query function completes; condition codes 1, 2, and 3 are not applicable to this function.

KMA-GCM-AES Functions

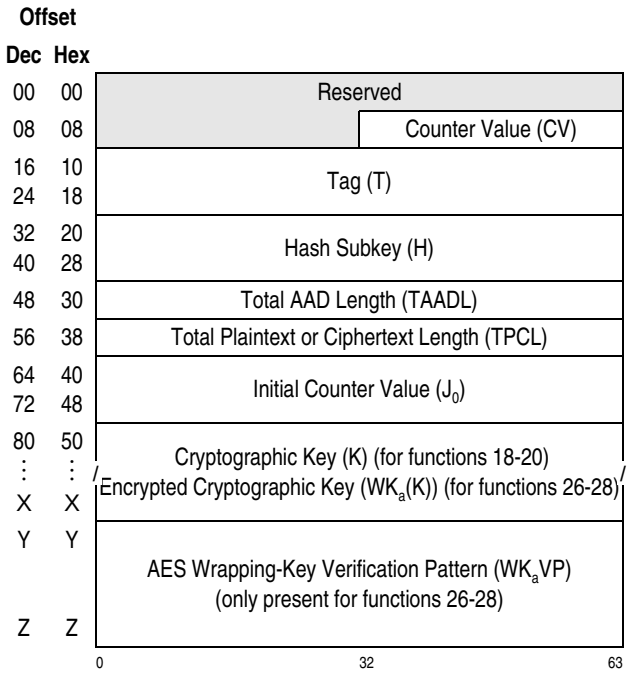
Note: The description of the KMA-GCM-AES instruction assumes that the reader is familiar with the Galois counter mode (GCM) described in Reference [17.] on page xxxii. In particular, see [17] for a description of the GCM functions GHASH and GCTR.

This section illustrates the operation for six KMA-GCM-AES functions:

- KMA-GCM-AES-128 (function code 18)
- KMA-GCM-AES-192 (function code 19)
- KMA-GCM-AES-256 (function code 20)
- KMA-GCM-Encrypted AES-128 (function code 26)
- KMA-GCM-Encrypted AES-192 (function code 27)
- KMA-GCM-Encrypted AES-256 (function code 28)

The locations of the operands and addresses used by each of these functions are as shown in Figure 7-88 on page 7-89.

The parameter block used for all KMA-GCM-AES functions has a common format as shown in Figure 7-90, below.



Explanation:

X 72 (48 hex) plus the length of K (in bytes)
Y 80 (50 hex) plus the length of K (in bytes)
Z Y plus 24 (18 hex; the first byte of the last 8 bytes).

Figure 7-90. Parameter Block for KMA-GCM-AES Functions

The fields of the parameter block for all KMA-GCM-AES functions are as follows:

Reserved: Bytes 0-11 of the parameter block are reserved. As an input to an operation, the reserved field should contain zeros; otherwise, the program may not operate compatibly in the future. The reserved field may contain model dependent values at the completion of the instruction. The reserved field should not be altered by the program after partial completion and before reexecution of the instruction for the purpose of resuming the operation; otherwise, results are unpredictable.

Counter Value (CV): Bytes 12-15 of the parameter block contain a 32-bit binary integer. The leftmost 12 bytes of the initial-counter value (J_0, in bytes 64-79 of the parameter block) are concatenated with the contents of the CV field on the right to form the initial-counter block (ICB) that is used by the GCTR function (described in Reference [17.] on page xxxii).

For each execution of the instruction, the CPU increments the CV field in the parameter block by the number of second-operand blocks processed. A carry out of bit position 0 of the CV field is ignored.

Tag (T): Bytes 16-31 of the parameter block contain the message-authentication tag field.

For each block of the third operand, and for each block of the resulting first operand (when M is 0) or each block of the second operand (when M is 1), the CPU uses the tag field as both input and output to the GHASH function. When all AAD and ciphertext has been hashed, the concatenation of the TAADL and TPCL fields are hashed using GHASH, and the results of the hash are encrypted using the GCTR function to produce a last tag (T) field in the parameter block.

Hash Subkey (H): For the KMA-GCM-AES functions, bytes 32-47 of the parameter block contain a 128-bit hash subkey that is used by the GHASH functions of the instruction. When the hash-subkey-supplied flag (HS, bit 53 of general register 0) is zero, the CPU computes the hash subkey by encrypting 128 bits of binary zeros using the cryptographic key (K), stores the hash subkey in the H field, and sets the HS flag to one. When the HS flag is one, the CPU uses the program-supplied hash subkey in the H field; the H field and HS flag are not altered in this case.

For the KMA-GCM-encrypted-AES functions, bytes 32-47 of the parameter block are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future. In this case, the CPU always computes the hash subkey by encrypting 128 bits of binary zeros using the deciphered cryptographic key (K); the H field and HS flag are not altered in this case.

Total AAD Length (TAADL): Bytes 48-55 of the parameter block contain a 64-bit unsigned binary integer designating the total length in bits of the entire additional-authenticated-data (AAD) for the message being processed.

Total Plaintext or Ciphertext Length (TPCL): Bytes 56-63 of the parameter block contain a 64-bit unsigned binary integer designating the total length

in bits of the entire plaintext or ciphertext for the message being processed.

Initial Counter Value (J_0): Bytes 64-79 of the parameter block contain a 128-bit initial counter value that is used (a) to provide the leftmost 96 bits of the initial-counter block used by the GCTR function, and (b) to encrypt the last authentication tag (T) field.

Cryptographic Key (K): The cryptographic key used in the encipher and decipher operations begins at byte 80 of the parameter block. The size of the key field and its offset in the parameter block are dependent on the function code, as shown in Figure 7-91.

Function Code	Function	Key Length (bytes)	Key Offset (bytes)
18	KMA-GCM-AES-128	16	80-95
19	KMA-GCM-AES-192	24	80-103
20	KMA-GCM-AES-256	32	80-111
26	KMA-GCM-Encrypted-AES-128	16	80-95
27	KMA-GCM-Encrypted-AES-192	24	80-103
28	KMA-GCM-Encrypted-AES-256	32	80-111

Figure 7-91. Key Lengths and Offsets for KMA-GCM Functions

AES Wrapping-Key Verification Pattern (WK_aVP): For the KMA-GCM-encrypted-AES functions (codes 26-28), the 32 bytes immediately following the key in the parameter block contain the AES wrapping-key verification pattern (WK_aVP).

For the KMA-AES functions (codes 18-20), the WK_aVP field is not present in the parameter block.

Symbols Used in KMA-GCM-AES Function Descriptions

The following symbols are used in the subsequent description of the KMA-GCM-AES functions.

Further description of the AES standard may be found in Reference [14.] on page xxxii. Further description of the Galois-counter mode of encryption and decryption may be found in Reference [17.] on page xxxii.

Figure 7-94. Symbols for AES Encryption

The following description applies to all KMA-GCM-AES functions. A sequence of operations is per-

formed, depending on the flags and function code in general register 0, as follows:

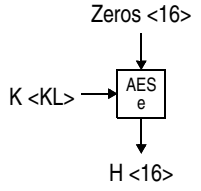
Wrapping-Key Verification: For the KMA-GCM-encrypted-AES functions (function codes 26-28), the contents of the 32-byte WK_aVP field are compared with the contents of the AES wrapping-key verification-pattern register. If they mismatch, the first-operand and parameter-block locations remain unchanged, and the operation is completed by setting condition code 1. If they match, the contents of the key field of the parameter block are deciphered using the AES wrapping key to obtain the cryptographic key, K. (See the section "Protection of Cryptographic Keys" on page 7-490 for details.)

For the KMA-GCM-AES functions that do not use encrypted keys (codes 18-20), wrapping-key verification is not performed.

Computing the Hash Subkey: A hash subkey is used in the GHASH processing to produce the resulting message-authentication tag. GHASH processing is described in Reference [17.] on page xxxii.

For KMA-GCM-AES functions (function codes 18-20), the following applies:

- When the hash-subkey-supplied flag (HS, bit 53 of general register 0) is zero, a block of 128 binary zeros is encrypted using the AES algorithm described in Reference [14.] on page xxxii. The AES algorithm uses the key (K) field from the parameter block, as shown in Figure 7-95, below.



Symbol	Explanation
<n>	Length of item in bytes
H	Hash subkey.
K	Key value.
KL	Key length (see Figure 7-91).

Figure 7-95. Encrypting the Hash Subkey

  The resulting 128-bit hash subkey is placed into the H field of the parameter block, and the HS flag is set to one in general register 0.

- When the HS flag is one, the H field in the parameter block is used as the hash subkey. In this case, the H field and HS flag are not altered.

For KMA-GCM-encrypted-AES functions (function codes 26-28), the HS flag is ignored. A block of 128 binary zeros is always encrypted using the AES algorithm as shown in Figure 7-95, using the decrypted key (K). In this case, the H field of the parameter block and the HS flag are not altered.

Additional-Authenticated-Data (AAD) Hashing: AAD hashing is not performed when either of the following conditions apply. In either of these conditions, general registers R_3 and R_3+1 are not modified, and it is model dependent whether the T field in the parameter block is fetched and stored back unmodified.

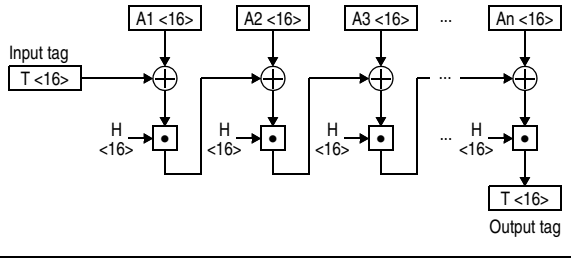
- The third-operand length in general register $R_3 + 1$ is initially less than 16, and the last-AAD flag (LAAD, bit 54 of general register 0) is zero. In this case, the instruction completes by setting condition code 2.

- The third-operand length is initially zero, and the LAAD flag is one. In this case, processing continues as described in "Ciphering and Hashing" on page 7-94.

When the third-operand length in general register $R_3 + 1$ is nonzero, additional-authenticated-data hashing is performed. In this case, general register R_3 contains the address of a storage location containing data from which a message-authentication tag is computed using the GHASH algorithm described in Reference [17.] on page xxxii. In addition to the blocks of the third operand, the GHASH function uses the hash subkey (described above) and the tag field in the parameter block as input values.

The result is obtained as if processing starts at the left end of the third operand and proceeds to the right, block by block. When one or more full 16-byte

blocks of AAD remain, the processing is illustrated in Figure 7-96.



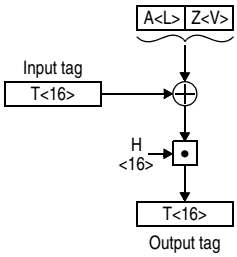
Symbol	Explanation
<n>	Length of item in bytes
An	Block n of additional authenticated data (third operand).
H	Hash subkey
T	Message-authentication tag (in the parameter block).

Figure 7-96. GHASH Processing of Full Blocks.

The AAD-hashing process ends when any of the following is true:

- A CPU-determined number of blocks that is less than the length of the third operand has been processed. In this case, the message-authentication tag computed thus far is placed into the T field of the parameter block, general register R_3 is incremented by the number of third-operand bytes processed, general register $R_3 + 1$ is decremented by the same amount, and the instruction completes by setting condition code 3.
- The last-AAD flag (LAAD, bit 54 of general register 0) is zero, and number of bytes remaining in the third operand is less than 16. In this case, the message-authentication tag computed thus far is placed into the T field of the parameter block, general register R_3 is incremented by the number of third-operand bytes processed (if any), general register $R_3 + 1$ is decremented by the same amount, and the instruction completes by setting condition code 2.
- The LAAD flag is one, and the number of bytes remaining in the third operand is between 1 and 15. In this case, the following is performed:
  - A copy of the remaining short block is padded on the right with sufficient binary zeros to form a full block that is hashed using GHASH.
  - General register R_3 is incremented by the number of third-operand bytes processed, and the third-operand length in general register $R_3 + 1$ is set to zero.

Processing of the last block of the third operand is illustrated in Figure 7-97.



Symbol	Explanation
<n>	Length of item in bytes
A	Last (short) block of additional authenticated data (in the third operand).
H	Hash subkey
L	Length of last 3rd-operand block in bytes (between 1 and 15).
T	Message-authentication tag (in the parameter block).
V	Number of bytes of zeros to pad the last block: 16 – L.
Z	Zeros.

Figure 7-97. GHASH Processing of Last (Short) Block

- The LAAD flag is one and the number of bytes remaining in the third operand is zero.

For either of the above two cases (when the LAAD flag is one), it is model dependent whether the instruction completes with condition code 3, or processing continues with the ciphering and hashing of the second operand, as described below.

Ciphering and Hashing: The ciphering-and-hashing process is not performed when either of the following conditions apply. In either of these conditions, general registers R_1, R_2, and R_2+1 are not modified, and it is model dependent whether the CV and T fields in the parameter block are fetched and stored back unmodified.

- The second-operand length in general register $R_2 + 1$ is initially less than 16, and the last-plaintext/ciphertext flag (LPC, bit 55 of general register 0) is zero. In this case, the instruction completes by setting condition code 2.
- The second-operand length is initially zero, and the LPC flag is one. In this case, processing continues as described in “Last Message-Authentication-Tag Hashing and Encryption” on page 7-97.

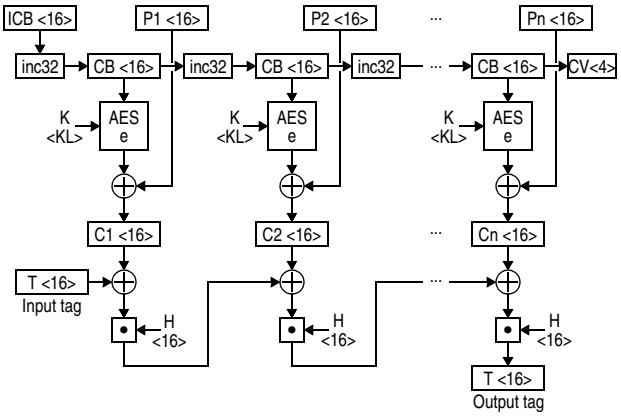
Depending on the M bit (bit 56 of general register 0), each block of the second operand is either encrypted or decrypted using the GCTR function described in Reference [17.] on page xxxii. The respective encrypted or decrypted result is placed at the first-operand location, and the encrypted operand is hashed using the GHASH function. The combination of the GCTR and GHASH processing is described as the GCM function in Reference [17.] on page xxxii.

Conceptually, the result is obtained as if processing starts at the left end of the first and second operands and proceeds to the right, block by block, as illustrated in Figure 7-98 and Figure 7-99. However, depending on the model, a unit of operation may process multiple blocks of the first and second operands in parallel; thus, the blocks may not necessarily be accessed in left-to-right order. Furthermore, multiple accesses may be made to a block, and in the case of the encryption operation, a first-operand block may be re-fetched after it is stored.

The GCTR function uses a 16-byte initial-counter block (ICB) formed from the concatenation of the leftmost 12 bytes of the initial-counter-value (J_0) on the left with the four-byte counter value (CV) on the right. GCTR also uses the key field (either directly from the parameter block for the KMA-GCM-AES functions, or the decrypted key for the KMA-GCM-encrypted-AES functions). For each block that is ciphered by GCTR, the counter value (CV) is incremented by one; a carry out of bit position 0 of the counter value is ignored. The GCTR function then uses a 16-byte counter block (CB) formed from the leftmost 12 bytes of J_0 concatenated with the incremented counter value.

The GHASH function uses the encrypted data (that is, the encrypted first-operand result when M is 0 or the second operand when M is one), the tag (T) field from either the parameter block or from the preceding step, and the hash subkey.

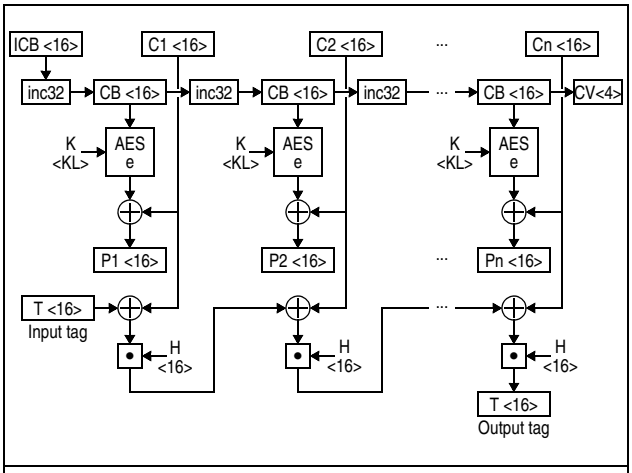
When the M bit is zero (that is, when the second operand is being encrypted), GCM processing of full blocks is illustrated in Figure 7-98.



Symbol	Explanation
<n>	Length of item in bytes
CB	Counter block formed from the concatenation of the leftmost 12 bytes of J_0 with the incremented counter value (CV)
Cn	Block n of the ciphertext (first operand).
CV	Counter value stored into the parameter block.
H	Hash subkey.
ICB	Initial counter block comprising the leftmost 12 bytes of the initial-counter value (J_0) concatenated with the 4-byte counter value (CV).
inc32	Incrementing of the 32-bit counter value (CV); a carry out of the leftmost bit position is ignored.
K	Key value.
KL	Key length (see Figure 7-91).
Pn	Block n of the plaintext (second operand).
T	Message-authentication tag (in the parameter block).

Figure 7-98. Combined Ciphering and Hashing of Full Blocks for Encryption

When the M bit is one (that is, when the second operand is being decrypted), GCM processing of full blocks is illustrated in Figure 7-99.



Explanation

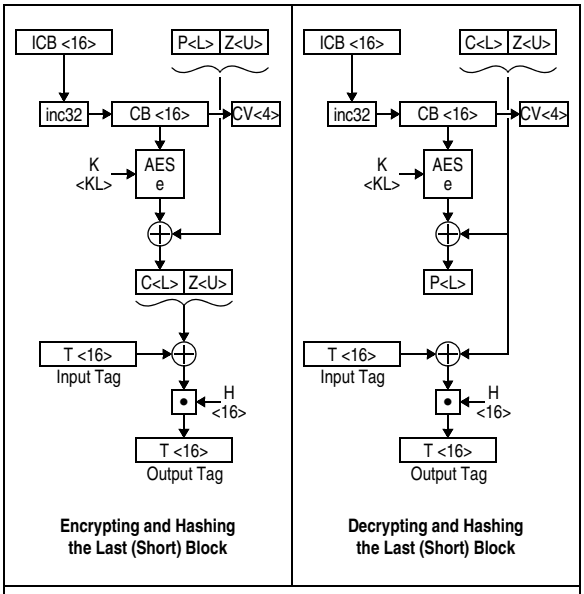
Cn Block n of the ciphertext (second operand).
Pn Block n of the plaintext (first operand).
Other symbols are the same as in Figure 7-98.

Figure 7-99. Combined Ciphering and Hashing of Full Blocks for Decryption

The ciphering-and-hashing process for either encryption or decryption continues until any of the following is true:

- A CPU-determined number of blocks that is less than the length of the second operand has been processed. In this case, the current counter value is placed into the CV field of the parameter block, the message-authentication tag computed thus far is placed into the T field of the parameter block, general registers R_1 and R_2 are incremented by the number of second-operand bytes processed, general register $R_2 + 1$ is decremented by the same amount, and the instruction completes by setting condition code 3.
- The last-plaintext/ciphertext flag (LPC, bit 55 of general register 0) is zero, and number of bytes remaining in the second operand is less than 16. In this case, the current counter value is placed into the CV field of the parameter block, the message-authentication tag computed thus far (if any) is placed into the T field of the parameter block, general registers R_1 and R_2 are incremented by the number of second-operand bytes processed (if any), general register $R_2 + 1$ is decremented by the same amount, and the instruction completes by setting condition code 2.
- The LPC flag is one, and the number of bytes remaining in the second operand is between 1 and 15. In this case, the following is performed:
  - A copy of the remaining bytes of the second operand is padded on the right with sufficient binary zeros to form a full block that is ciphered using the GCTR algorithm, and the leftmost bytes of the resulting encrypted or decrypted block are placed at the first-operand location. The number of bytes placed at the first-operand location is the same as the number of bytes remaining in the second operand (that is, less than 16).
  - The GHASH algorithm is then applied to the ciphertext. When M is zero, the input to the GHASH algorithm consists of a copy of the short block stored into the first-operand location, padded on the right with sufficient binary zeros to form a full block. When M is one, the input to the GHASH algorithm is the same as the input to the GCTR algorithm (that is, a copy of the remaining bytes of the second operand, padded on the right with sufficient binary zeros to form a full block).
  - The current counter value is placed into the CV field of the parameter block, the resulting tag value is placed in the parameter block, general registers R_1 and R_2 are incremented by the number of second-operand bytes processed, and general register $R_2 + 1$ is set to zero.

GCM processing of the last block of the second operand is illustrated in Figure 7-100.



Symbol	Explanation
<n>	Length of item in bytes
CB	Counter block formed from the concatenation of the leftmost 12 bytes of J_0 with the incremented counter value (CV)
C	Last (short) block of the ciphertext (first operand when M=0, second operand when M=1).
CV	Counter value (in the parameter block)
H	Hash subkey
ICB	Initial counter block comprising the leftmost 12 bytes of the initial-counter value (J_0) concatenated with the 4-byte counter value (CV).
inc32	Incrementing of the 32-bit counter value (CV); a carry out of the leftmost bit position is ignored.
K	Key value.
KL	Key length (see Figure 7-91).
L	Length of last second-operand block in bytes (between 1 and 15).
P	Last (short) block n of the plaintext (second operand when M=0, first operand when M=1).
T	Message-authentication tag (in the parameter block).
U	Number of bytes of zeros to pad the last block: 16 – L.
Z	Zeros.

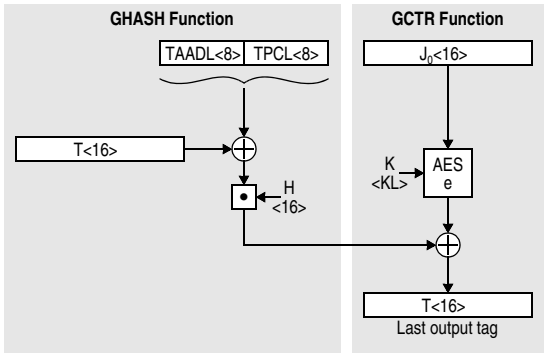
Figure 7-100. Ciphering and Hashing of the Last (Short) Block.

- The LPC flag is one, and the number of bytes remaining in the second operand is zero.

For either of the above two cases (when the LPC flag is one), it is model dependent whether the instruction completes with condition code 3 or continues processing with the last message-authentication-tag hashing and encryption, as described below.

Last Message-Authentication-Tag Hashing and Encryption: A 128-bit value comprising the concatenation of the 64-bit total-AAD-length (TAADL) and total-plaintext-or-ciphertext-length (TPCL) fields from the parameter block is hashed using the GHASH function. The GHASH function uses the concatenated lengths field, the tag (T) field as computed in the ciphering-and-hashing operation, and the hash subkey.

The resulting 128-bit output of GHASH is then processed by the GCTR algorithm. Note, unlike the ciphering-and-hashing operation, the input counter to GCTR is the initial-counter-block (J_0) field from the parameter block. The resulting 128-bit value replaces the tag (T) field in the parameter block. Subsequently, when the CPU is not enabled to update counters in the cryptography-counter set, the instruction completes with condition code 0; otherwise, the appropriate counter is updated before the instruction completes with condition code 0. Figure 7-101 illustrates the hashing and encryption of the last tag value.



Symbol	Explanation
<n>	Length of item in bytes
H	Hash subkey
J_0	Initial counter value (from the parameter block)
K	Key value.
KL	Key length (see Figure 7-91).
T	Message-authentication tag (in the parameter block).
TAADL	Total length of the message's additional-authenticated data (AAD) in bits (from the parameter block).
TPCL	Total length of the message's plaintext or ciphertext in bits (from the parameter block).

Figure 7-101. Hashing and Encrypting the Last Tag

Common Operation: The detection of conditions resulting in condition code 3 depends on the model, and may be a different number each time the instruction is executed. The CPU-determined number of blocks is usually nonzero. In certain unusual situa-

tions, this number may be zero, and condition code 3 may be set with no progress. However, the CPU protects against endless reoccurrence of this no-progress case.

The results are unpredictable if either of the following is true:

- The third operand overlaps destructively with any portion of the parameter block that may be updated during AAD processing.
- The LAAD flag is one, and any of the following is true:
  - The second operand overlaps destructively with any portion of the parameter block that may be updated during ciphering and hashing.
  - The first operand overlaps destructively with any portion of the parameter block that may be accessed during ciphering and hashing.
  - The first operand overlaps destructively with the second operand, but the operands do not designate the same location.

Operands are said to overlap destructively when a location would be used as a source after data would have been moved into it, assuming processing to be performed from left to right.

Figure 7-102 illustrates the various condition codes set by the instruction, and the resulting second- and third-operand lengths based on the LAAD and LPC flags.

Condition Code	LAAD	LPC	3rd-operand length	2nd-operand length
0	1	1	0	0
1	—	—	Unchanged†	Unchanged†
2	0	—	< 16	Unchanged
	1	0	0	< 16
3	0	—	>= 16	Unchanged
	1	0	0	>= 16
	1 ‡	1 ‡	0 ‡	0 ‡

Figure 7-102. Condition Codes and Resulting Operand Lengths, based on LAAD and LPC

Condition Code	LAAD	LPC	3rd-operand length	2nd-operand length

Explanation:

— Not applicable
† Also, first-, second-, and third-operand addresses in general registers R_1, R_2, and R_3 are unchanged
‡ It is model dependent whether CC3 is set for these conditions (which are identical to the CC0 conditions).
LAAD Last-additional-authenticated-data flag, bit 54 of general register 0
LPC Last-plaintext/ciphertext flag, bit 55 of general register 0

Figure 7-102. Condition Codes and Resulting Operand Lengths, based on LAAD and LPC

Store-type access exceptions may be recognized for any location in the parameter block, even though only the CV, T, and H fields are actually stored by the instruction.

A PER storage-alteration event may be recognized both for the first-operand location and for the portion of the parameter block that is stored. A PER zero-address-detection event may be recognized for the first-, second-, and third-operand locations and for the parameter block (including the reserved field of the parameter block). When PER events are detected for one or more of these locations, it is unpredictable which location is identified in the PER access identification (PAID) and PER ASCE ID (AI).

It is unpredictable how many bytes of the first-, second-, or third-operand locations has been processed when a PER storage-alteration event is recognized for the parameter block. When a storage-alteration PER event is recognized for the first-operand location, fewer than 4K additional bytes are stored into the first-operand locations before the event is reported.

When the third-operand length is initially zero, the third operand is not accessed, and the third-operand address and third-operand length in general registers R_3 and $R_3 + 1$, respectively, are not changed. When the second-operand length is initially zero, the second operand is not accessed, and the second-operand address and second-operand length in general registers R_2 and $R_2 + 1$, respectively, are not changed. However, the parameter block may be accessed even when the second- and third-operand lengths are both zero.

When the contents of the R_1 and R_2, fields are the same, the contents of the designated registers are

incremented only by the number of bytes processed, not by a multiple of the number of bytes processed.

As observed by this CPU, other CPUs, and channel programs, references to the parameter block and storage operands may be multiple-access references, accesses to these storage locations are not necessarily block-concurrent, and the sequence of these accesses or references is undefined.

In certain unusual situations, instruction execution may complete by setting condition code 3 without updating the registers to reflect the last unit of the first, second, and third operands processed. The size of the unit processed in this case depends on the situation and the model, but is limited such that the portion of the first and second operands which have been processed and not reported do not overlap in storage; and the portion of the first and third operands which have been processed and not reported do not overlap in storage. In all cases, change bits are set and PER storage-alteration events are reported, when applicable, for all first-operand locations processed.

For functions that perform a comparison of the wrapping-key verification pattern field in the parameter block with the wrapping-key verification-pattern register, it is unpredictable whether access exceptions and PER zero-address-detection events are recognized for the first, second, and third operands when the comparison results in a mismatch and respective operand's length is nonzero.

Access exceptions may be reported for a larger portion of an operand than is processed in a single execution of the instruction; however, access exceptions are not recognized for locations beyond the length of an operand nor for locations more than 4K bytes beyond the current location being processed.

If the CPU is enabled to update counters in the cryptography-counter set, then the following apply:

- Subsequent to performing the last message-authentication-tag hashing and encryption process, the appropriate counter is updated before the instruction completes with condition code 0.
- When the appropriate counter is not accessible after completing the ciphering-and-hashing process, an access exception is recognized for the counter location either before or after performing the last message-authentication-tag hashing and encryption process.
- If instruction execution includes completing the ciphering-and-hashing process and the appropriate counter is not accessible, then the instruction ends in partial completion with condition code 3 set or the last message-authentication-tag hashing and encryption process is started.
- If instruction execution includes completing the last message-authentication-tag hashing and encryption process and the appropriate counter is not accessible, then the instruction ends in partial completion with condition code 3 set.

KMA-Query-Authentication-Information (Function Code 127)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-88 on page 7-89.

The KMA-query-authentication-information function stores the information that can be used by the program to authenticate the running instruction's firmware code level (IFCL) currently installed on the model into the format-0 parameter block for KMA-query-authentication-information. Condition code 0 is set when execution of the KMA-query-authentication-information function completes; condition codes 1, 2, and 3 are not applicable to this function.

The format-0 parameter block used for the KMA-query-authentication-information function has the following format:

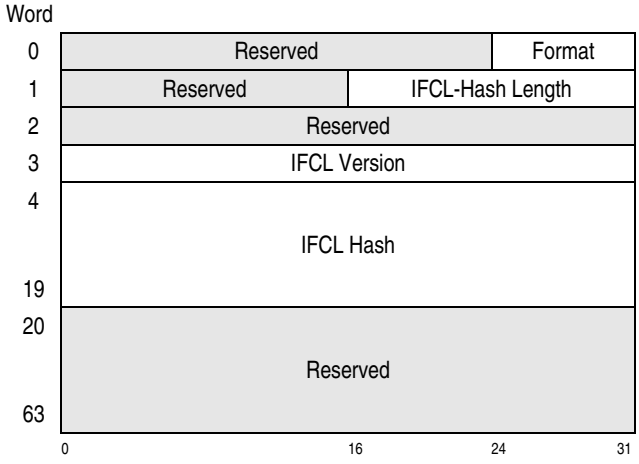


Figure 7-103. Format-0 Parameter Block for KMA-Query-Authentication-Information

The format-0 parameter block contains the following fields:

Reserved: Bytes 0-2 of word 0, bytes 0-1 of word 1, word 2, and words 20-63 are reserved and stored as zeros.

Format: Byte 3 of word 0 contains an 8-bit unsigned binary integer whose value specifies the format of the parameter block. A format value of zero indicates a format-0 parameter block. When a format-0 parameter block is stored, the value of this field is set to zero.

IFCL-Hash Length: Bytes 2-3 of word 1 contain a 16-bit unsigned binary integer specifying the number of bytes of the IFCL hash stored in the IFCL hash field. When the IFCL hash is less than or equal to 64 bytes, the IFCL-hash length field is set to the actual length of the IFCL hash. When the IFCL hash is larger than 64 bytes, the IFCL-hash length field is set to 64.

IFCL Version: Word 3 contains a 32-bit unsigned binary integer specifying the version number of the IFCL.

IFCL Hash: Words 4-19 contain the hash value of the IFCL. The IFCL-hash length field specifies the number of bytes that are in the IFCL hash field. The IFCL hash value is left aligned. When the IFCL hash is less than 64 bytes, it is padded with zeros on the right. When the IFCL hash is larger than 64 bytes, only the leftmost 64 bytes of the IFCL hash are stored.

Special Conditions for KMA

A specification exception is recognized and no other action is taken if any of the following occurs:

1. Bits 57-63 of general register 0 specify an unassigned or uninstalled function code.
2. The R_1 R_2, or R_3 field designates an odd-numbered register or general register 0.
3. The R_3 field designates the same register as either the R_1 or R_2 fields.
4. The function code is neither 0 nor 127, and the LPC flag is one (indicating that the last blocks of plaintext or ciphertext are being processed), but the LAAD flag is zero (indicating that not all AAD has been processed).

Resulting Condition Code:

0 Normal completion
1 Verification-pattern mismatch
2 Incomplete processing (remaining third-operand length is less than 16 when the LAAD flag is zero, or remaining second-operand length is less than 16 when the LPC flag is zero)
3 Partial completion (model-dependent limit exceeded)

Program Exceptions:

- Access (fetch, operand 2, operand 3, and parameter block fields; store, operand 1, counter value, hash subkey, tag, query parameter block, and query-authentication-information parameter block; fetch and store, cryptography counter)
- Operation (if the message-security-assist extension 8 is not installed)
- Specification
- Transaction constraint

1.-7.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
8.	Specification exception due to invalid function code or invalid register number.
9.	Specification exception due to LPC flag being one when the LAAD flag is zero (applicable only when the function code is nonzero).
10.A.1	Access exceptions for an access to the parameter block.
10.A.2	Condition code 1 due to verification-pattern mismatch.
10.B	Access exceptions for an access to the first, second, or third operand.
11.	Condition code 3 due to partial or complete processing of the third operand and a CPU-determined amount of processing completed.
12.	Condition code 2 due to the remaining third-operand length being less than 16 when the LAAD flag is zero.
13.	Condition code 3 due to partial or complete processing of the second operand and a CPU-determined amount of processing completed.

Figure 7-104. Priority of Execution: KMA

14.	Condition code 2 due to remaining second-operand length being less than 16 when the LPC flag is zero.
15.A	Condition code 3 due to second-operand length equal to zero, LPC flag is one and access-exception condition detected for an access to a cryptography counter.
15.B	Access exceptions for an access to a cryptography counter and second-operand length initially zero and LPC flag is one.
16.	Condition code 0 due to normal completion.

Figure 7-104. Priority of Execution: KMA (Continued)

Programming Notes:

1. The performance of the query function (code 0) may be significantly slower than that of simply examining a location in storage. If the program needs to frequently test for the availability of a function, it should perform the query function once during initialization; subsequently it should examine the stored results of the query function in memory with an instruction such as TEST UNDER MASK.

2. As observed by this CPU, other CPUs, and the I/O subsystem, inconsistent results may be briefly stored in the first-operand location. See the section “Effects of CPU Retry” on page 11-3 for further details.

3. When processing an individual message, the program should initially set the following fields in the parameter block and not alter these fields until the instruction completes with condition code 0; otherwise, the results will not conform to the GCM standard, as described in Reference [17.] on page xxxii.

   a. *Counter Value (CV):* The CV field should be initialized with the rightmost 4 bytes of the initial-counter-value (J_0) field.

   b. *Tag (T):* The tag field should be initialized to zeros.

   c. *The Hash Subkey (H):* For KMA-GCM-AES functions (codes 18-20), the following applies:

      - When the HS flag is one, the program supplies a pre-computed hash subkey in the H field. The subkey comprises 16 bytes of zeros, encrypted using the AES algorithm.
      - When the HS flag is zero, the CPU encrypts 16 bytes of zeros using the AES algorithm and key field in the parameter block, stores the results in the H field, and sets the HS flag to one.

      For KMA-GCM-encrypted-AES functions (codes 26-28), the CPU always calculates the hash subkey, and the H field and HS flags are not altered.

   d. *Initial-Counter Value (J_0):* The initial-counter value is derived from an initialization vector (IV) provided by the program. If the program uses a 96-bit IV (as recommended in Reference [17.] on page xxxii), then it should store the IV into the leftmost 12 bytes of the J_0 field, and store 00000001 hex in the rightmost bytes of the J_0 field. If the program uses an IV having a different length, then it must supply a 16-byte hashed value of the IV in the J_0 field using the GHASH algorithm (as described in Reference [17]).

   e. *Key Value (K) and Wrapping-Key Verification Pattern (WK_aVP):* For proper ciphering of an individual message, the key must be the same for all executions of the instruction. For KMA-encrypted-AES functions, the wrapping-key-verification-pattern field must also remain unchanged.

4. When processing the last plaintext or ciphertext block(s) (that is, when the LPC flag is one), the total-AAD-length (TAADL) and total-plaintext/ciphertext-length (TPCL) fields in the parameter block should contain the total length in bits of the respective AAD and plaintext or ciphertext for the entire message.

5. The program is responsible for comparing the hashed tag of a decrypted message with that of the message when it was encrypted to ensure authenticity of the message.

6. The LAAD and LPC flags provide the means by which a message can be ciphered and hashed when not all components of the message are available for a single execution of the instruction. For example, if the plaintext or ciphertext portion of a message spans multiple disk or tape records, and not all blocks of the message have been read into storage, the program can process

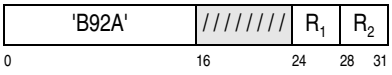
the earlier blocks of the message by issuing the instruction with the LPC flag set to zero. When the final plaintext or ciphertext blocks of the message are available, the program can then complete the message ciphering by issuing the instruction with the LPC flag set to one.

When condition code 2 is set due to either or both the LAAD or LPC flag being zero, the general registers containing the operand addresses and lengths, and the parameter block are updated to indicate the progress thus far. However, unlike condition code 3 (where the program can simply branch back to the instruction to continue the operation), the program is responsible for updating the operand addresses and lengths, and the LAAD and LPC flags, as necessary, before branching back to the instruction. If the program simply branches back to the instruction in response to condition code 2, a nonproductive program loop will result.

7. When condition code 3 is set, the general registers containing the operand addresses and lengths, and the parameter block, are usually updated such that the program can simply branch back to the instruction to continue the operation.

CIPHER MESSAGE WITH CIPHER FEEDBACK

KMF R_1,R_2 [RRE]



A function specified by the function code in general register 0 is performed.

Bits 16-23 of the instruction are ignored.

Bit positions 32-39 of general register 0 contain the length of cipher feedback in bytes (LCFB, also known as “s”), and bit positions 57-63 of general register 0 contain the function code. Figure 7-105 shows the assigned function codes for CIPHER MESSAGE WITH CIPHER FEEDBACK. When the message-security-assist extension 13 is installed, function code 127 is valid for CIPHER MESSAGE WITH CIPHER FEEDBACK. All other function codes are unassigned. For cipher functions, bit 56 is the modifier bit which specifies whether an encryption or a decryption operation is to be performed. The modifier bit is ignored for all other functions. Bits 0-31 and 40-55 of general register 0 are ignored.

General register 1 contains the logical address of the leftmost byte of the parameter block in storage. In the 24-bit addressing mode, the contents of bit positions 40-63 of general register 1 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of general register 1 constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register 1 constitute the address.

The function codes for CIPHER MESSAGE WITH CIPHER FEEDBACK are as follows.

Code	Function	Parm. Block Size (bytes)	Data Block Size[1] (bytes)
0	KMF-Query	16	—
1	KMF-DEA	16	8
2	KMF-TDEA-128	24	8
3	KMF-TDEA-192	32	8
9	KMF-Encrypted-DEA	40	8
10	KMF-Encrypted-TDEA-128	48	8
11	KMF-Encrypted-TDEA-192	56	8
18	KMF-AES-128	32	16
19	KMF-AES-192	40	16
20	KMF-AES-256	48	16
26	KMF-Encrypted-AES-128	64	16
27	KMF-Encrypted-AES-192	72	16
28	KMF-Encrypted-AES-256	80	16
127	KMF-Query-Authentication-Information	V	—

Explanation:

1 The size of ciphertext and plaintext segments (s) range from 1 to the data-block size, depending on the value of the LCFB in bits 32-39 of general register 0.

— Not applicable

V Variable parameter block size. See each format-x parameter block for the exact size of that parameter block.

Figure 7-105. Function Codes for CIPHER MESSAGE WITH CIPHER FEEDBACK

All other function codes are unassigned.

The query function provides the means of indicating the availability of the other functions. The contents of general registers R_1, R_2, and $R_2 + 1$ are ignored for the query function.

The query-authentication-information function provides the information that can be used by the program to authenticate the running instruction's firmware code level (IFCL) currently installed on the model. The contents of general registers R_1, R_2, and $R_2 + 1$ are ignored for the query-authentication-information function.

For all other functions, the second operand is ciphered as specified by the function code using a cryptographic key and an initial chaining value in the parameter block, and the result is placed in the first-operand location. The chaining value is updated as part of the operation.

The R_1 field designates a general register and must designate an even-numbered register other than general register 0; otherwise, a specification exception is recognized. The R_2 field designates an even-odd pair of general registers and must designate an even-numbered register other than general register 0; otherwise, a specification exception is recognized.

The location of the leftmost byte of the first and second operands is specified by the contents of the R_1 and R_2 general registers, respectively. The number of bytes in the second-operand location is specified in general register $R_2 + 1$ and must be a multiple of the cipher-feedback length in bits 32-39 of general register 0; otherwise, a specification exception is recognized. The first operand is the same length as the second operand.

As part of the operation, the addresses in general registers R_1 and R_2 are incremented by the number of bytes processed, and the length in general register $R_2 + 1$ is decremented by the same number. The formation and updating of the addresses and length is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers R_1 and R_2 constitute the addresses of the first and second operands, respectively, and the contents of bit positions 0-39 are ignored; bits 40-63 of the updated addresses replace the corresponding bits in general registers R_1 and R_2, carries out of bit position 40 of the updated address are ignored, and the contents of bit positions 32-39 of general registers R_1 and R_2 are set to zeros. In the 31-bit addressing mode, the contents of bit positions 33-63 of general registers R_1 and R_2 constitute the addresses of the first and second operands, respectively, and the contents of bit positions 0-32 are ignored; bits 33-63 of the updated addresses replace the corresponding bits in general registers R_1 and R_2, carries out of bit position 33 of the updated address are ignored, and the content of bit position 32 of general registers R_1 and R_2 is set to zero. In the 64-bit addressing mode, the contents of bit positions 0-63 of general registers R_1 and R_2 constitute the addresses of the first and second operands, respectively; bits 0-63 of the updated addresses replace the contents of general registers R_1 and R_2, and carries out of bit position 0 are ignored.

In both the 24-bit and the 31-bit addressing modes, the contents of bit positions 32-63 of general register $R_2 + 1$ form a 32-bit unsigned binary integer which specifies the number of bytes in the first and second operands, and the contents of bit positions 0-31 are ignored; bits 32-63 of the updated value replace the corresponding bits in general register $R_2 + 1$. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register $R_2 + 1$ form a 64-bit unsigned binary integer which specifies the number of bytes in the first and second operands; and the updated value replaces the contents of general register $R_2 + 1$.

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers R_1, R_2, and $R_2 + 1$, always remain unchanged.

Figure 7-106 on page 7-103 shows the contents of the general registers just described.

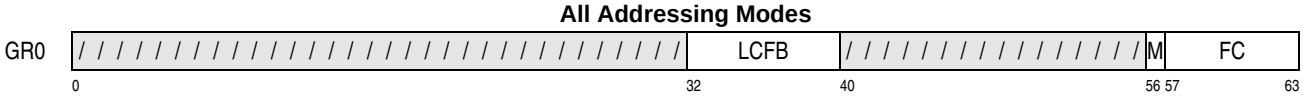


Figure 7-106. General Register Assignment for KMF (Part 1 of 2)

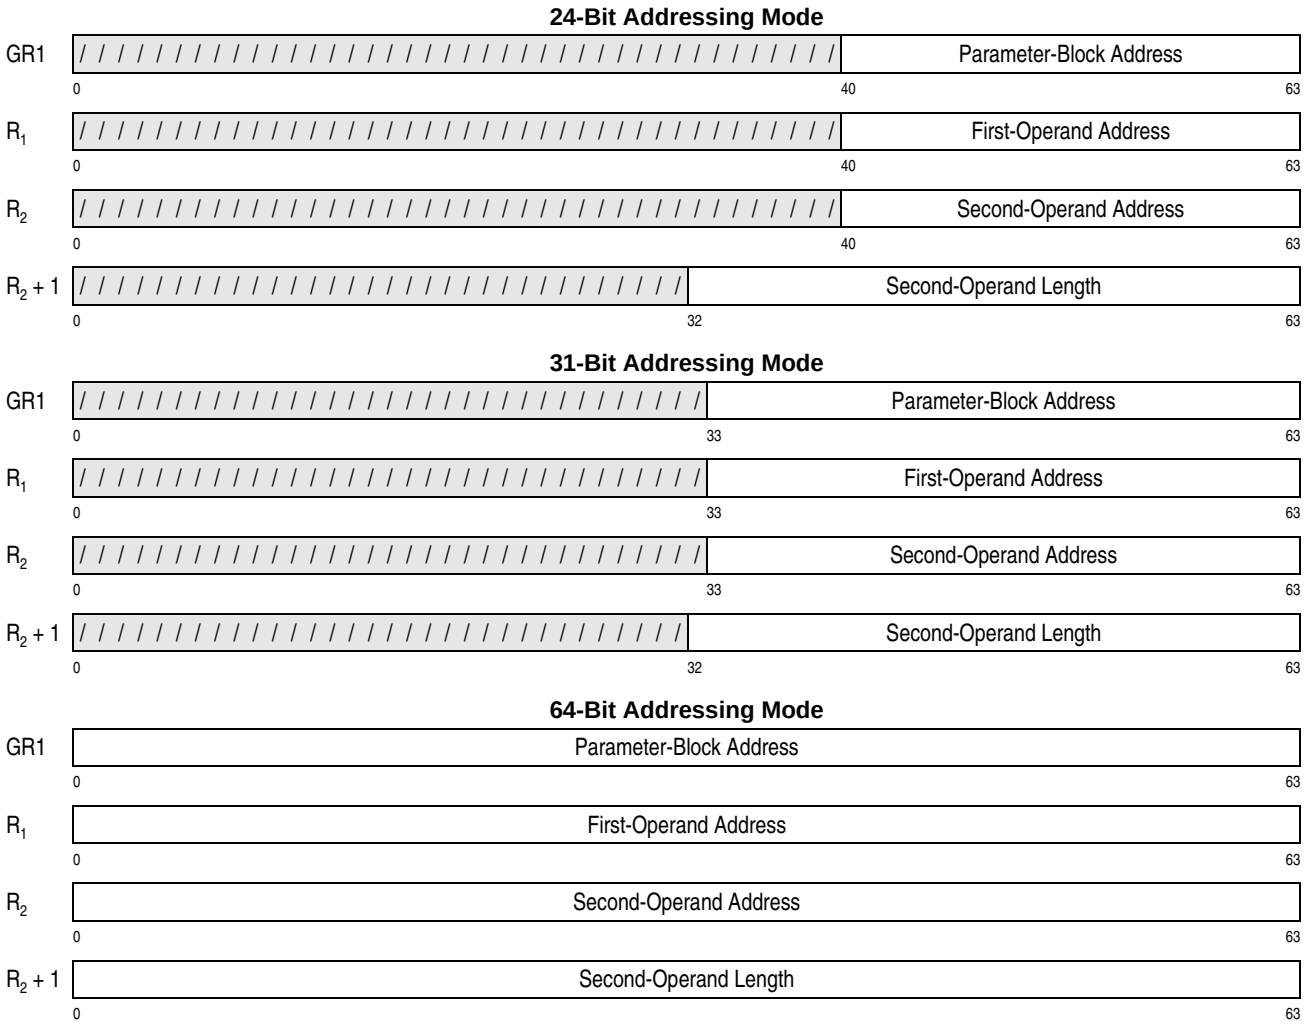

Figure 7-106. General Register Assignment for KMF (Part 2 of 2)

In the access-register mode, access registers 1, R_1, and R_2 specify the address spaces containing the parameter block, first, and second operands, respectively.

The result is obtained as if processing starts at the left end of both the first and second operands and proceeds to the right, block by block. The cipher operation is ended when the number of bytes in the second operand as specified in general register $R_2 + 1$ have been processed and placed at the first-operand location or when a CPU-determined number of blocks that is less than the length of the second operand have been processed. The CPU-determined number of blocks depends on the model, and may be a different number each time the instruction is executed. The CPU-determined number of blocks is usually nonzero. In certain unusual situations, this number may be zero, and condition code 3 may be set with no progress. However, the CPU protects against endless reoccurrence of this no-progress case.

If the CPU is enabled to update counters in the cryptography-counter set, then subsequent to processing all bytes of the second operand, the appropriate counter is updated.

The results in the first-operand location and the chaining-value field are unpredictable if any of the following situations occur:

1. The cryptographic-key field or the encrypted cryptographic-key field overlaps any portion of the first operand.
2. The chaining-value field overlaps any portion of the first operand or the second operand.

3. The first and second operands overlap destructively. Operands are said to overlap destructively when the first-operand location would be used as a source after data would have been moved into it, assuming processing to be performed from left to right and one byte at a time.

Normal completion occurs when the cipher operation has ended and, when applicable, a counter in the cryptography-counter set has been updated. Partial completion occurs when a CPU-determined number of blocks that is less than the length of the second operand have been processed or when the CPU is enabled to update a counter in the cryptography-counter set and the appropriate counter has not yet been updated.

When the operation ends due to normal completion, condition code 0 is set and the resulting value in $R_2 + 1$ is zero. When the operation ends due to partial completion, condition code 3 is set. In this case, if the CPU is enabled to update counters in the cryptography-counter set, all of the second operand has been processed, and the appropriate counter is not accessible, then the resulting value placed in general register $R_2 + 1$ is zero; otherwise the resulting value placed in general register $R_2 + 1$ is nonzero.

A PER storage-alteration event may be recognized both for the first-operand location and for the portion of the parameter block that is stored. A PER zero-address-detection event may be recognized for the first- and second-operand locations and for the parameter block. When PER events are detected for one or more of these locations, it is unpredictable which location is identified in the PER access identification (PAID) and PER ASCE ID (AI).

When a storage-alteration PER event is recognized, fewer than 4K additional bytes are stored into the first-operand locations before the event is reported.

When the second-operand length is initially zero, the following occurs. The parameter block, first, and second operands are not accessed, and general registers R_1, R_2, and $R_2 + 1$ are not changed. If the CPU is not enabled to update counters in the cryptography-counter set, then condition code 0 is set. If the CPU is enabled to update counters in the cryptography-counter set, and the appropriate counter is accessible, then the appropriate counter is updated and condition code 0 is set. If the CPU is enabled to update counters in the cryptography-counter set, and the appropriate counter is not accessible, then the condition code remains unchanged and an access exception is recognized for the location of the appropriate counter.

When the contents of the R_1 and R_2 fields are the same, the contents of the designated registers are incremented only by the number of bytes processed, not by twice the number of bytes processed.

As observed by this CPU, other CPUs, and channel programs, references to the parameter block and storage operands may be multiple-access references, accesses to these storage locations are not necessarily block-concurrent, and the sequence of these accesses or references is undefined.

In certain unusual situations, instruction execution may complete by setting condition code 3 without updating the registers and chaining value to reflect the last unit of the first and second operands processed. The size of the unit processed in this case depends on the situation and the model, but is limited such that the portion of the first and second operands which have been processed and not reported do not overlap in storage. In all cases, change bits are set and PER storage-alteration events are reported, when applicable, for all first-operand locations processed.

For functions that perform a comparison of the wrapping-key verification pattern field in the parameter block with the wrapping-key verification-pattern register, it is unpredictable whether access exceptions and PER zero-address-detection events are recognized for the first and second operands when the comparison results in a mismatch.

Access exceptions may be reported for a larger portion of an operand than is processed in a single execution of the instruction; however, access exceptions are not recognized for locations beyond the length of an operand nor for locations more than 4K bytes beyond the current location being processed.

Symbols Used in Function Descriptions

The following symbols are used in the subsequent description of the CIPHER MESSAGE WITH CIPHER FEEDBACK functions. For data-encryption-algorithm (DEA) functions, the DEA-key-parity bit in each byte of the DEA key is ignored, and the operation proceeds normally, regardless of the DEA-key parity of the key.

Further description of the data-encryption algorithm may be found in Reference [13.] on page xxxii. Further description of the AES standard may be found in Reference [14.] on page xxxii. Further description of the cipher-feedback mode of encryption and decryption may be found in Reference [16.] on page xxxii.

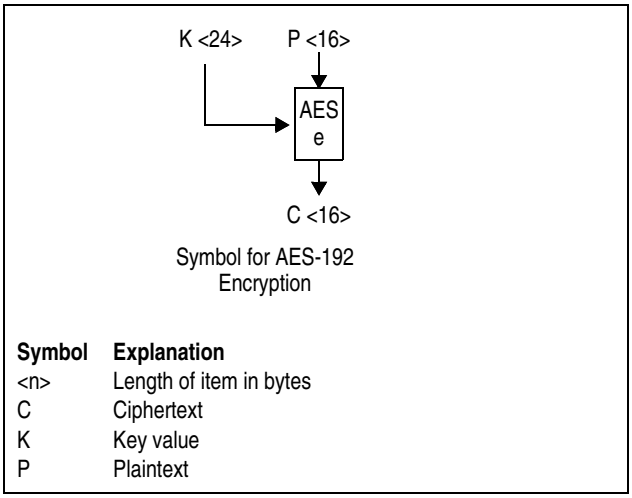

Figure 7-110. Symbols for AES-192 Encryption

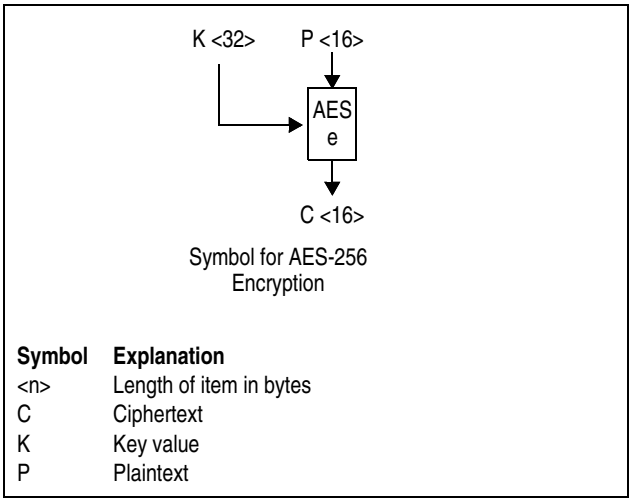

Figure 7-111. Symbols for AES-256 Encryption

KMF-Query (Function Code 0)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-106 on page 7-103.

The parameter block used for the function has the following format:

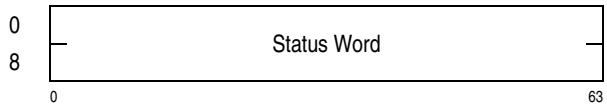

Figure 7-112. Parameter Block for KMF-Query

A 128-bit status word is stored in the parameter block. Bits 0-127 of this field correspond to function codes 0-127, respectively, of the CIPHER MESSAGE WITH CIPHER FEEDBACK instruction. When a bit is

one, the corresponding function is installed; otherwise, the function is not installed.

Condition code 0 is set when execution of the KMF-Query function completes; condition codes 1 and 3 are not applicable to this function.

In the following function descriptions, the term *input block* refers to the 8- or 16-byte input to the DEA or AES algorithms, respectively. Similarly, the term *output block* refers to the 8- or 16-byte results from the respective algorithms. The term *segment* refers to the s-byte portions of the first and second operands.

KMF-DEA (Function Code 1)

KMF-Encrypted-DEA (Function Code 9)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-106 on page 7-103.

The parameter block used for the KMF-DEA function has the following format:

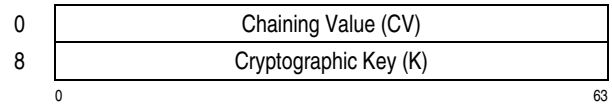

Figure 7-113. Parameter Block for KMF-DEA

For the KMF-DEA function, the chaining value is in byte offset 0-7 of the parameter block and the cryptographic key is in byte offsets 8-15 of the parameter block.

The parameter block used for the KMF-Encrypted-DEA function has the following format:

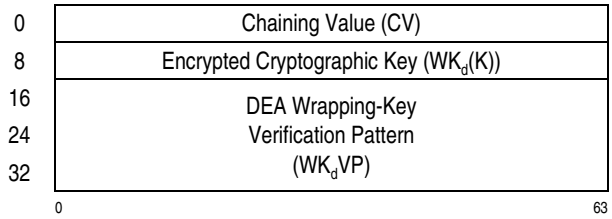

Figure 7-114. Parameter Block for KMF-Encrypted-DEA

For the KMF-Encrypted-DEA function, the contents of byte offsets 16-39 of the parameter block are compared with the contents of the DEA wrapping-key verification-pattern register. If they mismatch, the first-operand and parameter-block locations remain unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 0-7 of the parameter block contain the chaining value, and the contents of byte offsets 8-15 of the parameter block are deciphered using the DEA wrapping key to obtain the 64-bit cryptographic key. (See the section, “Protection of Cryptographic Keys” on page 7-490 for details.)

The following description applies to both functions.

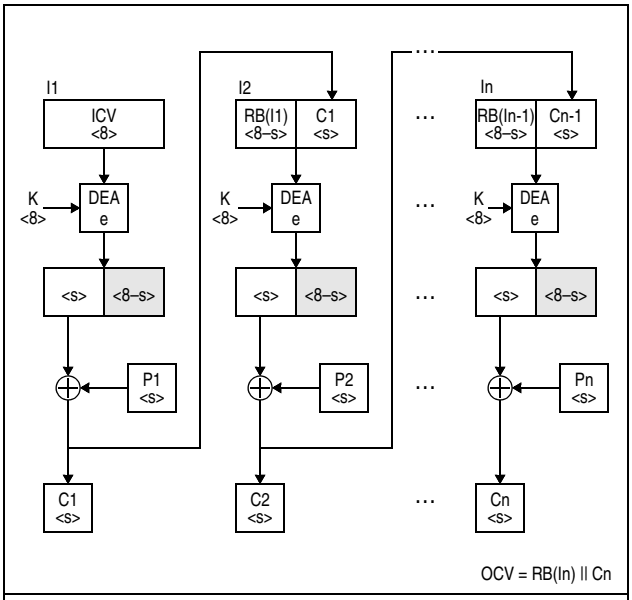
When the modifier bit in general register 0 is zero, an encipher operation is performed. The s-byte plaintext segments (P1, P2, …, Pn) in operand 2 are enciphered using the DEA-encryption algorithm with the 64-bit cryptographic key and the 64-bit chaining value, where s is the length of cipher feedback in bytes (LCFB).

The first input block to the DEA-encryption algorithm is the initial chaining value (ICV) in the parameter block. Each input block is enciphered to produce an output block. The s leftmost bytes of each output block are exclusive-ORed with the corresponding s-byte plaintext segment to form a s-byte ciphertext segment. The remaining (8 - s) bytes of each output block are ignored. Each ciphertext segment is concatenated to the right of the (8 - s) rightmost bytes of the previous input block to form the next input block.

The process is repeated with the successive input blocks until a ciphertext segment is produced for every plaintext segment, or until a CPU-determined number of ciphertext segments have been produced.

The ciphertext segments (C1, C2, …, Cn) are stored in operand 1. The final next-input block is stored into

the chaining-value field of the parameter block. The operation is shown in Figure 7-115.



Symbol	Explanation
||	Concatenation
Ij	Input block j to DEA
RB(Ij)	Rightmost (8-s) bytes of input block j
Note:	The rightmost (8–s) bytes of the output block from the DEA-encipher operation are ignored.

Figure 7-115. KMF-DEA Encipher Operation

When the modifier bit in general register 0 is one, a decipher operation is performed. The s-byte ciphertext segments (C1, C2, …, Cn) in operand 2 are deciphered using the DEA-encryption algorithm with the 64-bit cryptographic key and the 64-bit chaining value, where s is the length of cipher feedback in bytes.

The first input block to the DEA-encryption algorithm is the initial chaining value (ICV) in the parameter block. Each input block is enciphered to produce an output block. The s leftmost bytes of each output block are exclusive-ORed with the corresponding s-byte ciphertext segment to form a s-byte plaintext segment. The remaining (8 - s) bytes of each output block are ignored. Each ciphertext segment is concatenated to the right of the (8 - s) rightmost bytes of the previous input block to form the next input block.

The process is repeated with the successive input blocks until a plaintext segment is produced for every ciphertext segment, or until a CPU-determined number of plaintext segments have been produced.

The plaintext segments (P1, P2, …, Pn) are stored in operand 1. The final next-input block (OCV) is stored into the chaining-value field of the parameter block. The operation is shown in Figure 7-116.

Figure 7-116. KMF-DEA Decipher Operation

KMF-TDEA-128 (Function Code 2)

KMF-Encrypted-TDEA-128 (Function Code 10)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-106 on page 7-103.

The parameter block used for the KMF-TDEA-128 function has the following format:

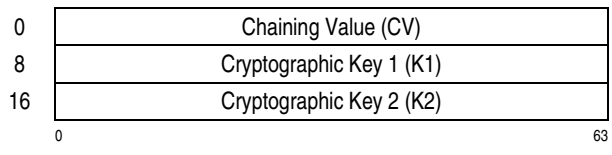

Figure 7-117. Parameter Block for KMF-TDEA-128

For the KMF-TDEA-128 function, the chaining value is in byte offset 0-7 of the parameter block and the cryptographic key is in byte offsets 8-23 of the parameter block.

The parameter block used for the KMF-Encrypted-TDEA-128 function has the following format:

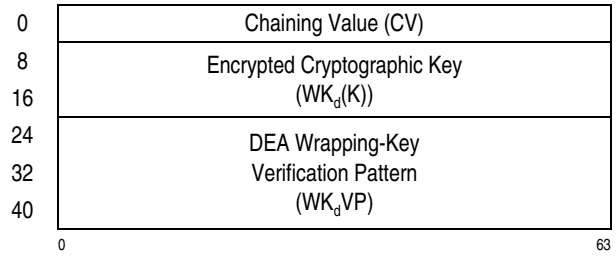

Figure 7-118. Parameter Block for KMF-Encrypted-TDEA-128

For the KMF-Encrypted-TDEA-128 function, the contents of byte offsets 24-47 of the parameter block are compared with the contents of the DEA wrapping-key verification-pattern register. If they mismatch, the first-operand and parameter-block locations remain unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 0-7 of the parameter block contain the chaining value, and the contents of byte offsets 8-23 of the parameter block are deciphered using the DEA wrapping key to obtain the 128-bit cryptographic key. (See the section, “Protection of Cryptographic Keys” on page 7-490 for details.)

The following description applies to both functions.

When the modifier bit in general register 0 is zero, an encipher operation is performed. The s-byte plaintext segments (P1, P2, …, Pn) in operand 2 are enciphered using the TDEA-encryption algorithm with the 128-bit cryptographic key and the 64-bit chaining value, where s is the length of cipher feedback in bytes.

The first input block to the TDEA-encryption algorithm is the initial chaining value (ICV) in the parameter block. Each input block is enciphered to produce an output block. The s leftmost bytes of each output block are exclusive-ORed with the corresponding s-byte plaintext segment to form a s-byte ciphertext segment. The remaining (8 - s) bytes of each output block are ignored. Each ciphertext segment is concatenated to the right of the (8 - s) rightmost bytes of the previous input block to form the next input block.

The process is repeated with the successive input blocks until a ciphertext segment is produced for every plaintext segment, or until a CPU-determined number of ciphertext segments have been produced. The ciphertext segments (C1, C2, …, Cn) are stored in operand 1. The final next-input block is stored into the chaining-value field of the parameter block. The operation is shown in Figure 7-119.

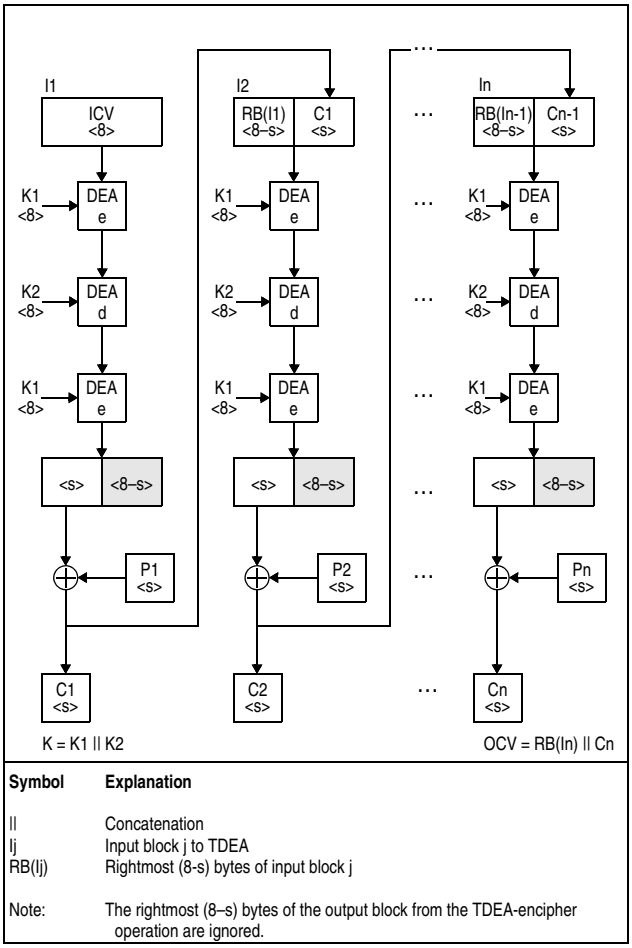

Figure 7-119. KMF-TDEA-128 Encipher Operation

When the modifier bit in general register 0 is one, a decipher operation is performed. The s-byte ciphertext segments (C1, C2, …, Cn) in operand 2 are deciphered using the TDEA-encryption algorithm with the 128-bit cryptographic key and the 64-bit chaining value, where s is the length of cipher feedback in bytes.

The first input block to the TDEA-encryption algorithm is the initial chaining value (ICV) in the parameter block. Each input block is enciphered to produce an output block. The s leftmost bytes of each output block are exclusive-ORed with the corresponding s-byte ciphertext segment to form a s-byte plaintext segment. The remaining (8 - s) bytes of each output block are ignored. Each ciphertext segment is con-

catenated to the right of the (8 - s) rightmost bytes of the previous input block to form the next input block.

The process is repeated with the successive input blocks until a plaintext segment is produced for every ciphertext segment, or until a CPU-determined number of plaintext segments have been produced.

The plaintext segments (P1, P2, …, Pn) are stored in operand 1. The final next-input block (OCV) is stored into the chaining-value field of the parameter block. The operation is shown in Figure 7-120.

Figure 7-120. KMF-TDEA-128 Decipher Operation

KMF-TDEA-192 (Function Code 3)

KMF-Encrypted-TDEA-192 (Function Code 11)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-106 on page 7-103.

The parameter block used for the KMF-TDEA-192 function has the following format:

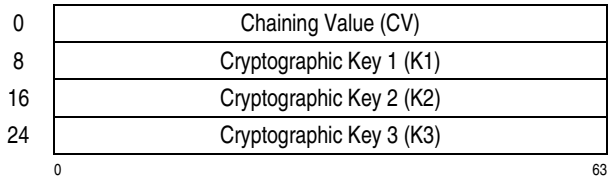

Figure 7-121. Parameter Block for KMF-TDEA-192

For the KMF-TDEA-192 function, the chaining value is in byte offset 0-7 of the parameter block and the cryptographic key is in byte offsets 8-31 of the parameter block.

The parameter block used for the KMF-Encrypted-TDEA-192 function has the following format:

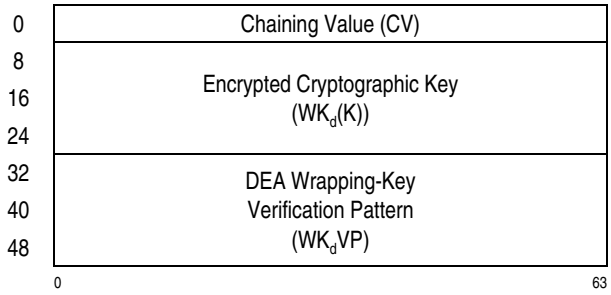

Figure 7-122. Parameter Block for KMF-Encrypted-TDEA-192

For the KMF-Encrypted-TDEA-192 function, the contents of byte offsets 32-55 of the parameter block are compared with the contents of the DEA wrapping-key verification-pattern register. If they mismatch, the first-operand and parameter-block locations remain unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 0-7 of the parameter block contain the chaining value, and the contents of byte offsets 8-31 of the parameter block are deciphered using the DEA wrapping key to obtain the 192-bit cryptographic key. (See the section, “Protection of Cryptographic Keys” on page 7-490 for details.)

The following description applies to both functions.

When the modifier bit in general register 0 is zero, an encipher operation is performed. The s-byte plaintext segments (P1, P2, …, Pn) in operand 2 are enciphered using the TDEA-encryption algorithm with the 192-bit cryptographic key and the 64-bit chaining

value, where s is the length of cipher feedback in bytes.

The first input block to the TDEA-encryption algorithm is the initial chaining value (ICV) in the parameter block. Each input block is enciphered to produce an output block. The s leftmost bytes of each output block are exclusive-ORed with the corresponding s-byte plaintext segment to form a s-byte ciphertext segment. The remaining (8 - s) bytes of each output block are ignored. Each ciphertext segment is concatenated to the right of the (8 - s) rightmost bytes of the previous input block to form the next input block.

The process is repeated with the successive input blocks until a ciphertext segment is produced for every plaintext segment, or until a CPU-determined number of ciphertext segments have been produced.

The ciphertext segments (C1, C2, …, Cn) are stored in operand 1. The final next-input block (OCV) is stored into the chaining-value field of the parameter block. The operation is shown in Figure 7-123.

Figure 7-124. KMF-TDEA-192 Decipher Operation

KMF-AES-128 (Function Code 18)

KMF-Encrypted-AES-128 (Function Code 26)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-106 on page 7-103.

The parameter block used for the KMF-AES-128 function has the following format:

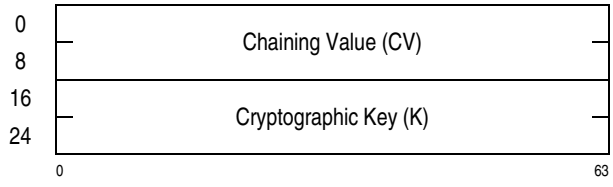

Figure 7-125. Parameter Block for KMF-AES-128

For the KMF-AES-128 function, the chaining value is in byte offset 0-15 of the parameter block and the cryptographic key is in byte offsets 16-31 of the parameter block.

The parameter block used for the KMF-Encrypted-AES-128 function has the following format:

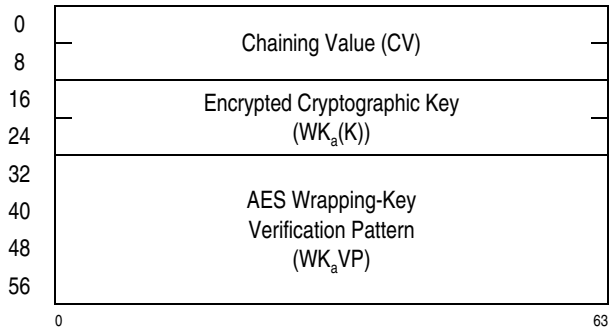

Figure 7-126. Parameter Block for KMF-Encrypted-AES-128

For the KMF-Encrypted-AES-128 function, the contents of byte offsets 32-63 of the parameter block are compared with the contents of the AES wrapping-key verification-pattern register. If they mismatch, the first-operand and parameter-block locations remain unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 0-15 of the parameter block contain the chaining value, and the contents of byte offsets 16-31 of the parameter block are deciphered using the AES wrapping key to obtain the 128-bit cryptographic key. (See the section “Protection of Cryptographic Keys” on page 7-490 for details.)

The following description applies to both functions.

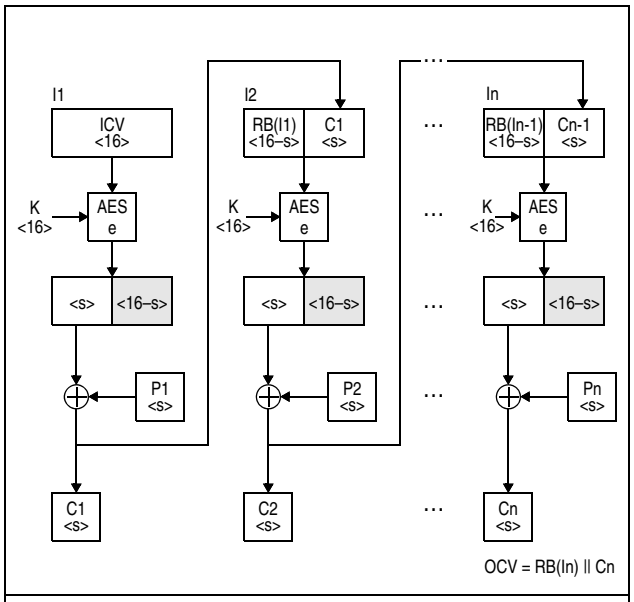
When the modifier bit in general register 0 is zero, an encipher operation is performed. The s-byte plaintext segments (P1, P2, …, Pn) in operand 2 are enciphered using the AES-encryption algorithm with the 128-bit cryptographic key and the 128-bit chaining value, where s is the length of cipher feedback in bytes.

The first input block to the AES-encryption algorithm is the initial chaining value (ICV) in the parameter block. Each input block is enciphered to produce an output block. The s leftmost bytes of each output block are exclusive-ORed with the corresponding s-byte plaintext segment to form a s-byte ciphertext segment. The remaining (16 - s) bytes of each output block are ignored. Each ciphertext segment is con-

catenated to the right of the (16 - s) rightmost bytes of the previous input block to form the next input block.

The process is repeated with the successive input blocks until a ciphertext segment is produced for every plaintext segment, or until a CPU-determined number of ciphertext segments have been produced.

The ciphertext segments (C1, C2, …, Cn) are stored in operand 1. The final next-input block is stored into the chaining-value field of the parameter block. The operation is shown in Figure 7-127.



Symbol	Explanation
||	Concatenation
Ij	Input block j to AES
RB(Ij)	Rightmost (16-s) bytes of input block j

Note: The rightmost (16–s) bytes of the output block from the AES-encipher operation are ignored.

Figure 7-127. KMF-AES-128 Encipher Operation

When the modifier bit in general register 0 is one, a decipher operation is performed. The s-byte ciphertext segments (C1, C2, …, Cn) in operand 2 are deciphered using the AES-encryption algorithm with the 128-bit cryptographic key and the 128-bit chaining value, where s is the length of cipher feedback in bytes.

The first input block to the AES-encryption algorithm is the initial chaining value (ICV) in the parameter block. Each input block is enciphered to produce an output block. The s leftmost bytes of each output block are exclusive-ORed with the corresponding s-byte ciphertext segment to form a s-byte plaintext segment. The remaining (16 - s) bytes of each output block are ignored. Each ciphertext segment is concatenated to the right of the (16 - s) rightmost bytes

of the previous input block to form the next input block.

The process is repeated with the successive input blocks until a plaintext segment is produced for every ciphertext segment, or until a CPU-determined number of plaintext segments have been produced.

The plaintext segments (P1, P2, …, Pn) are stored in operand 1. The final next-input block (OCV) is stored into the chaining-value field of the parameter block. The operation is shown in Figure 7-128.

Figure 7-136. KMF-AES-256 Decipher Operation

KMF-Query-Authentication-Information (Function Code 127)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-106 on page 7-103.

The KMF-query-authentication-information function stores the information that can be used by the program to authenticate the running instruction's firmware code level (IFCL) currently installed on the model into the format-0 parameter block for KMF-query-authentication-information. Condition code 0 is set when execution of the KMF-query-authentication-information function completes; condition codes 1 and 3 are not applicable to this function.

The format-0 parameter block used for the KMF-query-authentication-information function has the following format:

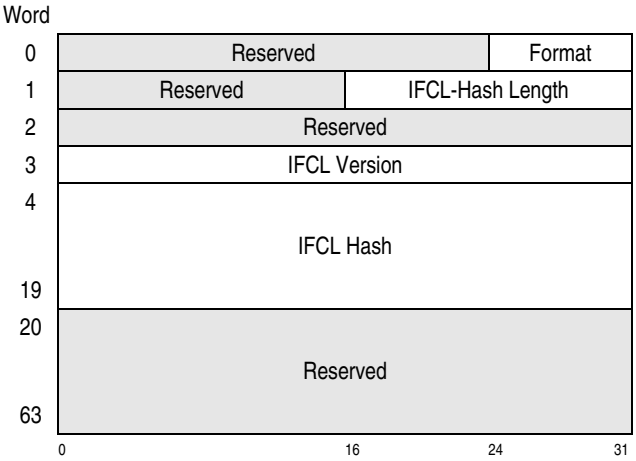

Figure 7-137. Format-0 Parameter Block for KMF-Query-Authentication-Information

The format-0 parameter block contains the following fields:

Reserved: Bytes 0-2 of word 0, bytes 0-1 of word 1, word 2, and words 20-63 are reserved and stored as zeros.

Format: Byte 3 of word 0 contains an 8-bit unsigned binary integer whose value specifies the format of the parameter block. A format value of zero indicates a format-0 parameter block. When a format-0 parameter block is stored, the value of this field is set to zero.

IFCL-Hash Length: Bytes 2-3 of word 1 contain a 16-bit unsigned binary integer specifying the number of bytes of the IFCL hash stored in the IFCL hash field. When the IFCL hash is less than or equal to 64 bytes, the IFCL-hash length field is set to the actual length of the IFCL hash. When the IFCL hash is larger than 64 bytes, the IFCL-hash length field is set to 64.

IFCL Version: Word 3 contains a 32-bit unsigned binary integer specifying the version number of the IFCL.

IFCL Hash: Words 4-19 contain the hash value of the IFCL. The IFCL-hash length field specifies the number of bytes that are in the IFCL hash field. The IFCL hash value is left aligned. When the IFCL hash is less than 64 bytes, it is padded with zeros on the

right. When the IFCL hash is larger than 64 bytes, only the leftmost 64 bytes of the IFCL hash are stored.

Special Conditions

A specification exception is recognized and no other action is taken if any of the following occurs:

1. For DEA or TDEA functions, bits 32-39 of general register 0 specify a value that is zero or greater than 8.
2. For AES functions, bits 32-39 of general register 0 specify a value that is zero or greater than 16.
3. Bits 57-63 of general register 0 specify an unassigned or uninstalled function code.
4. The R_1 or R_2 field designates an odd-numbered register or general register 0.
5. The second operand length is not a multiple of the length of cipher feedback. This specification-exception condition does not apply to the query functions.

Resulting Condition Code:

0 Normal completion
1 Verification-pattern mismatch
2 --
3 Partial completion

Program Exceptions:

- Access (fetch, operand 2, cryptographic key, and wrapping-key verification pattern; store, operand 1, query parameter block, and query-authentication-information parameter block; fetch and store, chaining value, cryptography counter)
- Operation (if the message-security-assist extension 4 is not installed)
- Specification
- Transaction constraint

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B	Operation exception.

Figure 7-138. Priority of Execution: KMF

7.C	Transaction constraint
8.	Specification exception due to invalid function code or invalid register number.
9.	Specification exception due to invalid operand length.
10.	Access exceptions for an access to a cryptography counter and second-operand length originally zero.
11.	Condition code 0 due to second-operand length originally zero.
12.A.1	Access exceptions for an access to the parameter block.
12.A.2	Condition code 1 due to verification-pattern mismatch.
12.B	Access exceptions for an access to the first, or second operand.
13.	Condition code 3 due to partial completion (second-operand length still nonzero).
14.	Condition code 3 due to second-operand length stepped to zero and access-exception condition detected for an access to a cryptography counter.
15.	Condition code 0 due to normal completion (second-operand length originally nonzero, but stepped to zero).

Figure 7-138. Priority of Execution: KMF (Continued)

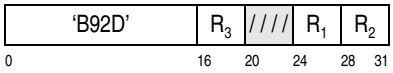
Programming Notes:

1. The performance of the query function (code 0) may be significantly slower than that of simply examining a location in storage. If the program needs to frequently test for the availability of a function, it should perform the query function once during initialization; subsequently it should examine the stored results of the query function in memory with an instruction such as TEST UNDER MASK.
2. See the programming notes for CIPHER MESSAGE WITH CHAINING.
3. In earlier versions of the architecture, CIPHER MESSAGE WITH CIPHER FEEDBACK was known as CIPHER MESSAGE WITH CFB.
4. As observed by this CPU, other CPUs, and the I/O subsystem, inconsistent results may be briefly stored in the first-operand location. See

the section “Effects of CPU Retry” on page 11-3 for further details.

CIPHER MESSAGE WITH COUNTER

KMCTR R_1,R_3,R_2 [RRF-b]



A function specified by the function code in general register 0 is performed.

Bits 20-23 of the instruction are ignored.

Bit positions 57-63 of general register 0 contain the function code. Figure 7-139 shows the assigned function codes for CIPHER MESSAGE WITH COUNTER. When the message-security-assist extension 13 is installed, function code 127 is valid for CIPHER MESSAGE WITH COUNTER. All other function codes are unassigned. For cipher functions, bit 56 is the modifier bit which specifies whether an encryption or a decryption operation is to be performed. The modifier bit is ignored for all other functions. All other bits of general register 0 are ignored.

General register 1 contains the logical address of the leftmost byte of the parameter block in storage. In the 24-bit addressing mode, the contents of bit positions 40-63 of general register 1 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of general register 1 constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register 1 constitute the address.

The function codes for CIPHER MESSAGE WITH COUNTER are as follows.

Code	Function	Parm. Block Size (bytes)	Data Block Size (bytes)
0	KMCTR-Query	16	—
1	KMCTR-DEA	8	8
2	KMCTR-TDEA-128	16	8
3	KMCTR-TDEA-192	24	8
9	KMCTR-Encrypted-DEA	32	8
10	KMCTR-Encrypted-TDEA-128	40	8
11	KMCTR-Encrypted-TDEA-192	48	8
18	KMCTR-AES-128	16	16
19	KMCTR-AES-192	24	16
20	KMCTR-AES-256	32	16
26	KMCTR-Encrypted-AES-128	48	16
27	KMCTR-Encrypted-AES-192	56	16
28	KMCTR-Encrypted-AES-256	64	16
127	KMCTR-Query-Authentication-Information	V	—

Explanation:

— Not applicable

V Variable parameter block size. See each format-x parameter block for the exact size of that parameter block.

Figure 7-139. Function Codes for CIPHER MESSAGE WITH COUNTER

All other function codes are unassigned.

The query function provides the means of indicating the availability of the other functions. The contents of general registers R_1, R_2, $R_2 + 1$, and R_3 are ignored for the query function.

The query-authentication-information function provides the information that can be used by the program to authenticate the running instruction’s firmware code level (IFCL) currently installed on the model. The contents of general registers R_1, R_2, $R_2 + 1$, and R_3 are ignored for the query-authentication-information function.

For all other functions, the second operand is ciphered as specified by the function code using a cryptographic key and counter values, and the result is placed in the first-operand location.

The R_1 and R_3 fields each designate a general register and must designate an even-numbered register other than general register 0; otherwise, a specification exception is recognized. The R_2 field designates an even-odd pair of general registers and must designate an even-numbered register other than general register 0; otherwise, a specification exception is recognized.

The location of the leftmost byte of the first, second, and third operands is specified by the contents of the R_1, R_2, and R_3 general registers, respectively. The number of bytes in the second-operand location is specified in general register $R_2 + 1$. The first operand and the third operand are the same length as the second operand.

As part of the operation, the addresses in general registers R_1, R_2, and R_3 are incremented by the number of bytes processed, and the length in general register $R_2 + 1$ is decremented by the same number. The formation and updating of the addresses and length is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers R_1, R_2, and R_3 constitute the addresses of the first, second, and third operands, respectively, and the contents of bit positions 0-39 are ignored; bits 40-63 of the updated addresses replace the corresponding bits in general registers R_1, R_2, and R_3, carries out of bit position 40 of the updated address are ignored, and the contents of bit positions 32-39 of general registers R_1, R_2, and R_3 are set to zeros. In the 31-bit addressing mode, the contents of bit positions 33-63 of general registers R_1, R_2, and R_3 constitute the addresses of the first, second, and third operands, respectively, and the contents of bit positions 0-32 are ignored; bits 33-63 of the updated addresses replace the corresponding bits in general registers R_1, R_2, and R_3, carries out of bit position 33 of the updated address are ignored, and the content of bit position 32 of general registers R_1, R_2, and R_3 is set to zero. In the 64-bit addressing mode, the contents of bit positions 0-63 of general registers R_1, R_2, and R_3 constitute the addresses of the first, second, and third operands, respectively; bits 0-63 of the updated addresses replace the contents of general registers R_1, R_2, and R_3, and carries out of bit position 0 are ignored.

In both the 24-bit and the 31-bit addressing modes, the contents of bit positions 32-63 of general register $R_2 + 1$ form a 32-bit unsigned binary integer which specifies the number of bytes in the first, second, and third operands, and the contents of bit positions 0-31 are ignored; bits 32-63 of the updated value replace the corresponding bits in general register $R_2 + 1$. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register $R_2 + 1$ form a 64-bit unsigned binary integer which specifies the number of bytes in the first, second, and third operands; the updated value replaces the contents of general register $R_2 + 1$.

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers R_1, R_2, $R_2 + 1$, and R_3 always remain unchanged.

Figure 7-140 on page 7-120 shows the contents of the general registers just described.

All Addressing Modes

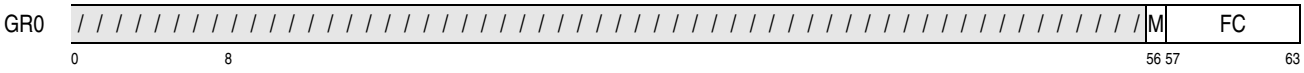


Figure 7-140. General Register Assignment for KMCTR (Part 1 of 2)

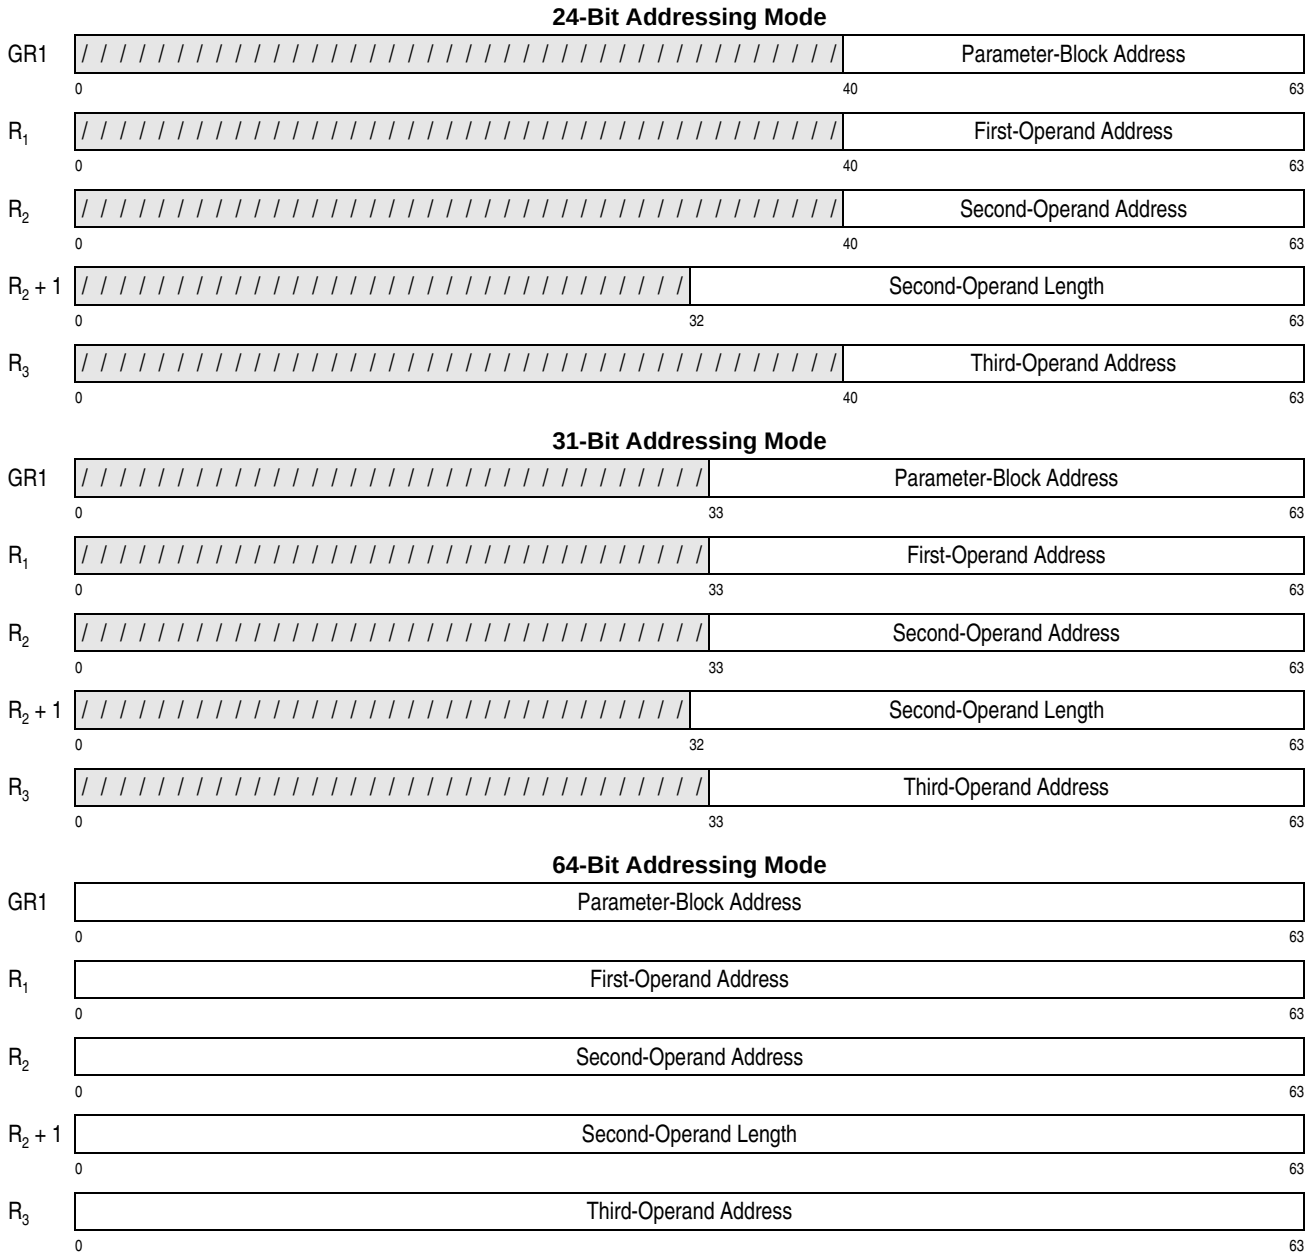

Figure 7-140. General Register Assignment for KMCTR (Part 2 of 2)

In the access-register mode, access registers 1, R_1, R_2, and R_3 specify the address spaces containing the parameter block, first, second, and third operands, respectively.

The result is obtained as if processing starts at the left end of both the first and second operands and proceeds to the right, block by block. The cipher operation is ended when the number of bytes in the second operand as specified in general register $R_2 + 1$ have been processed and placed at the first-operand location or when a CPU-determined number of blocks that is less than the length of the second operand have been processed. The CPU-determined number of blocks depends on the model, and may be a different number each time the instruction is executed. The CPU-determined number of blocks is usually nonzero. In certain unusual situations, this number may be zero, and condition code 3 may be set with no progress. However, the CPU protects against endless reoccurrence of this no-progress case.

If the CPU is enabled to update counters in the cryptography-counter set, then subsequent to processing all bytes of the second operand, the appropriate counter is updated.

The results in the first-operand location are unpredictable if any of the following situations occurs:

1. The cryptographic-key field or the encrypted cryptographic-key field overlaps any portion of the first operand.
2. The first and second operands overlap destructively.
3. The first and third operands overlap destructively.

Operands are said to overlap destructively when the first-operand location would be used as a source after data would have been moved into it, assuming processing to be performed from left to right and one byte at a time.

Normal completion occurs when the cipher operation has ended and, when applicable, a counter in the cryptography-counter set has been updated. Partial completion occurs when a CPU-determined number of blocks that is less than the length of the second operand have been processed or when the CPU is enabled to update a counter in the cryptography-counter set and the appropriate counter has not yet been updated.

When the operation ends due to normal completion, condition code 0 is set and the resulting value in $R_2 + 1$ is zero. When the operation ends due to partial completion, condition code 3 is set. In this case, if the CPU is enabled to update counters in the cryptography-counter set, all of the second operand has been processed, and the appropriate counter is not accessible, then the resulting value placed in general register $R_2 + 1$ is zero; otherwise the resulting value placed in general register $R_2 + 1$ is nonzero.

A PER storage-alteration event may be recognized both for the first-operand location and for the portion of the parameter block that is stored. A PER zero-address-detection event may be recognized for the first- , second-, and third-operand locations and for the parameter block. When PER events are detected for one or more of these locations, it is unpredictable which location is identified in the PER access identification (PAID) and PER ASCE ID (AI).

When a storage-alteration PER event is recognized, fewer than 4K additional bytes are stored into the first-operand locations before the event is reported.

When the second-operand length is initially zero, the following occurs. The parameter block, first, second, and third operands are not accessed, and general registers R_1, R_2, $R_2 + 1$, and R_3 are not changed. If the CPU is not enabled to update counters in the cryptography-counter set, then condition code 0 is set. If the CPU is enabled to update counters in the cryptography-counter set, and the appropriate counter is accessible, then the appropriate counter is updated and condition code 0 is set. If the CPU is enabled to update counters in the cryptography-counter set, and the appropriate counter is not accessible, then the condition code remains unchanged and an access exception is recognized for the location of the appropriate counter.

When the contents of any two or all three of the R_1, R_2, and R_3 fields are the same, the contents of the designated registers are incremented only by the number of bytes processed, not by a multiple of the number of bytes processed.

As observed by this CPU, other CPUs, and channel programs, references to the parameter block and storage operands may be multiple-access references, accesses to these storage locations are not necessarily block-concurrent, and the sequence of these accesses or references is undefined.

In certain unusual situations, instruction execution may complete by setting condition code 3 without updating the registers to reflect the last unit of the first, second, and third operands processed. The size of the unit processed in this case depends on the situation and the model, but is limited such that the portion of the first and second operands which have been processed and not reported do not overlap in storage; and the portion of the first and third operands which have been processed and not reported do not overlap in storage. In all cases, change bits are set and PER storage-alteration events are reported, when applicable, for all first-operand locations processed.

For functions that perform a comparison of the wrapping-key verification pattern field in the parameter block with the wrapping-key verification-pattern register, it is unpredictable whether access exceptions and PER zero-address-detection events are recog-

nized for the first, second, and third operands when the comparison results in a mismatch.

Access exceptions may be reported for a larger portion of an operand than is processed in a single execution of the instruction; however, access exceptions are not recognized for locations beyond the length of an operand nor for locations more than 4K bytes beyond the current location being processed.

Symbols Used in Function Descriptions

The following symbols are used in the subsequent description of the CIPHER MESSAGE WITH COUNTER functions. For data-encryption-algorithm (DEA) functions, the DEA-key-parity bit in each byte of the DEA key is ignored, and the operation proceeds normally, regardless of the DEA-key parity of the key.

Further description of the data-encryption algorithm may be found in Reference [13.] on page xxxii. Further description of the AES standard may be found in Reference [14.] on page xxxii. Further description of the counter mode of encryption and decryption may be found in Reference [16.] on page xxxii.

KMCTR-Query (Function Code 0)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-140 on page 7-120.

The parameter block used for the function has the following format:

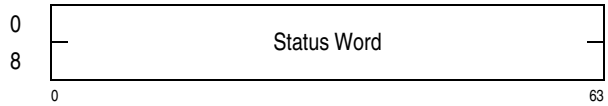

Figure 7-146. Parameter Block for KMCTR-Query

A 128-bit status word is stored in the parameter block. Bits 0-127 of this field correspond to function codes 0-127, respectively, of the CIPHER MESSAGE WITH COUNTER instruction. When a bit is one, the corresponding function is installed; otherwise, the function is not installed.

Condition code 0 is set when execution of the KMCTR-Query function completes; condition codes 1 and 3 are not applicable to this function.

KMCTR-DEA (Function Code 1)

KMCTR-Encrypted-DEA (Function Code 9)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-140 on page 7-120.

The parameter block used for the KMCTR-DEA function has the following format:

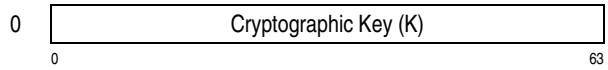

Figure 7-147. Parameter Block for KMCTR-DEA

For the KMCTR-DEA function, the cryptographic key is in byte offsets 0-7 of the parameter block.

The parameter block used for the KMCTR-Encrypted-DEA function has the following format:

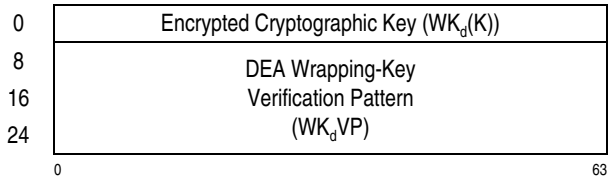

Figure 7-148. Parameter Block for KMCTR-Encrypted-DEA

For the KMCTR-Encrypted-DEA function, the contents of byte offsets 8-31 of the parameter block are compared with the contents of the DEA wrapping-key verification-pattern register. If they mismatch, the first-operand and parameter-block locations remain unchanged, and the operation is completed by setting condition code 1. If they match, the contents of byte offsets 0-7 of the parameter block are deciphered using the DEA wrapping key to obtain the 64-bit cryptographic key. (See the section “Protection of Cryptographic Keys” on page 7-490 for details.)

The following description applies to both functions.

When the modifier bit in general register 0 is zero, an encipher operation is performed. The 8-byte plaintext blocks (P1, P2, …, Pn) in operand 2 are enciphered using the DEA algorithm with the 64-bit cryptographic key and using 8-byte counter-value blocks (R1, R2, …, Rn) in operand 3. Each plaintext block is independently enciphered; that is, the encipher operation is performed without chaining. The ciphertext blocks (C1, C2, …, Cn) are stored in operand 1. The operation is shown in Figure 7-149.

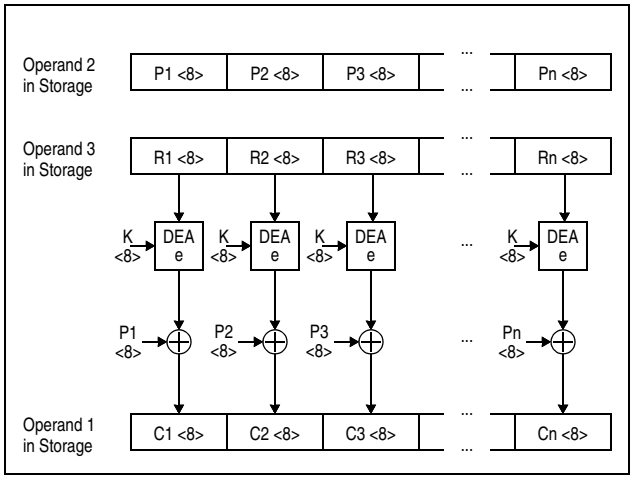

Figure 7-149. KMCTR DEA Encipher Operation Using 64-Bit Key

When the modifier bit in general register 0 is one, a decipher operation is performed. The 8-byte ciphertext blocks (C1, C2, …, Cn) in operand 2 are deciphered using the DEA algorithm with the 64-bit cryptographic key and using 8-byte counter-value blocks (R1, R2, …, Rn) in operand 3. Each ciphertext block is independently deciphered; that is, the decipher operation is performed without chaining. The plaintext blocks (P1, P2, …, Pn) are stored in operand 1. The operation is shown in Figure 7-150.

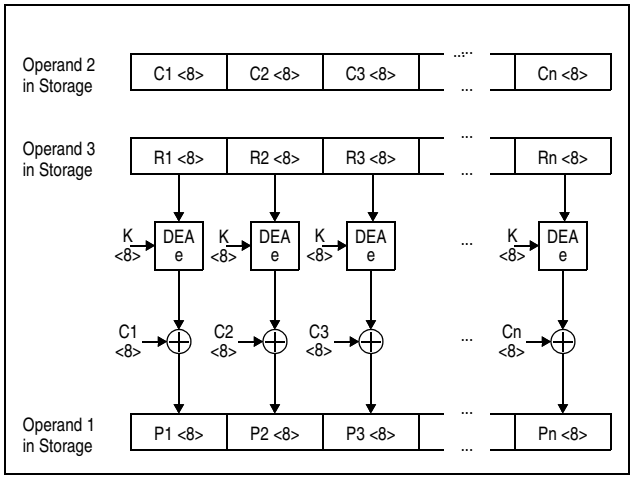

Figure 7-150. KMCTR DEA Decipher Operation Using 64-Bit Key

KMCTR-TDEA-128 (Function Code 2)

KMCTR-Encrypted-TDEA-128 (Function Code 10)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-140 on page 7-120.

The parameter block used for the KMCTR-TDEA-128 function has the following format:

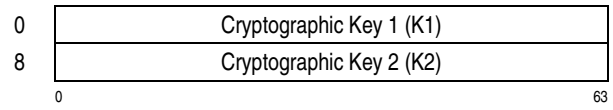

Figure 7-151. Parameter Block for KMCTR-TDEA-128

For the KMCTR-TDEA-128 function, the cryptographic key is in byte offsets 0-15 of the parameter block.

The parameter block used for the KMCTR-Encrypted-TDEA-128 function has the following format:

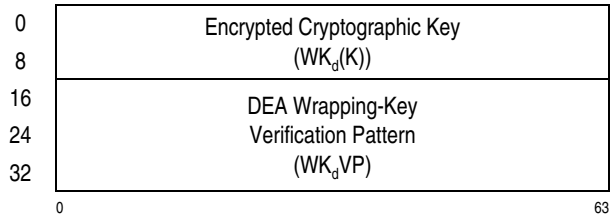

Figure 7-152. Parameter Block for KMCTR Encrypted-TDEA-128

For the KMCTR-Encrypted-TDEA-128 function, the contents of byte offsets 16-39 of the parameter block are compared with the contents of the DEA wrapping-key verification-pattern register. If they mismatch, the first-operand and parameter-block locations remain unchanged, and the operation is completed by setting condition code 1. If they match, the contents of byte offsets 0-15 of the parameter block are deciphered using the DEA wrapping key to obtain the 128-bit cryptographic key, K = K1 || K2, where K1 is the leftmost 64 bits of K and K2 is the rightmost 64 bits of K. (See the section “Protection of Cryptographic Keys” on page 7-490 for details.)

The following description applies to both functions.

When the modifier bit in general register 0 is zero, an encipher operation is performed. The 8-byte plaintext blocks (P1, P2, …, Pn) in operand 2 are enciphered using the TDEA (triple DEA) algorithm with the two 64-bit cryptographic keys and using 8-byte counter-value blocks (R1, R2, …, Rn) in operand 3. Each plaintext block is independently enciphered; that is, the encipher operation is performed without chaining.

The ciphertext blocks (C1, C2, …, Cn) are stored in operand 1. The operation is shown in Figure 7-153.

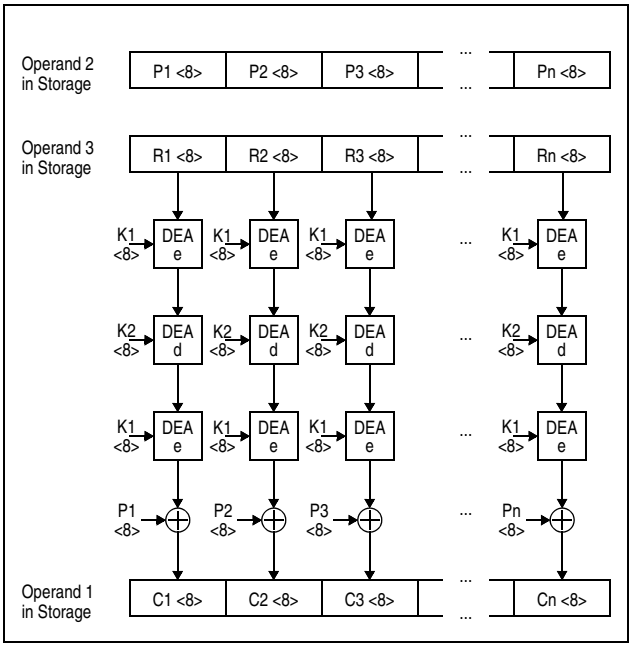

Figure 7-153. KMCTR TDEA Encipher Operation Using 128-Bit Key

When the modifier bit in general register 0 is one, a decipher operation is performed. The 8-byte ciphertext blocks (C1, C2, …, Cn) in operand 2 are deciphered using the TDEA algorithm with the two 64-bit cryptographic keys and using 8-byte counter-value blocks (R1, R2, …, Rn) in operand 3. Each ciphertext block is independently deciphered; that is, the decipher operation is performed without chaining. The plaintext blocks (P1, P2, …, Pn) are stored in operand 1. The operation is shown in Figure 7-154.

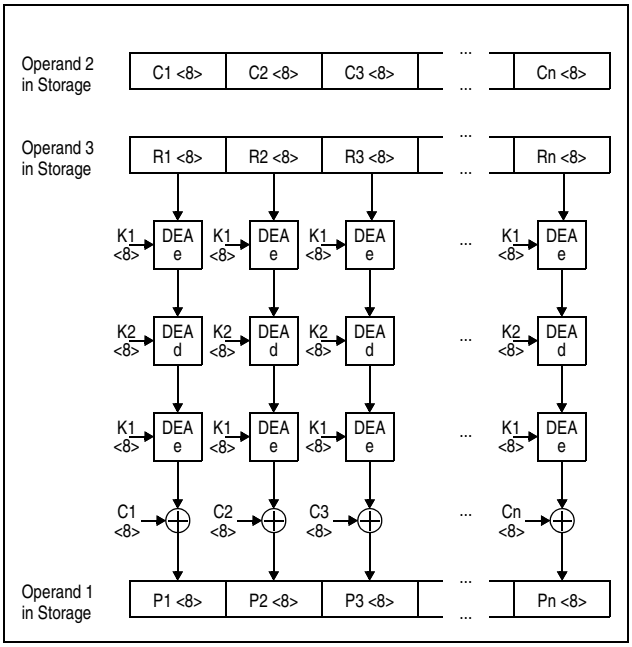

Figure 7-154. KMCTR TDEA Decipher Operation Using 128-Bit Key

KMCTR-TDEA-192 (Function Code 3)

KMCTR-Encrypted-TDEA-192 (Function Code 11)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-140 on page 7-120.

The parameter block used for the KMCTR-TDEA-192 function has the following format:

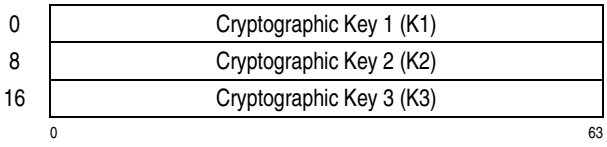

Figure 7-155. Parameter Block for KMCTR-TDEA-192

For the KMCTR-TDEA-192 function, the cryptographic key is in byte offsets 0-23 of the parameter block.

The parameter block used for the KMCTR-Encrypted-TDEA-192 function has the following format:

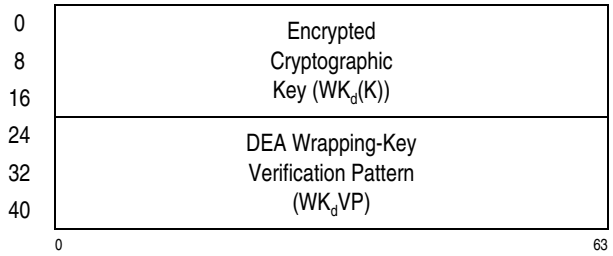

Figure 7-156. Parameter Block for KMCTR-Encrypted-TDEA-192

For the KMCTR-Encrypted-TDEA-192 function, the contents of byte offsets 24-47 of the parameter block are compared with the contents of the DEA wrapping-key verification-pattern register. If they mismatch, the first-operand and parameter-block locations remain unchanged, and the operation is completed by setting condition code 1. If they match, the contents of byte offsets 0-23 of the parameter block are deciphered using the DEA wrapping key to obtain the 192-bit cryptographic key, K = K1 || K2 || K3, where K1 is the leftmost 64 bits of K, K2 is the middle 64 bits of K, and K3 is the rightmost 64 bits of K. (See the section “Protection of Cryptographic Keys” on page 7-490 for details.)

The following description applies to both functions.

When the modifier bit in general register 0 is zero, an encipher operation is performed. The 8-byte plaintext blocks (P1, P2, …, Pn) in operand 2 are enciphered using the TDEA algorithm with the three 64-bit cryptographic keys and using 8-byte counter-value blocks (R1, R2, …, Rn) in operand 3. Each plaintext block is independently enciphered; that is, the encipher operation is performed without chaining. The ciphertext blocks (C1, C2, …, Cn) are stored in operand 1. The operation is shown in Figure 7-157.

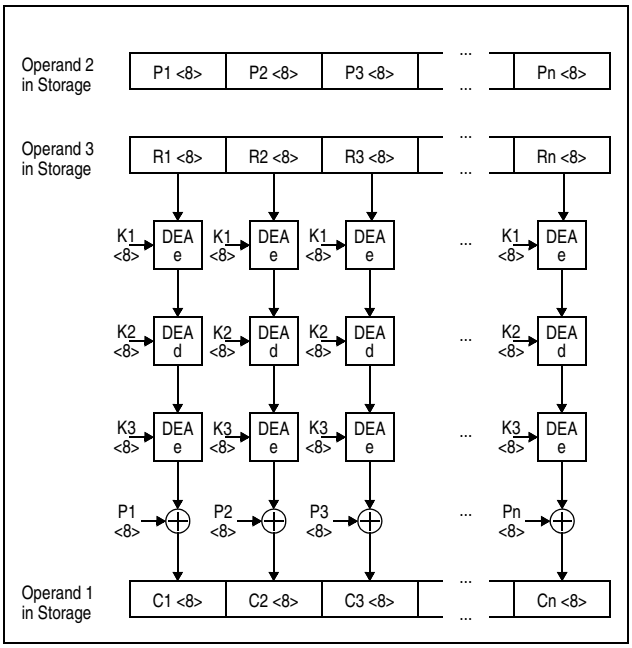

Figure 7-157. KMCTR TDEA Encipher Operation Using 192-Bit Key

When the modifier bit in general register 0 is one, a decipher operation is performed. The 8-byte ciphertext blocks (C1, C2, …, Cn) in operand 2 are deciphered using the TDEA algorithm with the three 64-bit cryptographic keys and using 8-byte counter-value blocks (R1, R2, …, Rn) in operand 3. Each ciphertext block is independently deciphered; that is, the decipher operation is performed without chaining.

The plaintext blocks (P1, P2, …, Pn) are stored in operand 1. The operation is shown in Figure 7-158.

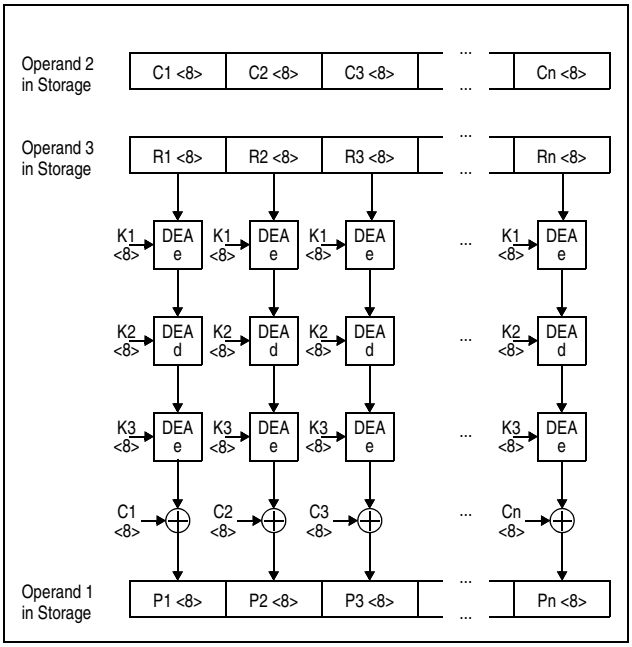

Figure 7-158. KMCTR TDEA Decipher Operation Using 192-Bit Key

KMCTR-AES-128 (Function Code 18)

KMCTR-Encrypted-AES-128 (Function Code 26)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-140 on page 7-120.

The parameter block used for the KMCTR-AES-128 function has the following format:

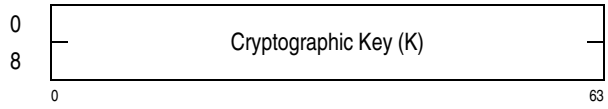

Figure 7-159. Parameter Block for KMCTR-AES-128

For the KMCTR-AES-128 function, the cryptographic key is in byte offsets 0-15 of the parameter block.

The parameter block used for the KMCTR-encrypted-AES-128 function has the following format:

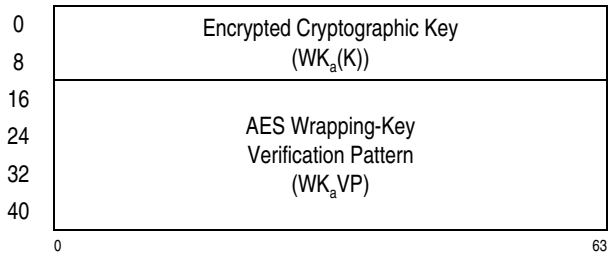

Figure 7-160. Parameter Block for KMCTR-Encrypted-AES-128

For the KMCTR-Encrypted-AES-128 function, the contents of byte offsets 16-47 of the parameter block are compared with the contents of the AES wrapping-key verification-pattern register. If they mismatch, the first-operand and parameter-block locations remain unchanged, and the operation is completed by setting condition code 1. If they match, the contents of byte offsets 0-15 of the parameter block are deciphered using the AES wrapping key to obtain the 128-bit cryptographic key, K. (See the section "Protection of Cryptographic Keys" on page 7-490 for details.)

The following description applies to both functions.

When the modifier bit in general register 0 is zero, an encipher operation is performed. The 16-byte plaintext blocks (P1, P2, …, Pn) in operand 2 are enciphered using the AES algorithm with the 128-bit cryptographic key and using 16-byte counter-value blocks (R1, R2, …, Rn) in operand 3. Each plaintext block is independently enciphered; that is, the encipher operation is performed without chaining. The

ciphertext blocks (C1, C2, …, Cn) are stored in operand 1. The operation is shown in Figure 7-161.

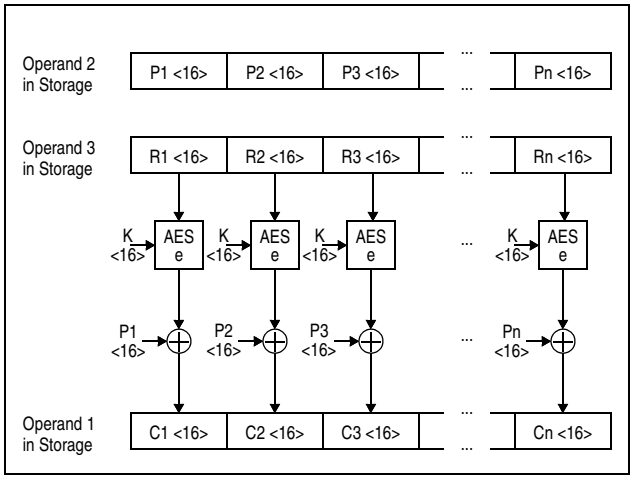

Figure 7-161. KMCTR AES Encipher Operation Using 128-Bit Key

When the modifier bit in general register 0 is one, a decipher operation is performed. Each ciphertext block is independently deciphered; that is, the decipher operation is performed without chaining. The plaintext blocks (P1, P2, …, Pn) are stored in operand 1. The operation is shown Figure 7-166.

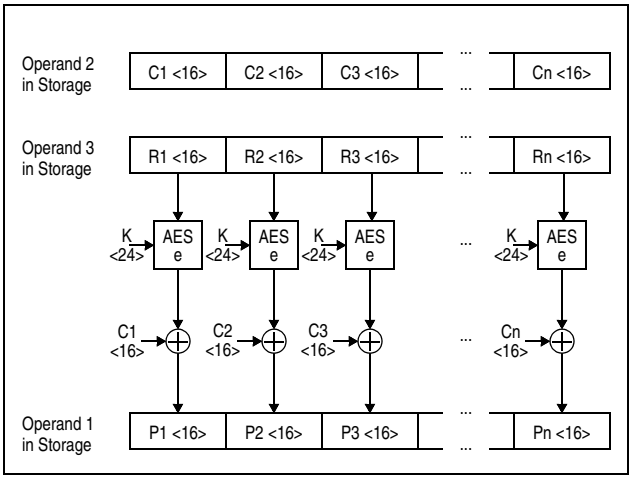

Figure 7-166. KMCTR AES Decipher Operation Using 192-Bit Key

KMCTR-AES-256 (Function Code 20)

KMCTR-Encrypted-AES-256 (Function Code 28)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-140 on page 7-120.

The parameter block used for the KMCTR-AES-256 function has the following format:

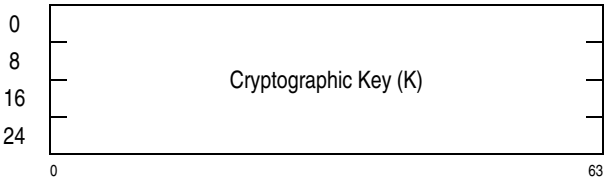

Figure 7-167. Parameter Block for KMCTR-AES-256

For the KMCTR-AES-256 function, the cryptographic key is in byte offsets 0-31 of the parameter block.

The parameter block used for the KMCTR-Encrypted-AES-256 function has the following format:

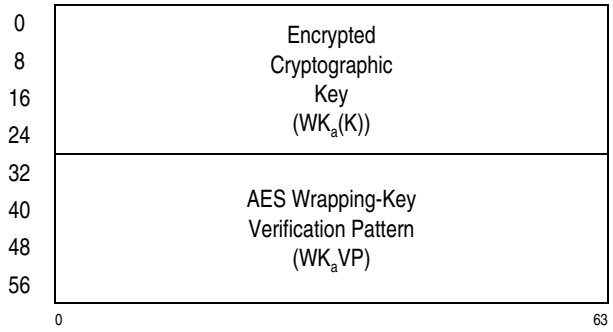

Figure 7-168. Parameter Block for KMCTR-Encrypted-AES-256

For the KMCTR-Encrypted-AES-256 function, the contents of byte offsets 32-63 of the parameter block are compared with the contents of the AES wrapping-key verification-pattern register. If they mismatch, the first-operand and parameter-block locations remain unchanged, and the operation is completed by setting condition code 1. If they match, the contents of byte offsets 0-31 of the parameter block are deciphered using the AES wrapping key to obtain the 256-bit cryptographic key, K. (See the section "Protection of Cryptographic Keys" on page 7-490 for details.)

The following description applies to both functions.

When the modifier bit in general register 0 is zero, an encipher operation is performed. The 16-byte plaintext blocks (P1, P2, …, Pn) in operand 2 are enciphered using the AES algorithm with the 256-bit cryptographic key and using 16-byte counter-value blocks (R1, R2, …, Rn) in operand 3. Each plaintext block is independently enciphered; that is, the encipher operation is performed without chaining. The ciphertext blocks (C1, C2, …, Cn) are stored in operand 1. The operation is shown in Figure 7-169.

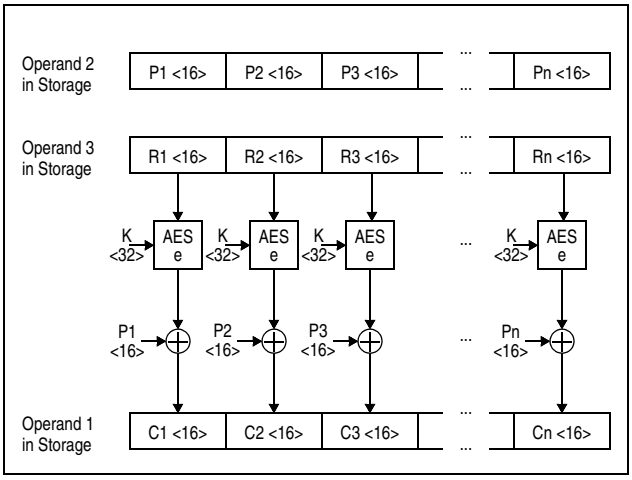

Figure 7-169. KMCTR AES Encipher Operation Using 256-Bit Key

When the modifier bit in general register 0 is one, a decipher operation is performed. The 16-byte ciphertext blocks (C1, C2, …, Cn) in operand 2 are deciphered using the AES algorithm with the 256-bit cryptographic key and using 16-byte counter-value blocks (R1, R2, …, Rn) in operand 3. Each ciphertext block is independently deciphered; that is, the decipher operation is performed without chaining. The plaintext blocks (P1, P2, …, Pn) are stored in operand 1. The operation is shown in Figure 7-170.

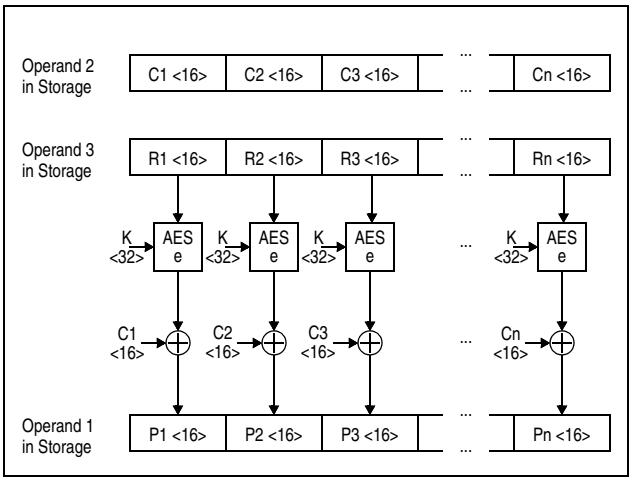

Figure 7-170. KMCTR AES Decipher Operation Using 256-Bit Key

KMCTR-Query-Authentication-Information (Function Code 127)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-140 on page 7-120.

The KMCTR-query-authentication-information function stores the information that can be used by the program to authenticate the running instruction's firmware code level (IFCL) currently installed on the model into the format-0 parameter block for KMCTR-query-authentication-information. Condition code 0 is set when execution of the KMCTR-query-authentication-information function completes; condition codes 1 and 3 are not applicable to this function.

The format-0 parameter block used for the KMCTR-query-authentication-information function has the following format:

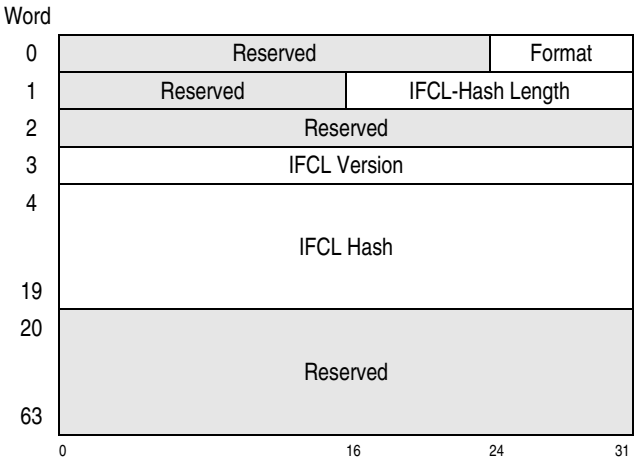

Figure 7-171. Format-0 Parameter Block for KMCTR-Query-Authentication-Information

The format-0 parameter block contains the following fields:

Reserved: Bytes 0-2 of word 0, bytes 0-1 of word 1, word 2, and words 20-63 are reserved and stored as zeros.

Format: Byte 3 of word 0 contains an 8-bit unsigned binary integer whose value specifies the format of the parameter block. A format value of zero indicates a format-0 parameter block. When a format-0 parameter block is stored, the value of this field is set to zero.

IFCL-Hash Length: Bytes 2-3 of word 1 contain a 16-bit unsigned binary integer specifying the number of bytes of the IFCL hash stored in the IFCL hash field. When the IFCL hash is less than or equal to 64 bytes, the IFCL-hash length field is set to the actual length of the IFCL hash. When the IFCL hash is larger than 64 bytes, the IFCL-hash length field is set to 64.

IFCL Version: Word 3 contains a 32-bit unsigned binary integer specifying the version number of the IFCL.

IFCL Hash: Words 4-19 contain the hash value of the IFCL. The IFCL-hash length field specifies the number of bytes that are in the IFCL hash field. The IFCL hash value is left aligned. When the IFCL hash is less than 64 bytes, it is padded with zeros on the right. When the IFCL hash is larger than 64 bytes, only the leftmost 64 bytes of the IFCL hash are stored.

Special Conditions for KMCTR

A specification exception is recognized and no other action is taken if any of the following occurs:

1. Bits 57-63 of general register 0 specify an unassigned or uninstalled function code.
2. The R_1 R_2, or R_3 field designates an odd-numbered register or general register 0.
3. The second operand length is not a multiple of the data block size of the designated function (see Figure 7-139 on page 7-119 to determine the data block sizes for CIPHER MESSAGE WITH COUNTER functions).This specification-exception condition does not apply to the query functions.

Resulting Condition Code:

0 Normal completion
1 Verification-pattern mismatch
2 --
3 Partial completion

Program Exceptions:

- Access (fetch, operand 2, operand 3, cryptographic key, and wrapping-key verification pattern; store, operand 1, query parameter block,

and query-authentication-information parameter block; fetch and store, cryptography counter)
- Operation (if the message-security-assist extension 4 is not installed)
- Specification
- Transaction constraint

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B	Operation exception.
7.C	Transaction constraint
8.	Specification exception due to invalid function code or invalid register number.
9.	Specification exception due to invalid operand length.
10.	Access exceptions for an access to a cryptography counter and second-operand length originally zero.
11.	Condition code 0 due to second-operand length originally zero.
12.A.1	Access exceptions for an access to the parameter block.
12.A.2	Condition code 1 due to verification-pattern mismatch.
12.B	Access exceptions for an access to the first, second, or third operand.
13.	Condition code 3 due to partial completion (second-operand length still nonzero).
14.	Condition code 3 due to second-operand length stepped to zero and access-exception condition detected for an access to a cryptography counter.
15.	Condition code 0 due to normal completion (second-operand length originally nonzero, but stepped to zero).

Figure 7-172. Priority of Execution: KMCTR

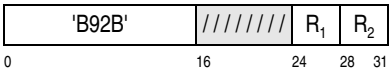
Programming Notes:

1. The performance of the query function (code 0) may be significantly slower than that of simply examining a location in storage. If the program needs to frequently test for the availability of a function, it should perform the query function once during initialization; subsequently it should examine the stored results of the query function in memory with an instruction such as TEST UNDER MASK.

2. As observed by this CPU, other CPUs, and the I/O subsystem, inconsistent results may be briefly stored in the first-operand location. See the section “Effects of CPU Retry” on page 11-3 for further details.

CIPHER MESSAGE WITH OUTPUT FEEDBACK

KMO R_1,R_2 [RRE]



A function specified by the function code in general register 0 is performed.

Bits 16-23 of the instruction are ignored.

Bit positions 57-63 of general register 0 contain the function code. Figure 7-173 shows the assigned function codes for CIPHER MESSAGE WITH OUTPUT FEEDBACK. When the message-security-assist extension 13 is installed, function code 127 is valid for CIPHER MESSAGE WITH OUTPUT FEEDBACK. All other function codes are unassigned. For cipher functions, bit 56 is the modifier bit which specifies whether an encryption or a decryption operation is to be performed. The modifier bit is ignored for all other functions. All other bits of general register 0 are ignored.

General register 1 contains the logical address of the leftmost byte of the parameter block in storage. In the 24-bit addressing mode, the contents of bit positions 40-63 of general register 1 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of general register 1 constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register 1 constitute the address.

The function codes for CIPHER MESSAGE WITH OUTPUT FEEDBACK are as follows.

Code	Function	Parm. Block Size (bytes)	Data Block Size (bytes)
0	KMO-Query	16	—
1	KMO-DEA	16	8
2	KMO-TDEA-128	24	8
3	KMO-TDEA-192	32	8
9	KMO-Encrypted-DEA	40	8
10	KMO-Encrypted-TDEA-128	48	8
11	KMO-Encrypted-TDEA-192	56	8
18	KMO-AES-128	32	16
19	KMO-AES-192	40	16
20	KMO-AES-256	48	16
26	KMO-Encrypted-AES-128	64	16
27	KMO-Encrypted-AES-192	72	16
28	KMO-Encrypted-AES-256	80	16
127	KMO-Query-Authentication-Information	V	—

Explanation:

— Not applicable

V Variable parameter block size. See each format-x parameter block for the exact size of that parameter block.

Figure 7-173. Function Codes for CIPHER MESSAGE WITH OUTPUT FEEDBACK

All other function codes are unassigned.

The query function provides the means of indicating the availability of the other functions. The contents of general registers R_1, R_2, and $R_2 + 1$ are ignored for the query function.

The query-authentication-information function provides the information that can be used by the program to authenticate the running instruction's firmware code level (IFCL) currently installed on the model. The contents of general registers R_1, R_2, and $R_2 + 1$ are ignored for the query-authentication-information function.

For all other functions, the second operand is ciphered as specified by the function code using a cryptographic key and an initial chaining value in the parameter block, and the result is placed in the first-operand location. The chaining value is updated as part of the operation.

The R_1 field designates a general register and must designate an even-numbered register other than general register 0; otherwise, a specification exception is recognized. The R_2 field designates an even-odd pair of general registers and must designate an even-numbered register other than general register 0; otherwise, a specification exception is recognized.

The location of the leftmost byte of the first and second operands is specified by the contents of the R_1 and R_2 general registers, respectively. The number of bytes in the second-operand location is specified in general register $R_2 + 1$. The first operand is the same length as the second operand.

As part of the operation, the addresses in general registers R_1 and R_2 are incremented by the number of bytes processed, and the length in general register $R_2 + 1$ is decremented by the same number. The formation and updating of the addresses and length is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers R_1 and R_2 constitute the addresses of the first and second operands, respectively, and the contents of bit positions 0-39 are ignored; bits 40-63 of the updated addresses replace the corresponding bits in general registers R_1 and R_2, carries out of bit position 40 of the updated address are ignored, and the contents of bit positions 32-39 of general registers R_1 and R_2 are set to zeros. In the 31-bit addressing mode, the contents of bit positions 33-63 of general registers R_1 and R_2 constitute the addresses of the first and second operands, respectively, and the contents of bit positions 0-32 are ignored; bits 33-63 of the updated addresses replace the corresponding bits in general registers R_1 and R_2, carries out of bit position 33 of the updated address are ignored, and the content of bit position 32 of general registers R_1 and R_2 is set to zero. In the 64-bit addressing mode, the contents of bit positions 0-63 of general registers R_1 and R_2 constitute the addresses of the first and second operands, respectively; bits 0-63 of the updated addresses replace the contents of general registers R_1 and R_2, and carries out of bit position 0 are ignored.

In both the 24-bit and the 31-bit addressing modes, the contents of bit positions 32-63 of general register $R_2 + 1$ form a 32-bit unsigned binary integer which specifies the number of bytes in the first and second

operands, and the contents of bit positions 0-31 are ignored; bits 32-63 of the updated value replace the corresponding bits in general register $R_2 + 1$. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register $R_2 + 1$ form a 64-bit unsigned binary integer which specifies the number of bytes in the first and second operands; and the updated value replaces the contents of general register $R_2 + 1$.

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers R_1, R_2, and $R_2 + 1$, always remain unchanged.

Figure 7-174 on page 7-135 shows the contents of the general registers just described.

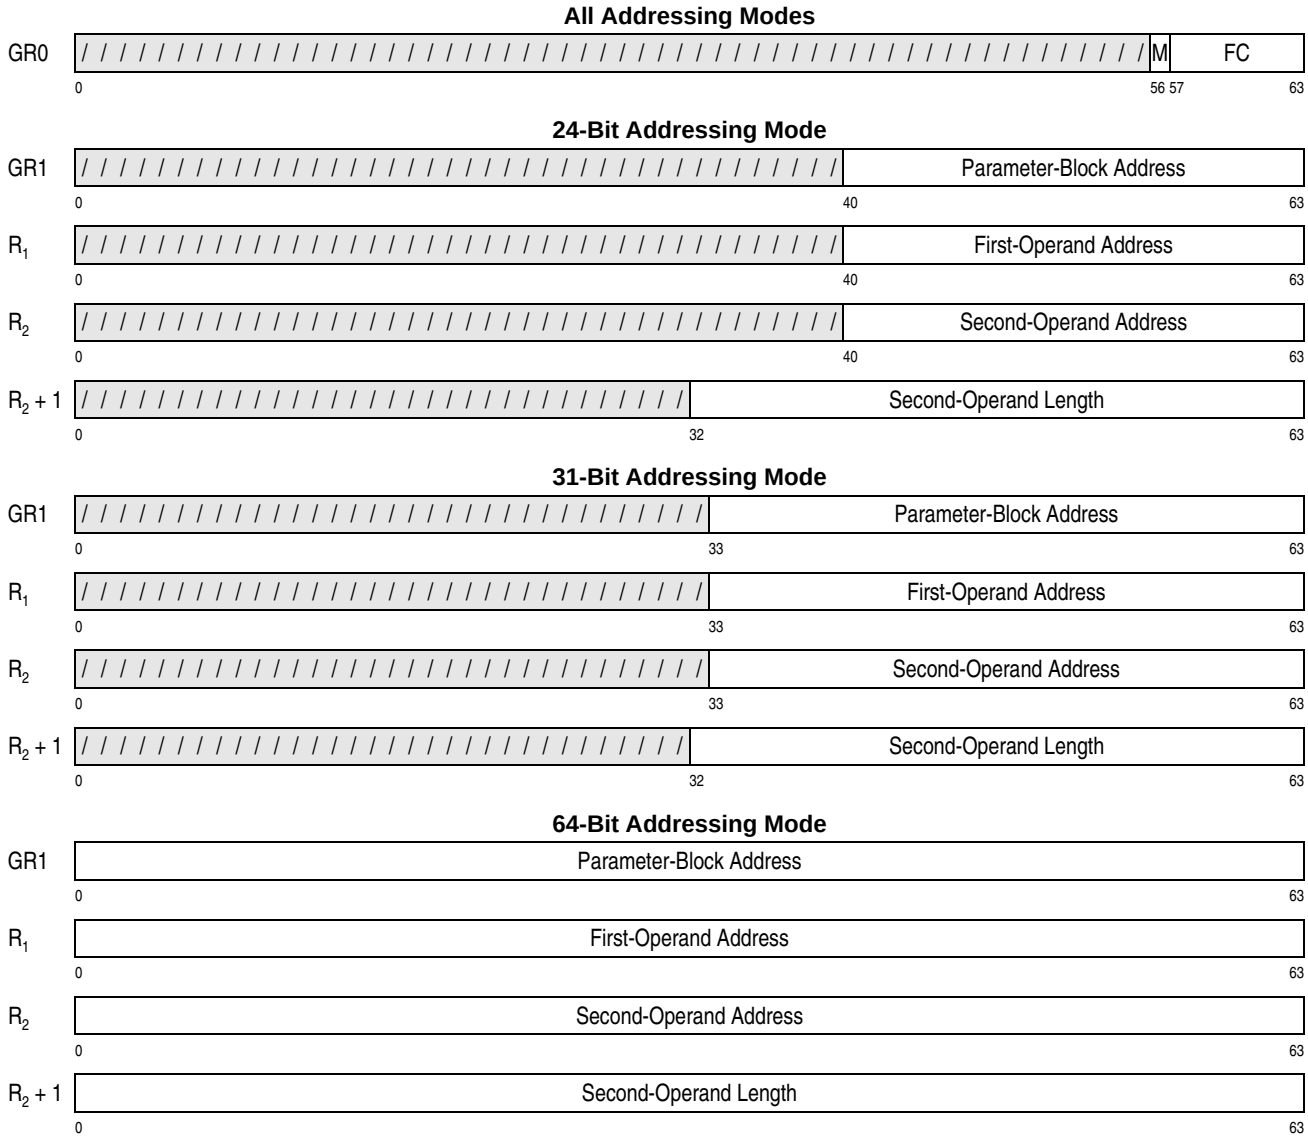


Figure 7-174. General Register Assignment for KMO

In the access-register mode, access registers 1, R_1, and R_2 specify the address spaces containing the parameter block, first, and second operands, respectively.

The result is obtained as if processing starts at the left end of both the first and second operands and proceeds to the right, block by block. The cipher operation is ended when the number of bytes in the second operand as specified in general register $R_2 + 1$ have been processed and placed at the first-

operand location or when a CPU-determined number of blocks that is less than the length of the second operand have been processed. The CPU-determined number of blocks depends on the model, and may be a different number each time the instruction is executed. The CPU-determined number of blocks is usually nonzero. In certain unusual situations, this number may be zero, and condition code 3 may be set with no progress. However, the CPU protects against endless reoccurrence of this no-progress case.

If the CPU is enabled to update counters in the cryptography-counter set, then subsequent to processing all bytes of the second operand, the appropriate counter is updated.

The results in the first-operand location and the chaining-value field are unpredictable if any of the following situations occur:

1. The cryptographic-key field or the encrypted cryptographic-key field overlaps any portion of the first operand.
2. The chaining-value field overlaps any portion of the first operand or the second operand.
3. The first and second operands overlap destructively. Operands are said to overlap destructively when the first-operand location would be used as a source after data would have been moved into it, assuming processing to be performed from left to right and one byte at a time.

Normal completion occurs when the cipher operation has ended and, when applicable, a counter in the cryptography-counter set has been updated. Partial completion occurs when a CPU-determined number of blocks that is less than the length of the second operand have been processed or when the CPU is enabled to update a counter in the cryptography-counter set and the appropriate counter has not yet been updated.

When the operation ends due to normal completion, condition code 0 is set and the resulting value in $R_2 + 1$ is zero. When the operation ends due to partial completion, condition code 3 is set. In this case, if the CPU is enabled to update counters in the cryptography-counter set, all of the second operand has been processed, and the appropriate counter is not accessible, then the resulting value placed in general register $R_2 + 1$ is zero; otherwise the resulting value placed in general register $R_2 + 1$ is nonzero.

A PER storage-alteration event may be recognized both for the first-operand location and for the portion of the parameter block that is stored. A PER zero-address-detection event may be recognized for the first- and second-operand locations and for the parameter block. When PER events are detected for one or more of these locations, it is unpredictable which location is identified in the PER access identification (PAID) and PER ASCE ID (AI).

When a storage-alteration PER event is recognized, fewer than 4K additional bytes are stored into the first-operand locations before the event is reported.

When the second-operand length is initially zero, the following occurs. The parameter block, first, and second operands are not accessed, and general registers R_1, R_2, and $R_2 + 1$ are not changed. If the CPU is not enabled to update counters in the cryptography-counter set, then condition code 0 is set. If the CPU is enabled to update counters in the cryptography-counter set, and the appropriate counter is accessible, then the appropriate counter is updated and condition code 0 is set. If the CPU is enabled to update counters in the cryptography-counter set, and the appropriate counter is not accessible, then the condition code remains unchanged and an access exception is recognized for the location of the appropriate counter.

When the contents of the R_1 and R_2 fields are the same, the contents of the designated registers are incremented only by the number of bytes processed, not by twice the number of bytes processed.

As observed by this CPU, other CPUs, and channel programs, references to the parameter block and storage operands may be multiple-access references, accesses to these storage locations are not necessarily block-concurrent, and the sequence of these accesses or references is undefined.

In certain unusual situations, instruction execution may complete by setting condition code 3 without updating the registers and chaining value to reflect the last unit of the first and second operands processed. The size of the unit processed in this case depends on the situation and the model, but is limited such that the portion of the first and second operands which have been processed and not reported do not overlap in storage. In all cases, change bits are set

and PER storage-alteration events are reported, when applicable, for all first-operand locations processed.

For functions that perform a comparison of the wrapping-key verification pattern field in the parameter block with the wrapping-key verification-pattern register, it is unpredictable whether access exceptions and PER zero-address-detection events are recognized for the first and second operands when the comparison results in a mismatch.

Access exceptions may be reported for a larger portion of an operand than is processed in a single execution of the instruction; however, access exceptions are not recognized for locations beyond the length of an operand nor for locations more than 4K bytes beyond the current location being processed.

Symbols Used in Function Descriptions

The following symbols are used in the subsequent description of the CIPHER MESSAGE WITH OUTPUT FEEDBACK functions. For data-encryption-algorithm (DEA) functions, the DEA-key-parity bit in each byte of the DEA key is ignored, and the operation proceeds normally, regardless of the DEA-key parity of the key.

Further description of the data-encryption algorithm may be found in Reference [13.] on page xxxii. Further description of the AES standard may be found in Reference [14.] on page xxxii. Further description of the output-feedback mode of encryption and decryption may be found in Reference [16.] on page xxxii.

P	Plaintext

Figure 7-179. Symbols for AES-256 Encryption

KMO-Query (Function Code 0)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-174 on page 7-135.

The parameter block used for the function has the following format:

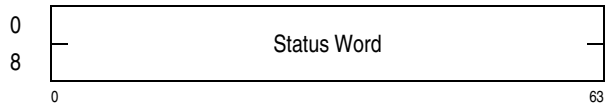

Figure 7-180. Parameter Block for KMO-Query

A 128-bit status word is stored in the parameter block. Bits 0-127 of this field correspond to function codes 0-127, respectively, of the CIPHER MESSAGE WITH OUTPUT FEEDBACK instruction. When a bit is one, the corresponding function is installed; otherwise, the function is not installed.

Condition code 0 is set when execution of the KMO-Query function completes; condition codes 1 and 3 are not applicable to this function.

KMO-DEA (Function Code 1)

KMO-Encrypted-DEA (Function Code 9)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-174 on page 7-135.

The parameter block used for the KMO-DEA function has the following format:

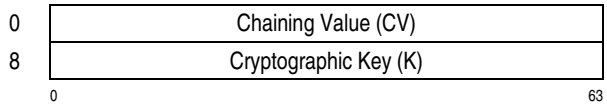

Figure 7-181. Parameter Block for KMO-DEA

For the KMO-DEA function, the chaining value is in byte offset 0-7 of the parameter block and the cryptographic key is in byte offsets 8-15 of the parameter block.

The parameter block used for the KMO-Encrypted - DEA function has the following format:

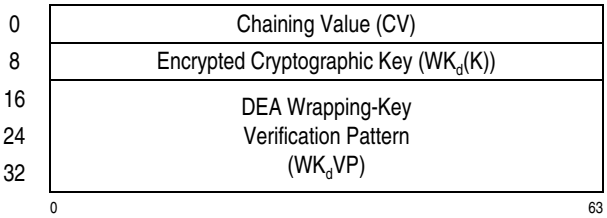

Figure 7-182. Parameter Block for KMO-Encrypted-DEA

For the KMO-Encrypted-DEA function, the contents of byte offsets 16-39 of the parameter block are compared with the contents of the DEA wrapping-key verification-pattern register. If they mismatch, the first-operand and parameter-block locations remain unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 0-7 of the parameter block contain the chaining value, and the contents of byte offsets 8-15 of the parameter block are deciphered using the DEA wrapping key to obtain the 64-bit cryptographic key. (See the section “Protection of Cryptographic Keys” on page 7-490 for details.)

The following description applies to both functions.

When the modifier bit in general register 0 is zero, an encipher operation is performed. The 8-byte plaintext blocks (P1, P2, …, Pn) in operand 2 are enciphered using the DEA-encryption algorithm with the 64-bit cryptographic key and the 64-bit chaining value.

The first input block to the DEA-encryption algorithm is the initial chaining value (ICV) in the parameter block. Each input block is enciphered to produce an output block. Each output block is exclusive-ORed with the corresponding plaintext block to form a

ciphertext block. Each output block is also used as the next input block.

The process is repeated with the successive input blocks until a ciphertext block is produced for every plaintext block, or until a CPU-determined number of ciphertext blocks have been produced.

The ciphertext blocks (C1, C2, …, Cn) are stored in operand 1. The next input block, called the output chaining value (OCV), is stored into the chaining-value field of the parameter block. The operation is shown in Figure 7-183.

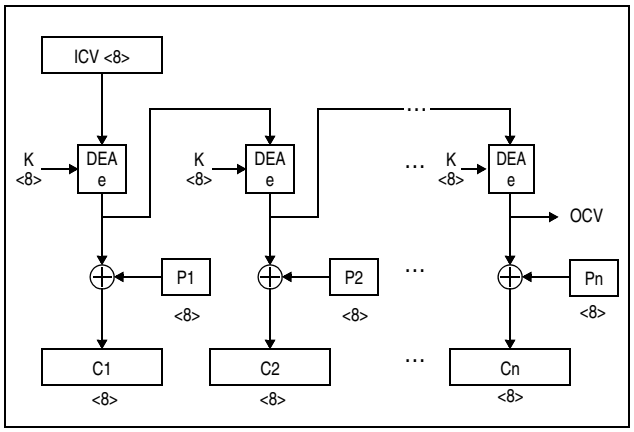

Figure 7-183. KMO-DEA Encipher Operation

When the modifier bit in general register 0 is one, a decipher operation is performed. The 8-byte ciphertext blocks (C1, C2, …, Cn) in operand 2 are deciphered using the DEA-encryption algorithm with the 64-bit cryptographic key and the 64-bit chaining value.

The first input block to the DEA-encryption algorithm is the initial chaining value (ICV) in the parameter block. Each input block is enciphered to produce an output block. Each output block is exclusive-ORed with the corresponding ciphertext block to form a plaintext block. Each output block is also used as the next input block.

The process is repeated with the successive input blocks until a plaintext block is produced for every ciphertext block, or until a CPU-determined number of plaintext blocks have been produced.

The plaintext blocks (P1, P2, …, Pn) are stored in operand 1. The next input block, called the output chaining value (OCV), is stored into the chaining-value field of the parameter block. The operation is shown in Figure 7-184.

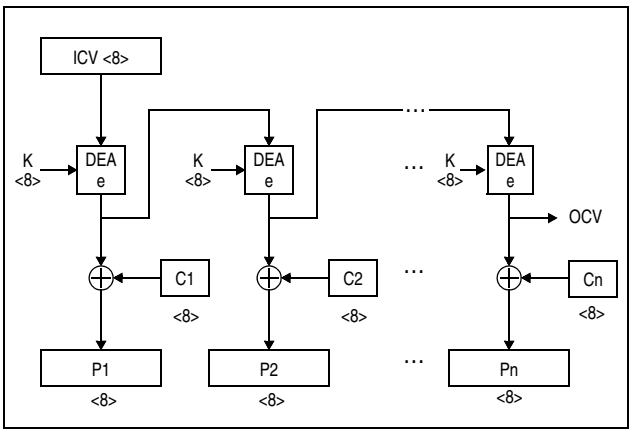

Figure 7-184. KMO-DEA Decipher Operation

KMO-TDEA-128 (Function Code 2)

KMO-Encrypted-TDEA-128 (Function Code 10)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-174 on page 7-135.

The parameter block used for the KMO-TDEA-128 function has the following format:

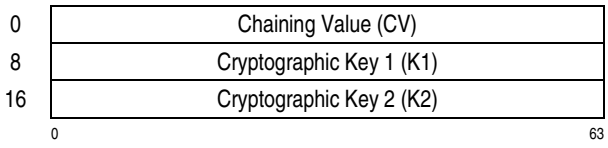

Figure 7-185. Parameter Block for KMO-TDEA-128

For the KMO-TDEA-128 function, the chaining value is in byte offset 0-7 of the parameter block and the cryptographic key is in byte offsets 8-23 of the parameter block.

The parameter block used for the KMO-Encrypted-TDEA-128 function has the following format:

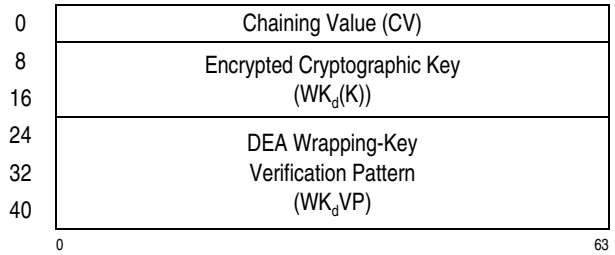

Figure 7-186. Parameter Block for KMO-Encrypted-TDEA-128

For the KMO-Encrypted-TDEA-128 function, the contents of byte offsets 24-47 of the parameter block are compared with the contents of the DEA wrapping-key verification-pattern register. If they mismatch, the first-operand and parameter-block locations remain unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 0-7 of the parameter block contain the chaining value, and the contents of byte offsets 8-23 of the parameter block are deciphered using the DEA wrapping key to obtain the 128-bit cryptographic key. (See the section "Protection of Cryptographic Keys" on page 7-490 for details.)

The following description applies to both functions.

When the modifier bit in general register 0 is zero, an encipher operation is performed. The 8-byte plaintext blocks (P1, P2, …, Pn) in operand 2 are enciphered using the TDEA-encryption algorithm with the 128-bit cryptographic key and the 64-bit chaining value.

The first input block to the TDEA-encryption algorithm is the initial chaining value (ICV) in the parameter block. Each input block is enciphered to produce an output block. Each output block is exclusive-ORed with the corresponding plaintext block to form a ciphertext block. Each output block is also used as the next input block.

The process is repeated with the successive input blocks until a ciphertext block is produced for every plaintext block, or until a CPU-determined number of ciphertext blocks have been produced.

The ciphertext blocks (C1, C2, …, Cn) are stored in operand 1. The next input block, called the output chaining value (OCV), is stored into the chaining-value field of the parameter block. The operation is shown in Figure 7-187.

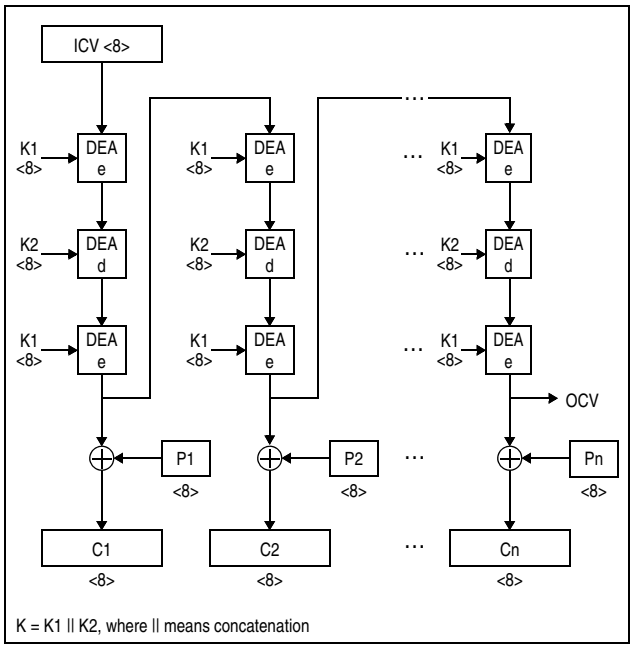

Figure 7-187. KMO-TDEA-128 Encipher Operation

When the modifier bit in general register 0 is one, a decipher operation is performed. The 8-byte ciphertext blocks (C1, C2, …, Cn) in operand 2 are deciphered using the TDEA-encryption algorithm with the 128-bit cryptographic key and the 64-bit chaining value.

The first input block to the TDEA-encryption algorithm is the initial chaining value (ICV) in the parameter block. Each input block is enciphered to produce an output block. Each output block is exclusive-ORed with the corresponding ciphertext block to form a plaintext block. Each output block is also used as the next input block.

The process is repeated with the successive input blocks until a plaintext block is produced for every ciphertext block, or until a CPU-determined number of plaintext blocks have been produced.

The plaintext blocks (P1, P2, …, Pn) are stored in operand 1. The next input block, called the output chaining value (OCV), is stored into the chaining-

value field of the parameter block. The operation is shown in Figure 7-188.

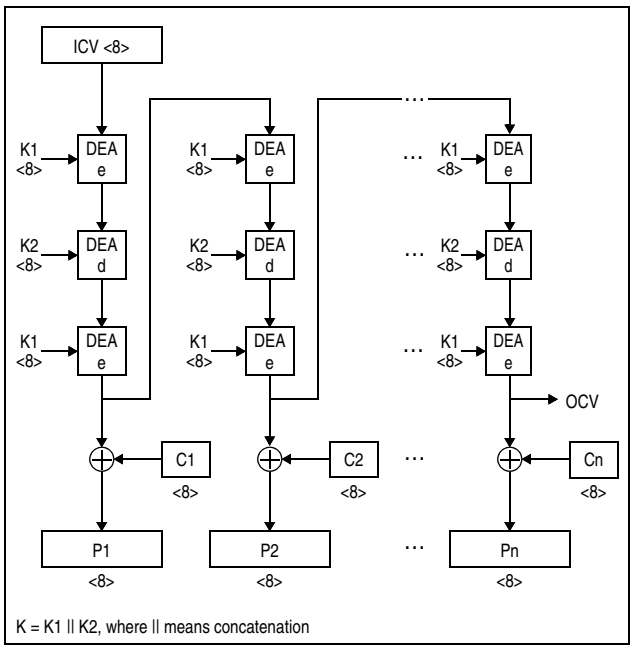

Figure 7-188. KMO-TDEA-128 Decipher Operation

KMO-TDEA-192 (Function Code 3)

KMO-Encrypted-TDEA-192 (Function Code 11)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-174 on page 7-135.

The parameter block used for the KMO-TDEA-192 function has the following format:

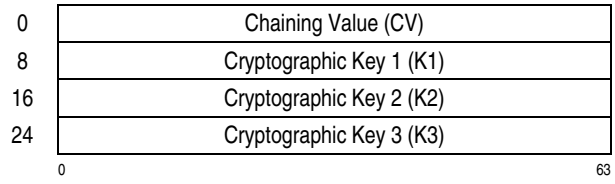

Figure 7-189. Parameter Block for KMO-TDEA-192

For the KMO-TDEA-192 function, the chaining value is in byte offset 0-7 of the parameter block and the cryptographic key is in byte offsets 8-31 of the parameter block.

The parameter block used for the KMO-Encrypted-TDEA-192 function has the following format:

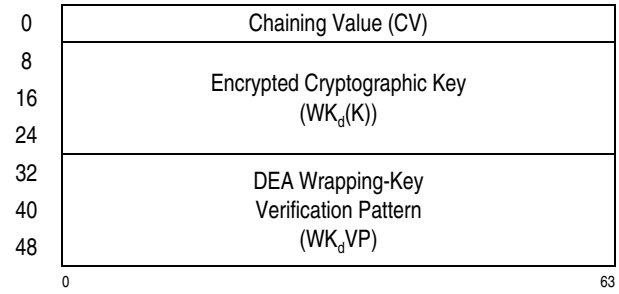

Figure 7-190. Parameter Block for KMO-Encrypted-TDEA-192

For the KMO-Encrypted-TDEA-192 function, the contents of byte offsets 32-55 of the parameter block are compared with the contents of the DEA wrapping-key verification-pattern register. If they mismatch, the first-operand and parameter-block locations remain unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 0-7 of the parameter block contain the chaining value, and the contents of byte offsets 8-31 of the parameter block are deciphered using the DEA wrapping key to obtain the 192-bit cryptographic key. (See the section "Protection of Cryptographic Keys" on page 7-490 for details.)

The following description applies to both functions.

When the modifier bit in general register 0 is zero, an encipher operation is performed. The 8-byte plaintext blocks (P1, P2, …, Pn) in operand 2 are enciphered using the TDEA-encryption algorithm with the 192-bit cryptographic key and the 64-bit chaining value.

The first input block to the TDEA-encryption algorithm is the initial chaining value (ICV) in the parameter block. Each input block is enciphered to produce an output block. Each output block is exclusive-ORed with the corresponding plaintext block to form a ciphertext block. Each output block is also used as the next input block.

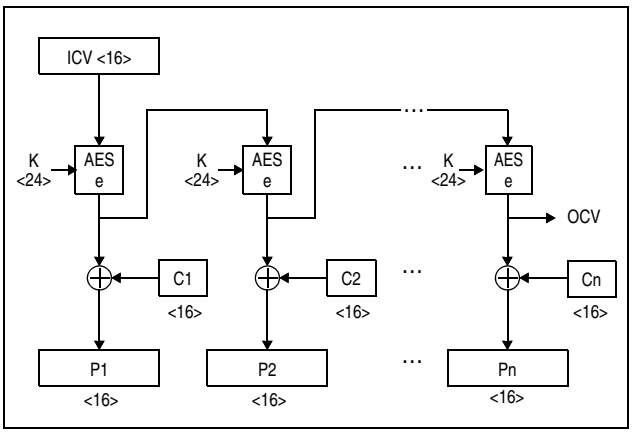

Figure 7-200. KMO-AES-192 Decipher Operation

KMO-AES-256 (Function Code 20)

KMO-Encrypted-AES-256 (Function Code 28)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-174 on page 7-135.

The parameter block used for the KMO-AES-256 function has the following format:

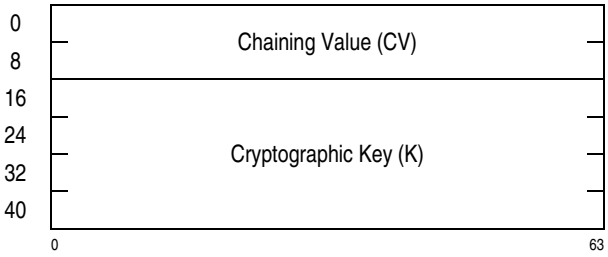

Figure 7-201. Parameter Block for KMO-AES-256

For the KMO-AES-256 function, the chaining value is in byte offset 0-15 of the parameter block and the cryptographic key is in byte offsets 16-47 of the parameter block.

The parameter block used for the KMO-Encrypted-AES-256 function has the following format:

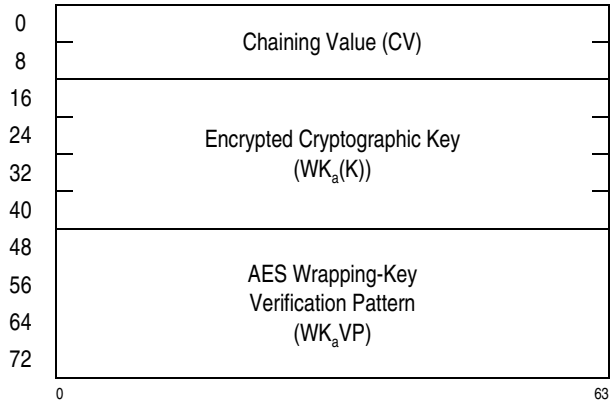

Figure 7-202. Parameter Block for KMO-AES-256

For the KMO-Encrypted-AES-256 function, the contents of byte offsets 48-79 of the parameter block are compared with the contents of the AES wrapping-key verification-pattern register. If they mismatch, the first-operand and parameter-block locations remain unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 0-15 of the parameter block contain the chaining value, and the contents of byte offsets 16-47 of the parameter block are deciphered using the AES wrapping key to obtain the 256-bit cryptographic key. (See the section "Protection of Cryptographic Keys" on page 7-490 for details.)

The following description applies to both functions.

When the modifier bit in general register 0 is zero, an encipher operation is performed. The 16-byte plaintext blocks (P1, P2, …, Pn) in operand 2 are enciphered using the AES-encryption algorithm with the 256-bit cryptographic key and the 128-bit chaining value.

The first input block to the AES-encryption algorithm is the initial chaining value (ICV) in the parameter block. Each input block is enciphered to produce an output block. Each output block is exclusive-ORed with the corresponding plaintext block to form a ciphertext block. Each output block is also used as the next input block.

The process is repeated with the successive input blocks until a ciphertext block is produced for every plaintext block, or until a CPU-determined number of ciphertext blocks have been produced.

The ciphertext blocks (C1, C2, …, Cn) are stored in operand 1. The next input block, called the output chaining value (OCV), is stored into the chaining-value field of the parameter block. The operation is shown in Figure 7-203.

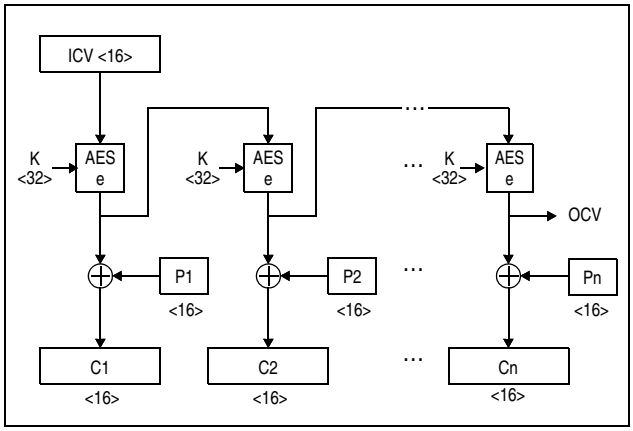

Figure 7-203. KMO-AES-256 Encipher Operation

When the modifier bit in general register 0 is one, a decipher operation is performed. The 16-byte ciphertext blocks (C1, C2, …, Cn) in operand 2 are deciphered using the AES-encryption algorithm with the 256-bit cryptographic key and the 128-bit chaining value.

The first input block to the AES-encryption algorithm is the initial chaining value (ICV) in the parameter block. Each input block is enciphered to produce an output block. Each output block is exclusive-ORed with the corresponding ciphertext block to form a plaintext block. Each output block is also used as the next input block.

The process is repeated with the successive input blocks until a plaintext block is produced for every ciphertext block, or until a CPU-determined number of plaintext blocks have been produced.

The plaintext blocks (P1, P2, …, Pn) are stored in operand 1. The next input block, called the output chaining value (OCV), is stored into the chaining-

value field of the parameter block. The operation is shown in Figure 7-204.

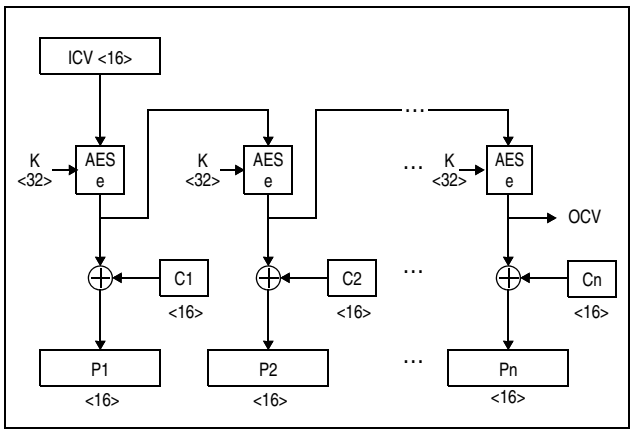

Figure 7-204. KMO-AES-256 Decipher Operation

KMO-Query-Authentication-Information (Function Code 127)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-174 on page 7-135.

The KMO-query-authentication-information function stores the information that can be used by the program to authenticate the running instruction's firmware code level (IFCL) currently installed on the model into the format-0 parameter block for KMO-query-authentication-information. Condition code 0 is set when execution of the KMO-query-authentication-information function completes; condition codes 1 and 3 are not applicable to this function.

The format-0 parameter block used for the KMO-query-authentication-information function has the following format:

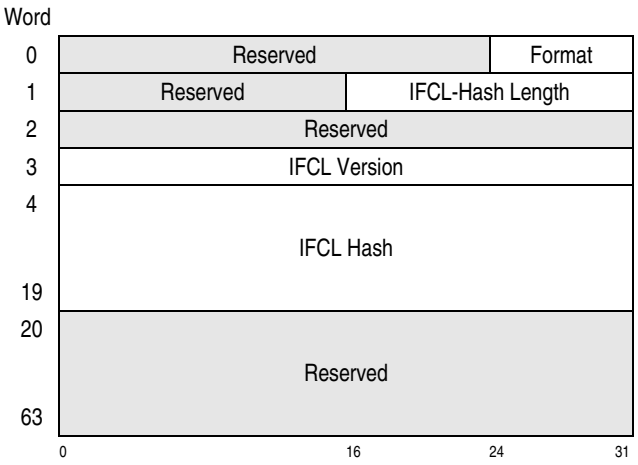

Figure 7-205. Format-0 Parameter Block for KMO-Query-Authentication-Information

The format-0 parameter block contains the following fields:

Reserved: Bytes 0-2 of word 0, bytes 0-1 of word 1, word 2, and words 20-63 are reserved and stored as zeros.

Format: Byte 3 of word 0 contains an 8-bit unsigned binary integer whose value specifies the format of the parameter block. A format value of zero indicates a format-0 parameter block. When a format-0 parameter block is stored, the value of this field is set to zero.

IFCL-Hash Length: Bytes 2-3 of word 1 contain a 16-bit unsigned binary integer specifying the number of bytes of the IFCL hash stored in the IFCL hash field. When the IFCL hash is less than or equal to 64 bytes, the IFCL-hash length field is set to the actual length of the IFCL hash. When the IFCL hash is larger than 64 bytes, the IFCL-hash length field is set to 64.

IFCL Version: Word 3 contains a 32-bit unsigned binary integer specifying the version number of the IFCL.

IFCL Hash: Words 4-19 contain the hash value of the IFCL. The IFCL-hash length field specifies the number of bytes that are in the IFCL hash field. The IFCL hash value is left aligned. When the IFCL hash is less than 64 bytes, it is padded with zeros on the

right. When the IFCL hash is larger than 64 bytes, only the leftmost 64 bytes of the IFCL hash are stored.

Special Conditions

A specification exception is recognized and no other action is taken if any of the following occurs:

1. Bits 57-63 of general register 0 specify an unassigned or uninstalled function code.
2. The R_1 or R_2 field designates an odd-numbered register or general register 0.
3. The second operand length is not a multiple of the data block size of the designated function (see Figure 7-173 on page 7-134 to determine the data block sizes for CIPHER MESSAGE WITH OUTPUT FEEDBACK functions). This specification-exception condition does not apply to the query functions.

Resulting Condition Code:

0 Normal completion
1 Verification-pattern mismatch
2 --
3 Partial completion

Program Exceptions:

- Access (fetch, operand 2, cryptographic key, and wrapping-key verification pattern; store, operand 1, query parameter block, and query-authentication-information parameter block; fetch and store, chaining value, cryptography counter)
- Operation (if the message-security-assist extension 4 is not installed)
- Specification
- Transaction constraint

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B	Operation exception.
7.C	Transaction constraint
8.	Specification exception due to invalid function code or invalid register number.
9.	Specification exception due to invalid operand length.
10.	Access exceptions for an access to a cryptography counter and second-operand length originally zero.
11.	Condition code 0 due to second-operand length originally zero.
12.A.1	Access exceptions for an access to the parameter block.
12.A.2	Condition code 1 due to verification-pattern mismatch.
12.B	Access exceptions for an access to the first or second operand.
13.	Condition code 3 due to partial completion (second-operand length still nonzero).
14.	Condition code 3 due to second-operand length stepped to zero and access-exception condition detected for an access to a cryptography counter.
15.	Condition code 0 due to normal completion (second-operand length originally nonzero, but stepped to zero).

Figure 7-206. Priority of Execution: KMO

Figure 7-206. Priority of Execution: KMO (Continued)

Programming Notes:

1. The performance of the query function (code 0) may be significantly slower than that of simply examining a location in storage. If the program needs to frequently test for the availability of a function, it should perform the query function once during initialization; subsequently it should examine the stored results of the query function in memory with an instruction such as TEST UNDER MASK.
2. See the programming notes for CIPHER MESSAGE WITH CHAINING.
3. In earlier versions of the architecture, CIPHER MESSAGE WITH OUTPUT FEEDBACK was known as CIPHER MESSAGE WITH OFB.
4. As observed by this CPU, other CPUs, and the I/O subsystem, inconsistent results may be briefly stored in the first-operand location. See the section “Effects of CPU Retry” on page 11-3 for further details.

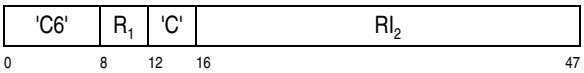
CGFRL R_1,RI_2 [RIL-b]



The first operand is compared with the second operand, and the result is indicated in the condition code.

For COMPARE (CR, C, CY), COMPARE IMMEDIATE (CFI), and COMPARE RELATIVE LONG (CRL), the operands are treated as 32-bit signed binary integers. For COMPARE (CGR, CG) and COMPARE RELATIVE LONG (CGRL), they are treated as 64-bit signed binary integers. For COMPARE (CGFR, CGF), COMPARE IMMEDIATE (CGFI), and COMPARE RELATIVE LONG (CGFRL), the second operand is treated as a 32-bit signed binary integer, and the first operand is treated as a 64-bit signed binary integer.

The displacement for COMPARE (C) is treated as a 12-bit unsigned binary integer. The displacement for COMPARE (CY, CG, and CGF) is treated as a 20-bit signed binary integer.

For COMPARE RELATIVE LONG, the contents of the RI_2 field are a signed binary integer specifying the number of halfwords that is added to the address of the instruction to generate the address of the second operand in storage. When DAT is on, the second operand is accessed using the same addressing-space mode as that used to access the instruction. When DAT is off, the second operand is accessed using a real address.

For COMPARE RELATIVE LONG (CRL, CGFRL), the second operand must be aligned on a word boundary, and for COMPARE RELATIVE LONG (CGRL), the second operand must be aligned on a doubleword boundary; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Operands equal
1 First operand low
2 First operand high
3 --

Program Exceptions:

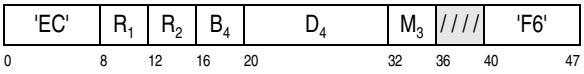
- Access (operand 2 of C, CY, CG, CGF, CRL, CGRL, and CGFRL only)
- Operation (CY, if the long-displacement facility is not installed; CFI and CGFI, if the extended-immediate facility is not installed; CGFRL, CGRL, and CRL, if the general-instructions-extension facility is not installed)
- Specification (CGFRL, CGRL, and CRL only)

Programming Notes:

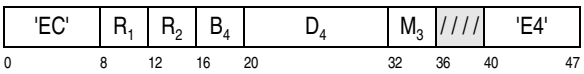
1. For COMPARE RELATIVE LONG, the second operand must be aligned on an integral boundary corresponding to the operand's size.
2. When COMPARE RELATIVE LONG is the target of an execute-type instruction, the second-operand address is relative to the target address.

COMPARE AND BRANCH

CRB $R_1,R_2,M_3,D_4(B_4)$ [RRS]

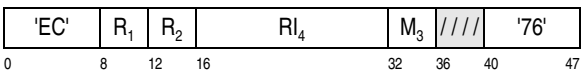


CGRB $R_1,R_2,M_3,D_4(B_4)$ [RRS]

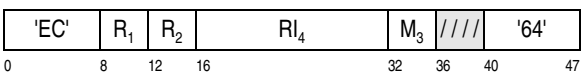


COMPARE AND BRANCH RELATIVE

CRJ R_1,R_2,M_3,RI_4 [RIE-b]

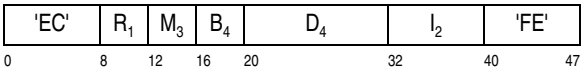


CGRJ R_1,R_2,M_3,RI_4 [RIE-b]

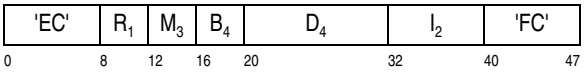


COMPARE IMMEDIATE AND BRANCH

CIB $R_1,I_2,M_3,D_4(B_4)$ [RIS]

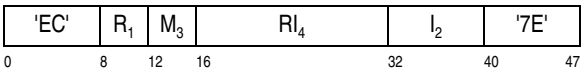


CGIB $R_1,I_2,M_3,D_4(B_4)$ [RIS]

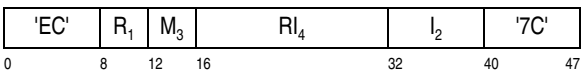


COMPARE IMMEDIATE AND BRANCH RELATIVE

CIJ R_1,I_2,M_3,RI_4 [RIE-c]



CGIJ R_1,I_2,M_3,RI_4 [RIE-c]



The first operand is compared with the second operand. If the mask bit in the M_3 field corresponding to the comparison result is one, the instruction address in the current PSW is replaced by the branch address specified by the fourth operand; otherwise, normal instruction sequencing proceeds with the updated instruction address.

For COMPARE AND BRANCH (CRB), COMPARE AND BRANCH RELATIVE (CRJ), COMPARE IMMEDIATE AND BRANCH (CIB) and COMPARE IMMEDIATE AND BRANCH RELATIVE (CIJ), the first operand is treated as a 32-bit signed binary integer. For COMPARE AND BRANCH (CGRB), COMPARE AND BRANCH RELATIVE (CGRJ), COMPARE IMMEDIATE AND BRANCH (CGIB) and COMPARE IMMEDIATE AND BRANCH RELATIVE (CGIJ), the first operand is treated as a 64-bit signed binary integer.

For COMPARE AND BRANCH (CRB) and COMPARE AND BRANCH RELATIVE (CRJ), the second operand is treated as a 32-bit signed binary integer. For COMPARE AND BRANCH (CGRB) and COMPARE AND BRANCH RELATIVE (CGRJ), the second operand is treated as a 64-bit signed binary integer. For COMPARE IMMEDIATE AND BRANCH

and COMPARE IMMEDIATE AND BRANCH RELATIVE, the second operand is treated as an 8-bit signed binary integer.

The comparison results and corresponding M_3 bits are as follows:

Comparison Result	M_3 Bit
Equal	0
First operand low	1
First operand high	2

Bit 3 of the M_3 field is reserved and should be zero; otherwise, the program may not operate compatibly in the future.

For COMPARE AND BRANCH and COMPARE IMMEDIATE AND BRANCH, the fourth-operand address is used as the branch address. For COMPARE AND BRANCH RELATIVE and COMPARE IMMEDIATE AND BRANCH RELATIVE, the contents of the RI_4 field are a signed binary integer specifying the number of halfwords that is added to the address of the instruction to generate the branch address.

Condition Code: The code remains unchanged.

Program Exceptions:

- Operation (if the general-instructions-extension facility is not installed).
- Transaction constraint

Programming Notes:

1. When bit positions 0-2 of the M_3 field contain zeros, the instruction acts as a NOP, however this is not the preferred instruction with which to create a NOP. When bit positions 0-2 of the M_3 field contain 111 binary, a branch always occurs.

2. When COMPARE AND BRANCH RELATIVE or COMPARE IMMEDIATE AND BRANCH RELATIVE are the target of an execute-type instruction, the branch is relative to the target address. See “Branch-Address Generation” on page 5-12.

3. The high-level assembler (HLASM) provides extended-mnemonic formats for all of the multiple-operation instructions which perform a compare (arithmetic or logical) followed by a branch or trap. In the extended-mnemonic format, the mask field is not explicitly coded; rather the branch mask is implicitly indicated by the extended mnemonic.

   The extended-mnemonic names are formed by concatenating the base mnemonic, followed by one of the suffix characters, as shown below.

Suffix Chars	Meaning	Mask Field
E	Equal	8
H	First operand high	2
L	First operand low	4
NE	Not equal	6
NH	First operand not high	12
NL	First operand not low	10

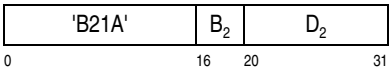
   Consider the following example of a COMPARE IMMEDIATE AND BRANCH RELATIVE (CGIJ) instruction that is coded using an extended mnemonic:

```
        CGIJNE                    10,-123,SKIP
          ⋮
SKIP    DS      0H      (128 bytes past CGIJNE)
```

   The implied mask field corresponding to the mnemonic suffix (NE) is 6, thus the generated code is ECA60040857C hex.

COMPARE AND FORM CODEWORD

CFC $D_2(B_2)$ [S]



General register 2 contains an index, which is used along with contents of general registers 1 and 3 to designate the starting addresses of two fields in storage, called the first and third operands. The first and third operands are logically compared, and a codeword is formed in general register 2 for use in sort/merge algorithms.

The second-operand address is not used to address data. Bits 49-62 of the second-operand address, with one rightmost and one leftmost zero appended, are used as a 16-bit index limit. Bit 63 of the second-operand address is the operand-control bit; the operand-control bit is applicable when the first and third operands are unequal. When bit 63 is zero, the codeword is formed from the one’s complement of the

high operand; when bit 63 is one, the codeword is formed from the low operand. The remainder of the second-operand address is ignored.

General registers 1 and 3 contain the base addresses of the first and third operands. Bits 48-63 of general register 2 are used as an index for addressing both the first and third operands. General registers 1, 2, and 3 must all initially contain even values; otherwise, a specification exception is recognized.

In the access-register mode, access register 1 specifies the address space containing the first and third operands.

The size of the units by which the first and third operands are compared, the size of the resulting codeword, and the participation of bits 0-31 of general registers 1, 2, and 3 in the operation depend on the addressing mode. In the 24-bit or 31-bit addressing mode, the comparison unit is two bytes, the codeword is four bytes, and bits 0-31 of the registers are ignored and remain unchanged. In the 64-bit addressing mode, the comparison unit is six bytes, the codeword is eight bytes, and bits 0-31 of the registers are used in and may be changed by the operation.

Operation in the 24-Bit or 31-Bit Addressing Mode

The operation consists in comparing the first and third operands halfword by halfword and incrementing the index until an unequal pair of halfwords is found or the index exceeds the index limit. This proceeds in units of operation, between which interruptions may occur.

At the start of a unit of operation, the index, bits 48-63 of general register 2, is logically compared with the index limit. If the index is larger, the instruction is completed by placing bits 32-63 of general register 3, with bit 32 set to one, in bit positions 32-63 of general register 2, and by setting condition code 0.

If the index is less than or equal to the index limit, the index is applied to the first-operand and third-operand base addresses to locate the current pair of halfwords to be compared. The index, with 48 leftmost zeros appended, and bits 32-63 of general register 1, with 32 leftmost zeros appended, are added to form a 64-bit intermediate value. A carry out of bit position 32, if any, is ignored. The address of the current first-operand halfword is generated from the intermediate value by following the normal rules for operand address generation. The address of the current third-operand halfword is formed in the same manner by adding bits 32-63 of general register 3 and the index.

The current first-operand and third-operand halfwords are logically compared. If they are equal, the contents of general register 2 are incremented by 2, and a unit of operation ends.

If the compare values are unequal, the contents of general register 2 are incremented by 2 and then shifted left logically by 16 bit positions. The shifting occurs only within bit positions 32-63. If the operand-control bit is zero, (1) the one's complement of the higher halfword is placed in bit positions 48-63 of general register 2, and (2) if operand 1 was higher, bits 32-63 of general registers 1 and 3 are interchanged. If the operand-control bit is one, (1) the lower halfword is placed in bit positions 48-63 of general register 2, and (2) if operand 1 was lower, bits 32-63 of general registers 1 and 3 are interchanged. Condition code 2 is set if general registers 1 and 3 are interchanged; otherwise, condition code 1 is set.

For the purpose of recognizing access exceptions, operand 1 and operand 3 are both considered to have a length equal to 2 more than the value of the index limit minus the index.

Operation in the 64-bit Addressing Mode

The operation consists in comparing the first and third operands in units of six bytes at a time and incrementing the index until an unequal pair of six-byte units is found or the index exceeds the index limit. This proceeds in units of operation, between which interruptions may occur.

At the start of a unit of operation, the index, bits 48-63 of general register 2, is logically compared with the index limit. If the index is larger, the instruction is completed by placing bits 0-63 of general register 3, with bit 0 set to one, in bit positions 0-63 of general register 2, and by setting condition code 0.

If the index is less than or equal to the index limit, the index is applied to the first-operand and third-operand base addresses to locate the current pair of six-byte units to be compared. The index, with 48 leftmost zeros appended, and bits 0-63 of general register 1 are added to form the 64-bit address of the current first-operand six-byte unit. A carry out of bit

position 0, if any, is ignored. The address of the current third-operand six-byte unit is formed in the same manner by adding bits 0-63 of general register 3 and the index.

The current first-operand and third-operand six-byte units are logically compared. If they are equal, the contents of general register 2 are incremented by 6, and a unit of operation ends.

If the compare values are unequal, the contents of general register 2 are incremented by 6 and then shifted left logically by 48 bit positions. If the operand-control bit is zero, (1) the one's complement of the higher six-byte unit is placed in bit positions 16-63 of general register 2, and (2) if operand 1 was higher, bits 0-63 of general registers 1 and 3 are interchanged. If the operand-control bit is one, (1) the lower six-byte unit is placed in bit positions 16-63 of general register 2, and (2) if operand 1 was lower, bits 0-63 of general registers 1 and 3 are interchanged. Condition code 2 is set if general registers 1 and 3 are interchanged; otherwise, condition code 1 is set.

For the purpose of recognizing access exceptions, operand 1 and operand 3 are both considered to have a length equal to 6 more than the value of the index limit minus the index. However, depending on the model, access exceptions may or may not be recognized for the portion of a storage operand to the right of the first unequal byte when the operand is not needed to form the codeword in general register 2.

Specifications Independent of Addressing Mode

The condition code is unpredictable if the instruction is interrupted.

When the index is initially larger than the index limit, access exceptions are not recognized for the storage operands. For operands longer than 4K bytes, access exceptions are not recognized more than 4K bytes beyond the byte being processed. Access exceptions are not recognized when a specification-exception condition exists.

If the B_2 field designates general register 2, it is unpredictable whether or not the index limit is recomputed; thus, in this case the operand length is unpredictable. However, in no case can the operands exceed 2^{15} bytes in length.

Resulting Condition Code:

0 Operands equal
1 Operand-control bit zero and operand 1 low, or operand-control bit one and operand 3 low
2 Operand-control bit zero and operand 1 high, or operand-control bit one and operand 3 high
3 --

Program Exceptions:

- Access (fetch, operands 1 and 3)
- Specification
- Transaction constraint

Programming Notes:

1. An example of the use of COMPARE AND FORM CODEWORD is given in "Sorting Instructions" in Appendix A, "Number Representation and Instruction-Use Examples."

2. The offset of the halfword or six-byte unit (depending on the addressing mode) of the first and third operands at which comparison is to begin should be placed in bit positions 48-63 of general register 2 before executing COMPARE AND FORM CODEWORD. The index limit derived from the second-operand address should be the offset of the last halfword or six-byte unit of the first and third operands for which comparison can be made. When the operands do not compare equal, the leftmost 16 bits of the codeword formed in general register 2 (bits 32-47 of the register in the 24-bit or 31-bit addressing mode, or bits 0-15 in the 64-bit addressing mode) by the execution of COMPARE AND FORM CODEWORD gives the offset of the first halfword or six-byte unit not compared. If the codewords compare equal in an UPDATE TREE operation, bit positions 32-47 of general register 2 in the 24-bit or 31-bit addressing mode, or bit positions 0-15 in the 64-bit addressing mode, will contain the offset at which another COMPARE AND FORM CODEWORD should resume comparison for breaking codeword ties. Operand-control-bit values of zero or one are used for sorting operands in ascending or descending order, respectively. Refer to "Sorting Instructions" on page A-53 for a discussion of the use of codewords in sorting.

3. The condition code indicates the results of comparing operands up to 32,768 bytes long. Equal

operands result in a negative codeword in bit positions 32-63 of general register 2 in the 24-bit or 31-bit addressing mode, or in bit positions 0-63 in the 64-bit addressing mode. A negative codeword also results in the 24-bit or 31-bit mode when the index limit is 32,766 and the operands that are compared differ in only their last two bytes, or in the 64-bit mode when the limit is 32,762 and the operands differ in only their last six bytes. If this latter codeword is used by UPDATE TREE, an incorrect result may be indicated in general registers 0 and 1. Therefore, the index limit should not exceed 32,764 in the 24-bit or 31-bit mode, or 32,760 in the 64-bit mode, when the resulting codeword is to be used by UPDATE TREE.

4. Special precautions should be taken if COMPARE AND FORM CODEWORD is made the target of an execute-type instruction. See the programming note concerning interruptible instructions under EXECUTE.

5. Further programming notes concerning interruptible instructions are included in “Interruptible Instructions” in Chapter 5, “Program Execution.”

6. The storage-operand references of COMPARE AND FORM CODEWORD may be multiple-access references. (See “Storage-Operand Consistency”.)

7. Figure 7-207 on page 7-154 and Figure 7-208 on page 7-155 contain summaries of the operation in the 24-bit or 31-bit addressing mode, and Figure 7-209 on page 7-156 and Figure 7-210 on page 7-157 contain summaries of the operation in the 64-bit addressing mode.

Operand-Control Bit	Relation	Resulting Condition Code	Result in GR2 (Bits 32-63)	Result in GR1 (Bits 32-63)	Result in GR3 (Bits 32-63)
0	op1 = op3	0	OGR3b1	–	–
0	op1 < op3	1	X, nop3	–	–
0	op1 > op3	2	X, nop1	OGR3	OGR1
1	op1 = op3	0	OGR3b1	–	–
1	op1 < op3	2	X, top1	OGR3	OGR1
1	op1 > op3	1	X, top3	–	–

Explanation:

–	The bits remain unchanged.
OGR1	The original value of GR1 bits 32-63.
OGR3	The original value of GR3 bits 32-63.
OBR3b1	The original value of GR3 bits 32-63 with bit 32 set to one.
X	Bits 32-47 of GR2 are 2 more than the index of the first unequal halfword.
nop1	Bits 48-63 of GR2 are the one's complement of the first unequal halfword in operand 1.
nop3	Bits 48-63 of GR2 are the one's complement of the first unequal halfword in operand 3.
top1	Bits 48-63 of GR2 are the first unequal halfword in operand 1.
top3	Bits 48-63 of GR2 are the first unequal halfword in operand 3.

Figure 7-207. Operation of COMPARE AND FORM CODEWORD in the 24-Bit or 31-bit Addressing Mode

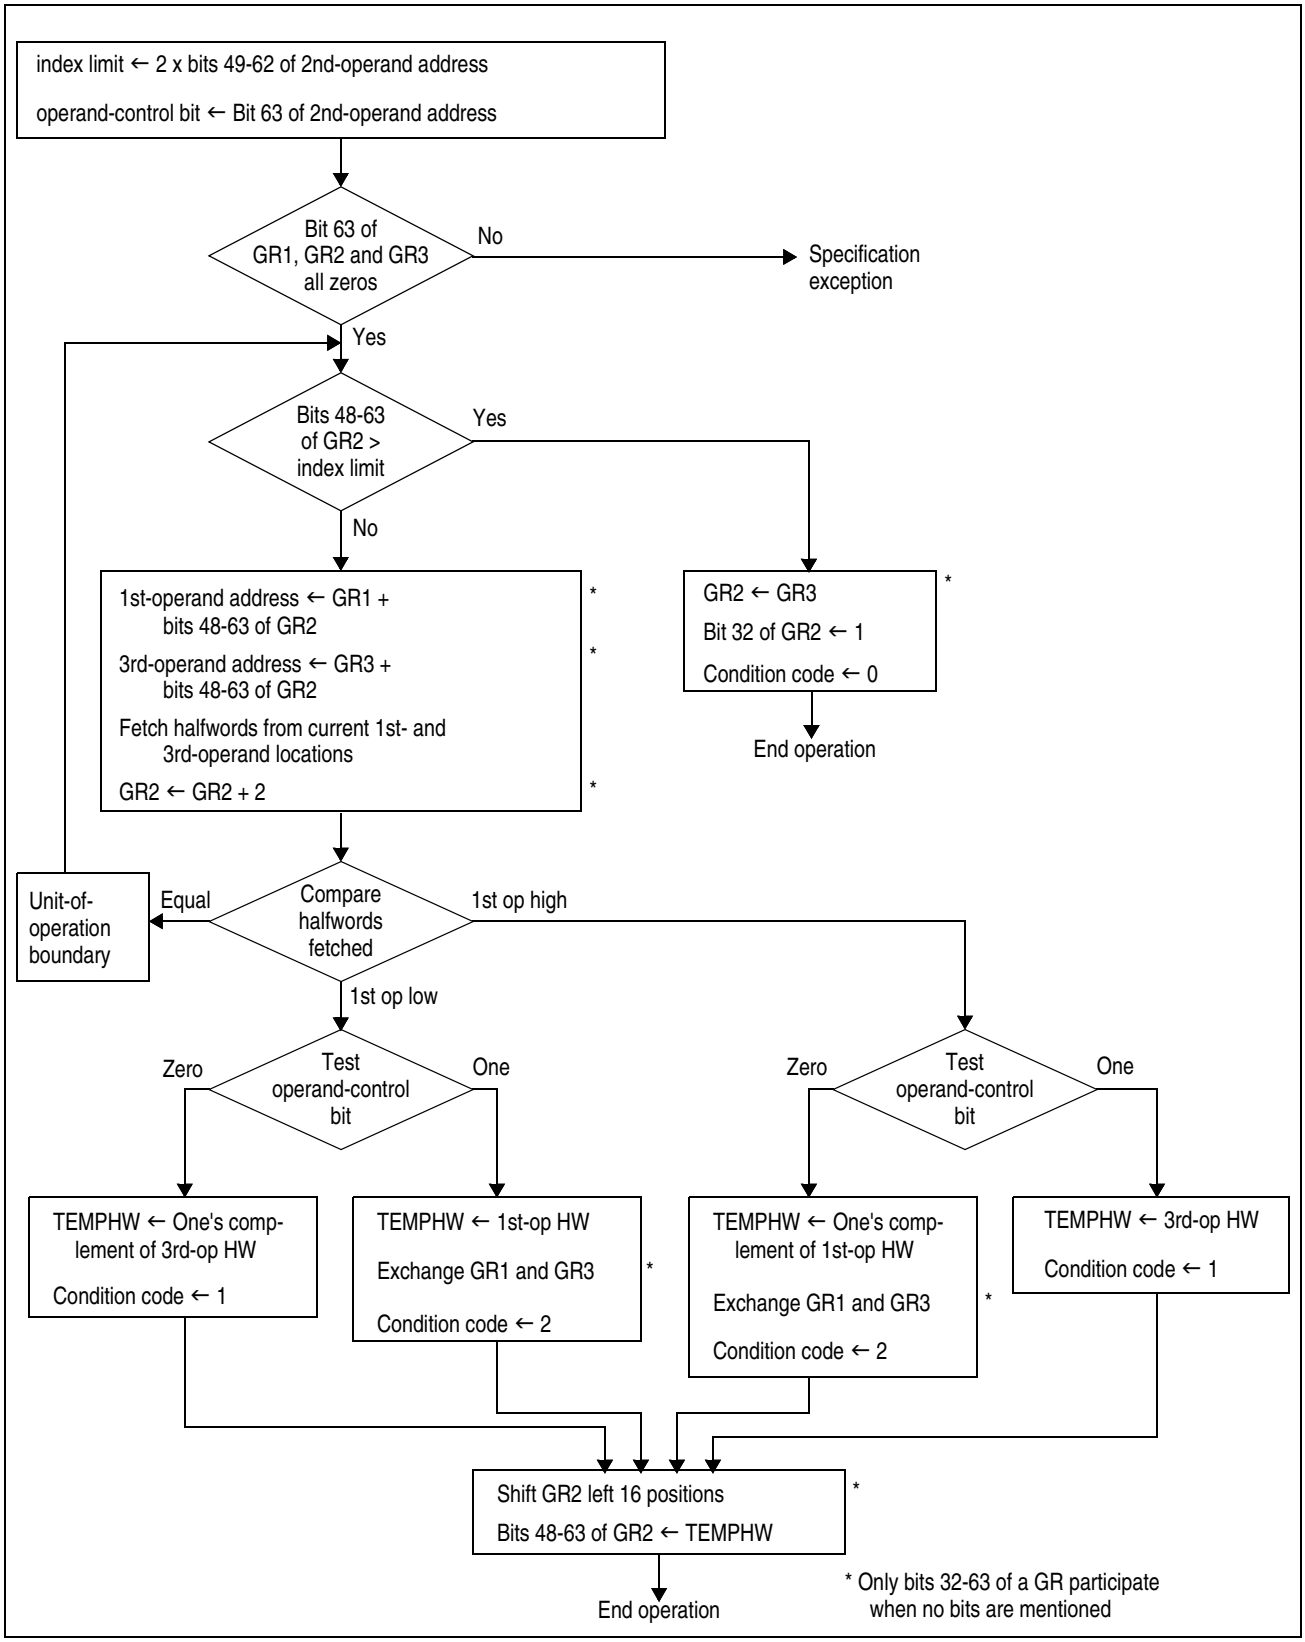


Figure 7-208. Execution of COMPARE AND FORM CODEWORD in the 24-Bit or 31-bit Addressing Mode

Operand-Control Bit	Relation	Resulting Condition Code	Result in GR2 (Bits 0-63)	Result in GR1 (Bits 0-63)	Result in GR3 (Bits 0-63)

OGR1 The original value of GR1 bits 0-63.
OGR3 The original value of GR3 bits 0-63.
OBR3b1 The original value of GR3 bits 0-63 with bit 0 set to one.
X Bits 0-15 of GR2 are 6 more than the index of the first unequal six-byte unit.
nop1 Bits 16-63 of GR2 are the one's complement of the first unequal six-byte unit in operand 1.
nop3 Bits 16-63 of GR2 are the one's complement of the first unequal six-byte unit in operand 3.
top1 Bits 16-63 of GR2 are the first unequal six-byte unit in operand 1.
top3 Bits 16-63 of GR2 are the first unequal six-byte unit in operand 3.

Figure 7-209. Operation of COMPARE AND FORM CODEWORD in the 64-bit Addressing Mode

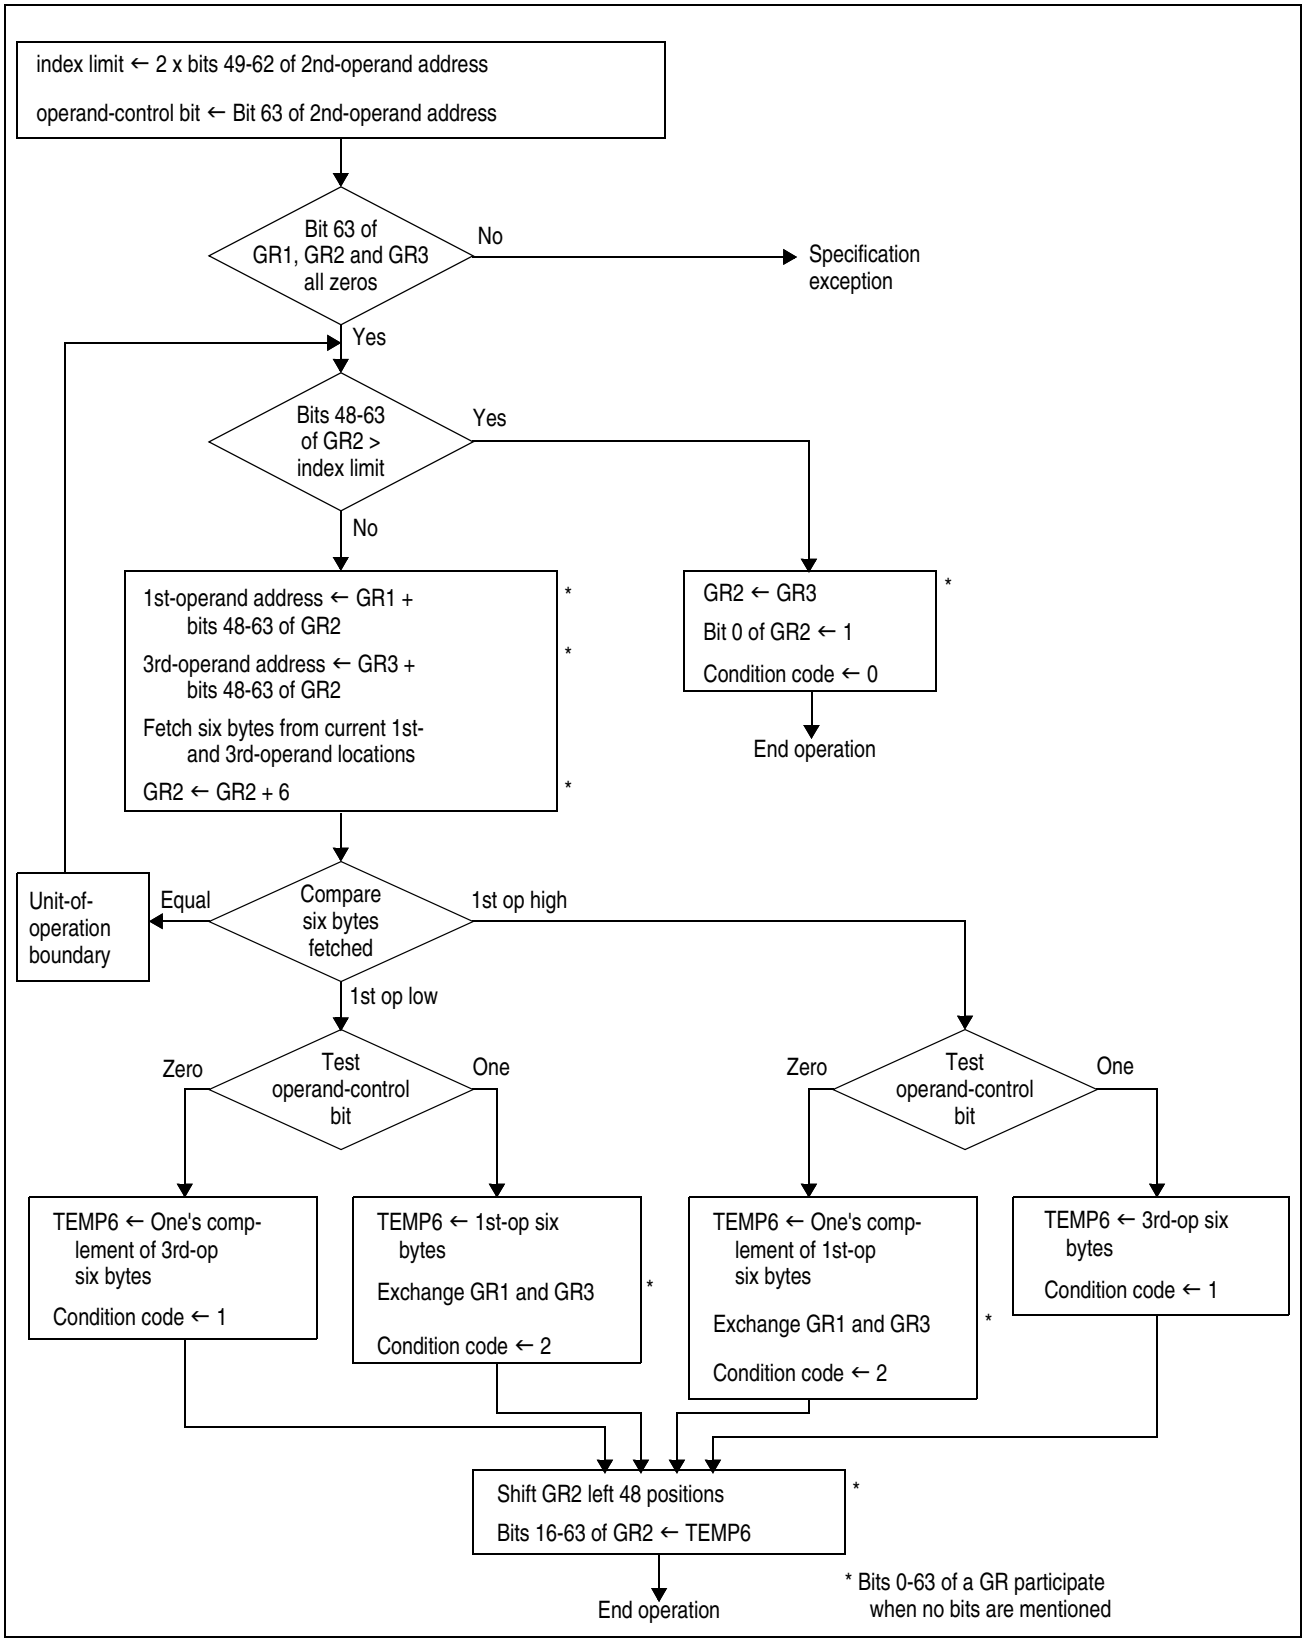

Figure 7-210. Execution of COMPARE AND FORM CODEWORD in the 64-bit Addressing Mode

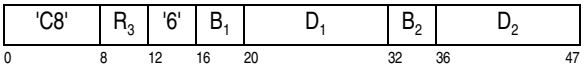
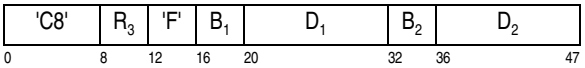
COMPARE AND LOAD

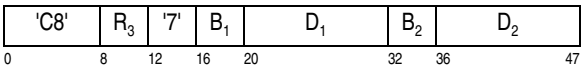
CAL $R_3,D_1(B_1),D_2(B_2)$ [SSF]



CALGF $R_3,D_1(B_1),D_2(B_2)$ [SSF]



CALG $R_3,D_1(B_1),D_2(B_2)$ [SSF]



The first operand is compared to the third operand. The result of the comparison determines whether the third operand is replaced by the first operand or the second operand.

For CAL, the first and second operands are 32 bits, the third operand is in bit positions 32-63 of general register R_3, and bit positions 0-31 of general register R_3 are unchanged.

For CALGF, the first operand is 32 bits, the second operand is 64 bits, the third operand is in bit positions 32-63 of general register R_3, and results are placed in bit positions 0-63 of general register R_3.

For CALG, the first, second, and third operands are 64 bits.

When the first and third operands are equal, the second operand is loaded into the third-operand location and condition code 0 is set.

For CAL and CALG, when the first and third operands are not equal, the first operand is loaded into the third-operand location and condition code 1 is set.

For CALGF, when the first and third operands are not equal, zeros are placed in bit positions 0-31 of the third-operand location, the first operand is loaded into bit positions 32-63 of the third-operand location and condition code 1 is set.

The displacements of the first and second operands are treated as 12-bit unsigned binary integers.

Accesses for the first and second operands appear to occur concurrently as observed by other CPUs and channel programs.

A serialization function is performed before the operation begins and again after the operation is completed.

For CAL and CALGF, the first operand must be aligned on a word boundary; otherwise, a specification exception is recognized. For CALG, the first operand must be aligned on a doubleword boundary; otherwise, a specification exception is recognized.

When the first and third operands are equal, the following applies:

- For CAL, the second operand must be aligned on a word boundary; otherwise, a specification exception is recognized.
- For CALGF and CALG, the second operand must be aligned on a doubleword boundary; otherwise, a specification exception is recognized.

When the first and third operands are not equal, the following applies:

- For CAL, it is model dependent whether a specification exception is recognized when the second operand is not aligned on a word boundary.
- For CALGF and CALG, it is model dependent whether a specification exception is recognized when the second operand is not aligned on a doubleword boundary.

For CAL, CALGF, and CALG, when the first and third operands are not equal, access exceptions and PER zero-address-detection events for the second operand are not recognized.

Resulting Condition Code:

0 The first and third operands are equal
1 The first and third operands not equal
2 --
3 --

Program Exceptions:

- Access (fetch, operands 1 and 2)
- Operation (if the concurrent-functions facility is not installed)

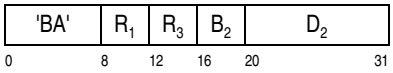
- Specification
- Transaction constraint

Programming Notes:

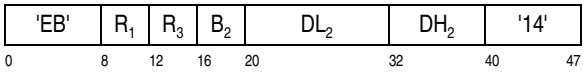
1. COMPARE AND LOAD (CAL, CALG) perform functions similar to that of PERFORM LOCKED OPERATION function codes 0 and 2, respectively, when the PLO-extension facility is installed, with the exception of the number of general registers used. However, COMPARE AND LOAD may provide better performance than that of PERFORM LOCKED OPERATION.
2. Models introduced after the z17 models may provide improved performance for the COMPARE AND LOAD instructions compared to that provided by the z17 models.

COMPARE AND SWAP

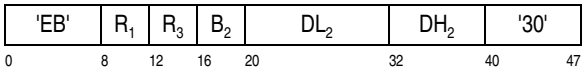
CS $R_1,R_3,D_2(B_2)$ [RS-a]



CSY $R_1,R_3,D_2(B_2)$ [RSY-a]

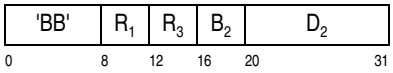


CSG $R_1,R_3,D_2(B_2)$ [RSY-a]

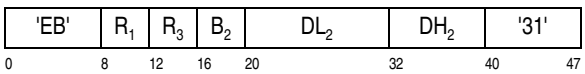


COMPARE DOUBLE AND SWAP

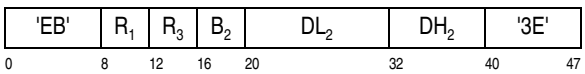
CDS $R_1,R_3,D_2(B_2)$ [RS-a]



CDSY $R_1,R_3,D_2(B_2)$ [RSY-a]



CDSG $R_1,R_3,D_2(B_2)$ [RSY-a]



The first and second operands are compared. If they are equal, the third operand is stored at the second-operand location. If they are unequal, the second operand is loaded into the first-operand location. The result of the comparison is indicated in the condition code.

For COMPARE AND SWAP (CS, CSY), the first and third operands are 32 bits in length, with each operand occupying bit positions 32-63 of a general register. The second operand is a word in storage.

For COMPARE AND SWAP (CSG), the first and third operands are 64 bits in length, with each operand occupying bit positions 0-63 of a general register. The second operand is a doubleword in storage.

For COMPARE DOUBLE AND SWAP (CDS, CDSY), the first and third operands are 64 bits in length. The first 32 bits of an operand occupy bit positions 32-63 of the even-numbered register of an even-odd pair of general registers, and the second 32 bits occupy bit positions 32-63 of the odd-numbered register of the pair. The second operand is a doubleword in storage.

For COMPARE DOUBLE AND SWAP (CDSG), the first and third operands are 128 bits in length. The first 64 bits of an operand occupy bit positions 0-63 of the even-numbered register of an even-odd pair of general registers, and the second 64 bits occupy bit positions 0-63 of the odd-numbered register of the pair. The second operand is a quadword in storage.

When an equal comparison occurs, the third operand is stored at the second-operand location. The fetch of the second operand for purposes of comparison and the store into the second-operand location appear to be a block-concurrent interlocked-update reference as observed by other CPUs.

When the result of the comparison is unequal, the second operand is loaded at the first-operand location, and the second-operand location remains unchanged. However, on some models, the contents may be fetched and subsequently stored back unchanged at the second-operand location. This update appears to be a block-concurrent interlocked-update reference as observed by other CPUs.

A serialization function is performed before the operand is fetched and again after the operation is completed.

The displacement for CS and CDS is treated as a 12-bit unsigned binary integer. The displacement for CSY, CSG, CDSY, and CDSG is treated as a 20-bit signed binary integer.

The second operand of COMPARE AND SWAP (CS, CSY) must be designated on a word boundary. The second operand of COMPARE AND SWAP (CSG) and COMPARE DOUBLE AND SWAP (CDS, CDSY) must be designated on a doubleword boundary. The second operand of COMPARE DOUBLE AND SWAP (CDSG) must be designated on a quadword boundary. The R_1 and R_3 fields for COMPARE DOUBLE AND SWAP must each designate an even-numbered register. Otherwise, a specification exception is recognized.

Resulting Condition Code:

0 First and second operands equal, second operand replaced by third operand
1 First and second operands unequal, first operand replaced by second operand
2 --
3 --

Program Exceptions:

- Access (fetch and store, operand 2)
- Operation (CSY and CDSY, if the long-displacement facility is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. Several examples of the use of the COMPARE AND SWAP and COMPARE DOUBLE AND SWAP instructions are given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. Some of the following notes are worded, with respect to operand size, for CS, CSY, CDS, and CDSY. Similar notes, worded for a larger operand size, would apply to CSG and CDSG.

3. COMPARE AND SWAP can be used by CPU programs sharing common storage areas in either a multiprogramming or multiprocessing environment. Two examples are:

   a. By performing the following procedure, a CPU program can modify the contents of a storage location even though the possibility exists that the CPU program may be interrupted by another CPU program that will update the location or that another CPU program may simultaneously update the location. First, the entire word containing the byte or bytes to be updated is loaded into a general register. Next, the updated value is computed and placed in another general register. Then COMPARE AND SWAP is executed with the R_1 field designating the register that contains the original value and the R_3 field designating the register that contains the updated value. If the update has been successful, condition code 0 is set. If the storage location no longer contains the original value, the update has not been successful, the general register designated by the R_1 field of the COMPARE AND SWAP instruction contains the new current value of the storage location, and condition code 1 is set. When condition code 1 is set, the CPU program can repeat the procedure using the new current value.

   b. COMPARE AND SWAP can be used for controlled sharing of a common storage area, including the capability of leaving a message (in a chained list of messages) when the common area is in use. To accomplish this, a word in storage can be used as a control word, with a zero value in the word indicating that the common area is not in use and that no messages exist, a negative value indicating that the area is in use and that no messages exist, and a nonzero positive value indicating that the common area is in use and that the value is the address of the most recent message added to the list. Thus, any number of CPU programs desiring to seize the area can use COMPARE AND SWAP to update the control word to indicate that the area is in use or to add messages to the list. The single CPU program which has seized the area can also safely use COMPARE AND SWAP to remove messages from the list.

4. COMPARE DOUBLE AND SWAP can be used in a manner similar to that described for COMPARE AND SWAP. In addition, it has another use. Consider a chained list, with a control word used to address the first message in the list, as described in programming note 3.b above. If multiple CPU programs are to be permitted to delete

messages by using COMPARE AND SWAP (and not just the single CPU program which has seized the common area), there is a possibility the list will be incorrectly updated. This would occur if, for example, after one CPU program has fetched the address of the most recent message in order to remove the message, another CPU program removes the first two messages and then adds the first message back into the chain. The first CPU program, on continuing, cannot easily detect that the list is changed. By increasing the size of the control word to a doubleword containing both the first message address and a word with a change number that is incremented for each modification of the list, and by using COMPARE DOUBLE AND SWAP to update both fields together, the possibility of the list being incorrectly updated is reduced to a negligible level. That is, an incorrect update can occur only if the first CPU program is delayed while changes exactly equal in number to a multiple of 2^{32} take place *and* only if the last change places the original message address in the control word.

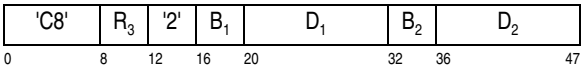
5. To ensure successful updating of a common storage field by two or more CPUs, all updates must be done by means of an interlocked-update reference (the section "Interlocked-Update References" on page 5-131 lists the instructions that perform an interlocked-update reference). For example, in a configuration where the interlocked-access facility 2 is not installed, if one CPU executes OR IMMEDIATE and another CPU executes COMPARE AND SWAP to update the same byte, the fetch by OR IMMEDIATE may occur either before the fetch by COMPARE AND SWAP or between the fetch and the store by COMPARE AND SWAP, and then the store by OR IMMEDIATE may occur after the store by COMPARE AND SWAP, in which case the change made by COMPARE AND SWAP is lost.

6. For the case of a condition-code setting of 1, COMPARE AND SWAP and COMPARE DOUBLE AND SWAP may or may not, depending on the model, cause any of the following to occur for the second-operand location: a PER storage-alteration event may be recognized; a protection exception for storing may be recognized; and, provided no access exception exists, the change bit may be set to one. Because the contents of storage remain unchanged, the change bit may or may not be one when a PER storage-alteration event is recognized.

7. The performance of CDSG on some models may be significantly slower than that of CSG. When quadword consistency is not required by the program, alternate code sequences should be used.

COMPARE AND SWAP AND STORE

CSST $D_1(B_1),D_2(B_2),R_3$ [SSF]



The first operand is compared with the third operand. If they are equal, the replacement value is stored into the first-operand location, and subsequently, the store value is placed into the second-operand location. If they are not equal, then the first operand is loaded into the third-operand location, and the second operand is not changed. The result is indicated by the condition code.

The size of the first and third operands, the size of the replacement value, and the alignment of the first operand are determined by the contents of a function code (FC) in bits 56-63 of general register 0. The assigned function codes are as follows:

- When the function code is 0, the operands are 32 bits in length. The first operand is a word in storage, and the third operand is in bits 32-63 of general register R_3. The replacement value is in bytes 0-3 of the parameter list.

- When the function code is 1, the operands are 64 bits in length. The first operand is a doubleword in storage, and the third operand is in bits 0-63 of general register R_3. The replacement value is bytes 0-7 of the parameter list.

- When the function code is 2 and the compare-and-swap-and-store facility 2 is installed, the operands are 128 bits in length. The first operand is a quadword in storage, and the third operand is in bits 0-63 of general registers R_3 and $R_3 + 1$. The replacement value is in bytes 0-15 of the parameter list.

The size of the store value and the alignment of the second operand are determined by a store characteristic (SC) in bits 48-55 of general register 0. The store characteristic is expressed as a power of two; the assigned store characteristics are 0, 1, 2, and 3.

An SC of 0 means that one byte is stored on a byte boundary; an SC of 1 means that two bytes are stored on a halfword boundary, an SC of 2 means that four bytes are stored on a word boundary, and an SC of 3 means that eight bytes are stored on a doubleword boundary. When the CSST facility 2 is installed, an SC of 4 is also assigned; an SC of 4 means that sixteen bytes are stored on a quadword boundary. The store value begins at byte 16 of the parameter list.

Bits 0-31 of general register 0 are ignored. Bits 32-47 of general register 0 and bits 60-63 of general register 1 are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.

General register 1 contains the logical address of a parameter list that contains the replacement value and the store value. The parameter list is on a quadword boundary. In the access-register mode, access register 1 specifies the address space containing the parameter list.

The handling of the parameter-list address is dependent on the addressing mode. In the 24-bit addressing mode, the contents of bit positions 40-59 of general register 1, with four zeros appended to the right, constitute the address, and bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-59 of the register, with four zeros appended to the right, constitute the address, and bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-59 of the register, with four zeros appended to the right, constitute the address.

Figure 7-211 illustrates contents of the registers and parameter list just described.

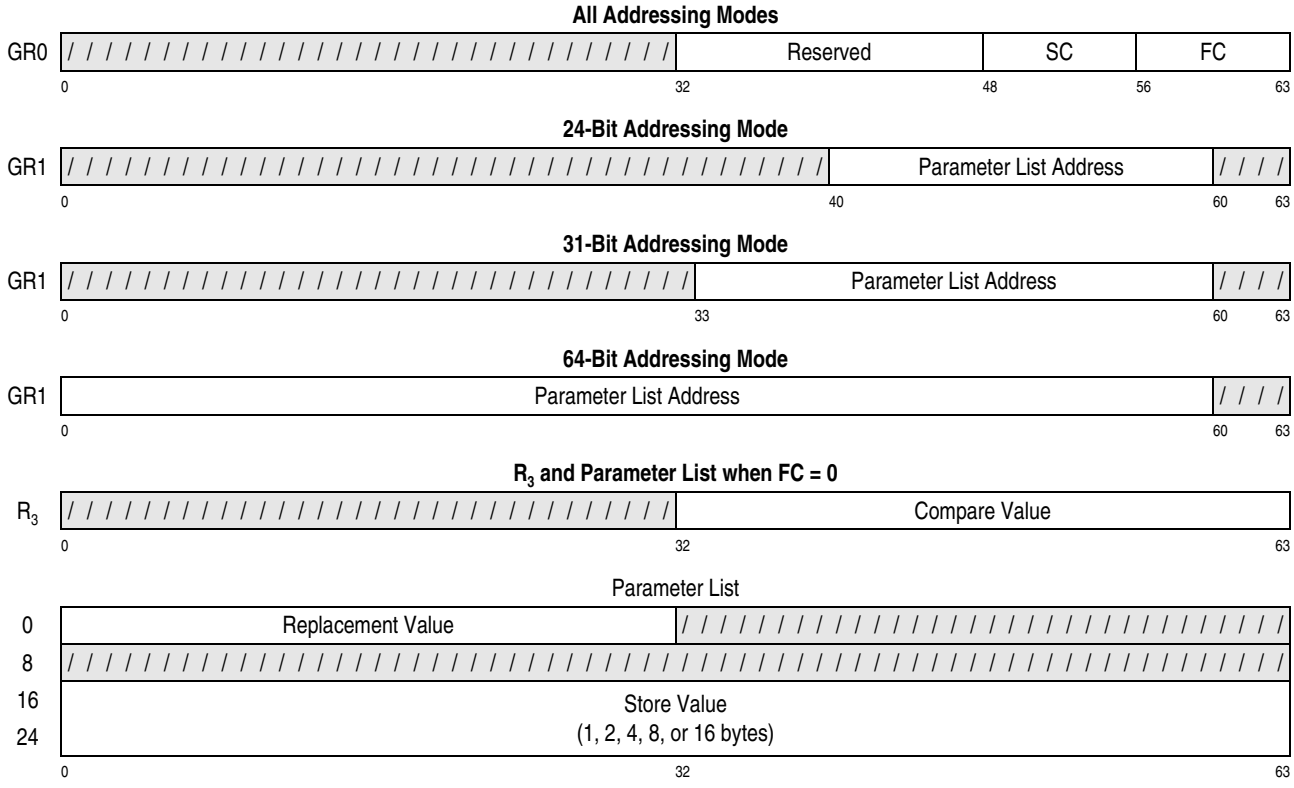


Figure 7-211. Register Contents for COMPARE AND SWAP AND STORE

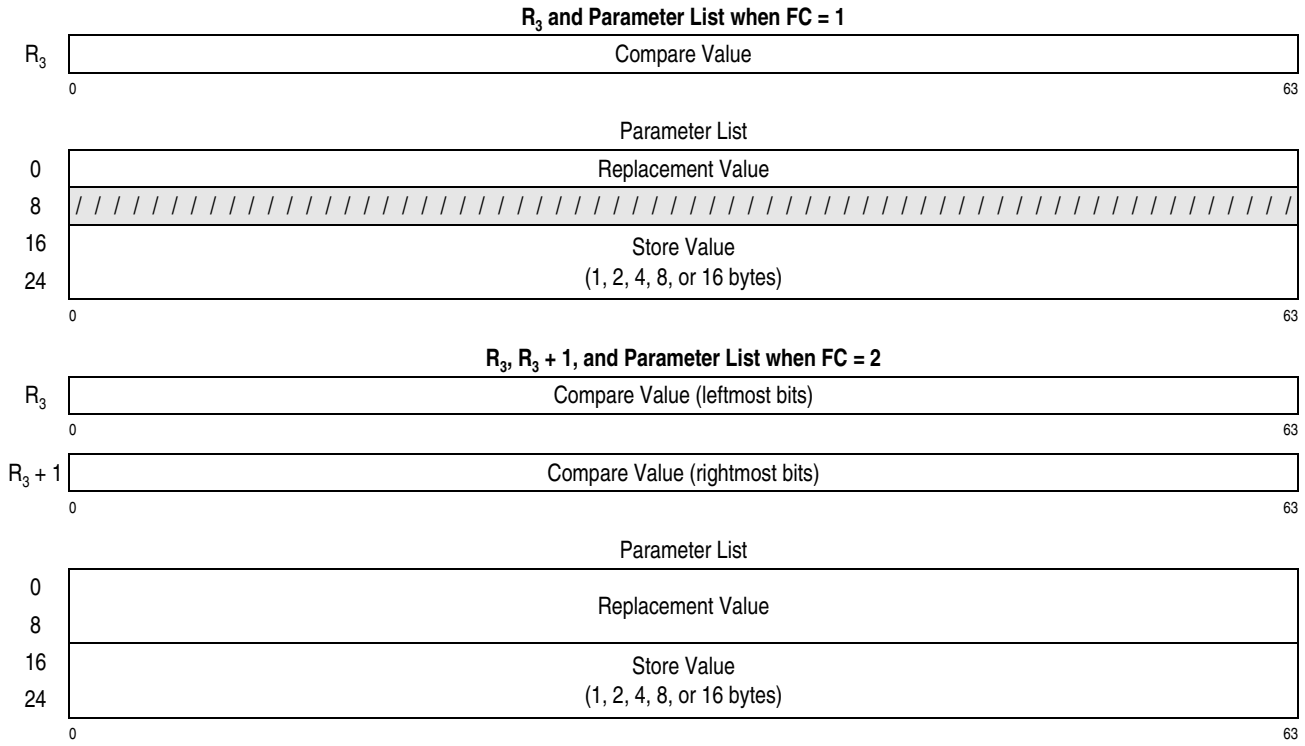

Figure 7-211. Register Contents for COMPARE AND SWAP AND STORE

When an equal comparison occurs, the replacement value is stored at the first-operand location, and the store value is stored at the second-operand location. The fetch of the first operand for purposes of comparison, and the store of the replacement value into the first-operand location, both appear to be a block-concurrent interlocked-update reference as observed by other CPUs. The store of the store value appears to be block-concurrent as observed by other CPUs.

When the result of the comparison is unequal, the first operand is loaded into the third-operand location, and the first operand remains unchanged. However, on some models, the contents of the first operand may be fetched and subsequently stored back unchanged at the first-operand location. This update appears to be a block-concurrent interlocked-update reference as observed by other CPUs.

As observed by this CPU and by other CPUs, all fetches appear to occur before all stores, and the store into the first operand appears to occur before the store into the second operand. Access-exception conditions are recognized for the entire 32-byte parameter list and for the second operand, regardless of whether the first and third operands are or are not equal. For the second operand, PER storage-alteration and zero-address-detection events are recognized, and a change bit is set, only if a store occurs.

A serialization function is performed before the operation begins and again after the operation is completed.

Special Conditions

A specification exception is recognized for any of the following conditions:

- The function code specifies an unassigned value.
- The store characteristic specifies an unassigned value.
- The function code is 0, and the first operand is not designated on a word boundary.
- The function code is 1, and the first operand is not designated on a doubleword boundary.
- The function code is 2, and any of the following is true:
  - The compare-and-swap-and-store facility 2 is not installed.
  - The first operand is not designated on a quadword boundary.
  - The R_3 field does not designate the even-numbered register of an even-odd register pair.
- The second operand is not designated on an integral boundary corresponding to the size of the store value.

For all of the above conditions, and for all addressing and protection exceptions, the operation is suppressed.

Resulting Condition Code:

0 First and third operands equal; first operand replaced by replacement value, and second operand replaced by store value
1 First and third operands unequal; third operand replaced by first operand
2 --
3 --

Program Exceptions:

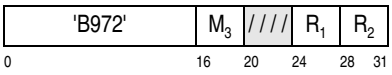
- Access (fetch, parameter list; fetch and store, operand 1; store, operand 2)
- Operation (if the compare-and-swap-and-store facility is not installed)
- Specification
- Transaction constraint

Programming Notes:

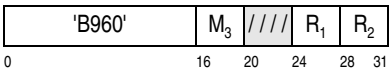
1. COMPARE AND SWAP AND STORE may be used in conjunction with other COMPARE AND SWAP or COMPARE DOUBLE AND SWAP instructions to manipulate locks, queue pointers, or other fields that require interlocked updates.
2. COMPARE AND SWAP AND STORE should not be used to manipulate fields that are also manipulated by PERFORM LOCKED OPERATION.
3. The store value is intended to provide a separate "footprint" of the interlocked-update operation in a location apart from the first operand in a single unit of operation.
4. The performance of COMPARE AND SWAP AND STORE may be significantly slower than the that of separate COMPARE AND SWAP, BRANCH ON CONDITION, and STORE instructions.
5. COMPARE AND SWAP AND STORE should only be used when an interruption between the compare-and-swap operation and the store operation cannot be tolerated, and other means of disabling for interruptions are not practical.

COMPARE AND TRAP

CRT R_1,R_2,M_3 [RRF-c]

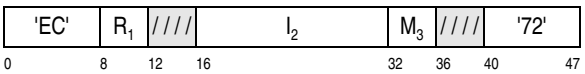


CGRT R_1,R_2,M_3 [RRF-c]

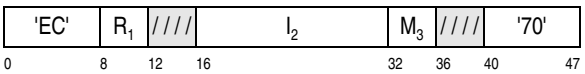


COMPARE IMMEDIATE AND TRAP

CIT R_1,I_2,M_3 [RIE-a]



CGIT R_1,I_2,M_3 [RIE-a]



The first operand is compared with the second operand. If the mask bit in the M_3 field corresponding to the comparison result is one, a compare-and-trap-instruction data exception is recognized, and the operation is completed; otherwise, normal instruction sequencing proceeds with the updated instruction address.

The comparison results and corresponding M_3 bits are as follows:

Comparison Result	M_3 Bit
Equal	0
First operand low	1
First operand high	2

Bit 3 of the M_3 field is reserved and should be zero; otherwise, the program may not operate compatibly in the future.

For COMPARE AND TRAP (CRT) and COMPARE IMMEDIATE AND TRAP (CIT), the first operand is treated as a 32-bit signed binary integer. For COMPARE AND TRAP (CGRT) and COMPARE IMMEDIATE AND TRAP (CGIT), the first operand is treated as a 64-bit signed binary integer.

For COMPARE IMMEDIATE AND TRAP, the second operand is treated as a 16-bit signed binary integer. For COMPARE AND TRAP (CRT), the second operand is treated as a 32-bit signed binary integer. For COMPARE AND TRAP (CGRT), the second operand is treated as a 64-bit signed binary integer.

Condition Code: The code remains unchanged.

Program Exceptions:

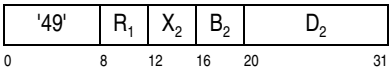
- Data
- Operation (if the general-instructions-extension facility is not installed)

Programming Notes:

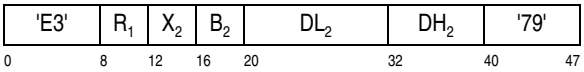
1. Possible uses of COMPARE AND TRAP and COMPARE IMMEDIATE AND TRAP include checking for pointers containing zero (null pointer), or array range checking.
2. On most models, when a data exception is not recognized, the performance of COMPARE AND TRAP and COMPARE IMMEDIATE AND TRAP is typically similar to other COMPARE instructions. When a data exception is recognized, the instruction may be significantly slower than an equivalent COMPARE instruction followed by a BRANCH ON CONDITION instruction.
3. When bit positions 0-2 of the M_3 field contain zeros, the instruction acts as a NOP, however this is not the preferred instruction with which to create a NOP. When bit positions 0-2 of the M_3 field contain 111 binary, a data exception is always recognized.
4. When a data exception is recognized, the compare-and-trap data-exception code (DXC FF hex) is stored, as described in “Data Exception” on page 6-25.
5. The discussion of extended mnemonics in programming note 3 for COMPARE AND BRANCH on page 7-151 also applies to the compare-and-trap instructions.

COMPARE HALFWORD

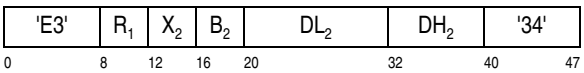
CH $R_1,D_2(X_2,B_2)$ [RX-a]



CHY $R_1,D_2(X_2,B_2)$ [RXY-a]



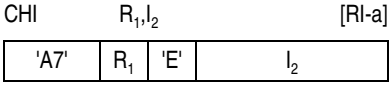
CGH $R_1,D_2(X_2,B_2)$ [RXY-a]



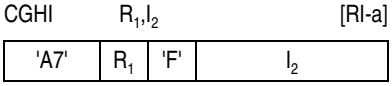
COMPARE HALFWORD IMMEDIATE

Register-and-immediate formats:

CHI R_1,I_2 [RI-a]

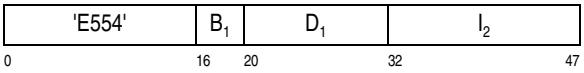


CGHI R_1,I_2 [RI-a]

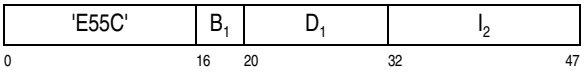


Storage-and-immediate formats:

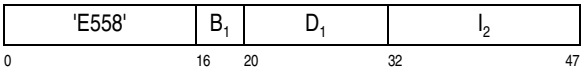
CHHSI $D_1(B_1),I_2$ [SIL]



CHSI $D_1(B_1),I_2$ [SIL]

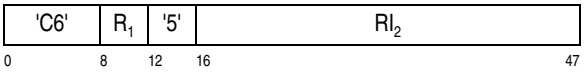


CGHSI $D_1(B_1),I_2$ [SIL]

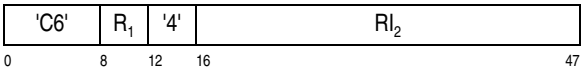


COMPARE HALFWORD RELATIVE LONG

CHRL R_1,RI_2 [RIL-b]



CGHRL R_1,RI_2 [RIL-b]



The first operand is compared with the second operand, and the result is indicated in the condition code. The second operand is two bytes in length and is treated as a 16-bit signed binary integer.

For COMPARE HALFWORD IMMEDIATE (CHHSI), the first operand is treated as a 16-bit signed binary integer. For COMPARE HALFWORD (CH, CHY), COMPARE HALFWORD IMMEDIATE (CHI and CHSI), and COMPARE HALFWORD RELATIVE LONG (CHRL), the first operand is treated as a 32-bit signed binary integer. For COMPARE HALFWORD (CGH), COMPARE HALFWORD IMMEDIATE (CGHI and CGHSI), and COMPARE HALFWORD RELATIVE LONG (CGHRL), the first operand is treated as a 64-bit signed binary integer.

The displacement for COMPARE HALFWORD (CH) and for COMPARE HALFWORD IMMEDIATE (CGHSI, CHHSI, CHSI) is treated as a 12-bit unsigned binary integer. The displacement for COMPARE HALFWORD (CHY, CGH) is treated as a 20-bit signed binary integer.

For COMPARE HALFWORD RELATIVE LONG, the contents of the RI_2 field are a signed binary integer specifying the number of halfwords that is added to the address of the instruction to generate the address of the second operand in storage. When DAT is on, the second operand is accessed using the same addressing-space mode as that used to access the instruction. When DAT is off, the second operand is accessed using a real address.

Resulting Condition Code:

0 Operands equal
1 First operand low
2 First operand high
3 --

Program Exceptions:

- Access (fetch, operand 1 of CGHSI, CHHSI, and CHSI only; fetch, operand 2 of CGH, CGHRL, CH, CHRL, CHY only)
- Operation (CHY, if the long-displacement facility is not installed; CGH, CHRL, CGHRL, CGHSI, CHHSI, and CHSI, if the general-instructions-extension facility is not installed)

Programming Notes:

1. An example of the use of the COMPARE HALFWORD instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

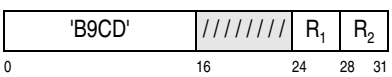
2. For COMPARE HALFWORD RELATIVE LONG, the second operand is necessarily aligned on an integral boundary corresponding to the operand’s size.

3. When COMPARE HALFWORD RELATIVE LONG is the target of an execute-type instruction, the second-operand address is relative to the target address.

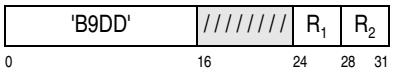
COMPARE HIGH

Register-and-register formats:

CHHR R_1,R_2 [RRE]

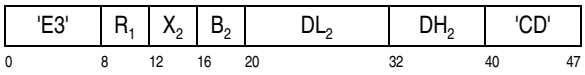


CHLR R_1,R_2 [RRE]



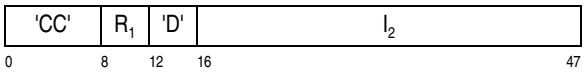
Register-and-storage format:

CHF $R_1,D_2(X_2,B_2)$ [RXY-a]



COMPARE IMMEDIATE HIGH

CIH R_1,I_2 [RIL-a]



The first operand is compared with the second operand, and the result is indicated in the condition code.

The operands are treated as 32-bit signed binary integers. The first operand is in bit positions 0-31 of general register R_1; bit positions 32-63 of the register are ignored. For COMPARE HIGH (CHHR), the second operand is in bit positions 0-31 of general register R_2; bit positions 32-63 of the register are ignored. For COMPARE HIGH (CHLR), the second operand is in bit positions 32-63 of general register R_2; bit positions 0-31 of the register are ignored.

The displacement for CHF is treated as a 20-bit signed binary integer.

Resulting Condition Code:

0 Operands equal
1 First operand low
2 First operand high
3 --

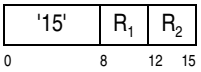
Program Exceptions:

- Access (operand 2 of CHF only)
- Operation (if the high-word facility is not installed)

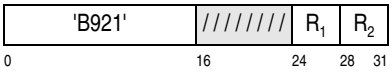
COMPARE LOGICAL

Register-and-register formats:

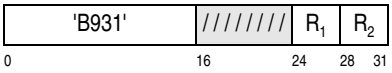
CLR R_1,R_2 [RR]



CLGR R_1,R_2 [RRE]

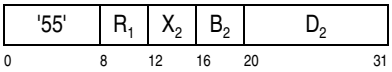


CLGFR R_1,R_2 [RRE]

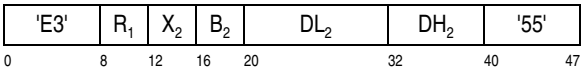


Register-and-storage formats:

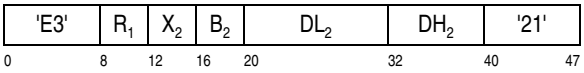
CL $R_1,D_2(X_2,B_2)$ [RX-a]



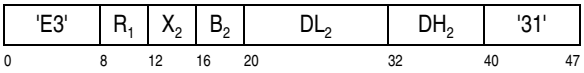
CLY $R_1,D_2(X_2,B_2)$ [RXY-a]



CLG $R_1,D_2(X_2,B_2)$ [RXY-a]

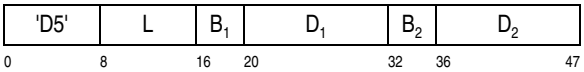


CLGF $R_1,D_2(X_2,B_2)$ [RXY-a]



Storage-and-storage format:

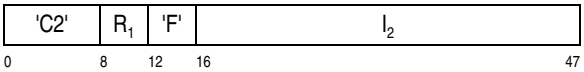
CLC $D_1(L,B_1),D_2(B_2)$ [SS-a]



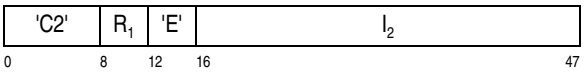
COMPARE LOGICAL IMMEDIATE

Register-and-immediate formats:

CLFI R_1,I_2 [RIL-a]

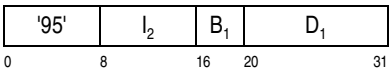


CLGFI R_1,I_2 [RIL-a]

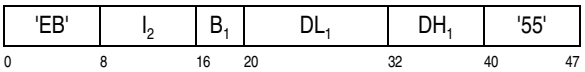


Storage-and-immediate formats:

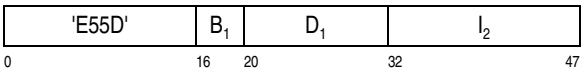
CLI $D_1(B_1),I_2$ [SI]



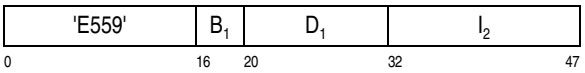
CLIY $D_1(B_1),I_2$ [SIY]



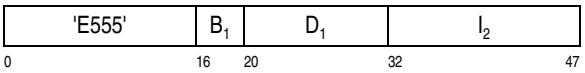
CLFHSI $D_1(B_1),I_2$ [SIL]



CLGHSI $D_1(B_1),I_2$ [SIL]

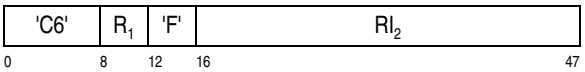


CLHHSI $D_1(B_1),I_2$ [SIL]

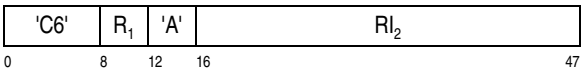


COMPARE LOGICAL RELATIVE LONG

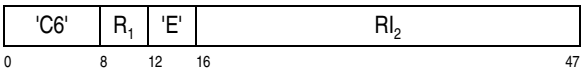
CLRL R_1,RI_2 [RIL-b]



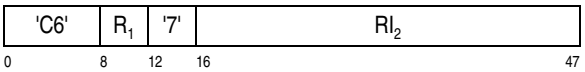
CLGRL R_1,RI_2 [RIL-b]



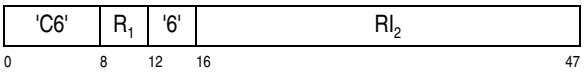
CLGFRL R_1,RI_2 [RIL-b]



CLHRL R_1,RI_2 [RIL-b]



CLGHRL R_1,RI_2 [RIL-b]



The first operand is compared with the second operand, and the result is indicated in the condition code.

The lengths of the operands are as follows:

- For COMPARE LOGICAL (CLR, CL, CLY), COMPARE LOGICAL IMMEDIATE (CLFI), and COMPARE LOGICAL RELATIVE LONG (CLRL), the operands are treated as 32 bits.
- For COMPARE LOGICAL (CLGR, CLG) and COMPARE LOGICAL RELATIVE LONG (CLGRL), the operands are treated as 64 bits.
- For COMPARE LOGICAL (CLGFR, CLGF), COMPARE LOGICAL IMMEDIATE (CLGFI), and COMPARE LOGICAL RELATIVE LONG (CLGFRL), the first operand is treated as 64 bits, and the second operand is treated as 32 bits with 32 zeros appended on the left.
- For COMPARE LOGICAL IMMEDIATE (CLHHSI), the operands are treated as 16 bits.
- For COMPARE LOGICAL IMMEDIATE (CLFHSI) and COMPARE LOGICAL RELATIVE LONG (CLHRL), the first operand is treated as 32 bits, and the second operand is treated as 16 bits with 16 zeros appended on the left.
- For COMPARE LOGICAL IMMEDIATE (CLGHSI) and COMPARE LOGICAL RELATIVE LONG (CLGHRL), the first operand is treated as 64 bits, and the second operand is treated as 16 bits with 48 zeros appended on the left.
- For COMPARE LOGICAL IMMEDIATE (CLI, CLIY), the operands are treated as 8 bits.
- For COMPARE LOGICAL (CLC), the first and second operands have the same length, in the range of one to 256 bytes.

The comparison proceeds left to right, byte by byte, and ends as soon as an inequality is found or the end of the fields is reached. For COMPARE LOGICAL (CL, CLY, CLG, CLGF, CLC), COMPARE LOGICAL IMMEDIATE (CLFHSI, CLGHSI, CLHHSI) and COMPARE LOGICAL RELATIVE LONG, access exceptions may or may not be recognized for the portion of

a storage operand to the right of the first unequal byte.

The displacements for CL, CLI, CLFHSI, CLGHSI, CLHHSI, and both operands of CLC are treated as 12-bit unsigned binary integers. The displacement for CLY, CLG, CLGF, and CLIY is treated as a 20-bit signed binary integer.

For COMPARE LOGICAL RELATIVE LONG, the contents of the RI_2 field are a signed binary integer specifying the number of halfwords that is added to the address of the instruction to generate the address of the second operand in storage. When DAT is on, the second operand is accessed using the same addressing-space mode as that used to access the instruction. When DAT is off, the second operand is accessed using a real address.

For COMPARE LOGICAL RELATIVE LONG (CLRL, CLGFRL), the second operand must be aligned on a word boundary, and for COMPARE LOGICAL RELATIVE LONG (CLGRL), the second operand must be aligned on a doubleword boundary; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Operands equal
1 First operand low
2 First operand high
3 --

Program Exceptions:

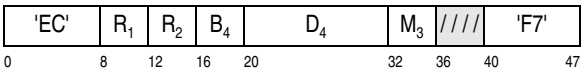
- Access (fetch, operand 2, CL, CLC, CLG, CLGF, CLGFRL, CLGHRL, CLGRL, CLHRL, CLRL, and CLY; fetch, operand 1, CLC, CLFHSI, CLGHSI, CLHHSI, CLI, and CLIY)
- Operation (CLY and CLIY, if the long-displacement facility is not installed; CLFI and CLGFI, if the extended-immediate facility is not installed; CLFHSI, CLGFRL, CLGHSI, CLGHRL, CLGRL, CLHHSI, CLHRL, and CLRL, if the general-instructions-extension facility is not installed)
- Specification (CLRL, CLGFRL, CLGRL)
- Transaction constraint (CLC)

Programming Notes:

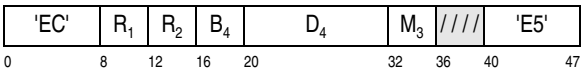
1. Examples of the use of the COMPARE LOGICAL instruction are given in Appendix A, “Number Representation and Instruction-Use Examples.”
2. COMPARE LOGICAL treats all bits of each operand alike as part of a field of unstructured logical data. For COMPARE LOGICAL (CLC), the comparison may extend to field lengths of 256 bytes.
3. For COMPARE LOGICAL RELATIVE LONG, the second operand must be aligned on an integral boundary corresponding to the operand’s size.
4. When COMPARE LOGICAL RELATIVE LONG is the target of an execute-type instruction, the second-operand address is relative to the target address.

COMPARE LOGICAL AND BRANCH

CLRB $R_1,R_2,M_3,D_4(B_4)$ [RRS]

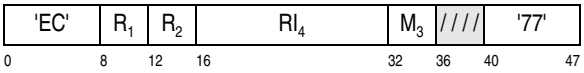


CLGRB $R_1,R_2,M_3,D_4(B_4)$ [RRS]

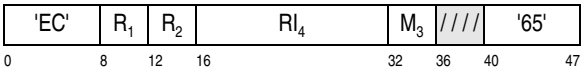


COMPARE LOGICAL AND BRANCH RELATIVE

CLRJ R_1,R_2,M_3,RI_4 [RIE-b]

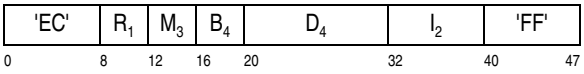


CLGRJ R_1,R_2,M_3,RI_4 [RIE-b]

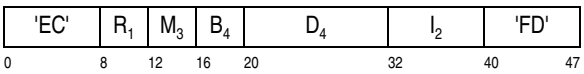


COMPARE LOGICAL IMMEDIATE AND BRANCH

CLIB $R_1,I_2,M_3,D_4(B_4)$ [RIS]



CLGIB $R_1,I_2,M_3,D_4(B_4)$ [RIS]



COMPARE LOGICAL IMMEDIATE AND BRANCH RELATIVE

CLIJ R_1,I_2,M_3,RI_4 [RIE-c]

CLGIJ R_1,I_2,M_3,RI_4 [RIE-c]

The first operand is compared with the second operand. If the mask bit in the M_3 field corresponding to the comparison result is one, the instruction address in the current PSW is replaced by the branch address specified by the fourth operand; otherwise, normal instruction sequencing proceeds with the updated instruction address.

For COMPARE LOGICAL AND BRANCH (CLRB), COMPARE LOGICAL AND BRANCH RELATIVE (CLRJ), COMPARE LOGICAL IMMEDIATE AND BRANCH (CLIB), and COMPARE LOGICAL IMMEDIATE AND BRANCH RELATIVE (CLIJ), the first operand is treated as a 32-bit unsigned binary integer. For COMPARE LOGICAL AND BRANCH (CLGRB), COMPARE LOGICAL AND BRANCH RELATIVE (CLGRJ), COMPARE LOGICAL IMMEDIATE AND BRANCH (CLGIB), and COMPARE LOGICAL IMMEDIATE AND BRANCH RELATIVE (CLGIJ), the first operand is treated as a 64-bit unsigned binary integer.

For COMPARE LOGICAL AND BRANCH (CLRB) and COMPARE LOGICAL AND BRANCH RELATIVE (CLRJ), the second operand is treated as a 32-bit unsigned binary integer. For COMPARE LOGICAL AND BRANCH (CLGRB) and COMPARE LOGICAL AND BRANCH RELATIVE (CLGRJ), the second operand is treated as a 64-bit unsigned binary integer. For COMPARE LOGICAL IMMEDIATE AND BRANCH and COMPARE LOGICAL IMMEDIATE AND BRANCH RELATIVE, the second operand is treated as an 8-bit unsigned binary integer. When the size of the second operand is smaller than the size of the first operand, the second operand is extended on the left with zeros to match the size of the first operand.

The comparison results and corresponding M_3 bits are as follows:

Comparison Result	M_3 Bit
Equal	0
First operand low	1
First operand high	2

Bit 3 of the M_3 field is reserved and should be zero; otherwise, the program may not operate compatibly in the future.

For COMPARE LOGICAL AND BRANCH and COMPARE LOGICAL IMMEDIATE AND BRANCH, the fourth operand is used as the branch address. For COMPARE LOGICAL AND BRANCH RELATIVE and COMPARE LOGICAL IMMEDIATE AND BRANCH RELATIVE, the contents of the RI_4 field are a signed binary integer specifying the number of halfwords that is added to the address of the instruction to generate the branch address.

Condition Code: The code remains unchanged.

Program Exceptions:

- Operation (if the general-instructions-extension facility is not installed).
- Transaction constraint

Programming Notes:

1. When bit positions 0-2 of the M_3 field contain zeros, the instruction acts as a NOP, however this is not the preferred instruction with which to create a NOP. When bit positions 0-2 of the M_3 field contain 111 binary, a branch always occurs.

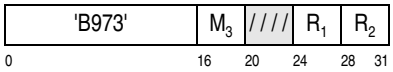
2. When COMPARE LOGICAL AND BRANCH RELATIVE or COMPARE LOGICAL IMMEDIATE AND BRANCH RELATIVE are the target of an execute-type instruction, the branch is relative to the target address. See “Branch-Address Generation” on page 5-12.

3. The discussion of extended mnemonics in programming note 3 for COMPARE AND BRANCH on page 7-151 also applies to the compare-logical-and-branch instructions.

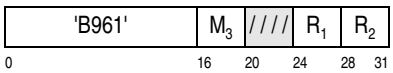
COMPARE LOGICAL AND TRAP

Register-and-register formats:

CLRT R_1,R_2,M_3 [RRF-c]

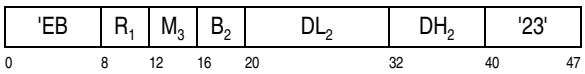


CLGRT R_1,R_2,M_3 [RRF-c]

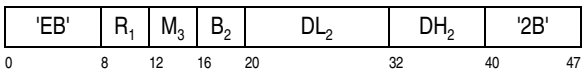


Register-and-storage formats:

CLT $R_1,M_3,D_2(B_2)$ [RSY-b]

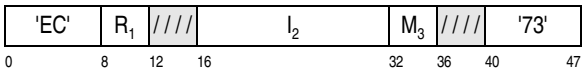


CLGT $R_1,M_3,D_2(B_2)$ [RSY-b]

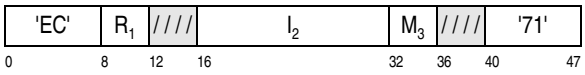


COMPARE LOGICAL IMMEDIATE AND TRAP

CLFIT R_1,I_2,M_3 [RIE-a]



CLGIT R_1,I_2,M_3 [RIE-a]



The first operand is compared with the second operand. If the mask bit in the M_3 field corresponding to the comparison result is one, a compare-and-trap-instruction data exception is recognized, and the operation is completed; otherwise, normal instruction sequencing proceeds with the updated instruction address.

The comparison results and corresponding M_3 bits are as follows:

Comparison Result	M_3 Bit
Equal	0
First operand low	1
First operand high	2

Bit 3 of the M_3 field is reserved and should be zero; otherwise, the program may not operate compatibly in the future.

For COMPARE LOGICAL AND TRAP (CLRT, CLT) and COMPARE LOGICAL IMMEDIATE AND TRAP (CLFIT), the first operand is treated as a 32-bit unsigned binary integer. For COMPARE LOGICAL AND TRAP (CLGRT, CLGT) and COMPARE LOGICAL IMMEDIATE AND TRAP (CLGIT), the first operand is treated as a 64-bit unsigned binary integer.

For COMPARE LOGICAL IMMEDIATE AND TRAP, the second operand is treated as a 16-bit unsigned binary integer. For COMPARE LOGICAL AND TRAP (CLRT, CLT), the second operand is treated as a 32-bit unsigned binary integer. For COMPARE LOGICAL AND TRAP (CLGRT, CLGT), the second operand is treated as a 64-bit unsigned binary integer. When the size of the second operand is smaller than the size of the first operand, the second operand is extended on the left with zeros to match the size of the first operand.

For COMPARE LOGICAL AND TRAP (CLT, CLGT), when bit positions 0-2 of the M_3 field contain either 000 or 111 binary, it is model dependent whether an access exception is recognized for the second-operand location; if accessible, it is model dependent whether a PER zero-address-detection event is recognized for the location.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2, CLT, CLGT)
- Data
- Operation (CLRT, CLGRT, CLFIT, CLGIT, if the general-instructions-extension facility is not installed; CLT, CLGT if the miscellaneous-instruction-extensions facility 1 is not installed)

Programming Notes:

1. Possible uses of COMPARE LOGICAL AND TRAP and COMPARE LOGICAL IMMEDIATE AND TRAP include checking for pointers containing zero (null pointer), or array range checking.

2. On most models, when a data exception is not recognized, the performance of COMPARE LOGICAL AND TRAP and COMPARE LOGICAL

IMMEDIATE AND TRAP is typically similar to other COMPARE LOGICAL instructions. When a data exception is recognized, the instruction may be significantly slower than an equivalent COMPARE LOGICAL instruction followed by a BRANCH ON CONDITION instruction.

3. For CLFIT, CLGIT, CLGRT, and CLRT, when bit positions 0-2 of the M_3 field contain zeros, the instruction acts as a NOP, however this is not the preferred instruction with which to create a NOP. This NOP characteristic may not apply to CLGT and CLT.

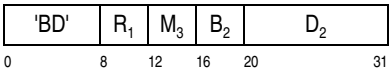
   When bit positions 0-2 of the M_3 field contain 111 binary, a data exception is always recognized.

4. When a data exception is recognized, the compare-and-trap data-exception code (DXC FF hex) is stored, as described in “Data Exception” on page 6-25.

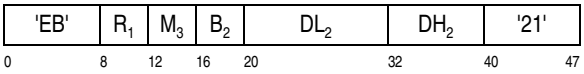
5. The discussion of extended mnemonics in programming note 3 for COMPARE AND BRANCH on page 7-151 also applies to the compare-logical-and-trap instructions.

COMPARE LOGICAL CHARACTERS UNDER MASK

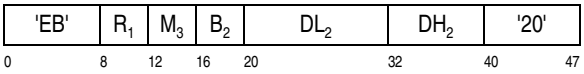
CLM $R_1,M_3,D_2(B_2)$ [RS-b]



CLMY $R_1,M_3,D_2(B_2)$ [RSY-b]



CLMH $R_1,M_3,D_2(B_2)$ [RSY-b]



The first operand is compared with the second operand under control of a mask, and the result is indicated in the condition code.

The contents of the M_3 field are used as a mask. These four bits, left to right, correspond one for one with four bytes, left to right, of general register R_1. For COMPARE LOGICAL CHARACTERS UNDER MASK (CLM, CLMY), the four bytes to which the mask bits correspond are in bit positions 32-63 of general register R_1. For COMPARE LOGICAL CHARACTERS UNDER MASK (CLMH), the four bytes are in the high-order half, bit positions 0-31, of the register. The byte positions corresponding to ones in the mask are considered as a contiguous field and are compared with the second operand. The second operand is a contiguous field in storage, starting at the second-operand address and equal in length to the number of ones in the mask. The bytes in the general register corresponding to zeros in the mask do not participate in the operation.

The comparison proceeds left to right, byte by byte, and ends as soon as an inequality is found or the end of the fields is reached.

When the mask is not zero, exceptions associated with storage-operand access are recognized for no more than the number of bytes specified by the mask. Access exceptions may or may not be recognized for the portion of a storage operand to the right of the first unequal byte. When the mask is zero, access exceptions are recognized for one byte at the second-operand address.

The displacement for CLM is treated as a 12-bit unsigned binary integer. The displacement for CLMY and CLMH is treated as a 20-bit signed binary integer.

Resulting Condition Code:

0 Operands equal, or mask bits all zeros
1 First operand low
2 First operand high
3 --

Program Exceptions:

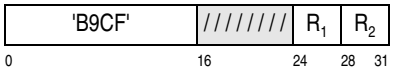
- Access (fetch, operand 2)
- Operation (CLMY, if the long-displacement facility is not installed)

Programming Note: An example of the use of the COMPARE LOGICAL CHARACTERS UNDER MASK instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

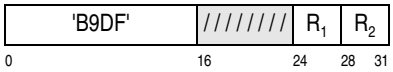
COMPARE LOGICAL HIGH

Register-and-register formats:

CLHHR R_1,R_2 [RRE]

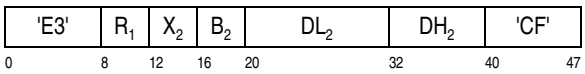


CLHLR R_1,R_2 [RRE]



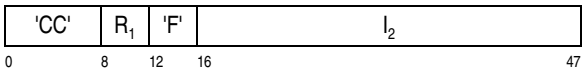
Register-and-storage format:

CLHF $R_1,D_2(X_2,B_2)$ [RXY-a]



COMPARE LOGICAL IMMEDIATE HIGH

CLIH R_1,I_2 [RIL-a]



The first operand is compared with the second operand, and the result is indicated in the condition code.

The operands are treated as 32-bit unsigned binary integers. The first operand is in bit positions 0-31 of general register R_1; bit positions 32-63 of the register are ignored. For COMPARE LOGICAL HIGH (CLHHR), the second operand is in bit positions 0-31 of general register R_2; bit positions 32-63 of the register are ignored. For COMPARE LOGICAL HIGH (CLHLR), the second operand is in bit positions 32-63 of general register R_2; bit positions 0-31 of the register are ignored.

The displacement for CLHF is treated as a 20-bit signed binary integer.

Resulting Condition Code:

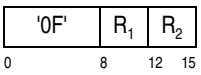
0 Operands equal
1 First operand low
2 First operand high
3 --

Program Exceptions:

- Access (operand 2 of CLHF only)
- Operation (if the high-word facility is not installed)

COMPARE LOGICAL LONG

CLCL R_1,R_2 [RR]



The first operand is compared with the second operand, and the result is indicated in the condition code. The shorter operand is considered to be extended on the right with padding bytes.

The R_1 and R_2 fields each designate an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The location of the leftmost byte of the first operand and second operand is designated by the contents of general registers R_1 and R_2, respectively. The number of bytes in the first-operand and second-operand locations is specified by unsigned binary integers in bit positions 40-63 of general registers $R_1 + 1$ and $R_2 + 1$, respectively. Bit positions 32-39 of general register $R_2 + 1$ contain the padding byte. The contents of bit positions 0-39 of general register $R_1 + 1$ and of bit positions 0-31 of general register $R_2 + 1$ are ignored.

The handling of the addresses in general registers R_1 and R_2 is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers R_1 and R_2 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the registers constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 constitute the address.

The contents of the registers just described are shown in Figure 7-212.

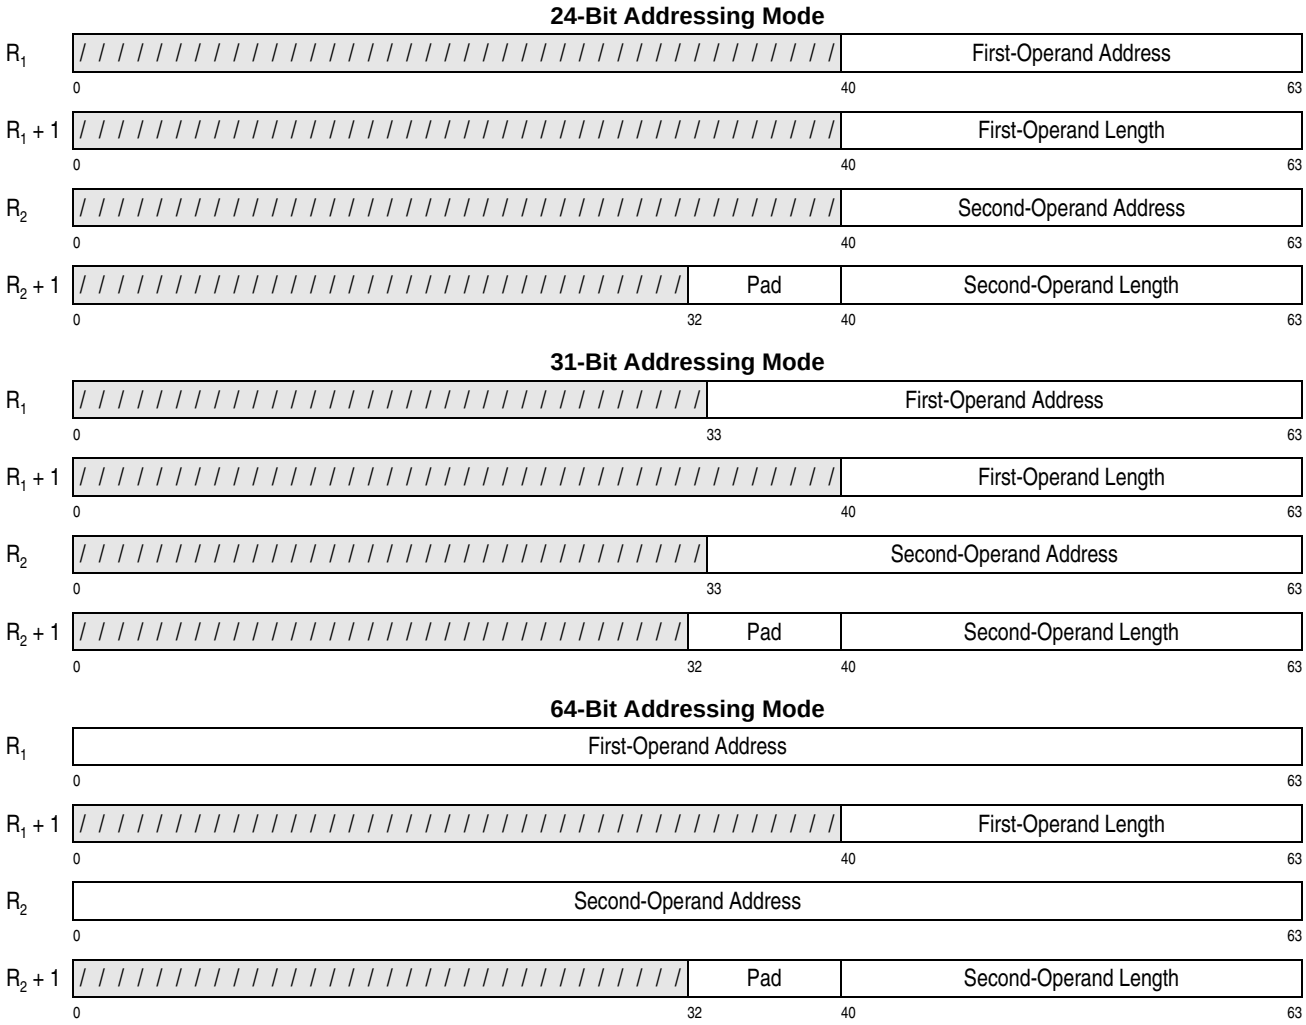


Figure 7-212. Register Contents for COMPARE LOGICAL LONG

The comparison proceeds left to right, byte by byte, and ends as soon as an inequality is found or the end of the longer operand is reached. If the operands are not of the same length, the shorter operand is considered to be extended on the right with the appropriate number of padding bytes.

If both operands are of zero length, the operands are considered to be equal.

The execution of the instruction is interruptible. When an interruption occurs, other than one that follows termination, the lengths in general registers $R_1 + 1$ and $R_2 + 1$ are decremented by the number of bytes compared, and the addresses in general registers R_1 and R_2 are incremented by the same number, so that the instruction, when reexecuted, resumes at the point of interruption. In the 24-bit or 31-bit addressing mode, the leftmost bits which are not part of the address in bit positions 32-63 of general registers R_1 and R_2 are set to zeros, and the contents of bit positions 0-31 remain unchanged. In any addressing mode, the contents of bit positions 0-39 of general registers $R_1 + 1$ and $R_2 + 1$ remain unchanged, and the condition code is unpredictable. If the operation is interrupted after the shorter operand has been exhausted, the length field pertaining to the shorter operand is zero, and its address is updated accordingly.

If the operation ends because of an inequality, the address fields in general registers R_1 and R_2 at com-

pletion identify the first unequal byte in each operand. The lengths in bit positions 40-63 of general registers $R_1 + 1$ and $R_2 + 1$ are decremented by the number of bytes that were equal, unless the inequality occurred with the padding byte, in which case the length field for the shorter operand is set to zero. The addresses in general registers R_1 and R_2 are incremented by the amounts by which the corresponding length fields were reduced.

If the two operands, including the padding byte, if necessary, are equal, both length fields are made zero at completion, and the addresses are incremented by the corresponding operand-length values.

At the completion of the operation, in the 24-bit or 31-bit addressing mode, the leftmost bits which are not part of the address in bit positions 32-63 of general registers R_1 and R_2 are set to zeros, even when one or both of the initial length values are zero. In any addressing mode, the contents of bit positions 0-39 of general registers $R_1 + 1$ and $R_2 + 1$ remain unchanged.

Access exceptions for the portion of a storage operand to the right of the first unequal byte may or may not be recognized. For operands longer than 2K bytes, access exceptions are not recognized more than 2K bytes beyond the byte being processed. Access exceptions are not indicated for locations more than 2K bytes beyond the first unequal byte.

When the length of an operand is zero, no access exceptions are recognized for that operand. Access exceptions are not recognized for an operand if the R field associated with that operand is odd.

Resulting Condition Code:

0 Operands equal, or both zero length
1 First operand low
2 First operand high
3 --

Program Exceptions:

- Access (fetch, operands 1 and 2)
- Specification
- Transaction constraint

Programming Notes:

1. An example of the use of the COMPARE LOGICAL LONG instruction is given in Appendix A, "Number Representation and Instruction-Use Examples."

2. When the R_1 and R_2 fields are the same, the operation proceeds in the same way as when two distinct pairs of registers having the same contents are specified, except that the contents of the designated registers are incremented or decremented only by the number of bytes compared, not by twice the number of bytes compared. In the absence of dynamic modification of the operand area by another CPU or by a channel program, condition code 0 is set. However, it is unpredictable whether access exceptions are recognized for the operand since the operation can be completed without storage being accessed.

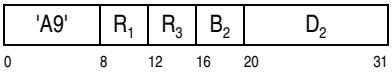
3. Special precautions should be taken when COMPARE LOGICAL LONG is made the target of an execute-type instruction. See the programming note concerning interruptible instructions under EXECUTE.

4. Other programming notes concerning interruptible instructions are included in "Interruptible Instructions" in Chapter 5, "Program Execution."

5. In the access-register mode, access register 0 designates the primary address space regardless of the contents of access register 0.

COMPARE LOGICAL LONG EXTENDED

CLCLE $R_1,R_3,D_2(B_2)$ [RS-a]



The first operand is compared with the third operand until unequal bytes are compared, the end of the longer operand is reached, or a CPU-determined number of bytes have been compared, whichever occurs first. The shorter operand is considered to be extended on the right with padding bytes. The result is indicated in the condition code.

The R_1 and R_3 fields each designate an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The location of the leftmost byte of the first operand and third operand is designated by the contents of general registers R_1 and R_3, respectively. In the 24-bit or 31-bit addressing mode, the number of bytes in the first-operand and third-operand locations is specified by the contents of bit positions 32-63 of general registers $R_1 + 1$ and $R_3 + 1$, respectively, and those contents are treated as 32-bit unsigned binary integers. In the 64-bit addressing mode, the number of bytes in the first-operand and third-operand locations is specified by the entire contents of general registers $R_1 + 1$ and $R_3 + 1$, respectively, and those contents are treated as 64-bit unsigned binary integers.

The handling of the addresses in general registers R_1 and R_3 is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers R_1 and R_3 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the registers constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 constitute the address.

The second-operand address is not used to address data; instead, the rightmost eight bits of the second-operand address, bits 56-63, are the padding byte. Bits 0-55 of the second-operand address are ignored.

The contents of the registers and address just described are shown in Figure 7-213.

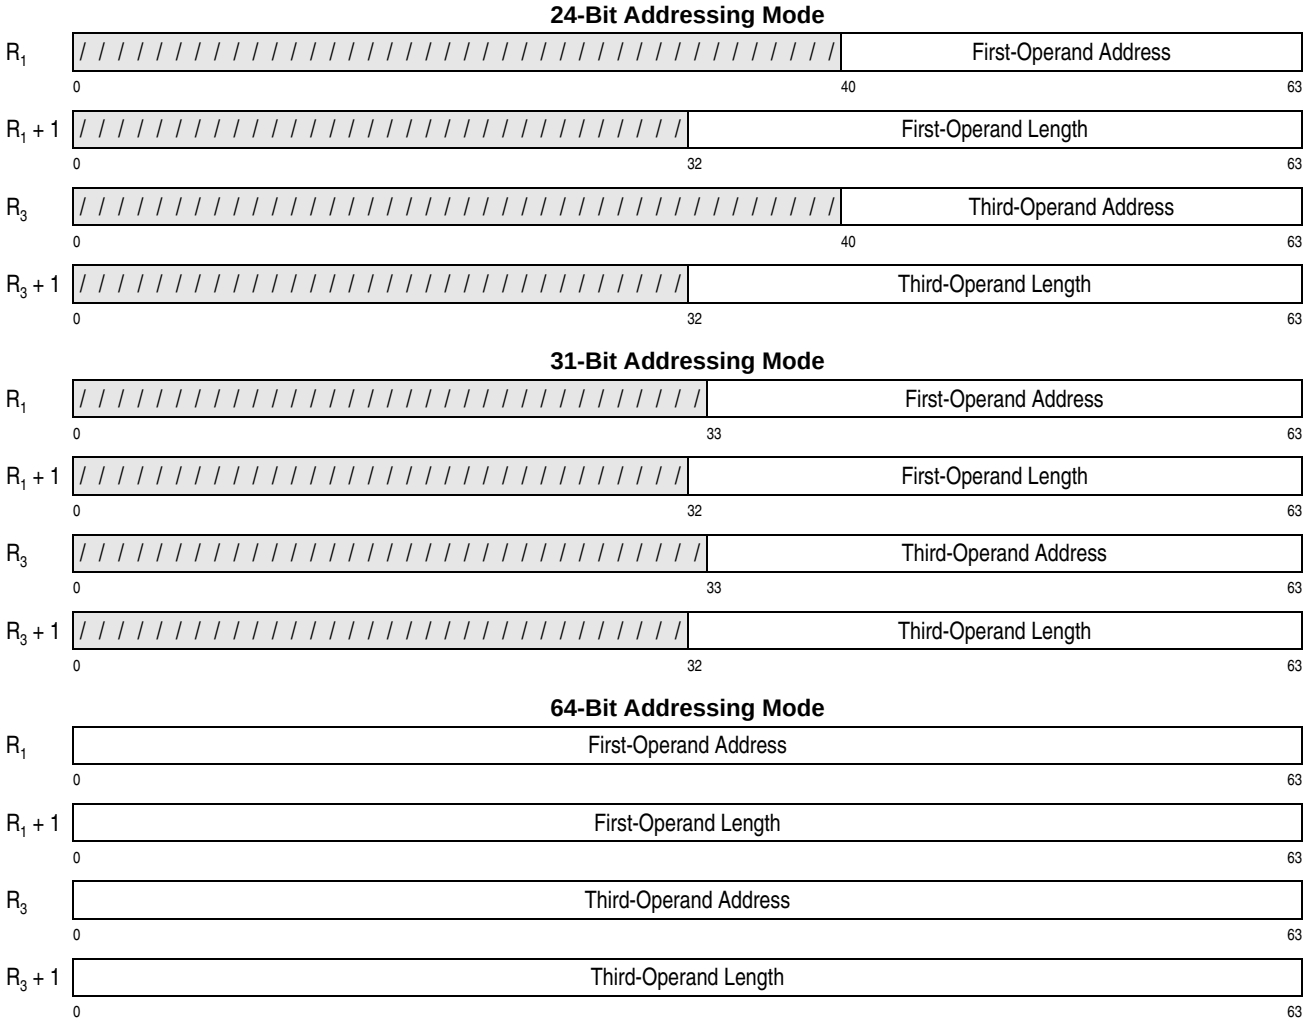


Figure 7-213. Register Contents and Second-Operand Address for COMPARE LOGICAL LONG EXTENDED (Part 1 of 2)

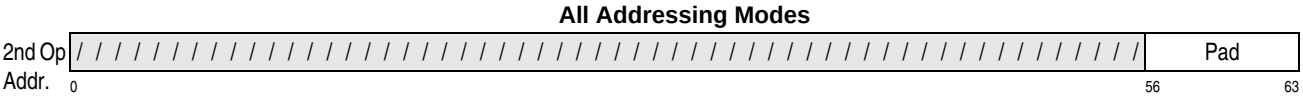

Figure 7-213. Register Contents and Second-Operand Address for COMPARE LOGICAL LONG EXTENDED (Part 2 of 2)

The comparison proceeds left to right, byte by byte, and ends as soon as an inequality is found, the end of the longer operand is reached, or a CPU-determined number of bytes have been compared, whichever occurs first. If the operands are not of the same length, the shorter operand is considered to be extended on the right with the appropriate number of padding bytes.

If both operands are of zero length, the operands are considered to be equal.

If the operation ends because of an inequality, the address fields in general registers R_1 and R_3 at completion identify the first unequal byte in each operand. The lengths in bit positions 32-63, in the 24-bit or 31-bit addressing mode, or in bit positions 0-63, in the 64-bit addressing mode, of general registers $R_1 + 1$ and $R_3 + 1$ are decremented by the number of bytes that were equal, unless the inequality occurred with the padding byte, in which case the length field for the shorter operand is set to zero. The addresses in general registers R_1 and R_3 are incremented by the amounts by which the corresponding length fields were decremented. Condition code 1 is set if the first operand is low, or condition code 2 is set if the first operand is high.

If the two operands, including the padding byte, if necessary, are equal, both length fields are made zero at completion, and the addresses are incremented by the corresponding operand-length values. Condition code 0 is set.

If the operation is completed because a CPU-determined number of bytes have been compared without finding an inequality or reaching the end of the longer operand, the lengths in general registers $R_1 + 1$ and $R_3 + 1$ are decremented by the number of bytes compared, and the addresses in general registers R_1 and R_3 are incremented by the same number, so that the instruction, when reexecuted, resumes at the next bytes to be compared. If the operation is completed after the shorter operand has been exhausted, the length field pertaining to the shorter operand is zero, and the operand address is updated accordingly. Condition code 3 is set.

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers R_1, $R_1 + 1$, R_3, and $R_3 + 1$, always remain unchanged.

The padding byte may be formed from $D_2(B_2)$ multiple times during the execution of the instruction, and the registers designated by R_1 and R_3 may be updated multiple times. Therefore, if B_2 equals R_1, $R_1 + 1$, R_3, or $R_3 + 1$ and is subject to change during the execution of the instruction, the results are unpredictable.

The amount of processing that results in the setting of condition code 3 is determined by the CPU on the basis of improving system performance, and it may be a different amount each time the instruction is executed. The maximum amount is approximately 4K bytes of either operand.

At the completion of the operation in the 24-bit or 31-bit addressing mode, the leftmost bits which are not part of the address in bit positions 32-63 of general registers R_1 and R_3 may be set to zeros or may remain unchanged from their original values, even when one or both of the initial length values are zero.

Access exceptions for the portion of a storage operand to the right of the first unequal byte may or may not be recognized. For operands longer than 4K bytes, access exceptions are not recognized more than 4K bytes beyond the byte being processed. Access exceptions are not indicated for locations more than 4K bytes beyond the first unequal byte.

When the length of an operand is zero, no access exceptions are recognized for that operand. Access exceptions are not recognized for an operand if the R field associated with that operand is odd.

Resulting Condition Code:

0 All bytes compared; operands equal, or both zero length
1 All bytes compared, first operand low
2 All bytes compared, first operand high
3 CPU-determined number of bytes compared without finding an inequality

Program Exceptions:

- Access (fetch, operands 1 and 3)
- Specification
- Transaction constraint

Programming Notes:

1. COMPARE LOGICAL LONG EXTENDED is intended for use in place of COMPARE LOGICAL LONG when the operand lengths are specified as 32-bit or 64-bit binary integers. COMPARE LOGICAL LONG EXTENDED sets condition code 3 in cases in which COMPARE LOGICAL LONG would be interrupted.

2. When condition code 3 is set, the program can simply branch back to the instruction to continue the comparison. The program need not determine the number of bytes that were compared.

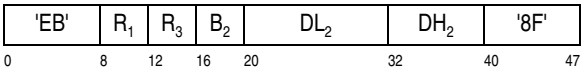
3. The function of not processing more than approximately 4K bytes of either operand is intended to permit software polling of a flag that may be set by a program on another CPU during long operations.

4. When the R_1 and R_3 fields are the same, the operation proceeds in the same way as when two distinct pairs of registers having the same contents are specified, except that the contents of the designated registers are incremented or decremented only by the number of bytes compared, not by twice the number of bytes compared. In the absence of dynamic modification of the operand area by another CPU or by a channel program, the condition code is finally set to 0 after possible settings to 3. However, it is unpredictable whether access exceptions are recognized for the operand since the operation can be completed without storage being accessed. If storage is not accessed, condition code 3 may or may not be set regardless of the operand length.

5. In the access-register mode, access register 0 designates the primary address space regardless of the contents of access register 0.

COMPARE LOGICAL LONG UNICODE

CLCLU $R_1,R_3,D_2(B_2)$ [RSY-a]



The first operand is compared with the third operand until unequal two-byte Unicode characters are compared, the end of the longer operand is reached, or a CPU-determined number of characters have been compared, whichever occurs first. The shorter operand is considered to be extended on the right with two-byte padding characters. The result is indicated in the condition code.

The R_1 and R_3 fields each designate an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The location of the leftmost character of the first operand and third operand is designated by the contents of general registers R_1 and R_3, respectively. In the 24-bit or 31-bit addressing mode, the number of bytes in the first-operand and third-operand locations is specified by the contents of bit positions 32-63 of general registers $R_1 + 1$ and $R_3 + 1$, respectively, and those contents are treated as 32-bit unsigned binary integers. In the 64-bit addressing mode, the number of bytes in the first-operand and third-operand locations is specified by the contents of bit positions 0-63 of general registers $R_1 + 1$ and $R_3 + 1$, respectively, and those contents are treated as 64-bit unsigned binary integers.

The contents of general registers $R_1 + 1$ and $R_3 + 1$ must specify an even number of bytes; otherwise, a specification exception is recognized.

The handling of the addresses in general registers R_1 and R_3 is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers R_1 and R_3 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the registers constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 of the registers constitute the address.

The second-operand address is not used to address data; instead, the rightmost 16 bits of the second-operand address, bits 48-63, are the two-byte padding character. Bits 0-47 of the second-operand address are ignored.

The contents of the registers and address just described are shown in Figure 7-214.

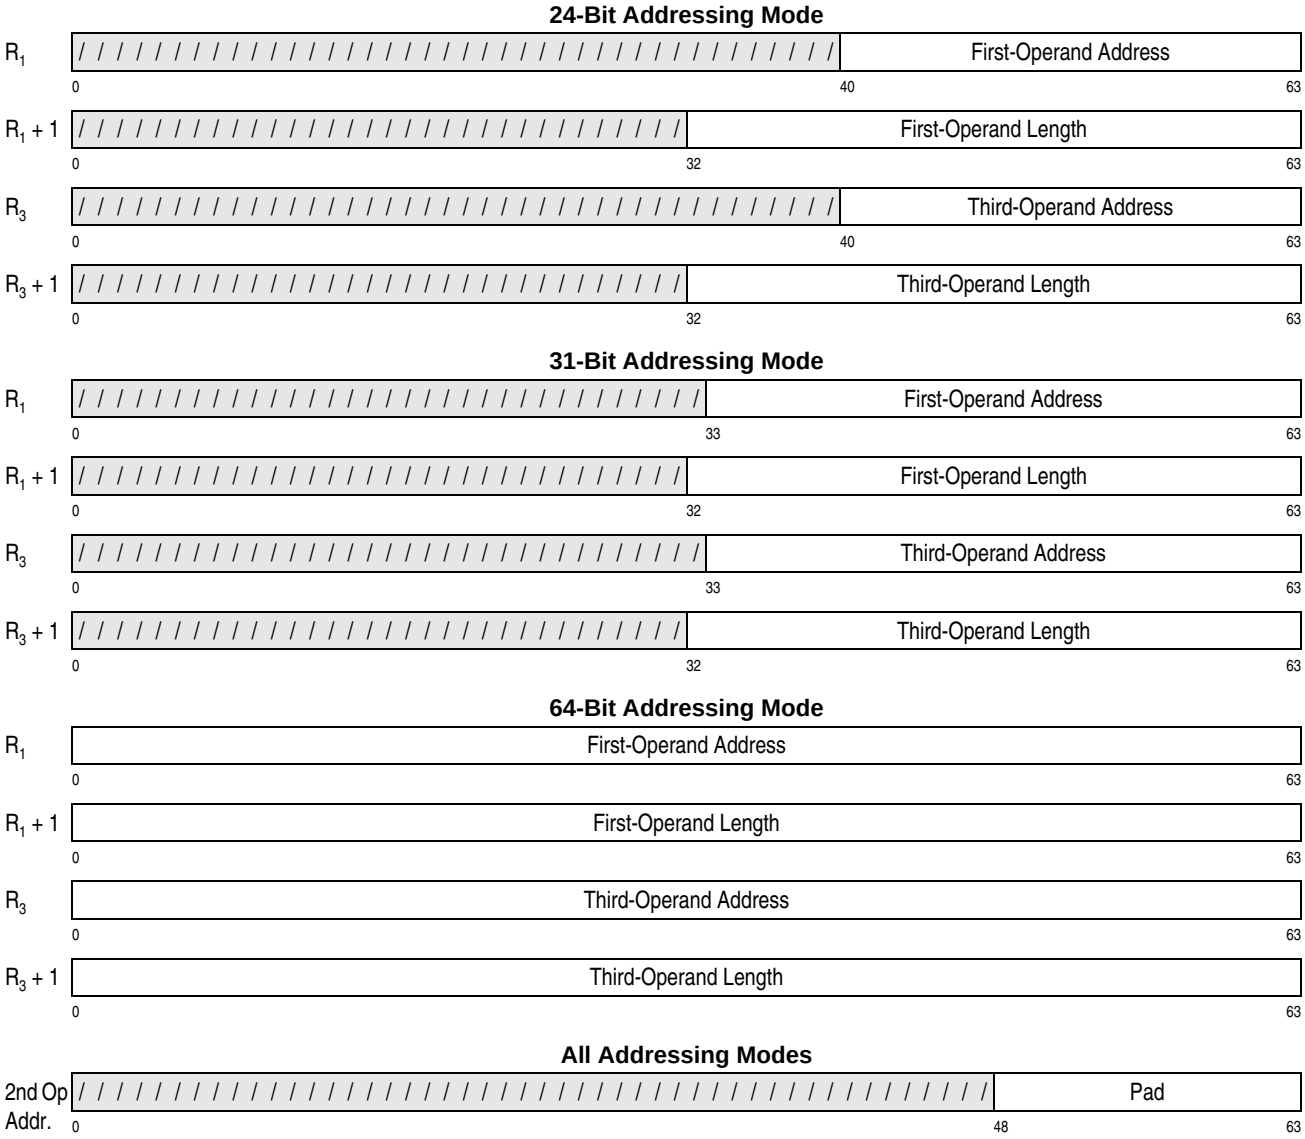


Figure 7-214. Register Contents and Second-Operand Address for COMPARE LOGICAL LONG UNICODE

The comparison proceeds left to right, character by character, and ends as soon as an inequality is found, the end of the longer operand is reached, or a CPU-determined number of characters have been compared, whichever occurs first. If the operands are not of the same length, the shorter operand is considered to be extended on the right with the appropriate number of two-byte padding characters.

If both operands are of zero length, the operands are considered to be equal.

If the operation ends because of an inequality, the address fields in general registers R_1 and R_3 at completion identify the first unequal two-byte character in each operand. The lengths in bit positions 32-63, in the 24-bit or 31-bit addressing mode, or in bit positions 0-63, in the 64-bit addressing mode, of general

registers $R_1 + 1$ and $R_3 + 1$ are decremented by 2 times the number of characters that were equal, unless the inequality occurred with the two-byte padding character, in which case the length field for the shorter operand is set to zero. The addresses in general registers R_1 and R_3 are incremented by the amounts by which the corresponding length fields were decremented. Condition code 1 is set if the first operand is low, or condition code 2 is set if the first operand is high.

If the two operands, including the two-byte padding character, if necessary, are equal, both length fields are made zero at completion, and the addresses are incremented by the corresponding operand-length values. Condition code 0 is set.

If the operation is completed because a CPU-determined number of characters have been compared without finding an inequality or reaching the end of the longer operand, the lengths in general registers $R_1 + 1$ and $R_3 + 1$ are decremented by 2 times the number of characters compared, and the addresses in general registers R_1 and R_3 are incremented by the same number, so that the instruction, when reexecuted, resumes at the next characters to be compared. If the operation is completed after the shorter operand has been exhausted, the length field pertaining to the shorter operand is zero, and the operand address is updated accordingly. Condition code 3 is set.

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers R_1, $R_1 + 1$, R_3, and $R_3 + 1$, always remain unchanged.

The two-byte padding character may be formed from $D_2(B_2)$ multiple times during the execution of the instruction, and the registers designated by R_1 and R_3 may be updated multiple times. Therefore, if B_2 equals R_1, $R_1 + 1$, R_3, or $R_3 + 1$ and is subject to change during the execution of the instruction, the results are unpredictable.

The amount of processing that results in the setting of condition code 3 is determined by the CPU on the basis of improving system performance, and it may be a different amount each time the instruction is executed.

At the completion of the operation in the 24-bit or 31-bit addressing mode, the leftmost bits which are not part of the address in bit positions 32-63 of general registers R_1 and R_3 may be set to zeros or may remain unchanged from their original values, including the case when one or both of the initial length values are zero.

Access exceptions for the portion of a storage operand to the right of the first unequal character may or may not be recognized. For operands longer than 4K bytes, access exceptions are not recognized more than 4K bytes beyond the character being processed. Access exceptions are not indicated for locations more than 4K bytes beyond the first unequal character.

When the length of an operand is zero, no access exceptions are recognized for that operand. Access exceptions are not recognized for an operand if the R field or length associated with that operand is odd.

Resulting Condition Code:

0 All characters compared; operands equal, or both zero length
1 First operand low
2 First operand high
3 CPU-determined number of characters compared without finding an inequality

Program Exceptions:

- Access (fetch, operands 1 and 3)
- Operation (if the extended-translation facility 2 is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. COMPARE LOGICAL LONG UNICODE is intended for use in place of COMPARE LOGICAL LONG or COMPARE LOGICAL LONG EXTENDED when two-byte characters are to be compared. The characters may be Unicode characters or any other double-byte characters. COMPARE LOGICAL LONG UNICODE sets condition code 3 in cases in which COMPARE LOGICAL LONG would be interrupted.

2. When condition code 3 is set, the program can simply branch back to the instruction to continue the comparison. The program need not determine the number of characters that were compared.

3. When the R_1 and R_3 fields are the same, the operation proceeds in the same way as when two distinct pairs of registers having the same contents are specified, except that the contents of the designated registers are incremented or decremented only by 2 times the number of characters compared, not by 4 times the number of characters compared. In the absence of dynamic modification of the operand area by another CPU or by a channel program, the condition code is finally set to 0 after possible settings to 3. However, it is unpredictable whether access exceptions are recognized for the operand since the operation can be completed without storage being accessed. If storage is not accessed, condition code 3 may or may not be set regardless of the operand length.

4. In the access-register mode, access register 0 designates the primary address space regardless of the contents of access register 0.

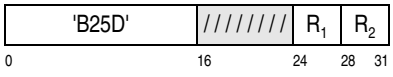
5. The padding character may be represented in the displacement field of the instruction. The following example illustrates padding with a Unicode space character.

   ```
   CLCLU   6,8,X'020'
   ```

   When the B_2 field of the instruction designates general register 0, and the long-displacement facility is not installed, the padding character is limited to a character whose representation is less than or equal to FFF hex.

COMPARE LOGICAL STRING

CLST R_1,R_2 [RRE]



The first operand is compared with the second operand until unequal bytes are compared, the end of either operand is reached, or a CPU-determined number of bytes have been compared, whichever occurs first. The CPU-determined number is at least 256. The result is indicated in the condition code.

The location of the leftmost byte of the first operand and second operand is designated by the contents of general registers R_1 and R_2, respectively.

The handling of the addresses in general registers R_1 and R_2 is dependent on the addressing mode. In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers R_1 and R_2 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the registers constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 constitute the address.

The first and second operands may be of the same or different lengths. The end of an operand is indicated by an ending character in the last byte position of the operand. The ending character to be used to determine the end of an operand is specified in bit positions 56-63 of general register 0. Bit positions 32-55 of general register 0 are reserved for possible future extensions and must contain all zeros; otherwise, a specification exception is recognized.

The operation proceeds left to right, byte by byte, and ends as soon as the ending character is encountered in either or both operands, unequal bytes which do not include an ending character are compared, or a CPU-determined number of bytes have been compared, whichever occurs first. The CPU-determined number is at least 256. When the ending character is encountered simultaneously in both operands, including when it is in the first byte position of the operands, the operands are of the same length and are considered to be equal, and condition code 0 is set. When the ending character is encountered in only one operand, that operand, which is the shorter operand, is considered to be low, and condition code 1 or 2 is set. Condition code 1 is set if the first operand is low, or condition code 2 is set if the second operand is low. Similarly, when unequal bytes which do not include an ending character are compared, condition code 1 is set if the lower byte is in the first operand, or condition code 2 is set if the lower byte is in the second operand. When a CPU-determined number of bytes have been compared, condition code 3 is set.

When condition code 1 or 2 is set, the address of the last byte processed in the first and second operands is placed in general registers R_1 and R_2, respectively. That is, when condition code 1 is set, the address of the ending character or first unequal byte in the first operand, whichever was encountered, is placed in general register R_1, and the address of the second-operand byte corresponding in position to the first-operand byte is placed in general register R_2. When

condition code 2 is set, the address of the ending character or first unequal byte in the second operand, whichever was encountered, is placed in general register R_2, and the address of the first-operand byte corresponding in position to the second-operand byte is placed in general register R_1. When condition code 3 is set, the address of the next byte to be processed in the first and second operands is placed in general registers R_1 and R_2, respectively. Whenever an address is placed in a general register, bits 32-39 of the register, in the 24-bit addressing mode, or bit 32 in the 31-bit addressing mode, are set to zeros. Bits 0-31 of the R_1 and R_2 registers always remain unchanged in the 24-bit or 31-bit mode.

When condition code 0 is set, the contents of general registers R_1 and R_2 remain unchanged.

The amount of processing that results in the setting of condition code 3 is determined by the CPU on the basis of improving system performance, and it may be a different amount each time the instruction is executed.

Access exceptions for the first and second operands are recognized only for that portion of the operand which is necessarily examined in the operation.

Resulting Condition Code:

0 Entire operands equal; general registers R_1 and R_2 unchanged
1 First operand low; general registers R_1 and R_2 updated with addresses of last bytes processed
2 First operand high; general registers R_1 and R_2 updated with addresses of last bytes processed
3 CPU-determined number of bytes equal; general registers R_1 and R_2 updated with addresses of next bytes

Program Exceptions:

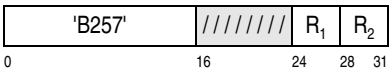
- Access (fetch, operands 1 and 2)
- Specification
- Transaction constraint

Programming Notes:

1. Several examples of the use of the COMPARE LOGICAL STRING instruction are given in Appendix A, “Number Representation and Instruction-Use Examples.”
2. When condition code 0 is set, no indication is given of the position of either ending character.
3. When condition code 3 is set, the program can simply branch back to the instruction to continue the comparison. The program need not determine the number of bytes that were compared.
4. R_1 or R_2 may be zero, in which case general register 0 is treated as containing an address and also the ending character.
5. In the access-register mode, access register 0 designates the primary address space regardless of the contents of access register 0.

COMPARE UNTIL SUBSTRING EQUAL

CUSE R_1,R_2 [RRE]



The first operand is compared with the second operand until equal substrings (sequences of bytes) of a specified length are found, the end of the longer operand is reached, or a CPU-determined number of unequal bytes have been compared, whichever occurs first. The shorter operand is considered to be extended on the right with padding bytes. The CPU-determined number is at least 256. The result is indicated in the condition code.

The R_1 and R_2 fields each designate an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The location of the leftmost byte of the first operand and second operand is specified by the contents of the R_1 and R_2 general registers, respectively. In the 24-bit or 31-bit addressing mode, the number of bytes in the first-operand and second-operand locations is specified by the 32-bit signed binary integer in bit positions 32-63 of general registers $R_1 + 1$ and $R_2 + 1$, respectively. In the 64-bit addressing mode, the number of bytes is specified by the 64-bit signed binary integer in bit positions 0-63 of those registers. When an operand length is negative, it is treated as zero, and it remains unchanged upon completion of the instruction.

Bits 56-63 of general register 0 specify the unsigned substring length, a value of 0-255, in bytes. Bits 56-63 of general register 1 are the padding byte. Bits 0-55 of general registers 0 and 1 are ignored.

The handling of the addresses in general registers R_1 and R_2 is dependent on the addressing mode. In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers R_1 and R_2 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the registers constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 constitute the address.

The contents of the registers just described are shown in Figure 7-215.

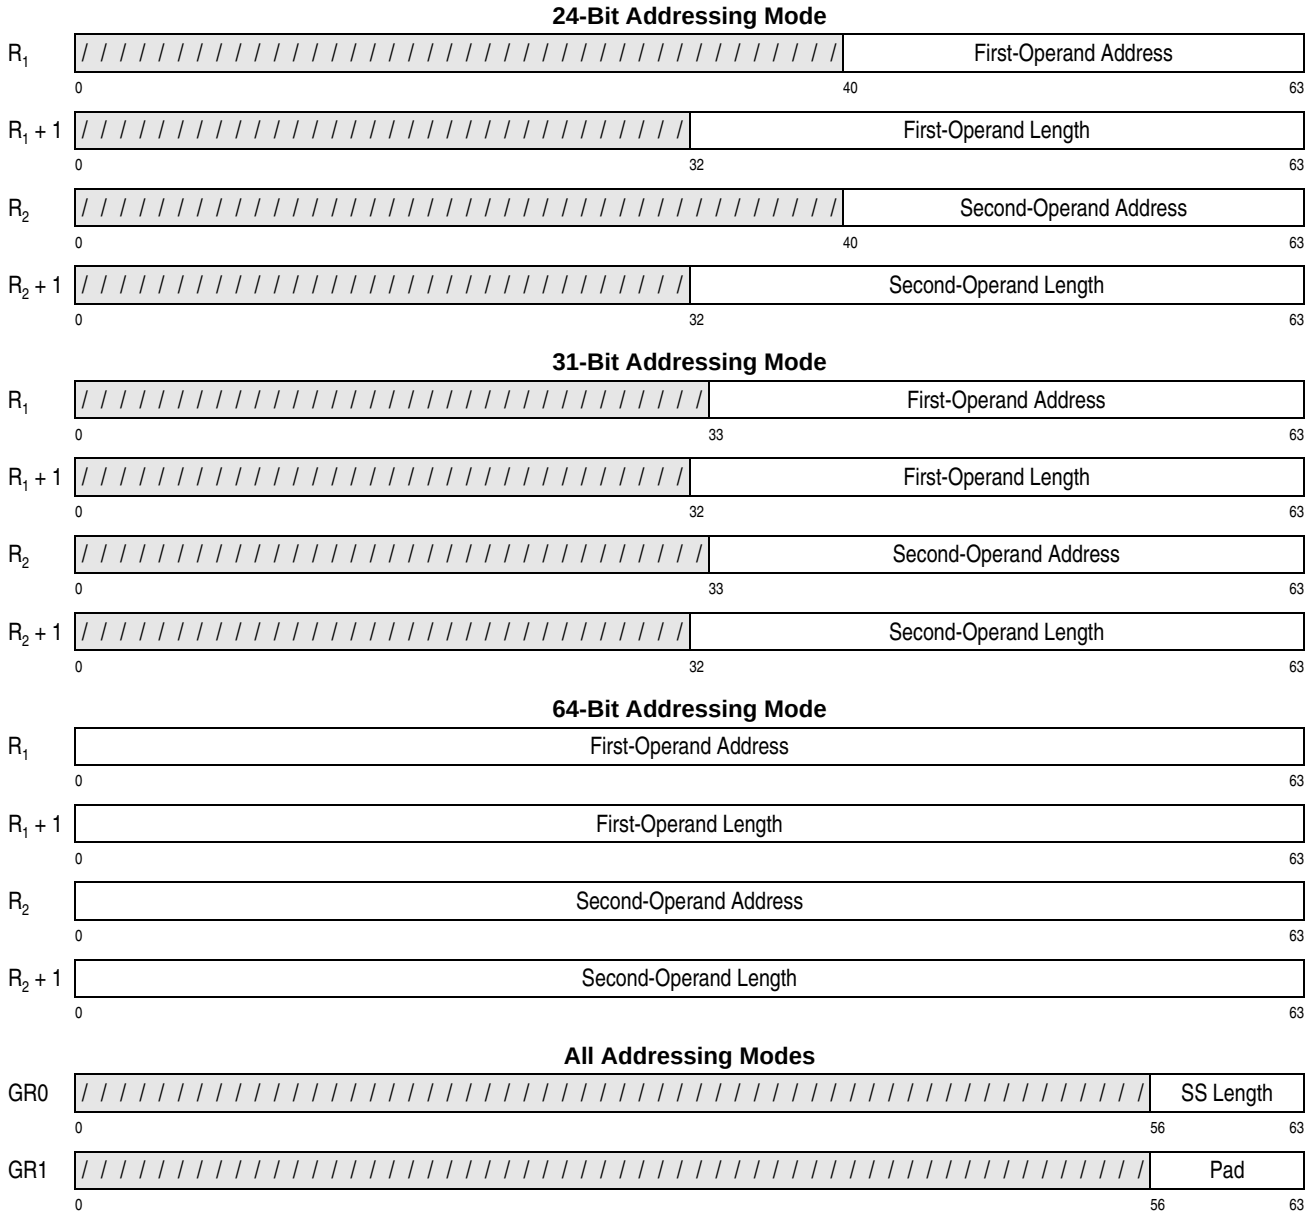


Figure 7-215. Register Contents for COMPARE UNTIL SUBSTRING EQUAL

The result is obtained as if the operands were processed from left to right. However, multiple accesses may be made to all or some of the bytes of each operand.

The comparison proceeds left to right, byte by byte, and ends as soon as (1) equal substrings of the specified length are found, (2) the end of the longer operand is reached without finding equal substrings of the specified length, or (3) the last bytes compared are unequal, and a CPU-determined number of bytes have been compared. The CPU-determined number is at least 256. If the operands are not of the same length, the shorter operand is considered to be extended on the right with the appropriate number of padding bytes.

If the operation ends because equal substrings of the specified length were found, the condition code is set to 0. If the operation ends because the end of the longer operand was reached without finding equal substrings of the specified length, the condition code is set to 1 if equal bytes were the last bytes compared, or it is set to 2 if unequal bytes were the last bytes compared. If the operation ends because unequal bytes were compared when a CPU-determined number of bytes had been compared, the condition code is set to 3.

If the specified substring length is zero, it is considered that equal substrings of the specified length were found, and condition code 0 is set.

If both operands are of zero length but the specified substring length is not zero, it is considered that the end of the longer operand was reached when unequal bytes were the last bytes compared, and condition code 2 is set.

If equal bytes have been compared but then unequal bytes are compared, it is considered that all bytes so far compared are unequal.

At the completion of the operation, the operand-length fields in the $R_1 + 1$ and $R_2 + 1$ registers are decremented by the number of unequal bytes compared (including equal bytes before unequal bytes compared), and the addresses in the R_1 and R_2 registers are incremented by the same number. However, in the case when a byte of the longer operand is compared against the padding byte, the length field for the shorter operand is not decremented below zero, and the corresponding address is not incremented above the address of the first byte after the shorter operand. In the 24-bit or 31-bit addressing mode, the leftmost bits which are not part of the addresses in bit positions 32-63 of registers R_1 and R_2 are set to zeros, even if the substring length is zero or both operand lengths are initially zero.

Thus, when condition code 0 or 1 is set, the resulting addresses in the R_1 and R_2 registers designate the first bytes of equal substrings in the two operands, and the lengths in the $R_1 + 1$ and $R_2 + 1$ registers have been decremented by the number of bytes preceding the equal substrings, except when the equal substring in the shorter operand begins with the padding byte, in which case the length field for the shorter operand is zero, and the corresponding address field has been incremented by the operand length. When condition code 2 is set, each address field designates the first byte after the corresponding operand, and both length fields are zero. When condition code 3 is set, each address field designates the first byte after the last compared byte of the corresponding operand, and both length fields have been decremented by the number of bytes compared, except that a length field is not decremented below zero.

When the contents of the R_1 and R_2 fields are the same, the first and second operands may be compared, or the condition code may be set to 0 or 1 without comparing the operands.

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers R_1, $R_1 + 1$, R_2, and $R_2 + 1$, always remain unchanged.

The substring length and padding byte may be fetched from general registers 0 and 1 multiple times during the execution of the instruction, and the registers designated by R_1 and R_2 may be updated multiple times. Therefore, if R_1 or R_2 is zero, the results are unpredictable.

When condition code 3 is set, the general registers used by the instruction have been set so that the remainder of the operands can be processed by simply branching back and reexecuting the instruction.

The amount of processing that results in the setting of condition code 3 is determined by the CPU on the basis of improving system performance, and it may be a different amount each time the instruction is executed.

The execution of the instruction is interruptible when the last bytes compared are unequal; it is not interruptible when the last bytes compared are equal. When an interruption occurs, other than one that follows termination, the contents of the registers designated by the R_1 and R_2 fields are updated the same as upon normal completion of the instruction, so that

the instruction, when reexecuted, resumes at the point of interruption. The condition code is unpredictable.

Access exceptions for the portion of a storage operand to the right of the last byte processed may or may not be recognized. For operands longer than 4K bytes, access exceptions are not recognized for locations more than 4K bytes beyond the last byte processed.

When the length of an operand is zero, no access exceptions are recognized for that operand. Access exceptions are not recognized for an operand if the R field associated with that operand is odd. Although the operand address and length fields remain unchanged when a zero substring length is specified, the recognition of access exceptions is not necessarily prevented.

Resulting Condition Code:

0 Equal substrings of specified length found
1 End of longer operand reached when last bytes compared are equal
2 End of longer operand reached when last bytes compared are unequal
3 Last bytes compared are unequal, and CPU-determined number of bytes compared

Program Exceptions:

- Access (fetch, operands 1 and 2)
- Specification
- Transaction constraint

Programming Notes:

1. When the R_1 and R_2 fields are the same, the operation proceeds in the same way as when two distinct pairs of registers having the same contents are specified, and, in the absence of dynamic modification of the operand area by another CPU or by a channel program, condition code 0, 1, or 2 is set (as explained in the next note). However, it is unpredictable whether access exceptions are recognized for the operand since the operation can be completed without storage being accessed.

2. If the contents of the R_1 and R_2 fields are the same and the operand length is nonzero, and provided that another CPU or a channel program is not changing an operand, condition code 0 is set if the operand length is equal to or greater than the specified substring length, or condition code 1 is set if the operand length is less than the specified substring length. Whether or not R_1 equals R_2, if both operand lengths are zero, condition code 0 is set if the specified substring length is zero, or condition code 2 is set if the specified substring length is nonzero. In all of these cases, the addresses in the R_1 and R_2 registers and the lengths in the $R_1 + 1$ and $R_2 + 1$ registers remain unchanged.

3. Special precautions should be taken when COMPARE UNTIL SUBSTRING EQUAL is made the target of an execute-type instruction. See the programming note concerning interruptible instructions under EXECUTE.

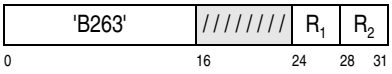
4. Other programming notes concerning interruptible instructions are included in “Interruptible Instructions” on page 5-24.

5. In the access-register mode, access register 0 designates the primary address space regardless of the contents of access register 0.

6. The storage-operand references of COMPARE UNTIL SUBSTRING EQUAL may be multiple-access references. (See “Storage-Operand Consistency” on page 5-133.)

COMPRESSION CALL

CMPSC R_1,R_2 [RRE]



This definition assumes knowledge of the introductory information and information about dictionary formats in Appendix D.

The second operand is compressed or expanded, depending on a specification in general register 0, and the results are placed at the first-operand location. The compressed-data operand consists of either index symbols corresponding to entries in a dictionary designated by an address in general register 1, or codewords which are converted to index symbols depending on the specification of entropy encoding. This dictionary is a compression dictionary during a compression operation or an expansion dictionary during an expansion operation.

During compression when format-1 sibling descriptors are specified in general register 0, an expansion dictionary immediately follows the compression dictionary. During compression when the symbol-translation option is specified in general register 0, the index symbols resulting from compression are translated to interchange symbols by means of a symbol-translation table designated by the address and an offset in general register 1, and it is the interchange symbols that are placed at the first-operand location. During compression when the order preservation option is specified in general register 0, a modified form of symbol translation occurs. During compression when the entropy-encoding option is specified in general register 0, the index symbols are translated into codewords via a modified version of symbol translation whose parameters are specified by the address and offset in general register 1. The number of bits in an index or interchange symbol in the compressed-data operand or in an index symbol used in entropy encoding is specified in general register 0. The operation proceeds until the end of either operand is reached or a CPU-determined amount of data has been processed, whichever occurs first. The results are indicated in the condition code.

The R_1 and R_2 fields each designate an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The location of the leftmost byte containing any bit of the first operand and second operand is designated by an address in general registers R_1 and R_2, respectively. The number of bytes containing any bits of the first operand and second operand is specified by bits 32-63 of general registers $R_1 + 1$ and $R_2 + 1$, respectively, in the 24-bit or 31-bit addressing mode or by bits 0-63 of the registers in the 64-bit addressing mode. The contents of general registers $R_1 + 1$ and $R_2 + 1$ are treated as 32-bit unsigned binary integers in the 24-bit or 31-bit addressing mode or as 64-bit unsigned binary integers in the 64-bit addressing mode.

The location of the leftmost byte of the compression dictionary during compression, or of the expansion dictionary during expansion, is designated on a 4 K-byte boundary by an address in general register 1. Optionally, general register 1 also contains an offset to the first byte of an entropy descriptor or symbol translation table.

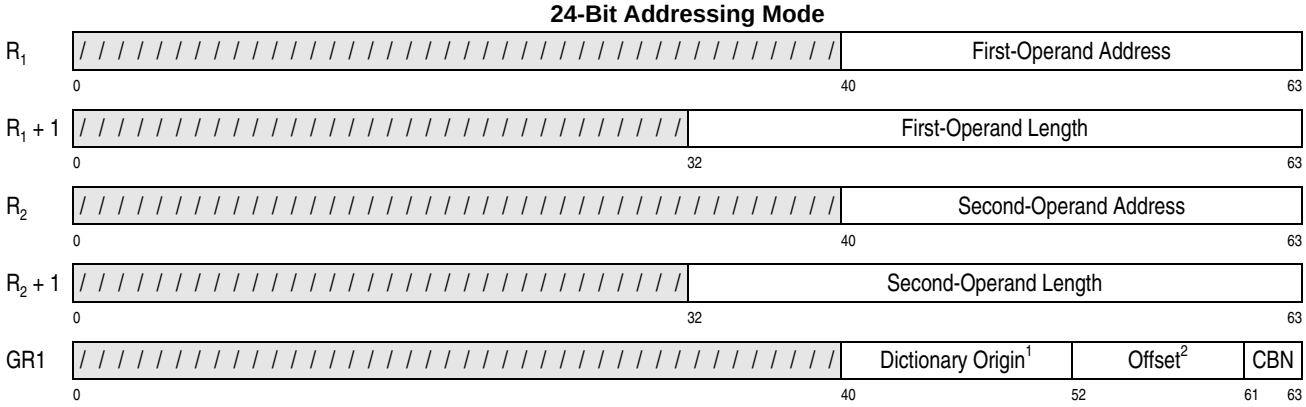


Figure 7-216. Register Contents for COMPRESSION CALL (Part 1 of 2)

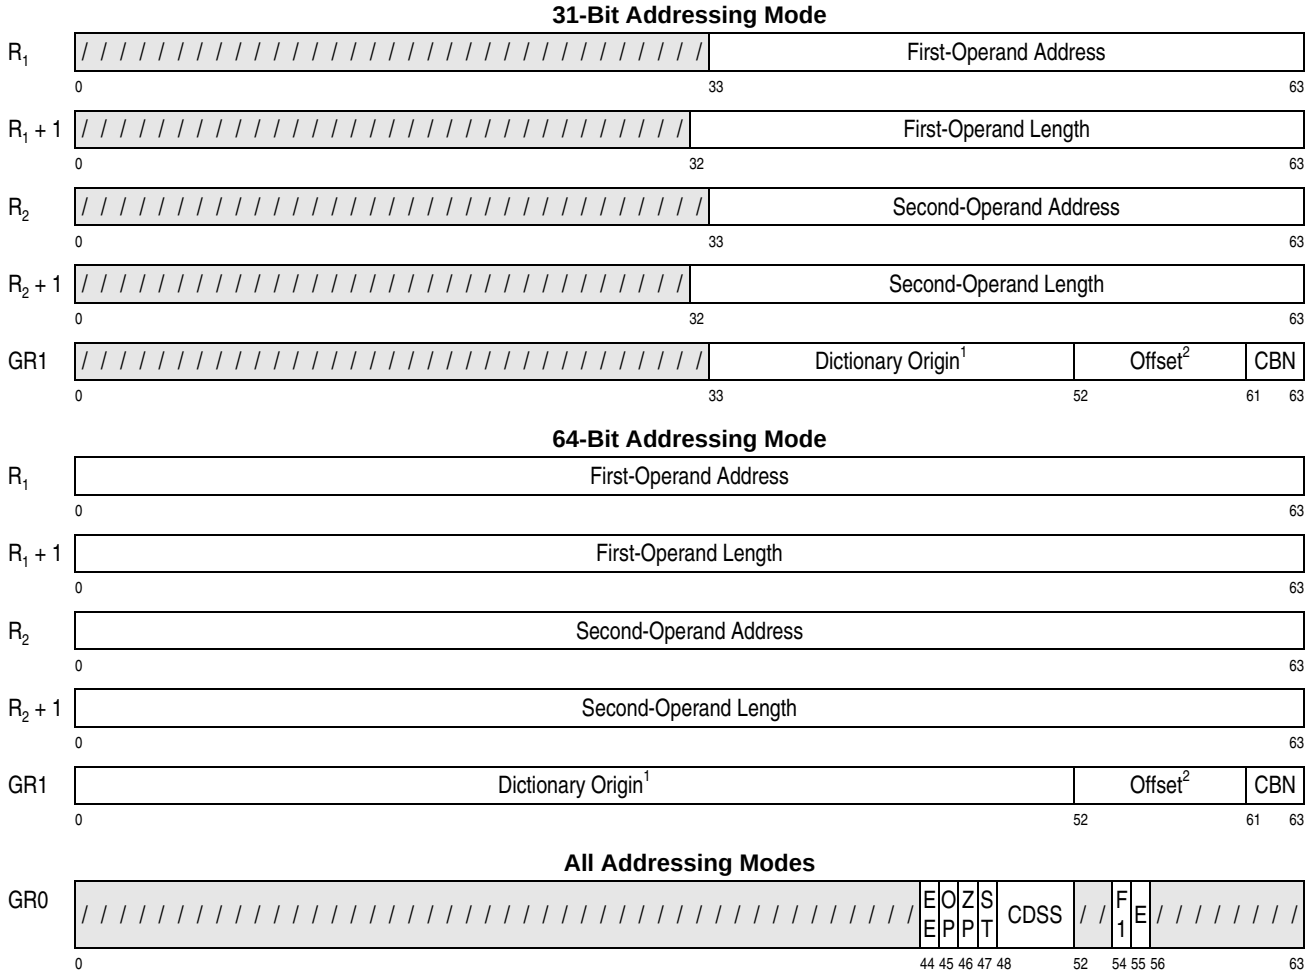

Explanation:

1 Compression dictionary during compression, or expansion dictionary during expansion

2 The Offset field is only meaningful during compression when any of the ST, EE, and OP bits are one. When the ST, EE, and OP bits are zero during compression, or the EE bit is zero during expansion, the Offset field is ignored.

CBN Compressed-data bit number

CDSS Compressed-data symbol size

CDSS (binary)	Symbol Size	Dictionary Size
0000	Causes a specification exception to be recognized	
0001	9 bits	512 entries, 4K bytes
0010	10 bits	1K entries, 8K bytes
0011	11 bits	2K entries, 16K bytes
0100	12 bits	4K entries, 32K bytes
0101	13 bits	8K entries, 64K bytes
0110-1111	Causes a specification exception to be recognized	

E Expansion operation

EE Entropy-encoding option (when the entropy-encoding compression facility is installed).

F1 Format-1 sibling descriptors (ignored during expansion)

Offset Offset to symbol translation table or entropy descriptor

OP Order-preservation option (ignored during expansion, or when the order-preserving-compression facility is not installed)

ST Symbol-translation option (ignored during expansion, implied one for entropy encoding)

ZP Zero padding control (when the CMPSC-enhancement facility is installed).

Figure 7-216. Register Contents for COMPRESSION CALL (Part 2 of 2)

The handling of the addresses in general registers R_1, R_2, and 1 is dependent on the addressing mode. In the 24-bit addressing mode, the contents of bit positions 40-63 of registers R_1 and R_2 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of registers R_1 and R_2 constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 of registers R_1 and R_2 constitute the address. In the 24-bit addressing mode, the contents of bit positions 40-51 of register 1, with 12 rightmost zeros appended, constitute the address, and the contents of bit positions 0-39 and 52-63 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-51 of register 1, with 12 rightmost zeros appended, constitute the address, and the contents of bit positions 0-32 and 52-63 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-51 of register 1, with 12 rightmost zeros appended, constitute the address, and the contents of bit positions 52-63 are ignored.

Although the contents of bit positions 52-63 of general register 1 are ignored in the formation of a dictionary address, those contents are used as follows. The contents of bit positions 61-63 of the register are the compressed-data bit number (CBN). At the beginning of the operation, the CBN designates the leftmost bit within the leftmost byte of the compressed-data operand. The compressed-data operand is the first operand during compression, or it is the second operand during expansion. When the symbol-translation or order-preservation option is specified during compression and the entropy-encoding option is not specified, the contents of bit positions 52-60 of the register, with seven rightmost zeros appended, are the byte offset from the beginning of the compression dictionary to the leftmost byte of the symbol-translation table. When the entropy-encoding option is specified the contents of bit positions 52-60 of the register, with seven rightmost zeros appended, are the byte offset from the beginning of the compression dictionary to the leftmost byte of the entropy descriptor. When the entropy encoding option is specified during compression, the leftmost byte of the entropy encoding symbol translation table is located at the byte offset plus 32. Symbol translation and order-preservation cannot be specified during expansion, and the contents of bit positions 52-60 are ignored during expansion.

The contents of the registers just described and also of general register 0 are shown in Figure 7-216 on page 7-186.

Bit 55 (E) of general register 0 specifies the compression operation if zero or the expansion operation if one.

When the CMPSC-enhancement facility is installed, bit 46 of general register 0 is the zero-padding (ZP) control. When the ZP control is zero, zero padding of the first operand is not performed. When the ZP control is one, zero padding of the first operand may be performed, as described below. When the CMPSC-enhancement facility is not installed, bit 46 of general register 0 is ignored.

Bit 44 (EE) of general register 0 is the entropy-encoding-option bit; this bit is only meaningful when the entropy-encoding-compression facility is installed. Bit 45 (OP) of general register 0 is the order-preservation-option bit; this bit is only meaningful when the order-preserving-compression facility is installed. Bit 47 (ST) of general register 0 is the symbol-translation-option bit. When bit 44 (EE) is one, bit 45 (OP) must be zero; otherwise results are unpredictable.

During compression when bits 45 and 47 are both zero, the operation produces indexes, called index symbols, to compression-dictionary entries that represent character strings, and the operation then places the index symbols in the compressed-data operand. During compression when bit 45 is zero and bit 47 is one, the operation still produces index symbols but then translates the index symbols to other symbols, called interchange symbols, that it then places in the compressed-data operand. This symbol translation is done by using the symbol-translation table specified by the address and offset in general register 1. During compression when bit 45 is one, bit 47 is ignored, and a modified form of symbol translation is done by using the symbol-translation table. Bits 45 and 47 and the offset in general register 1 are ignored during expansion. During expansion, the compressed-data operand always contains index symbols that designate entries in the expansion dictionary.

When bit 44 of general register 0 is one during compression the operation produces indexes called index symbols which are translated to codewords which are then placed in the compressed-data operand. The translation is done by using the symbol-translation table specified by the address and offset + 32

bytes. During expansion the compressed-data operand always contains codewords that are converted to index symbols by the process shown in Figure 7-221, “Entropy Encoded Expansion” on page 7-202 which are then used to designate entries in the expansion dictionary.

When bit 44 of general register 0 is zero, bits 48-51 (CDSS) of the register specify the number of bits in the index symbols or interchange symbols in the compressed-data operand, as shown in the figure. Bits 48-51 must not have any of the values 0000 or 0110-1111 binary; otherwise, a specification exception is recognized. When bit 44 (EE) of general register 0 is one, bits 48-51 (CDSS) are ignored. When order preservation, entropy encoding, and symbol-translation are not specified, bits 48-51 also specify, as shown in the figure, the number of eight-byte entries in each of the compression and expansion dictionaries, and, thus, they specify the size in bytes of each of the dictionaries. When order preservation, entropy encoding or symbol translation is specified, the compression dictionary is considered to extend to the beginning of the symbol-translation table, that is, the size in bytes of the compression dictionary is the offset in bit positions 52-60 of general register 1, with seven rightmost zeros appended. The size in bytes of the symbol-translation table is considered to be one fourth that of the compression dictionary. However, the offset in general register 1 must be at least as large as the size of the compression dictionary would be if symbol translation were not specified and the CDSS were one less than it actually is, and, when the CDSS is 0001 binary, the offset must be at least 2K bytes; otherwise, the results are unpredictable. For example, if the CDSS is 0101, the offset must be at least 32 K-bytes. When entropy encoding is specified, the compression dictionary must be at least 2K bytes and at most 64 K-bytes; otherwise, the results are unpredictable.

Bit 54 (F1) of general register 0 specifies that the compression dictionary contains format-0 sibling descriptors if the bit is zero or format-1 sibling descriptors if the bit is one. Sibling descriptors are used during the compression operation. A format-0 sibling descriptor is eight bytes at an index position in the compression dictionary. A format-1 sibling descriptor is 16 bytes, with the first eight bytes at an index position in the compression dictionary and the second eight bytes at the same index position in the expansion dictionary. During compression when bit 54 is one, an expansion dictionary is considered to immediately follow the compression dictionary specified by the address in general register 1. Bit 54 is ignored during expansion. During compression when bit 54 is one, bits 44, 45 and 47 of general register 0 must be zeros; otherwise, the results are unpredictable.

Bits 47 and 54 of general register 0 must not both be ones; otherwise, the results are unpredictable.

The unused bit positions in general register 0 are reserved for possible future extensions and should contain zeros; otherwise, the program may not operate compatibly in the future.

In the access-register mode, the contents of access register R_1 are used for accessing the first operand, and the contents of access register R_2 are used for accessing the second operand, the dictionaries, the entropy descriptor, and the symbol-translation table.

When the entropy-encoding option is not specified and the first or second operand lengths are initially zero, the dictionary, first, and second operands are not accessed and condition code 0 or 1 is set.

The operation starts at the left end of both operands and proceeds to the right. The operation is ended when the end of either operand is reached or when a CPU-determined amount of data has been processed, whichever occurs first.

During a compression operation, the end of the first operand is considered to be reached when the number of unused bit positions remaining in the first-operand location is not sufficient to contain additional compressed data. When the entropy-encoding option is specified and the first operand length is non-zero, this check can only be performed after compression is attempted and the codeword size is determined.

During an expansion operation, the end of the first-operand location is considered to be reached when any of the following conditions are met:

1. The number of unused byte positions remaining in the first-operand location is not sufficient to contain all the characters that would result from expansion of the next index symbol or codeword.
2. Immediately when the number of unused byte positions is zero, that is, immediately when the expansion of an index symbol or codeword completely fills the first-operand location.

During an expansion operation, the end of the second-operand location is considered to be reached when the next index symbol or codeword does not reside entirely within the second-operand location or if the entropy-encoding option is specified and a codeword of all zeros is encountered. The second-operand location ends at the beginning of the byte designated by the sum of the address in general register R_2 and the length in general register $R_2 + 1$, regardless of the compressed-data bit number in bit positions 61-63 of general register 1.

If the operation is ended because the end of the second operand is reached, condition code 0 is set. If the operation is ended because the end of the first operand is reached, condition code 1 is set, except that condition code 0 is set provided that the end of the second operand is also reached. If the operation is ended because a CPU-determined amount of data has been processed, condition code 3 is set.

At the completion of the operation, the length in general register $R_1 + 1$ is decremented by the number of complete bytes stored at the first-operand location, and the address in general register R_1 is incremented by the same amount. During compression, a complete byte is considered to be stored only if all of its bit positions contain bits of compressed data. During compression when the first bit of compressed data stored is not in bit position 0 of a byte, the bits in the byte to the left of the first bit of compressed data remain unchanged. During compression if the last byte stored does not completely contain compressed data, the bits in the byte to the right of the rightmost bit of compressed data in the byte either are unchanged or are set to zeros.

The length in general register $R_2 + 1$ is decremented by the number of complete bytes processed at the second-operand location, and the address in general register R_2 is incremented by the same amount. During expansion, a complete byte is considered to be processed only if all of its bits have been used to produce expanded data.

The leftmost bits which are not part of the address in general registers R_1 and R_2 may be set to zeros or may remain unchanged. However, in the 24-bit or 31-bit addressing mode, bits 0-31 of these registers and also of general registers $R_1 + 1$ and $R_2 + 1$ always remain unchanged.

When all of the following conditions are met, zero padding may be performed, as described below.

- The CMPSC-enhancement facility is installed.
- The zero-padding (ZP) control, bit 46 of general register 0, is one.
- Any of the following is true:
  - The end of the first operand is reached (CC1).
  - The end of the second operand is reached (CC0).
  - A CPU-determined amount of data has been processed (CC3).
  - A codeword consisting of all zero bits is found in the middle of the compressed operand (CC0).
- The last byte of compressed or expanded data does not coincide with the rightmost byte of a model-dependent integral storage boundary.
- The remaining length in general register $R_1 + 1$ is sufficient to store up to the model-dependent integral storage boundary.

It is model dependent whether zero padding is performed. When none of the conditions listed above are met, zero padding is not performed.

Zero padding consists of storing zeros to the right of the last compressed or expanded byte, up to a model-dependent integral storage boundary. The address in general register R_1 and the length in general register $R_1 + 1$ are not updated to account for the zero padding. PER storage-alteration events are recognized for stores that occur as a result of zero padding. The model-dependent integral storage boundary is no larger than 4,096.

When the R_1 and R_2 fields do not designate general register 0, the handling of general register 1 is as follows. The bit number of the bit following the last bit of compressed data processed is placed in bit positions 61-63 of general register 1, and bits 52-60 of the register and the leftmost bits which are not part of the address in the register may be set to zeros or may remain unchanged, except that when one or both of the original length values are so small that no compressed data can be processed, all bits in the register may remain unchanged. However, when bits 44, 45 or 47 of general register 0 are one, bits 52-60 of general register 1 always remain unchanged. Also, in

the 24-bit or 31-bit addressing mode, bits 0-31 of the register always remain unchanged.

If (a) the operands overlap one another, (b) the first operand overlaps the dictionaries, entropy descriptor, or the symbol-translation table in storage in any way, or (c) either the R_1 or the R_2 field designates general register 0, the results are unpredictable.

The compression dictionary is a tree of entries in which a parent entry may have child entries. Each entry represents one or more characters called extension characters, and it also represents a character symbol consisting of the extension characters represented by the entry preceded by the extension characters represented by all of the entry's ancestors.

When order preservation is not specified, the compression process uses an unordered comparison algorithm: the children of a parent are not considered to be in any particular order, and the next characters from the string being compressed are compared against the extension characters represented by the children in the left-to-right order of the children until either a match is found or all of the children have been processed. (However, see Appendix D, “Restriction on Identical Child and Sibling Characters” for a restriction on identical first extension characters of children of the same parent.) The result of the compression process is the index symbol that designates the last matched entry, which is the parent entry if no match was found on any child or there are no children.

The order-preservation option causes the compression process to use an ordered comparison algorithm: the children of a parent are considered to be ordered such that the string of one or more extension characters represented by any child is always earlier in the collating sequence than the string of one or more extension characters represented by the next child of the same parent, that is, the children are considered to be in collating-sequence order. The next characters from the string being compressed are compared against the extension characters represented by the children in the left-to-right order of the children until any of the following is true: (1) a match is found on an entry without children, or a match is found on an entry with children but there is not another character in the string; (2) the next characters from the string have a collating-sequence value less than that of the extension characters represented by a child of the last matched parent; or (3) the next characters from the string have a collating-sequence value greater than that of the extension characters represented by the last child of the last matched parent. The result of the compression process in each of the three cases is as follows:

Case	Resulting Index Symbol
1	If the process ends because of a match on an entry without children or because of a match on an entry when there is not another character in the string, the result is the index symbol that designates the entry.
2	If the process ends because the next characters of the string have a value less than that of the characters represented by a child, the result is the index symbol that designates the child.
3	If the process ends because the next characters of the string have a value greater than that of the characters represented by the last child, the result is the index symbol that designates the last child.

Note that Case 2 includes the case when the next character of the string match the leftmost extension characters represented by a child but there are not as many next characters remaining in the string as there are additional extension characters represented in the child.

When symbol translation is specified, the symbol-translation table consists of two-byte entries, and an entry contains an interchange symbol in the rightmost bit positions of the entry. The length of the interchange symbol is specified by bits 48-51 of general register 0. The left-hand bits that are not part of the interchange symbol in a symbol-translation-table entry must be zeros; otherwise, the results are unpredictable.

To translate an index symbol to an interchange symbol, the index symbol is multiplied by 2 and then added to the address of the beginning of the symbol-translation table to locate an entry in the table, and then the interchange symbol is obtained from the entry.

When order preservation is specified, the index symbol produced by the compression process is used to locate a symbol-translation-table entry containing an interchange symbol just as when the symbol-translation option is specified. The resulting interchange symbol that is placed in the compressed-data operand depends on which of the above three cases the

index symbol was produced. The resulting interchange symbol is as follows:

Case	Resulting Interchange Symbol
1	The interchange symbol in the entry.
2	The interchange symbol in the entry, minus one; that is, one is subtracted from the value of the interchange symbol that is in the entry to form the interchange symbol that is stored.
3	The interchange symbol in the entry, plus one; that is, one is added to the value of the interchange symbol that is in the entry to form the interchange symbol that is stored.

In the above, the result of subtracting one from an interchange symbol consisting of all zero bits is an interchange symbol consisting of all one bits, and the result of adding one to an interchange symbol consisting of all one bits is an interchange symbol consisting of all zero bits.

When entropy encoding is specified, the index symbol produced by the compression process is used to locate a two-byte symbol-translation-table entry containing a codeword. The size of the codeword is determined and that number of leftmost bits of the symbol-translation-table entry are placed in the compressed data operand. The size of the codeword can be determined by the process shown in Figure 7-222, “Entropy Encoded Compression” on page 7-203.

The execution of the instruction is interruptible. When an interruption occurs, other than one that follows termination, the contents of the registers designated by the R_1 and R_2 fields and of general register 1 are updated the same as upon normal completion of the instruction, so that the instruction, when reexecuted, resumes at the point of interruption. The condition code is unpredictable.

For operands longer than 4K bytes, access exceptions are not recognized for locations more than 4K bytes beyond the current location being processed. Access exceptions may be recognized for all locations in the dictionaries and symbol-translation table if those areas are specified to be used and even if the locations would not be used during the operation. Access exceptions are not recognized for an operand, the dictionaries, or the symbol-translation table if the R field associated with that operand is odd. Also, when the R_1 field is odd, PER storage-alteration events are not recognized, and no change bits are set.

If an access exception is due to be recognized for either of the operands or for a dictionary, entropy descriptor, or the symbol-translation table, the result is that either the exception is recognized or condition code 3 is set. If condition code 3 is set, the exception will be recognized when the instruction is executed again to continue processing the same operands, assuming that the exception condition still exists.

During compression, regardless of whether the exception is recognized or condition code 3 is set, a nullifying access-exception condition or a suppressing DAT-protection exception conditionis handled so that an index symbol is generated only if it is the one that would result if there were no access-exception condition.

During compression or expansion, regardless of whether the exception is recognized or condition code 3 is set, a nullifying or suppressing access-exception condition may result in data having been stored at the first-operand location at or to the right of the location designated by the final address in general register R_1, which result is not true nullification or suppression. The amount of data stored depends on the reason for the access-exception condition. If the condition is due to a reference to a dictionary or the symbol-translation table, up to 4K bytes of data may have been stored at or to the right of the location designated by the final address. If the condition is due to a reference to the first or second operand, part of one index or interchange symbol, during compression, or part of one character symbol, during expansion, may have been stored at or to the right of the location designated by the final address. In all cases, the storing will be repeated when the instruction is executed again to continue processing the same operands.

If the end of the first operand is reached and an access exception is due to be recognized for the second operand, it is unpredictable whether condition code 1 is set or the access exception is recognized.

During expansion when the expansion dictionary is not logically correct, unusual storing may occur as described in Appendix D, “Expansion Process”. The results of an access exception in this case may not be true nullification or suppression.

Special Conditions

A specification exception is recognized for any of the following conditions:

1. Either the R_1 or R_2 fields contain an odd-numbered register.
2. Bits 48-51 of general register 0 contain any value not in the range of 0001-0101 binary and bit 44 of general register 0 is zero.

During compression of each character symbol, either the characters in the symbol or the dictionary character entries (not sibling descriptors) representing characters of the symbol are counted, and a general-operand data exception is recognized if this count becomes too large. The count can reach at least 260 without the exception being recognized.

During compression, the number of child characters or sibling characters processed during the processing of each parent entry are counted, and a general-operand data exception is recognized if this count becomes too large. The count can reach at least 260 without the exception being recognized. That is, a parent must not have more than 260 children; otherwise, a general-operand data exception may be recognized. Extension characters are not counted toward the maximum number of child and sibling characters until a child becomes a parent. When the examine child bit is zero, and a match is encountered, further matches are stopped and the child does not become a parent.

During expansion of each character symbol, either the characters in the symbol or the dictionary entries representing characters of the symbol are counted, and a general-operand data exception is recognized if this count becomes too large. If the characters in the symbol are counted, the count can reach at least 260 without the exception being recognized. If the dictionary entries representing characters of the symbol are counted, the count can reach at least 127 without the exception being recognized.

Certain error conditions in the dictionaries cause a general-operand data exception to be recognized and the operation to be either suppressed or terminated. Some of these error conditions are described in the sections “Expansion Process”, “Results of Dictionary Errors”, “Compression Dictionary”, and “Expansion Dictionary” in Appendix D.

When entropy encoding is specified, the entropy descriptor must satisfy the following properties otherwise a general-operand data exception is recognized.

1. The sum of the sixteen entries must add up to the number of dictionary entries plus one.
2. There is no arithmetic underflow or overflow when performing bounds calculations see Figure 7-220, “Entropy Descriptor Validation” on page 7-202.

During compression, when entropy encoding is specified, a symbol-translation-table entry with a zero value or an entry not padded on the right with zeros will cause a general-operand data exception to be recognized.

Resulting Condition Code:

0 End of second operand reached
1 End of first operand reached and end of second operand not reached
2 --
3 CPU-determined amount of data processed

Program Exceptions:

- Access (fetch, operand 2, dictionaries, and symbol-translation table; store, operand 1)
- Data with DXC 0, general operand
- Specification
- Transaction constraint

Programming Notes:

1. When condition code 3 is set, the program can simply branch back to the instruction to continue the operation. The program need not determine the amount of data processed.
2. During compression when a nullifying access exception is due to be recognized, an index symbol is generated only if it is the one that would result if there were no access-exception condition. The result of this is that compression of the same expanded data by means of one or more executions of the instruction and by using the same dictionary always results in the same compressed data. That is, (1) the best possible matches in the dictionary are always found for the characters in the second operand, or else the execution is ended by either setting CC3 or rec-

ognizing the exception, and (2) the results of compression are repeatable (although possibly by means of a different number of executions of the instruction) and predictable.

For example, if the next characters of the string being compressed are ABC, and dictionary entry A has a child B, which has a child C, the normal operation is to compress ABC as a single index symbol, but if the C of the string is in the first byte of an invalid page (a page-translation exception is due to be recognized), no index symbol is generated. More specifically, an index symbol corresponding to the character symbol AB is not generated because this is not the index symbol that would be generated if the access-exception condition did not exist.

In the above, "best possible match" refers only to the characters in the second operand. In the example above, if the next two characters of the second operand (the string) are AB, and these are the last two characters of the second operand, the best possible match is on AB, even though there could be a match on ABC if the second operand included one more byte containing C.

Expansion is normally always repeatable. An index symbol is always expanded to exactly the character symbol it represents unless an exception that causes termination is recognized.

3. During expansion, if at least one unused byte position remains in the first operand location, COMPRESSION CALL may completely process the next index symbol in the second operand before it determines that the first-operand location does not have sufficient unused byte positions to contain the expanded data that would result from the next index symbol. If that next index symbol causes encountering of bad dictionary entries, the result can be either a data exception or condition code 1.

   COMPRESSION CALL immediately sets condition code 1 when processing of an index symbol exactly fills the first-operand location, except that it sets condition code 0 if the end of the second-operand location also has been reached. Immediately setting condition code 1 has the advantage that data can be compressed using one dictionary and then followed immediately, possibly on a bit boundary, by a different type of data compressed using another dictionary. The compressed data can be successfully expanded if, during the expansion of the data compressed using the first dictionary, the length of the first-operand location is specified to be exactly the length of the expanded data that will be produced. Condition code 1 will then be set when the first-operand location is full, at which time the specification of the dictionary can be changed in order to expand the remainder of the compressed data using the second dictionary. If the definition allowed condition code 1 not to be set, it might be attempted to expand the next index symbol, which resulted from use of the second dictionary, by means of the first dictionary, and this might cause recognition of a general-operand data exception. For example, the next index symbol, which properly designates a character entry in the second dictionary, might designate the second half of a format-1 sibling descriptor in the first dictionary, and that second half might begin with a character, such as 0 (F0 hex), that would appear to be an invalid partial symbol length in a character entry.

4. A nullifying access-exception condition due to a reference to a dictionary or the symbol-translation table may result in the storing of data at or to the right of the location designated by the final address in general register R_1. This storing and the processing needed to produce the data stored will be repeated when COMPRESSION CALL is executed again to continue processing the same operands. The repeated processing will reduce the performance of the instruction execution, and it should be avoided by ensuring that the environment in which the program is executed is one in which page-translation-exception conditions for the dictionaries and symbol-translation table are infrequent.

5. Following is an example of how the compressed-data bit number (CBN) is used and set. In this example:

   - The operation is an expansion operation.
   - The CDSS in general register 0 is 0010 binary. Therefore, there are 1K entries in the expansion dictionary, and the length of an index symbol is 10 bits.
   - The second operand (compressed-data operand) begins at location 6000 hex and has a length of five bytes. The initial CBN is

7. Therefore, there are three index symbols to be expanded, and the final CBN will be 5.

- The compressed data beginning at location 6000 hex is 0081FF9FF8 hex. Therefore, the three index symbols are 103, 3FC, and 3FF hex.
- The first operand (expanded-data operand) begins at location 5000 hex and has a length of 64 bytes. The three index symbols are expanded to a total of 14 bytes of expanded data.

The following figure shows the initial and final contents of general registers R_1, $R_1 + 1$, R_2, and $R_2 + 1$, the contents of locations 6000-6004 hex in binary, and the way a cursor corresponding to the CBN is advanced during the expansion operation.

Register	Initial Contents in Hex	Final Contents in Hex
R_1	5000	500E
R_1+1	40	32
R_2	6000	6004
R_2+1	5	1

Contents of Locations 6000-6004 Hex in Binary

```
00000000 10000001 11111111 10011111 11111000
    ↑                ↑        ↑        ↑
 Initial                                Final
  CBN                                   CBN
  (7)                                   (5)
```

6. The reason for allowing a parent to have no more than 260 children is as follows. The parent can contain five identical child characters. Then, 255 different sibling characters are possible — all of these must be different from the child characters and each other, or else they may be wasted (never matched against), depending on the implementation. Thus, every possible child is permitted.

7. Symbol translation is for use by VTAM. VTAM will begin by doing compression by means of software and an adaptive dictionary. When the adaptive dictionary has matured such that the degree of compression becomes sufficiently good (crosses some threshold), VTAM will "freeze" (stop adapting) its dictionary, inform the other end of the session to freeze also, transform its adaptive dictionary to the dictionary form used by COMPRESSION CALL, and then use COMPRESSION CALL to continue on with the compression. The other end of the session can continue to use its frozen adaptive dictionary.

   Following is clarification about the STT offset. Assume VTAM uses a 4K-entry adaptive dictionary, which is the largest size VTAM uses. All of the entries in this dictionary correspond to character symbols because there are no sibling descriptors in the VTAM dictionary. The VTAM dictionary cannot map one-to-one to a COMPRESSION CALL dictionary because the latter requires that some of the entries be sibling descriptors. Therefore, VTAM must have an 8K-entry dictionary for use in the basic compression operation. Only the first hundred or so entries in the second 4K of the 8K need to be used, and these entries compensate for (take the place of) the entries in the first 4K that must be sibling descriptors. The STT can and should, to save space, begin immediately after those hundred or so entries in the second 4K. In this example, the index symbols will be 13 bits but will be transformed to 12-bit interchange symbols.

8. A program may place the dictionaries in pages that are managed by means of chaining fields at their beginnings. In this case, either the parts of a dictionary have to be moved to be compacted into contiguous locations or there have to be holes in the dictionaries. The definition of COMPRESSION CALL contains nothing explicitly to support holes. However, assuming there is at least one character that never appears in the expanded data, that character can be used as a child character in a parent entry or as a sibling character in a sibling descriptor to specify a child or children that will never be referenced, thus creating a hole.

9. The references to the operands, dictionaries, and symbol-translation table for COMPRESSION CALL may be multiple-access references. (See "Storage-Operand Consistency" on page 5-133.)

10. Setting the ZP control to one may provide improved performance on models in which the CMPSC-enhancement facility is installed.

11. Zero padding is not necessarily performed in every case where it is permissible.

12. Figure 7-217 on page 7-197 and Figure 7-219 on page 7-201 show possible forms (not the only possible forms) of the compression process

(without order preservation), the order preservation compression process and expansion processes. The figures do not show testing for or the results of dictionary errors.

13. As observed by this CPU, other CPUs, and the I/O subsystem, inconsistent results may be briefly stored in the first-operand location. See the section “Effects of CPU Retry” on page 11-3 for further details.

14. When the entropy-encoding option is specified the minimum dictionary size is 128-bytes or 16 entries. The dictionary must also be a multiple of 16 entries.

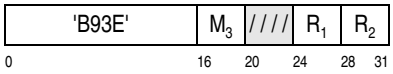
COMPUTE INTERMEDIATE MESSAGE DIGEST

KIMD $R_1,R_2[,M_3]$ [RRF-c]

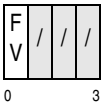


A function specified by the function code in general register 0 is performed.

When the message-security-assist extension 12 is not installed, bits 16-19, the M_3 field, of the instruction are reserved. Bits 20-23 of the instruction and the R_1 field are reserved. Reserved fields should contain zeros; otherwise, the program may not operate compatibly in the future.

When the message-security-assist extension 12 is installed, the M_3 field is meaningful. When the message-security-assist extension 12 is installed and bit 0 of the M_3 field is one, the flags (F) field is defined in bit positions 48-55 of general register 0.

The M_3 field has the following format:

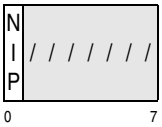


The bits of the M_3 field are defined as follows:

- ***Flags Field Valid (FV):*** The FV bit, bit 0 of the M_3 field, controls whether the flags field in general register 0 is valid. When the FV bit is zero, the flags field is not valid. When the FV bit is one, the flags field is valid.
- ***Reserved:*** Bits 1-3 are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.

Bit positions 0-31 of general register 0 are ignored for all function codes. When bit 0 of the M_3 field is zero, bit positions 32-55 of general register 0 are ignored. When bit 0 of the M_3 field is one, bit positions 32-47 of general register 0 are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future. When bit 0 of the M_3 field is one, the flags (F) field of general register 0 contains additional operation controls.

Flags (F): Bit positions 48-55 of general register 0 contain an 8-bit flags field controlling the operation of the function. The flags field is meaningful only when the message-security-assist extension 12 is installed, bit 0 of the M_3 field is one, and the function code in bit positions 57-63 of general register 0 designates a specific function (see each flag description for details). The format of the flags field is as follows:



The individual flag fields are as follows:

Reserved: Bits 1-7 of the flags field are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.

No-ICV-Parameter (NIP): Bit 0 of the flags field indicates whether the ICV parameter value is provided by the program in the parameter block. The NIP flag is meaningful only when the function code in bit positions 57-63 of general register 0 of COMPUTE INTERMEDIATE MESSAGE DIGEST designates a SHA-3 or SHAKE function (function codes 32-37).

When the NIP flag is zero, the ICV parameter value provided by the program in the parameter block is used as the ICV; otherwise, zeros are used as the ICV.

Function Code (FC): Bit positions 57-63 of general register 0 contain the function code. Figure 7-223 shows the assigned function codes for COMPUTE INTERMEDIATE MESSAGE DIGEST. When the message-security-assist extension 13 is installed, function code 127 is valid for COMPUTE INTERMEDIATE MESSAGE DIGEST. All other function codes are unassigned. Bit 56 of general register 0 must be zero; otherwise, a specification exception is recognized.

The assigned function codes are enumerated in Figure 7-223. All other function codes are unassigned.

Code	Function	Parm. Block Size (bytes)	Data Block Size (bytes)
0	KIMD-Query *	16	—
1	KIMD-SHA-1 *	20	64

Figure 7-223. Function Codes for COMPUTE INTERMEDIATE MESSAGE DIGEST (Part 1 of 2)

Code	Function	Parm. Block Size (bytes)	Data Block Size (bytes)
65	KIMD-GHASH	32	16
127	KIMD-Query-Authentication-Information	V	—

Explanation:

— Not applicable

* Function is also defined in the ESA/390 architectural mode and the ESA/390-compatibility mode. It is unpredictable whether other function codes are available in the ESA/390-compatibility mode.

V Variable parameter block size. See each format-x parameter block for the exact size of that parameter block.

Figure 7-223. Function Codes for COMPUTE INTERMEDIATE MESSAGE DIGEST (Part 2 of 2) (Continued)

General register 1 contains the logical address of the leftmost byte of the parameter block in storage. In the 24-bit addressing mode, the contents of bit positions 40-63 of general register 1 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of general register 1 constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register 1 constitute the address.

The query function provides the means of indicating the availability of the other functions. The contents of general registers R_2 and $R_2 + 1$ are ignored for the query function.

The query-authentication-information function provides the information that can be used by the program to authenticate the running instruction's firmware code level (IFCL) currently installed on the model. The contents of general registers R_2, and $R_2 + 1$ are ignored for the query-authentication-information function.

For all other functions, the second operand is processed as specified by the function code using an initial chaining value in the parameter block, and the result replaces the chaining value in the parameter block. For the SHA-3 and SHAKE functions, an initial chaining value in the parameter block is not used when the NIP flag is one. The operation proceeds

until the end of the second-operand location is reached or a CPU-determined number of bytes have been processed, whichever occurs first. The result is indicated in the condition code.

The R_2 field designates an even-odd pair of general registers and must designate an even-numbered register other than general register 0; otherwise, a specification exception is recognized.

The location of the leftmost byte of the second operand is specified by the contents of the R_2 general register. The number of bytes in the second-operand location is specified in general register $R_2 + 1$. For all functions except KIMD-query, the number of bytes in general register $R_2 + 1$ must be a multiple of the data block size for the function; otherwise, a specification exception is recognized.

As part of the operation, the address in general register R_2 is incremented by the number of bytes processed from the second operand, and the length in general register $R_2 + 1$ is decremented by the same number. The formation and updating of the address and length is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general register R_2 constitute the address of the second operand, and the contents of bit positions 0-39 are ignored; bits 40-63 of the updated address replace the corresponding bits in general register R_2, carries out of bit position 40 of the updated address are ignored, and the contents of bit positions 32-39 of general register R_2 are set to zeros. In the 31-bit addressing mode, the contents of bit positions 33-63 of general register R_2 constitute the address of the second operand, and the contents of bit positions 0-32 are ignored; bits 33-63 of the updated address replace the corresponding bits in general register R_2, carries out of bit position 33 of the updated address are ignored, and the content of bit position 32 of general register R_2 is set to zero. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register R_2 constitute the address of the second operand; bits 0-63 of the updated address replace the contents of general register R_2 and carries out of bit position 0 are ignored.

In both the 24-bit and the 31-bit addressing modes, the contents of bit positions 32-63 of general register $R_2 + 1$ form a 32-bit unsigned binary integer which specifies the number of bytes in the second operand; and the updated value replaces the contents of bit positions 32-63 of general register $R_2 + 1$. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register $R_2 + 1$ form a 64-bit unsigned binary integer which specifies the number of bytes in the second operand; and the updated value replaces the contents of general register $R_2 + 1$.

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers R_2 and $R_2 + 1$, always remain unchanged.

Figure 7-224 shows the contents of the general registers just described.

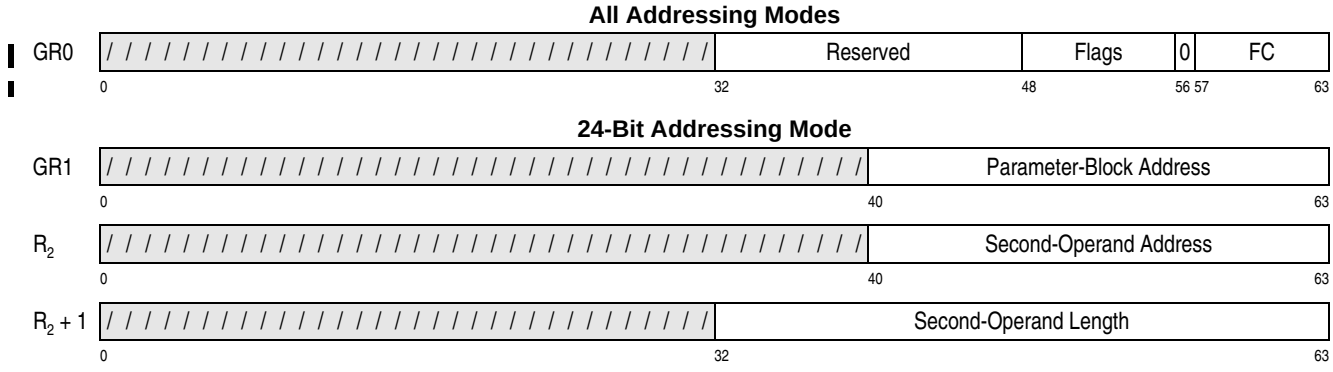

Figure 7-224. General Register Assignment for KIMD (Part 1 of 2)

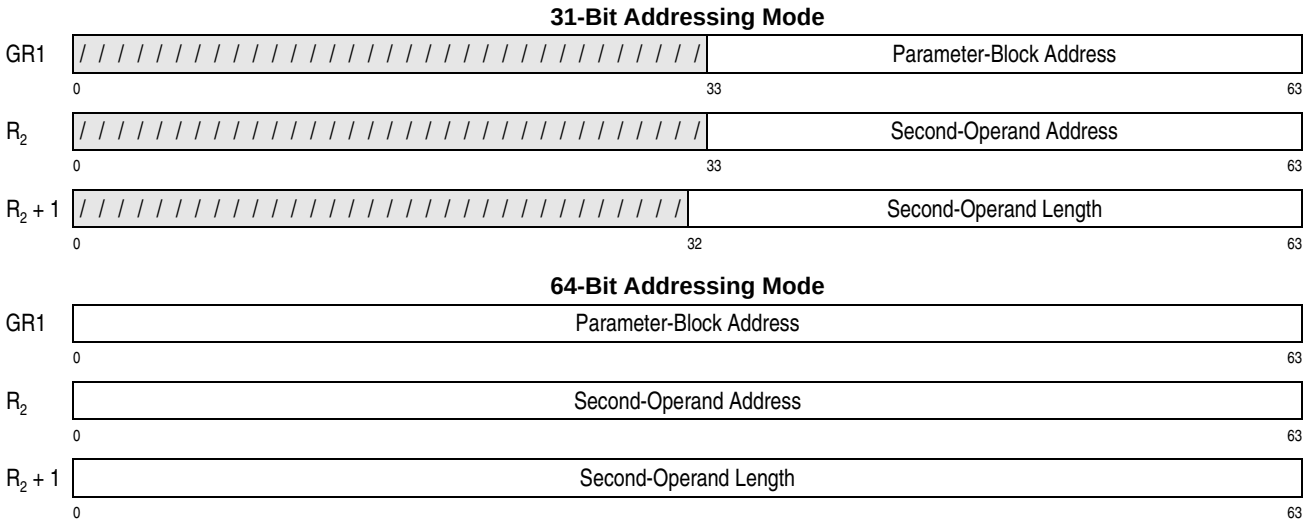

Figure 7-224. General Register Assignment for KIMD (Part 2 of 2)

In the access-register mode, access registers 1 and R_2 specify the address spaces containing the parameter block and second operand, respectively.

The result is obtained as if processing starts at the left end of both the first and second operands and proceeds to the right, block by block. The digest operation is ended when the number of bytes in the second operand as specified in general register $R_2 + 1$ have been processed and placed at the first-operand location or when a CPU-determined number of blocks that is less than the length of the second operand have been processed. The CPU-determined number of blocks depends on the model, and may be a different number each time the instruction is executed. The CPU-determined number of blocks is usually nonzero. In certain unusual situations, this number may be zero, and condition code 3 may be set with no progress. However, the CPU protects against endless reoccurrence of this no-progress case.

If the CPU is enabled to update counters in the cryptography-counter set, then subsequent to processing all bytes of the second operand, the appropriate counter is updated.

When the chaining-value field overlaps any portion of the second operand, the result in the chaining-value field is unpredictable.

Normal completion occurs when the digest operation has ended and, when applicable, a counter in the cryptography-counter set has been updated. Partial completion occurs when a CPU-determined number of blocks that is less than the length of the second operand have been processed or when the CPU is enabled to update a counter in the cryptography-counter set and the appropriate counter has not yet been updated.

When the operation ends due to normal completion, condition code 0 is set, the second-operand address in general register R_2 is updated, and the second-operand length in $R_2 + 1$ is zero. When the operation ends due to partial completion, condition code 3 is set. In this case, if the CPU is enabled to update counters in the cryptography-counter set, all of the second operand has been processed, and the appropriate counter is not accessible, then the resulting value placed in general register $R_2 + 1$ is zero; otherwise the resulting value placed in general register $R_2 + 1$ is nonzero.

When the second-operand length is initially zero, the following occurs. The second operand is not accessed and the second-operand address and second-operand length in general registers R_2 and $R_2 + 1$, respectively, are not changed. If the CPU is not enabled to update counters in the cryptography-counter set, then condition code 0 is set. If the CPU is enabled to update counters in the cryptography-counter set, and the appropriate counter is accessible, then the appropriate counter is updated and condition code 0 is set. If the CPU is enabled to update counters in the cryptography-counter set, and the appropriate counter is not accessible, then the condition code remains unchanged and an access excep-

tion is recognized for the location of the appropriate counter.

A PER storage-alteration event is recognized, when applicable, for the portion of the parameter block that is stored. A PER zero-address-detection event is recognized, when applicable, for the second-operand location and for the parameter block. When PER events are detected for more than one location, it is unpredictable which location is identified in the PER access identification (PAID) and PER ASCE ID (AI).

As observed by this CPU, other CPUs, and channel programs, references to the parameter block and storage operands may be multiple-access references, accesses to these storage locations are not necessarily block-concurrent, and the sequence of these accesses or references is undefined.

Access exceptions may be reported for a larger portion of the second operand than is processed in a single execution of the instruction; however, access exceptions are not recognized for locations beyond the length of the second operand nor for locations more than 4K bytes beyond the current location being processed.

Symbols Used in Function Descriptions

The following symbols are used in the subsequent description of the COMPUTE INTERMEDIATE MESSAGE DIGEST and COMPUTE LAST MESSAGE DIGEST functions. Further description of the secure hash algorithm may be found in Reference [15.] on page xxxii. Further description of the GCM (Galois/counter mode) multiplication over GF(2^{128}) may be found in Reference [17.] on page xxxii. Further description of the SHA-3 and SHAKE hash algorithms and the KECCAK family of sponge functions may be found in Reference [21.] on page xxxii.

KIMD-Query (KIMD Function Code 0)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-224 on page 7-205.

The parameter block used for the function has the following format:

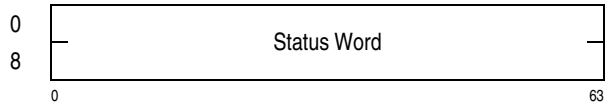

Figure 7-229. Parameter Block for KIMD-Query

A 128-bit status word is stored in the parameter block. Bits 0-127 of this field correspond to function codes 0-127, respectively, of the COMPUTE INTERMEDIATE MESSAGE DIGEST instruction. When a bit is one, the corresponding function is installed; otherwise, the function is not installed.

Condition code 0 is set when execution of the KIMD-Query function completes; condition code 3 is not applicable to this function.

KIMD-SHA-1 (KIMD Function Code 1)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-224 on page 7-205.

The parameter block used for the function has the following format:

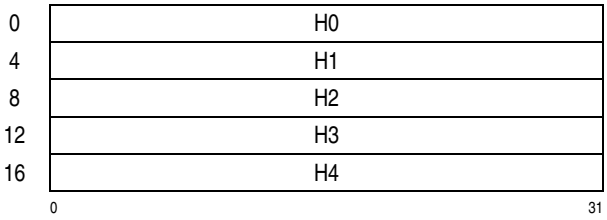

Figure 7-230. Parameter Block for KIMD-SHA-1

A 20-byte intermediate message digest is generated for the 64-byte message blocks in operand 2 using the SHA-1 block digest algorithm with the 20-byte chaining value (called H fields) in the parameter block. The generated intermediate message digest, also called the output chaining value (OCV), is stored in the chaining-value field of the parameter block. The operation is shown in Figure 7-231.

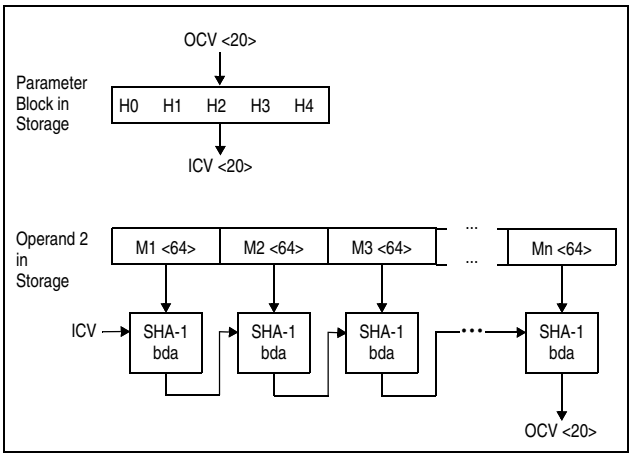

Figure 7-231. KIMD-SHA-1

KIMD-SHA-256 (KIMD Function Code 2)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-224 on page 7-205.

The parameter block used for the function has the following format:

0	H0
4	H1
8	H2
12	H3
16	H4
20	H5
24	H6
28	H7

0 31

Figure 7-232. Parameter Block for KIMD-SHA-256

A 32-byte intermediate message digest is generated for the 64-byte message blocks in operand 2 using the SHA-256 block digest algorithm with the 32-byte chaining value (called H fields) in the parameter block. The generated intermediate message digest, also called the output chaining value (OCV), is stored in the chaining-value field of the parameter block. The operation is shown in Figure 7-233.

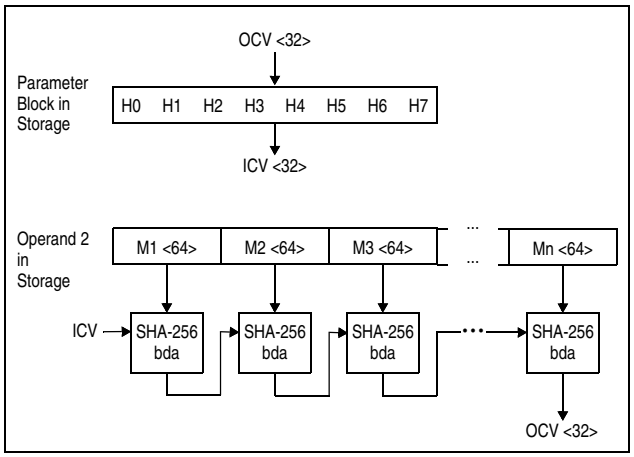

Figure 7-233. KIMD-SHA-256

KIMD-SHA-512 (KIMD Function Code 3)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-224 on page 7-205.

The parameter block used for the function has the following format:

0	H0
8	H1
16	H2
24	H3
32	H4
40	H5
48	H6
56	H7

0 63

Figure 7-234. Parameter Block for KIMD-SHA-512

A 64-byte intermediate message digest is generated for the 128-byte message blocks in operand 2 using the SHA-512 block digest algorithm with the 64-byte chaining value (called H fields) in the parameter block. The generated intermediate message digest, also called the output chaining value (OCV), is stored in the chaining-value field of the parameter block. The operation is shown in Figure 7-235.

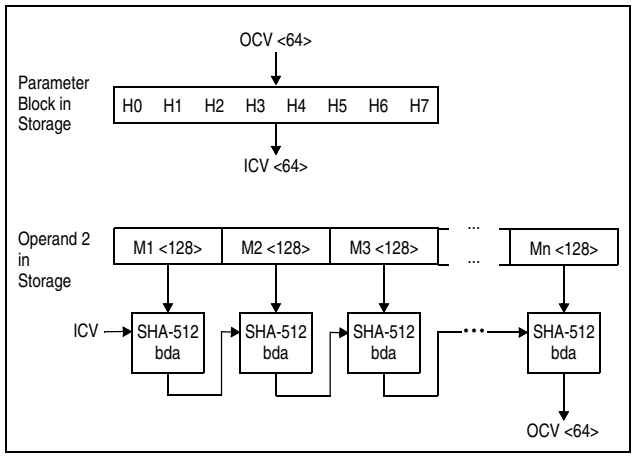

Figure 7-235. KIMD-SHA-512

KIMD-SHA3-224 (KIMD Function Code 32)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-224 on page 7-205.

The parameter block used for the function has the following format:

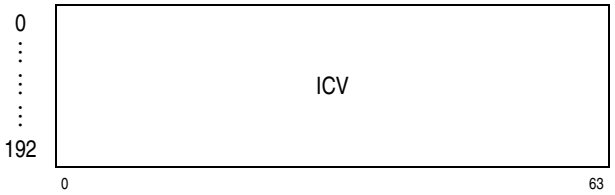

Figure 7-236. Parameter Block for KIMD-SHA3-224

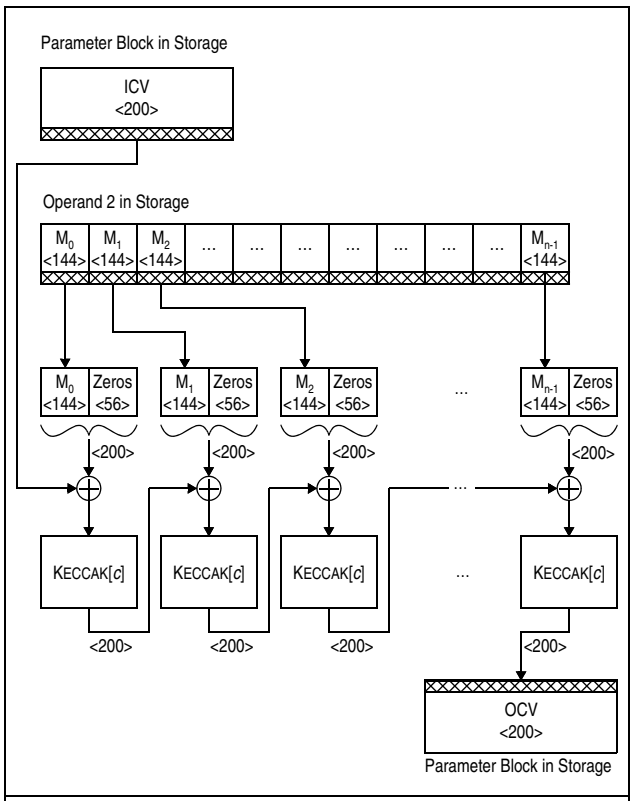
The initial chaining value (ICV) represents the 1600-bit state array used by the KECCAK[*c*] functions which implement the SHA-3 algorithms described in Reference [21.] on page xxxii.

A 200-byte intermediate message digest is generated for the 144-byte message blocks in operand 2 using the KECCAK[*c*] algorithm with the 200-byte initial chaining value in the parameter block when the NIP flag (bit 0 of the flags field in general register 0) is zero or with 200 bytes of zeros when the NIP flag is one. The generated intermediate message digest, also called the output chaining value (OCV), is stored in the chaining-value field of the parameter block and the NIP flag is set to zero if the operand 2 length is not initially zero. See programming note 10 on page 7-218 regarding the numbering of the bits in the parameter block and second operand as compared with the numbering of the bits in the state array.

The operation is shown in Figure 7-237.



Explanation:

⊠	The bit positions of each byte of the parameter block and the message block(s) appear in storage in descending order from left to right, respective to their corresponding bit positions in the bytes of the KECCAK[*c*] state array.
<#>	Size of an item in bytes
ICV	Input chaining value (in the parameter block when the NIP flag is zero or 200 bytes of zeros when the NIP flag is one)
M	144-byte block of the second-operand message
n	Number of blocks in the second-operand (that is, the second operand length divided by the block size of 144)
OCV	Output chaining value (in the parameter block)

Figure 7-237. KIMD-SHA3-224 Processing

KIMD-SHA3-256 (KIMD Function Code 33)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-224 on page 7-205.

The parameter block used for the function has the following format:

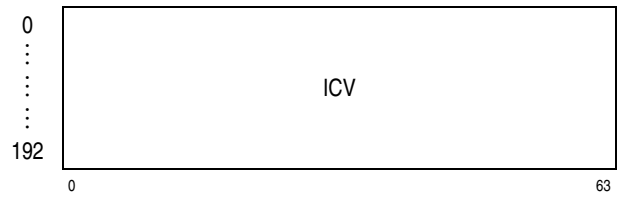


Figure 7-238. Parameter Block for KIMD-SHA3-256

The initial chaining value (ICV) represents the 1600-bit state array used by the KECCAK[*c*] functions which implement the SHA-3 algorithms described in Reference [21.] on page xxxii.

A 200-byte intermediate message digest is generated for the 136-byte message blocks in operand 2 using the KECCAK[*c*] algorithm with the 200-byte initial chaining value in the parameter block when the NIP flag (bit 0 of the flags field in general register 0) is zero or with 200 bytes of zeros when the NIP flag is one. The generated intermediate message digest, also called the output chaining value (OCV), is stored in the chaining-value field of the parameter block and the NIP flag is set to zero if the operand 2 length is not initially zero. See programming note 10 on page 7-218 regarding the numbering of the bits in the parameter block and second operand as compared with the numbering of the bits in the state array.

The operation is shown in Figure 7-239.

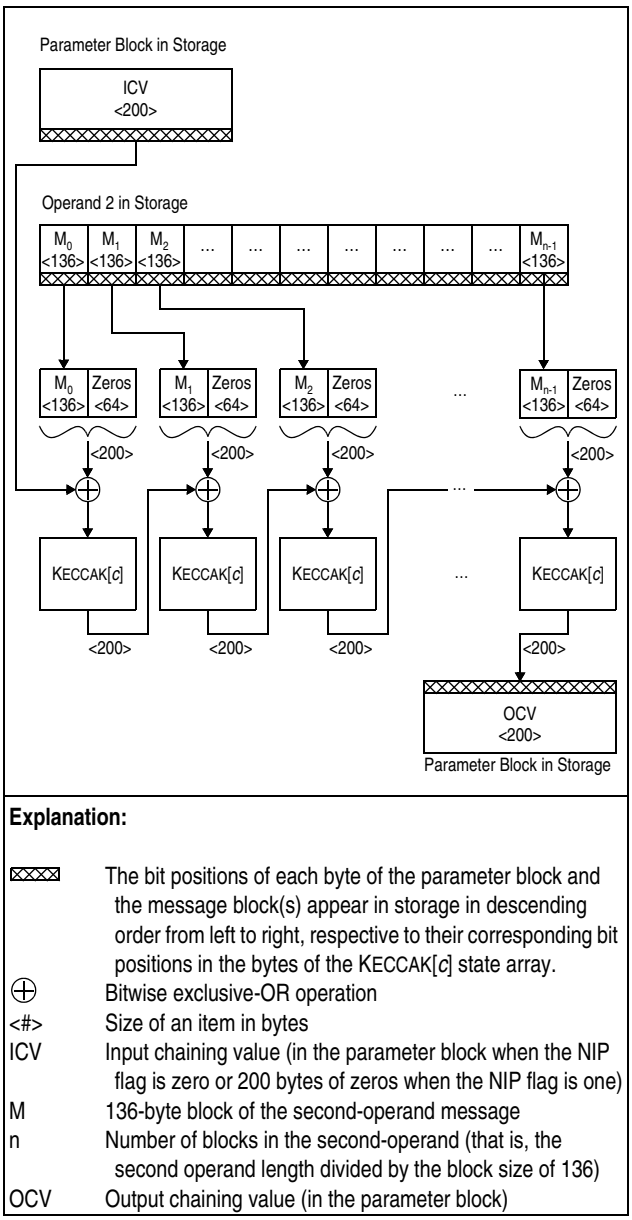

Figure 7-239. KIMD-SHA3-256 Processing

KIMD-SHA3-384 (KIMD Function Code 34)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-224 on page 7-205.

The parameter block used for the function has the following format:

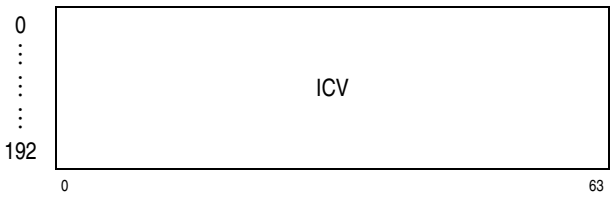

Figure 7-240. Parameter Block for KIMD-SHA3-384

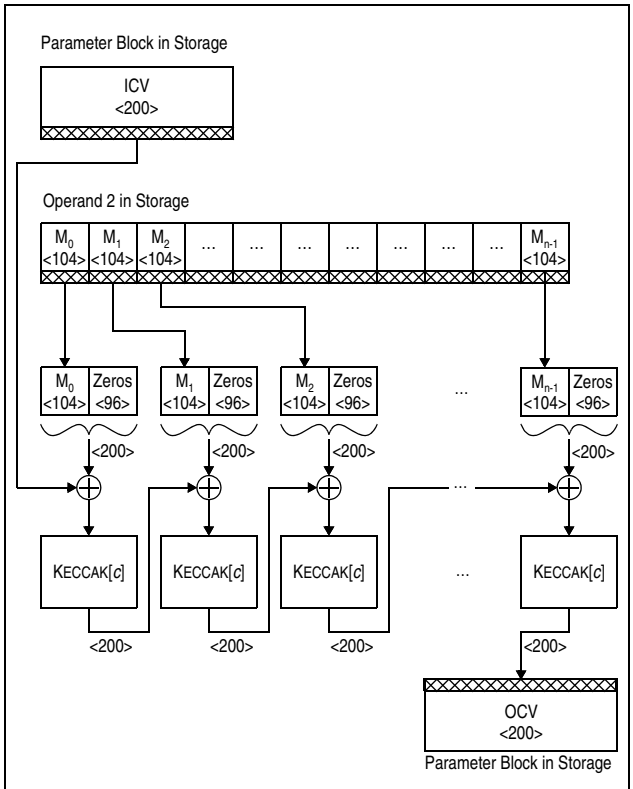
The initial chaining value (ICV) represents the 1600-bit state array used by the KECCAK[*c*] functions which implement the SHA-3 algorithms described in Reference [21.] on page xxxii.

A 200-byte intermediate message digest is generated for the 104-byte message blocks in operand 2 using the KECCAK[*c*] algorithm with the 200-byte initial chaining value in the parameter block when the NIP flag (bit 0 of the flags field in general register 0) is zero or with 200 bytes of zeros when the NIP flag is one. The generated intermediate message digest, also called the output chaining value (OCV), is stored in the chaining-value field of the parameter block and the NIP flag is set to zero if the operand 2 length is not initially zero. See programming note 10 on page 7-218 regarding the numbering of the bits in the parameter block and second operand as compared with the numbering of the bits in the state array.

The operation is shown in Figure 7-241.



Explanation:

⊠	The bit positions of each byte of the parameter block and the message block(s) appear in storage in descending order from left to right, respective to their corresponding bit positions in the bytes of the KECCAK[*c*] state array.
⊕	Bitwise exclusive-OR operation
<#>	Size of an item in bytes
ICV	Input chaining value (in the parameter block when the NIP flag is zero or 200 bytes of zeros when the NIP flag is one)
M	104-byte block of the second-operand message
n	Number of blocks in the second-operand (that is, the second operand length divided by the block size of 104)
OCV	Output chaining value (in the parameter block)

Figure 7-241. KIMD-SHA3-384 Processing

KIMD-SHA3-512 (KIMD Function Code 35)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-224 on page 7-205.

The parameter block used for the function has the following format:

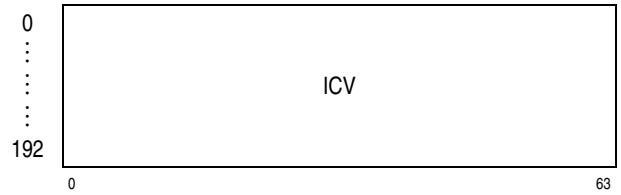


Figure 7-242. Parameter Block for KIMD-SHA3-512

The initial chaining value (ICV) represents the 1600-bit state array used by the KECCAK[*c*] functions which implement the SHA-3 algorithms described in Reference [21.] on page xxxii.

A 200-byte intermediate message digest is generated for the 72-byte message blocks in operand 2 using the KECCAK[*c*] algorithm with the 200-byte initial chaining value in the parameter block when the NIP flag (bit 0 of the flags field in general register 0) is zero or with 200 bytes of zeros when the NIP flag is one. The generated intermediate message digest, also called the output chaining value (OCV), is stored in the chaining-value field of the parameter block and the NIP flag is set to zero if the operand 2 length is not initially zero. See programming note 10 on page 7-218 regarding the numbering of the bits in the parameter block and second operand as compared with the numbering of the bits in the state array.

The operation is shown in Figure 7-243.

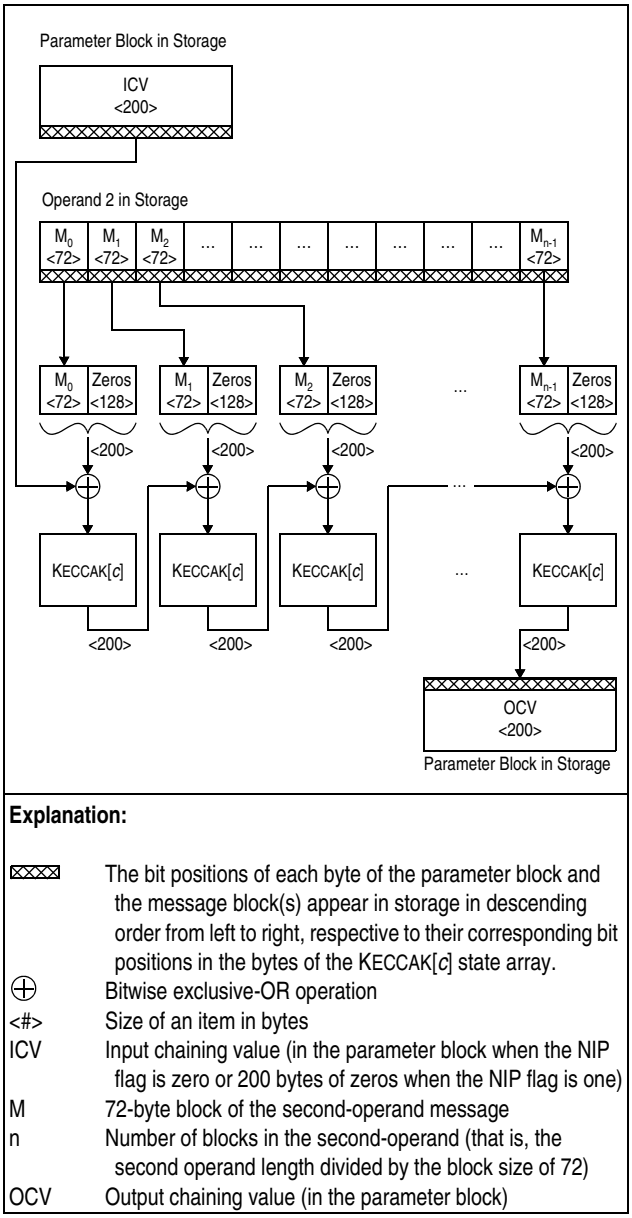

Figure 7-243. KIMD-SHA3-512 Processing

KIMD-SHAKE-128 (KIMD Function Code 36)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-224 on page 7-205.

The parameter block used for the function has the following format:

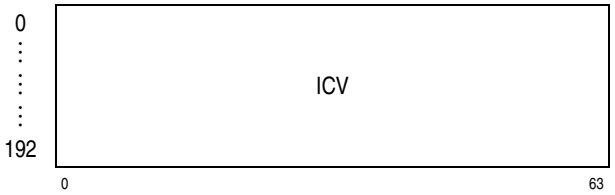

Figure 7-244. Parameter Block for KIMD-SHAKE-128

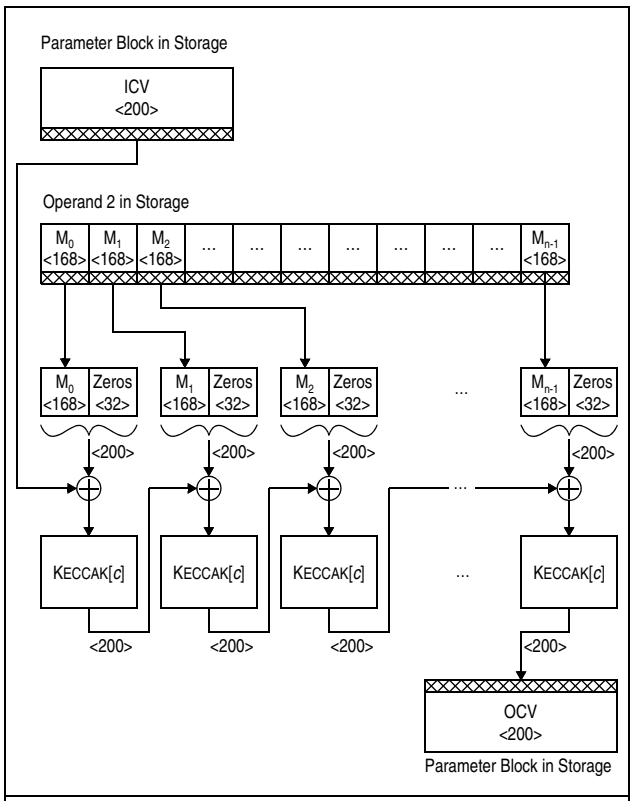
The initial chaining value (ICV) represents the 1600-bit state array used by the KECCAK[*c*] functions which implement the SHAKE algorithms described in Reference [21.] on page xxxii.

A 200-byte intermediate message digest is generated for the 168-byte message blocks in operand 2 using the KECCAK[*c*] algorithm with the 200-byte initial chaining value in the parameter block when the NIP flag (bit 0 of the flags field in general register 0) is zero or with 200 bytes of zeros when the NIP flag is one. The generated intermediate message digest, also called the output chaining value (OCV), is stored in the chaining-value field of the parameter block and the NIP flag is set to zero if the operand 2 length is not initially zero. See programming note 10 on page 7-218 regarding the numbering of the bits in the parameter block and second operand as compared with the numbering of the bits in the state array.

The operation is shown in Figure 7-245.



Explanation:

⊠	The bit positions of each byte of the parameter block and the message block(s) appear in storage in descending order from left to right, respective to their corresponding bit positions in the bytes of the KECCAK[*c*] state array.
⊕	Bitwise exclusive-OR operation
<#>	Size of an item in bytes
ICV	Input chaining value (in the parameter block when the NIP flag is zero or 200 bytes of zeros when the NIP flag is one)
M	168-byte block of the second-operand message
n	Number of blocks in the second-operand (that is, the second operand length divided by the block size of 168)
OCV	Output chaining value (in the parameter block)

Figure 7-245. KIMD-SHAKE-128 Processing

KIMD-SHAKE-256 (KIMD Function Code 37)

The operands, addresses, parameter-block format, and operation of the KIMD-SHAKE-256 function are identical to those of the KIMD-SHA3-256 function.

Note: A separate function code for KIMD-SHAKE-256 is defined to retain symmetry with the KLMD functions (where the operation of KLMD-SHAKE-256 differs from that of KLMD-SHA3-256).

KIMD-GHASH (Function Code 65)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-224 on page 7-205.

The parameter block used for the KIMD-GHASH function has the following format:

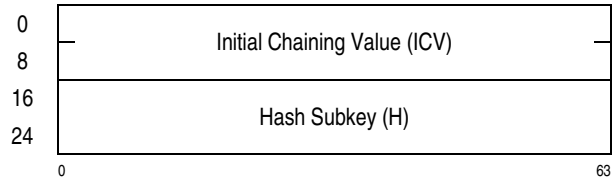


Figure 7-246. Parameter Block for KIMD-GHASH

The initial-chaining value is in byte offsets 0-15 of the parameter block, and the hash subkey is in byte offsets 16-31 of the parameter block.

The GHASH for the 16-byte message blocks (M1, M2, …, Mn) in operand 2 is computed using the hash subkey and the 128-bit chaining value.

The first message block is exclusive-ORed with the initial chaining value (ICV) in the parameter block. The result of the exclusive-OR operation and the hash subkey (H) are multiplied using a Galois/counter-mode (GCM) multiplication operation over a Galois field (GF(2^{128})) to produce the chaining value for the next message block. The process is repeated until all message blocks have been processed, or until a CPU-determined number of message blocks have been processed.

The GHASH, called the output chaining value (OCV), is stored into the Initial-chaining-value field of the parameter block. The operation is shown in Figure 7-247 on page 7-215.

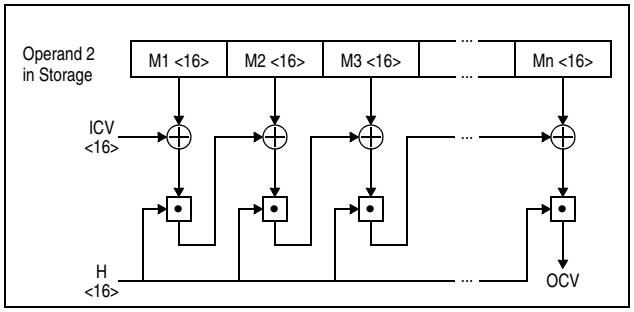

Figure 7-247. KIMD-GHASH

KIMD-Query-Authentication-Information (Function Code 127)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-224 on page 7-205.

The KIMD-query-authentication-information function stores the information that can be used by the program to authenticate the running instruction's firmware code level (IFCL) currently installed on the model into the format-0 parameter block for KIMD-query-authentication-information. Condition code 0 is set when execution of the KIMD-query-authentication-information function completes; condition code 3 is not applicable to this function.

The format-0 parameter block used for the KIMD-query-authentication-information function has the following format:

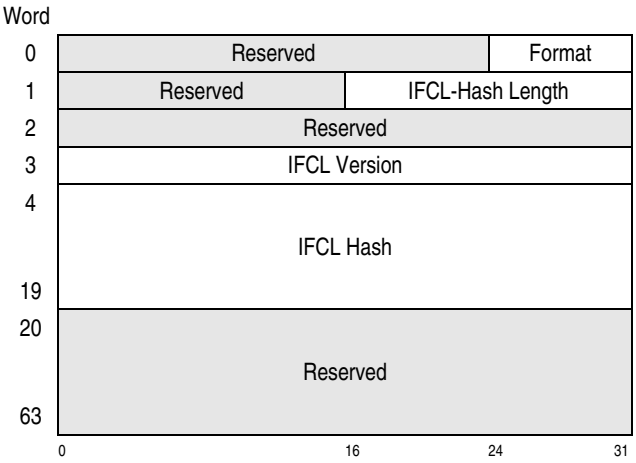

Figure 7-248. Format-0 Parameter Block for KIMD-Query-Authentication-Information

The format-0 parameter block contains the following fields:

Reserved: Bytes 0-2 of word 0, bytes 0-1 of word 1, word 2, and words 20-63 are reserved and stored as zeros.

Format: Byte 3 of word 0 contains an 8-bit unsigned binary integer whose value specifies the format of the parameter block. A format value of zero indicates a format-0 parameter block. When a format-0 parameter block is stored, the value of this field is set to zero.

IFCL-Hash Length: Bytes 2-3 of word 1 contain a 16-bit unsigned binary integer specifying the number of bytes of the IFCL hash stored in the IFCL hash field. When the IFCL hash is less than or equal to 64 bytes, the IFCL-hash length field is set to the actual length of the IFCL hash. When the IFCL hash is larger than 64 bytes, the IFCL-hash length field is set to 64.

IFCL Version: Word 3 contains a 32-bit unsigned binary integer specifying the version number of the IFCL.

IFCL Hash: Words 4-19 contain the hash value of the IFCL. The IFCL-hash length field specifies the number of bytes that are in the IFCL hash field. The IFCL hash value is left aligned. When the IFCL hash is less than 64 bytes, it is padded with zeros on the right. When the IFCL hash is larger than 64 bytes, only the leftmost 64 bytes of the IFCL hash are stored.

Special Conditions

A specification exception is recognized and no other action is taken if any of the following occurs:

1. Bit 56 of general register 0 is not zero.
2. Bits 57-63 of general register 0 specify an unassigned or uninstalled function code.
3. The R_2 field designates an odd-numbered register or general register 0.
4. The second-operand length is not a multiple of the data block size of the designated function (see Figure 7-223 on page 7-204 for COMPUTE INTERMEDIATE MESSAGE DIGEST functions).

Resulting Condition Code:

0 Normal completion
1 --
2 --
3 Partial completion

Program Exceptions:

- Access (fetch, operand 2 and message bit length; store, query parameter block and query-authentication-information parameter block; fetch and store, chaining value, cryptography counter)
- Operation (if the message-security assist is not installed)
- Specification
- Transaction constraint

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B	Operation exception.
7.C	Transaction constraint
8.	Specification exception due to invalid function code or invalid register number.
9.	Specification exception due to invalid operand length.
10.	Access exceptions for an access to a cryptography counter and second-operand length originally zero.
11.	Condition code 0 due to second-operand length originally zero.
12.	Access exceptions for an access to the parameter block or second operand.
13.	Condition code 3 due to partial completion (second-operand length still nonzero).
14.	Condition code 3 due to second-operand length stepped to zero and access-exception condition detected for an access to a cryptography counter.
15.	Condition code 0 due to normal completion (second-operand length originally nonzero, but stepped to zero).

Figure 7-249. Priority of Execution: KIMD

Programming Notes:

1. The performance of the query function (code 0) may be significantly slower than that of simply examining a location in storage. If the program needs to frequently test for the availability of a function, it should perform the query function once during initialization; subsequently it should examine the stored results of the query function in memory with an instruction such as TEST UNDER MASK.
2. Bit 56 of general register 0 is reserved for future extension and should be set to zero.

3. When condition code 3 is set, the second operand address and length in general registers R_2 and $R_2 + 1$, respectively, and the chaining-value in the parameter block are usually updated such that the program can simply branch back to the instruction to continue the operation.

   For unusual situations, the CPU protects against endless reoccurrence for the no-progress case. Thus, the program can safely branch back to the instruction whenever condition code 3 is set with no exposure to an endless loop.

4. If the length of the second operand is nonzero initially and condition code 0 is set, the registers are updated in the same manner as for condition code 3; the chaining value in this case is such that additional operands can be processed as if they were part of the same chain.

5. The instructions COMPUTE INTERMEDIATE MESSAGE DIGEST and COMPUTE LAST MESSAGE DIGEST are designed to be used by a security service application programming interface (API). These APIs provide the program with means to compute the digest of messages of almost unlimited size, including those too large to fit in storage all at once. This is accomplished by permitting the program to pass the message to the API in parts. The following programming notes are described in terms of these APIs.

6. Before processing the first part of a message, the program must set the initial values for the chaining-value field. For SHA-1, the initial hexadecimal chaining values are listed as follows:

   ```
   H0 = 6745  2301
   H1 = EFCD  AB89
   H2 = 98BA  DCFE
   H3 = 1032  5476
   H4 = C3D2  E1F0
   ```

   For SHA-256, the initial hexadecimal chaining values are listed as follows:

   ```
   H0 = 6A09  E667
   H1 = BB67  AE85
   H2 = 3C6E  F372
   H3 = A54F  F53A
   H4 = 510E  527F
   H5 = 9B05  688C
   H6 = 1F83  D9AB
   H7 = 5BE0  CD19
   ```

   For SHA-512, the initial hexadecimal chaining value are listed as follows:

   ```
   H0 = 6A09  E667  F3BC  C908
   H1 = BB67  AE85  84CA  A73B
   H2 = 3C6E  F372  FE94  F82B
   H3 = A54F  F53A  5F1D  36F1
   H4 = 510E  527F  ADE6  82D1
   H5 = 9B05  688C  2B3E  6C1F
   H6 = 1F83  D9AB  FB41  BD6B
   H7 = 5BE0  CD19  137E  2179
   ```

   For the SHA3 and SHAKE functions, the initial chaining value must be set to all zeros.

7. When computing a message digest, the program may not initially be aware of the total message-bit length; for example, for a message being read from an I/O device, the message-bit length may not be known until the final block is read. When computing a message digest for a message whose length is not known, or for a message where it is known that the last message block is not included in the calculation, COMPUTE INTERMEDIATE MESSAGE DIGEST may be used. When computing a message digest for a message that includes the last block, COMPUTE LAST MESSAGE DIGEST must be used.

8. The SHA-224 algorithm is the same as the SHA-256 algorithm, except that the initial chaining values and the final message digest lengths are different. The program may obtain the SHA-224 message digest using the SHA-256 functions with the following two actions:

   a. The following initial hexadecimal chaining values for SHA-224 are used:

      ```
      H0 = C105  9ED8
      H1 = 367C  D507
      H2 = 3070  DD17
      H3 = F70E  5939
      H4 = FFC0  0B31
      H5 = 6858  1511
      H6 = 64F9  8FA7
      H7 = BEFA  4FA4
      ```

   b. The 224-bit message digest is obtained by truncating the final message digest to its leftmost 224 bits.

9. The SHA-384 algorithm is the same as the SHA-512 algorithm, except that the initial chaining values and the final message digest lengths are different. The program may obtain the SHA-384

message digest using the SHA-512 functions with the following two actions:

a. The following initial hexadecimal chaining values for SHA-384 are used:

H0 = CBBB 9D5D C105 9ED8
H1 = 629A 292A 367C D507
H2 = 9159 015A 3070 DD17
H3 = 152F ECD8 F70E 5939
H4 = 6733 2667 FFC0 0B31
H5 = 8EB4 4A87 6858 1511
H6 = DB0C 2E0D 64F9 8FA7
H7 = 47B5 481D BEFA 4FA4

b. The 384-bit message digest is obtained by truncating the final message digest to its leftmost 384 bits.

10. For the SHA3 and SHAKE functions (for both KIMD and KLMD), the KECCAK[*c*] algorithm uses a 1,600-bit state array in the parameter block. The state array comprises 25 *lanes* having 64 bits each. The bits of the state array are numbered from 0 to from 1,599, and the bits of each lane are numbered from 0 to 63.

    In the parameter block, the bytes of the state array appear in ascending order from left-to-right; but within each byte, the bits appear in descending order from left to right. That is, byte 0 of the parameter block contains (from left to right) bits 7, 6, 5, 4, 3, 2, 1, and 0 of the state array; byte 1 contains bits 15, 14, 13, 12, 11, 10, 9 and 8 of the state array; and so forth. When represented in memory, the bit positions of any individual lane of the state array correspond to powers of two, as shown below.

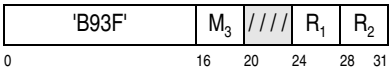
Byte	0								1									6								7							
Lane Bit	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	...	55	54	53	52	51	50	49	48	63	62	61	60	59	58	57	56

    The bit ordering of the parameter block described above also applies to the message bytes of the second operand. For the KLMD-SHAKE functions, the results stored in the first operand are similar to that of the parameter block in that the left-to-right ordering of bits within each byte is 7, 6, 5, 4, 3, 2, 1, and 0.

11. For the GHASH function, the hash subkey, H, is the result of encrypting a 128-bit zero using the AES encryption algorithm with a 128-bit, 192-bit, or 256-bit cryptographic key.

COMPUTE LAST MESSAGE DIGEST

KLMD $R_1,R_2[,M_3]$ [RRF-c]

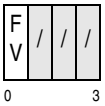


A function specified by the function code in general register 0 is performed.

When the message-security-assist extension 12 is not installed, bits 16-19, the M_3 field, of the instruction are reserved. Bits 20-23 of the instruction are reserved, and for all functions except KLMD-SHAKE-128 and KLMD-SHAKE-256, the R_1 field is reserved. Reserved fields should contain zeros; otherwise, the program may not operate compatibly in the future.

When the message-security-assist extension 12 is installed, the M_3 field is meaningful. When the message-security-assist extension 12 is installed and bit 0 of the M_3 field is one, the flags (F) field is defined in bit positions 48-55 of general register 0.

The M_3 field has the following format:



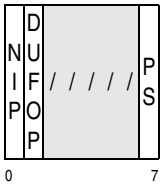
The bits of the M_3 field are defined as follows:

- ***Flags Field Valid (FV):*** The FV bit, bit 0 of the M_3 field, controls whether the flags field in general register 0 is valid. When the FV bit is zero, the flags field is not valid. When the FV bit is one, the flags field is valid.
- ***Reserved:*** Bits 1-3 are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.

Bit positions 0-31 of general register 0 are ignored for all function codes. When bit 0 of the M_3 field is zero, bit positions 32-55 of general register 0 are ignored. When bit 0 of the M_3 field is one, bit positions 32-47 of general register 0 are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future. When bit 0 of the M_3 field is one, the flags (F) field of general register 0 contains additional operation controls.

When the message-security-assist extension 6 is installed, the padding state (PS) flag is defined in bit position 55 of general register 0; otherwise, bit position 55 of general register 0 is ignored.

Flags (F): Bit positions 48-55 of general register 0 contain an 8-bit flags field controlling the operation of the function. Bits 0-6 are meaningful when the message-security-assist extension 12 is installed, bit 0 of the M_3 field is one, and the function code in bit positions 57-63 of general register 0 designates a specific function (see each flag description for details). Bit 7 is meaningful when the message-security-assist extension 6 is installed, and the function code in bit positions 57-63 of general register 0 designates a specific function (see each flag description for details). Any bit of the flags field that is not applicable to the specified function is reserved and should contain a zero; otherwise, the program may not operate compatibly in the future. The format of the flags field is as follows:



The individual flag fields are as follows:

Reserved: Bits 2-6 of the flags field are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.

No-ICV Provided (NIP): Bit 0 of the flags field indicates whether the ICV value is provided by the program in the parameter block. The NIP flag is meaningful only when the function code in bit positions 57-63 of general register 0 of COMPUTE LAST MESSAGE DIGEST designates a SHA-3 or SHAKE function (function codes 32-37).

When the NIP flag is zero, the ICV value provided by the program in the parameter block is used as the ICV; otherwise, zeros are used as the ICV.

Discard-Unneeded-Final-OCV Part (DUFOP): Bit 1 of the flags field indicates whether the unneeded portion of the final OCV is saved in the parameter block. The DUFOP flag is meaningful only when the function code in bit positions 57-63 of general register 0 of COMPUTE LAST MESSAGE DIGEST designates a SHA-3 or SHAKE function (function codes 32-37).

When the DUFOP flag is one and the instruction completes with condition code 0, the unneeded portion of the final OCV is not necessarily saved in the parameter block. For this case, it is model dependent if the unneeded portion of the final OCV is saved in the parameter block. When the DUFOP flag is zero and the instruction completes with condition code 0, the entire OCV is saved in the parameter block.

Padding State (PS): Bit 7 of the flags field indicates whether the padding of the second operand has been performed. The PS flag is meaningful only when the function code in bit positions 57-63 of general register 0 of COMPUTE LAST MESSAGE DIGEST designates a SHAKE function (function codes 36-37).

When the PS flag is zero, the padding of the second operand has not yet been performed; otherwise, the padding of the second operand has been performed.

Function Code (FC): Bit positions 57-63 of general register 0 contain the function code. Figure 7-250 show the assigned function codes. When the message-security-assist extension 13 is installed, function code 127 is valid for COMPUTE LAST MESSAGE DIGEST. All other function codes are unassigned. Bit 56 of general register 0 must be zero; otherwise, a specification exception is recognized.

The assigned function codes are enumerated in Figure 7-250. All other function codes are unassigned.

Code	Function	Parm. Block Size (bytes)	Data Block Size[1] (bytes)
0	KLMD-Query *	16	—
1	KLMD-SHA-1 *	28	64
2	KLMD-SHA-256 *	40	64
3	KLMD-SHA-512 *	80	128
32	KLMD-SHA3-224	200	144
33	KLMD-SHA3-256	200	136
34	KLMD-SHA3-384	200	104
35	KLMD-SHA3-512	200	72
36	KLMD-SHAKE-128	200	168
37	KLMD-SHAKE-256	200	136

Figure 7-250. Function Codes for COMPUTE LAST MESSAGE DIGEST

Code	Function	Parm. Block Size (bytes)	Data Block Size[1] (bytes)
127	KLMD-Query-Authentication-Information	V	—

Explanation:

— Not applicable

1 For all data blocks except the last block. The size of the last data block ranges from 0 to one less than the value shown.

* Function is also defined in the ESA/390 architectural mode and the ESA/390-compatibility mode. It is unpredictable whether other function codes are available in the ESA/390-compatibility mode.

V Variable parameter block size. See each format-x parameter block for the exact size of that parameter block.

Figure 7-250. Function Codes for COMPUTE LAST MESSAGE DIGEST (Continued)

General register 1 contains the logical address of the leftmost byte of the parameter block in storage. In the 24-bit addressing mode, the contents of bit positions 40-63 of general register 1 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of general register 1 constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register 1 constitute the address.

The query function provides the means of indicating the availability of the other functions. The contents of general registers R_1, $R_1 + 1$, R_2 and $R_2 + 1$ are ignored for the query function.

The query-authentication-information function provides the information that can be used by the program to authenticate the running instruction's firmware code level (IFCL) currently installed on the model. The contents of general registers R_1, $R_1 + 1$, R_2 and $R_2 + 1$ are ignored for the query-authentication-information function.

For all other functions, the second operand is processed as specified by the function code using an initial chaining value in the parameter block, and the result replaces the chaining value in the parameter block. For the SHA-3 and SHAKE functions, an initial chaining value in the parameter block is not used when the NIP flag is one, and the result replaces partial chaining value in the parameter block when the DUFOP flag is one. For the SHA-1, SHA-256, and SHA-512 functions, the operation also uses a message bit length in the parameter block. The operation proceeds until the end of the second-operand location is reached or a CPU-determined number of bytes have been processed, whichever occurs first.

For the KLMD-SHAKE functions, when the end of the second operand is reached, an extended-output-function (XOF) digest is stored at the first operand location. The operation then proceeds until either the end of the first-operand location is reached or a CPU-determined number of bytes have been stored, whichever occurs first.

The result is indicated in the condition code.

The R_2 field designates an even-odd pair of general registers and must designate an even-numbered register other than general register 0; otherwise, a specification exception is recognized.

The location of the leftmost byte of the second operand is specified by the contents of the R_2 general register. The number of bytes in the second-operand location is specified in general register $R_2 + 1$.

As part of the operation, the address in general register R_2 is incremented by the number of bytes processed from the second operand, and the length in general register $R_2 + 1$ is decremented by the same number. The formation and updating of the address and length is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general register R_2 constitute the address of the second operand, and the contents of bit positions 0-39 are ignored; bits 40-63 of the updated address replace the corresponding bits in general register R_2, carries out of bit position 40 of the updated address are ignored, and the contents of bit positions 32-39 of general register R_2 are set to zeros. In the 31-bit addressing mode, the contents of bit positions 33-63 of general register R_2 constitute the address of the second operand, and the contents of bit positions 0-32 are ignored; bits 33-63 of the updated address replace the corresponding bits in general register R_2, carries out of bit position 33 of the updated address are ignored, and the content of bit position 32 of general register R_2 is set to zero. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register R_2 constitute the

address of the second operand; bits 0-63 of the updated address replace the contents of general register R_2 and carries out of bit position 0 are ignored.

In both the 24-bit and the 31-bit addressing modes, the contents of bit positions 32-63 of general register $R_2 + 1$ form a 32-bit unsigned binary integer which specifies the number of bytes in the second operand; and the updated value replaces the contents of bit positions 32-63 of general register $R_2 + 1$. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register $R_2 + 1$ form a 64-bit unsigned binary integer which specifies the number of bytes in the second operand; and the updated value replaces the contents of general register $R_2 + 1$.

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers R_2 and $R_2 + 1$, always remain unchanged.

For the two KLMD-SHAKE functions, the following applies:

- Bit 7 of the flags field in general register 0 is the padding state (PS) flag. A value of zero indicates that padding of the second operand has not yet been performed. A value of one indicates that padding of the second operand has been performed.

  A specification exception is recognized, and the operation is suppressed when the padding state (PS) flag is one and the second-operand length in general register $R_2 + 1$ is nonzero at the beginning of the instruction.

  A specification exception is recognized, and the operation is suppressed when the PS flag is one and the NIP flag is one at the beginning of the instruction.

  When the remaining second-operand length is zero, the CPU inspects the padding state to determine whether padding of the second operand is to be performed. The PS flag is set to one by the CPU when padding of the second operand has been performed.

- The R_1 field designates an even-odd pair of general registers and must designate an even-numbered register other than general register 0 and other than general register R_2; otherwise a specification exception is recognized.

- The location of the leftmost byte of the first operand is specified by the contents of general register R_1. The number of bytes in the first-operand location is specified in general register $R_1 + 1$.

- As a part of the operation, the address in general register R_1 is incremented by the number of bytes stored into the first operand, and the length in general register $R_1 + 1$ is decremented by the same number. The formation and updating of the address and length is dependent on the addressing mode.

- The addressing-mode characteristics for general registers R_1 and $R_1 + 1$ are identical to those for general registers R_2 and $R_2 + 1$, respectively, as described above.

For functions other than the two KLMD-SHAKE functions, bit 55 of general register 0 and the R_1 field of the instruction are ignored. In this case, a first operand is not present, and general registers R_1 and $R_1 + 1$ are not modified.

Figure 7-251 shows the contents of the general registers just described.

All Addressing Modes

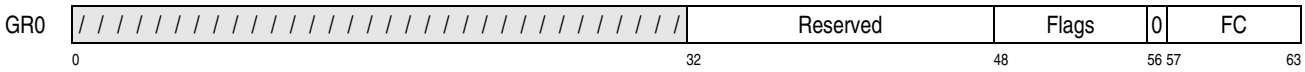


Figure 7-251. General Register Assignment for KLMD (Part 1 of 2)

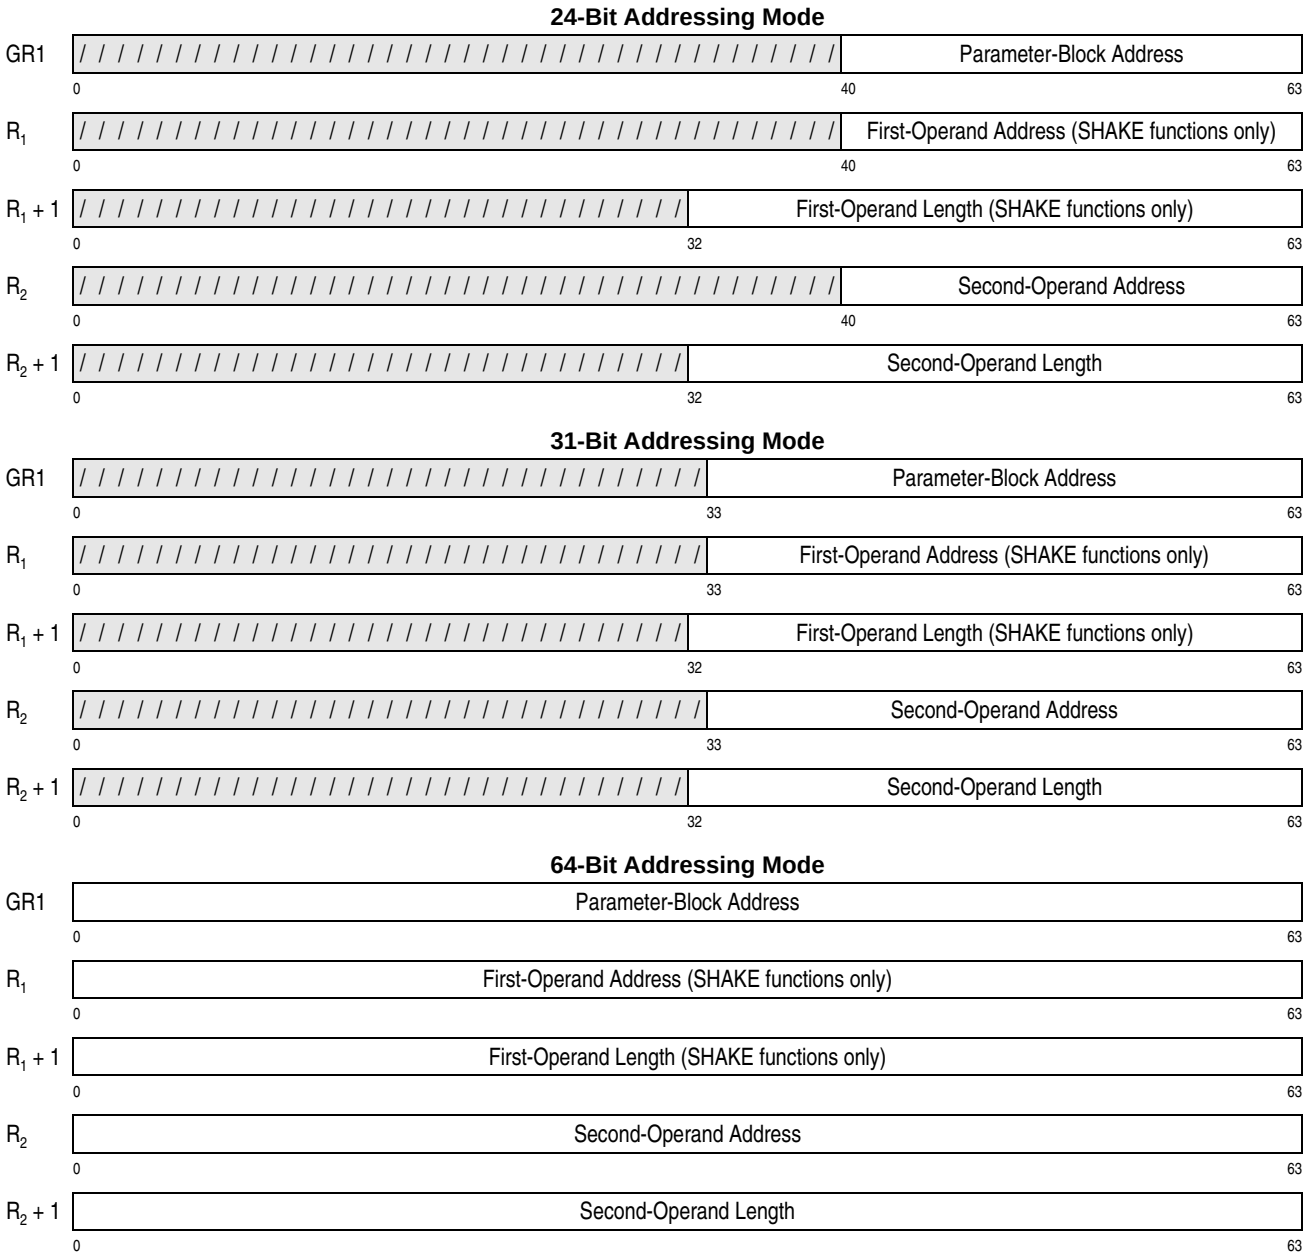

Figure 7-251. General Register Assignment for KLMD (Part 2 of 2)

In the access-register mode, access registers 1 and R_2 specify the address spaces containing the parameter block and second operand, respectively. For the KLMD-SHAKE functions, access register R_1 specifies the address space containing the first operand.

The result is obtained as if processing starts at the left end of the second operand and proceeds to the right, block by block. For all functions except the KLMD-SHAKE functions, the operation is ended when all source bytes in the second operand have been processed (called normal completion), or when a CPU-determined number of blocks that is less than the length of the second operand have been processed (called partial completion). The CPU-determined number of blocks depends on the model, and may be a different number each time the instruction is executed. The CPU-determined number of blocks is usually nonzero. In certain unusual situations, this number may be zero, and condition code 3 may be set with no progress. However, the CPU protects against endless reoccurrence of this no-progress case.

When the chaining-value field overlaps any portion of the first or second operand, the result in the chaining-value field is unpredictable.

For the KLMD-SHAKE functions, when the first operand overlaps any portion of the second operand or the chaining-value field, the result in the first operand is unpredictable.

For the KLMD-SHA-1, KLMD-SHA-256, and KLMD-SHA-512 functions, after all bytes in the second operand as specified in general register $R_2 + 1$ have been processed, the padding operation is performed, a final hashing operation is performed on the padded block, a counter in the cryptography-counter set is updated when appropriate, and then normal completion occurs.

For the KLMD-SHA3 functions, after all full blocks of the second operand have been processed, the padding operation is performed on either the remaining partial block or on a null block, a final hashing operation is performed on the padded block, a counter in the cryptography-counter set is updated when appropriate, and then normal completion occurs.

For the KLMD-SHAKE functions, after all full blocks of the second operand have been processed, the padding operation is performed on either the remaining partial block or on a null block, a final hashing operation is performed on the padded block. When padding has been performed, the padding state is set to one in general register 0, and an extended-output-function (XOF) message digest is stored into the first-operand location. XOF message-digest generation is ended when all of the first operand has been stored or when a CPU-determined number of blocks that is less than the length of the first operand have been stored (called partial completion). The CPU-determined number of blocks depends on the model, and may be a different number each time the instruction is executed. The CPU-determined number of blocks is usually nonzero. In certain unusual situations, this number may be zero, and condition code 3 may be set with no progress. However, the CPU protects against endless reoccurrence of this no-progress case. Subsequent to the end of extended-output-function (XOF) processing, a counter in the cryptography-counter set is updated when appropriate, and then normal completion occurs.

If the CPU is enabled to update counters in the cryptography-counter set, then the following apply for all functions other than KLMD-Query and KLMD-Query-Authentication-Information:

- The appropriate counter has been updated when the instruction ends with condition code 0 set.
- For the SHA-1, SHA-256, SHA-512, and SHA3 functions, if the second-operand length is initially less than or equal to the model-dependent maximum number of second-operand bytes processed during a unit of operation and the appropriate counter is not accessible, then an access exception is recognized for the counter location and instruction execution ends in nullification or suppression, as appropriate.
- For the SHAKE functions, if the second and first-operand lengths are initially less than or equal to the model-dependent maximum number of second and first-operand bytes processed during a unit of operation and the appropriate counter is not accessible, then an access exception is recognized for the counter location and instruction execution ends in nullification or suppression, as appropriate.

When the operation ends due to normal completion, condition code 0 is set, the second-operand address in general register R_2 is updated, and the second-operand length in general register $R_2 + 1$ is zero; for the KLMD-SHAKE functions, the first-operand address in general register R_1 is updated, and the first-operand length in general register $R_1 + 1$ is zero.

When the operation ends due to partial completion, condition code 3 is set. For all functions except the KLMD-SHAKE functions, the resulting value in general register $R_2 + 1$ is nonzero. For the KLMD-SHAKE functions, if the second operand has not been completely processed, the resulting value in general register $R_2 + 1$ is nonzero, and if the first operand has not been completely processed, the resulting value in general register R_1 is nonzero.

When the second-operand length is initially zero, the second operand is not accessed, the second-operand address and second-operand length in general registers R_2 and $R_2 + 1$, respectively, are not changed, a counter in the cryptography-counter set is updated when appropriate, and condition code 0 is set. Except for the KLMD-SHAKE functions when the padding-state (PS) control is one, the empty block

padding operation is performed and the result is stored into the parameter block.

For the KLMD-SHAKE functions, when the first-operand length is initially zero, the first operand is not accessed, and the first-operand address and first-operand length in general registers R_1 and $R_1 + 1$, respectively, are not changed. When the first-operand length is initially zero and the PS control is one, it is model dependent whether the parameter block is updated.

A PER storage-alteration event is recognized, when applicable, for the portion of the parameter block and first-operand location that is stored. A PER zero-address-detection event is recognized, when applicable, for the first-operand location, for the second-operand location and for the parameter block. When PER events are detected for more than one location, it is unpredictable which location is identified in the PER access identification (PAID) and PER ASCE ID (AI).

As observed by this CPU, other CPUs, and channel programs, references to the parameter block and storage operands may be multiple-access references, accesses to these storage locations are not necessarily block-concurrent, and the sequence of these accesses or references is undefined.

Access exceptions may be reported for a larger portion of the first operand (when applicable) and second operand than is processed in a single execution of the instruction; however, access exceptions are not recognized for locations beyond the length of the first or second operand nor for locations more than 4K bytes beyond the current location being processed.

Symbols Used in Function Descriptions

The subsequent description of COMPUTE LAST MESSAGE DIGEST uses the same symbols as those used in COMPUTE INTERMEDIATE MESSAGE DIGEST, plus the following additional symbols. Further description of the secure hash algorithm may be found in Reference [15.] on page xxxii. Further description of the SHA-3 and SHAKE hash algorithms and the KECCAK family of sponge functions may be found in Reference [21.] on page xxxii.

Symbol	Explanation for KLMD Function Figures
L	Byte length of operand 2 in storage.
p <n>	n padding bytes; leftmost byte is 80 hex; all other bytes are 00 hex.
z <n>	n padding bytes of zero.
mbl	an 8-byte or 16-byte value specifying the bit length of the total message.
q <64>	a padding block, consisting of 56 bytes of zero followed by an 8-byte mbl.
q <128>	a padding block, consisting of 112 bytes of zero followed by a 16-byte mbl.
sp<n>	n padding bytes used by SHA-3 functions. Bit positions 7, 6, and 5 of the leftmost byte of the pad contain binary 0, 1, and 1, respectively, and bit position 0 of the rightmost byte of the pad contains a binary one. All other bits are zeros. Padding for SHA-3 functions is performed even if the second-operand length is zero.
xp<n>	n padding bytes used by SHAKE functions. Bit positions 3 through 7 of the leftmost byte of the pad all contain binary ones, and bit position 0 of the rightmost pad byte contains a binary one. All other bits are zeros. Padding for SHAKE functions is performed when the padding state (PS, bit 55 of general register 0) is zero and the remaining second-operand length is less than the data-block size.

KLMD-Query (KLMD Function Code 0)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-251 on page 7-221.

The parameter block used for the function has the following format:

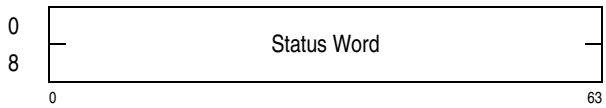

Figure 7-252. Parameter Block for KLMD-Query

A 128-bit status word is stored in the parameter block. Bits 0-127 of this field correspond to function codes 0-127, respectively, of the COMPUTE LAST MESSAGE DIGEST instruction. When a bit is one,

the corresponding function is installed; otherwise, the function is not installed.

Condition code 0 is set when execution of the KLMD-Query function completes; condition code 3 is not applicable to this function.

KLMD-SHA-1 (KLMD Function Code 1)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-251 on page 7-221.

The parameter block used for the function has the following format:

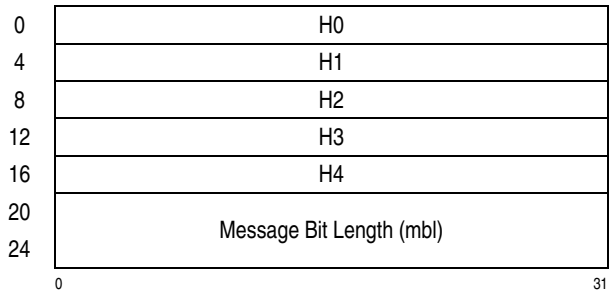

Figure 7-253. Parameter Block for KLMD-SHA-1

The message digest for the message (M) in operand 2 is generated using the SHA-1 algorithm with the chaining value (called H fields) and message-bit-length information in the parameter block.

If the length of the message in operand 2 is equal to or greater than 64 bytes, an intermediate message digest is generated for each 64-byte message block using the SHA-1 block digest algorithm with the 20-byte chaining value in the parameter block, and the generated intermediate message digest, also called the output chaining value (OCV), is stored into the chaining-value field of the parameter block. This operation is shown in Figure 7-254 and repeats until the remaining message is less than 64 bytes or until a CPU-determined number of blocks have been stored.

If the length of the message or the remaining message is zero bytes, then the operation in Figure 7-255 is performed. If the length of the message or the remaining message is between one byte and 55 bytes inclusive, then the operation in Figure 7-256 is performed; if the length is between 56 bytes and 63 bytes inclusive, then the operation in Figure 7-257 is performed. The message digest, also called the output chaining value (OCV), is stored into the chaining-value field of the parameter block.

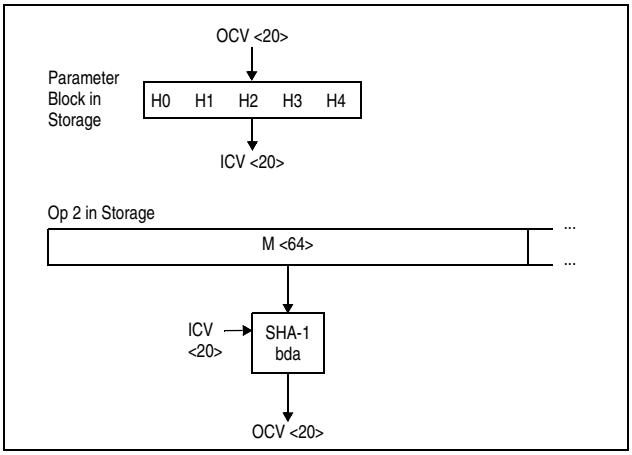

Figure 7-254. KLMD-SHA-1 Full Block (L ≥ 64)

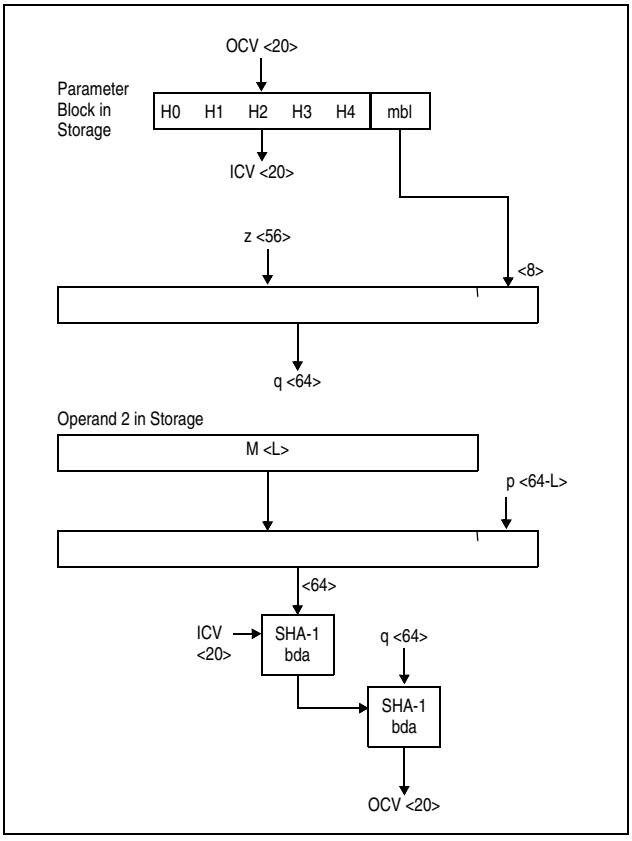

Figure 7-257. KLMD-SHA-1 Partial-Block Case 2 (56 ≤ L ≤ 63)

KLMD-SHA-256 (KLMD Function Code 2)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-251 on page 7-221.

The parameter block used for the function has the following format:

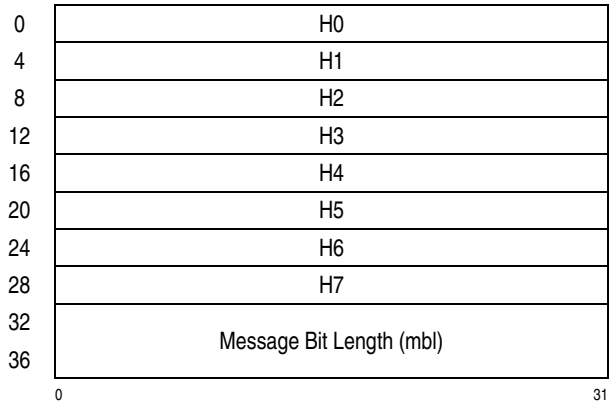

Figure 7-258. Parameter Block for KLMD-SHA-256

The message digest for the message (M) in operand 2 is generated using the SHA-256 algorithm with the chaining value (called H fields) and message-bit-length information in the parameter block.

If the message in operand 2 is equal to or greater than 64 bytes, an intermediate message digest is generated for each 64-byte message block using the SHA-256 block digest algorithm with the 32-byte chaining value in the parameter block, and the generated intermediate message digest, also called the output chaining value (OCV), is stored into the chaining-value field of the parameter block. This operation is shown in Figure 7-259 and repeats until the remaining message is less than 64 bytes or until a CPU-determined number of blocks have been stored.

If the length of the message or the remaining message is zero bytes, then the operation in Figure 7-260 is performed. If the length of the message or the remaining message is between one byte and 55 bytes inclusive, then the operation in Figure 7-261 is performed; if the length is between 56 bytes and 63 bytes inclusive, then the operation in Figure 7-262 is performed. The message digest, also called the out-

put chaining value (OCV), is stored into the chaining-value field of the parameter block.

KLMD-SHA-512 (KLMD Function Code 3)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-251 on page 7-221.

The parameter block used for the function has the following format:

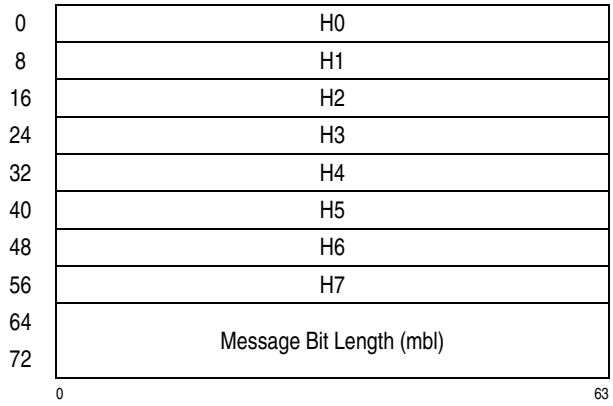

Figure 7-263. Parameter Block for KLMD-SHA-512

The message digest for the message (M) in operand 2 is generated using the SHA-512 algorithm with the chaining value (called H fields) and message-bit-length information in the parameter block.

If the message in operand 2 is equal to or greater than 128 bytes, an intermediate message digest is generated for each 128-byte message block using the SHA-512 block digest algorithm with the 64-byte chaining value in the parameter block, and the generated intermediate message digest, also called the output chaining value (OCV), is stored into the chaining-value field of the parameter block. This operation is shown in Figure 7-264 and repeats until the remaining message is less than 128 bytes or until a CPU-determined number of blocks have been stored.

If the length of the message or the remaining message is zero bytes, then the operation in Figure 7-265 is performed. If the length of the message or the remaining message is between one byte and 111 bytes inclusive, then the operation in Figure 7-266 is performed; if the length is between 112 bytes and 127 bytes inclusive, then the operation in Figure 7-267 is performed. The message digest, also called the output chaining value (OCV), is stored into the chaining-value field of the parameter block.

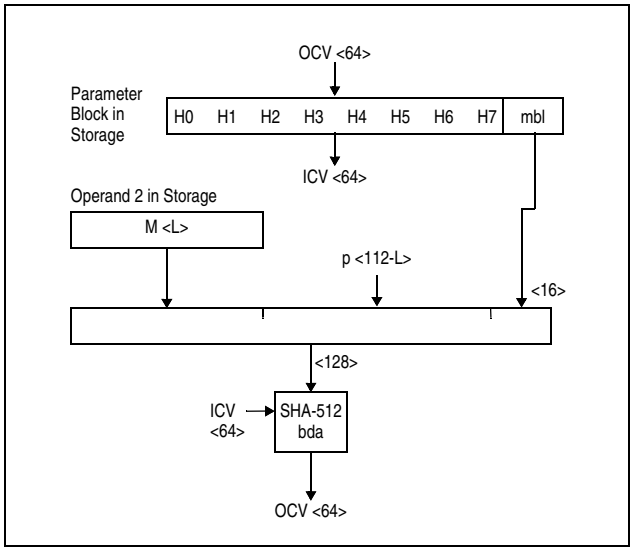

Figure 7-266. KLMD-SHA-512 Partial-Block Case 1 (1 ≤ L ≤ 111)

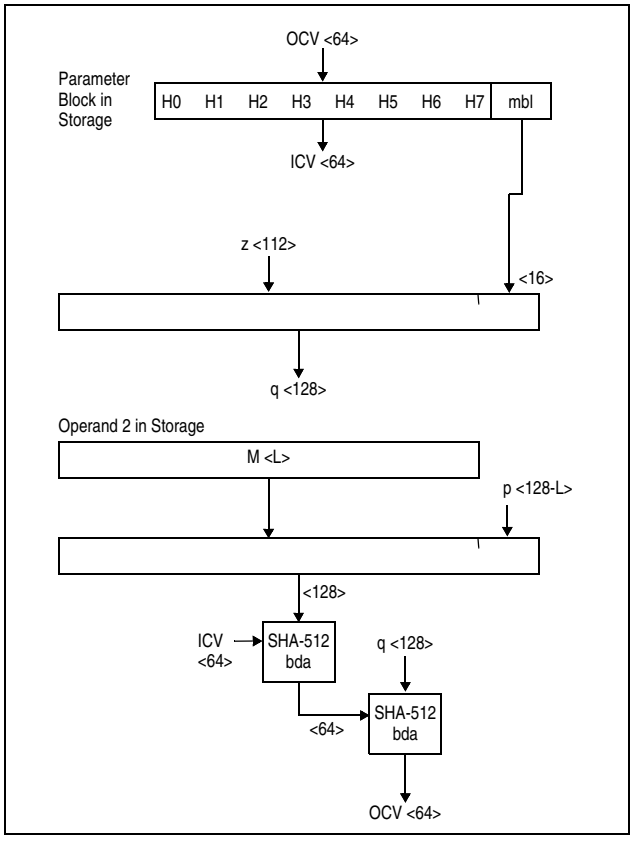

Figure 7-267. KLMD-SHA-512 Partial-Block Case 2 (112 ≤ L ≤ 127)

KLMD-SHA3-224 (KLMD Function Code 32)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-251 on page 7-221.

The parameter block used for the function has the following format:

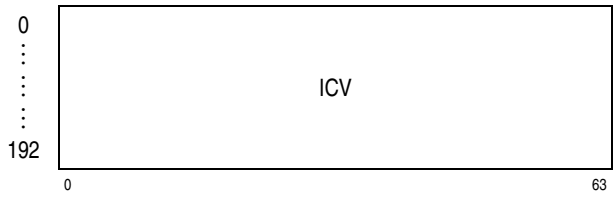

Figure 7-268. Parameter Block for KLMD-SHA3-224

The initial chaining value (ICV) represents the 1600-bit state array used by the KECCAK[*c*] functions which implement the SHA-3 algorithms described in Reference [21.] on page xxxii.

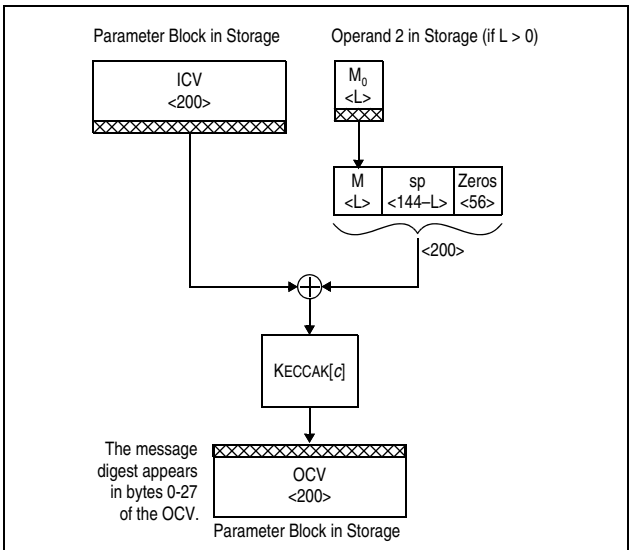
When the length of the second operand in general register $R_2 + 1$ is greater than or equal to 144 bytes, then the operation is identical to that described in the section “KIMD-SHA3-224 (KIMD Function Code 32)” on page 7-209. This operation proceeds until the length of the second operand is less than 144 bytes, at which point the operation continues as described below.

Any remaining bytes of the second operand are padded on the right to form a 144-byte message block as described for the symbol “sp<n>” on page 7-224. Padding occurs even when there are no remaining bytes in the second operand and does not alter the contents of the second operand.

A 224-bit (28-byte) message digest is generated for the padded message block using the KECCAK[*c*] algorithm with the 200-byte initial chaining value in the parameter block when the NIP flag (bit 0 of the flags field in general register 0) is zero or with 200 bytes of zeros when the NIP flag is one. The message digest is generated regardless of whether the second-operand length is zero and the NIP flag is set to zero. When the DUFOP flag (bit 1 of the flags field in general register 0) is zero or the instruction completes with condition code 3, the entire 200-byte output of the KECCAK[*c*] algorithm, also called the output chaining value (OCV), is stored into the parameter block; otherwise, only the leftmost 28 bytes of the OCV is stored in the parameter block. The generated mes-

sage digest is contained in bytes 0-27 of the parameter block. See programming note 10 on page 7-218 regarding the numbering of the bits in the parameter block and second operand as compared with the numbering of the bits in the state array. The contents of bytes 28-199 of the parameter block are unpredictable when the DUFOP flag is one and the instruction completes with condition code 0. See programming note 10 on page 7-239 regarding the effects of storing OCV after completing each unit of operation.

The operation is shown in Figure 7-269.



Explanation:

⊠	The bit positions of each byte of the parameter block and the message block(s) appear in storage in descending order from left to right, respective to their corresponding bit positions in the bytes of the KECCAK[*c*] state array.
⊕	Bitwise exclusive-OR operation
<#>	Size of an item in bytes
ICV	Input chaining value (in the parameter block when the NIP flag is zero or 200 bytes of zeros when the NIP flag is one)
L	Length of the second operand (< 144 bytes)
M	Message block (when L > 0)
OCV	Output chaining value (in the parameter block); bytes 0-27 contain the 224-bit message digest
sp	SHA-3 padding algorithm

Figure 7-269. KLMD-SHA3-224 Processing (L < 144)

KLMD-SHA3-256 (KLMD Function Code 33)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-251 on page 7-221.

The parameter block used for the function has the following format:

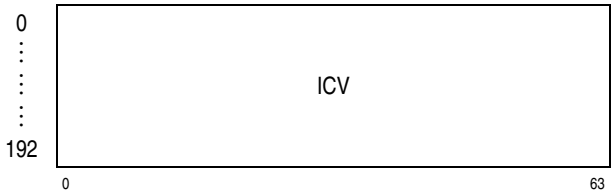


Figure 7-270. Parameter Block for KLMD-SHA3-256

The initial chaining value (ICV) represents the 1600-bit state array used by the KECCAK[*c*] functions which implement the SHA-3 algorithms described in Reference [21.] on page xxxii.

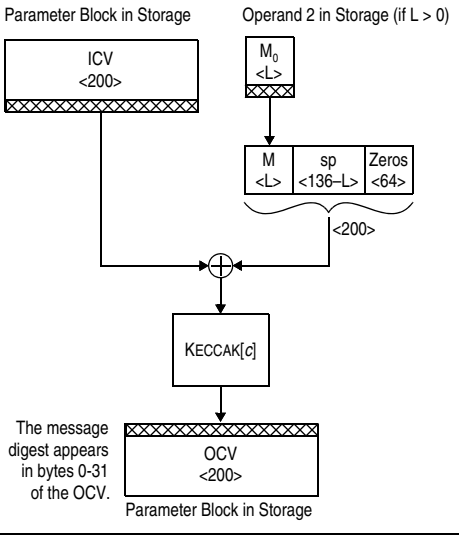
When the length of the second operand in general register R_2 + 1 is greater than or equal to 136 bytes, then the operation is identical to that described in the section “KIMD-SHA3-256 (KIMD Function Code 33)” on page 7-210. This operation proceeds until the length of the second operand is less than 136 bytes, at which point the operation continues as described below.

Any remaining bytes of the second operand are padded on the right to form a 136-byte message block as described for the symbol “sp<n>” on page 7-224. Padding occurs even when there are no remaining bytes in the second operand and does not alter the contents of the second operand.

A 256-bit (32-byte) message digest is generated for the padded message block using the KECCAK[*c*] algorithm with the 200-byte initial chaining value in the parameter block when the NIP flag (bit 0 of the flags field in general register 0) is zero or with 200 bytes of zeros when the NIP flag is one. The message digest is generated regardless of whether the second-operand length is zero and the NIP flag is set to zero. When the DUFOP flag (bit 1 of the flags field in general register 0) is zero or the instruction completes with condition code 3, the entire 200-byte output of the KECCAK[*c*] algorithm, also called the output chaining value (OCV), is stored into the parameter block; otherwise, only the leftmost 32 bytes of the OCV is stored in the parameter block. The generated message digest is contained in bytes 0-31 of the parameter block. See programming note 10 on page page 7-218 regarding the numbering of the bits in the parameter block and second operand as compared with the numbering of the bits in the state array. The contents of bytes 32-199 of the parameter block are

unpredictable when the DUFOP flag is one and the instruction completes with condition code 0. See programming note 10 on page 7-239 regarding the effects of storing OCV after completing each unit of operation.

The operation is shown in Figure 7-271.



Explanation:

⊠	The bit positions of each byte of the parameter block and the message block(s) appear in storage in descending order from left to right, respective to their corresponding bit positions in the bytes of the KECCAK[*c*] state array.
⊕	Bitwise exclusive-OR operation
<#>	Size of an item in bytes
ICV	Input chaining value (in the parameter block when the NIP flag is zero or 200 bytes of zeros when the NIP flag is one)
L	Length of the second operand (< 136 bytes)
M	Message block (when L > 0)
OCV	Output chaining value (in the parameter block); bytes 0-31 contain the 256-bit message digest
sp	SHA-3 padding algorithm

Figure 7-271. KLMD-SHA3-256 Processing (L < 136)

KLMD-SHA3-384 (KLMD Function Code 34)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-251 on page 7-221.

The parameter block used for the function has the following format:

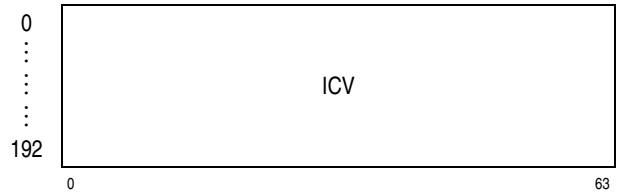


Figure 7-272. Parameter Block for KLMD-SHA3-384

The initial chaining value (ICV) represents the 1600-bit state array used by the KECCAK[*c*] functions which implement the SHA-3 algorithms described in Reference [21.] on page xxxii.

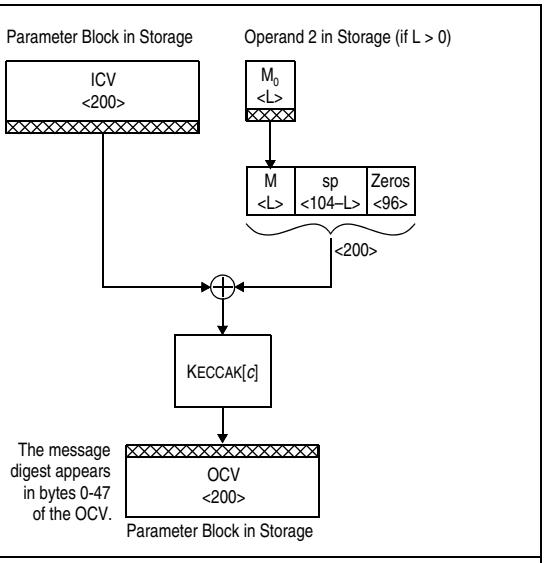
When the length of the second operand in general register $R_2 + 1$ is greater than or equal to 104 bytes, then the operation is identical to that described in the section "KIMD-SHA3-384 (KIMD Function Code 34)" on page 7-211. This operation proceeds until the length of the second operand is less than 104 bytes, at which point the operation continues as described below.

Any remaining bytes of the second operand are padded on the right to form a 104-byte message block as described for the symbol "sp<n>" on page 7-224. Padding occurs even when there are no remaining bytes in the second operand and does not alter the contents of the second operand.

A 384-bit (48-byte) message digest is generated for the padded message block using the KECCAK[*c*] algorithm with the 200-byte initial chaining value in the parameter block when the NIP flag (bit 0 of the flags field in general register 0) is zero or with 200 bytes of zeros when the NIP flag is one. The message digest is generated regardless of whether the second-operand length is zero and the NIP flag is set to zero. When the DUFOP flag (bit 1 of the flags field in general register 0) is zero or the instruction completes with condition code 3, the entire 200-byte output of the KECCAK[*c*] algorithm, also called the output chaining value (OCV), is stored into the parameter block; otherwise, only the leftmost 48 bytes of the OCV is stored in the parameter block. The generated message digest is contained in bytes 0-47 of the parameter block. See programming note 10 on page 7-218 regarding the numbering of the bits in the parameter block and second operand as compared with the numbering of the bits in the state array. The contents of bytes 48-199 of the parameter block are unpredict-

able when the DUFOP flag is one and the instruction completes with condition code 0. See programming note 10 on page 7-239 regarding the effects of storing OCV after completing each unit of operation.

The operation is shown in Figure 7-273.



Explanation:

⊠	The bit positions of each byte of the parameter block and the message block(s) appear in storage in descending order from left to right, respective to their corresponding bit positions in the bytes of the KECCAK[*c*] state array.

OCV	Output chaining value (in the parameter block); bytes 0-47 contain the 384-bit message digest
sp	SHA-3 padding algorithm

Figure 7-273. KLMD-SHA3-384 Processing (L < 104)

KLMD-SHA3-512 (KLMD Function Code 35)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-251 on page 7-221.

The parameter block used for the function has the following format:

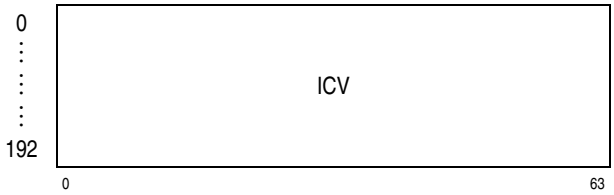

Figure 7-274. Parameter Block for KLMD-SHA3-512

The initial chaining value (ICV) represents the 1600-bit state array used by the KECCAK[*c*] functions which implement the SHA-3 algorithms described in Reference [21.] on page xxxii.

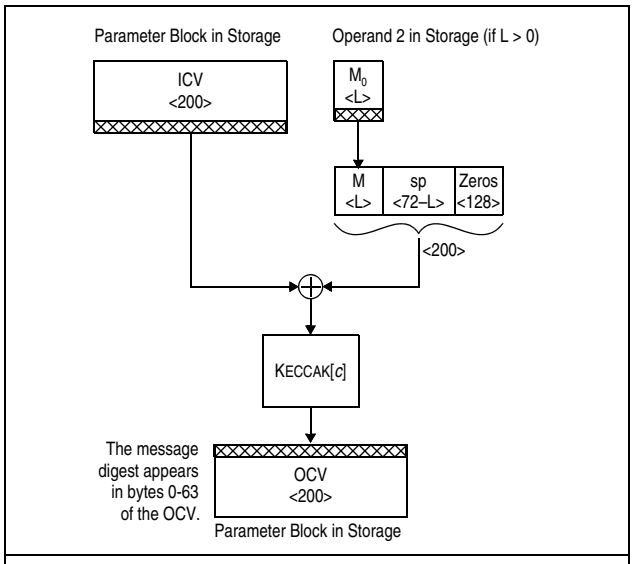
When the length of the second operand in general register $R_2 + 1$ is greater than or equal to 72 bytes, then the operation is identical to that described in the section "KIMD-SHA3-512 (KIMD Function Code 35)" on page 7-212. This operation proceeds until the length of the second operand is less than 72 bytes, at which point the operation continues as described below.

Any remaining bytes of the second operand are padded on the right to form a 72-byte message block as described for the symbol "sp<n>" on page 7-224. Padding occurs even when there are no remaining bytes in the second operand and does not alter the contents of the second operand.

A 512-bit (64-byte) message digest is generated for the padded message block using the KECCAK[*c*] algorithm with the 200-byte initial chaining value in the parameter block when the NIP flag (bit 0 of the flags field in general register 0) is zero or with 200 bytes of zeros when the NIP flag is one. The message digest is generated regardless of whether the second-operand length is zero and the NIP flag is set to zero. When the DUFOP flag (bit 1 of the flags field in general register 0) is zero or the instruction completes with condition code 3, the entire 200-byte output of the KECCAK[*c*] algorithm, also called the output chaining value (OCV), is stored into the parameter block; otherwise, only the leftmost 64 bytes of the OCV is stored in the parameter block. The generated message digest is contained in bytes 0-63 of the parameter block. See programming note 10 on page 7-218 regarding the numbering of the bits in the parameter block and second operand as compared with the numbering of the bits in the state array. The contents of bytes 64-199 of the parameter block are unpredict-

able when the DUFOP flag is one and the instruction completes with condition code 0. See programming note 10 on page 7-239 regarding the effects of storing OCV after completing each unit of operation.

The operation is shown in Figure 7-275.



Explanation:

⊠	The bit positions of each byte of the parameter block and the message block(s) appear in storage in descending order from left to right, respective to their corresponding bit positions in the bytes of the KECCAK[*c*] state array.

KLMD-SHAKE-128 (KLMD Function Code 36)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-251 on page 7-221.

The parameter block used for the function has the following format:

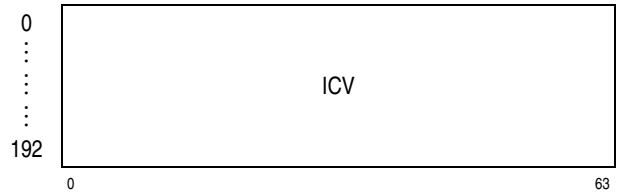

Figure 7-276. Parameter Block for KLMD-SHAKE-128

The initial chaining value (ICV) represents the 1600-bit state array used by the KECCAK[*c*] functions which implement the SHA-3 algorithms described in Reference [21.] on page xxxii.

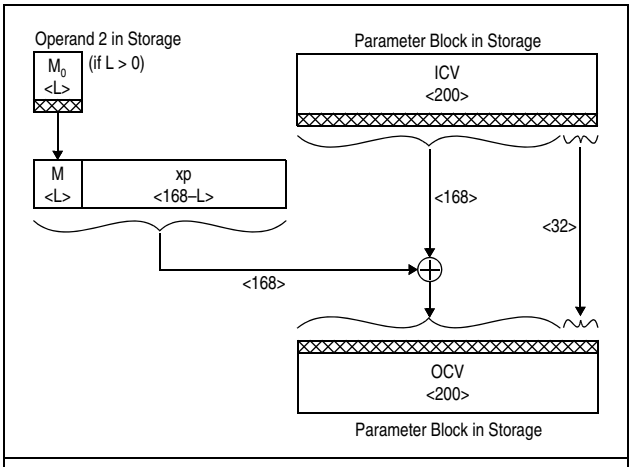
When the length of the second operand in general register R_2 + 1 is greater than or equal to 168 bytes, the operation is identical to that described in the section "KIMD-SHAKE-128 (KIMD Function Code 36)" on page 7-213, except that when the remaining second-operand length is less than 168 bytes, processing is as described below.

When the padding state (PS), bit 7 of the flags field of general register 0, is zero (indicating that padding has not yet been performed), the following occurs:

- Any remaining bytes of the second operand are padded on the right to form a 168-byte message block as described for the symbol "xp<n>" on page 7-224. Padding occurs even when there are no remaining bytes in the second operand and does not alter the contents of the second operand.
- The PS flag is set to one, indicating that padding has been performed.
- The second-operand address in general register R_2 is incremented by the number of message bytes processed, and the second-operand length in general register R_2+1 is set to zero.
- The 168-byte padded message, is exclusive ORed with the contents of the leftmost 168 bytes of the state array (from the ICV in the parameter block or from the OCV resulting from the previous block's processing) when the NIP flag (bit 0 of the flags field in general register 0) is zero or with 168 bytes of zeros when the NIP flag is one to form an output chaining value that is used in the extended-output-function (XOF) processing

and the NIP flag is set to zero. The rightmost 32 bytes of the state array are unchanged.

The padding operation is shown in Figure 7-277.



Explanation:

⊠	The bit positions of each byte of the parameter block and the message block(s) appear in storage in descending order from left to right, respective to their corresponding bit positions in the bytes of the KECCAK[*c*] state array.
⊕	Bitwise exclusive-OR operation
<#>	Size of an item in bytes
ICV	Input chaining value (in the parameter block when the NIP flag is zero or 200 bytes of zeros when the NIP flag is one)
L	Length of the second operand (< 168 bytes)
M	Message block (when L > 0)
OCV	Output chaining value (used in XOF processing, below)
xp	SHAKE padding algorithm

Figure 7-277. KLMD-SHAKE-128 Padding (L < 168)

Depending on the number of second-operand blocks processed when padding is completed, either (a) the output chaining value is stored into the parameter block, and the instruction completes by setting condition code 3 (partial completion), or (b) the operation continues with extended-output-function (XOF) processing, as described below.

When the PS flag is one (indicating that padding has been performed for the message, either by the current or a previous execution of the instruction), extended-output-function (XOF) processing is performed as follows.

1. If the first-operand length in general register $R_1 + 1$ is zero and the DUFOP flag (bit 1 of the flags field in general register 0) is zero, then the output chaining value is stored into the parameter block, a counter in the cryptography-counter set is updated when appropriate, and the instruction completes with condition code 0. If the first-operand length in general register $R_1 + 1$ is zero and the DUFOP flag is one, then the output chaining value is not stored into the parameter block, a counter in the cryptography-counter set is updated when appropriate, and the instruction completes with condition code 0. If the first-operand length is zero at the beginning of the instruction, then it is model dependent whether the ICV is fetched from the parameter block and stored back unmodified as the OCV when the DUFOP flag is zero.

2. The KECCAK[*c*] function is invoked using the previous output-chaining value (OCV) as input, and replacing the output-chaining value.

3. General register R_1 contains the current address of the first operand, and general register $R_1 + 1$ contains the remaining length of the first operand. The number of bytes to be stored, *n*, is either the remaining first-operand length or 168, whichever is smaller.

   The first *n* bytes of the output-chaining value are stored at the first-operand location. See programming note 10 on page 7-218 regarding the numbering of the bits in the first operand as compared with the numbering of the bits in the state array.

   The first-operand address in general register R_1 is incremented by *n*, and the first-operand length general register $R_1 + 1$ is decremented by *n*.

Steps 1-3 of this process are repeated until the first-operand length becomes zero (in which case, a counter in the cryptography-counter set is updated when appropriate and the instruction completes with condition code 0) or until a CPU-determined number of bytes have been stored (in which case, the instruction completes with condition code 3). The output-chaining value is stored into bytes 0-199 of the parameter block either when condition code 3 is set or when the DUFOP flag is zero and condition code 0 is set.

The contents of the parameter block are unpredictable when the DUFOP flag is one and the instruction completes with condition code 0. See programming note 10 on page 7-239 regarding the effects of storing OCV after completing each unit of operation.

KLMD-SHAKE-256 (KLMD Function Code 37)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-251 on page 7-221.

The parameter block used for the function has the following format:

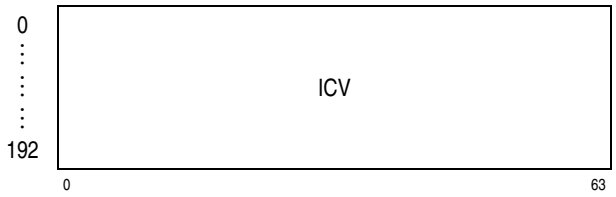


Figure 7-278. Parameter Block for KLMD-SHAKE-256

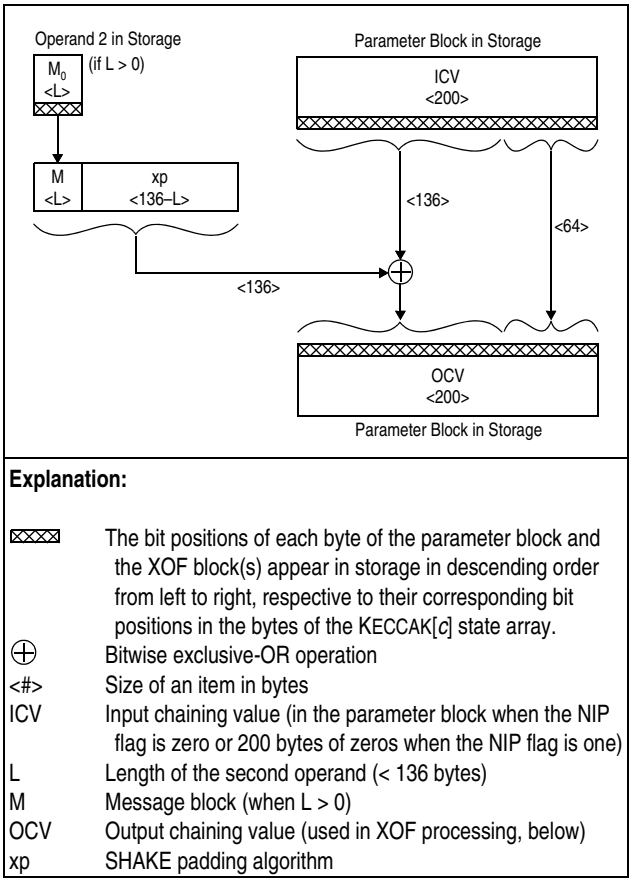
The initial chaining value (ICV) represents the 1600-bit state array used by the KECCAK[*c*] functions which implement the SHA-3 algorithms described in Reference [21.] on page xxxii.

When the length of the second operand in general register R_2 + 1 is greater than or equal to 136 bytes, the operation is identical to that described in the section "KIMD-SHAKE-256 (KIMD Function Code 37)" on page 7-214, except that when the remaining second-operand length is zero, processing is as described below. This operation proceeds until the length of the second operand is less than 136 bytes, at which point the operation continues as described below.

When the padding state (PS), bit 7 of the flags field of general register 0, is zero (indicating that padding has not yet been performed), the following occurs:

- Any remaining bytes of the second operand are padded on the right to form a 136-byte message block as described for the symbol "xp<n>" on page 7-224. Padding occurs even when there are no remaining bytes in the second operand and does not alter the contents of the second operand.
- The PS flag is set to one, indicating that padding has been performed.
- The second-operand address in general register R_2 is incremented by the number of message bytes processed, and the second-operand length in general register R_2+1 is set to zero.
- The 136-byte padded message, is exclusive ORed with the contents of the leftmost 136 bytes of the state array (from the ICV in the parameter block or from the OCV resulting from the previous block's processing) when the NIP flag (bit 0 of the flags field in general register 0) is zero or with 168 bytes of zeros when the NIP flag is one to form an output chaining value that is used in the extended-output-function (XOF) processing and the NIP flag is set to zero. The rightmost 64 bytes of the state array are unchanged.

The padding operationis shown in Figure 7-279.



Explanation:

⊠	The bit positions of each byte of the parameter block and the XOF block(s) appear in storage in descending order from left to right, respective to their corresponding bit positions in the bytes of the KECCAK[*c*] state array.
⊕	Bitwise exclusive-OR operation
<#>	Size of an item in bytes
ICV	Input chaining value (in the parameter block when the NIP flag is zero or 200 bytes of zeros when the NIP flag is one)
L	Length of the second operand (< 136 bytes)
M	Message block (when L > 0)
OCV	Output chaining value (used in XOF processing, below)
xp	SHAKE padding algorithm

Figure 7-279. KLMD-SHAKE-256 Padding (L < 136)

Depending on the number of second-operand blocks processed when padding is completed, either (a) the output chaining value is stored into the parameter block, and the instruction completes by setting condition code 3 (partial completion), or (b) the operation continues with extended-output-function (XOF) processing, as described below.

When the PS flag is one (indicating that padding has been performed for the message, either by the cur-

rent or a previous execution of the instruction), extended-output-function (XOF) processing is performed as follows.

1. If the first-operand length in general register $R_1 + 1$ is zero and the DUFOP flag (bit 1 of the flags field in general register 0) is zero, then the output chaining value is stored into the parameter block, a counter in the cryptography-counter set is updated when appropriate, and the instruction completes with condition code 0. If the first-operand length in general register $R_1 + 1$ is zero and the DUFOP flag is one, then the output chaining value is not stored into the parameter block, a counter in the cryptography-counter set is updated when appropriate, and the instruction completes with condition code 0. If the first-operand length is zero at the beginning of the instruction, then it is model dependent whether the ICV is fetched from the parameter block and stored back unmodified as the OCV when the DUFOP flag is zero.

2. The KECCAK[*c*] function is invoked using the previous output-chaining value (OCV) as input, and replacing the output-chaining value.

3. General register R_1 contains the current address of the first operand, and general register $R_1 + 1$ contains the remaining length of the first operand. The number of bytes to be stored, *n*, is either the remaining first-operand length or 136, whichever is smaller.

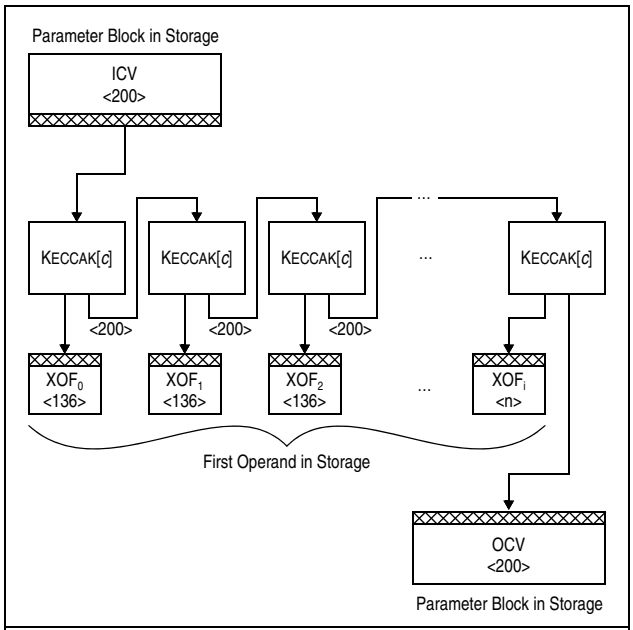
   The first *n* bytes of the output-chaining value are stored at the first-operand location. See programming note 10 on page 7-218 regarding the numbering of the bits in the first operand as compared with the numbering of the bits in the state array.

   The first-operand address in general register R_1 is incremented by *n*, and the first-operand length general register $R_1 + 1$ is decremented by *n*.

Steps 1-3 of this process are repeated until the first-operand length becomes zero (in which case, a counter in the cryptography-counter set is updated when appropriate and the instruction completes with condition code 0) or until a CPU-determined number of bytes have been stored (in which case, the instruction completes with condition code 3). The output-chaining value is stored into bytes 0-199 of the parameter block either when condition code 3 is set or when the DUFOP flag is zero and condition code 0 is set.

The contents of the parameter block is unpredictable when the DUFOP flag is one and the instruction completes with condition code 0. See programming note 10 on page 7-239 regarding the effects of storing OCV after completing each unit of operation.

Figure 7-280 illustrates the XOF processing described above.



Explanation:

⊠	The bit positions of each byte of the parameter block and the XOF block(s) appear in storage in descending order from left to right, respective to their corresponding bit positions in the bytes of the KECCAK[*c*] state array.
<#>	Size of an item in bytes
ICV	Input chaining value (from the parameter block when the NIP flag is zero, 200 bytes of zeros when the NIP flag is one, or from the output of the padding operation).
OCV	Output chaining value; (the final OCV appears in the parameter block)
n	The residual length of the final block of the first operand (less than or equal to 136 bytes)
XOF_i<n>	Block i of the extended-output-function results in the first operand.

Figure 7-280. KLMD-SHAKE-256 Extended-Output-Function (XOF) Processing

KLMD-Query-Authentication-Information (Function Code 127)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-251 on page 7-221.

The KLMD-query-authentication-information function stores the information that can be used by the program to authenticate the running instruction's firmware code level (IFCL) currently installed on the model into the format-0 parameter block for KLMD-query-authentication-information. Condition code 0 is set when execution of the KLMD-query-authentication-information function completes; condition code 3 is not applicable to this function.

The format-0 parameter block used for the KLMD-query-authentication-information function has the following format:

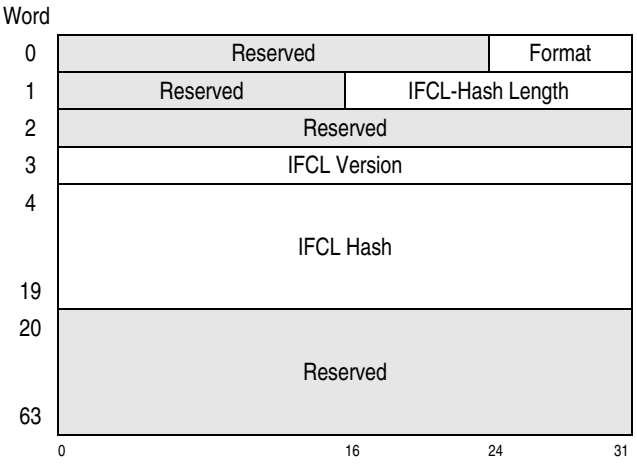


Figure 7-281. Format-0 Parameter Block for KLMD-Query-Authentication-Information

The format-0 parameter block contains the following fields:

Reserved: Bytes 0-2 of word 0, bytes 0-1 of word 1, word 2, and words 20-63 are reserved and stored as zeros.

Format: Byte 3 of word 0 contains an 8-bit unsigned binary integer whose value specifies the format of the parameter block. A format value of zero indicates a format-0 parameter block. When a format-0 parameter block is stored, the value of this field is set to zero.

IFCL-Hash Length: Bytes 2-3 of word 1 contain a 16-bit unsigned binary integer specifying the number of bytes of the IFCL hash stored in the IFCL hash field. When the IFCL hash is less than or equal to 64 bytes, the IFCL-hash length field is set to the actual length of the IFCL hash. When the IFCL hash is larger than 64 bytes, the IFCL-hash length field is set to 64.

IFCL Version: Word 3 contains a 32-bit unsigned binary integer specifying the version number of the IFCL.

IFCL Hash: Words 4-19 contain the hash value of the IFCL. The IFCL-hash length field specifies the number of bytes that are in the IFCL hash field. The IFCL hash value is left aligned. When the IFCL hash is less than 64 bytes, it is padded with zeros on the right. When the IFCL hash is larger than 64 bytes, only the leftmost 64 bytes of the IFCL hash are stored.

Special Conditions

A specification exception is recognized and no other action is taken if any of the following occurs:

- Bit 56 of general register 0 is not zero.
- Bits 57-63 of general register 0 specify an unassigned or uninstalled function code.
- The R_2 field designates an odd-numbered register or general register 0.
- For the KLMD-SHAKE functions, either of the following is true:
  - The R_1 field designates an odd-numbered register, general register 0, or register R_2.
  - The second-operand length is nonzero, and the PS flag is one.

Resulting Condition Code:

0 Normal completion
1 --
2 --
3 Partial completion

Program Exceptions:

- Access (fetch, operand 2 and message bit length; fetch and store, chaining value; store,

operand 1, cryptography counter, query parameter block, and query-authentication-information parameter block)
- Operation (if the message-security assist is not installed)
- Specification
- Transaction constraint

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B	Operation exception.
7.C	Transaction constraint
8.A	Specification exception due to invalid function code, or invalid register number.
8.B	Specification exception due to nonzero second-operand length when the PS flag is one (SHAKE functions only).
9.	Access exceptions for an access to the parameter block or second operand.
10.	Access exceptions for an access to the first operand (SHAKE functions only).
11.	Condition code 3 due to partial completion and one or more units of operation remain to be processed.
12.	Access exceptions for an access to a cryptography counter and second-operand length initially less than or equal to UopOpLen for SHA-1, SHA-256, SHA-512, and SHA-3 functions, or second and first-operand lengths initially less than or equal to UopOpLen for SHAKE functions, where UopOpLen is the maximum amount of second or first operand processed during a unit of operation.
13.	Condition code 3 due to partial completion and second-operand length initially less than or equal to UopOpLen for SHA and SHA-3 functions, or second and first-operand lengths initially less than or equal to UopOpLen for SHAKE functions, where UopOpLen is the maximum amount of second or first operand processed during a unit of operation.
14.	Condition code 0 due to normal completion.

Figure 7-282. Priority of Execution: KLMD

Programming Notes:

1. The performance of the query function (code 0) may be significantly slower than that of simply examining a location in storage. If the program needs to frequently test for the availability of a function, it should perform the query function once during initialization; subsequently it should examine the stored results of the query function in memory with an instruction such as TEST UNDER MASK.

2. Programming notes 2-10 for COMPUTE INTERMEDIATE MESSAGE DIGEST are also applicable to COMPUTE LAST MESSAGE DIGEST.

3. For the KLMD-SHAKE functions, when condition code 3 is set during the XOF processing, the first operand address and length in general registers R_1 and $R_1 + 1$, respectively, are updated such that the program can simply branch back to the instruction to continue the operation.

   For unusual situations, the CPU protects against endless reoccurrence for the no-progress case. Thus, the program can safely branch back to the instruction whenever condition code 3 is set with no exposure to an endless loop.

4. For the KLMD-SHA-1, KLMD-SHA-256, and KLMD-SHA-512 functions, if the length of the second operand is nonzero initially and condition code 0 is set, the registers are updated in the same manner as for condition code 3; the chaining value in this case is such that additional operands can be processed as if they were part of the same chain.

5. For the KLMD-SHA-1, KLMD-SHA-256, and KLMD-SHA-512 functions, when processing the last message part, the program must compute the length of the original message in bits and place this length value in the message-bit-length field of the parameter block, and use the COMPUTE LAST MESSAGE DIGEST instruction.

6. The COMPUTE LAST MESSAGE DIGEST instruction does not require the second operand to be a multiple of the data block size. It first processes complete blocks, and may set condition code 3 before processing all blocks. After processing all complete blocks, it then performs the padding operation including the remaining portion of the second operand. This may require one or two iterations of the designated block digest algorithm.

7. The COMPUTE LAST MESSAGE DIGEST instruction provides the SHA padding for messages that are a multiple of eight bits in length. If a SHA function is to be applied to a bit string which is not a multiple of eight bits, the program must perform the SHA padding and use the COMPUTE INTERMEDIATE MESSAGE DIGEST instruction.

8. The following applies to the message-bit length (MBL) in the parameter block of KLMD-SHA-1, KLMD-SHA-256, and KLMD-SHA-512.

   a. The MBL is completely independent of the second-operand length in general register $R_2 + 1$.

   b. Regardless of whether the instruction ends with condition code 0 or 3, the MBL is not decremented by the number of bytes processed.

   c. In normal usage, the MBL is expected to be eight times the total size of the message in bytes. If the program supplies a MBL that is not a multiple of eight, the results will be algorithmically correct, but may not be usable in any practical application.

   d. The secure-hash algorithm described in Reference [21.] on page xxxii allows for message-bit length that are not multiples of eight. COMPUTE LAST MESSGE DIGEST requires the message-bit length to be a multiple of eight.

9. For the KLMD-SHAKE functions, the following applies:

   a. The padding state (PS), bit 7 of the flags field of general register 0, should be set to zero prior to the first execution of KLMD for a message, and the padding state should not be altered by the program for any subsequent executions of KLMD for the same message until normal completion occurs.

   b. If padding of the final (short or null) block of the second operand is performed when the first-operand length is zero, then the padded block is exclusive ORed with the contents of the state array, the result is stored as the output-chaining value in the parameter block when the DUFOP flag is zero, and the instruction completes with condition code 0. The KECCAK[c] function is not invoked in this case.

10. For the SHA-3 and SHAKE functions, the entire OCV is stored in the parameter block after completing a unit of operation if the instruction does not complete with condition code 0 immediately after completing the unit of operation.

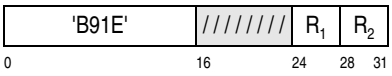
11. For the SHA-3 and SHAKE functions, the following applies:

    a. The NIP flag of general register 0 should be set to one (instead of setting the initial-chaining value in the parameter block to zeros) prior to the first execution for a message using either KIMD or KLMD, and the NIP flag should not be altered by the program for any subsequent executions of KIMD or KLMD for the same message to improve performance.

    b. If the entire final OCV is not needed by the program, the DUFOP flag of general register 0 should be set to one prior to the first execution of KLMD for a message, and the DUFOP flag should not be altered by the program for any subsequent executions of KLMD for the same message to improve performance.

COMPUTE MESSAGE AUTHENTICATION CODE

KMAC R_1,R_2 [RRE]



A function specified by the function code in general register 0 is performed.

Bits 16-23 of the instruction and the R_1 field are ignored.

Function Code (FC): Bit positions 57-63 of general register 0 contain the function code. Figure 7-283 shows the assigned function codes. When the message-security-assist extension 11 is installed, function codes 112-115 and 120-123 are valid for COMPUTE MESSAGE AUTHENTICATION CODE. When the message-security-assist extension 13 is installed, function code 127 is valid for COM-

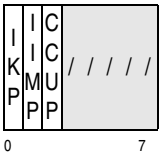
PUTE MESSAGE AUTHENTICATION CODE. All other function codes are unassigned.

Bit positions 0-31 of general register 0 are ignored for all function codes.

Bit positions 32-55 of general register 0 are ignored when the specified function code is 0, 1, 2, 3, 9, 10, 11, 18, 19, 20, 26, 27, or 28. Bit positions 32-47 of general register 0 are reserved and should contain zeros when the message-security-assist extension 11 is installed and any other function code is specified; otherwise, the program may not operate compatibly in the future.

When the message-security-assist extension 11 is installed, bit positions 48-55 of general register 0 contain an 8-bit flags (F) field and bits 0-2 of the flags field contain the inner-key padding (IKP) flag (bit 0), the intermediate-input-message part (IIMP) flag (bit 1), and the cryptography counter update pending (CCUP) flag (bit 2), respectively. The flags field does not apply to function codes 0, 1, 2, 3, 9, 10, 11, 18, 19, 20, 26, 27, or 28.

Flags (F): Bit positions 48-55 of general register 0 contain an 8-bit flags field controlling the operation of the function. The flags field is meaningful only for specific function codes (see each flag description for details). The format of the flags field is as follows:



The individual flag fields are defined as follows:

Reserved: Bits 3-7 of the flags field are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.

Inner-Key Padding (IKP): Bit 0 of the flags field indicates if the inner-key padding and hashing operation has been performed. The IKP flag is meaningful only when the function code in bit positions 57-63 of general register 0 designates an HMAC function (function codes 112-115 and 120-123).

The inner-key padding and hashing operation includes exclusive-OR of the cryptographic key (K) with the inner pad (ipad) to produce the inner key followed by hash of the inner key using the $H^{(0)}$ value.

When the IKP flag is zero, the inner-key padding and hashing operation has not been performed; otherwise, the inner-key padding and hashing operation has been performed.

Intermediate-Input-Message Part (IIMP): Bit 1 of the flags field indicates if operand 2 contains the intermediate input message part. The IIMP flag is meaningful only when the function code in bit positions 57-63 of general register 0 designates an HMAC function (function codes 112-115 and 120-123).

When the IIMP flag is zero, operand 2 contains the last input message part; otherwise, the operand 2 contains the intermediate input message part.

Cryptography Counter Update Pending (CCUP): Bit 2 of the flags field indicates if the cryptography counter access exception has been detected. The CCUP flag is meaningful only when the function code in bit positions 57-63 of general register 0 designates an HMAC function (function codes 112-115 and 120-123) and the second-operand length is zero. The program should set the CCUP flag to zero before the first issuance of the instruction and not update it in the subsequent re-drive of the same instruction; otherwise, the HMAC algorithm may not be processed correctly.

When the CCUP flag is zero, the cryptography counter access exception either has not been detected or the cryptography counter access exception has been resolved; otherwise, the cryptography counter access exception has been detected.

When the CCUP flag is not initially one and the cryptography counter access exception is detected, the CCUP flag is set to one and condition code 3 is set. When the CCUP flag is initially one, the appropriate cryptography counter is updated and condition code 0 is set.

Bit 56 of general register 0 must be zero; otherwise, a specification exception is recognized.

General register 1 contains the logical address of the leftmost byte of the parameter block in storage. In the 24-bit addressing mode, the contents of bit positions 40-63 of general register 1 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of general register 1 constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents

of bit positions 0-63 of general register 1 constitute the address.

The function codes for COMPUTE MESSAGE AUTHENTICATION CODE are as follows.

Code	Function	Parm. Block Size (bytes)	Data Block Size (bytes)
0	KMAC-Query *	16	—
1	KMAC-DEA *	16	8
2	KMAC-TDEA-128 *	24	8
3	KMAC-TDEA-192 *	32	8
9	KMAC-Encrypted-DEA	40	8
10	KMAC-Encrypted-TDEA-128	48	8
11	KMAC-Encrypted-TDEA-192	56	8
18	KMAC-AES-128	32	16
19	KMAC-AES-192	40	16
20	KMAC-AES-256	48	16
26	KMAC-Encrypted-AES-128	64	16

123	KMAC-HMAC-Encrypted-SHA-512	240	128
127	KMAC-Query-Authentication-Information	V	—

Explanation:

— Not applicable

* Function is also defined in the ESA/390 architectural mode and the ESA/390-compatibility mode. It is unpredictable whether other function codes are available in the ESA/390-compatibility mode.

V Variable parameter block size. See each format-x parameter block for the exact size of that parameter block.

Figure 7-283. Function Codes for COMPUTE MESSAGE AUTHENTICATION CODE (Part 1 of 2)

Figure 7-283. Function Codes for COMPUTE MESSAGE AUTHENTICATION CODE (Part 2 of 2)

The query function provides the means of indicating the availability of the other functions. The contents of general registers R_2 and $R_2 + 1$ are ignored.

The query-authentication-information function provides the information that can be used by the program to authenticate the running instruction's firmware code level (IFCL) currently installed on the model. The contents of general registers R_2, and $R_2 + 1$ are ignored for the query-authentication-information function.

For the HMAC functions, the inner-key padding and hashing operation is performed if the IKP flag is zero and the full input message blocks based on second operand length is processed. If the IIMP flag is zero, the SHA padding and hashing operation is performed on the last (partial or empty) input message block, the output chaining value (OCV) is saved, the outer-key padding and hashing operation is performed, the SHA padding and hashing operation is performed on

the saved OCV, and the result is stored into the chaining value (CV) field of the parameter block. The operation completes with either condition code 0 (normal completion) or condition code 3 (partial completion).

For all other functions, the second operand is processed as specified by the function code using an initial chaining value in the parameter block, and the result replaces the initial chaining value. The operation also uses a cryptographic key in the parameter block. The operation proceeds until the end of the second-operand location is reached or a CPU-determined number of bytes have been processed, whichever occurs first. The result is indicated in the condition code.

The R_2 field designates an even-odd pair of general registers and must designate an even-numbered register other than general register 0; otherwise, a specification exception is recognized.

The location of the leftmost byte of the second operand is specified by the contents of the R_2 general register. The number of bytes in the second-operand location is specified in general register $R_2 + 1$.

The second-operand length must be a multiple of the data block size when the designated function is either not an HMAC function or is an HMAC function (function codes 112-115 and 120-123) and the IIMP flag is one (see Figure 7-283 on page 7-241 to determine the data block size for COMPUTE MESSAGE AUTHENTICATION CODE functions); otherwise, a specification exception is recognized. When an HMAC function is specified and the IIMP flag is zero, the second-operand length can have any value, including zero. When an HMAC function is specified and the IIMP flag is one and the IKP flag is initially zero and the second-operand length is initially zero, a specification exception is recognized. When an HMAC function is specified and the CCUP flag is one and the second-operand length is not initially zero, the CCUP flag is set to zero. When an HMAC function is specified and the CCUP flag is one and the IIMP flag is zero and the IKP flag is initially zero and the second-operand length is initially zero, the CCUP flag is set to zero.

As part of the operation, the address in general register R_2 is incremented by the number of bytes processed from the second operand, and the length in general register $R_2 + 1$ is decremented by the same number. The formation and updating of the address and length is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general register R_2 constitute the address of the second operand, and the contents of bit positions 0-39 are ignored; bits 40-63 of the updated address replace the corresponding bits in general register R_2, carries out of bit position 40 of the updated address are ignored and, the contents of bit positions 32-39 of general register R_2 are set to zeros. In the 31-bit addressing mode, the contents of bit positions 33-63 of general register R_2 constitute the address of the second operand, and the contents of bit positions 0-32 are ignored; bits 33-63 of the updated address replace the corresponding bits in general register R_2, carries out of bit position 33 of the updated address are ignored, and the content of bit position 32 of general register R_2 is set to zero. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register R_2 constitute the address of the second operand; bits 0-63 of the updated address replace the contents of general register R_2 and carries out of bit position 0 are ignored.

In both the 24-bit and the 31-bit addressing modes, the contents of bit positions 32-63 of general register $R_2 + 1$ form a 32-bit unsigned binary integer which specifies the number of bytes in the second operand; and the updated value replaces the contents of bit positions 32-63 of general register $R_2 + 1$. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register $R_2 + 1$ form a 64-bit unsigned binary integer which specifies the number of bytes in the second operand; and the updated value replaces the contents of general register $R_2 + 1$.

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers R_2 and $R_2 + 1$, always remain unchanged.

Figure 7-284 shows the contents of the general registers just described.

All Addressing Modes

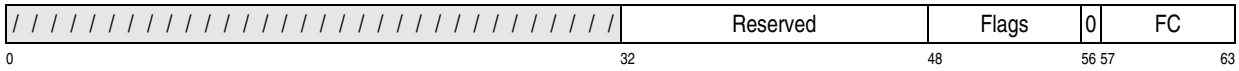

Figure 7-284. General Register Assignment for KMAC (Part 1 of 2)

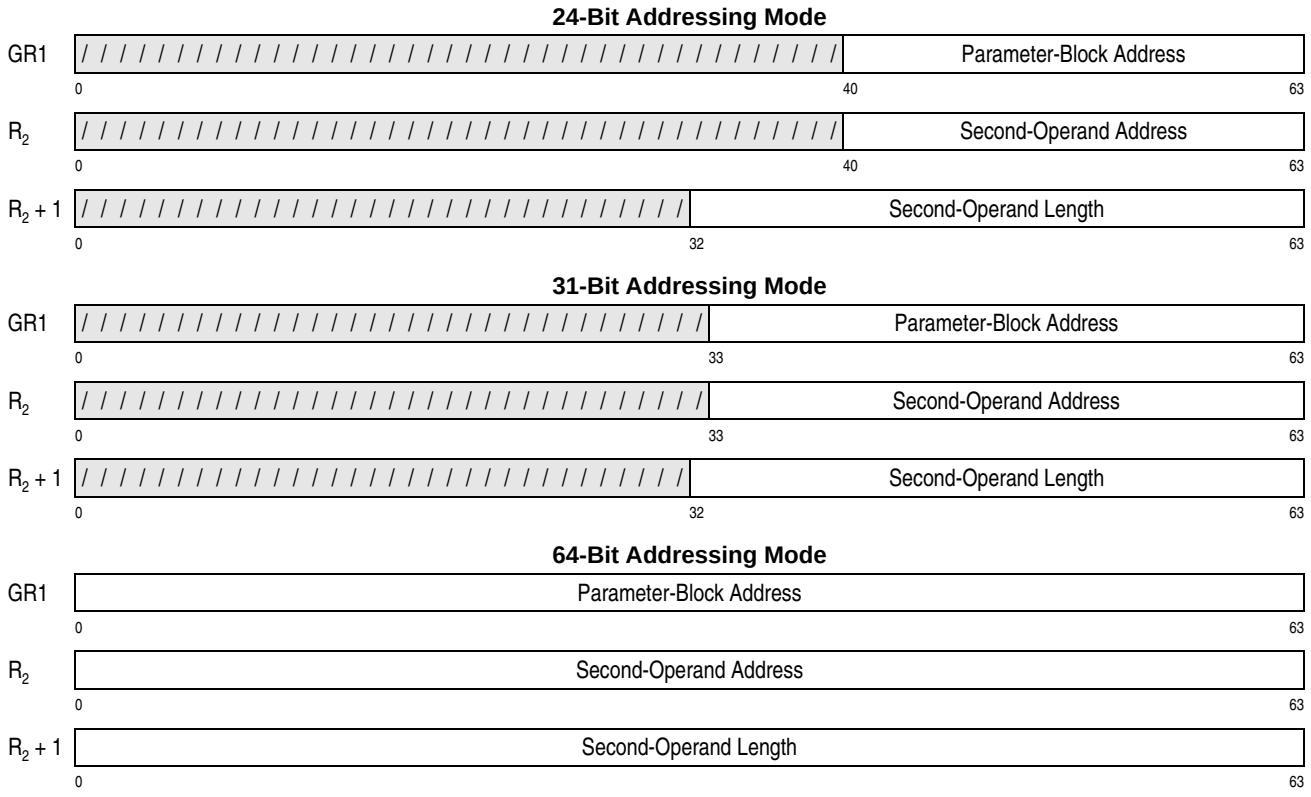

Figure 7-284. General Register Assignment for KMAC (Part 2 of 2)

In the access-register mode, access registers 1 and R_2 specify the address spaces containing the parameter block and second operand, respectively.

For the HMAC functions, the result is obtained as if processing starts at the inner-key padding and hashing operation followed by the hashing of the input message blocks based on second operand length from left to right, and if the IIMP flag is zero, then continuing with the input message padding and hashing operation followed by the outer-key padding and hashing operation and then ending with the output message padding and hashing operation. The authentication operation is ended when all source bytes in the second operand have been processed if the IIMP flag is one or when the output message padding and hashing operation has been processed if the IIMP flag is zero, or when a CPU-determined number of blocks that is less than the number of blocks of the entire process have been processed.

For functions other than the HMAC and query functions, the result is obtained as if processing starts at the left end of the second operand and proceeds to the right, block by block. The authentication operation is ended when all source bytes in the second operand have been processed, or when a CPU-determined number of blocks that is less than the length of the second operand have been processed.

The CPU-determined number of blocks depends on the model, and may be a different number each time the instruction is executed. The CPU-determined number of blocks is usually nonzero. In certain unusual situations, this number may be zero, and condition code 3 may be set with no progress. However, the CPU protects against endless reoccurrence of this no-progress case.

For the HMAC functions, if the CPU is enabled to update counters in the cryptography-counter set and the appropriate cryptography counter is accessible, then subsequent to performing the inner-key padding and hashing operation and processing all bytes of the second operand followed by the input message block padding and hashing operation, the outer-key padding and hashing operation, and the output message block padding and hashing operation if the IIMP flag is zero, the appropriate cryptography counter is updated.

For functions other than the HMAC and query functions, if the CPU is enabled to update counters in the cryptography-counter set, then subsequent to processing all bytes of the second operand, the appropriate counter is updated.

When the initial-chaining-value field overlaps any portion of the second operand, the result in the chaining-value field is unpredictable.

Normal completion occurs when the authentication operation has ended and, when applicable, a counter in the cryptography-counter set has been updated. Partial completion occurs when a CPU-determined number of blocks that is less than the length of the second operand have been processed or when the CPU is enabled to update a counter in the cryptography-counter set and the appropriate cryptography counter has not yet been updated.

For the HMAC functions, when the operation ends due to normal completion, condition code 0 is set, the IKP flag is set to one, the value in general register $R_2 + 1$ is set to zero, and the CCUP flag is set to zero. When the operation ends due to partial completion, condition code 3 is set. In this case, if the CPU is enabled to update counters in the cryptography-counter set, the inner-key padding and hashing operation has been performed, all of the second operand has been processed, the input message block padding and hashing operation has been performed, the outer-key padding and hashing operation has been performed, the output message block padding and hashing operation has been performed, and the appropriate counter is not accessible, then the IKP flag is set to one, the resulting value placed in general register $R_2 + 1$ is zero, and the CCUP flag is set to one; otherwise the IKP flag is set to one if the inner-key padding and hashing operation has been performed, the resulting value placed in general register $R_2 + 1$ is nonzero if all of the second operand has not been processed, or the resulting value placed in general register $R_2 + 1$ is zero if all of the second operand has been processed.

For functions other than the HMAC and query functions, when the operation ends due to normal completion, condition code 0 is set and the resulting value in $R_2 + 1$ is zero. When the operation ends due to partial completion, condition code 3 is set. In this case, if the CPU is enabled to update counters in the cryptography-counter set, all of the second operand has been processed, and the appropriate counter is not accessible, then the resulting value placed in general register $R_2 + 1$ is zero; otherwise the resulting value placed in general register $R_2 + 1$ is nonzero.

For the HMAC functions, when the second-operand length is initially zero, the following occurs. The second operand is not accessed, the parameter block is not accessed if the IIMP flag is one, and general registers R_2 and $R_2 + 1$ are not changed. The inner-key padding and hashing operation is performed if the IKP flag is zero. If the IIMP flag is zero and the CCUP flag is zero, the empty input message block SHA padding and hashing operation is performed followed by the outer-key padding and hashing operation and the final SHA padding and hashing operation and the result is stored into the chaining value (CV) field of the parameter block. If the CPU is not enabled to update counters in the cryptography-counter set, then condition code 0 is set and the CCUP flag is set to zero. If the CPU is enabled to update counters in the cryptography-counter set, and the appropriate counter is accessible, then the appropriate cryptography counter is updated, condition code 0 is set, and the CCUP flag is set to zero. If the CPU is enabled to update counters in the cryptography-counter set and the appropriate counter is not accessible, then condition code 3 is set and the CCUP flag is set to one if the CCUP flag is zero, or the condition code remains unchanged and an access exception is recognized for the location of the appropriate cryptography counter if the CCUP flag is one.

For functions other than the HMAC and query functions, when the second-operand length is initially zero, the following occurs. The second operand and the parameter block are not accessed and general registers R_2 and $R_2 + 1$ are not changed. If the CPU is not enabled to update counters in the cryptography-counter set, then condition code 0 is set. If the CPU is enabled to update counters in the cryptography-counter set, and the appropriate cryptography counter is accessible, then the appropriate cryptography counter is updated and condition code 0 is set. If the CPU is enabled to update counters in the cryptography-counter set, and the appropriate cryptography counter is not accessible, then the condition code remains unchanged and an access exception is recognized for the location of the appropriate cryptography counter.

A PER storage-alteration event may be recognized for the portion of the parameter block that is stored. For the HMAC functions, the entire parameter block may be tested for store-type accesses even though

part of it may not be stored. A PER zero-address-detection event may be recognized for the second-operand location and for the parameter block when the second-operand length is not initially zero. For the HMAC functions, a PER zero-address-detection event may also be recognized for the parameter block when the second-operand length is initially zero and the IIMP flag is zero. When PER events are detected for more than one location, it is unpredictable which location is identified in the PER access identification (PAID) and PER ASCE ID (AI).

As observed by this CPU, other CPUs, and channel programs, references to the parameter block and storage operand may be multiple-access references, accesses to these storage locations are not necessarily block-concurrent, and the sequence of these accesses or references is undefined.

For functions that perform a comparison of the wrapping-key verification pattern field in the parameter block with the wrapping-key verification-pattern register, it is unpredictable whether access exceptions and PER zero-address-detection events are recognized for the second operand when the comparison results in a mismatch.

Access exceptions may be reported for a larger portion of the second operand than is processed in a single execution of the instruction; however, access exceptions are not recognized for locations beyond the length of the second operand nor for locations more than 4K bytes beyond the current location being processed.

Symbols Used in Function Descriptions

The following symbols are used in the subsequent description of the COMPUTE MESSAGE AUTHENTICATION CODE functions. For data-encryption-algorithm (DEA) functions, the DEA-key-parity bit in each byte of the DEA key is ignored, and the operation proceeds normally, regardless of the DEA-key parity of the key. Further description of the data-encryption algorithm may be found in Reference [13.] on page xxxii. Further description of the AES standard may be found in Reference [14.] on page xxxii. Further description of the SHA algorithm may be found in Reference [36.] on page xxxiii. Further description of the HMAC algorithm may be found in Reference [44.] on page xxxiii.

Other Symbols Used in Function Descriptions

The following additional symbols are used in the subsequent description of the COMPUTE MESSAGE AUTHENTICATION CODE functions. Further description of the HMAC algorithm may be found in Reference [44.] on page xxxiii. Further description of the secure hash algorithm may be found in Reference [15.] on page xxxii.

Symbol	Explanation for KMAC Function Figures
L	Byte length of operand 2 in storage.
p <n>	n padding bytes; leftmost byte is 80 hex; all other bytes are 00 hex.
z <n>	n padding bytes of zero.
IMBL	An 8-byte or 16-byte value specifying the bit length of the total input message.
OMBL	An 8-byte or 16-byte value specifying the bit length of the total output message.
q <64>	A padding block, consisting of 56 bytes of zero followed by an 8-byte IMBL.
q <128>	A padding block, consisting of 112 bytes of zero followed by a 16-byte IMBL.
ipad <64>	Inner pad, consisting of 64 bytes of 36 hex.
ipad <128>	Inner pad, consisting of 128 bytes of 36 hex.
opad <64>	Outer pad, consisting of 64 bytes of 5C hex.
opad <128>	Outer pad, consisting of 128 bytes of 5C hex.

KMAC-Query (Function Code 0)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-284 on page 7-242.

The parameter block used for the function has the following format:

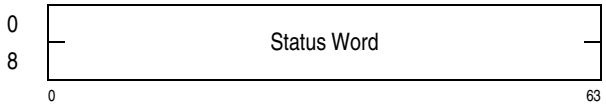

Figure 7-292. Parameter Block for KMAC-Query

A 128-bit status word is stored in the parameter block. Bits 0-127 of this field correspond to function codes 0-127, respectively, of the KMAC instruction. When a bit is one, the corresponding function is installed; otherwise, the function is not installed.

Condition code 0 is set when execution of the KMAC-Query function completes; condition codes 1 and 3 are not applicable to this function.

KMAC-DEA (Function Code 1)

KMAC-Encrypted-DEA (Function Code 9)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-284 on page 7-242.

The parameter block used for the KMAC-DEA function has the following format:

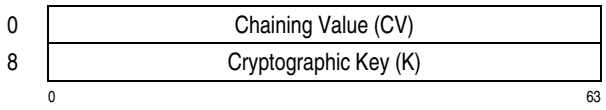

Figure 7-293. Parameter Block for KMAC-DEA

For the KMAC-DEA function, the initial chaining value is in byte offsets 0-7 of the parameter block and the cryptographic key is in byte offsets 8-15 of the parameter block.

The parameter block used for the KMAC-Encrypted-DEA function has the following format:

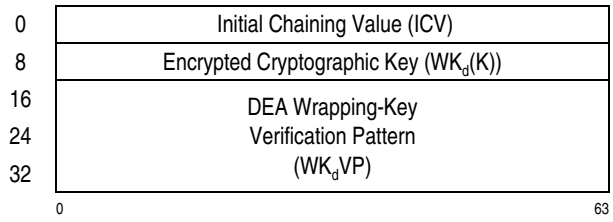

Figure 7-294. Parameter Block for KMAC-Encrypted-DEA

For the KMAC-Encrypted-DEA function, the contents of byte offsets 16-39 of the parameter block are compared with the contents of the DEA wrapping-key verification-pattern register. If they mismatch, the parameter-block location remains unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 0-7 of the parameter block contain the initial chaining value, and the contents of byte offsets 8-15 of the parameter block are deciphered using the DEA wrapping key to obtain the 64-bit cryptographic key. (See the section, “Protection of Cryptographic Keys” on page 7-490, for details.)

The description in the following paragraph applies to both functions.

The message authentication code for the 8-byte message blocks (M1, M2, …, Mn) in operand 2 is computed using the DEA algorithm with the 64-bit cryptographic key and the 64-bit initial chaining value.

The message authentication code, also called the output chaining value (OCV), is stored in the initial-

chaining-value field of the parameter block. The operation is shown in Figure 7-295.

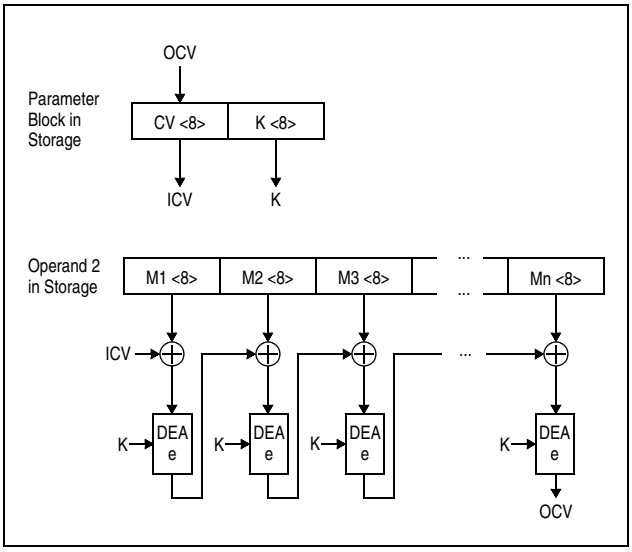

Figure 7-295. MAC Computation Using 64-bit DEA Key

KMAC-TDEA-128 (Function Code 2)

KMAC-Encrypted-TDEA-128 (Function Code 10)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-284 on page 7-242.

The parameter block used for the KMAC-TDEA-128 function has the following format:

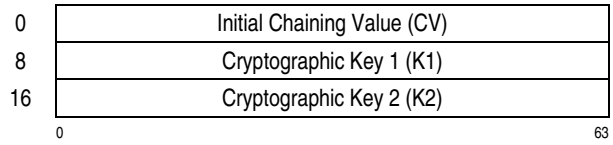

Figure 7-296. Parameter Block for KMAC-TDEA-128

For the KMAC-TDEA-128 function, the initial chaining value is in byte offsets 0-7 of the parameter block and the cryptographic key is in byte offsets 8-23 of the parameter block.

The parameter block used for the KMAC-Encrypted-TDEA-128 function has the following format:

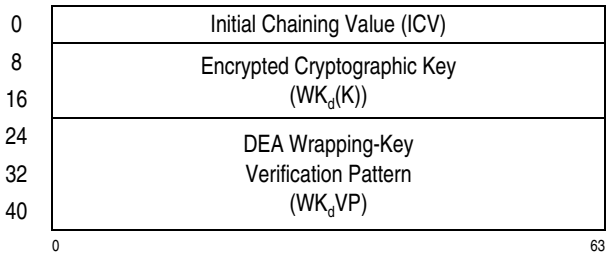

Figure 7-297. Parameter Block for KMAC-Encrypted-TDEA-128

For the KMAC-Encrypted-TDEA-128 function, the contents of byte offsets 24-47 of the parameter block are compared with the contents of the DEA wrapping-key verification-pattern register. If they mismatch, the parameter-block location remains unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 0-7 of the parameter block contain the initial chaining value, and the contents of byte offsets 8-23 of the parameter block are deciphered using the DEA wrapping key to obtain the 128-bit cryptographic key, K. (See the section, “Protection of Cryptographic Keys” on page 7-490, for details.)

The description in the following paragraph applies to both functions.

The message authentication code for the 8-byte message blocks (M1, M2, …, Mn) in operand 2 is computed using the TDEA algorithm with the two 64-bit cryptographic keys and the 64-bit initial chaining value.

The message authentication code, also called the output chaining value (OCV), is stored in the initial-

chaining-value field of the parameter block. The operation is shown in Figure 7-298.

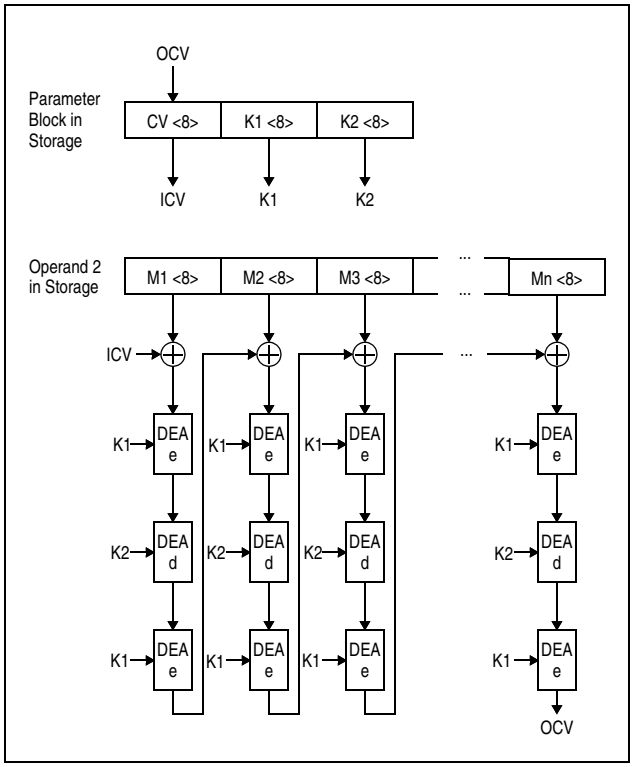

Figure 7-298. MAC Computation Using 128-bit TDEA Key

KMAC-TDEA-192 (Function Code 3)

KMAC-Encrypted-TDEA-192 (Function Code 11)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-284 on page 7-242.

The parameter block used for the KMAC-TDEA-192 function has the following format:

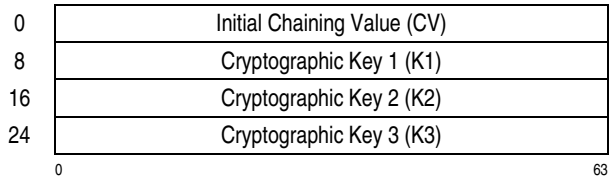

Figure 7-299. Parameter Block for KMAC-TDEA-192

For the KMAC-TDEA-192 function, the initial chaining value is in byte offsets 0-7 of the parameter block and the cryptographic key is in byte offsets 8-31 of the parameter block.

The parameter block used for the KMAC-Encrypted-TDEA-192 function has the following format:

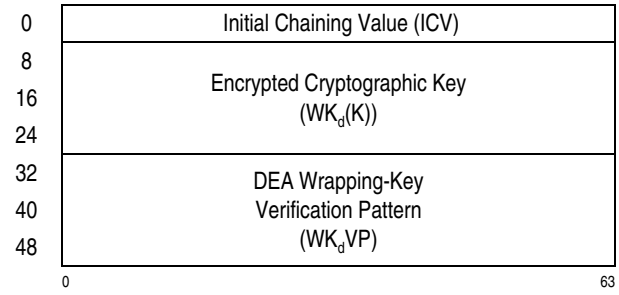

Figure 7-300. Parameter Block for KMAC-Encrypted-TDEA-192

For the KMAC-Encrypted-TDEA-192 function, the contents of byte offsets 32-55 of the parameter block are compared with the contents of the DEA wrapping-key verification-pattern register. If they mismatch, the parameter-block location remains unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 0-7 of the parameter block contain the initial chaining value, and the contents of byte offsets 8-31 of the parameter block are deciphered using the DEA wrapping key to obtain the 192-bit cryptographic key, K. (See the section, “Protection of Cryptographic Keys” on page 7-490, for details.)

The description in the following paragraph applies to both functions.

The message authentication code for the 8-byte message blocks (M1, M2, …, Mn) in operand 2 is computed using the TDEA algorithm with the three 64-bit cryptographic keys and the 64-bit chaining value.

The message authentication code, also called the output chaining value (OCV), is stored in the initial-

chaining-value field of the parameter block. The operation is shown in Figure 7-301.

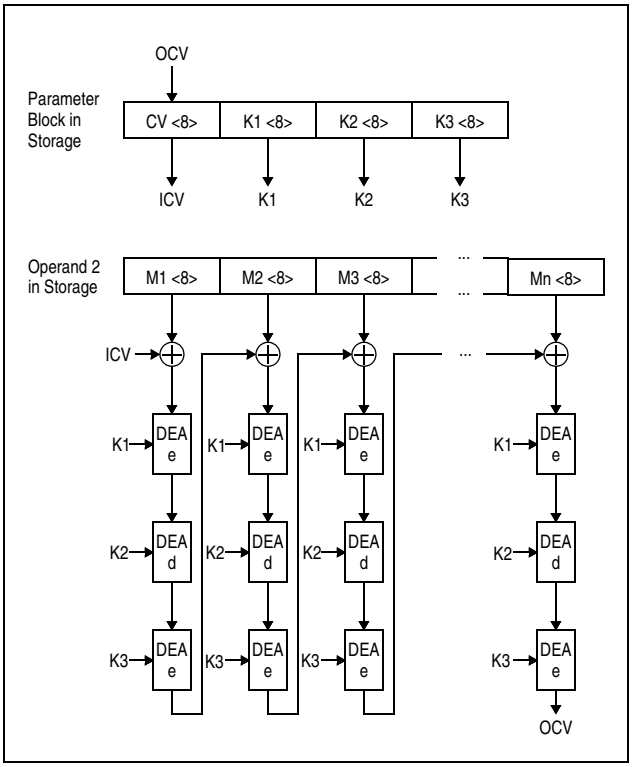

Figure 7-301. MAC Computation Using 192-bit TDEA Key

KMAC-AES-128 (Function Code 18)

KMAC-Encrypted-AES-128 (Function Code 26)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-284 on page 7-242.

The parameter block used for the KMAC-AES-128 function has the following format:

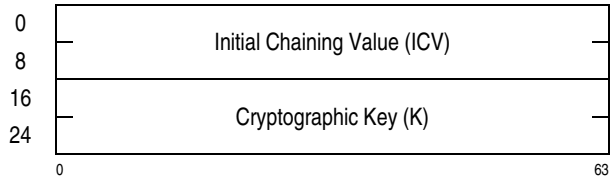

Figure 7-302. Parameter Block for KMAC-AES-128

For the KMAC-AES-128 function, the initial-chaining value is in byte offsets 0-15 of the parameter block and the cryptographic key is in byte offsets 16-31of the parameter block.

The parameter block used for the KMAC-Encrypted-AES-128 function has the following format:

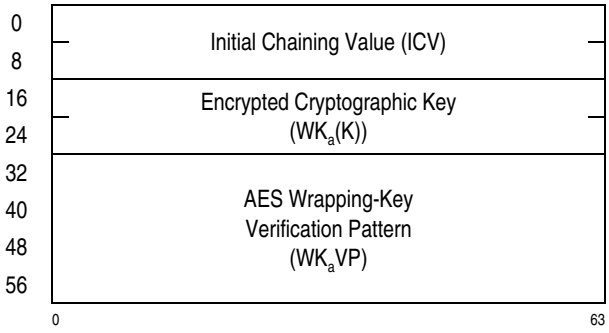

Figure 7-303. Parameter Block for KMAC-Encrypted-AES-128

For the KMAC-Encrypted-AES-128 function, the contents of byte offsets 32-63 of the parameter block are compared with the contents of the AES wrapping-key verification-pattern register. If they mismatch, the parameter-block location remains unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 0-15 of the parameter block contain the initial chaining value, and the contents of byte offsets 16-31 of the parameter block are deciphered using the AES wrapping key to obtain the 128-bit cryptographic key, K. (See the section “Protection of Cryptographic Keys” on page 7-490 for details.)

The description in the following paragraph applies to both functions.

The message authentication code for the 16-byte message blocks (M1, M2, …, Mn) in operand 2 is computed using the AES algorithm with the 128-bit cryptographic key and the 128-bit chaining value.

The message authentication code, also called the output chaining value (OCV), is stored in the initial-

chaining-value field of the parameter block. The operation is shown in Figure 7-304.

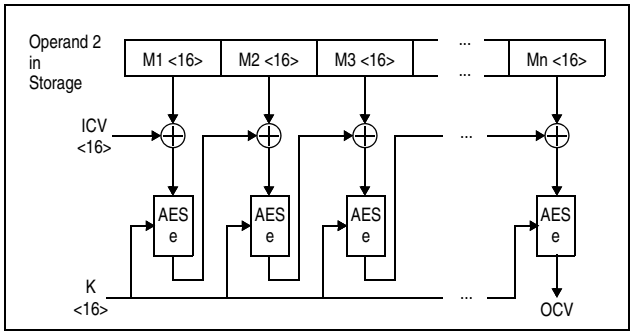

Figure 7-304. KMAC-AES-128

KMAC-AES-192 (Function Code 19)

KMAC-Encrypted-AES-192 (Function Code 27)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-284 on page 7-242.

The parameter block used for the KMAC-AES-192 function has the following format:

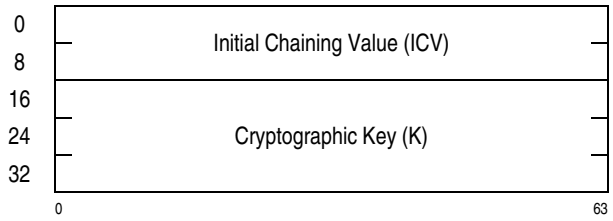

Figure 7-305. Parameter Block for KMAC-AES-192

For the KMAC-AES-192 function, the initial-chaining value is in byte offsets 0-15 of the parameter block and the cryptographic key is in byte offsets 16-39 of the parameter block.

The parameter block used for the KMAC-Encrypted-AES-192 function has the following format:

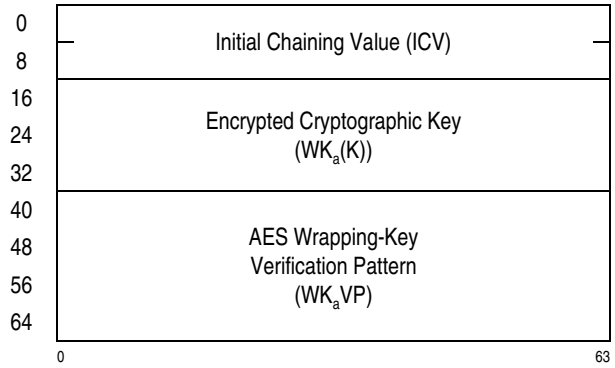

Figure 7-306. Parameter Block for KMAC-Encrypted-AES-192

For the KMAC-Encrypted-AES-192 function, the contents of byte offsets 40-71 of the parameter block are compared with the contents of the AES wrapping-key verification-pattern register. If they mismatch, the parameter-block location remains unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 0-15 of the parameter block contain the initial chaining value, and the contents of byte offsets 16-39 of the parameter block are deciphered using the AES wrapping key to obtain the 192-bit cryptographic key, K. (See the section “Protection of Cryptographic Keys” on page 7-490 for details.)

The description in the following paragraph applies to both functions.

The message authentication code for the 16-byte message blocks (M1, M2, …, Mn) in operand 2 is computed using the AES algorithm with the 192-bit cryptographic key and the 128-bit chaining value.

The message authentication code, also called the output chaining value (OCV), is stored in the initial-

chaining-value field of the parameter block. The operation is shown in Figure 7-307.

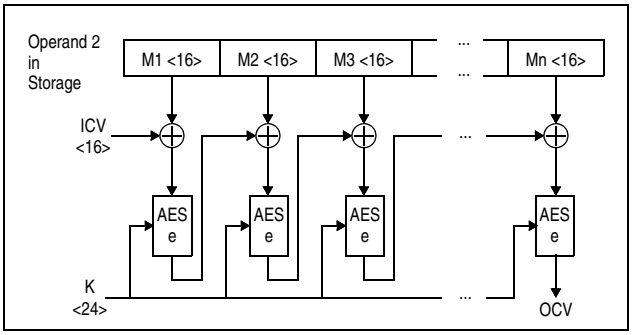

Figure 7-307. KMAC-AES-192

KMAC-AES-256 (Function Code 20)

KMAC-Encrypted-AES-256 (Function Code 28)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-284 on page 7-242.

The parameter block used for the KMAC-AES-256 function has the following format:

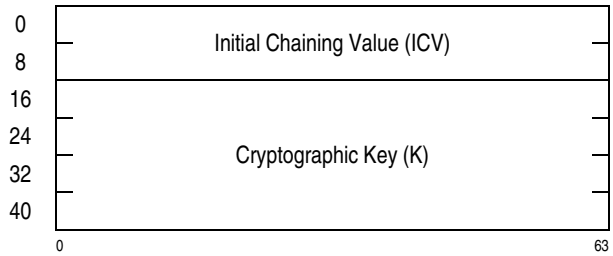

Figure 7-308. Parameter Block for KMAC-AES-256

For the KMAC-AES-256 function, the initial-chaining value is in byte offsets 0-15 of the parameter block and the cryptographic key is in byte offsets 16-47 of the parameter block.

The parameter block used for the KMAC-Encrypted-AES-256 function has the following format:

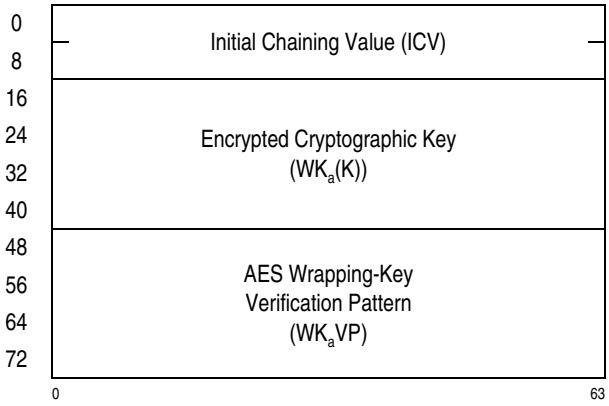

Figure 7-309. Parameter Block for KMAC-Encrypted-AES-256

For the KMAC-Encrypted-AES-256 function, the contents of byte offsets 48-79 of the parameter block are compared with the contents of the AES wrapping-key verification-pattern register. If they mismatch, the parameter-block location remains unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 0-15 of the parameter block contain the initial chaining value, and the contents of byte offsets 16-47 of the parameter block are deciphered using the AES wrapping key to obtain the 256-bit cryptographic key, K. (See the section “Protection of Cryptographic Keys” on page 7-490 for details.)

The description in the following paragraph applies to both functions.

The message authentication code for the 16-byte message blocks (M1, M2, …, Mn) in operand 2 is computed using the AES algorithm with the 256-bit cryptographic key and the 128-bit chaining value.

The message authentication code, also called the output chaining value (OCV), is stored in the initial-

chaining-value field of the parameter block. The operation is shown in Figure 7-310.

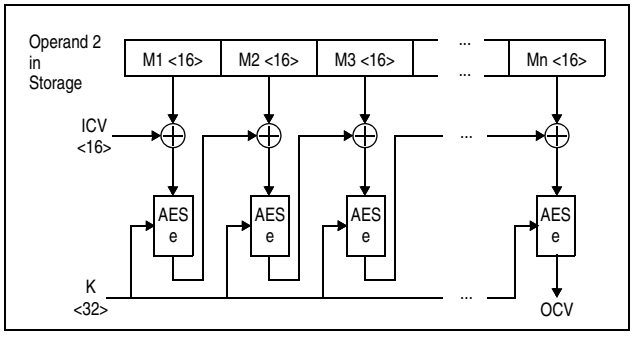

Figure 7-310. KMAC-AES-256

KMAC-HMAC-SHA-224 (Function Code 112)

KMAC-HMAC-SHA-256 (Function Code 113)

KMAC-HMAC-Encrypted-SHA-224 (Function Code 120)

KMAC-HMAC-Encrypted-SHA-256 (Function Code 121)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-284 on page 7-242.

The parameter block used for the KMAC-HMAC-SHA-224 and KMAC-HMAC-SHA-256 functions has the following format:

0	H0	H1
8	H2	H3
16	H4	H5
24	H6	H7
32	Input Message Bit Length (IMBL)	
40	Cryptographic Key (K)	
96		

0 32 63

Figure 7-311. Parameter Block for KMAC-HMAC-SHA-224 and KMAC-HMAC-SHA-256

For the KMAC-HMAC-SHA-224 and KMAC-HMAC-SHA-256 functions, the chaining value (called H fields) is in byte offsets 0-31 of the parameter block, the input-message-bit length (IMBL) is in byte offsets 32-39 of the parameter block, and the cryptographic key (K) is in byte offsets 40-103 of the parameter block.

The parameter block used for the KMAC-HMAC-Encrypted-SHA-224 and KMAC-HMAC-Encrypted-SHA-256 functions has the following format:

0	H0	H1
8	H2	H3
16	H4	H5
24	H6	H7
32	Input Message Bit Length (IMBL)	
40	Encrypted Cryptographic Key ($WK_a(K)$)	
96		
104	AES Wrapping-Key Verification Pattern (WK_aVP)	
128		

0 32 63

Figure 7-312. Parameter Block for KMAC-HMAC-Encrypted-SHA-224 and KMAC-HMAC-Encrypted-SHA-256

For the KMAC-HMAC-Encrypted-SHA-224 and KMAC-HMAC-Encrypted-SHA-256 functions, the contents of byte offsets 104-135 of the parameter block are compared with the contents of the AES wrapping-key verification-pattern register. If they mismatch, the parameter-block location remains unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 0-31 of the parameter block contain the chaining value (called H fields), byte offsets 32-39 of the parameter block contain the input-message-bit length (IMBL), and the contents of byte offsets 40-103 of the parameter block are deciphered using the AES wrapping key to obtain the 512-bit cryptographic key (K). (See the section “Protection of Cryptographic Keys” on page 7-490 for details.)

The description in the following paragraphs apply to all functions and the process is shown in Figure 7-313 on page 7-256.

The input-message-bit length (IMBL) in the parameter block contains the bit length of the total input message to be hashed.

The input-message-bit length (IMBL) in the parameter block contains the bit length of the total input message to be hashed (the input message bit length and the input key bit length). The IMBL field is ignored when IIMP flag is one.

The output-message-bit length (OMBL) contains the bit length of the total output message to be hashed.

The chaining value (CV) is formed by concatenating all the H fields together in order, starting with H0 on the left and ending with H7 on the right.

The initial chaining value (ICV) is the chaining value (CV) in the parameter block which is used as input to the SHA block digest algorithm.

Each SHA block digest algorithm contains a specific set of constants called the initial hash value ($H^{(0)}$). It is used as the initial chaining value (ICV) of the very first (leftmost) message block of a set of message blocks to be hashed. See Programming Notes on page 7-266 through page 7-266 for the specific SHA algorithm's initial hash value ($H^{(0)}$).

The output chaining value (OCV) is the output of the SHA block digest algorithm which is stored into the chaining value (CV) of the parameter block.

Programming Notes:

1. If the IMBL is not a multiple of 8, the program must store zeros in the unused bit positions of the last byte of the input message and round-up the input message bit length (IMBL) to a multiple of 8.

2. If the program's cryptographic key is smaller than the cryptographic key in the parameter block, the program must append zeros on the right side of the program's cryptographic key to enlarge it to the same size as the cryptographic key in the parameter block.

3. The program's original cryptographic key cannot be larger than the cryptographic key in the parameter block because $H^{(0)}$ (instead of CV from the parameter block) is used when hashing the inner-padded key. That is, the program must not use appropriate SHA algorithm to reduce the original cryptographic key to the same size as the cryptographic key in the parameter block.

When the IIMP flag is one, the second-operand length must be a multiple of the data block size. When the IIMP flag is zero and the last input message block contains a partial input message, the partial message block length (L), used in the final step of SHA padding, is set to the length of the last input message block; otherwise, L is set to zero. If the operation ends due to partial completion, condition code 3 is set.

When the CCUP flag is one and the second-operand length is not initially zero, the CCUP flag is set to zero. When the CCUP flag is one, the IIMP flag is zero, the IKP flag is initially zero, and the second-operand length is initially zero, the CCUP flag is set to zero. If the operation ends due to partial completion, condition code 3 is set.

When the IKP flag is zero (indicating that the inner-key padding and hashing operation has not been performed), the $H^{(0)}$ value of the SHA-224 block digest algorithm is used as the ICV for the KMAC-HMAC-SHA-224 and KMAC-HMAC-Encrypted-SHA-224 functions whereas the $H^{(0)}$ value of the SHA-256 block digest algorithm is used as the ICV for the KMAC-HMAC-SHA-256 and KMAC-HMAC-Encrypted-SHA-256 functions.

When the IKP flag is zero (indicating that the inner-key padding and hashing operation has not been performed), $H^{(0)}$ is used (instead of the CV from the parameter block) as input to perform the inner-key padding and hashing operation. When the IKP flag is one (indicating that the inner-key padding and hashing operation has been performed), the inner-key padding and hashing operation is not performed.

When the IKP flag is zero (indicating that inner-key padding and hashing operation has not yet been performed), the 512-bit (64-byte) cryptographic key (K) is exclusive-ORed with the inner pad (ipad) to produce the 64-byte inner key. A 32-byte chaining value 1 (CV_1) is generated for the 64-byte inner key using the SHA-256 block digest algorithm with the 32-byte $H^{(0)}$ value and the IKP flag is set to one. The generated chaining value 1 (OCV_1), also called the output chaining value (OCV), is stored into the chaining value (CV) field of the parameter block. If the operation ends due to partial completion, condition code 3 is set.

A 32-byte intermediate message digest (IMD) is generated for the 64-byte full input message blocks (M1, M2, …, Mn) in operand 2 using the SHA-256 block digest algorithm with the 32-byte chaining value (ICV_1) from the parameter block. If the IIMP flag is one or L is zero, M_{LFB} is the last input message block (Mn); otherwise, M_{LFB} is the input message block that is immediately precedes the last (partial) input message block (Mn-1). The generated intermediate message digest (OCV_2), also called the output chaining value (OCV), is stored into the chaining value (CV) field of the parameter block. This operation repeats until the remaining input message is less than 64 bytes or until a CPU-determined number of blocks have been stored. If the operation ends due to partial completion, condition code 3 is set.

When the IIMP flag is one (indicating intermediate input message part), the following occurs. If the CPU is not enabled to update counters in the cryptography-counter set, then condition code 0 is set (indicating normal completion) and the CCUP flag is set to zero. If the CPU is enabled to update counters in the cryptography-counter set and the appropriate counter is accessible, then the appropriate counter is updated, condition code 0 is set (indicating normal completion), and the CCUP flag is set to zero. If the CPU is enabled to update counters in the cryptography-counter set and the appropriate counter is not accessible, then condition code 3 is set and the CCUP flag is set to one if the CCUP flag is zero, or the condition code remains unchanged and an access exception is recognized for the location of the appropriate cryptography counter if the CCUP flag is one.

When the IIMP flag is zero (indicating the last input message part) and the operation ends due to partial completion, condition code 3 is set.

The description in the following paragraphs apply to all functions when the IIMP flag is zero (indicating the last input message part).

If the CCUP flag is one, the input message padding and hashing, the outer key padding and hashing, and the output message padding and hashing operations are not performed. Instead, only the appropriate counter in the cryptography-counter set is updated.

After all full input message blocks of operand 2 have been processed, the IMBL is updated to include the input key bit length by adding 512 (input key bit length) to IMBL and any carry is ignored. Then the padding operation is performed either on the last (partial) input message block or on a null block (M_{PMB}) in operand 2 (based on the calculated L value) using the input-message-bit length (IMBL) in byte offsets 32-39 of the parameter block to produce the padded input message block. Next, the hashing operation is performed on the padded input message block, and the final input message digest (FIMD) is generated using the SHA-256 block digest algorithm with the 32-byte chaining value (ICV_2) from the parameter block.

The padding and hashing operation of the input message is performed as follows. If the length of the partial message block length (L) is zero bytes, then the operation in Figure 7-314 is performed. If the length of the partial message block length (L) is between one byte and 55 bytes inclusive, then the operation in Figure 7-315 is performed; if the length of the partial message block length (L) is between 56 bytes and 63 bytes inclusive, then the operation in Figure 7-316 is performed.

The 512-bit (64-byte) cryptographic key (K) is exclusive-ORed with the outer pad (opad) to produce the 64-byte outer key. A 32-byte chaining value 3 (OCV_3) is generated for the 64-byte outer key using the SHA-256 block digest algorithm with the 32-byte $H^{(0)}$ value.

After the chaining value 3 (OCV_3) is generated, the padding operation is performed on the final input message digest (FIMD), also called the (partial) output message block (M_{PMB}), using the final input message digest (FIMD) bit length to produce the padded output message block. For KMAC-HMAC-SHA-224 and KMAC-HMAC-Encrypted-SHA-224 functions, the leftmost 28 bytes of the final input message digest (FIMD) is used as the (partial) output message block (M_{PMB}), L is set to 28, and OMBL is set to 736. For KMAC-HMAC-SHA-256 and KMAC-HMAC-Encrypted-SHA-256 functions, the entire final input message digest (FIMD) is used as the (partial) output message block (M_{PMB}), L is set to 32, and OMBL is set to 768.

Next, the final hashing operation is performed on the padded output message block and the final output message digest (OCV) is generated using the SHA-256 block digest algorithm with the 32-byte chaining value 3 (OCV_3). The entire final output message digest (OCV) is stored into the chaining value (CV) field of the parameter block.

The final padding and hashing operation of the output message is shown in Figure 7-317.

When the IIMP flag is zero (indicating the last input message part), the following occurs. If the CPU is not enabled to update counters in the cryptography-counter set, then condition code 0 is set (indicating normal completion) and the CCUP flag is set to zero. If the CPU is enabled to update counters in the cryptography-counter set and the appropriate counter is accessible, then the appropriate counter is updated, condition code 0 is set (indicating normal completion), and the CCUP flag is set to zero. If the CCUP flag is zero and the CPU is enabled to update counters in the cryptography-counter set and the appropriate counter is not accessible, then the condition code 3 is set and the CCUP flag is set to one. If the CCUP flag is one and the CPU is enabled to update counters in the cryptography-counter set and the appropriate counter is not accessible, then an access exception is recognized for the location of the appropriate cryptography counter.

KMAC-HMAC-SHA-384 (Function Code 114)

KMAC-HMAC-SHA-512 (Function Code 115)

KMAC-HMAC-Encrypted-SHA-384 (Function Code 122)

KMAC-HMAC-Encrypted-SHA-512 (Function Code 123)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-284 on page 7-242.

The parameter block used for the KMAC-HMAC-SHA-384 and KMAC-HMAC-SHA-512 functions has the following format:

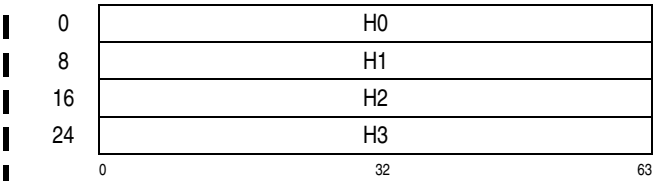

Figure 7-318. Parameter Block for KMAC-HMAC-SHA-384 and KMAC-HMAC-SHA-512 (Part 1 of 2)

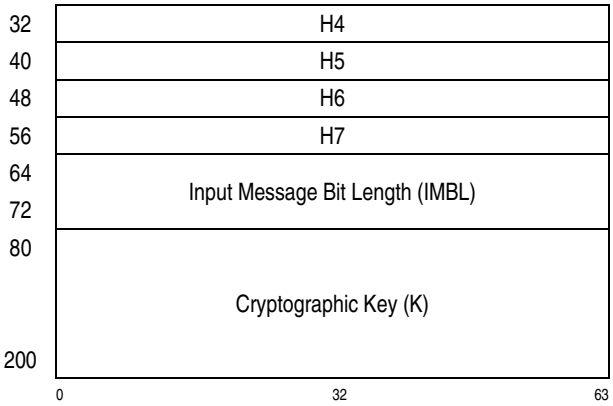

Figure 7-318. Parameter Block for KMAC-HMAC-SHA-384 and KMAC-HMAC-SHA-512 (Part 2 of 2)

For the KMAC-HMAC-SHA-384 and KMAC-HMAC-SHA-512 functions, the chaining value (called H fields) is in byte offsets 0-63 of the parameter block, the input-message-bit length (IMBL) is in byte offsets 64-79 of the parameter block, and the cryptographic key (K) is in byte offsets 80-207 of the parameter block.

The parameter block used for the KMAC-HMAC-Encrypted-SHA-384 and KMAC-HMAC-Encrypted-SHA-512 functions has the following format:

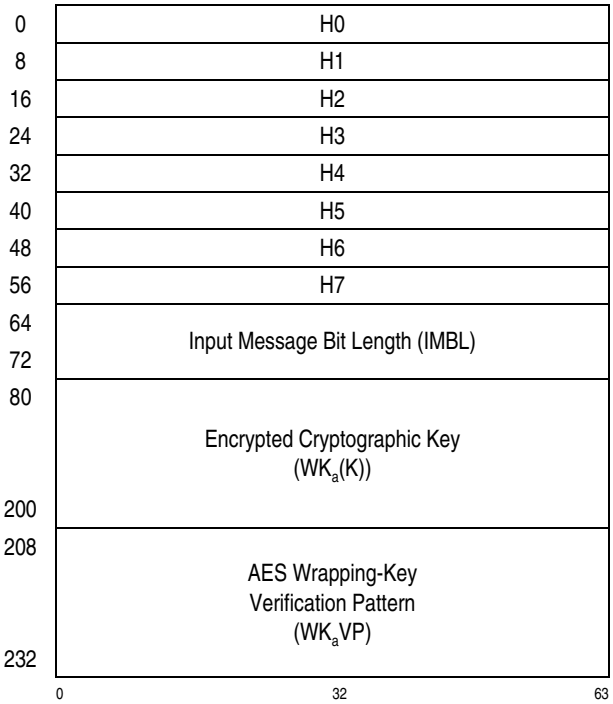

Figure 7-319. Parameter Block for KMAC-HMAC-Encrypted-SHA-384 and KMAC-HMAC-Encrypted-SHA-512

For the KMAC-HMAC-Encrypted-SHA-384 and KMAC-HMAC-Encrypted-SHA-512 functions, the contents of byte offsets 208-239 of the parameter block are compared with the contents of the AES wrapping-key verification-pattern register. If they mismatch, the parameter-block location remains unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 0-63 of the parameter block contain the chaining value (called H fields), byte offsets 64-79 of the parameter block contain the input-message-bit length (IMBL), and the contents of byte offsets 80-207 of the parameter block are deciphered using the AES wrapping key to obtain the 1024-bit cryptographic key (K). (See the section “Protection of Cryptographic Keys” on page 7-490 for details.)

The description in the following paragraphs apply to all functions and process is shown in Figure 7-320.

The input-message-bit length (IMBL) in the parameter block contains the bit length of the total input message to be hashed (the input message bit length and the input key bit length). The IMBL field is ignored when IIMP flag is one.

The output-message-bit length (OMBL) contains the bit length of the total output message to be hashed (the output message bit length and the input key bit length).

The chaining value (CV) is formed by concatenating all the H fields together in order, starting with H0 on the left and ending with H7 on the right.

The initial chaining value (ICV) is the chaining value (CV) in the parameter block which is used as input to the SHA block digest algorithm.

Each SHA block digest algorithm contains a specific set of constants called the initial hash value ($H^{(0)}$). It is used as the initial chaining value (ICV) of the very first (leftmost) message block of a set of message blocks to be hashed. See Programming Notes on page 7-266 through page 7-266 for the specific SHA algorithm’s initial hash value ($H^{(0)}$).

The output chaining value (OCV) is the output of the SHA block digest algorithm which is stored into the chaining value (CV) of the parameter block.

Programming Notes:

1. If the IMBL is not a multiple of 8, the program must store zeros in the unused bit positions of the last byte of the input message and round-up the input-message-bit length (IMBL) to a multiple of 8.

2. If the program's cryptographic key is smaller than the cryptographic key in the parameter block, the program must append zeros on the right side of the program's cryptographic key to enlarge it to the same size as the cryptographic key in the parameter block.

3. The program's original cryptographic key cannot be larger than the cryptographic key in the parameter block because $H^{(0)}$ (instead of CV from the parameter block) is used when hashing the inner-padded key. That is, the program must not use appropriate SHA algorithm to reduce the original cryptographic key to the same size as the cryptographic key in the parameter block.

When the IIMP flag is one, the second-operand length must be a multiple of the data block size. When the IIMP flag is zero and the last input message block contains a partial input message, the partial message block length (L), used in the final step of SHA padding, is set to the length of the last input message block; otherwise, L is set to zero.

When the CCUP flag is one and the second-operand length is not initially zero, the CCUP flag is set to zero. When the CCUP flag is one, the IIMP flag is zero, the IKP flag is initially zero, and the second-operand length is initially zero, the CCUP flag is set to zero. If the operation ends due to partial completion, condition code 3 is set.

When the IKP flag is zero (indicating that the inner-key padding and hashing operation has not been performed), the $H^{(0)}$ value of the SHA-384 block digest algorithm is used as the ICV for the KMAC-HMAC-SHA-384 and KMAC-HMAC-Encrypted-SHA-384 functions whereas the $H^{(0)}$ value of the SHA-512 block digest algorithm is used as the ICV for the KMAC-HMAC-SHA-512 and KMAC-HMAC-Encrypted-SHA-512 functions.

When the IKP flag is zero (indicating that the inner-key padding and hashing operation has not been performed), $H^{(0)}$ is used (instead of the CV from the parameter block) as input to perform the inner-key padding and hashing operation. When the IKP flag is one (indicating that the inner-key padding and hashing operation has been performed), the inner-key padding and hashing operation is not performed.

When the IKP flag is zero (indicating that inner-key padding and hashing operation has not yet been performed), the 1024-bit (128-byte) cryptographic key (K) is exclusive-ORed with the inner pad (ipad) to produce the 128-byte inner key. A 64-byte chaining value 1 (CV_1) is generated for the 128-byte inner key using the SHA-512 block digest algorithm with the 64-byte $H^{(0)}$ value and the IKP flag is set to one. The generated chaining value 1 (OCV_1), also called the output chaining value (OCV), is stored into the chaining value (CV) field of the parameter block. If the operation ends due to partial completion, condition code 3 is set.

A 64-byte intermediate message digest (IMD) is generated for the 128-byte full input message blocks (M1, M2, …, Mn) in operand 2 using the SHA-512 block digest algorithm with the 64-byte chaining value (ICV_1) from the parameter block. If the IIMP flag is one or L is zero, M_{LFB} is the last input message block (Mn); otherwise, M_{LFB} is the input message block that is immediately precedes the last (partial) input message block (Mn-1). The generated intermediate message digest (OCV_2), also called the output chaining value (OCV), is stored into the chaining value (CV) field of the parameter block. This operation repeats until the remaining input message is less than 64 bytes or until a CPU-determined number of blocks have been stored. If the operation ends due to partial completion, condition code 3 is set.

When the IIMP flag is one (indicating intermediate input message part), the following occurs. If the CPU is not enabled to update counters in the cryptography-counter set, then condition code 0 is set (indicating normal completion) and the CCUP flag is set to zero. If the CPU is enabled to update counters in the cryptography-counter set, and the appropriate counter is accessible, then the appropriate counter is updated, condition code 0 is set (indicating normal completion), and the CCUP flag is set to zero. If the CCUP flag is zero and the CPU is enabled to update counters in the cryptography-counter set and the appropriate counter is not accessible, then the condition code 3 is set and the CCUP flag is set to one. If the CCUP flag is one and the CPU is enabled to update counters in the cryptography-counter set and the appropriate counter is not accessible, then an

access exception is recognized for the location of the appropriate cryptography counter.

When the IIMP flag is zero (indicating the last input message part) and the operation ends due to partial completion, condition code 3 is set.

The description in the following paragraphs apply to all functions when the IIMP flag is zero (indicating the last input message part).

If the CCUP flag is one, the input message padding and hashing, the outer key padding and hashing, and the output message padding and hashing operations are not performed. Instead, only the appropriate counter in the cryptography-counter set is updated.

After all full input message blocks of operand 2 have been processed, the IMBL is updated to include the input key bit length by adding 1024 (input key bit length) to IMBL and any carry is ignored. Then the padding operation is performed on either the last (partial) input message block or on a null block (M_{PMB}) in operand 2 (based on the calculated L value) using the input-message-bit length (IMBL) in byte offsets 64-79 of the parameter block to produce the padded input message block. Next, the hashing operation is performed on the padded input message block, and the final input message digest (FIMD) is generated using the SHA-512 block digest algorithm with the 64-byte chaining value (ICV_2) from the parameter block.

The padding and hashing operation of the input message is performed as follows. If the length of the partial message block length (L) is zero bytes, then the operation in Figure 7-321 is performed. If the length of the partial message block length (L) is between one byte and 111 bytes inclusive, then the operation in Figure 7-322 is performed; if the length of the partial message block length (L) is between 112 bytes and 127 bytes inclusive, then the operation in Figure 7-323 is performed.

The 1024-bit (128-byte) cryptographic key (K) is exclusive-ORed with the outer pad (opad) to produce the 128-byte outer key. A 64-byte chaining value 3 (OCV_3) is generated for the 128-byte outer key using the SHA-512 block digest algorithm with the 64-byte $H^{(0)}$ value.

After the chaining value 3 (OCV_3) is generated, the padding operation is performed on the final input message digest (FIMD), also called the (partial) output message block (M_{PMB}), using the final input message digest (FIMD) bit length to produce the padded output message block. For KMAC-HMAC-SHA-384 and KMAC-HMAC-Encrypted-SHA-384 functions, the leftmost 48 bytes of the final input message digest (FIMD) is used as the (partial) output message block (M_{PMB}), L is set to 48, and OMBL is set to 1408. For KMAC-HMAC-SHA-512 and KMAC-HMAC-Encrypted-SHA-512 functions, the entire final input message digest (FIMD) is used as the (partial) output message block (M_{PMB}), L is set to 64, and OMBL is set to 1536.

Next, the final hashing operation is performed on the padded output message block and the final output message digest (OCV) is generated using the SHA-512 block digest algorithm with the 64-byte chaining value 3 (OCV_3). The entire final output message digest (OCV) is stored into the chaining value (CV) field of the parameter block.

The final padding and hashing operation of the output message is shown in Figure 7-324.

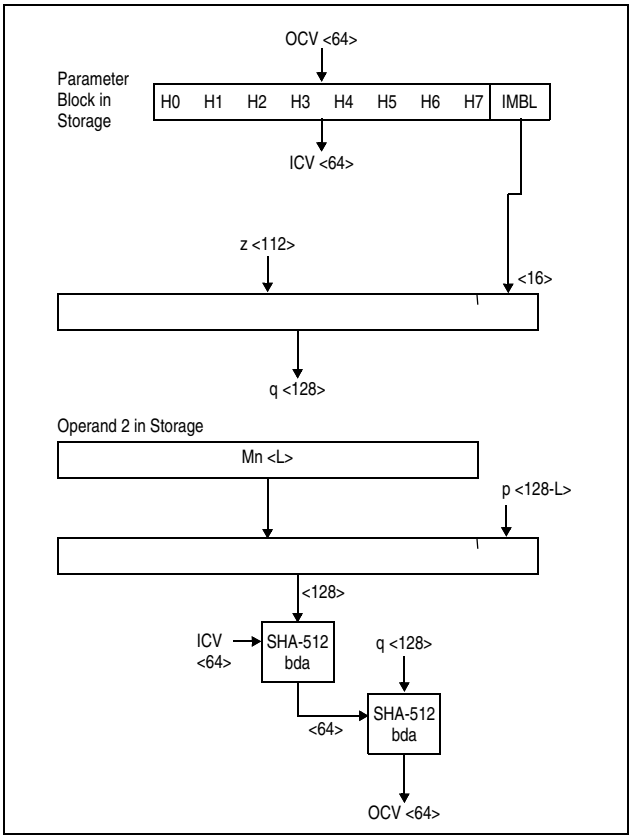

Figure 7-323. HMAC-384 and HMAC-512 for Partial-Block Case 2 (112 ≤ L ≤ 127) Using IMBL

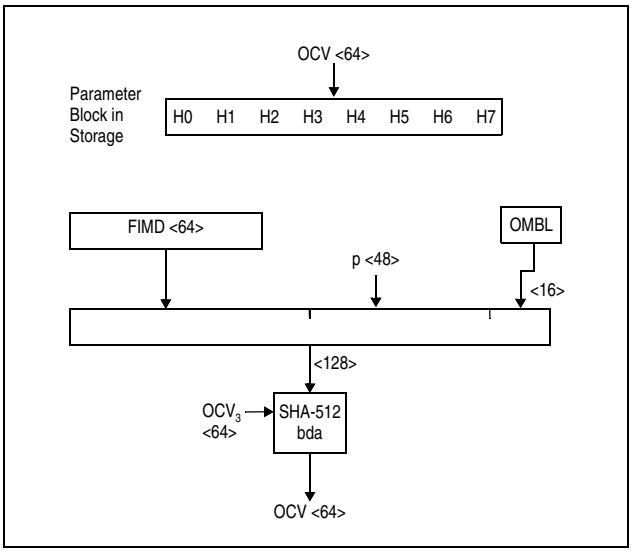

Figure 7-324. HMAC-384 and HMAC-512 for Partial-Block Case 1 (1 ≤ L ≤ 111) Using OMBL

When the IIMP flag is zero (indicating the last input message part), the following occurs. If the CPU is not enabled to update counters in the cryptography-counter set, then condition code 0 is set (indicating normal completion) and the CCUP flag is set to zero. If the CPU is enabled to update counters in the cryptography-counter set, and the appropriate counter is accessible, then the appropriate counter is updated, condition code 0 is set (indicating normal completion), and the CCUP flag is set to zero. If the CPU is enabled to update counters in the cryptography-counter set, and the appropriate counter is not accessible, then the condition code 3 is set, and the CCUP flag is set to one.

KMAC-Query-Authentication-Information (Function Code 127)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-284 on page 7-242.

The KMAC-query-authentication-information function stores the information that can be used by the program to authenticate the running instruction's firmware code level (IFCL) currently installed on the model into the format-0 parameter block for KMAC-query-authentication-information. Condition code 0 is set when execution of the KMAC-query-authentication-information function completes; condition codes 1 and 3 are not applicable to this function.

The format-0 parameter block used for the KMAC-query-authentication-information function has the following format:

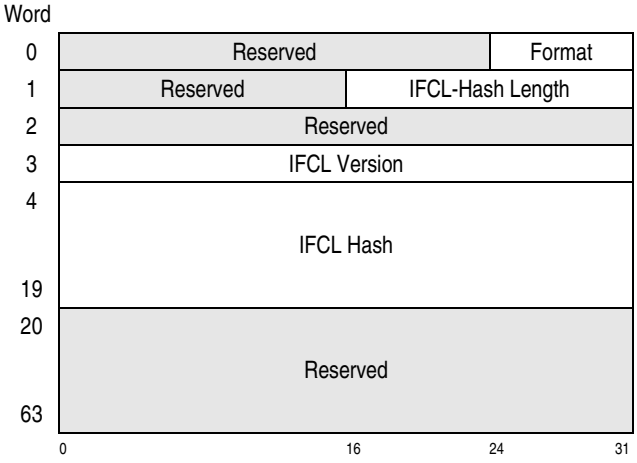

Figure 7-325. Format-0 Parameter Block for KMAC-Query-Authentication-Information

The format-0 parameter block contains the following fields:

Reserved: Bytes 0-2 of word 0, bytes 0-1 of word 1, word 2, and words 20-63 are reserved and stored as zeros.

Format: Byte 3 of word 0 contains an 8-bit unsigned binary integer whose value specifies the format of the parameter block. A format value of zero indicates a format-0 parameter block. When a format-0 parameter block is stored, the value of this field is set to zero.

IFCL-Hash Length: Bytes 2-3 of word 1 contain a 16-bit unsigned binary integer specifying the number of bytes of the IFCL hash stored in the IFCL hash field. When the IFCL hash is less than or equal to 64 bytes, the IFCL-hash length field is set to the actual length of the IFCL hash. When the IFCL hash is larger than 64 bytes, the IFCL-hash length field is set to 64.

IFCL Version: Word 3 contains a 32-bit unsigned binary integer specifying the version number of the IFCL.

IFCL Hash: Words 4-19 contain the hash value of the IFCL. The IFCL-hash length field specifies the number of bytes that are in the IFCL hash field. The IFCL hash value is left aligned. When the IFCL hash is less than 64 bytes, it is padded with zeros on the right. When the IFCL hash is larger than 64 bytes, only the leftmost 64 bytes of the IFCL hash are stored.

Special Conditions

A specification exception is recognized and no other action is taken if any of the following occurs:

1. Bit 56 of general register 0 is not zero.
2. Bits 57-63 of general register 0 specify an unassigned or uninstalled function code.
3. The R_2 field designates an odd-numbered register or general register 0.
4. The second-operand length is not a multiple of the data block size when the designated function is either not an HMAC function (function codes 112-115 and 120-123) or it is an HMAC function but the IIMP flag is one (see Figure 7-283 on page 7-241 to determine the data block size for COMPUTE MESSAGE AUTHENTICATION CODE functions).
5. When an HMAC function is specified and the IIMP flag is one and the IKP flag is zero and the second-operand length is zero.

Resulting Condition Code:

0 Normal completion
1 Verification-pattern mismatch
2 --
3 Partial completion

Program Exceptions:

- Access (fetch, operand 2, cryptographic key, input-message-bit length (IMBL), and wrapping-key verification pattern; store, query parameter block and query-authentication-information parameter block; fetch and store, chaining value, cryptography counter)
- Operation (if the message-security assist is not installed)
- Specification
- Transaction constraint

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B	Operation exception.
7.C	Transaction constraint
8.	Specification exception due to invalid function code or invalid register number.
9.	Specification exception due to invalid operand length.
10.	Access exceptions for an access to a cryptography counter and second-operand length originally zero and the designated function is not an HMAC function.
11.	Condition code 0 (normal completion) due to second-operand length originally zero and the designated function is not an HMAC function.
12.A.1.A	Access exceptions for an access to the entire parameter block when the designated function is an HMAC function.
12.A.1.B	Access exceptions for an access to the parameter block when the designated function is not an HMAC function.

Figure 7-326. Priority of Execution: KMAC

12.A.2	Condition code 1 due to verification-pattern mismatch.
12.A.3.A	Condition code 3 due to the second-operand length is not originally zero and the designated function is an HMAC function and the CCUP flag is one.
12.A.3.B	Condition code 3 due to the second-operand length is originally zero and the designated function is an HMAC function and the IIMP flag is zero and the IKP flag is originally zero and and the CCUP flag is one.
12.A.4	Condition code 3 due to the second-operand length is originally zero and the designated function is an HMAC function and the IIMP flag is one and the IKP flag is one and access-exception condition is detected for an access to a cryptography counter.
12.A.5	Access exceptions for an access to a cryptography counter and the second-operand length originally zero and the designated function is an HMAC function and the IIMP flag is one and the IKP flag is one.
12.A.6	Condition code 0 (normal completion) due to the second-operand length is originally zero and the designated function is an HMAC function and the IIMP flag is one and the IKP flag is one.
12.B	Access exceptions for an access to the parameter block when the designated function is not an HMAC function or second operand storage area.
13.	Condition code 3 due to partial completion (second-operand length still nonzero).
14.A	Condition code 3 due to second-operand length stepped to zero and the designated function is either not an HMAC function, or it is an HMAC function and the IIMP flag is one, and access-exception condition detected for an access to a cryptography counter.
14.B	Condition code 3 due to the second-operand length stepped to zero and the designated function is an HMAC function and the IIMP flag is zero and the outer key padding and hashing operation is performed and access-exception condition is detected for an access to a cryptography counter.

Figure 7-326. Priority of Execution: KMAC (Continued)

14.C	Condition code 3 due to the second-operand length originally zero and the designated function is an HMAC function and the IIMP flag is zero and the CCUP flag is originally zero and the outer key padding and hashing operation is performed and access-exception condition is detected for an access to a cryptography counter.
15.A	Access exceptions for an access to a cryptography counter and the second-operand length stepped to zero and the designated function is either not an HMAC function, or it is an HMAC function and the IIMP flag is one.
15.B	Access exceptions for an access to a cryptography counter and the second-operand length stepped to zero and the designated function is an HMAC function and the IIMP flag is zero and the outer key padding and hashing operation is performed.
15.C	Access exceptions for an access to a cryptography counter and the second-operand length originally zero and the designated function is an HMAC function and the IIMP flag is zero and the CCUP flag is originally one.
16.A	Condition code 0 (normal completion) due to the second-operand length stepped to zero and the designated function is either not an HMAC function, or it is an HMAC function and the IIMP flag is one and access-exception condition is not detected for an access to a cryptography counter.
16.B	Condition code 0 (normal completion) due to the second-operand length stepped to zero and the designated function is an HMAC function and the IIMP flag is zero and the outer key padding and hashing operation is performed and access-exception condition is not detected for an access to a cryptography counter.
16.C	Condition code 0 (normal completion) due to the second-operand length originally zero and the designated function is an HMAC function and the IIMP flag is zero and the CCUP flag is originally one and access-exception condition is not detected for an access to a cryptography counter.

Figure 7-326. Priority of Execution: KMAC (Continued)

Programming Notes:

1. The performance of the query function (code 0) may be significantly slower than that of simply examining a location in storage. If the program needs to frequently test for the availability of a

function, it should perform the query function once during initialization; subsequently it should examine the stored results of the query function in memory with an instruction such as TEST UNDER MASK.

2. When condition code 3 is set, the second operand address and length in general registers R_2 and $R_2 + 1$, respectively, and the initial-chaining-value in the parameter block are usually updated such that the program can simply branch back to the instruction to continue the operation. For unusual situations, the CPU protects against endless reoccurrence for the no-progress case. Thus, the program can safely branch back to the instruction whenever condition code 3 is set with no exposure to an endless loop.

3. If the length of the second operand is nonzero initially and condition code 0 is set, the registers are updated in the same manner as for condition code 3; the initial chaining value in this case is such that additional operands can be processed as if they were part of the same chain.

4. Before processing the first part of a message, the program must set the initial values for the initial-chaining-value field. To comply with ANSI X9.9, ANSI X9.19, or Reference [17.] on page xxxii, the initial chaining value shall be set to all binary zeros.

5. The following applies to the input-message-bit length (IMBL) in the parameter block of the HMAC functions.

   a. The program supplied IMBL value includes only the bit length of the entire input message. The HMAC function adds the bit length of the input key to IMBL when performing the input message padding and hashing operation.

   b. The IMBL is completely independent of the second-operand length in general register $R_2 + 1$.

   c. Regardless of whether the instruction ends with condition code 0 or 3, the IMBL is not decremented by the number of bytes processed.

   d. In normal usage, the IMBL is expected to be eight times the total size of the input message in bytes. If the program supplies a IMBL that is not a multiple of eight, the results will be algorithmically correct, but may not be usable in any practical application.

   e. The secure-hash algorithm described in Reference [21.] on page xxxii allows for input-message-bit length that are not multiples of eight. The HMAC functions require the input-message-bit length to be a multiple of eight.

6. Each SHA block digest algorithm contains a specific set of constants called the initial hash value ($H^{(0)}$). It is used as the initial chaining value (ICV) of the very first (leftmost) message block of a set of message blocks to be hashed.

   For SHA-256, the initial hexadecimal chaining value ($H^{(0)}$) constants are listed as follows:

   H0 = 6A09 E667
   H1 = BB67 AE85
   H2 = 3C6E F372
   H3 = A54F F53A
   H4 = 510E 527F
   H5 = 9B05 688C
   H6 = 1F83 D9AB
   H7 = 5BE0 CD19

   For SHA-512, the initial hexadecimal chaining value ($H^{(0)}$) constants are listed as follows:

   H0 = 6A09 E667 F3BC C908
   H1 = BB67 AE85 84CA A73B
   H2 = 3C6E F372 FE94 F82B
   H3 = A54F F53A 5F1D 36F1
   H4 = 510E 527F ADE6 82D1
   H5 = 9B05 688C 2B3E 6C1F
   H6 = 1F83 D9AB FB41 BD6B
   H7 = 5BE0 CD19 137E 2179

7. The SHA-224 algorithm is the same as the SHA-256 algorithm, except that the initial chaining value ($H^{(0)}$) constants and the final message digest lengths are different. The program may

obtain the SHA-224 message digest using the SHA-256 functions with the following two actions:

a. The following initial hexadecimal chaining value ($H^{(0)}$) constants for SHA-224 are used:

```
H0 = C105 9ED8
H1 = 367C D507
H2 = 3070 DD17
H3 = F70E 5939
H4 = FFC0 0B31
H5 = 6858 1511
H6 = 64F9 8FA7
H7 = BEFA 4FA4
```

b. The 224-bit message digest is obtained by truncating the final message digest to its leftmost 224 bits.

8. The SHA-384 algorithm is the same as the SHA-512 algorithm, except that the initial chaining value ($H^{(0)}$) constants and the final message digest lengths are different. The program may obtain the SHA-384 message digest using the SHA-512 functions with the following two actions:

a. The following initial hexadecimal chaining value ($H^{(0)}$) constants for SHA-384 are used:

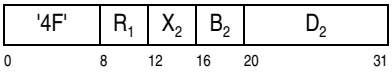
```
H0 = CBBB 9D5D C105 9ED8
H1 = 629A 292A 367C D507
H2 = 9159 015A 3070 DD17
H3 = 152F ECD8 F70E 5939
H4 = 6733 2667 FFC0 0B31
H5 = 8EB4 4A87 6858 1511
H6 = DB0C 2E0D 64F9 8FA7
H7 = 47B5 481D BEFA 4FA4
```

b. The 384-bit message digest is obtained by truncating the final message digest to its leftmost 384 bits.

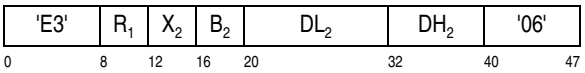
9. When computing a message digest, the program may not initially be aware of the total message-bit length; for example, for a message being read from an I/O device, the message-bit length may not be known until the final block is read. When computing a message digest for a message whose length is not known, or for a message where it is known that the last message block is not included in the calculation, an HMAC function with IIMP flag set to one may be used. When computing a message digest for a message that includes the last block, an HMAC function with IIMP flag set to zero must be used.

CONVERT TO BINARY

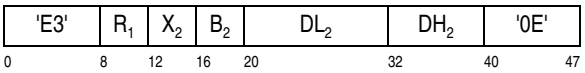
CVB $R_1,D_2(X_2,B_2)$ [RX-a]



CVBY $R_1,D_2(X_2,B_2)$ [RXY-a]



CVBG $R_1,D_2(X_2,B_2)$ [RXY-a]



The second operand is changed from decimal to binary, and the result is placed at the first-operand location.

For CONVERT TO BINARY (CVB, CVBY), the second operand occupies eight bytes in storage, and, for CONVERT TO BINARY (CVBG), the second operand occupies sixteen bytes in storage. The second operand has the format of signed-packed-decimal data, as described in Chapter 8, “Decimal Instructions.” It is checked for valid sign and digit codes, and a general-operand data exception is recognized when an invalid code is detected.

For CONVERT TO BINARY (CVB, CVBY), the result of the conversion is a 32-bit signed binary integer, which is placed in bit positions 32-63 of general register R_1. Bits 0-31 of the register remain unchanged. The maximum positive number that can be converted and still be contained in 32 bit positions is 2,147,483,647; the maximum negative number (the negative number with the greatest absolute value) that can be converted is -2,147,483,648.

For any decimal number outside this range, the operation is completed by placing the 32 rightmost bits of the binary result in the register, and a fixed-point-divide exception is recognized.

For CONVERT TO BINARY (CVBG), the result of the conversion is a 64-bit signed binary integer, which is placed in bit positions 0-63 of general register R_1. The maximum positive number that can be converted and still be contained in a 64-bit register is 9,223,372,036,854,775,807; the maximum negative

number (the negative number with the greatest absolute value) that can be converted is -9,223,372,036,854,775,808. For any decimal number outside this range, a fixed-point-divide exception is recognized, and the operation is suppressed.

The displacement for CVB is treated as a 12-bit unsigned binary integer. The displacement for CVBY and CVBG is treated as a 20-bit signed binary integer.

Condition Code: The code remains unchanged.

Program Exceptions:

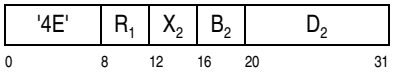
- Access (fetch, operand 2)
- Data with DXC 0, general operand
- Fixed-point divide
- Operation (CVBY, if the long-displacement facility is not installed)
- Transaction constraint

Programming Notes:

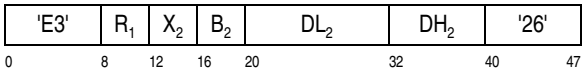
1. An example of the use of the CONVERT TO BINARY instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”
2. When the second operand is negative, the result is in two’s-complement notation.
3. The storage-operand references for CONVERT TO BINARY may be multiple-access references. (See “Storage-Operand Consistency” on page 5-133.)

CONVERT TO DECIMAL

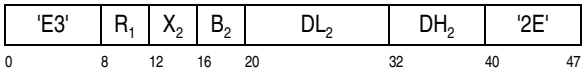
CVD $R_1,D_2(X_2,B_2)$ [RX-a]



CVDY $R_1,D_2(X_2,B_2)$ [RXY-a]



CVDG $R_1,D_2(X_2,B_2)$ [RXY-a]



The first operand is changed from binary to decimal, and the result is stored at the second-operand location.

For CONVERT TO DECIMAL (CVD, CVDY), the first operand is treated as a 32-bit signed binary integer, and the result occupies eight bytes in storage. For CONVERT TO DECIMAL (CVDG), the first operand is treated as a 64-bit signed binary integer, and the result occupies sixteen bytes in storage.

The result is in the format for signed-packed-decimal data, as described in Chapter 8, “Decimal Instructions.” The rightmost four bits of the result represent the sign. A positive sign is encoded as 1100; a negative sign is encoded as 1101.

The displacement for CVD is treated as a 12-bit unsigned binary integer. The displacement for CVDY and CVDG is treated as a 20-bit signed binary integer.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)
- Operation (CVDY, if the long-displacement facility is not installed)
- Transaction constraint

Programming Notes:

1. An example of the use of the CONVERT TO DECIMAL instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”
2. For CVD and CVDY, the number to be converted is a 32-bit signed binary integer obtained from a general register. Since 15 decimal digits are available for the result, and the decimal equivalent of 31 bits requires at most 10 decimal digits, an overflow cannot occur. Similarly, for CVDG, 31 decimal digits are available, the decimal equivalent of 63 bits is at most 19 digits, and an overflow cannot occur.
3. The storage-operand references for CONVERT TO DECIMAL may be multiple-access references. (See “Storage-Operand Consistency” on page 5-133.)

CONVERT UTF-16 TO UTF-32

CU24 $R_1,R_2[,M_3]$ [RRF-c]

'B9B1'	M_3	////	R_1	R_2
0	16	20	24	28 31

The two-byte UTF-16 (Unicode) characters of the second operand are converted to UTF-32 characters and placed at the first-operand location. The UTF-32 characters are four bytes. The operation proceeds until the end of the first or second operand is reached, a CPU-determined number of characters have been converted, or an invalid Unicode character is encountered, whichever occurs first. The result is indicated in the condition code.

The R_1 and R_2 fields each designate an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The location of the leftmost byte of the first operand and the second operand is designated by the contents of general registers R_1 and R_2, respectively. In the 24-bit or 31-bit addressing mode, the number of bytes in the first-operand and second-operand locations is specified by the contents of bit positions 32-63 of general registers $R_1 + 1$ and $R_2 + 1$, respectively, and those contents are treated as 32-bit unsigned binary integers. In the 64-bit addressing mode, the number of bytes in the first-operand and second-operand locations is specified by the entire contents of general registers $R_1 + 1$ and $R_2 + 1$, respectively, and those contents are treated as 64-bit unsigned binary integers.

The handling of the addresses in general registers R_1 and R_2 is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers R_1 and R_2 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the registers constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 constitute the address.

The contents of the registers just described are shown in Figure 7-327.

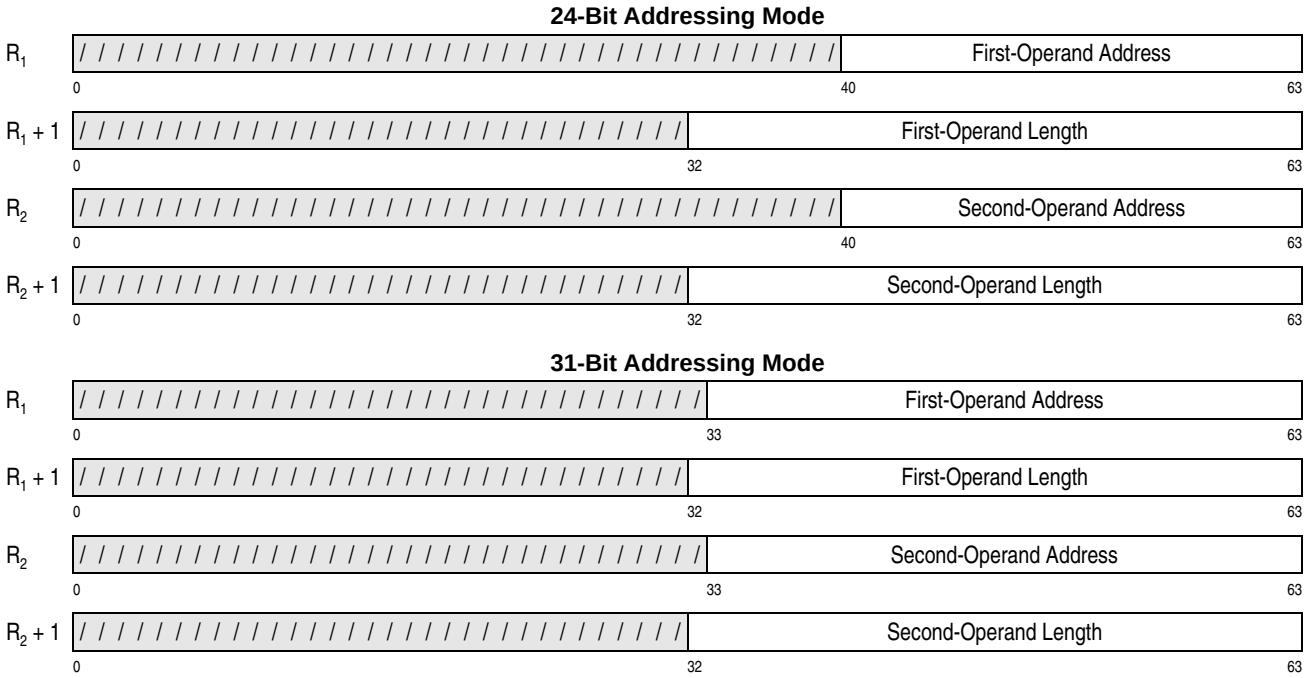


Figure 7-327. Register Contents for CONVERT UTF-16 TO UTF-32 (Part 1 of 2)

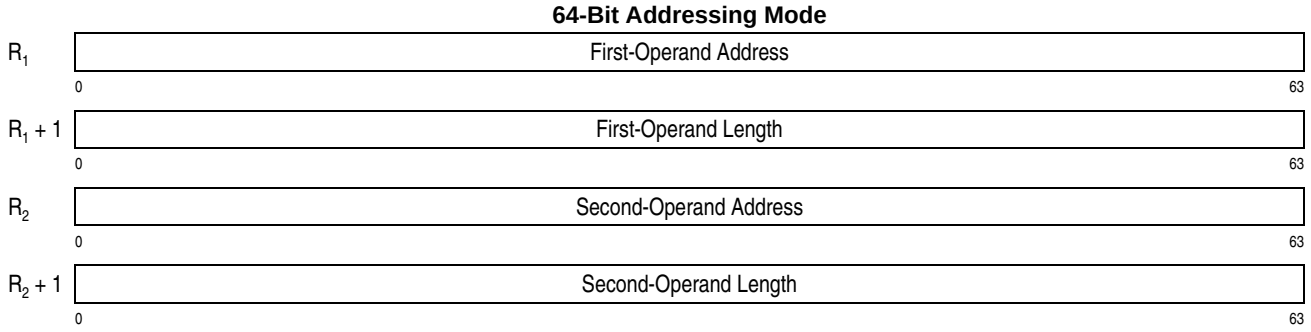

Figure 7-327. Register Contents for CONVERT UTF-16 TO UTF-32 (Part 2 of 2)

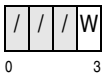
When the ETF3-enhancement facility is installed, the M_3 field has the following format:



The bits of the M_3 field are defined as follows:

- ***Unassigned:*** Bits 0-2 are unassigned and should contain zeros; otherwise, the program may not operate compatibly in the future.
- ***Enhanced Well-Formedness-Checking (W):*** The W bit, bit 3 of the M_3 field, controls whether enhanced well-formedness checking of the Unicode characters is performed. When the W bit is zero, enhanced checking is not performed. When the W bit is one, enhanced checking is performed, as described below.

When the ETF3-enhancement facility is not installed, the M_3 field is ignored.

The characters of the second operand are selected one by one for conversion, proceeding left to right. The characters resulting from a conversion are placed at the first-operand location, proceeding left to right. The operation proceeds until the first-operand or second-operand location is exhausted, a CPU-determined number of second-operand characters have been converted, or on some models when the W bit of the M_3 field is one, an invalid Unicode character is detected.

To show the method of converting a UTF-16 character to a UTF-32 character, the bits of a Unicode character are identified by letters as follows:

Unicode Character Bit Numbers	0 1 2 3 4 5 6 7	8 9 10 11 12 13 14 15
Identifying Bit Letters	a b c d e f g h	i j k l m n o p

In the case of a Unicode surrogate pair, which is a character pair consisting of a character called a high surrogate followed by a character called a low surrogate, the bits are identified by letters as follows:

Unicode High Surrogate Bit Numbers	0 1 2 3 4 5 6 7	8 9 10 11 12 13 14 15
Identifying Bit Letters	1 1 0 1 1 0 a b	c d e f g h i j

Unicode Low Surrogate Bit Numbers	16 17 18 19 20 21 22 23	24 25 26 27 28 29 30 31
Identifying Bit Letters	1 1 0 1 1 1 k l	m n o p q r s t

A low surrogate (that is, a Unicode character in the range of DC00 to DFFF hex) that is not immediately preceded by a high surrogate (that is, a Unicode character in the range of D800 to DBFF hex) is called an isolated low surrogate.

Any Unicode character in the range 0000 to D7FF or E000 to FFFF hex is converted to a four-byte UTF-32 character as follows:

Unicode Character	a b c d e f g h	i j k l m n o p		
UTF-32 Character	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0	a b c d e f g h	i j k l m n o p

On some models, an isolated low surrogate (that is, a Unicode character in the range of DC00 to DFFF hex) is also converted to a four-byte UTF-32 character as shown above, regardless of whether the ETF3-

enhancement facility is installed and regardless of the W bit of the M_3 field. On other models, when the ETF3-enhancement facility is installed, the W bit of the M_3 field is one, and the next Unicode character is an isolated low surrogate, condition code 2 is set.

Any Unicode surrogate pair starting with a high surrogate in the range D800 to DBFF hex is converted to a four-byte UTF-32 character as follows:

Unicode Characters	1 1 0 1 1 0 a b	c d e f g h i j	1 1 0 1 1 1 k l	m n o p q r s t
UTF-32 Character	0 0 0 0 0 0 0 0	0 0 0 u v w x y	e f g h i j k l	m n o p q r s t
where uvwxy = abcd + 1				

When the ETF3-enhancement facility is not installed, or when the W bit of the M_3 field is zero, the first six bits of an expected Unicode low surrogate are ignored. When the ETF3-enhancement facility is installed, and the W bit is one, the first six bits of the Unicode low surrogate must contain 110111 binary; otherwise, the Unicode low surrogate is invalid, and condition code 2 is set.

The second-operand location is considered exhausted when it does not contain at least two remaining bytes or at least four remaining bytes when the first two bytes are a Unicode high surrogate. The first-operand location is considered exhausted when it does not contain at least four remaining bytes.

When the second-operand location is exhausted, condition code 0 is set. When the first-operand location is exhausted, condition code 1 is set, except that condition code 0 is set if the second-operand location also is exhausted. When a CPU-determined number of characters have been converted, condition code 3 is set.

When the conditions for setting condition codes 1 and 2 are both met, condition code 2 is set.

When the operation is completed, the contents of general register $R_2 + 1$ are decremented by the number of bytes converted, and the contents of general register R_2 are incremented by the same number. Also, the contents of general register $R_1 + 1$ are decremented by the number of bytes placed at the first-operand location, and the contents of general register R_1 are incremented by the same number. When general registers R_1 and R_2 are updated in the 24-bit or 31-bit addressing mode, bits 32-39 of them, in the 24-bit mode, or bit 32, in the 31-bit mode, may be set to zeros or may remain unchanged.

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers R_1, $R_1 + 1$, R_2, and $R_2 + 1$, always remain unchanged.

When condition code 2 is set, the following applies:

- When a Unicode high surrogate immediately precedes an invalid low surrogate, general register R_2 contains the address of the Unicode high surrogate.
- When an isolated Unicode low surrogate is detected, general register R_2 contains the address of the isolated low surrogate.

When condition code 3 is set, the registers have been updated so that the instruction, when reexecuted, resumes at the next byte locations to be processed.

The amount of processing that results in the setting of condition code 3 is determined by the CPU on the basis of improving system performance, and it may be a different amount each time the instruction is executed.

When the R_1 register is the same register as the R_2 register, the results are unpredictable.

When the second operand overlaps the first operand, the results are unpredictable.

Access exceptions for the portions of the operands to the right of the last byte processed may or may not be recognized. For an operand longer than 4K bytes, access exceptions are not recognized for locations more than 4K bytes beyond the last byte processed.

When the length of an operand is zero, no access exceptions are recognized for that operand. Access exceptions are not recognized for an operand if the R field associated with that operand is odd.

Resulting Condition Code:

0 Entire second operand processed
1 End of first operand reached
2 Invalid Unicode low surrogate
3 CPU-determined number of characters converted

Program Exceptions:

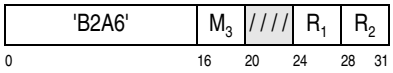
- Access (fetch, operand 2; store, operand 1)
- Operation (if the extended-translation facility 3 is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. When condition code 3 is set, the program can simply branch back to the instruction to continue the conversion. The program need not determine the number of first-operand or second-operand bytes that were processed.
2. The storage-operand references of CONVERT UTF-16 TO UTF-32 may be multiple-access references. (See “Storage-Operand Consistency” on page 5-133.)
3. The CONVERT UTF-16 TO UTF-32 instruction supports UTF-16 and UTF-32 characters only in the big-endian encoding.
4. As observed by this CPU, other CPUs, and the I/O subsystem, inconsistent results may be briefly stored in the first-operand location. See the section “Effects of CPU Retry” on page 11-3 for further details.
5. Determining that isolated Unicode low surrogates are invalid is a model-dependent behavior that is not available on the IBM z13 and earlier models.

CONVERT UTF-16 TO UTF-8
CONVERT UNICODE TO UTF-8

CU21 $R_1,R_2[,M_3]$ [RRF-c]
CUUTF $R_1,R_2[,M_3]$ [RRF-c]



The two-byte Unicode characters of the second operand are converted to UTF-8 characters and placed at the first-operand location. The UTF-8 characters are one, two, three, or four bytes, depending on the Unicode characters that are converted. The operation proceeds until the end of the first or second operand is reached, a CPU-determined number of characters have been converted, or an invalid Unicode character is encountered in the second operand, whichever occurs first. The result is indicated in the condition code.

The R_1 and R_2 fields each designate an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The location of the leftmost byte of the first operand and the second operand is designated by the contents of general registers R_1 and R_2, respectively. In the 24-bit or 31-bit addressing mode, the number of bytes in the first-operand and second-operand locations is specified by the contents of bit positions 32-63 of general registers $R_1 + 1$ and $R_2 + 1$, respectively, and those contents are treated as 32-bit unsigned binary integers. In the 64-bit addressing mode, the number of bytes in the first-operand and second-operand locations is specified by the entire contents of general registers $R_1 + 1$ and $R_2 + 1$, respectively, and those contents are treated as 64-bit unsigned binary integers.

The handling of the addresses in general registers R_1 and R_2 is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers R_1 and R_2 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the registers constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 constitute the address.

The contents of the registers just described are shown in Figure 7-328.

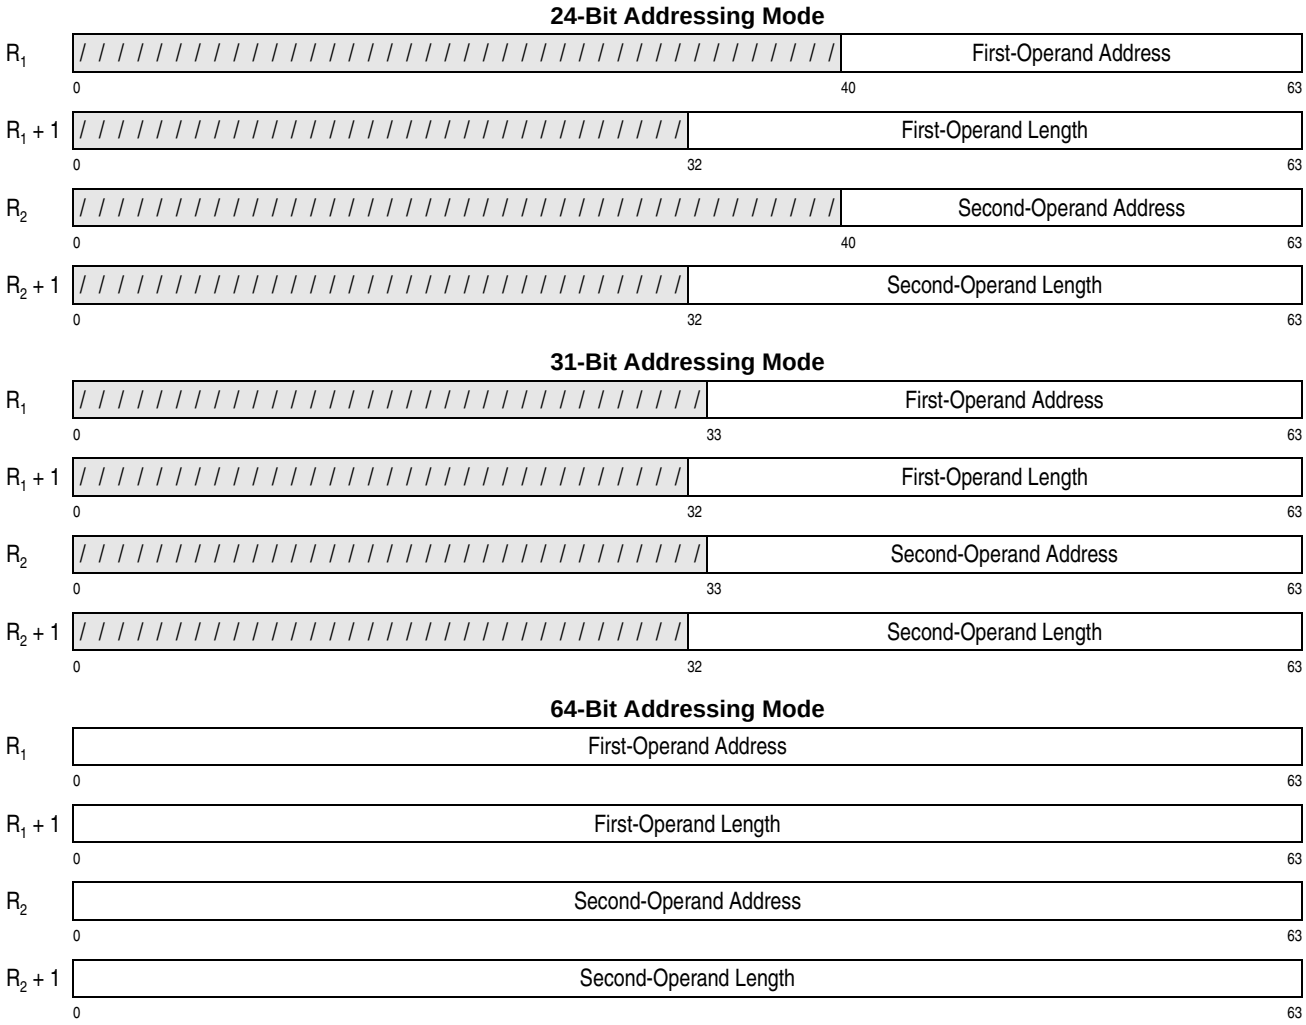


Figure 7-328. Register Contents for CONVERT UTF-16 TO UTF-8

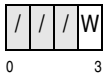
When the ETF3-enhancement facility is installed, the M_3 field has the following format:



The bits of the M_3 field are defined as follows:

- ***Unassigned:*** Bits 0-2 are unassigned and should contain zeros; otherwise, the program may not operate compatibly in the future.
- ***Enhanced Well-Formedness-Checking (W):*** The W bit, bit 3 of the M_3 field, controls whether enhanced well-formedness checking of the Unicode characters is performed. When the W bit is zero, enhanced checking is not performed. When the W bit is one, enhanced checking is performed, as described below.

When the ETF3-enhancement facility is not installed, the M_3 field is ignored. When the ETF3-enhancement facility is installed in the z/Architecture architectural mode, it is unpredictable whether the M_3 field is ignored in the ESA/390-compatibility mode.

The characters of the second operand are selected one by one for conversion, proceeding left to right. The bytes resulting from a conversion are placed at the first-operand location, proceeding left to right. The operation proceeds until the first-operand or sec-

ond-operand location is exhausted, a CPU-determined number of second-operand characters have been converted, or an invalid Unicode character is encountered in the second operand.

To show the method of converting a Unicode character to a UTF-8 character, the bits of a Unicode character are identified by letters as follows:

Unicode Character Bit Numbers	0 1 2 3 4 5 6 7	8 9 10 11 12 13 14 15
Identifying Bit Letters	a b c d e f g h	i j k l m n o p

In the case of a Unicode surrogate pair, which is a character pair consisting of a character called a high surrogate followed by a character called a low surrogate, the bits are identified by letters as follows:

Unicode High Surrogate Bit Numbers	0 1 2 3 4 5 6 7	8 9 10 11 12 13 14 15
Identifying Bit Letters	1 1 0 1 1 0 a b	c d e f g h i j

Unicode Low Surrogate Bit Numbers	16 17 18 19 20 21 22 23	24 25 26 27 28 29 30 31
Identifying Bit Letters	1 1 0 1 1 1 k l	m n o p q r s t

A low surrogate (that is, a Unicode character in the range of DC00 to DFFF hex) that is not immediately preceded by a high surrogate (that is, a Unicode character in the range of D800 to DBFF hex) is called an isolated low surrogate.

Any Unicode character in the range 0000 to 007F hex is converted to a one-byte UTF-8 character as follows:

Unicode Character	0 0 0 0 0 0 0 0	0 j k l m n o p
UTF-8 Character	0 j k l m n o p	

Any Unicode character in the range 0080 to 07FF hex is converted to a two-byte UTF-8 character as follows:

Unicode Character	0 0 0 0 0 f g h	i j k l m n o p
UTF-8 Character	1 1 0 f g h i j	1 0 k l m n o p

Any Unicode character in the range 0800 to D7FF or E000 to FFFF hex is converted to a three-byte UTF-8 character as follows:

Unicode Character	a b c d e f g h	i j k l m n o p	
UTF-8 Character	1 1 1 0 a b c d	1 0 e f g h i j	1 0 k l m n o p

On some models, an isolated low surrogate (that is, a Unicode character in the range of DC00 to DFFF hex) is also converted to a three-byte UTF-8 character as shown above, regardless of whether the ETF3-enhancement facility is installed and regardless of the W bit of the M_3 field. On other models, when the ETF3-enhancement facility is installed, the W bit of the M_3 field is one, and the next Unicode character is an isolated low surrogate, condition code 2 is set.

Any Unicode surrogate pair starting with a high surrogate in the range D800 to DBFF hex is converted to a four-byte UTF-8 character as follows:

Unicode Characters	1 1 0 1 1 0 a b	c d e f g h i j	1 1 0 1 1 1 k l	m n o p q r s t
UTF-8 Character	1 1 1 1 0 u v w	1 0 x y e f g h	1 0 i j k l m n	1 0 o p q r s t
where uvwxy = abcd + 1				

When the ETF3-enhancement facility is not installed, or when the W bit of the M_3 field is zero, the first six bits of an expected Unicode low surrogate are ignored. When the ETF3-enhancement facility is installed, and the W bit is one, the first six bits of the Unicode low surrogate must contain 110111 binary; otherwise, the Unicode low surrogate is invalid, and condition code 2 is set.

The second-operand location is considered exhausted when it does not contain at least two remaining bytes or at least four remaining bytes when the first two bytes are a Unicode high surrogate. The first-operand location is considered exhausted when it does not contain at least the one, two, three, or four remaining bytes required to contain the UTF-8 character resulting from the conversion of the next second-operand character or surrogate pair.

When the second-operand location is exhausted, condition code 0 is set. When the first-operand location is exhausted, condition code 1 is set, except that condition code 0 is set if the second-operand location also is exhausted. When a CPU-determined number

of characters have been converted, condition code 3 is set.

When the conditions for setting condition codes 1 and 2 are both met, condition code 2 is set.

When the operation is completed, the contents of general register $R_2 + 1$ are decremented by the number of bytes converted, and the contents of general register R_2 are incremented by the same number. Also, the contents of general register $R_1 + 1$ are decremented by the number of bytes placed at the first-operand location, and the contents of general register R_1 are incremented by the same number. When general registers R_1 and R_2 are updated in the 24-bit or 31-bit addressing mode, bits 32-39 of them, in the 24-bit mode, or bit 32, in the 31-bit mode, may be set to zeros or may remain unchanged.

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers R_1, $R_1 + 1$, R_2, and $R_2 + 1$, always remain unchanged.

When condition code 2 is set, the following applies:

- When a Unicode high surrogate immediately precedes an invalid low surrogate, general register R_2 contains the address of the Unicode high surrogate.
- When an isolated Unicode low surrogate is detected, general register R_2 contains the address of the isolated low surrogate.

When condition code 3 is set, the registers have been updated so that the instruction, when reexecuted, resumes at the next byte locations to be processed.

The amount of processing that results in the setting of condition code 3 is determined by the CPU on the basis of improving system performance, and it may be a different amount each time the instruction is executed.

When the R_1 register is the same register as the R_2 register, the results are unpredictable.

When the second operand overlaps the first operand, the results are unpredictable.

Access exceptions for the portions of the operands to the right of the last byte processed may or may not be recognized. For an operand longer than 4K bytes, access exceptions are not recognized for locations more than 4K bytes beyond the last byte processed.

When the length of an operand is zero, no access exceptions are recognized for that operand. Access exceptions are not recognized for an operand if the R field associated with that operand is odd.

Resulting Condition Code:

0 Entire second operand processed
1 End of first operand reached
2 Invalid Unicode low surrogate
3 CPU-determined number of characters converted

Program Exceptions:

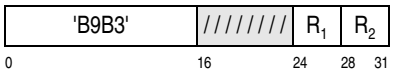
- Access (fetch, operand 2; store, operand 1)
- Specification
- Transaction constraint

Programming Notes:

1. When condition code 3 is set, the program can simply branch back to the instruction to continue the conversion. The program need not determine the number of first-operand or second-operand bytes that were processed.
2. The storage-operand references of CONVERT UNICODE TO UTF-8 may be multiple-access references. (See “Storage-Operand Consistency” on page 5-133.)
3. The CONVERT UTF-16 TO UTF-8 (CONVERT UNICODE TO UTF-8) instruction supports UTF-16 characters only in the big-endian encoding.
4. As observed by this CPU, other CPUs, and the I/O subsystem, inconsistent results may be briefly stored in the first-operand location. See the section “Effects of CPU Retry” on page 11-3 for further details.
5. Determining that isolated Unicode low surrogates are invalid is a model-dependent behavior that is not available on the IBM z13 and earlier models.

CONVERT UTF-32 TO UTF-16

CU42 R_1,R_2 [RRE]



The four-byte UTF-32 characters of the second operand are converted to two-byte UTF-16 characters and placed at the first-operand location. The operation proceeds until the end of the first or second operand is reached, a CPU-determined number of characters have been converted, or an invalid UTF-32 character is encountered, whichever occurs first. The result is indicated in the condition code.

The R_1 and R_2 fields each designate an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The location of the leftmost byte of the first operand and the second operand is designated by the contents of general registers R_1 and R_2, respectively. In the 24-bit or 31-bit addressing mode, the number of bytes in the first-operand and second-operand locations is specified by the contents of bit positions 32-63 of general registers $R_1 + 1$ and $R_2 + 1$, respectively, and those contents are treated as 32-bit unsigned binary integers. In the 64-bit addressing mode, the number of bytes in the first-operand and second-operand locations is specified by the entire contents of general registers $R_1 + 1$ and $R_2 + 1$, respectively, and those contents are treated as 64-bit unsigned binary integers.

The handling of the addresses in general registers R_1 and R_2 is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers R_1 and R_2 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the registers constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 constitute the address.

The contents of the registers just described are shown in Figure 7-329.

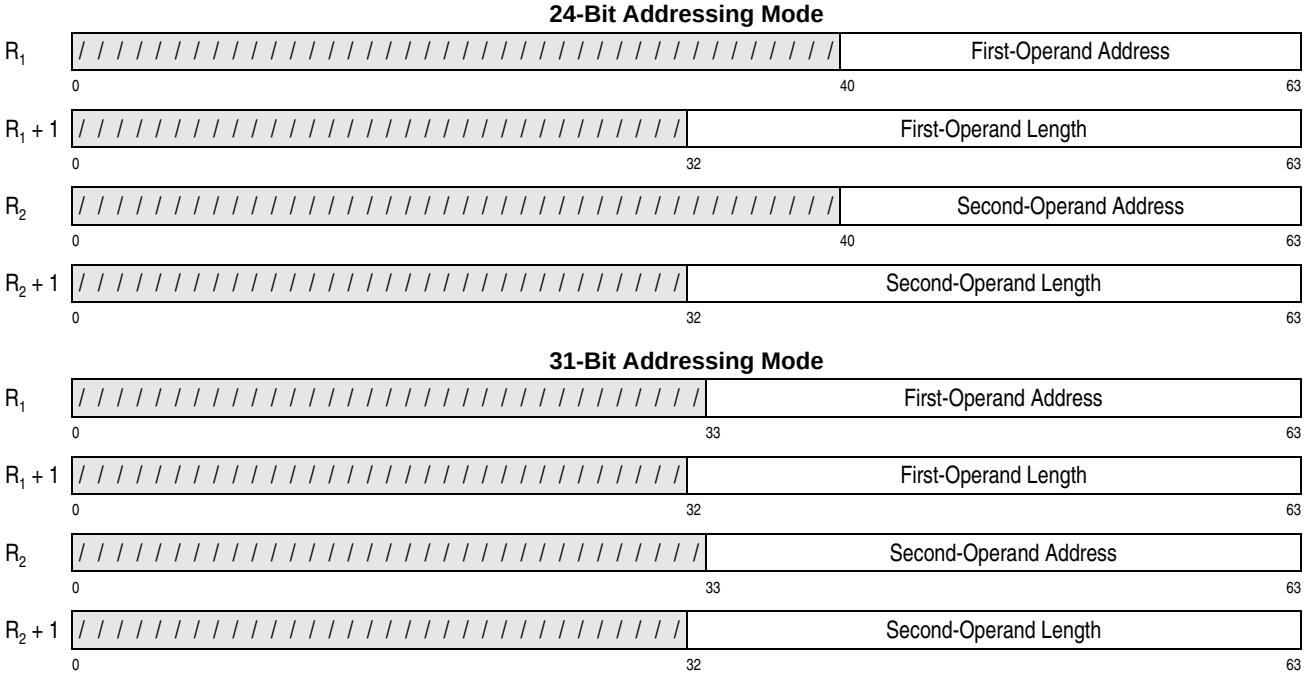


Figure 7-329. Register Contents for CONVERT UTF-32 TO UTF-16 (Part 1 of 2)

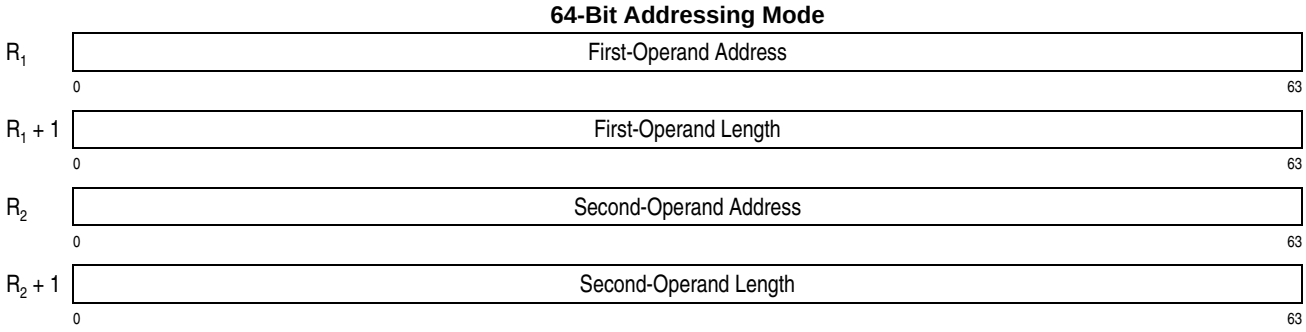

Figure 7-329. Register Contents for CONVERT UTF-32 TO UTF-16 (Part 2 of 2)

The characters of the second operand are selected one by one for conversion, proceeding left to right. The bytes resulting from a conversion are placed at the first-operand location, proceeding left to right. The operation proceeds until the first-operand or second-operand location is exhausted, a CPU-determined number of second-operand characters have been converted, or an invalid UTF-32 character is encountered in the second operand.

To show the method of converting a UTF-32 character to a UTF-16 character, the bits of a UTF-32 character in the range 00000000 to 0000D7FF or 0000DC00 to 0000FFFF hex are identified by letters as follows:

UTF-32 Character Bit Numbers	0 1 2 3 4 5 6 7	8 9 10 11 12 13 14 15
Identifying Bit Letters	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0

UTF-32 Character Bit Numbers	16 17 18 19 20 21 22 23	24 25 26 27 28 29 30 31
Identifying Bit Letters	a b c d e f g h	i j k l m n o p

The bits of a UTF-32 character in the range 00010000 to 0010FFFF hex are identified by letters as follows:

UTF-32 Character Bit Numbers	0 1 2 3 4 5 6 7	8 9 10 11 12 13 14 15
Identifying Bit Letters	0 0 0 0 0 0 0 0	0 0 0 u v w x y

UTF-32 Character Bit Numbers	16 17 18 19 20 21 22 23	24 25 26 27 28 29 30 31
Identifying Bit Letters	e f g h i j k l	m n o p q r s t

The bits of a UTF-16 character in the range 0000 to D7FF or DC00 to FFFF hex are identified by letters as follows:

UTF-16 Character Bit Numbers	0 1 2 3 4 5 6 7	8 9 10 11 12 13 14 15
Identifying Bit Letters	a b c d e f g h	i j k l m n o p

In the case of a UTF-16 surrogate pair, which is a character pair consisting of a character called a high surrogate followed by a character called a low surrogate, the bits are identified by letters as follows:

UTF-16 High Surrogate Bit Numbers	0 1 2 3 4 5 6 7	8 9 10 11 12 13 14 15
Identifying Bit Letters	1 1 0 1 1 0 a b	c d e f g h i j

UTF-16 Low Surrogate Bit Numbers	16 17 18 19 20 21 22 23	24 25 26 27 28 29 30 31
Identifying Bit Letters	1 1 0 1 1 1 k l	m n o p q r s t

When the contents of the UTF-32 characters are in the range 00000000 to 0000D7FF or 0000E000 to 0000FFFF hex, the character is converted to a two-byte UTF-16 character as follows:

UTF-32 Character	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0	a b c d e f g h	i j k l m n o p
UTF-16 Character	a b c d e f g h	i j k l m n o p		

On some models, when the contents of the UTF-32 character are in the range of 0000DC00 to 0000DFFF hex, the character is also converted to a two-byte UTF-16 character as described above.

When the contents of a UTF-32 character are in the range 00010000 to 0010FFFF hex, the character is

converted to two two-byte UTF-16 characters (a surrogate pair) as follows:

UTF-32 Character	0 0 0 0 0 0 0 0	0 0 0 u v w x y	e f g h i j k l	m n o p q r s t
UTF-16 Characters	1 1 0 1 1 0 a b	c d e f g h i j	1 1 0 1 1 1 k l	m n o p q r s t
where zabcd = uvwxy - 1				

The high order bit (z) produced by the subtract operation is necessarily zero and is ignored.

The second-operand location is considered exhausted when it does not contain at least four remaining bytes. The first-operand location is considered exhausted when it does not contain at least two remaining bytes or at least four remaining bytes in the case when a UTF-32 character in the range 00010000 to 0010FFFF hex is converted.

When the second-operand location is exhausted, condition code 0 is set. When the first-operand location is exhausted, condition code 1 is set, except that condition code 0 is set if the second-operand location also is exhausted. When a CPU-determined number of characters have been processed, condition code 3 is set.

When the contents of the next UTF-32 character are in the range 0000D800 to 0000DBFF or 00110000 to FFFFFFFF hex, the character is invalid, and condition code 2 is set. On some models, when the contents of the next UTF-32 character are in the range of 0000DC00 to 0000DFFF hex, the character is invalid, and condition code 2 is set.

When the conditions for setting condition codes 1 and 2 are both met, condition code 2 is set.

When the operation is completed, the contents of general register $R_2 + 1$ are decremented by the number of bytes converted, and the contents of general register R_2 are incremented by the same number. Also, the contents of general register $R_1 + 1$ are decremented by the number of bytes placed at the first-operand location, and the contents of general register R_1 are incremented by the same number. When general registers R_1 and R_2 are updated in the 24-bit or 31-bit addressing mode, bits 32-39 of them, in the 24-bit mode, or bit 32, in the 31-bit mode, may be set to zeros or may remain unchanged.

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers R_1, $R_1 + 1$, R_2, and $R_2 + 1$, always remain unchanged.

When condition code 2 is set, general register R_2 contains the address of the invalid UTF-32 character.

When condition code 3 is set, the registers have been updated so that the instruction, when reexecuted, resumes at the next byte locations to be processed.

The amount of processing that results in the setting of condition code 3 is determined by the CPU on the basis of improving system performance, and it may be a different amount each time the instruction is executed.

When the R_1 register is the same register as the R_2 register, the results are unpredictable.

When the second operand overlaps the first operand, the results are unpredictable.

Access exceptions for the portions of the operands to the right of the last byte processed may or may not be recognized. For an operand longer than 4K bytes, access exceptions are not recognized for locations more than 4K bytes beyond the last byte processed.

When the length of an operand is zero, no access exceptions are recognized for that operand. Access exceptions are not recognized for an operand if the R field associated with that operand is odd.

Resulting Condition Code:

0 Entire second operand processed
1 End of first operand reached
2 Invalid UTF-32 character
3 CPU-determined number of characters processed

Program Exceptions:

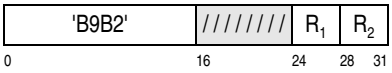
- Access (fetch, operand 2; store, operand 1)
- Operation (if the extended-translation facility 3 is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. When condition code 3 is set, the program can simply branch back to the instruction to continue the conversion. The program need not determine the number of first-operand or second-operand bytes that were processed.
2. The storage-operand references of CONVERT UTF-32 TO UTF-16 may be multiple-access references. (See “Storage-Operand Consistency” on page 5-133.)
3. The CONVERT UTF-32 TO UTF-16 instruction supports UTF-16 and UTF-32 characters only in the big-endian encoding.
4. As observed by this CPU, other CPUs, and the I/O subsystem, inconsistent results may be briefly stored in the first-operand location. See the section “Effects of CPU Retry” on page 11-3 for further details.
5. Determining that UTF-32 characters in the range of 0000DC00 to 0000DFFF are invalid is a model-dependent behavior that is not available on the IBM z13 and earlier models.

CONVERT UTF-32 TO UTF-8

CU41 R_1,R_2 [RRE]



The four-byte UTF-32 characters of the second operand are converted to UTF-8 characters and placed at the first-operand location. The UTF-8 characters are one, two, three, or four bytes, depending on the Unicode characters that are converted. The operation proceeds until the end of the first or second operand is reached or a CPU-determined number of characters have been converted, whichever occurs first. The result is indicated in the condition code.

The R_1 and R_2 fields each designate an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The location of the leftmost byte of the first operand and the second operand is designated by the contents of general registers R_1 and R_2, respectively. In the 24-bit or 31-bit addressing mode, the number of bytes in the first-operand and second-operand locations is specified by the contents of bit positions 32-63 of general registers $R_1 + 1$ and $R_2 + 1$, respectively, and those contents are treated as 32-bit unsigned binary integers. In the 64-bit addressing mode, the number of bytes in the first-operand and second-operand locations is specified by the entire contents of general registers $R_1 + 1$ and $R_2 + 1$, respectively, and those contents are treated as 64-bit unsigned binary integers.

The handling of the addresses in general registers R_1 and R_2 is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers R_1 and R_2 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the registers constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 constitute the address.

The contents of the registers just described are shown in Figure 7-330.

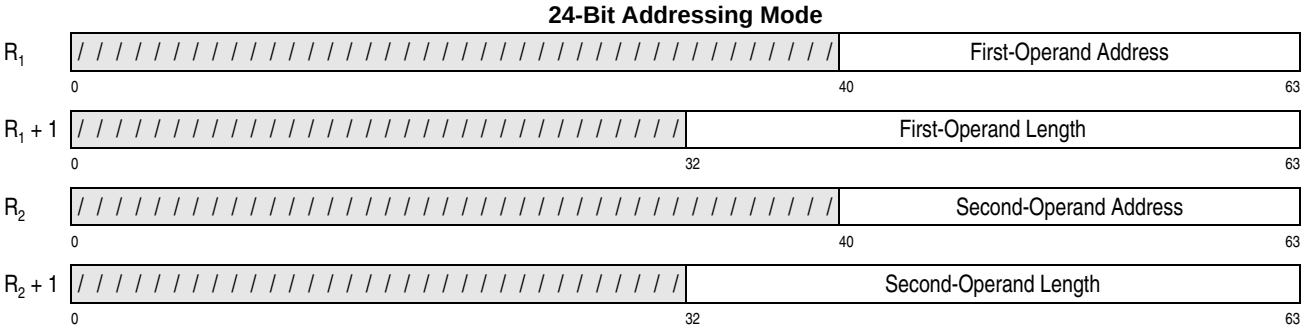


Figure 7-330. Register Contents for CONVERT UTF-32 TO UTF-8 (Part 1 of 2)

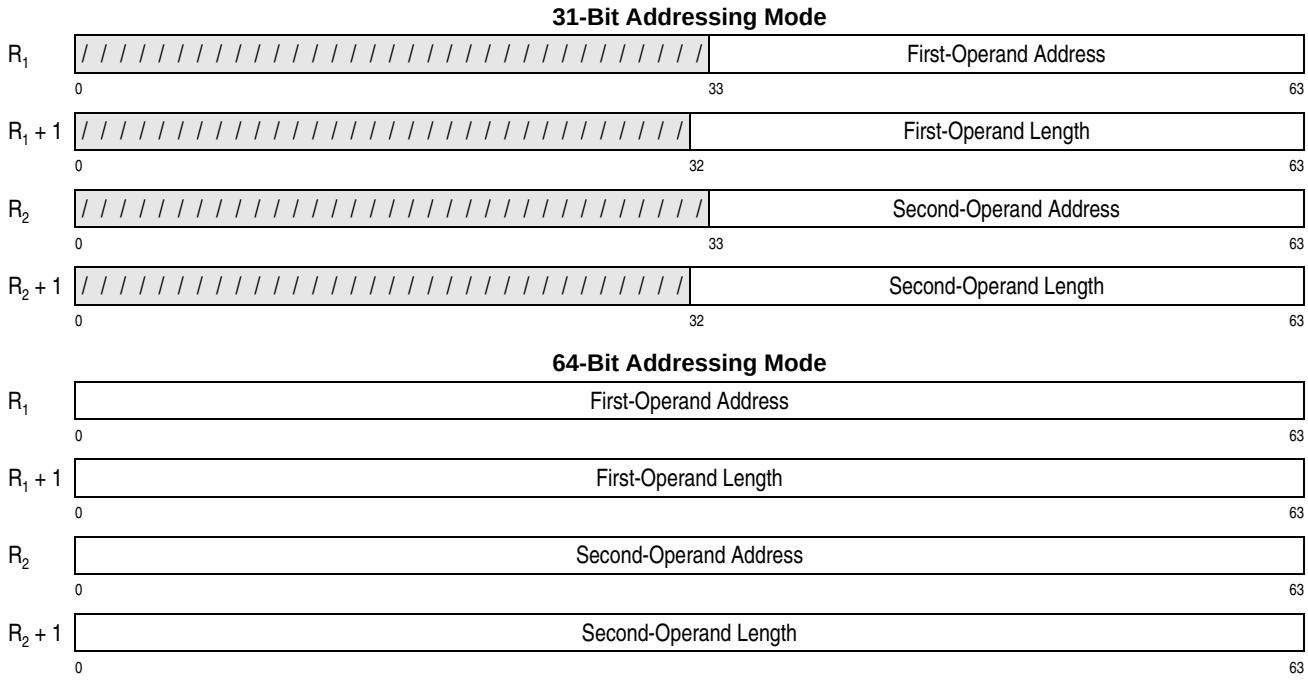

Figure 7-330. Register Contents for CONVERT UTF-32 TO UTF-8 (Part 2 of 2)

The characters of the second operand are selected one by one for conversion, proceeding left to right. The bytes resulting from a conversion are placed at the first-operand location, proceeding left to right. The operation proceeds until the first-operand or second-operand location is exhausted, a CPU-determined number of second-operand characters have been converted, or on some models, until an invalid Unicode character is detected.

To show the method of converting a UTF-32 character to a UTF-8 character, the bits of a UTF-32 character in the range 00000000 to 0000D7FF or 0000DC00 to 0000FFFF hex are identified by letters as follows:

UTF-32 Character Bit Numbers	0 1 2 3 4 5 6 7	8 9 10 11 12 13 14 15
Identifying Bit Letters	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0

UTF-32 Character Bit Numbers	16 17 18 19 20 21 22 23	24 25 26 27 28 29 30 31
Identifying Bit Letters	a b c d e f g h	i j k l m n o p

Any UTF-32 character in the range 00000080 to 000007FF hex is converted to a two-byte UTF-8 character as follows:

UTF-32 Character	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0	0 j k l m n o p
UTF-8 Character	0 j k l m n o p			

The bits of a UTF-32 character in the range 00010000 to 0010FFFF hex (UTF-16 surrogate pair) are identified by letters as follows:

UTF-32 Character Bit Numbers	0 1 2 3 4 5 6 7	8 9 10 11 12 13 14 15
Identifying Bit Letters	0 0 0 0 0 0 0 0	0 0 0 u v w x y

UTF-32 Character Bit Numbers	16 17 18 19 20 21 22 23	24 25 26 27 28 29 30 31
Identifying Bit Letters	e f g h i j k l	m n o p q r s t

Any UTF-32 character in the range 00000000 to 0000007F hex is converted to a one-byte UTF-8 character as follows:

UTF-32 Character	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0	0 j k l m n o p
UTF-8 Character	0 j k l m n o p			

character as follows:

UTF-32 Character	00000000	00000000	00000fgh	ijklmnop
UTF-8 Character	110fghij	10klmnop		

Any UTF-32 character in the range 00000800 to 0000D7FF or 0000E000 to 0000FFFF hex is converted to a three-byte UTF-8 character as follows:

UTF-32 Character	00000000	00000000	abcdefgh	ijklmnop
UTF-8 Character	1110abcd	10efghij	10klmnop	

On some models, any UTF-32 character the range of 0000DC00 to 0000DFFF hex is converted to a three-byte UTF-8 character as described above.

Any UTF-32 character in the range 00010000 to 0010FFFF hex is converted to a four-byte UTF-8 character as follows:

UTF-32 Character	00000000	000uvwxy	efghijkl	mnopqrst
UTF-8 Character	11110uvw	10xyefgh	10ijklmn	10opqrst

The second-operand location is considered exhausted when it does not contain at least four remaining bytes. The first-operand location is considered exhausted when it does not contain at least the one, two, three, or four remaining bytes required to contain the UTF-8 character resulting from the conversion of the next second-operand character or surrogate pair.

When the second-operand location is exhausted, condition code 0 is set. When the first-operand location is exhausted, condition code 1 is set, except that condition code 0 is set if the second-operand location also is exhausted. When a CPU-determined number of characters have been converted, condition code 3 is set.

When the contents of the next UTF-32 character are in the range 0000D800 to 0000DBFF or 00110000 to FFFFFFFF hex, the character is invalid, and condition code 2 is set. On some models, when the contents of the next UTF-32 character are in the range of 0000DC00 to 0000DFFF hex, the character is invalid, and condition code 2 is set.

When the conditions for setting condition codes 1 and 2 are both met, condition code 2 is set.

When the operation is completed, the contents of general register $R_2 + 1$ are decremented by the number of bytes converted, and the contents of general register R_2 are incremented by the same number. Also, the contents of general register $R_1 + 1$ are decremented by the number of bytes placed at the first-operand location, and the contents of general register R_1 are incremented by the same number. When general registers R_1 and R_2 are updated in the 24-bit or 31-bit addressing mode, bits 32-39 of them, in the 24-bit mode, or bit 32, in the 31-bit mode, may be set to zeros or may remain unchanged.

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers R_1, $R_1 + 1$, R_2, and $R_2 + 1$, always remain unchanged.

When condition code 2 is set, general register R_2 contains the address of the invalid UTF-32 character.

When condition code 3 is set, the registers have been updated so that the instruction, when reexecuted, resumes at the next byte locations to be processed.

The amount of processing that results in the setting of condition code 3 is determined by the CPU on the basis of improving system performance, and it may be a different amount each time the instruction is executed.

When the R_1 register is the same register as the R_2 register, the results are unpredictable.

When the second operand overlaps the first operand, the results are unpredictable.

Access exceptions for the portions of the operands to the right of the last byte processed may or may not be recognized. For an operand longer than 4K bytes, access exceptions are not recognized for locations more than 4K bytes beyond the last byte processed.

When the length of an operand is zero, no access exceptions are recognized for that operand. Access exceptions are not recognized for an operand if the R field associated with that operand is odd.

Resulting Condition Code:

0 Entire second operand processed
1 End of first operand reached
2 Invalid UTF-32 character.
3 CPU-determined number of characters converted

Program Exceptions:

- Access (fetch, operand 2; store, operand 1)
- Operation (if the extended-translation facility 3 is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. When condition code 3 is set, the program can simply branch back to the instruction to continue the conversion. The program need not determine the number of first-operand or second-operand bytes that were processed.

2. The storage-operand references of CONVERT UTF-32 TO UTF-8 may be multiple-access references. (See “Storage-Operand Consistency” on page 5-133.)

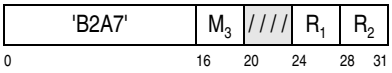
3. The CONVERT UTF-32 TO UTF-8 instruction supports UTF-32 characters only in the big-endian encoding.

4. As observed by this CPU, other CPUs, and the I/O subsystem, inconsistent results may be briefly stored in the first-operand location. See the section “Effects of CPU Retry” on page 11-3 for further details.

5. Determining that UTF-32 characters in the range of 0000DC00 to 0000DFFF are invalid is a model-dependent behavior that is not available on the IBM z13 and earlier models.

CONVERT UTF-8 TO UTF-16
CONVERT UTF-8 TO UNICODE

CU12 $R_1,R_2[,M_3]$ [RRF-c]
CUTFU $R_1,R_2[,M_3]$ [RRF-c]



The one-, two-, three-, or four-byte UTF-8 characters of the second operand are converted to two-byte Unicode characters and placed at the first-operand location. The operation proceeds until the end of the first or second operand is reached, a CPU-determined number of characters have been converted, or an invalid UTF-8 character is encountered, whichever occurs first. The result is indicated in the condition code.

The R_1 and R_2 fields each designate an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The location of the leftmost byte of the first operand and the second operand is designated by the contents of general registers R_1 and R_2, respectively. In the 24-bit or 31-bit addressing mode, the number of bytes in the first-operand and second-operand locations is specified by the contents of bit positions 32-63 of general registers $R_1 + 1$ and $R_2 + 1$, respectively, and those contents are treated as 32-bit unsigned binary integers. In the 64-bit addressing mode, the number of bytes in the first-operand and second-operand locations is specified by the entire contents of general registers $R_1 + 1$ and $R_2 + 1$, respectively, and those contents are treated as 64-bit unsigned binary integers.

The handling of the addresses in general registers R_1 and R_2 is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers R_1 and R_2 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the registers constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 constitute the address.

The contents of the registers just described are shown in Figure 7-331.

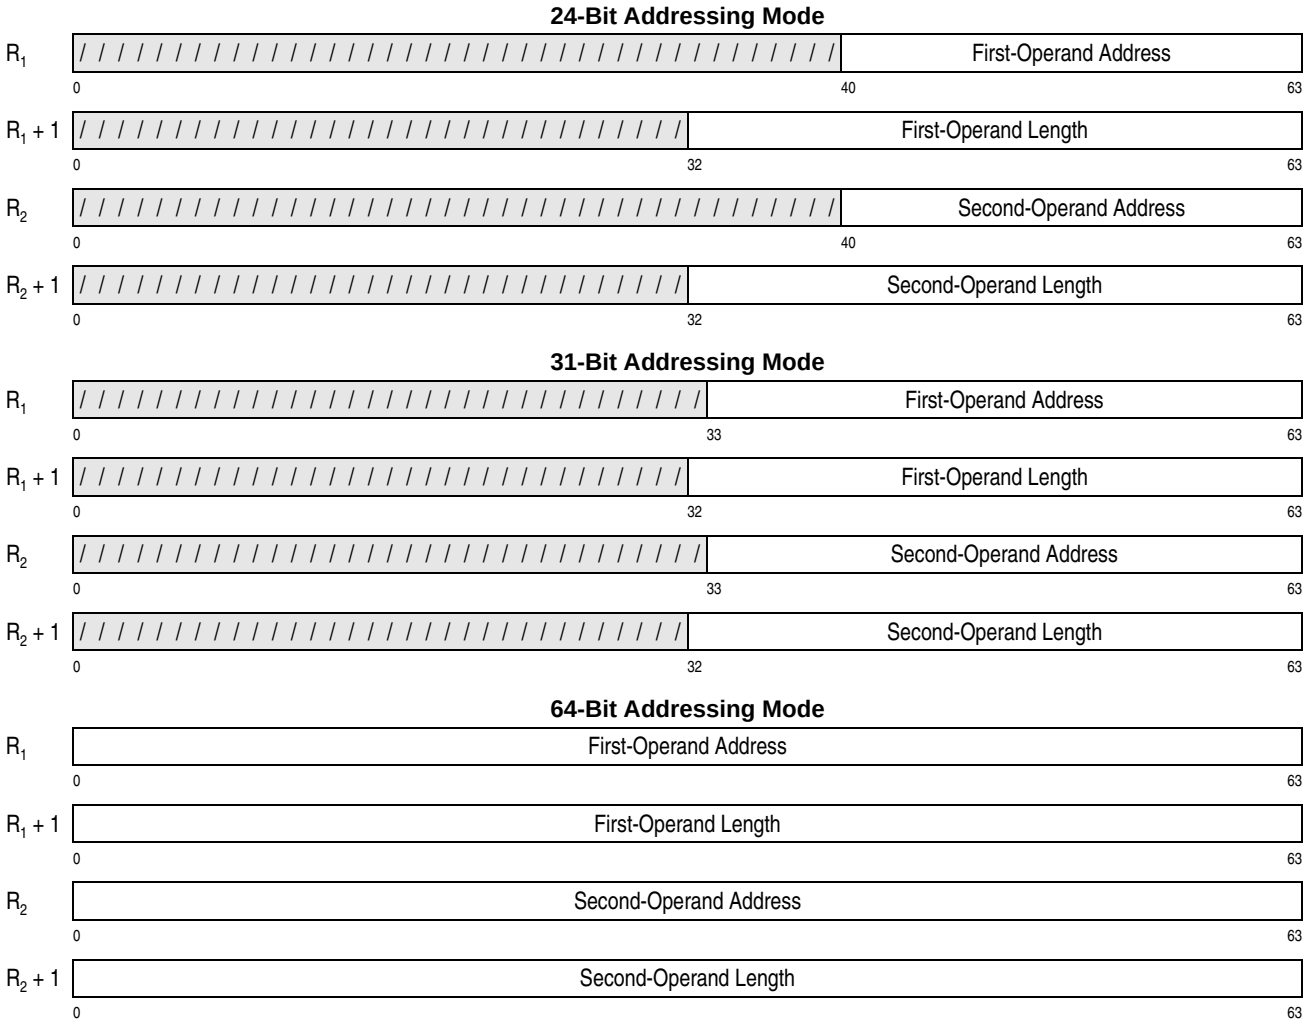


Figure 7-331. Register Contents for CONVERT UTF-8 TO UTF-16

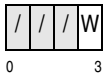
When the ETF3-enhancement facility is installed, the M_3 field has the following format:



The bits of the M_3 field are defined as follows:

- ***Unassigned:*** Bits 0-2 are unassigned and should contain zeros; otherwise, the program may not operate compatibly in the future.
- ***Enhanced Well-Formedness-Checking (W):*** The W bit, bit 3 of the M_3 field, controls whether enhanced well-formedness checking of the UTF-8 characters is performed. When the W bit is zero, enhanced checking is not performed. When the W bit is one, enhanced checking is performed, as described below.

When the ETF3-enhancement facility is not installed, the M_3 field is ignored. When the ETF3-enhancement facility is installed in the z/Architecture architectural mode, it is unpredictable whether the M_3 field is ignored in the ESA/390-compatibility mode.

The characters of the second operand are selected one by one for conversion, proceeding left to right. The bytes resulting from a conversion are placed at the first-operand location, proceeding left to right. The operation proceeds until the first-operand or sec-

ond-operand location is exhausted, a CPU-determined number of second-operand characters have been converted, or an invalid UTF-8 character is encountered in the second operand.

To show the method of converting a UTF-8 character to a Unicode character, the bits of a Unicode character are identified by letters as follows:

Unicode Character Bit Numbers	0 1 2 3 4 5 6 7	8 9 10 11 12 13 14 15
Identifying Bit Letters	a b c d e f g h	i j k l m n o p

In the case of a Unicode surrogate pair, which is a character pair consisting of a character called a high surrogate followed by a character called a low surrogate, the bits are identified by letters as follows:

Unicode High Surrogate Bit Numbers	0 1 2 3 4 5 6 7	8 9 10 11 12 13 14 15
Identifying Bit Letters	1 1 0 1 1 0 a b	c d e f g h i j

Unicode Low Surrogate Bit Numbers	16 17 18 19 20 21 22 23	24 25 26 27 28 29 30 31
Identifying Bit Letters	1 1 0 1 1 1 k l	m n o p q r s t

Conversion of a UTF-8 character to a Unicode character is as follows:

1. When the contents of the first byte of a UTF-8 character are in the range 00 to 7F hex, the character is a one-byte character, and it is converted to a two-byte Unicode character as follows:

UTF-8 Character	0 j k l m n o p	
Unicode Character	0 0 0 0 0 0 0 0	0 j k l m n o p

2. When the contents of the first byte of the UTF-8 character are in the range 80 to BF hex, the character is invalid. When the ETF3-enhancement facility is installed, the W bit of the M_3 field is one, and the contents of the first byte of the UTF-8 character are in the range C0 to C1 hex, the character is also invalid.

3. When the ETF3-enhancement facility is not installed or the W bit of the M_3 field is zero, and the contents of the first byte of the UTF-8 character are in the range of C0 to DF hex; or when the ETF3-enhancement facility is installed, the W bit is one, and the contents of the first byte of the UTF-8 character are in the range of C2 to DF hex; the character is a two-byte character, and it is converted to a two-byte Unicode character as follows:

UTF-8 Character	1 1 0 f g h i j	1 0 k l m n o p
Unicode Character	0 0 0 0 0 f g h	i j k l m n o p

When the ETF3-enhancement facility is not installed or when the W bit of the M_3 field is zero, the first two bits in the second byte of the UTF-8 character are ignored. When the ETF3-enhancement facility is installed and the W bit of the M_3 field is one, the contents of the second byte of the UTF-8 character must be in the range 80 to BF; otherwise the character is invalid.

4. When the contents of the first byte of a UTF-8 character are in the range E0 to EF hex, the character is a three-byte character, and it is converted to a two-byte Unicode character as follows:

UTF-8 Character	1 1 1 0 a b c d	1 0 e f g h i j	1 0 k l m n o p
Unicode Character	a b c d e f g h	i j k l m n o p	

When the ETF3-enhancement facility is not installed or when the W bit of the M_3 field is zero, the first two bits in the second and third bytes of the UTF-8 character are ignored.

When the ETF3-enhancement facility is installed and the W bit of the M_3 field is one, the contents of the second and third bytes of the UTF-8 character must be as follows:

- When the first byte is E0 hex, the second and third bytes must be in the ranges A0 to BF and 80 to BF, respectively.
- When the first byte is in the range E1 to EC hex or EE to EF, the second and third bytes must both be in the range 80 to BF hex.
- When the first byte is ED hex, the second and third bytes must be in the ranges 80 to 9F and 80 to BF, respectively.

Otherwise, the character is invalid.

5. When the ETF3-enhancement facility is not installed or the W bit of the M_3 field is zero, and the contents of the first byte of the UTF-8 character are in the range of F0 to F7 hex; or when the ETF3-enhancement facility is installed, the W bit

is one, and the contents of the first byte of the UTF-8 character are in the range of F0 to F4 hex; the character is a four-byte character, and it is converted to two two-byte Unicode characters (a surrogate pair) as follows:

UTF-8 Character	1 1 1 1 0 u v w	1 0 x y e f g h	1 0 i j k l m n	1 0 o p q r s t
Unicode Characters	1 1 0 1 1 0 a b	c d e f g h i j	1 1 0 1 1 1 k l	m n o p q r s t
where zabcd = uvwxy - 1				

When the ETF3-enhancement facility is not installed or when the W bit of the M_3 field is zero, the first two bits in the second, third, and fourth bytes of the UTF-8 character are ignored, and the high order bit (z) produced by the subtract operation should be zero but is ignored.

When the ETF3-enhancement facility is installed and the W bit of the M_3 field is one, the contents of the second, third, and fourth bytes of the UTF-8 character must be as follows:

- When the first byte is F0 hex, the second, third, and fourth bytes must be in the ranges 90 to BF, 80 to BF, and 80 to BF, respectively.
- When the first byte is in the range F1 to F3, the second, third, and fourth bytes must all be in the range 80 to BF hex.
- When the first byte is F4 hex, the second, third, and fourth bytes must be in the ranges 80 to 8F, 80 to BF, and 80 to BF, respectively.

Otherwise, the character is invalid.

6. When the ETF3-enhancement facility is installed, the W bit of the M_3 field is one, and the contents of the first byte of the UTF-8 character are in the range of F5 to F7 hex, the character is invalid.
7. When the contents of the first byte of the UTF-8 character are in the range of F8-FF, the character is invalid.

If an invalid character is encountered, condition code 2 is set, and general register R_2 contains the address of the first byte of the invalid UTF-8 character.

The second-operand location is considered exhausted when it does not contain at least one remaining byte or when it does not contain at least the two, three, or four remaining bytes required to contain the two-, three-, or four-byte UTF-8 character indicated by the contents of the first remaining byte. The first-operand location is considered exhausted when it does not contain at least two remaining bytes or at least four remaining bytes in the case when a four byte UTF-8 character is to be converted.

When the second-operand location is exhausted, condition code 0 is set. When the first-operand location is exhausted, condition code 1 is set, except that condition code 0 is set if the second-operand location also is exhausted. When a CPU-determined number of characters have been processed, condition code 3 is set.

When the conditions for setting condition codes 1 and 2 are both met, condition code 2 is set.

When the operation is completed, the contents of general register $R_2 + 1$ are decremented by the number of bytes converted, and the contents of general register R_2 are incremented by the same number. Also, the contents of general register $R_1 + 1$ are decremented by the number of bytes placed at the first-operand location, and the contents of general register R_1 are incremented by the same number. When general registers R_1 and R_2 are updated in the 24-bit or 31-bit addressing mode, bits 32-39 of them, in the 24-bit mode, or bit 32, in the 31-bit mode, may be set to zeros or may remain unchanged.

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers R_1, $R_1 + 1$, R_2, and $R_2 + 1$, always remain unchanged.

When condition code 2 is set, general register R_2 contains the address of the invalid UTF-8 character.

When condition code 3 is set, the registers have been updated so that the instruction, when reexecuted, resumes at the next byte locations to be processed.

The amount of processing that results in the setting of condition code 3 is determined by the CPU on the basis of improving system performance, and it may be a different amount each time the instruction is executed.

When the R_1 register is the same register as the R_2 register, the results are unpredictable.

When the second operand overlaps the first operand, the results are unpredictable.

Access exceptions for the portions of the operands to the right of the last byte processed may or may not be recognized. For an operand longer than 4K bytes, access exceptions are not recognized for locations more than 4K bytes beyond the last byte processed.

When the length of an operand is zero, no access exceptions are recognized for that operand. Access exceptions are not recognized for an operand if the R field associated with that operand is odd.

Resulting Condition Code:

0 Entire second operand processed
1 End of first operand reached
2 Invalid UTF-8 character
3 CPU-determined number of characters processed

Program Exceptions:

- Access (fetch, operand 2; store, operand 1)
- Specification
- Transaction constraint

Programming Notes:

1. When condition code 3 is set, the program can simply branch back to the instruction to continue the conversion. The program need not determine the number of first-operand or second-operand bytes that were processed.

2. When the ETF3-enhancement facility is not installed, or when the W bit of the M_3 operand is zero, bits 0 and 1 of the continuation bytes of multiple-byte UTF-8 characters are not checked in order to improve the performance of the conversion. Therefore, invalid continuation bytes are not detected.

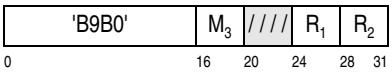
3. The storage-operand references of CONVERT UTF-8 TO UTF-16 may be multiple-access references. (See “Storage-Operand Consistency” on page 5-133.)

4. The CONVERT UTF-8 TO UTF-16 (CONVERT UTF-8 TO UNICODE) instruction supports UTF-16 characters only in the big-endian encoding.

5. As observed by this CPU, other CPUs, and the I/O subsystem, inconsistent results may be briefly stored in the first-operand location. See the section “Effects of CPU Retry” on page 11-3 for further details.

CONVERT UTF-8 TO UTF-32

CU14 $R_1,R_2[,M_3]$ [RRF-c]



The one-, two-, three-, or four-byte UTF-8 characters of the second operand are converted to four-byte UTF-32 characters and placed at the first-operand location. The operation proceeds until the end of the first or second operand is reached, a CPU-determined number of characters have been converted, or an invalid UTF-8 character is encountered, whichever occurs first. The result is indicated in the condition code.

The R_1 and R_2 fields each designate an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The location of the leftmost byte of the first operand and the second operand is designated by the contents of general registers R_1 and R_2, respectively. In the 24-bit or 31-bit addressing mode, the number of bytes in the first-operand and second-operand locations is specified by the contents of bit positions 32-63 of general registers $R_1 + 1$ and $R_2 + 1$, respectively, and those contents are treated as 32-bit unsigned binary integers. In the 64-bit addressing mode, the number of bytes in the first-operand and second-operand locations is specified by the entire contents of general registers $R_1 + 1$ and $R_2 + 1$, respectively, and those contents are treated as 64-bit unsigned binary integers.

The handling of the addresses in general registers R_1 and R_2 is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers R_1 and R_2 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the registers constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 constitute the address.

The contents of the registers just described are shown in Figure 7-332.

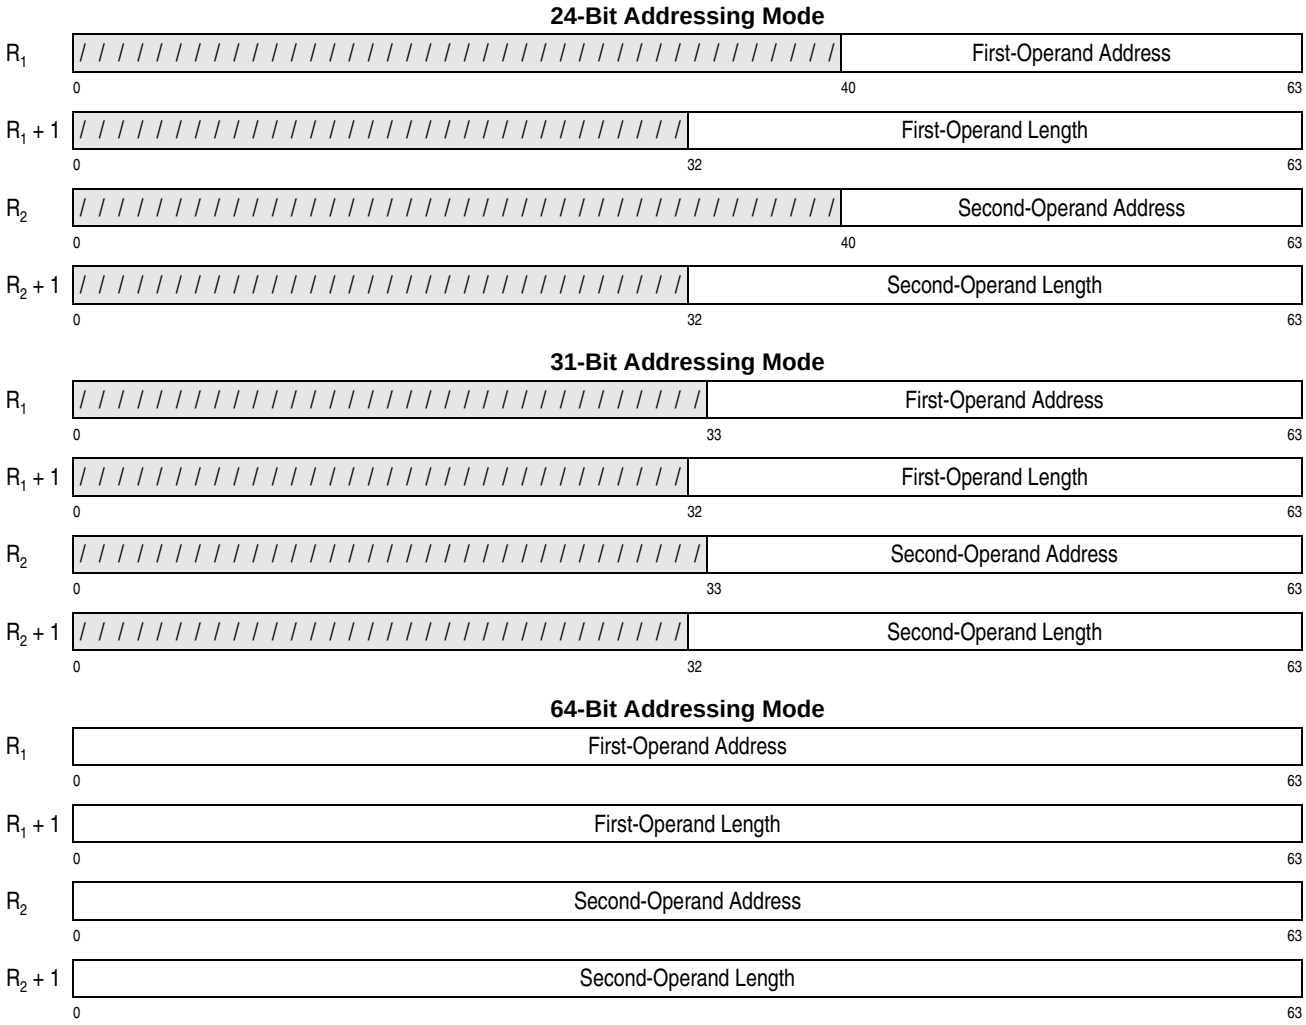


Figure 7-332. Register Contents for CONVERT UTF-8 TO UTF32

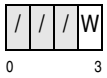
When the ETF3-enhancement facility is installed, the M_3 field has the following format:



The bits of the M_3 field are defined as follows:

- ***Unassigned:*** Bits 0-2 are unassigned and should contain zeros; otherwise, the program may not operate compatibly in the future.
- ***Enhanced Well-Formedness-Checking (W):*** The W bit, bit 3 of the M_3 field, controls whether enhanced well-formedness checking of the UTF-8 characters is performed. When the W bit is zero, enhanced checking is not performed. When the W bit is one, enhanced checking is performed, as described below.

When the ETF3-enhancement facility is not installed, the M_3 field is ignored.

The characters of the second operand are selected one by one for conversion, proceeding left to right. The bytes resulting from a conversion are placed at the first-operand location, proceeding left to right. The operation proceeds until the first-operand or second-operand location is exhausted, a CPU-determined number of second-operand characters have

been converted, or an invalid UTF-8 character is encountered in the second operand.

To show the method of converting a UTF-8 character to a UTF-32 character, the bits of a UTF-32 character in the range 00000000 to 0000D7FF or 0000DC00 to 0000FFFF hex are identified by letters as follows:

UTF-32 Character Bit Numbers	0 1 2 3 4 5 6 7	8 9 10 11 12 13 14 15
Identifying Bit Letters	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0

UTF-32 Character Bit Numbers	16 17 18 19 20 21 22 23	24 25 26 27 28 29 30 31
Identifying Bit Letters	a b c d e f g h	i j k l m n o p

The bits of a UTF-32 character in the range 00010000 0010FFFF hex (UTF-16 surrogate pair) are identified by letters as follows:

UTF-32 Character Bit Numbers	0 1 2 3 4 5 6 7	8 9 10 11 12 13 14 15
Identifying Bit Letters	0 0 0 0 0 0 0 0	0 0 0 u v w x y

UTF-32 Character Bit Numbers	16 17 18 19 20 21 22 23	24 25 26 27 28 29 30 31
Identifying Bit Letters	e f g h i j k l	m n o p q r s t

Conversion of a UTF-8 character to a UTF-32 character is as follows:

1. When the contents of the first byte of a UTF-8 character are in the range 00 to 7F hex, the character is a one-byte character, and it is converted to a four-byte UTF-32 character as follows:

UTF-8 Character	0 j k l m n o p			
UTF-32 Character	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0	0 j k l m n o p

2. When the contents of the first byte of the UTF-8 character are in the range 80 to BF hex, the character is invalid. When the ETF3-enhancement facility is installed, the W bit of the M_3 field is one, and the contents of the first byte of the UTF-8 character are in the range C0 to C1 hex, the character is also invalid.

3. When the ETF3-enhancement facility is not installed or the W bit of the M_3 field is zero, and the contents of the first byte of the UTF-8 character are in the range of C0 to DF hex; or when the ETF3-enhancement facility is installed, the W bit is one, and the contents of the first byte of the UTF-8 character are in the range of C2 to DF hex; the character is a two-byte character, and it is converted to a four-byte UTF-32 character as follows:

UTF-8 Character	1 1 0 f g h i j	1 0 k l m n o p		
UTF-32 Character	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0	0 0 0 0 0 f g h	i j k l m n o p

When the ETF3-enhancement facility is not installed or when the W bit of the M_3 field is zero, the first two bits in the second byte of the UTF-8 character are ignored. When the ETF3-enhancement facility is installed and the W bit of the M_3 field is one, the contents of the second byte of the UTF-8 character must be in the range 80 to BF; otherwise the character is invalid.

4. When the contents of the first byte of a UTF-8 character are in the range E0 to EF hex, the character is a three-byte character, and it is converted to a four-byte UTF-32 character as follows:

UTF-8 Character	1 1 1 0 a b c d	1 0 e f g h i j	1 0 k l m n o p	
UTF-32 Character	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0	a b c d e f g h	i j k l m n o p

When the ETF3-enhancement facility is not installed or when the W bit of the M_3 field is zero, the first two bits in the second and third bytes of the UTF-8 character are ignored.

When the ETF3-enhancement facility is installed and the W bit of the M_3 field is one, the contents of the second and third bytes of the UTF-8 character must be as follows:

- When the first byte is E0 hex, the second and third bytes must be in the ranges A0 to BF and 80 to BF, respectively.
- When the first byte is in the range E1 to EC hex or EE to EF, the second and third bytes must both be in the range 80 to BF hex.
- When the first byte is ED hex, the second and third bytes must be in the ranges 80 to 9F and 80 to BF, respectively.

Otherwise, the character is invalid.

5. When the ETF3-enhancement facility is not installed or the W bit of the M_3 field is zero, and the contents of the first byte of the UTF-8 character are in the range of F0 to F7 hex; or when the ETF3-enhancement facility is installed, the W bit is one, and the contents of the first byte of the UTF-8 character are in the range of F0 to F4 hex; the character is a four-byte character, and it is converted to a four-byte UTF-32 character (a surrogate pair) as follows:

UTF-8 Character	1 1 1 1 0 u v w	1 0 x y e f g h	1 0 i j k l m n	1 0 o p q r s t
UTF-32 Character	0 0 0 0 0 0 0 0	0 0 0 u v w x y	e f g h i j k l	m n o p q r s t

When the ETF3-enhancement facility is not installed or when the W bit of the M_3 field is zero, the first two bits in the second, third, and fourth bytes of the UTF-8 character are ignored.

When the ETF3-enhancement facility is installed and the W bit of the M_3 field is one, the contents of the second, third, and fourth bytes of the UTF-8 character must be as follows:

- When the first byte is F0 hex, the second, third, and fourth bytes must be in the ranges 90 to BF, 80 to BF, and 80 to BF, respectively.
- When the first byte is in the range F1 to F3, the second, third, and fourth bytes must all be in the range 80 to BF hex.
- When the first byte is F4 hex, the second, third, and fourth bytes must be in the ranges 80 to 8F, 80 to BF, and 80 to BF, respectively.

Otherwise, the character is invalid.

6. When the ETF3-enhancement facility is installed, the W bit of the M_3 field is one, and the contents of the first byte of the UTF-8 character are in the range of F5 to F7 hex, the character is invalid.
7. When the contents of the first byte of the UTF-8 character are in the range of F8-FF, the character is invalid.

If an invalid character is encountered, condition code 2 is set, and general register R_2 contains the address of the first byte of the invalid UTF-8 character.

The second-operand location is considered exhausted when it does not contain at least one remaining byte or when it does not contain at least the two, three, or four remaining bytes required to contain the two-, three-, or four-byte UTF-8 character indicated by the contents of the first remaining byte. The first-operand location is considered exhausted when it does not contain at least four remaining bytes.

When the second-operand location is exhausted, condition code 0 is set. When the first-operand location is exhausted, condition code 1 is set, except that condition code 0 is set if the second-operand location also is exhausted. When a CPU-determined number of characters have been processed, condition code 3 is set.

When the conditions for setting condition codes 1 and 2 are both met, condition code 2 is set.

When the operation is completed, the contents of general register $R_2 + 1$ are decremented by the number of bytes converted, and the contents of general register R_2 are incremented by the same number. Also, the contents of general register $R_1 + 1$ are decremented by the number of bytes placed at the first-operand location, and the contents of general register R_1 are incremented by the same number. When general registers R_1 and R_2 are updated in the 24-bit or 31-bit addressing mode, bits 32-39 of them, in the 24-bit mode, or bit 32, in the 31-bit mode, may be set to zeros or may remain unchanged.

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers R_1, $R_1 + 1$, R_2, and $R_2 + 1$, always remain unchanged.

When condition code 2 is set, general register R_2 contains the address of the invalid UTF-8 character.

When condition code 3 is set, the registers have been updated so that the instruction, when reexecuted, resumes at the next byte locations to be processed.

The amount of processing that results in the setting of condition code 3 is determined by the CPU on the basis of improving system performance, and it may be a different amount each time the instruction is executed.

When the R_1 register is the same register as the R_2 register, the results are unpredictable.

When the second operand overlaps the first operand, the results are unpredictable.

Access exceptions for the portions of the operands to the right of the last byte processed may or may not be recognized. For an operand longer than 4K bytes, access exceptions are not recognized for locations more than 4K bytes beyond the last byte processed.

When the length of an operand is zero, no access exceptions are recognized for that operand. Access exceptions are not recognized for an operand if the R field associated with that operand is odd.

Resulting Condition Code:

0 Entire second operand processed
1 End of first operand reached
2 Invalid UTF-8 character
3 CPU-determined number of characters processed

Program Exceptions:

- Access (fetch, operand 2; store, operand 1)
- Operation (if the extended-translation facility 3 is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. When condition code 3 is set, the program can simply branch back to the instruction to continue the conversion. The program need not determine the number of first-operand or second-operand bytes that were processed.

2. When the ETF3-enhancement facility is not installed, or when the W bit of the M_3 operand is zero, bits 0 and 1 of the continuation bytes of multiple-byte UTF-8 characters are not checked in order to improve the performance of the conversion. Therefore, invalid continuation bytes are not detected.

3. The storage-operand references of CONVERT UTF-8 TO UTF-32 may be multiple-access references. (See “Storage-Operand Consistency” on page 5-133.)

4. The CONVERT UTF-8 TO UTF-32 instruction supports UTF-32 characters only in the big-endian encoding.

5. As observed by this CPU, other CPUs, and the I/O subsystem, inconsistent results may be briefly stored in the first-operand location. See the section “Effects of CPU Retry” on page 11-3 for further details.

COPY ACCESS

CPYA R_1,R_2 [RRE]

The contents of access register R_2 are placed in access register R_1.

Condition Code: The code remains unchanged.

Program Exceptions:

- Transaction constraint

COUNT LEADING ZEROS

CLZG R_1,R_2 [RRE]

Bits 0-63 of general register R_2 are scanned left-to-right to find the leftmost one bit. A 64-bit binary integer designating the count of leading zero bits until a one bit is found is placed in general register R_1. If bit 0 of general register R_2 is a one the result in R_1 will be zero; if all bits are zero the result in R_1 will be 64. Unless the R_1 and R_2 fields designate the same register the original contents of general register R_2 are unchanged.

Condition Code: The code remains unchanged.

Program Exceptions:

- Operation (if the miscellaneous-instruction-extensions facility 4 is not installed)

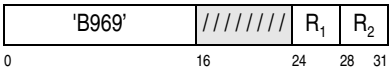
Programming Note: This instruction is similar to FIND LEFTMOST ONE (FLOGR) instruction. The differences are:

- FLOGR sets the condition code. CLZG leaves the condition code unchanged.

- FLOGR places into R_1+1 a copy of the second operand with the leftmost one bit, if any, zeroed. CLZG does not provide an updated second operand as a result of execution.
- FLOGR requires an even-odd register pair for the R_1. CLZG only needs a single register for the result of execution.

COUNT TRAILING ZEROS

CTZG R_1,R_2 [RRE]



Bits 0-63 of general register R_2 are scanned right-to-left to find the rightmost one bit. A 64-bit binary integer designating the count of trailing zero bits until a one bit is found is placed in general register R_1. If bit 63 of general register R_2 is a one the result in R_1 will be zero; if all bits are zero the result in R_1 will be 64. Unless the R_1 and R_2 fields designate the same register the original contents of general register R_2 are unchanged.

Condition Code: The code remains unchanged.

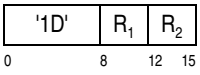
Program Exceptions:

- Operation (if the miscellaneous-instruction-extensions facility 4 is not installed)

DIVIDE

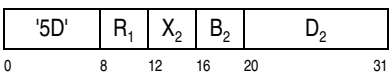
Register-and-register format:

DR R_1,R_2 [RR]



Register-and-storage format:

D $R_1,D_2(X_2,B_2)$ [RX-a]



The 64-bit first operand (the dividend) is divided by the 32-bit second operand (the divisor), and the 32-bit remainder and quotient are placed at the first-operand location.

The R_1 field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The dividend is treated as a 64-bit signed binary integer. The leftmost 32 bits of the dividend are in bit positions 32-63 of general register R_1, and the rightmost 32 bits are in bit positions 32-63 of general register R_1 + 1.

The divisor, remainder, and quotient are treated as 32-bit signed binary integers. For DIVIDE (DR), the divisor is in bit positions 32-63 of general register R_2. The remainder is placed in bit positions 32-63 of general register R_1, and the quotient is placed in bit positions 32-63 of general register R_1 + 1. Bits 0-31 of the registers remain unchanged.

The sign of the quotient is determined by the rules of algebra, and the remainder has the same sign as the dividend, except that a zero quotient or a zero remainder is always positive.

When the divisor is zero, or when the magnitudes of the dividend and divisor are such that the quotient cannot be expressed by a 32-bit signed binary integer, a fixed-point-divide exception is recognized. This includes the case of division of zero by zero.

Condition Code: The code remains unchanged.

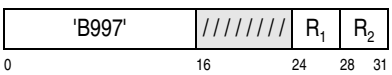
Program Exceptions:

- Access (fetch, operand 2 of D only)
- Fixed-point divide
- Specification
- Transaction constraint

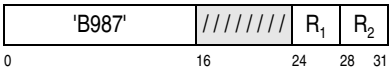
DIVIDE LOGICAL

Register-and-register formats:

DLR R_1,R_2 [RRE]

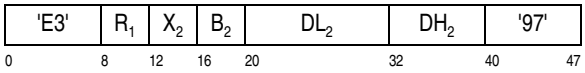


DLGR R_1,R_2 [RRE]

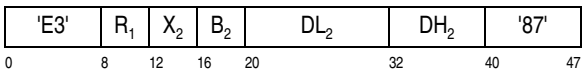


Register-and-storage formats:

DL $R_1,D_2(X_2,B_2)$ [RXY-a]



DLG $R_1,D_2(X_2,B_2)$ [RXY-a]



The 64-bit or 128-bit first operand (the dividend) is divided by the 32-bit or 64-bit second operand (the divisor), and the 32-bit or 64-bit remainder and quotient are placed at the first-operand location.

The R_1 field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

For DIVIDE LOGICAL (DLR, DL), the dividend is treated as a 64-bit unsigned binary integer. The leftmost 32 bits of the dividend are in bit positions 32-63 of general register R_1, and the rightmost 32 bits are in bit positions 32-63 of general register $R_1 + 1$.

The divisor, remainder, and quotient are treated as 32-bit unsigned binary integers. For DIVIDE LOGICAL (DLR), the divisor is in bit positions 32-63 of general register R_2. The remainder is placed in bit positions 32-63 of general register R_1, and the quotient is placed in bit positions 32-63 of general register $R_1 + 1$. Bits 0-31 of the registers remain unchanged.

For DIVIDE LOGICAL (DLGR, DLG), the dividend is treated as a 128-bit unsigned binary integer. The leftmost 64 bits of the dividend are in general register R_1, and the rightmost 64 bits are in general register $R_1 + 1$. The divisor, remainder, and quotient are treated as 64-bit unsigned binary integers. The remainder is placed in general register R_1, and the quotient is placed in general register $R_1 + 1$.

When the divisor is zero, or when the magnitudes of the dividend and divisor are such that the quotient cannot be expressed as a 32-bit unsigned binary integer for DIVIDE LOGICAL (DLR, DL), or a 64-bit unsigned binary integer for DIVIDE LOGICAL (DLGR, DLG), a fixed-point-divide exception is recognized. This includes the case of division of zero by zero.

Condition Code: The code remains unchanged.

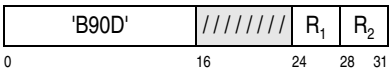
Program Exceptions:

- Access (fetch, operand 2 of DL or DLG only)
- Fixed-point divide
- Specification
- Transaction constraint

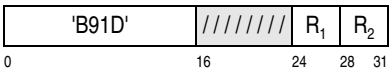
DIVIDE SINGLE

Register-and-register formats:

DSGR R_1,R_2 [RRE]

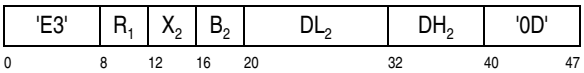


DSGFR R_1,R_2 [RRE]

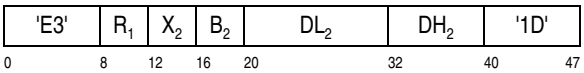


Register-and-storage formats:

DSG $R_1,D_2(X_2,B_2)$ [RXY-a]



DSGF $R_1,D_2(X_2,B_2)$ [RXY-a]



The 64-bit contents of general register $R_1 + 1$ (the dividend) are divided by the 64-bit or 32-bit second operand (the divisor), the 64-bit remainder is placed in general register R_1, and the 64-bit quotient is placed in general register $R_1 + 1$.

The R_1 field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The dividend, quotient, and remainder are treated as 64-bit signed binary integers. For DIVIDE SINGLE (DSGR, DSG), the divisor is treated as a 64-bit signed binary integer. For DIVIDE SINGLE (DSGFR, DSGF), the divisor is treated as a 32-bit signed binary integer. For DSGFR, the divisor is in bit positions 32-63 of general register R_2.

The sign of the quotient is determined by the rules of algebra, and the remainder has the same sign as the dividend, except that a zero quotient or a zero remainder is always positive.

When the divisor is zero, or when the magnitudes of the dividend and divisor are such that the quotient cannot be expressed by a 64-bit signed binary integer, a fixed-point-divide exception is recognized. This includes the case of division of zero by zero.

Condition Code: The code remains unchanged.

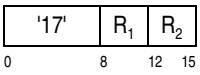
Program Exceptions:

- Access (fetch, operand 2 of DSG and DSGF only)
- Fixed-point divide
- Specification
- Transaction constraint

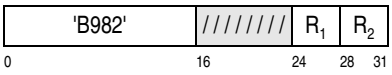
EXCLUSIVE OR

Register-and-register formats:

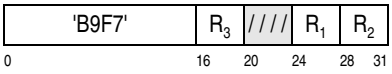
XR R_1,R_2 [RR]



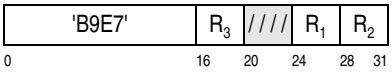
XGR R_1,R_2 [RRE]



XRK R_1,R_2,R_3 [RRF-a]

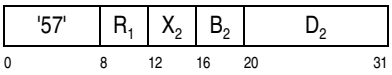


XGRK R_1,R_2,R_3 [RRF-a]

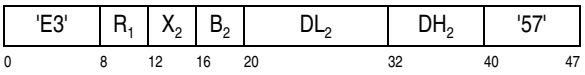


Register-and-storage formats:

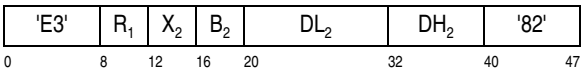
X $R_1,D_2(X_2,B_2)$ [RX-a]



XY $R_1,D_2(X_2,B_2)$ [RXY-a]

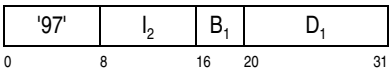


XG $R_1,D_2(X_2,B_2)$ [RXY-a]

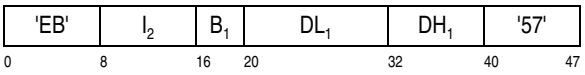


Storage-and-immediate formats:

XI $D_1(B_1),I_2$ [SI]

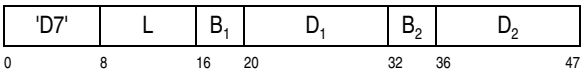


XIY $D_1(B_1),I_2$ [SIY]



Storage-and-storage format:

XC $D_1(L,B_1),D_2(B_2)$ [SS-a]



For X, XC, XG, XGR, XI, XIY, XR, and XY, the EXCLUSIVE OR of the first and second operands is placed at the first-operand location. For XGRK and XRK, the EXCLUSIVE OR of the second and third operands is placed at the first-operand location.

The connective EXCLUSIVE OR is applied to the operands bit by bit. The contents of a bit position in the result are set to one if the bits in the corresponding bit positions in the two operands are unlike; otherwise, the result bit is set to zero.

For EXCLUSIVE OR (XC), each operand is processed left to right. When the operands overlap, the result is obtained as if the operands were processed one byte at a time and each result byte were stored immediately after fetching the necessary operand bytes.

For EXCLUSIVE OR (XI, XIY), the first operand is one byte in length, and only one byte is stored. When the interlocked-access facility 2 is installed, the update of the first operand appears to be an interlocked-update reference as observed by other CPUs and channel programs, and a specific-operand-serialization operation is performed.

For EXCLUSIVE OR (X, XR, XRK, and XY), the operands are 32 bits, and for EXCLUSIVE OR (XG, XGR, and XGRK), they are 64 bits.

The displacements for X, XI, and both operands of XC are treated as 12-bit unsigned binary integers. The displacement for XY, XIY, and XG is treated as a 20-bit signed binary integer.

Resulting Condition Code:

0 Result zero
1 Result not zero
2 --
3 --

Program Exceptions:

- Access (fetch, operand 2, X, XY, XG, and XC; fetch and store, operand 1, XI, XIY, and XC)
- Operation (XY and XIY, if the long-displacement facility is not installed; XGRK and XRK, if the distinct-operands facility is not installed)
- Transaction constraint (XC)

Programming Notes:

1. An example of the use of the EXCLUSIVE OR instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. EXCLUSIVE OR may be used to invert a bit, an operation particularly useful in testing and setting programmed binary switches.

3. A field EXCLUSIVE-ORed with itself becomes all zeros.

4. For EXCLUSIVE OR (XR or XGR), the sequence A EXCLUSIVE-OR B, B EXCLUSIVE-OR A, A EXCLUSIVE-OR B results in the exchange of the contents of A and B without the use of an additional general register.

5. Accesses to the first operand of EXCLUSIVE OR (XC) – and, when the interlocked-access facility 2 is not installed, accesses to the first operand of EXCLUSIVE OR (XI, XIY) – consist in fetching a first-operand byte from storage and subsequently storing the updated value. These fetch and store accesses to a particular byte do not necessarily occur one immediately after the other. Thus, these instructions cannot be safely used to update a location in storage if the possibility exists that another CPU or a channel program may also be updating the location. An example of this effect is shown for OR (OI) in “Multiprogramming and Multiprocessing Examples” on page A-45.

   When the interlocked-access facility 2 is installed, EXCLUSIVE OR (XI, XIY) can be safely used to update a location in storage, even if the possibility exists that another CPU or a channel program may also be updating the location.

EXCLUSIVE OR IMMEDIATE

XIHF R_1,I_2 [RIL-a]

XILF R_1,I_2 [RIL-a]

The second operand is EXCLUSIVE ORed with bits of the first operand, and the result replaces those bits of the first operand. The remainder of the first operand remains unchanged.

For each instruction, the bits of the first operand that are EXCLUSIVE ORed with the second operand and then replaced are as follows:

Instruction	Bits Exclusive ORed and Replaced
XIHF	0-31
XILF	32-63

The connective EXCLUSIVE OR is applied to the operands bit by bit. The contents of a bit position in the result are set to one if the bits in the corresponding bit positions in the two operands are unlike; otherwise, the result bit is set to zero.

The condition code is set based on the result of the 32-bit EXCLUSIVE OR operation.

Resulting Condition Code:

0 Result is zero
1 Result is not zero
2 --
3 --

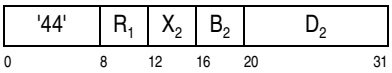
Program Exceptions:

- Operation, if the extended-immediate facility is not installed)

Programming Note: The setting of the condition code is based only on the bits that are exclusive ORed and replaced.

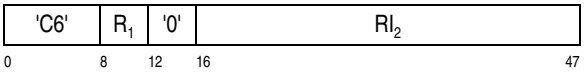
EXECUTE

EX $R_1,D_2(X_2,B_2)$ [RX-a]



EXECUTE RELATIVE LONG

EXRL R_1,RI_2 [RIL-b]



The single instruction at the second-operand address is modified by the contents of general register R_1, and the resulting instruction, called the target instruction, is executed.

When the R_1 field is not zero, bits 8-15 of the instruction designated by the second-operand address are ORed with bits 56-63 of general register R_1. The ORing does not change either the contents of general register R_1 or the instruction in storage, and it is effective only for the interpretation of the instruction to be executed. When the R_1 field is zero, no ORing takes place.

The target instruction may be two, four, or six bytes in length. The execution and exception handling of the target instruction are exactly as if the target instruction were obtained in normal sequential operation, except for the instruction address and the instruction-length code.

The instruction address in the current PSW is increased by the length of the execute-type instruction (EXECUTE or EXECUTE RELATIVE LONG). This updated address and the instruction-length code of the execute-type instruction are used, for example, as part of the link information when the target instruction is BRANCH AND LINK. When the target instruction is a successful branching instruction, the instruction address in the current PSW is replaced by the branch address specified by the target instruction.

When the target instruction is any of the following instructions, an execute exception is recognized.

- Another execute-type instruction
- TRANSACTION ABORT
- TRANSACTION BEGIN
- TRANSACTION END

The effective address of EXECUTE must be even; otherwise, a specification exception is recognized.

When the target instruction is two or three halfwords in length but can be executed without fetching its second or third halfword, it is unpredictable whether access exceptions are recognized for the unused halfwords. Access exceptions are not recognized for the second-operand address when the address is odd.

The second-operand address of an execute-type instruction is an instruction address rather than a logical address; thus, the target instruction is fetched from the primary address space when in the primary-space, secondary-space, or access-register mode.

For EXECUTE RELATIVE LONG, the contents of the RI_2 field are a signed binary integer specifying the number of halfwords that is added to the address of the instruction to generate the address of the target instruction in storage.

Condition Code: The code may be set by the target instruction.

Program Exceptions:

- Access (fetch, target instruction)
- Execute
- Operation (EXRL, when the execute-extensions facility is not installed)
- Specification (EX)
- Transaction constraint

Programming Notes:

1. An example of the use of the EXECUTE instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. The ORing of eight bits from the general register with the designated instruction permits the indi-

rect specification of the length, index, mask, immediate-data, register, or extended-op-code field.

3. The fetching of the target instruction is considered to be an instruction fetch for purposes of program-event recording and for purposes of reporting access exceptions.

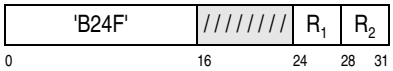
4. An access or specification exception may be caused by execute-type instructions or by the target instruction, except that EXECUTE RELATIVE LONG cannot cause a specification exception due to a misaligned target operand.

5. When an interruptible instruction is made the target of an execute-type instruction, the program normally should not designate any register updated by the interruptible instruction as the R_1, X_2, or B_2 register for EXECUTE or R_1 register for EXECUTE RELATIVE LONG. Otherwise, on resumption of execution after an interruption, or if the instruction is refetched without an interruption, the updated values of these registers will be used in the execution of the execute-type instruction. Similarly, the program should normally not let the destination field in storage of an interruptible instruction include the location of an execute-type instruction, since the new contents of the location may be interpreted when resuming execution.

6. Exception conditions that occur during the execution of EXECUTE or EXECUTE RELATIVE LONG are recognized before exception conditions for the target instruction.

EXTRACT ACCESS

EAR R_1,R_2 [RRE]



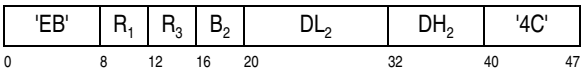
The contents of access register R_2 are placed in bit positions 32-63 of general register R_1. Bits 0-31 of general register R_1 remain unchanged.

Condition Code: The code remains unchanged.

Program Exceptions: None.

EXTRACT CPU ATTRIBUTE

ECAG $R_1,R_3,D_2(B_2)$ [RSY-a]



Information regarding the specified attribute of the CPU or storage subsystem is placed into the first-operand location. The first operand is 64 bits.

The second-operand address is not used to address data; rather, the rightmost 24 bits of the address are treated as a code specifying which attribute is returned in general register R_1.

The rightmost 24 bits of the second-operand address are defined as follows:

Attribute-Set Indication (ASI): Bit positions 54-55 of the second-operand address contain a 2-bit unsigned binary integer indicating the set of attributes from which an attribute to be extracted is selected. The attribute-set indications are:

0 Cache attributes

1 CPU attributes

All other attribute-set-indication values are reserved.

Cache-Attribute-Set Operation

The rightmost 24 bits of the second-operand address are defined as follows:

The attribute, level, and type indications for the cache-attribute set are as follows:

Attribute Indication (AI): Bit positions 56-59 of the second-operand address contain a 4-bit

unsigned binary integer indicating the cache attribute to be extracted, as follows:

0	Extract topology summary
1	Extract line size of the cache, in bytes
2	Extract total size of the cache, in bytes
3	Extract set-associativity level of the cache
4-15	Reserved

Level Indication (LI): Bit positions 60-62 of the second-operand address contain a 3-bit unsigned binary integer indicating the level of the cache for which the cache attribute is to be extracted, with 0 indicating the first-level cache, 1 indicating the second-level cache and so forth. If a cache level is not implemented on a model, its corresponding level indication is reserved.

Type Indication (TI): Bit 63 of the second-operand address indicates the type of cache for which the cache attribute is to be extracted, with 0 indicating the data cache and 1 indicating the instruction cache. When a cache level has a unified data and instruction cache, the same result is returned regardless of the type indication.

When the attribute indication is zero, the level indication (LI) and type indication (TI) are ignored.

CPU-Attribute-Set Operation

The rightmost 24 bits of the second-operand address are defined as follows:

The attribute indication for the CPU-attribute set are as follows:

Attribute Indication (AI): Bit positions 56-59 of the second-operand address contain a 4-bit unsigned binary integer indicating the CPU attribute to be extracted, as follows:

0	Extract CPU speed
1-15	Reserved

Reserved: Bit positions 60-63 of the second-operand address are reserved and ignored.

Common Operation

Bits 0-39 of the second-operand address are ignored. Bits 40-53 of the second-operand address are reserved and should contain zeros.

Bits 0-63 of general register R_1 are set to ones if any of the following apply:

- A reserved bit position in the second-operand address contains one and is otherwise not specifically designated as ignored.
- A reserved ASI, AI, or, when applicable, LI value is specified and is otherwise not specifically designated as ignored.
- The specified ASI and AI values and, when applicable, the LI value are all valid, but the model does not provide the data.

The contents of general register R_3 are ignored, however the R_3 field should specify register 0; otherwise, the program may not operate compatibly in the future.

Cache-Attribute Results (ASI = 0)

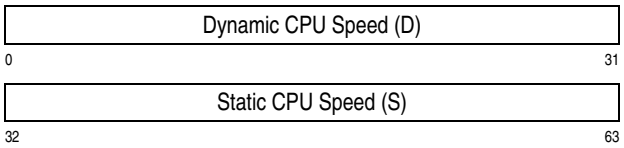
When the cache attribute indication is zero, a summary of each level of cache is returned in general register R_1. Each summary field is eight bits, where bits 0-7 of the register contain the summary for the first-level cache, bits 8-15 contain the summary for the second-level cache, and so forth. The contents of an eight-bit summary field are as follows:

Bits	Meaning
0-3	Reserved, stored as zeros
4-5	Cache scope, as follows: 00 Cache does not exist at this level 01 Cache is private to the CPU 10 Cache may be shared by multiple CPUs 11 Reserved
6-7	When bit positions 4-5 contain a nonzero value, bit positions 6-7 contain the cache type, as follows: 00 Separate instruction and data caches exist at this level 01 Only an instruction cache exists at this level 10 Only a data cache exists at this level 11 A unified instruction and data cache exists at this level When bit positions 4-5 contain zeros, bit positions 6-7 also contain zeros.

When the cache attribute indication is one, two, or three, the attribute value is returned in general register R_1, as a 64-bit unsigned integer.

CPU-Attribute Results (ASI = 1)

When the CPU attribute indication is zero, the CPU speeds are returned in general register R_1, specified in the following format:



The fields are defined as follows:

Bits **Meaning**

0-31 Bit positions 0-31 (D) contain a 32-bit unsigned binary integer whose value represents the dynamic CPU speed, encoded as the approximate number of CPU cycles per microsecond.

32-63 Bit positions 32-63 (S) contain a 32-bit unsigned binary integer whose value represents the static CPU speed, encoded as the approximate number of CPU cycles per microsecond.

The dynamic CPU speed may or may not be the same as the static CPU speed. The static CPU speed reflects a CPU running at its nominal capacity and corresponds to the particular model. The dynamic CPU speed reflects a CPU running at a changed capacity caused by, for example, a manual control set to a power-save position.

Condition Code: The code remains unchanged.

Program Exceptions:

- Operation (if the general-instructions-extension facility is not installed)
- Transaction constraint

Programming Notes:

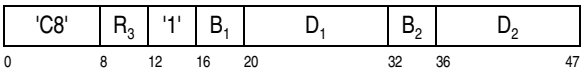
1. Knowledge of the cache line size is useful when determining the placement of PREFETCH DATA and PREFETCH DATA RELATIVE LONG instructions.
2. The value placed in the first-operand location is model dependent and may differ significantly from one model to another. For example, the size of the data cache on one model may be smaller or larger than the size of the data cache on another model. To ensure compatible operation across multiple models, the program should not rely on any particular value being returned in the first-operand location.
3. When the attribute-set indication is 00 binary and the attribute indication is 0000 binary, bit positions 4-5 of each 8-bit field returned in general register R_1 contain a cache-scope indication. When the cache-scope indication is 10 binary, the cache may be shared by more than one CPU in the configuration. The System Library publication for the model may provide further explanation of cache topology.
4. When the attribute-set indication is 00 binary and the attribute indication is 0000 binary, the summary indications are returned in contiguous 8-bit fields in general register R_1. Thus if the program scans the resulting summary-indication fields from left to right and encounters an 8-bit field containing all zeros, no further meaningful fields exist.
5. Cache information returned reflects the depth specified by the level indication and the cache information accessible from the issuing CPU. The total sizes and associativity do not include other, parallel cache structures accessible from other CPUs of the configuration.
6. The static CPU speed (S) may be less than, equal to, or greater than the dynamic CPU speed (D), as follows:
   - When the CPU is operating at nominal capacity, the D and S values are equal.
   - The sections “Capacity-Change Reason (CCR)” on page 10-156 and “Capacity-Adjustment Indication (CAI)” on page 10-156 describe various reasons why a CPU may not be operating at nominal capacity, in which case, D may be less than S.
   - Under certain circumstances, D may be greater than S.
7. Depending on the model, the dynamic CPU speed (D) values may be different from one CPU

to another. Similarly, the static CPU speed values may be different from one CPU to another.

8. In most cases, the dynamic CPU speed returned for CPU-attribute-indicator zero is the same as would be returned by the QUERY SAMPLING INFORMATION (QSI) instruction of the CPU-measurement facility. The value returned is also subject to most of the same factors that affect the value returned by QSI.

EXTRACT CPU TIME

ECTG $D_1(B_1),D_2(B_2),R_3$ [SSF]



The value of the current CPU timer is subtracted from the first operand, and the difference is placed in general register 0. The second operand is placed unchanged in general register 1. The eight bytes at the third operand location replace the contents of general register R_3.

The first and second operands and the results in general registers 0, 1, and R_3 are treated as 64-bit unsigned binary integers.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general register R_3 constitute the address of the third operand, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the register constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 constitute the address. In the access-register mode, the contents of access register R_3 are used for accessing the third operand.

All operands are fetched before any general register is modified. If the R_3 field designates general register 0, it is unpredictable whether the result placed in the register is the first operand minus the CPU timer or the third operand. If the R_3 field designates general register 1, it is unpredictable whether the result placed in the register is the second operand or the third operand.

The contents of the registers just described are shown in Figure 7-333.

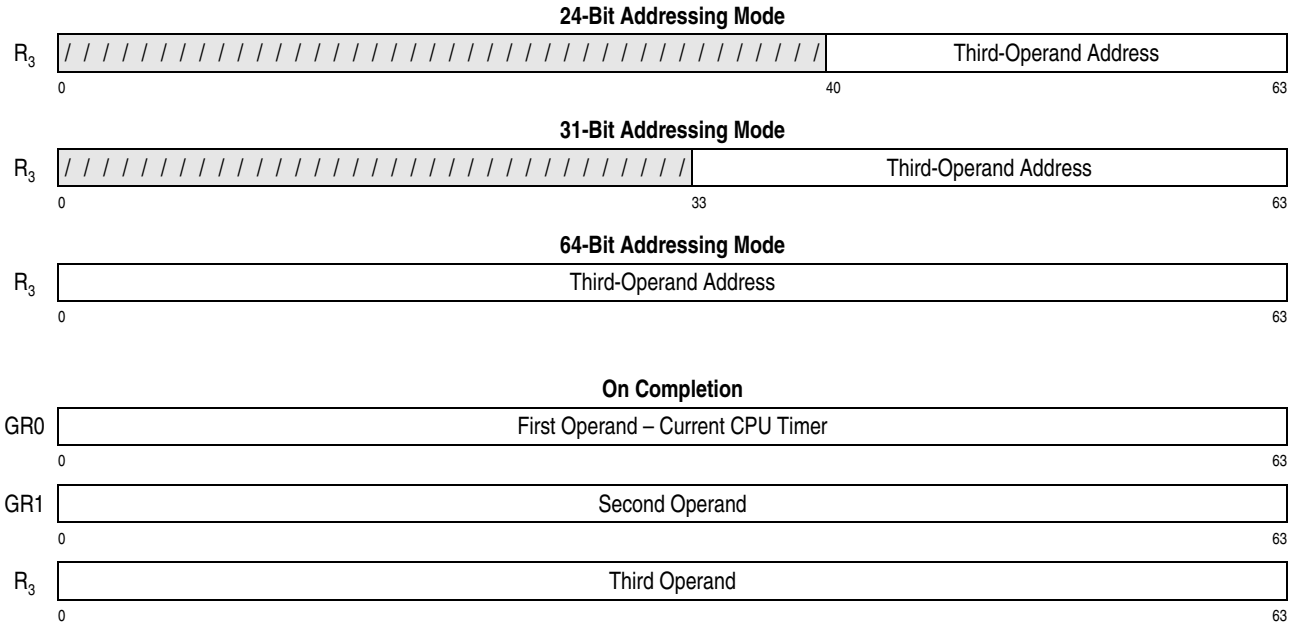


Figure 7-333. General Register Assignment for EXTRACT CPU TIME

Condition Code: The code remains unchanged.

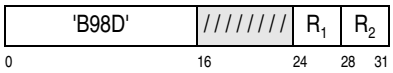
Program Exceptions:

- Access (fetch, operands 1, 2, and 3)
- Operation (the extract-CPU-time facility is not installed)

- Transaction constraint

EXTRACT PSW

EPSW R_1,R_2 [RRE]



Bits 0-11 and 13-31 of the current PSW are placed in bit positions 32-43 and 45-63 of the first operand, and bits 0-31 of the operand remain unchanged. When the configuration is in the z/Architecture architectural mode, bit 44 of the first operand is set to zero, and when the configuration is in the ESA/390-compatibility mode, bit 44 of the first operand is set to one.

Subsequently, bits 32-63 of the current PSW are placed in bit positions 32-63 of the second operand, and bits 0-31 of the operand remain unchanged. The action associated with the second operand is not performed if the R_2 field is zero.

Bits 0-63 of the 128-bit PSW are illustrated in Figure 4-2 on page 4-5.

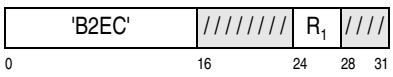
Condition Code: The code remains unchanged.

Program Exceptions:

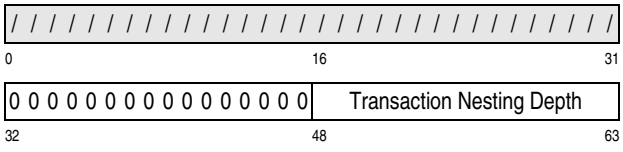
- Transaction constraint

EXTRACT TRANSACTION NESTING DEPTH

ETND R_1 [RRE]



The current transaction nesting depth is placed in bits 48-63 of general register R_1. Bits 0-31 of the register remain unchanged, and bits 32-47 of the register are set to zero, as illustrated below.



A special-operation exception is recognized and the operation is suppressed if the transactional-execution control, bit 8 of control register 0, is zero.

Condition Code: The code remains unchanged.

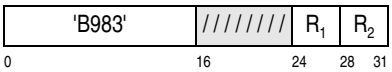
Program Exceptions:

- Operation (transactional-execution facility not installed)
- Special operation
- Transaction constraint

Programming Note: A transaction nesting depth of zero indicates that the CPU is not in the transactional-execution mode.

FIND LEFTMOST ONE

FLOGR R_1,R_2 [RRE]



Bits 0-63 of general register R_2 are scanned left to right for the leftmost one bit. A 64-bit binary integer designating the bit position of the leftmost one bit, or 64 if there is no one bit, is placed in general register R_1. When a one bit is found in the second operand, the original contents of general register R_2, with the leftmost one bit set to zero, are placed in general register $R_1 + 1$. When a one bit is not found, the contents of general register $R_1 + 1$ are set to zeros.

The condition code indicates whether or not a one bit was found in the second operand.

The R_1 field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 No one bit found
1 --
2 One bit found
3 --

Program Exceptions:

- Operation (if the extended-immediate facility is not installed)

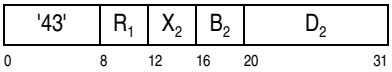
- Specification

Programming Notes:

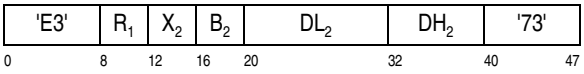
1. An example of the use of the FIND LEFTMOST ONE instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”
2. When the R_1 and R_2 fields designate the same register, the original contents of general register R_2 are replaced by the resulting bit-position value, or 64 if no one bit was found.
3. When the R_2 field designates general register $R_1 + 1$, the leftmost one bit (if any) of general register R_2 is set to zero; if no one bit is found, the entire register is set to zero.
4. When the R_2 field designates neither the even nor the odd registers designated by the R_1 field, then general register R_2 is not modified.

INSERT CHARACTER

IC $R_1,D_2(X_2,B_2)$ [RX-a]



ICY $R_1,D_2(X_2,B_2)$ [RXY-a]



The byte at the second-operand location is inserted into bit positions 56-63 of general register R_1. The remaining bits in the register remain unchanged.

The displacement for IC is treated as a 12-bit unsigned binary integer. The displacement for ICY is treated as a 20-bit signed binary integer.

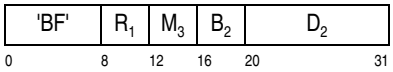
Condition Code: The code remains unchanged.

Program Exceptions:

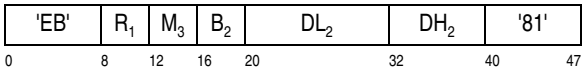
- Access (fetch, operand 2)
- Operation (ICY, if the long-displacement facility is not installed)

INSERT CHARACTERS UNDER MASK

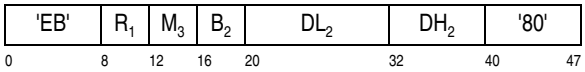
ICM $R_1,M_3,D_2(B_2)$ [RS-b]



ICMY $R_1,M_3,D_2(B_2)$ [RSY-b]



ICMH $R_1,M_3,D_2(B_2)$ [RSY-b]



Bytes from contiguous locations beginning at the second-operand address are inserted into general register R_1 under control of a mask.

The contents of the M_3 field are used as a mask. These four bits, left to right, correspond one for one with four bytes, left to right, of general register R_1. For INSERT CHARACTERS UNDER MASK (ICM, ICMY), the four bytes to which the mask bits correspond are in the low-order half, bit positions 32-63 of general register R_1. For INSERT CHARACTERS UNDER MASK (ICMH), the four bytes are in the high-order half, bit positions 0-31, of the register. The byte positions corresponding to ones in the mask are filled, left to right, with bytes from successive storage locations beginning at the second-operand address. When the mask is not zero, the length of the second operand is equal to the number of ones in the mask. The bytes in the general register corresponding to zeros in the mask remain unchanged. For ICM and ICMY, bits 0-31 of the register remain unchanged, and, for ICMH, bits 32-63 remain unchanged.

The resulting condition code is based on the mask and on the value of the bits inserted. When the mask is zero or when all inserted bits are zeros, the condition code is set to 0. When the inserted bits are not all zeros, the code is set according to the leftmost bit of the storage operand: if this bit is one, the code is set to 1; if this bit is zero, the code is set to 2.

When the mask is not zero, exceptions associated with storage-operand access are recognized only for the number of bytes specified by the mask. When the mask is zero, access exceptions are recognized for one byte at the second-operand address.

The displacement for ICM is treated as a 12-bit unsigned binary integer. The displacement for ICMY and ICMH is treated as a 20-bit signed binary integer.

Resulting Condition Code:

0 All inserted bits zeros, or mask bits all zeros
1 Leftmost inserted bit one
2 Leftmost inserted bit zero, and not all inserted bits zeros
3 --

Program Exceptions:

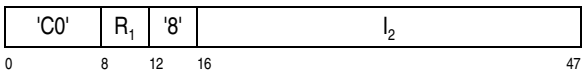
- Access (fetch, operand 2)
- Operation (ICMY, if the long-displacement facility is not installed)

Programming Notes:

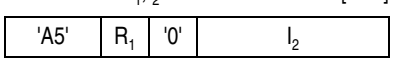
1. Examples of the use of the INSERT CHARACTERS UNDER MASK instruction are given in Appendix A, “Number Representation and Instruction-Use Examples.”
2. The condition code for INSERT CHARACTERS UNDER MASK (ICM, ICMY only) is defined such that, when the mask is 1111, the instruction causes the same condition code to be set as for LOAD AND TEST (LTR only) Thus, the instruction may be used as a storage-to-register load-and-test operation.
3. INSERT CHARACTERS UNDER MASK (ICM, ICMY) with a mask of 1111 or 0001 performs a function similar to that of a LOAD (L) or INSERT CHARACTER (IC) instruction, respectively, with the exception of the condition-code setting. However, the performance of INSERT CHARACTERS UNDER MASK may be slower.

INSERT IMMEDIATE

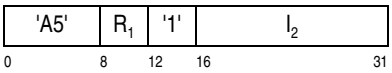
IIHF R_1,I_2 [RIL-a]



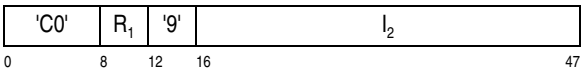
IIHH R_1,I_2 [RI-a]



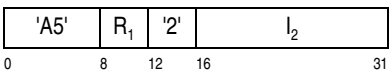
IIHL R_1,I_2 [RI-a]



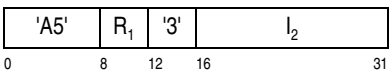
IILF R_1,I_2 [RIL-a]



IILH R_1,I_2 [RI-a]



IILL R_1,I_2 [RI-a]



The second operand is placed in bit positions of the first operand. The remainder of the first operand remains unchanged.

For each instruction, the bit positions of the first operand that are loaded with the second operand are as follows:

Instruction	Bit Positions Loaded
IIHF	0-31
IIHH	0-15
IIHL	16-31
IILF	32-63
IILH	32-47
IILL	48-63

Condition Code: The code remains unchanged.

Program Exceptions:

- Operation (IIHF and IILF, if the extended-immediate facility is not installed)

Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
LFI	R_1,I_2	IILF	R_1,I_2

INSERT PROGRAM MASK

IPM R_1 [RRE]

The condition code and program mask from the current PSW are inserted into bit positions 34 and 35 and 36-39, respectively, of general register R_1. Bits 32 and 33 of the register are set to zeros; bits 0-31 and 40-63 are left unchanged.

Condition Code: The code remains unchanged.

Program Exceptions: None.

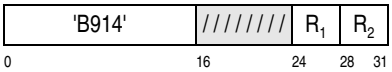
LOAD

Register-and-register formats:

LR R_1,R_2 [RR]

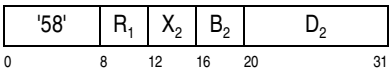
LGR R_1,R_2 [RRE]

LGFR R_1,R_2 [RRE]

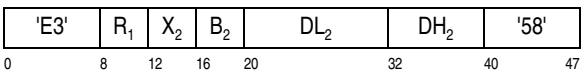


Register-and-storage formats:

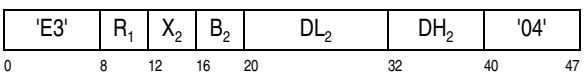
L $R_1,D_2(X_2,B_2)$ [RX-a]



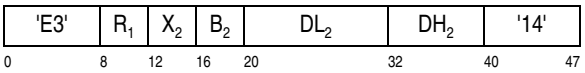
LY $R_1,D_2(X_2,B_2)$ [RXY-a]



LG $R_1,D_2(X_2,B_2)$ [RXY-a]

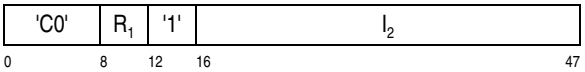


LGF $R_1,D_2(X_2,B_2)$ [RXY-a]



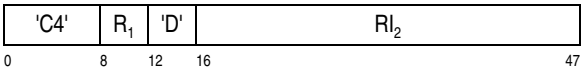
LOAD IMMEDIATE

LGFI R_1,I_2 [RIL-a]

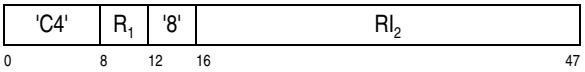


LOAD RELATIVE LONG

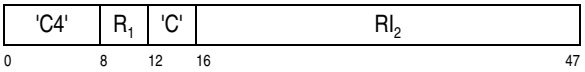
LRL R_1,RI_2 [RIL-b]



LGRL R_1,RI_2 [RIL-b]



LGFRL R_1,RI_2 [RIL-b]



The second operand is placed unchanged at the first-operand location, except that, for LOAD (LGFR, LGF), LOAD IMMEDIATE (LGFI), and LOAD RELATIVE LONG (LGFRL), it is sign extended.

For LOAD (LR, L, LY) and LOAD RELATIVE LONG (LRL), the operands are 32 bits, and, for LOAD (LGR, LG), and LOAD RELATIVE LONG (LGRL), the operands are 64 bits. For LOAD (LGFR, LGF), LOAD IMMEDIATE (LGFI), and LOAD RELATIVE LONG (LGFRL), the second operand is treated as a 32-bit signed binary integer, and the first operand is treated as a 64-bit signed binary integer.

The displacement for L is treated as a 12-bit unsigned binary integer. The displacement for LY, LG, and LGF is treated as a 20-bit signed binary integer.

For LOAD IMMEDIATE, the contents of the I_2 field form the second operand directly.

For LOAD RELATIVE LONG, the contents of the RI_2 field are a signed binary integer specifying the num-

ber of halfwords that is added to the address of the instruction to generate the address of the second operand in storage. When DAT is on, the second operand is accessed using the same addressing-space mode as that used to access the instruction. When DAT is off, the second operand is accessed using a real address.

For LOAD RELATIVE LONG (LRL, LGFRL), the second operand must be aligned on a word boundary, and for LOAD RELATIVE LONG (LGRL), the second operand must be aligned on a doubleword boundary; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

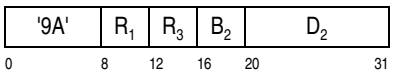
- Access (fetch, operand 2 of L, LY, LG, LGF, LRL, LGRL, and LGFRL only)
- Operation (LY, if the long-displacement facility is not installed; LGFI, if the extended-immediate facility is not installed; LRL, LGRL, LGFRL, if the general-instructions-extension facility is not installed)
- Specification (LRL, LGFRL, LGRL only)

Programming Notes:

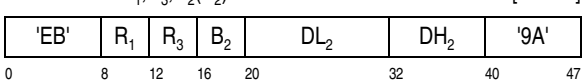
1. An example of the use of the LOAD instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”
2. For LOAD RELATIVE LONG, the second operand must be aligned on an integral boundary corresponding to the operand’s size.
3. When LOAD RELATIVE LONG is the target of an execute-type instruction, the second-operand address is relative to the target address.

LOAD ACCESS MULTIPLE

LAM $R_1,R_3,D_2(B_2)$ [RS-a]



LAMY $R_1,R_3,D_2(B_2)$ [RSY-a]



The set of access registers starting with access register R_1 and ending with access register R_3 is loaded from the locations designated by the second-operand address.

The storage area from which the contents of the access registers are obtained starts at the location designated by the second-operand address and continues through as many storage words as the number of access registers specified. The access registers are loaded in ascending order of their register numbers, starting with access register R_1 and continuing up to and including access register R_3, with access register 0 following access register 15.

The displacement for LAM is treated as a 12-bit unsigned binary integer. The displacement for LAMY is treated as a 20-bit signed binary integer.

The second operand must be designated on a word boundary; otherwise, a specification exception is recognized.

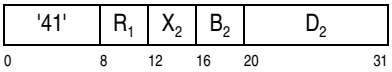
Condition Code: The code remains unchanged.

Program Exceptions:

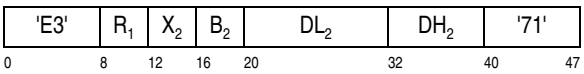
- Access (fetch, operand 2)
- Operation (LAMY, if the long-displacement facility is not installed)
- Specification
- Transaction constraint

LOAD ADDRESS

LA $R_1,D_2(X_2,B_2)$ [RX-a]



LAY $R_1,D_2(X_2,B_2)$ [RXY-a]



The address specified by the X_2, B_2, and D_2 fields is placed in general register R_1. The address computation follows the rules for address arithmetic.

In the 24-bit addressing mode, the address is placed in bit positions 40-63, bits 32-39 are set to zeros, and bits 0-31 remain unchanged. In the 31-bit addressing mode, the address is placed in bit positions 33-63, bit

32 is set to zero, and bits 0-31 remain unchanged. In the 64-bit addressing mode, the address is placed in bit positions 0-63.

The displacement for LA is treated as a 12-bit unsigned binary integer. The displacement for LAY is treated as a 20-bit signed binary integer.

No storage references for operands take place, and the address is not inspected for access exceptions.

Condition Code: The code remains unchanged.

Program Exceptions:

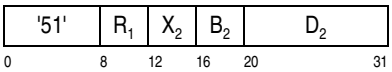
- Operation (LAY if the long-displacement facility is not installed)

Programming Notes:

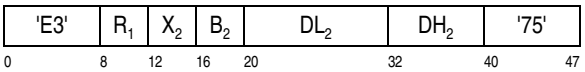
1. An example of the use of the LOAD ADDRESS instruction is given in Appendix A, "Number Representation and Instruction-Use Examples."
2. LOAD ADDRESS may be used to increment the rightmost bits of a general register, other than register 0, by the contents of the D_2 field of the instruction. LOAD ADDRESS (LAY) may also be used to decrement the rightmost bits of a register, other than register 0. The register to be incremented should be designated by R_1 and by either X_2 (with B_2 set to zero) or B_2 (with X_2 set to zero). The instruction increments 24 bits in the 24-bit addressing mode, 31 bits in the 31-bit addressing mode, and 64 bits in the 64-bit addressing mode.

LOAD ADDRESS EXTENDED

LAE $R_1,D_2(X_2,B_2)$ [RX-a]



LAEY $R_1,D_2(X_2,B_2)$ [RXY-a]



The address specified by the X_2, B_2, and D_2 fields is placed in general register R_1. Access register R_1 is loaded with a value that depends on the current value of the address-space-control bits, bits 16 and 17 of the PSW. If the address-space-control bits are 01 binary, the value placed in the access register also depends on whether the B_2 field is zero or nonzero.

The address computation follows the rules for address arithmetic. In the 24-bit addressing mode, the address is placed in bit positions 40-63 of general register R_1, bits 32-39 are set to zeros, and bits 0-31 remain unchanged. In the 31-bit addressing mode, the address is placed in bit positions 33-63, bit 32 is set to zero, and bits 0-31 remain unchanged. In the 64-bit addressing mode, the address is placed in bit positions 0-63.

The value placed in access register R_1 is as shown in the following table:

PSW Bits 16 and 17	Value Placed in Access Register R_1
00	00000000 hex (zeros in bit positions 0-31)
10	00000001 hex (zeros in bit positions 0-30 and one in bit position 31)
01	If B_2 field is zero: 00000000 hex (zeros in bit positions 0-31) If B_2 field is nonzero: Contents of access register B_2
11	00000002 hex (zeros in bit positions 0-29 and 31, and one in bit position 30)

The displacement for LAE is treated as a 12-bit unsigned binary integer. The displacement for LAEY is treated as a 20-bit signed binary integer.

No storage references for operands take place, and the address is not inspected for access exceptions.

Condition Code: The code remains unchanged.

Program Exceptions:

- Operation (LAEY; if the general-instructions-extension facility is not installed)
- Transaction constraint

Programming Notes:

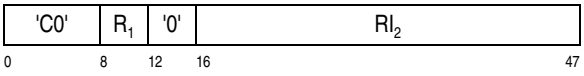
1. When DAT is on, the different values of the address-space-control bits correspond to translation modes as follows:

PSW Bits 16 and 17	Translation Mode
00	Primary-space mode
10	Secondary-space mode
01	Access-register mode
11	Home-space mode

2. In the access-register mode, the value 00000000 hex in an access register designates the primary address space, and the value 00000001 hex designates the secondary address space. The value 00000002 hex designates the home address space if the control program assigns entry 2 of the dispatchable-unit access list as designating the home address space and places a zero access-list-entry sequence number (ALESN) in that entry.

LOAD ADDRESS RELATIVE LONG

LARL R_1,RI_2 [RIL-b]



The address specified by the RI_2 field is placed in general register R_1. The address computation follows the rules for the branch address of BRANCH RELATIVE ON CONDITION LONG and BRANCH RELATIVE AND SAVE LONG.

In the 24-bit addressing mode, the address is placed in bit positions 40-63, bits 32-39 are set to zeros, and bits 0-31 remain unchanged. In the 31-bit addressing mode, the address is placed in bit positions 33-63, bit 32 is set to zero, and bits 0-31 remain unchanged. In the 64-bit addressing mode, the address is placed in bit positions 0-63.

The contents of the RI_2 field are a signed binary integer specifying the number of halfwords that is added to the address of the instruction to generate the computed address.

No storage references for operands take place, and the address is not inspected for access exceptions.

Condition Code: The code remains unchanged.

Program Exceptions: None.

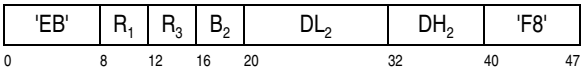
Programming Notes:

1. Only even addresses (halfword addresses) can be generated. If an odd address is desired, LOAD ADDRESS can be used to add one to an address formed by LOAD ADDRESS RELATIVE LONG.

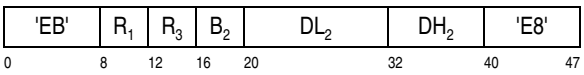
2. When LOAD ADDRESS RELATIVE LONG is the target of an execute-type instruction, the address produced is relative to the location of the LOAD ADDRESS RELATIVE LONG instruction, not of the execute-type instruction. This is consistent with the operation of the relative-branch instructions.

LOAD AND ADD

LAA $R_1,R_3,D_2(B_2)$ [RSY-a]



LAAG $R_1,R_3,D_2(B_2)$ [RSY-a]



The second operand is added to the third operand, and the sum is placed at the second-operand location. Subsequently, the original contents of the second operand (prior to the addition) are placed unchanged at the first-operand location.

For LAA, the operands are treated as being 32-bit signed binary integers. For LAAG, the operands are treated as being 64-bit signed binary integers.

All accesses to the second-operand location appear to be a block-concurrent interlocked-update reference as observed by other CPUs and the I/O subsystem. A specific-operand-serialization operation is performed.

The displacement is treated as a 20-bit signed binary integer.

The second operand of LAA must be designated on a word boundary. The second operand of LAAG must

be designated on a doubleword boundary. Otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Result zero; no overflow
1 Result less than zero; no overflow
2 Result greater than zero; no overflow
3 Overflow

Program Exceptions:

- Access (fetch and store, operand 2)
- Fixed-point overflow
- Operation (if the interlocked-access facility 1 is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. Except for the case where the R_1 and R_3 fields designate the same register, general register R_3 is unchanged.

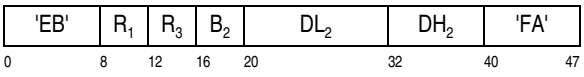
2. The operation of LOAD AND ADD, LOAD AND ADD LOGICAL, LOAD AND AND, LOAD AND EXCLUSIVE OR, and LOAD AND OR may be expressed as follows.

   temp ← operand_2;
   operand_2 ← temp OP operand_3;
   operand_1 ← temp;

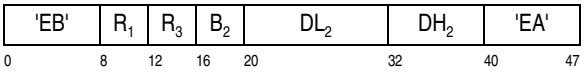
   OP represents the arithmetic or logical operation being performed by the instruction.

LOAD AND ADD LOGICAL

LAAL $R_1,R_3,D_2(B_2)$ [RSY-a]



LAALG $R_1,R_3,D_2(B_2)$ [RSY-a]



The second operand is added to the third operand, and the sum is placed at the second-operand location. Subsequently, the original contents of the second operand (prior to the addition) are placed unchanged at the first-operand location.

For LAAL, the operands are treated as being 32-bit unsigned binary integers. For LAALG, the operands are treated as being 64-bit unsigned binary integers.

All accesses to the second-operand location appear to be a block-concurrent interlocked-update reference as observed by other CPUs and the I/O subsystem. A specific-operand-serialization operation is performed.

The displacement is treated as a 20-bit signed binary integer.

The second operand of LAAL must be designated on a word boundary. The second operand of LAALG must be designated on a doubleword boundary. Otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Result zero; no carry
1 Result not zero; no carry
2 Result zero; carry
3 Result not zero; carry

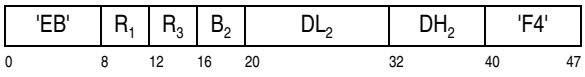
Program Exceptions:

- Access (fetch and store, operand 2)
- Operation (if the interlocked-access facility 1 is not installed)
- Specification
- Transaction constraint

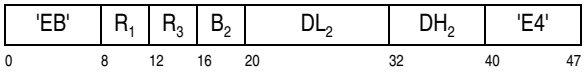
Programming Note: See the programming notes for LOAD AND ADD.

LOAD AND AND

LAN $R_1,R_3,D_2(B_2)$ [RSY-a]



LANG $R_1,R_3,D_2(B_2)$ [RSY-a]



The AND of the second operand and third operand is placed at the second-operand location. Subsequently, the original contents of the second operand (prior to the AND operation) are placed unchanged at the first-operand location.

For LAN, the operands are 32 bits. For LANG, the operands are 64 bits.

The connective AND is applied to the operands bit by bit. The contents of a bit position in the result are set to one if the corresponding bit positions in both operands contain ones; otherwise, the result bit is set to zero.

All accesses to the second-operand location appear to be a block-concurrent interlocked-update reference as observed by other CPUs and the I/O subsystem. A specific-operand-serialization operation is performed.

The displacement is treated as a 20-bit signed binary integer.

The second operand of LAN must be designated on a word boundary. The second operand of LANG must be designated on a doubleword boundary. Otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Result zero
1 Result not zero
2 --
3 --

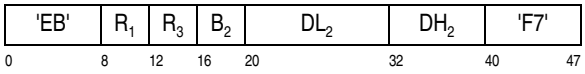
Program Exceptions:

- Access (fetch and store, operand 2)
- Operation (if the interlocked-access facility 1 is not installed)
- Specification
- Transaction constraint

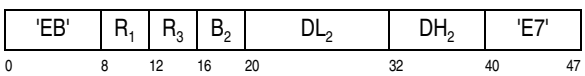
Programming Note: See the programming notes for LOAD AND ADD.

LOAD AND EXCLUSIVE OR

LAX $R_1,R_3,D_2(B_2)$ [RSY-a]



LAXG $R_1,R_3,D_2(B_2)$ [RSY-a]



The EXCLUSIVE OR of the second operand and third operand is placed at the second-operand location. Subsequently, the original contents of the second operand (prior to the EXCLUSIVE OR operation) are placed unchanged at the first-operand location.

For LAX, the operands are 32 bits. For LAXG, the operands are 64 bits.

The connective exclusive OR is applied to the operands bit by bit. The contents of a bit position in the result are set to one if the bits in the corresponding bit positions in the two operands are unlike; otherwise, the result bit is set to zero.

All accesses to the second-operand location appear to be a block-concurrent interlocked-update reference as observed by other CPUs and the I/O subsystem. A specific-operand-serialization operation is performed.

The displacement is treated as a 20-bit signed binary integer.

The second operand of LAX must be designated on a word boundary. The second operand of LAXG must be designated on a doubleword boundary. Otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Result zero
1 Result not zero
2 --
3 --

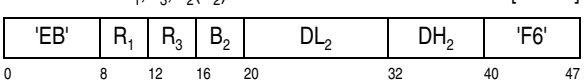
Program Exceptions:

- Access (fetch and store, operand 2)
- Operation (if the interlocked-access facility 1 is not installed)
- Specification
- Transaction constraint

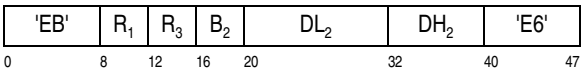
Programming Note: See the programming notes for LOAD AND ADD.

LOAD AND OR

LAO $R_1,R_3,D_2(B_2)$ [RSY-a]



LAOG $R_1,R_3,D_2(B_2)$ [RSY-a]



The OR of the second operand and third operand is placed at the second-operand location. Subsequently, the original contents of the second operand (prior to the OR operation) are placed unchanged at the first-operand location.

For LAO, the operands are 32 bits. For LAOG, the operands are 64 bits.

The connective OR is applied to the operands bit by bit. The contents of a bit position in the result are set to one if the corresponding bit position in one or both operands contains a one; otherwise, the result bit is set to zero.

All accesses to the second-operand location appear to be a block-concurrent interlocked-update reference as observed by other CPUs and the I/O subsystem. A specific-operand-serialization operation is performed.

The displacement is treated as a 20-bit signed binary integer.

The second operand of LAO must be designated on a word boundary. The second operand of LAOG must be designated on a doubleword boundary. Otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Result zero
1 Result not zero
2 --
3 --

Program Exceptions:

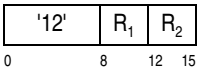
- Access (fetch and store, operand 2)
- Operation (if the interlocked-access facility 1 is not installed)
- Specification
- Transaction constraint

Programming Note: See the programming notes for LOAD AND ADD.

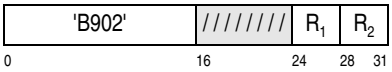
LOAD AND TEST

Register-and-register formats:

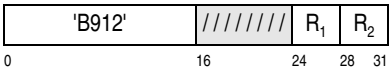
LTR R_1,R_2 [RR]



LTGR R_1,R_2 [RRE]

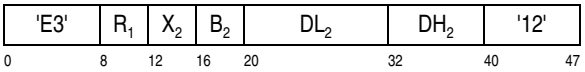


LTGFR R_1,R_2 [RRE]

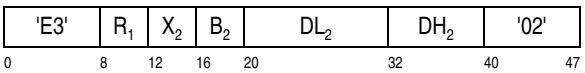


Register-and-storage formats:

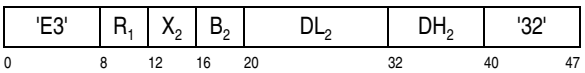
LT $R_1,D_2(X_2,B_2)$ [RXY-a]



LTG $R_1,D_2(X_2,B_2)$ [RXY-a]



LTGF $R_1,D_2(X_2,B_2)$ [RXY-a]



The second operand is placed unchanged at the first-operand location, except that, for LTGF and LTGFR, it is sign extended. The sign and magnitude of the second operand, treated as a signed binary integer, are indicated in the condition code.

For LT and LTR, the operands are 32 bits, and, for LTG and LTGR, the operands are 64 bits. For LTGF and LTGFR, the second operand is 32 bits, and the first operand is treated as a 64-bit signed binary integer.

Resulting Condition Code:

0 Result zero
1 Result less than zero
2 Result greater than zero
3 --

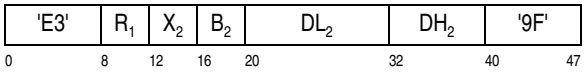
Program Exceptions:

- Access (fetch, operand 2 of LT, LTG, and LTGF only)
- Operation (LT and LTG, if the extended-immediate facility is not installed; LTGF, if the general-instructions-extension facility is not installed)

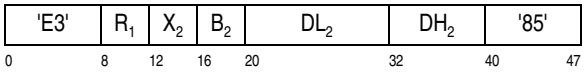
Programming Note: For LOAD AND TEST (LTR and LTGR) when the R_1 and R_2 fields designate the same register, the operation is equivalent to a test without data movement.

LOAD AND TRAP

LAT $R_1,D_2(X_2,B_2)$ [RXY-a]



LGAT $R_1,D_2(X_2,B_2)$ [RXY-a]



The second operand is placed unchanged at the first operand location. If all zeros are placed at the first operand location, a compare-and-trap-instruction data exception is recognized.

For LAT, the second operand is treated as a 32-bit signed integer and placed in bit positions 32-63 of general register R_1, and bit positions 0-31 remain unchanged.

For LGAT, the second operand is treated as a 64-bit signed integer and placed in bit positions 0-63 of general register R_1.

Condition Code: The code remains unchanged.

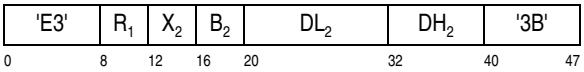
Program Exceptions:

- Data
- Access (fetch, operand 2)
- Operation (if the load-and-trap facility is not installed)

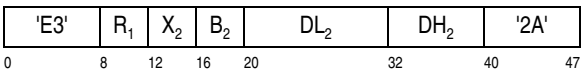
Programming Note: Possible uses of LOAD AND TRAP include checking for pointers containing zero (null pointer).

LOAD AND ZERO RIGHTMOST BYTE

LZRF $R_1,D_2(X_2,B_2)$ [RXY-a]



LZRG $R_1,D_2(X_2,B_2)$ [RXY-a]



The second operand, with the rightmost byte set to zero, is placed at the first-operand location. For LZRF, the first and second operands are 32 bits, and for LZRG, the first and second operands are 64 bits.

The displacement is treated as a 20-bit signed binary integer.

It is unpredictable whether an access exception is recognized for the rightmost byte of the second operand.

Condition Code: The code remains unchanged.

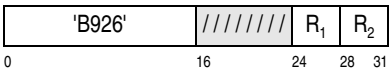
Program Exceptions:

- Access (fetch, operand 2)
- Operation (if the load-and-zero-rightmost-byte facility is not installed)

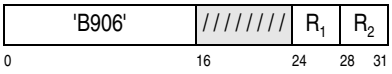
LOAD BYTE

Register-and-register formats:

LBR R_1,R_2 [RRE]

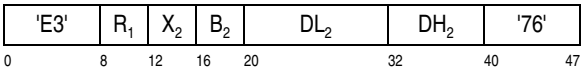


LGBR R_1,R_2 [RRE]

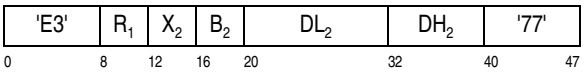


Register-and-storage formats:

LB $R_1,D_2(X_2,B_2)$ [RXY-a]



LGB $R_1,D_2(X_2,B_2)$ [RXY-a]



The second operand is sign extended and placed at the first-operand location. The second operand is one byte in length and is treated as an eight-bit signed binary integer. For LOAD BYTE (LB and LGB), the second operand is a byte in storage. For LOAD BYTE (LBR and LGBR), the second operand is in bits 56-63 of general register R_2.

For LOAD BYTE (LB and LBR), the first operand is treated as a 32-bit signed binary integer. For LOAD BYTE (LGB and LGBR), the first operand is treated as a 64-bit signed binary integer.

The displacement for LB and LGB is treated as a 20-bit signed binary integer.

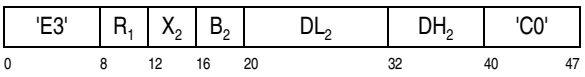
Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2 of LB and LGB)
- Operation (LB and LGB, if the long-displacement facility is not installed; LBR and LGBR, if the extended-immediate facility is not installed)

LOAD BYTE HIGH

LBH $R_1,D_2(X_2,B_2)$ [RXY-a]



The second operand is sign extended and placed at the first-operand location. The second operand is one byte in length and is treated as an eight-bit signed binary integer.

The first operand is treated as a 32-bit signed binary integer in bits 0-31 of general register R_1; bits 32-63 of the register are unchanged.

The displacement is treated as a 20-bit signed binary integer.

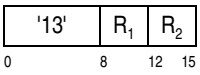
Condition Code: The code remains unchanged.

Program Exceptions:

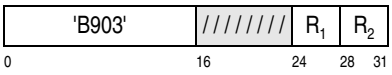
- Access (fetch, operand 2)
- Operation (if the high-word facility is not installed)

LOAD COMPLEMENT

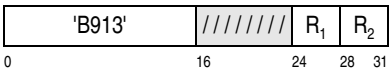
LCR R_1,R_2 [RR]



LCGR R_1,R_2 [RRE]



LCGFR R_1,R_2 [RRE]



The two's complement of the second operand is placed at the first-operand location. For LOAD COMPLEMENT (LCR), the second operand and result are treated as 32-bit signed binary integers. For LOAD COMPLEMENT (LCGR), they are treated as 64-bit signed binary integers. For LOAD COMPLEMENT (LCGFR), the second operand is treated as a 32-bit signed binary integer, and the result is treated as a 64-bit signed binary integer.

When there is an overflow, the result is obtained by allowing any carry into the sign-bit position and ignoring any carry out of the sign-bit position, and condition code 3 is set. If the fixed-point-overflow mask is one, a program interruption for fixed-point overflow occurs.

Resulting Condition Code:

0 Result zero; no overflow
1 Result less than zero; no overflow
2 Result greater than zero; no overflow
3 Overflow

Program Exceptions:

- Fixed-point overflow (LCR and LCGR only)

Programming Note: The operation complements all numbers. Zero remains unchanged. For LCR or LCGR, the maximum negative 32-bit number or 64-bit number, respectively, remains unchanged, and an overflow condition occurs when the number is

complemented. LCGFR complements the maximum negative 32-bit number without recognizing overflow.

LOAD COUNT TO BLOCK BOUNDARY

LCBB $R_1,D_2(X_2,B_2),M_3$ [RXE]

A 32-bit unsigned binary integer containing the number of bytes possible to load from the second operand location without crossing a specified block boundary, with a maximum of sixteen is placed in the first operand. If the number of bytes is greater than sixteen, sixteen is placed in the first operand.

The displacement is treated as a 12-bit unsigned integer.

The second operand address is not used to address data.

The M_3 field specifies a code that is used to signal the CPU as to the block boundary size to compute the number of possible bytes loaded. If a reserved value is specified then a specification exception is recognized.

Code	Boundary
0	64 Byte
1	128 Byte
2	256 Byte
3	512 Byte
4	1 K-byte
5	2 K-Byte
6	4 K-Byte
7-15	Reserved

Resulting Condition Code:

0 Operand one is sixteen
1 --
2 --
3 Operand one is less than sixteen

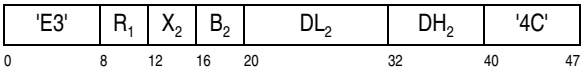
Program Exceptions:

- Operation (if the vector facility for z/Architecture is not installed)
- Specification

Programming Note: It is expected that LOAD COUNT TO BLOCK BOUNDARY will be used in conjunction with VECTOR LOAD TO BLOCK BOUNDARY to determine the number of bytes that were loaded.

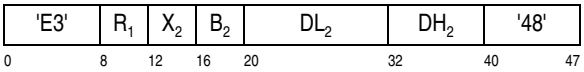
LOAD GUARDED

LGG $R_1,D_2(X_2,B_2)$ [RXY-a]



LOAD LOGICAL AND SHIFT GUARDED

LLGFSG $R_1,D_2(X_2,B_2)$ [RXY-a]



Note: See the section "Guarded-Storage Facility" on page 4-66 for details on the terminology used below.

A 64-bit intermediate result is formed as follows:

- For LOAD GUARDED: The second operand is a doubleword in storage. A specification exception is recognized and the operation is suppressed if the second-operand address is not on a doubleword boundary.

  In the 24-bit addressing mode, the intermediate result is formed from the concatenation of 40 binary zeros with bits 40-63 of the second operand. In the 31-bit addressing mode, the intermediate result is formed from the concatenation of 33 binary zeros with bits 33-63 of the second operand. In the 64-bit addressing mode, the intermediate result is formed from the entire second operand.

- For LOAD LOGICAL AND SHIFT GUARDED: The second operand is a word in storage. A specification exception is recognized and the operation is suppressed if the second-operand address is not on a word boundary.

When the guarded-storage facility is enabled (by means of bit 59 of control register 2), the intermediate result is formed using the guarded-load-shift value (GLS, in bits 53-55 of the guarded-storage-designation register). When the guarded-storage facility is not enabled, the GLS value is assumed to be zero.

In the 24-bit addressing mode, the intermediate result is formed from the concatenation of 40 binary zeros, bits (8+GLS) through 31 of the second operand, and GLS binary zeros. In the 31-bit addressing mode, the intermediate result is formed from the concatenation of 33 binary zeros, bits (1+GLS) through 31 of the second operand, and GLS binary zeros. In the 64-bit addressing mode, the intermediate result is formed from the concatenation of (32-GLS) binary zeros, the entire 32-bit second operand, and GLS binary zeros.

When the guarded-storage facility is enabled, the intermediate result is used as described in "Guarded-Storage-Event Detection" on page 4-71. If a guarded-storage event is recognized, then general register R_1 is not modified, and the instruction is completed as described in "Guarded-Storage-Event Processing" on page 4-72.

When either the guarded-storage facility is not enabled, or the facility is enabled but a guarded-storage event is not recognized, then the 64-bit intermediate result is placed into general register R_1, and the instruction is completed.

The displacement is treated as a 20-bit signed binary integer.

The guarded-storage-event parameter list (GSEPL) is only accessed when a guarded-storage event is recognized. Store-type accesses apply to the entire GSEPL.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, second operand; when a guarded-storage-event is recognized, fetch and store, GSEPL fields)
- Operation (guarded-storage facility not installed)
- Specification

1.-7.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
8.	Access exceptions for the second operand in storage.
9.	Completion with no guarded-storage-event recognized.
10.	Side-effect access exceptions for the guarded-storage-event parameter list.
11.	Completion with a guarded-storage-event recognized.

Figure 7-334. Priority of Execution: LGG and LLGFSG

Programming Notes:

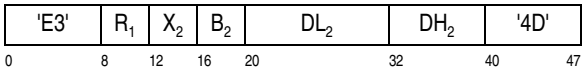
1. LOAD LOGICAL AND SHIFT GUARDED may be useful in loading what are sometimes referred to as *compressed pointers* in which some number of rightmost bits of the pointer address are absent in storage and assumed to be zeros.

2. When the guarded-storage facility is installed in a configuration, the LOAD GUARDED and LOAD LOGICAL AND SHIFT GUARDED instructions can be executed regardless of the contents of the guarded-storage-facility-enablement control (GSFE, bit 59 of control register 2). However, guarded-storage events are only recognized as a result of executing LGG or LLGFSG when (a) the GSFE control is one, and (b) the GSSM is non-zero. The GSSM cannot be loaded without the GSFE control being one.

3. A guarded-storage event is never recognized when all 64 bits of the guarded-storage selection mask (GSSM) are zero. The program can ensure that guarded-storage events are not recognized by either (a) not loading the guarded-storage controls, in which case the GSSM will contain its reset state of zeros, or (b) loading zeros into the GSSM.

LOAD GUARDED STORAGE CONTROLS

LGSC $R_1,D_2(X_2,B_2)$ [RXY-a]



The contents of the guarded-storage control block (GSCB) at the second-operand address are loaded into the three guarded-storage registers. The format of the guarded-storage control block is shown in Figure 4-19 on page 4-68. The R_1 field of the instruction is reserved and should contain zero; otherwise, the program may not operate compatibly in the future.

Access exceptions are recognized for all 32 bytes of the GSCB.

The section "Guarded-Storage-Designation (GSD) Register" on page 4-67 describes the valid values of the GSD register. If either the GLS or GSC fields of the GSD register being loaded contain invalid values, or if reserved bit positions of the register do not contain zeros the results are unpredictable. If the second operand contains either (a) invalid GLS or GSC values, or (b) nonzero values in the reserved bit positions, then it is model dependent whether the CPU replaces the invalid or nonzero values with corrected values. Furthermore, it is unpredictable whether such corrected values are subsequently stored by STORE GUARDED STORAGE CONTROLS.

Special Conditions

A special-operation exception is recognized and the operation is suppressed when the guarded-storage-facility-enablement control, bit 59 of control register 2, is zero.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, second operand)
- Operation (if the guarded-storage facility is not installed)
- Special operation
- Transaction constraint

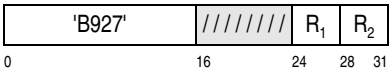
Programming Notes:

1. If the GSC field of the GSD register contains an invalid value, guarded-storage events may not occur or erroneous guarded-storage events may be detected.
2. If the GLS field of the GSD register contains an invalid value, the intermediate result used by LLGFSG may be formed from an unpredictable range of bits in the second operand, shifted by an unpredictable number of bits.

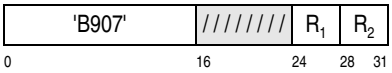
LOAD HALFWORD

Register-and-register formats:

LHR R_1,R_2 [RRE]

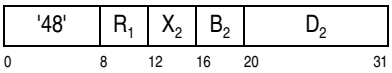


LGHR R_1,R_2 [RRE]

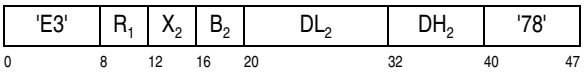


Register-and-storage formats:

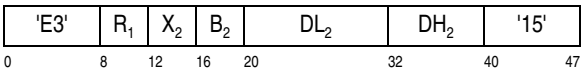
LH $R_1,D_2(X_2,B_2)$ [RX-a]



LHY $R_1,D_2(X_2,B_2)$ [RXY-a]

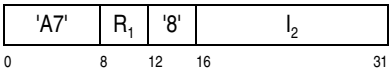


LGH $R_1,D_2(X_2,B_2)$ [RXY-a]

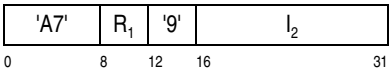


LOAD HALFWORD IMMEDIATE

LHI R_1,I_2 [RI-a]

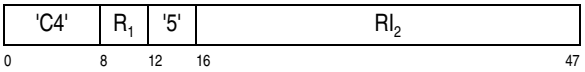


LGHI R_1,I_2 [RI-a]

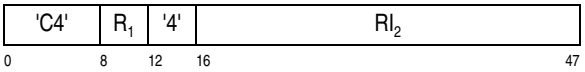


LOAD HALFWORD RELATIVE LONG

LHRL R_1,RI_2 [RIL-b]



LGHRL R_1,RI_2 [RIL-b]



The second operand is sign extended and placed at the first-operand location. The second operand is two bytes in length and is treated as a 16-bit signed binary integer. For LOAD HALFWORD (LH, LHY, and LGH) and LOAD HALFWORD RELATIVE LONG, the second operand is in storage. For LOAD HALFWORD (LHI and LGHI), the second operand is the immediate field of the instruction. For LOAD HALFWORD (LHR and LGHR), the second operand is in bits 48-63 of general register R_2.

For LOAD HALFWORD (LH, LHR, and LHY), LOAD HALFWORD IMMEDIATE (LHI), and LOAD HALFWORD RELATIVE LONG (LHRL), the first operand is treated as a 32-bit signed binary integer. For LOAD HALFWORD (LGH and LGHR), LOAD HALFWORD IMMEDIATE (LGHI), and LOAD HALFWORD RELATIVE LONG (LGHRL), the first operand is treated as a 64-bit signed binary integer.

The displacement for LH is treated as a 12-bit unsigned binary integer. The displacement for LHY and LGH is treated as a 20-bit signed binary integer.

For LOAD HALFWORD RELATIVE LONG, the contents of the RI_2 field are a signed binary integer specifying the number of halfwords that is added to the address of the instruction to generate the address of the second operand in storage. When DAT is on, the second operand is accessed using the same addressing-space mode as that used to access the instruction. When DAT is off, the second operand is accessed using a real address.

Condition Code: The code remains unchanged.

Program Exceptions:

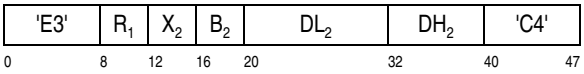
- Access (fetch, operand 2 of LH, LHY, LGH, LHRL and LGHRL)
- Operation (LHY, if the long-displacement facility is not installed; LHR and LGHR, if the extended-immediate facility is not installed; LHRL and LGHRL, if the general-instructions-extension facility is not installed)

Programming Notes:

1. An example of the use of the LOAD HALFWORD instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”
2. For LOAD HALFWORD RELATIVE LONG, the second operand is necessarily aligned on an integral boundary corresponding to the operand’s size.
3. When LOAD HALFWORD RELATIVE LONG is the target of an execute-type instruction, the second-operand address is relative to the target address.

LOAD HALFWORD HIGH

LHH R_1,D_2(X_2,B_2) [RXY-a]



The second operand is sign extended and placed at the first-operand location. The second operand is two bytes in length and is treated as an 16-bit signed binary integer.

The first operand is treated as a 32-bit signed binary integer in bits 0-31 of general register R_1; bits 32-63 of the register are unchanged.

The displacement is treated as a 20-bit signed binary integer.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Operation (if the high-word facility is not installed)

LOAD HALFWORD IMMEDIATE ON CONDITION

LOCHI R_1,I_2,M_3 [RIE-g]

LOCGHI R_1,I_2,M_3 [RIE-g]

LOAD HALFWORD HIGH IMMEDIATE ON CONDITION

LOCHHI R_1,I_2,M_3 [RIE-g]

The second operand is sign extended and placed at the first-operand location if the condition code has one of the values specified by M_3; otherwise, the first operand remains unchanged.

For LOAD HALFWORD IMMEDIATE ON CONDITION (LOCHI), the first operand is treated as a 32-bit signed binary integer in bits 32-63 of general register R_1, and bits 0-31 of the register are unchanged. For LOAD HALFWORD HIGH IMMEDIATE ON CONDITION, the first operand is treated as a 32-bit signed binary integer in bits 0-31 of general register R_1, and bits 32-63 of the register are unchanged. For LOAD HALFWORD IMMEDIATE ON CONDITION (LOCGHI), the first operand is treated as a 64-bit signed binary integer in bits 0-63 of general register R_1.

The second operand is the two byte I_2 field of the instruction and is treated as a 16-bit signed binary integer.

The M_3 field is used as a four-bit mask. The four condition codes (0, 1, 2, and 3) correspond, left to right, with the four bits of the mask, as follows:

Condition Code	0	1	2	3
Instruction Bit Number of Mask	12	13	14	15
Mask Position Value	8	4	2	1

The current condition code is used to select the corresponding mask bit. If the mask bit selected by the condition code is one, the load is performed. If the mask bit selected is zero, the load is not performed.

Condition Code: The code remains unchanged.

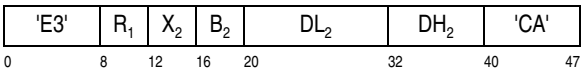
Program Exceptions:

- Operation (if the load/store-on-condition facility 2 is not installed)

Programming Notes: See programming note 4 on page 7-326 for details on extended mnemonics for the instructions of the load/store-on-condition facilities.

LOAD HIGH

LFH $R_1,D_2(X_2,B_2)$ [RXY-a]



The second operand is placed unchanged at the first-operand location. The second operand is 32 bits, and the first operand is in bits 0-31 of general register R_1; bits 32-63 of the register are unchanged.

The displacement is treated as a 20-bit signed binary integer.

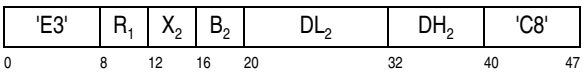
Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Operation (if the high-word facility is not installed)

LOAD HIGH AND TRAP

LFHAT $R_1,D_2(X_2,B_2)$ [RXY-a]



The second operand is treated as a 32-bit signed integer and placed unchanged in bit positions 0-31 of general register R_1, and bit positions 32-63 remain unchanged. If all zeros are placed at the first operand location, a compare-and-trap-instruction data exception is recognized.

Condition Code: The code remains unchanged.

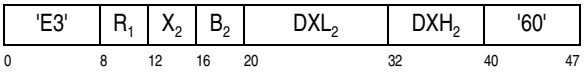
Program Exceptions:

- Data
- Access (fetch, operand 2)
- Operation (if the load-and-trap facility is not installed)

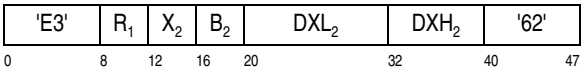
Programming Note: Possible uses of LOAD HIGH AND TRAP include checking for pointers containing zero (null pointer).

LOAD INDEXED ADDRESS

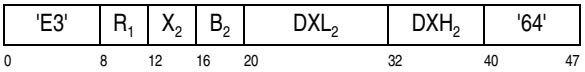
LXAB $R_1,DX_2(X_2,B_2)$ [RXY-c]



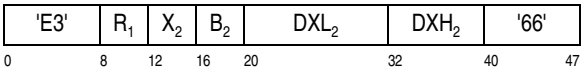
LXAH $R_1,DX_2(X_2,B_2)$ [RXY-c]



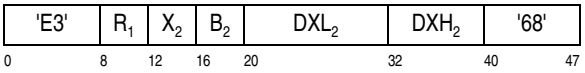
LXAF $R_1,DX_2(X_2,B_2)$ [RXY-c]



LXAG $R_1,DX_2(X_2,B_2)$ [RXY-c]



LXAQ $R_1,DX_2(X_2,B_2)$ [RXY-c]



The second-operand address specified by the X_2, B_2, and DX_2 fields is placed in general register R_1.

A zero in the B_2 or X_2 fields indicates the absence of the corresponding address component. For the absent component, a zero is used in forming the intermediate sum, regardless of the contents of the general register 0. The value in the register specified by the X_2 and in the value in the DX_2 field is a number of elements and not a number of bytes.

Normal address arithmetic is not used, the address computation is performed by the following steps:

- When general register X_2 is not zero, bits 32 to 63 of the register are added to the sign-extended 20-bit displacement field DX_2 to form a 32-bit intermediate result. Bits 0 to 31 of general register X_2 are ignored. Any carry out of the 32-bit addition is discarded. The 64-bit intermediate result will have the most significant bit of the 32-bit addition sign extended to bits 0 to 31 prepended to the result of the 32-bit intermediate addition.
- A 64-bit left shift of the 64-bit intermediate result of the previous addition by 0, 1, 2, 3, or 4 bits to form a shifted intermediate result. Zeros are supplied to the vacated bit positions on the right, and the bits shifted out of bit 0 on the left are discarded. The left shift amount is specified as follows:

Instructions	Left Shift Amount
LXAB	0
LXAH	1
LXAF	2
LXAG	3
LXAQ	4

- A 64-bit addition of the contents of general register B_2 and the intermediate result of the shift to form a 64-bit intermediate result.
- The final address is placed in general register R_1 as follows: In the 24-bit addressing mode, the address is placed in bit positions 40-63, bits 32-39 are set to zeros, and bits 0-31 remain unchanged. In the 31-bit addressing mode, the address is placed in bit positions 33-63, bit 32 is set to zero, and bits 0-31 remain unchanged. In the 64-bit addressing mode, the address is placed in bit positions 0-63.

The displacement is treated as a 20-bit signed binary integer.

No storage references for operands take place, and the address is not inspected for access exceptions or program event recording.

Condition Code: The code remains unchanged.

Program Exceptions:

- Operation (if the miscellaneous-instruction-extensions facility 4 is not installed)

Programming Notes:

1. This instruction may be used to form the address to access the elements of an array.
2. The shift amount corresponds to the size (1, 2, 4, 8, or 16 bytes) of the array elements.
3. The first intermediate result that is performed is a 32-bit addition due to using a default integer variable size of 32 bits for the address to the arrays. The displacement index is used as an addition to the array index. The C language standard states the addition needs to be done in the data type of the signed index variable which is normally a 32 bit integer.
4. In the high-level assembler (HLASM) the address expression should not be relocatable with a base register and displacement determined by a USING instruction if the array element size is larger than one byte, because the resulting displacement in the instruction will be in bytes rather than elements, so it will not refer to the same location as the address expression.
5. Programming example of a C code function that increments a signed integer element of an array:

```
int ary[10];
void aryindx(int i)
{
        ary[i + 1]++;
}
```

In the these programming examples it is assumed that GR2 bits 32-63 contains the value of i, passed by value as a parameter.

Example without LOAD INDEXED ADDRESS:

```
ARY     DS      10F

ARYINDX EQU *
        LAY     1,ARY
        AHI     2,1
        LGFR    2,2
        SLLG    2,2,2
        AGR     1,2
        ASI     0(1),1
        BR      14
```

Example with LOAD INDEXED ADDRESS:

```
ARY     DS      10F

ARYINDX EQU *
        LAY     1,ARY
        LXAF    1,1(2,1)
        ASI     0(1),1
        BR      14
```

Programming example of a C code function implemented with a structure that contains a signed integer and an array of signed integers that increments a signer integer element of that array:

```
struct {
        int foo;
        int ary[10];
} s;
void aryindx (int i)
{
        s.ary[i + 1]++;
}
```

Example without LOAD INDEXED ADDRESS:

```
FOO     DS      F
ARY     DS      10F

ARYINDX EQU *
        LAY     1,S
        AHI     2,1
        LGFR    2,2
        SLLG    2,2,2
        AGR     1,2
        ASI     4(1),1
        BR      14
```

Example with LOAD INDEXED ADDRESS:

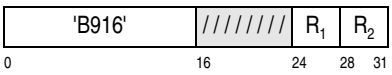
```
FOO     DS      F
ARY     DS      10F

ARYINDX EQU *
        LAY     1,S
        LXAF    1,1(2,1)
        ASI     4(1),1
        BR      14
```

LOAD LOGICAL

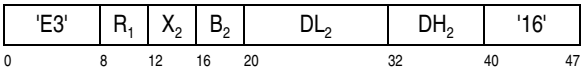
Register-and-register format:

LLGFR R_1,R_2 [RRE]



Register-and-storage format:

LLGF $R_1,D_2(X_2,B_2)$ [RXY-a]



LOAD LOGICAL RELATIVE LONG

LLGFRL R_1,RI_2 [RIL-b]

The four-byte second operand is placed in bit positions 32-63 of general register R_1, and zeros are placed in bit positions 0-31 of general register R_1.

For LOAD LOGICAL (LLGFR), the second operand is in bit positions 32-63 of general register R_2.

For LOAD LOGICAL RELATIVE LONG, the contents of the RI_2 field are a signed binary integer specifying the number of halfwords that is added to the address of the instruction to generate the address of the second operand in storage. When DAT is on, the second operand is accessed using the same addressing-space mode as that used to access the instruction. When DAT is off, the second operand is accessed using a real address.

For LOAD LOGICAL RELATIVE LONG, the second operand must be aligned on a word boundary; otherwise, a specification exception is recognized.

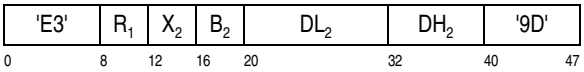
Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2 of LLGF and LLGFRL only)
- Operation (LLGFRL, if the general-instructions-extension facility is not installed)
- Specification (LLGFRL only)

LOAD LOGICAL AND TRAP

LLGFAT $R_1,D_2(X_2,B_2)$ [RXY-a]



The four-byte second operand is placed unchanged in bit positions 32-63 of general register R_1, and zeros are placed in bit positions 0-31. If all zeros are placed at the first operand location, a compare-and-trap-instruction data exception is recognized.

Condition Code: The code remains unchanged.

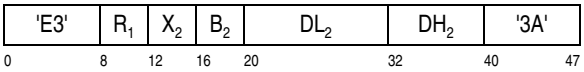
Program Exceptions:

- Data
- Access (fetch, operand 2)
- Operation (if the load-and-trap facility is not installed)

Programming Note: Possible uses of LOAD LOGICAL AND TRAP include checking for pointers containing zero (null pointer).

LOAD LOGICAL AND ZERO RIGHTMOST BYTE

LLZRGF $R_1,D_2(X_2,B_2)$ [RXY-a]



The four-byte second operand, with the rightmost byte set to zero, is placed in bit positions 32-63 of general register R_1, and zeros are placed in bit positions 0-31 of the register.

The displacement is treated as a 20-bit signed binary integer.

It is unpredictable whether an access exception is recognized for the rightmost byte of the second operand.

Condition Code: The code remains unchanged.

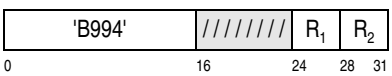
Program Exceptions:

- Access (fetch, operand 2)
- Operation (if the load-and-zero-rightmost-byte facility is not installed)

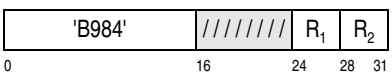
LOAD LOGICAL CHARACTER

Register-and-register formats:

LLCR R_1,R_2 [RRE]

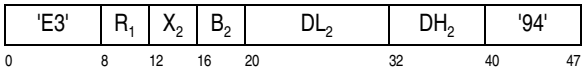


LLGCR R_1,R_2 [RRE]

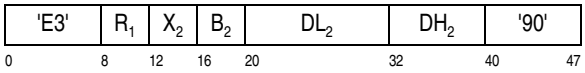


Register-and-storage formats:

LLC $R_1,D_2(X_2,B_2)$ [RXY-a]



LLGC $R_1,D_2(X_2,B_2)$ [RXY-a]



The one-byte second operand is placed in bit positions 56-63 of general register R_1. For LOAD LOGICAL CHARACTER (LLGC, LLGCR), zeros are placed in bit positions 0-55 of general register R_1. For LOAD LOGICAL CHARACTER (LLC, LLCR), zeros are placed in bit positions 32-55 of general register R_1; bit positions 0-31 of general register R_1 are unchanged.

For LOAD LOGICAL CHARACTER (LLC, LLGC), the second operand is in storage. For LOAD LOGICAL CHARACTER (LLCR, LLGCR), the second operand is in bits 56-63 of general register R_2.

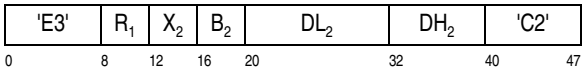
Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2 of LLC and LLGC)
- Operation (LLC, LLCR, and LLGCR, if the extended-immediate facility is not installed)

LOAD LOGICAL CHARACTER HIGH

LLCH $R_1,D_2(X_2,B_2)$ [RXY-a]



The one-byte second operand is placed in bit positions 24-31 of general register R_1, and zeros are placed in bit positions 0-23 of general register R_1; bit positions 32-63 of general register R_1 are unchanged.

The displacement is treated as a 20-bit signed binary integer.

Condition Code: The code remains unchanged.

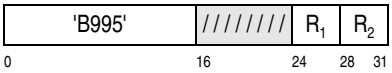
Program Exceptions:

- Access (fetch, operand 2)
- Operation (if the high-word facility is not installed)

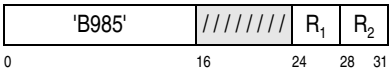
LOAD LOGICAL HALFWORD

Register-and-register formats:

LLHR R_1,R_2 [RRE]

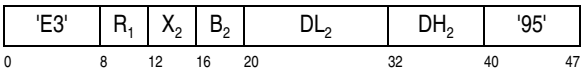


LLGHR R_1,R_2 [RRE]

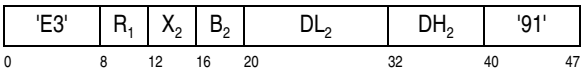


Register-and-storage formats:

LLH $R_1,D_2(X_2,B_2)$ [RXY-a]



LLGH $R_1,D_2(X_2,B_2)$ [RXY-a]



LOAD LOGICAL HALFWORD RELATIVE LONG

LLHRL R_1,RI_2 [RIL-b]

LLGHRL R_1,RI_2 [RIL-b]

The two-byte second operand is placed in bit positions 48-63 of general register R_1. For LOAD LOGICAL HALFWORD (LLGH, LLGHR) and LOAD LOGICAL HALFWORD RELATIVE LONG (LLGHRL), zeros are placed in bit positions 0-47 of general register R_1. For LOAD LOGICAL HALFWORD (LLH, LLHR) and LOAD LOGICAL HALFWORD RELATIVE LONG (LLHRL), zeros are placed

in bit positions 32-47 of general register R_1; bit positions bits 0-31 of general register R_1 are unchanged.

For LOAD LOGICAL HALFWORD (LLGH, LLH) and LOAD LOGICAL HALFWORD RELATIVE LONG, the second operand is in storage. For LOAD LOGICAL HALFWORD (LLGHR, LLHR), the second operand is in bits 48-63 of general register R_2.

For LOAD LOGICAL HALFWORD RELATIVE LONG, the contents of the RI_2 field are a signed binary integer specifying the number of halfwords that is added to the address of the instruction to generate the address of the second operand in storage. When DAT is on, the second operand is accessed using the same addressing-space mode as that used to access the instruction. When DAT is off, the second operand is accessed using a real address.

Condition Code: The code remains unchanged.

Program Exceptions:

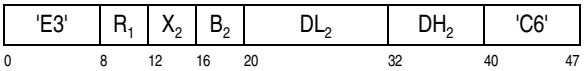
- Access (fetch, operand 2 of LLGH, LLH, LLHRL, and LLGHRL)
- Operation (LLGHR, LLH, and LLHR, if the extended-immediate facility is not installed; LLHRL and LLGHRL, if the general-instructions-extension facility is not installed)

Programming Notes:

1. For LOAD LOGICAL HALFWORD RELATIVE LONG, the second operand is necessarily aligned on an integral boundary corresponding to the operand's size.
2. When LOAD LOGICAL HALFWORD RELATIVE LONG is the target of an execute-type instruction, the second-operand address is relative to the target address.

LOAD LOGICAL HALFWORD HIGH

LLHH $R_1,D_2(X_2,B_2)$ [RXY-a]



The two-byte second operand is placed in bit positions 16-31 of general register R_1, and zeros are placed in bit positions 0-15 of general register R_1; bit positions 32-63 of general register R_1 are unchanged.

The displacement is treated as a 20-bit signed binary integer.

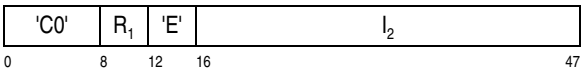
Condition Code: The code remains unchanged.

Program Exceptions:

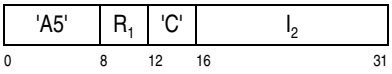
- Access (fetch, operand 2)
- Operation (if the high-word facility is not installed)

LOAD LOGICAL IMMEDIATE

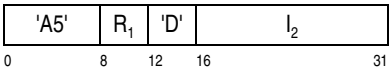
LLIHF R_1,I_2 [RIL-a]



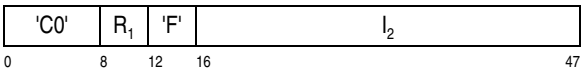
LLIHH R_1,I_2 [RI-a]



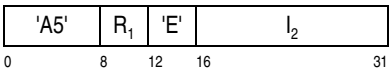
LLIHL R_1,I_2 [RI-a]



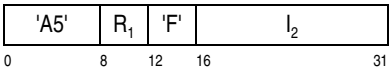
LLILF R_1,I_2 [RIL-a]



LLILH R_1,I_2 [RI-a]



LLILL R_1,I_2 [RI-a]



The second operand is placed in bit positions of the first operand. The remainder of the first operand is set to zeros.

For each instruction, the bit positions of the first operand that are loaded with the second operand are as follows:

Instruction	Bit Positions Loaded
LLIHF	0-31
LLIHH	0-15
LLIHL	16-31
LLILF	32-63
LLILH	32-47
LLILL	48-63

Condition Code: The code remains unchanged.

Program Exceptions:

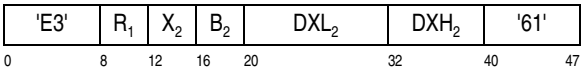
- Operation (LLIHF and LLILF, if the extended-immediate facility is not installed)

Extended Mnemonics:

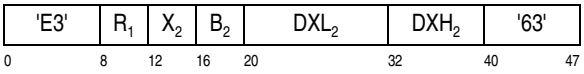
Extended Mnemonic		Base Mnemonic	
LLGFI	R_1,I_2	LLILF	R_1,I_2
LLGHI	R_1,I_2	LLILL	R_1,I_2

LOAD LOGICAL INDEXED ADDRESS

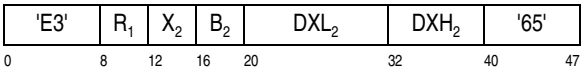
LLXAB $R_1,DX_2(X_2,B_2)$ [RXY-c]



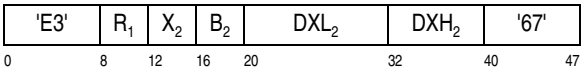
LLXAH $R_1,DX_2(X_2,B_2)$ [RXY-c]



LLXAF $R_1,DX_2(X_2,B_2)$ [RXY-c]

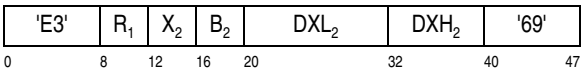


LLXAG $R_1,DX_2(X_2,B_2)$ [RXY-c]



the 64-bit addressing mode, the address is

LLXAQ $R_1,DX_2(X_2,B_2)$ [RXY-c]



The second-operand address specified by the X_2, B_2, and DX_2 fields is placed in general register R_1.

A zero in the B_2 or X_2 fields indicates the absence of the corresponding address component. For the absent component, a zero is used in forming the intermediate sum, regardless of the contents of the general register 0. The value in the register specified by the X_2 and the value in the DX_2 field is a number of elements and not a number of bytes.

Normal address arithmetic is not used, the address computation is performed by the following steps:

- When general register X_2 is not zero, bits 32 to 63 of the register are added to the sign-extended 20-bit displacement field DX_2 to form a 32-bit intermediate result. Bits 0 to 31 of general register X_2 are ignored. Any carry out of the 32-bit addition is discarded. The 64-bit intermediate result will have bits 0 to 31 of the results are forced to zeros prepended to the result of the 32-bit intermediate addition.
- A 64-bit left shift of the 64-bit intermediate result of the previous addition by 0, 1, 2, 3, or 4 bits to form a shifted intermediate result. Zeros are supplied to the vacated bit positions on the right, and the bits shifted out of bit 0 on the left are discarded. The left shift amount is specified as follows:

Instructions	Left Shift Amount
LLXAB	0
LLXAH	1
LLXAF	2
LLXAG	3
LLXAQ	4

- A 64-bit addition of the contents of general register B_2 and the intermediate result of the shift to form an intermediate result.
- The final address is placed in general register R_1 as follows: In the 24-bit addressing mode, the address is placed in bit positions 40-63, bits 32-39 are set to zeros, and bits 0-31 remain unchanged. In the 31-bit addressing mode, the address is placed in bit positions 33-63, bit 32 is set to zero, and bits 0-31 remain unchanged. In placed in bit positions 0-63.

The displacement is treated as a 20-bit signed binary integer.

No storage references for operands take place, and the address is not inspected for access exceptions or program event recording.

Condition Code: The code remains unchanged.

Program Exceptions:

- Operation (if the miscellaneous-instruction-extensions facility 4 is not installed)

Programming Notes:

1. This instruction may be used to form the address to access the elements of an array.
2. The shift amount corresponds to the size (1, 2, 4, 8, or 16 bytes) of the array elements.
3. The first intermediate result that is performed is a 32-bit addition due to using a default integer variable size of 32 bits for the address to the arrays. The displacement index is used as an addition to the array index. The C language standard states the addition needs to be done in the data type of the unsigned index variable which is normally a 32 bit integer.
4. In the high-level assembler (HLASM) the address expression should not be relocatable with a base register and displacement determined by a USING instruction if the array element size is larger than one byte, because the resulting displacement in the instruction will be in bytes rather than elements, so it will not refer to the same location as the address expression.
5. See programming note 5 in LOAD INDEXED ADDRESS for a code usage example, except that the array index variable *i* is declared as an unsigned int rather than an int.
6. When the array index variable *i* is declared to be an unsigned integer in the usage example from programming note 5 in LOAD INDEXED ADDRESS the compiler generated code without the use of LOAD INDEXED ADDRESS does not need to be different. However, the LOAD INDEXED ADDRESS code is required to change to use the LOAD LOGICAL INDEXED ADDRESS.
7. When in 24-bit or 31-bit addressing mode there is no functional difference between the LOAD INDEXED ADDRESS and the LOAD LOGICAL INDEXED ADDRESS.

LOAD LOGICAL THIRTY ONE BITS

Register-and-register format:

LLGTR R_1,R_2 [RRE]

Register-and-storage format:

LLGT $R_1,D_2(X_2,B_2)$ [RXY-a]

For LLGTR, bits 33-63 of general register R_2, with 33 zeros appended on the left, are placed in general register R_1. For LLGT, bits 1-31 of the four bytes at the second-operand location, with 33 zeros appended on the left, are placed in general register R_1.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2 of LLGT only)

LOAD LOGICAL THIRTY ONE BITS AND TRAP

LLGTAT $R_1,D_2(X_2,B_2)$ [RXY-a]

Bits 1-31 of the four bytes at the second operand location are placed unchanged in bit positions 33-63 of general register R_1, and zeros are placed in bit positions 0-32. If all zeros are placed at the first operand location, a compare-and-trap-instruction data exception is recognized.

Condition Code: The code remains unchanged.

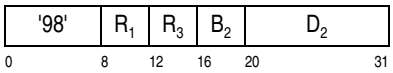
Program Exceptions:

- Data
- Access (fetch, operand 2)
- Operation (if the load-and-trap facility is not installed)

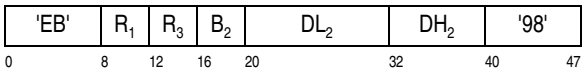
Programming Note: Possible uses of LOAD LOGICAL THIRTY ONE BITS AND TRAP include checking for pointers containing zero (null pointer).

LOAD MULTIPLE

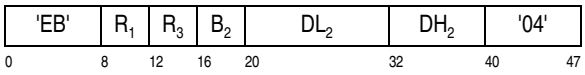
LM $R_1,R_3,D_2(B_2)$ [RS-a]



LMY $R_1,R_3,D_2(B_2)$ [RSY-a]



LMG $R_1,R_3,D_2(B_2)$ [RSY-a]



Bit positions of the set of general registers starting with general register R_1 and ending with general register R_3 are loaded from storage beginning at the location designated by the second-operand address and continuing through as many locations as needed.

For LOAD MULTIPLE (LM, LMY), bit positions 32-63 of the general registers are loaded from successive four-byte fields beginning at the second-operand address, and bits 0-31 of the registers remain unchanged. For LOAD MULTIPLE (LMG), bit positions 0-63 of the general registers are loaded from successive eight-byte fields beginning at the second-operand address.

The general registers are loaded in the ascending order of their register numbers, starting with general register R_1 and continuing up to and including general register R_3, with general register 0 following general register 15.

The displacement for LM is treated as a 12-bit unsigned binary integer. The displacement for LMY and LMG is treated as a 20-bit signed binary integer.

Condition Code: The code remains unchanged.

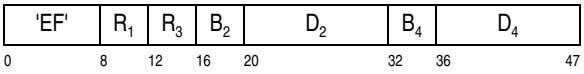
Program Exceptions:

- Access (fetch, operand 2)
- Operation (LMY, if the long-displacement facility is not installed)

Programming Note: All combinations of register numbers specified by R_1 and R_3 are valid. When the register numbers are equal, only four bytes, for LM or LMY or eight bytes, for LMG, are transmitted. When the number specified by R_3 is less than the number specified by R_1, the register numbers wrap around from 15 to 0.

LOAD MULTIPLE DISJOINT

LMD $R_1,R_3,D_2(B_2),D_4(B_4)$ [SS-e]



Bit positions 0-31 of the set of general registers starting with general register R_1 and ending with general register R_3 are loaded from storage beginning at the location designated by the second-operand address and continuing through as many locations as needed. Bit positions 32-63 of the same registers are similarly loaded from storage beginning at the location designated by the fourth-operand address.

The general registers are loaded in the ascending order of their register numbers, starting with general register R_1 and continuing up to and including general register R_3, with general register 0 following general register 15.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operands 2 and 4)
- Transaction constraint

Programming Notes:

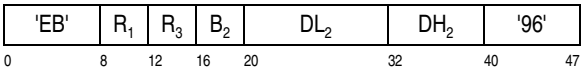
1. All combinations of register numbers specified by R_1 and R_3 are valid. When the register numbers are equal, only eight bytes are transmitted. When the number specified by R_3 is less than the number specified by R_1, the register numbers wrap around from 15 to 0.

2. The second-operand and fourth-operand addresses are computed before the contents of any register are changed.

3. The combination of a LOAD MULTIPLE instruction and a LOAD MULTIPLE HIGH instruction provides equal or better performance than a LOAD MULTIPLE DISJOINT instruction for the same register range. LOAD MULTIPLE DISJOINT is for use when the second or fourth operand must be addressed by means of one of the registers loaded.

LOAD MULTIPLE HIGH

LMH $R_1,R_3,D_2(B_2)$ [RSY-a]



The high-order halves, bit positions 0-31, of the set of general registers starting with general register R_1 and ending with general register R_3 are loaded from storage beginning at the location designated by the second-operand address and continuing through as many locations as needed, that is, bit positions 0-31 are loaded from successive four-byte fields beginning at the second-operand address. Bits 32-63 of the registers remain unchanged.

The general registers are loaded in the ascending order of their register numbers, starting with general register R_1 and continuing up to and including general register R_3, with general register 0 following general register 15.

Condition Code: The code remains unchanged.

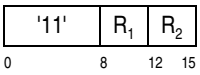
Program Exceptions:

- Access (fetch, operand 2)

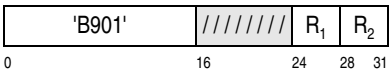
Programming Note: All combinations of register numbers specified by R_1 and R_3 are valid. When the register numbers are equal, only four bytes are transmitted. When the number specified by R_3 is less than the number specified by R_1, the register numbers wrap around from 15 to 0.

LOAD NEGATIVE

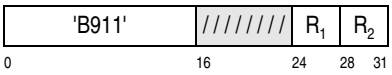
LNR R_1,R_2 [RR]



LNGR R_1,R_2 [RRE]



LNGFR R_1,R_2 [RRE]



The two's complement of the absolute value of the second operand is placed at the first-operand location. For LOAD NEGATIVE (LNR), the second operand and result are treated as 32-bit signed binary integers, and, for LOAD NEGATIVE (LNGR), they are treated as 64-bit signed binary integers. For LOAD NEGATIVE (LNGFR), the second operand is treated as a 32-bit signed binary integer, and the result is treated as a 64-bit signed binary integer.

Resulting Condition Code:

0 Result zero
1 Result less than zero
2 --
3 --

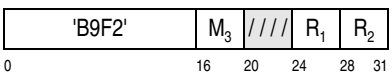
Program Exceptions: None.

Programming Note: The operation complements positive numbers; negative numbers remain unchanged. The number zero remains unchanged.

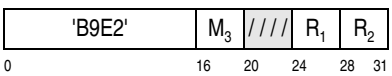
LOAD ON CONDITION

Register-and-register formats:

LOCR R_1,R_2,M_3 [RRF-c]

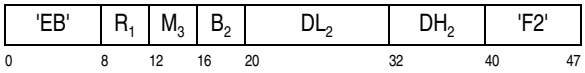


LOCGR R_1,R_2,M_3 [RRF-c]

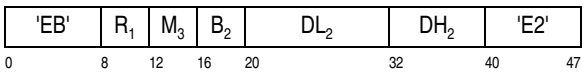


Register-and-storage formats:

LOC $R_1,D_2(B_2),M_3$ [RSY-b]

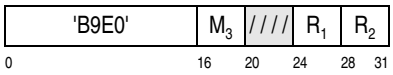


LOCG $R_1,D_2(B_2),M_3$ [RSY-b]

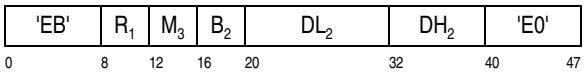


LOAD HIGH ON CONDITION

LOCFHR R_1,R_2,M_3 [RRF-c]



LOCFH $R_1,D_2(B_2),M_3$ [RSY-b]



The second operand is placed unchanged at the first-operand location if the condition code has one of the values specified by M_3; otherwise, the first operand remains unchanged.

For LOC, LOCFH, LOCFHR, and LOCR, the first and second operands are 32 bits, and for LOCG and LOCGR, the first and second operands are 64 bits.

For LOC and LOCR, the first operand is in bits 32-63 of general register R_1, and bits 0-31 of the register are unchanged. For LOCFH and LOCFHR, the first operand is in bits 0-31 of general register R_1, and bits 32-63 of the register are unchanged.

For LOCR, the second operand is in bits 32-63 of general register R_2, and bits 0-31 of the register are ignored. For LOCFHR, the second operand is in bits 0-31 of general register R_2, and bits 32-63 of the register are ignored.

The M_3 field is used as a four-bit mask. The four condition codes (0, 1, 2, and 3) correspond, left to right, with the four bits of the mask, as follows:

Condition Code	0	1	2	3
Mask Position Value	8	4	2	1

The current condition code is used to select the corresponding mask bit. If the mask bit selected by the condition code is one, the load is performed. If the mask bit selected is zero, the load is not performed.

The displacement for LOC, LOCFH, and LOCG is treated as a 20-bit signed binary integer.

For LOC, LOCFH, and LOCG, when the condition specified by the M_3 field is not met (that is, the load operation is not performed), it is model dependent whether an access exception or a PER zero-address detection event is recognized for the second operand.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2 of LOC, LOCFH, and LOCG)
- Operation (LOC, LOCG, LOCGR, LOCR, if the load/store-on-condition facility 1 is not installed; LOCFH, LOCFHR, if the load/store-on-condition facility 2 is not installed)

Programming Notes:

1. When the M_3 field contain all zeros and no exception condition exists, the instruction acts as a NOP. When the M_3 field contains all ones and no exception condition exists, the load operation is always performed. However, these are not the preferred means of implementing a NOP or unconditional load, respectively.

2. For LOC, LOCFH, and LOCG, when the condition specified by the M_3 field is not met, it is model dependent whether the second operand is brought into the cache.

3. LOAD ON CONDITION provides a function similar to that of a separate BRANCH ON CONDITION instruction followed by a LOAD instruction, except that LOAD ON CONDITION does not provide an index register. For example, the following two instruction sequences are equivalent.

```
LOCG    15,256(7),8          BC      7,SKIP
                             LG      15,256(0,7)
                        SKIP DS      0H
```

   On models that implement predictive branching, the combination of the BRANCH ON CONDITION and LOAD instructions may perform some-

what better than the LOAD ON CONDITION instruction when the CPU is able to successfully predict the branch condition. However, on models where the CPU is not able to successfully predict the branch condition, such as when the condition is more random, the LOAD ON CONDITION instruction may provide significant performance improvement.

4. The High-Level Assembler (HLASM) provides the following extended-mnemonic suffixes for the load/store-on-condition facilities' instructions in place of the M_3 field.

Suffix	Meaning	Effective M_3 Value
E	Equal	B'1000'
L	Low	B'0100'
H	High	B'0010'
NE	Not equal	B'0111'
NL	Not low	B'1011'
NH	Not high	B'1101'

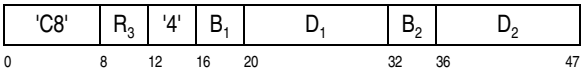
Later versions of HLASM provide the following extended-mnemonic suffixes for the load/store-on-condition facilities' instructions in place of the M_3 field.

Suffix	Meaning	Effective M_3 Value
Z	Zero	B'1000'
M	Minus or mixed	B'0100'
P	Plus	B'0010'
O	Overflow or ones	B'0001'
NZ	Not zero	B'0111'
NM	Not minus or not mixed	B'1011'
NP	Not plus	B'1101'
NO	Not overflow or not ones	B'1110'

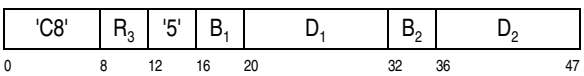
When the extended mnemonic is coded, the M_3 field must be omitted.

LOAD PAIR DISJOINT

LPD $R_3,D_1(B_1),D_2(B_2)$ [SSF]



LPDG $R_3,D_1(B_1),D_2(B_2)$ [SSF]



General register R_3 designates the even numbered register of an even-odd register pair.

The first operand is placed unchanged into the even-numbered register of the third operand, and the second operand is placed unchanged into odd-numbered register of the third operand. The condition code indicates whether the first and second operands appear to be fetched by means of an interlocked fetch.

For LPD, the first and second operands are words in storage, and the third operand is in bits 32-63 of general registers R_3 and $R_3 + 1$; bits 0-31 of the registers are unchanged. For LPDG, the first and second operands are doublewords in storage, and the third operand is in bits 0-63 of general registers R_3 and $R_3 + 1$.

Each of the two operand accesses is block concurrent as observed by other CPUs.

When, as observed by other CPUs, the first and second operands appear to be fetched by means of an interlocked fetch, condition code 0 is set. When the first and second operands do not appear to be fetched by means of an interlocked fetch, condition code 3 is set. The third operand is loaded regardless of the condition code.

The displacement of the first and second operands is treated as a 12-bit unsigned binary integer.

The first and second operands of LPD must be designated on a word boundary. The first and second operands of LPDG must be designated on a doubleword boundary. General register R_3 must designate the even numbered register. Otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Register pair loaded by means of interlocked fetch
1 --
2 --
3 Register pair not loaded by means of interlocked fetch

Program Exceptions:

- Access (fetch, operands 1 and 2)
- Operation (if the interlocked-access facility 1 is not installed)
- Specification

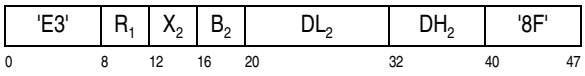
- Transaction constraint

Programming Notes:

1. The setting of the condition code is dependent upon storage accesses by other CPUs in the configuration.
2. When the resulting condition code is 3, the program may branch back to re-execute the LOAD PAIR DISJOINT instruction. However, after repeated unsuccessful attempts to attain an interlocked fetch, the program should use an alternate means of serializing access to the storage operands. It is recommended that the program re-execute the LOAD PAIR DISJOINT no more than 10 times before branching to the alternate path.
3. The program should be able to accommodate a situation where condition code 0 is never set.
4. When the PLO-extension facility is installed and an interlocked fetch is required, the PERFORM LOCKED OPERATION functions PLO.TL and PLO.TLG provide alternatives to LPD and LPDG, respectively. When using a PLO triple load function and only two operands are required, the program can specify the same address and ALET for two of the three operands.

LOAD PAIR FROM QUADWORD

LPQ $R_1,D_2(X_2,B_2)$ [RXY-a]



The quadword second operand is loaded into the first-operand location. The second operand appears to be fetched with quadword concurrency as observed by other CPUs. The left doubleword of the quadword is loaded into general register R_1, and the right doubleword is loaded into general register $R_1 + 1$.

The R_1 field designates an even-odd pair of general registers and must designate an even-numbered register. The second operand must be designated on a quadword boundary. Otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

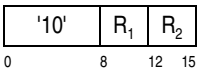
- Access (fetch, operand 2)
- Specification
- Transaction constraint

Programming Notes:

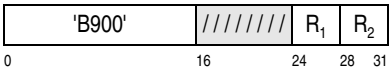
1. The LOAD MULTIPLE (LM or LMG) instruction does not necessarily provide quadword-concurrent access.
2. It is model dependent whether the performance of LOAD MULTIPLE (LMG) with two general registers specified and LOAD PAIR FROM QUADWORD are similar or differ significantly.

LOAD POSITIVE

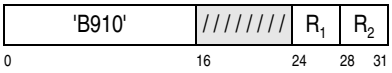
LPR R_1,R_2 [RR]



LPGR R_1,R_2 [RRE]



LPGFR R_1,R_2 [RRE]



The absolute value of the second operand is placed at the first-operand location. For LOAD POSITIVE (LPR), the second operand and result are treated as 32-bit signed binary integers, and, for LOAD POSITIVE (LPGR), they are treated as 64-bit signed binary integers. For LOAD POSITIVE (LPGFR), the second operand is treated as a 32-bit signed binary integer, and the result is treated as a 64-bit signed binary integer.

When there is an overflow, the result is obtained by allowing any carry into the sign-bit position and ignoring any carry out of the sign-bit position, and condition code 3 is set. If the fixed-point-overflow mask is one, a program interruption for fixed-point overflow occurs.

Resulting Condition Code:

0 Result zero; no overflow
1 --
2 Result greater than zero; no overflow
3 Overflow

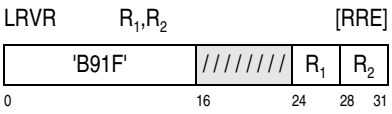
Program Exceptions:

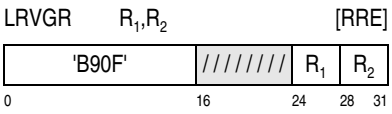
- Fixed-point overflow (LPR and LPGR only)

Programming Note: The operation complements negative numbers; positive numbers and zero remain unchanged. For LPR or LPGR, an overflow condition occurs when the maximum negative 32-bit number or 64-bit number, respectively, is complemented; the number remains unchanged. LPGFR complements the maximum negative 32-bit number without recognizing overflow.

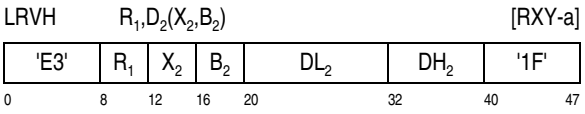
LOAD REVERSED

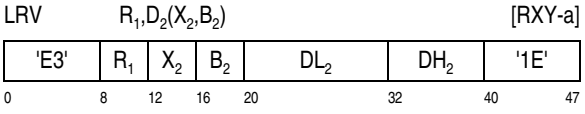
Register-and-register formats:

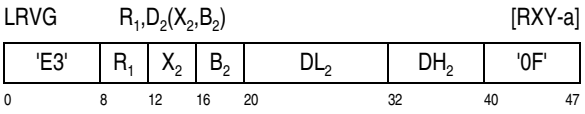




Register-and-storage formats:







The second operand is placed at the first-operand location with the left-to-right sequence of the bytes reversed.

For LOAD REVERSED (LRVH), the second operand is two bytes, the result is placed in bit positions 48-63 of general register R_1, and bits 0-47 of the register remain unchanged.

For LOAD REVERSED (LRVR, LRV), the second operand is four bytes, the result is placed in bit positions 32-63 of general register R_1, and bits 0-31 of the register remain unchanged. For LOAD REVERSED (LRVR), the second operand is in bit positions 32-63 of general register R_2.

For LOAD REVERSED (LRVGR, LRVG), the second operand is eight bytes.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2 of LRVH, LRV, LRVG only)

Programming Notes:

1. The instruction can be used to convert two, four, or eight bytes from a “little-endian” format to a “big-endian” format, or vice versa. In the big-endian format, the bytes in a left-to-right sequence are in the order most significant to least significant. In the little-endian format, the bytes are in the order least significant to most significant. For example, the bytes ABCD in the big-endian format are DCBA in the little-endian format.

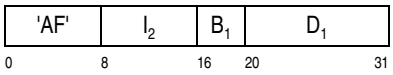
2. LOAD REVERSED (LRVR) can be used with a two-byte value already in a register as shown in the following example. In the example, the two bytes of interest are in bit positions 48-63 of the R1 register.

   ```
   LRVR   R1,R1
   SRA    R1,16
   ```

   The LOAD REVERSED instruction places the two bytes of interest in bit positions 32-47 of the register, with the order of the bytes reversed. The SHIFT RIGHT SINGLE (SRA) instruction shifts the two bytes to bit positions 48-63 of the register and extends them on their left, in bit positions 32-47, with their sign bit. The instruction SHIFT RIGHT SINGLE LOGICAL (SRL) should be used, instead, if the two bytes of interest are unsigned.

MONITOR CALL

MC $D_1(B_1),I_2$ [SI]



Subject to the control of the monitor class and the monitor masks, a monitor event may be recognized. When the enhanced-monitor facility is not installed, a monitor event results in a monitor-event program interruption. When the enhanced-monitor facility is installed, a monitor event results in either a monitor-event program interruption or a monitor-event counting operation.

Bit positions 12-15 of the instruction (bit positions 4-7 of the I_2 field) contain a 4-bit unsigned binary number specifying the monitor class. The monitor-mask bits are in bit positions 48-63 of control register 8, which correspond to monitor classes 0-15, respectively.

When the monitor-mask bit corresponding to the specified monitor class is one, a monitor event occurs. When the monitor-mask bit corresponding to the specified monitor class is zero, no monitor-event occurs, and the instruction is executed as a no-operation.

When the enhanced-monitor facility is installed, the enhanced-monitor-mask bits are in bit positions 16-31 of control register 8, which correspond to monitor classes 0-15 respectively. When a monitor event occurs and either (a) the enhanced-monitor facility is not installed, or (b) the facility is installed but the enhanced-monitor-mask bit corresponding to the monitor class is zero, then a monitor-event program interruption occurs, as described below. When a monitor event occurs and the enhanced-monitor-mask bit corresponding to the monitor class is one, a monitor-event counting operation is performed.

The first-operand address is not used to address data; instead, the address specified by the B_1 and D_1 fields forms the monitor code. Address computation follows the rules of address arithmetic; in the 24-bit addressing mode, bits 0-39 are set to zeros; in the 31-bit addressing mode, bits 0-32 are set to zeros.

Monitor-Event Program Interruption

When a monitor-event program interruption occurs:

- The monitor code formed by the first-operand address is placed in the doubleword at real location 176.
- The contents of the I_2 field are stored at real location 149, with zeros stored at real location 148.
- Bit 9 of the program-interruption code is set to one.

Monitor-Event Counting Operation

The monitor-event counting operation is described in “Monitor-Event Counting” on page 5-116.

Special Conditions

Bit positions 8-11 of the instruction must contain zeros; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Monitor event
- Specification
- Transaction constraint

Programming Notes:

1. The monitor-event program interruption provides the capability for passing control to a monitoring program when selected points are reached in the monitored program. This is accomplished by implanting MONITOR CALL instructions at the desired points in the monitored program. This function may be useful in performing various measurement functions; specifically, tracing information can be generated indicating which programs were executed, counting information can be generated indicating how often particular programs were used, and timing information can be generated indicating the amount of time a particular program required for execution.
2. The monitor masks provide a means of disallowing all monitor events or allowing monitor events for all or selected classes.
3. When used to generate a monitor-event program interruption, the monitor code provides a means of associating descriptive information, in addition to the class number, with each MONITOR CALL.

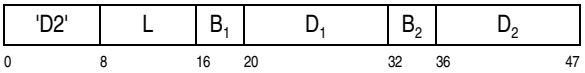
Without the use of a base register, up to 4,096 distinct monitor codes can be associated with a monitor event. With the base register designated by a nonzero value in the B_1 field, each monitoring interruption can be identified by a 24-bit, 31-bit, or 64-bit code, depending on the addressing mode.

4. A monitor-event counting operation can never occur in the ESA/390-compatibility mode.

MOVE

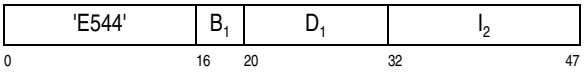
Storage-and-storage format:

MVC $D_1(L,B_1),D_2(B_2)$ [SS-a]

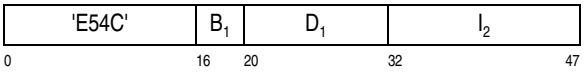


Storage-and-immediate formats:

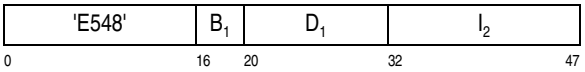
MVHHI $D_1(B_1),I_2$ [SIL]



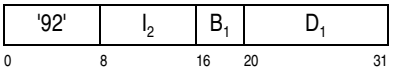
MVHI $D_1(B_1),I_2$ [SIL]



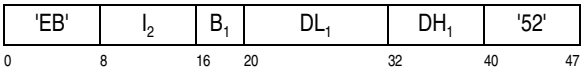
MVGHI $D_1(B_1),I_2$ [SIL]



MVI $D_1(B_1),I_2$ [SI]



MVIY $D_1(B_1),I_2$ [SIY]



The second operand is placed at the first-operand location.

For MOVE (MVC), each operand is processed left to right. When the operands overlap, the result is obtained as if the operands were processed one byte at a time and each result byte were stored immediately after fetching the necessary operand byte.

For MOVE (MVI, MVIY), the first operand is one byte in length, and only one byte is stored.

For MOVE (MVGHI, MVHHI, and MVHI), the second operand is treated as a 16-bit signed integer, sign-extended as necessary, and placed in the first-operand location. The first operand is two, four, or eight bytes for MVHHI, MVHI, and MVGHI, respectively.

The displacements for MVGHI, MVHHI, MVHI, MVI and both operands of MVC are treated as 12-bit unsigned binary integers. The displacement for MVIY is treated as a 20-bit signed binary integer.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2 of MVC; store, operand 1, MVC, MVGHI, MVHHI, MVHI, MVI, and MVIY)
- Operation (MVIY, if the long-displacement facility is not installed; MVGHI, MVHHI, and MVHI, if the general-instructions-extension facility is not installed)
- Transaction constraint (MVC)

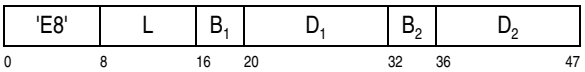
Programming Notes:

1. Examples of the use of the MOVE instruction are given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. For MOVE (MVC), it is possible to propagate one byte through an entire field by having the first operand start one byte to the right of the second operand.

MOVE INVERSE

MVCIN $D_1(L,B_1),D_2(B_2)$ [SS-a]



The second operand is placed at the first-operand location with the left-to-right sequence of the bytes inverted.

The first-operand address designates the leftmost byte of the first operand. The second-operand address designates the rightmost byte of the second operand. Both operands have the same length.

The result is obtained as if the second operand were processed from right to left and the first operand from left to right. The second operand may wrap around from location 0 to location $2^{24} - 1$ in the 24-bit addressing mode, to location $2^{31} - 1$ in the 31-bit addressing mode, or to location $2^{64} - 1$ in the 64-bit addressing mode. The first operand may wrap around from location $2^{24} - 1$ to location 0 in the 24-bit addressing mode, from location $2^{31} - 1$ to location 0 in the 31-bit addressing mode, or from location $2^{64} - 1$ to location 0 in the 64-bit addressing mode.

When the operands overlap by more than one byte, the contents of the overlapped portion of the result field are unpredictable.

Condition Code: The code remains unchanged.

Program Exceptions:

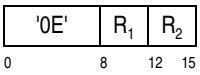
- Access (fetch, operand 2; store, operand 1)
- Transaction constraint

Programming Notes:

1. An example of the use of the MOVE INVERSE instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”
2. The contents of each byte moved remain unchanged.
3. MOVE INVERSE is the only SS-format instruction for which the second-operand address designates the rightmost, instead of the leftmost, byte of the second operand.
4. The storage-operand references for MOVE INVERSE may be multiple-access references. (See “Storage-Operand Consistency” on page 5-133)

MOVE LONG

MVCL R_1,R_2 [RR]



The second operand is placed at the first-operand location, provided overlapping of operand locations would not affect the final contents of the first-operand location. The remaining rightmost byte positions, if any, of the first-operand location are filled with padding bytes.

The R_1 and R_2 fields each designate an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The location of the leftmost byte of the first operand and second operand is designated by the contents of general registers R_1 and R_2, respectively. The number of bytes in the first-operand and second-operand locations is specified by unsigned binary integers in bit positions 40-63 of general registers $R_1 + 1$ and $R_2 + 1$, respectively. Bit positions 32-39 of general register $R_2 + 1$ contain the padding byte. The contents of bit positions 0-39 of general register $R_1 + 1$ and of bit positions 0-31 of general register $R_2 + 1$ are ignored.

The handling of the addresses in general registers R_1 and R_2 is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers R_1 and R_2 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the registers constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 constitute the address.

The contents of the registers just described are shown in Figure 7-335.

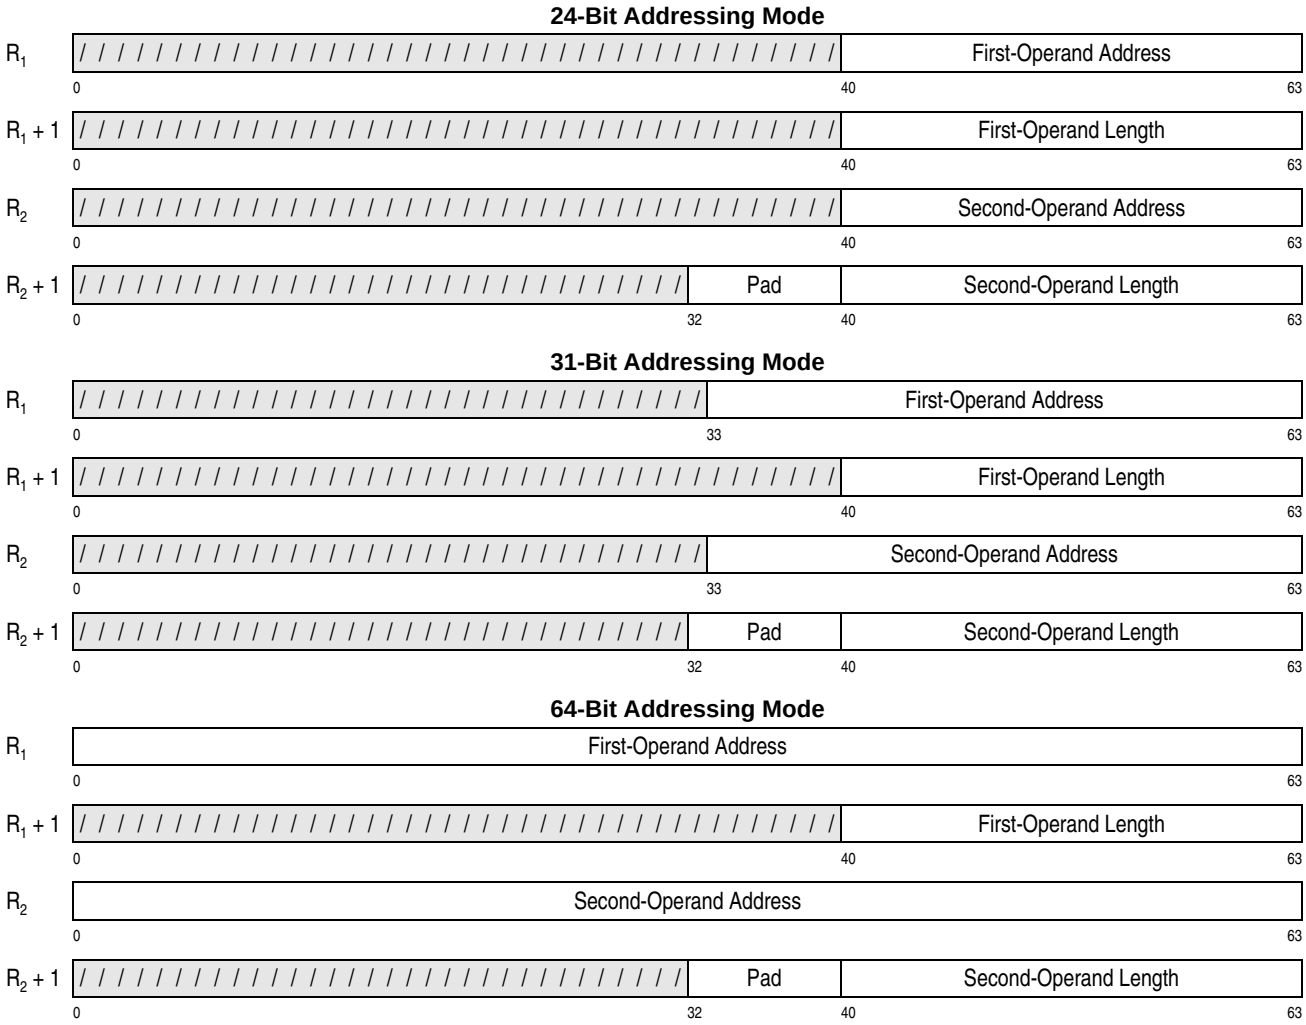


Figure 7-335. Register Contents for MOVE LONG

The result is obtained as if the movement starts at the left end of both fields and proceeds to the right, byte by byte. The operation is ended when the number of bytes specified by bits 40-63 of general register $R_1 + 1$ have been moved into the first-operand location. If the second operand is shorter than the first operand, the remaining rightmost bytes of the first-operand location are filled with the padding byte.

As part of the execution of the instruction, the values of the two length fields are compared for the setting of the condition code, and a check is made for destructive overlap of the operands. Operands are said to overlap destructively when the first-operand location is used as a source after data has been moved into it, assuming the inspection for overlap is performed by the use of logical operand addresses. When the operands overlap destructively, no movement takes place, and condition code 3 is set.

Operands do not overlap destructively, and movement is performed, if the leftmost byte of the first operand does not coincide with any of the second-operand bytes participating in the operation other than the leftmost byte of the second operand. When an operand wraps around from location $2^{24} - 1$ (or $2^{31} - 1$ or $2^{64} - 1$) to location 0, operand bytes in locations up to and including $2^{24} - 1$ (or $2^{31} - 1$ or $2^{64} - 1$) are considered to be to the left of bytes in locations from 0 up.

In the 24-bit addressing mode, wraparound is from location 2^{24} - 1 to location 0; in the 31-bit addressing mode, wraparound is from location 2^{31} - 1 to location 0; in the 64-bit addressing mode, wraparound is from location 2^{64} - 1 to location 0.

In the access-register mode, the contents of access register R_1 and access register R_2 are compared. If the R_1 or R_2 field is zero, 32 zeros are used rather than the contents of access register 0. If all 32 bits of the compared values are equal, then the destructive overlap test is made. If all 32 bits of the compared values are not equal, destructive overlap is declared not to exist. If, for this case, the operands actually overlap in real storage, it is unpredictable whether the result reflects the overlap condition.

When the length specified by bits 40-63 of general register $R_1 + 1$ is zero, no movement takes place, and condition code 0 or 1 is set to indicate the relative values of the lengths.

The execution of the instruction is interruptible. When an interruption occurs, other than one that follows termination, the lengths in general registers $R_1 + 1$ and $R_2 + 1$ are decremented by the number of bytes moved, and the addresses in general registers R_1 and R_2 are incremented by the same number, so that the instruction, when reexecuted, resumes at the point of interruption. In the 24-bit or 31-bit addressing mode, the leftmost bits which are not part of the address in bit positions 32-63 of general registers R_1 and R_2 are set to zeros, and the contents of bit positions 0-31 remain unchanged. In any addressing mode, the contents of bit positions 0-39 of general registers $R_1 + 1$ and $R_2 + 1$ remain unchanged; and the condition code is unpredictable. If the operation is interrupted during padding, the length field in general register $R_2 + 1$ is 0, the address in general register R_2 is incremented by the original length in general register $R_2 + 1$, and general registers R_1 and $R_1 + 1$ reflect the extent of the padding operation.

When the first-operand location includes the location of the instruction or of an execute-type instruction, the instruction may be refetched from storage and reinterpreted even in the absence of an interruption during execution. The exact point in the execution at which such a refetch occurs is unpredictable.

Padding byte values of B0 hex and B8 hex may be used during the nonpadding part of the operation by some models, in certain cases, as an indication of whether the movement should be performed bypassing the cache or using the cache, respectively. Thus, a padding byte of B0 hex indicates no intention to reference the destination area after the move, and a padding byte of B8 hex indicates an intention to reference the destination area.

For the nonpadding part of the operation when the padding byte is not B1 hex, accesses to the operands for MOVE LONG may be multiple-access references, and these accesses do not necessarily appear to occur in a left-to-right direction as observed by other CPUs and by the channel subsystem. When the padding byte is B1 hex, accesses to the operands are single-access references, and these accesses appear to occur in a left-to-right direction as observed by other CPUs and by the channel subsystem. During the nonpadding part of the operation, operands appear to be accessed doubleword concurrent as observed by other CPUs, provided that both operands start on doubleword boundaries, are an integral number of doublewords in length, and do not overlap.

As observed by other CPUs and by the channel subsystem, that portion of the first operand which is filled with the padding byte is not necessarily stored into in a left-to-right direction and may appear to be stored into more than once. During the padding operation, stores by other CPUs or by the channel subsystem into that portion of the first operand which is filled with the padding byte may cause unpredictable results.

At the completion of the operation, the length in general register $R_1 + 1$ is decremented by the number of bytes stored at the first-operand location, and the address in general register R_1 is incremented by the same amount. The length in general register $R_2 + 1$ is decremented by the number of bytes moved out of the second-operand location, and the address in general register R_2 is incremented by the same amount. In the 24-bit or 31-bit addressing mode, the leftmost bits which are not part of the address in bit positions 32-63 of general registers R_1 and R_2 are set to zeros, even when one or both of the original length values are zeros or when condition code 3 is set. The contents of bit positions 0-31 of the registers remain unchanged. In any addressing mode, the contents of bit positions 0-39 of general registers $R_1 + 1$ and $R_2 + 1$ remain unchanged.

When condition code 3 is set, no exceptions associated with operand access are recognized. When the length of an operand is zero, no access exceptions

for that operand are recognized. Similarly, when the second operand is longer than the first operand, access exceptions are not recognized for the part of the second-operand field that is in excess of the first-operand field. For operands longer than 2K bytes, access exceptions are not recognized for locations more than 2K bytes beyond the current location being processed. Access exceptions are not recognized for an operand if the R field associated with that operand is odd. Also, when the R_1 field is odd, PER storage-alteration events are not recognized, and no change bits are set.

Resulting Condition Code:

0 Operand lengths equal; no destructive overlap
1 First-operand length low; no destructive overlap
2 First-operand length high; no destructive overlap
3 No movement performed because of destructive overlap

Program Exceptions:

- Access (fetch, operand 2; store, operand 1)
- Specification
- Transaction constraint

Programming Notes:

1. An example of the use of the MOVE LONG instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. MOVE LONG may be used for clearing storage by setting the padding byte to zero and the second-operand length to zero. However, the stores associated with this clearing may be multiple-access stores and should not be used to clear an area if the possibility exists that another CPU or a channel program will attempt to access and use the area as soon as it appears to be zero. For more details, see “Storage-Operand Consistency” on page 5-133.

3. When the first-operand length is zero, the operation consists in setting the condition code and, in the 24-bit or 31-bit addressing mode, of setting the leftmost bits in bit positions 32-63 of general registers R_1 and R_2 to zero.

4. When the contents of the R_1 and R_2 fields are the same, the contents of the designated registers are incremented or decremented only by the number of bytes moved, not by twice the number of bytes moved. Condition code 0 is set.

5. The following is a detailed description of those cases in which movement takes place, that is, where destructive overlap does not exist.

   In the access-register mode, the contents of the access registers used are called the effective space designations. When the effective space designations are not equal, destructive overlap is declared not to exist and movement occurs. When the effective space designations are the same or when not in the access-register mode, then the following cases apply.

   Depending on whether the second operand wraps around from location $2^{24} - 1$ (or $2^{31} - 1$ or $2^{64} - 1$, depending on the addressing mode) to location 0, movement takes place in the following cases:

   a. When the second operand does not wrap around, movement is performed if the leftmost byte of the first operand coincides with or is to the left of the leftmost byte of the second operand, *or* if the leftmost byte of the first operand is to the right of the rightmost second-operand byte participating in the operation.

   b. When the second operand wraps around, movement is performed if the leftmost byte of the first operand coincides with or is to the left of the leftmost byte of the second operand, *and* if the leftmost byte of the first operand is to the right of the rightmost second-operand byte participating in the operation.

   The rightmost second-operand byte is determined by using the smaller of the first-operand and second-operand lengths.

   When the second-operand length is one or zero, destructive overlap cannot exist.

6. Special precautions should be taken if MOVE LONG is made the target of an execute-type instruction. See the programming note concerning interruptible instructions under EXECUTE.

7. Since the execution of MOVE LONG is interruptible, the instruction cannot be used for situations where the program must rely on uninterrupted execution of the instruction. Similarly, the program should normally not let the first operand of MOVE LONG include the location of the instruction or of an execute-type instruction because the new contents of the location may be interpreted

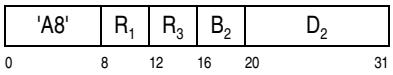
for a resumption after an interruption, or the instruction may be refetched without an interruption.

8. Further programming notes concerning interruptible instructions are included in “Interruptible Instructions” in Chapter 5, “Program Execution.”

9. In the access-register mode, access register 0 designates the primary address space regardless of the contents of access register 0.

MOVE LONG EXTENDED

MVCLE $R_1,R_3,D_2(B_2)$ [RS-a]



All or part of the third operand is placed at the first-operand location. The remaining rightmost byte positions, if any, of the first-operand location are filled with padding bytes. The operation proceeds until the end of the first-operand location is reached or a CPU-determined number of bytes have been placed at the first-operand location, whichever occurs first. The result is indicated in the condition code.

The R_1 and R_3 fields each designate an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The location of the leftmost byte of the first operand and third operand is designated by the contents of general registers R_1 and R_3, respectively. In the 24-bit or 31-bit addressing mode, the number of bytes in the first-operand and third-operand locations is specified by the contents of bit positions 32-63 of general registers $R_1 + 1$ and $R_3 + 1$, respectively, and those contents are treated as 32-bit unsigned binary integers. In the 64-bit addressing mode, the number of bytes in the first-operand and third-operand locations is specified by the entire contents of general registers $R_1 + 1$ and $R_3 + 1$, respectively, and those contents are treated as 64-bit unsigned binary integers.

The handling of the addresses in general registers R_1 and R_3 is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers R_1 and R_3 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the registers constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 constitute the address.

The second-operand address is not used to address data; instead, the rightmost eight bits of the second-operand address, bits 56-63, are the padding byte. Bits 0-55 of the second-operand address are ignored.

The contents of the registers and address just described are shown in Figure 7-336.

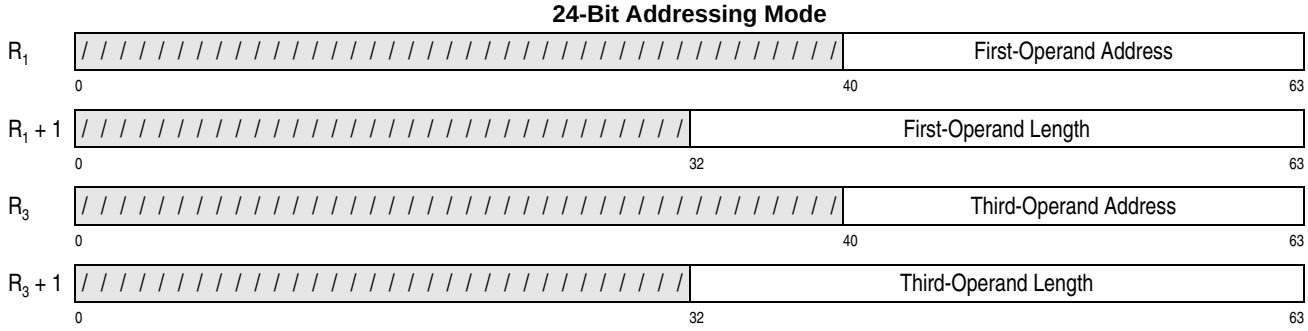


Figure 7-336. Register Contents and Second-Operand Address for MOVE LONG EXTENDED (Part 1 of 2)

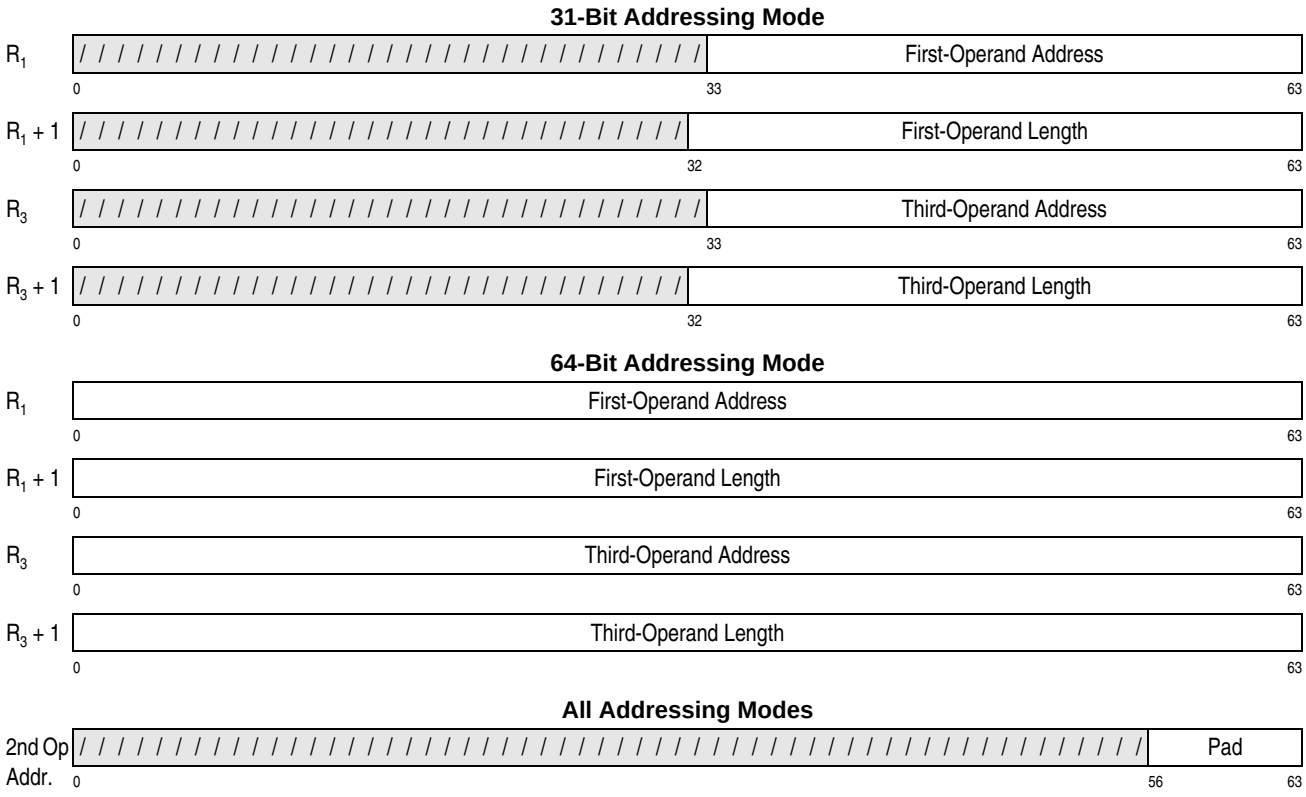

Figure 7-336. Register Contents and Second-Operand Address for MOVE LONG EXTENDED (Part 2 of 2)

The result is obtained as if the movement starts at the left end of both fields and proceeds to the right, byte by byte. The operation is ended when the number of bytes specified in general register $R_1 + 1$ have been placed at the first-operand location or when a CPU-determined number of bytes have been placed, whichever occurs first. If the third operand is shorter than the first operand, the remaining rightmost bytes of the first-operand location are filled with the padding byte.

When the operation is completed because the end of the first operand has been reached, the condition code is set to 0 if the two operand lengths are equal, it is set to 1 if the first-operand length is less than the third-operand length, or it is set to 2 if the first-operand length is greater than the third-operand length. When the operation is completed because a CPU-determined number of bytes have been moved without reaching the end of the first operand, condition code 3 is set.

No test is made for destructive overlap, and the results in the first-operand location are unpredictable when destructive overlap exists. Operands are said to overlap destructively when the first-operand location is used as a source after data has been moved into it.

Operands do not overlap destructively if the leftmost byte of the first operand does not coincide with any of the third-operand bytes participating in the operation other than the leftmost byte of the third operand. When an operand wraps around from location $2^{24} - 1$ (or $2^{31} - 1$ or $2^{64} - 1$) to location 0, operand bytes in locations up to and including $2^{24} - 1$ (or $2^{31} - 1$ or $2^{64} - 1$) are considered to be to the left of bytes in locations from 0 up.

In the 24-bit addressing mode, wraparound is from location $2^{24} - 1$ to location 0; in the 31-bit addressing mode, wraparound is from location $2^{31} - 1$ to location 0; and, in the 64-bit addressing mode, wraparound is from location $2^{64} - 1$ to location 0.

When the length specified in general register $R_1 + 1$ is zero, no movement takes place, and condition code 0 or 1 is set to indicate the relative values of the lengths.

Padding byte values of B0 hex and B8 hex may be used during the nonpadding part of the operation by

some models, in certain cases, as an indication of whether the movement should be performed bypassing the cache or using the cache, respectively. Thus, a padding byte of B0 hex indicates no intention to reference the destination area after the move, and a padding byte of B8 hex indicates an intention to reference the destination area.

For the nonpadding part of the operation when the padding byte is not B1 hex, accesses to the operands for MOVE LONG EXTENDED may be multiple-access references, and these accesses do not necessarily appear to occur in a left-to-right direction as observed by other CPUs and by the channel subsystem. When the padding byte is B1 hex, accesses to the operands are single-access references, and these accesses appear to occur in a left-to-right direction as observed by other CPUs and by the channel subsystem. During the nonpadding part of the operation, operands appear to be accessed doubleword concurrent as observed by other CPUs, provided that both operands start on doubleword boundaries, are an integral number of doublewords in length, and do not overlap.

As observed by other CPUs and by the channel subsystem, that portion of the first operand which is filled with the padding byte is not necessarily stored into in a left-to-right direction and may appear to be stored into more than once. During the padding operation, stores by other CPUs or by the channel subsystem into that portion of the first operand which is filled with the padding byte may cause unpredictable results.

At the completion of the operation, the length in general register $R_1 + 1$ is decremented by the number of bytes stored at the first-operand location, and the address in general register R_1 is incremented by the same amount. The length in general register $R_3 + 1$ is decremented by the number of bytes moved out of the third-operand location, and the address in general register R_3 is incremented by the same amount.

If the operation is completed because a CPU-determined number of bytes have been moved without reaching the end of the first operand, the lengths in general registers $R_1 + 1$ and $R_3 + 1$ are decremented by the number of bytes moved, and the addresses in general registers R_1 and R_3 are incremented by the same number, so that the instruction, when reexecuted, resumes at the next byte to be moved. If the operation is completed during padding, the length field in general register $R_3 + 1$ is zero, the address in general register R_3 is incremented by the original length in general register $R_3 + 1$, and general registers R_1 and $R_1 + 1$ reflect the extent of the padding operation.

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers R_1, $R_1 + 1$, R_3, and $R_3 + 1$, always remain unchanged.

The padding byte may be formed from $D_2(B_2)$ multiple times during the execution of the instruction, and the registers designated by R_1 and R_3 may be updated multiple times. Therefore, if B_2 equals R_1, $R_1 + 1$, R_3, or $R_3 + 1$ and is subject to change during the execution of the instruction, the results are unpredictable.

The amount of processing that results in the setting of condition code 3 is determined by the CPU on the basis of improving system performance, and it may be a different amount each time the instruction is executed. The maximum amount is approximately 4K bytes of either operand.

At the completion of the operation in the 24-bit or 31-bit addressing mode, the leftmost bits which are not part of the address in bit positions 32-63 of general registers R_1 and R_3 may be set to zeros or may remain unchanged from their original values, even when one or both of the original length values are zeros.

When the length of an operand is zero, no access exceptions for that operand are recognized. Similarly, when the third operand is longer than the first operand, access exceptions are not recognized for the part of the third-operand field that is in excess of the first-operand field. For operands longer than 4K bytes, access exceptions are not recognized for locations more than 4K bytes beyond the current location being processed. Access exceptions are not recognized for an operand if the R field associated with that operand is odd. Also, when the R_1 field is odd, PER storage-alteration events are not recognized, and no change bits are set.

Resulting Condition Code:

0 All bytes moved, operand lengths equal
1 All bytes moved, first-operand length low
2 All bytes moved, first-operand length high
3 CPU-determined number of bytes moved without reaching end of first operand

Program Exceptions:

- Access (fetch, operand 3; store, operand 1)
- Specification
- Transaction constraint

Programming Notes:

1. MOVE LONG EXTENDED is intended for use in place of MOVE LONG when the operand lengths are specified as 32-bit or 64-bit binary integers and a test for destructive overlap is not required. MOVE LONG EXTENDED sets condition code 3 in cases in which MOVE LONG would be interrupted.

2. When condition code 3 is set, the program can simply branch back to the instruction to continue the movement. The program need not determine the number of bytes that were moved.

3. The function of not processing more than approximately 4K bytes of either operand is intended to permit software polling of a flag that may be set by a program on another CPU during long operations.

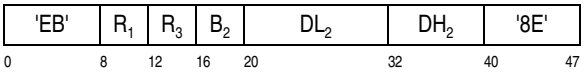
4. MOVE LONG EXTENDED may be used for clearing storage by setting the padding byte to zero and the third-operand length to zero. However, the stores associated with this clearing may be multiple-access stores and should not be used to clear an area if the possibility exists that another CPU or a channel program will attempt to access and use the area as soon as it appears to be zero. For more details, see “Storage-Operand Consistency” on page 5-133.

5. When the contents of the R_1 and R_3 fields are the same, the contents of the designated registers are incremented or decremented only by the number of bytes moved, not by twice the number of bytes moved. The condition code is finally set to 0 after possible settings to 3.

6. In the access-register mode, access register 0 designates the primary address space regardless of the contents of access register 0.

MOVE LONG UNICODE

MVCLU $R_1,R_3,D_2(B_2)$ [RSY-a]



All or part of the third operand is placed at the first-operand location. The remaining rightmost positions, if any, of the first-operand location are filled with one or more padding bytes, alternating between the even padding byte and the odd padding byte. The operation proceeds until the end of the first-operand location is reached or a CPU-determined number of bytes have been placed at the first-operand location, whichever occurs first. The result is indicated in the condition code.

The R_1 and R_3 fields each designate an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The location of the leftmost byte of the first operand and third operand is designated by the contents of general registers R_1 and R_3, respectively. In the 24-bit or 31-bit addressing mode, the number of bytes in the first-operand and third-operand locations is specified by the contents of bit positions 32-63 of general registers $R_1 + 1$ and $R_3 + 1$, respectively, and those contents are treated as 32-bit unsigned binary integers. In the 64-bit addressing mode, the number of bytes in the first-operand and third-operand locations is specified by the contents of bit positions 0-63 of general registers $R_1 + 1$ and $R_3 + 1$, respectively, and those contents are treated as 64-bit unsigned binary integers.

On some models, the contents of general registers $R_1 + 1$ and $R_3 + 1$ must specify an even number of bytes; otherwise, a specification exception is recognized.

The handling of the addresses in general registers R_1 and R_3 is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers R_1 and R_3 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the registers constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 of the registers constitute the address.

The second-operand address is not used to address data; instead, the rightmost 16 bits of the second-operand address, bits 48-63, are the two padding bytes; bits 48-55 are the even padding byte, and bits

56-63 are the odd padding byte. Bits 0-47 of the second-operand address are ignored.

The contents of the registers and address just described are shown in Figure 7-337.

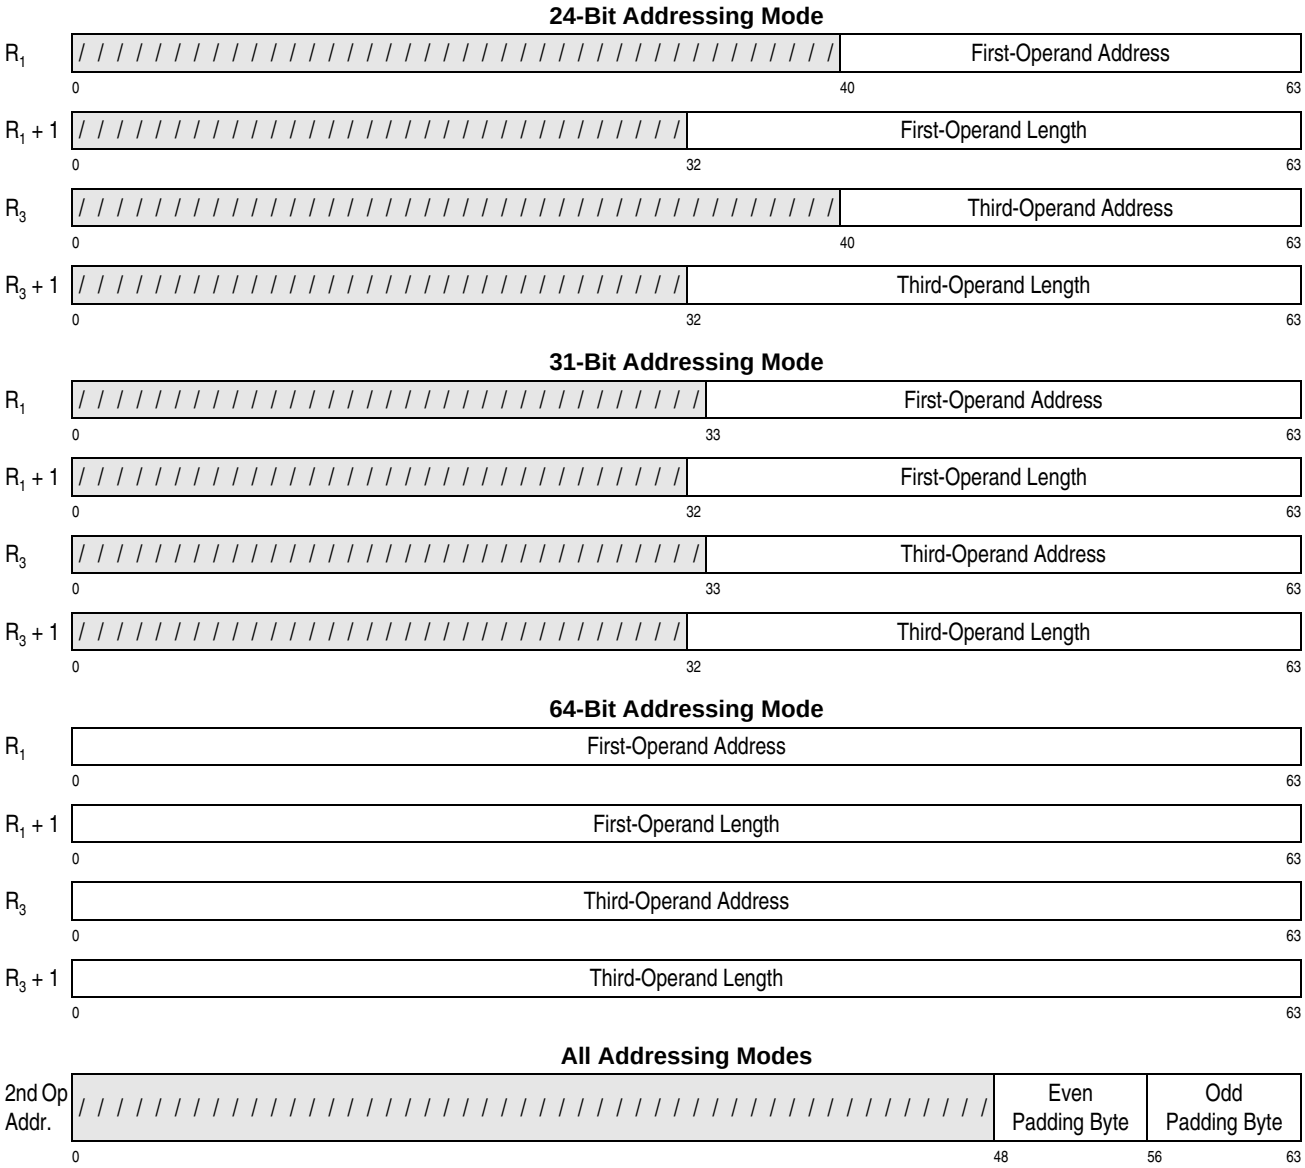


Figure 7-337. Register Contents and Second-Operand Address for MOVE LONG UNICODE

The result is obtained as if the movement starts at the left end of both fields and proceeds to the right, byte by byte. The operation is ended when the number of bytes specified by the contents of general register $R_1 + 1$ have been placed at the first-operand location or when a CPU-determined number of bytes have been placed, whichever occurs first.

If the third operand is shorter than the first operand, the remaining rightmost positions of the first-operand location are filled with alternating padding bytes. When the number of bytes remaining in the first-operand location is an even number, the even padding byte is placed first; when the number of bytes remaining in the first-operand location is odd, the odd padding byte is placed first.

When the operation is completed because the end of the first operand has been reached, the condition code is set to 0 if the two operand lengths are equal, it is set to 1 if the first-operand length is less than the third-operand length, or it is set to 2 if the first-oper-

and length is greater than the third-operand length. When the operation is completed because a CPU-determined number of bytes have been moved without reaching the end of the first operand, condition code 3 is set.

No test is made for destructive overlap, and the results in the first-operand location are unpredictable when destructive overlap exists. Operands are said to overlap destructively when the first-operand location is used as a source after data has been moved into it.

Operands do not overlap destructively if the leftmost byte of the first operand does not coincide with any of the third-operand bytes participating in the operation other than the leftmost byte of the third operand. When an operand wraps around from location $2^{24} - 1$ (or $2^{31} - 1$ or $2^{64} - 1$) to location 0, operand bytes in locations up to and including $2^{24} - 1$ (or $2^{31} - 1$ or $2^{64} - 1$) are considered to be to the left of bytes in locations from 0 up.

In the 24-bit addressing mode, wraparound is from location $2^{24} - 1$ to location 0; in the 31-bit addressing mode, wraparound is from location $2^{31} - 1$ to location 0; and, in the 64-bit addressing mode, wraparound is from location $2^{64} - 1$ to location 0.

When the length specified in general register $R_1 + 1$ is zero, no movement takes place, and condition code 0 or 1 is set to indicate the relative values of the lengths.

For the nonpadding part of the operation, accesses to the operands for MOVE LONG UNICODE may be multiple-access references. These accesses do not necessarily appear to occur in a left-to-right direction as observed by other CPUs and by channel programs. During the nonpadding part of the operation, operands appear to be accessed doubleword concurrent as observed by other CPUs, provided that both operands start on doubleword boundaries, are an integral number of doublewords in length, and do not overlap.

As observed by other CPUs and by he channel subsystem, that portion of the first operand which is filled with the padding bytes is not necessarily stored into in a left-to-right direction and may appear to be stored into more than once. During the padding operation, stores by other CPUs or by the channel subsystem into that portion of the first operand which is filled with the padding bytes may cause unpredictable results.

At the completion of the operation, the length in general register $R_1 + 1$ is decremented by the number of bytes stored at the first-operand location, and the address in general register R_1 is incremented by the same amount. The length in general register $R_3 + 1$ is decremented by the number of bytes moved out of the third-operand location, and the address in general register R_3 is incremented by the same amount.

If the operation is completed because a CPU-determined number of bytes have been moved without reaching the end of the first operand, the lengths in general registers $R_1 + 1$ and $R_3 + 1$ are decremented by the number of bytes moved, and the addresses in general registers R_1 and R_3 are incremented by the same number, so that the instruction, when reexecuted, resumes at the next byte to be moved. If the operation is completed during padding, the length field in general register $R_3 + 1$ is zero, the address in general register R_3 is incremented by the number of bytes moved from operand 3, and general registers R_1 and $R_1 + 1$ reflect the extent of the padding operation.

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers R_1, $R_1 + 1$, R_2, and $R_2 + 1$, always remain unchanged.

The padding bytes may be formed from $D_2(B_2)$ multiple times during the execution of the instruction, and the registers designated by R_1 and R_3 may be updated multiple times. Therefore, if B_2 equals R_1, $R_1 + 1$, R_3, or $R_3 + 1$ and is subject to change during the execution of the instruction, the results are unpredictable.

The amount of processing that results in the setting of condition code 3 is determined by the CPU on the basis of improving system performance, and it may be a different amount each time the instruction is executed.

At the completion of the operation in the 24-bit or 31-bit addressing mode, the leftmost bits which are not part of the address in bit positions 32-63 of general registers R_1 and R_3 may be set to zeros or may remain unchanged from their original values, including the case when one or both of the original length values are zeros.

When the length of an operand is zero, no access exceptions for that operand are recognized. Similarly, when the third operand is longer than the first operand, access exceptions are not recognized for the part of the third-operand field that is in excess of the first-operand field. For operands longer than 4K bytes, access exceptions are not recognized for locations more than 4K bytes beyond the current location being processed. Access exceptions are not recognized for an operand if the R field associated with that operand is odd. Also, when the R_1 field is odd, PER storage-alteration events are not recognized, and no change bits are set. On models that recognize a specification exception if the length associated with an operand is odd, access exceptions and PER storage-alteration events are not recognized and no change bits are set if the length is odd.

Resulting Condition Code:

0 All bytes moved, operand lengths equal
1 All bytes moved, first-operand length low
2 All bytes moved, first-operand length high
3 CPU-determined number of bytes moved without reaching end of first operand

Program Exceptions:

- Access (fetch, operand 3; store, operand 1)
- Operation (if the extended-translation facility 2 is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. MOVE LONG UNICODE is intended for use in place of MOVE LONG or MOVE LONG EXTENDED when padding with double-byte characters. The character may be a Unicode character or any other double-byte character. MOVE LONG UNICODE may set condition code 3 in cases in which MOVE LONG would be interrupted.

2. When condition code 3 is set, the program can simply branch back to the instruction to continue the movement. The program need not determine the number of bytes that were moved.

3. MOVE LONG UNICODE may be used for filling storage with padding bytes by placing the padding bytes in the second-operand address and setting the third-operand length to zero. However, the stores associated with this clearing may be multiple-access stores and should not be used to clear an area if the possibility exists that another CPU or a channel program will attempt to access and use the area as soon as it appears to be zero. For more details, see “Storage-Operand Consistency” on page 5-133.

4. When the contents of the R_1 and R_3 fields are the same, the contents of the designated registers are incremented or decremented only by the number of bytes moved, not by two times the number of bytes moved. The condition code is finally set to 0 after possible settings to 3.

5. In the access-register mode, access register 0 designates the primary address space regardless of the contents of access register 0.

6. The padding bytes may be represented in the displacement field of the instruction. The following example illustrates padding with a Unicode space character.

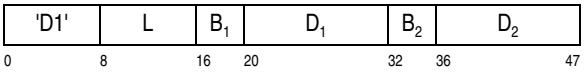
   ```
   MVCLU   6,8,X'0020'
   ```

   When the B_2 field of the instruction designates general register 0, and the long-displacement facility is not installed, the padding bytes are limited to a character whose representation is less than or equal to 0FFF hex.

7. MOVE LONG UNICODE is intended to be used to move and pad pairs of bytes. Although some models allow the first- and third-operand length registers to designate an odd length, without recognizing a specification exception, the program should always be coded to provide an even length. This ensures that the program will operate compatibly in configurations that recognize a specification exception for an odd length value.

MOVE NUMERICS

MVN $D_1(L,B_1),D_2(B_2)$ [SS-a]



The rightmost four bits of each byte in the second operand are placed in the rightmost bit positions of the corresponding bytes in the first operand. The leftmost four bits of each byte in the first operand remain unchanged.

Each operand is processed left to right. When the operands overlap, the result is obtained as if the operands were processed one byte at a time and each result byte were stored immediately after fetching the necessary operand bytes.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2; fetch and store, operand 1)
- Transaction constraint

Programming Notes:

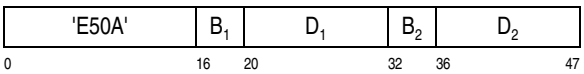
1. An example of the use of the MOVE NUMERICS instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. MOVE NUMERICS moves the numeric portion of a decimal-data field that is in the zoned format. The zoned-decimal format is described in Chapter 8, “Decimal Instructions.” The operands are not checked for valid sign and digit codes.

3. Accesses to the first operand of MOVE NUMERICS consist in fetching the leftmost four bits of each byte in the first operand and subsequently storing the updated value of the byte. These fetch and store accesses to a particular byte do not necessarily occur one immediately after the other. Thus, this instruction cannot be safely used to update a location in storage if the possibility exists that another CPU or a channel program may also be updating the location. An example of this effect is shown for OR (OI) in “Multiprogramming and Multiprocessing Examples” in Appendix A, “Number Representation and Instruction-Use Examples.”

MOVE RIGHT TO LEFT

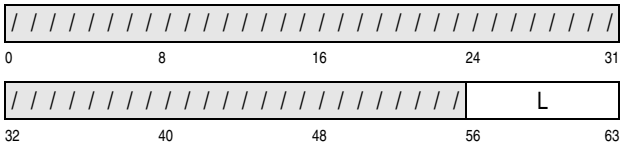
MVCRL $D_1(B_1),D_2(B_2)$ [SSE]



The second operand is placed at the first-operand location by moving bytes in a right-to-left sequence, beginning with the rightmost byte of each operand.

Both operand addresses designate the leftmost byte of their respective operands. The displacements for both operands are treated as 12-bit unsigned binary integers.

The first and second operands are of the same length, which is specified by bits 56-63 of general register 0. Bits 32-55 of general register 0 should contain zeros; otherwise, the program may not operate compatibly in the future. Bits 0-31 of general register 0 are ignored. The contents of general register 0 are shown below:



L specifies the number of bytes to the right of the first byte of each operand. Therefore, the length in bytes of each operand is 1-256, corresponding to a length code in L of 0-255.

The result is obtained as if both operands are processed from right to left. However, as observed by other CPUs and channel programs, the sequence of accesses to the operands is undefined. Either operand may wrap around from location 2^{24} - 1 to 0 in the 24-bit addressing mode, from location 2^{31} - 1 to 0 in the 31-bit addressing mode, or from location 2^{64} - 1 to 0 in the 64-bit addressing mode.

Destructive overlap occurs and results are unpredictable when the byte location designated by the second-operand address (the leftmost byte of the source) overlaps with any byte location of the first operand, other than the byte location designated by the first-operand address (the leftmost byte of the target).

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2; store, operand 1)
- Operation (if the miscellaneous-instruction-extensions facility 3 is not installed)
- Transaction Constraint

Programming Notes:

1. MOVE RIGHT TO LEFT can be used to open a hole in an array, for subsequent insertion of an element, by moving the original element and all higher elements to the right. The MVC instruc-

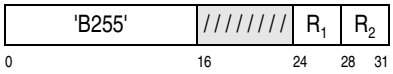
tion, which moves left to right, can not be used in this case since it would destructively overwrite array elements.

2. For most other instructions with more than one storage operand, destructive overlap occurs when the leftmost byte of the destination operand lies within the source operand and the two operands do not perfectly overlap. However, for MOVE RIGHT TO LEFT, destructive overlap occurs when the rightmost byte of the destination operand lies within the source operand and does not perfectly overlap the source operand. Therefore, the scenario described in programming note 1 is not destructive overlap for MVCRL but would be if MVC were used. If there is no overlap of any type between the operands, MVC and MVCRL perform similarly, as observed by this CPU, except that the manner the length is specified is different.

3. Since results are unpredictable if destructive overlap exists on MOVE RIGHT TO LEFT, this instruction can not be used to replicate data from higher addresses to lower addresses. However, MVC which has precisely defined left to right behavior with destructive overlap, can be used for the purpose of replicating data from lower addresses to higher addresses.

MOVE STRING

MVST R_1,R_2 [RRE]



All or part of the second operand is placed in the first-operand location. The operation proceeds until the end of the second operand is reached or a CPU-determined number of bytes have been moved, whichever occurs first. The CPU-determined number is at least one. The result is indicated in the condition code.

The location of the leftmost byte of the first operand and second operand is designated by the contents of general registers R_1 and R_2, respectively.

The handling of the addresses in general registers R_1 and R_2 is dependent on the addressing mode. In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers R_1 and R_2 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the registers constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 constitute the address.

The end of the second operand is indicated by an ending character in the last byte position of the operand. The ending character to be used to determine the end of the second operand is specified in bit positions 56-63 of general register 0. Bit positions 32-55 of general register 0 are reserved for possible future extensions and must contain all zeros; otherwise, a specification exception is recognized.

The operation proceeds left to right and ends as soon as the second-operand ending character has been moved or a CPU-determined number of second-operand bytes have been moved, whichever occurs first. The CPU-determined number is at least one. When the ending character is in the first byte position of the second operand, only the ending character is moved. When the ending character has been moved, condition code 1 is set. When a CPU-determined number of second-operand bytes not including an ending character have been moved, condition code 3 is set. Destructive overlap is not recognized. If the second operand is used as a source after it has been used as a destination, the results are unpredictable.

When condition code 1 is set, the address of the ending character in the first operand is placed in general register R_1, and the contents of general register R_2 remain unchanged. When condition code 3 is set, the address of the next byte to be processed in the first and second operands is placed in general registers R_1 and R_2, respectively. Whenever an address is placed in a general register, bits 32-39 of the register, in the 24-bit addressing mode, or bit 32, in the 31-bit addressing mode, are set to zeros. Bits 0-31 of the R_1 and R_2 registers always remain unchanged in the 24-bit or 31-bit mode.

The amount of processing that results in the setting of condition code 3 is determined by the CPU on the basis of improving system performance, and it may be a different amount each time the instruction is executed.

Access exceptions for the first and second operands are recognized only for that portion of the operand that is necessarily used in the operation.

The storage-operand-consistency rules are the same as for the MOVE (MVC) instruction, except that destructive overlap is not recognized.

Resulting Condition Code:

0 --
1 Entire second operand moved; general register R_1 updated with address of ending character in first operand; general register R_2 unchanged
2 --
3 CPU-determined number of bytes moved; general registers R_1 and R_2 updated with addresses of next bytes

Program Exceptions:

- Access (fetch, operand 2; store, operand 1)
- Specification
- Transaction constraint

Programming Notes:

1. An example of the use of the MOVE STRING instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. When condition code 3 is set, the program can simply branch back to the instruction to continue the data movement. The program need not determine the number of bytes that were moved.

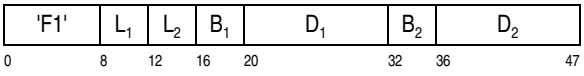
3. R_1 or R_2 may be zero, in which case general register 0 is treated as containing an address and also the ending character.

4. In the access-register mode, access register 0 designates the primary address space regardless of the contents of access register 0.

5. If the second operand is used as a source after it has been used as a destination, an ending character in the second operand may not be recognized.

MOVE WITH OFFSET

MVO $D_1(L_1,B_1),D_2(L_2,B_2)$ [SS-b]



The second operand is placed to the left of and adjacent to the rightmost four bits of the first operand. The rightmost four bits of the first operand are attached as the rightmost bits to the second operand, the second-operand bits are offset by four bit positions, and the result is placed at the first-operand location.

The result is obtained as if the operands were processed right to left. When necessary, the second operand is considered to be extended on the left with zeros. If the first operand is too short to contain all of the second operand, the remaining leftmost portion of the second operand is ignored. Access exceptions for the unused portion of the second operand may or may not be indicated.

When the operands overlap, the result is obtained as if the operands were processed one byte at a time, as if each result byte were stored immediately after fetching the necessary operand bytes, and as if the left digit of each second-operand byte were to remain available for the next result byte and need not be refetched.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2; fetch and store, operand 1)
- Transaction constraint

Programming Notes:

1. An example of the use of the MOVE WITH OFFSET instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. MOVE WITH OFFSET may be used to shift packed decimal data by an odd number of digit positions. The packed-decimal format is described in Chapter 8, “Decimal Instructions.” The operands are not checked for valid sign and digit codes. In many cases, however, SHIFT AND ROUND DECIMAL may be more convenient to use.

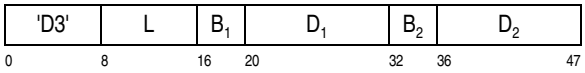
3. Access to the rightmost byte of the first operand of MOVE WITH OFFSET consists in fetching the rightmost four bits and subsequently storing the updated value of this byte. These fetch and store accesses to the rightmost byte of the first operand do not necessarily occur one immediately after the other. Thus, this instruction cannot be safely used to update a location in storage if the

possibility exists that another CPU or a channel program may also be updating the location. An example of this effect is shown for OR (OI) in "Multiprogramming and Multiprocessing Examples" in Appendix A, "Number Representation and Instruction-Use Examples."

4. The storage-operand references for MOVE WITH OFFSET may be multiple-access references. (See "Storage-Operand Consistency" on page 5-133.)

MOVE ZONES

MVZ $D_1(L,B_1),D_2(B_2)$ [SS-a]



The leftmost four bits of each byte in the second operand are placed in the leftmost four bit positions of the corresponding bytes in the first operand. The rightmost four bits of each byte in the first operand remain unchanged.

Each operand is processed left to right. When the operands overlap, the result is obtained as if the operands were processed one byte at a time and each result byte were stored immediately after the necessary operand byte is fetched.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2; fetch and store, operand 1)
- Transaction constraint

Programming Notes:

1. An example of the use of the MOVE ZONES instruction is given in Appendix A, "Number Representation and Instruction-Use Examples."

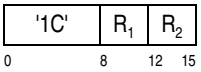
2. MOVE ZONES moves the zoned portion of a decimal field in the zoned format. The zoned format is described in Chapter 8, "Decimal Instructions." The operands are not checked for valid sign and digit codes.

3. Accesses to the first operand of MOVE ZONES consist in fetching the rightmost four bits of each byte in the first operand and subsequently storing the updated value of the byte. These fetch and store accesses to a particular byte do not necessarily occur one immediately after the other. Thus, this instruction cannot be safely used to update a location in storage if the possibility exists that another CPU or a channel program may also be updating the location. An example of this effect is shown for the OR (OI) instruction in "Multiprogramming and Multiprocessing Examples" in Appendix A, "Number Representation and Instruction-Use Examples."

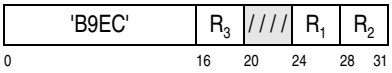
MULTIPLY

Register-and-register format:

MR R_1,R_2 [RR]

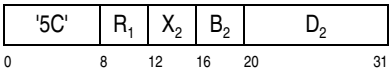


MGRK R_1,R_2,R_3 [RRF-a]

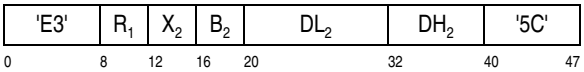


Register-and-storage formats:

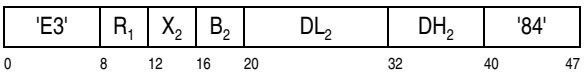
M $R_1,D_2(X_2,B_2)$ [RX-a]



MFY $R_1,D_2(X_2,B_2)$ [RXY-a]



MG $R_1,D_2(X_2,B_2)$ [RXY-a]



For M, MFY, and MR, the 32-bit first operand (the multiplicand) is multiplied by the 32-bit second-operand (the multiplier), and the 64-bit product is placed at the first-operand location. For MG, the 64-bit first operand (the multiplicand) is multiplied by the 64-bit second-operand (the multiplier), and the 128-bit product is placed at the first-operand location. For MGRK, the 64-bit third operand (the multiplicand) is multiplied by the 64-bit second-operand (the multiplier), and the 128-bit product is placed at the first-operand location.

The R_1 field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The following applies to M, MFY, and MR:

- Both the multiplicand and multiplier are treated as 32-bit signed binary integers.
- The multiplicand is in bit positions 32-63 of general register $R_1 + 1$.
- For MULTIPLY (MR), the multiplier is in bit positions 32-63 of general register R_2. The contents of general register R_1 and of bit positions 0-31 of general register $R_1 + 1$ and, for MR, of general register R_2 are ignored.

  For M and MFY, the multiplier is at the second-operand location in storage.
- The product is a 64-bit signed binary integer. Bits 0-31 of the product replace bits 32-63 of general register R_1. Bits 32-63 of the product replace bits 32-63 of general register $R_1 + 1$. Bits 0-31 of general registers R_1 and $R_1 + 1$ remain unchanged.

The following applies to MG and MGRK:

- Both the multiplicand and multiplier are treated as 64-bit signed binary integers.
- For MG, the multiplicand is in bit positions 0-63 of general register $R_1 + 1$, and the contents of general register R_1 are ignored. For MGRK, the multiplicand is in bit positions 0-63 of general register R_3, and the contents of general registers R_1 and $R_1 + 1$ are ignored.
- For MG, the multiplier is at the second-operand location in storage. For MGRK, the multiplier is in bit positions 0-63 of general register R_2.
- For both MG and MGRK, the product is a 128-bit signed binary integer. Bits 0-63 of the product replace bits 0-63 of general register R_1. Bits 64-127 of the product replace bits 0-63 of general register $R_1 + 1$.

The sign of the product is determined by the rules of algebra from the multiplier and multiplicand sign, except that a zero result is always positive. An overflow cannot occur.

The displacement for M is treated as a 12-bit unsigned binary integer. The displacement for MFY and MG is treated as a 20-bit signed binary integer.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2 of M, MFY, and MG only)
- Operation (MFY, if the general-instructions-extension facility is not installed; MG, MGRK, if the miscellaneous-instruction-extensions facility 2 is not installed)
- Specification

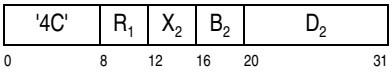
Programming Notes:

1. An example of the use of the MULTIPLY instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”
2. For M, MFY, and MR, the significant part of the product usually occupies 62 bit positions or fewer. Only when two maximum 32-bit negative numbers are multiplied are 63 significant product bits formed.

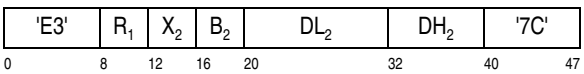
   Similarly, for MG and MGRK, the significant part of the product usually occupies 126 bit positions or fewer. Only when two maximum 64-bit negative numbers are multiplied are 127 significant product bits formed.
3. Care should be taken not to confuse the mnemonic for MULTIPLY UNNORMALIZED (MY) with the mnemonic for MULTIPLY (MFY).

MULTIPLY HALFWORD

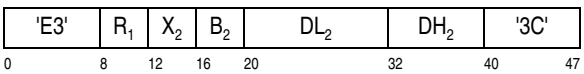
MH $R_1,D_2(X_2,B_2)$ [RX-a]



MHY $R_1,D_2(X_2,B_2)$ [RXY-a]

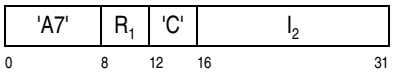


MGH $R_1,D_2(X_2,B_2)$ [RXY-a]

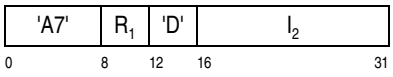


MULTIPLY HALFWORD IMMEDIATE

MHI R_1,I_2 [RI-a]



MGHI R_1,I_2 [RI-a]



The 32-bit or 64-bit first operand (the multiplicand) is multiplied by the 16-bit second operand (the multiplier), and the rightmost 32 or 64 bits of the product are placed at the first-operand location. The second operand is two bytes in length and is treated as a 16-bit signed binary integer.

For MULTIPLY HALFWORD (MH, MHY) and MULTIPLY HALFWORD IMMEDIATE (MHI), the multiplicand is treated as a 32-bit signed binary integer in bit positions 32-63 of general register R_1, and it is replaced by the rightmost 32 bits of the signed-binary-integer product. The bits to the left of the 32 rightmost bits of the product are not tested for significance; no overflow indication is given. Bits 0-31 of general register R_1 are ignored and remain unchanged.

For MULTIPLY HALFWORD (MGH) and MULTIPLY HALFWORD IMMEDIATE (MGHI), the multiplicand is treated as a 64-bit signed binary integer in bit positions 0-63 of general register R_1, and it is replaced by the rightmost 64 bits of the signed-binary-integer product. The bits to the left of the 64 rightmost bits of the product are not tested for significance; no overflow indication is given.

The sign of the product is determined by the rules of algebra from the multiplier and multiplicand sign, except that a zero result is always positive.

The displacement for MH is treated as a 12-bit unsigned binary integer. The displacement for MHY and MGH is treated as a 20-bit signed binary integer.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2 of MH, MHY, and MGH only)
- Operation (MHY; if the general-instructions-extension facility is not installed; MGH, if the miscellaneous-instruction-extensions facility 2 is not installed)

Programming Notes:

1. An example of the use of the MULTIPLY HALFWORD instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

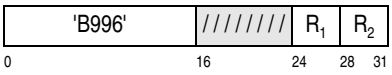
2. For MH, MHY, and MHI, the significant part of the product usually occupies 46 bit positions or fewer. Only when two maximum negative numbers are multiplied are 47 significant product bits formed. Since the rightmost 32 bits of the product are placed unchanged at the first-operand location, ignoring all bits to the left, the sign bit of the result may differ from the true sign of the product in the case of overflow. For a negative product, the 32 bits placed in register R_1 are the rightmost part of the product in two's-complement notation.

   Similarly, for MGH and MGHI, the significant part of the product usually occupies 78 bit positions or fewer, but may occupy 79 bits when two maximum negative numbers are multiplied. Since the rightmost 64 bits of the product are placed unchanged at the first-operand location, the sign of the result may differ from the true sign of the 80-bit product in the case of overflow.

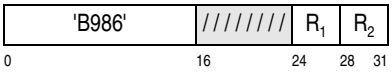
MULTIPLY LOGICAL

Register-and-register formats:

MLR R_1,R_2 [RRE]

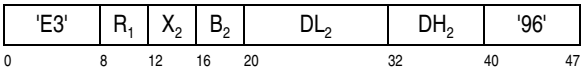


MLGR R_1,R_2 [RRE]

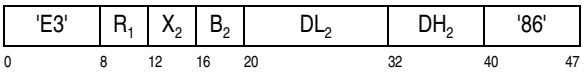


Register-and-storage formats:

ML $R_1,D_2(X_2,B_2)$ [RXY-a]



MLG $R_1,D_2(X_2,B_2)$ [RXY-a]



The 32-bit or 64-bit first operand (the multiplicand) is multiplied by the 32-bit or 64-bit second operand (the multiplier), and the 64-bit or 128-bit product is placed at the first-operand location.

The R_1 field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

For MULTIPLY LOGICAL (MLR, ML), both the multiplicand and the multiplier are treated as 32-bit unsigned binary integers. The multiplicand is in bit positions 32-63 of general register $R_1 + 1$. For MULTIPLY LOGICAL (MLR), the multiplier is in bit positions 32-63 of general register R_2. The contents of general register R_1 and of bit positions 0-31 of general register $R_1 + 1$ and, for MLR, of general register R_2 are ignored. The product is a 64-bit unsigned binary integer. Bits 0-31 of the product replace bits 32-63 of general register R_1, and bits 32-63 of the product replace bits 32-63 of general register $R_1 + 1$. Bits 0-31 of general registers R_1 and $R_1 + 1$ remain unchanged. An overflow cannot occur.

For MULTIPLY LOGICAL (MLGR, MLG), the multiplicand and the multiplier are treated as 64-bit unsigned binary integers. The multiplicand is in general register $R_1 + 1$. The contents of general register R_1 are ignored. The product is a 128-bit unsigned binary integer. Bits 0-63 of the product replace the contents of general register R_1, and bits 64-127 of the product replace the contents of general register $R_1 + 1$. An overflow cannot occur.

Condition Code: The code remains unchanged.

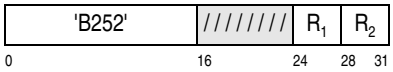
Program Exceptions:

- Access (fetch, operand 2 of ML and MLG only)
- Specification

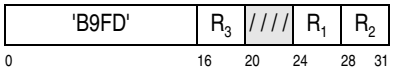
MULTIPLY SINGLE

Register-and-register formats:

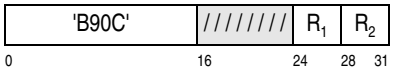
MSR R_1,R_2 [RRE]



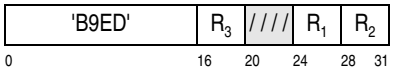
MSRKC R_1,R_2,R_3 [RRF-a]



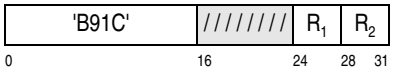
MSGR R_1,R_2 [RRE]



MSGRKC R_1,R_2,R_3 [RRF-a]

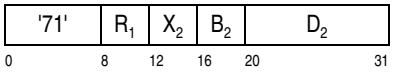


MSGFR R_1,R_2 [RRE]

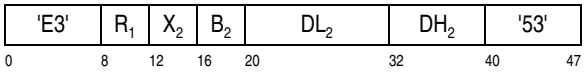


Register-and-storage formats:

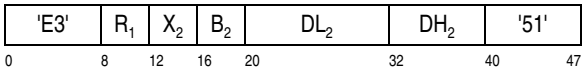
MS $R_1,D_2(X_2,B_2)$ [RX-a]



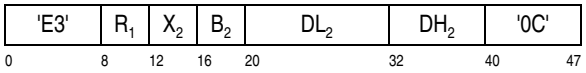
MSC $R_1,D_2(X_2,B_2)$ [RXY-a]



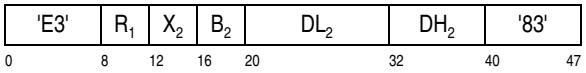
MSY $R_1,D_2(X_2,B_2)$ [RXY-a]



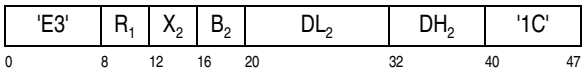
MSG $R_1,D_2(X_2,B_2)$ [RXY-a]



MSGC $R_1,D_2(X_2,B_2)$ [RXY-a]

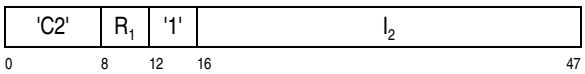


MSGF $R_1,D_2(X_2,B_2)$ [RXY-a]

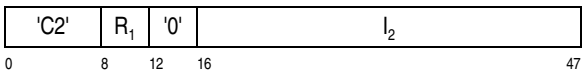


MULTIPLY SINGLE IMMEDIATE

MSFI R_1,I_2 [RIL-a]



MSGFI R_1,I_2 [RIL-a]



The multiplicand is multiplied by the second operand (multiplier), and the rightmost 32 or 64 bits of the product are placed at the first-operand location. Depending on the instruction format, the multiplicand is in either general register R_1 or R_3.

The following applies to MULTIPLY SINGLE (MS, MSC, MSR, MSRKC, MSY) and to MULTIPLY SINGLE IMMEDIATE (MSFI) – that is, to those operations which produce a 32-bit result:

- The multiplicand is a 32-bit signed binary integer. For MS, MSC, MSFI, MSR, and MSY, the multiplicand is in bit positions 32-63 of general register R_1. For MSRKC, the multiplicand is in bit positions 32-63 of general register R_3.
- The multiplier is a 32-bit signed binary integer. For MSR and MSRKC, the multiplier is in bit positions 32-63 of general register R_2. For MSFI, the multiplier is in the I_2 field of the instruction. For MS, MSC, and MSY, the multiplier is at the second-operand location in storage.
- The rightmost 32 bits of the signed-binary-integer product replace bits 32-63 of general register R_1, and bits 0-31 of the register remain unchanged. For MS, MSFI, MSR, and MSY, the bits to the left of the 32 rightmost bits of the product are not tested for significance.

  For MSC and MSRKC, an overflow condition exists when the leftmost 33 bits of an intermediate 64-bit product are neither all zeros nor all ones. Condition code 3 is set. If the fixed-point-overflow mask in the PSW is one, a program interruption for fixed-point overflow occurs.

The following applies to MULTIPLY SINGLE (MSG, MSGC, MSGF, MSGFR, MSGR, MSGRKC) and to MULTIPLY SINGLE IMMEDIATE (MSGFI) – that is, to those operations which produce a 64-bit result:

- The multiplicand is a 64-bit signed binary integer. For MSG, MSGC, MSGF, MSGFI, MSGR, and MSGFR, the multiplicand is in bit positions 0-63 of general register R_1. For MSGRKC, the multiplicand is in bit positions 0-63 of general register R_3.
- For MSGR and MSGRKC, the multiplier is a 64-bit signed binary integer in bit positions 0-63 of general register R_2. For MSGFR, the multiplier is a 32-bit signed-binary integer in bit positions 32-63 of general register R_2. For MSGFI, the multiplier is a 32-bit signed-binary integer in the I_2 field of the instruction. For MSG and MSGC, the multiplier is a 64-bit signed binary integer at the second-operand location in storage. For MSGF, the multiplier is a 32-bit signed binary integer at the second-operand location in storage.
- The rightmost 64 bits of the signed-binary-integer product replace bits 0-63 of general register R_1. For MSG, MSGF, MSGFR, MSGR, MSGFI, the bits to the left of the 64 rightmost bits of the product are not tested for significance.

  For MSGC and MSGRKC, an overflow condition exists when the leftmost 65 bits of an intermediate 128-bit product are neither all zeros or all ones. Condition code 3 is set. If the fixed-point-overflow mask in the PSW is one, a program interruption for fixed-point overflow occurs.

The sign of the product is determined by the rules of algebra from the multiplier and multiplicand sign, except that a zero result is always positive.

The displacement for MS is treated as a 12-bit unsigned binary integer. The displacement for MSC, MSG, MSGF, and MSY is treated as a 20-bit signed binary integer.

Resulting Condition Code: For MSC, MSGC, MSGRKC, and MSRKC, the condition code is set as follows:

0 Result zero; no overflow
1 Result less than zero; no overflow
2 Result greater than zero; no overflow
3 Overflow

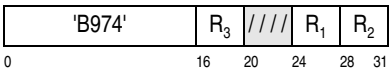
For all other operations, the condition code remains unchanged, and no overflow indication is provided.

Program Exceptions:

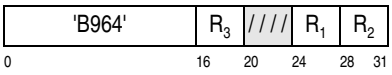
- Access (fetch, operand 2 of MS, MSC, MSG, MSGC, MSGF, MSY only)
- Fixed-point overflow (MSC, MSGC, MSGRKC, MSRKC only)
- Operation (MSY, if the long-displacement facility is not installed; MSFI, MSGFI, if the general-instructions-extension facility is not installed; MSC, MSGC, MSGRKC, MSRKC, if the miscellaneous-instruction-extensions facility 2 is not installed.))

NAND

NNRK R_1,R_2,R_3 [RRF-a]



NNGRK R_1,R_2,R_3 [RRF-a]



The one's complement of the AND of the second and third operands is placed at the first-operand location.

The connective NAND is applied to the operands bit-by-bit. The contents of a bit position in the result are set to zero if the corresponding bit positions in both source operands contain ones; otherwise, the result bit is set to one.

For NNRK, the operands are 32 bits, and for NNGRK, they are 64 bits.

Resulting Condition Code:

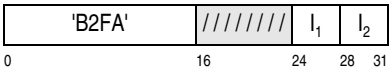
0 Result zero
1 Result not zero
2 --
3 --

Program Exceptions:

- Operation (if the miscellaneous-instruction-extensions facility 3 is not installed)

NEXT INSTRUCTION ACCESS INTENT

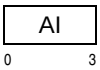
NIAI I_1,I_2 [IE]



Note: In this instruction definition, the term primary-access operand means the lowest numbered storage operand of an instruction. Similarly, the term secondary-access operand means the next-lowest numbered storage operand of the instruction. These terms do not have the same meaning as the terms first operand and second operand, even though there may be some correlation. For example, for the MOVE instruction the first operand is the primary-access operand and the second operand is the secondary-access operand. However, for the LOAD MULTIPLE DISJOINT instruction, the second operand is the primary-access operand and the fourth operand is the secondary-access operand.

Subject to the controls in the I_1 and I_2 fields, the CPU is signaled the future access intent for either or both the primary-access and secondary-access operands of the next-sequential instruction. The I_1 field contains a code to signal the CPU the access intent for the primary-access operand of the next-sequential instruction. The I_2 field contains a code to signal the CPU the access intent for the secondary-access operand of the next-sequential instruction. When the next-sequential instruction has only a single storage operand, the I_2 field is ignored.

The I_1 and the I_2 fields have the following format:



Access Intent (AI): Bits 0-3 of the I_1 and I_2 fields contain an unsigned integer that is used as a code to signal the CPU the access intent for the corresponding operand of the next-sequential instruction as follows:

Code	Meaning
0	The corresponding operand of the next-sequential instruction may or may not be accessed as an instruction operand by subsequent instructions.

Code	Meaning
1	The corresponding operand of the next-sequential instruction will be accessed by subsequent instructions for operand store access, and may also be accessed for operand fetch access.
2	The corresponding operand of the next-sequential instruction will be accessed by subsequent instructions for operand fetch access.
3	The corresponding operand of the next-sequential instruction will not be accessed as an instruction operand by subsequent instructions.
4-15	Reserved.

Reserved access-intent codes should not be specified; otherwise, the program may not operate compatibly in the future.

Depending on the model, the CPU may not recognize all of the access intents for an operand. For access intents that are not recognized by the CPU, the instruction acts as a no-operation. If the instruction has more than two storage operands, no access intent is specified for the additional operands.

Depending on the model, the CPU may not recognize access intents for a particular instruction. For such cases, the instruction acts as a no-operation.

The NEXT INSTRUCTION ACCESS INTENT instruction only affects subsequent instruction's operand accesses; it does not affect subsequent instruction fetches.

No references to storage are made.

Condition Code: The code remains unchanged.

Program Exceptions:

- Operation (if the execution-hint facility is not installed)

Programming Notes:

1. NEXT INSTRUCTION ACCESS INTENT signals the CPU of the future access intent for the storage operands of the next-sequential instruction, but it does not guarantee that the CPU will necessarily retain or use this information.
2. Specifying an incorrect access intent or an access intent for a non-existent operand may lead to performance degradation.
3. Caches are managed on a cache-line-size granularity. Therefore, when a corresponding storage operand specifies any portion of a cache line, the access intent is signaled for the entire cache line. The cache line size can be determined by executing the EXTRACT CPU ATTRIBUTE instruction.
4. When a corresponding storage operand specifies crossing one or more cache-line boundaries, it is model dependent whether the access intent is signaled for one or multiple cache lines.

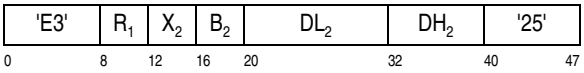
   It is anticipated a program may use access-intent values of one, two, or three, with corresponding storage operands that may cross one or more cache-line boundaries.
5. Specifying an access-intent value of three does not signal the CPU to actively release the cache line from the cache for the specified operand. Instead, it signals the CPU that it should not actively try to retain that line in the cache.
6. Specifying an access-intent value of zero to a single operand instruction is not encouraged and not necessary. However, in the case where an instruction has two operands and access intent is known for one operand, but not the other, the access intent value of zero can be used for the operand of unknown intent.
7. If an interruption occurs after the execution of NEXT INSTRUCTION ACCESS INTENT and before the execution of the next-sequential instruction, NEXT INSTRUCTION ACCESS INTENT acts as a no-operation and the specified access intent is ignored.
8. If the next sequential instruction after NEXT INSTRUCTION ACCESS INTENT is a PREFETCH DATA (RELATIVE LONG) instruction, it is unpredictable what the CPU will do with data prefetching.
9. When the next-sequential instruction after NEXT INSTRUCTION ACCESS INTENT is an execute-type instruction (EX or EXRL), the following applies:

   - Access-intent codes are not associated with the execute-type instruction. The second operand of an execute-type instruction corresponds to an instruction fetch.

- Depending on the model, access-intent codes may be associated with the target instruction of the execute-type instruction.

NONTRANSACTIONAL STORE

NTSTG $R_1,D_2(X_2,B_2)$ [RXY-a]



The 64-bit first operand is nontransactionally placed unchanged at the second-operand location.

The displacement is treated as a 20-bit signed binary integer.

The second operand must be aligned on a doubleword boundary; otherwise, a specification exception is recognized and the operation is suppressed.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, second operand)
- Operation (transactional-execution facility not installed)
- Specification
- Transaction constraint

Programming Notes:

1. NONTRANSACTIONAL STORE provides a means by which a program executing in the nonconstrained transactional-execution mode can perform stores that will be retained, even if the transaction aborts. This may facilitate debugging of the transaction if it is aborted.

2. When the CPU is not in the transactional-execution mode, the operation of NONTRANSACTIONAL STORE is identical to that of STORE (STG), except that the second operand of NONTRANSACTIONAL STORE is required to be on a doubleword boundary (regardless of transactional-execution mode) whereas the second operand of STG has no alignment requirements.

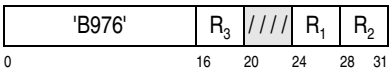
3. Depending on the model, the performance of NONTRANSACTIONAL STORE may be slower than that of STORE (STG).

4. If a CPU makes transactional and non-transactional stores to the same storage location within a transaction, and the transaction then aborts, the content of all storage locations altered by either the transactional or nontransactional store are unpredictable.

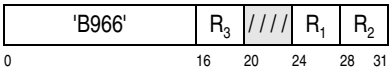
5. On some models, attempting to execute a nontransactional store and a transactional store in a transaction when both designate any locations within the same cache line results in the transaction being aborted with abort code 16 (cache other condition) and condition code 3 set. This occurs even if the nontransactional store does not overlap the transactional store. The cache line size may be determined by the EXTRACT CPU ATTRIBUTES (ECAG) instruction.

NOR

NORK R_1,R_2,R_3 [RRF-a]



NOGRK R_1,R_2,R_3 [RRF-a]



The one's complement of the OR of the second and third operands is placed at the first-operand location.

The connective NOR is applied to the operands bit-by-bit. The contents of a bit position in the result are set to one if the corresponding bit positions in both source operands contain zero; otherwise, the result bit is set to zero.

For NORK, the operands are 32 bits, and for NOGRK, they are 64 bits.

Resulting Condition Code:

0 Result zero
1 Result not zero
2 --
3 --

Program Exceptions:

- Operation (if the miscellaneous-instruction-extensions facility 3 is not installed)

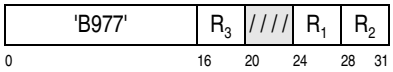
Programming Note: NOR can be used to provide the functionality of a bit-wise NOT operation by specifying the same general register for R_2 and R_3. The high-level assembler (HLASM) provides the extended-mnemonic forms shown below.

Extended Mnemonics:

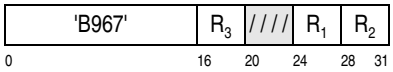
Extended Mnemonic		Base Mnemonic	
NOTR	R_1,R_2	NORK	R_1,R_2,R_2
NOTGR	R_1,R_2	NOGRK	R_1,R_2,R_2

NOT EXCLUSIVE OR

NXRK R_1,R_2,R_3 [RRF-a]



NXGRK R_1,R_2,R_3 [RRF-a]



The one's complement of the EXCLUSIVE OR of the second and third operands is placed at the first-operand location.

The connective EXCLUSIVE OR and complementation is applied to the operands bit-by-bit. The contents of a bit position in the result are set to zero if the bits in the corresponding bit positions in the two source operands are unlike; otherwise, the result bit is set to one.

For NXRK, the operands are 32 bits, and for NXGRK, they are 64 bits

Resulting Condition Code:

0 Result zero
1 Result not zero
2 --
3 --

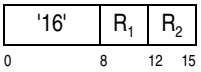
Program Exceptions:

- Operation (if the miscellaneous-instruction-extensions facility 3 is not installed)

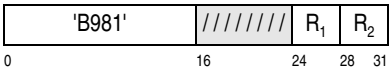
OR

Register-and-register formats:

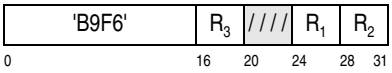
OR R_1,R_2 [RR]



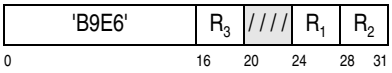
OGR R_1,R_2 [RRE]



ORK R_1,R_2,R_3 [RRF-a]

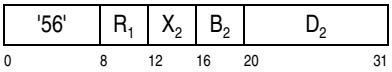


OGRK R_1,R_2,R_3 [RRF-a]

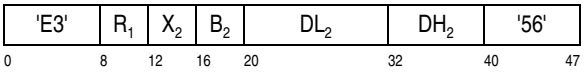


Register-and-storage formats:

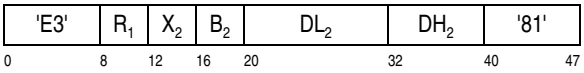
O $R_1,D_2(X_2,B_2)$ [RX-a]



OY $R_1,D_2(X_2,B_2)$ [RXY-a]

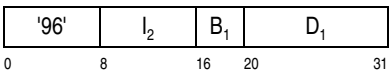


OG $R_1,D_2(X_2,B_2)$ [RXY-a]

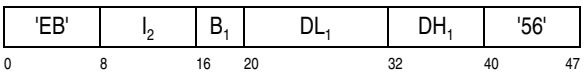


Storage-and-immediate formats:

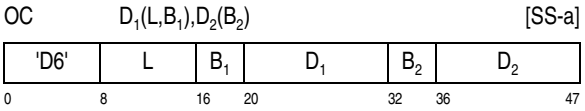
OI $D_1(B_1),I_2$ [SI]



OIY $D_1(B_1),I_2$ [SIY]



Storage-and-storage format:



For O, OC, OG, OGR, OI, OIY, OR, and OY, the OR of the first and second operands is placed at the first-operand location. For OGRK and ORK, the OR of the second and third operands is placed at the first-operand location.

The connective OR is applied to the operands bit by bit. The contents of a bit position in the result are set to one if the corresponding bit position in one or both operands contains a one; otherwise, the result bit is set to zero.

For OR (OC), each operand is processed left to right. When the operands overlap, the result is obtained as if the operands were processed one byte at a time and each result byte were stored immediately after fetching the necessary operand bytes.

For OR (OI, OIY), the first operand is one byte in length, and only one byte is stored. When the interlocked-access facility 2 is installed, the update of the first operand appears to be an interlocked-update reference as observed by other CPUs and channel programs, and a specific-operand-serialization operation is performed.

For OR (O, OR, ORK, and OY), the operands are 32 bits, and for OR (OG, OGR, and OGRK), they are 64 bits.

The displacements for O, OI, and both operands of OC are treated as 12-bit unsigned binary integers. The displacement for OY, OIY, and OG is treated as a 20-bit signed binary integer.

Resulting Condition Code:

0 Result zero
1 Result not zero
2 --
3 --

Program Exceptions:

- Access (fetch, operand 2, O, OY, OG, and OC; fetch and store, operand 1, OI, OIY, and OC)
- Operation (OY and OIY, if the long-displacement facility is not installed; OGRK and ORK, if the distinct-operands facility is not installed)
- Transaction constraint (OC)

Programming Notes:

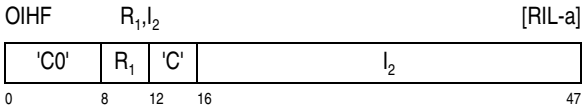
1. Examples of the use of the OR instruction are given in Appendix A, “Number Representation and Instruction-Use Examples.”

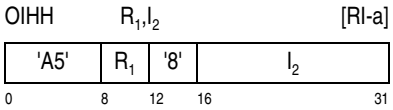
2. OR may be used to set a bit to one.

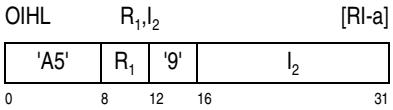
3. Accesses to the first operand of OR (OC) – and, when the interlocked-access facility 2 is not installed, accesses to the first operand of OR (OI, OIY) – consist in fetching a first-operand byte from storage and subsequently storing the updated value. These fetch and store accesses to a particular byte do not necessarily occur one immediately after the other. Thus, these instructions cannot be safely used to update a location in storage if the possibility exists that another CPU or a channel program may also be updating the location. An example of this effect is shown in “Multiprogramming and Multiprocessing Examples” on page A-45.

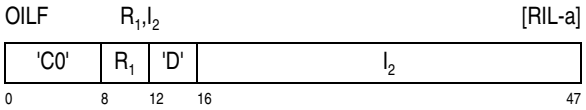
   When the interlocked-access facility 2 is installed, OR (OI, OIY) can be safely used to update a location in storage, even if the possibility exists that another CPU or a channel program may also be updating the location.

OR IMMEDIATE

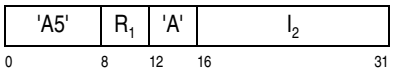




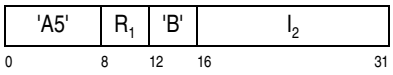




OILH R_1,I_2 [RI-a]



OILL R_1,I_2 [RI-a]



The second operand is ORed with bits of the first operand, and the result replaces those bits of the first operand. The remainder of the first operand remains unchanged.

For each instruction, the bits of the first operand that are ORed with the second operand and then replaced are as follows:

Instruction	Bits ORed and Replaced
OIHF	0-31
OIHH	0-15
OIHL	16-31
OILF	32-63
OILH	32-47
OILL	48-63

The connective OR is applied to the operands bit by bit. The contents of a bit position in the result are set to one if the corresponding bit position in one or both operands contains a one; otherwise, the result bit is set to zero.

Resulting Condition Code:

0 Result is zero
1 Result is not zero
2 --
3 --

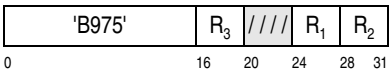
Program Exceptions:

- Operation (OIHF and OILF, if the extended-immediate facility is not installed)

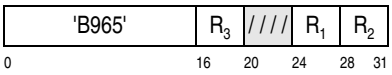
Programming Note: The setting of the condition code is based only on the bits that are ORed and replaced.

OR WITH COMPLEMENT

OCRK R_1,R_2,R_3 [RRF-a]



OCGRK R_1,R_2,R_3 [RRF-a]



The second operand is ORed with the bit-wise complement of the third operand and the result is placed in the first-operand location.

The connective OR is applied to the second operand and bit-wise complemented third operand, bit by bit. The contents of a bit position in the result are set to zero if the corresponding bit positions in the second and third operands contain zero and one, respectively; otherwise, the result bit is set to one.

For OCRK, the operands are 32 bits, and for OCGRK, they are 64 bits.

Resulting Condition Code:

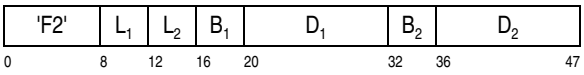
0 Result zero
1 Result not zero
2 --
3 --

Program Exceptions:

- Operation (if the miscellaneous-instruction-extensions facility 3 is not installed)

PACK

PACK $D_1(L_1,B_1),D_2(L_2,B_2)$ [SS-b]



The format of the second operand is changed from zoned to signed-packed-decimal, and the result is placed at the first-operand location. The zoned and signed-packed-decimal formats are described in Chapter 8, “Decimal Instructions.”

The second operand is treated as having the zoned format. The numeric bits of each byte are treated as

a digit. The zone bits are ignored, except the zone bits in the rightmost byte, which are treated as a sign.

The sign and digits are moved unchanged to the first operand and are not checked for valid codes. The sign is placed in the rightmost four bit positions of the rightmost byte of the result field, and the digits are placed adjacent to the sign and to each other in the remainder of the result field.

The result is obtained as if the operands were processed right to left. When necessary, the second operand is considered to be extended on the left with zeros. If the first operand is too short to contain all digits of the second operand, the remaining leftmost portion of the second operand is ignored. Access exceptions for the unused portion of the second operand may or may not be indicated.

When the operands overlap, the result is obtained as if each result byte were stored immediately after fetching the necessary operand bytes. Two second-operand bytes are needed for each result byte, except for the rightmost byte of the result field, which requires only the rightmost second-operand byte.

Condition Code: The code remains unchanged.

Program Exceptions:

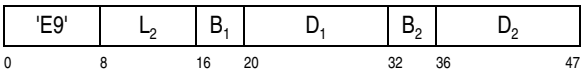
- Access (fetch, operand 2; store, operand 1)
- Transaction constraint

Programming Notes:

1. An example of the use of the PACK instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”
2. PACK may be used to interchange the two hexadecimal digits in one byte by specifying a zero in the L_1 and L_2 fields and the same address for both operands.
3. To remove the zone bits of all bytes of a field, including the rightmost byte, both operands should be extended on the right with a dummy byte, which subsequently should be ignored in the result field.
4. The storage-operand references for PACK may be multiple-access references. (See “Storage-Operand Consistency” on page 5-133.)

PACK ASCII

PKA $D_1(B_1),D_2(L_2,B_2)$ [SS-f]



The format of the second operand is changed from ASCII to signed-packed-decimal, and the result is placed at the first-operand location. The signed-packed-decimal format is described in Chapter 8, “Decimal Instructions.”

The second-operand bytes are treated as containing decimal digits, having the binary encoding 0000-1001 for 0-9, in their rightmost four bit positions. The leftmost four bit positions of a byte are ignored. The second operand is considered to be positive.

The implied positive sign (1100 binary) and the source digits are placed at the first-operand location. The source digits are moved unchanged and are not checked for valid codes. The sign is placed in the rightmost four bit positions of the rightmost byte of the result field, and the digits are placed adjacent to the sign and to each other in the remainder of the result field.

The result is obtained as if the operands were processed right to left. When necessary, the second operand is considered to be extended on the left with zeros.

The length of the first operand is 16 bytes.

The length of the second operand is designated by the contents of the L_2 field. The second-operand length must not exceed 32 bytes (L_2 must be less than or equal to 31); otherwise, a specification exception is recognized.

When the length of the second operand is 32 bytes, the leftmost byte is ignored.

The results are unpredictable if the first and second operands overlap in any way.

As observed by other CPUs and by channel programs, the first-operand location is not necessarily stored into in any particular order.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2; store, operand 1)
- Operation (if the extended-translation facility 2 is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. Although PACK ASCII is primarily intended to change the format of ASCII decimal digits, its use is not restricted to ASCII since the leftmost four bits of each byte are ignored.

2. The following example illustrates the use of the instruction to pack ASCII digits:

```
ASDIGITS  DS    0CL31
          DC    X'3132333435'
          DC    X'3637383930'
          DC    X'3132333435'
          DC    X'3637383930'
          DC    X'3132333435'
          DC    X'3637383930'
          DC    X'31'
PKDIGITS  DS    PL16
           ⋮
          PKA   PKDIGITS,ASDIGITS(31)
```

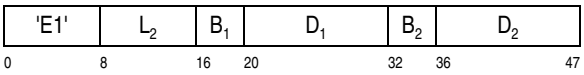
3. The instruction can also be used to pack EBCDIC digits, which is especially useful when the length of the second operand is greater than the 16-byte second-operand limit of PACK.

```
EBDIGITS  DS    0CL31
          DC    X'F1F2F3F4F5'
          DC    X'F6F7F8F9F0'
          DC    X'F1F2F3F4F5'
          DC    X'F6F7F8F9F0'
          DC    X'F1F2F3F4F5'
          DC    X'F6F7F8F9F0'
          DC    X'F1'
PKDIGITS  DS    PL16
           ⋮
          PKA   PKDIGITS,EBDIGITS(31)
```

4. The storage-operand references for PACK ASCII may be multiple-access references. (See “Storage-Operand Consistency” on page 5-133.)

PACK UNICODE

PKU $D_1(B_1),D_2(L_2,B_2)$ [SS-f]



The format of the second operand is changed from Unicode to signed-packed-decimal, and the result is placed at the first-operand location. The signed-packed-decimal format is described in Chapter 8, “Decimal Instructions.”

The two-byte second-operand characters are treated as Unicode Basic Latin characters containing decimal digits, having the binary encoding 0000-1001 for 0-9, in their rightmost four bit positions. The leftmost 12 bit positions of a character are ignored. The second operand is considered to be positive.

The implied positive sign (1100 binary) and the source digits are placed at the first-operand location. The source digits are moved unchanged and are not checked for valid codes. The sign is placed in the rightmost four bit positions of the rightmost byte of the result field, and the digits are placed adjacent to the sign and to each other in the remainder of the result field.

The result is obtained as if the operands were processed right to left. When necessary, the second operand is considered to be extended on the left with zeros.

The length of the first operand is 16 bytes.

The byte length of the second operand is designated by the contents of the L_2 field. The second-operand length must not exceed 32 characters or 64 bytes, and the byte length must be even (L_2 must be less than or equal to 63 and must be odd); otherwise, a specification exception is recognized.

When the length of the second operand is 32 characters (64 bytes), the leftmost character is ignored.

The results are unpredictable if the first and second operands overlap in any way.

As observed by other CPUs and by channel programs, the first-operand location is not necessarily stored into in any particular order.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2; store, operand 1)
- Operation (if the extended-translation facility 2 is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. The following example illustrates the use of PACK UNICODE to pack European numbers:

```
UNDIGITS  DS    0CL62
          DC    X'0031003200330034 0035'
          DC    X'0036003700380039 0030'
          DC    X'0031003200330034 0035'
          DC    X'0036003700380039 0030'
          DC    X'0031003200330034 0035'
          DC    X'0036003700380039 0030'
          DC    X'0031'
PKDIGITS  DS    PL16
          ⋮
          PKU   PKDIGITS,UNDIGITS(62)
```

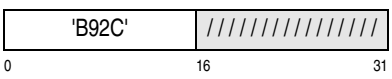
2. Because the leftmost 12 bits of each character are ignored, those Unicode decimal digits where the digit zero has four rightmost zero bits can also be packed by the instruction. For example, for Thai digits:

```
UNDIGITS  DS    0CL62
          DC    X'0E510E520E530E540E55'
          DC    X'0E560E570E580E590E50'
          DC    X'0E510E520E530E540E55'
          DC    X'0E560E570E580E590E50'
          DC    X'0E510E520E530E540E55'
          DC    X'0E560E570E580E590E50'
          DC    X'0E51'
PKDIGITS  DS    PL16
          ⋮
          PKU   PKDIGITS,UNDIGITS(62)
```

3. The storage-operand references for PACK UNICODE may be multiple-access references. (See "Storage-Operand Consistency" on page 5-133.)

PERFORM CRYPTOGRAPHIC COMPUTATION

PCC [RRE]



A function specified by the function code in general register 0 is performed.

Bits 16-31 of the instruction are ignored.

Bit positions 57-63 of general register 0 contain the function code. Figure 7-338 on page 7-358 shows the assigned function codes. When the message-security-assist extension 13 is installed, function code 127 is valid for PERFORM CRYPTOGRAPHIC COMPUTATION. All other function codes are unassigned. Bit 56 of general register 0 must be zero; otherwise, a specification exception is recognized. All other bits of general register 0 are ignored.

General register 1 contains the logical address of the leftmost byte of the parameter block in storage. In the 24-bit addressing mode, the contents of bit positions 40-63 of general register 1 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of general register 1 constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register 1 constitute the address.

If the message-security-assist extension 9 is installed, elliptic curve scalar multiply is supported in PCC-Scalar-Multiply function codes 64, 65, 66, 72, 73, 80, and 81.

The function codes for PERFORM CRYPTOGRAPHIC COMPUTATION are as follows.

Code	Function	Parm. Block Size (bytes)	Data Block Size (bytes)
0	PCC-Query	16	—
1	PCC-Compute-Last-Block-CMAC-Using-DEA	32	8
2	PCC-Compute-Last-Block-CMAC-Using-TDEA-128	40	8
3	PCC-Compute-Last-Block-CMAC-Using-TDEA-192	48	8
9	PCC-Compute-Last-Block-CMAC-Using-Encrypted-DEA	56	8
10	PCC-Compute-Last-Block-CMAC-Using-Encrypted-TDEA-128	64	8

Figure 7-338. Function Codes for PERFORM CRYPTOGRAPHIC COMPUTATION (Part 1 of 3)

81	PCC-Scalar-Multiply-X448	4096	—
127	PCC-Query-Authentication-Information	V	—

Explanation:

— Not applicable

V Variable parameter block size. See each format-x parameter block for the exact size of that parameter block.

Figure 7-338. Function Codes for PERFORM CRYPTOGRAPHIC COMPUTATION (Part 3 of 3)

All other function codes are unassigned.

The query function provides the means of indicating the availability of the other functions.

The query-authentication-information function provides the information that can be used by the program to authenticate the running instruction's firmware code level (IFCL) currently installed on the model.

Figure 7-339 shows the contents of general registers 0 and 1.

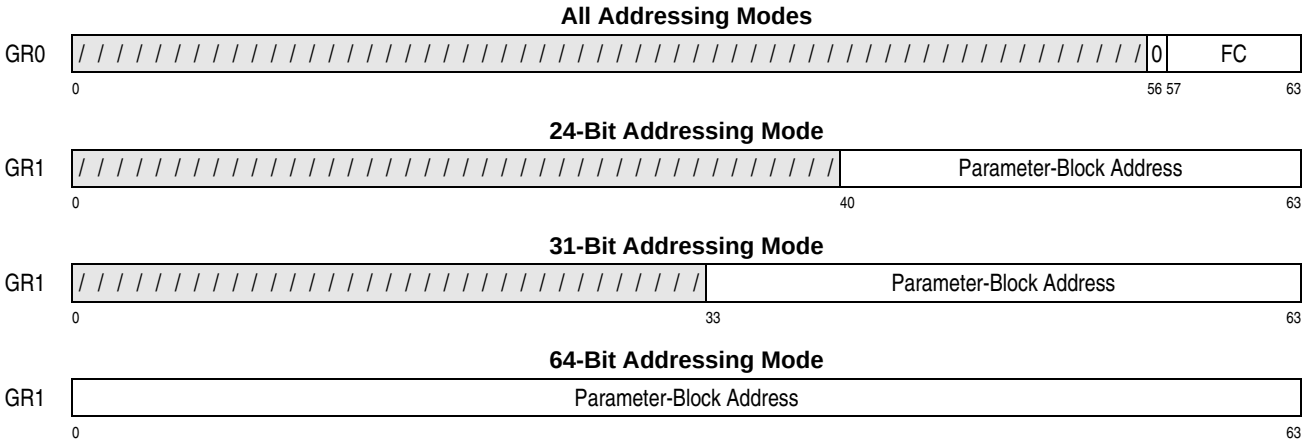

Figure 7-339. General Register Assignment for PCC

In the access-register mode, access register 1 specifies the address space containing the parameter block.

As observed by this CPU, other CPUs, and channel programs, reference to the parameter block may be multiple-access references, accesses to these storage locations are not necessarily block-concurrent, and the sequence of these accesses or references is undefined.

Symbols Used in Function Descriptions

The following symbols are used in the subsequent description of the PERFORM CRYPTOGRAPHIC COMPUTATION functions. Further description of the AES standard may be found in Reference [14.] on page xxxii. The XTS multiplication operation is the same as the GCM (Galois/counter mode) multiplication operation. Further description of the GCM multiplication over GF(2^{128}) may be found in Reference [17.] on page xxxii.

PCC-Query (Function Code 0)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-339 on page 7-359.

The parameter block used for the function has the following format:

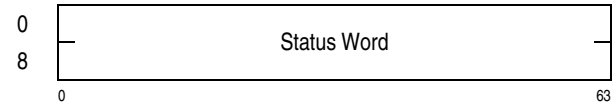

Figure 7-347. Parameter Block for PCC-Query

A 128-bit status word is stored in the parameter block. Bits 0-127 of this field correspond to function codes 0-127, respectively, of the PCC instruction. When a bit is one, the corresponding function is installed; otherwise, the function is not installed.

Condition code 0 is set when execution of the PCC-Query function completes; condition codes 1, 2, and 3 are not applicable to this function.

PCC-Compute-Last-Block-CMAC-Using-DEA (Function Code 1)

PCC-Compute-Last-Block-CMAC-Using-Encrypted-DEA (Function Code 9)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-339 on page 7-359.

The parameter block used for the PCC-Compute-Last-Block-CMAC-Using-DEA function has the following format:

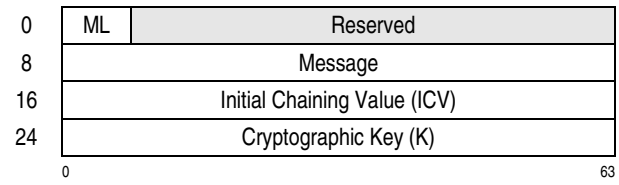

Figure 7-348. Parameter Block for PCC-Compute-Last-Block-CMAC-Using-DEA

For the PCC-Compute-Last-Block-CMAC-Using-DEA function, the initial-chaining value is in byte offsets 16-23 of the parameter block and the cryptographic key is in byte offsets 24-31 of the parameter block.

The parameter block used for the PCC-Compute-Last-Block-CMAC-Using-Encrypted-DEA function has the following format:

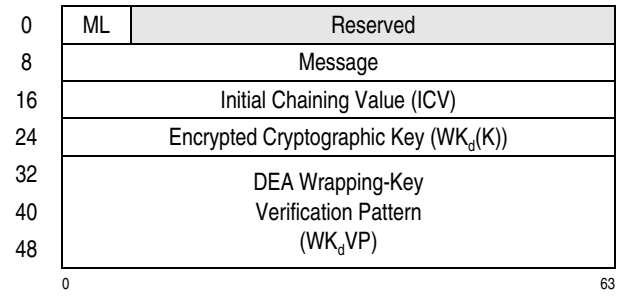

Figure 7-349. Parameter Block for PCC-Compute-Last-Block-CMAC-Using-Encrypted-DEA

For the PCC-Compute-Last-Block-CMAC-Using-Encrypted-DEA function, the contents of byte offsets 32-55 of the parameter block are compared with the contents of the DEA wrapping-key verification-pattern register. If they mismatch, the parameter-block location remains unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 16-23 of the parameter block contain the initial chaining value, and the contents of byte offsets 24-31 of the parameter block are deciphered using the DEA wrapping key to obtain the 64-bit cryptographic key, K. (See the section "Protection of Cryptographic Keys" on page 7-490 for details.)

The description in the following paragraphs applies to both functions.

The bit length of the message in byte offsets 8-15 of the parameter block is specified by an 8-bit unsigned binary integer in the message-length (ML) field at byte offset 0. When the ML field contains a value greater than 64, the operation is completed by setting condition code 2. Otherwise, the ML field specifies the number of leftmost bits in byte offsets 8-15 that constitute the message. All other bits in byte offsets 8-15 are ignored.

When the ML field specifies a value of 0, a 64-bit message block is formed by setting the leftmost bit to one and all other bits to zero; when the ML field specifies a value of 64, the contents of byte offsets 8-15 form the 64-bit message block; when the ML field specifies a value of 63, the leftmost 63 bits in byte offsets 8-15 padded with a bit of one on the right form the 64-bit message block; when the ML field specifies a value in the range between 1 and 62, inclusively, the specified number of leftmost bits in byte offsets 8-15 padded on the right with a bit of one followed by the necessary number of bits of zero form a 64-bit message block.

When the ML field specifies the value of 64, a 64-bit subkey, K_x, is derived using the 64-bit cryptographic key, K. When the ML field specifies a value in the range between 0 and 63, inclusively, a different subkey, K_y, is derived using the 64-bit cryptographic key, K. The subkey generation algorithm is shown in the following figure.

Steps:

1. $L = CIPH_K(0)$
2. If MSB (L) = 0, then $K_X = L << 1$; Else, $K_X = (L << 1)$ XOR (R_{64})
3. If MSB (K_X) = 0, then $K_Y = K_X << 1$; Else $K_Y = (K_X << 1)$ XOR (R_{64})

Explanation:

$CIPH_K(0)$	Encryption of the value zero using a 64-bit key and the DEA encryption algorithm.
MSB(A)	Most significant (leftmost) bit of A
B<<1	The bit string that results from discarding the leftmost bit of B and appending a '0' bit on the right.
XOR	Bit-wise exclusive OR.
R_{64}	A 64-bit value of 27.

Figure 7-350. Subkey Generation Algorithm

When the ML field specifies the value of 64, the 64-bit message block is exclusive-ORed with the subkey K_x. The result of the exclusive-OR operation is then exclusive-ORed with initial-chaining value. The result of the second exclusive-OR operation is then enciphered using the 64-bit cryptographic key, K, and the DEA encryption algorithm. The result of the encryption operation is the CMAC and is placed in byte offsets 16-23 of the parameter block.

When the ML field specifies a value in the range between 0 and 63, inclusively, the 64-bit message block is exclusive-ORed with the subkey K_y. The result of the exclusive-OR operation is then exclusive-ORed with initial-chaining value. The result of the second exclusive-OR operation is then enciphered using the 64-bit cryptographic key, K, and the DEA encryption algorithm. The result of the encryption operation is the CMAC and is placed in byte offsets 16-23 of the parameter block.

When the ML field specifies a value in the range between 0 and 64, inclusively, condition code 0 is set when execution of the function completes. Condition code 3 is not applicable to either function; condition code 1 is not applicable to the PCC-Compute-Last-Block-CMAC-Using-DEA function.

PCC-Compute-Last-Block-CMAC-Using-TDEA-128 (Function Code 2)

PCC-Compute-Last-Block-CMAC-Using-Encrypted-TDEA-128 (Function Code 10)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-339 on page 7-359.

The parameter block used for the PCC-Compute-Last-Block-CMAC-Using-TDEA-128 function has the following format:

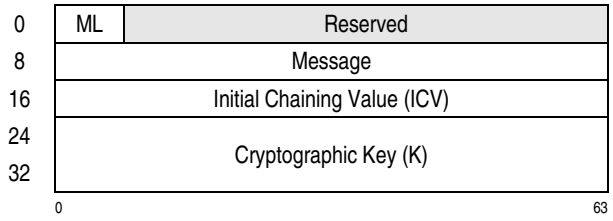

Figure 7-351. Parameter Block for PCC-Compute-Last-Block-CMAC-Using-TDEA-128

For the PCC-Compute-Last-Block-CMAC-Using-TDEA-128 function, the initial-chaining value is in byte offsets 16-23 of the parameter block and the cryptographic key is in byte offsets 24-39 of the parameter block.

The parameter block used for the PCC-Compute-Last-Block-CMAC-Using-Encrypted-TDEA-128 function has the following format:

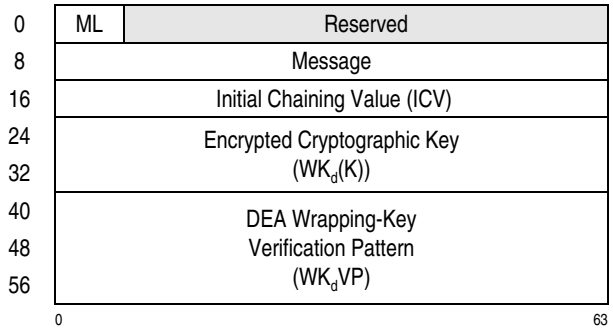

Figure 7-352. Parameter Block for PCC-Compute-Last-Block-CMAC-Using-Encrypted-TDEA-128

For the PCC-Compute-Last-Block-CMAC-Using-Encrypted-TDEA-128 function, the contents of byte offsets 40-63 of the parameter block are compared with the contents of the DEA wrapping-key verification-pattern register. If they mismatch, the parameter-block location remains unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 16-23 of the parameter block contain the initial chaining value, and the contents of byte offsets 24-39 of the parameter block are deciphered using the DEA wrapping key to obtain the 128-bit cryptographic key, K. (See the section "Protection of Cryptographic Keys" on page 7-490 for details.)

The description in the following paragraphs applies to both functions.

The bit length of the message in byte offsets 8-15 of the parameter block is specified by an 8-bit unsigned binary integer in the message-length (ML) field at byte offset 0. When the ML field contains a value greater than 64, the operation is completed by setting condition code 2. Otherwise, the ML field specifies the number of leftmost bits in byte offsets 8-15 that constitute the message. All other bits in byte offsets 8-15 are ignored.

When the ML field specifies a value of 0, a 64-bit message block is formed by setting the leftmost bit to one and all other bits to zero; when the ML field specifies a value of 64, the contents of byte offsets 8-15 form the 64-bit message block; when the ML field specifies a value of 63, the leftmost 63 bits in byte offsets 8-15 padded with a bit of one on the right form the 64-bit message block; when the ML field specifies a value in the range between 1 and 62, inclusively, the specified number of leftmost bits in byte offsets 8-15 padded on the right with a bit of one followed by the necessary number of bits of zero form a 64-bit message block.

When the ML field specifies the value of 64, a 64-bit subkey, K_X, is derived using the 128-bit cryptographic key, K. When the ML field specifies a value in the range between 0 and 63, inclusively, a different subkey, K_Y, is derived using the 128-bit cryptographic key, K. The subkey generation algorithm is shown in the following figure.

Steps:

1. $L = CIPH_K(0)$
2. If MSB (L) = 0, then $K_X = L << 1$; Else, $K_X = (L << 1)$ XOR (R_{64})
3. If MSB $(K_X) = 0$, then $K_Y = K_X << 1$; Else $K_Y = (K_X << 1)$ XOR (R_{64})

Figure 7-353. Subkey Generation Algorithm

Explanation:

$CIPH_K(0)$	Encryption of the value zero using a 128-bit key and the TDEA-128 encryption algorithm.
MSB(A)	Most significant (leftmost) bit of A
B<<1	The bit string that results from discarding the leftmost bit of B and appending a '0' bit on the right.
XOR	Bit-wise exclusive OR.
R_{64}	A 64-bit value of 27.

Figure 7-353. Subkey Generation Algorithm (Continued)

When the ML field specifies the value of 64, the 64-bit message block is exclusive-ORed with the subkey K_x. The result of the exclusive-OR operation is then exclusive-ORed with initial-chaining value. The result of the second exclusive-OR operation is then enciphered using the 128-bit cryptographic key, K, and the TDEA-128 encryption algorithm. The result of the encryption operation is the CMAC and is placed in byte offsets 16-23 of the parameter block.

When the ML field specifies a value in the range between 0 and 63, inclusively, the 64-bit message block is exclusive-ORed with the subkey K_y. The result of the exclusive-OR operation is then exclusive-ORed with initial-chaining value. The result of the second exclusive-OR operation is then enciphered using the 128-bit cryptographic key, K, and the TDEA-128 encryption algorithm. The result of the encryption operation is the CMAC and is placed in byte offsets 16-23 of the parameter block.

When the ML field specifies a value in the range between 0 and 64, inclusively, condition code 0 is set when execution of the function completes. Condition code 3 is not applicable to either function; condition code 1 is not applicable to the PCC-Compute-Last-Block-CMAC-Using-TDEA-128 function.

PCC-Compute-Last-Block-CMAC-Using-TDEA-192 (Function Code 3)

PCC-Compute-Last-Block-CMAC-Using-Encrypted-TDEA-192 (Function Code 11)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-339 on page 7-359.

The parameter block used for the PCC-Compute-Last-Block-CMAC-Using-TDEA-192 function has the following format:

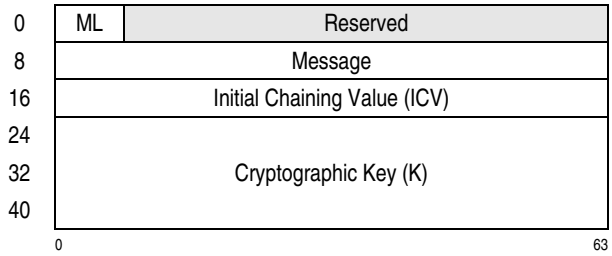

Figure 7-354. Parameter Block for PCC-Compute-Last-Block-CMAC-Using-TDEA-192

For the PCC-Compute-Last-Block-CMAC-Using-TDEA-192 function, the initial-chaining value is in byte offsets 16-23 of the parameter block and the cryptographic key is in byte offsets 24-47 of the parameter block.

The parameter block used for the PCC-Compute-Last-Block-CMAC-Using-Encrypted-TDEA-192 function has the following format:

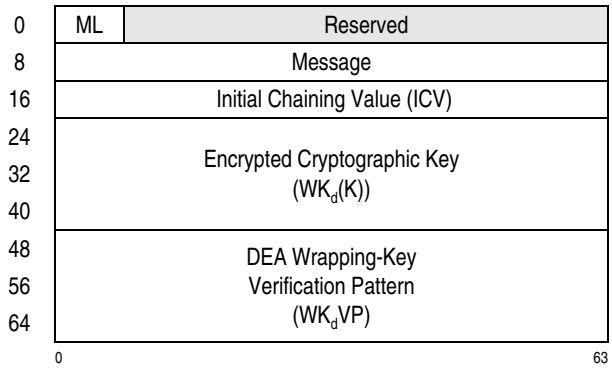

Figure 7-355. Parameter Block for PCC-Compute-Last-Block-CMAC-Using-Encrypted-TDEA-192

For the PCC-Compute-Last-Block-CMAC-Using-Encrypted-TDEA-192 function, the contents of byte offsets 48-71 of the parameter block are compared with the contents of the DEA wrapping-key verification-pattern register. If they mismatch, the parameter-block location remains unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 16-23 of the parameter block contain the initial chaining value, and the contents of byte offsets 24-47 of the parameter block are deciphered using the DEA wrapping key to obtain the 192-bit cryptographic key, K. (See the section “Pro-

tection of Cryptographic Keys" on page 7-490 for details.)

The description in the following paragraphs applies to both functions.

The bit length of the message in byte offsets 8-15 of the parameter block is specified by an 8-bit unsigned binary integer in the message-length (ML) field at byte offset 0. When the ML field contains a value greater than 64, the operation is completed by setting condition code 2. Otherwise, the ML field specifies the number of leftmost bits in byte offsets 8-15 that constitute the message. All other bits in byte offsets 8-15 are ignored.

When the ML field specifies a value of 0, a 64-bit message block is formed by setting the leftmost bit to one and all other bits to zero; when the ML field specifies a value of 64, the contents of byte offsets 8-15 form the 64-bit message block; when the ML field specifies a value of 63, the leftmost 63 bits in byte offsets 8-15 padded with a bit of one on the right form the 64-bit message block; when the ML field specifies a value in the range between 1 and 62, inclusively, the specified number of leftmost bits in byte offsets 8-15 padded on the right with a bit of one followed by the necessary number of bits of zero form a 64-bit message block.

When the ML field specifies the value of 64, a 64-bit subkey, K_x, is derived using the 192-bit cryptographic key, K. When the ML field specifies a value in the range between 0 and 63, inclusively, a different subkey, K_y, is derived using the 192-bit cryptographic key, K. The subkey generation algorithm is shown in the following figure.

Steps:

1. $L = CIPH_K(0)$
2. If MSB (L) = 0, then $K_X = L << 1$; Else, $K_X = (L << 1)$ XOR (R_{64})
3. If MSB (K_X) = 0, then $K_Y = K_X << 1$; Else $K_Y = (K_X << 1)$ XOR (R_{64})

Figure 7-356. Subkey Generation Algorithm

Explanation:

MSB(A)	Most significant (leftmost) bit of A
B<<1	The bit string that results from discarding the leftmost bit of B and appending a '0' bit on the right.
XOR	Bit-wise exclusive OR.
R_{64}	A 64-bit value of 27.

Figure 7-356. Subkey Generation Algorithm (Continued)

When the ML field specifies the value of 64, the 64-bit message block is exclusive-ORed with the subkey K_x. The result of the exclusive-OR operation is then exclusive-ORed with initial-chaining value. The result of the second exclusive-OR operation is then enciphered using the 192-bit cryptographic key, K, and the TDEA-192 encryption algorithm. The result of the encryption operation is the CMAC and is placed in byte offsets 16-23 of the parameter block.

When the ML field specifies a value in the range between 0 and 63, inclusively, the 64-bit message block is exclusive-ORed with the subkey K_y. The result of the exclusive-OR operation is then exclusive-ORed with initial-chaining value. The result of the second exclusive-OR operation is then enciphered using the 192-bit cryptographic key, K, and the TDEA-192 encryption algorithm. The result of the encryption operation is the CMAC and is placed in byte offsets 16-23 of the parameter block.

When the ML field specifies a value in the range between 0 and 64, inclusively, condition code 0 is set when execution of the function completes. Condition code 3 is not applicable to either function; condition code 1 is not applicable to the PCC-Compute-Last-Block-CMAC-Using-TDEA-192 function.

PCC-Compute-Last-Block-CMAC-Using-AES-128 (Function Code 18)

PCC-Compute-Last-Block-CMAC-Using-Encrypted-AES-128 (Function Code 26)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-339 on page 7-359.

The parameter block used for the PCC-Compute-Last-Block-CMAC-Using-AES-128 function has the following format:

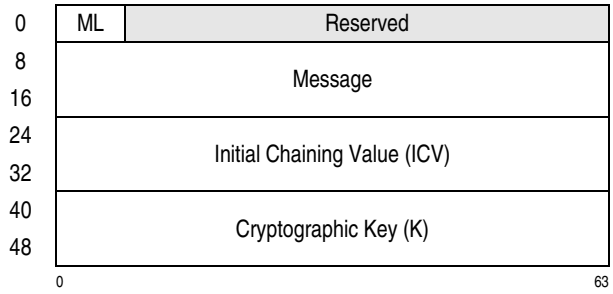

Figure 7-357. Parameter Block for PCC-Compute-Last-Block-CMAC-Using-AES-128

For the PCC-Compute-Last-Block-CMAC-Using-AES-128 function, the initial-chaining value is in byte offsets 24-39 of the parameter block and the cryptographic key is in byte offsets 40-55 of the parameter block.

The parameter block used for the PCC-Compute-Last-Block-CMAC-Using-Encrypted-AES-128 function has the following format:

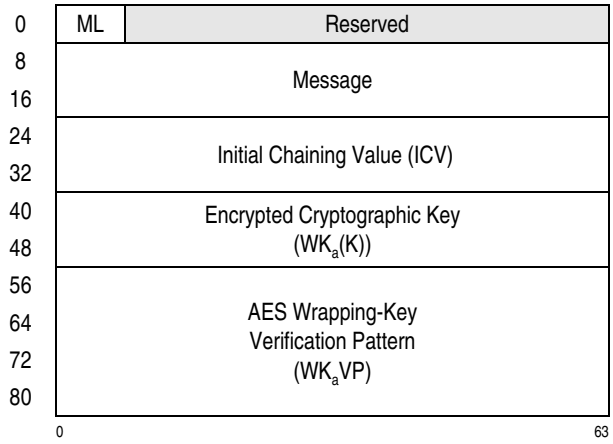

Figure 7-358. Parameter Block for PCC-Compute-Last-Block-CMAC-Using-Encrypted-AES-128

For the PCC-Compute-Last-Block-CMAC-Using-Encrypted-AES-128 function, the contents of byte offsets 56-87 of the parameter block are compared with the contents of the AES wrapping-key verification-pattern register. If they mismatch, the parameter-block location remains unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 24-39 of the parameter block contain the initial chaining value, and the contents of byte offsets 40-55 of the parameter block are deciphered using the AES wrapping key to obtain the 128-bit cryptographic key, K. (See the section "Protection of Cryptographic Keys" on page 7-490 for details.)

The description in the following paragraphs applies to both functions.

The bit length of the message in byte offsets 8-23 of the parameter block is specified by an 8-bit unsigned binary integer in the message-length (ML) field at byte offset 0. When the ML field contains a value greater than 128, the operation is completed by setting condition code 2. Otherwise, the ML field specifies the number of leftmost bits in byte offsets 8-23 that constitute the message. All other bits in byte offsets 8-23 are ignored.

When the ML field specifies a value of 0, a 128-bit message block is formed by setting the leftmost bit to one and all other bits to zero; when the ML field specifies a value of 128, the contents of byte offsets 8-23 form the 128-bit message block; when the ML field specifies a value of 127, the leftmost 127 bits in byte offsets 8-23 padded with a bit of one on the right form the 128-bit message block; when the ML field specifies a value in the range between 1 and 126, inclusively, the specified number of leftmost bits in byte offsets 8-23 padded on the right with a bit of one followed by the necessary number of bits of zero form a 128-bit message block.

When the ML field specifies the value of 128, a 128-bit subkey, K_x, is derived using the 128-bit cryptographic key, K. When the ML field specifies a value in the range between 0 and 127, inclusively, a different subkey, K_y, is derived using the 128-bit cryptographic key, K. The subkey generation algorithm is shown in the following figure.

Steps:

1. $L = CIPH_K(0)$
2. If MSB (L) = 0, then K_X = L << 1; Else, $K_X = (L << 1)\ XOR\ (R_{128})$
3. If MSB (K_X) = 0, then $K_Y = K_X << 1$; Else $K_Y = (K_X << 1)\ XOR\ (R_{128})$

Figure 7-359. Subkey Generation Algorithm

Explanation:

$CIPH_K(0)$	Encryption of the value zero using a 128-bit key and the AES-128 encryption algorithm.
MSB(A)	Most significant (leftmost) bit of A
B<<1	The bit string that results from discarding the leftmost bit of B and appending a '0' bit on the right.
XOR	Bit-wise exclusive OR.
R_{128}	A 128-bit value of 135.

Figure 7-359. Subkey Generation Algorithm (Continued)

When the ML field specifies the value of 128, the 128-bit message block is exclusive-ORed with the subkey K_x. The result of the exclusive-OR operation is then exclusive-ORed with initial-chaining value. The result of the second exclusive-OR operation is then enciphered using the 128-bit cryptographic key, K, and the AES-128 encryption algorithm. The result of the encryption operation is the CMAC and is placed in byte offsets 24-39 of the parameter block.

When the ML field specifies a value in the range between 0 and 127, inclusively, the 128-bit message block is exclusive-ORed with the subkey K_y. The result of the exclusive-OR operation is then exclusive-ORed with initial-chaining value. The result of the second exclusive-OR operation is then enciphered using the 128-bit cryptographic key, K, and the AES-128 encryption algorithm. The result of the encryption operation is the CMAC and is placed in byte offsets 24-39 of the parameter block.

When the ML field specifies a value in the range between 0 and 128, inclusively, condition code 0 is set when execution of the function completes. Condition code 3 is not applicable to either function; condition code 1 is not applicable to the PCC-Compute-Last-Block-CMAC-Using-AES-128 function.

PCC-Compute-Last-Block-CMAC-Using-AES-192 (Function Code 19)

PCC-Compute-Last-Block-CMAC-Using-Encrypted-AES-192 (Function Code 27)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-339 on page 7-359.

The parameter block used for the PCC-Compute-Last-Block-CMAC-Using-AES-192 function has the following format:

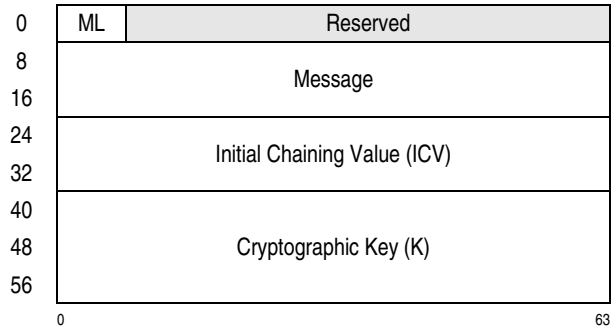

Figure 7-360. Parameter Block for PCC-Compute-Last-Block-CMAC-Using-AES-192

For the PCC-Compute-Last-Block-CMAC-Using-AES-192 function, the initial-chaining value is in byte offsets 24-39 of the parameter block and the cryptographic key is in byte offsets 40-63 of the parameter block.

The parameter block used for the PCC-Compute-Last-Block-CMAC-Using-Encrypted-AES-192 function has the following format:

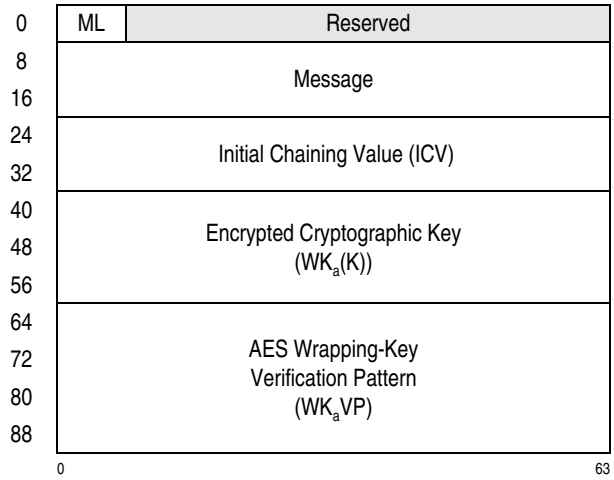

Figure 7-361. Parameter Block for PCC-Compute-Last-Block-CMAC-Using-Encrypted-AES-192

For the PCC-Compute-Last-Block-CMAC-Using-Encrypted-AES-192 function, the contents of byte offsets 64-95 of the parameter block are compared with the contents of the AES wrapping-key verification-pattern register. If they mismatch, the parameter-block location remains unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 24-39 of the parameter block con-

tain the initial chaining value, and the contents of byte offsets 40-63 of the parameter block are deciphered using the AES wrapping key to obtain the 192-bit cryptographic key, K. (See the section "Protection of Cryptographic Keys" on page 7-490 for details.)

The description in the following paragraphs applies to both functions.

The bit length of the message in byte offsets 8-23 of the parameter block is specified by an 8-bit unsigned binary integer in the message-length (ML) field at byte offset 0. When the ML field contains a value greater than 128, the operation is completed by setting condition code 2. Otherwise, the ML field specifies the number of leftmost bits in byte offsets 8-23 that constitute the message. All other bits in byte offsets 8-23 are ignored.

When the ML field specifies a value of 0, a 128-bit message block is formed by setting the leftmost bit to one and all other bits to zero; when the ML field specifies a value of 128, the contents of byte offsets 8-23 form the 128-bit message block; when the ML field specifies a value of 127, the leftmost 127 bits in byte offsets 8-23 padded with a bit of one on the right form the 128-bit message block; when the ML field specifies a value in the range between 1 and 126, inclusively, the specified number of leftmost bits in byte offsets 8-23 padded on the right with a bit of one followed by the necessary number of bits of zero form a 128-bit message block.

When the ML field specifies the value of 128, a 128-bit subkey, K_x, is derived using the 192-bit cryptographic key, K. When the ML field specifies a value in the range between 0 and 127, inclusively, a different subkey, K_y, is derived using the 192-bit cryptographic key, K. The subkey generation algorithm is shown in the following figure.

Steps:

1. $L = CIPH_K(0)$
2. If MSB (L) = 0, then $K_X = L << 1$; Else, $K_X = (L << 1)$ XOR (R_{128})
3. If MSB $(K_X) = 0$, then $K_Y = K_X << 1$; Else $K_Y = (K_X << 1)$ XOR (R_{128})

Figure 7-362. Subkey Generation Algorithm

MSB(A)	Most significant (leftmost) bit of A
B<<1	The bit string that results from discarding the leftmost bit of B and appending a '0' bit on the right.
XOR	Bit-wise exclusive OR.
R_{128}	A 128-bit value of 135.

Figure 7-362. Subkey Generation Algorithm (Continued)

When the ML field specifies the value of 128, the 128-bit message block is exclusive-ORed with the subkey K_x. The result of the exclusive-OR operation is then exclusive-ORed with initial-chaining value. The result of the second exclusive-OR operation is then enciphered using the 192-bit cryptographic key, K, and the AES-192 encryption algorithm. The result of the encryption operation is the CMAC and is placed in byte offsets 24-39 of the parameter block.

When the ML field specifies a value in the range between 0 and 127, inclusively, the 128-bit message block is exclusive-ORed with the subkey K_y. The result of the exclusive-OR operation is then exclusive-ORed with initial-chaining value. The result of the second exclusive-OR operation is then enciphered using the 192-bit cryptographic key, K, and the AES-192 encryption algorithm. The result of the encryption operation is the CMAC and is placed in byte offsets 24-39 of the parameter block.

When the ML field specifies a value in the range between 0 and 128, inclusively, condition code 0 is set when execution of the function completes. Condition code 3 is not applicable to either function; condition code 1 is not applicable to the PCC-Compute-Last-Block-CMAC-Using-AES-192 function.

PCC-Compute-Last-Block-CMAC-Using-AES-256 (Function Code 20)

PCC-Compute-Last-Block-CMAC-Using-Encrypted-AES-256(Function Code 28)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-339 on page 7-359.

The parameter block used for the PCC-Compute-Last-Block-CMAC-Using-AES-256 function has the following format:

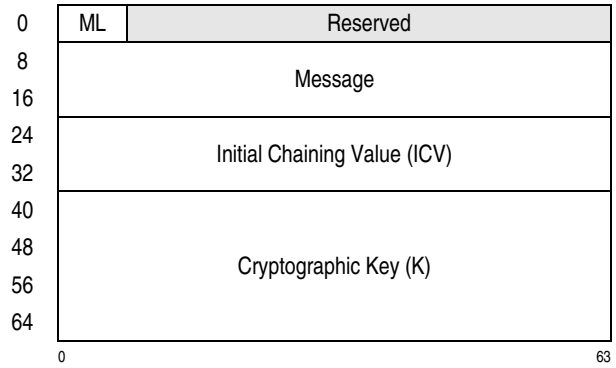

Figure 7-363. Parameter Block for PCC-Compute-Last-Block-CMAC-Using-AES-256

For the PCC-Compute-Last-Block-CMAC-Using-AES-256 function, the initial-chaining value is in byte offsets 24-39 of the parameter block and the cryptographic key is in byte offsets 40-71 of the parameter block.

The parameter block used for the PCC-Compute-Last-Block-CMAC-Using-Encrypted-AES-256 function has the following format:

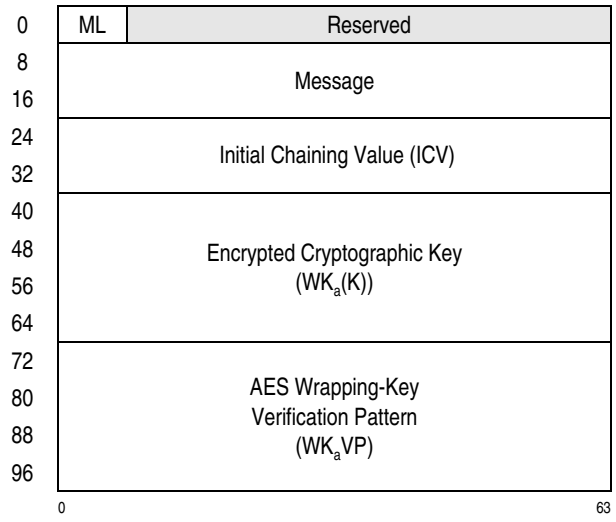

Figure 7-364. Parameter Block for PCC-Compute-Last-Block-CMAC-Using-Encrypted-AES-256

For the PCC-Compute-Last-Block-CMAC-Using-Encrypted-AES-256 function, the contents of byte offsets 72-103 of the parameter block are compared with the contents of the AES wrapping-key verification-pattern register. If they mismatch, the parameter-block location remains unchanged, and the operation is completed by setting condition code 1. If they match, byte offsets 24-39 of the parameter block contain the initial chaining value, and the contents of byte offsets 40-71 of the parameter block are deciphered using the AES wrapping key to obtain the 256-bit cryptographic key, K. (See the section "Protection of Cryptographic Keys" on page 7-490 for details.)

The description in the following paragraphs applies to both functions.

The bit length of the message in byte offsets 8-23 of the parameter block is specified by an 8-bit unsigned binary integer in the message-length (ML) field at byte offset 0. When the ML field contains a value greater than 128, the operation is completed by setting condition code 2. Otherwise, the ML field specifies the number of leftmost bits in byte offsets 8-23 that constitute the message. All other bits in byte offsets 8-23 are ignored.

When the ML field specifies a value of 0, a 128-bit message block is formed by setting the leftmost bit to one and all other bits to zero; when the ML field specifies a value of 128, the contents of byte offsets 8-23 form the 128-bit message block; when the ML field specifies a value of 127, the leftmost 127 bits in byte offsets 8-23 padded with a bit of one on the right form the 128-bit message block; when the ML field specifies a value in the range between 1 and 126, inclusively, the specified number of leftmost bits in byte offsets 8-23 padded on the right with a bit of one followed by the necessary number of bits of zero form a 128-bit message block.

When the ML field specifies the value of 128, a 128-bit subkey, K_X, is derived using the 256-bit cryptographic key, K. When the ML field specifies a value in the range between 0 and 127, inclusively, a different subkey, K_y, is derived using the 256-bit cryptographic key, K. The subkey generation algorithm is shown in the following figure.

Steps:

1. $L = CIPH_K(0)$
2. If MSB (L) = 0, then $K_X = L << 1$; Else, $K_X = (L << 1)$ XOR (R_{128})
3. If MSB (K_X) = 0, then $K_Y = K_X << 1$; Else $K_Y = (K_X << 1)$ XOR (R_{128})

R_{128}	A 128-bit value of 135.

Figure 7-365. Subkey Generation Algorithm (Continued)

When the ML field specifies the value of 128, the 128-bit message block is exclusive-ORed with the subkey K_x. The result of the exclusive-OR operation is then exclusive-ORed with initial-chaining value. The result of the second exclusive-OR operation is then enciphered using the 256-bit cryptographic key, K, and the AES-256 encryption algorithm. The result of the encryption operation is the CMAC and is placed in byte offsets 24-39 of the parameter block.

When the ML field specifies a value in the range between 0 and 127, inclusively, the 128-bit message block is exclusive-ORed with the subkey K_y. The result of the exclusive-OR operation is then exclusive-ORed with initial-chaining value. The result of the second exclusive-OR operation is then enciphered using the 256-bit cryptographic key, K, and the AES-256 encryption algorithm. The result of the encryption operation is the CMAC and is placed in byte offsets 24-39 of the parameter block.

When the ML field specifies a value in the range between 0 and 128, inclusively, condition code 0 is set when execution of the function completes. Condition code 3 is not applicable to either function; condition code 1 is not applicable to the PCC-Compute-Last-Block-CMAC-Using-AES-256 function.

PCC-Compute-XTS-Parameter-Using-AES-128 (Function Code 50)

PCC-Compute-XTS-Parameter-Using-Encrypted-AES-128 (Function Code 58)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-339 on page 7-359.

The parameter block used for the PCC-Compute-XTS-Parameter-Using-AES-128 function has the following format:

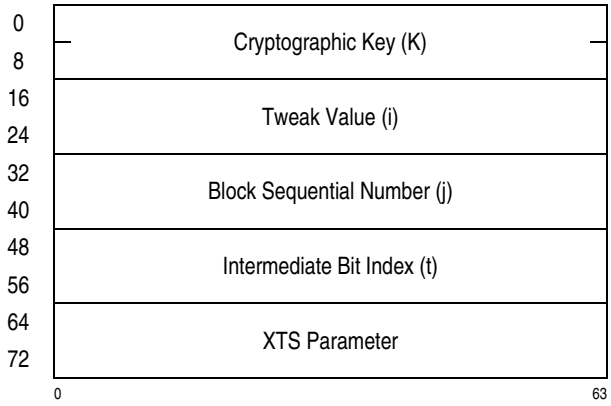

Figure 7-366. Parameter Block for PCC-Compute-XTS-Parameter-Using-AES-128

For the PCC-Compute-XTS-Parameter-Using-AES-128 function, the cryptographic key is in byte offsets 0-15 of the parameter block; the 128-bit tweak value (i) and the 128-bit block sequential number (j) are in byte offsets 16-31 and 32-47, respectively, of the parameter block. When the block sequential number is zero, the contents of byte offsets 48-79 of the parameter block are ignored, the encrypted tweak value is placed in byte offsets 64-79 of the parameter block, and the operation is completed by setting condition code 0. When the block sequential number is nonzero, byte offsets 48-63 of the parameter block contain the index of the next bit in j to be processed. In this case, if the contents of byte offsets 48-63 are zero, then it is the initial execution of the computation, and the contents of byte offsets 64-79 of the parameter block are ignored; if the contents of byte offsets 48-63 are in the range between 1 and 127, inclusively, then byte offsets 64-79 contain the partial XTS parameter computed by a previous iteration; if byte offsets 48-63 of the parameter block contain a value greater than 127, the operation is completed by setting condition code 2.

The parameter block used for the PCC-Compute-XTS-Parameter-Using-Encrypted-AES-128 function has the following format:

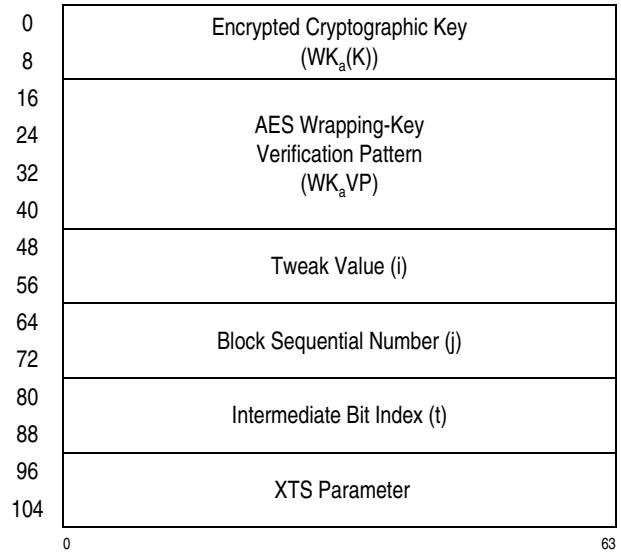

Figure 7-367. Parameter Block for PCC-Compute-XTS-Parameter-Using-Encrypted-AES-128

For the PCC-Compute-XTS-Parameter-Using-Encrypted-AES-128 function, the contents of byte offsets 16-47 of the parameter block are compared with the contents of the AES wrapping-key verification-pattern register. If they mismatch, the parameter-block location remains unchanged, and the operation is completed by setting condition code 1. If they match, the contents of byte offsets 0-15 of the parameter block are deciphered using the AES wrapping key to obtain the 128-bit cryptographic key, K. (See the section “Protection of Cryptographic Keys” on page 7-490 for details.) The 128-bit tweak value (i) and the 128-bit block sequential number (j) are in byte offsets 48-63 and 64-79, respectively, of the parameter block. When the block sequential number is zero, the contents of byte offsets 80-111 of the parameter block are ignored, the encrypted tweak value is placed in byte offsets 96-111 of the parameter block, and the operation is completed by setting condition code 0. When the block sequential number is nonzero, byte offsets 80-95 of the parameter block contain the index of the next bit in j to be processed. In this case, if the contents of byte offsets 80-95 are zero, then it is the initial execution of the computation, and the contents of byte offsets 96-111 of the parameter block are ignored; if the contents of byte offsets 80-95 are in the range between 1 and 127, inclusively, then byte offsets 96-111 contain the partial XTS parameter computed by a previous iteration; if byte offsets 80-95 of the parameter block contain a value greater than 127, the operation is completed by setting condition code 2.

The following description applies to both functions.

The 128-bit XTS parameter is the result of multiplying the encrypted tweak value by the value of 2 raised to the power of the block sequential number (j). Both the power and multiplication operations are performed over GF(2^{128}). The 128-bit tweak value (i) is encrypted using the 128-bit cryptographic key and the AES encryption algorithm. The operation is shown in Figure 7-368.

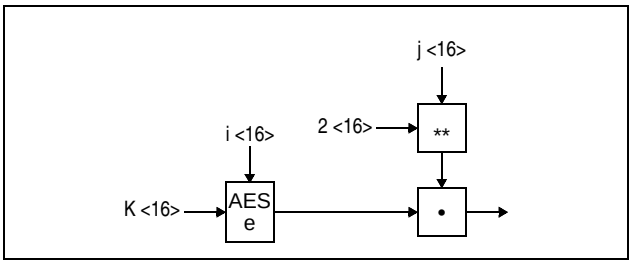

Figure 7-368. Compute XTS Parameter Using AES 128

The value of 2 raised to the power of j is computed as follows: For each bit in j, the value of 2 raised to the power of an exponent, that is a 128-bit unsigned binary integer with an one in that bit and zeros in all other bits, is pre-computed. To obtain the value of 2 raised to the power of j, the pre-computed values that correspond to a bit of one in j are multiplied together. The power and multiplication operations are performed over GF(2^{128}).

For a nonzero j, bits in j are processed from left to right, with an index of 0 for the leftmost bit and an index of 127 for the rightmost bit. The operation is ended when all bits in j have been processed (called normal completion) or when a CPU-determined number of bits that is less than the total number of bits in j have been processed (called partial completion). The CPU-determined number of bits depends on the model, and may be a different number each time the instruction is executed. The CPU-determined number of bits is usually nonzero. In certain unusual situations, this number may be zero, and condition code 3 may be set with no progress. However, the CPU protects against endless reoccurrence of this no-progress case.

When the operation ends due to normal completion, condition code 0 is set and the intermediate bit index field (t) in the parameter block is set to 128. When the

operation ends due to partial completion, condition code 3 is set and the intermediate bit index field (t) in the parameter block is set to the index of the next bit in j to be processed. For the Compute-XTS-Parameter-Using-AES-128 function, the computed XTS parameter or partial XTS parameter is placed in byte offsets 64-79 of the parameter block. For the Compute-XTS-Parameter-Using-Encrypted-AES-128 function, the computed XTS parameter or partial XTS parameter is placed in byte offsets 96-111 of the parameter block.

Condition code 1 is not applicable to the PCC-Compute-XTS-Parameter-Using-AES-128 function.

PCC-Compute-XTS-Parameter-Using-AES-256 (Function Code 52)

PCC-Compute-XTS-Parameter-Using-Encrypted-AES-256 (Function Code 60)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-339 on page 7-359.

The parameter block used for the PCC-Compute-XTS-Parameter-Using-AES-256 function has the following format:

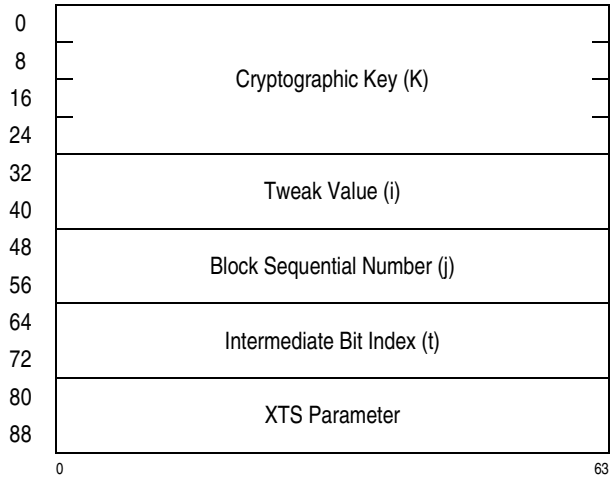

Figure 7-369. Parameter Block for PCC-Compute-XTS-Parameter-Using-AES-256

For the PCC-Compute-XTS-Parameter-Using-AES-256 function, the cryptographic key is in byte offsets 0-31 of the parameter block; the 128-bit tweak value (i) and the 128-bit block sequential number (j) are in byte offsets 32-47 and 48-63, respectively, of the parameter block. When the block sequential number is zero, the contents of byte offsets 64-95 of the parameter block are ignored, the encrypted tweak value is placed in byte offsets 80-95 of the parameter block, and the operation is completed by setting condition code 0. When the block sequential number is nonzero, byte offsets 64-79 of the parameter block contain the index of the next bit in j to be processed. In this case, if the contents of byte offsets 64-79 are zero, then it is the initial execution of the computation, and the contents of byte offsets 80-95 of the parameter block are ignored; if the contents of byte offsets 64-79 are in the range between 1 and 127, inclusively, then byte offsets 80-95 contain the partial XTS parameter computed by a previous iteration; if byte offsets 64-79 of the parameter block contain a value greater than 127, the operation is completed by setting condition code 2.

The parameter block used for the PCC-Compute-XTS-Parameter-Using-Encrypted-AES-256 function has the following format:

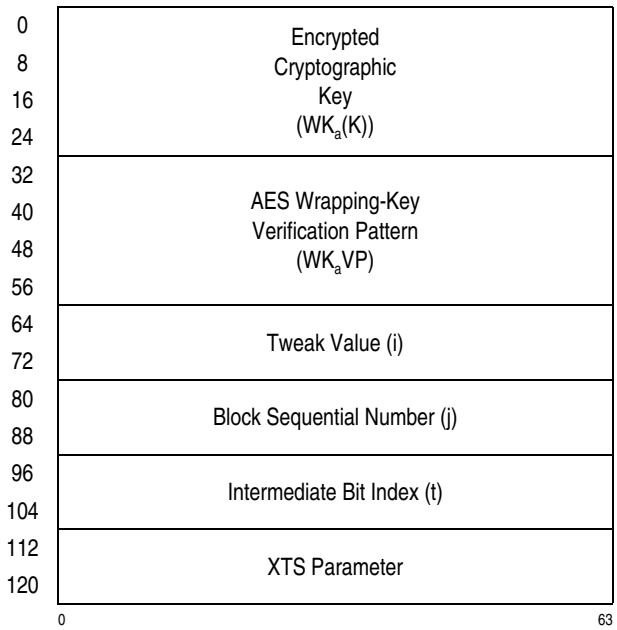

Figure 7-370. Parameter Block for PCC-Compute-XTS-Parameter-Using-Encrypted-AES-256

For the PCC-Compute-XTS-Parameter-Using-Encrypted-AES-256 function, the contents of byte offsets 32-63 of the parameter block are compared with the contents of the AES wrapping-key verification-pattern register. If they mismatch, the parameter-block location remains unchanged, and the operation is completed by setting condition code 1. If they match, the contents of byte offsets 0-31 of the parameter block are deciphered using the AES wrap-

ping key to obtain the 256-bit cryptographic key, K. (See the section “Protection of Cryptographic Keys” on page 7-490 for details.) The 128-bit tweak value (i) and the 128-bit block sequential number (j) are in byte offsets 64-79 and 80-95, respectively, of the parameter block. When the block sequential number is zero, the contents of byte offsets 96-127 of the parameter block are ignored, the encrypted tweak value is placed in byte offsets 112-127 of the parameter block, and the operation is completed by setting condition code 0. When the block sequential number is nonzero, byte offsets 96-111 of the parameter block contain the index of the next bit in j to be processed. In this case, if the contents of byte offsets 96-111 are zero, then it is the initial execution of the computation, and the contents of byte offsets 112-127 of the parameter block are ignored; if the contents of byte offsets 96-111 are in the range between 1 and 127, inclusively, then byte offsets 112-127 contain the partial XTS parameter computed by a previous iteration; if byte offsets 96-111 of the parameter block contain a value greater than 127, the operation is completed by setting condition code 2.

The following description applies to both functions.

The 128-bit XTS parameter is the result of multiplying the encrypted tweak value by the value of 2 raised to the power of the block sequential number (j). Both the power and multiplication operations are performed over GF(2^{128}). The 128-bit tweak value (i) is encrypted using the 256-bit cryptographic key and the AES encryption algorithm. The operation is shown in Figure 7-371.

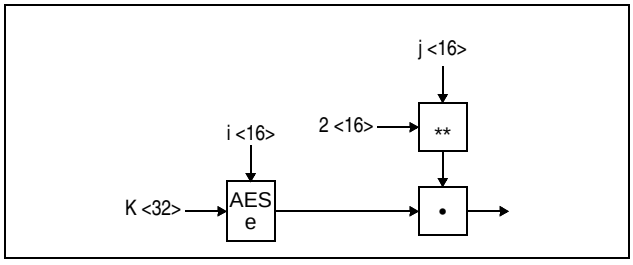

Figure 7-371. Compute XTS Parameter Using AES 256

The value of 2 raised to the power of j is computed as follows: For each bit in j, the value of 2 raised to the power of an exponent, that is a 128-bit unsigned binary integer with an one in that bit and zeros in all other bits, is pre-computed. To obtain the value of 2 raised to the power of j, the pre-computed values that correspond to a bit of one in j are multiplied together. The power and multiplication operations are performed over GF(2^{128}).

For a nonzero j, bits in j are processed from left to right, with an index of 0 for the leftmost bit and an index of 127 for the rightmost bit. The operation is ended when all bits in j have been processed (called normal completion) or when a CPU-determined number of bits that is less than the total number of bits in j have been processed (called partial completion). The CPU-determined number of bits depends on the model, and may be a different number each time the instruction is executed. The CPU-determined number of bits is usually nonzero. In certain unusual situations, this number may be zero, and condition code 3 may be set with no progress. However, the CPU protects against endless reoccurrence of this no-progress case.

When the operation ends due to normal completion, condition code 0 is set and the intermediate bit index field (t) in the parameter block is set to 128. When the operation ends due to partial completion, condition code 3 is set and the intermediate bit index field (t) in the parameter block is set to the index of the next bit in j to be processed. For the Compute-XTS-Parameter-Using-AES-256 function, the computed XTS parameter or partial XTS parameter is placed in byte offsets 80-95 of the parameter block. For the Compute-XTS-Parameter-Using-Encrypted-AES-256 function, the computed XTS parameter or partial XTS parameter is placed in byte offsets 112-127 of the parameter block.

Condition code 1 is not applicable to the PCC-Compute-XTS-Parameter-Using-AES-256 function.

PCC-Scalar-Multiply (Function Codes 64, 65, 66, 72, and 73)

Note: The description of the PCC-Scalar-Multiply functions assumes that the reader is familiar with the Elliptic Curve Digital Signal Algorithm (ECDSA) described in Reference [24.] on page xxxii. This section illustrates the operation for five PCC-Scalar-Multiply functions:

- PCC-Scalar-Multiply-P256 (function code 64)
- PCC-Scalar-Multiply-P384 (function code 65)
- PCC-Scalar-Multiply-P521 (function code 66)
- PCC-Scalar-Multiply-Ed25519 (function code 72)
- PCC-Scalar-Multiply-Ed448 (function code 73)

The three functions with P256, P384, and P521 use NIST curves from Reference [24.] on page xxxii. Also see Reference [27.] on page xxxii section 5.4 p.17-18

for algorithm details and see D.1.2.3-5 in Reference [24.] on page xxxii p.100 for the curve parameter values including the prime modulus, the order, the coefficient, the base point x coordinate, and the base point y coordinate used by these functions.

Two functions, PCC-Scalar-Multiply Ed25519 and Ed448 use twisted Edwards Curves using the EdDSA algorithm, see Reference [25.] on page xxxii for algorithm details and curve parameter values, section 5.1 and 5.2 detail curve parameters for Ed25519 and Ed448 respectively.

The PCC-Scalar-Multiply function implements a scalar multiply of point on an elliptic curve as shown by the following:

- (Xr, Yr) <= d * (Xs, Ys)

where the input point is represented by the coordinates, Xs and Ys, is multiplied by a scalar, d, and results in the point represented by the coordinates Xr and Yr. The scalar multiply of a point can be accomplished by a series of point additions and point doublings along the elliptic curve. The bits of d are scanned from most significant to least significant. For every bit equal to one in the scalar, d, a point addition occurs and after each bit scanned a point doubling occurs and terminates on the scanning of the least significant bit and its possible point addition.

d equal to zero is a special case of point multiplication and results in infinity which can't be represented with the two (Affine) coordinates Xr and Yr and instead is represented by setting condition code two and leaving the result unchanged.

The parameter block for PCC-Scalar-Multiply-P256 and Ed25519 functions is shown in Figure 7-372, below.

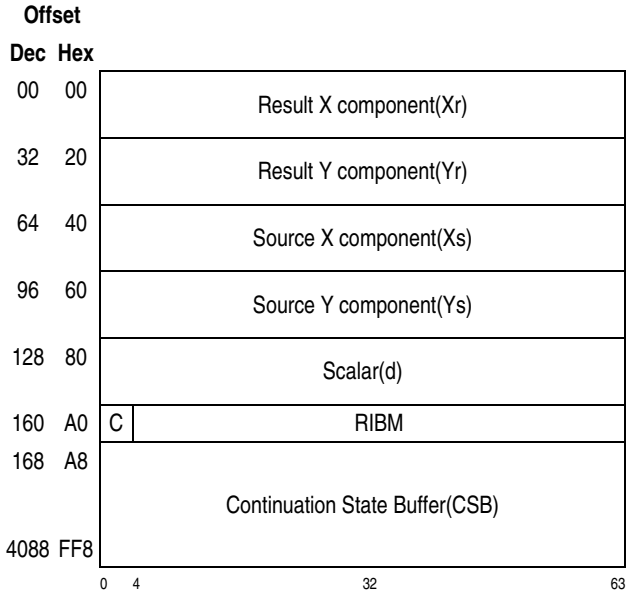

Figure 7-372. Parameter Block for PCC-Scalar-Multiply-P256 and Ed25519, Function

The parameter block for PCC-Scalar-Multiply-P384 function is shown in Figure 7-373, below.

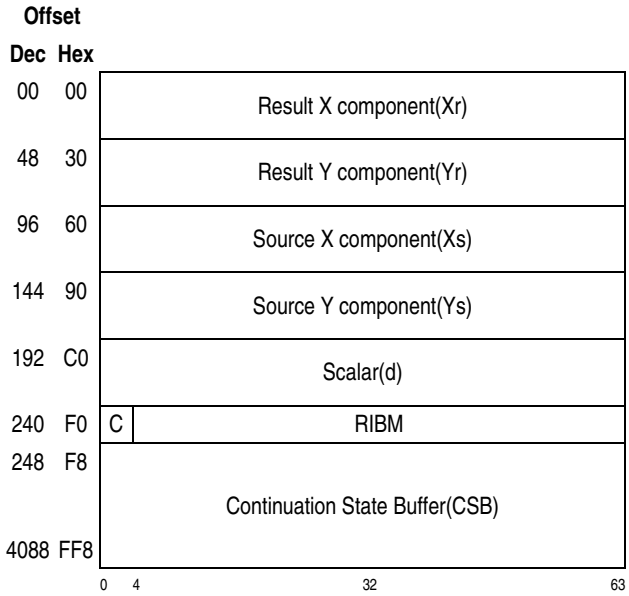

Figure 7-373. Parameter Block for PCC-Scalar-Multiply-P384 Function

The parameter block for PCC-Scalar-Multiply-P521 function is shown in Figure 7-374, below. The left-

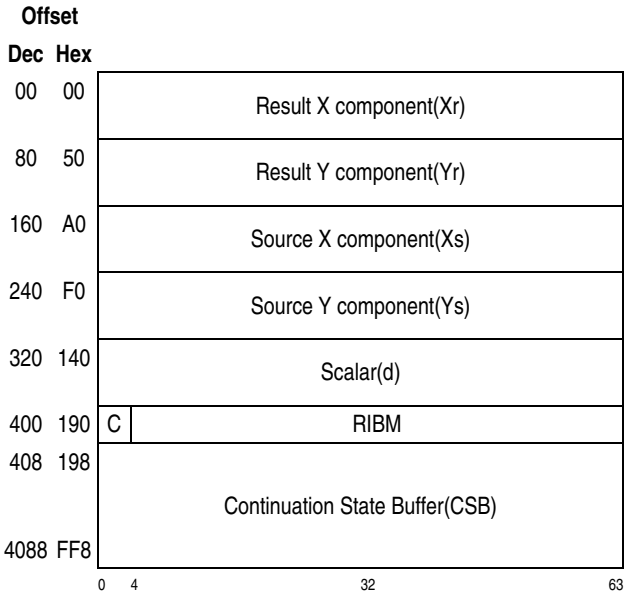

Figure 7-374. Parameter Block for PCC-Scalar-Multiply-P521 Function

most 14 bytes of the source operands are ignored, and for the result operands are not updated.

The parameter block for PCC-Scalar-Multiply-Ed448 function is shown in Figure 7-375, below. The left-

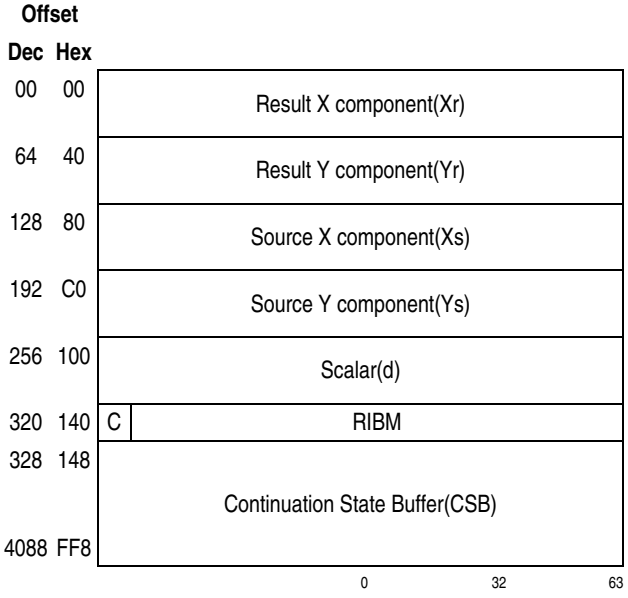

Figure 7-375. Parameter Block for PCC-Scalar-Multiply-Ed448 Function

most 8 bytes of each source operand is ignored and of each result operand is not updated.

Note that all fields are considered to be multiple bytes in width including Ed25519 and P521. The operands are right aligned within these bytes. And the most significant bits should be zero filled including 1 bit for Ed25519 format and 7 bits for P521 format. If these bits in the source operands are non-zero then the condition code is set to 1. The fields of the parameter block for all PCC-Scalar-Multiply function are as follows:

Result X component (Xr): This is the X component of the point on elliptic curve resulting from the multiply of scalar times the source point on curve. It is an integer greater than or equal to zero and less than the prime of the function and right aligned in this field. For P256, P384, and P521, are in Weierstrass form and for Ed25519 and Ed448 this coordinate is on an Edwards curve. Part of the result of PCC-Scalar-Multiply is stored to this field in the parameter block.

Result Y component (Yr): This is the Y component of the point on elliptic curve resulting from the multiply of scalar times the source point on curve. For P256, P384, and P521 this coordinate is on a Weierstrass curve and for Ed25519 and Ed448 this coordinate is on an Edwards curve. It is an integer greater than or equal to zero and less than the prime of the function and is right aligned in this field. Part of the result of PCC-Scalar-Multiply is stored to this field in the parameter block.

Source X component (Xs): This is the X component of the point on elliptic curve which is the source of the scalar multiply. For P256, P384, and P521, are in Weierstrass form and for Ed25519 and Ed448 this coordinate is on an Edwards curve. Xs is right aligned in this field and bytes to the left are ignored. Xs is an integer greater than or equal to zero and less than the prime of the function. For P256, P384, P521, Ed25519, and Ed448, if Xs is greater than or equal to the prime, the condition code is set to 1, or if the point is not on the curve.

Source Y component (Ys): This is the Y component of the point on elliptic curve which is the source of the scalar multiply. For P256, P384, and P521 this coordinate is in Weierstrass form, and for Ed25519 and Ed448 this coordinate is on an Edwards curve.Ys is right aligned in this field and bytes to the left are ignored and can be random values. Ys is an integer less than the prime of the function. If it is greater than or equal to the prime, the condition code is set to 1, or if the point is not on the curve.

Scalar (d): This is the source scalar to PCC-Scalar-Multiply function. d which is right aligned and bytes to the left are ignored. d is an unsigned integer. For P256, P384, and P521 the scalar has to be less than the order of the curve otherwise the condition code is set to 1. For Ed25519 the most significant bit of the most significant byte must be zero, for P521 the most significant 7 bits of the most significant byte must be zero otherwise the condition code is set to 1. For Ed448 the scalar can have any value. If d equals zero then the condition code is set to 2 to represent infinity.

Reserved for IBM use (RIBM), informational Code (C) and Continuation State Buffer (CSB): The C and RIBM must be initialized to zero prior to the first invocation of the instruction. The RIBM contains status and control information and continuation state buffer (CSB) is provided to hold intermediate results for partial completion reported by setting the condition code equal to 3. The CSB should not be altered by the programmer after partial completion and before subsequent invocation, otherwise intermediate results may be discarded causing long execution times. The CSB after a restart is cleared by the CPU of any intermediate state. The informational code, C, is reserved for future use.

Store-type access exceptions may be recognized for any location in the parameter block, even though only the Xr, Yr, RIBM, and CSB are stored by the instruction.

For P256, P384, P521, Ed25519, and Ed448 if Xs and Ys are zero or greater than or equal to the prime modulus, or not on the specified curve, or if P256, P384, or P521 and d is greater than or equal to the order of the curve, the condition code is set to 1 and the result is not updated. If d is equal to zero, the result is infinity which can not be represented with two coordinates, so the condition code is set to 2 and the result is not updated. Condition code 3 is set if the operation ends in partial completion and the parameter block may be updated. If none of these cases, Xr and Yr are updated and the condition code is set to 0.

PCC-Scalar-Multiply-Montgomery Form (Function Codes 80 and 81)

Note: The description of the PCC-Scalar Multiply for Montgomery Form function assumes that the reader is familiar with the Elliptic Curve Diffie-Hellman key exchange described in Reference [40.] on page xxxiii.

This section illustrates the operation for two PCC-Scalar-Multiply functions using the Montgomery form of the curves:

- PCC-Scalar-Multiply-X25519 (function code 80)
- PCC-Scalar-Multiply-X448 (function code 81)

The two functions, PCC-Scalar-Multiply-X25519 and PCC-Scalar-Multiply-X448 use the ECDH algorithm and use curves defined in RFC-7748. Reference [40.] on page xxxiii gives algorithm details and curve parameter values, section 4.1 and 4.2 gives curve parameters for X25519 and X448 respectively, which are used by these function codes. In Reference [40.] on page xxxiii point coordinates are given on a Montgomery curve as (U, V) and on a twisted Edwards curve as (X, Y). For the PCC-Scalar-Multiply-X25519 and X448 functions the source and result coordinates are defined to be on the Montgomery form of the curve which uses the U and V coordinate naming in RFC-7748. The scalar multiplication function as defined in RFC-7748 has as input the scalar, d, and the U coordinate of a point, and the V coordinate is implied. The result is the U coordinate of the point produced. PCC-Scalar-Multiply-X25519 and X448 support this definition and the source and result V components do not appear in the parameter block. Also the source U component is assumed to be less than prime of the field.

The PCC-Scalar-Multiply function implements a scalar multiply of a point on an elliptic curve as shown by the following:

- (Ur, Vr) <= d * (Us, Vs)

where the input point represented by the coordinates, Us and Vs, is multiplied by a scalar, d, and results in the point represented by the coordinates Ur and Vr, where Vs and Vr are implied. The scalar multiply of a point can be accomplished by a series of point additions and point doublings along the elliptic curve. RFC-7748 gives a faster algorithm than using point additions and point doublings for special values of d. The scalar d must be of the form 2^254 + 8*k where k is between 0 and 2^251 -1 inclusive for X25519, and of the form 2^447 + 4*k where k is between 0 and 2^445 - 1 inclusive for X448. PCC-Scalar-Multiply-X25519 and X448 are unpredictable if the scalar d is not in this form or the U coordinate not less than the prime.

The parameter block for PCC-Scalar-Multiply-X25519 function is shown in Figure 7-376, below.

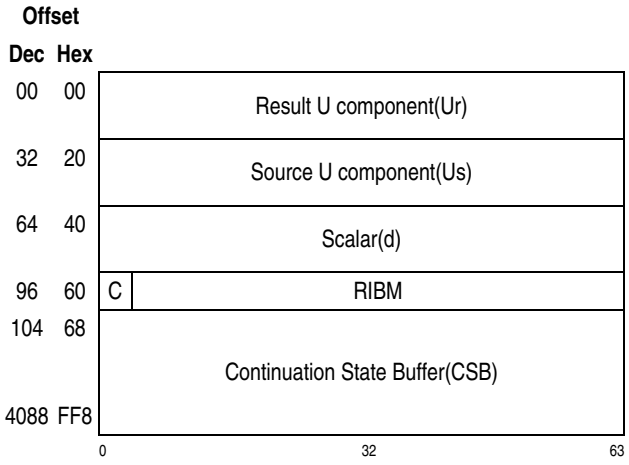

Figure 7-376. Parameter Block for PCC-Scalar-Multiply-X25519 Function

For X448 bytes 0 through 7 of the input operands are ignored. For both X25519 and X448 if Us is zero or greater than the prime modulus the condition code is set to 1, and the result is not updated; otherwise, Ur is updated and the condition code is set to 0.

The parameter block for PCC-Scalar-Multiply-X448 function is shown in Figure 7-377, below.

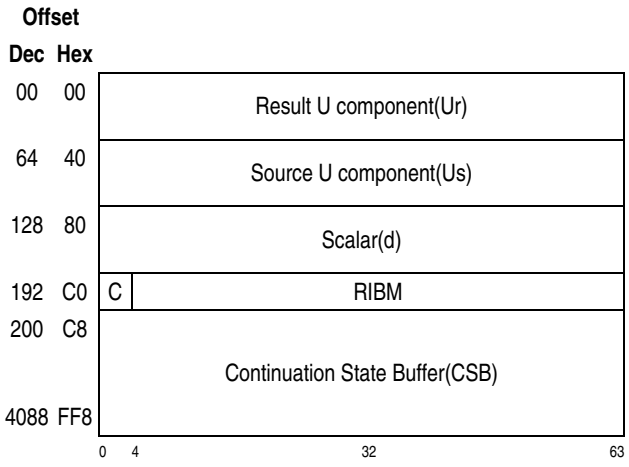

Figure 7-377. Parameter Block for PCC-Scalar-Multiply-X448 Function

Note that all the fields are considered to be multiple bytes in width including X25519 format. The most significant bit in X25519 is considered significant and should be zero otherwise the condition code is set to 1. The fields of the parameter block for all PCC-Scalar-Multiply functions are as follows:

Result U component (Ur): This is the U component of the point on the Montgomery form of the elliptic curve resulting from the multiply of scalar times the source point on curve. It is an integer greater than or equal to zero and less than the prime of the functions and right aligned in this field. The result of PCC-Scalar-Multiply is stored to this field in the parameter block. For X448 bytes 0 through 7 are not updated.

Source U component (Us): This is the U component of the point on the Montgomery form of the elliptic curve which is the source of the scalar multiply. Us is right aligned in this field and bytes to the left are ignored. Us is an integer less than the prime of the functions. If Us is greater than or equal to the prime, the condition code is set to 1. Note for X448 bytes 0 through 7 are ignored, though the most significant bit of X25519 format is significant and should be zero otherwise the condition code is set to 1.

Scalar (d): This is the source scalar to PCC-Scalar-Multiply function. d which is an unsigned integer and is right aligned and bytes to the left are ignored and can be random values. Note for X448 bytes 0 through 7 are ignored. Results are unpredictable if d is not of the form 2^254 + 8*k where k is between 0 and 2^251 -1 inclusive for X25519, and of the form 2^447 + 4*k where k is between 0 and 2^445 - 1 inclusive for X448. d should not be equal to zero.

Reserved for IBM use (RIBM), informational Code (C), and Continuation State Buffer (CSB): The C and RIBM must be initialized to zero prior to the first invocation of the instruction. The RIBM contains status and control information and continuation state buffer (CSB) is provided to hold intermediate results for partial completion reported by setting the condition code equal to 3. The parameter block should not be altered by the programmer after partial completion and before subsequent invocation, otherwise the CPU may clear the CSB of intermediate status and results and end in partial completion which will allow a clean re-execution of the instruction. This results in longer execution. The CSB after a restart is cleared by the CPU of any intermediate state. The informational code (C) is reserved for future use on this instruction.

If Us is greater than or equal to the prime, condition code one is set and the result remains unchanged. Condition code 3 is set if the operation results in partial completion and the parameter block may be updated. If none of the above conditions, the result is

updated and condition code zero is set. If d is not in the proper form the results are unpredictable.

Store-type access exceptions may be recognized for any location in the parameter block.

Common Operation

If the CPU is enabled to update counters in the cryptography-counter set and an operation other than PCC-Query ends with setting condition code 0, then instruction execution also includes updating the appropriate counter.

PCC-Query-Authentication-Information (Function Code 127)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-339 on page 7-359.

The PCC-query-authentication-information function stores the information that can be used by the program to authenticate the running instruction's firmware code level (IFCL) currently installed on the model into the format-0 parameter block for PCC-query-authentication-information. Condition code 0 is set when execution of the PCC-query-authentication-information function completes; condition codes 1, 2, and 3 are not applicable to this function.

The format-0 parameter block used for the PCC-query-authentication-information function has the following format:

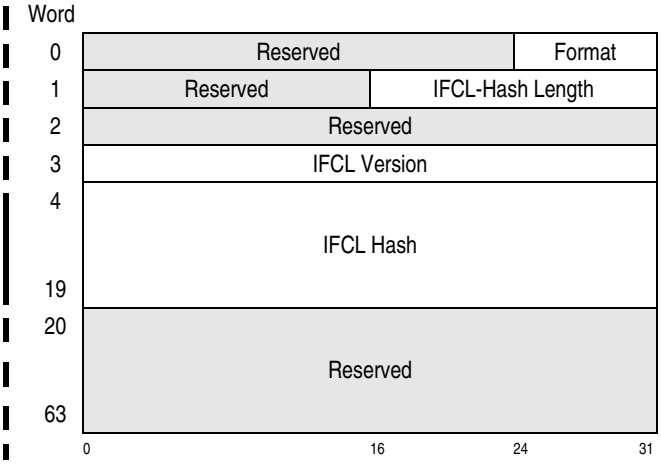

Figure 7-378. Format-0 Parameter Block for PCC-Query-Authentication-Information

The format-0 parameter block contains the following fields:

Reserved: Bytes 0-2 of word 0, bytes 0-1 of word 1, word 2, and words 20-63 are reserved and stored as zeros.

Format: Byte 3 of word 0 contains an 8-bit unsigned binary integer whose value specifies the format of the parameter block. A format value of zero indicates a format-0 parameter block. When a format-0 parameter block is stored, the value of this field is set to zero.

IFCL-Hash Length: Bytes 2-3 of word 1 contain a 16-bit unsigned binary integer specifying the number of bytes of the IFCL hash stored in the IFCL hash field. When the IFCL hash is less than or equal to 64 bytes, the IFCL-hash length field is set to the actual length of the IFCL hash. When the IFCL hash is larger than 64 bytes, the IFCL-hash length field is set to 64.

IFCL Version: Word 3 contains a 32-bit unsigned binary integer specifying the version number of the IFCL.

IFCL Hash: Words 4-19 contain the hash value of the IFCL. The IFCL-hash length field specifies the number of bytes that are in the IFCL hash field. The IFCL hash value is left aligned. When the IFCL hash is less than 64 bytes, it is padded with zeros on the right. When the IFCL hash is larger than 64 bytes, only the leftmost 64 bytes of the IFCL hash are stored.

Special Conditions

A specification exception is recognized and no other action is taken if any of the following occurs:

1. Bit 56 of general register 0 is not zero.
2. Bits 57-63 of general register 0 specify an unassigned or uninstalled function code.

Resulting Condition Code:

0 Normal completion
1 Verification-pattern mismatch or source operand out of range
2 Invalid bit index or message length, or for Scalar Multiply result is infinity for d equal to zero
3 Partial completion

Program Exceptions:

- Access (fetch, parameter block; store, query parameter block and query-authentication-information parameter block; fetch and store, intermediate bit index, XTS parameter, initial chaining value, cryptography counter)
- Operation (if the message-security-assist extension 4 is not installed)
- Specification
- Transaction constraint

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B	Operation exception.
7.C	Transaction constraint
8.	Specification exception due to invalid function code or bit 56 of general register 0 is not zero.
9.	Access exceptions for an access to the parameter block.
10.A	Condition code 1 due to verification-pattern mismatch or source point Us, Xs, Ys coordinates out of range or (Xs,Ys) not on the curve. For scalar-multiply P256, P384, or P521 and scalar (d) greater than or equal to the order of the curve, condition code 1 is set. For scalar-multiply Ed25519 if bit 0 of d is 1 then condition code 1 is set.
10.B	Condition code 2 due to invalid bit index or message length.
10.C	Condition code 2 due to scalar (d) equal to zero for scalar-multiply functions (infinity case).
10.D	Access exceptions for an access to a cryptography counter.
11.	Condition code 0 due to normal completion.
12.	Condition code 3 due to partial completion.

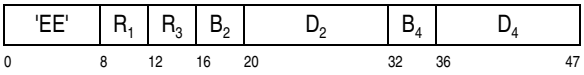
Figure 7-379. Priority of Execution: PCC

Programming Notes:

1. The performance of the query function (code 0) may be significantly slower than that of simply examining a location in storage. If the program needs to frequently test for the availability of a function, it should perform the query function once during initialization; subsequently it should examine the stored results of the query function in memory with an instruction such as TEST UNDER MASK.
2. For the initial execution of a PCC Compute-XTS-Parameter function, the contents of the intermediate-bit-index (t) field in the parameter block shall be set to zeros.

PERFORM LOCKED OPERATION

PLO $R_1,D_2(B_2),R_3,D_4(B_4)$ [SS-e]



An operation specified by the test bit and the function code in general register 0 is performed.

If the PLO-extension facility is not installed and the test operation is not specified, then after the lock specified in general register 1 has been obtained, the operation specified by the function code is performed, and then the lock is released. However, as observed by other CPUs: (1) storage locations which contain the second operand or any field of the parameter list may be tested for access exceptions and fetched before the lock is obtained, and (2) operands may be stored in the parameter list after the lock has been released. If the second operand is fetched before the lock is obtained, it is fetched again after the lock has been obtained.

If the PLO-extension facility is installed and the test operation is not specified, then the operation specified by the function code is performed with all accesses for all storage operands not in the parameter list appearing to occur concurrently as observed by other CPUs and channel programs. In this case, general register 1 does not specify a PLT address corresponding to a lock and a lock is not obtained.

The test bit (T) is in bit position 55 of general register 0. When the test bit is one, a test operation is performed, which provides the means of indicating which of the defined function codes are valid (installed). During the test operation, condition code 0 is set if the function code (FC) specified in bit posi-

tions 56-63 of general register 0 is valid (installed); otherwise, condition code 3 is set, indicating the function code specified is invalid (not installed). When the test operation is performed, a lock is not obtained and the operation specified by the function code is not performed. When the test operation is performed in the ESA/390-compatibility mode, function codes unique to z/Architecture are considered invalid. That is, only function codes 0, 1, 4, 5, 8, 9, 12, 13, 16, 17, 20, and 21 are valid in the ESA/390-compatibility mode. The remaining descriptions for this instruction assume the test bit is zero, except when stated otherwise.

When the test bit is zero, the function code (FC) in bit positions 56-63 of general register 0 specify the operation to be performed. If the function code specified is invalid (not installed), then a specification exception is recognized.

Function codes specifying operations that are available to the program are called valid or installed. Function codes that have not been assigned to operations or that specify operations that are not available to the program are called invalid or not installed. In the z/Architecture architectural mode, the operations specified by function codes 0-23 are always installed and operations specified by function codes 24-61 are installed when the PLO-extension facility is installed. In the ESA/390-compatibility mode, it is unpredictable whether operations that are unique to the z/Architecture architectural mode are available to the program (that is, function codes 2, 3, 6, 7, 10, 11, 14, 15, 18, 19, 22, 23, and 24-61).

The function code specifies the length of all operands used in the operation and the location of each operand used in the operation. Each operand is located in a general register, a field in the parameter list, a storage location designated by the B_2 and D_2 fields of the instruction, a storage location designated by the B_4 and D_4 fields of the instruction, or a storage location designated by a field in the parameter list, depending on the function code.

Figure 7-380 on page 7-380 shows the function codes, operation names, operand lengths, and symbols that may be used to refer to the operations in discussions. For example, PLO.DCS may be used to mean PERFORM LOCKED OPERATION with function code 8. In the symbols, the letter “G” indicates a 64-bit operand length, the letter “R” indicates that some or all 64-bit operands are in general registers, the letter “X” indicates a 128-bit operand length, and the letter “O” indicates a 256-bit operand length.

Figure 7-380. PERFORM LOCKED OPERATION Attributes for Function Codes 0-61 (Part 3 of 4)

Function	Function Code	Operand Length (Bytes)[2]	Function Symbol	Compare Operations[3]	Swap Operations[4]	Load or Store Operations[5]

Explanation:

–	This function does not include this type of operation.
1	Function code is available when the PLO-extension facility is installed.
2	The operand length in bytes also indicates the integral boundary for storage operands.
3	When a result for a compare is not equal, the compare operand on the left is replaced by the compare operand on the right.
4	Only performed when the results for all compares are equal.
5	Only performed when the results for all compares are equal.
←	Assignment operation.
==	Compare operation.
$D_2(B_2)$	Storage location at address specified by $D_2(B_2)$.
$D_4(B_4)$	Storage location at address specified by $D_4(B_4)$.
PL.n	The field beginning at byte offset n in the parameter list.
(PL.n)	Storage location at address specified by the field beginning at byte offset n in the parameter list.
R_n	General register R_n. For function codes 0, 4, 8, 12, 16, and 20, operands in general registers are in bit positions 32-63 of the registers, and bits positions 0-31 of the registers are ignored and remain unchanged. For all other function codes, operands in general registers are in bit positions 0-63 of the registers.

Figure 7-380. PERFORM LOCKED OPERATION Attributes for Function Codes 0-61 (Part 4 of 4)

Bits 32-54 of general register 0 must be all zeros; otherwise, a specification exception is recognized. When bit 55 of the register is one, this is the only exception that can be recognized. Bits 0-31 of general register 0 are ignored.

When the PLO-extension facility is not installed, the lock to be used is represented by a program lock token (PLT) whose logical address is specified in general register 1. In the 24-bit addressing mode, the PLT address is bits 40-63 of general register 1, and bits 0-39 of the register are ignored. In the 31-bit addressing mode, the PLT address is bits 33-63 of the register, and bits 0-32 of the register are ignored. In the 64-bit addressing mode, the PLT address is bits 0-63 of the register. When the PLO-extension facility is installed, general register 1 does not specify a PLT address corresponding to a lock and a lock is not obtained for function codes 0-61.

The contents of general registers 0 and 1 described above are shown in Figure 7-381.

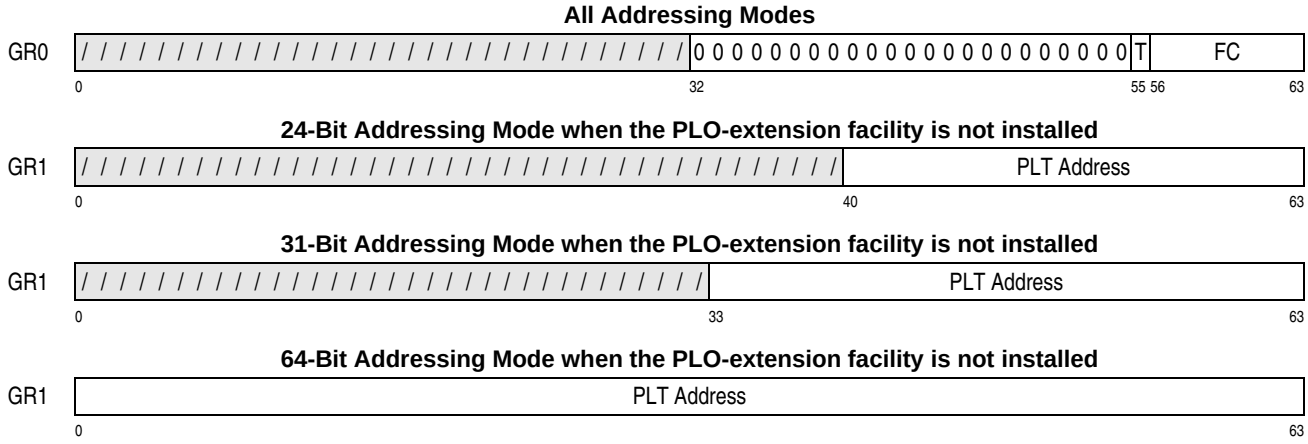

Figure 7-381. General Register Assignment for PLO

For function codes 0, 2, 4, 6, 8, 10, 12, 14, 16, 18, 20 and 22, the first-operand comparison value is in general register R_1. For function codes 4, 6, 8, 10, 12, 14, 16, 18, 20, and 22, the first-operand replacement value is in general register $R_1 + 1$, and R_1 designates an even-odd pair of registers and must designate an even-numbered register; otherwise, a specification exception is recognized. For function codes 0 and 2,

R_1 can be even or odd. For function codes 1, 3, 5, 7, 9, 11, 13, 15, 17, 19, 21, and 23-61, the R_1 field of the instruction is ignored.

For function codes 0, 2, 12, and 14, the third operand is in general register R_3, and R_3 can be even or odd. For function codes 8 and 10, the third-operand comparison value is in general register R_3, the third-operand replacement value is in general register $R_3 + 1$, and R_3 designates an even-odd pair of registers and must designate an even-numbered register; otherwise, a specification exception is recognized. For function codes 4-7 and 25, the R_3 field of the instruction is ignored. When not in the access-register mode, the R_3 field of the instruction is ignored for function codes 1, 3, 9, 11, 13, 15-24, and 26-61.

In the access-register mode, for function codes that use a parameter list containing an ALET, R_3 must not be zero; otherwise, a specification exception is recognized.

For function codes 0-29, the B_2 and D_2 fields of the instruction specify the second-operand address. For function codes 30-61, the B_2 and D_2 fields of the instruction are ignored.

For function codes 0, 2, 8, 10, 12, and 14, the B_4 and D_4 fields of the instruction specify the fourth-operand address.

For function codes 1, 3, 5, 7, 9, 11, 13, and 15-29, the B_4 and D_4 fields of the instruction specify the address of a parameter list that is used by the instruction, and this address is not called the fourth-operand address. The parameter list contains odd-numbered operands, including comparison and replacement values, and addresses of even-numbered operands other than the second operand. In the access-register mode, the parameter list also contains access-list-entry tokens (ALETs) associated with the even-numbered-operand addresses.

For function codes 30-61, the B_4 and D_4 fields of the instruction specify the address of a parameter list that is used by the instruction, and this address is not called the fourth-operand address. The parameter list contains the addresses of all operands, input data, and output data required for the operation. In the access-register mode, the parameter list also contains access-list-entry tokens (ALETs) associated with all operand addresses.

Figure 7-380 on page 7-380 shows the locations of the operands used during the compare, swap, load and store operations performed by the instruction.

Operand addresses in a parameter list, if used, are in doublewords in the list. In the 24-bit addressing mode, an operand address is bits 40-63 of a doubleword, and bits 0-39 of the doubleword are ignored. In the 31-bit addressing mode, an operand address is bits 33-63 of a doubleword, and bits 0-32 of the doubleword are ignored. In the 64-bit addressing mode, an operand address is bits 0-63 of a doubleword.

In the access-register mode, the following applies:

- For function codes 0-29, access register B_2 specifies the address space containing the second operand.
- For function codes 0, 2, 8, 10, 12, and 14, access register B_4 specifies the address space containing the fourth operand.
- For function codes 1, 3, 5, 7, 9, 11, 13, and 15-61, access register B_4 specifies the address space containing the parameter list.
- For function codes 1, 3, 9, 11, 13, 15-24, and 26-61, each operand address in the parameter list has a corresponding access-list-entry token (ALET) in the parameter list which specifies the address space containing the operand.
- For function codes 0-23, when the PLO-extension facility is not installed, access register 1 specifies the address space containing the program-lock token (PLT).

When not in the access-register mode, the contents of access register R_3 remain unchanged.

In the access-register mode, the following applies to access register R_3:

- If an access exception or PER storage-alteration event is recognized for an operand whose address is in the parameter list, then the associated ALET in the parameter list is loaded into access register R_3 when the exception or event is recognized. Then, during the resulting program interruption, if a value is due to be stored as the exception access identification at real location 160 or the PER access identification at real location 161, R_3 is stored.

- If access exception conditions exist for multiple operands designated by the contents of the parameter list and one of these conditions is recognized, then it is model dependent which of these conditions is recognized. In this case, access register R_3 is loaded with the ALET associated with the condition being recognized.
- If PER storage-alteration events exist for multiple operands designated by the contents of the parameter list and one of these conditions is recognized, then it is model dependent which of these conditions is recognized. In this case, access register R_3 is loaded with the ALET associated with the condition being recognized.
- If an access exception or PER storage-alteration event is recognized for the operand designated by $D_2(B_2)$, then it is model dependent whether the contents of access register R_3 are changed.
- If the instruction execution is completed without the recognition of an exception or PER storage-alteration event, then it is model dependent whether the contents of access register R_3 are changed.

For function codes 0-29, storage operand 2, and, when present, storage operands 4, 6, and 8 must be designated on an integral boundary, which is a word boundary for function codes 0, 4, 8, 12, 16, and 20, a doubleword boundary for function codes 1, 2, 5, 6, 9, 10, 13, 14, 17, 18, 21, and 22, a quadword boundary for function codes 3, 7, 11, 15, 19, and 23, and an octoword boundary for function codes 24-29. For each of these storage operands, the following applies:

- If accessing the operand is required to complete the operation and the operand is not designated on the specified boundary, then a specification exception is recognized.
- If accessing the operand is not required to complete the operation and the operand is not designated on the specified boundary, then it is model dependent whether a specification exception is recognized.

For function codes 30-61, all storage operands not in the parameter list must be designated on an integral boundary, which is a word boundary for function codes 30, 34, 41, 45, 50, 54, and 58, a doubleword boundary for function codes 31, 35, 42, 46, 51, 55, and 59, a quadword boundary for function codes 32, 36, 39, 43, 47, 52, 56, and 60, and an octoword boundary for function codes 33, 37, 38, 40, 44, 48, 49, 53, 57, and 61. Otherwise, a specification exception is recognized.

For all function codes which utilize a parameter list, the parameter list, must be designated on a doubleword boundary. Otherwise, a specification exception is recognized.

For function codes 0-23, the program-lock-token (PLT) address in general register 1 does not have a boundary-alignment requirement.

All unused fields in a parameter list should contain all zeros; otherwise, the program may not operate compatibly in the future.

When the PLO-extension facility is not installed, a serialization function is performed immediately after the lock is obtained and again immediately before it is released. However, values fetched from the parameter list before the lock is obtained are not necessarily refetched.

When the PLO-extension facility is installed, a serialization function is performed at the beginning and end of any operation other than the test operation.

A serialization function is not performed if the test bit, bit 55 of general register 0, is one.

For comparisons, all comparands are treated as unsigned binary integers.

Note: The result of an equal comparison is the same whether the comparands are treated as signed or unsigned binary integers.

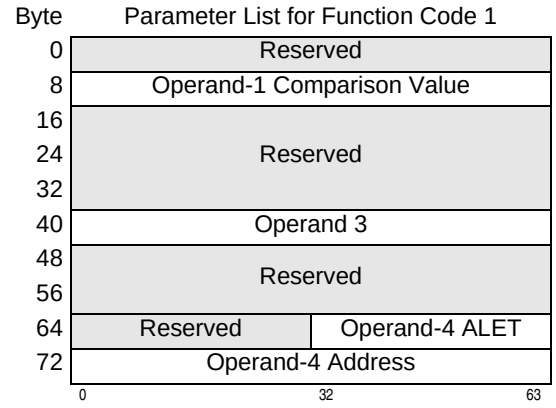
For operations specifying one or two comparisons, the result of the operation is indicated in the condition code. For operations specifying three or four comparisons, the result of the operation is indicated in a combination of the condition code and the unequal results field in the parameter list. For operations specifying no comparisons, the condition code remains unchanged.

In the following figures showing the parameter lists for the different function codes, the offsets shown on the left are byte values.

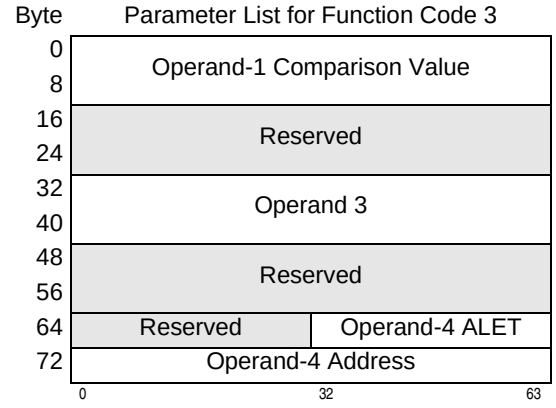
Function Codes 0-3, 24 (Compare and Load)

The operands, operand lengths, and operations for each function are shown in Figure 7-380 on page 7-380.

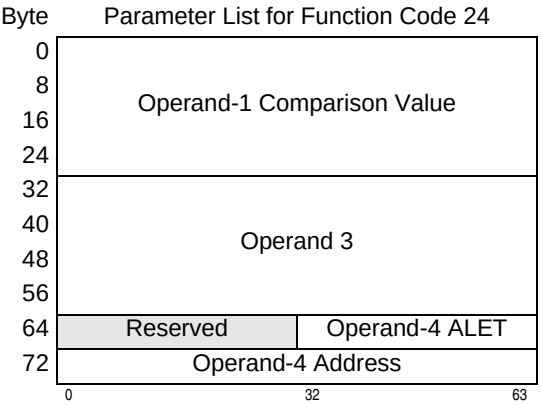
The parameter list used for function code 1 has the following format:



The parameter list used for function code 3 has the following format:



The parameter list used for function code 24 has the following format:



The first-operand comparison value is compared to the second operand.

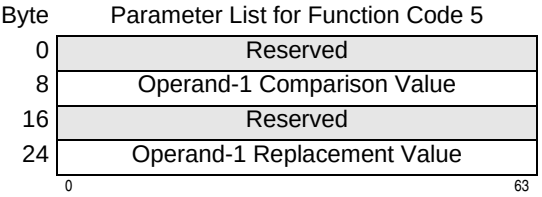
When the first-operand comparison value is not equal to the second operand, the first-operand comparison value is replaced by the second operand, and condition code 1 is set.

When the first-operand comparison value is equal to the second operand, the third operand is replaced by the fourth operand, and condition code 0 is set.

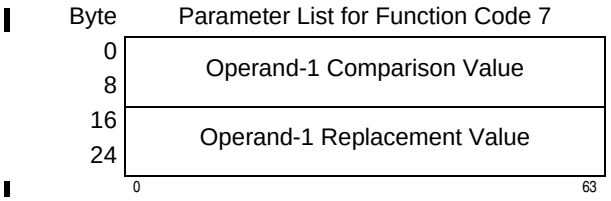
Function Codes 4-7, 25 (Compare and Swap)

The operands, operand lengths, and operations for each function are shown in Figure 7-380 on page 7-380.

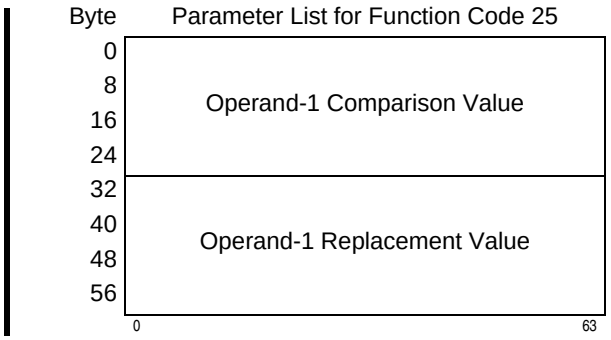
The parameter list used for function code 5 has the following format:



The parameter list used for function code 7 has the following format:



The parameter list used for function code 25 has the following format:



The first-operand comparison value is compared to the second operand.

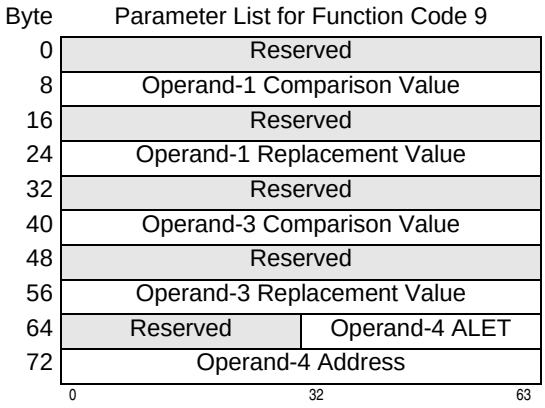
When the first-operand comparison value is not equal to the second operand, the first-operand comparison value is replaced by the second operand, and condition code 1 is set.

When the first-operand comparison value is equal to the second operand, the first-operand replacement value is stored at the second-operand location, and condition code 0 is set.

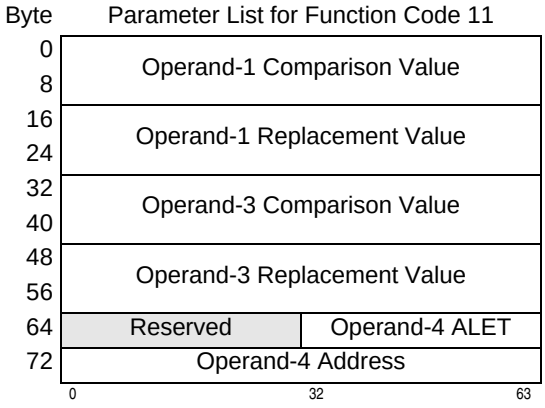
Function Codes 8-11, 26 (Double Compare and Swap)

The operands, operand lengths, and operations for each function are shown in Figure 7-380 on page 7-380.

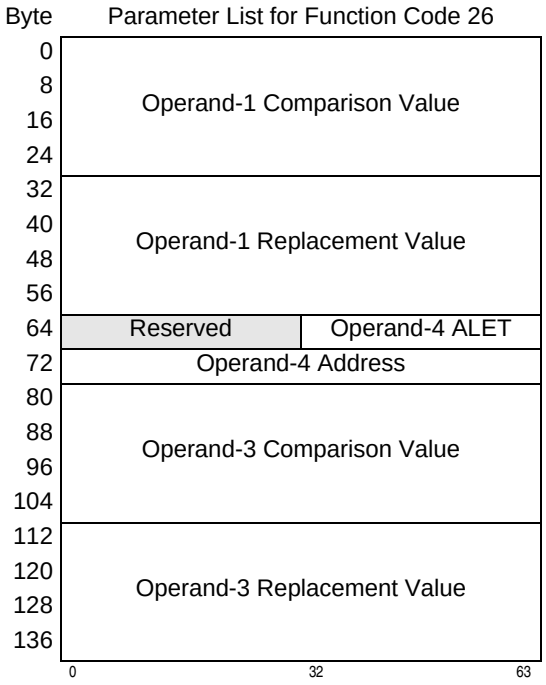
The parameter list used for function code 9 has the following format:



The parameter list used for function code 11 has the following format:



The parameter list used for function code 26 has the following format:



The first-operand comparison value is compared to the second operand.

When the first-operand comparison value is not equal to the second operand, the first-operand comparison value is replaced by the second operand, and condition code 1 is set.

When the first-operand comparison value is equal to the second operand, the third-operand comparison value is compared to the fourth operand.

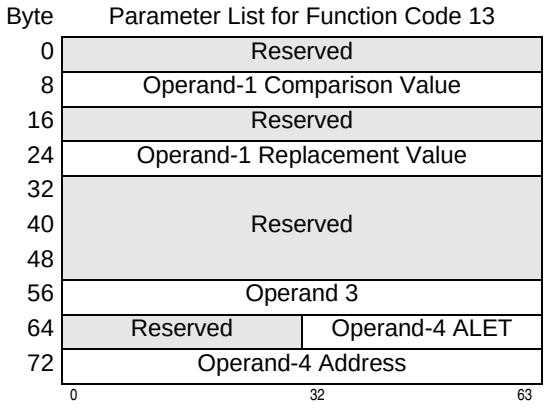
When the third-operand comparison value is not equal to the fourth operand (after the first-operand comparison value has been found equal to the second operand), the third-operand comparison value is replaced by the fourth operand, and condition code 2 is set.

When the third-operand comparison value is equal to the fourth operand (after the first-operand comparison value has been found equal to the second operand), the third-operand replacement value is stored at the fourth-operand location, followed by the first-operand replacement value being stored at the second-operand location, and condition code 0 is set.

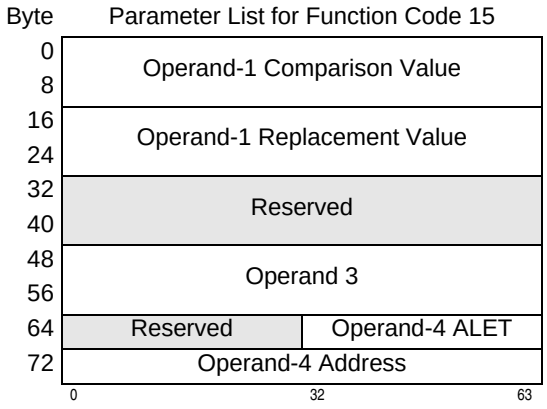
Function Codes 12-15, 27 (Compare and Swap and Store)

The operands, operand lengths, and operations for each function are shown in Figure 7-380 on page 7-380.

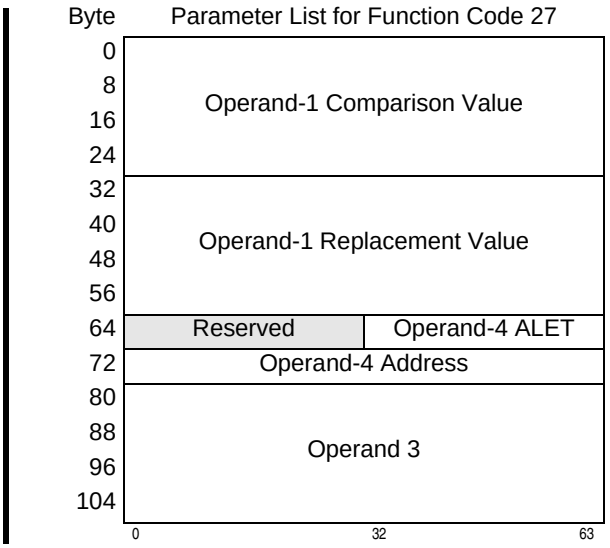
The parameter list used for function code 13 has the following format:



The parameter list used for function code 15 has the following format:



The parameter list used for function code 27 has the following format:



The first-operand comparison value is compared to the second operand.

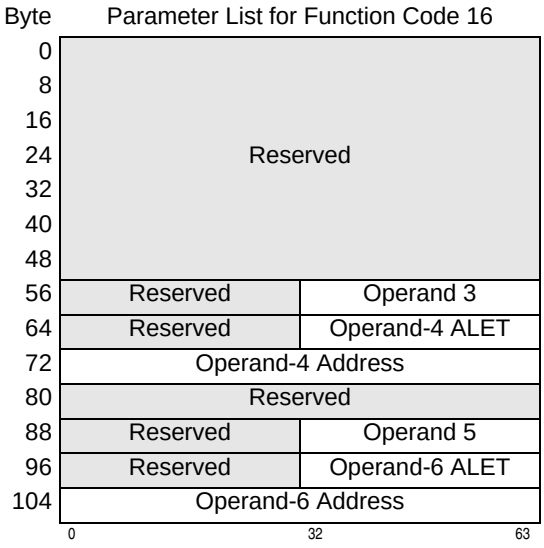
When the first-operand comparison value is not equal to the second operand, the first-operand comparison value is replaced by the second operand, and condition code 1 is set.

When the first-operand comparison value is equal to the second operand, the third operand is stored at the fourth-operand location, followed by the first-operand replacement value being stored at the second-operand location, and condition code 0 is set.

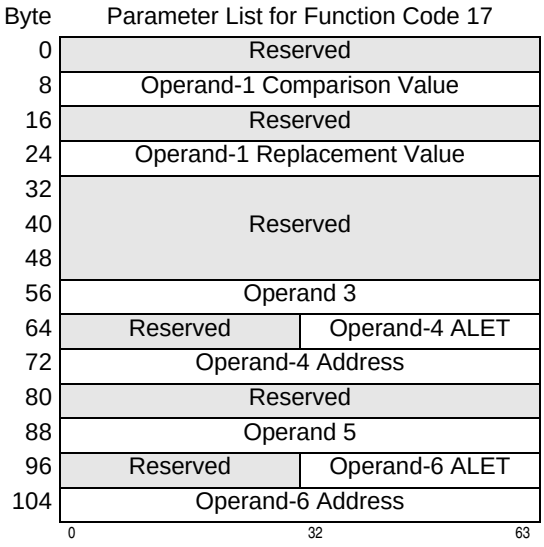
Function Codes 16-19, 28 (Compare and Swap and Double Store)

The operands, operand lengths, and operations for each function are shown in Figure 7-380 on page 7-380.

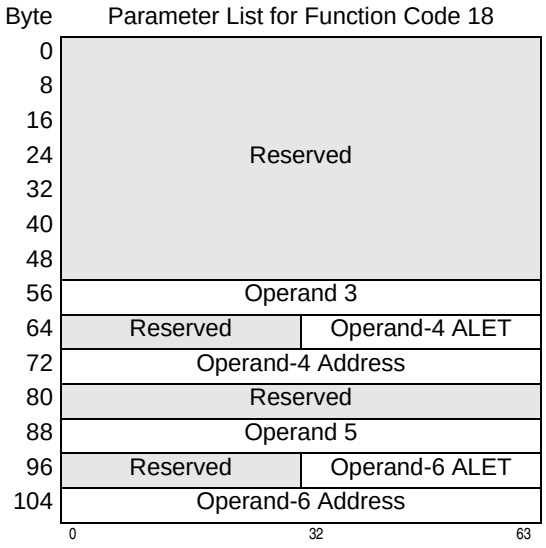
The parameter list used for function code 16 has the following format:



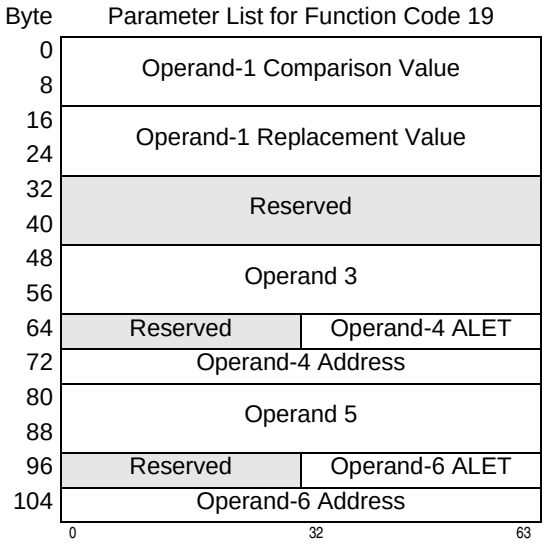
The parameter list used for function code 17 has the following format:



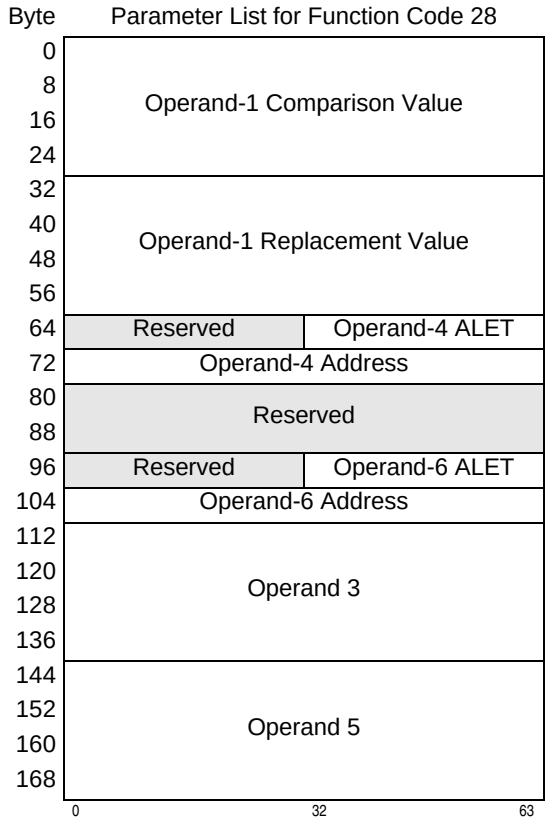
The parameter list used for function code 18 has the following format:



The parameter list used for function code 19 has the following format:



The parameter list used for function code 28 has the following format:



The first-operand comparison value is compared to the second operand.

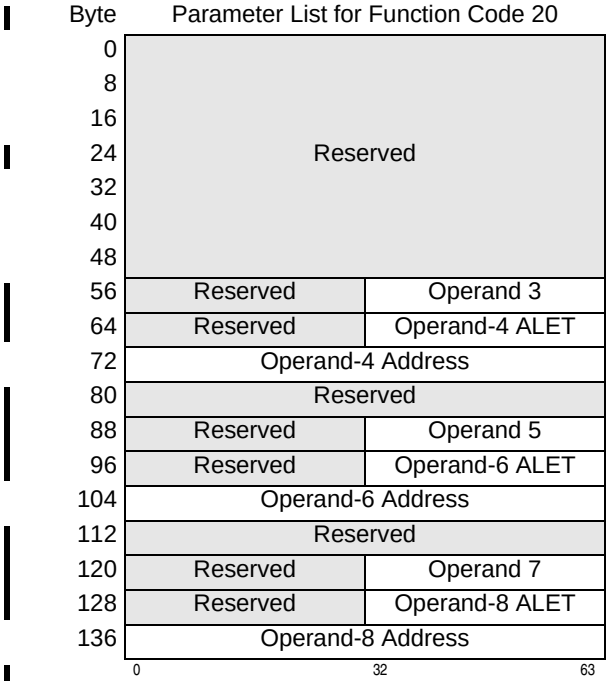
When the first-operand comparison value is not equal to the second operand, the first-operand comparison value is replaced by the second operand, and condition code 1 is set.

When the first-operand comparison value is equal to the second operand, the third operand is stored at the fourth-operand location, followed by the fifth operand being stored at the sixth-operand location, followed by the first-operand replacement value being stored at the second-operand location, and condition code 0 is set.

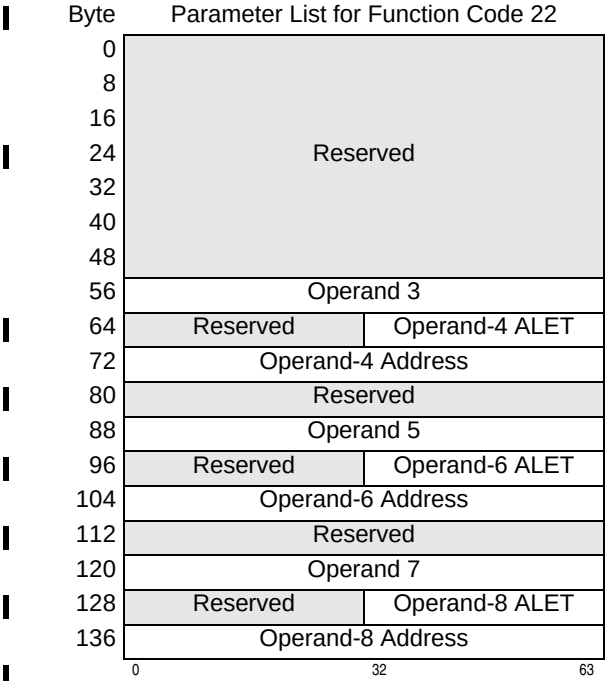
Function Codes 20-23, 29 (Compare and Swap and Triple Store)

The operands, operand lengths, and operations for each function are shown in Figure 7-380 on page 7-380.

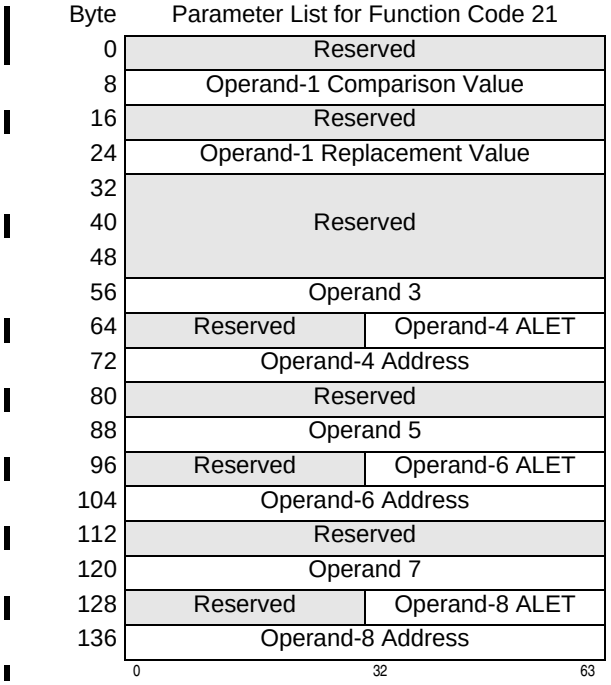
The parameter list used for function code 20 has the following format:



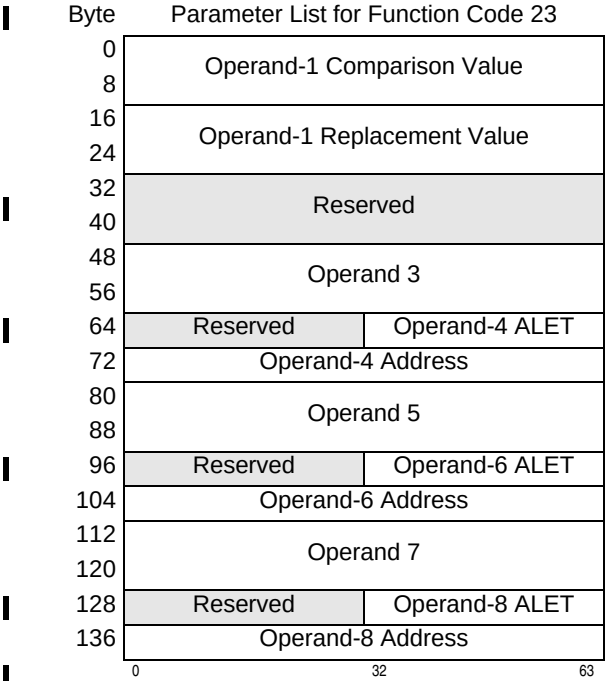
The parameter list used for function code 22 has the following format:



The parameter list used for function code 21 has the following format:

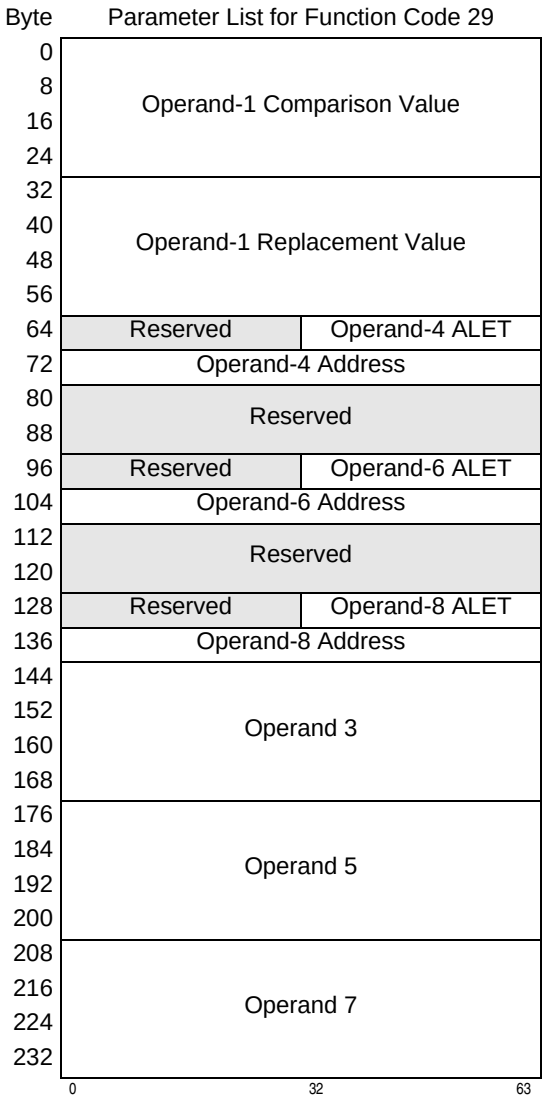


The parameter list used for function code 23 has the following format:



The parameter list used for function code 29 has the

following format:



The first-operand comparison value is compared to the second operand.

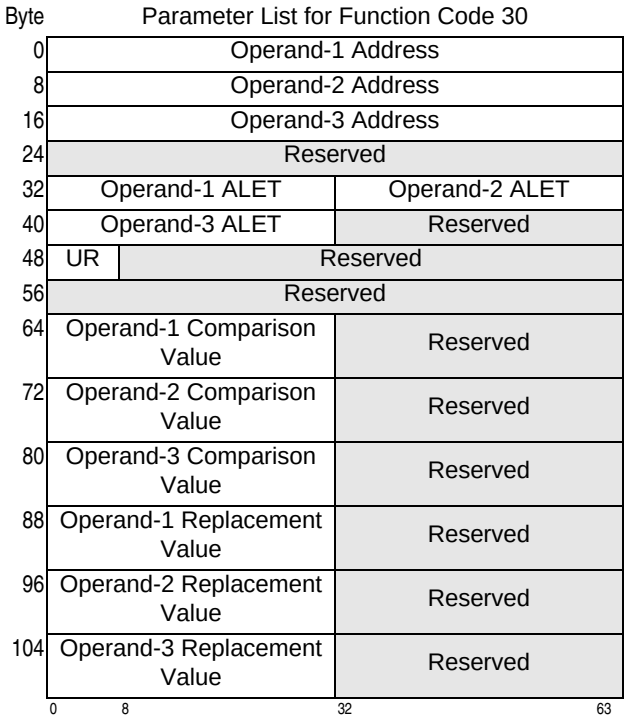
When the first-operand comparison value is not equal to the second operand, the first-operand comparison value is replaced by the second operand, and condition code 1 is set.

When the first-operand comparison value is equal to the second operand, the third operand is stored at the fourth-operand location, followed by the fifth operand being stored at the sixth-operand location, followed by the seventh operand being stored at the eighth-operand location, followed by the first-operand replacement value being stored at the second-operand location, and condition code 0 is set.

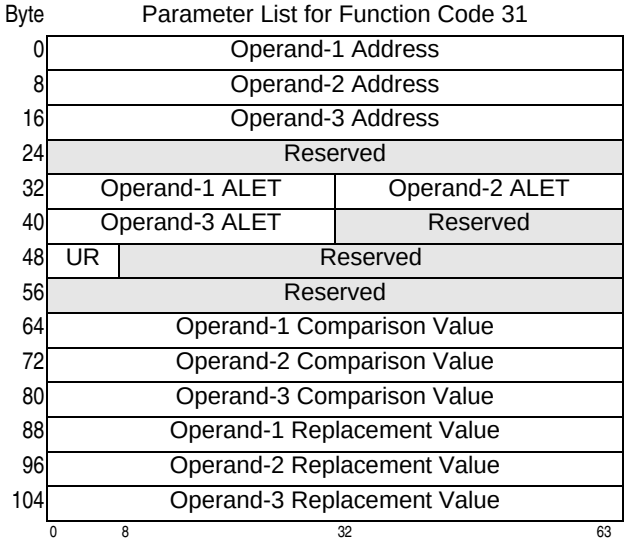
Function Codes 30-33 (Triple Compare and Swap)

The locations of the operands and addresses used by the instruction are specified in the parameter list.

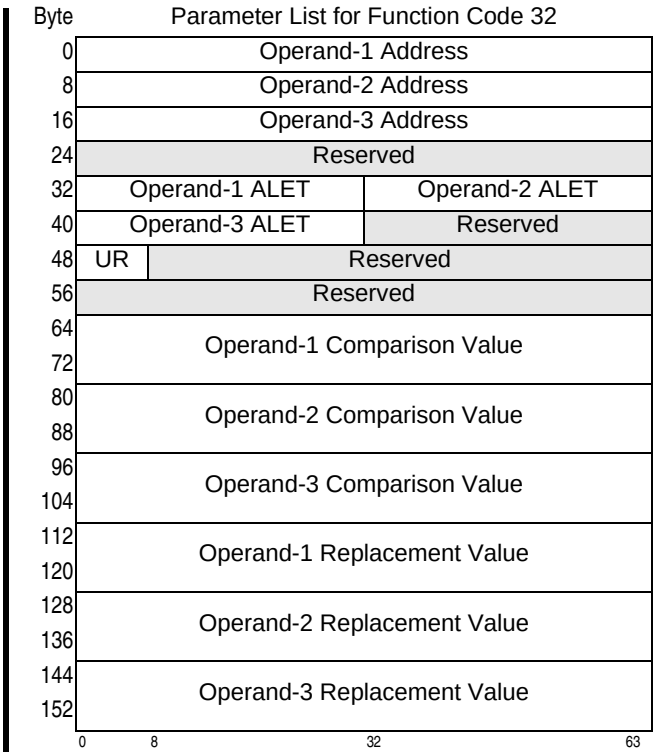
The parameter list used for function code 30 has the following format:



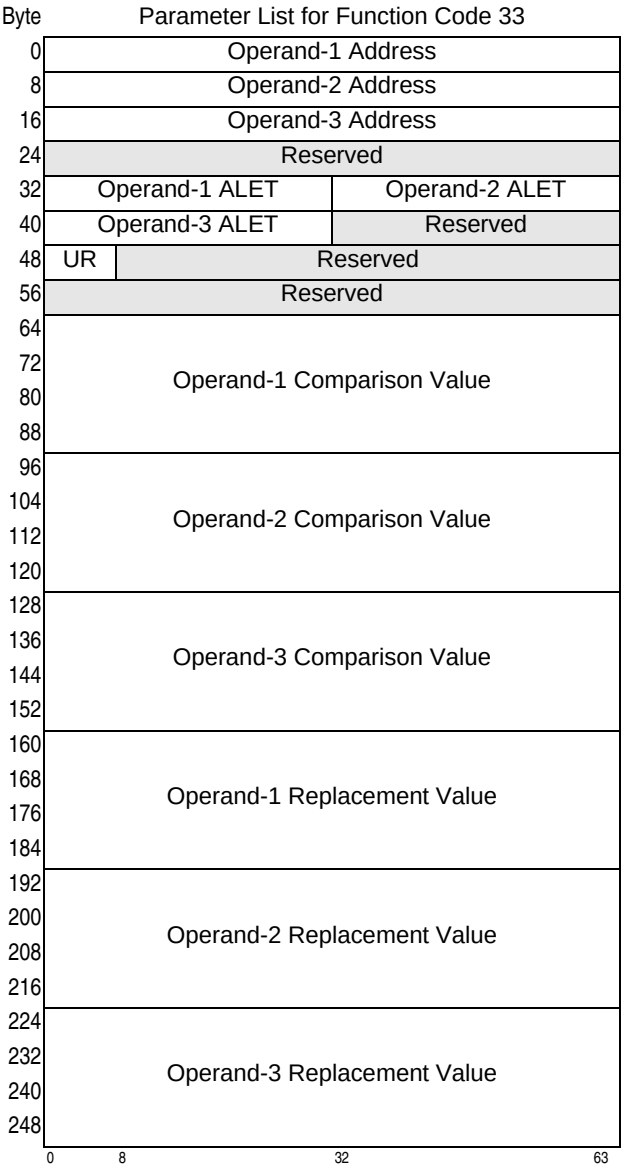
The parameter list used for function code 31 has the following format:



The parameter list used for function code 32 has the following format:



The parameter list used for function code 33 has the following format:



The first-operand comparison value is compared to the first operand. When the first-operand comparison value is not equal to the first operand, the first-operand comparison value is replaced by the first operand, condition code 2 is set, and 01 hex is placed in the unequal results (UR) field at byte 48 of the parameter list.

When the first-operand comparison value is equal to the first operand, the second-operand comparison value is compared to the second operand. When the second-operand comparison value is not equal to the second operand (after the first-operand comparison

value has been found equal to the first operand), the second-operand comparison value is replaced by the second operand, condition code 2 is set, and 02 hex is placed in the unequal results (UR) field at byte 48 of the parameter list.

When the second-operand comparison value is equal to the second operand (after the first-operand comparison value has been found equal to the first operand), the third-operand comparison value is compared to the third operand. When the third-operand comparison value is not equal to the third operand (after the first and second-operand comparison values have been found equal to the first and second operands, respectively), the third-operand comparison value is replaced by the third operand, condition code 2 is set, and 03 hex is placed in the unequal results (UR) field at byte 48 of the parameter list.

When the third-operand comparison value is equal to the third operand (after the first and second-operand comparison values have been found equal to the first and second operands, respectively), the second-operand replacement value is stored at the second-operand location, followed by the third-operand replacement value being stored at the third-operand location, followed by the first-operand replacement value being stored at the first-operand location, and condition code 0 is set. In this case, the contents of the UR field of the parameter list remain unchanged.

As observed by other CPUs and channel programs, all accesses for all storage operands not in the parameter list appear to occur concurrently as observed by other CPUs and channel programs.

Function Codes 34-37 (Quadruple Compare and Swap)

The locations of the operands and addresses used by the instruction are specified in the parameter list.

The parameter list used for function code 34 has the following format:

Parameter List for Function Code 34

Byte			
0	Operand-1 Address		
8	Operand-2 Address		
16	Operand-3 Address		
24	Operand-4 Address

256 264 272 280	Operand-3 Replacement Value	
288 296 304 312	Operand-4 Replacement Value	
	0 8	32 63

The first-operand comparison value is compared to the first operand. When the first-operand comparison value is not equal to the first operand, the first-operand comparison value is replaced by the first oper-

and, condition code 2 is set, and 01 hex is placed in the unequal results (UR) field at byte 48 of the parameter list.

When the first-operand comparison value is equal to the first operand, the second-operand comparison value is compared to the second operand. When the second-operand comparison value is not equal to the second operand (after the first-operand comparison value has been found equal to the first operand), the second-operand comparison value is replaced by the second operand, condition code 2 is set, and 02 hex is placed in the unequal results (UR) field at byte 48 of the parameter list.

When the second-operand comparison value is equal to the second operand (after the first-operand comparison value has been found equal to the first operand), the third-operand comparison value is compared to the third operand. When the third-operand comparison value is not equal to the third operand (after the first and second-operand comparison values have been found equal to the first and second operands, respectively), the third-operand comparison value is replaced by the third operand, condition code 2 is set, and 03 hex is placed in the unequal results (UR) field at byte 48 of the parameter list.

When the third-operand comparison value is equal to the third operand (after the first and second-operand comparison values have been found equal to the first and second operands, respectively), the fourth-operand comparison value is compared to the fourth operand. When the fourth-operand comparison value is not equal to the fourth operand (after the first, second, and third-operand comparison values have been found equal to the first, second, and third operands, respectively), the fourth-operand comparison value is replaced by the fourth operand, condition code 2 is set, and 04 hex is placed in the unequal results (UR) field at byte 48 of the parameter list.

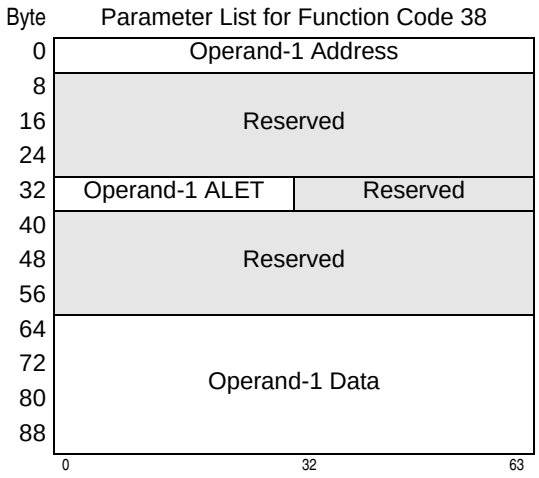
When the fourth-operand comparison value is equal to the fourth operand (after the first, second, and third-operand comparison values have been found equal to the first, second, and third operands, respectively), the second-operand replacement value is stored at the second-operand location, followed by the third-operand replacement value being stored at the third-operand location, followed by the fourth-operand replacement value being stored at the fourth-operand location, followed by the first-operand replacement value being stored at the first-operand location, and condition code 0 is set. In this case, the contents of the UR field of the parameter list remain unchanged.

As observed by other CPUs and channel programs, all accesses for all storage operands not in the parameter list appear to occur concurrently as observed by other CPUs and channel programs.

Function Code 38 (Load)

The locations of the operands and addresses used by the instruction are specified in the parameter list.

The parameter list used for function code 38 has the following format:



The contents of the first operand are fetched and placed in the operand-1 data field of the parameter list.

The condition code remains unchanged.

As observed by other CPUs and channel programs, all bytes of the first operand appear to be fetched concurrently.

Function Codes 39-40 (Double Load)

The locations of the operands and addresses used by the instruction are specified in the parameter list.

The parameter list used for function code 39 has the following format:

Parameter List for Function Code 39

Byte		
0	Operand-1 Address	
8	Operand-2 Address	
16	Reserved	
24		
32	Operand-1 ALET	Operand-2 ALET
40	Reserved	
48		
56		
64	Operand-1 Data	
72		
80	Operand-2 Data	
88		
	0	32 63

The parameter list used for function code 40 has the following format:

Parameter List for Function Code 40

Byte		
0	Operand-1 Address	
8	Operand-2 Address	
16	Reserved	
24		
32	Operand-1 ALET	Operand-2 ALET
40	Reserved	
48		
56		
64	Operand-1 Data	
72		
80		
88		
96	Operand-2 Data	
104		
112		
120		
	0	32 63

The contents of the first operand are fetched and placed in the operand-1 data field of the parameter list and the contents of the second operand are fetched and placed in the operand-2 data field of the parameter list.

The condition code remains unchanged.

As observed by other CPUs and channel programs, all bytes of the first and second operands appear to be fetched concurrently.

Function Codes 41-44 (Triple Load)

The locations of the operands and addresses used by the instruction are specified in the parameter list.

The parameter list used for function code 41 has the following format:

Parameter List for Function Code 41

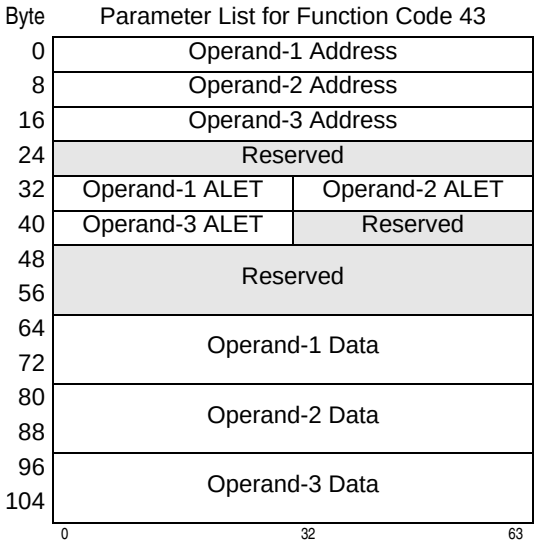
Byte		
0	Operand-1 Address	
8	Operand-2 Address	
16	Operand-3 Address	
24	Reserved	
32	Operand-1 ALET	Operand-2 ALET
40	Operand-3 ALET	Reserved
48	Reserved	
56		
64	Operand-1 Data	Reserved
72	Operand-2 Data	Reserved
80	Operand-3 Data	Reserved
	0	32 63

The parameter list used for function code 42 has the following format:

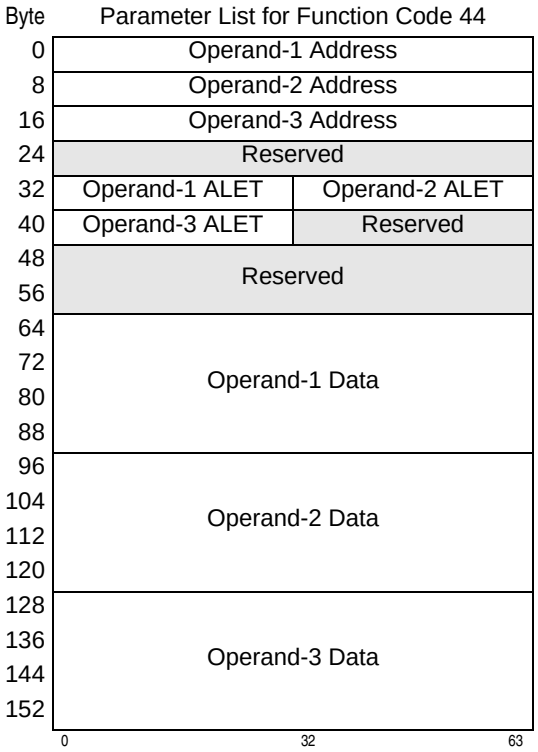
Parameter List for Function Code 42

Byte		
0	Operand-1 Address	
8	Operand-2 Address	
16	Operand-3 Address	
24	Reserved	
32	Operand-1 ALET	Operand-2 ALET
40	Operand-3 ALET	Reserved
48	Reserved	
56		
64	Operand-1 Data	
72	Operand-2 Data	
80	Operand-3 Data	
	0	32 63

The parameter list used for function code 43 has the following format:



The parameter list used for function code 44 has the following format:



The contents of the first operand are fetched and placed in the operand-1 data field of the parameter list, the contents of the second operand are fetched and placed in the operand-2 data field of the parameter list, and the contents of the third operand are fetched and placed in the operand-3 data field of the parameter list.

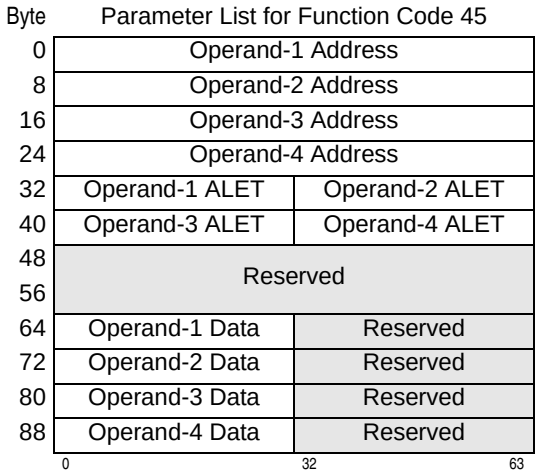
The condition code remains unchanged.

As observed by other CPUs and channel programs, all bytes of the first, second, and third operands appear to be fetched concurrently.

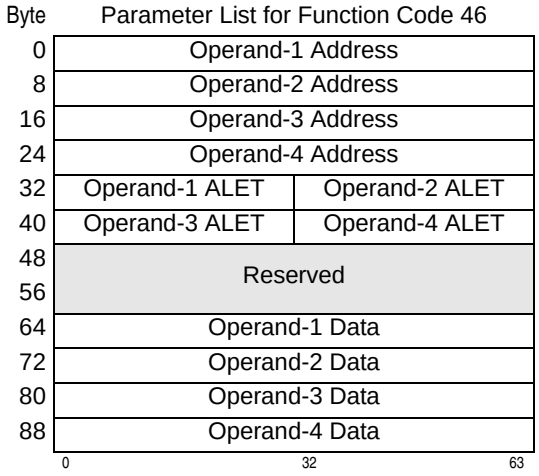
Function Codes 45-48 (Quadruple Load)

The locations of the operands and addresses used by the instruction are specified in the parameter list.

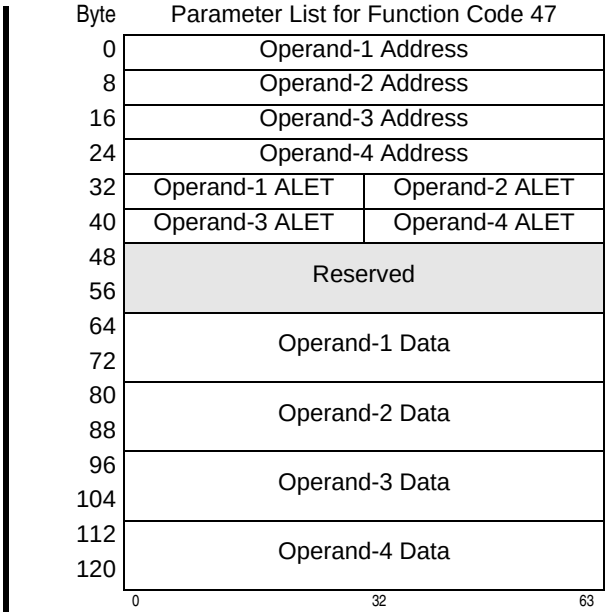
The parameter list used for function code 45 has the following format:



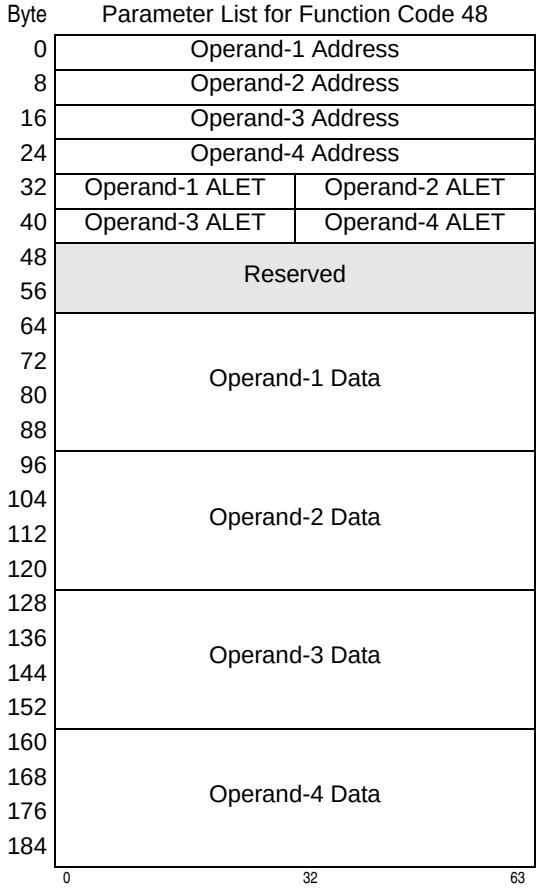
The parameter list used for function code 46 has the following format:



The parameter list used for function code 47 has the following format:



The parameter list used for function code 48 has the following format:



The contents of the first operand are fetched and placed in the operand-1 data field of the parameter list, the contents of the second operand are fetched and placed in the operand-2 data field of the parameter list, the contents of the third operand are fetched and placed in the operand-3 data field of the parameter list, and the contents of the fourth operand are fetched and placed in the operand-4 data field of the parameter list.

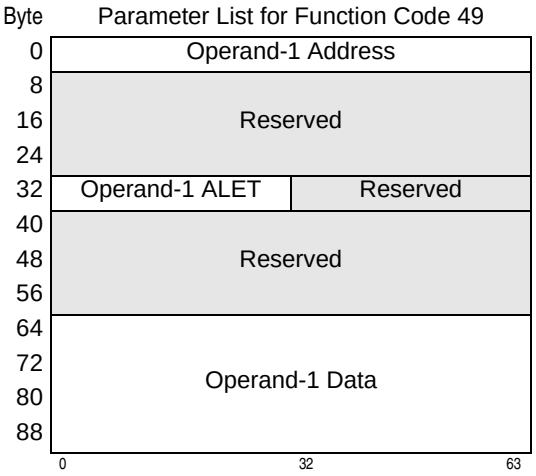
The condition code remains unchanged.

As observed by other CPUs and channel programs, all bytes of the first, second, third, and fourth operands appear to be fetched concurrently.

Function Code 49 (Store)

The locations of the operands and addresses used by the instruction are specified in the parameter list.

The parameter list used for function code 49 has the following format:



The contents of the operand-1 data field of the parameter list are stored to the first-operand location.

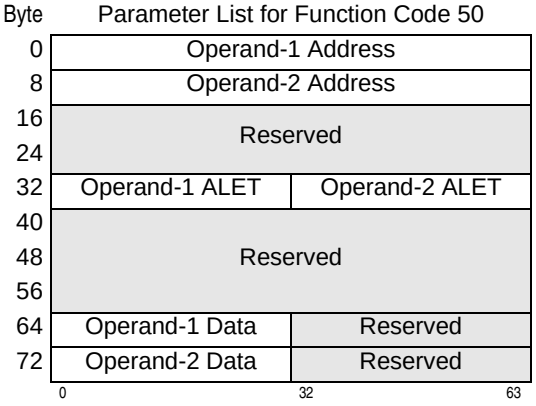
The condition code remains unchanged.

As observed by other CPUs and channel programs, all bytes of the first operand appear to be stored concurrently.

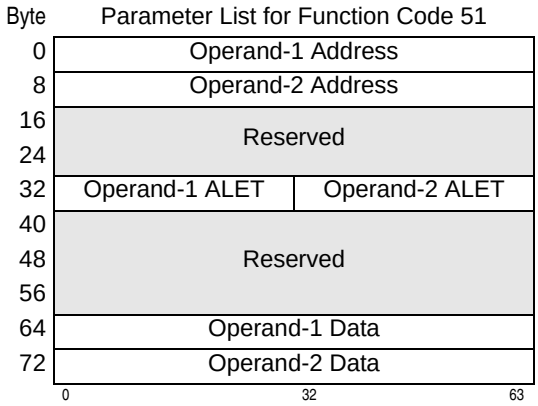
Function Codes 50-53 (Double Store)

The locations of the operands and addresses used by the instruction are specified in the parameter list.

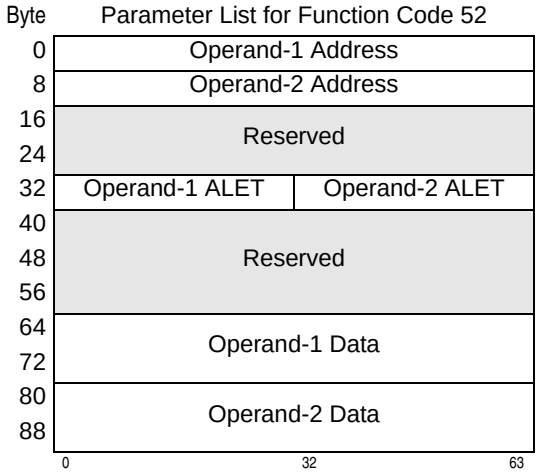
The parameter list used for function code 50 has the following format:



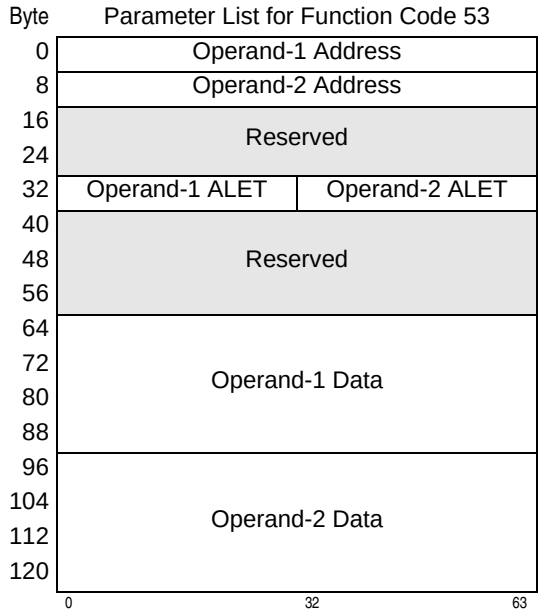
The parameter list used for function code 51 has the following format:



The parameter list used for function code 52 has the following format:



The parameter list used for function code 53 has the following format:



The contents of the operand-1 data field of the parameter list are stored to the first-operand location and then the contents of the operand-2 data field of the parameter list are stored to the second-operand location.

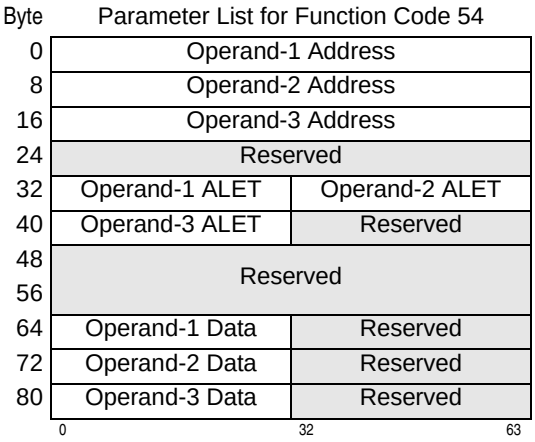
The condition code remains unchanged.

As observed by other CPUs and channel programs, all bytes of the first and second operands appear to be stored concurrently.

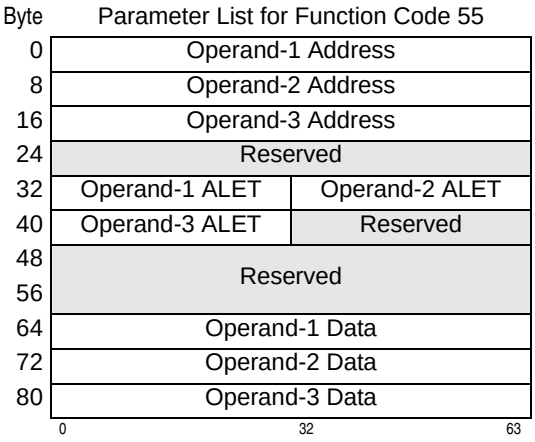
Function Codes 54-57 (Triple Store)

The locations of the operands and addresses used by the instruction are specified in the parameter list.

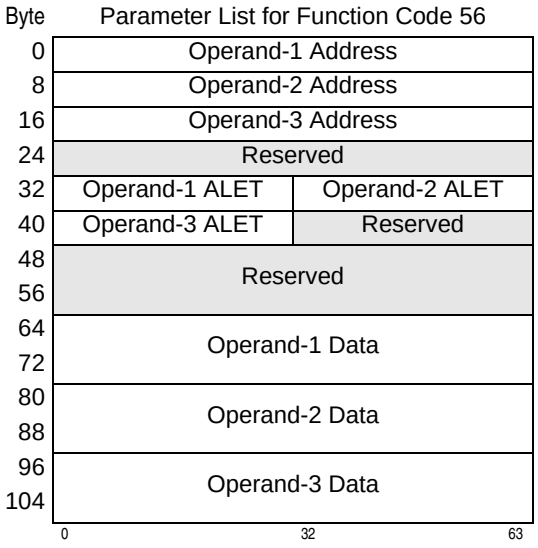
The parameter list used for function code 54 has the following format:



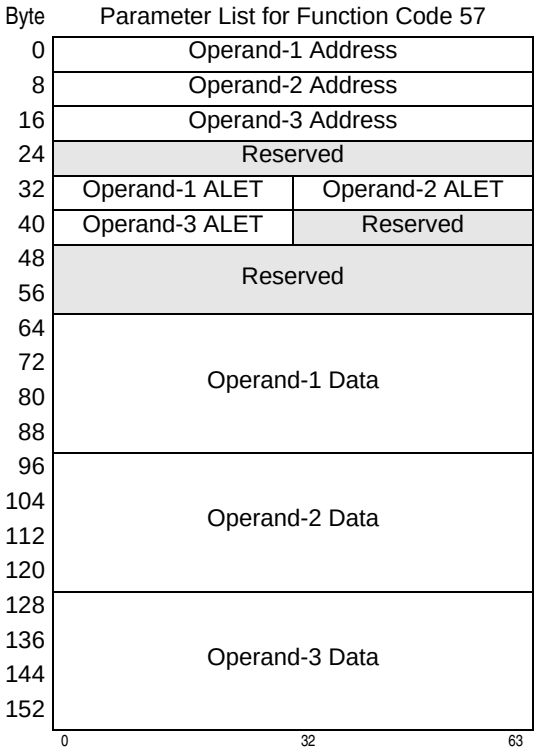
The parameter list used for function code 55 has the following format:



The parameter list used for function code 56 has the following format:



The parameter list used for function code 57 has the following format:



The contents of the operand-1 data field of the parameter list are stored to the first-operand location, then the contents of the operand-2 data field of the parameter list are stored to the second-operand location, and then the contents of the operand-3 data field of the parameter list are stored to the third-operand location.

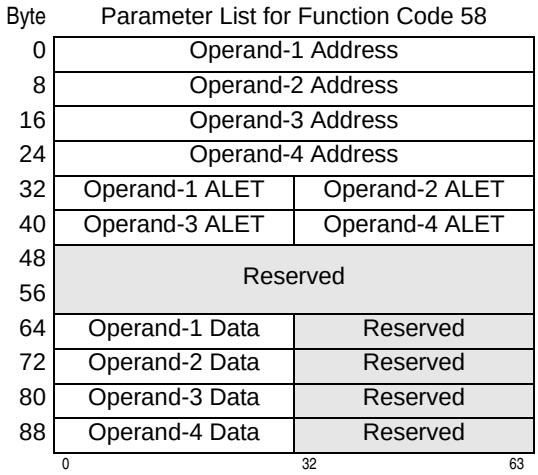
The condition code remains unchanged.

As observed by other CPUs and channel programs, all bytes of the first, second, and third operands appear to be stored concurrently.

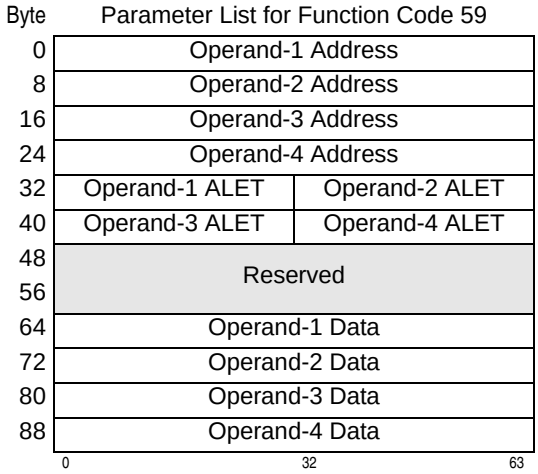
Function Codes 58-61 (Quadruple Store)

The locations of the operands and addresses used by the instruction are specified in the parameter list.

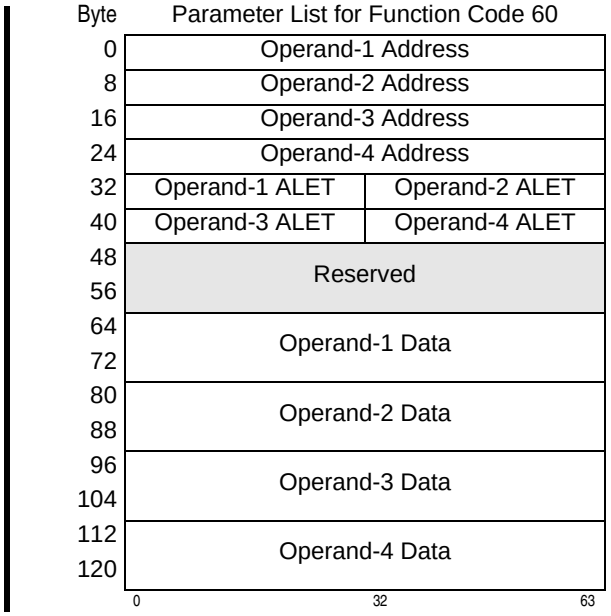
The parameter list used for function code 58 has the following format:



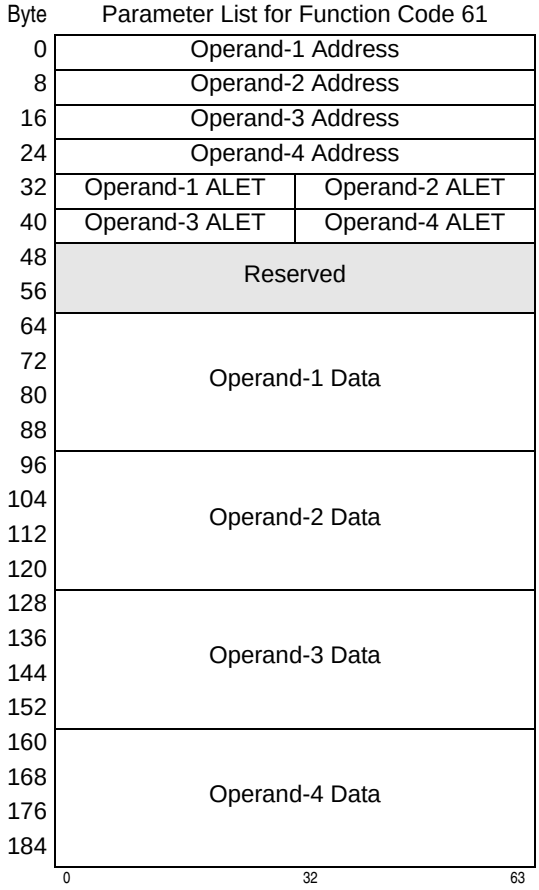
The parameter list used for function code 59 has the following format:



The parameter list used for function code 60 has the following format:



The parameter list used for function code 61 has the following format:



The contents of the operand-1 data field of the parameter list are stored to the first-operand location, then the contents of the operand-2 data field of the parameter list are stored to the second-operand location, then the contents of the operand-3 data field of the parameter list are stored to the third-operand location, and then the contents of the operand-4 data field of the parameter list are stored to the fourth-operand location.

The condition code remains unchanged.

As observed by other CPUs and channel programs, all bytes of the first, second, third, and fourth operands appear to be stored concurrently.

Locking

When the PLO-extension facility is not installed and the test operation is not specified, a lock is obtained

during any operation specified by function codes 0-23. When the PLO-extension facility is installed, a lock is not obtained during any operation specified by function codes 0-23.

A lock is not obtained during the test operation or any operation specified by function codes 24-61.

When a lock is not obtained during an operation, a program-lock token (PLT) and a PLT address are not defined.

All of the remaining text in this section titled “Locking” only applies when the PLO-extension facility is not installed in the configuration.

A lock is obtained at the beginning of the operation and released at the end of the operation. The lock obtained is represented by a program lock token (PLT) whose logical address is specified in general register 1 as already described.

A PLT is a value produced by a model-dependent transformation of the PLT logical address. Depending on the model, the PLT may be derived directly from the PLT logical address or, when DAT is on, from the real address that results from transformation of the PLT logical address by DAT. If DAT is used, access-register translation (ART) precedes DAT in the access-register mode.

A PLT selects one of a model-dependent number of locks within the configuration. Programs being executed by different CPUs can be assured of specifying the same lock only by specifying PLT logical addresses that are the same and that can be transformed to the same real address by the different CPUs.

Since a model may or may not use ART and DAT when forming a PLT, access-exception conditions that can be encountered during ART and DAT may or may not be recognized as exceptions. There is no accessing of a location designated by a PLT, but an addressing exception may be recognized for the location. A protection exception is not recognized for any reason during processing of a PLT logical address.

The CPU can hold one lock at a time.

When PERFORM LOCKED OPERATION is executed by this CPU and is to use a lock that is already held by another CPU due to the execution of a PERFORM LOCKED OPERATION instruction by the other CPU, the execution by this CPU is delayed until the lock is no longer held. An excessive delay can be caused only by a machine malfunction and is a machine-check condition.

The order in which multiple requests for the same lock are satisfied is undefined.

Storage References

Accesses to fields which are 32 bits or less in the parameter list appear to be word concurrent, as observed by other CPUs and channel programs, regardless of the function code. Accesses to fields which are 64 bits or more in the parameter list appear to be doubleword concurrent, as observed by other CPUs and channel programs, regardless of the function code.

Access exceptions may be recognized for parameter-list locations even when the locations are not required in the operation. The locations are those beginning at offset 0 and extending up through the last location defined for the function code used. For parameter lists with one or more fields which may be stored to, store-type access exceptions may be recognized for any location in the parameter list.

Regarding fields of the parameter list which are conditionally stored to, the change bit for the corresponding storage key is set and a PER storage-alteration event is recognized, when applicable, only when a store to the field occurs.

If any byte of any store-type or update-type operand not in the parameter list used in the operation overlaps with any byte of the parameter list, then results are unpredictable.

If another CPU modifies any byte of the parameter list while the instruction is being executed, then results are unpredictable.

When the PLO-extension facility is not installed, the following applies to function codes 0-23:

- All accesses for each storage operand not in the parameter list appear to be word concurrent for function codes 0, 4, 8, 12, 16, and 20; and all accesses for each storage operand appear to be doubleword concurrent for function codes 1-3, 5-7, 9-11, 13-15, 17-19, and 21-23, as observed by other CPUs.

- As observed by other CPUs, storage locations which contain the second operand or any field of the parameter list may be tested for access exceptions and fetched before a lock is obtained. (A channel program cannot observe a lock.) However, if the second operand is fetched before the lock is obtained, it is fetched again after the lock has been obtained.

- As observed by other CPUs, in all operations except the compare-and-swap operation (which does not have a fourth operand), the fourth operand is accessed while the lock is held only if a comparison of the first-operand comparison value to the second operand while the lock is held has indicated equality. In the compare-and-swap-and-double-store and compare-and-swap-and-triple-store operations, the sixth operand, and also the eighth operand in the triple-store operation, are treated the same as the fourth operand described above.

- Provided that accessing of an operand is not prohibited as described in the preceding paragraph, store-type access exceptions may be recognized for the second operand and storage operands in the parameter list, even when a store does not occur because of the results of a comparison. A storage-alteration PER event is recognized, and a change bit is set, only if a store occurs.

- When a comparison is made between an operand comparison value and an operand before the lock is obtained and indicates inequality, the lock still is obtained. The condition code is set only as a result of a comparison made while the lock is held. When condition code 1 or 2 is set, the first-operand comparison value or third-operand comparison value is replaced only by means of a fetch of the second operand or fourth operand, respectively, made while the lock is held, as observed by other CPUs.

- In those cases when a store is performed to the second-operand location and one or more of the fourth-, sixth-, and eighth-operand locations, the store to the second-operand location is always performed last, as observed by other CPUs and by channel programs.

- When a lock is obtained, stores into the parameter list may be performed while the lock is held or after it has been released.

- For the compare-and-load and compare-and-swap operations, the operation is suppressed on all addressing and protection exceptions.

When the PLO-extension facility is installed, the following applies:

- All accesses for all storage operands not in the parameter list appear to occur concurrently as observed by other CPUs and channel programs.

- For operations specifying one or more comparisons, if the operation can be completed without any access to a storage operand not in the parameter list, then access exceptions, a PER storage-alteration event, and a PER zero-address-detection event for the storage operand are not recognized. This means for function codes 0-29, the fourth, sixth, and eighth operands, when defined, are not tested for access exceptions and are not accessed unless the second operand is equal to the value it is being compared to. This also means, for function codes 30-37, the second operand is not tested for access exceptions and is not accessed unless the first operand is equal to the value it is being compared to; the third operand is not tested for access exceptions and is not accessed unless the second operand is equal to the value it is being compared to; the fourth operand, when defined, is not tested for access exceptions and is not accessed unless the third operand is equal to the value it is being compared to.

  Even if an update-type operand is only fetched, store-type access exceptions are still recognized.

- Accesses to the parameter list do not appear to occur concurrently with accesses to the storage operands not in the parameter list, as observed by other CPUs and channel programs.

Resulting Condition Code:

When the test bit is zero and the function code is in the range 0-37:

0 All comparisons equal (function codes 0-37)
1 First comparison not equal (function codes 0-29)
2 -- (function codes 0-7, 12-25, and 27-29)
2 Second comparison not equal (function codes 8-11 and 26); any comparison not equal (function codes 30-37)
3 --

When the test bit is zero and the function code is in the range 38-61, the condition code remains unchanged.

When the test bit is one:

0 Function code valid
1 --
2 --
3 Function code invalid

Program Exceptions:

- Access (for function codes 0-23 when the PLO-extension facility is not installed, fetch, except addressing and protection for PLT location, program lock token, model-dependent; for function codes 38-48, fetch, operand 1; for function codes 30-37, fetch and store, operand 1; for function codes 49-61, store, operand 1; for function codes 0-3, 24, and 39-48, fetch, operand 2; for function codes 4-23, 25-29, and 30-37, fetch and store, operand 2; for function codes 50-61, store, operand 2; for function codes 1, 3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 23, and 24-48, fetch and store, parameter list; for function codes 16, 18, 20, 22, and 49-61, fetch, parameter list; for function codes 41-48, fetch, operand 3; for function codes 30-37, fetch and store, operand 3; for function codes 54-61, store, operand 3; for function codes 0-3, 24 and 45-48, fetch, operand 4; for function codes 8-11, 26, and 34-37, fetch and store, operand 4; for function codes 12-23, 27-29, and 58-61, store, operand 4; for function codes 16-23 and 28-29, store, operand 6; for function codes 20-23 and 29, store, operand 8)
- Specification
- Transaction constraint

The priority for recognizing exceptions for PERFORM LOCKED OPERATION when the test bit (T) is zero is shown in Figure 7-382.

1.-7.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
8.A	Specification exception due to bits 32-54 of general register 0 being nonzero.
8.B	Specification exception due to invalid function code.

Figure 7-382. Priority of Execution: PERFORM LOCKED OPERATION when T is zero (Part 1 of 2)

8.C	Specification exception due to invalid register number.
8.D	Specification exception due to address specified by the B_2 and D_2 fields not designating a specified boundary.
8.E	Specification exception due to address specified by the B_4 and D_4 fields not designating a specified boundary[1].
8.F	Access exceptions for the operand specified by the B_2 and D_2 fields.
8.G	Access exceptions for the parameter list.
9.A	Specification exception due to an address field in the parameter list not designating a specified boundary[1].
9.B	Access exceptions for the operand specified by the B_4 and D_4 fields[2] (not the parameter list).
9.C	Access exceptions for an operand specified by an address in the parameter list[2].

Explanation:

1 If accessing the corresponding operand is not required to complete the operation, then it is model dependent whether this exception is recognized.
2 If accessing the operand is not required to complete the operation, then the exception is not recognized.

Figure 7-382. Priority of Execution: PERFORM LOCKED OPERATION when T is zero (Part 2 of 2)

Programming Notes:

1. In configurations that support the transactional-execution facility, a transaction may provide benefits over the use of PERFORM LOCKED OPERATION, as follows:

   a. Transactional execution may provide improved performance over an equivalent code path that uses PLO.

   b. Transactional execution does not require the specification of a program lock token in general register 1.

   c. Transactional execution does not require the use of a parameter list for more complex operations.

d. Transactional execution provides a much broader scope of operations that can be performed, all of which appear to execute in a block-concurrent manner as observed by other CPUs and the channel subsystem.

e. The use of classic interlocked-access techniques on one CPU can correctly coexist with transactional execution on another CPU. This coexistence is not possible using PLO, as explained in programming note 4, below.

If a program that uses PLO is changed to use transactional execution, then all occurrences of PLO that designate the same storage locations as the transaction should be changed to use transactional accesses to those locations if predictable storage results are to be obtained.

2. An example of the use of the PERFORM LOCKED OPERATION instruction is given in Appendix A, "Number Representation and Instruction-Use Examples."

3. When the contents of storage locations are changed by PERFORM LOCKED OPERATION instructions that are executed concurrently by different CPUs and that use the same lock, the changes to operands not in the parameter list will be completed by one of the CPUs before they are begun by the other CPU, depending on which CPU first obtains the lock.

4. When the PLO-extension facility is not installed, the compare-and-swap functions of PERFORM LOCKED OPERATION are not performed by means of interlocked-update references. Concurrent store references by another CPU to the storage operands, even if they are interlocked-update references, will interfere unpredictably, in terms of the resulting register and storage contents, with the intended operation of PERFORM LOCKED OPERATION. All changes to the contents of the storage locations must be made by PERFORM LOCKED OPERATION instructions that use the same lock, if predictable storage results are to be obtained.

5. When programs in different address spaces are using the same lock when DAT is on, the programs must ensure that they are using PLT logical addresses that are the same and that will be translated to the same real address regardless of the address space in which a translation occurs. Otherwise, the programs may in fact use different locks.

6. For functions that use a parameter list in the access register mode, the value in the R_3 field of the instruction should be different from that of the B_2 and B_4 fields. Because access register R_3 is modified as a result of an access exception, subsequent re-execution of the instruction (for example, following the resolution of a page-translation exception) may yield unpredictable results if the R_3 field designates the same access register as that of the second operand or parameter list.

7. "Summary of results for function codes 0-29 of PERFORM LOCKED OPERATION" on

page 7-408 summarizes the results of the operation specified by function codes 0-29.

Op1c=Op2	Op3c=Op4	Cond Code	Action		
Function Codes 0-3 and 24 (Compare and Load)					
No	-	1			Op2 → Op1c
Yes	-	0	Op4 → Op3		
Function Codes 4-7 and 25 (Compare and Swap)					
No	-	1			Op2 → Op1c
Yes	-	0	Op1r → Op2		
Function Codes 8-11 and 26 (Double Compare and Swap)					
No	-	1			Op2 → Op1c
Yes	No	2			Op4 → Op3c
Yes	Yes	0	Op1r → Op2	Op3r → Op4	
Function Codes 12-15 and 27 (Compare and Swap and Store)					
No	-	1			Op2 → Op1c
Yes	-	0	Op1r → Op2	Op3 → Op4	
Function Codes 16-19 and 28 (Compare and Swap and Double Store)					
No	-	1			Op2 → Op1c
Yes	-	0	Op1r → Op2	Op3 → Op4	
				Op5 → Op6	
Function Codes 20-23 and 29 (Compare and Swap and Triple Store)					
No	-	1			Op2 → Op1c
Yes	-	0	Op1r → Op2	Op3 → Op4	
				Op5 → Op6	
				Op7 → Op8	

Explanation:

- Not applicable.
OpNc Operand-N comparison value.
OpNr Operand-N replacement value.

Figure 7-383. Summary of results for function codes 0-29 of PERFORM LOCKED OPERATION

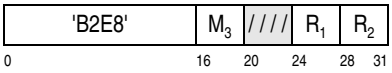
8. For function codes 0-23, the results of executing PERFORM LOCKED OPERATION when the PLO-extension facility is installed in the configuration and a lock is not obtained are compatible with the results of executing PERFORM LOCKED OPERATION when the PLO-extension facility is not installed in the configuration and a lock is obtained.

9. When the PLO-extension facility is installed, the B_2, B_4, R_1, and R_3 fields of the instruction which do not specify a register pair may specify general register 1.

10. When the PLO-extension facility is installed and conflicts for storage operands of the operation are caused by other CPUs or the channel subsystem, the CPU employs escalating algorithms to ensure the operation eventually completes.

PERFORM PROCESSOR ASSIST

PPA R_1,R_2,M_3 [RRF-c]



The M_3 field contains a 4-bit unsigned binary integer function code specifying the processor-assist function to be performed. The function codes for PERFORM PROCESSOR ASSIST are as follows.

Code	Meaning
0	Reserved
1	Transaction-abort assist
2-14	Reserved
15	In-order-execution assist

The operation of each assist function, and the registers used by the function are as follows:

Transaction-Abort Assist: When the function code in the M_3 field is 1 and the processor-assist facility is installed, the processor is requested to assist following an aborted nonconstrained transaction.

The program is expected to provide an unsigned 32-bit binary integer in bits 32-63 of general register R_1, specifying the number of times the nonconstrained transaction has been repeatedly aborted. Depending on the value of this integer, the processor may take escalating actions to increase the likelihood of successful completion of the transaction in a subsequent execution.

Bits 0-31 of general register R_1 are ignored, and bits 32-63 of the register are unchanged. General register R_2 is ignored, however the R_2 field of the instruction should contain zeros; otherwise, the program may not operate compatibly in the future.

In-order-execution assist: When the function code in the M_3 field is 15 and the PPA-in-order facility is installed, the processor is requested to complete processing all instructions prior to this PPA instruction, as observed by this CPU, before attempting storage-operand references for any instruction after this PPA instruction.

The R_1 and R_2 fields are ignored and the instruction is executed as a no-operation.

The in-order-execution assist does not necessarily perform any of the steps for architectural serialization described in the section “CPU Serialization” on page 5-138.

Reserved: Reserved function codes should not be specified; otherwise, the program may not operate compatibly in the future.

Condition Code: The code remains unchanged.

Program Exceptions:

- Operation (neither the PPA-in-order facility nor the processor-assist facility is installed)
- Transaction constraint

Programming Notes:

1. For the transaction-abort-assist function, a larger value in general register R_1 does not necessarily guarantee successful completion when the transaction is reexecuted, and it may unnecessarily delay the CPU. Therefore, the program should provide an accurate count of the number of times a transaction has been aborted in the register.

   A value of one in bits 32-63 of general register R_1 means that the transaction has been aborted once, a value of two means the transaction has been aborted twice, and so forth.

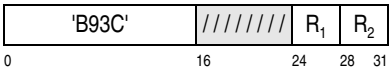
2. An example of the use of PERFORM PROCESSOR ASSIST is shown in programming note 2 on page 5-107.

3. The processor-assist facility is indicated by facility bit 49.

4. The in-order-execution assist is designed to be used to prevent the out of order execution of conditional paths.

PERFORM RANDOM NUMBER OPERATION

PRNO R_1,R_2 [RRE]
PPNO R_1,R_2 [RRE]



A function specified by the function code in general register 0 is performed.

Bits 16-23 of the instruction are reserved and should contain zeros; otherwise, the instruction may not operate compatibly in the future.

Bit positions 57-63 of general register 0 contain the function code. Figure 7-384 shows the assigned function codes for PERFORM RANDOM NUMBER OPERATION. When the message-security-assist extension 13 is installed, function code 127 is valid

for PERFORM RANDOM NUMBER OPERATION.All other function codes are unassigned.

Code	Function	Parameter Block Size (bytes)
0	PRNO Query	16
3	PRNO-SHA-512-DRNG	240
112	PRNO-TRNG-Query-Raw-to-Conditioned-Ratio	8
114	PRNO-TRNG	—
127	PRNO-Query-Authentication-Information	V

Explanation:

— Not applicable to the function.
DRNG Deterministic random-number generation.
TRNG True random-number generation.
V Variable parameter block size. See each format-x parameter block for the exact size of that parameter block.

Figure 7-384. Function Codes for PERFORM RANDOM NUMBER OPERATION

If bits 57-63 of general register 0 designate an unassigned or uninstalled function code, a specification exception is recognized.

The PRNO-Query function provides the means of indicating the availability of the other functions. The contents of general registers R_1, $R_1 + 1$, R_2 and $R_2 + 1$ are ignored for the query function.

The query-authentication-information function provides the information that can be used by the program to authenticate the running instruction's firmware code level (IFCL) currently installed on the model. The contents of general registers R_1, $R_1 + 1$, R_2 and $R_2 + 1$ are ignored for the query-authentication-information function.

For the PRNO-SHA-512-DRNG function, bit 56 of general register 0 is the modifier bit. When the modifier bit is zero, a generate operation is performed, and when the modifier bit is one, a seed operation is performed. The modifier bit is ignored for all other functions. All other bits of general register 0 are ignored.

Depending on the function, a parameter block, first operand, and second operand in storage may be accessed by the instruction. When applicable, general register 1 contains the address of the leftmost byte of the parameter block in storage. When applicable, general registers R_1 and R_2 designate an even-odd pair of general registers corresponding to the first and second operands, respectively. The even-numbered register contains the address of the operand in storage, and the odd-numbered register contains the length of the operand. The storage location corresponding to an operand is only accessed when the length of the corresponding operand is nonzero.

All general registers that contain an address are subject to the current addressing mode. In the 24-bit addressing mode, the contents of bit positions 40-63 of the register constitute the address of the storage location, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the register constitute the address of the storage location, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 of the register constitute the address of the storage location. In the access register mode, access register 1, R_1, and R_2 specifies the address space containing the parameter block, first operand, and second operand, respectively.

The odd-numbered registers containing an operand's length are also subject to the current addressing mode. In either the 24- or 31-bit addressing mode, the contents of bit positions 32-63 of the register form a 32-bit unsigned binary integer which specifies the number of bytes in the storage operand, and bit positions 0-31 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 of the register form a 64-bit unsigned binary integer which specifies the number of bytes in the storage operand.

For the PRNO-SHA-512-DRNG function's generate operation, the first-operand length is updated in general register $R_1 + 1$ at the completion of the instruction. The first-operand address in general register R_1 is not updated by the PRNO-SHA-512-DRNG function; however in the 24-bit addressing mode, bits 32-39 may be set to zero or remain unchanged, and in the 31-bit addressing mode, bit 32 may be set to zero or remain unchanged, regardless of the first-operand length.

For the PRNO-TRNG function, the first-operand address, first-operand length, second-operand address, and second-operand length in general registers R_1, $R_1 + 1$, R_2, and $R_2 + 1$, respectively, are updated at the completion of the instruction. In the

24-bit addressing mode, bits 40-63 of the even-numbered register are incremented by the number of bytes processed for the respective operand, bits 0-31 of the register remain unchanged, and regardless of the operand's length, bits 32-39 of the register may be set to zero or may remain unchanged. In the 31-bit addressing mode, bits 33-63 of the even-numbered register are incremented by the number of bytes processed for the respective operand, bits 0-31 of the register remain unchanged, and regardless of the operand's length, bit 32 of the register may be set to zero or may remain unchanged. In the 64-bit addressing mode, bits 0-63 of the even-numbered register are incremented by the number of bytes processed for the respective operand. In either the 24- or 31-bit addressing mode, bits 32-63 of the odd-numbered register are decremented by the number of bytes processed for the respective operand, and bits 0-31 of the register remain unchanged. In the 64-bit addressing mode, bits 0-63 of the odd-numbered register are decremented by the number of bytes processed for the respective operand.

Figure 7-385 shows the contents of the general registers just described.

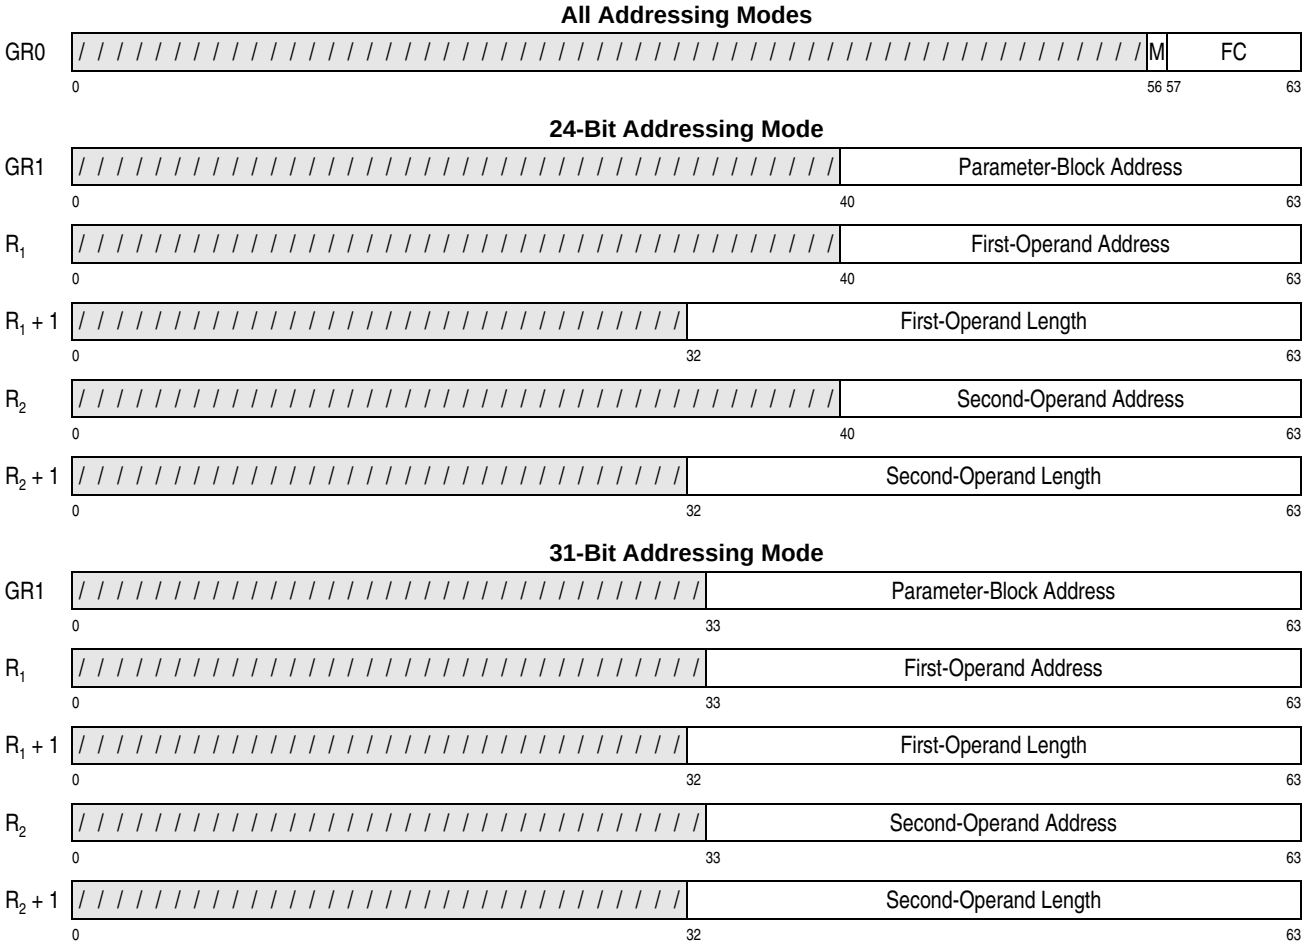


Figure 7-385. General Register Assignment for PERFORM RANDOM NUMBER OPERATION (Part 1 of 2)

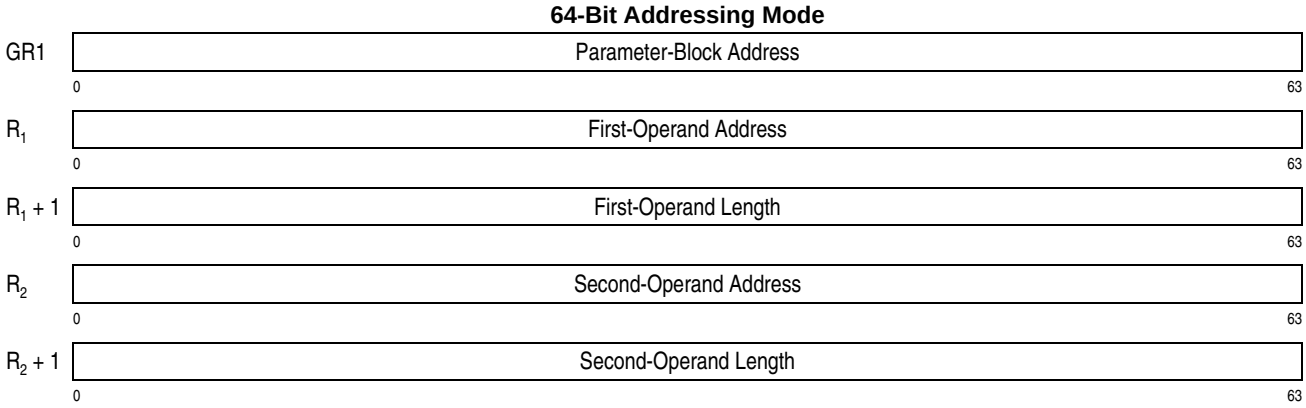

Explanation:

FC Function code.
M Modifier bit determining whether a seed or generate operation is performed.

Figure 7-385. General Register Assignment for PERFORM RANDOM NUMBER OPERATION (Part 2 of 2)

Depending on the function code in general register 0, one or more registers designating the parameter block, first operand, or second operand may not be used by the function. Figure 7-386 summarizes the registers that are used by the various functions.

Function (Operation)	GR1	R_1	$R_1 + 1$	R_2	$R_2 + 1$
PRNO-Query	PBA (S)	—	—	—	—
PRNO-SHA-512-DRNG (Seed)	PBA (F,S)	—	—	O_2A (F)	O_2L
PRNO-SHA-512-DRNG (Generate)	PBA (F,S)	O_1A (S)	O_1L (D)	—	—
PRNO-TRNG-Query-Raw-to-Conditioned-Ratio	PBA (S)	—	—	—	—
PRNO-TRNG	—	O_1A (S,I)	O_1L (D)	O_2A (S,I)	O_2L (D)

Explanation:

— Not applicable to the function or operation. Storage location not accessed; register not modified.
D The register is decremented by the number of bytes processed by the instruction.
F Fetch access
I The register is incremented by the number of bytes processed by the instruction. Note, general register R_1 is not incremented for PRNO-SHA-512-DRNG generate operation.

Figure 7-386. Summary of Register Usage for PRNO Functions (Part 1 of 2)

Function (Operation)	GR1	R_1	$R_1 + 1$	R_2	$R_2 + 1$

O_1A When the first-operand length is nonzero, the address of the leftmost byte of the first operand; otherwise, not applicable.
O_1L First-operand length.
O_2A When the second-operand length is nonzero, the address of the leftmost byte of the second operand; otherwise, not applicable.
O_2L Second-operand length.
PBA Address of the leftmost byte of the parameter block.
S Store access.

Figure 7-386. Summary of Register Usage for PRNO Functions (Part 2 of 2)

When the parameter block overlaps any portion of the storage operands, the results are unpredictable.

When the R_1 or R_2 field is not applicable to a function (as shown in Figure 7-386), any storage location designated by the respective operand is not accessed, and access exceptions and PER zero-address-detection events are not recognized for the location. When an applicable storage-operand length is zero, access exceptions for the storage-operand location are not recognized. However, for functions that access the parameter block, the parameter block is accessed even when the storage-operand length is zero.

As observed by other CPUs and the I/O subsystem, references to the parameter block and storage operands may be multiple-access references, accesses

to these locations are not necessarily block-concurrent, and the sequence of these accesses or references is undefined.

A PER storage-alteration event is recognized only for the portion of the parameter block that is stored. For functions that store to the first- or second-operand locations, when a PER storage-alteration event is recognized, fewer than 4K additional bytes are stored into the respective locations before the event is reported. When a PER storage-alteration event is recognized for any combination of the first-operand location, the second-operand location, and the portion of the parameter block that is stored, it is unpredictable which of these locations is indicated in the PER access identification (PAID) and PER ASCE ID (AI). Similarly, when a PER zero-address-detection event is recognized for any combination of the first-operand location, the second-operand location, and the parameter block, it is unpredictable which of these locations is identified in the PAID and AI.

PRNO-Query (PRNO Function Code 0)

The contents of general registers R_1, $R_1 + 1$, R_2, and $R_2 + 1$ are ignored by the query function.

The locations of the operands and addresses used by the instruction are as shown in Figure 7-385 on page 7-411.

The parameter block used for the function has the following format:

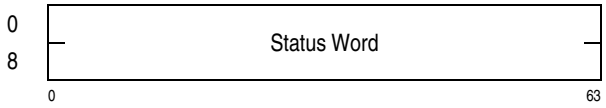

Figure 7-387. Parameter Block for PRNO-Query

A 128-bit status word is stored in the parameter block. Bits 0-127 of this field correspond to function codes 0-127, respectively, of the PERFORM RANDOM NUMBER OPERATION instruction. When a bit is one, the corresponding function is installed; otherwise, the function is not installed.

Condition code 0 is set when execution of the PRNO-Query function completes; condition code 3 is not applicable to this function.

PRNO-SHA-512-DRNG (PRNO Function Code 3)

Depending on the modifier bit, bit 56 of general register 0, the PRNO-SHA-512-DRNG function performs either a deterministic pseudorandom-number generate operation or a deterministic pseudorandom-number seed operation using the 512-bit secure-hash algorithm (SHA-512).

Deterministic pseudorandom-number generation, also known as deterministic random-bit generation, is defined in Reference [18.] on page xxxii; refer to this publication for further description on terms used in this definition. Further description of the secure hash algorithm may be found in Reference [15.] on page xxxii.

The locations of the operands and addresses used by the instruction are as shown in Figure 7-385 on page 7-411.

The parameter block used for the function represents the internal state of a deterministic random-number generator and has the following format:

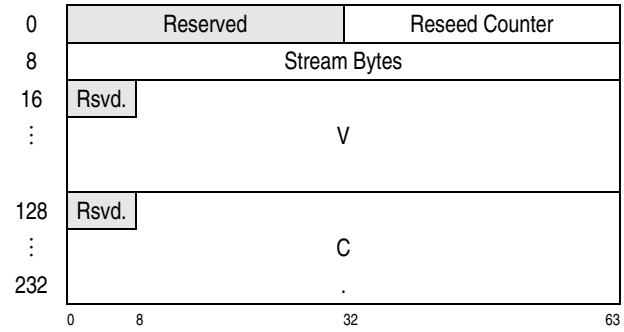

Figure 7-388. Parameter Block for PRNO-SHA-512-DRNG Function

The same parameter block format is used by both the generate operation and the seed operation (including instantiation and reseeding). A parameter block containing all zeros is considered to be not instantiated. The program should zero the parameter block prior to issuing the seed operation to instantiate the parameter block, and subsequently, the program should not alter the contents of the parameter block except to zero it; otherwise, unpredictable results may be produced by the instruction.

Reserved: Bytes 0-3, 16, and 128 of the parameter block are reserved. As observed by other CPUs and the I/O subsystem, the contents of byte 16 may appear to change during the execution of the instruc-

tion; however, byte 16 will contain zero when the instruction completes with condition code 0. As observed by other CPUs and the I/O subsystem, the contents of byte 128 may appear to change during the execution of the seed operation, however, byte 128 will contain zero at the completion of the seed operation.

Reseed Counter: Bytes 4-7 of the parameter block contain a 32-bit unsigned binary integer indicating the number of times that the instruction has completed with condition code 0 since the parameter block was last instantiated or reseeded.

When the reseed counter contains zero, the parameter block is considered to be not instantiated, and the following applies:

- Execution of the seed operation causes the parameter block to be instantiated with initial values, including setting the reseed counter to a value of one.
- Execution of the generate operation results in a general-operand data exception being recognized.

When the reseed counter contains a nonzero value, the parameter block is considered to be instantiated, and the following applies:

- Execution of the seed operation causes the parameter block to be reseeded, including resetting the reseed counter to a value of one.
- Execution of a generate operation that results in condition code 0 causes the reseed counter to be incremented by one; any carry out of bit position 0 of the reseed-counter field is ignored.

Stream Bytes: Bytes 8-15 of the parameter block contain a 64-bit unsigned binary integer. The stream-bytes field is set to zero by the execution of the seed operation when instantiating the parameter block (that is, when the reseed counter is zero); the field is not changed by the execution of the seed operation when the parameter block is already instantiated.

Partial or full completion of a generate operation causes the contents of the stream-bytes field to be incremented by the number of bytes stored into the first operand; any carry out of bit position 0 of the stream-bytes field is ignored.

Value (V): Bytes 17-127 of the parameter block contains an 888-bit value indicating the internal state of the random-number generator represented by the parameter block. V is initialized by the execution of the seed operation when instantiating the parameter block. V is updated by either (a) the execution of the seed operation when the reseed counter is nonzero, or (b) the execution of the generate operation that ends in condition code 0.

Constant (C): Bytes 129-239 of the parameter block contain an 888-bit value indicating the internal state of the random-number generator represented by the block. C is initialized by the execution of the seed operation, and inspected by the generate operation.

PRNO-SHA-512-DRNG Seed Operation

The PRNO-SHA-512-DRNG seed operation instantiates or reseeds a deterministic-pseudorandom-number-generation parameter block using the 512-bit secure-hash algorithm.

Depending on whether the reseed counter in bytes 4-7 of the parameter block is zero or nonzero, an instantiation or reseeding operation is performed, respectively.

- For the instantiation operation, the second operand in storage contains entropy input, nonce, and an optional personalization string, used to form seed material.
- For the reseed operation, the second operand in storage contains entropy input and optional additional input, used to form the seed material.

See Reference [18.] on page xxxii for the definition and usage of entropy input, nonce, personalization string, and additional input, and for details on the algorithms used. The length of the second operand in general register $R_2 + 1$ must not exceed 512 bytes, otherwise, a specification exception is recognized.

When performing an instantiation operation, seed material is formed using only the second operand. When performing a reseeding operation, seed material is formed from a concatenation of the value 01 hex, the V field of the parameter block, and the sec-

ond operand. The formation of the seed material is illustrated in Figure 7-389.

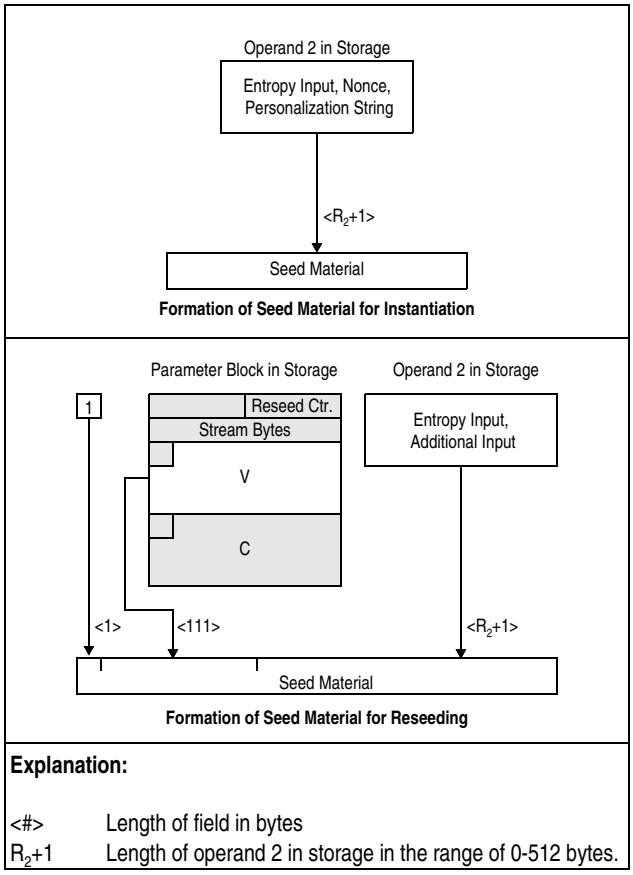

Figure 7-389. PRNO-SHA-512-DRNG Function's Seed Operation Generation of Seed Material

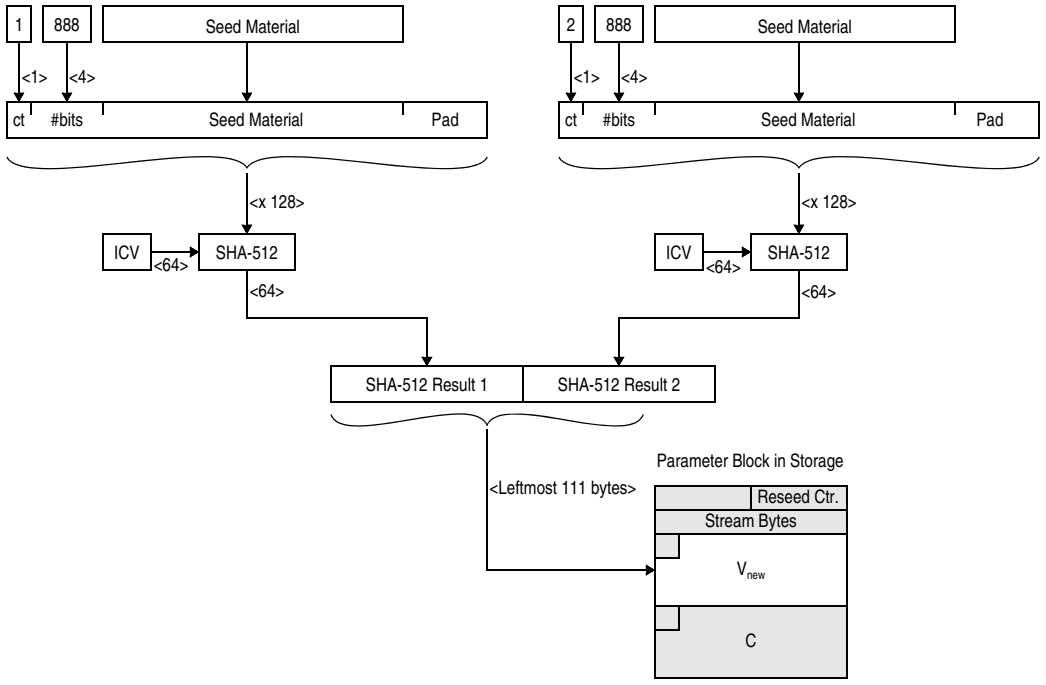
For either the instantiation or reseeding operation, a new value field (V_{new}) is formed as follows: A one byte counter, four-byte value of 888, the seed material, and padding are used as input to the SHA-512 algorithm. The padding consists of a value of 80 hex, concatenated with 0-127 bytes of zeros, concatenated with a 16-byte binary integer designating the length in bits of the input to the SHA-512 algorithm not including the padding (that is, the length of the one-byte counter, four-byte value of 888, and the seed material). The SHA-512 algorithm is invoked twice to form two 64-byte hashed results; the one-byte counter contains the value 1 for the first invocation of the SHA-512 algorithm, and it contains the value 2 for the second invocation. The two 64-byte hashed results are concatenated together, and the leftmost 111 bytes of the 128-byte concatenation form the new value field (V_{new}) in the parameter

block. The generation of V_{new} is illustrated in Figure 7-390.



Explanation:

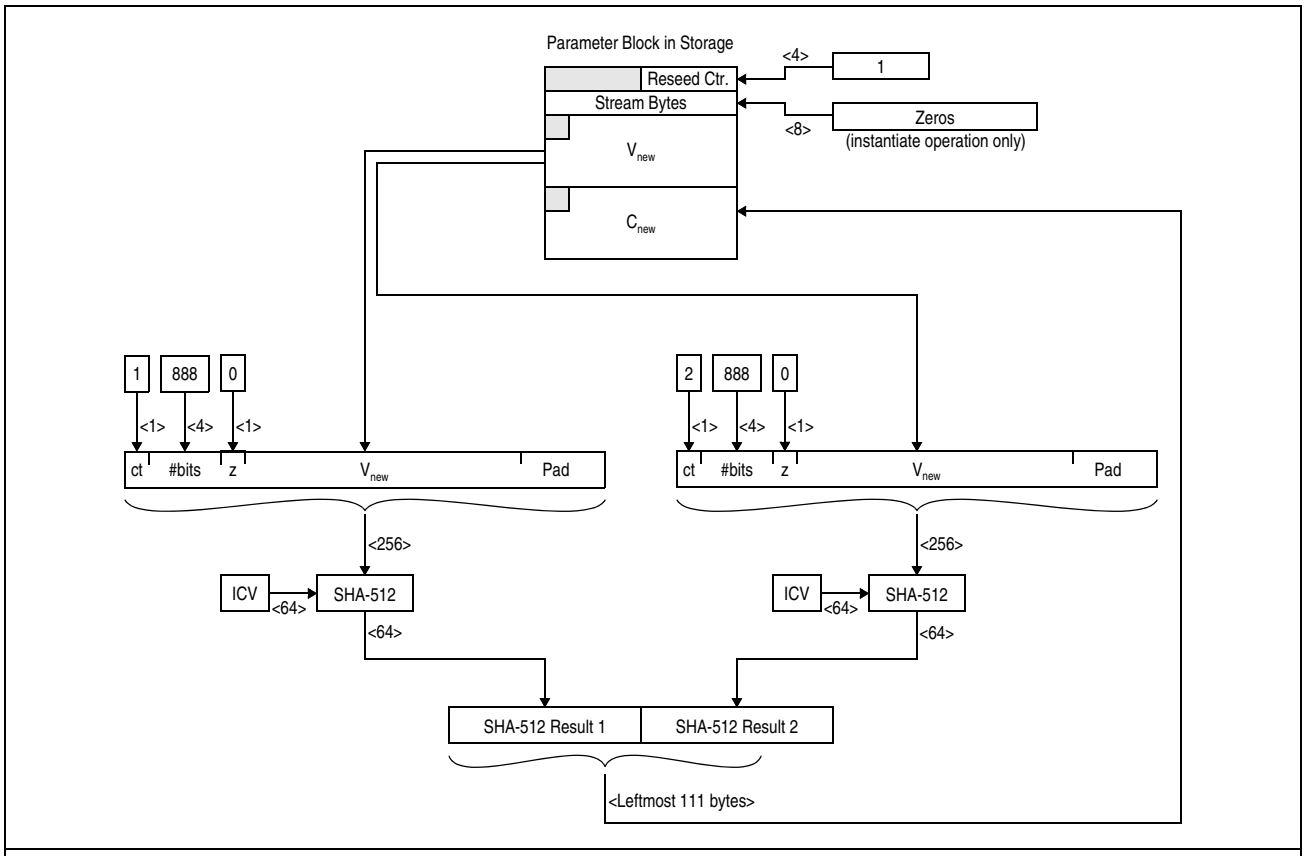
#bits	32-bit count of bits to be produced by the SHA-512 algorithm: 888 bits (378 hex)
<#>	Length of the field in bytes.
<x #>	Length of the field is a multiple of # bytes.
ct	8-bit counter used by the hash-derivation function (hash_df, defined in Reference [18.] on page xxxii).
ICV	Initial chaining value used for the SHA-512 algorithm (initial chaining values are described in programming note 6 for KLMD on page 7-217.
Pad	Variable number of pad bytes, beginning with 80 hex, followed by 0-127 bytes of zeros, followed by a 16-byte binary integer representing the length in bits of the input to the SHA-512 algorithm not including the padding. An appropriate number of zero bytes are inserted such that the length of the input to the SHA-512 algorithm is a multiple of 128 bytes.

Figure 7-390. PRNO-SHA-512-DRNG Function's Seed Operation Formation of New Value (V_{new})

Similar to the formation of the V_{new} field, the new constant field (C_{new}) is formed during both the instantiation or reseeding operation. A one byte counter, four-byte value of 888, one byte value of zero, the V_{new} field, and padding are concatenated to form input to the SHA-512 algorithm. The padding consists of a value of 80 hex, concatenated with 122 bytes of zeros, concatenated with a 16-byte binary integer designating the length in bits of the input to the SHA-512 algorithm not including the padding (that is, the length of the one-byte counter, four-byte value of 888, one-byte value of zero, and the V_{new} field). The SHA-512 algorithm is invoked twice to form two 64-byte hashed results; the one-byte counter contains the value 1 for the first invocation of the SHA-512 algorithm, and it contains the value 2 for the second invocation. The two 64-byte hashed results are concatenated together, and the leftmost 111 bytes of the 128-byte concatenation form the new constant field (C_{new}) in the parameter block.

For either the instantiate or reseeding operation, the reseed-counter field in the parameter block is set to a value of one. For the instantiate operation only, the stream-bytes field in the parameter block is set to zeros; the stream-bytes field remains unchanged by a reseeding operation.

The generation of C_{new} and the initialization of the reseed-counter and stream-bytes fields is illustrated in Figure 7-391.



Explanation:

#bits	32-bit count of bits to be produced by the SHA-512 algorithm: 888 bits (378 hex)
<#>	Length of field in bytes.
ct	8-bit counter used by the hash-derivation function (hash_df, defined in Reference [18.] on page xxxii).
ICV	Initial chaining value used for the SHA-512 algorithm (initial chaining values are described in programming note 6 for KLMD on page 7-217.
Pad	Pad bytes, beginning with 80 hex, followed 122 bytes of zeros, followed by a 16-byte binary integer representing the length of the input to the SHA-512 algorithm not including the padding.
z	8-bit field of zeros.

Figure 7-391. PRNO-SHA-512-DRNG Function's Seed Operation Formation of New Constant (C_{new}) and Initialization of the Reseed-Counter and Stream-Bytes Fields

Condition code 0 is set when execution of the PRNO-SHA-512-DRNG function's seed operation completes; condition code 3 is not applicable to the seed operation.

PRNO-SHA-512-DRNG Generate Operation

If the reseed counter in the parameter block is zero, a general-operand data exception is recognized and the operation is suppressed.

General register R_1 contains the address of the *leftmost* byte of the first operand. When the first-operand length in general register $R_1 + 1$ is nonzero, the first operand is formed in right-to-left order in units of 64-byte blocks, except that the rightmost block may contain fewer than 64 bytes. The number of blocks to be stored, including any partial rightmost block, is determined by rounding the first-operand length in general register $R_1 + 1$ up to a multiple of 64 and dividing this value by 64. The blocks of the first oper-

and are numbered from left to right as 0 to n–1, where n–1 represents the rightmost block. The following procedure is performed for each block of the first-operand location, beginning with the rightmost (n–1) block and proceeding to the left.

1. The value (V) from the parameter block is added to the block number being processed, with any overflow from the addition ignored.

2. The 111-byte sum of this addition, concatenated with 17 bytes of padding, are used as input to the SHA-512 algorithm, resulting in a 64-byte hashed value. The 17-byte padding provided to the SHA-512 algorithm consists of a value of 80 hex followed by a 16-byte binary integer value of 888 (the length of V in bits).

3. If the first-operand length in general register $R_1 + 1$ is a multiple of 64, then the resulting 64-byte hashed value is stored in the respective block of the first-operand location, and the length in general register $R_1 + 1$ is decremented by 64.

   If the first-operand length is not a multiple of 64, then the leftmost *m* bytes of the resulting 64-byte hashed value is stored in the rightmost partial block of the first operand, where *m* represents the remainder of the first-operand length divided by 64. In this case, the length in general register $R_1 + 1$ is decremented by *m*.

4. Regardless of whether a full or partial block is stored, the stream-bytes field in bytes 8-15 of the parameter block is incremented by the number of bytes stored into the first-operand location.

The above process is repeated until either the first-operand length in general register $R_1 + 1$ is zero (called normal completion) or a CPU-determined number of blocks has been processed (called partial completion). The CPU-determined number of blocks depends on the model, and may be a different number each time the instruction is executed. The CPU-determined number of blocks is usually nonzero. In certain unusual situations, this number may be zero, and condition code 3 may be set with no progress. However, the CPU protects against endless reoccurrence of this no-progress case.

The process of generating the deterministic pseudorandom numbers in the first operand is shown in Figure 7-392.

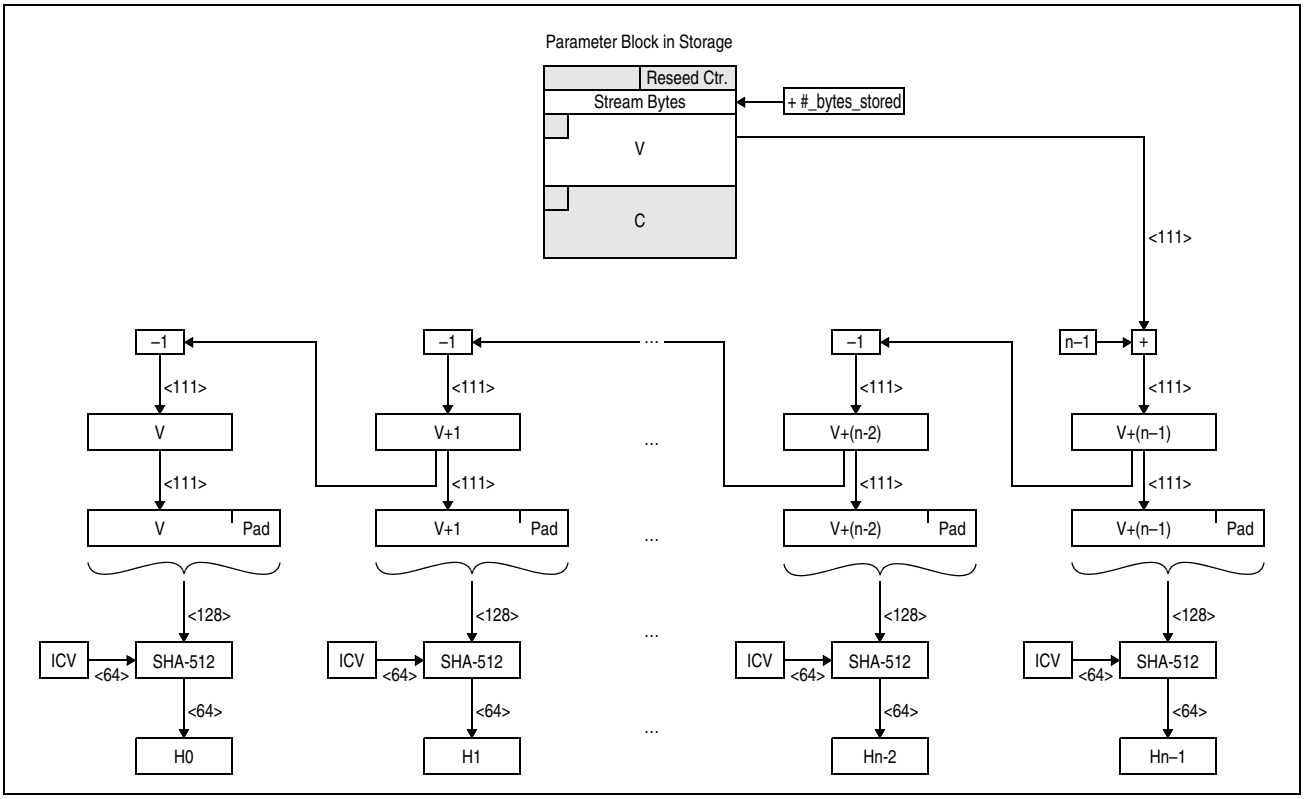


Figure 7-392. PRNO-SHA-512-DRNG Function's Generate Operation Generation of Deterministic Pseudorandom Numbers (Part 1 of 2)

Explanation:

<#>	Length of field in bytes.
Hn	64-byte hashed value stored in the first-operand location; the rightmost value (Hn–1) may contain fewer than 64 bytes.
ICV	Initial chaining value used for the SHA-512 algorithm (initial chaining values are described in programming note 6 for KLMD on page 7-217.
n	Number of 64-byte blocks in the first operand; n is equal to the integer quotient of ((length in general register R_1 + 1) + 63) ÷ 64.
Pad	Pad bytes, beginning with 80 hex, followed by a 16-byte unsigned binary integer representing the length of V in bits: 888 (378 hex).

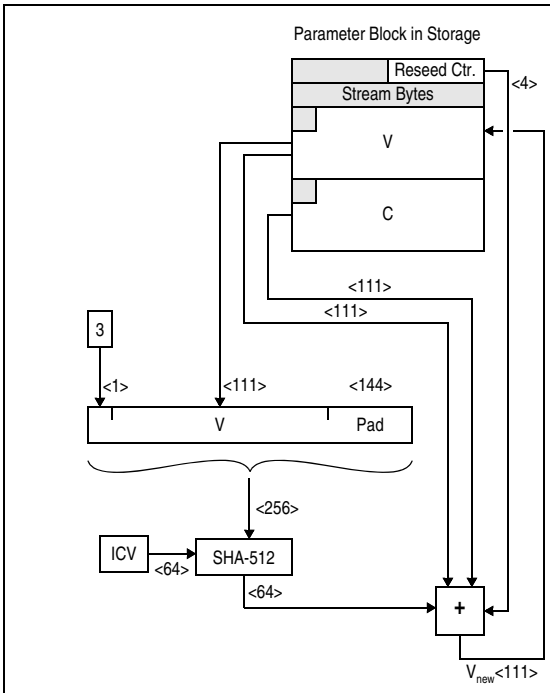
Figure 7-392. PRNO-SHA-512-DRNG Function's Generate Operation Generation of Deterministic Pseudorandom Numbers (Part 2 of 2)

When the first-operand length in general register R_1 + 1 is initially zero, normal completion occurs without storing into the first-operand location; however, the parameter block is updated as described below.

When the pseudorandom-number-generation process ends due to normal completion, the parameter block is updated as described below.

1. A one byte value of 03 hex, 111-byte value (V) from the parameter block, and 144 bytes of padding are used as input to the SHA-512 algorithm, resulting in a 64-byte hashed value. The padding consists of a value of 80 hex, concatenated with 127 bytes of zeros, concatenated with a 16-byte binary integer designating the length in bits of the input to the SHA-512 algorithm not including the padding (that is, the length of the one-byte value of 03 hex and the V field). The values of the 4-byte reseed-counter field and the 111-byte value (V) and constant (C) fields in the parameter block, and the 64-byte hashed value (from the above computation) are added. For the purposes of this addition, each value is treated as an unsigned binary integer, extended to the left with zeros as necessary. Any overflow from the addition is ignored, and the resulting 111-byte sum replaces the value field in the parameter block (V_{new}).
2. The 4-byte reseed-counter field in the parameter block is incremented by one.
3. Condition code 0 is set.

Steps 1 and 2 of the normal completion processing are illustrated in Figure 7-393.



Explanation:

<#>	Length of field in bytes
ICV	Initial chaining value used for the SHA-512 algorithm (initial chaining values are described in programming note 6 for KLMD on page 7-217.
Pad	Pad bytes, beginning with 80 hex, followed 127 bytes of zeros, followed by a 16-byte unsigned binary integer representing the length of the input to the SHA-512 algorithm not including the padding.

Figure 7-393. PRNO-SHA-512-DRNG Function's Generate Operation Normal Completion

When the pseudorandom-number-generation process ends due to partial completion, the first-operand length in general register R_1 + 1 contains a nonzero multiple of 64, the reseed-counter and value (V) fields in the parameter block are not updated, and condition code 3 is set.

For a generate operation, access exceptions may be reported for a larger portion of the first operand than is processed in a single execution of the instruction. However, access exceptions are not recognized for locations that do not encompass the first operand nor for locations more than 4K bytes from the current location being processed.

For a generate operation, when the operation ends due to normal completion, condition code 0 is set and the resulting value in general register $R_1 + 1$ is zero. When the operation ends due to partial completion, condition code 3 is set and the resulting value in general register $R_1 + 1$ is nonzero.

PRNO-TRNG-Query-Raw-to-Conditioned Ratio (PRNO Function Code 112)

The PRNO-TRNG-query-raw-to-conditioned ratio function may be used to determine the ratio of raw to conditioned entropy produced when both types of entropy are requested by the PRNO-TRNG function. See Reference [19.] on page xxxii for a description of these terms.

The parameter block is stored with two 32-bit unsigned binary integers indicating the ratio of raw entropy to conditioned entropy produced by the PRNO-TRNG function.

The locations of the operands and addresses used by the instruction are as shown in Figure 7-385 on page 7-411. The contents of general registers R_1, $R_1 + 1$, R_2, and $R_2 + 1$ are ignored by the function.

The parameter block used for the function has the following format:

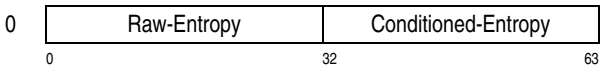


Figure 7-394. Parameter Block for PRNO-TRNG-Query-Raw-to-Conditioned Ratio

The fields of the parameter block are as follows:

Raw Entropy: The numerator in a fraction designating the ratio of raw entropy to conditioned entropy produced by the PRNO-TRNG function.

Conditioned Entropy: The denominator in a fraction designating the ratio of raw entropy to conditioned entropy produced by the PRNO-TRNG function.

The raw-entropy to conditioned-entropy ratio indicates the relative sizes of the first and second operands stored by the PRNO-TRNG function when the operands contain a proportionate number of raw and conditioned bits.

Condition code 0 is set when execution of the PRNO-TRNG-query-raw-to-conditioned function completes; condition code 3 is not applicable to this function.

PRNO-TRNG (PRNO Function Code 114)

A series of hardware-generated random numbers is stored at either or both the first- and second-operand locations. The locations of the operands and addresses used by the instruction are as shown in Figure 7-385 on page 7-411. A parameter block is not used by the PRNO-TRNG function, and general register 1 is ignored.

The R_1 field designates an even-odd pair of general registers. The even-numbered register contains the address of the leftmost byte of the first operand, and the odd-numbered register contains the length of the first operand. The first operand comprises random numbers in the form of raw entropy, produced directly by a hardware source.

The R_2 field designates an even-odd pair of general registers. The even-numbered register contains the address of the leftmost byte of the second operand, and the odd-numbered register contains the length of the second operand. The second operand comprises random numbers extracted from the raw entropy source and then conditioned by an approved algorithm (section 6.4.2 of Reference [19.] on page xxxii describes approved algorithms).

The ratio of raw-entropy bits needed to produce conditioned-entropy bits can be determined by the PRNO-TRNG-query-raw-to-conditioned-ratio function. When the lengths of both the first and second operands are nonzero, the raw and conditioned entropy are stored at the first- and second-operand locations, respectively, in the raw-to-conditioned ratio. The number of bytes stored in a single unit of operation is model dependent, and may vary from one execution of the instruction to another.

When the length of the first operand is nonzero but the length of the second operand is zero, the process continues with storing the raw entropy in the first operand only. Similarly, when the length of the second operand is nonzero but the length of the first

operand is zero, the process continues with storing the conditioned entropy in the second operand only.

Access exceptions may be reported for a larger portion of the first and second operands than is processed in a single execution of the instruction. However, access exceptions are not recognized for locations that do not encompass the first or second operand nor for locations more than 4K bytes from the current location being processed.

The process continues either until both operand lengths are zero (called normal completion), or until a CPU-determined number of bytes have been stored (called partial completion), whichever occurs first. When the operation ends due to normal completion, condition code 0 is set. When the operation ends due to partial completion, condition code 3 is set. The CPU-determined number of bytes depends on the model, and may be a different number each time the instruction is executed. The CPU-determined number of bytes is usually nonzero. In certain unusual situations, this number may be zero, and condition code 3 may be set with no progress. However, the CPU protects against endless recurrence of this no-progress case.

Regardless of whether the operation ends due to normal or partial completion, general registers R_1 and $R_1 + 1$ are incremented and decremented, respectively, by the number of bytes stored into the first operand, and general registers R_2 and $R_2 + 1$ are incremented and decremented, respectively, by the number of bytes stored into the second operand.

If the first and second operands overlap, the results are unpredictable.

Common Operation

If the CPU is enabled to update counters in the cryptography-counter set, then the following applies to all functions other than PRNO-Query and PRNO-Query-Authentication-Information:

- Prior to the start of any operation, fetch and store accessibility to the appropriate counter is tested. If the counter cannot be accessed, then an access exception is recognized and instruction execution ends in nullification or suppression, as appropriate. The priority of recognizing an access exception for an access to a counter is the same as that for access exceptions for an access to the parameter block, first operand, and second operand.
- When instruction execution includes setting condition code 0, instruction execution also includes updating the appropriate counter.

PRNO-Query-Authentication-Information (Function Code 127)

The locations of the operands and addresses used by the instruction are as shown in Figure 7-385 on page 7-411.

The PRNO-query-authentication-information function stores the information that can be used by the program to authenticate the running instruction's firmware code level (IFCL) currently installed on the model into the format-0 parameter block for PRNO-query-authentication-information. Condition code 0 is set when execution of the PRNO-query-authentication-information function completes; condition code 3 is not applicable to this function.

The format-0 parameter block used for the PRNO-query-authentication-information function has the following format:

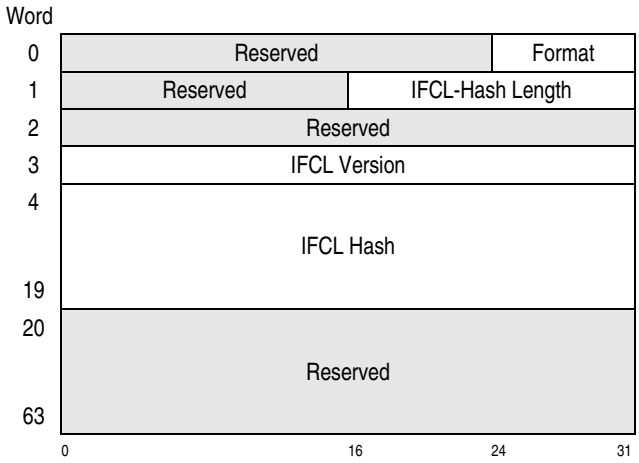

Figure 7-395. Format-0 Parameter Block for PRNO-Query-Authentication-Information

The format-0 parameter block contains the following fields:

Reserved: Bytes 0-2 of word 0, bytes 0-1 of word 1, word 2, and words 20-63 are reserved and stored as zeros.

Format: Byte 3 of word 0 contains an 8-bit unsigned binary integer whose value specifies the format of the parameter block. A format value of zero indicates a format-0 parameter block. When a format-0 parameter block is stored, the value of this field is set to zero.

IFCL-Hash Length: Bytes 2-3 of word 1 contain a 16-bit unsigned binary integer specifying the number of bytes of the IFCL hash stored in the IFCL hash field. When the IFCL hash is less than or equal to 64 bytes, the IFCL-hash length field is set to the actual length of the IFCL hash. When the IFCL hash is larger than 64 bytes, the IFCL-hash length field is set to 64.

IFCL Version: Word 3 contains a 32-bit unsigned binary integer specifying the version number of the IFCL.

IFCL Hash: Words 4-19 contain the hash value of the IFCL. The IFCL-hash length field specifies the number of bytes that are in the IFCL hash field. The IFCL hash value is left aligned. When the IFCL hash is less than 64 bytes, it is padded with zeros on the right. When the IFCL hash is larger than 64 bytes, only the leftmost 64 bytes of the IFCL hash are stored.

Special Conditions

A specification exception is recognized and no other action is taken if any of the following conditions exist:

1. Bits 57-63 of general register 0 specify an unassigned or uninstalled function code.
2. The R_1 or R_2 fields designate an odd-numbered register or general register 0. This exception is recognized regardless of the function code.
3. For the PRNO-SHA-512-DRNG function's seed operation, the length in general register $R_2 + 1$ is greater than 512.

For the PRNO-SHA-512-DRNG function's generate operation, a general-operand data exception is recognized if the reseed counter in the parameter block is zero.

Condition Code:

0 Normal completion
1 --
2 --
3 Partial completion

Program Exceptions:

- Access (store, operand 1, query parameter block, and query-authentication-information parameter block; fetch and store, operand 2 and parameter block, cryptography counter)
- Data with DXC 0, general operand
- Operation (if the message-security-assist extension 5 is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. The performance of the query function (code 0) may be significantly slower than that of simply examining a location in storage. If the program needs to frequently test for the availability of a function, it should perform the query function once during initialization; subsequently it should examine the stored results of the query function in memory with an instruction such as TEST UNDER MASK.
2. With the advent of the message-security-assist extension 7, the instruction is capable of producing both true and deterministic random numbers. Thus, the former PERFORM PSEUDORANDOM NUMBER OPERATION (PPNO) instruction is renamed to PERFORM RANDOM NUMBER OPERATION (PRNO) to encompass both types of numbers. Although it is now deprecated, the mnemonic PPNO is retained for compatibility.
3. The following considerations apply to the PRNO-SHA-512-DRNG function:

    a. For the generate operation, when condition code 3 is set, the first operand length in general register $R_1 + 1$ is updated such that the program can simply branch back to the instruction to continue the operation.

    b. The seed operation (instantiation and reseeding) and generate operation correspond to the following algorithm specifications in Reference [19.] on page xxxii:

- Section 10.1.1.2: Instantiation of Hash_DRBG
- Section 10.1.1.3: Reseeding a Hash_DRBG Instantiation
- Section 10.1.1.4: Generating Pseudorandom Bits Using Hash_DRBG (steps 3–7)

c. If a carry out of bit position 0 of the reseed-counter field occurs during a generate operation, then the counter wraps around to zero; in this case, the parameter block is considered not to be instantiated. Unless a seed operation is performed to reinstantiate the parameter block, a subsequent generate operation will result in a general-operand data exception being recognized.

d. The PRNO-SHA-512-DRNG function does not implement the testing and uninstantiation functions described in Reference [19.] on page xxxii. As the parameter block exists in program storage, the program can effect the testing function by directly inspecting the parameter block; similarly, the program can effect the uninstantiation function by zeroing the parameter block.

e. The program is responsible for reseeding the parameter block depending on policy and pseudorandom-number-generation state. For example, reseeding may be required after each generate operation if prediction resistance is required. Reseeding may be appropriate after a preset number of stream bytes is produced. See Reference [18.] on page xxxii for further explanation.

f. Even though the generate operation processes the blocks of the first operand in right to left order, it is the address of the leftmost byte of the operand in general register R_1 that is used for PER zero-address detection. If the first-operand address is nonzero, and length of the operand is such that the operand wraps around to location zero, stores to the first-operand location – including stores to location zero – will not result in the recognition of a PER zero-address-detection event.

g. The length in bits of the input to the SHA-512 algorithm is implicitly determined by the instruction; this length is described as occupying the rightmost 16 bytes of the padding field. This differs from the KLMD-SHA-512 function of the COMPUTE LAST MESSAGE DIGEST instruction where the message-bit length (mbl) is explicitly specified in the parameter block, and the padding (p) and mbl are described separately.

h. The initial chaining value (ICV) is described as the initial-hash value (IHV) in Reference [18.] on page xxxii.

i. The program may issue a seed operation with the second-operand length in general register $R_2 + 1$ set to zero. However, the results in this case will always be deterministic.

4. The following considerations apply to the PRNO-TRNG function:

   a. Depending on the model, significant performance degradation may be experienced either by requesting excessively large results or by frequently-repeated executions of the instruction.

   b. The PRNO-TRNG function may be useful when implementing a hybrid random-number generator, using the conditioned entropy source from PRNO-TRNG to periodically reseed a deterministic random-number generation (such as that provided by the PRNO-SHA-512-DRNG function).

   c. The conditioned entropy provided by the PRNO-TRNG function may be shared by multiple, independently-seeded deterministic random number generators. Independence may be achieved by a unique program-supplied entropy, nonce, or personalization string when seeding a deterministic random number generator.

   d. The raw entropy provided by the first operand is intended for use by diagnostic programs that test the quality of entropy provided by the function. It is recommended that for normal usage, the first-operand length be set to zero.

   e. The ratio of raw-to-conditioned entropy provided by the function is constant across all processors of the same model type. Therefore, once the program has determined the ratio, it need not re-execute the PRNO-

TRNG-query-raw-to-conditioned-ratio function unless it is relocated to another model type.

f. Although entropy is produced by the PRNO-TRNG function in the raw-to-conditioned ratio reported by the PRNO-TRNG-query-raw-to-conditioned-ratio function, the program is in no way obliged to request raw and conditioned entropy in that ratio.

5. As observed by this CPU, other CPUs, and the I/O subsystem, inconsistent results may be briefly stored in a location defined to be stored for a particular function. See the section “Effects of CPU Retry” on page 11-3 for further details.

POPULATION COUNT

POPCNT $R_1,R_2[,M_3]$ [RRF-c]

A count of the number of bits in the second operand containing a value of one, is placed into the first operand.

When the miscellaneous-instruction-extensions facility 3 is not installed or bit 0 of the M_3 field is zero, a count of the number of one bits in each of the eight bytes of general register R_2 is placed into the corresponding byte of general register R_1. Each byte of general register R_1 is an 8-bit binary integer in the range of 0-8.

When the miscellaneous-instruction-extensions facility 3 is installed and bit 0 of the M_3 field is one, a count of the total number of one bits in the 64-bit general register R_2 is placed into general register R_1. The result is a 64-bit unsigned integer in the range 0 to 64.

Bits 1-3 of the M_3 field are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future. If the miscellaneous-instruction-extensions facility 3 is not installed, bit 0 of the M_3 field should also contain zero.

Resulting Condition Code:

0 Result zero
1 Result not zero
2 --
3 --

Program Exceptions:

- Operation (if the population-count facility is not installed)

Programming Notes:

1. The condition code is set based on all 64 bits of general register R_1.

2. If the miscellaneous-instruction-extensions facility 3 is installed, bit 0 of the M_3 field should be set to one to compute the total number of one bits in a general register. If the facility is not installed, the total number of one bits in a general register can be computed as shown below. In this example, general register 15 contains the bits to be counted; the result containing the total number of one bits in general register 15 is placed in general register 8. (General register 9 is used as a work register and contains residual values on completion.)

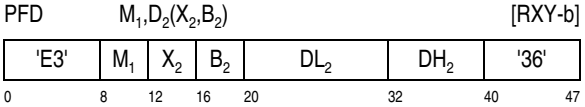
```
POPCNT  8,15
AHHLR   8,8,8
SLLG    9,8,16
ALGR    8,9
SLLG    9,8,8
ALGR    8,9
SRLG    8,8,56
```

   If there is a high probability that the results of the POPCNT instruction are zero, a conditional branch instruction may be inserted to skip the adding and shifting operations based on the condition code set by POPCNT.

3. Using techniques similar to that shown in programming note 2, the number of one bits in a word, halfword, or discontiguous bytes of the second operand may be determined.

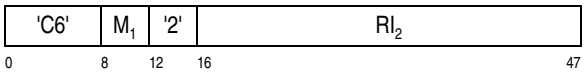
PREFETCH DATA

PFD $M_1,D_2(X_2,B_2)$ [RXY-b]



PREFETCH DATA RELATIVE LONG

PFDRL M_1,RI_2 [RIL-c]



Note: In this instruction definition, the name "PREFETCH DATA (RELATIVE LONG)" refers to both the PREFETCH DATA instruction and the PREFETCH DATA RELATIVE LONG instruction.

Subject to the controls specified in the M_1 field, the CPU is signaled to perform one of the following operations:

- Prefetch the second operand into a cache line.
- Release a cache line containing the second operand.

The second operand designates a logical address.

The M_1 field contains a 4-bit unsigned binary integer that is used as a code to signal the CPU as to the intended use of the second operand. The codes are as follows:

Code	Function Performed
1	Prefetch the data at the second-operand address into a cache line for fetch access.
2	Prefetch the data at the second-operand address into a cache line for store access.
6	Release the cache line containing the second operand from store access; retain the data in the cache line for fetch access.
7	Release the cache line containing the second operand from all accesses

All other codes are reserved. Depending on the model, the CPU may not implement all of the prefetch functions. For functions that are not implemented by the CPU, and for reserved functions, the instruction acts as a no-op. Code 0 always acts as a no-op.

No access exceptions or PER storage-alteration events are recognized for the second operand.

Code 2 has no effect on the change bit for the second operand. For all codes, it is model dependent whether any TLB entry is formed for the data that is prefetched.

For PREFETCH DATA, the displacement is treated as a 20-bit signed binary integer.

For PREFETCH DATA RELATIVE LONG, the contents of the RI_2 field are signed binary integer specifying the number of halfwords that is added to the address of the instruction to generate the address of the second operand. When DAT is on, the second operand is accessed using the same addressing-space mode as that used to access the instruction. When DAT is off, the second operand is accessed using a real address.

When PREFETCH DATA (RELATIVE LONG) is attempted in a nonconstrained transaction, and the code in the M_1 field is 6 or 7, it is model dependent whether the instruction is restricted; if the instruction is not restricted, it is unpredictable whether the transaction is aborted due to abort code 16. When PREFETCH DATA (RELATIVE LONG) is attempted in a constrained transaction, a transaction-constraint program interruption is recognized, and the transaction is aborted with abort code 4.

Condition Code: The code remains unchanged.

Program Exceptions:

- Operation (if the general-instructions-extension facility is not installed)
- Transaction constraint

Programming Notes:

1. PREFETCH DATA (RELATIVE LONG) signals the CPU to perform the specified operation, but it does not guarantee that the CPU will necessarily honor the request.

2. There is no guarantee that storage location will still be in the cache when a subsequent instruction references the location. Likewise, there is no guarantee that when a cache line is released, that the CPU will not subsequently refetch it (independent of any prefetching operations). Rather, PREFETCH DATA (RELATIVE LONG) simply provides hints as to the program's anticipated use of storage areas.

3. If an exception condition would otherwise be recognized when accessing the second operand, PREFETCH DATA (RELATIVE LONG) is completed with no indication of the exception provided to the program, however, the performance

of PREFETCH DATA (RELATIVE LONG) may be significantly slower than if the exception condition did not exist.

4. A significant delay may be experienced if a storage location has been prefetched and then released, and then a subsequent instruction references the same storage location. Similarly, a delay may be experienced if a storage location has been prefetched for fetch access, and then a subsequent instruction references the same location for storing.

5. On models that implement a unified data and instruction cache, the function performed may affect both subsequent operand accesses and instruction fetches from the second-operand location. On such models, a significant delay may be experienced if the code 7 is used to release data in a cache line from which an instruction is subsequently fetched.

6. On models that implement separate data and instruction caches, codes 1 and 2 cause the second operand to be prefetched into the data cache. Similarly, on such models, codes 6 and 7 cause the second operand to be released from the data cache. However, on certain models with separate data and instruction caches, code 7 may also cause the second operand to be released from the instruction cache, in addition to being released from the data cache.

7. On models that implement separate data and instruction caches, the use of code 2 to prefetch (for storing) a cache line from which instructions will subsequently be fetched may cause significant delays. Similar delays may be experienced for any store operation into a cache line from which instructions are subsequently fetched.

8. The use of PREFETCH DATA (RELATIVE LONG) to prefetch operands that are frequently updated in a multiprocessing environment may actually degrade performance by causing unnecessary contention for the cache line.

9. A prefetch operation consists of fetching a cache line on an integral boundary. The cache line size (and corresponding integral boundary) may be determined by executing EXTRACT CPU ATTRIBUTE.

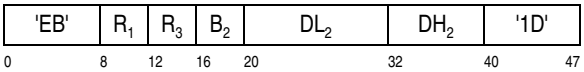
10. The second operand is fetched into the cache line in model-dependent units, on an integral boundary, the minimum size of which is a doubleword. Thus, at least the rightmost three bits of the second-operand address are assumed to contain zeros, regardless of what is specified by the program.

11. On most models, the unit directly addressed by the second-operand address is prefetched first. The order in which the remaining units of the cache line are prefetched is also model dependent.

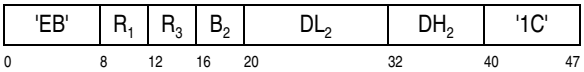
12. When PREFETCH DATA RELATIVE LONG is the target of an execute-type instruction, the second-operand address is relative to the target address.

ROTATE LEFT SINGLE LOGICAL

RLL $R_1,R_3,D_2(B_2)$ [RSY-a]



RLLG $R_1,R_3,D_2(B_2)$ [RSY-a]



The 32-bit or 64-bit third operand is rotated left the number of bits specified by the second-operand address, and the result is placed at the first-operand location. Except for when the R_1 and R_3 fields designate the same register, the third operand remains unchanged in general register R_3. For ROTATE LEFT SINGLE LOGICAL (RLL), bits 0-31 of general registers R_1 and R_3 remain unchanged.

The second-operand address is not used to address data; its rightmost six bits indicate the number of bit positions to be rotated. The remainder of the address is ignored.

For RLL, the first and third operands are in bit positions 32-63 of general registers R_1 and R_3, respectively. For RLLG, the operands are in bit positions 0-63 of the registers.

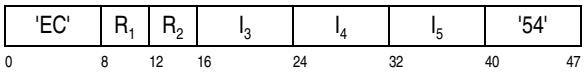
All 32 or 64 bits of the third operand participate in a left shift. Each bit shifted out of the leftmost bit position of the operand is placed in the rightmost bit position of the operand.

Condition Code: The code remains unchanged.

Program Exceptions: None.

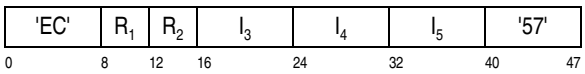
ROTATE THEN AND SELECTED BITS

RNSBG $R_1,R_2,I_3,I_4[,I_5]$ [RIE-f]



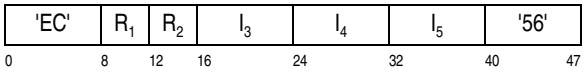
ROTATE THEN EXCLUSIVE OR SELECTED BITS

RXSBG $R_1,R_2,I_3,I_4[,I_5]$ [RIE-f]



ROTATE THEN OR SELECTED BITS

ROSBG $R_1,R_2,I_3,I_4[,I_5]$ [RIE-f]



The second operand is rotated left by the number of bits specified in the fifth operand. Each bit shifted out of the leftmost bit position of the operand is placed in the rightmost bit position of the operand. Depending on the instruction, the selected bits of the rotated second operand are logically ANDed, exclusive ORed, or ORed with the corresponding bits of the first operand, and the results of the logical operation may replace the selected bits of the first operand. The result is indicated by the condition code.

The second operand remains unchanged in general register R_2.

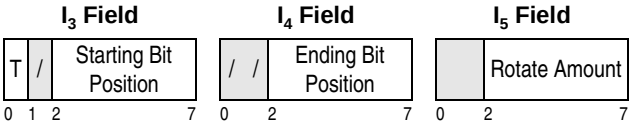
Bits 2-7 of the I_3 field (bits 18-23 of the instruction) contain an unsigned binary integer specifying the starting bit position of the selected range of bits in the first operand and in the second operand after rotation. Bits 2-7 of the I_4 field (bits 26-31 of the instruction) contain an unsigned binary integer specifying the ending bit position (inclusive) of the selected range of bits. When the ending bit position is less than the starting bit position, the range of bits wraps around from bit 63 to bit 0.

Bits 2-7 of the I_5 field (bits 34-39 of the instruction) contain an unsigned binary integer specifying the number of bits that the second operand is rotated to the left.

Bit 0 of the I_3 field (bit 16 of the instruction) contains the test-results control (T). When the T bit is zero, the results of the logical operation replace the selected bits of the first operand, and the remaining bits of the first operand are unchanged. When the T bit is one, the entire first operand is unchanged.

The condition code is set based on the results of the logical operation, regardless of the setting of the T bit. Only the selected range of bits is used to determine the condition code.

The immediate fields just described are as follows:



Bit 1 of the I_3 field and bits 0-1 of the I_4 field (bits 17 and 24-25 of the instruction) are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future. Bits 0-1 of the I_5 field (bits 32-33 of the instruction) are ignored.

Resulting Condition Code:

0 Result is zero
1 Result is not zero
2 --
3 --

Program Exceptions:

- Operation (if the general-instructions-extension facility is not installed)

Programming Notes:

1. Although the bits 2-7 of the I_5 field are defined to contain an unsigned binary integer specifying the number of bits that the second operand is rotated to the left, a negative value may be coded which effectively specifies a rotate-right amount.

2. The first operand is always used in its unrotated form. When the R_1 and R_2 fields designate the same register, the contents of the register are first rotated, and then the selected bits of the

rotated value logically operate upon the corresponding bits of the unrotated register contents.

3. Examples of the use of ROTATE THEN EXCLUSIVE OR SELECTED BITS, and ROTATE THEN OR SELECTED BITS are given in “Number Representation and Instruction-Use Examples” on page A-1.

4. In the assembler syntax, the I_5 operand containing the rotate amount is considered to be optional. When the I_5 field is not coded, a rotate amount of zero is implied.

5. The I_3 field contains both the test-results control (in bit 0) and the starting bit position value (in bits 2-7). For example, to AND bits 40-43 of register 5 with the corresponding bits of register 7 (no rotation) and simply test the results, the programmer might code:

```
RNSBG    R5,R7,X'80'+40,43,0
```

The X‘80’ represents the test-results control which is added to the starting-bit position to form the I_3 field.

The high-level assembler (HLASM) provides extended mnemonics for the test versions of these instructions, as shown below:

```
RNSBGT   R5,R7,40,43,0
```

The “T” suffix to the mnemonic indicates that the specified I_3 field is ORed with a value of X’80’ when generating the object code. The T mnemonic suffix also applies to ROSBG and RXSBG.

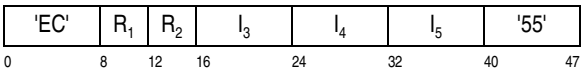
6. The High-Level Assembler implements various high-word logical operations by providing extended-mnemonics for the RNSBG, ROSBG, and RXSBG instructions, as shown in Figure 7-396.

Instruction Name	Extended-Mnemonic Syntax		RxSBG Equivalent	
AND HIGH (HIGH ← HIGH)	NHHR	R_1,R_2	RNSBG	$R_1,R_2,0,31$
AND HIGH (HIGH ← LOW)	NHLR	R_1,R_2	RNSBG	$R_1,R_2,0,31,32$
AND HIGH (LOW ← HIGH)	NLHR	R_1,R_2	RNSBG	$R_1,R_2,32,63,32$
EXCLUSIVE OR HIGH (HIGH ← HIGH)	XHHR	R_1,R_2	RXSBG	$R_1,R_2,0,31$
EXCLUSIVE OR HIGH (HIGH ← LOW)	XHLR	R_1,R_2	RXSBG	$R_1,R_2,0,31,32$
EXCLUSIVE OR HIGH (LOW ← HIGH)	XLHR	R_1,R_2	RXSBG	$R_1,R_2,32,63,32$
OR HIGH (HIGH ← HIGH)	OHHR	R_1,R_2	ROSBG	$R_1,R_2,0,31$
OR HIGH (HIGH ← LOW)	OHLR	R_1,R_2	ROSBG	$R_1,R_2,0,31,32$
OR HIGH (LOW ← HIGH)	OLHR	R_1,R_2	ROSBG	$R_1,R_2,32,63,32$

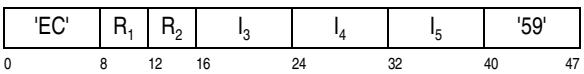
Figure 7-396. Extended-Mnemonics Formed Using RNSBG, RXSBG, and ROSBG

ROTATE THEN INSERT SELECTED BITS

RISBG $R_1,R_2,I_3,I_4[,I_5]$ [RIE-f]



RISBGN $R_1,R_2,I_3,I_4[,I_5]$ [RIE-f]



The second operand is rotated left by the number of bits specified in the fifth operand. Each bit shifted out of the leftmost bit position of the operand is placed in the rightmost bit position of the operand. The selected bits of the rotated second operand replace the contents of the corresponding bit positions of the first operand. For RISBG, the result is indicated by the condition code.

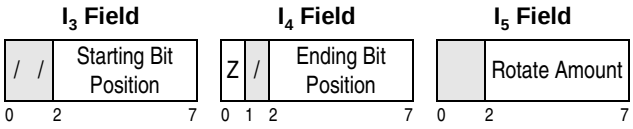
The second operand remains unchanged in general register R_2.

Bits 2-7 of the I_3 field (bits 18-23 of the instruction) contain an unsigned binary integer specifying the starting bit position of the selected range of bits in the first operand and in the second operand after rotation. Bits 2-7 of the I_4 field (bits 26-31 of the instruction) contain an unsigned binary integer specifying the ending bit position (inclusive) of the selected range of bits. When the ending bit position is less than the starting bit position, the range of bits wraps around from bit 63 to bit 0.

Bits 2-7 of the I_5 field (bits 34-39 of the instruction) contain an unsigned binary integer specifying the number of bits that the second operand is rotated to the left.

Bit 0 of the I_4 field (bit 24 of the instruction) contains the zero-remaining-bits control (Z). The Z bit controls how the remaining bits of the first operand are set (that is, those bits, if any, that are outside of the specified range). When the Z bit is zero, the remaining bits of the first operand are unchanged. When the Z bit is one, the remaining bits of the first operand are set to zeros.

The immediate fields just described are as follows:



Bits 0-1 of the I_3 field and bit 1 of the I_4 field (bits 16-17 and 25 of the instruction) are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future. Bits 0-1 of the I_5 field (bits 32-33 of the instruction) are ignored.

For the purposes of setting the condition code for RISBG, the result in general register R_1 is treated as being a 64-bit signed binary integer.

Resulting Condition Code:

For RISBG, the condition code is set as follows:

0 Result is zero
1 Result is less than zero
2 Result is greater than zero
3 --

For RISBGN, the condition code remains unchanged.

Program Exceptions:

- Operation (RISBG, if the general-instructions-extension facility is not installed; RISBGN, if the miscellaneous-instruction-extensions facility 1 is not installed)

Programming Notes:

1. Although the bits 2-7 of the I_5 field are defined to contain an unsigned binary integer specifying the number of bits that the second operand is rotated to the left, a negative value may be coded which effectively specifies a rotate-right amount.

2. When used with the zero-remaining-bits control, ROTATE THEN INSERT SELECTED BITS provides a means of effecting a shift operation.

3. When the R_1 and R_2 fields designate the same register and the Z bit is one, ROTATE THEN INSERT SELECTED BITS may be used to zero a selected range of bits in a register. Note, this technique cannot be used to zero all 64 bits of the register.

4. The first operand is always used in its unrotated form. When the R_1 and R_2 fields designate the same register, the contents of the register are first rotated, and then the selected bits of the rotated value are inserted into the corresponding bits of the unrotated register contents.

5. Examples of the use of ROTATE THEN INSERT SELECTED BITS are given in “Number Representation and Instruction-Use Examples” on page A-1.

6. In the assembler syntax, the I_5 operand containing the rotate amount is considered to be optional. When the I_5 field is not coded, a rotate amount of zero is implied.

7. The I_4 field contains both the zero-remaining-bits control (in bit 0) and the ending bit position value (in bits 2-7). For example, to insert bits 40-43 of register 7 into the corresponding bits of register 5 (no rotation) and zero the remaining bits in register 5, the programmer might code:

   ```
   RISBG    R5,R7,40,X'80'+43,0
   RISBGN   R5,R7,40,X'80'+43,0
   ```

   The X‘80’ represents the zero-remaining-bits control which is added to the ending-bit position to form the I_4 field.

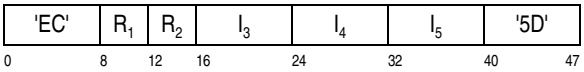
   The high-level assembler (HLASM) provides an extended mnemonic for the zero-remaining-bits versions of the instruction, as shown below:

   ```
   RISBGZ   R5,R7,40,43,0
   RISBGNZ  R5,R7,40,43,0
   ```

The “Z” suffix to the mnemonic indicates that the specified I_4 field is ORed with a value of X’80’ when generating the object code.

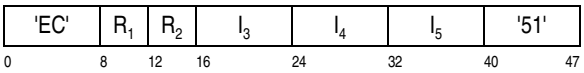
ROTATE THEN INSERT SELECTED BITS HIGH

RISBHG $R_1,R_2,I_3,I_4[,I_5]$ [RIE-f]



ROTATE THEN INSERT SELECTED BITS LOW

RISBLG $R_1,R_2,I_3,I_4[,I_5]$ [RIE-f]



The 64-bit second operand is rotated left by the number of bits specified in the fifth operand. Each bit shifted out of the leftmost bit position of the operand is placed in the rightmost bit position of the operand. The selected bits of the rotated second operand replace the contents of the corresponding bit positions of the first operand.

For ROTATE THEN INSERT SELECTED BITS HIGH, the first operand is in bits 0-31 of general register R_1, and bits 32-63 of the register are unchanged. For ROTATE THEN INSERT SELECTED BITS LOW, the first operand is in bits 32-63 of general register R_1, and bits 0-31 of the register are unchanged.

The second operand remains unchanged in general register R_2.

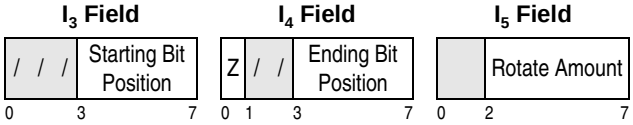
For ROTATE THEN INSERT SELECTED BITS HIGH, bits 3-7 of the I_3 and I_4 fields (bits 19-23 and 27-31 of the instruction, respectively), with a binary zero appended on the left of each, form six-bit unsigned binary integers specifying the starting and ending bit positions (inclusive) of the selected range of bits in the first operand and in the second operand after rotation. When the ending bit position is less than the starting bit position, the range of selected bits wraps around from bit 31 to bit 0. Thus, the starting and ending bit positions of the selected range of bits are always between 0 and 31.

For ROTATE THEN INSERT SELECTED BITS LOW, bits 3-7 of the I_3 and I_4 fields, with a binary one appended on the left of each, form six-bit unsigned binary integers specifying the starting and ending bit positions (inclusive) of the selected range of bits in the first operand and in the second operand after rotation. When the ending bit position is less than the starting bit position, the range of selected bits wraps around from bit 63 to bit 32. Thus, the starting and ending bit positions of the selected range of bits are always between 32 and 63.

Bits 2-7 of the I_5 field (bits 34-39 of the instruction) contain an unsigned binary integer specifying the number of bits that the second operand is rotated to the left.

Bit 0 of the I_4 field (bit 24 of the instruction) contains the zero-remaining-bits control (Z). The Z bit controls how the remaining bits of the first operand are set (that is, those bits, if any, that are outside of the specified range). When the Z bit is zero, the remaining bits of the first operand are unchanged. When the Z bit is one, the remaining bits of the first operand are set to zeros.

The immediate fields just described are as follows:



Bits 0-2 of the I_3 field and bits 1-2 of the I_4 field (bits 16-18 and 25-26 of the instruction) are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future. Bits 0-1 of the I_5 field (bits 32-33 of the instruction) are ignored.

Condition Code: The code remains unchanged

Program Exceptions:

- Operation (if the high-word facility is not installed)

Programming Notes:

1. Although the bits 2-7 of the I_5 field are defined to contain an unsigned binary integer specifying the number of bits that the second operand is rotated to the left, a negative value may be coded which effectively specifies a rotate-right amount.

2. The first operand is always used in its unrotated form. When the R_1 and R_2 fields designate the same register, the value contained in the register is first rotated, and then the selected bits of the rotated value are inserted into the corresponding bits of the unrotated register contents.

3. In the assembler syntax, the I_5 operand containing the rotate amount is considered to be optional. When the I_5 field is not coded, a rotate amount of zero is implied.

4. The I_4 field contains both the zero-remaining-bits control (in bit 0) and the ending bit position value (in bits 3-7). For example, to insert bits 40-43 of register 7 into the corresponding bits of register 5 (no rotation) and zero the remaining bits in the right half of register 5, the programmer might code:

```
RISBLG   R5,R7,8,X'80'+11,0
```

   The X‘80’ represents the zero-remaining-bits control which is added to the ending-bit position to form the I_4 field.

   The High-Level Assembler (HLASM) provides extended mnemonics for the zero-remaining-bits versions of RISBHG and RISBLG in the form of RISBHGZ and RISBLGZ, respectively. The “Z” suffix to the mnemonic indicates that the specified I_4 field is ORed with a value of X’80’ when generating the object code.

   An equivalent to the example shown above using the Z-suffixed mnemonic is as follows:

```
RISBLGZ  R5,R7,8,11,0
```

5. On some models, improved performance of RISBHG and RISBLG may be realized by setting the zero-remaining-bits control to one (or using the Z mnemonic suffix).

6. Unlike ROTATE THEN INSERT SELECTED BITS which sets the condition code, ROTATE THEN INSERT SELECTED BITS HIGH and ROTATE THEN INSERT SELECTED BITS LOW do not set the condition code.

7. The high-level assembler (HLASM) implements various high-word logical operations by providing extended-mnemonics for the RISBHG and RISBLG instructions, as shown in Figure 7-397.

8. The high-level assembler (HLASM) provides extended mnemonics for shift logical versions of these instructions, as shown in Figure 7-398.

Instruction Name	Extended-Mnemonic Syntax	RISBHG / RISBLG Equivalent
LOAD (HIGH ← HIGH)	LHHR R_1,R_2	RISBHGZ R_1,R_2,0,31
LOAD (HIGH ← LOW)	LHLR R_1,R_2	RISBHGZ R_1,R_2,0,31,32
LOAD (LOW ← HIGH)	LLHFR R_1,R_2	RISBLGZ R_1,R_2,0,31,32
LOAD LOGICAL HALFWORD (HIGH ← HIGH)	LLHHHR R_1,R_2	RISBHGZ R_1,R_2,16,31
LOAD LOGICAL HALFWORD (HIGH ← LOW)	LLHHLR R_1,R_2	RISBHGZ R_1,R_2,16,31,32
LOAD LOGICAL HALFWORD (LOW ← HIGH)	LLHLHR R_1,R_2	RISBLGZ R_1,R_2,16,31,32
LOAD LOGICAL CHARACTER (HIGH ← HIGH)	LLCHHR R_1,R_2	RISBHGZ R_1,R_2,24,31
LOAD LOGICAL CHARACTER (HIGH ← LOW)	LLCHLR R_1,R_2	RISBHGZ R_1,R_2,24,31,32
LOAD LOGICAL CHARACTER (LOW ← HIGH)	LLCLHR R_1,R_2	RISBLGZ R_1,R_2,24,31,32

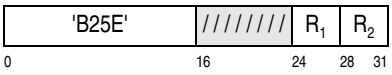
Figure 7-397. Extended Mnemonics for High-Word Operations Formed Using RISBHG and RISBLG

Extended-Mnemonic Syntax	Base-Mnemonic Syntax	Comments
SLLHH R_1,R_2,I_3	RISBHGZ R_1,R_2,0,31-I_3,I_3	Shift left logical (high ← high)
SLLHL R_1,R_2,I_3	RISBHGZ R_1,R_2,0,31-I_3,32+I_3	Shift left logical (high ← low)
SRLHH R_1,R_2,I_3	RISBHGZ R_1,R_2,I_3,31,-I_3	Shift right logical (high ← high)
SRLHL R_1,R_2,I_3	RISBHGZ R_1,R_2,I_3,31,32-I_3	Shift right logical (high ← low)
SLLLH R_1,R_2,I_3	RISBLGZ R_1,R_2,0,31-I_3,32+I_3	Shift left logical (low ← high)
SRLLH R_1,R_2,I_3	RISBLGZ R_1,R_2,I_3,31,32-I_3	Shift right logical (low ← high)

Figure 7-398. Extended Mnemonics for Shift-Logical Operations Formed Using RISBHG and RISBLG

SEARCH STRING

SRST R_1,R_2 [RRE]



The second operand is searched until a specified character is found, the end of the second operand is reached, or a CPU-determined number of bytes have been searched, whichever occurs first. The CPU-determined number is at least 256. The result is indicated in the condition code.

The location of the first byte of the second operand is designated by the contents of general register R_2. The location of the first byte after the second operand is designated by the contents of general register R_1.

The handling of the addresses in general registers R_1 and R_2 is dependent on the addressing mode. In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers R_1 and R_2 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the registers constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 constitute the address.

In the access-register mode, the address space containing the second operand is specified only by means of access register R_2. The contents of access register R_1 are ignored.

The character for which the search occurs is specified in bit positions 56-63 of general register 0. Bit positions 32-55 of general register 0 are reserved for possible future extensions and must contain all zeros; otherwise, a specification exception is recognized.

The operation proceeds left to right and ends as soon as the specified character has been found in the second operand, the address of the next second-operand byte to be examined equals the address in general register R_1, or a CPU-determined number of second-operand bytes have been examined, whichever occurs first. The CPU-determined number is at least 256. When the specified character is found, condition code 1 is set. When the address of the next second-operand byte to be examined equals the address in general register R_1, condition code 2 is set. When a CPU-determined number of second-operand bytes have been examined, condition code 3 is set. When the CPU-determined number of second-operand bytes have been examined and the address of the next second-operand byte is in general register R_1, it is unpredictable whether condition code 2 or 3 is set.

When condition code 1 is set, the address of the specified character found in the second operand is placed in general register R_1, and the contents of general register R_2 remain unchanged. When condition code 3 is set, the address of the next byte to be processed in the second operand is placed in general register R_2, and the contents of general register R_1 remain unchanged. When condition code 2 is set, the contents of general registers R_1 and R_2 remain unchanged. Whenever an address is placed in a general register, bits 32-39 of the register, in the 24-bit addressing mode, or bit 32, in the 31-bit addressing mode, are set to zeros. Bits 0-31 of the R_1 and R_2 registers always remain unchanged in the 24-bit or 31-bit mode.

When the address in general register R_1 equals the address in general register R_2, condition code 2 is set immediately, and access exceptions are not recognized. When the address in general register R_1 is less than the address in general register R_2, condition code 2 can be set only if the operand wraps around from the top of storage to location 0.

The amount of processing that results in the setting of condition code 3 is determined by the CPU on the basis of improving system performance, and it may be a different amount each time the instruction is executed.

Access exceptions for the second operand are recognized only for that portion of the operand that is necessarily examined.

The storage-operand-consistency rules are described in the section “Storage-Operand Consistency” on page 5-133.

Resulting Condition Code:

0 --
1 Specified character found; general register R_1 updated with address of character; general register R_2 unchanged
2 Specified character not found in entire second operand; general registers R_1 and R_2 unchanged
3 CPU-determined number of bytes searched; general register R_1 unchanged; general register R_2 updated with address of next byte

Program Exceptions:

- Access (fetch, operand 2)
- Specification
- Transaction constraint

Programming Notes:

1. Examples of the use of the SEARCH STRING instruction are given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. When condition code 3 is set, the program can simply branch back to the instruction to continue the search. The program need not determine the number of bytes that were searched.

3. The R_1 or R_2 fields may designate general register 0, in which case general register 0 is treated as containing an address and also the specified character.

   However, if the program branches back to the SEARCH STRING instruction following condition code 3, specifying R_2 as register 0 is impractical. This is because bits 32-55 of the register will have been altered to a nonzero value, thus resulting in a specification exception on the subsequent execution. The search character in bit positions 56-63 of the register also may have been altered.

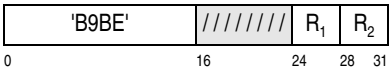
4. When it is desired to search a string of unknown length for its ending character, and assuming that the specified character in general register 0 need not be preserved, then the R_1 field can designate general register 0 in order to have SEARCH STRING use only two general registers instead of three. In this case, the rightmost portion of general register 0 containing the required zeros and the 8-bit search character is also used to form the address of the first byte after the second operand.

5. If the program branches back to the SEARCH STRING instruction when condition code 3 is set, and a subsequent execution results in condition code 1 or 2, general register R_2 will have changed from its initial value, even though the definition states that the register is unchanged when the character is found.

6. If the length of the string (as determined by the difference between the addresses in general registers R_1 and R_2) is 255 characters or less, condition code 3 will never be set, and branching on that condition is not necessary. However, if the length of the string is 256 or more characters, condition code 3 may be set – even if condition code 2 also applies.

SEARCH STRING UNICODE

SRSTU R_1,R_2 [RRE]



The second operand is searched until a specified two-byte character is found, the end of the second operand is reached, or a CPU-determined number of two-byte characters have been searched, whichever occurs first. The CPU-determined number is at least 256 two-byte characters. The result is indicated in the condition code.

The location of the first two-byte character of the second operand is designated by the contents of general register R_2. When the contents of bit position 63 of general registers R_1 and R_2 are identical (that is, when both addresses are even or both addresses are odd), the location of the first two-byte character after the second operand is designated by the contents of general register R_1. When the contents of bit position 63 of general registers R_1 and R_2 differ (that is, when one address is even and the other is odd), the location of the first two-byte character after the second operand is one more than the contents of general register R_1.

The handling of the addresses in general registers R_1 and R_2 is dependent on the addressing mode. In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers R_1 and R_2 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the registers constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 constitute the address.

In the access-register mode, the address space containing the second operand is specified only by means of access register R_2. The contents of access register R_1 are ignored.

The two-byte character for which the search occurs is specified in bit positions 48-63 of general register 0. Bit positions 32-47 of general register 0 are reserved

for possible future extensions and must contain all zeros; otherwise, a specification exception is recognized.

Except for the case when the address in general register R_1 equals the address in general register R_2, the operation proceeds from left to right in steps of two bytes and ends as soon as the specified two-byte character has been found in the second operand, the address of the next second-operand two-byte character to be examined (excluding the first two-byte character) is equal to the address of the first two-byte character after the second operand (as designated by general register R_1), or a CPU-determined number of second-operand two-byte characters have been examined, whichever occurs first. The CPU-determined number is at least 256. When the specified two-byte character is found, condition code 1 is set. When the address of the next second-operand two-byte character to be examined (excluding the first two-byte character) is equal to the address of the first two-byte character after the second operand, condition code 2 is set. When a CPU-determined number of second-operand two-byte characters have been examined, condition code 3 is set, except that condition code 2 is set if the conditions for setting it also apply.

When condition code 1 is set, the address of the specified two-byte character found in the second operand is placed in general register R_1, and the contents of general register R_2 remain unchanged. When condition code 3 is set, the address of the next two-byte character to be processed in the second operand is placed in general register R_2, and the contents of general register R_1 remain unchanged. When condition code 2 is set, the contents of general registers R_1 and R_2 remain unchanged. Whenever an address is placed in a general register, bits 32-39 of the register, in the 24-bit addressing mode, or bit 32, in the 31-bit addressing mode, are set to zeros. Bits 0-31 of the R_1 and R_2 registers always remain unchanged in the 24-bit or 31-bit mode.

When the address in general register R_1 equals the address in general register R_2, condition code 2 is set immediately, and access exceptions are not recognized. When the address in general register R_1 is less than the address in general register R_2, condition code 2 can be set only if the operand wraps around from the top of storage to location 0.

The amount of processing that results in the setting of condition code 3 is determined by the CPU on the basis of improving system performance, and it may be a different amount each time the instruction is executed.

Access exceptions for the second operand are recognized only for that portion of the operand that is necessarily examined.

The storage-operand-consistency rules are described in the section “Storage-Operand Consistency” on page 5-133.

Resulting Condition Code:

0 --
1 Specified two-byte character found; general register R_1 updated with address of character; general register R_2 unchanged
2 Specified two-byte character not found in entire second operand; general registers R_1 and R_2 unchanged
3 CPU-determined number of two-byte characters searched; general register R_1 unchanged; general register R_2 updated with address of next two-byte character

Program Exceptions:

- Access (fetch, operand 2)
- Operation (if the extended-translation facility 3 is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. When condition code 3 is set, the program can simply branch back to the instruction to continue the search. The program need not determine the number of two-byte characters that were searched.

2. The R_1 or R_2 fields may designate general register 0, in which case general register 0 is treated as containing an address and also the specified character.

   However, if the program branches back to the SEARCH STRING UNICODE instruction following condition code 3, specifying R_2 as register 0 is impractical. This is because bits 32-47 of the register may have been altered to a nonzero value, thus resulting in a specification exception on the subsequent execution. The search char-

acter in bit positions 48-63 of the register also may have been altered.

3. When it is desired to search a string of unknown length for its ending two-byte character, and assuming that the specified two-byte character in general register 0 need not be preserved, then the R_1 field can designate general register 0 in order to have SEARCH STRING UNICODE use only two general registers instead of three. In this case, the rightmost portion of general register 0 containing the required zeros and the 16-bit search character is also used to form the address of the first byte after the second operand.

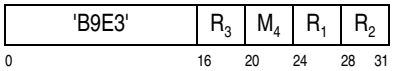
4. If the program branches back to the SEARCH STRING UNICODE instruction when condition code 3 is set, and a subsequent execution results in condition code 1 or 2, general register R_2 will have changed from its initial value, even though the definition states that the register is unchanged when the two-byte character is found.

5. If the length of the string (as determined by the difference between the addresses in general registers R_1 and R_2) is 256 two-byte characters or less, condition code 3 will never be set, and branching on that condition is not necessary. However, if the length of the string is 257 or more two-byte characters, condition code 3 may be set.

SELECT

SELR R_1,R_2,R_3,M_4 [RRF-a]

SELGR R_1,R_2,R_3,M_4 [RRF-a]



SELECT HIGH

SELFHR R_1,R_2,R_3,M_4 [RRF-a]

The second operand is placed unchanged at the first-operand location if the condition code has one of the values specified by M_4; otherwise, the third operand is placed unchanged at the first operand location.

For SELR, all operands are in bits 32-63 in their respective general registers; bits 0-31 of general register R_1 are unchanged. For SELGR, all operands are in bits 0-63 in their respective general registers. For SELFHR, all operands are in bits 0-31 in their respective general registers; bits 32-63 of general register R_1 are unchanged.

The M_4 field is used as a four-bit mask. The four condition codes (0, 1, 2, and 3) correspond, left to right, with the four bits of the mask, as follows:

Condition Code	Mask Position Value
0	8
1	4
2	2
3	1

The current condition code is used to select the corresponding mask bit. If the mask bit selected by the condition code is one, the second operand is loaded. If the mask bit selected is zero, the third operand is loaded.

Condition Code: The code remains unchanged.

Program Exceptions:

- Operation (if the miscellaneous-instruction-extensions facility 3 is not installed)

Programming Notes:

1. SELECT may be used to provide better performance when it is difficult for the CPU to predict the branch condition and also uses fewer instructions. For example, the following two instruction sequences are equivalent.

```
SELR    4,5,6,7          BRC     7,REG5
                         LR      4,6
                         BRC     15,FIN
                 REG5    LR      4,5
                 FIN     DS      0H
```

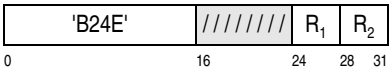
2. The High-Level Assembler (HLASM) provides the following extended-mnemonic suffixes for the SELECT instructions in place of the M_4 field.

Suffix	Meaning	Effective M_4 Value
E	Equal	B'1000'
L	Low	B'0100'
H	High	B'0010'
NE	Not equal	B'0111'
NL	Not low	B'1011'
NH	Not high	B'1101'
Z	Zero	B'1000'
M	Minus or mixed	B'0100'
P	Plus	B'0010'
O	Overflow or ones	B'0001'
NZ	Not zero	B'0111'
NM	Not minus or not mixed	B'1011'
NP	Not plus	B'1101'
NO	Not overflow or not ones	B'1110'

When the extended mnemonic is coded, the M_4 field must be omitted.

SET ACCESS

SAR R_1,R_2 [RRE]



The contents of bit positions 32-63 of general register R_2 are placed in access register R_1.

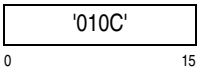
Condition Code: The code remains unchanged.

Program Exceptions:

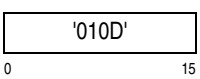
- Transaction constraint

SET ADDRESSING MODE

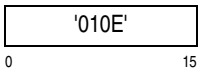
SAM24 [E]



SAM31 [E]



SAM64 [E]



The addressing mode is set by setting the extended-addressing-mode bit, bit 31 of the current PSW, and the basic-addressing-mode bit, bit 32 of the current PSW, as follows:

Instruction	PSW Bit 31	PSW Bit 32	Resulting Addressing Mode
SAM24	0	0	24-bit
SAM31	0	1	31-bit
SAM64	1	1	64-bit

The instruction address in the PSW is updated under the control of the new addressing mode, as follows. The value 2 (the instruction length) is added to the contents of bit positions 64-127 of the PSW, or the value 4 is added if the instruction is the target of EXECUTE, or the value 6 is added if the instruction is the target of EXECUTE RELATIVE LONG. In any case, a carry out of bit position 0 is ignored. Then bits 64-103 of the PSW are set to zeros if the new addressing mode is the 24-bit mode, or bits 64-96 are set to zeros if the new addressing mode is the 31-bit mode.

The instruction is completed only if the new addressing mode and the unupdated instruction address in the PSW are a valid combination. When the new addressing mode is to be the 24-bit mode, bits 64-103 of the unupdated PSW must be all zeros, or, when the new addressing mode is to be the 31-bit mode, bits 64-96 of the unupdated PSW must be all zeros; otherwise, a specification exception is recognized.

In the ESA/390-compatibility mode, it is unpredictable whether SAM64 is supported. If not supported, attempted execution of SAM64 results in an operation exception.

Condition Code: The code remains unchanged.

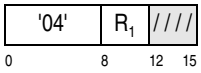
Program Exceptions:

- Operation (SAM64, in the ESA/390-compatibility mode)
- Specification (SAM24 and SAM31 only)
- Trace
- Transaction constraint

Programming Note: Checking the unupdated instruction address prevents completion in two major cases: the instruction is located at address 2^{24} or above and the new addressing mode is to be the 24-bit mode, or the instruction is located at address 2^{31} or above and the new addressing mode is to be the 24-bit or 31-bit mode. In these cases, if the instruction were completed, the updating of the instruction address under the control of the new addressing mode would cause one or more leftmost bits of the address to be set to zeros, which would cause the next instruction to be fetched from other than the next sequential location. This action is sometimes called a "wild branch." A wild branch still can occur if the instruction is located at 2^{24} - 2 or 2^{31} - 2, or at 2^{24} - 4 or 2^{31} - 4 if EXECUTE or EXECUTE RELATIVE LONG is used, or at 2^{24} - 6 or 2^{31} - 6 if EXECUTE RELATIVE LONG is used.

SET PROGRAM MASK

SPM R_1 [RR]



The first operand is used to set the condition code and the program mask of the current PSW.

Bits 34 and 35 of general register R_1 replace the condition code, and bits 36-39 replace the program mask. Bits 0-33 and 40-63 of general register R_1 are ignored.

Resulting Condition Code:

The code is set as specified by bits 34 and 35 of general register R_1.

Program Exceptions: None.

Programming Notes:

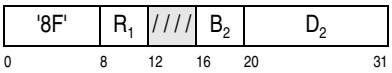
1. Bits 34-39 of the general register may have been loaded from the PSW by execution of BRANCH AND LINK in the 24-bit addressing mode or by execution of INSERT PROGRAM MASK in any addressing mode.

2. SET PROGRAM MASK permits setting of the condition code and the mask bits in either the problem state or the supervisor state.

3. The program should take into consideration that the setting of the program mask can have a significant effect on subsequent execution of the program. Not only do the four mask bits control whether the corresponding interruptions occur, but the HFP-exponent-underflow and HFP-significance masks also determine the result which is obtained.

SHIFT LEFT DOUBLE

SLDA $R_1,D_2(B_2)$ [RS-a]



The 63-bit numeric part of the signed first operand is shifted left the number of bits specified by the second-operand address, and the result is placed at the first-operand location. The first operand consists of bits 32-63 of general register R_1 followed on the right by bits 32-63 of general register R_1 + 1.

The R_1 field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The second-operand address is not used to address data; its rightmost six bits indicate the number of bit positions to be shifted. The remainder of the address is ignored.

The first operand is treated as a 64-bit signed binary integer. The sign bit of the first operand, bit 32 of the even-numbered register, remains unchanged. Bit position 32 of the odd-numbered register contains a numeric bit, which participates in the shift in the same manner as the other numeric bits. Zeros are supplied to the vacated bit positions on the right. Bits 0-31 of general registers R_1 and R_1 + 1 remain unchanged.

If one or more bits unlike the sign bit are shifted out of bit position 33 of the even-numbered register, an overflow occurs, and condition code 3 is set. If the fixed-point-overflow mask bit is one, a program interruption for fixed-point overflow occurs.

Resulting Condition Code:

0 Result zero; no overflow
1 Result less than zero; no overflow
2 Result greater than zero; no overflow
3 Overflow

Program Exceptions:

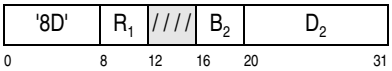
- Fixed-point overflow
- Specification

Programming Notes:

1. An example of the use of the SHIFT LEFT DOUBLE instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”
2. The eight shift instructions that are in both ESA/390 and z/Architecture provide the following three pairs of alternatives for 32 bits in one general register or, for double, in each of two general registers: left or right, single or double, and signed or logical. The four additional shift instructions in z/Architecture provide left or right, signed or logical shifts of 64 bits in one general register. The signed shifts differ from the logical shifts in that, in the signed shifts, overflow is recognized, the condition code is set, and the leftmost bit participates as a sign.
3. A zero shift amount in the two signed double-shift operations provides a double-length sign and magnitude test.
4. The base register participating in the generation of the second-operand address permits indirect specification of the shift amount by means of placement of the shift amount in the base register. A zero in the B_2 field indicates the absence of indirect shift specification.

SHIFT LEFT DOUBLE LOGICAL

SLDL $R_1,D_2(B_2)$ [RS-a]



The 64-bit first operand is shifted left the number of bits specified by the second-operand address, and the result is placed at the first-operand location. The first operand consists of bits 32-63 of general register R_1 followed on the right by bits 32-63 of general register $R_1 + 1$.

The R_1 field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The second-operand address is not used to address data; its rightmost six bits indicate the number of bit positions to be shifted. The remainder of the address is ignored.

All 64 bits of the first operand participate in the shift. Bits shifted out of bit position 32 of the even-numbered register are not inspected and are lost. Zeros are supplied to the vacated bit positions on the right. Bits 0-31 of general registers R_1 and $R_1 + 1$ remain unchanged.

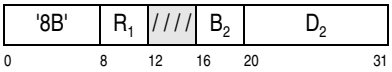
Condition Code: The code remains unchanged.

Program Exceptions:

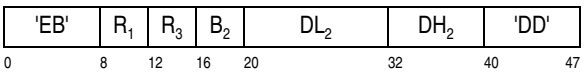
- Specification

SHIFT LEFT SINGLE

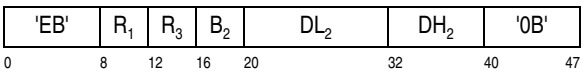
SLA $R_1,D_2(B_2)$ [RS-a]



SLAK $R_1,R_3,D_2(B_2)$ [RSY-a]



SLAG $R_1,R_3,D_2(B_2)$ [RSY-a]



For SLA, the 31-bit numeric part of the signed first operand is shifted left the number of bits specified by the second-operand address, and the result is placed at the first-operand location. Bits 0-31 of general register R_1 remain unchanged.

For SLAK, the 31-bit numeric part of the signed third operand is shifted left the number of bits specified by the second-operand address, and the result, with the sign bit of the third operand appended on its left, is placed at the first-operand location. Bits 0-31 of gen-

eral register R_1 remain unchanged. Except for when the R_1 and R_3 fields designate the same register, the third operand remains unchanged in general register R_3.

For SLAG, the 63-bit numeric part of the signed third operand is shifted left the number of bits specified by the second-operand address, and the result, with the sign bit of the third operand appended on its left, is placed at the first-operand location. Except for when the R_1 and R_3 fields designate the same register, the third operand remains unchanged in general register R_3.

The second-operand address is not used to address data; its rightmost six bits indicate the number of bit positions to be shifted. The remainder of the address is ignored.

For SLA, the first operand is treated as a 32-bit signed binary integer in bit positions 32-63 of general register R_1. The sign of the first operand remains unchanged. All 31 numeric bits of the operand participate in the left shift.

For SLAK, the first and third operands are treated as 32-bit signed binary integers in bit positions 32-63 of general registers R_1 and R_3, respectively. The sign of the first operand is set equal to the sign of the third operand. All 31 numeric bits of the third operand participate in the left shift.

For SLAG, the first and third operands are treated as 64-bit signed binary integers in bit positions 0-63 of general registers R_1 and R_3, respectively. The sign of the first operand is set equal to the sign of the third operand. All 63 numeric bits of the third operand participate in the left shift.

For SLA, SLAG, or SLAK, zeros are supplied to the vacated bit positions on the right.

If one or more bits unlike the sign bit are shifted out of bit position 33, for SLA or SLAK, or 1, for SLAG, an overflow occurs, and condition code 3 is set. If the fixed-point-overflow mask bit is one, a program interruption for fixed-point overflow occurs.

Resulting Condition Code:

0 Result zero; no overflow
1 Result less than zero; no overflow
2 Result greater than zero; no overflow
3 Overflow

Program Exceptions:

- Fixed-point overflow
- Operation (SLAK, if the distinct-operands facility is not installed)

Programming Notes:

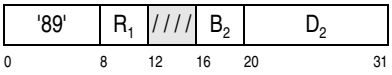
1. An example of the use of the SHIFT LEFT SINGLE instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. For SHIFT LEFT SINGLE (SLA and SLAK), for numbers with a value greater than or equal to -2^{30} and less than 2^{30}, a left shift of one bit position is equivalent to multiplying the number by 2. For SHIFT LEFT SINGLE (SLAG), the comparable values are -2^{62} and 2^{62}.

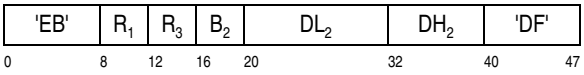
3. For SHIFT LEFT SINGLE (SLA and SLAK), shift amounts from 31 to 63 cause the entire numeric part to be shifted out of the register, leaving a result of the maximum negative number or zero, depending on whether or not the initial contents were negative. For SHIFT LEFT SINGLE (SLAG), a shift amount of 63 causes the same effect.

SHIFT LEFT SINGLE LOGICAL

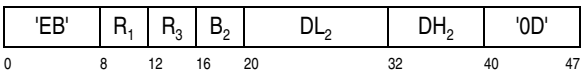
SLL $R_1,D_2(B_2)$ [RS-a]



SLLK $R_1,R_3,D_2(B_2)$ [RSY-a]



SLLG $R_1,R_3,D_2(B_2)$ [RSY-a]



For SLL, the 32-bit first operand is shifted left the number of bits specified by the second-operand address, and the result is placed at the first-operand location. Bits 0-31 of general register R_1 remain unchanged.

For SLLK, the 32-bit third operand is shifted left the number of bits specified by the second-operand address, and the result is placed at the first-operand

location. Bits 0-31 of general register R_1 remain unchanged. Except for when the R_1 and R_3 fields designate the same register, the third operand remains unchanged in general register R_3.

For SLLG, the 64-bit third operand is shifted left the number of bits specified by the second-operand address, and the result is placed at the first-operand location. Except for when the R_1 and R_3 fields designate the same register, the third operand remains unchanged in general register R_3.

The second-operand address is not used to address data; its rightmost six bits indicate the number of bit positions to be shifted. The remainder of the address is ignored.

For SLL, the first operand is in bit positions 32-63 of general register R_1. All 32 bits of the operand participate in the left shift.

For SLLK, the first and third operands are in bit positions 32-63 of general registers R_1 and R_3, respectively. All 32 bits of the third operand participate in the left shift.

For SLLG, the first and third operands are in bit positions 0-63 of general registers R_1 and R_3, respectively. All 64 bits of the third operand participate in the left shift.

For SLL, SLLG, or SLLK, zeros are supplied to the vacated bit positions on the right.

Condition Code: The code remains unchanged.

Program Exceptions:

- Operation (SLLK, if the distinct-operands facility is not installed)

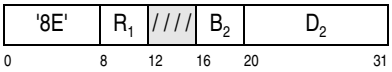
Programming Note: The rightmost six bits of the second-operand address are treated as a 6-bit unsigned binary integer specifying the number of bit positions to be shifted to the left. Thus, the number of bit positions to be shifted is the value of the second-operand address, modulo 64.

When the number of bit positions to be shifted is between 32 and 63, SLL and SLLK can be used to zero the rightmost 32 bits of the result in general register R_1. However, because of the modulo 64 behavior, it is not true that any second-operand-address value greater than 32 produces a result of zero.

Because the number of shifted bit positions is limited to 63, SLLG cannot be used to zero all 64 bits of the result.

SHIFT RIGHT DOUBLE

SRDA $R_1,D_2(B_2)$ [RS-a]



The 63-bit numeric part of the signed first operand is shifted right the number of bits specified by the second-operand address, and the result is placed at the first-operand location. The first operand consists of bits 32-63 of general register R_1 followed on the right by bits 32-63 of general register $R_1 + 1$.

The R_1 field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The second-operand address is not used to address data; its rightmost six bits indicate the number of bit positions to be shifted. The remainder of the address is ignored.

The first operand is treated as a 64-bit signed binary integer. The sign bit of the first operand, bit 32 of the even-numbered register, remains unchanged. Bit position 32 of the odd-numbered register contains a numeric bit, which participates in the shift in the same manner as the other numeric bits. Bits shifted out of bit position 63 of the odd-numbered register are not inspected and are lost. Bits equal to the sign are supplied to the vacated bit positions on the left. Bits 0-31 of general registers R_1 and $R_1 + 1$ remain unchanged.

Resulting Condition Code:

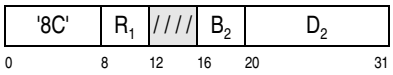
0 Result zero
1 Result less than zero
2 Result greater than zero
3 --

Program Exceptions:

- Specification

SHIFT RIGHT DOUBLE LOGICAL

SRDL $R_1,D_2(B_2)$ [RS-a]



The 64-bit first operand is shifted right the number of bits specified by the second-operand address, and the result is placed at the first-operand location. The first operand consists of bits 32-63 of general register R_1 followed on the right by bits 32-63 of general register $R_1 + 1$.

The R_1 field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The second-operand address is not used to address data; its rightmost six bits indicate the number of bit positions to be shifted. The remainder of the address is ignored.

All 64 bits of the first operand participate in the shift. Bits shifted out of bit position 63 of the odd-numbered register are not inspected and are lost. Zeros are supplied to the vacated bit positions on the left. Bits 0-31 of general registers R_1 and $R_1 + 1$ remain unchanged.

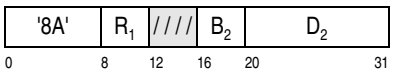
Condition Code: The code remains unchanged.

Program Exceptions:

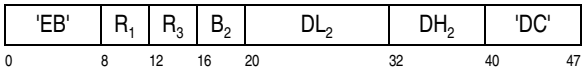
- Specification

SHIFT RIGHT SINGLE

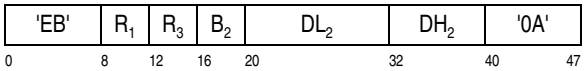
SRA $R_1,D_2(B_2)$ [RS-a]



SRAK $R_1,R_3,D_2(B_2)$ [RSY-a]



SRAG $R_1,R_3,D_2(B_2)$ [RSY-a]



For SRA, The 31-bit numeric part of the signed first operand is shifted right the number of bits specified by the second-operand address, and the result is placed at the first-operand location. Bits 0-32 of general register R_1 remain unchanged.

For SRAK, the 31-bit numeric part of the signed third operand is shifted right the number of bits specified by the second-operand address, and the result, with the sign bit of the third operand appended on its left, is placed at the first-operand location. Bits 0-31 of general register R_1 remain unchanged. Except for when the R_1 and R_3 fields designate the same register, the third operand remains unchanged in general register R_3.

For SHIFT RIGHT SINGLE (SRAG), the 63-bit numeric part of the signed third operand is shifted right the number of bits specified by the second-operand address, and the result, with the sign bit of the third operand appended on its left, is placed at the first-operand location. Except for when the R_1 and R_3 fields designate the same register, the third operand remains unchanged in general register R_3.

The second-operand address is not used to address data; its rightmost six bits indicate the number of bit positions to be shifted. The remainder of the address is ignored.

For SRA, The first operand is treated as a 32-bit signed binary integer in bit positions 32-63 of general register R_1. The sign of the first operand remains unchanged. All 31 numeric bits of the operand participate in the right shift.

For SRAK, the first and third operands are treated as 32-bit signed binary integers in bit positions 32-63 of general registers R_1 and R_3, respectively. The sign of the first operand is set equal to the sign of the third operand. All 31 numeric bits of the third operand participate in the right shift.

For SRAG, the first and third operands are treated as 64-bit signed binary integers in bit positions 0-63 of general registers R_1 and R_3, respectively. The sign of the first operand is set equal to the sign of the third operand. All 63 numeric bits of the third operand participate in the right shift.

For SRA, SRAG, or SRAK, bits shifted out of bit position 63 are not inspected and are lost. Bits equal to the sign are supplied to the vacated bit positions on the left.

Resulting Condition Code:

0 Result zero
1 Result less than zero
2 Result greater than zero
3 --

Program Exceptions:

- Operation (SRAK, if the distinct-operands facility is not installed)

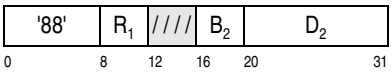
Programming Notes:

1. A right shift of one bit position is equivalent to division by 2 with rounding downward. When an even number is shifted right one position, the result is equivalent to dividing the number by 2. When an odd number is shifted right one position, the result is equivalent to dividing the *next lower* number by 2. For example, +5 shifted right by one bit position yields +2, whereas -5 yields -3.

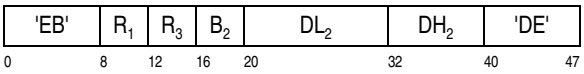
2. For SRA and SRAK, shift amounts from 31 to 63 cause the entire numeric part to be shifted out of the register, leaving a result of -1 or zero, depending on whether or not the initial contents were negative. For SHIFT RIGHT SINGLE (SRAG), a shift amount of 63 causes the same effect.

SHIFT RIGHT SINGLE LOGICAL

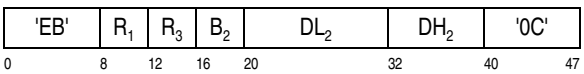
SRL $R_1,D_2(B_2)$ [RS-a]



SRLK $R_1,R_3,D_2(B_2)$ [RSY-a]



SRLG $R_1,R_3,D_2(B_2)$ [RSY-a]



For SRL, the 32-bit first operand is shifted right the number of bits specified by the second-operand address, and the result is placed at the first-operand location. Bits 0-31 of general register R_1 remain unchanged.

For SRLK, the 32-bit third operand is shifted right the number of bits specified by the second-operand address, and the result is placed at the first-operand location. Bits 0-31 of general register R_1 remain unchanged. Except for when the R_1 and R_3 fields designate the same register, the third operand remains unchanged in general register R_3.

For SRLG, the 64-bit third operand is shifted right the number of bits specified by the second-operand address, and the result is placed at the first-operand location. Except for when the R_1 and R_3 fields designate the same register, the third operand remains unchanged in general register R_3.

The second-operand address is not used to address data; its rightmost six bits indicate the number of bit positions to be shifted. The remainder of the address is ignored.

For SRL, the first operand is in bit positions 32-63 of general register R_1. All 32 bits of the operand participate in the right shift.

For SRLK, the first and third operands are in bit positions 32-63 of general registers R_1 and R_3, respectively. All 32 bits of the third operand participate in the right shift.

For SRLG, the first and third operands are in bit positions 0-63 of general registers R_1 and R_3, respectively. All 64 bits of the third operand participate in the right shift.

For SRL, SRLG, or SRLK, bits shifted out of bit position 63 are not inspected and are lost. Zeros are supplied to the vacated bit positions on the left.

Condition Code: The code remains unchanged.

Program Exceptions:

- Operation (SRLK, if the distinct-operands facility is not installed)

Programming Note: The rightmost six bits of the second-operand address are treated as a 6-bit unsigned binary integer specifying the number of bit positions to be shifted to the right. Thus, the number of bit positions to be shifted is the value of the second-operand address, modulo 64.

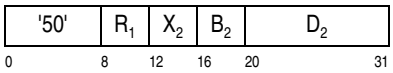
When the number of bit positions to be shifted is between 32 and 63, SRL and SRLK can be used to

zero the rightmost 32 bits of the result in general register R_1. However, because of the modulo 64 behavior, it is not true that any second-operand-address value greater than 32 produces a result of zero.

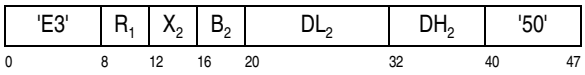
Because the number of shifted bit positions is limited to 63, SRLG cannot be used to zero all 64 bits of the result.

STORE

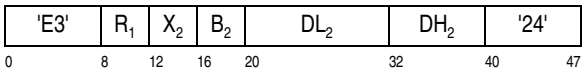
ST $R_1,D_2(X_2,B_2)$ [RX-a]



STY $R_1,D_2(X_2,B_2)$ [RXY-a]

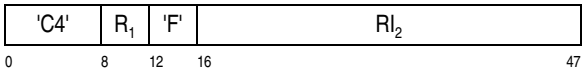


STG $R_1,D_2(X_2,B_2)$ [RXY-a]

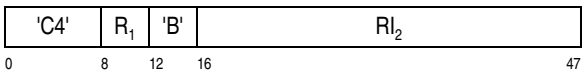


STORE RELATIVE LONG

STRL R_1,RI_2 [RIL-b]



STGRL R_1,RI_2 [RIL-b]



The first operand is placed unchanged at the second-operand location.

For STORE (ST, STY) and STORE RELATIVE LONG (STRL), the operands are 32 bits, and, for STORE (STG) and STORE RELATIVE LONG (STGRL), the operands are 64 bits.

The displacement for ST is treated as a 12-bit unsigned binary integer. The displacement for STY and STG is treated as a 20-bit signed binary integer.

For STORE RELATIVE LONG, the contents of the RI_2 field are a signed binary integer specifying the number of halfwords that is added to the address of the instruction to generate the address of the second operand in storage. When DAT is on, the second operand is accessed using the same addressing-space mode as that used to access the instruction. When DAT is off, the second operand is accessed using a real address.

For STORE RELATIVE LONG (STRL), the second operand must be aligned on a word boundary, and for STORE RELATIVE LONG (STGRL), the second operand must be aligned on a doubleword boundary; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

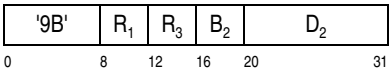
- Access (store, operand 2)
- Operation (STY, if the long-displacement facility is not installed; STRL and STGRL, if the general-instructions-extension facility is not installed)
- Specification (STRL, STGRL only)

Programming Notes:

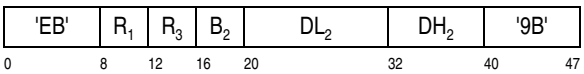
1. For STORE RELATIVE LONG, the second operand must be aligned on an integral boundary corresponding to the operand's size.
2. When STORE RELATIVE LONG is the target of an execute-type instruction, the second-operand address is relative to the target address.
3. Significant delay may be incurred if the program stores into the same cache line as that containing the storing instruction or into the cache line from which a subsequent instruction may be fetched. The EXTRACT CPU ATTRIBUTE instruction may be used to determine the cache-line size.

STORE ACCESS MULTIPLE

STAM $R_1,R_3,D_2(B_2)$ [RS-a]



STAMY $R_1,R_3,D_2(B_2)$ [RSY-a]



The contents of the set of access registers starting with access register R_1 and ending with access register R_3 are stored at the locations designated by the second-operand address.

The storage area where the contents of the access registers are placed starts at the location designated by the second-operand address and continues through as many storage words as the number of access registers specified. The contents of the access registers are stored in ascending order of their register numbers, starting with access register R_1 and continuing up to and including access register R_3, with access register 0 following access register 15. The contents of the access registers remain unchanged.

The displacement for STAM is treated as a 12-bit unsigned binary integer. The displacement for STAMY is treated as a 20-bit signed binary integer.

The second operand must be designated on a word boundary; otherwise, a specification exception is recognized.

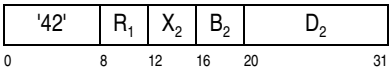
Condition Code: The code remains unchanged.

Program Exceptions:

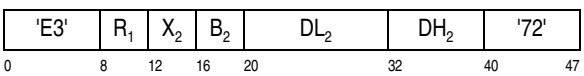
- Access (store, operand 2)
- Operation (STAMY, if the long-displacement facility is not installed)
- Specification

STORE CHARACTER

STC $R_1,D_2(X_2,B_2)$ [RX-a]



STCY $R_1,D_2(X_2,B_2)$ [RXY-a]



Bits 56-63 of general register R_1 are placed unchanged at the second-operand location. The second operand is one byte in length.

The displacement for STC is treated as a 12-bit unsigned binary integer. The displacement for STCY is treated as a 20-bit signed binary integer.

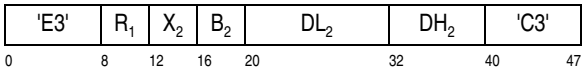
Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)
- Operation (STCY, if the long-displacement facility is not installed)

STORE CHARACTER HIGH

STCH $R_1,D_2(X_2,B_2)$ [RXY-a]



Bits 24-31 of general register R_1 are placed unchanged at the second-operand location. The second operand is one byte in length.

The displacement is treated as a 20-bit signed binary integer.

Condition Code: The code remains unchanged.

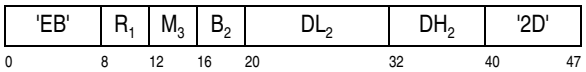
Program Exceptions:

- Access (store, operand 2)
- Operation (if the high-word facility is not installed)

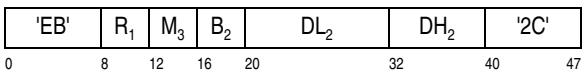
STORE CHARACTERS UNDER MASK

STCM $R_1,M_3,D_2(B_2)$ [RS-b]

STCMY $R_1,M_3,D_2(B_2)$ [RSY-b]



STCMH $R_1,M_3,D_2(B_2)$ [RSY-b]



Bytes selected from general register R_1 under control of a mask are placed at contiguous byte locations beginning at the second-operand address.

The contents of the M_3 field are used as a mask. These four bits, left to right, correspond one for one

with four bytes, left to right, of general register R_1. For STORE CHARACTERS UNDER MASK (STCM, STCMY), the four bytes to which the mask bits correspond are in bit positions 32-63 of general register R_1. For STORE CHARACTERS UNDER MASK (STCMH), the four bytes are in the high-order half, bit positions 0-31, of the register. The bytes corresponding to ones in the mask are placed in the same order at successive and contiguous storage locations beginning at the second-operand address. When the mask is not zero, the length of the second operand is equal to the number of ones in the mask. The contents of the general register remain unchanged.

When the mask is not zero, exceptions associated with storage-operand accesses are recognized only for the number of bytes specified by the mask.

When the mask is zero, the single byte designated by the second-operand address remains unchanged. However, on some models, an access exception may be recognized for the location. If accessible, (a) a PER zero-address-detection event may be recognized for the location, and (b) the contents may be fetched and subsequently stored back unchanged at the same storage location; this update appears to be an interlocked-update reference as observed by other CPUs.

The displacement for STCM is treated as a 12-bit unsigned binary integer. The displacement for STCMY and STCMH is treated as a 20-bit signed binary integer.

When STORE CHARACTERS UNDER MASK (STCMH) is attempted in a nonconstrained transaction, the M_3 field is 0, and the code in the R_1 field is 6 or 7, it is model dependent whether the instruction is restricted; if the instruction is not restricted, it is unpredictable whether the transaction is aborted due to abort code 16. When STORE CHARACTER UNDER MASK (STCMH) is attempted in a constrained transaction and the M_3 field is 0, a transaction-constraint program interruption is recognized, and the transaction is aborted with abort code 4.

Condition Code: The code remains unchanged.

Program Exceptions:

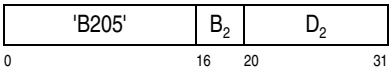
- Access (store, operand 2)
- Operation (STCMY, if the long-displacement facility is not installed)
- Transaction constraint (STCMH)

Programming Notes:

1. An example of the use of the STORE CHARACTERS UNDER MASK instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”
2. STORE CHARACTERS UNDER MASK (STCM, STCMY), with a mask of 0111 binary may be used to store a three-byte address, for example, in modifying the address in a format-0 CCW.
3. STORE CHARACTERS UNDER MASK (STCM, STCMY) with a mask of 1111, 0011, or 0001 binary performs the same function as STORE (ST), STORE HALFWORD, or STORE CHARACTER, respectively.
4. Using STORE CHARACTERS UNDER MASK with a zero mask may cause any of the following to occur for the byte designated by the second-operand address: a PER storage-alteration event may be recognized; access exceptions may be recognized; and, provided no access exceptions exist, the change bit may be set to one. Because the contents of storage remain unchanged, the change bit may or may not be one when a PER storage-alteration event is recognized.
5. On certain models, STORE CHARACTERS UNDER MASK with mask field that specifies discontiguous bytes may perform slower than when the mask specifies contiguous bytes.

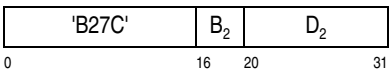
STORE CLOCK

STCK $D_2(B_2)$ [S]



STORE CLOCK FAST

STCKF $D_2(B_2)$ [S]



The current value of bits 0-63 of the TOD clock is stored in the eight-byte field designated by the second-operand address, provided the clock is in the set, stopped, or not-set state.

When the clock is stopped, zeros are stored in positions to the right of the rightmost bit position that is incremented when the clock is running. For STORE CLOCK, when the value of a running clock is stored, nonzero values may be stored in positions to the right of the rightmost incremented bit; this is to ensure that a unique value is stored. For STORE CLOCK FAST, when the value of a running clock is stored, bits to the right of the rightmost bit that is incremented are stored as zeros.

Zeros are stored at the operand location when the clock is in the error state or the not-operational state.

The quality of the clock value stored by the instruction is indicated by the resultant condition-code setting.

For STORE CLOCK, a serialization function is performed before the value of the clock is fetched and again after the value is placed in storage.

Resulting Condition Code:

0 Clock in set state
1 Clock in not-set state
2 Clock in error state
3 Clock in stopped state or not-operational state

Program Exceptions:

- Access (store, operand 2)
- Operation (STCKF, if the store-clock-fast facility is not installed)
- Transaction constraint

Programming Notes:

1. Bit position 31 of the clock is incremented every 1.048576 seconds; hence, for timing applications involving human responses, the leftmost clock word may provide sufficient resolution.

2. Condition code 0 normally indicates that the clock has been set by the control program. Accordingly, the value may be used in elapsed-time measurements and as a valid time-of-day and calendar indication. Condition code 1 indicates that the clock value is the elapsed time since the power for the clock was turned on. In this case, the value may be used in elapsed-time measurements but is not a valid time-of-day indication. Condition codes 2 and 3 mean that the value provided by STORE CLOCK cannot be used for time measurement or indication.

3. Condition code 3 indicates that the clock is in either the stopped state or the not-operational state. These two states can normally be distinguished because an all-zero value is stored when the clock is in the not-operational state.

4. Two executions of STORE CLOCK FAST, or an execution of STORE CLOCK FAST and STORE CLOCK, either on the same or different CPUs, do not necessarily return different values of the clock if the clock is running. Similarly, an execution of STORE CLOCK FAST and STORE CLOCK EXTENDED, either on the same or different CPUs, do not necessarily return different values of TOD clock bits 0-63 if the clock is running.

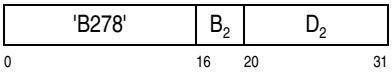
   Two executions of STORE CLOCK FAST, an execution of STORE CLOCK FAST and STORE CLOCK, or an execution of STORE CLOCK FAST and STORE CLOCK EXTENDED on different CPUs, may produce results that make it appear that the TOD clock is running backwards (see Figure 4-13 on page 4-52 for details).

5. When the TOD-clock-steering facility is installed, and assuming a valid operating system, then, for the problem program, the TOD clock is always in the set state and there is no need to test the condition code after issuing STORE CLOCK or STORE CLOCK FAST.

6. Using the standard epoch beginning January 1, 1900, the TOD clock provided by STORE CLOCK and STORE CLOCK FAST will wrap around to zero on September 17, 2042 at 23:53:57.370496 TAI. When the multiple-epoch facility is installed, the STORE CLOCK EXTENDED instruction provides an extended result that does not wrap around to zero at the end of an epoch.

STORE CLOCK EXTENDED

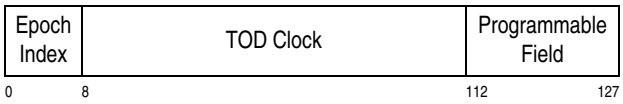
STCKE $D_2(B_2)$ [S]



Provided that the clock is in the set, stopped, or not-set state, the following are stored into the 16-byte second operand:

- When the multiple-epoch facility (MEF) is not installed in the configuration, it is unpredictable whether the epoch index or zeros are stored in byte position 0. When the multiple epoch facility is installed in the configuration, the epoch index is stored in byte position 0.
- The current value of the TOD clock is stored in byte positions 1-13.
- The TOD programmable field, bits 16-31 of the TOD programmable register, is stored in byte positions 14 and 15.

The operand just described has the following format:



When the clock is stopped, zeros are stored in the clock value in positions to the right of the rightmost bit position that is incremented when the clock is running. The programmable field still is stored.

When the value of a running clock is stored, the value in bit positions 64-103 of the clock (bit positions 72-111 of the storage operand) is always nonzero; this ensures that values stored by STORE CLOCK EXTENDED are unique when compared with values stored by STORE CLOCK and extended with zeros.

Zeros are stored at the operand location when the clock is in the error state or the not-operational state.

The quality of the clock value stored by the instruction is indicated by the resultant condition-code setting.

A serialization function is performed before the value of the clock is fetched and again after the value is placed in storage.

Resulting Condition Code:

0 Clock in set state
1 Clock in not-set state
2 Clock in error state
3 Clock in stopped state or not-operational state

Program Exceptions:

- Access (store, operand 2)
- Transaction constraint

Programming Notes:

1. Condition code 0 normally indicates that the clock has been set by the control program. Accordingly, the value may be used in elapsed-time measurements and as a valid time-of-day and calendar indication. Condition code 1 indicates that the clock value is the elapsed time since the power for the clock was turned on. In this case, the value may be used in elapsed-time measurements but is not a valid time-of-day indication. Condition codes 2 and 3 mean that the value provided by STORE CLOCK EXTENDED cannot be used for time measurement or indication.
2. When the TOD-clock-steering facility is installed, and assuming a valid operating system, then, for the problem program, the TOD clock is always in the set state and there is no need to test the condition code after issuing STORE CLOCK EXTENDED.
3. Programming notes 7-9 beginning on page 4-54 show hex values related to the value of the TOD clock as it is stored by the STORE CLOCK instruction. Notes 4-6, below, are repetitions of those notes except with the text and hex values adjusted so they apply to bits 0-71 of the value stored by STORE CLOCK EXTENDED.
4. The following chart shows the time interval between instants at which various bits of the TOD-clock value stored by STORE CLOCK EXTENDED are stepped. This time value may also be considered as the weighted time value that the bit, when one, represents. The bit numbers are those of the STORE CLOCK EXTENDED operand.

	Stepping Interval			
STCKE Bit	Days	Hours	Min.	Seconds
59				0.000 001
55				0.000 016
51				0.000 256
47				0.004 096
43				0.065 536
39				1.048 576
35				16.777 216
31			4	28.435 456
27		1	11	34.967 296

STCKE Bit	Stepping Interval			
	Days	Hours	Min.	Seconds
23		19	5	19.476 736
19	12	17	25	11.627 776
15	203	14	43	6.044 416
11	3257	19	29	36.710 656

5. The following chart shows the setting of bits 0-63 of the STORE CLOCK EXTENDED operand for 00:00:00 (0 am), UTC time, for several dates: January 1, 1900, January 1, 1972, and for that instant in time just after each of the 27 leap seconds that will have occurred through January, 2017. Each of these leap seconds is inserted in the UTC time scale beginning at 23:59:60 UTC of the day previous to the one listed and ending at 00:00:00 UTC of the day listed.

Year	Month	Day	Leap Sec.	STCKE Value (Hex) Bits 0-63
1900	1	1		0000 0000 0000 0000
1972	1	1		0081 26D6 0E46 0000
1972	7	1	1	0082 0BA9 811E 2400
1973	1	1	2	0082 F300 AEE2 4800
1974	1	1	3	0084 BDE9 7114 6C00
1975	1	1	4	0086 88D2 3346 9000
1976	1	1	5	0088 53BA F578 B400
1977	1	1	6	008A 1FE5 9520 D800
1978	1	1	7	008B EACE 5752 FC00

2012	7	1	25	00C9 CC9A 704D 8400
2015	7	1	26	00CF 2D54 B4FB A800
2017	1	1	27	00D1 E0D6 8173 CC00

6. The stepping value of TOD-clock bit position 63, if implemented, is 2^{-12} microseconds, or approximately 244 picoseconds. This value is called a clock unit.

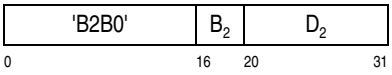
The following chart shows various time intervals in clock units expressed in hexadecimal notation. The chart shows the values stored in bit positions 0-71 of the STORE CLOCK EXTENDED operand. Bit 71 of the operand represents a clock unit.

Interval	Clock Units (Hex) Bits 0-71
1 microsecond	0010 00
1 millisecond	3E80 00
1 second	00F4 2400 00
1 minute	3938 7000 00
1 hour	000D 693A 4000 00
1 day	0141 DD76 0000 00
365 days	0001 CAE8 C13E 0000 00
366 days	0001 CC2A 9EB4 0000 00
1,461 days*	0007 2CE4 E26E 0000 00

* Number of days in four years, including a leap year. Note that the year 1900 was not a leap year. Thus, the four-year span starting in 1900 has only 1,460 days.

STORE FACILITY LIST EXTENDED

STFLE $D_2(B_2)$ [S]



A list of bits providing information about facilities is stored beginning at the doubleword specified by the second operand address.

For the leftmost doublewords in which facility bits are assigned, the reserved bits are stored as zeros. Doublewords to the right of the doubleword in which the highest-numbered facility bit is assigned for a configuration may or may not be stored. Access exceptions and PER events are not recognized for doublewords that are not stored.

The size of the second operand, in doublewords, is one more than the value specified in bits 56-63 of general register 0. The remaining bits of general register 0 are unassigned and should contain zeros; otherwise, the program may not operate compatibly in the future.

When the size of the second operand is large enough to contain all of the facility bits assigned for a configuration, then the complete facility list is stored in the second operand location, bits 56-63 of general register 0 are updated to contain one less than the number of doublewords needed to contain all of the facility bits assigned for the configuration, and condition code 0 is set.

When the size of the second operand is not large enough to contain all of the facility bits assigned for a configuration, then only the number of doublewords specified by the second-operand size are stored, bits 56-63 of general register 0 are updated to contain one less than the number of doublewords needed to contain all of the facility bits assigned for the configuration, and condition code 3 is set.

Figure 4-36, “Assigned Facility Bits” on page 4-101 shows the meanings of the assigned facility bits.

Special Conditions

The second operand must be designated on a doubleword boundary; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Complete facility list stored
1 --
2 --
3 Incomplete facility list stored

Program Exceptions:

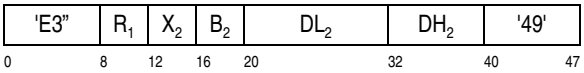
- Access (store, second operand)
- Operation (if the store-facility-list-extended facility is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. The performance of STORE FACILITY LIST EXTENDED may be significantly slower than that of simply testing a byte in storage. Programs that need to frequently test for the presence of a facility — for example, dual-path code in which the facility is used in one path but not another — should execute the STORE FACILITY LIST EXTENDED instruction once during initialization. Subsequently, the program may test for the presence of the facility by examining the stored result, using an instruction such as TEST UNDER MASK.
2. Bits 56-63 of general register 0 are updated to contain a value that is one less than the number of doublewords needed to contain all of the facility bits assigned. If the program chooses to ignore the results in general register 0 when condition code 0 is set, then it should ensure that the entire second operand in storage is set to zero prior to executing STORE FACILITY LIST EXTENDED. This is relevant when the number of doublewords specified for the second operand is greater than the number of doublewords required to contain all assigned facility bits.

STORE GUARDED STORAGE CONTROLS

STGSC $R_1,D_2(X_2,B_2)$ [RXY-a]



The contents of the three guarded-storage registers are stored at the second-operand location. The second operand has the format of a guarded-storage control block (GSCB), as shown in Figure 4-19 on page 4-68.

Access exceptions are recognized for all 32 bytes of the GSCB.

The R_1 field of the instruction is reserved and should contain zero; otherwise, the program may not operate compatibly in the future.

Special Conditions

A special-operation exception is recognized and the instruction is suppressed if the guarded-storage-facility-enablement control, bit 59 of control register 2, is zero.

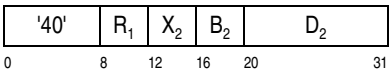
Condition Code: The code remains unchanged.

Program Exceptions:

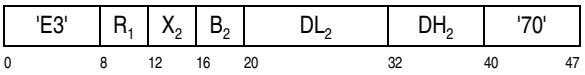
- Access (store, second operand)
- Operation (if the guarded-storage facility is not installed)
- Special operation
- Transaction constraint

STORE HALFWORD

STH $R_1,D_2(X_2,B_2)$ [RX-a]

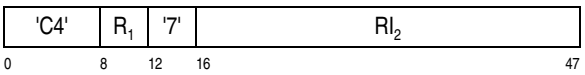


STHY $R_1,D_2(X_2,B_2)$ [RXY-a]



STORE HALFWORD RELATIVE LONG

STHRL R_1,RI_2 [RIL-b]



Bits 48-63 of general register R_1 are placed unchanged at the second-operand location. The second operand is two bytes in length.

The displacement for STH is treated as a 12-bit unsigned binary integer. The displacement for STHY is treated as a 20-bit signed binary integer.

For STORE HALFWORD RELATIVE LONG, the contents of the RI_2 field are a signed binary integer specifying the number of halfwords that is added to the address of the instruction to generate the address of the second operand in storage. When DAT is on, the second operand is accessed using the same addressing-space mode as that used to access the instruction. When DAT is off, the second operand is accessed using a real address.

Condition Code: The code remains unchanged.

Program Exceptions:

Access (store, operand 2)

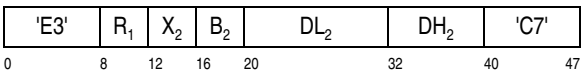
Operation (STHY if the long-displacement facility is not installed; STHRL, if the general-instructions-extension facility is not installed.)

Programming Notes:

1. For STORE HALFWORD RELATIVE LONG, the second operand is necessarily aligned on an integral boundary corresponding to the operand's size.
2. When STORE HALFWORD RELATIVE LONG is the target of an execute-type instruction, the second-operand address is relative to the target address.
3. Significant delay may be incurred if the program stores into the same cache line as that containing the storing instruction. The EXTRACT CPU ATTRIBUTE instruction may be used to determine the cache-line size.

STORE HALFWORD HIGH

STHH $R_1,D_2(X_2,B_2)$ [RXY-a]



Bits 16-31 of general register R_1 are placed unchanged at the second-operand location. The second operand is two bytes in length.

The displacement is treated as a 20-bit signed binary integer.

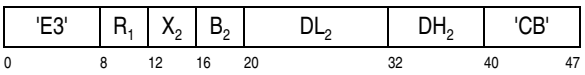
Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)
- Operation (if the high-word facility is not installed)

STORE HIGH

STFH $R_1,D_2(X_2,B_2)$ [RXY-a]



The first operand is placed unchanged at the second-operand location. The first operand is in bits 0-31 of general register R_1, and the second operand is 32 bits in storage.

The displacement is treated as a 20-bit signed binary integer.

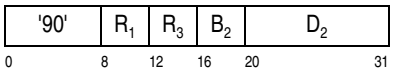
Condition Code: The code remains unchanged.

Program Exceptions:

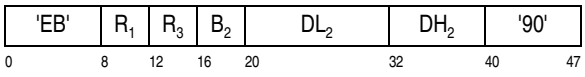
- Access (store, operand 2)
- Operation (if the high-word facility is not installed)

STORE MULTIPLE

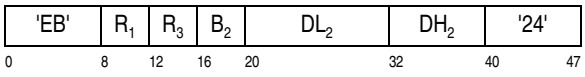
STM $R_1,R_3,D_2(B_2)$ [RS-a]



STMY $R_1,R_3,D_2(B_2)$ [RSY-a]



STMG $R_1,R_3,D_2(B_2)$ [RSY-a]



The contents of bit positions of the set of general registers starting with general register R_1 and ending with general register R_3 are placed in the storage area beginning at the location designated by the second-operand address and continuing through as many locations as needed.

For STORE MULTIPLE (STM, STMY), the contents of bit positions 32-63 of the general registers are stored in successive four-byte fields beginning at the second-operand address. For STORE MULTIPLE (STMG), the contents of bit positions 0-63 of the general registers are stored in successive eight-byte fields beginning at the second-operand address.

The general registers are stored in the ascending order of their register numbers, starting with general register R_1 and continuing up to and including general register R_3, with general register 0 following general register 15.

The displacement for STM is treated as a 12-bit unsigned binary integer. The displacement for STMY and STMG is treated as a 20-bit signed binary integer.

Condition Code: The code remains unchanged.

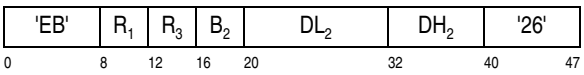
Program Exceptions:

- Access (store, operand 2)
- Operation (STMY, if the long-displacement facility is not installed)

Programming Note: An example of the use of the STORE MULTIPLE instruction is given in Appendix A, "Number Representation and Instruction-Use Examples."

STORE MULTIPLE HIGH

STMH $R_1,R_3,D_2(B_2)$ [RSY-a]



The contents of the high-order halves, bit positions 0-31, of the set of general registers starting with general register R_1 and ending with general register R_3 are placed in the storage area beginning at the location designated by the second-operand address and continuing through as many locations as needed, that is, the contents of bit positions 0-31 are stored in successive four-byte fields beginning at the second-operand address. Bits 32-63 of the registers are ignored.

The general registers are stored in the ascending order of their register numbers, starting with general register R_1 and continuing up to and including general register R_3, with general register 0 following general register 15.

Condition Code: The code remains unchanged.

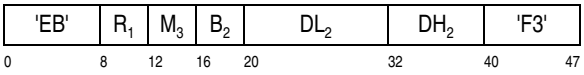
Program Exceptions:

- Access (store, operand 2)

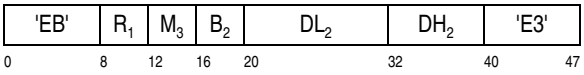
Programming Note: All combinations of register numbers specified by R_1 and R_3 are valid. When the register numbers are equal, only four bytes are transmitted. When the number specified by R_3 is less than the number specified by R_1, the register numbers wrap around from 15 to 0.

STORE ON CONDITION

STOC $R_1,D_2(B_2),M_3$ [RSY-b]

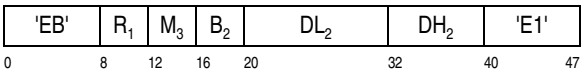


STOCG $R_1,D_2(B_2),M_3$ [RSY-b]



STORE HIGH ON CONDITION

STOCFH $R_1,D_2(B_2),M_3$ [RSY-b]



The first operand is placed unchanged at the second-operand location if the condition code has one of the values specified by M_3; otherwise, the second operand remains unchanged.

For STOC and STOCFH, the first and second operands are 32 bits, and for STOCG, the first and second operands are 64 bits. For STOC, the first operand is in bits 32-63 of general register R_1, and bits 0-31 of the register are ignored. For STOCFH, the first operand is in bits 0-31 of general register R_1, and bits 32-63 of the register are ignored.

The M_3 field is used as a four-bit mask. The four condition codes (0, 1, 2, and 3) correspond, left to right, with the four bits of the mask, as follows:

Condition Code	0	1	2	3
Instruction Bit Number of Mask	12	13	14	15
Mask Position Value	8	4	2	1

The current condition code is used to select the corresponding mask bit. If the mask bit selected by the condition code is one, the store is performed. If the mask bit selected is zero, the store is not performed.

The displacement is treated as a 20-bit signed binary integer.

When the condition specified by the M_3 field is not met (that is, store operation is not performed), it is model dependent whether any or all of the following occur for the second operand: (a) an access exception is recognized, (b) the change bit is set, or (c) a PER storage-alteration or zero-address-detection event is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)
- Operation (if the load/store-on-condition facility 1 is not installed; STOCFH, if the load/store-on-condition facility 2 is not installed)

Programming Notes:

1. When the M_3 field contain all zeros and no exception condition exists, the instruction acts as a NOP. When the M_3 field contains all ones and no exception condition exists, the store operation is always performed. However, these are not the preferred means of implementing a NOP or unconditional store, respectively.

2. When the condition specified by the M_3 field is not met, it is model dependent whether the second operand is brought into the cache.

3. STORE ON CONDITION provides a function similar to that of a separate BRANCH ON CONDITION instruction followed by a STORE instruction, except that STORE ON CONDITION does not provide an index register. For example, assuming the storage location is accessible, the following two instruction sequences are equivalent.

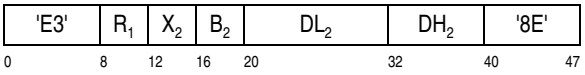
```
STOCG   15,256(7),8        BC      7,SKIP
                           STG     15,256(0,7)
                   SKIP    DS      0H
```

   On models that implement predictive branching, the combination of the BRANCH ON CONDITION and STORE instructions may perform somewhat better than the STORE ON CONDITION instruction when the CPU is able to successfully predict the branch condition. However, on models where the CPU is not able to successfully predict the branch condition, such as when the condition is more random, the STORE ON CONDITION instruction may provide significant performance improvement.

4. See programming note 4 on page 7-326 for details on extended mnemonics for the instructions of the load/store-on-condition facilities.

STORE PAIR TO QUADWORD

STPQ $R_1,D_2(X_2,B_2)$ [RXY-a]



The quadword first operand is stored at the second-operand location. The store at the second-operand location appears to be quadword concurrent as observed by other CPUs. The left doubleword of the

first operand is in general register R_1, and the right doubleword is in general register $R_1 + 1$.

The R_1 field designates an even-odd pair of general registers and must designate an even-numbered register. The second operand must be designated on a quadword boundary. Otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

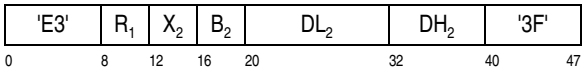
- Access (store, operand 2)
- Specification
- Transaction constraint

Programming Notes:

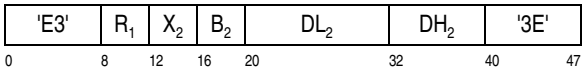
1. The STORE MULTIPLE (STM or STMG) instruction does not necessarily provide quadword-concurrent access.
2. It is model dependent whether the performance of STORE MULTIPLE (STMG) with two general registers specified and STORE PAIR TO QUADWORD are similar or differ significantly.

STORE REVERSED

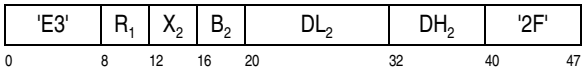
STRVH $R_1,D_2(X_2,B_2)$ [RXY-a]



STRV $R_1,D_2(X_2,B_2)$ [RXY-a]



STRVG $R_1,D_2(X_2,B_2)$ [RXY-a]



The first operand is placed at the second-operand location with the left-to-right sequence of the bytes reversed.

For STORE REVERSED (STRVH), the first operand is two bytes in bit positions 48-63 of general register R_1. For STORE REVERSED (STRV), the first operand is four bytes in bit positions 32-63 of general register R_1. For STORE REVERSED (STRVG), the first operand is eight bytes in bit positions 0-63 of general register R_1.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)

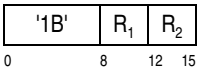
Programming Notes:

1. The instruction can be used to convert two, four, or eight bytes from a “little-endian” format to a “big-endian” format, or vice versa. In the big-endian format, the bytes in a left-to-right sequence are in the order most significant to least significant. In the little-endian format, the bytes are in the order least significant to most significant. For example, the bytes ABCD in the big-endian format are DCBA in the little-endian format.

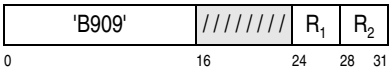
SUBTRACT

Register-and-register formats:

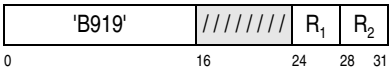
SR R_1,R_2 [RR]



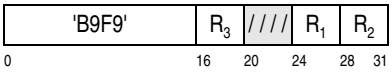
SGR R_1,R_2 [RRE]



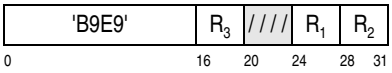
SGFR R_1,R_2 [RRE]



SRK R_1,R_2,R_3 [RRF-a]

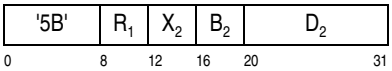


SGRK R_1,R_2,R_3 [RRF-a]

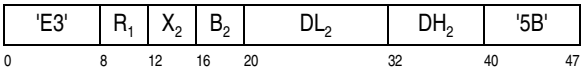


Register-and-storage formats:

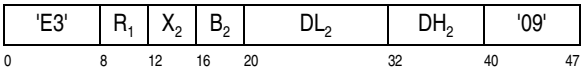
S $R_1,D_2(X_2,B_2)$ [RX-a]



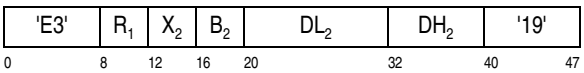
SY $R_1,D_2(X_2,B_2)$ [RXY-a]



SG $R_1,D_2(X_2,B_2)$ [RXY-a]



SGF $R_1,D_2(X_2,B_2)$ [RXY-a]



For S, SG, SGF, SGFR, SGR, SR, and SY, the second operand is subtracted from the first operand, and the difference is placed at the first-operand location. For SGRK and SRK, the third operand is subtracted from the second operand, and the difference is placed at the first-operand location.

For S, SR, SRK, and SY, the operands and the difference are treated as 32-bit signed binary integers. For SG, SGR, and SGRK, they are treated as 64-bit signed binary integers. For SGFR and SGF, the second operand is treated as a 32-bit signed binary integer, and the first operand and the difference are treated as 64-bit signed binary integers.

When there is an overflow, the result is obtained by allowing any carry into the sign-bit position and ignoring any carry out of the sign-bit position, and condition code 3 is set. If the fixed-point-overflow mask is one, a program interruption for fixed-point overflow occurs.

The displacement for S is treated as a 12-bit unsigned binary integer. The displacement for SY, SG, and SGF is treated as a 20-bit signed binary integer.

Resulting Condition Code:

0 Result zero; no overflow
1 Result less than zero; no overflow
2 Result greater than zero; no overflow
3 Overflow

Program Exceptions:

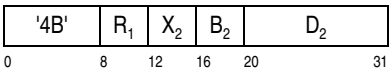
- Access (fetch, operand 2 of S, SY, SG, and SGF only)
- Fixed-point overflow
- Operation (SY, if the long-displacement facility is not installed; SRK, SGRK, if the distinct-operands facility is not installed)

Programming Notes:

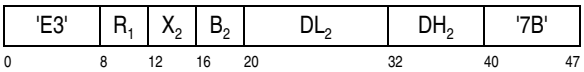
1. For SR and SGR, when R_1 and R_2 designate the same register, subtracting is equivalent to clearing the register.
2. Subtracting a maximum negative number from itself gives a zero result and no overflow.

SUBTRACT HALFWORD

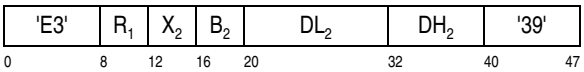
SH $R_1,D_2(X_2,B_2)$ [RX-a]



SHY $R_1,D_2(X_2,B_2)$ [RXY-a]



SGH $R_1,D_2(X_2,B_2)$ [RXY-a]



The second operand is subtracted from the first operand, and the difference is placed at the first-operand location. The second operand is two bytes in length and is treated as a 16-bit signed binary integer. The first operand and the difference are treated as 32-bit signed binary integers. For SGH, the first operand and the difference are treated as 64-bit signed binary integers.

When there is an overflow, the result is obtained by allowing any carry into the sign-bit position and ignoring any carry out of the sign-bit position, and condition code 3 is set. If the fixed-point-overflow mask is one, a program interruption for fixed-point overflow occurs.

The displacement for SH is treated as a 12-bit unsigned binary integer. The displacement for SGH and SHY is treated as a 20-bit signed binary integer.

Resulting Condition Code:

0 Result zero; no overflow
1 Result less than zero; no overflow
2 Result greater than zero; no overflow
3 Overflow

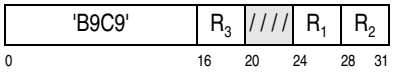
Program Exceptions:

- Access (fetch, operand 2)
- Fixed-point overflow
- Operation (SHY, if the long-displacement facility is not installed; SGH, if the miscellaneous-instruction-extensions facility 2 is not installed)

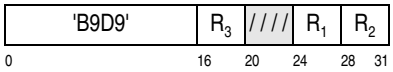
Programming Note: The function of a SUBTRACT HALFWORD IMMEDIATE instruction, which is an instruction not provided, can be obtained by using an ADD HALFWORD IMMEDIATE instruction with a negative I_2 field.

SUBTRACT HIGH

SHHHR R_1,R_2,R_3 [RRF-a]



SHHLR R_1,R_2,R_3 [RRF-a]



The third operand is subtracted from the second operand, and the difference is placed at the first-operand location. The operands and the difference are treated as 32-bit signed binary integers.

The first and second operands are in bits 0-31 of general registers R_1 and R_2, respectively; bits 32-63 of general register R_1 are unchanged, and bits 32-63 of general register R_2 are ignored. For SHHHR, the third operand is in bits 0-31 of general register R_3; bits 32-63 of the register are ignored. For SHHLR, the third operand is in bits 32-63 of general register R_3; bits 0-31 of the register are ignored.

When there is an overflow, the result is obtained by allowing any carry into the sign-bit position and ignoring any carry out of the sign-bit position, and condition code 3 is set. If the fixed-point-overflow mask is one, a program interruption for fixed-point overflow occurs.

Resulting Condition Code:

0 Result zero; no overflow
1 Result less than zero; no overflow
2 Result greater than zero; no overflow
3 Overflow

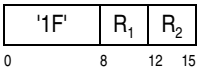
Program Exceptions:

- Fixed-point overflow
- Operation (if the high-word facility is not installed)

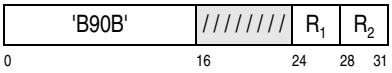
SUBTRACT LOGICAL

Register-and-register formats:

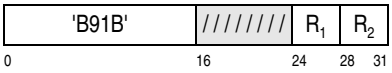
SLR R_1,R_2 [RR]



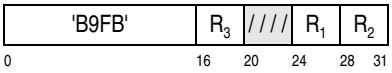
SLGR R_1,R_2 [RRE]



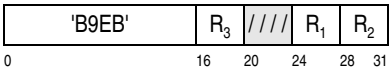
SLGFR R_1,R_2 [RRE]



SLRK R_1,R_2,R_3 [RRF-a]

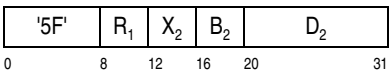


SLGRK R_1,R_2,R_3 [RRF-a]

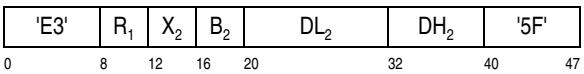


Register-and-storage formats:

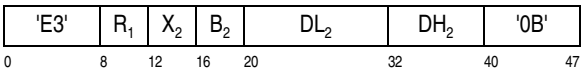
SL $R_1,D_2(X_2,B_2)$ [RX-a]



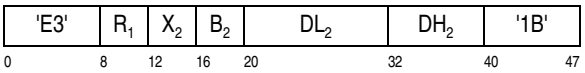
SLY $R_1,D_2(X_2,B_2)$ [RXY-a]



SLG $R_1,D_2(X_2,B_2)$ [RXY-a]

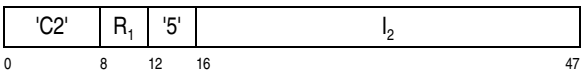


SLGF $R_1,D_2(X_2,B_2)$ [RXY-a]

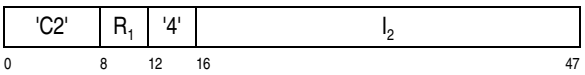


SUBTRACT LOGICAL IMMEDIATE

SLFI R_1,I_2 [RIL-a]



SLGFI R_1,I_2 [RIL-a]



For SUBTRACT LOGICAL (SL, SLG, SLGF, SLGFR, SLGR, SLR, SLY) and for SUBTRACT LOGICAL IMMEDIATE, the second operand is subtracted from the first operand, and the difference is placed at the first-operand location. For SUBTRACT LOGICAL (SLGRK and SLRK), the third operand is subtracted from the second operand, and the difference is placed at the first-operand location.

For SUBTRACT LOGICAL (SL, SLR, SLRK, and SLY) and for SUBTRACT LOGICAL IMMEDIATE (SLFI), the operands and the difference are treated as 32-bit unsigned binary integers. For SUBTRACT LOGICAL (SLG, SLGR, and SLGRK), they are treated as 64-bit unsigned binary integers. For SUBTRACT LOGICAL (SLGFR, SLGF) and for SUBTRACT LOGICAL IMMEDIATE (SLGFI), the second operand is treated as a 32-bit unsigned binary integer, and the first operand and the difference are treated as 64-bit unsigned binary integers.

The displacement for SL is treated as a 12-bit unsigned binary integer. The displacement for SLY, SLG, and SLGF is treated as a 20-bit signed binary integer.

Resulting Condition Code:

0 --
1 Result not zero; borrow
2 Result zero; no borrow
3 Result not zero; no borrow

Program Exceptions:

- Access (fetch, operand 2 of SL, SLY, SLG, and SLGF only)
- Operation (SLY, if the long-displacement facility is not installed; SLFI and SLGFI, if the extended-immediate facility is not installed; SLRK and SLGRK, if the distinct-operands facility is not installed)

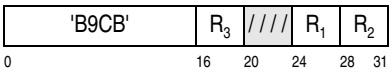
Programming Notes:

1. Logical subtraction is performed by adding the one's complement of the subtrahend and a value of one to the minuend. The use of the one's complement and the value of one instead of the two's complement of the second operand results in a carry when the second operand is zero.
2. SUBTRACT LOGICAL differs from SUBTRACT only in the meaning of the condition code and in the absence of the interruption for overflow.
3. A zero difference is always accompanied by a carry out of bit position 0 for 64-bit results or bit position 32 for 32-bit results, and, therefore, no borrow.
4. The condition-code setting for SUBTRACT LOGICAL can also be interpreted as indicating the presence or absence of a carry, as follows:

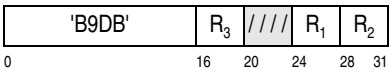
   1 Result not zero; no carry
   2 Result zero; carry
   3 Result not zero; carry

SUBTRACT LOGICAL HIGH

SLHHHR R_1,R_2,R_3 [RRF-a]



SLHHLR R_1,R_2,R_3 [RRF-a]



The third operand is subtracted from the second operand, and the difference is placed at the first-operand location. The operands and the difference are treated as 32-bit unsigned binary integers.

The first and second operands are in bits 0-31 of general registers R_1 and R_2, respectively; bits 32-63 of general register R_1 are unchanged, and bits 32-63 of general register R_2 are ignored. For SLHHHR, the third operand is in bits 0-31 of general register R_3; bits 32-63 of the register are ignored. For SLHHLR, the third operand is in bits 32-63 of general register R_3; bits 0-31 of the register are ignored.

Resulting Condition Code:

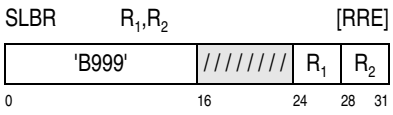
0 --
1 Result not zero; borrow
2 Result zero; no borrow
3 Result not zero; no borrow

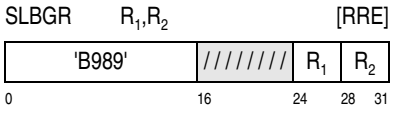
Program Exceptions:

- Operation (if the high-word facility is not installed)

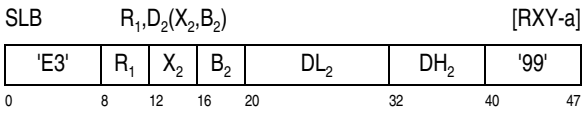
SUBTRACT LOGICAL WITH BORROW

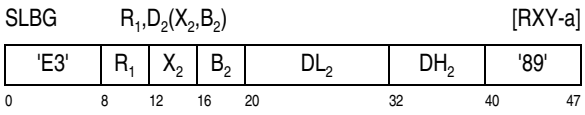
Register-and-register formats:





Register-and-storage formats:





The second operand and the borrow are subtracted from the first operand, and the difference is placed at the first-operand location. For SUBTRACT LOGICAL WITH BORROW (SLBR, SLB), the operands, the borrow, and the difference are treated as 32-bit unsigned binary integers. For SUBTRACT LOGICAL WITH BORROW (SLBGR, SLBG), they are treated as 64-bit unsigned binary integers.

Resulting Condition Code:

0 Result zero; borrow
1 Result not zero; borrow
2 Result zero; no borrow
3 Result not zero; no borrow

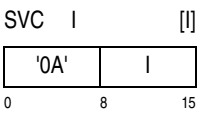
Program Exceptions:

- Access (fetch, operand 2 of SLB and SLBG only)

Programming Notes:

1. A borrow is represented by a zero value of bit 18 of the current PSW. Bit 18 is the leftmost bit of the two-bit condition code in the PSW. Bit 18 is set to zero by an execution of a SUBTRACT LOGICAL or SUBTRACT LOGICAL WITH BORROW instruction that produces a borrow into the leftmost bit position of the 32-bit or 64-bit result.
2. Logical subtraction with borrow is performed by adding the one's complement of the second operand and bit 18 of the current PSW to the first operand. Therefore, when bit 18 is one, indicating no borrow, the addition is the same as for SUBTRACT LOGICAL.
3. Condition code zero is set for SUBTRACT LOGICAL WITH BORROW (SLBR, SLB), when the maximum 32-bit unsigned binary integer, $2^{32} - 1$, is subtracted from zero when PSW bit 18 indicates a borrow. For SUBTRACT LOGICAL WITH BORROW (SLBGR, SLBG) condition code zero is set when the maximum 64-bit unsigned binary integer, $2^{64} - 1$, is subtracted from zero when PSW bit 18 indicates a borrow.
4. SUBTRACT and SUBTRACT LOGICAL may provide better performance than SUBTRACT LOGICAL WITH BORROW, depending on the model.

SUPERVISOR CALL



The instruction causes a supervisor-call interruption, with the I field of the instruction providing the rightmost byte of the interruption code.

Bits 8-15 of the instruction, with eight zeros appended on the left, are placed in the supervisor-call interruption code that is stored in the course of the interruption. See "Supervisor-Call Interruption" on page 6-59.

A serialization and checkpoint-synchronization function is performed.

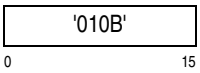
Condition Code: The code remains unchanged and is saved as part of the old PSW. A new condition code is loaded as part of the supervisor-call interruption.

Program Exceptions:

- Transaction constraint

TEST ADDRESSING MODE

TAM [E]



The extended-addressing-mode bit and basic-addressing-mode bit, bits 31 and 32 of the current PSW, respectively, are tested, and the result is indicated in the condition code.

Resulting Condition Code:

0 PSW bits 31 and 32 zeros (indicating 24-bit addressing mode)
1 PSW bit 31 zero and bit 32 one (indicating 31-bit addressing mode)
2 --
3 PSW bits 31 and 32 ones (indicating 64-bit addressing mode)

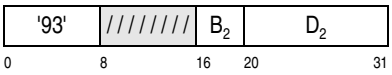
Program Exceptions:

- Transaction constraint

Programming Note: The case when PSW bit 31 is one and bit 32 is zero causes an early PSW specification exception to be recognized.

TEST AND SET

TS $D_2(B_2)$ [SI]



The leftmost bit (bit position 0) of the byte located at the second-operand address is used to set the condition code, and then the byte is set to all ones.

Bits 8-15 of the instruction are ignored.

The byte in storage is set to all ones as it is fetched for the testing of bit 0. This update appears to be an interlocked-update reference as observed by other CPUs.

A serialization function is performed before the byte is fetched and again after the storing of all ones.

Resulting Condition Code:

0 Leftmost bit zero
1 Leftmost bit one
2 --
3 --

Program Exceptions:

- Access (fetch and store, operand 2)
- Transaction constraint

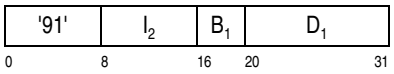
Programming Notes:

1. TEST AND SET may be used for controlled sharing of a common storage area by programs operating on different CPUs. This instruction is provided primarily for compatibility with programs written for System/360. The instructions COMPARE AND SWAP and COMPARE DOUBLE AND SWAP provide functions which are more suitable for sharing among programs on a single CPU or for programs that may be interrupted. See the description of these instructions and the associated programming notes for details.

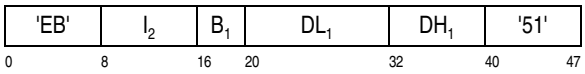
2. TEST AND SET does not interlock against storage accesses by channel programs. Therefore, the instruction should not be used to update a location into which a channel program may store, since the channel-program data may be lost.

TEST UNDER MASK (TEST UNDER MASK HIGH, TEST UNDER MASK LOW)

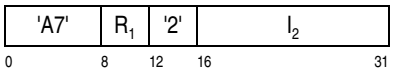
TM $D_1(B_1),I_2$ [SI]



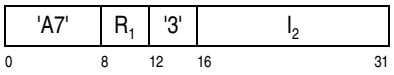
TMY $D_1(B_1),I_2$ [SIY]



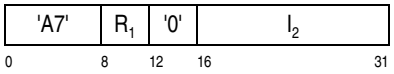
TMHH R_1,I_2 [RI-a]



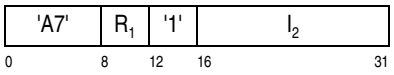
TMHL R_1,I_2 [RI-a]



TMH R_1,I_2 [RI-a]
TMLH R_1,I_2 [RI-a]



TML R_1,I_2 [RI-a]
TMLL R_1,I_2 [RI-a]



A mask is used to select bits of the first operand, and the result is indicated in the condition code.

TEST UNDER MASK is a new name of, and TMLH and TMLL are new mnemonics for, the ESA/390 instructions TEST UNDER MASK HIGH (TMH) and TEST UNDER MASK LOW (TML), respectively.

In TEST UNDER MASK (TM, TMY), the byte of immediate data, I_2, is used as an eight-bit mask. The bits of the mask are made to correspond one for one with the bits of the byte in storage designated by the first-operand address.

A mask bit of one indicates that the storage bit is to be tested. When the mask bit is zero, the storage bit is ignored. When all storage bits thus selected are zero, condition code 0 is set. Condition code 0 is also set when the mask is all zeros. When the selected bits are all ones, condition code 3 is set; otherwise, condition code 1 is set.

Access exceptions associated with the storage operand are recognized for one byte even when the mask is all zeros.

In TEST UNDER MASK (TMHH, TMHL, TMLH, TMLL), the contents of the I_2 field are used as a 16-bit mask. For each instruction, the bits of the mask are made to correspond one for one with 16 bits of the first operand as follows:

Instruction	Bits Tested
TMHH	0-15
TMHL	16-31
TMLH (or TMH)	32-47
TMLL (or TML)	48-63

A mask bit of one indicates that the first-operand bit is to be tested. When the mask bit is zero, the first-operand bit is ignored. When all first-operand bits thus selected are zero, condition code 0 is set. Condition code 0 is also set when the mask is all zeros. When the selected bits are mixed zeros and ones, condition code 1 is set if the leftmost selected bit is zero, or condition code 2 is set if the leftmost selected bit is one. When the selected bits are all ones, condition code 3 is set.

The displacement for TM is treated as a 12-bit unsigned binary integer. The displacement for TMY is treated as a 20-bit signed binary integer.

Resulting Condition Code:

0 Selected bits all zeros; or mask bits all zeros
1 Selected bits mixed zeros and ones (TM and TMY only)
1 Selected bits mixed zeros and ones, and leftmost is zero (TMHH, TMHL, TMLH, TMLL)
2 -- (TM and TMY only)
2 Selected bits mixed zeros and ones, and leftmost is one (TMHH, TMHL, TMLH, TMLL)
3 Selected bits all ones

Program Exceptions:

- Access (fetch, operand 1, TM and TMY only)
- Operation (TMY, if the long-displacement facility is not installed)

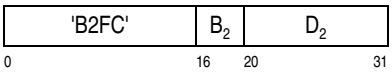
Programming Notes:

1. An example of the use of the TEST UNDER MASK (TM) instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. When the mask for TMHH, TMHL, TMLH, or TMLL selects exactly two bits, the two selected bits effectively are loaded into the condition code.

TRANSACTION ABORT

TABORT $D_2(B_2)$ [S]



If the CPU is in the nonconstrained transactional-execution mode, the transaction is aborted.

The second-operand address is not used to address data; instead, the address specified by the B_2 and D_2 fields forms the transaction abort code which is placed in the transaction diagnostic block during abort processing. Address computation for the second-operand address follows the rules of address arithmetic; in the 24-bit addressing mode, bits 0-39 are set to zeros; in the 31-bit addressing mode, bits 0-32 are set to zeros.

Aborting of a transaction by the TABORT instruction consists of performing steps 1-7 of the section “Transaction Abort Processing” on page 5-103. The condition code in the transaction-abort PSW is set to either 2 or 3, depending on whether bit 63 of the second-operand address is zero or one, respectively.

A serialization function is implicitly performed by the abort processing.

When TRANSACTION ABORT is the target of an execute-type instruction, the operation is suppressed and an execute exception is recognized.

A specification exception is recognized and the operation is suppressed if the second-operand address is between 0 and 255.

A special-operation exception is recognized and the operation is suppressed if the CPU is not in the transactional-execution mode at the beginning of the instruction.

If the CPU is in the constrained transactional-execution mode, a transaction-constraint program exception condition is recognized.

Condition Code: The code remains unchanged. However, the condition code of the transaction-abort PSW will be set by the subsequent transaction-abort processing.

Program Exceptions:

- Execute
- Operation (transactional-execution facility not installed)
- Special-operation
- Specification
- Transaction constraint

Programming Notes:

1. If the transactional-execution control, bit 8 of control register 0, is zero, the CPU cannot be in the transactional-execution mode; Attempted execution of a TRANSACTION ABORT in this case results in a special-operation exception.

2. Abort codes 0-255 are reserved for transactions that are implicitly aborted by the CPU. See “Transaction Abort Conditions” on page 5-101 for details.

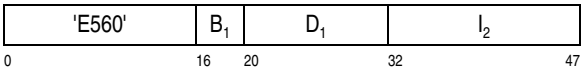
3. Program interruptions are subject to the effective program-interruption filtering control.

4. Execution of TABORT may result in significant performance degradation, potentially causing high contention which, in turn, can lead to other abort conditions.

5. Following the TABORT instruction, program execution continues at the instruction designated by the transaction-abort PSW.

TRANSACTION BEGIN (TBEGIN)

TBEGIN $D_1(B_1),I_2$ [SIL]



Execution of the TRANSACTION BEGIN (TBEGIN) instruction causes the CPU either to enter or to remain in the nonconstrained transactional-execution mode.

When the B_1 field is nonzero, the following applies;

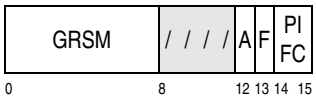
- When the transaction nesting depth is initially zero, the first-operand address designates the location of the 256-byte transaction diagnostic block, called the TBEGIN-specified TDB, into which various diagnostic information may be stored if the transaction is aborted (see "Transaction Diagnostic Block (TDB)" on page 5-95). When the CPU is in the primary-space mode or access-register mode, the first-operand address designates a location in the primary address space. When the CPU is in the secondary-space or home-space mode, the first-operand address designates a location in the secondary or home address space, respectively. When DAT is off, the TDBA designates a location in real storage.

  Store accessibility to the first operand is determined. If accessible, the logical address of the operand is placed into the transaction-diagnostic-block address (TDBA), and the TDBA is valid.

- When the CPU is already in the nonconstrained transactional-execution mode, the TDBA is not modified, and it is unpredictable whether the first operand is tested for accessibility.

When the B_1 field is zero, no access exceptions are detected for the first operand, and, for the outermost TBEGIN instruction, the TDBA is invalid.

The I_2 field contains various controls for the instruction and has the following format:



The bits of the I_2 field are defined as follows:

General Register Save Mask (GRSM): Bits 0-7 of the I_2 field contain the general register save mask (GRSM). Each bit of the GRSM represents an even-odd pair of general registers, where bit 0 represents registers 0 and 1, bit 1 represents registers 2 and 3, and so forth. When a bit in the GRSM of the outermost TBEGIN instruction is zero, the corresponding register pair is not saved. When a bit in the GRSM of the outermost TBEGIN instruction is one, the corresponding register pair is saved in a model-dependent location that is not directly accessible by the program.

If the transaction aborts, saved register pairs are restored to their contents when the outermost TBEGIN instruction was executed. The contents of all other (unsaved) general registers are not restored when a transaction aborts.

The general register save mask is ignored on all TBEGINs except for the outermost one.

Allow AR Modification (A): The A control, bit 12 of the I_2 field, controls whether the transaction is allowed to modify an access register. The effective allow-AR-modification control is the logical AND of the A control in the TBEGIN instruction for the current nesting level and for all outer levels.

If the effective A control is zero, the transaction will be aborted with abort code 11 (restricted instruction) if an attempt is made to modify any access register. If the effective A control is one, the transaction will not be aborted if an access register is modified (absent of any other abort condition).

Allow Floating-Point Operation (F): The F control, bit 13 of the I_2 field, controls whether the transaction is allowed to execute any floating-point instruction (that is, any instruction defined in Chapters 9, 18, 19, or 20) or any vector instruction (that is, any instruction defined in chapters 21 to 26 having an instruction format which begins with the letter "V"). The effective allow-floating-point-operation control is the logical AND of the F control in the TBEGIN instruction for the current nesting level and for all outer levels.

If the effective F control is zero, then (a) the transaction will be aborted with abort code 11 (restricted instruction) if an attempt is made to execute a floating-point or vector instruction, and (b) the data-exception code (DXC) in byte 2 of the floating-point control register (FPCR) will not be set by any data-exception program-exception condition. If the effective F control is one, then (a) the transaction will not be aborted if an attempt is made to execute a floating-point or vector instruction (absent any other abort condition), and (b) the DXC or VXC in the FPCR may be set by a data-exception or vector-exception program-exception condition.

Program-Interruption-Filtering Control (PIFC): Bits 14-15 of the I_2 field are the program-interruption-filtering control (PIFC). The PIFC controls whether certain classes of program-exception conditions that occur while the CPU is in the transactional-execution

mode result in an interruption. See “Program-Interruption Filtering on a Transaction Abort” on page 5-105 for a description of these classes.

The effective PIFC is the highest value of the PIFC in the TBEGIN instruction for the current nesting level and for all outer levels. When the effective PIFC is zero, all program-exception conditions result in an interruption. When the effective PIFC is one, program-exception conditions having a transactional-execution class of 1 and 2 result in an interruption. When the effective PIFC is two, program-exception conditions having a transactional-execution class of 1 result in an interruption. A PIFC of 3 is reserved.

Bits 8-11 of the I_2 field (bits 40-43 of the instruction) are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.

TRANSACTION BEGIN (TBEGIN) Processing

Execution of the TRANSACTION BEGIN (TBEGIN) instruction consists of the following steps: Note, exception checking does not necessarily need to occur in the order listed below. See Figure 7-399 on page 7-463 for the precise ordering requirements for exception checking.

1. A serialization function is performed.
2. A special-operation exception is recognized and the operation is suppressed if the transactional-execution control, bit 8 of control register 0, is zero.
3. A specification exception is recognized and the operation is suppressed if either of the following is true.

   a. The program-interruption-filtering control, bits 14-15 of I_2 field of the instruction, contains the value 3.

   b. The first-operand address does not designate a doubleword boundary. It is model dependent whether a specification exception is recognized when the first-operand address does not designate a doubleword boundary if either the B_1 field is zero or the transaction-nesting depth is nonzero.
4. If the CPU is in the constrained transactional-execution mode, then a transaction-constraint-exception program exception is recognized and the operation is suppressed.
5. When the B_1 field is nonzero, the following applies:

   - If the CPU is not in the transactional-execution mode (that is, the transaction nesting depth is zero), then the following occurs:
     – Store accessibility to the first operand is determined. If the first operand cannot be accessed for stores, then an access exception is recognized and the operation is either nullified, suppressed, or terminated, depending on the specific access-exception condition.
     – Any PER storage-alteration or zero-address-detection event for the first operand is recognized.
   - If the CPU is already in the transactional-execution mode, it is unpredictable whether (a) store accessibility to the first operand is determined, and (b) PER storage-alteration or zero-address-detection events are detected for the first operand.

   If the B_1 field is zero, then the first operand is not accessed.
6. If the transaction nesting depth, when incremented by one, would exceed a model-dependent maximum transaction nesting depth, the transaction is aborted with abort code 13. See “Transaction Abort Processing” on page 5-103 for details on the handling of a transaction abort.
7. If the CPU is not in the transactional-execution mode, the following occurs:

   a. If the B_1 field is nonzero, the first-operand address is placed in the transaction-diagnostic-block address, and the transaction-diagnostic-block address is valid. If the B_1 field is zero, the transaction-diagnostic-block address is invalid.

   b. The transaction-abort PSW is set from the contents of the current PSW. The instruction address of the transaction-abort PSW designates the next-sequential instruction (that is, the instruction following the outermost TBEGIN).

8. An effective value of the allow-AR-modification (A) control, bit 12 of the I_2 field of the instruction, is determined. The effective A control is the logical AND of the A control in the TBEGIN instruction for the current level and for all outer levels.

9. An effective value of the allow-floating-point-operation (F) control, bit 13 of the I_2 field of the instruction, is determined. The effective F control is the logical AND of the F control in the TBEGIN instruction for the current level and for all outer levels.

10. An effective value of the program-interruption-filtering control (PIFC), bits 14-15 of the I_2 field of the instruction, is determined. The effective PIFC value is highest value in the TBEGIN instruction for the current level and for all outer levels.

11. If the CPU is not in the transactional-execution mode, the contents of the general register pairs designated by the general-register save mask are saved in a model-dependent location that is not directly accessible by the program.

12. A value of one is added to the transaction nesting depth, and the instruction completes by setting condition code 0. If the transaction nesting depth transitions from zero to one, the CPU enters the nonconstrained transactional-execution mode; otherwise, the CPU remains in the nonconstrained transactional-execution mode.

When TBEGIN is the target of an execute-type instruction, the operation is suppressed and an execute exception is recognized.

See “Event-Suppression Control (ES)” on page 4-28 for additional details on the recognition of PER instruction-fetching events during the execution of TRANSACTION BEGIN.

The preceding descriptions for TBEGIN apply when the ineffective-nonconstrained-transaction facility is not installed. The ineffective-nonconstrained-transaction facility provides an environment for identifying programs that should replace the use of nonconstrained transactions in case the facility becomes completely unsupported. It is expected programs issuing TBEGIN have also provided an abort-handler routine and that routine will be executed in this environment. The following applies when the ineffective-nonconstrained-transaction facility is installed:

- It is model dependent whether any of the program-exception conditions defined for the instruction are recognized.
- It is model dependent whether a PER storage-alteration event or a PER zero-address-detection event for the TBEGIN-specified TDB is suppressed due to the event-suppression (ES) control (bit 41 of control register 9) being one. It is also model dependent whether a PER instruction-fetching basic event for the TRANSACTION BEGIN instruction is suppressed due to the ES control being one.
- It is model dependent whether a serialization function is performed.
- At the end of the execution of the instruction, the transaction-diagnostic-block address (TDBA) is invalid, the CPU is not in the nonconstrained-transactional mode, the transactional nesting depth is zero, a TBEGIN-specified TDB is not stored, and condition code 1 is set.

Resulting Condition Code:

0 Transaction initiation successful
1 – (see programming notes 3, 4, and 11)
2 – (see programming notes 3 and 4)
3 – (see programming notes 3 and 4)

Program Exceptions:

- Access (store, first operand)
- Execute
- Operation (transactional-execution facility not installed)
- Special operation
- Specification
- Transaction constraint

1.-7	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
8.A	Specification exception due to reserved PIFC value.
8.B	Specification exception due to first-operand address not on a doubleword boundary.
8.C	Access exception (when B_1 field is nonzero).

Figure 7-399. Priority of Execution: TRANSACTION BEGIN (TBEGIN)

8.D	Abort due to exceeding maximum transaction nesting depth.
9	Condition code 0 due to normal completion.

Figure 7-399. Priority of Execution: TRANSACTION BEGIN (TBEGIN) (Continued)

Programming Notes:

1. When the B_1 field is nonzero, the following applies:

   - An accessible transaction diagnostic block (TDB) must be provided when an outermost transaction is initiated – even if the transaction never aborts.
   - Since it is unpredictable whether accessibility of the TDB is tested for nested transactions, an accessible TDB should be provided for any nested TBEGIN instruction.
   - The performance of any TBEGIN in which the B_1 field is nonzero, and the performance of any abort processing that occurs for a transaction that was initiated by an outermost TBEGIN in which the B_1 field is nonzero, may be slower than when the B_1 field is zero.

2. Registers designated to be saved by the general register save mask are only restored if the transaction aborts, not when the transaction ends normally by means of TRANSACTION END. Only the registers designated by the GRSM of the outermost TRANSACTION BEGIN instruction are restored on abort.

   The I_2 field should designate all register pairs that provide input values that are changed by the transaction. Thus, if the transaction is aborted, the input register values will be restored to their original contents when the abort handler is entered.

3. The TRANSACTION BEGIN (TBEGIN) instruction is expected to be followed by a conditional branch instruction that will determine whether the transaction was successfully initiated. See programming note 3 on page 5-104 for a complete explanation of each condition code.

4. If a transaction is aborted due to conditions that do not result in an interruption, the instruction designated by the transaction-abort PSW receives control (that is, the instruction following the outermost TRANSACTION BEGIN [TBEGIN]). In addition to the condition code set by the TRANSACTION BEGIN (TBEGIN) instruction, condition codes 1-3 are also set when a transaction aborts.

   Therefore, the instruction sequence following the outermost TRANSACTION BEGIN (TBEGIN) instruction should be able to accommodate all four condition codes, even though the TBEGIN instruction only sets code 0. See the explanation of abort condition codes in programming note 3 on page 5-104.

5. On most models, improved performance may be realized, both on TRANSACTION BEGIN and when a transaction aborts, by specifying the minimum number of registers needed to be saved and restored in the general-register save mask.

6. While in the nonconstrained transactional-execution mode, a program may call a service function which may alter access registers, floating-point registers (including the floating-point control register), or vector registers. Although such a service routine may save the altered registers on entry and restore them at exit, the transaction may be aborted prior to normal exit of the routine. If the calling program makes no provision for preserving these registers while the CPU is in the nonconstrained transactional-execution mode, it may not be able to tolerate the service function's alteration of the registers.

   To prevent inadvertent alteration of access registers while in the nonconstrained transactional-execution mode, the program can set the allow-AR-modification control, bit 12 of the I_2 field of the TRANSACTION BEGIN instruction, to zero. Similarly, to prevent the inadvertent alteration of the floating-point registers or vector registers, the program can set the allow-floating-point-operation control, bit 13 of the I_2 field of the TBEGIN instruction, to zero.

7. Program-interruption conditions recognized during the execution of TRANSACTION BEGIN (TBEGIN) instruction are subject to the effective program-interruption filtering control set by any outer TBEGIN instructions. Program-interruption conditions recognized during the execution of the outermost TBEGIN instruction are not subject to filtering.

8. In order to update multiple storage locations in a serialized manner, conventional code sequences

may employ a lock word (semaphore). If (a) transactional execution is used to implement updates of multiple storage locations, (b) the program also provides a "fall-back" path to be invoked if the transaction aborts, and (c) the fall-back path employs a lock word, then the transactional-execution path should also test for the availability of the lock, and, if the lock is unavailable, end the transaction by means of the TRANSACTION END instruction and branch to the fall-back path. This ensures consistent access to the serialized resources, regardless of whether they are updated transactionally.

Alternatively, the program could abort if the lock is unavailable, however the abort processing may be significantly slower than simply ending the transaction via TEND.

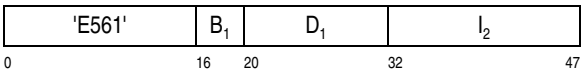
9. If the effective program-interruption filtering control (PIFC) is greater than zero, the CPU filters most data-exception program interruptions. If the effective allow-floating-point-operation (F) control is zero, the data-exception code (DXC) will not be set in the floating-point control register as a result of an abort due to a data-exception program-exception condition. In this scenario (filtering applies and the effective F control is zero), the only location in which the DXC can be inspected is in the TBEGIN-specified TDB. If the program's abort handler needs to inspect the DXC in such a situation, general register B_1 should be nonzero, such that a valid transaction-diagnostic-block address (TDBA) is set.

10. If a PER storage-alteration or zero-address-detection condition exists for the TBEGIN-specified TDB of the outermost TBEGIN instruction, and PER event suppression does not apply, the PER event will be recognized during the execution of the instruction, thus causing the transaction to be aborted immediately, regardless of whether any other abort condition exists.

11. When the ineffective-nonconstrained-transaction facility is installed, attempted uses of TBEGIN are unproductive. As observed by the program issuing TBEGIN when the facility is installed, the CPU appears to initiate a nonconstrained transaction and subsequently aborts the transaction. In this case, a TBEGIN-specified TDB is not stored and condition code 1 is set.

TRANSACTION BEGIN (TBEGINC)

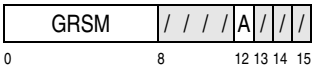
TBEGINC $D_1(B_1),I_2$ [SIL]



Execution of the TRANSACTION BEGIN (TBEGINC) instruction causes the CPU to enter the constrained transactional-execution mode or remain in the nonconstrained transactional-execution mode.

The first-operand address is not used to access storage. The B_1 field, bits 16-19 of the instruction, must contain zeros; otherwise, a specification exception is recognized.

The I_2 field contains various controls for the instruction and has the following format:



The bits of the I_2 field are defined as follows:

General Register Save Mask (GRSM): Bits 0-7 of the I_2 field contain the general register save mask (GRSM). Each bit of the GRSM represents an even-odd pair of general registers, where bit 0 represents registers 0 and 1, bit 1 represents registers 2 and 3, and so forth. When a bit in the GRSM is zero, the corresponding register pair is not saved. When a bit in the GRSM is one, the corresponding register pair is saved in a model-dependent location that is not directly accessible by the program.

If the transaction aborts, saved register pairs are restored to their contents when the outermost TRANSACTION BEGIN instruction was executed. The contents of all other (unsaved) general registers are not restored when a constrained transaction aborts.

When TBEGINC is used to continue execution in the nonconstrained transactional-execution mode, the general register save mask is ignored.

Allow AR Modification (A): The A control, bit 12 of the I_2 field, controls whether the transaction is allowed to modify an access register. The effective allow-AR-modification control is the logical AND of the A control in the TBEGINC instruction for the cur-

rent nesting level and for any outer TBEGIN or TBEGINC instructions.

If the effective A control is zero, the transaction will be aborted with abort code 11 (restricted instruction) if an attempt is made to modify any access register. If the effective A control is one, the transaction will not be aborted if an access register is modified (absent of any other abort condition).

Bits 8-11 and 13-15 of the I_2 field (bits 40-43 and 45-47 of the instruction) are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.

TRANSACTION BEGIN (TBEGINC) Processing

Execution of the TRANSACTION BEGIN (TBEGINC) instruction consists of the following steps: Note, exception checking does not necessarily need to occur in the order listed below. See Figure 7-400 on page 7-467 for the precise ordering requirements for exception checking.

1. A serialization function is performed.
2. A special-operation exception is recognized and the operation is suppressed if the transactional-execution control, bit 8 of control register 0, is zero.
3. A specification exception is recognized and the operation is suppressed if the B_1 field, bits 16-19 of the instruction, is nonzero.
4. If the CPU is already in the constrained transactional-execution mode, then a transaction-constraint-exception program exception is recognized and the operation is suppressed.
5. If the transaction nesting depth, when incremented by one, would exceed a model-dependent maximum transaction nesting depth, the transaction is aborted with abort code 13. See "Transaction Abort Processing" on page 5-103 for details on the handling of a transaction abort.
6. If the transaction nesting depth is zero, then the following is performed:

   a. The transaction-diagnostic-block address is considered to be invalid.

   b. The transaction-abort PSW is set from the contents of the current PSW, except that the instruction address of the transaction-abort PSW designates the TBEGINC instruction (rather than the next-sequential instruction).

   c. The contents of the general register pairs designated by the general-register save mask are saved in a model-dependent location that is not directly accessible by the program.
7. An effective value of the allow-AR-modification (A) control, bit 12 of the I_2 field of the instruction, is determined. The effective A control is the logical AND of the A control in the TBEGINC instruction for the current level and for any outer TRANSACTION BEGIN instructions.
8. If the transaction nesting depth is zero, then it is set to one, and the CPU enters the constrained transactional-execution mode. The effective allow-floating-point-operation and program-interruption-filtering controls (F and PIFC, respectively) are set to zero.

   If the transaction nesting depth is nonzero, then it is incremented by one, and the CPU remains in the nonconstrained transactional-execution mode. In this case, the effective value of the allow-floating-point-operation control is set to zero, and the effective value of the program-interruption-filtering control is unchanged. See "Allow Floating-Point Operation (F)" on page 7-461 and "Program-Interruption-Filtering Control (PIFC)" on page 7-461 for a description of these controls.
9. The instruction completes by setting condition code 0.

When TBEGINC is the target of an execute-type instruction, the operation is suppressed and an execute exception is recognized.

See "Event-Suppression Control (ES)" on page 4-28 for additional details on the recognition of PER instruction-fetching events during the execution of TRANSACTION BEGIN.

Resulting Condition Code:

0 Transaction initiation successful
1 –
2 –
3 –

Program Exceptions:

- Execute
- Operation (constrained transactional-execution facility not installed)
- Special operation
- Specification
- Transaction constraint

1.-7	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
8.A	Specification exception due to the B_1 field containing a nonzero value.
8.B	Abort due to exceeding transaction nesting depth.
9	Condition code 0 due to normal completion.

Figure 7-400. Priority of Execution: TRANSACTION BEGIN (TBEGINC)

Programming Notes:

1. Registers designated to be saved by the general register save mask are only restored if the transaction aborts, not when the transaction ends normally by means of TRANSACTION END. Only the registers designated by the GRSM of the outermost TRANSACTION BEGIN instruction are restored on abort.

   The I_2 field should designate all register pairs that provide input values that are changed by a constrained transaction. Thus, if the transaction is aborted, the input register values will be restored to their original contents when constrained transaction is reexecuted.

2. On most models, improved performance may be realized, both on TRANSACTION BEGIN and when a transaction aborts, by specifying the minimum number of registers needed to be saved and restored in the general-register save mask.

3. Figure 7-401 on page 7-467 illustrates the results of the TRANSACTION BEGIN instruction (both TBEGIN and TBEGINC) based on the current transaction nesting depth and, when the TND is nonzero, whether the CPU is in the nonconstrained or constrained transactional-execution mode.

		TND > 0	
Instruction	**TND = 0**	**NTX Mode**	**CTX Mode**
TBEGIN	Enter the nonconstrained transactional-execution mode	Continue in the nonconstrained transactional-execution mode	Transaction-constraint exception
TBEGINC	Enter the constrained transactional-execution mode	Continue in the nonconstrained transactional-execution mode	Transaction-constraint exception

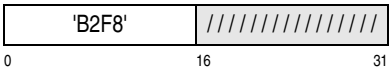
Explanation:

CTX	CPU is in the constrained transactional-execution mode
NTX	CPU is in the nonconstrained transactional-execution mode
TND	Transaction nesting depth at the beginning of the instruction

Figure 7-401. Operation of TRANSACTION BEGIN based on Transaction Nesting Depth and Transactional-Execution Mode

TRANSACTION END

TEND [S]



If the CPU is in the transactional-execution mode, the transaction nesting depth is decremented. If the transactional nesting depth is zero following the decrementing, all store accesses made by the transaction are committed, the CPU leaves the transactional-execution mode, and the instruction completes.

The effective allow-floating-point-operation (F) control, allow-AR-modification (A) control, and program-interruption-filtering control (PIFC) are reset to their respective values prior to the TRANSACTION BEGIN instruction that initiated the level being ended.

If the CPU is in the transactional-execution mode at the beginning the operation, the condition code is set to 0; otherwise, the condition code is set to 2.

A serialization function is performed at the completion of the operation.

When TRANSACTION END is the target of an execute-type instruction, the operation is suppressed and an execute exception is recognized.

A special-operation exception is recognized and the operation is suppressed if the transactional-execution control, bit 8 of control register 0, is zero.

Resulting Condition Code:

0 CPU in the transactional-execution mode at the beginning of the operation
1 –
2 CPU not in the transactional-execution mode at the beginning of the operation
3 –

Program Exceptions:

- Execute
- Operation (transactional-execution facility not installed)
- Special operation

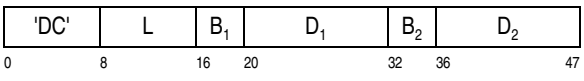
Programming Notes:

1. If the transactional-execution control, bit 8 of control register 0, is zero, the CPU cannot be in the transactional-execution mode. Attempted execution of a TRANSACTION END in this case results in a special-operation exception.

2. PER instruction-fetching and transaction-end events that are recognized at the completion of the outermost TRANSACTION END instruction do not result in the transaction being aborted. See “Event-Suppression Control (ES)” on page 4-28 for additional details on the recognition of PER instruction-fetching events during the execution of TRANSACTION END.

TRANSLATE

TR $D_1(L,B_1),D_2(B_2)$ [SS-a]



The bytes of the first operand are used as eight-bit arguments to reference a list designated by the second-operand address. Each function byte selected from the list replaces the corresponding argument in the first operand.

The L field specifies the length of only the first operand.

The bytes of the first operand are selected one by one for translation, proceeding left to right. Each argument byte is added to the initial second-operand address. The addition is performed following the rules for address arithmetic, with the argument byte treated as an eight-bit unsigned binary integer and extended with zeros on the left. The sum is used as the address of the function byte, which then replaces the original argument byte.

The operation proceeds until the first-operand field is exhausted. The list is not altered unless an overlap occurs.

When the operands overlap, the result is obtained as if each result byte were stored immediately after fetching the corresponding function byte.

Access exceptions are recognized only for those bytes in the second operand which are actually required.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2; fetch and store, operand 1)
- Transaction constraint

Programming Notes:

1. An example of the use of the TRANSLATE instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. TRANSLATE may be used to convert data from one code to another code.

3. The instruction may also be used to rearrange data. This may be accomplished by placing a pattern in the destination area, by designating the pattern as the first operand of TRANSLATE, and by designating the data that is to be rearranged as the second operand. Each byte of the pattern contains an eight-bit number specifying the byte destined for this position. Thus, when the instruction is executed, the pattern selects the bytes of the second operand in the desired order.

4. Because each eight-bit argument byte is added to the initial second-operand address to obtain the address of a function byte, the list may contain 256 bytes. In cases where it is known that not all eight-bit argument values will occur, it is possible to reduce the size of the list.

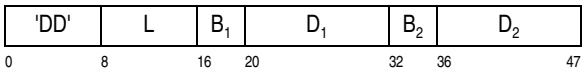
5. Significant performance degradation is possible when the second-operand address of TRANSLATE designates a location that is less than 256 bytes to the left of a 4 K-byte boundary. This is because the machine may perform a trial execution of the instruction to determine if the second operand actually crosses the boundary.

6. The fetch and subsequent store accesses to a particular byte in the first-operand field do not necessarily occur one immediately after the other. Thus, this instruction cannot be safely used to update a location in storage if the possibility exists that another CPU or a channel program may also be updating the location. An example of this effect is shown for OR (OI) in "Multiprogramming and Multiprocessing Examples" in Appendix A, "Number Representation and Instruction-Use Examples."

7. The storage-operand references of TRANSLATE may be multiple-access references. (See "Storage-Operand Consistency" on page 5-133.)

TRANSLATE AND TEST

TRT $D_1(L,B_1),D_2(B_2)$ [SS-a]



The bytes of the first operand are used as eight-bit arguments to select function bytes from a list designated by the second-operand address. The first nonzero function byte is inserted in general register 2, and the related argument address in general register 1.

The L field specifies the length of only the first operand.

The bytes of the first operand are selected one by one for translation, proceeding left to right. The first operand remains unchanged in storage. Calculation of the address of the function byte is performed as in the TRANSLATE instruction. The function byte retrieved from the list is inspected for a value of zero.

When the function byte is zero, the operation proceeds with the next byte of the first operand. When the first-operand field is exhausted before a nonzero function byte is encountered, the operation is completed by setting condition code 0. The contents of general registers 1 and 2 remain unchanged.

When the function byte is nonzero, the operation is completed by inserting the function byte in general register 2 and the related argument address in general register 1. This address points to the argument byte last translated. The function byte replaces bits 56-63 of general register 2, and bits 0-55 of this register remain unchanged. In the 24-bit addressing mode, the address replaces bits 40-63 of general register 1, and bits 0-39 of this register remain unchanged. In the 31-bit addressing mode, the address replaces bits 33-63 of general register 1, bit 32 of this register is set to zero, and bits 0-31 of the register remain unchanged. In the 64-bit addressing mode, the address replaces bits 0-63 of general register 1.

When the function byte is nonzero, either condition code 1 or 2 is set, depending on whether the argument byte is the rightmost byte of the first operand. Condition code 1 is set if one or more argument bytes remain to be translated. Condition code 2 is set if no more argument bytes remain.

The contents of access register 1 always remain unchanged.

Access exceptions are recognized only for those bytes in the second operand which are actually required. Access exceptions are not recognized for those bytes in the first operand which are to the right of the first byte for which a nonzero function byte is obtained.

Resulting Condition Code:

0 All function bytes zero
1 Nonzero function byte; first-operand field not exhausted
2 Nonzero function byte; first-operand field exhausted
3 --

Program Exceptions:

- Access (fetch, operands 1 and 2)
- Transaction constraint

Programming Notes:

1. An example of the use of the TRANSLATE AND TEST instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. TRANSLATE AND TEST may be used to scan the first operand for characters with special meaning. The second operand, or list, is set up with all-zero function bytes for those characters to be skipped over and with nonzero function bytes for the characters to be detected.

TRANSLATE AND TEST EXTENDED

TRTE $R_1,R_2[,M_3]$ [RRF-c]

TRANSLATE AND TEST REVERSE EXTENDED

TRTRE $R_1,R_2[,M_3]$ [RRF-c]

The argument characters of the first operand are used to select function codes from a function-code table designated by general register 1. For TRANSLATE AND TEST EXTENDED, the argument characters are processed in a left-to-right direction; for TRANSLATE AND TEST REVERSE EXTENDED, the argument characters are processed in a right-to-left direction. When a nonzero function code is selected, it is inserted in general register R_2, the related argument address is placed in general register R_1, and the first-operand length in general register $R_1 + 1$ is decremented by the number of bytes processed. The operation proceeds until a nonzero function code is encountered, the end of the first operand is reached, or a CPU-determined number of characters have been processed, whichever occurs first. The result is indicated in the condition code.

The R_1 field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

General register $R_1 + 1$ contains the length of the first operand in bytes.

Operation of the instruction is subject to controls specified in the M_3 field, bits 16-19 of the instruction. The M_3 field has the following format:

The bits of the M field are defined as follows:

- ***Argument-Character Control (A):*** The A bit, bit 0 of the M_3 field, controls the size of the argument characters in the first operand. When the A bit is zero, the argument characters are one byte in length. When the A bit is one, the argument characters are two bytes in length.

  When the A bit is one, the first-operand length in general register $R_1 + 1$ must specify an even number of bytes; otherwise, a specification exception is recognized.

- ***Function-Code Control (F):*** The F bit, bit 1 of the M_3 field, controls the size of the function codes in the function-code table designated by general register 1. When the F bit is zero, a function code is one byte in length. When the F bit is one, a function code is two bytes in length.

- ***Argument-Character Limit (L):*** The L bit, bit 2 of the M_3 field, controls whether argument characters with a value greater than 255 are used to select function codes. When the L bit is zero, argument character values are unlimited. When the L bit is one, an argument character with a value greater than 255 is not used to select a function code; rather, the function code is assumed to contain zeros.

  When the A bit of the M_3 field is zero, the L bit is ignored.

- ***Unassigned:*** Bit 3 of the M_3 field is unassigned and should contain zero; otherwise, the program may not operate compatibly in the future.

Figure 7-402 summarizes the size of the function-code table based on the A, F, and L bits.

The location of the first argument character in the first operand is designated by the contents of general register R_1. The location of the leftmost byte of the function-code table is designated by the contents of

A bit	F bit	L bit	Table Size (bytes)
0	0	–	256
0	1	–	512
1	0	0	65,536
1	1	0	131,072
1	0	1	256
1	1	1	512

Explanation:

– Not applicable

Figure 7-402. Function-Code Table Size

general register 1. In the 24-bit or 31-bit addressing mode, the number of bytes in the first-operand location is specified by the contents of bit positions 32-63 of general register $R_1 + 1$, and those contents are treated as a 32-bit unsigned binary integer. In the 64-bit addressing mode, the number of bytes in the first-operand location is specified by the entire contents of general register $R_1 + 1$, and those contents are treated as a 64-bit unsigned binary integer.

The handling of the argument-character address in general register R_1 is dependent on the addressing mode. In the 24-bit addressing mode, the contents of bit positions 40-63 of the register constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the register constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 constitute the address.

The function-code table is treated as being on a doubleword boundary. The handling of the function-code-table address in general register 1 is dependent on the addressing mode. In the 24-bit addressing mode, the contents of bit positions 40-60 of the register constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-60 of the register constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-60 of the register constitute the address. In all addressing modes, bit positions 61-63 are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.

When a nonzero function code is selected, it is inserted into either bits 56-63 or bits 48-63 of general register R_2, depending on whether the F bit of the M_3 field is zero or one, respectively. In the 24-bit or 31-bit addressing mode, bits 0-31 of general register R_2 are unchanged, and bits 32-55 (F=0) or 32-47 (F=1) of the register are set to zero. In the 64-bit addressing mode, bits 0-55 (F=0) or 0-47 (F=1) are set to zero.

The contents of the registers just described are shown in Figure 7-403.

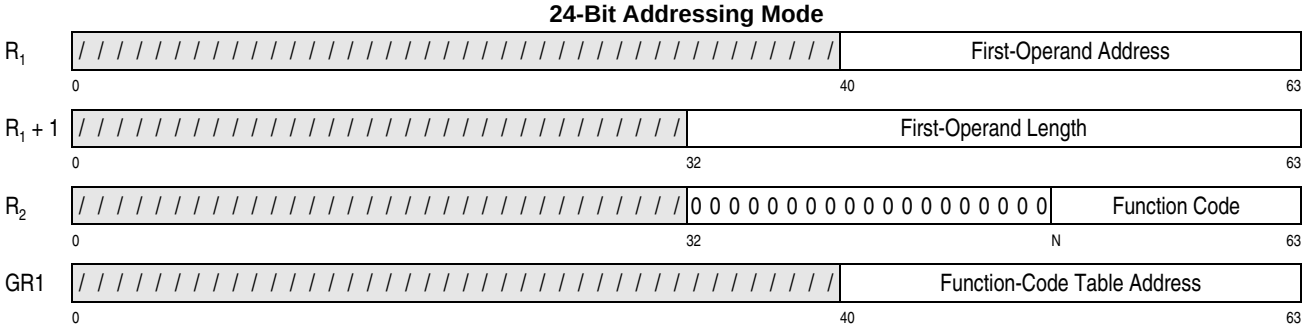


Figure 7-403. Register Contents for TRANSLATE AND TEST EXTENDED and TRANSLATE AND TEST REVERSE EXTENDED (Part 1 of 2)

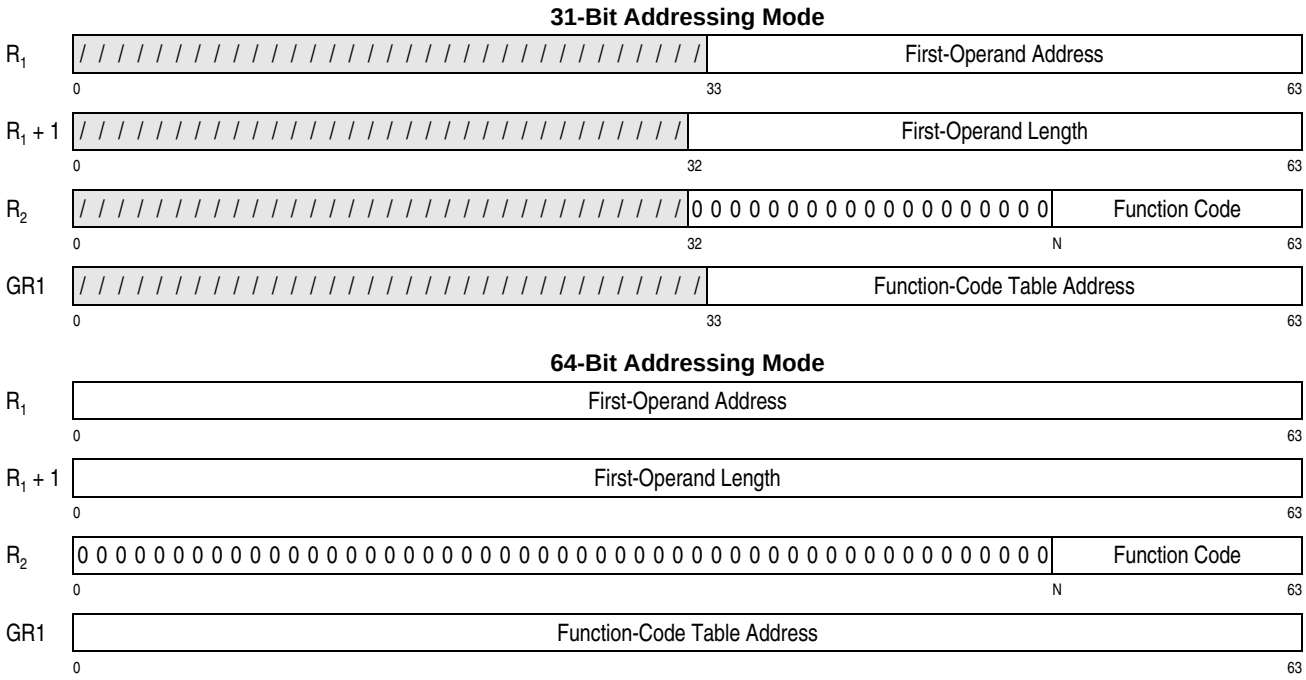

Explanation:

N 56 when the F-bit = 0; 48 when the F-bit = 1

Figure 7-403. Register Contents for TRANSLATE AND TEST EXTENDED and TRANSLATE AND TEST REVERSE EXTENDED (Part 2 of 2)

The argument characters of the first operand are selected one by one for processing, proceeding in a left-to-right direction for TRANSLATE AND TEST EXTENDED, or in a right-to-left direction for TRANSLATE AND TEST REVERSE EXTENDED. Depending on the A bit of the M_3 field, the argument characters are treated as either eight-bit or sixteen-bit unsigned binary integers, extended with zeros on the left.

When the F bit of the M_3 field is zero, the argument character is added to the function-code-table address in general register 1 to form the address of the selected 8-bit function code. When the F bit is one, the argument character, extended on the right with a binary 0, is added to the function-code-table address in general register 1 to form the address of the selected 16-bit function code. These additions follow the rules for address arithmetic.

When both the A and L bits are one, and the value of the argument character is greater than 255, then the function-code table is not accessed. The function code is assumed to contain zero in this case.

When the selected function code contains zero, or when the function code is assumed to contain zero, processing continues with the next argument character in the first operand. The operation proceeds until a nonzero function code is selected, the first-operand location is exhausted, or a CPU-determined number of first-operand bytes have been processed.

When the first-operand location is exhausted without having selected a nonzero function code, general register R_1 is either incremented or decremented by the first operand length in general register $R_1 + 1$; general register $R_1 + 1$ is set to zero; general register R_2 is set as though a function code of zero was selected; and condition code 0 is set. For TRANSLATE AND TEST EXTENDED, general register R_1 is incremented by the first operand length; for TRANSLATE AND TEST REVERSE EXTENDED, general register R_1 is decremented by the first operand length. In the 24-bit or 31-bit addressing mode, bits 0-31 of general register R_2 are unchanged, and bits 32-63 of the register are set to zeros; in the 64-bit addressing mode, bits 0-63 of general register R_2 are set to zeros.

When a nonzero function code is selected, the function code replaces bits 56-63 or bits 48-63 of general register R_2, depending on whether the F bit is zero or one, respectively; depending on the addressing mode, the remaining bits in general register R_2 are set to zeros; the address of the argument character used to select the nonzero function code is placed in general register R_1; general register $R_1 + 1$ is decremented by the number of first-operand bytes processed prior to selecting the nonzero function byte; and condition code 1 is set. In the 24-bit or 31-bit addressing mode, bits 0-31 of general register R_2 are unchanged, and bits 32-55 (F=0) or 32-47 (F=1) are set to zero; in the 64-bit addressing mode, bits 0-55 (F=0) or 0-47 (F=1) are set to zeros.

When a CPU-determined number of bytes have been processed, general register R_1 is either incremented or decremented by the number of bytes in the first operand that were processed, general register $R_1 + 1$ is decremented by this number, and condition code 3 is set. For TRANSLATE AND TEST EXTENDED, general register R_1 is incremented by the number of bytes processed; for TRANSLATE AND TEST REVERSE EXTENDED, general register R_1 is decremented by the number of bytes processed. Condition code 3 may be set even when the first-operand location is exhausted or when the next argument character to be processed selects a nonzero function byte. In these cases, condition code 0 or 1 will be set when the instruction is executed again.

When the R_2 field designates the same register as register R_1, the updated first-operand address is placed in the register. When the R_2 field designates the same register as register R_1+1, the updated first-operand length is placed in the register.

When general register R_1 is updated in the 24-bit or 31-bit addressing mode, bits 32-39, in the 24-bit mode, or bit 32, in the 31-bit mode, may be set to zeros or may remain unchanged from their original values.

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers R_1, $R_1 + 1$, and R_2 always remain unchanged.

The amount of processing that results in the setting of condition code 3 is determined by the CPU on the basis of improving system performance, and it may be a different amount each time the instruction is executed.

Access exceptions for the portion of the first operand beyond the last byte processed may or may not be recognized. For an operand longer than 4K bytes, access exceptions are not recognized for locations more than 4K bytes beyond the last byte processed. When the length of the first operand is zero, no access exceptions for the first operand are recognized.

Access exceptions for any byte of the function-code table specified by general register 1 may be recognized, even if not all bytes are used.

Special Conditions

A specification exception is recognized for any of the following conditions:

1. The R_1 field designates an odd-numbered register.
2. The A bit of the M_3 field is one and the first operand length in general register $R_1 + 1$ is odd.

Resulting Condition Code:

0 Entire first operand processed without selecting a nonzero function code
1 Nonzero function code selected
2 --
3 CPU-determined number of bytes processed

Program Exceptions:

- Access (fetch, operand 1 and the function-code table)
- Operation (if the parsing-enhancement facility is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. When condition code 3 is set, the program can simply branch back to the instruction to continue processing. The program need not determine the number of bytes that were processed.
2. The storage-operand references of TRANSLATE AND TEST EXTENDED and TRANSLATE AND TEST REVERSE EXTENDED may be multiple-access references. (See “Storage-Operand Consistency” on page 5-133.)

3. The following example illustrates the use of TRANSLATE AND TEST EXTENDED to parse a buffer of 16-bit Unicode argument characters for delimiters such as those used in common markup languages. Because the Unicode representation of such delimiters is in the range of 0000 - 00FF hex, a limited function-code table is used (the L bit of the M_3 field is one).

   In this example, the variable BUFFER is used to hold the 16-bit characters to be parsed. If a delimiting character is not found, control passes to the label NOTFND. If a delimiting character is found, the function code placed in general register R_2 is used as an index to the branch table that passes control to a specific processing routine (not shown).

BUFFER   DS     CL8192           Buffer of 16-bit chars.
```

   Note, the branch to label NOT_FND does not result from a function-code-table entry of zeros. Rather, the branch is taken when the first operand is exhausted without selecting a nonzero function-code-table entry.

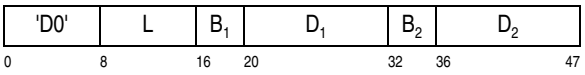
4. As an alternative to treating the selected function-code value as a table index (as shown in programming note 3, above), the function-code value may be used directly as a branch offset.

5. The performance of TRANSLATE AND TEST EXTENDED and TRANSLATE AND TEST REVERSE EXTENDED may be significantly slower if the program modifies the function-code table prior to execution of the instruction.

6. In the assembler syntax, the M_3 operand is considered to be optional. When the M_3 field is not coded, it is considered to contain zeros by the assembler.

TRANSLATE AND TEST REVERSE

TRTR $D_1(L,B_1),D_2(B_2)$ [SS-a]



The bytes of the first operand are used as eight-bit arguments to select function bytes from a list designated by the second-operand address. The first-operand address designates the rightmost byte of the first operand. The first nonzero function byte is inserted in general register 2, and the related argument address in general register 1.

The L field specifies the length of only the first operand.

The bytes of the first operand are selected one by one for translation, proceeding from right to left. The first operand remains unchanged in storage. Calculation of the address of the function byte is performed as in the TRANSLATE instruction. The function byte retrieved from the list is inspected for a value of zero.

When the function byte is zero, the operation proceeds with the preceding byte of the first operand. When the first-operand field is exhausted before a nonzero function byte is encountered, the operation is completed by setting condition code 0. The contents of general registers 1 and 2 remain unchanged.

When the function byte is nonzero, the operation is completed by inserting the function byte in general register 2 and the related argument address in general register 1. This address points to the argument byte last translated. The function byte replaces bits 56-63 of general register 2, and bits 0-55 of this reg-

ister remain unchanged. In the 24-bit addressing mode, the address replaces bits 40-63 of general register 1, and bits 0-39 of this register remain unchanged. In the 31-bit addressing mode, the address replaces bits 33-63 of general register 1, and bits 0-32 of this register remain unchanged. In the 64-bit addressing mode, the address replaces bits 0-63 of general register 1.

When the function byte is nonzero, either condition code 1 or 2 is set, depending on whether the argument byte is the leftmost byte of the first operand. Condition code 1 is set if one or more argument bytes remain to be translated. Condition code 2 is set if no more argument bytes remain.

The contents of access register 1 always remain unchanged.

Access exceptions can be recognized for any byte in either the first or in the second operand.

Resulting Condition Code:

0 All function bytes zero
1 Nonzero function byte; first-operand field not exhausted
2 Nonzero function byte; first-operand field exhausted
3 --

Program Exceptions:

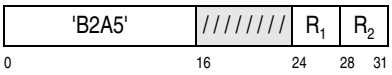
- Access (fetch, operands 1 and 2)
- Operation (if the extended-translation facility 3 is not installed)
- Transaction constraint

Programming Note:

TRANSLATE AND TEST REVERSE may be used to scan the first operand for characters with special meaning. The second operand, or list, is set up with all-zero function bytes for those characters to be skipped over and with nonzero function bytes for the characters to be detected.

TRANSLATE EXTENDED

TRE R_1,R_2 [RRE]



The bytes of the first operand are compared to a test byte in general register 0 and, unless an equal comparison occurs, are used as eight-bit arguments to reference a 256-byte translation table designated by the second-operand address. Each function byte selected from the second operand replaces the corresponding argument in the first operand. The operation proceeds until a first-operand byte equal to the test byte is encountered, the end of the first operand is reached, or a CPU-determined number of bytes have been processed, whichever occurs first. The result is indicated in the condition code.

The R_1 field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The location of the leftmost byte of the first operand and second operand is designated by the contents of general registers R_1 and R_2, respectively. In the 24-bit or 31-bit addressing mode, the number of bytes in the first-operand location is specified by the contents of bit positions 32-63 of general register $R_1 + 1$, and those contents are treated as a 32-bit unsigned binary integer. In the 64-bit addressing mode, the number of bytes in the first-operand location is specified by the entire contents of general register $R_1 + 1$, and those contents are treated as a 64-bit unsigned binary integer.

The handling of the addresses in general registers R_1 and R_2 is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers R_1 and R_2 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of the registers constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 constitute the address.

The test byte is in bit positions 56-63 of general register 0, and the contents of bit positions 0-55 of this register are ignored.

The contents of the registers just described are shown in Figure 7-404.

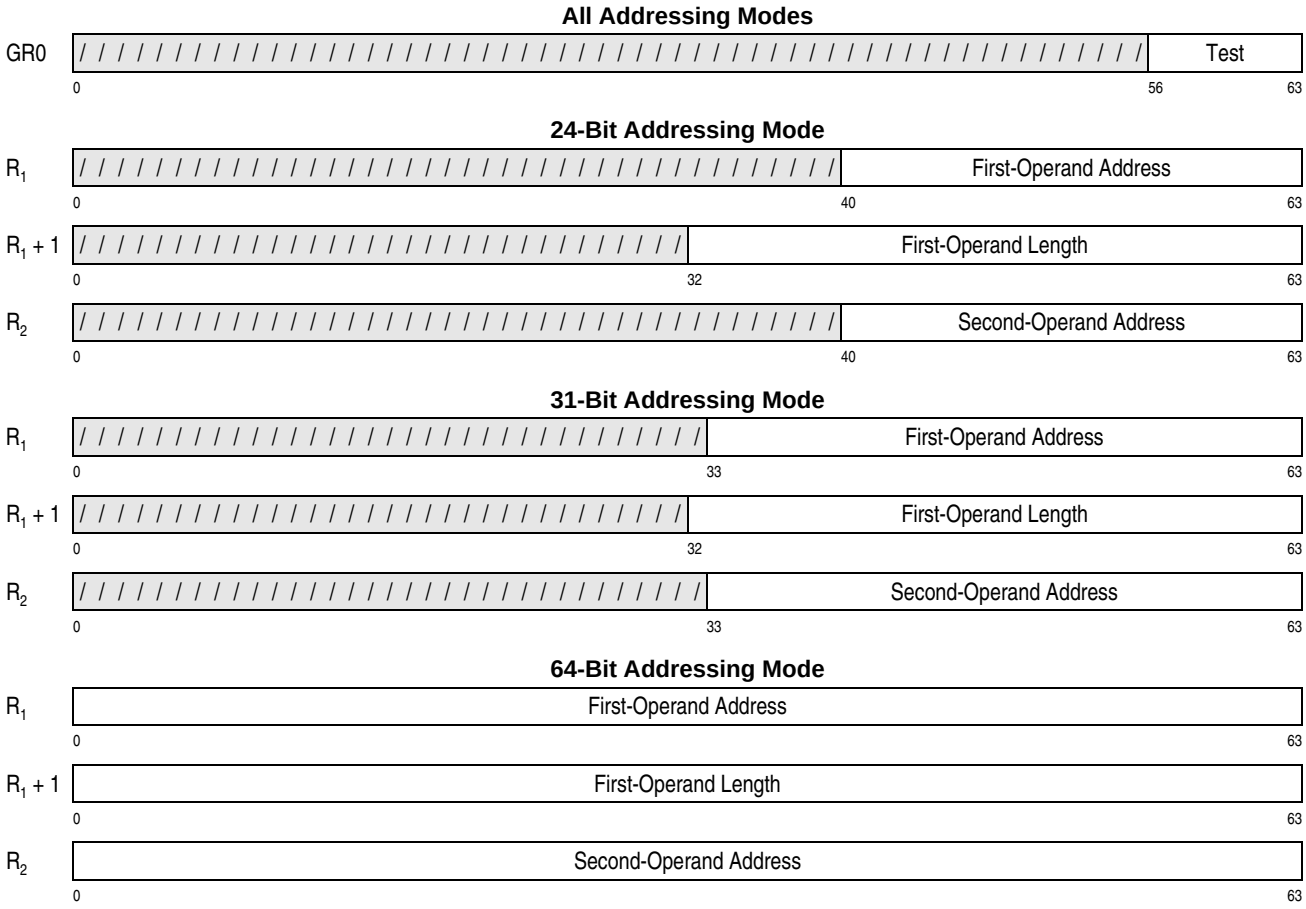


Figure 7-404. Register Contents for TRANSLATE EXTENDED

The bytes of the first operand are selected one by one for translation, proceeding left to right. Each argument byte is first compared to the test byte in general register 0. If the result is an equal comparison, the operation is completed. If the argument byte is not equal to the test byte, the argument byte is added to the initial second-operand address. The addition is performed following the rules for address arithmetic, with the argument byte treated as an eight-bit unsigned binary integer and extended with zeros on the left. The sum is used as the address of the function byte, which then replaces the original argument byte. The second operand is not altered unless an overlap occurs.

The operation proceeds until a first-operand byte equal to the test byte is encountered, the first-operand location is exhausted, or a CPU-determined number of first-operand bytes have been processed.

When the first-operand location is exhausted without finding a byte equal to the test byte, condition code 0 is set. When a first-operand byte equal to the test byte is encountered, condition code 1 is set. When a CPU-determined number of bytes have been processed, condition code 3 is set. Condition code 3 may be set even when the first-operand location is exhausted or when the next byte to be processed is equal to the test byte. In these cases, condition code 0 or 1, respectively, will be set when the instruction is executed again.

If the operation is completed with condition code 0, the contents of general register R_1 are incremented by the contents of general register $R_1 + 1$, and then the contents of general register $R_1 + 1$ are set to zero. If the operation is completed with condition code 1, the contents of general register $R_1 + 1$ are decremented by the number of bytes processed

before the first-operand byte equal to the test byte was encountered, and the contents of general register R_1 are incremented by the same number, so that general register R_1 contains the address of the equal byte. If the operation is completed with condition code 3, the contents of general register $R_1 + 1$ are decremented by the number of bytes processed, and the contents of general register R_1 are incremented by the same number, so that the instruction, when reexecuted, resumes at the next byte to be processed. When general register R_1 is updated in the 24-bit or 31-bit addressing mode, bits 32-39 of it, in the 24-bit mode, or bit 32, in the 31-bit mode, may be set to zeros or may remain unchanged from their original values.

In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers R_1 and $R_1 + 1$ always remain unchanged.

The amount of processing that results in the setting of condition code 3 is determined by the CPU on the basis of improving system performance, and it may be a different amount each time the instruction is executed.

When the R_2 register is the same register as the R_1 or $R_1 + 1$ register, the results are unpredictable.

When R_1 or R_2 is zero, the results are unpredictable.

When the second operand overlaps the first operand, the results are unpredictable.

Access exceptions for the portion of the first operand to the right of the last byte processed may or may not be recognized. For an operand longer than 4K bytes, access exceptions are not recognized for locations more than 4K bytes beyond the last byte processed.

Access exceptions for all 256 bytes of the second operand may be recognized, even if not all bytes are used.

Access exceptions are not recognized if the R_1 field is odd. When the length of the first operand is zero, no access exceptions for the first operand are recognized.

Resulting Condition Code:

0 Entire first operand processed without finding a byte equal to the test byte
1 First-operand byte is equal to the test byte
2 --
3 CPU-determined number of bytes processed

Program Exceptions:

- Access (fetch, operand 2; store, operand 1)
- Specification
- Transaction constraint

Programming Notes:

1. When condition code 3 is set, the program can simply branch back to the instruction to continue the translation. The program need not determine the number of bytes that were translated.
2. The instruction can improve performance by being used in place of a TRANSLATE AND TEST instruction that locates an escape character, followed by a TRANSLATE instruction that translates the bytes preceding the escape character.
3. The storage-operand references of TRANSLATE EXTENDED may be multiple-access references. (See “Storage-Operand Consistency” on page 5-133.)

TRANSLATE ONE TO ONE

TROO $R_1,R_2[,M_3]$ [RRF-c]

TRANSLATE ONE TO TWO

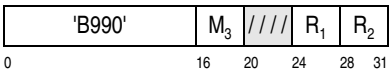
TROT $R_1,R_2[,M_3]$ [RRF-c]

TRANSLATE TWO TO ONE

TRTO $R_1,R_2[,M_3]$ [RRF-c]

TRANSLATE TWO TO TWO

TRTT $R_1,R_2[,M_3]$ [RRF-c]



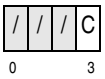
The characters of the second operand are used as arguments to select function characters from a translation table designated by the address in general register 1.

When the ETF2-enhancement facility is not installed, or when the test-character-comparison control is zero, each function character selected from the translation table is compared to a test character in general register 0, and, unless an equal comparison occurs, is placed at the first-operand location. The operation proceeds until a selected function character equal to the test character is encountered, the end of the second operand is reached, or a CPU-determined number of characters have been processed, whichever occurs first.

When the ETF2-enhancement facility is installed and the test-character-comparison control is one, test-character comparison is not performed. Each function character selected from the translation table is placed at the first operation location. The operation proceeds until the end of the second operand is reached, or a CPU-determined number of characters have been processed, whichever occurs first.

The result is indicated in the condition code.

When the ETF2-enhancement facility is installed, the M_3 field has the following format:



The bits of the M_3 field are defined as follows:

- ***Unassigned:*** Bits 0-2 are unassigned and should contain zeros; otherwise, the program may not operate compatibly in the future.
- ***Test-Character-Comparison Control (C):*** The C bit, bit 3 of the M_3 field, controls test-character comparison. When the C bit is zero, test-character comparison is performed. When the C bit is one, test-character comparison is not performed.

When the ETF2-enhancement facility is not installed, the M_3 field is ignored. When the ETF2-enhancement facility is installed in the z/Architecture architectural mode, it is unpredictable whether the M_3 field is ignored in the ESA/390-compatibility mode.

The lengths of the operand and test characters are as follows:

- For TRANSLATE ONE TO ONE, the second-operand, first-operand, and test characters are single bytes.
- For TRANSLATE ONE TO TWO, the second-operand characters are single bytes, and the first-operand and test characters are double bytes.
- For TRANSLATE TWO TO ONE, the second-operand characters are double bytes, and the first-operand and test characters are single bytes.
- For TRANSLATE TWO TO TWO, the second-operand, first-operand, and test characters are double bytes.

For TRANSLATE ONE TO ONE and TRANSLATE TWO TO ONE, the test character is in bit positions 56-63 of general register 0. For TRANSLATE ONE TO TWO and TRANSLATE TWO TO TWO, the test character is in bit positions 48-63 of general register 0.

The R_1 field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The location of the leftmost byte of the first operand and second operand is designated by the contents of general registers R_1 and R_2, respectively. In the 24-bit or 31-bit addressing mode, the number of bytes in the second-operand location is specified by the contents of bit positions 32-63 of general register $R_1 + 1$, and those contents are treated as a 32-bit unsigned binary integer. In the 64-bit addressing mode, the number of bytes in the second-operand location is specified by the contents of bit positions 0-63 of general register $R_1 + 1$, and those contents are treated as a 64-bit unsigned binary integer. The length of the first-operand location is considered to be the same as that of the second operand for TRANSLATE ONE TO ONE and TRANSLATE TWO

TO TWO, twice that for TRANSLATE ONE TO TWO, and one half that for TRANSLATE TWO TO ONE.

For TRANSLATE TWO TO ONE and TRANSLATE TWO TO TWO, the length in general register $R_1 + 1$ must be an even number of bytes; otherwise, a specification exception is recognized.

The translation table is treated as being on a doubleword boundary for TRANSLATE ONE TO ONE and TRANSLATE ONE TO TWO. For TRANSLATE TWO TO ONE and TRANSLATE TWO TO TWO, the translation table is treated as follows:

- When the ETF2-enhancement facility is not installed, the translation table is treated as being on a 4 K-byte boundary.
- When the ETF2-enhancement facility is installed, the translation table is treated as being on a doubleword boundary.

The rightmost bits of the register that are not used to form the address, which are bits 61-63 in the doubleword case and bits 52-63 in the 4 K-byte case, are ignored but should contain zeros; otherwise, the program may not operate compatibly in the future.

The handling of the addresses in general registers R_1, R_2, and 1 is dependent on the addressing mode.

In the 24-bit addressing mode, the contents of bit positions 40-63 of general registers R_1 and R_2 and 40-60 or 40-51 of 1 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of registers R_1 and R_2 and 33-60 or 33-51 of 1 constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 of registers R_1 and R_2 and 0-60 or 0-51 of 1 constitute the address.

The contents of the registers just described are shown in Figure 7-405.

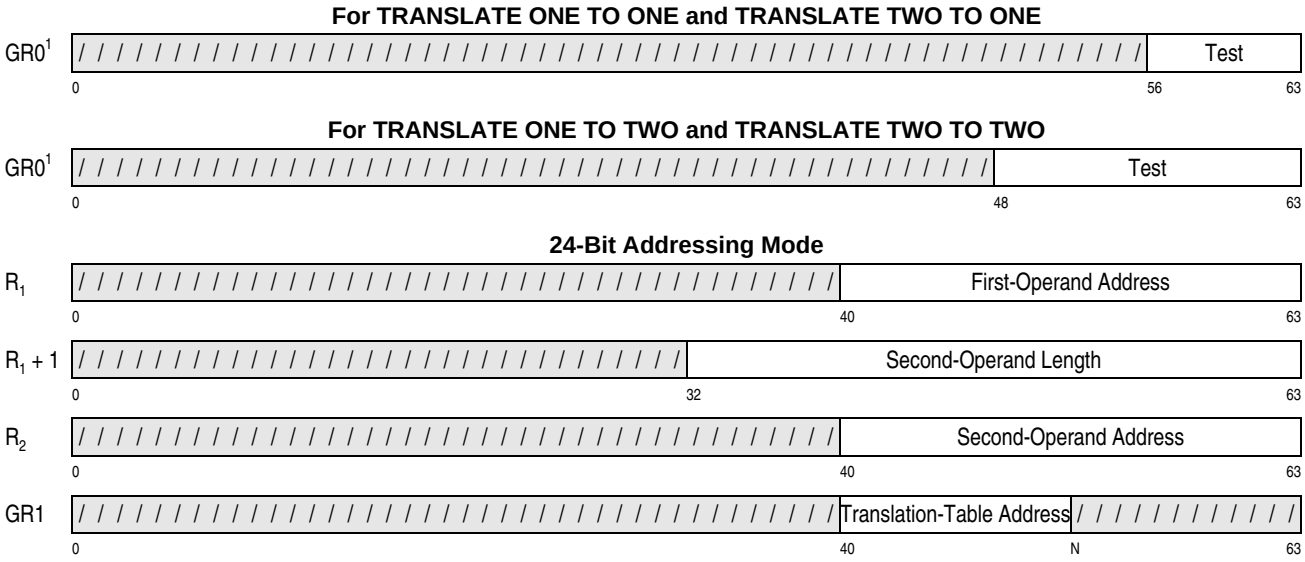


Figure 7-405. Register Contents for TRANSLATE ONE TO ONE, TRANSLATE ONE TO TWO, TRANSLATE TWO TO ONE, and TRANSLATE TWO TO TWO (Part 1 of 2)

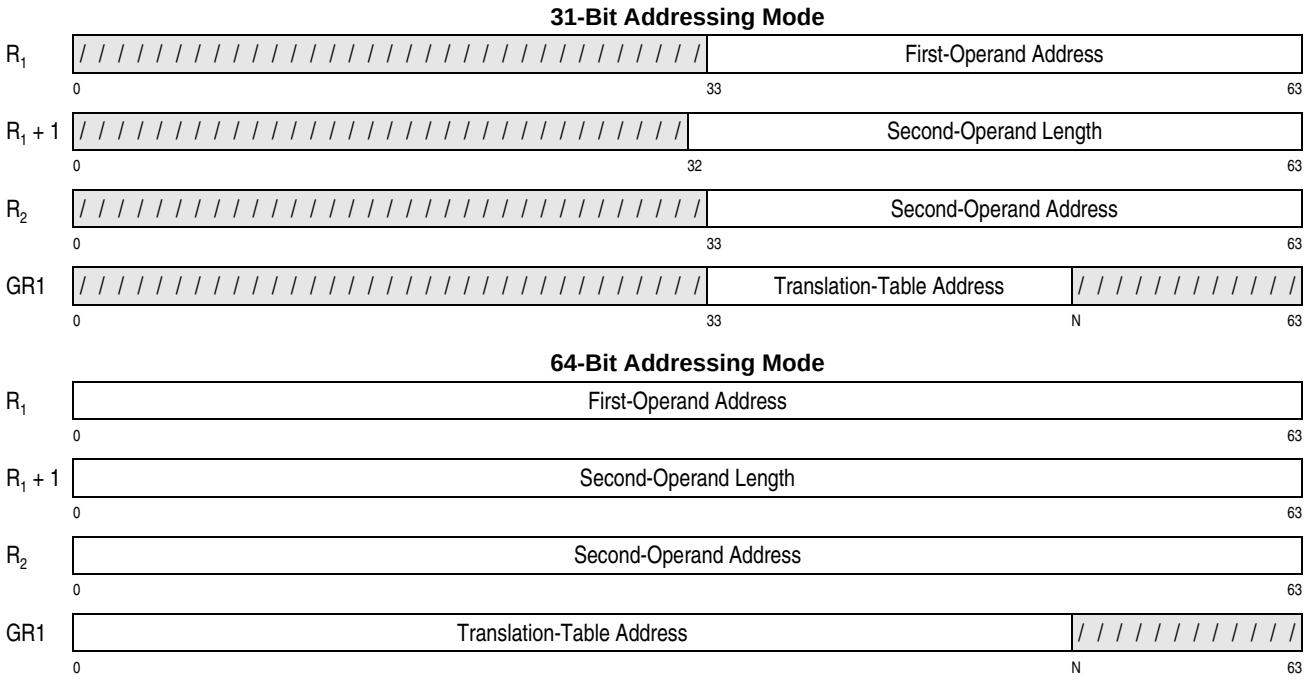


Explanation:

1 When the ETF2-enhancement facility is not installed, or when the C bit, bit 3 of the M3 field, is zero, test-character comparison is performed. When the ETF2-enhancement facility is installed and the C bit is one, test-character comparison is not performed, and general register 0 is ignored.

N When the ETF2-enhancement facility is not installed, N is 61 for TRANSLATE ONE TO ONE and TRANSLATE ONE TO TWO, and N is 52 for TRANSLATE TWO TO ONE and TRANSLATE TWO TO TWO. When the ETF2-enhancement facility is installed, N is 61.

Figure 7-405. Register Contents for TRANSLATE ONE TO ONE, TRANSLATE ONE TO TWO, TRANSLATE TWO TO ONE, and TRANSLATE TWO TO TWO (Part 2 of 2)

In the access-register mode, the contents of access registers R_1, R_2, and 1 are used for accessing the first operand, second operand, and translation table, respectively.

The length of the translation table designated by the address contained in general register 1 is as follows:

- For TRANSLATE ONE TO ONE, the translation-table length is 256 bytes; each of the 256 function characters is a single byte.
- For TRANSLATE ONE TO TWO, the translation-table length is 512 bytes; each of the 256 function characters is a double byte.
- For TRANSLATE TWO TO ONE, the translation-table length is 65,536 (64K) bytes; each of the 64K function characters is a single byte.
- For TRANSLATE TWO TO TWO, the translation-table length is 131,072 (128K) bytes; each of the 64K function characters is a double byte.

The characters of the second operand are selected one by one for translation, proceeding left to right. Each argument character is added to the initial translation-table address. The addition is performed following the rules for address arithmetic, with the argument character treated as follows:

- For TRANSLATE ONE TO ONE, the argument character is treated as an eight-bit unsigned binary integer extended on the left with 56 zeros.
- For TRANSLATE ONE TO TWO, the argument character is treated as an eight-bit unsigned binary integer extended on the right with a zero and on the left with 55 zeros.
- For TRANSLATE TWO TO ONE, the argument character is treated as a 16-bit unsigned binary integer extended on the left with 48 zeros.
- For TRANSLATE TWO TO TWO, the argument character is treated as a 16-bit unsigned binary

integer extended on the right with a zero and on the left with 47 zeros.

The rightmost bits of the translation-table address that are ignored (61-63 or 52-63) are treated as zeros during this addition.

The sum is used as the address of the function character.

When the ETF2-enhancement facility is not installed, or when the test-character-comparison control is zero, processing is as follows. Each function character selected as described above is first compared to the test character in general register 0. If the result is an equal comparison, the operation is completed. If the function character is not equal to the test character, the function character is placed in the next available character position in the first operand, that is, the first function character is placed at the beginning of the first-operand location, and each successive function character is placed immediately to the right of the preceding character. The second operand and the translation table are not altered unless an overlap occurs.

The operation proceeds until a selected function character equal to the test character is encountered, the second-operand location is exhausted, or a CPU-determined number of second-operand characters have been processed.

When the ETF2-enhancement facility is installed and the test-character-comparison control is one, processing is as described above, except that no test-character comparison is performed.

When a selected function character equal to the test character is encountered, condition code 1 is set. When the second-operand location is exhausted without finding a selected function character equal to the test character, condition code 0 is set. When a CPU-determined number of characters have been processed, condition code 3 is set. Condition code 3 may be set even when the next character to be processed results in a function character equal to the test character or when the second-operand location is exhausted. In these cases, condition code 1 or 0, respectively, will be set when the instruction is executed again. When the ETF2-enhancement facility is installed and the test-character-comparison control is one, condition code 1 does not apply.

If the operation is completed with condition code 0, the contents of general register R_2 are incremented by the contents of general register $R_1 + 1$, and the contents of general register R_1 are incremented as follows:

- For TRANSLATE ONE TO ONE and TRANSLATE TWO TO TWO, the same as for general register R_2.
- For TRANSLATE ONE TO TWO, by twice the amount for general register R_2.
- For TRANSLATE TWO TO ONE, by one half the amount for general register R_2.

The contents of general register $R_1 + 1$ are then set to zero.

If the operation is completed with condition code 1, the contents of general register $R_1 + 1$ are decremented by the number of second-operand bytes processed before the character that selected a function character equal to the test character was encountered, and the contents of general register R_2 are incremented by the same number, so that general register R_2 contains the address of the character that selected a function character equal to the test character. The contents of general register R_1 are incremented by the same, twice, or one half the number, as described above for condition code 0.

If the operation is completed with condition code 3, the contents of general register $R_1 + 1$ are decremented by the number of second-operand bytes processed, and the contents of general register R_2 are incremented by the same number, so that the instruction, when reexecuted, contains the address of the next character to be processed. The contents of general register R_1 are incremented by the same, twice, or one half the number, as described above for condition code 0.

When general registers R_1 and R_2 are updated in the 24-bit or 31-bit addressing mode, the bits in bit positions 32-39 of them that are not part of the address may be set to zeros or may remain unchanged from their original values. In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general registers R_1, $R_1 + 1$, and R_2 always remain unchanged.

The contents of general registers 0 and 1 remain unchanged.

The amount of processing that results in the setting of condition code 3 is determined by the CPU on the basis of improving system performance, and it may be a different amount each time the instruction is executed.

When any of the following conditions are true, the results are unpredictable:

- Either the R_1 or $R_1 + 1$ registers are the same register as the R_2 register.
- The R_1 register is register 0,
- The R_2 register is register 0, and either the ETF2-enhancement facility is not installed, or the facility is installed and the C bit is zero.
- The R_2 register is register 1.
- Any of the first and second operands and the translation table overlaps another of them.

Access exceptions for the portion of the first or second operand to the right of the last character processed may or may not be recognized. For an operand longer than 4K bytes, access exceptions are not recognized for locations more than 4K bytes beyond the last character processed.

Access exceptions for all characters of the translation table may be recognized even if not all characters are used.

Access exceptions are not recognized if the R_1 field is odd. When the length of the second operand is zero, no access exceptions for the first or second operand are recognized, and access exceptions for the translation table may or may not be recognized.

Resulting Condition Code:

0 Entire second operand processed; if test-character comparison was performed, no resulting function character was equal to the test character
1 Second-operand character found resulting in a function character equal to the test character (applicable only when test-character comparison is performed)
2 --
3 CPU-determined number of characters processed

Program Exceptions:

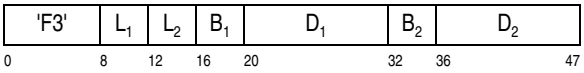
- Access (fetch, operand 2 and translation table; store, operand 1)
- Operation (if the extended-translation facility 2 is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. These instructions differ from the TRANSLATE EXTENDED instruction by having the following attributes:
   - Depending on the instruction used, the sets of argument characters and function characters each can contain single-byte or double-byte characters.
   - The test character is compared to a resulting function character instead of to an argument character.
   - The argument (source) and function (destination) operands are different operands.
2. When condition code 3 is set, the program can simply branch back to the instruction to continue the translation. The program need not determine the number of characters that were translated.
3. The storage operand references of these instructions may be multiple-access references. (See “Storage-Operand Consistency” on page 5-133.)
4. As observed by this CPU, other CPUs, and the I/O subsystem, inconsistent results may be briefly stored in the first-operand location. See the section “Effects of CPU Retry” on page 11-3 for further details.

UNPACK

UNPK $D_1(L_1,B_1),D_2(L_2,B_2)$ [SS-b]



The format of the second operand is changed from signed-packed-decimal to zoned, and the result is placed at the first-operand location. The signed-packed-decimal and zoned formats are described in Chapter 8, “Decimal Instructions.”

The second operand is treated as having the signed-packed-decimal format. Its digits and sign are placed

unchanged in the first-operand location, using the zoned format. Zone bits with coding of 1111 are supplied for all bytes except the rightmost byte, the zone of which receives the sign of the second operand. The sign and digits are not checked for valid codes.

The result is obtained as if the operands were processed right to left. When necessary, the second operand is considered to be extended on the left with zeros. If the first-operand field is too short to contain all digits of the second operand, the remaining leftmost portion of the second operand is ignored. Access exceptions for the unused portion of the second operand may or may not be indicated.

When the operands overlap, the result is obtained as if the operands were processed one byte at a time and as if the first result byte were stored immediately after fetching the first operand byte. The entire rightmost second-operand byte is used in forming the first result byte. For the remainder of the field, information for two result bytes is obtained from a single second-operand byte, and execution proceeds as if the leftmost four bits of the byte were to remain available for the next result byte and need not be refetched. Thus, the result is as if two result bytes were to be stored immediately after fetching a single operand byte.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2; store, operand 1)
- Transaction constraint

Programming Notes:

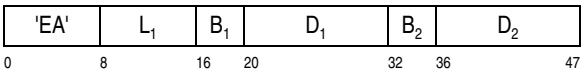
1. An example of the use of the UNPACK instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. A field that is to be unpacked can be destroyed by improper overlapping. To save storage space for unpacking by overlapping the operands, the rightmost byte of the first operand must be to the right of the rightmost byte of the second operand by the number of bytes in the second operand minus 2. If only one or two bytes are to be unpacked, the rightmost bytes of the two operands may coincide.

3. The storage-operand references of UNPACK may be multiple-access references. (See “Storage-Operand Consistency” on page 5-133.)

UNPACK ASCII

UNPKA $D_1(L_1,B_1),D_2(B_2)$ [SS-a]



The format of the second operand is changed from signed-packed-decimal to ASCII, and the result is placed at the first-operand location. The signed-packed-decimal format is described in Chapter 8, “Decimal Instructions.”

The second operand is treated as having the signed-packed-decimal format. Its digits are converted to ASCII characters by extending them on the left with 0011 binary, and the ASCII characters are then placed at the first operand location. The digits are not checked for valid codes.

The sign of the second operand is not transferred to the first operand but is checked for validity and determines the condition code. If the sign is 1010, 1100, 1110 or 1111 binary (plus), condition code 0 is set. If the sign is 1011 or 1101 binary (minus), condition code 1 is set. If the sign is not one of the codes for plus or minus, condition code 3 is set.

The converted last digit is placed in the rightmost byte position of the result field, and the other converted digits are placed adjacent to the last and to each other in the remainder of the result field.

The result is obtained as if the operands were processed right to left.

The length of the second operand is 16 bytes. The second operand consists of 31 digits and a sign.

The length of the first operand is designated by the contents of the L_1 field. The first-operand length must not exceed 32 bytes (L_1 must be less than or equal to 31); otherwise, a specification exception is recognized.

If the first operand is too short to contain all digits of the second operand, the remaining leftmost portion of the second operand is ignored. Access exceptions for the unused portion of the second operand may or may not be indicated.

When the length of the first operand is 32 bytes, the leftmost byte is set to ASCII zero, 30 hex.

The results are unpredictable if the first and second operands overlap in any way.

As observed by other CPUs and by channel programs, the first operand is not necessarily stored into in any particular order.

Resulting Condition Code:

0 Sign is plus
1 Sign is minus
2 --
3 Sign is invalid

Program Exceptions:

- Access (fetch, operand 2; store, operand 1)
- Operation (if the extended-translation facility 2 is not installed)
- Specification
- Transaction constraint

Programming Note:

1. The following example illustrates the use of the instruction to unpack to ASCII digits:

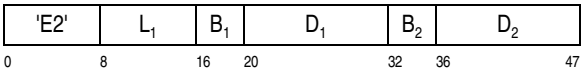
```
ASDIGITS  DS    CL31
PKDIGITS  DS    0PL16
          DC    X'1234567890'
          DC    X'1234567890'
          DC    X'1234567890'
          DC    X'1C'
           ⋮
          UNPKA ASDIGITS(31),PKDIGITS
```

2. The storage-operand references of UNPACK ASCII may be multiple-access references. (See "Storage-Operand Consistency" on page 5-133.)

3. The UNPACK ASCII and UNPACK UNICODE instructions set condition code 0 to indicate a positive sign, and these instructions provide no indication of a zero result. In all other instructions that indicate a signed result, condition code 0 indicates a result of zero, and condition code 2 indicates a positive result.

UNPACK UNICODE

UNPKU $D_1(L_1,B_1),D_2(B_2)$ [SS-a]



The format of the second operand is changed from signed-packed-decimal to Unicode Basic Latin, and the result is placed at the first-operand location. The signed-packed-decimal format is described in Chapter 8, "Decimal Instructions."

The second operand is treated as having the signed-packed-decimal format. Its digits are converted to two-byte Unicode characters by extending them on the left with 000000000011 binary (003 hex), and the Unicode characters are then placed at the first operand location. The digits are not checked for valid codes. The sign of the second operand is not transferred to the first operand but is checked for validity and determines the condition code. If the sign is 1010, 1100, 1110 or 1111 binary (plus), condition code 0 is set. If the sign is 1011 or 1101 binary (minus), condition code 1 is set. If the sign is not one of the codes for plus or minus, condition code 3 is set.

The converted last digit is placed in the rightmost character position of the result field, and the other converted digits are placed adjacent to the last and to each other in the remainder of the result field.

The result is obtained as if the operands were processed right to left.

The length of the second operand is 16 bytes; the second operand consists of 31 digits and a sign.

The length of the first operand is designated by the contents of the L_1 field. The first-operand length must not exceed 32 characters or 64 bytes (L_1 must be less than or equal to 63 and must be odd); otherwise a specification exception is recognized.

If the first operand is too short to contain all digits of the second operand, the remaining leftmost portion of the second operand is ignored. Access exceptions for the unused portion of the second operand may or may not be indicated.

When the length of the first operand is 32 characters, the leftmost character is set to Unicode Basic Latin zero, 0030 hex.

The results are unpredictable if the first and second operands overlap in any way.

As observed by other CPUs and by channel programs, the first operand is not necessarily stored into in any particular order.

Resulting Condition Code:

0 Sign is plus
1 Sign is minus
2 --
3 Sign is invalid

Program Exceptions:

- Access (fetch, operand 2; store, operand 1)
- Operation (if the extended-translation facility 2 is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. The following example illustrates the use of the instruction to unpack to European numbers:

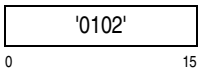
```
UNDIGITS  DS      CL62
PKDIGITS  DS      0PL16
          DC      X'1234567890'
          DC      X'1234567890'
          DC      X'1234567890'
          DC      X'1C'
          UNPKU UNDIGITS(62),PKDIGITS
```

2. The storage-operand references of UNPACK UNICODE may be multiple-access references. (See “Storage-Operand Consistency” on page 5-133.)

3. The UNPACK ASCII and UNPACK UNICODE instructions set condition code 0 to indicate a positive sign, and these instructions provide no indication of a zero result. In all other instructions that indicate a signed result, condition code 0 indicates a result of zero, and condition code 2 indicates a positive result.

UPDATE TREE

UPT [E]



The nodes of a tree in storage are examined successively on a path toward the base of the tree, and contents of general register 0, conceptually followed on the right by contents of general register 1, are conditionally interchanged with the contents of the nodes so as to give a unique maximum logical value in general register 0. The first half of a node and general register 0 contain a codeword, which is for use in sort/merge algorithms.

If the codeword in general register 0 equals the codeword in a node, the contents of the node are placed in general registers 2 and 3.

General register 4 contains the base address of the tree, and general register 5 contains the index of a node whose parent node will be examined first.

In the access-register mode, access register 4 specifies the address space containing the tree.

This instruction may be interrupted between units of operation. The condition code is unpredictable if the instruction is interrupted.

The size of a node, the size of a codeword, and the participation of bits 0-31 of general registers 1-5 in the operation depend on the addressing mode. In the 24-bit or 31-bit addressing mode, a node is eight bytes, a codeword is four bytes, and bits 0-31 are ignored and remain unchanged. In the 64-bit addressing mode, a node is 16 bytes, a codeword is eight bytes, and bits 0-31 are used in and may be changed by the operation.

Operation in the 24-Bit or 31-Bit Addressing Mode

In the 24-bit or 31-bit addressing mode, the doubleword nodes of a tree in storage are examined successively on a path toward the base of the tree, and the contents of bit positions 32-63 of general register 0, conceptually followed on the right by the contents of bit positions 32-63 of general register 1, are conditionally interchanged with the contents of the nodes so as to give a unique maximum logical value in bit positions 32-63 of general register 0.

Bit positions 32-63 of general register 4 contain the base address of the tree, and bit positions 32-63 of general register 5 contain the index of a node whose parent node will be examined first. The base address is eight less than the address of the root node of the tree. The initial contents of bit positions 32-63 of general registers 4 and 5 must be a multiple of 8; otherwise, a specification exception is recognized.

A unit of operation begins by shifting the contents of bit positions 32-63 of general register 5 right logically one position and then setting bit 61 to zero. However,

bits 32-63 of general register 5 remain unchanged if the execution of a unit of operation is nullified or suppressed. If after shifting and setting bit 61 to zero, bits 32-63 of general register 5 are all zeros, the instruction is completed, and condition code 1 is set; otherwise, the unit of operation continues.

Bit 32 of general register 0 is tested. If bit 32 of general register 0 is one, the instruction is completed, and condition code 3 is set.

If bit 32 of general register 0 is zero, the sum of bits 32-63 of general registers 4 and 5 is used as the intermediate value for normal operand address generation. The generated address is the address of a node in storage.

Bits 32-63 of general register 0 are logically compared with the contents of the first word of the currently addressed node. If the register operand is low, the contents of bit positions 32-63 of general registers 0 and 1 are interchanged with those of the node, and a unit of operation is completed. If the register operand is high, no additional action is taken, and the unit of operation is completed. If the compare values are equal, bit positions 32-63 of general register 2, conceptually followed on the right by bit positions 32-63 of general register 3, are loaded from the currently addressed node, the instruction is completed, and condition code 0 is set.

In those cases when the value in the first word of the node is less than or equal to the value in bit positions 32-63 of the register, the contents of the node remain unchanged. However, in some models, these contents may be fetched and subsequently stored back.

Operation in the 64-Bit Addressing Mode

In the 64-bit addressing mode, the quadword nodes of a tree in storage are examined successively on a path toward the base of the tree, and the contents of general register 0, conceptually followed on the right by the contents of general register 1, are conditionally interchanged with the contents of the nodes so as to give a unique maximum logical value in general register 0.

General register 4 contains the base address of the tree, and general register 5 contain the index of a node whose parent node will be examined first. The base address is 16 less than the address of the root node of the tree. The initial contents of general registers 4 and 5 must be a multiple of 16; otherwise, a specification exception is recognized.

A unit of operation begins by shifting the contents of general register 5 right logically one position and then setting bit 60 to zero. However, general register 5 remains unchanged if the execution of a unit of operation is nullified or suppressed. If after shifting and setting bit 60 to zero, the contents of general register 5 are zero, the instruction is completed, and condition code 1 is set; otherwise, the unit of operation continues.

Bit 0 of general register 0 is tested. If bit 0 of general register 0 is one, the instruction is completed, and condition code 3 is set.

If bit 0 of general register 0 is zero, the sum of the contents of general registers 4 and 5 is used as the intermediate value for normal operand address generation. The generated address is the address of a node in storage.

The contents of general register 0 are logically compared with the contents of the first doubleword of the currently addressed node. If the register operand is low, the contents of general registers 0 and 1 are interchanged with those of the node, and a unit of operation is completed. If the register operand is high, no additional action is taken, and the unit of operation is completed. If the compare values are equal, general registers 2 and 3 are loaded from the currently addressed node, the instruction is completed, and condition code 0 is set.

In those cases when the value in the first doubleword of the node is less than or equal to the value in the register, the contents of the node remain unchanged. However, in some models, these contents may be fetched and subsequently stored back.

Specifications Independent of Addressing Mode

Access exceptions are recognized only for one node at a time. Access exceptions, change-bit action, and PER storage alteration do not occur for subsequent nodes until the previous node has been successfully compared and updated, and they also do not occur if a specification-exception condition exists.

Resulting Condition Code:

0 Equal compare values at currently addressed node
1 No equal compare values found on path, or no comparison made
2 --
3 In 24-bit or 31-bit mode, bits 32-63 of general register 5 nonzero and bits 32-63 of general register 0 negative; in 64-bit mode, general register 5 nonzero and general register 0 negative

Program Exceptions:

- Access (fetch and store, nodes of tree)
- Specification
- Transaction constraint

Programming Notes:

1. An example of the use of UPDATE TREE is given in “Sorting Instructions” in Appendix A, “Number Representation and Instruction-Use Examples.”

2. For use in sorting in the 24-bit or 31-bit addressing mode, when equal compare values have been found, the contents of bit positions 32-63 of general registers 1 and 3 can be appropriate (depending on the contents of the tree) for the subsequent execution of COMPARE AND FORM CODEWORD. The contents of bit positions 32-63 of general register 2, shifted right 16 bit positions, can be similarly appropriate, and they can provide for minimal recomparison of partially equal keys. The same applies in the 64-bit addressing mode except to the contents of bit positions 0-63 of the registers and with the contents of bit positions 0-63 of general register 2 shifted right 48 bit positions. Refer to “Sorting Instructions” on page A-53 for a discussion of trees and their use in sorting.

3. The program should avoid placing a nonzero value in bit positions 32-38 of general register 5 when in the 24-bit addressing mode. If any bit in bit positions 32-38 is a one, the nodes of the tree will not be examined successively.

4. When bits 32-63 of general register 0 are negative in the 24-bit or 31-bit addressing mode, or when bits 0-63 are negative in the 64-bit mode, and provided that the tree has been updated properly previously, the node represented by general registers 0 and 1 either is the node or is equal to the node (equal keys) that would be selected if the unit of operation continued. In this case, ending the unit of operation and setting condition code 3 is a faster means of selecting an appropriate node because it does not require further examination and updating of the tree.

5. Setting condition code 3 provides improved performance when the replacement record is equal to the old winner and, more importantly (since the first case can be detected by means of the condition code of CFC), when the update path contains a negative codeword, indicating equality with the old winner.

6. In those cases when the codeword in the node is less than or equal to the codeword in general register 0, depending on the model, the contents of the node may be fetched and subsequently stored back. As a result, any of the following may occur for the storage location containing the node: a PER storage-alteration event may be recognized; a protection exception for storing may be recognized; and, provided no access exceptions exist, the change bit may be set to one. Because the contents of storage remain unchanged, the change bit may or may not be one when a PER storage-alteration event is recognized.

7. Special precautions should be taken when UPDATE TREE is made the target of an execute-type instruction. See the programming note concerning interruptible instructions under EXECUTE.

8. Further programming notes concerning interruptible instructions are included in “Interruptible Instructions” on page 5-24.

9. The storage-operand references for UPDATE TREE may be multiple-access references. (See “Storage-Operand Consistency” on page 5-133.)

10. Figure 7-406 on page 7-488 is a summary of the operation of UPDATE TREE in the 24-bit or 31-bit addressing mode, and Figure 7-407 on page 7-489 is a summary of the operation in the 64-bit addressing mode.

UPDATE TREE

Protection of Cryptographic Keys

When the message-security-assist extension 3 is installed, two wrapping-key registers and two wrapping-key-verification-pattern registers are provided for each configuration. The two wrapping-key registers consist of a 192-bit DES wrapping-key (WK_d) register and a 256-bit AES wrapping-key (WK_a) register. The two wrapping-key-verification-pattern registers consist of a 192-bit DES wrapping-key-verification-pattern (WK_dVP) register and a 256-bit AES wrapping-key-verification-pattern (WK_aVP) register.

WK_d is used to protect user DES or TDES keys, and WK_dVP is used to verify the value of WK_d. WK_a is used to protect user AES keys, and WK_aVP is used to verify the value of WK_a. Whenever the contents of the WK_d or WK_a register are changed, the contents of the corresponding verification-pattern register are also changed.

When the message-security-assist extension 9 is installed, the 256-bit AES wrapping key (WK_a) register and the 256-bit AES wrapping-key-verification-pattern (WK_aVP) register are also used to protect ECC keys.

When the message-security-assist extension 10 is installed, the 256-bit AES wrapping key (WK_a) register and the 256-bit AES wrapping-key-verification-pattern (WK_aVP) register are also used to protect AES-XTS double keys.

When the message-security-assist extension 11 is installed, the 256-bit AES wrapping key (WK_a) register and the 256-bit AES wrapping-key-verification-pattern (WK_aVP) register are also used to protect HMAC keys.

Each time a clear reset is performed, a new set of wrapping keys and their associated verification patterns are generated. The contents of the two wrapping-key registers are kept internal to the model so that no program, including the operating system, can directly observe their clear value.

The following instructions provide functions supporting encrypted cryptographic keys:

- CIPHER MESSAGE
- CIPHER MESSAGE WITH AUTHENTICATION
- CIPHER MESSAGE WITH CHAINING
- CIPHER MESSAGE WITH CIPHER FEEDBACK
- CIPHER MESSAGE WITH COUNTER
- CIPHER MESSAGE WITH OUTPUT FEEDBACK
- COMPUTE DIGITAL SIGNATURE AUTHENTICATION
- COMPUTE MESSAGE AUTHENTICATION CODE
- PERFORM CRYPTOGRAPHIC COMPUTATION

For each of these instructions, a program-specified DES or AES wrapping-key-verification-pattern in the parameter block is compared with the respective wrapping-key-verification-pattern register. the instruction completes with condition code 1 if the two do not match.

A privileged program may use the PERFORM CRYPTOGRAPHIC KEY MANAGEMENT OPERATION (PCKMO) instruction to encrypt DES or TDES keys using WK_d or to encrypt AES, AES-XTS, ECC, or HMAC keys using WK_a. A privileged program may also use PCKMO to inspect the current DES or AES wrapping-key-verification pattern used to encrypt the respective key.

Programming Notes:

1. Upon condition code 1, the program should re-import the cryptographic key for encrypting it under the appropriate wrapping key before the operation is resumed.

2. Even though the architecture defines that a new set of wrapping keys are generated upon a clear reset, condition code 1 could occur at any time for message-security-assist functions using an encrypted key because the application may be relocated to another system with a different set of wrapping keys.

3. The sections “Protection of DES Keys” on page 7-491, “Protection of AES Keys” on page 7-493, “Protection of ECC Keys” on page 7-496 and “Protection of HMAC Keys” on page 7-500 illustrate encryption and decryption algorithms in support of encrypted cryptographic keys. The encryption algorithms are used by the PERFORM CRYPTOGRAPHIC KEY MANAGEMENT OPERATION instruction when encrypting a cryptographic key, and the decryption algorithms are used by the various message-security-assist

instructions that support the use of encrypted keys.

Symbols Used in Subsequent Descriptions

The following symbols are used in the subsequent description. For data-encryption-algorithm (DEA) functions, the DEA-key-parity bit in each byte of the DEA key is ignored, and the operation proceeds normally, regardless of the DEA-key parity of the key.

Further description of the data-encryption algorithm may be found in Reference [13.] on page xxxii. Further description of the AES standard may be found in Reference [14.] on page xxxii.

Protection of ECC Keys

When the message-security-assist extension 9 is installed, user ECC keys may be protected using the 256-bit AES wrapping key. ECC keys and any necessary padding are encrypted together.

Figure 7-415 on page 7-497 shows the encryption and decryption for ECC P256 and Ed25519 keys. On the left hand side of the figure encryption of a 256-bit (P256), or 255-bit key and 1 bit zero pad (Ed25519) is encrypted to a 256-bit encrypted key. On the right hand side decryption of the 256-bit key is shown. Encryption and decryption uses the 256-bit AES wrapping key. The Ed25519 key is right aligned in the 256-bit field and padded with 1 bit zero on the left.

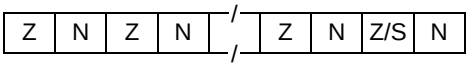
The decimal instructions of this chapter perform arithmetic and editing operations on decimal data. Additional operations on decimal data are also provided by several instructions in Chapter 7, “General Instructions,” several instructions in Chapter 20, “Decimal-Floating-Point Instructions,” and several instructions in Chapter 25, “Vector Decimal Instructions.” Generally, decimal operands reside in storage. For some of the instructions described in Chapter 20, decimal operands may reside in a general register or general register pair. For some of the instructions described in Chapter 25, decimal operands may reside in a vector register. The storage fields for decimal operands residing in storage may start on any byte boundary and may have variable lengths. The decimal operands residing in general registers and vector registers have fixed lengths.

Decimal-Number Formats

Decimal numbers may be represented in several formats, including zoned, signed-packed-decimal and unsigned-packed-decimal. These formats are of variable length; most instructions used to operate on these formats specify the length of their operands and results. Each byte of a format consists of a pair of four-bit codes; the four-bit codes include decimal-digit codes, sign codes, and a zone code.

Zoned Format



In the zoned format, the rightmost four bits of a byte are called the numeric bits (N) and normally consist of a code representing a decimal digit. The leftmost four bits of a byte are called the zone bits (Z), except for the rightmost byte of a decimal operand, where these bits may be treated either as a zone or as a sign (S).

Decimal digits in the zoned format may be part of a larger character set, which includes also alphabetic and special characters. The zoned format is, therefore, suitable for input, editing, and output of numeric data in human-readable form. There are no decimal-arithmetic instructions which operate directly on decimal numbers in the zoned format; such numbers must first be converted to the signed-packed-decimal format or one of the DFP formats.

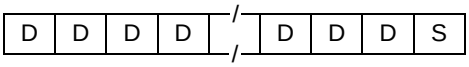
The editing instructions produce a result of up to 256 bytes; each byte may be a decimal digit in the zoned format, a message byte, or a fill byte.

Packed-Decimal Formats

There are two packed-decimal formats, signed-packed, and unsigned-packed.

© Copyright IBM Corp. 2000, 2025

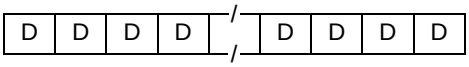
Signed-Packed-Decimal Format



In the signed-packed-decimal format, each byte contains two decimal digits (D), except for the rightmost byte, which contains a sign (S) to the right of a decimal digit. Decimal arithmetic is performed with operands in the signed-packed-decimal format and generates results in the signed-packed-decimal format.

The signed-packed-decimal operands and results of decimal-arithmetic instructions may be up to 16 bytes (31 digits and sign), except that the maximum length of a multiplier or divisor is eight bytes (15 digits and sign). In division, the sum of the lengths of the quotient and remainder may be from two to 16 bytes. The editing instructions can fetch as many as 256 decimal digits from one or more decimal numbers of variable length, each in the signed-packed-decimal format. CONVERT FROM PACKED and CONVERT TO PACKED may have signed-packed-decimal operands up to 18 bytes (34 digits and sign).

Unsigned-Packed-Decimal Format



In the unsigned-packed-decimal format, each byte contains two decimal digits (D) and there is no sign. The unsigned-packed-decimal format can be used as the source operand of the editing instructions, as the second operand of MOVE WITH OFFSET, and is also used by the decimal floating-point (DFP) instructions CONVERT FROM PACKED, CONVERT FROM UNSIGNED PACKED, CONVERT TO PACKED, and CONVERT TO UNSIGNED PACKED.

Decimal Codes

The decimal digits 0-9 have the binary encoding 0000-1001.

The preferred sign codes are 1100 for plus and 1101 for minus. These are the sign codes generated for the results of the decimal-arithmetic instructions and the CONVERT TO DECIMAL instruction. The instructions PACK ASCII and PACK UNICODE supply an implied positive sign (1100 binary). The DFP instructions CONVERT TO PACKED, CONVERT TO SIGNED PACKED, and CONVERT TO ZONED include a plus sign-code selection bit. The plus sign can be encoded as either 1100 or 1111. The sign codes generated for vector decimal instruction results are either preferred sign codes 1100 for positive and 1101 for negative or can be forced to positive with sign code 1111.

Alternate sign codes are also recognized as valid in the sign position: 1010, 1110, and 1111 are alternate codes for plus, and 1011 is an alternate code for minus. Alternate sign codes are accepted for any decimal source operand, but are not generated in the completed result of a decimal-arithmetic instruction , vector decimal-arithmetic instruction, CONVERT TO DECIMAL, or VECTOR CONVERT TO DECIMAL. This is true even when an operand remains otherwise unchanged, such as when adding zero to a number. An alternate sign code is, however, left unchanged by MOVE NUMERICS, MOVE WITH OFFSET, MOVE ZONES, PACK, UNPACK, VECTOR PACK ZONED and VECTOR UNPACK ZONED.

When an invalid sign or digit code is detected, a general-operand data exception is recognized. For CONVERT TO BINARY, the decimal-arithmetic instructions, the decimal floating-point instructions CONVERT FROM PACKED, CONVERT FROM SIGNED PACKED, CONVERT FROM UNSIGNED PACKED, and CONVERT FROM ZONED, the vector decimal-arithmetic instructions, and the vector decimal instruction VECTOR CONVERT TO BINARY, the operation is suppressed.

For the editing instructions EDIT and EDIT AND MARK, an invalid sign code is not recognized. It is model dependent whether the operation is suppressed or terminated for a general-operand data exception due to an invalid digit code. No validity checking is performed by MOVE NUMERICS, MOVE WITH OFFSET, MOVE ZONES, PACK, PACK ASCII, PACK UNICODE, and UNPACK. The instructions UNPACK ASCII and UNPACK UNICODE do not check for invalid digit codes; invalid sign codes are recognized, but are not reported as a general-operand data exception, instead condition code 3 is set.

The zone code 1111 is generated in the left four bit positions of each byte representing a zone and a decimal digit in zoned-format results. Zoned-format results are produced by EDIT, EDIT AND MARK, and UNPACK. For EDIT and EDIT AND MARK, each result byte representing a zoned-format decimal digit contains the zone code 1111 in the left four bit positions and the decimal-digit code in the right four bit

positions. For UNPACK, zone bits with a coding of 1111 are supplied for all bytes except the rightmost byte, the zone of which receives the sign.

The zone code 0011 is generated in the leftmost four bit positions of each byte representing a zone for a decimal digit in ASCII format. ASCII formats are produced by CONVERT TO ZONED when the zone-control bit is one and by UNPACK ASCII.

The meaning of the decimal codes is summarized in Figure 8-1.

Code (Binary)	Recognized As	
	Digit	Sign
0000	0	Invalid
0001	1	Invalid
0010	2	Invalid
0011	3	Invalid *
0100	4	Invalid
0101	5	Invalid
0110	6	Invalid
0111	7	Invalid
1000	8	Invalid
1001	9	Invalid
1010	Invalid	Plus
1011	Invalid	Minus
1100	Invalid	Plus (preferred)
1101	Invalid	Minus (preferred)
1110	Invalid	Plus
1111	Invalid	Plus (zone)

Explanation:

* The zone code 0011 binary is generated in the leftmost four bit positions of each byte representing a decimal digit in the ASCII format.

Figure 8-1. Summary of Digit and Sign Codes

Programming Note: Since 1111 is both the zone code and an alternate code for plus, unsigned (positive) decimal numbers may be represented in the zoned format with 1111 zone codes in all byte positions. The result of the PACK instruction converting such a number to the signed-packed-decimal format may be used directly as an operand for decimal instructions.

Decimal Operations

The decimal instructions in this chapter consist of two classes, the decimal-arithmetic instructions and the editing instructions.

Decimal-Arithmetic Instructions

The decimal-arithmetic instructions perform addition, subtraction, multiplication, division, comparison, and shifting.

Operands of the decimal-arithmetic instructions are in the signed-packed-decimal format and are treated as signed decimal integers. A decimal integer is represented in true form as an absolute value with a separate plus or minus sign. It contains an odd number of decimal digits, from one to 31, and the sign; this corresponds to an operand length of one to 16 bytes.

A decimal zero normally has a plus sign, but multiplication, division, and overflow may produce a zero value with a minus sign. Such a negative zero is a valid operand and is treated as equal to a positive zero by COMPARE DECIMAL.

The lengths of the two operands specified in the instruction need not be the same. If necessary, the shorter operand is considered to be extended with zeros on the left. Results, however, cannot exceed the first-operand length as specified in the instruction.

When a carry or leftmost nonzero digits of the result are lost because the first-operand field is too short, the result is obtained by ignoring the overflow digits, condition code 3 is set, and, if the decimal-overflow mask bit is one, a program interruption for decimal overflow occurs. The operand lengths alone are not an indication of overflow; nonzero digits must have been lost during the operation.

The operands of decimal-arithmetic instructions should not overlap at all or should have coincident rightmost bytes. In ZERO AND ADD, the operands may also overlap in such a manner that the rightmost byte of the first operand (which becomes the result) is to the right of the rightmost byte of the second operand. For these cases of proper overlap, the result is obtained as if operands were processed right to left. Because the codes for digits and signs are verified during the performance of the arithmetic, improperly overlapping operands are recognized as general-operand data exceptions. However, in ZERO AND ADD when the rightmost byte of the first operand is to the left of the rightmost byte of the second operand, the entire second operand may be fetched, depending on the model, before any storing occurs,

which will cause a general-operand data exception not to be recognized. See “Interlocks within a Single Instruction” on page 5-123 for how overlap is detected in the access-register mode.

Programming Note: A signed-packed-decimal number in storage may be designated as both the first and second operand of ADD DECIMAL, COMPARE DECIMAL, DIVIDE DECIMAL, MULTIPLY DECIMAL, SUBTRACT DECIMAL, or ZERO AND ADD. Thus, a decimal number may be added to itself, compared with itself, and so forth; SUBTRACT DECIMAL may be used to set a decimal field in storage to zero; and, for MULTIPLY DECIMAL, a decimal number may be squared in place. In these cases, the lengths of the two operands are not necessarily equal and may, depending on the instruction, be prohibited from being equal.

Editing Instructions

The editing instructions are EDIT and EDIT AND MARK. For these instructions, only the first operand (the pattern) has an explicitly specified length. The second operand (the source) is considered to have as many digits as necessary for the completion of the operation.

Overlapping operands for the editing instructions yield unpredictable results.

Execution of Decimal Instructions

During the execution of a decimal instruction, all bytes of the operands are not necessarily accessed concurrently, and the fetch and store accesses to a single location do not necessarily occur one immediately after the other. Furthermore, for decimal instructions, data in source fields may be accessed more than once, and intermediate values may be placed in the result field that may differ from the original operand and final result values. (See “Storage-Operand Consistency” on page 5-133.) Thus, in a multiprocessing configuration, an instruction such as ADD DECIMAL cannot be safely used to update a shared storage location when the possibility exists that another CPU may also be updating that location.

Other Instructions for Decimal Operands

In addition to the decimal-arithmetic instructions in this chapter, (which operate on decimal numbers in the signed-packed-decimal format) several other instructions are provided for operating on decimal data in the zoned, signed-packed-decimal, or unsigned-packed-decimal format.

The editing instructions (described in this chapter) convert decimal numbers in either the signed-packed-decimal or unsigned-packed-decimal format to the zoned format. Zoned results of up to 256 bytes in length can be produced.

CONVERT TO DECIMAL and CONVERT TO BINARY (described in Chapter 7) provide conversion between signed-binary-integer formats and decimal numbers in the signed-packed-decimal format. Signed-packed-decimal operands of up to 16 bytes in length (31 digits and a sign) can be processed.

CONVERT TO SIGNED PACKED and CONVERT FROM SIGNED PACKED (described in Chapter 20) provide conversion between decimal floating point (DFP) formats and the signed-packed-decimal format. Signed-packed-decimal operands of up to 16 bytes in length (31 digits and a sign) can be processed.

CONVERT TO UNSIGNED PACKED and CONVERT FROM UNSIGNED PACKED (described in Chapter 20) provide conversion between decimal floating point (DFP) formats and the unsigned-packed-decimal format. Unsigned-packed-decimal operands of up to 16 bytes in length (32 digits) can be processed.

MOVE WITH OFFSET (described in Chapter 7) operates on data in the packed format. (The first operand is treated as signed-packed decimal and the second operand as unsigned-packed decimal.) Operands are not checked for valid codes. Signed-packed-decimal operands of up to 16 bytes in length (31 digits and a sign) can be processed.

PACK, UNPACK, PACK ASCII, UNPACK ASCII, PACK UNICODE, and UNPACK UNICODE provide conversion between zoned or character data and signed-packed-decimal data. Operands are not checked for valid codes. Signed-packed-decimal operands of up to 16 bytes in length (31 digits and a sign) can be processed.

MOVE NUMERICS and MOVE ZONES (described in Chapter 7) operate on data in the zoned format. Operands are not checked for valid codes. Zoned operands of up to 256 bytes in length can be processed.

The vector decimal instructions (described in Chapter 25) provide register-to-register decimal-arithmetic operations of addition, subtraction, multiplication, division, comparison, and shifting of data in the packed-decimal format.

VECTOR CONVERT TO BINARY and VECTOR CONVERT TO DECIMAL (described in Chapter 25) provide register-to-register conversion between signed-packed-decimal format and binary-integer (signed and unsigned) format numbers. Signed-packed-decimal operands of up to 16 bytes in length (31 digits and a sign) can be processed.

VECTOR PACK ZONED and VECTOR UNPACK ZONED (described in Chapter 25) provide conversion between a zoned format storage operand and a signed-packed-decimal format register operand. Operands are not checked for valid codes. Signed-packed-decimal operands of up to 16 bytes in length (31 digits and a sign) can be processed.

General-Operand Data Exception

A general-operand data exception is recognized when any of the following is true:

1. A sign or digit code is invalid in an operand of a decimal instruction other than TEST DECIMAL, as described in Chapter 8, “Decimal Instructions”.
2. A sign or digit code is invalid in the second operand of CONVERT TO BINARY, as described in Chapter 7, “General Instructions”.
3. A sign or digit code is invalid in an operand of CONVERT FROM PACKED, CONVERT FROM SIGNED PACKED, CONVERT FROM UNSIGNED PACKED, or CONVERT FROM ZONED, as described in Chapter 20, “Decimal-Floating-Point Instructions”.
4. A sign or digit code is invalid in an operand of a vector decimal instruction other than VECTOR CONVERT HFP TO SCALED DECIMAL, VECTOR CONVERT TO DECIMAL, VECTOR PACK ZONED, VECTOR TEST DECIMAL, and VECTOR UNPACK ZONED and no control bit of the instruction specifies the validity check is not performed, as described in Chapter 25, “Vector-Decimal Instructions”.
5. The operand fields in ADD DECIMAL, COMPARE DECIMAL, DIVIDE DECIMAL, MULTIPLY DECIMAL, and SUBTRACT DECIMAL overlap in a way other than with coincident rightmost bytes; or operand fields in ZERO AND ADD overlap, and the rightmost byte of the second operand is to the right of the rightmost byte of the first operand. On some models, the improper overlap of operands for ZERO AND ADD is not recognized as a general-operand data exception; instead, the operation is performed as if the entire second operand were fetched before any byte of the result is stored.
6. The multiplicand in MULTIPLY DECIMAL has an insufficient number of leftmost zeros.
7. COMPRESSION CALL encounters errors in its dictionaries.
8. The reseed counter is zero for a PERFORM RANDOM NUMBER OPERATION instruction’s PRNO-SHA-512-DRNG generate operation.

A general-operand data exception causes the operation to be suppressed, except that, for EDIT and EDIT AND MARK, and COMPRESSION CALL, the operation may be suppressed or terminated. In the case of EDIT and EDIT AND MARK, and COMPRESSION CALL, an invalid sign code cannot occur.

Note: In earlier versions of the architecture, the general-operand data exception was known as the decimal-operand data exception.

Instructions

The decimal instructions and their mnemonics, formats, and operation codes are listed in Figure 8-2 on page 8-6. The figure also indicates when the condition code is set, the instruction fields that designate access registers, and the exceptional conditions in operand designations, data, or results that cause a program interruption.

Note: In the detailed descriptions of the individual instructions, the mnemonic and the symbolic operand designation for the assembler language are

shown with each instruction. For ADD DECIMAL, for example, AP is the mnemonic and $D_1(L_1,B_1),D_2(L_2,B_2)$ the operand designation.

Programming Note: The decimal instruction TEST DECIMAL is available when the extended-translation facility 2 is installed.

Name	Mnemonic	Characteristics	Op Code	Page
ADD DECIMAL	AP	SS-b C ¤[9] A Dg DF ST B_1 B_2	FA	8-6

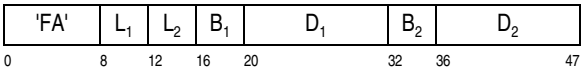
Explanation:

¤[9]	Restricted in the constrained transactional-execution mode; a transaction-constraint program exception may be recognized.
A	Access exceptions for logical addresses.
B_1	B_1 field designates an access register in the access-register mode.
B_2	B_2 field designates an access register in the access-register mode.
C	Condition code is set.
DF	Decimal-overflow exception.
Dg	General-operand data exception.
DK	Decimal-divide exception.
E2	Extended-translation facility 2.
G1	Instruction execution includes the implied use of general register 1.
RSL	RSL instruction format.
SP	Specification exception.
SS	SS instruction format.
ST	PER storage-alteration event.

Figure 8-2. Summary of Decimal Instructions

ADD DECIMAL

AP $D_1(L_1,B_1),D_2(L_2,B_2)$ [SS-b]



The second operand is added to the first operand, and the resulting sum is placed at the first-operand location. The operands and result are in the signed-packed-decimal format.

Addition is algebraic, taking into account the signs and all digits of both operands. All sign and digit codes are checked for validity.

If the first operand is too short to contain all leftmost nonzero digits of the sum, decimal overflow occurs. The operation is completed. The result is obtained by ignoring the overflow digits, and condition code 3 is set. If the decimal-overflow mask is one, a program interruption for decimal overflow occurs.

The sign of the sum is determined by the rules of algebra. In the absence of overflow, the sign of a zero result is made positive. If overflow occurs, a zero result is given either a positive or negative sign, as determined by what the sign of the correct sum would have been.

Resulting Condition Code:

0 Result zero; no overflow
1 Result less than zero; no overflow
2 Result greater than zero; no overflow
3 Overflow

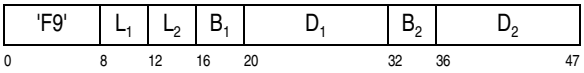
Program Exceptions:

- Access (fetch, operand 2; fetch and store, operand 1)
- Data with DXC 0, general operand
- Decimal overflow
- Transaction constraint

Programming Note: An example of the use of the ADD DECIMAL instruction is given in Appendix A, "Number Representation and Instruction-Use Examples."

COMPARE DECIMAL

CP $D_1(L_1,B_1),D_2(L_2,B_2)$ [SS-b]



The first operand is compared with the second operand, and the result is indicated in the condition code. The operands are in the signed-packed-decimal format.

Comparison is algebraic and follows the procedure for decimal subtraction, except that both operands remain unchanged. When the difference is zero, the operands are equal. When a nonzero difference is positive or negative, the first operand is high or low, respectively.

Overflow cannot occur because the difference is discarded.

All sign and digit codes are checked for validity.

Resulting Condition Code:

0 Operands equal
1 First operand low
2 First operand high
3 --

Program Exceptions:

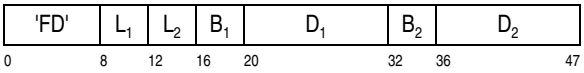
- Access (fetch, operands 1 and 2)
- Data with DXC 0, general operand
- Transaction constraint

Programming Notes:

1. An example of the use of the COMPARE DECIMAL instruction is given in Appendix A, "Number Representation and Instruction-Use Examples."
2. The preferred and alternate sign codes for a particular sign are treated as equivalent for comparison purposes.
3. A negative zero and a positive zero compare equal.

DIVIDE DECIMAL

DP $D_1(L_1,B_1),D_2(L_2,B_2)$ [SS-b]



The first operand (the dividend) is divided by the second operand (the divisor). The resulting quotient and remainder are placed at the first-operand location. The operands and results are in the signed-packed-decimal format.

The quotient is placed leftmost in the first-operand location. The number of bytes in the quotient field is equal to the difference between the dividend and divisor lengths ($L_1 - L_2$). The remainder is placed rightmost in the first-operand location and has a length equal to the divisor length. Together, the quotient and remainder fields occupy the entire first operand; therefore, the address of the quotient is the address of the first operand.

The divisor length cannot exceed 15 digits and sign (L_2 not greater than seven) and must be less than the dividend length (L_2 less than L_1); otherwise, a specification exception is recognized.

The dividend, divisor, quotient, and remainder are each signed decimal integers in the signed-packed-decimal format and are right-aligned in their fields. All sign and digit codes of the dividend and divisor are checked for validity.

The sign of the quotient is determined by the rules of algebra from the dividend and divisor signs. The sign of the remainder has the same value as the dividend sign. These rules hold even when the quotient or remainder is zero.

Overflow cannot occur. If the divisor is zero or the quotient is too large to be represented by the number of digits specified, a decimal-divide exception is recognized. This includes the case of division of zero by zero. The decimal-divide exception is indicated only if the sign codes of both the dividend and divisor are

valid, and only if the digit or digits used in establishing the exception are valid.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2; fetch and store, operand 1)
- Data with DXC 0, general operand
- Decimal divide
- Specification
- Transaction constraint

Programming Notes:

1. An example of the use of the DIVIDE DECIMAL instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

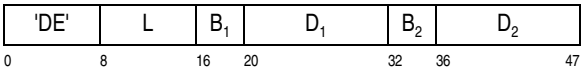
2. The dividend cannot exceed 31 digits and sign. Since the remainder cannot be shorter than one digit and sign, the quotient cannot exceed 29 digits and sign.

3. The condition for a decimal-divide exception can be determined by a trial comparison. The leftmost digit of the divisor is aligned one digit to the right of the leftmost dividend digit, with rightmost zeros appended up to the length of the dividend. When the divisor, so aligned, is less than or equal to the dividend, ignoring signs, a divide exception is indicated.

4. If a general-operand data exception does not exist, a decimal-divide exception occurs when the leftmost dividend digit is not zero.

EDIT

ED $D_1(L,B_1),D_2(B_2)$ [SS-a]



The second operand (the source), which normally contains one or more decimal numbers in the signed-packed-decimal or unsigned-packed-decimal format, is changed to the zoned format and modified under the control of the first operand (the pattern). The edited result replaces the first operand.

The length field specifies the length of the first operand, which may contain bytes of any value.

The length of the source is determined by the operation according to the contents of the pattern. The source normally consists of one or more decimal numbers, each in the signed-packed-decimal or unsigned-packed-decimal format. The leftmost four bits of each source byte must specify a decimal-digit code (0000-1001); a sign code (1010-1111) is recognized as a general-operand data exception. The rightmost four bits may specify either a sign code or a decimal-digit code. Access and data exceptions and PER zero-address-detection events are recognized only for those bytes in the second operand which are actually required.

The result is obtained as if both operands were processed left to right one byte at a time. Overlapping pattern and source fields give unpredictable results.

During the editing process, each byte of the pattern is affected in one of three ways:

1. It is left unchanged.

2. It is replaced by a source digit expanded to the zoned format.

3. It is replaced by the first byte in the pattern, called the fill byte.

Which of the three actions takes place is determined by one or more of the following: the type of the pattern byte, the state of the significance indicator, and whether the source digit examined is zero.

Pattern Bytes: There are four types of pattern bytes: digit selector, significance starter, field separator, and message byte. Their coding is as follows:

	Code	
Name	**(Binary)**	**(Hex)**
Digit Selector	0010 0000	20
Significance starter	0010 0001	21
Field separator	0010 0010	22
Message byte	Any other	Any other

The detection of either a digit selector or a significance starter in the pattern causes an examination to be made of the significance indicator and of a source digit. As a result, either the expanded source digit or the fill byte, as appropriate, is selected to replace the pattern byte. Additionally, encountering a digit selector or a significance starter may cause the significance indicator to be changed.

The field separator identifies individual fields in a multiple-field editing operation. It is always replaced in the result by the fill byte, and the significance indicator is always off after the field separator is encountered.

Message bytes in the pattern are either replaced by the fill byte or remain unchanged in the result, depending on the state of the significance indicator. They may thus be used for padding, punctuation, or text in the significant portion of a field or for the insertion of sign-dependent symbols.

Fill Byte: The first byte of the pattern is used as the fill byte. The fill byte can have any code and may concurrently specify a control function. If this byte is a digit selector or significance starter, the indicated editing action is taken after the code has been assigned to the fill byte.

Source Digits: Each time a digit selector or significance starter is encountered in the pattern, a new source digit is examined for placement in the pattern field. Either the source digit is disregarded, or it is expanded to the zoned format, by appending the zone code 1111 on the left, and stored in place of the pattern byte.

Execution is as if the source digits were selected one byte at a time. The leftmost four bits of each byte are examined first, and the rightmost four bits, when they represent a decimal-digit code, remain available for the next pattern byte that calls for a digit examination. When the leftmost four bits contain an invalid digit code, a general-operand data exception is recognized, and the operation is either suppressed or terminated.

At the time the left digit of a source byte is examined, the rightmost four bits are checked for the existence of a sign code. When a sign code is encountered in the rightmost four bit positions, these bits are not treated as a decimal-digit code, and a new source byte is fetched from storage when the next pattern byte calls for a source-digit examination.

When the pattern contains no digit selector or significance starter, no source bytes are fetched and examined.

Significance Indicator: The significance indicator is turned on or off to indicate the significance or non significance, respectively, of subsequent source digits or message bytes. Significant source digits replace their corresponding digit selectors or significance starters in the result. Significant message bytes remain unchanged in the result.

The significance indicator, by its on or off state, indicates also the negative or positive value, respectively, of a completed source field and is used as one factor in the setting of the condition code.

The significance indicator is set to off at the start of the editing operation, after a field separator is encountered, or after a source byte is examined that has a plus code in the rightmost four bit positions.

The significance indicator is set to on when a significance starter is encountered whose source digit is a valid decimal digit, or when a digit selector is encountered whose source digit is a nonzero decimal digit, provided that in both instances the source byte does not have a plus code in the rightmost four bit positions.

In all other situations, the significance indicator is not changed. A minus sign code has no effect on the significance indicator.

Result Bytes: The result of an editing operation replaces and is equal in length to the pattern. It is composed of pattern bytes, fill bytes, and zoned source digits.

If the pattern byte is a message byte and the significance indicator is on, the message byte remains unchanged in the result. If the pattern byte is a field separator or if the significance indicator is off when a message byte is encountered in the pattern, the fill byte replaces the pattern byte in the result.

If the digit selector or significance starter is encountered in the pattern with the significance indicator off and the source digit zero, the source digit is considered nonsignificant, and the fill byte replaces the pattern byte. If the digit selector or significance starter is encountered either with the significance indicator on or with a nonzero decimal source digit, then the source digit (a) is considered significant, (b) is changed to the zoned format, and (c) replaces the pattern byte in the result. Examination of the significance indicator occurs prior to the processing of the source digit (which might change the significance indicator).

Condition Code: The sign and magnitude of the last field edited are used to set the condition code.

The term “last field” refers to those source digits, if any, in the second operand selected by digit selectors or significance starters after the last field separator; if the pattern contains no field separator, there is only one field, which is considered to be the last field. If no such source digits are selected, the last field is considered to be of zero length.

Condition code 0 is set when the last field edited is zero or of zero length.

Condition code 1 is set when the last field edited is nonzero and the significance indicator is on. (This indicates a result less than zero if the last source byte examined contained a sign code in the rightmost four bits.)

Condition code 2 is set when the last field edited is nonzero and the significance indicator is off. (This indicates a result greater than zero if the last source byte examined contained a sign code in the rightmost four bits.)

For the purposes of setting condition code 2, the significance indicator is examined after the processing of the last source digit.

Figure 8-3 on page 8-10 summarizes the functions of the EDIT and EDIT AND MARK operations. The leftmost four columns list all the significant combinations of the four conditions that can be encountered in the execution of an editing operation. The rightmost two columns list the action taken for each case — the type of byte placed in the result field and the new setting of the significance indicator.

Conditions				Results	
Pattern Byte	**Previous State of Significance Indicator**	**Source Digit**	**Right Four Source Bits Are Plus Code**	**Result Byte**	**State of Significance Indicator at End of Digit Examination**
Digit selector	Off	0	*	Fill byte	Off
		1-9	No	Source digit#	On
			Yes	Source digit#	Off
	On	0-9	No	Source digit	On
			Yes	Source digit	Off
Significance starter	Off	0	No	Fill byte	On
			Yes	Fill byte	Off
		1-9	No	Source digit#	On
			Yes	Source digit#	Off
	On	0-9	No	Source digit	On
			Yes	Source digit	Off
Field separator	*	**	**	Fill byte	Off
Message byte	Off	**	**	Fill byte	Off
	On	**	**	Message byte	On

Explanation:

* No effect on result byte or on new state of significance indicator.
** Not applicable because source is not examined.
\# For EDIT AND MARK only, the address of the rightmost such result byte is placed in general register 1.

Figure 8-3. Summary of Editing Functions

Resulting Condition Code:

0 Last field zero or zero length
1 Last field less than zero
2 Last field greater than zero
3 --

Program Exceptions:

- Access (fetch, operand 2; fetch and store, operand 1)
- Data with DXC 0, general operand
- Transaction constraint

Programming Notes:

1. Examples of the use of the EDIT instruction are given in Appendix A, “Number Representation and Instruction-Use Examples.”

2. Editing includes sign and punctuation control, and the suppression of leading zeros by replacing them with blanks, or the protection of leading zeros from malicious alteration by replacing them with asterisks or other characters. It also facilitates programmed blanking of all-zero fields. Several fields may be edited in one operation, and numeric information may be combined with text.

3. In most cases, the source is shorter than the pattern because each four-bit source digit produces an eight-bit byte in the result.

4. The total number of digit selectors and significance starters in the pattern always equals the number of source digits edited.

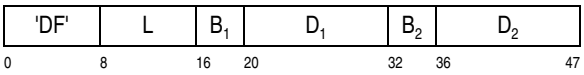
5. If the fill byte is a blank, if no significance starter exists in the pattern, and if the source digit examined for each digit selector is zero, the editing operation blanks the result field.

6. The resulting condition code indicates whether or not the last field is all zeros and, if nonzero, reflects the state of the significance indicator. The significance indicator reflects the sign of the source field only if the last source byte examined contains a sign code in the rightmost four bits. For multiple-field editing operations, the condition code reflects the sign and value only of the field following the last field separator.

7. Significant performance degradation is possible when the second-operand address of an EDIT instruction designates a location that is closer to the left of an access boundary than the length of the first operand of that instruction (for the purposes of this discussion, an access boundary is 4 K-bytes, except when fetch-protection override applies in which case it is 2 K-bytes). This is because the machine may perform a trial execution of the instruction to determine if the second operand actually crosses the boundary. The second operand of EDIT, while normally shorter than the first operand, can in the extreme case have the same length as the first.

EDIT AND MARK

EDMK $D_1(L,B_1),D_2(B_2)$ [SS-a]



The second operand (the source), which normally contains one or more decimal numbers in the signed-packed-decimal or unsigned-packed-decimal format, is changed to the zoned format and modified under the control of the first operand (the pattern). The address of the first significant result byte of the rightmost (or only) field is inserted in general register 1. The edited result replaces the pattern.

EDIT AND MARK is identical to EDIT, except for the additional function of inserting the address of the result byte in general register 1 if the result byte is a zoned source digit and the significance indicator was off before the examination of the source digit. If no result byte meets the criteria, general register 1 remains unchanged; if more than one result byte meets the criteria, the address of the rightmost such result byte is inserted.

In the 24-bit addressing mode, the address replaces bits 40-63 of general register 1, and bits 0-39 of the register are not changed. In the 31-bit addressing mode, the address replaces bits 33-63 of general register 1, bit 32 of the register is set to zero, and bits 0-31 of the register remain unchanged. In the 64-bit addressing mode, the address replaces bits 0-63 of general register 1.

The contents of access register 1 remain unchanged.

See Figure 8-3 on page 8-10 for a summary of the EDIT and EDIT AND MARK operations.

Resulting Condition Code:

0 Last field zero or zero length
1 Last field less than zero
2 Last field greater than zero
3 --

Program Exceptions:

- Access (fetch, operand 2; fetch and store, operand 1)
- Data
- Transaction constraint

Programming Notes:

1. Examples of the use of the EDIT AND MARK instruction are given Appendix A, “Number Representation and Instruction-Use Examples.”

2. EDIT AND MARK facilitates the programming of floating currency-symbol insertion. Using appropriate source and pattern data, the address inserted in general register 1 is one greater than the address where a floating currency-sign would be inserted.

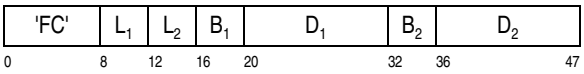
3. No address is inserted in general register 1 when the significance indicator is turned on as a result of encountering a significance starter with the corresponding source digit zero. To ensure that general register 1 contains a proper address when this occurs, the address of the pattern byte that immediately follows the appropriate significance starter could be placed in the register beforehand.

4. When multiple fields are edited with one execution of the EDIT AND MARK instruction, the address, if any, inserted in general register 1 applies to the rightmost field edited for which the criteria were met.

5. See also the programming note under EDIT regarding performance degradation due to a possible trial execution.

MULTIPLY DECIMAL

MP $D_1(L_1,B_1),D_2(L_2,B_2)$ [SS-b]



The product of the first operand (the multiplicand) and the second operand (the multiplier) is placed at the first-operand location. The operands and result are in the signed-packed-decimal format.

The multiplier length cannot exceed 15 digits and sign (L_2 not greater than seven) and must be less than the multiplicand length (L_2 less than L_1); otherwise, a specification exception is recognized.

The multiplicand must have at least as many bytes of leftmost zeros as the number of bytes in the multiplier; otherwise, a general-operand data exception is recognized. This restriction ensures that no product overflow occurs.

The multiplicand, multiplier, and product are each signed decimal integers in the signed-packed-decimal format and are right-aligned in their fields. All sign and digit codes of the multiplicand and multiplier are checked for validity. The sign of the product is determined by the rules of algebra from the multiplier and multiplicand signs, even if one or both operands are zeros.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2; fetch and store, operand 1)
- Data with DXC 0, general operand
- Specification
- Transaction constraint

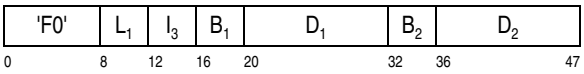
Programming Notes:

1. An example of the use of the MULTIPLY DECIMAL instruction is given Appendix A, “Number Representation and Instruction-Use Examples.”

2. The product cannot exceed 31 digits and sign. The leftmost digit of the product is always zero.

SHIFT AND ROUND DECIMAL

SRP $D_1(L_1,B_1),D_2(B_2),I_3$ [SS-c]



The first operand is shifted in the direction and for the number of decimal-digit positions specified by the second-operand address, and, when shifting to the right is specified, the absolute value of the first operand is rounded by the rounding digit, I_3. The first operand and the result are in the signed-packed-decimal format.

The first operand is considered to be in the signed-packed-decimal format. Only its digit portion is shifted; the sign position does not participate in the shifting. Zeros are supplied for the vacated digit positions. The result replaces the first operand. Nothing is stored outside of the specified first-operand location.

The second-operand address, specified by the B_2 and D_2 fields, is not used to address data; bits 58-63 of that address are the shift value, and the leftmost bits of the address are ignored.

The shift value is a six-bit signed binary integer, indicating the direction and the number of decimal-digit positions to be shifted. Positive shift values specify shifting to the left. Negative shift values, which are represented in two's complement notation, specify shifting to the right. The following are examples of the interpretation of shift values:

Shift Value (Binary)	Amount and Direction
011111	31 digits to the left
000001	One digit to the left
000000	No shift
111111	One digit to the right
100000	32 digits to the right

For a right shift, the I_3 field, bits 12-15 of the instruction, is used as a decimal rounding digit. The first operand, which is treated as positive by ignoring the sign, is rounded by decimally adding the rounding digit to the leftmost of the digits to be shifted out and by propagating the carry, if any, to the left. The result of this addition is then shifted right. Except for validity checking and the participation in rounding, the digits shifted out of the rightmost decimal-digit position are ignored and are lost.

If one or more nonzero digits are shifted out during a left shift, decimal overflow occurs. The operation is completed. The result is obtained by ignoring the overflow digits, and condition code 3 is set. If the decimal-overflow mask is one, a program interruption for decimal overflow occurs. Overflow cannot occur for a right shift, with or without rounding, or when no shifting is specified.

In the absence of overflow, the sign of a zero result is made positive. If overflow occurs, the sign of the result is the same as the original sign but with the preferred sign code.

A general-operand data exception is recognized when the first operand does not have valid sign and digit codes or when the rounding digit is not a valid digit code. The validity of the first-operand codes is checked even when no shift is specified, and the validity of the rounding digit is checked even when no addition for rounding takes place.

Resulting Condition Code:

0 Result zero; no overflow
1 Result less than zero; no overflow
2 Result greater than zero; no overflow
3 Overflow

Program Exceptions:

- Access (fetch and store, operand 1)
- Data with DXC 0, general operand
- Decimal overflow
- Transaction constraint

Programming Notes:

1. Examples of the use of the SHIFT AND ROUND DECIMAL instruction are given in Appendix A, "Number Representation and Instruction-Use Examples."

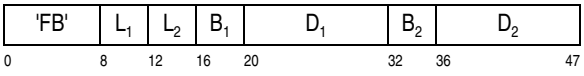
2. SHIFT AND ROUND DECIMAL can be used for shifting up to 31 digit positions left and up to 32 digit positions right. This is sufficient to clear all digits of any decimal number even with rounding.

3. For right shifts, the rounding digit 5 provides conventional rounding of the result. The rounding digit 0 specifies truncation without rounding.

4. When the B_2 field is zero, the six-bit shift value is obtained directly from bits 42-47 of the instruction.

SUBTRACT DECIMAL

SP $D_1(L_1,B_1),D_2(L_2,B_2)$ [SS-b]



The second operand is subtracted from the first operand, and the resulting difference is placed at the first-operand location. The operands and result are in the signed-packed-decimal format.

SUBTRACT DECIMAL is executed the same as ADD DECIMAL, except that the second operand is considered to have a sign opposite to the sign in storage. The second operand in storage remains unchanged.

Resulting Condition Code:

0 Result zero; no overflow

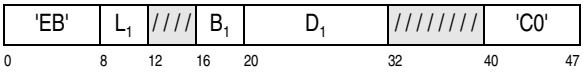
1 Result less than zero; no overflow
2 Result greater than zero; no overflow
3 Overflow

Program Exceptions:

- Access (fetch, operand 2; fetch and store, operand 1)
- Data with DXC 0, general operand
- Decimal overflow
- Transaction constraint

TEST DECIMAL

TP $D_1(L_1,B_1)$ [RSL-a]



The first operand is tested for valid decimal digits and a valid sign code, and the result is indicated in the condition code. The operand is in the signed-packed-decimal format.

Resulting Condition Code:

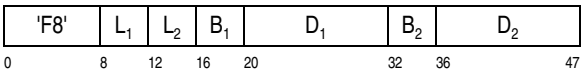
0 All digit codes and the sign valid
1 All digit codes valid and sign invalid
2 At least one digit code invalid and sign valid
3 At least one digit code invalid and sign invalid

Program Exceptions:

- Access (fetch, operand 1)
- Operation (if the extended-translation facility 2 is not installed)
- Transaction constraint

ZERO AND ADD

ZAP $D_1(L_1,B_1),D_2(L_2,B_2)$ [SS-b]



The second operand is placed at the first-operand location. The operation is equivalent to an addition to zero. The operand and result are in the signed-packed-decimal format.

Only the second operand is checked for valid sign and digit codes. Extra zeros are supplied on the left for the shorter operand if needed.

If the first operand is too short to contain all leftmost nonzero digits of the second operand, decimal overflow occurs. The operation is completed. The result is obtained by ignoring the overflow digits, and condition code 3 is set. If the decimal-overflow mask is one, a program interruption for decimal overflow occurs.

In the absence of overflow, the sign of a zero result is made positive. If overflow occurs, a zero result is given the sign of the second operand but with the preferred sign code.

The two operands may overlap, provided the rightmost byte of the first operand is coincident with or to the right of the rightmost byte of the second operand. In this case, the result is obtained as if the operands were processed right to left. When the operands overlap and the rightmost byte of the first operand is to the left of the rightmost byte of the second operand, then, depending on the model, either a general-operand data exception is recognized or the result is obtained as if the entire second operand were fetched before any byte of the result is stored.

Resulting Condition Code:

0 Result zero; no overflow
1 Result less than zero; no overflow
2 Result greater than zero; no overflow
3 Overflow

Program Exceptions:

- Access (fetch, operand 2; store, operand 1)
- Data with DXC 0, general operand
- Decimal overflow
- Transaction constraint

Programming Note: An example of the use of the ZERO AND ADD instruction is given in Appendix A, “Number Representation and Instruction-Use Examples.”

Floating-point instructions are used to perform calculations on operands having a wide range of magnitude and to obtain results scaled to preserve precision.

Floating-Point Data Formats

Floating-point operands have formats based on three radixes: 2, 10, or 16. These radix values lead to the terminology “binary,” “decimal,” and “hexadecimal” floating point (BFP, DFP, and HFP), respectively. The formats are also based on four operand lengths: tiny (16 bits), short (32 bits), long (64 bits), and extended (128 bits). Short operands require less storage than long or extended operands. On the other hand, long and extended operands permit greater precision in computation.

Sign Bit

All floating-point data have a sign bit. The sign bit is zero for plus and one for minus.

Finite Floating-Point Numbers

A finite floating-point number has three components: a sign bit, an exponent, and a significand. The magnitude (an unsigned value) of the number is the product of the significand and the radix raised to the power of the exponent. The number is positive or negative depending on whether the sign bit is zero or one, respectively.

The significand consists of a string of digits, where each digit is an integral value from zero to one less than the radix (2, 10, or 16). (Thus, a BFP digit is one bit, an HFP digit is four bits, and a DFP digit is a value from zero to nine.) The number of digit positions in the significand is called the precision of the floating-point number. The significand has an implied radix point, which, depending on the view, may be considered to be on the left, to the right of the leftmost digit, on the right, or elsewhere.

The exponent, a signed value, is represented as an unsigned binary value by adding a bias; the result, for BFP and DFP, is called the biased exponent; for HFP, it is called the characteristic. The value of the bias depends on the view. In the *fraction view*, the radix point is considered to be the left of the significand. In the *left-units view*, the radix point is considered to be to the right of the leftmost digit. In the *right-units view*, the radix point is considered to be on the right of the significand. By choosing the appropriate bias, any finite floating-point number can be considered in any of these views, or even in another view. For the first three of these views, the bias is called the *fraction-view bias, left-units-view bias,* and *right-units-view bias,* respectively. Except where otherwise indicated, HFP is defined in terms of the fraction view, BFP terms of the left-units view, and DFP in terms of the right-units view.

For HFP, the significand is considered to be a fraction with the implied radix point on the left. In this view, the significand is referred to as the fraction. For BFP, the significand consists of an implicit unit digit to the left of an implied radix point and an explicit fraction field to the right. For DFP, the significand is considered to be an integer with the implied radix point on the right.

Infinities

BFP and DFP data include an infinite numeric datum, called infinity. Infinities can participate in most arithmetic operations and give a consistent result, usually infinity. An infinity has a sign bit. In comparisons, infinities of the same sign compare equal, +∞ compares greater than any finite number, and -∞ compares less than any finite number.

Not-A-Number (NaN)

BFP and DFP data types include a nonnumeric datum, called not-a-number (or NaN). A NaN is produced in place of a numeric result after an invalid operation when there is no IEEE trap action. NaNs may also be used by the program to flag special operands, such as the contents of an uninitialized storage area. A NaN has a sign bit, a NaN-type bit, and a payload.

Signaling and Quiet NaNs

There are two types of NaNs, signaling and quiet. A signaling NaN (SNaN) is distinguished from the corresponding quiet NaN (QNaN) by the NaN-type bit.

For BFP, the NaN-type bit is the leftmost bit of the fraction field, and is called the QNaN bit: a BFP NaN is an SNaN, or a QNaN, depending on whether the QNaN bit is zero, or one, respectively. For DFP, the

NaN-type bit is in bit position 6 in all three formats, and is called the SNaN bit: a DFP NaN is a QNaN, or an SNaN, depending on whether the SNaN bit is zero, or one, respectively.

Payload

NaNs include diagnostic information called the payload. For BFP, the payload has two fewer bits than the precision and is considered to be a left-aligned bit-reversed binary integer. For DFP, the payload has one fewer digit than the precision and is considered to be a right-aligned decimal integer.

For both BFP and DFP the payload of a NaN is considered to be an unsigned integer. Let p represent the precision, in digits, of a particular format. For DFP, bit 6 of the format is called the SNaN bit and the p-1 digits in the trailing significand field are the numeric value of the payload. For BFP, the leftmost bit in the fraction field is called the QNaN bit and the remaining p-2 bits of the fraction field are the numeric value of the payload.

The numeric value of the BFP NaN payload is bit-reversed. That is, the first bit to the right of the QNaN bit is considered to have a value of one, the next bit a value of two, and so on, with each bit having a value of twice the value of the bit to its left.

Propagation of NaNs

Normally, QNaNs are just propagated during computations so that they will remain visible at the end; while an SNaN operand causes an IEEE-invalid-operation exception. If the IEEE-invalid-operation mask (FPC 0.0) is zero, the result is the corresponding QNaN, which is produced by inverting the NaN-type bit, and setting the IEEE-invalid-operation flag (FPC 1.0) is set to one. If the IEEE-invalid-operation mask (FPC 0.0) is one, the operation is suppressed, and a data exception for IEEE-invalid operation occurs.

Where applicable, the propagation of NaNs is illustrated in the action figure for an instruction.

Default QNaN

A special QNaN is supplied as the default result for an IEEE-invalid-operation exception or as a result of the NNPA-TRANSFORM function when transforming a nonnumeric NNP-data-type-1 value into a binary-floating-point value; it has a plus sign and a payload of zeros.

Programming Notes:

1. The program can generate and assign values to the payload of a NaN. The CPU propagates those values unchanged, except that an SNaN is changed to the corresponding QNaN if the IEEE-invalid-operation mask bit is zero, and conversion to a narrower format truncates digits from the payload. For BFP, bits are truncated on the right; for DFP, digits are truncated on the left. For the PFPO-convert-floating-point-radix operation, payloads are preserved, except that payloads larger than the capacity of the target format are replaced by the default QNaN (payload zero).
2. Depending on the application, the program may or may not desire that an SNaN signal the IEEE invalid-operation exception. The sign-handling instructions LOAD COMPLEMENT, LOAD NEGATIVE, and LOAD POSITIVE do not signal the invalid-operation exception but, instead, treat SNaNs like any other data. LOAD AND TEST signals the invalid-operation exception when the operand is an SNaN. This instruction, in conjunction with the above instructions, gives the program the choice of either option.
3. The instructions LOAD LENGTHENED and LOAD ROUNDED change the precision of a floating-point datum. The BFP versions of these instructions signal the invalid-operation exception when the operand is an SNaN. The DFP instructions have a modifier bit to control whether the exception is signaled.

Floating-Point Number Representations

Hexadecimal-Floating-Point (HFP)

Hexadecimal-floating-point (HFP) operands have formats which provide for exponents that specify powers of the radix 16 and significands that are hexadecimal numbers. The exponent range is the same for the short, long, and extended formats.

The results of most operations on HFP data are truncated to fit into the target format, but there are instructions available to round the result when converting to a narrower format. Additionally, the PERFORM FLOATING POINT OPERATION instruction

provides rounding methods when converting to an HFP format from BFP or DFP.

For HFP operands, the implicit unit digit of the significand is always zero. Since the value of the significand and fraction are the same, HFP operations are described in terms of the fraction, and the term significand is not used.

Either normalized or unnormalized numbers may be used as operands for any HFP or DFP operation, where, for HFP, a normalized number is one having a nonzero leftmost fraction digit, or, for DFP, a normalized number is one having a nonzero leftmost significand digit. Most HFP instructions generate normalized results for greatest precision. HFP add and subtract instructions that generate unnormalized results are also available. When the HFP-unnormalized-extensions facility is installed, the MULTIPLY UNNORMALIZED and MULTIPLY AND ADD UNNORMALIZED instructions also generate unnormalized results.

Binary Floating-Point (BFP)

Binary-floating-point (BFP) operands have formats which provide for exponents that specify powers of the radix 2 and significands that are binary numbers. The exponent range differs for different formats, the range being greater for the longer formats. In the long and extended formats, the exponent range is significantly greater for BFP data than for HFP data.

The results of operations performed on BFP data are rounded automatically to fit into the target format. The manner of rounding is determined by a program-settable BFP rounding mode; however, explicit rounding modes may be specified in various BFP instructions.

There are no unnormalized operands for BFP operations. For normal BFP numbers, the implicit unit digit of the significand is one. For values too small in magnitude to be represented in normalized form, the implicit unit digit is zero. These numbers are called *subnormal* numbers.[1] Unlike the HFP and DFP formats, where the same value can have multiple representations in a given format because of the possibility of unnormalized numbers, the BFP format does not allow such redundancy.

Decimal Floating-Point (DFP)

Decimal-floating-point (DFP) operands have formats which provide for exponents that specify powers of the radix 10 and significands that are decimal numbers. The exponent range differs for different formats, the range being greater for the longer formats. The exponent range is greater for DFP data than for BFP data.

The results of operations performed on DFP data are rounded automatically to fit into the target format. The manner of rounding is determined by a program-settable DFP rounding mode; however, explicit rounding modes may be specified in various DFP instructions.

Like HFP, DFP numbers can be normalized or unnormalized. Either normalized or unnormalized numbers may be used as operands for any DFP operation. For DFP, a normalized number is one having a nonzero leftmost significand digit. Because of the possibility of unnormalized numbers, the same value can have multiple representations in a given DFP format. The representations having the same value are called members of a cohort. Unlike HFP, DFP instructions generate normalized results for greater precision only when the result is inexact. When the result is exact, most DFP instructions produce a value in the form that preserves information called the quantum.

Canonical DFP Data

A *canonical DFP number* has only canonical declets, that is, the digits in the trailing-significand field are encoded using only the preferred DPD codes.

A *canonical DFP infinity* has bit 6 and all bits to the right of this in the format set to zeros.

A *canonical DFP NaN* has zeros in all bits to the right of the NaN-type bit in the combination field and only canonical declets in the trailing significand field.

Noncanonical DFP numbers, infinities, and NaNs are accepted as source operands, but all DFP results are canonical.

1. Subnormal numbers were previously called *denormalized* numbers.

Comparison of Floating-Point Number Representations

Floating-Point Number Ranges

Figure 9-1 shows the range of numbers, in decimal form, that can be represented in different floating-point formats.

	Type	Short	Long	Extended
Nmax	HFP	$\pm 7.2\times10^{+75}$	$\pm 7.2\times10^{+75}$	$\pm 7.2\times10^{+75}$
	BFP	$\pm 3.4\times10^{+38}$	$\pm 1.8\times10^{+308}$	$\pm 1.2\times10^{+4932}$
	DFP	$\pm 1.0\times10^{+97}$	$\pm 1.0\times10^{+385}$	$\pm 1.0\times10^{+6145}$
Nmin	HFP	$\pm 5.4\times10^{-79}$	$\pm 5.4\times10^{-79}$	$\pm 5.4\times10^{-79}$
	BFP	$\pm 1.2\times10^{-38}$	$\pm 2.2\times10^{-308}$	$\pm 3.4\times10^{-4932}$
	DFP	$\pm 1.0\times10^{-95}$	$\pm 1.0\times10^{-383}$	$\pm 1.0\times10^{-6143}$
Dmin	HFP	$\pm 5.1\times10^{-85}$	$\pm 1.2\times10^{-94}$	$\pm 1.7\times10^{-111}$
	BFP	$\pm 1.4\times10^{-45}$	$\pm 4.9\times10^{-324}$	$\pm 6.5\times10^{-4966}$
	DFP	$\pm 1.0\times10^{-101}$	$\pm 1.0\times10^{-398}$	$\pm 1.0\times10^{-6176}$

Explanation:

Dmin Smallest (in magnitude) representable subnormal (BFP or DFP) or nonzero unnormalized (HFP) number.
Nmax Largest (in magnitude) representable number.
Nmin Smallest (in magnitude) representable normal (BFP or DFP) or normalized (HFP) number.

Values are decimal approximations for all of the HFP, BFP, and DFP formats.

Figure 9-1. Decimal Approximations of Number Ranges for HFP, BFP, and DFP Formats

Equivalent Floating-Point Number Representations

The exponent of an HFP number is represented in the format as an unsigned seven-bit binary integer called the characteristic. The characteristic is obtained by adding 64 to the exponent value (excess-64 notation). The range of the characteristic is 0 to 127, which corresponds to an exponent range of -64 to +63.

The exponent of a BFP or DFP datum is represented in the format as an unsigned binary integer called the biased exponent. The biased exponent is obtained by adding a bias to the exponent value. The number of bit positions containing the biased exponent, the value of the bias, and the exponent range depend on the data format (short, long, or extended) and are shown for the three formats in Figure 19-5 on page 19-3 and the three DFP formats in Figure 20-3 on page 20-6. Biased exponents are similar to the characteristics of the HFP format, except that, for BFP, special meanings are attached to biased exponents of all zeros and all ones. This is discussed in the section “Classes of BFP Data” on page 19-4.

In each of the four BFP formats and three HFP formats, the binary or hexadecimal point of a number, respectively, is considered to be to the left of the leftmost fraction digit. To the left of the point there is an implied unit digit, which is considered to be zero for HFP numbers or, for BFP numbers, one for normal numbers and zero for zeros and subnormal numbers.

Figure 9-2 on page 9-6 and Figure 9-3 on page 9-7 give examples of the closest representation of the same numbers in the BFP, DFP, and HFP formats, with BFP and DFP values being rounded to nearest and HFP values being truncated.

The figures do not necessarily show the results of conversions exactly. Rounding errors may make a small difference. Also, Figure 9-2 on page 9-6 shows corresponding rounded short-format numbers, not the long HFP results of conversion from short BFP operands.

Figure 9-3. Examples of Floating-Point Numbers in Long Format

Effective Width

The resolution of a floating-point format may be described in terms of the spacing between adjacent representable numbers in the format. This is called an ulp (unit in the last place). Thus, for example, when rounding to nearest, the maximum error is 1/2 ulp. The magnitude of an ulp is directly related to the precision of the format. Another way to measure the resolution of the format in the vicinity of a particular value is in terms of relative spacing, which is simply the value of an ulp divided by the value of the number. Relative spacing may be converted to a form called effective width, which is very similar to precision. The *effective width* (W_x) for any particular normalized floating-point value, v, is defined as:

$$W_x(v) = \log_x(v/u)$$

Where:

u Value of a unit in the last position (ulp).
v Value of the number.
W_x Effective width represented in base x.
x Any arbitrary base.

When effective width is measured using the native base for a particular format, it differs from the precision (p) of the format as shown in the following relation:

$p-1 \leq W_b \leq p$

Where:

b Native base of a particular format.
p Precision of the format.
W_b Effective width for any normalized value represented in the native base b of the format.

The following figure shows the maximum and minimum values of the effective width for normalized numbers for all supported floating-point formats.

Length	Radix	W_2		W_{10}	
		Max	Min	Max	Min
Short	HFP	24.00	20.00	7.22	6.02
	BFP	24.00	23.00	7.22	6.92
	DFP	23.25	19.93	7.00	6.00
Long	HFP	56.00	52.00	16.86	15.65
	BFP	53.00	52.00	15.95	15.65
	DFP	53.15	49.83	16.00	15.00
Extended	HFP	112.00	108.00	33.72	32.51
	BFP	113.00	112.00	34.02	33.72
	DFP	112.95	109.62	34.00	33.00

Explanation:

W_2 effective width represented in base 2.
W_{10} effective width represented in base 10.

Figure 9-4. Maximum and Minimum Effective Width

Programming Note: The following example using a 3-digit decimal significand, may be helpful in understanding the concept of effective width and the maximum and minimum values. Consider the three adjacent representable numbers, Va, Vb, and Vc, as shown in the following figure:

Symbol or Formula	Value
Va	9.99
Vb	10.0
Vc	10.1
Vb-Va	0.01
Vc-Vb	0.1

The distance between points Va and Vb (Vb-Va) represents a resolution of one part in a thousand; whereas, the distance between points Vb and Vc (Vc-Vb) represents a resolution of one part in a hundred. In the first case, the effective width is three digits; in the second case, it is only two digits. For other values in the format, the effective width lies between these two extremes.

Floating-Point Data in Storage

All floating-point data formats appear in storage in the same left-to-right sequence as all other data formats. Bits of a data format that are numbered 0-7 constitute the byte in the leftmost (lowest-numbered) byte location in storage, bits 8-15 form the byte in the next sequential location, and so on. (See also the section “Storage Addressing” on page 3-2.)

Most of the floating-point instructions are defined in detail in this publication in Chapter 18, “Hexadecimal-Floating-Point Instructions,” Chapter 19, “Binary-Floating-Point Instructions,” Chapter 20, “Decimal-Floating-Point Instructions,” Chapter 24, “Vector Floating-Point Instructions,” and Chapter 26, “Specialized-Function-Assist Instructions.” This chapter, Chapter 9, defines in detail instructions called floating-point-support (FPS) instructions. The FPS instructions either have operands that may be in any floating-point format or have the function of converting between formats. This chapter also provides summary information about all of the floating-point instructions.

Registers And Controls

Floating-Point Registers

All floating-point instructions (FPS, BFP, DFP, and HFP) use the same 16 floating-point registers. The

floating-point registers are identified by the numbers 0-15 and are designated by a four-bit R field in floating-point instructions. Each floating-point register is 64 bits long and can contain either a short (32-bit) or a long (64-bit) floating-point operand.

A short floating-point datum requires only the leftmost 32 bit positions of a floating-point register. The rightmost 32 bit positions of the register are ignored when the register is the source of an operand in the short format, and they remain unchanged when a short result is placed in the register.

A datum in the extended (128-bit) format occupies a register pair. Register pairs are formed by coupling the 16 registers as follows: 0 and 2, 4 and 6, 8 and 10, 12 and 14, 1 and 3, 5 and 7, 9 and 11, and 13 and 15.

Each of the eight pairs is referred to by the number of the lower-numbered register of the pair.

Additional Floating-Point (AFP) Registers

Floating-point registers 0, 2, 4, and 6 are ones that were originally available on ESA/390 models. The remaining 12 floating-point registers (1, 3, 5, and 7-15) were added to ESA/390 and are referred to as the additional floating-point (AFP) registers. The AFP registers can be used only if bit 45 of control register 0, the AFP-register-control bit, is one. Attempting to use an AFP register when the AFP-register-control bit is zero results in an AFP-register data exception (DXC 1).

Valid Floating-Point-Register Designations

Any installed register may be designated by an instruction to specify the register location of a short or long floating-point operand.

An instruction specifying a floating-point operand in the extended format must designate register 0, 1, 4, 5, 8, 9, 12, or 13; otherwise, a specification exception is recognized.

Floating-Point-Control (FPC) Register

The floating-point-control (FPC) register is a 32-bit register that contains mask bits, flag bits, a data-exception code, and two rounding-mode fields. An overview of the FPC register is shown in Figure 9-5. Details are shown in Figure 9-6 and in Figure 9-8. (In Figure 9-6, the abbreviations “IM” and “SF” are based on the terms “interruption mask” and “status flag,” respectively.)

The bits of the FPC register are often referred to as, for example, FPC 1.0, meaning bit 0 of byte 1 of the register.

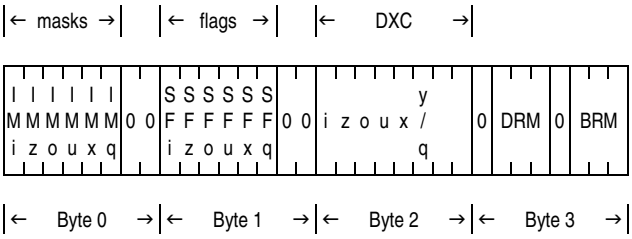

Figure 9-5. FPC Register Overview

Byte	Bit(s)	Name	Abbr.
0	0	IEEE-invalid-operation mask	IMi
0	1	IEEE-division-by-zero mask	IMz
0	2	IEEE-overflow mask	IMo
0	3	IEEE-underflow mask	IMu
0	4	IEEE-inexact mask	IMx
0	5	Quantum-exception mask	IMq
0	6-7	(Unassigned)	0
1	0	IEEE-invalid-operation flag	SFi
1	1	IEEE-division-by-zero flag	SFz
1	2	IEEE-overflow flag	SFo
1	3	IEEE-underflow flag	SFu

Explanation:

1 Used when the floating-point extension facility is not installed.

2 Used when the floating-point extension facility is installed. However, bits 5-7 may be used by the other architecture mode of the configuration. (See the section, "Impacts on ESA/390 and ESA/390-Compatibility Mode", for details.)

— Does not apply

Figure 9-8. BFP Rounding Mode

IEEE Masks and Flags

When the floating-point extension facility is installed, the FPC register contains six IEEE mask bits and six IEEE flag bits that each correspond to one of the six IEEE exceptions that may be recognized when an IEEE computational instruction is executed. When the floating-point extension facility is not installed, the quantum exception is not recognized; the mask bit FPC 0.5 and the status flag bit FPC 1.5 corresponding to the quantum exception are unsupported and are zeros.

The mask bits, when one, in the FPC register cause an interruption to occur if an exception is recognized. If the mask bit for an exception is zero, the recognition of the exception causes the corresponding flag bit to be set to one. Thus, a flag bit indicates whether the corresponding exception has been recognized at least once since the program last set the flag bit to zero. Except for PFPO, the mask bits are ignored, and the flag bits remain unchanged, when exceptions are recognized for floating-point-support (FPS) and HFP instructions.

The IEEE flag bits in the FPC register are set to zero only by explicit program action, initial CPU reset, clear reset, or power-on reset.

Note: The quantum exception is not part of the IEEE Standard 754-2008 (see Reference [20.] on page xxxii). However, since this data exception with its mask and status flag in the FPC is handled very much like the five IEEE exceptions, this architecture lists the quantum exception among the IEEE exceptions.

FPC DXC Byte

Byte 2 of the FPC register contains the data-exception code (DXC), which is an eight-bit code indicating the specific cause of a data exception. When the AFP-register-control bit, bit 45 of control register 0, is one and a program interruption causes the DXC to be placed at real location 147, the DXC is also placed in the DXC field of the FPC register. The DXC field in the FPC register remains unchanged when the AFP-register-control bit is zero or when any other program exception is reported. The DXC is described in "Data-Exception Code (DXC)" on page 6-17.

The DXC is a code, meaning it should be treated as an integer rather than as individual bits. However, when bits 6 and 7 are zero, bits 0-5 are bit significant; bits 0-4 (i, z, o, u, and x) are trap flags and correspond to the same bits in bytes 0 and 1 of the FPC register (IEEE masks and IEEE flags), and bit 5 (y) is used in conjunction with bit 4, inexact (x), to indicate that the result has been incremented in magnitude. When the floating-point extension facility is installed, DXC bit 5 (q) is also the quantum-exception trap flag. The trap flag for an exception, instead of the IEEE flag, is set to one when an interruption for the exception is enabled by the corresponding IEEE mask bit.

Operations on the FPC Register

The following unprivileged instructions allow problem-state programs to operate on the FPC register:

EXTRACT FPC (DXC 2)
LOAD FPC (DXC 2)

LOAD FPC AND SIGNAL (DXC 3)
SET BFP ROUNDING MODE (DXC 2)
SET DFP ROUNDING MODE (DXC 3)
SET FPC (DXC 2)
SET FPC AND SIGNAL (DXC 3)
STORE FPC (DXC 2)

These instructions are subject to the AFP-register-control bit, bit 45 of control register 0. An attempt to execute any of the above instructions when the AFP-register-control bit is zero results in a data exception. The term (DXC 2) or (DXC 3) after the name indicates the type of exception: that is, BFP-instruction data exception, (DXC 2), or DFP-instruction data exception, (DXC 3), respectively.

Programming Note: The use of DXC 2 and DXC 3 for these floating-point-support (FPS) instructions is rather arbitrary, but assuming a valid operating system, these exceptions are never reported to the user, as the operating system will set bit 45 of control register 0 to one and re-issue the instruction.

AFP-Register-Control Bit

Bit 45 of control register 0 is the AFP-register-control bit. The AFP registers, the BFP instructions, the DFP instructions, and PFPO can be used successfully only when the AFP-register-control bit is one. Attempting to use one of the 12 additional floating-point registers or executing PFPO when the AFP-register-control bit is zero results in an AFP-register data exception (DXC 1). Attempting to execute any BFP instruction when the AFP-register-control bit is zero results in a BFP-instruction data exception (DXC 2). Attempting to execute any DFP instruction when the AFP-register-control bit is zero results in a DFP-instruction data exception (DXC 3).

DXC 2 and 3 are mutually exclusive and are of higher priority than any other DXC. Thus, for example, DXC 2 (BFP instruction) takes precedence over any IEEE exception; and DXC 3 (DFP instruction) takes precedence over any IEEE exception. As another example, if the conditions for both DXC 3 (DFP instruction) and DXC 1 (AFP register) exist, DXC 3 is reported.

If the conditions for both a data exception and a specification exception exist, it is unpredictable which exception is reported.

The initial value of the AFP-register-control bit is zero.

IEEE Computational Operations

Notes:

1. The following section primarily discusses the BFP and DFP formats, however the topics on rounding also discuss the HFP format, as indicated in the text.

2. The description of binary-floating-point operations in this document is based on the original *IEEE Standard for Binary Floating-Point Arithmetic* (IEEE Std. 754-1985). The current *IEEE Standard for Floating-Point Arithmetic* (see Reference [20.] on page xxxii), which encompasses both binary and decimal floating point operations, made various terminology changes from the original standard, as follows:

   - The term *subnormal* replaces the term *denormalized*.
   - The term *exception* functionally replaces the former term *trap*. The term *default handling* (or *default non-stop execution handling*) correspond to the former *nontrap* action. and the term *alternate exception handling* encompasses the former *trap* action, as well as other actions.
   - The term *loss* (as in *loss of accuracy* or *denormalization loss*) is no longer used.

   Because of their pervasive use in the original description of binary floating point, the terms *denormalized*, *trap*, and *nontrap* still appear in this document. It is understood that they refer to the equivalent newer terms. A program-exception condition represents the only IEEE-defined alternate exception handling.

Instructions which operate on BFP or DFP source operands or produce BFP or DFP results and recognize IEEE exceptions are called IEEE computational operations, and the associated operands and results are sometimes referred to as IEEE operands and IEEE results, respectively.

Execution of IEEE computational operations normally follows a certain pattern. Source operands are first tested for special cases and then processed to form a result. The priority for testing of special cases is SNaN, QNaN, infinity, and then finite number.

If a source operand is an SNaN, an IEEE-invalid-operation exception is recognized; and, in the non-trap case, the result is set to the corresponding QNaN.

In the absence of a source SNaN, if a source operand is a QNaN the result is set to that QNaN.

Handling of the case when more than one source operand is a NaN is covered in the individual instruction descriptions.

In the absence of a NaN, if an operand is an infinity, special “infinity arithmetic” rules are followed to produce the result.

Programming Note: PERFORM FLOATING-POINT OPERATION is an IEEE computational operation.

Intermediate Values

In the normal case (when all source operands are finite numbers), first, a *precise intermediate value* is produced, then a *rounded intermediate value*. In the absence of trapped overflow and trapped underflow, the rounded intermediate value is used as the *delivered value*. For trapped overflow and trapped underflow, the rounded intermediate value is divided by a *scale factor* to produce a *scaled value*, which is used as the delivered value. Finally, the delivered value is placed in the target location. For DFP, since the cohort for the delivered value may have multiple members, one member from the cohort must be selected. Selection is performed by choosing the member having a quantum closest to the *preferred quantum* (or for trapped overflow and trapped underflow, a *scaled preferred quantum*.

Precise Intermediate Value

Every IEEE computational operation producing a numeric result computes a value called the *precise intermediate value.* This is the value that would have been computed were both the precision and exponent range unbounded.

Precision-Rounded Value

Except when otherwise specified, the precise intermediate value is rounded to the precision of the target format, but with unbounded exponent range. This process is called *target-precision-constrained rounding*, and the value selected by this type of rounding is called the *precision-rounded value*.

Denormalized Value

For IEEE targets, when the IEEE-underflow trap is disabled and the tininess condition exists, the precise intermediate value is rounded to fit in the destination format (that is, with both precision and exponent range of the target format). This process is called *denormalization rounding* and the value selected by this type of rounding is called the *denormalized value*.

Functionally-Rounded Value

The instructions CONVERT TO FIXED, LOAD FP INTEGER, QUANTIZE, and REROUND, as an integral part of the function, take a source operand and modify it to fit in a subset of the destination format. This process is called *functionally-constrained rounding* and the value selected by this type of rounding is called the *functionally-rounded value*.

Rounded Intermediate Value

In any particular instance, only one of the three rounding processes is performed and the value selected (precision-rounded value, denormalized value, or functionally-rounded value) is generically referred to as the *rounded intermediate value*.

Scaled Value

For both overflow and underflow when the associated trap is enabled, the precision-rounded value is scaled to bring it into the representable exponent range of the target. This is called the *scaled value* and is derived as explained in the next section.

Scale Factor (Ψ)

IEEE-overflow trap action and IEEE-underflow trap action produce a *scaled value* using a *scale factor*. The scaled value (z) is computed from the precision-rounded value (g) using the scale factor (Ψ) as follows:

$$z = g \div \Psi$$

Unsigned Scaling Exponent (α)

For BFP and DFP instructions, the scale factor (Ψ) is computed using the unsigned scaling exponent (α) and different formulas are used for overflow and underflow.

$$\Psi = \begin{cases} b^{+\alpha} & \text{For overflow:} \\ b^{-\alpha} & \text{For underflow:} \end{cases}$$

where b is the radix of the target (2 for BFP and 10 for DFP). The unsigned scaling exponent (α) depends on the type of operation and operand format.

For all BFP operations except LOAD ROUNDED, α depends on the target format and is 192 for short, 1536 for long, and 24576 for extended. For BFP LOAD ROUNDED, α depends on the source format, and is 512 for long and 8192 for extended.

For all DFP operations except LOAD ROUNDED, α depends on the target format and is 576 for long and 9216 for extended. For DFP LOAD ROUNDED, α depends on the source format, and is 192 for long and 3072 for extended.

Signed Scaling Exponent (Ω)

For PFPO convert floating-point radix, the scale factor (Ψ) is computed using the signed scaling exponent (Ω) and the formula for the scale factor (Ψ) is the same for overflow and underflow:

$$\Psi = b^{\Omega}$$

Where b is the radix (2, 10, and 16) for BFP, DFP and HFP, respectively. Thus, for overflow, the signed scaling exponent (Ω) is a positive value, and for underflow it is a negative value.

IEEE Rounding

Rounding takes an input value, and, using the effective rounding method, selects a value from a permissible set. The input value, considered to be infinitely-precise, may be an operand of an instruction or the numeric output from an arithmetic operation. The effective rounding method may be the current rounding method specified in the BFP-rounding-mode or DFP-rounding-mode field of the FPC register; or, for some instructions, an explicit rounding method is specified by a modifier field. For the PFPO-convert-floating-point-radix operation, rounding is specified by a field in an implicit register.

For target-precision-constrained rounding and denormalization rounding, the input is the precise intermediate value. For functionally-constrained rounding, the input is a source operand.

Permissible Set

Rounding selects a value from the permissible set. A permissible set is a set of values, and not representations; thus, for DFP, the selection of a member from the cohort is considered to be performed after rounding. A permissible set differs from the values representable in a particular format in the following ways:

1. A permissible set does not include infinity. Infinity is handled as a special case.
2. For target-precision-constrained rounding, the permissible set is considered to have an unbounded exponent range.
3. For denormalization rounding, the permissible set is limited to the values representable in a particular format.
4. For LOAD FP INTEGER, the permissible set contains only integral values.
5. For QUANTIZE, the permissible set is similar to LOAD FP INTEGER, containing only those values which are integral multiples of the requested quantum.
6. For REROUND, the permissible set contains only those values which can be represented within the requested precision.

Selection of Candidates

If a member of the permissible set is equal in value to the input value, then that member is selected; otherwise, two adjacent candidates with the same sign as the input value are chosen from the permissible set. One candidate, called TZ (toward zero), is the member of the permissible set nearest to and smaller in magnitude than the input value; the other candidate, called AZ (away from zero), is the member of the permissible set nearest to and larger in magnitude than the input value. Which of the two candidates is selected depends on the rounding method.

Ties

Three rounding methods depend on a condition called a “tie.” This condition exists when the two candidates are equidistant from the input value.

Voting Digit and Common-Rounding-Point View

Two rounding methods depend on the value of the voting digit of each candidate. (Each “digit” is an integral value from zero to one less than the radix. Thus,

a BFP digit is one bit, an HFP digit is four bits, and a DFP digit is a value from zero to nine.) The voting digit is the units digit of the significand when considered in the common-rounding-point view.

Without changing the value of a floating-point number, the significand may be viewed with the implied radix point in different positions, provided a corresponding adjustment is made to the exponent. In the common-rounding-point view, an implied radix point (called the common rounding point) and an associated exponent are selected for the input value and the two candidates, TZ and AZ. The common-rounding point is selected to satisfy the following requirements:

1. The input value and the two candidates all have the same exponent.
2. The significand of TZ is equal to the significand of the input value truncated at the rounding point.
3. The significand of AZ is one greater in magnitude than the significand of TZ.

Rounding Methods

Figure 9-8 and Figure 9-7 on page 9-10 show the implicit rounding methods available for BFP and DFP operations respectively. The section “Explicit Rounding Methods” on page 9-17 describes rounding methods that may be explicitly specified in an instruction, overriding the implicit rounding method. The rounding methods are as follows:

Round to nearest with ties to even: The candidate nearest to the input value is selected. In case of a tie, the candidate selected is the one whose voting digit has an even value.

Round toward 0: The candidate that is smaller in magnitude is selected.

Round toward +∞: The candidate that is algebraically greater is selected.

Round toward -∞: The candidate that is algebraically less is selected.

Round to nearest with ties away from 0: The candidate nearest to the input value is selected. In case of a tie, the candidate selected is the one that is larger in magnitude.

Round to nearest with ties toward 0: The candidate nearest to the input value is selected. In case of a tie, the candidate selected is the one that is smaller in magnitude.

Round away from 0: The candidate that is greater in magnitude is selected.

Round to prepare for shorter precision: For a BFP or HFP permissible set, the candidate selected is the one whose voting digit has an odd value. For a DFP permissible set, the candidate that is smaller in magnitude is selected, unless its voting digit has a value of either 0 or 5; in that case, the candidate that is greater in magnitude is selected.

Programming Notes:

1. The two candidates are defined as: “nearest to and smaller” and “nearest to and larger”. Note that the simpler definition, “the two closest values,” is incorrect, as it is possible that the two closest values to the input value can be on the same side (toward zero). To illustrate this, Figure 9-9 on page 9-15 gives an example of rounding the integer value 10,000,003 to DFP short. Several members in the permissible set near this value are shown in three views: left-units view, right-units view, and integer view. The fourth column shows the distance of each member from the input value. In this example, the four closest members are all smaller in magnitude than the input value. Although the example is shown using DFP, corresponding examples can be shown for both BFP and HFP. In the extreme case, the number of members in the permissible set which are closer than candidate AZ, is 2, 10, and 16, for BFP, DFP, and HFP, respectively.
2. Except for rounding methods using the voting digit, rounding can normally be considered to be performed using values independent of the representation and the view. Figure 9-10 on page 9-16 is an example, using the instruction LOAD FP INTEGER, to illustrate the concepts of different representations, views, rounding point, common-rounding-point view, and voting digit. In the example, the input value (source operand) is 29.5 and the two candidates are 29 and 30. The figure shows all three of these values using the left-units, right-units, and common-rounding-point views in both decimal and binary representations. Note that as shown in the left-units and right-units view columns, the rightmost digit is

odd for both TZ and AZ. (But as represented in all BFP formats, these values would have an even rightmost digit; and as represented in DFP formats, these values could have an even or odd rightmost digit, depending on the quantum.) The voting digit can be identified in the common-rounding-point view as the digit to the immediate left of the rounding point. In both the decimal and binary representations, candidate TZ has an odd voting digit and candidate AZ has an even voting digit.

LOAD FP INTEGER produces consistent results between decimal and binary for five of the six rounding methods currently supported by the BFP instruction; for the round-to-prepare-for-shorter-precision rounding method, this is not always the case. Figure 9-11 on page 9-16 shows results of LOAD FP INTEGER for several input values for all eight rounding methods. Only in the round-to-prepare-for-shorter-precision method are the results different for decimal and binary.

3. An example of LOAD ROUNDED (long to short DFP) is shown in Figure 9-12 on page 9-16 In this example, the integer 99,999,995 is rounded from DFP long to DFP short. The cohort for candidate TZ in this case, has only one member and is odd. The cohort of candidate AZ has seven members, one of which is odd and the other six are even. The common-rounding-point view makes it clear that in this case, candidate AZ should be considered to be even.

4. The rightmost digit and the voting digit of a candidate are not necessarily the same digit. Figure 9-13 on page 9-16 and Figure 9-14 on page 9-17 give two examples using the instruction REROUND (long DFP). In both examples, the requested significance is one (Result Digits=1). The input value is 95 in the first example and 150 in the second example. Note that candidate AZ in the first example is the same value as candidate TZ in the second example. In the first example, this member is considered to be even, and in the second example it is considered to be odd.

Value in Permissible Set			Distance from 10000003	Notes

Explicit Rounding Methods

The floating-point-support instruction CONVERT HFP TO BFP includes an M_3 modifier field which can specify any of six rounding methods. One HFP instruction (CONVERT TO FIXED); three BFP instructions (CONVERT TO FIXED, DIVIDE TO INTEGER, and LOAD FP INTEGER); and five DFP instructions (CONVERT TO FIXED, LOAD FP INTEGER, LOAD ROUNDED, QUANTIZE, and REROUND) also include either an M_3 modifier field or a similar M_4 modifier field. When the floating-point extension facility is installed, four more BFP instructions (CONVERT FROM FIXED, CONVERT FROM LOGICAL, CONVERT TO LOGICAL, and LOAD ROUNDED) and seven more DFP instructions (ADD, CONVERT FROM FIXED, CONVERT FROM LOGICAL, CONVERT TO LOGICAL, DIVIDE, MULTIPLY, and SUBTRACT) also include an M_3 or M_4 modifier field.

The handling of an M_3 or M_4 value of zero depends on the type of instruction. For BFP instructions, an M_3 or M_4 value of zero causes rounding to be performed according to the current BFP rounding mode specified in the FPC register. For DFP instructions, an M_3 or M_4 value of zero causes rounding to be performed according to the current DFP rounding mode specified in the FPC register. The floating-point-support instruction CONVERT HFP TO BFP and the HFP instruction CONVERT TO FIXED treat an M_3 value of zero the same as five; that is, round toward zero.

For PERFORM FLOATING POINT OPERATION (PFPO), any of the rounding methods described in this section may be explicitly specified, or the program may specify the current BFP or DFP rounding method (in the floating-point-control register). The program-specified rounding method is used by PFPO regardless of whether the target-operand format is BFP, DFP or HFP.

Summary of Rounding Action

Figure 9-15 on page 9-17 summarizes the rounding action for floating-point-support (FPS), BFP, DFP, and HFP instructions.

Instruction	Rounding Action For			
	FPS Inst.	HFP Inst.	BFP Inst.	DFP Inst.
ADD	—	—	CBRM	MDD
ADD NORMALIZED	—	GD	—	—
ADD UNNORMALIZED	—	GD	—	—
CONVERT BFP TO HFP	E	—	—	—
CONVERT FROM FIXED	—	RTZ	MBB	MDD
CONVERT FROM LOGICAL	—	—	MA	MD
CONVERT HFP TO BFP	MC	—	—	—
CONVERT TO FIXED	—	M	MB	MD
CONVERT TO LOGICAL	—	—	MA	MD
DIVIDE	—	RTZ	CBRM	MDD
DIVIDE TO INTEGER	—	—	MB	—
HALVE	—	RTZ	—	—
LOAD FP INTEGER	—	RTZ	MB	MD
LOAD ROUNDED	—	RNTA	MBB	MD
MULTIPLY	—	RTZ	CBRM	MDD
MULTIPLY AND ADD	—	RTZ	CBRM	—
MULTIPLY AND ADD UNNORMALIZED	—	RTZ	—	—
MULTIPLY AND SUBTRACT	—	RTZ	CBRM	—
MULTIPLY UNNORMALIZED	—	RTZ	—	—
PERFORM FLOATING-POINT OPERATION	MBD	—	—	—
QUANTIZE	—	—	—	MD
REROUND	—	—	—	MD
SQUARE ROOT	—	RNTA	CBRM	—
SUBTRACT	—	—	CBRM	MDD
SUBTRACT NORMALIZED	—	GD	—	—
SUBTRACT UNNORMALIZED	—	GD	—	—

Explanation:

CBRM	Rounded according to current BFP rounding mode.
E	Result is exact, no rounding is required.
GD	Round using a guard digit; see the instruction definition. This is almost, but not quite, round toward 0.
M	Rounding is specified by a modifier field in the instruction. Five rounding methods are supported.

Figure 9-15. Comparison of Rounding Action (Part 1 of 2)

Instruction	Rounding Action For			
	FPS Inst.	HFP Inst.	BFP Inst.	DFP Inst.
MA	Rounding is specified by a modifier field in the instruction. Six rounding methods are supported; current BFP rounding mode can also be specified.			
MB	Rounding is specified by a modifier field in the instruction. When the floating-point extension facility is not installed, five rounding methods are supported; when the floating-point extension facility is installed, six rounding modes are supported; current BFP rounding mode can also be specified.			
MBB	When the floating-point extension facility is not installed, rounding is specified by the current BFP rounding mode; four rounding modes are supported. When the floating-point extension facility is installed, rounding is specified by a modifier field in the instruction; six rounding modes are supported; current BFP rounding mode can also be specified.			
MBD	Rounding is specified by a field in general register 0. Eight rounding methods are supported; current BFP rounding mode and current DFP rounding mode can also be specified.			
MC	Rounding is specified by a modifier field in the instruction. When the floating-point extension facility is not installed, five rounding methods are supported; when the floating-point extension facility is installed, six rounding modes are supported; current BFP rounding mode cannot be specified.			
MD	Rounding is specified by a modifier field in the instruction. Eight rounding methods are supported; current DFP rounding mode can also be specified.			
MDD	When the floating-point extension facility is not installed, rounding is specified by the current DFP rounding mode. When the floating-point extension facility is installed, rounding is specified by a modifier field in the instruction; eight rounding modes are supported; current DFP rounding mode can also be specified.			
RNTA	Round to nearest with ties away from 0.			
RTZ	Round toward 0.			

Figure 9-15. Comparison of Rounding Action (Part 2 of 2)

IEEE Exceptions

This section defines handling of IEEE exceptions for most IEEE computational operations. For some instructions the action may differ from the general rules; including, for example, a special controls to suppress recognition of certain IEEE exceptions. These differences are described in the individual instruction descriptions.

The action taken for each IEEE exception is controlled by a mask bit in the FPC register. When an IEEE exception is recognized, one of two actions is taken:

- If the corresponding mask bit in the FPC register is zero, a default action, called IEEE nontrap action, is taken, as specified for each condition, and the corresponding flag bit in the FPC register is set to one. Program execution then continues normally.
- If the corresponding mask bit in the FPC register is one, an action, called IEEE trap action, is taken for that exception, a program interruption for a data exception occurs, and the operation is suppressed or completed, depending on the exception, and the data-exception code (DXC) assigned for that exception is provided. For PFPO, a control bit in GR0 can select alternate exception handling, where overflow or underflow can be reflected by completion with a distinguished condition code, avoiding the interruption.

Concurrent IEEE Exceptions

IEEE-overflow or IEEE-underflow exception, IEEE-inexact exception, and quantum exception can coincide concurrently.

When the action for IEEE overflow (or underflow) is a nontrap action, the IEEE-overflow (or IEEE-underflow) flag bit in the FPC register is set to one and then the action for IEEE inexact (which could be a nontrap or trap action) occurs.

When the action for IEEE overflow (or underflow) is a trap action, the inexact exception is not recognized and not reported directly; instead, the DXC is set to indicate whether the result is exact, inexact and truncated, or inexact and incremented.

When the action for all concurrent IEEE exceptions, except the quantum exception, is a nontrap action, the flag bits in the FPC register corresponding to these nontrap concurrent exceptions are set to one, and then the action for the quantum exception (which could be a nontrap or trap action) occurs.

When the action for any concurrent IEEE exception, except the quantum exception, is a trap action, the quantum exception is not recognized, not reported directly, and not indicated in the DXC.

IEEE Invalid Operation

An IEEE-invalid-operation exception is recognized when, in the execution of an IEEE computational operation, any of the following occurs:

1. An SNaN is encountered in an IEEE computational operation.
2. A QNaN is encountered in an unordered-signaling comparison (COMPARE AND SIGNAL with a QNaN operand).
3. An IEEE difference is undefined (addition of infinities of opposite sign, or subtraction of infinities of like sign).
4. An IEEE product is undefined (zero times infinity).
5. An IEEE quotient is undefined (DIVIDE instruction with both operands zero or both operands infinity).
6. A BFP remainder is undefined (DIVIDE TO INTEGER with a dividend of infinity or a divisor of zero).
7. A BFP square root is undefined (negative nonzero operand).
8. Any other IEEE computational operation whose result is either undefined or not representable in the target format.

Even though an invalid-operation condition exists, the exception is not recognized if recognition of the exception is suppressed by means of an IEEE-invalid-operation-exception control (XiC).

IEEE-Invalid-Operation Nontrap Action: IEEE-invalid-operation nontrap action occurs when the IEEE-invalid-operation exception is recognized and the IEEE-invalid-operation mask bit in the FPC register is zero. The operation is completed and the IEEE-invalid-operation flag bit in the FPC register is set to one. The result of the operation depends on the type of operation and the operands.

If the instruction performs a comparison, the comparison result is *unordered*.

If the instruction is one that produces an IEEE result and none of the operands is a NaN, the result is the default QNaN.

If the instruction is one that produces an IEEE result and one of the operands is a NaN, that operand becomes the result unchanged, except that an SNaN is first converted to the corresponding QNaN and, for DFP, NaNs are canonicalized.

IEEE-Invalid-Operation Trap Action: IEEE-invalid-operation trap action occurs when the IEEE-invalid-operation exception is recognized and the IEEE-invalid-operation mask bit in the FPC register is one. The operation is suppressed, and the exception is reported as a program interruption for a data exception with DXC 80 hex.

IEEE Division-By-Zero

An IEEE-division-by-zero exception is recognized when in IEEE division the divisor is zero and the dividend is a nonzero finite number.

IEEE-Division-By-Zero Nontrap Action: IEEE-division-by-zero nontrap action occurs when the IEEE-division-by-zero exception is recognized and the IEEE-division-by-zero mask bit in the FPC register is zero. The operation is completed and the IEEE-division-by-zero flag bit in the FPC register is set to one. The result is set to an infinity with a sign that is the exclusive or of the dividend and divisor signs.

IEEE-Division-By-Zero Trap Action: IEEE-division-by-zero trap action occurs when the IEEE-division-by-zero exception is recognized and the IEEE-division-by-zero mask bit in the FPC register is one. The operation is suppressed, and the exception is reported as a program interruption for a data exception with DXC 40 hex.

IEEE Overflow

An IEEE-overflow exception is recognized for an IEEE target when the precision-rounded value of an IEEE computational operation is greater in magnitude than the largest finite number (Nmax) representable in the target format.

IEEE-Overflow Nontrap Action: IEEE-overflow nontrap action occurs when the IEEE-overflow exception is recognized and the IEEE-overflow mask bit in the FPC register is zero.

The operation is completed and the IEEE-overflow flag bit in the FPC register is set to one. The result of the operation depends on the sign of the precise intermediate value and on the effective rounding method:

1. For all round-to-nearest methods and round-away-from-0, the result is infinity with the sign of the precise intermediate value.
2. For round-toward-0 and round-to-prepare-for-shorter-precision, the result is the largest finite number of the format, with the sign of the precise intermediate value.
3. For round toward +∞, the result is +∞. if the sign is plus, or it is the negative finite number with the largest magnitude if the sign is minus.
4. For round toward -∞, the result is the largest positive finite number if the sign is plus or -∞. if the sign is minus.

IEEE-Overflow Trap Action: IEEE-overflow trap action occurs when the IEEE-overflow exception is recognized and the IEEE-overflow mask bit in the FPC register is one.

The operation is completed by setting the result to the scaled value and the exception is reported as a program interruption for a data exception with DXC 20, 28, or 2C hex, depending on whether the delivered value is exact, inexact and truncated, or inexact and incremented, respectively.

The result of the operation is derived from the precision-rounded value, the scale factor, and, for DFP, on the scaled preferred quantum. The value of the scale factor depends on the type of operation and operand format. The scaled preferred quantum for a particular operation is equal to the preferred quantum for that operation divided by the scale factor for that operation.

The delivered value is equal to the precision-rounded value divided by the scale factor. For DFP targets, the cohort member with the quantum nearest to the scaled preferred quantum is selected.

IEEE Underflow

An IEEE-underflow exception is recognized for an IEEE target when the tininess condition exists and either: (1) the IEEE-underflow mask bit in the FPC register is zero and the result value is inexact, or (2) the IEEE-underflow mask bit in the FPC register is one.

The tininess condition exists when the precise intermediate value of an IEEE computational operation is nonzero and smaller in magnitude than the smallest normal number (Nmin) representable in the target format.

The result value is inexact if it is not equal to the precise intermediate value.

IEEE-Underflow Nontrap Action: IEEE-underflow nontrap action occurs when the IEEE-underflow exception is recognized and the IEEE-underflow mask bit in the FPC register is zero.

The operation is completed and the IEEE-underflow flag bit in the FPC register is set to one. The result is set to the denormalized value or Nmin. For DFP targets, the cohort member with the smallest quantum is selected.

IEEE-Underflow Trap Action: IEEE-underflow trap action occurs when the IEEE-underflow exception is recognized and the IEEE-underflow mask bit in the FPC register is one.

The operation is completed by setting the result to the scaled value and the exception is reported as a program interruption for a data exception with DXC 10, 18, or 1C hex, depending on whether the delivered value is exact, inexact and truncated, or inexact and incremented, respectively.

The result of the operation is derived from the precision-rounded value, the scale factor and, for DFP, on the scaled preferred quantum. The value of the scale factor depends on the type of operation and operand format. The scaled preferred quantum for a particular operation is equal to the preferred quantum for that operation divided by the scale factor for that operation.

The result is set to the precision-rounded value divided by the scale factor. For DFP targets, the cohort member with the quantum nearest to the scaled preferred quantum is selected.

IEEE Inexact

An IEEE-inexact exception is recognized when, for an IEEE computational operation, an inexact condition exists, recognition of the exception is not suppressed, and neither IEEE-overflow trap action nor IEEE-underflow trap action occurs.

For the VECTOR FP CONVERT AND LENGTHEN FROM NNP HIGH, VECTOR FP CONVERT AND LENGTHEN FROM NNP LOW, VECTOR FP CON-

VERT FROM NNP, and VECTOR FP CONVERT TO NNP instructions, an IEEE-inexact exception is recognized if the combination of M_3 and M_4 values is not supported by the model. For the VECTOR FP CONVERT AND ROUND TO NNP instruction, an IEEE-inexact exception is recognized if the combination of M_4 and M_5 values is not supported by the model. If this IEEE-inexact condition exists, then any other potential IEEE exceptions generated by the instruction are suppressed and do not set FPC flag bits.

In the absence of an IEEE-invalid-operation condition, an inexact condition exists when the rounded intermediate value differs from the precise intermediate value. The condition also exists when IEEE-overflow nontrap action occurs. When the inexact condition exists, the delivered value and the result are said to be inexact.

Even though an inexact condition exists, the IEEE-inexact exception is not recognized if recognition of the exception is suppressed by means of an IEEE-inexact-exception control (XxC) or if IEEE overflow or IEEE underflow trap action occurs. When an inexact condition exists and the conditions for an IEEE-overflow trap action or IEEE-underflow trap action also apply, the trap action takes precedence and the inexact condition is reported in the DXC.

IEEE-Inexact Nontrap Action: IEEE-inexact nontrap action occurs when the IEEE-inexact exception is recognized and the IEEE-inexact mask bit in the FPC register is zero.

In the absence of another IEEE nontrap action, the operation is completed using the rounded intermediate value and the IEEE-inexact flag bit in the FPC register is set to one. For DFP targets, except for QUANTIZE and REROUND, the cohort member with the smallest quantum is selected.

When an IEEE-inexact nontrap action and another IEEE nontrap action coincide, the operation is completed using the result specified for the other exception and the flag bits for both exceptions are set to one.

IEEE-Inexact Trap Action: IEEE-inexact trap action occurs when the IEEE-inexact exception is recognized and the IEEE-inexact mask bit in the FPC register is one. The operation is completed and the exception is reported as a program interruption for a data exception with DXC 08 or 0C hex, depending on whether the result is inexact and truncated or inexact and incremented, respectively.

In the absence of a coincident IEEE nontrap action, the delivered value is set to the rounded intermediate value. For DFP targets, the cohort member with the smallest quantum is selected.

When the IEEE-inexact trap action coincides with an IEEE nontrap action, the operation is completed using the result specified for the IEEE nontrap action, the flag bit for the nontrap exception is set to one, and the IEEE-inexact trap action takes place.

Quantum Exception

A quantum exception is recognized when floating-point extension facility is installed and when, for an IEEE computational operation, a quantum-exception condition exists, recognition of the exception is not suppressed, and none of IEEE-overflow trap action, IEEE-underflow trap action, and IEEE-inexact trap action occurs.

For computational operations except DIVIDE, LOAD FP INTEGER, PERFORM FLOATING-POINT OPERATION, QUANTIZE, and REROUND, a quantum-exception condition exists when the delivered DFP result is inexact, or when the delivered DFP result is exact and finite, but the delivered quantum is different from the preferred quantum.

For DIVIDE, a quantum-exception condition exists (1) when the delivered DFP result is inexact, or (2) when the dividend is a finite number and the divisor is an infinity, or (3) when the delivered DFP result is exact and is a finite number, the delivered quantum is the maximum quantum and is not the preferred quantum, and the rightmost significand digit is zero, or (4) when the delivered DFP result is exact and is a finite number, the delivered quantum is the minimum quantum and is greater than the preferred quantum. Note that the maximum quantum is the value of 1×10^{Qmax} and the minimum quantum is the value of 1×10^{Qmin}, where Qmax and Qmin are the maximum and minimum right-units-view exponents, respectively.

For LOAD FP INTEGER, QUANTIZE, and REROUND, a quantum-exception condition exists when the delivered DFP result is a finite number, but the delivered quantum is different from the quantum of the source operand (the second operand for LOAD FP INTEGER, and the third operand for QUANTIZE and REROUND).

For PERFORM FLOATING-POINT OPERATION, a quantum-exception condition exists when the delivered quantum exceeds the preferred quantum of 1.

When floating-point extension facility is not installed, no quantum exception is recognized by executing any instruction.

Even though a quantum-exception condition exists, the exception is not recognized if recognition of the exception is suppressed or if IEEE-overflow, IEEE-underflow, or IEEE-inexact trap action occurs. When a quantum-exception condition exists and the conditions for an IEEE-overflow, IEEE-underflow, or IEEE-inexact trap action also apply, the trap action takes precedence and the quantum-exception condition is not reported.

Quantum-Exception Nontrap Action: Quantum-exception nontrap action occurs when the quantum exception is recognized and the quantum-exception mask bit in the FPC register is zero.

In the absence of another IEEE nontrap action, the operation is completed using the rounded intermediate value and the quantum-exception flag bit in the FPC register is set to one. The delivered result, if it is a finite number, is the cohort member with the quantum closest to the preferred quantum.

When a quantum-exception nontrap action and other concurrent IEEE nontrap actions coincide, the operation is completed using the result specified for the other exceptions and the flag bits for all exceptions are set to one.

Quantum-Exception Trap Action: Quantum-exception trap action occurs when the quantum-exception is recognized and the quantum-exception mask bit in the FPC register is one. The operation is completed and the exception is reported as a program interruption for a data exception with DXC 04 hex.

In the absence of a coincident IEEE nontrap action, the delivered value is set to the rounded intermediate value, and the delivered result, if it is a finite number, is the cohort member with the quantum closest to the preferred quantum.

When the quantum-exception trap action coincides with other IEEE nontrap actions, the operation is completed using the result specified for the other IEEE nontrap actions, the flag bits for the other IEEE nontrap exceptions are set to one, and the quantum-exception trap action takes place.

Programming Notes:

1. IEEE traps are reported by means of a program interruption for a data exception with a data-exception code.[1] The use of data exception provides the application program with a convenient interface since this exception is one of the original 15 exceptions in the System/360 architecture and is supported by most control programs that support the z/Architecture.

2. ANSI/IEEE Standard 754-2008 includes recommendations for the trap handler (see Reference [20.] on page xxxii). When a system traps, the trap handler should be able to determine:

   a. Which exception(s) were recognized on this operation.

   b. The kind of operation that was being performed.

   c. The destination's format.

   d. For overflow, underflow, and inexact exceptions, the correctly rounded result, including information that might not fit in the destination's format.

   e. For invalid-operation and divide-by-zero exceptions, the operand values.

   Items a and d are supplied as part of the interruption action. Items b, c, and e can be obtained starting with the instruction address in the old PSW and from this finding the instruction (which indicates the operation and format) and then the operands.

3. The description of underflow is one of the most difficult parts of the standard to understand. This is because:

   a. For tininess, ANSI/IEEE Standard 754-2008 provides two options for detection for BFP formats: “after rounding” or “before rounding”. For DFP formats, tininess detection occurs before rounding.

   b. Implementation of the trap is optional.

1. PFPO provides an option for trap action without the program interruption.

c. The conditions to signal underflow are different depending on whether or not the trap is taken.

Each of the above items is discussed below.

a. Detection of tininess after or before rounding differs only for the case when “rounding” would increase the magnitude of the result to exactly ±Nmin. It must be noted, however, that the action which ANSI/IEEE Standard 754-2008 here calls “rounding” is not the rounding to produce the delivered result but rounding to compute an intermediate value having the precision of the result but “as though the exponent range were unbounded”. In fact, it is possible that the delivered result may not be tiny even though the intermediate value “after rounding” is tiny.

   The option selected in the z/Architecture (and the Power architecture) is to detect tininess before rounding.

b. Although ANSI/IEEE Standard 754-2008 does not require traps to be implemented for underflow or the other IEEE exceptions, it does state that “with each exception should be associated a trap under user control”. Since it also defines “should” as “that which is strongly recommended as being in keeping with the intent of the standard”, the z/Architecture provides traps by means of program interruptions.

c. When the underflow trap is enabled, underflow is to be signaled when tininess is detected regardless of loss of accuracy. When the underflow trap is not enabled, the underflow flag bit is to be set only when both tininess and loss of accuracy have been detected. Add and subtract can result in tiny or inexact results, but not both. Thus, when underflow is disabled, add and subtract never set the underflow flag bit.

Suppression of Certain IEEE Exceptions

For IEEE-invalid-operation exception, IEEE-inexact exception, and quantum exception, a special control may be provided for an IEEE computational operation to control whether recognition of the exception is suppressed. These controls are called IEEE-invalid-operation-exception control (XiC), IEEE-inexact-exception control (XxC), and quantum-exception control (XqC), respectively.

When a special control is zero, recognition of the designated exception is not suppressed, and normal handling of the exception is performed. And, when the exception is recognized, it further depends on the mask bit in the FPC register to determine if a trap action occurs.

When a special control is one, recognition of the designated exception is suppressed, and no trap or nontrap action for the exception occurs. This suppression affects only recognition of the exception for setting the status flag or for causing the trap action. For example, the IEEE-inexact-exception control (XxC) has no effect on the DXC; that is, the DXC for IEEE-overflow or IEEE-underflow exceptions along with the detail for exact, inexact and truncated, or inexact and incremented, is reported according to the actual condition. Also, it has no effect on recognition of a quantum exception, which may depend on the actual inexact condition regardless of the setting of IEEE-inexact-exception control.

Multiple exception controls may be provided to a single IEEE computational operation. In this case, the effect and setting of each control is independent of other controls. The specific exception controls that are provided are described in the individual instruction descriptions.

IEEE Same-Radix Format Conversion

The instructions LOAD LENGTHENED and LOAD ROUNDED perform conversions of data between the short, long, and extended formats, where the source and target operands are in the same radix. (For mixed-radix conversions, see PFPO.) For BFP and DFP formats, same-radix conversion involves adjustments to both the significand and the biased exponent. Conversion to a narrower format requires rounding of the significand and an IEEE-inexact exception may result.

When converting to a narrower format, adjustment of the biased exponent causes IEEE underflow if the resultant left-units-view (LUV) exponent would be less than the minimum LUV exponent (Emin), or

IEEE overflow if the resultant LUV exponent would be greater than the maximum LUV exponent (Emax) for the new format.

Programming Notes:

1. When a NaN is converted to a narrower format, for BFP the appropriate number of payload bits on the right (or for DFP, the appropriate number of payload digits on the left) are simply dropped with no indication. This is unlike the conversion of nonzero numbers, where the loss of nonzero significand digits causes an IEEE-inexact exception. Thus, programs which encode NaN payloads for specific purposes must ensure that the distinguishing bits (or digits) are placed in the left part of the payload for BFP and in the right part of the payload for DFP.
2. For BFP, converting a NaN to a narrower format cannot turn the NaN into an infinity because an SNaN either causes an interruption or turns into a QNaN, and all QNaNs have a leftmost fraction bit of one.

IEEE Comparison

Comparisons are always exact and cannot cause IEEE-overflow or IEEE-underflow exceptions.

Comparison ignores the sign of zero, that is, +0 equals -0.

Infinities with like sign compare equal, that is, +∞. equals +∞, and -∞. equals -∞.

A NaN compares as *unordered* with any other operand, whether a finite number, an infinity, or another NaN, including itself.

Two sets of instructions are provided: COMPARE and COMPARE AND SIGNAL. In the absence of QNaNs, these instructions work the same. These instructions work differently only when both of the following are true:

- Neither operand of the instruction is an SNaN
- At least one operand of the instruction is a QNaN

In this case, COMPARE simply sets condition code 3, but COMPARE AND SIGNAL recognizes the IEEE-invalid-operation exception. If any operand is an SNaN, both instructions recognize the IEEE-invalid-operation exception.

The action when the IEEE-invalid-operation exception is recognized depends on the IEEE-invalid-operation mask bit in the FPC register. If the mask bit is zero, then the instruction execution is completed by setting condition code 3, and the IEEE-invalid-operation flag in the FPC register is set to one. If the mask bit is one, then the exception is reported as a program interruption for a data exception with DXC 80 hex (IEEE invalid operation).

Programming Note: A compiler can select either COMPARE or COMPARE AND SIGNAL for a comparison, depending on whether it is desired that a QNaN to be recognized as an exception.

Condition Codes for IEEE Instructions

For those operations which set the condition code to indicate the value of an IEEE result, condition codes 0, 1, and 2 are set to indicate that the result is a zero of either sign, less than zero, or greater than zero, respectively. The condition-code setting depends only on an inspection of the rounded result. For comparison operations, condition codes 0, 1, and 2 indicate equal, low, or high, respectively. These settings are the same as for the HFP instructions.

Condition code 3 can also be set. After an arithmetic operation, condition code 3 indicates a NaN result of either sign. After a comparison, it indicates that a NaN was involved in the comparison (the unordered condition). See Figure 9-16.

CC	Arithmetic	Comparison
0	±0	Equal
1	<0	Low
2	>0	High
3	±NaN	Unordered

Figure 9-16. Condition Codes

Instructions

The floating-point-support instructions and their mnemonics and operation codes are listed in Figure 9-17 on page 9-26. The figure indicates, in the column labeled “Characteristics”, the instruction format,

when the condition code is set, the instruction fields that designate access registers, and the exceptional conditions in operand designations, data, or results that cause a program interruption.

All floating-point-support instructions are subject to the AFP-register-control bit, bit 45 of control register 0. The AFP-register-control bit must be one when an AFP register is specified as an operand location; otherwise, an AFP-register data exception, DXC 1, is recognized.

Mnemonics for the floating-point instructions have an R as the last letter when the instruction is in the RR, RRE, or RRF format. Certain letters are used for floating-point instructions to represent operand-format length, as follows:

D Long
E Short
X Extended

Note: In the detailed descriptions of the individual instructions, the mnemonic and the symbolic operand designation for the assembler language are shown with each instruction. For a register-to-register operation using LOAD (short), for example, LER is the mnemonic and R_1,R_2 the operand designation.

Programming Notes:

1. The following additional floating-point-support instruction is available when the decimal-floating-point facility is installed:
   - SET DFP ROUNDING MODE (SRNMT)
2. The following additional floating-point-support instructions are available when the floating-point-support-sign-handling facility is installed:
   - COPY SIGN (CPSDR)
   - LOAD COMPLEMENT (LCDFR)
   - LOAD NEGATIVE (LNDFR)
   - LOAD POSITIVE (LPDFR)
3. The following additional floating-point-support instructions are available when the FPR-GR-transfer facility is installed:
   - LOAD FPR FROM GR (LDGR)
   - LOAD GR FROM FPR (LGDR)
4. The following additional floating-point-support instructions are available when the IEEE-exception-simulation facility is installed:
   - LOAD FPC AND SIGNAL (LFAS)
   - SET FPC AND SIGNAL (SFASR)
5. The following additional floating-point-support instructions are available when the long-displacement facility is installed:
   - LOAD (LDY, LEY)
   - STORE (STDY, STEY)
6. The following additional floating-point-support instruction is available when the PFPO facility is installed:
   - PERFORM FLOATING POINT OPERATION (PFPO)
7. The following additional floating-point-support instruction and features are available when the floating-point extension facility is installed:
   - A new floating-point-support instruction, SET BFP ROUNDING MODE (SRNMB), is added.
   - A new exception, the quantum exception, is defined for some computational operations.
   - Bit 5 of the floating-point-control (FPC) register is assigned to the quantum-exception mask
   - Bit 13 of the FPC register is assigned to the quantum-exception flag.
   - Data-exception code (DXC) 04 (hex) is assigned to the quantum exception.
   - DXC 07 (hex) is assigned to the simulated quantum exception.
   - The BFP-rounding-mode field in the FPC register is changed to 3 bits to support one additional BFP rounding mode, round to prepare for shorter precision.
   - One new value of the effective rounding method field is assigned to support the round to prepare for shorter precision rounding method for CONVERT HFP TO BFP.
   - For PFPO with a DFP result, bit 58 of general register 0 is assigned to be the DFP quantum-permission control.

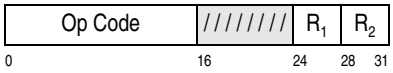
Figure 9-17. Summary of Floating-Point-Support Instructions (Part 2 of 2)

CONVERT BFP TO HFP

Mnemonic R_1,R_2 [RRE]



Mnemonic	Op Code	Operands
THDER	'B358'	Short BFP operand, long HFP result
THDR	'B359'	Long BFP operand, long HFP result

The second operand (the source operand) is converted from the binary-floating-point (BFP) format to the hexadecimal-floating-point (HFP) format, and the normalized result is placed at the first-operand location. The sign and magnitude of the source operand are tested to determine the setting of the condition code.

For numeric operands, the sign of the result is the sign of the source operand. If the source operand has a sign bit of one and all other operand bits are zeros, the result also is a one followed by all zeros.

When, for THDR, the characteristic of the result would be negative, the result is made all zeros but with the same sign as that of the source operand, and condition code 1 or 2 is set to indicate the sign of the source operand.

When, for THDR, the characteristic of the hexadecimal intermediate result is too large to fit into the target format, the result is set to all ones (that is, the largest-in-magnitude representable finite number) but with the same sign as that of the source operand, and condition code 3 is set.

See Figure 9-18 for a detailed description of the results of this instruction.

Resulting Condition Code:

0 Source was zero
1 Source was less than zero
2 Source was greater than zero
3 Special case

Program Exceptions:

- Data with DXC 1, AFP register
- Transaction constraint

Programming Notes:

1. The BFP-to-HFP conversion instructions are summarized in Figure 9-19.

2. CONVERT BFP TO HFP (THDER) converts BFP operands in the short format to HFP operands in the long format, rather than converting short to short, to retain full precision. Using this long HFP result subsequently as a short operand requires no extra conversion steps.

Source Operand (a)	Results
$-\infty \le a < -Hmax$	T(-Hmax), cc3
$-Hmax \le a \le -Hmin$	T(r), cc1
$-Hmin < a < 0$	T(-0)[1], cc1
-0	T(-0), cc0
+0	T(+0), cc0
$0 < a < +Hmin$	T(+0)[2], cc2
$+Hmin \le a \le +Hmax$	T(r), cc2
$+Hmax < a \le +\infty$	T(+Hmax), cc3
NaN	T(+Hmax), cc3

Explanation:

[1] Condition code 1 is set to indicate the source was less than zero.
[2] Condition code 2 is set to indicate the source was greater than zero.
ccn Condition code is set to n.
r The value derived when the BFP source value a is converted to the HFP format. This result is always exact.
Hmax Largest (in magnitude) representable number in the target HFP format.
Hmin Smallest (in magnitude) representable normalized number in the target HFP format.
T(x) The value x is placed at the target operand location.

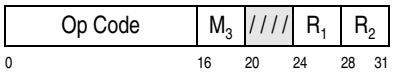
Figure 9-18. Results: CONVERT BFP TO HFP

Instruction	Mnemonic	Source		Target			Overflow, Underflow Possible
		Format	Significant Bits	Format	Significant Bits	Result	
CONVERT BFP TO HFP	THDER	BFP short	24	HFP long	53-56	Exact	No
	THDR	BFP long	53	HFP long	53-56	Exact	Yes
CONVERT HFP TO BFP	TBEDR	HFP long	53-56	BFP short	24	Rounded	Yes
	TBDR	HFP long	53-56	BFP long	53	Rounded	No

Figure 9-19. Summary of BFP-to/from-HFP Conversion Instructions

CONVERT HFP TO BFP

Mnemonic R_1,M_3,R_2 [RRF-e]



Mnemonic	Op Code	Operands
TBEDR	'B350'	Long HFP operand, short BFP result
TBDR	'B351'	Long HFP operand, long BFP result

The second operand (the source operand) is converted from the hexadecimal-floating-point (HFP) format to the binary-floating-point (BFP) format, and the result rounded according to the rounding method specified by the M_3 field is placed at the first-operand location. The sign and magnitude of the source operand are tested to determine the setting of the condition code.

The M_3 field contains a modifier specifying a rounding method, as follows:

M_3	Effective Rounding Method
0	Round toward 0
1	Round to nearest with ties away from 0
3	Round to prepare for shorter precision
4	Round to nearest with ties to even
5	Round toward 0
6	Round toward +∞
7	Round toward -∞

A modifier other than 0, 1, or 3-7 is invalid. If the floating-point extension facility is not installed, an M_3 modifier of 3 is also invalid.

The sign of the result is the sign of the second operand. If the second operand has a sign bit of one and all other operand bits are zeros, the result also is a one followed by all zeros.

See Figure 9-20 on page 9-29 for a detailed description of the results of this instruction.

If the M_3 field designates any of the following invalid modifier values: 2 and 8-15, then a specification exception is recognized. When the floating-point extension facility is not installed, if the M_3 field designates the invalid value 3, it is undefined whether a specification exception is recognized or an unpredictable rounding method is performed.

Resulting Condition Code:

0 Source was zero
1 Source was less than zero
2 Source was greater than zero
3 Overflow

IEEE Exceptions: None.

Program Exceptions:

- Data with DXC 1, AFP register
- Specification
- Transaction constraint

Programming Notes:

1. The HFP-to-BFP conversion instructions are summarized in Figure 9-19 on page 9-28.

2. Conversion to short BFP data requires HFP operands in the long format; a short HFP operand should be extended to long by ensuring that the right half of the register is cleared. Thus, the entire register should be cleared before loading a short HFP operand into it for conversion to BFP. This avoids unrepeatable rounding errors in the BFP result due to data left over from previous use.

Precision Rounded Source Operand (g)	Results
g < -Nmax	See Part 2 of this figure.
-Nmax ≤ g ≤ -Nmin	T(r), cc1
-Nmin < g ≤ -Dmin	T(d*), cc1
-Dmin < g < 0	T(d)[1], cc1
-0	T(-0), cc0
+0	T(+0), cc0
0 < g < +Dmin	T(d)[2], cc2
+Dmin ≤ g < +Nmin	T(d*), cc2
+Nmin ≤ g ≤ +Nmax	T(r), cc2
+Nmax < g	See Part 2 of this figure.

Figure 9-20. (Part 1 of 2) Results: CONVERT HFP to BFP

Precision Rounded Source Operand (g)	Results for Rounding Method Specified in M_3					
	Round to Nearest with Ties away from 0	Round to Nearest with Ties to Even	Round to Prepare for Shorter Precision	Round toward 0	Round toward +∞	Round toward -∞
g < -Nmax	T(-∞), cc3	T(-∞), cc3	T(-Nmax), cc3	T(-Nmax), cc3	T(-Nmax), cc3	T(-∞), cc3
+Nmax < g	T(+∞), cc3	T(+∞), cc3	T(+Nmax), cc3	T(+Nmax), cc3	T(+∞), cc3	T(+Nmax), cc3

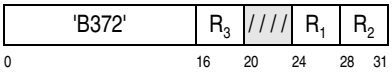
Explanation:

[1]	Condition code 1 is set for this case, even when the rounded result is zero.
[2]	Condition code 2 is set for this case, even when the rounded result is zero.
*	The rounded value, in the extreme case, may be Nmin.
ccn	Condition code is set to n.
d	The denormalized value derived when the HFP source value a is rounded to the format of the target using the rounding method specified in the M_3 field.
g	The precision-rounded value. The value derived when the HFP source value is rounded to the precision of the target, but assuming an unbounded exponent range.
r	The value derived when the HFP source value is rounded to the format of the target using the rounding method specified in the M_3 field.
Dmin	Smallest (in magnitude) representable subnormal number in the target BFP format.
Nmax	Largest (in magnitude) representable finite number in the target BFP format.
Nmin	Smallest (in magnitude) representable normal number in the target BFP format.
T(x)	The value x is placed at the target operand location.

Figure 9-20. (Part 2 of 2) Results: CONVERT HFP to BFP

COPY SIGN

CPSDR R_1,R_3,R_2 [RRF-b]



The second operand is placed at the first-operand location with the sign bit set to the sign of the third operand. The first, second, and third operands are each in a 64-bit floating-point register. The sign bit of the second operand and bits 1-63 of the third operand are ignored.

Condition Code: The code remains unchanged.

Program Exceptions:

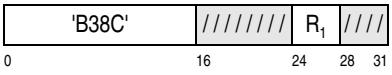
- Data with DXC 1, AFP register
- Operation (if the floating-point-support-sign-handling facility is not installed)
- Transaction constraint

Programming Notes:

1. COPY SIGN is radix independent and can be used to operate on HFP, BFP, or DFP operands or even to copy the sign between operands having different radixes.
2. Since the sign is in the same bit position (the left-most bit) in all widths for all radixes, the third operand can be a short, long, or extended format.
3. COPY SIGN can be used in conjunction with LOAD (LDR) to copy the sign of an operand in the extended format.

EXTRACT FPC

EFPC R_1 [RRE]



The contents of the FPC (floating-point-control) register are placed in bit positions 32-63 of the general register designated by R_1. Bit positions 0-31 of the general register remain unchanged.

Condition Code: The code remains unchanged.

IEEE Exceptions: None.

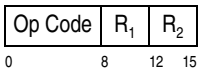
Program Exceptions:

- Data with DXC 2, BFP instruction

- Transaction constraint

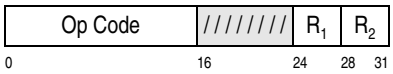
LOAD

Mnemonic1 R_1,R_2 [RR]



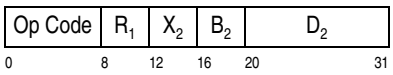
Mnemonic1	Op Code	Operands
LER	'38'	Short
LDR	'28'	Long

Mnemonic2 R_1,R_2 [RRE]



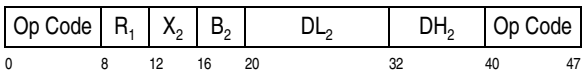
Mnemonic2	Op Code	Operands
LXR	'B365'	Extended

Mnemonic3 $R_1,D_2(X_2,B_2)$ [RX-a]



Mnemonic3	Op Code	Operands
LE	'78'	Short
LD	'68'	Long

Mnemonic4 $R_1,D_2(X_2,B_2)$ [RXY-a]



Mnemonic4	Op Code	Operands
LEY	'ED64'	Short
LDY	'ED65'	Long

The second operand is placed unchanged at the first-operand location.

The operation is performed without inspecting the contents of the second operand; no arithmetic exceptions are recognized.

For LXR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

The displacement for LE and LD is treated as a 12-bit unsigned binary integer. The displacement for LEY and LDY is treated as a 20-bit signed binary integer.

Condition Code: The code remains unchanged.

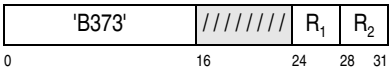
Program Exceptions:

- Access (fetch, operand 2 of LE, LD, LEY, and LDY)
- Data with DXC 1, AFP register
- Operation (LEY and LDY, if the long-displacement facility is not installed)
- Specification (LXR only)
- Transaction constraint

Programming Note: Data can be loaded into the vector registers from the little endian format using the extended mnemonics LERV and LDRV for the VLLEBRZ instruction (see page 21-10).

LOAD COMPLEMENT

LCDFR R_1,R_2 [RRE]



The second operand is placed at the first-operand location with the sign bit inverted. Both the first and second operands are each in a 64-bit floating-point register.

Condition Code: The code remains unchanged.

Program Exceptions:

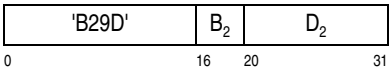
- Data with DXC 1, AFP register
- Operation (if the floating-point-support-sign-handling facility is not installed)
- Transaction constraint

Programming Notes:

1. LOAD COMPLEMENT (LCDFR) is radix independent and can be used to operate on HFP, BFP, or DFP operands.
2. LOAD COMPLEMENT (LCDFR) can be used in conjunction with LOAD (LDR) to set the sign of an operand in the extended format.

LOAD FPC

LFPC $D_2(B_2)$ [S]



The four-byte second operand in storage is loaded into the FPC (floating-point-control) register.

Bits corresponding to unsupported bit positions in the FPC register must be zero; otherwise, a specification exception is recognized. For purposes of this checking, a bit position is considered to be unsupported only if it is either unassigned or assigned to a facility which is not installed in any architectural mode of the configuration.

When the floating-point extension facility is installed, the bits corresponding to the BFP rounding mode must specify a valid rounding mode; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions: None.

Program Exceptions:

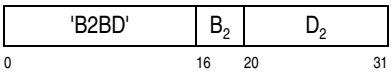
- Access (fetch, operand 2)
- Data with DXC 2, BFP instruction
- Specification
- Transaction constraint

Programming Notes:

1. When the architectural mode of a CPU is changed without resetting the FPC register (by means of the set architecture signal-processor order, for example) the entire contents of the FPC register are preserved. This is true even when some of these bits are associated with a facility which is not available in both architectural modes. Checking for unsupported bit positions of the FPC register is performed independently of the current architectural mode of the CPU; thus, it is always safe to restore the FPC register from a value previously saved on this CPU, even after the architectural mode has changed.
2. When the floating-point extension facility is installed, bits 29-31 of the second operand must specify a valid BFP rounding mode and bits 6-7, 14-15, 24, and 28 must be zero; otherwise, a specification exception is recognized.
3. When the floating-point extension facility is not installed, bits 5-7, 13-15, 24, and 28-29 are unassigned and must be zero; otherwise, a specification exception is recognized.

LOAD FPC AND SIGNAL

LFAS $D_2(B_2)$ [S]



First, flags of byte 1 of the floating-point-control (FPC) register at the beginning of the operation are preserved to be used as signaling flags. Next, the contents of the source operand are placed in the FPC register; then the flags in the FPC register are set to the logical OR of the signaling flags and the source flags. Finally, the conditions for simulated-IEEE-exception trap action are examined.

The source operand is the second operand in storage.

If any signaling flag is one and the corresponding source mask is also one, simulated-IEEE-exception trap action occurs. The data-exception code (DXC) in the FPC register is updated to indicate the specific cause of the interruption and a data-exception program interruption occurs at completion of the instruction execution. The DXC for the interruption is shown in Figure 9-21.

If no signaling flag is enabled, the DXC in the FPC register remains as loaded from the source and instruction execution completes with no trap action.

See Figure 9-22 for a detailed description of the result of this instruction.

Bits in the source operand that correspond to unsupported bit positions in the FPC register must be zero; otherwise, a specification exception is recognized. For purposes of this checking, a bit position is considered to be unsupported only if it is either unassigned or assigned to a facility which is not installed in any architectural mode of the configuration.

When the floating-point extension facility is installed, the bits corresponding to the BFP rounding mode must specify a valid rounding mode; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Data with DXC 3, DFP instruction

- Data with DXC for simulated IEEE exception
- Operation (if the IEEE-exception-simulation facility is not installed)
- Specification
- Transaction constraint

Enabled[1] Signaling Flags Bit 0 1 2 3 4 5	DXC (Binary)
1 – – – – –	1000 0011
0 1 – – – –	0100 0011
0 0 1 – – –	0010 w011
0 0 0 1 – –	0001 w011
0 0 0 0 1 –	0000 1011
0 0 0 0 0 1	0000 0111[2]

Explanation:

DRM DFP rounding mode

DXC Data-exception code

OR Set to the logical OR of signaling flags and source flags.

S Set to the contents of the corresponding field in the source operand.

Trap Simulated-IEEE-exception trap action. This action occurs when the logical AND of the signaling flags and source masks is nonzero.

Xg DXC for simulated IEEE exception. See Figure 9-21

Figure 9-22. Result: LFAS and SFASR

Programming Notes:

1. When the floating-point extension facility is installed, bits 29-31 of the second operand must specify a valid BFP rounding mode and bits 6-7, 14-15, 24, and 28 must be zero; otherwise, a specification exception is recognized.

2. When the floating-point extension facility is not installed, bits 5-7, 13-15, 24, and 28-29 are unassigned and must be zero; otherwise, a specification exception is recognized.

3. The IEEE-exception-simulation instructions (LOAD FPC AND SIGNAL and SET FPC AND SIGNAL) are provided to facilitate program simulation of IEEE operations not provided directly in the machine. These instructions permit the simulation routine to restore the caller's masks, flags, and rounding modes; and, when appropriate, to simulate IEEE exceptions, including traps when enabled.

4. On entry, the simulation routine should first save the FPC register contents (containing the caller's masks, flags, and rounding modes), disable all traps, clear all flags, establish appropriate rounding modes, and then perform the necessary floating-point operations. Finally, the routine should set the current flags (called signaling flags) appropriately, and invoke either LOAD FPC AND SIGNAL or SET FPC AND SIGNAL.

5. When a program interruption for a data exception occurs, and both bit 6 and 7 of the DXC are ones, it indicates to the trap handler that the interruption was caused by a simulated-IEEE-exception trap action. The remaining bits of the DXC indicate the type of IEEE exception. Additional information required by the trap handler can be determined by the contents of a trap-information block, located by convention, at a fixed offset from the location where the instruction causing the trap resides.

   The following shows an example of this scheme. The block and the code below are inserted at an appropriate place where a trap can occur. In this example, the LOAD FPC AND SIGNAL instruction is used, and the caller's FPC register contents are at the location, SAVEDFPC.

```
          BC     15,LOADPFC
        +-------------------+
        |       Trap        |
        |    Information    |
        |       Block       |
        +-------------------+
LOADFPC LFAS   SAVEDFPC
```

The trap information block can contain the designation of floating-point registers and general registers containing the information (or addresses of the information) for the following types of items:

a. The operation being simulated

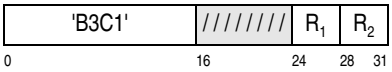
b. Format and values of source operands

c. Format and value of the result

d. Any additional information useful to the trap handler.

LOAD FPR FROM GR

LDGR R_1,R_2 [RRE]



The second operand is placed at the first-operand location. The second operand is in a general register, and the first operand is in a floating-point register.

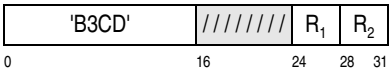
Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC 1, AFP register
- Operation (if the FPR-GR-transfer facility is not installed)
- Transaction constraint

LOAD GR FROM FPR

LGDR R_1,R_2 [RRE]



The second operand is placed at the first-operand location. The second operand is in a floating-point register, and the first operand is in a general register.

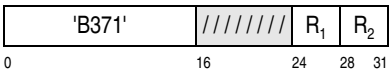
Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC 1, AFP register
- Operation (if the FPR-GR-transfer facility is not installed)
- Transaction constraint

LOAD NEGATIVE

LNDFR R_1,R_2 [RRE]



The second operand is placed at the first-operand location with the sign bit set to one. Both the first and second operands are each in a 64-bit floating-point register.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC 1, AFP register
- Operation (if the floating-point-support-sign-handling facility is not installed)
- Transaction constraint

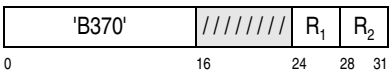
Programming Notes:

1. LOAD NEGATIVE (LNDFR) is radix independent and can be used to operate on HFP, BFP, or DFP operands.

2. LOAD NEGATIVE (LNDFR) can be used in conjunction with LOAD (LDR) to set the sign of an operand in the extended format.

LOAD POSITIVE

LPDFR R_1,R_2 [RRE]



The second operand is placed at the first-operand location with the sign bit set to zero. Both the first and second operands are each in a 64-bit floating-point register.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC 1, AFP register
- Operation (if the floating-point-support-sign-handling facility is not installed)
- Transaction constraint

Programming Notes:

1. LOAD POSITIVE (LPDFR) is radix independent and can be used to operate on HFP, BFP, or DFP operands.
2. LOAD POSITIVE (LPDFR) can be used in conjunction with LOAD (LDR) to set the sign of an operand in the extended format.

LOAD ZERO

Mnemonic R_1 [RRE]

Mnemonic	Op Code	Operands
LZER	'B374'	Short
LZDR	'B375'	Long
LZXR	'B376'	Extended

All bits of the first operand are set to zeros.

For LZXR, The R_1 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

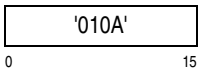
Program Exceptions:

- Data with DXC 1, AFP register
- Specification (LZXR only)
- Transaction constraint

Programming Note: LOAD ZERO sets all bits of a register to zeros, which produces a positive zero value in the BFP, DFP, and HFP formats. For DFP, addition of an all-zero value to any normal value, X, normalizes X.

PERFORM FLOATING-POINT OPERATION

PFPO [E]



The operation specified by the function code in general register 0 is performed and the condition code is set to indicate the result. When there are no exceptional conditions, condition code 0 is set. When an IEEE nontrap exception is recognized, condition code 1 is set. When an IEEE trap exception with alternate action is recognized, condition code 2 is set. In the absence of suppression, a 32-bit return code is placed in bits 32-63 of general register 1; bits 0-31 of general register 1 remain unchanged.

The PERFORM FLOATING-POINT OPERATION (PFPO) instruction is subject to the AFP-register-control bit, bit 45 of control register 0. For PFPO to be executed successfully, the AFP-register-control bit must be one; otherwise, an AFP-register data exception, DXC 1, is recognized.

Bit 32 of general register 0 is the test bit. When bit 32 is zero, the function specified by bits 33-63 of general register 0 is performed; each field in bits 33-63 must be valid and the combination must be a valid and installed function; otherwise a specification exception is recognized. When bit 32 is one, the function specified by bits 33-63 is not performed; rather, the condition code is set to indicate whether these bits specify a valid and installed function; the condition code is set to 0 if the function is valid and installed, or to 3 if the function is invalid or not installed. This definition is written as if the test bit is zero except when stated otherwise.

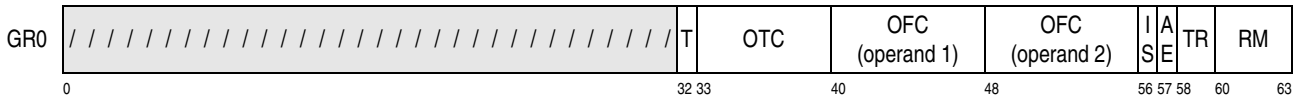
Bits 33-39 of GR0 specify the operation type. Only one operation type is currently defined: 01, hex, is the PFPO-convert-floating-point-radix operation.

For the PFPO-convert-floating-point-radix operation, other fields in general register 0 include first-operand format, second operand format, control flags, and rounding method. The second operand is converted to the format of the first operand and placed at the first-operand location, a return code is placed in bits 32-63 of general register 1, and the condition code is set to indicate whether an exceptional condition was recognized. Alternatively, an exceptional condition may be indicated by the recognition of a data exception resulting in either completion or suppression.

The first and second operands are in implicit floating-point registers. The first operand is in floating-point register 0 (paired with floating-point register 2 for extended). The second operand is in floating-point register 4 (paired with floating-point register 6 for extended).

General Register 0 (GR0)

Figure 9-23 illustrates the contents of general register 0; bits 0-31 of the register are ignored.



Explanation:

/	Ignored
T	Test bit (bit 32)
OTC	PFPO-operation-type code (bits 33-39)
OFC	PFPO-operand format code (bits 40-47 for operand 1, bits 48-55 for operand 2)
IS	Inexact-suppression control (bit 56)
AE	Alternate-exception-action control (bit 57)
TR	Target-radix-dependent controls (bits 58-59)
RM	PFPO rounding method (bits 60-63)

Figure 9-23. General Register 0 for PERFORM FLOATING POINT OPERATION

Figure 9-24 illustrates the contents of the PFPO-operation-type code in bits 33-39 of general register 0.

Op Type Code (hex)	Operation
00	Reserved/Invalid
01	PFPO Convert Floating-Point Radix
02-7F	Reserved/Invalid

Figure 9-24. PFPO-Operation-Type Code (GR0 bits 33-39)

Figure 9-25 illustrates the contents of the PFPO-operand-format codes for the first and second operands (in bits 40-47 and 48-55 of general register 0, respectively).

Code (hex)	Format
00	HFP short
01	HFP long
02	HFP extended
03	Reserved/Invalid
04	Reserved/Invalid
05	BFP short
06	BFP long
07	BFP extended
08	DFP short
09	DFP long
0A	DFP extended
0B-FF	Reserved/Invalid

Figure 9-25. PFPO-Operand-Format Codes (GR0 bits 40-47 and 48-55)

Figure 9-26 illustrates the contents of the PFPO-target-radix-dependent controls in bits 58-59 of general register 0.

Radix of Target	GR0 Bit	Meaning
HFP	58	HFP-overflow control
HFP	59	HFP-underflow control
BFP	58	Reserved, must be zero
BFP	59	Reserved, must be zero
DFP	58	Reserved, must be zero when the floating-point extension facility is not installed; it is the DFP quantum-permission control (DQPC) when the facility is installed.
DFP	59	DFP preferred-quantum control (DPQC)

Figure 9-26. PFPO-Target-Radix-Dependent Controls (GR0, bits 58-59)

Figure 9-27 illustrates the PFPO-rounding-method codes in bits 60-63 of general register 0.

Value	Method*
0	According to current DFP rounding mode in bits 25-27 of the floating-point-control register
1	According to current BFP rounding mode in bits 29-31 of the floating-point-control register
2-7	Reserved/Invalid
8	Round to nearest with ties to even
9	Round toward 0
10	Round toward +∞
11	Round toward -∞
12	Round to nearest with ties away from 0
13	Round to nearest with ties toward 0
14	Round away from 0
15	Round to prepare for shorter precision
*	All rounding methods, other than those listed as reserved, are valid for any conversion function, regardless of the radix of the result.

Figure 9-27. PFPO-Rounding Method (GR0 bits 60-63)

Figure 9-28 shows the basic PFPO functions. PFPO basic functions comprise the set of combinations of the operation-type, first-operand-format, and second-operand-format fields which are valid when the PFPO instruction is installed. Other combinations of operation type and format are not valid and will result in either a specification exception being recognized (when the test bit is zero) or condition code 3 (when the test bit is one).

Explanation:

Da	AFP-register data exception.
SP	Specification exception due to invalid PFPO rounding method; for BFP target, specification exception due to nonzero target-radix-dependent controls; for DFP target, specification exception due to nonzero DFP-quantum-permission control when the floating-point-extension facility is not installed.
Xi	IEEE-invalid-operation exception.
Xo	IEEE-overflow exception.
Xq	Quantum exception, if the floating-point extension facility is installed.
Xu	IEEE-underflow exception.
Xx	IEEE-inexact exception.

In the detailed descriptions that follow there are many references to quantum exceptions. Those apply only when the floating-point extension facility is installed, and bit 58 of general register 0 is one.

Inexact-Suppression Control: Bit 56 of general register 0 is the inexact-suppression control. When the inexact-suppression control is zero, IEEE-inexact exceptions are recognized and reported in the normal manner. When the inexact-suppression control is one, IEEE-inexact exceptions are not recognized, and no trap or nontrap action for the exceptions

occurs. The inexact-suppression control has no effect on the DXC; that is, the DXC for IEEE-overflow or IEEE-underflow exceptions along with the detail for exact, inexact and truncated, or inexact and incremented, is reported according to the actual condition.

Alternate-Exception-Action Control: Bit 57 of general register 0 is the alternate-exception-action control. The setting of this control affects the action taken for IEEE-overflow and IEEE-underflow trap exceptions.

When the alternate-exception-action control is zero, IEEE-overflow and IEEE-underflow trap exceptions are reported in the normal manner. That is, the appropriate data exception code (DXC) is placed in byte 2 of the floating-point control register, the operation is completed, and a program interruption for a data exception occurs. (As part of the program interruption, the DXC is stored at location 147.) This is called an *IEEE trap exception with normal action*.

When the alternate-exception-action control is one, the DXC is placed in byte 2 of the floating-point control register, the operation is completed, condition code 2 is set, and program execution continues with the next sequential instruction. (There is no program interruption and the DXC is not stored at location 147.) This is called an *IEEE trap exception with alternate action*.

Target-Radix-Dependent Controls: Bits 58 and 59 comprise controls for a target (first) operand having either the HFP or DFP format, as described below. When the operand-format control for the first operand designates the BFP format, both bits 58 and 59 must contain zeros; otherwise, a specification exception is recognized (when the test bit is zero) or condition code 3 is set (when the test bit is one).

HFP-Overflow Control: Bit 58 of general register 0 is the HFP-overflow control. When the HFP-overflow control is zero, an HFP-overflow condition is reported as an IEEE-invalid-operation exception and is subject to the IEEE-invalid-operation mask. When the HFP-overflow control is one, an HFP-overflow condition is reported as an IEEE-overflow exception and is subject to the IEEE-overflow mask.

HFP-Underflow Control: For HFP targets, bit 59 of general register 0 is the HFP alternate underflow control. When the HFP-underflow control is zero, HFP underflow causes the result to be set to a true zero with the same sign as the source and underflow is not reported. (The result in this case is inexact and subject to the inexact-suppression control.) When the HFP-underflow control is one, the condition is reported as an IEEE-underflow exception and is subject to the IEEE-underflow mask.

DFP Quantum-Permission Control (DQPC):
When the floating-point extension facility is installed, for DFP targets, bit 58 of general register 0 is the DFP quantum-permission control (DQPC). If this control is zero, recognition of the quantum exception is suppressed so that no trap or nontrap action for the exception occurs; if the control is one, recognition of the quantum exception is not suppressed.

DFP Preferred Quantum Control (DPQC): For DFP targets, bit 59 of general register 0 is the DFP preferred quantum control (DPQC). For radix conversion with DFP targets, if the delivered value is inexact, the cohort member with the smallest quantum is selected; if the delivered value is exact, selection depends on the value of bit 59 of general register 0, the DFP preferred quantum control (DPQC). When the delivered value is exact and the DPQC bit is zero, the cohort member with the largest quantum is selected. When the delivered value is exact and the DPQC bit is one, the preferred quantum is one and the cohort member with the quantum closest to one is selected.

Return Code

Regardless of what condition code is set, and independent of whether the test bit is one, a 32-bit return code is placed in bits 32-63 of general register 1; bits 0-31 of general register 1 remain unchanged. A return code is also placed in general register 1 when a program interruption occurs for an IEEE trap exception that completes; general register 1 is not updated when a program interruption occurs for an IEEE trap exception that suppresses. Thus, general register 1 is updated on a program interruption for IEEE-overflow, IEEE-underflow, IEEE-inexact, and quantum-exception trap exceptions, but is not updated on a program interruption for an IEEE-invalid-operation trap exception.

Except where otherwise specified, the return code is a value of zero.

Sign Preservation

For PFPO convert floating-point radix, the sign of the result is the same as the sign of the source. The only exception to this is when the source is a NaN and the

target is HFP; in this case, the result is the largest representable number in the target HFP format (Hmax) with the sign set to plus.

Preferred Quantum

For radix conversion with DFP targets, the handling of the quantum is described in “DFP Preferred Quantum Control (DPQC)” on page 9-38.

NaN Conversion

When converting between DFP and BFP, the sign of the NaN is always preserved, and the value of the payload is preserved, when possible. If the value of the source payload exceeds the maximum value of the target payload, the target is set to the default QNaN, but with the same sign as the source.

When traps are disabled, an SNaN is converted to the corresponding QNaN, and the payload is preserved, when possible; that is, SNaN(x) is converted to QNaN(x), where x is the value of the payload. See the section “Propagation of NaNs” on page 9-3 for additional details.

For DFP, both QNaN(0) and SNaN(0) can be represented; but in BFP, there is a representation for QNaN(0), but not for SNaN(0).

Scaled Value and Signed Scaling Exponent (Ω) for PFPO

When, for the PFPO-convert-floating-point-radix operation, IEEE-overflow trap action or IEEE-underflow trap action occurs, the scaled value is computed using the following steps:

$$\Psi = b^{\Omega}$$

$$z = g \div \Psi$$

Where Ω is the signed scaling exponent, b is the target radix (2, 10, or 16), Ψ is the scale factor, g is the precision-rounded value, and z is the scaled value.

The signed scaling exponent (Ω) is selected to make the magnitude of the value of the scaled result (z) lie in the range:

$1 \leq |z| < b$.

The value of the signed scaling exponent (Ω), treated as a 32-bit signed binary integer, is placed in bits 32-63 of general register 1; bits 0-31 of general register 1 remain unchanged.

The scaled value is used as the delivered value and is placed in the result location. For DFP targets, the cohort member with the quantum nearest to the scaled preferred quantum is selected. (But it should be noted that for all currently supported conversions where scaling is required, the result is always inexact, so the cohort member with the smallest quantum is selected.) For BFP targets, there are no redundant representations, there is only one member in a cohort. For HFP targets, the result is normalized.

HFP Values

Unnormalized HFP values are accepted on input, but all HFP results are normalized. If an HFP result would be less than the smallest (in magnitude) representable normalized number, an HFP underflow condition exists.

HFP Zero Result

For PFPO-convert-BFP-to-HFP or PFPO-convert-DFP-to-HFP functions, if the source operand is zero, the result has the same sign as that of the source operand, and has all zeros in fraction and characteristic.

HFP Overflow and Underflow for PFPO

For an HFP target of a PFPO-convert-floating-point-radix operation, the handling of overflow and underflow conditions is controlled by the HFP-overflow control and the HFP-underflow control, respectively.

HFP Overflow: An HFP-overflow condition exists when an HFP target precision's largest number (Hmax) is exceeded in magnitude by the precision-rounded value. That is, when the characteristic of a normalized HFP result would exceed 127 and the fraction is not zero.

When the HFP-overflow control is zero, HFP-overflow is reported as an IEEE-invalid-operation exception and is subject to the IEEE-invalid-operation mask in the FPC register. This is called an *HFP-overflow-as-IEEE-invalid-operation condition.*

When the HFP-overflow control is one, HFP overflow is reported as an IEEE-overflow exception and is subject to the IEEE-overflow mask in the FPC register. This is called an *HFP-overflow-as-IEEE-overflow condition.*

HFP Underflow: An HFP-underflow condition exists when the precision-rounded value is nonzero and less in magnitude than the HFP target preci-

sion's smallest normalized number, Hmin. That is, when the characteristic of a normalized HFP result would be less than zero and the fraction is not zero. Reporting of the HFP-underflow condition is subject to the HFP-underflow control. The result in this case, however, is inexact and is subject to the controls for that condition.

When the HFP-underflow control is zero, the HFP-underflow condition is not reported. The result is set to a true zero with the same sign as the source.

When the HFP-underflow control is one, HFP underflow is reported as an IEEE-underflow exception and is subject to the IEEE-underflow mask (IMu) in the FPC register. This is called an *HFP-underflow-as-IEEE-underflow condition.* When IMu is zero, the result is set to a true zero with the same sign as the source, and the return code in general register 1 is zero; when IMu is one, the result is set to a scaled value, and the return code is nonzero.

IEEE Exceptions for PFPO

Except where otherwise stated, the following sections on IEEE exceptions apply to both BFP and DFP.

IEEE Invalid Operation: An IEEE-invalid-operation exception is recognized when any of the following occurs:

1. An SNaN is encountered in an IEEE source.
2. In an IEEE-to-HFP conversion, a NaN (QNaN or SNaN) or an infinity is encountered in the IEEE source.
3. An HFP-overflow-as-IEEE-invalid-operation condition exists.

IEEE-invalid-operation exceptions are recognized as either IEEE-invalid-operation nontrap exceptions or IEEE-invalid-operation trap exceptions.

IEEE-Invalid-Operation Nontrap Action: IEEE-invalid-operation nontrap action occurs when an IEEE-invalid-operation exception is recognized and the IEEE-invalid-operation mask bit in the FPC register is zero. The operation is completed, the IEEE-invalid-operation flag bit in the FPC register is set to one, and condition code 1 is set. The result is as follows:

- When the target is IEEE and the source is an IEEE SNaN, the result is the source NaN converted to the corresponding canonical QNaN in the target format.
- When the target is HFP and the source is an IEEE NaN, the result is the largest representable number in the target HFP format (Hmax) with the sign set to plus.
- When the target is HFP and the source is an IEEE infinity, the result is Hmax with the same sign as the source.
- When an HFP-overflow-as-IEEE-invalid-operation condition exists, the result is Hmax with the same sign as the source.

IEEE-Invalid-Operation Trap Action: IEEE-invalid-operation trap action occurs when an IEEE-invalid-operation exception is recognized and the IEEE-invalid-operation mask bit in the FPC register is one. The operation is suppressed, and the exception is reported as a program interruption for a data exception with DXC 80 hex.

IEEE Overflow: For IEEE targets, an IEEE-overflow exception is recognized when the precision-rounded value is greater in magnitude than the largest finite number (Nmax) representable in the target format. For HFP targets, an IEEE-overflow exception is recognized when the HFP-overflow condition exists and the HFP-overflow control is one.

IEEE-Overflow Nontrap Action: IEEE-overflow nontrap action occurs when the IEEE-overflow exception is recognized and the IEEE-overflow mask bit in the FPC register is zero.

The operation is completed and the IEEE-overflow flag bit in the FPC register is set to one. For IEEE targets, the result of the operation depends on the sign of the precise intermediate value and on the effective rounding method:

1. For all round-to-nearest methods and round-away-from-0, the result is infinity with the sign of the precise intermediate value.
2. For round-toward-0 and round-to-prepare-for-shorter-precision, the result is the largest finite number of the format, with the sign of the precise intermediate value.
3. For round toward +∞, the result is +∞ if the sign is plus, or it is the negative finite number with the largest magnitude if the sign is minus.

4. For round toward -∞, the result is the largest positive finite number if the sign is plus or -∞ if the sign is minus.

For HFP targets, the result is set to the largest representable number in the target HFP format (Hmax) with the same sign as the source.

Additional action depends on whether there is also an IEEE-inexact exception or a quantum exception.

When IEEE-overflow nontrap action occurs, and neither IEEE-inexact exception nor quantum exception has been recognized, the IEEE-overflow flag bit in the FPC register is set to one and condition code 1 is set.

When an IEEE-overflow nontrap action occurs together with an IEEE-inexact nontrap action, or with a quantum-exception nontrap action, or with nontrap actions for both IEEE-inexact and quantum-exception, the IEEE flag bits in the FPC register for all the recognized exceptions are set to ones and condition code 1 is set.

When IEEE-overflow nontrap action and IEEE-inexact trap action occur, the condition code is not set, the IEEE-overflow flag bit in the FPC register is set to one, and the IEEE-inexact exception is reported as a program interruption for a data exception with DXC 08 or 0C hex, depending on whether the result is inexact and truncated (rounded toward zero) or inexact and incremented, respectively.

When IEEE-overflow nontrap action and quantum-exception trap action occur, the condition code is not set, the IEEE-overflow flag bit in the FPC register is set to one, and the quantum exception is reported as a program interruption for a data exception with DXC 04 hex. When in addition an IEEE-inexact nontrap action occurs, the IEEE-inexact flag bit in the FPC register is set to one.

IEEE-Overflow Trap Action: IEEE-overflow trap action occurs when the IEEE-overflow exception is recognized and the IEEE-overflow mask bit in the FPC register is one.

The operation is completed by setting the result to the scaled value; placing the value of the signed scaling exponent (Ω), treated as a 32-bit signed binary integer in bits 32-63 of general register 1; and setting DXC 20, 28, or 2C hex, depending on whether the delivered value is exact, inexact and truncated (rounded toward zero), or inexact and incremented, respectively. When the precise intermediate result is rounded to an infinity, it is considered to be an incremented result.

For DFP targets, the delivered value is always inexact and the cohort member with the smallest quantum is selected.

Additional action depends on the value of the alternate-exception-action control.

When the alternate-exception-action control is zero, the condition code is not set and the exception is reported as a program interruption for a data exception.

When the alternate-exception-action control is one, condition code 2 is set and no program interruption occurs.

IEEE Underflow: For IEEE targets, an IEEE-underflow exception is recognized when the tininess condition exists and either: (1) the IEEE-underflow mask bit in the FPC register is zero and the result value is inexact, or (2) the IEEE-underflow mask bit in the FPC register is one.

The tininess condition exists when the precise intermediate value of an IEEE computational operation is nonzero and smaller in magnitude than the smallest normal number (Nmin) representable in the target format.

The result value is inexact if it is not equal to the precise intermediate value.

For HFP targets, an IEEE-underflow exception is recognized when the HFP-underflow condition exists and the HFP-underflow control is one.

IEEE-Underflow Nontrap Action: IEEE-underflow nontrap action occurs when the IEEE-underflow exception is recognized and the IEEE-underflow mask bit in the FPC register is zero.

The operation is completed and the IEEE-underflow flag bit in the FPC register is set to one.

For IEEE targets, the result is rounded to the denormalized value or Nmin. For DFP targets, the cohort member with the smallest quantum is selected.

For HFP targets, the result is set to a true zero with the same sign as the source.

Additional action depends on whether there is also an IEEE-inexact exception or a quantum exception.

When IEEE-underflow nontrap action occurs, and neither IEEE-inexact exception nor quantum exception has been recognized, the IEEE-underflow flag bit in the FPC register is set to one and condition code 1 is set.

When an IEEE-underflow nontrap action occurs together with an IEEE-inexact nontrap action, or with a quantum-exception nontrap action, or with nontrap actions for both IEEE-inexact and quantum-exception, the IEEE flag bits in the FPC register for all the recognized exceptions are set to ones and condition code 1 is set.

When IEEE-underflow nontrap action and IEEE-inexact trap action occur, the condition code is not set, the IEEE-underflow flag bit in the FPC register is set to one, and the IEEE-inexact trap exception is reported as a program interruption for a data exception with DXC 08 or 0C hex, depending on whether the result is inexact and truncated (rounded toward zero) or inexact and incremented, respectively.

When IEEE-underflow nontrap action and quantum-exception trap action occur, the condition code is not set, the IEEE-underflow flag bit in the FPC register is set to one, and the quantum exception is reported as a program interruption for a data exception with DXC 04 hex. When in addition an IEEE-inexact nontrap action occurs, the IEEE-inexact flag bit in the FPC register is set to one.

IEEE-Underflow Trap Action: IEEE-underflow trap action occurs when the IEEE-underflow exception is recognized and the IEEE-underflow mask bit in the FPC register is one.

The operation is completed by setting the result to the scaled value; placing the value of the signed scaling exponent (Ω), treated as a 32-bit signed binary integer in bits 32-63 of general register 1; and setting DXC 10, 18, or 1C hex, depending on whether the result is exact, inexact and truncated (rounded toward zero), or inexact and incremented, respectively.

For DFP targets, the delivered value is always inexact and the cohort member with the smallest quantum is selected.

Additional action depends on the value of the alternate-exception-action control.

When the alternate-exception-action control is zero, the condition code is not set and the exception is reported as a program interruption for a data exception.

When the alternate-exception-action control is one, condition code 2 is set and no program interruption occurs.

IEEE Inexact: An IEEE-inexact exception is recognized when, for a PFPO-convert-floating-point-radix operation, an inexact condition exists, recognition of the exception is not suppressed, and neither IEEE-overflow trap action nor IEEE-underflow trap action occurs.

In the absence of an IEEE-invalid-operation condition, an inexact condition exists when the rounded intermediate value differs from the precise intermediate value. The condition also exists when IEEE-overflow nontrap action occurs.

Even though an inexact condition exists, the IEEE-inexact exception is not recognized if the inexact-suppression control is one or if IEEE overflow or IEEE underflow trap action occurs. When an inexact condition exists and the conditions for an IEEE-overflow trap action or IEEE-underflow trap action also apply, the trap action takes precedence and the inexact condition is reported in the DXC.

IEEE-Inexact Nontrap Action: IEEE-inexact nontrap action occurs when the IEEE-inexact exception is recognized and the IEEE-inexact mask bit in the FPC register is zero.

In the absence of another IEEE nontrap action, the operation is completed using the rounded intermediate value, condition code 1 is set, and the IEEE-inexact flag bit in the FPC register is set to one. For DFP targets, the cohort member with the smallest quantum is selected.

When an IEEE-inexact nontrap action and an IEEE-overflow or IEEE-underflow nontrap action coincide, the operation is completed using the result specified for the other exception and the flag bits for both

exceptions are set to one, and condition code 1 is set. When in addition, a quantum-exception nontrap action occurs, the quantum-exception flag bit in the FPC register is also set to one.

IEEE-Inexact Trap Action: IEEE-inexact trap action occurs when the IEEE-inexact exception is recognized and the IEEE-inexact mask bit in the FPC register is one. The operation is completed, the condition code is not set, and the exception is reported as a program interruption for a data exception with DXC 08 or 0C hex, depending on whether the result is inexact and truncated (rounded toward zero) or inexact and incremented, respectively. When the precise intermediate result is rounded to an infinity, it is considered to be an incremented result.

In the absence of a coincident IEEE nontrap action, the delivered value is set to the rounded intermediate value. For DFP targets, the cohort member with the smallest quantum is selected.

When the IEEE-inexact trap action coincides with an IEEE nontrap action, the operation is completed using the result specified for the IEEE nontrap action, the flag bit for the nontrap exception is set to one, and the IEEE-inexact trap action takes place.

Quantum Exception: A quantum exception is recognized when the floating-point extension facility is installed, and when a quantum-exception condition exists, recognition of the exception is not suppressed (DQPC = 1), and none of IEEE-overflow trap action, IEEE-underflow trap action, and IEEE-inexact trap action occurs.

For a PFPO-convert-floating-point-radix operation with DFP result, a quantum-exception condition exists when the delivered DFP result is inexact, or when the delivered DFP result is exact and finite, but the delivered quantum exceeds the preferred quantum of 1. (See programming note 6.)

When the floating-point extension facility is not installed, no quantum exception is recognized.

Even though a quantum-exception condition exists, the quantum exception is not recognized if recognition of the exception is suppressed (DQPC = 0), or if IEEE-overflow, IEEE-underflow, or IEEE-inexact trap action occurs. When a quantum-exception condition exists, and the conditions for an IEEE-overflow, IEEE-underflow, or IEEE-inexact trap action also apply, the trap action takes precedence and the quantum exception is not reported in status flag or DXC.

Quantum-Exception Nontrap Action: Quantum-exception nontrap action occurs when the quantum exception is recognized and the quantum-exception mask bit in the FPC register is zero.

In the absence of another IEEE nontrap action, the operation is completed using the rounded intermediate value, condition code 1 is set, and the quantum-exception flag bit in the FPC register is set to one.

When a quantum-exception nontrap action and another one or two IEEE nontrap actions coincide, the operation is completed using the result specified for the other exceptions and the flag bits for all two or three exceptions are set to one, and condition code 1 is set.

Quantum-Exception Trap Action: Quantum-exception trap action occurs when the quantum exception is recognized and the quantum-exception mask bit in the FPC register is one. The operation is completed, the condition code is not set, and the exception is reported as a program interruption for a data exception with DXC 04 hex.

In the absence of a coincident IEEE nontrap action, the delivered value is set to the rounded intermediate value.

When the quantum-exception trap action coincides with other IEEE nontrap actions, the operation is completed using the result specified for the other IEEE nontrap actions, the flag bits for the nontrap exceptions are set to one, and the quantum-exception trap action takes place.

Resulting Condition Code (when test bit is zero):

0 Normal result
1 Nontrap exception
2 Trap exception with alternate action
3 --

Resulting Condition Code (when test bit is one):

0 Function is valid
1 --
2 --
3 Function is invalid

IEEE Exceptions:

- Invalid operation
- Overflow
- Underflow
- Inexact
- Quantum (if the floating-point extension facility is installed)

Program Exceptions:

- Data with DXC 1, AFP register
- Data with DXC for IEEE exception
- Operation (if the PFPO facility is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. The PFPO-convert-floating-point-radix operation performs "correct rounding"; that is, the result is accurately obtained from the precise intermediate value using the effective rounding method. This is in contrast to some radix conversion programs, which may produce results with larger rounding errors.

2. Note that a value of zero in the rounding-method field (GR0 bits 60-63) specifies rounding according to the current DFP rounding mode (FPC 3.1-3) regardless of whether the target is DFP, BFP, or HFP. Similarly, a value of one in the rounding-method field specifies rounding according to the current BFP rounding mode (FPC 3.5-7), regardless of the target format.

3. If the program does not supply a default QNaN (payload = zero) as a source, then its presence as a result indicates that the machine either created a new QNaN or the program attempted to convert a payload which was too large for this format.

   If the program restricts payloads to values within the smallest payload capacity of any first-operand format, then payloads are preserved across radix conversions.

4. In the absence of suppression, bits 32-63 of general register 1 are always set to a return code, even though, in most cases, the return code is zero. Future extensions of PFPO may make more use of nonzero return codes. With the current definition, the only nonzero return codes are set for IEEE-overflow trap exceptions and IEEE-underflow trap exceptions. In this case, the value of the signed scaling exponent (Ω), is placed in bits 32-63 of general register 1. For IEEE-inexact trap exceptions, the return code is set to zero, thus indicating that no scaling has occurred.

5. To display a value in scientific notation, many programming languages, calculators, and spread sheets use the letter e (or E) to separate the significand from the exponent. This is referred to as e-form notation. In this document, e-form notation, along with other forms of conventional numeric notation, is used to represent a value without regard to quantum. To indicate that both value and quantum are being represented, a variation of e-form notation, called q-form notation, is used. In q-form notation, the letter q replaces the letter e and the value shown after q is the right-units-view exponent, that is, the base 10 logarithm of the quantum. Thus, for example, the seven members of the cohort for the value 1e6 in the DFP short format are: 1q6, 10q5, 100q4, 1000q3, 10000q2, 100000q1, and 1000000q0.

   As an example of the distinction between e-form and q-form notation, consider the representation of the members of the cohort of zero. The DFP short format, for example, can represent 198 exact powers of 10, ranging in value from 1e-101 to 1e96; but can represent only 192 values for a quantum, ranging from 1e-101 to 1e90. Thus, the 192 members of the cohort for zero range from 0q-101 to 0q90.

   The effect of the DFP preferred quantum control is shown in Figure 9-29.

Rounded Intermediate Value	Result If Inexact	Result If Exact and DPQC = 0	Result If Exact and DPQC = 1
0	0q-101	0q90	0q0
0.125	1250000q-7	125q-3	125q-3
1	1000000q-6	1q0	1q0
10	1000000q-5	1q1	10q0
100	1000000q-4	1q2	100q0
1000	1000000q-3	1q3	1000q0
9999	9999000q-3	9999q0	9999q0
10000	1000000q-2	1q4	10000q0
10001	1000100q-2	10001q0	10001q0
1e5	1000000q-1	1q5	100000q0
1e6	1000000q0	1q6	1000000q0
1e10	1000000q4	1q10	1000000q4
1e15	1000000q9	1q15	1000000q9

Figure 9-29. Effect of DPQC on DFP Short Results

6. When the floating-point extension facility is installed, for a PFPO-convert-floating-point-radix operation with DFP result, if DPQC is zero and the DFP result is finite and exact, no quantum exception is recognized. This is because the operation always delivers the DFP result with the preferred quantum in this case.

7. The test bit (bit 32 of general register 0) provides a means of determining whether any future extensions to the operation-type code, operand-format code, target-radix-dependent controls, rounding method, and various combinations thereof are supported by the CPU.

PFPO Actions

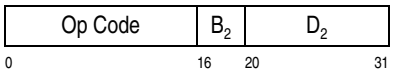
Explanation:

Caa	Alternate-exception-action control (GR0.57)
Cho	HFP-overflow control (GR0.58 for HFP targets)
Chu	HFP-underflow control (GR0.59 for HFP targets)
Csx	Inexact-suppression control (GR0.56)
DQPC	DFP quantum-permission control (GR0.58 for DFP targets)
DXC	Data-Exception Code (shown in binary)
Hmax	The largest (in magnitude) representable number in this HFP format with the same sign as the source.
+Hmax	Hmax with a plus sign
Ho	HFP-overflow condition
Hu	HFP-underflow condition
IMi	IEEE-invalid-operation mask (FPC.0)
IMo	IEEE-overflow mask (FPC.2)
IMq	Quantum-exception mask (FPC.5)
IMu	IEEE-underflow mask (FPC.3)
IMx	IEEE-inexact mask (FPC.4)
N	No
N'	No (true by virtue of other conditions in this row)
PI	Program interruption
Rq	Quantum-exception condition
Rx	Inexact-result condition
SFi	IEEE-invalid-operation flag (FPC.8)
SFo	IEEE-overflow flag (FPC.10)
SFq	Quantum-exception flag (FPC.13)
SFu	IEEE-underflow flag (FPC.11)
SFx	IEEE-inexact flag (FPC.12)
Tz	True zero with the same sign as the source.
x	Inexact result (bit 4 of the DXC)
Xi	IEEE-invalid-operation exception
Xo	IEEE-overflow exception
Xu	IEEE-underflow exception
y	Inexact result was incremented in magnitude (bit 5 of the DXC)
Y	Yes
Y'	Yes (true by virtue of other conditions in this row)

Figure 9-30. Actions for Various PERFORM FLOATING POINT Conditions (Part 2 of 2)

SET BFP ROUNDING MODE

Mnemonic $D_2(B_2)$ [S]



Mnemonic	Op Code	Operands
SRNM	'B299'	2-bit BFP rounding mode
SRNMB	'B2B8'	3-bit BFP rounding mode

The BFP rounding-mode bits in the FPC register are set from the second-operand address.

For SRNM, the second-operand address is not used to address data; instead, bits 30-31 of the FPC register are set to bits 62 and 63, respectively, of the address. Bits other than 62 and 63 of the second-operand address are ignored. When the floating-point extension facility is installed, bit 29 of the FPC register is set to zero.

For SRNMB, the second-operand address is not used to address data; instead, bits 29-31 of the FPC register are set to bits 61-63, respectively, of the address. Bits 0-55 of the second-operand address are ignored, bits 56-60 must be zero, and bits 61-63 must designate a valid rounding mode; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions: None.

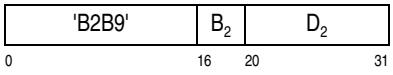
Program Exceptions:

- Data with DXC 2, BFP instruction
- Operation (SRNMB only if the floating-point extension facility is not installed)
- Specification (SRNMB only)
- Transaction constraint

Programming Note: SRNMB is a complete superset of the functionality of SRNM. It is recommended that newly developed software use the SRNMB instruction exclusively.

SET DFP ROUNDING MODE

SRNMT $D_2(B_2)$ [S]



The DFP rounding-mode bits are set from the second-operand address.

The second-operand address is not used to address data; instead, the DFP rounding-mode bits in the FPC register are set with bits 61-63 of the address.

Bits other than 61-63 of the second-operand address are ignored.

Condition Code: The code remains unchanged.

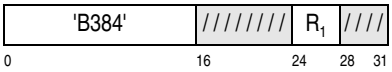
IEEE Exceptions: None.

Program Exceptions:

- Data with DXC 3, DFP instruction
- Operation (if the decimal-floating-point-rounding facility is not installed)
- Transaction constraint

SET FPC

SFPC R_1 [RRE]



The contents of bit positions 32-63 of the general register designated by R_1 are placed in the FPC (floating-point-control) register.

All of bits 32-63 corresponding to unsupported bit positions in the FPC register must be zero; otherwise, a specification exception is recognized. For purposes of this checking, a bit position is considered to be unsupported only if it is either unassigned or assigned to a facility which is not installed in any architectural mode of the configuration. Bits 0-31 of the general register are ignored.

When the floating-point extension facility is installed, the bits corresponding to the BFP rounding mode must specify a valid rounding mode; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions: None.

Program Exceptions:

- Data with DXC 2, BFP instruction

- Specification
- Transaction constraint

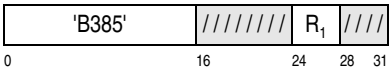
Programming Notes:

1. When the architectural mode of a CPU is changed without resetting the FPC register (by means of the set architecture signal-processor order, for example) the entire contents of the FPC register are preserved. This is true even when some of these bits are associated with a facility which is not available in both architectural modes. Checking for unsupported bit positions of the FPC register is performed independently of the current architectural mode of the CPU; thus, it is always safe to restore the FPC register from a value previously saved on this CPU, even after the architectural mode has changed.

2. See also the programming notes under LOAD FPC.

SET FPC AND SIGNAL

SFASR R_1 [RRE]



First, bits 0-4 of byte 1 of the floating-point-control (FPC) register at the beginning of the operation are preserved to be used as signaling flags. Next, the contents of the source operand are placed in the FPC register; then the flags in the FPC register are set to the logical OR of the signaling flags and the source flags. Finally, the conditions for simulated-IEEE-exception trap action are examined.

The source operand is in bits 32-63 of the general register designated by R_1; bits 0-31 of the general register are ignored.

If any signaling flag is one and the corresponding source mask is also one, simulated-IEEE-exception trap action occurs. The data-exception code (DXC) in the FPC register is updated to indicate the specific cause of the interruption and a data-exception program interruption occurs at completion of the instruction execution. The DXC for the interruption is shown in Figure 9-21 on page 9-33.

If no signaling flag is enabled, the DXC in the FPC register remains as loaded from the source and instruction execution completes with no trap action.

See Figure 9-22 on page 9-33 for a detailed description of the result of this instruction.

Bits in the source operand that correspond to unsupported bit positions in the FPC register must be zero; otherwise, a specification exception is recognized. For purposes of this checking, a bit position is considered to be unsupported only if it is either unassigned or assigned to a facility which is not installed in any architectural mode of the configuration.

When the floating-point extension facility is installed, the bits corresponding to the BFP rounding mode must specify a valid rounding mode; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC 3, DFP instruction
- Data with DXC for simulated IEEE exception
- Operation (if the IEEE-exception-simulation facility is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. See also the programming notes under LOAD FPC AND SIGNAL.

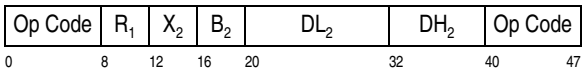
2. Bits 0-31 of the general register designated by the R_1 field are reserved for future extension and should be set to zeros.

STORE

Mnemonic $R_1,D_2(X_2,B_2)$ [RX-a]

Mnemonic	Op Code	Operands
STE	'70'	Short
STD	'60'	Long

Mnemonic2 $R_1,D_2(X_2,B_2)$ [RXY-a]



Mnemonic2	Op Code	Operands
STEY	'ED66'	Short
STDY	'ED67'	Long

The first operand is placed unchanged in storage at the second-operand location.

The displacement for STE and STD is treated as a 12-bit unsigned binary integer. The displacement for STEY and STDY is treated as a 20-bit signed binary integer.

Condition Code: The code remains unchanged.

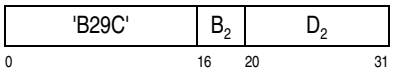
Program Exceptions:

- Access (store, operand 2)
- Data with DXC 1, AFP register
- Operation (STEY and STDY, if the long-displacement facility is not installed)
- Transaction constraint

Programming Note: Data can be stored from the vector registers to the little endian format using the extended mnemonics STERV and STDRV for the VSTEBRF and VSTEBRG instructions (see page 21-23).

STORE FPC

STFPC $D_2(B_2)$ [S]



The contents of the FPC (floating-point-control) register are placed in storage at the second-operand location.

The operand is four bytes in length. All 32 bits of the FPC register are stored.

Condition Code: The code remains unchanged.

IEEE Exceptions: None.

Program Exceptions:

- Access (store, operand 2)
- Data with DXC 2, BFP instruction
- Transaction constraint

Summary of All Floating-Point Instructions

Figures 9-31 through 9-37 on the following pages show mnemonics for all floating-point instructions (except for PFPO) arranged in various categories of operand format and type of operation. Figure 9-31 shows those instructions which operate on the FPC register. Figure 9-32 on page 9-50 shows the floating-point instructions which have all operands in the same format (same radix and same length), including those FPS (floating-point support) instructions which operate on floating-point operands in a radix-independent manner. Figure 9-33 on page 9-51 and Figure 9-34 on page 9-51 show the floating-point instructions in which all operands are in the same radix but not all of the same length. Figure 9-35 on page 9-51 and Figure 9-36 on page 9-52 show the floating-point instructions in which the source or the result is in a general register. Figure 9-37 on page 9-52 shows the floating-point instructions other than PFPO which perform radix conversion.

Instruction Name	Mnemonic	Type
EXTRACT FPC	EFPC	BFP
LOAD FPC	**LFPC**	BFP
LOAD FPC AND SIGNAL	**LFAS**	DFP
SET BFP ROUNDING MODE	SRNM, SRNMB[1]	BFP
SET DFP ROUNDING MODE	SRNMT	DFP
SET FPC	SFPC	BFP
SET FPC AND SIGNAL	SFASR	DFP
STORE FPC	**STFPC**	BFP

Explanation:

bold Mnemonics in **bold** indicate a register-and-storage operation.

1 The instruction is only available if the floating-point extension facility is installed.

BFP The instruction is considered to be part of the BFP facility. An attempt to execute this instruction when the AFP-register-control bit is zero results in a BFP-instruction data exception, DXC 2.

DFP The instruction is considered to be part of the DFP facility. An attempt to execute this instruction when the AFP-register-control bit is zero results in a DFP-instruction data exception, DXC 3.

Impacts on ESA/390 and ESA/390-Compatibility Mode

When the decimal-floating-point facility or the floating-point extension facility is installed in the z/Architecture architectural mode, the behavior of some instructions in the ESA/390 mode and ESA/390-compatibility mode deviates from the definition in the ESA/390 architecture.

The following summarizes the different behavior of affected ESA/390 instructions caused by those two facilities in the z/Architecture architectural mode.

Impacts of the Decimal-Floating-Point Facility

When the decimal-floating-point facility is installed in the z/Architectural architecture mode, it causes the following deviations from the ESA/390 architecture.

- For LOAD FPC (LFPC) and SET FPC (SFPC), if bits 25-27 of the source operand contain a nonzero value, it is unpredictable whether a specification exception is recognized or the corresponding bits in the FPC register are set to this nonzero value.

Impacts of the Floating-Point Extension Facility

When the floating-point extension facility is installed in the z/Architectural architecture mode, it causes the following deviations from the ESA/390 architecture.

1. For LOAD FPC (LFPC) and SET FPC (SFPC), if either or both bit 5 and bit 13 of the source operand are one, it is unpredictable whether a specification exception is recognized or the corresponding bit in the FPC register is set to one; if bits 29-31 of the source operand contain all ones, is unpredictable whether a specification exception is recognized or the corresponding bits in the FPC register are set to all ones.

2. For CONVERT HFP TO BFP (TBEDR, TBDR), if the M_3 field designates the value 3, it is unpredictable whether a specification exception is recognized or an undefined rounding method is performed.

3. For BFP CONVERT TO FIXED (CFEBR, CFDBR, CFXBR), if the M_3 field designates the value 3, it is unpredictable whether a specification exception is recognized or an undefined rounding method is performed. In addition, if bits 20-23 of the instruction contain a nonzero value, it is unpredictable whether recognition of IEEE-inexact exception is suppressed.

4. For BFP CONVERT FROM FIXED (CEFBR, CDFBR, CXFBR), if bits 16-19 of the instruction contain a nonzero value, it is unpredictable whether a specification exception is recognized or an undefined rounding method is performed. In addition, if bits 20-23 of the instruction contain a nonzero value, it is unpredictable whether recognition of IEEE-inexact exception is suppressed.

5. For BFP DIVIDE TO INTEGER (DIEBR, DIDBR), if the M_3 field designates the value 3, it is unpredictable whether a specification exception is recognized or an undefined rounding method is performed.

6. For BFP LOAD FP INTEGER (FIEBR, FIDBR, FIXBR), if the M_3 field designates the value 3, it is unpredictable whether a specification exception is recognized or an undefined rounding method is performed. In addition, if bits 20-23 of the instruction contain a nonzero value, it is unpredictable whether recognition of IEEE-inexact exception is suppressed.

7. For BFP LOAD ROUNDED (LEDBR, LDXBR, LEXBR), if bits 16-19 of the instruction contain a nonzero value, it is unpredictable whether a specification exception is recognized or an undefined rounding method is performed. In addition, if bits 20-23 of the instruction contain a nonzero value, it is unpredictable whether recognition of IEEE-inexact exception is suppressed.

This chapter includes all privileged and semiprivileged instructions described in this publication, except the input/output instructions, which are described in “I/O Instructions” on page 14-1.

© Copyright IBM Corp. 2000, 2025

Privileged instructions may be executed only when the CPU is in the supervisor state. An attempt to execute a privileged instruction in the problem state generates a privileged-operation exception.

The semiprivileged instructions are those instructions that can be executed in the problem state when certain authority requirements are met. An attempt to execute a semiprivileged instruction in the problem state when the authority requirements are not met generates a privileged-operation exception or some other program-interruption condition depending on the particular requirement which is violated. Those requirements which cause a privileged-operation exception to be generated in the problem state are not enforced when execution is attempted in the supervisor state.

The control instructions and their mnemonics, formats, and operation codes are listed in Figure 10-1 on page 10-3. The figure also indicates which instructions are new in z/Architecture as compared to ESA/390, when the condition code is set, the instruction fields that designate access registers, and the exceptional conditions in operand designations, data, or results that cause a program interruption.

The instructions that are new in z/Architecture are indicated in Figure 10-1 by “N.”

When the operands of an instruction are 32-bit operands, the mnemonic for the instruction does not include a letter indicating the operand length. If there is an instruction with the same name but with 64-bit operands, its mnemonic includes the letter “G.” In Figure 10-1, when there is an instruction with 32-bit operands and another instruction with the same name but with “G” added in its mnemonic, the first instruction has “(32)” after its name, and the other instruction has “(64)” after its name.

For those control instructions which have special rules regarding the handling of exceptional situations, a section called “Special Conditions” is included. This section indicates the type of ending (suppression, nullification, or completion) only for those exceptions for which the ending may vary.

Note: In the detailed descriptions of the individual instructions, the mnemonic and the symbolic operand designation for the assembler language are shown with each instruction. For LOAD PSW, for example, LPSW is the mnemonic and $D_2(B_2)$ the operand designation.

Programming Notes:

1. The following additional control instructions are available when the DAT-enhancement facility 1 is installed:

   - COMPARE AND SWAP AND PURGE (CSPG)
   - INVALIDATE DAT TABLE ENTRY

   CSPG operates on a doubleword in storage, in contrast to the previously existing instruction COMPARE AND SWAP AND PURGE (CSP), which operates on a word in storage.

2. The long-displacement facility uses new instruction formats, named RSY, RXY, and SIY, to provide 20-bit signed displacements. In connection with the long-displacement facility, all previously existing control instructions of the RSE or RXE format are changed to be of format RSY or RXY, respectively, where the new formats differ from the old by using a previously unused byte, now named DH, in the instructions. When the long-displacement facility is installed, the displacement for an instruction operand address is formed by appending DH on the left of the previous displacement field, now named DL, of the instruction. When the long-displacement facility is not installed, eight zero bits are appended on the left of DL, and DH is ignored.

   The following additional control instruction is available when the long-displacement facility is installed:

   - LOAD REAL ADDRESS (LRAY)

3. The following additional control instructions are available when the ASN-and-LX-reuse facility is installed:

   - EXTRACT PRIMARY ASN AND INSTANCE
   - EXTRACT SECONDARY ASN AND INSTANCE
   - PROGRAM TRANSFER WITH INSTANCE
   - SET SECONDARY ASN WITH INSTANCE

4. The LOAD PAGE TABLE ENTRY ADDRESS control instruction is available when the DAT-enhancement facility 2 is installed.

5. The PERFORM TIMING FACILITY FUNCTION control instruction is available when the TOD-clock-steering facility is installed.

6. The MOVE WITH OPTIONAL SPECIFICATIONS control instruction is available when the move-with-optional-specifications facility is installed.

7. The PERFORM TOPOLOGY FUNCTION control instruction is available when the configuration-topology facility is installed.

8. The PERFORM CRYPTOGRAPHIC KEY MANAGEMENT OPERATION control instruction is available when the message-security-assist extension 3 is installed.

9. The RESET REFERENCE BITS MULTIPLE control instruction is available when the reset-reference-bits-multiple facility is installed.

10. The COMPARE AND REPLACE DAT TABLE ENTRY instruction is available when the enhanced-DAT facility 2 is installed.

11. The INSERT REFERENCE BITS MULTIPLE control instruction is available when the insert-reference-bits-multiple facility is installed.

12. The TEST PENDING EXTERNAL INTERRUPTION control instruction is available when the test-pending-external-interruption facility is installed.

13. The LOAD PSW EXTENDED (LPSWEY), LOAD BEAR. and STORE BEAR control instructions are available when the BEAR-enhancement facility is installed.

14. The RESET DAT PROTECTION (RDP) control instruction is available when the reset DAT-protection facility is installed.

15. The QUERY PROCESSOR ACTIVITY COUNTER INFORMATION (QPACI) control instruction is available when the processor-activity-instrumentation facility is installed.

Explanation:

¢ Causes serialization and checkpoint synchronization.

¢[2] Causes serialization and checkpoint synchronization when the state entry to be unstacked is a program-call state entry.

¢[3] Causes serialization and checkpoint synchronization when the set-key control is one.

¢[4] Causes serialization and checkpoint synchronization when the KFC value is 4 or 5.

$ Causes serialization.

¤[1] Restricted from transactional execution.

* PER zero-address-detection not recognized.

A Access exceptions for logical addresses.

A^1 Access exceptions; not all access exceptions may occur; see instruction description for details.

B PER branch event.

B_1 B_1 field designates an access register in the access-register mode.

B_2 B_2 field designates an access register in the access-register mode.

BE BEAR-enhancement facility.

BP B_2 field designates an access register when PSW bits 16 and 17 have the value 01 binary.

B† B_1 field designates an access register when bit 47 of GR0 is zero, and bits 16-17 of the current PSW are 01 binary; or when bit 47 of GR0 is one, and bits 40-41 of GR0 are 01 binary.

B‡ B_2 field designates an access register when bit 63 of GR0 is zero, and bits 16-17 of the current PSW are 01 binary; or when bit 63 of GR0 is one, and bits 56-57 of GR0 are 01 binary.

C Condition code is set.

C^1 Condition code is set when the conditional-SSKE facility is installed, and either or both of the MR and MC bits are one.

CT Configuration-topology facility.

DE DAT-enhancement facility 1.

DM Depending on the model, DIAGNOSE may generate various program exceptions and may change the condition code.

DP Reset-DAT-protection facility.

D2 DAT-enhancement facility 2.

E E instruction format.

Figure 10-1. Summary of Control Instructions (Part 3 of 5)

Name	Mnemonic	Characteristics	Op-code	Page
ED1	Enhanced-DAT facility 1.			
ED2	Enhanced-DAT facility 2.			
ES	Expanded-storage facility.			
FC	Designation of access registers depends on the function code of the instruction.			
G0	Instruction execution includes the implied use of general register 0.			
G2	Instruction execution includes the implied use of general register 2.			
GM	Instruction execution includes the implied use of multiple general registers: General registers 0 and 1 for MOVE WITH DESTINATION KEY, MOVE WITH SOURCE KEY, PERFORM CRYPTOGRAPHIC KEY MANAGEMENT OPERATION, PERFORM TIMING FACILITY FUNCTION, and STORE SYSTEM INFORMATION. General registers 3, 4, and 14, and, when the ASN-and-LX-reuse facility is installed, general register 15 for PROGRAM CALL.			
II	Interruptible instruction (for IPTE, the instruction is interruptible when the R_3 field is nonzero).			
IS	Interruptible instruction and special-operation exception (for SSKE, the instruction is interruptible when the multiple-block control is one).			
IM	Insert-reference-bits--multiple facility.			
K	PER storage-key-alteration event.			
L	New condition code is loaded.			
LD	Long-displacement facility.			
MD	Designation of access registers in the access-register mode is model-dependent.			
MO	Move-with-optional-specifications facility.			
M3	Message-security assist extension 3.			
N	Instruction is new in z/Architecture as compared to ESA/390.			
N3	Instruction is new in z/Architecture and has been added to ESA/390.			
OP	Operand exception			
P	Privileged-operation exception; also, restricted from transactional execution.			
PI	Processor-activity-instrumentation facility.			
Q	Privileged-operation exception for semiprivileged instructions also, restricted from transactional execution.			
R_1	R_1 field designates an access register in the access-register mode.			
R_2	R_2 field designates an access register in the access-register mode.			
RA	Reusable-ASN-and-LX facility.			
RB	Reset-reference-bits-multiple facility.			
RRE	RRE instruction format.

RS	RS instruction format.			
RSY	RSY instruction format.			
RX	RX instruction format.			
RXY	RXY instruction format.			
S	S instruction format.			
SE	Special-operation, stack-empty, stack-specification, and stack-type exceptions.			
SF	Special-operation, stack-full, and stack-specification exceptions.			
SI	SI instruction format.			
SIY	SIY instruction format.			
SO	Special-operation exception.			
SP	Specification exception.			
SS	SS instruction format.			
SSE	SSE instruction format.			

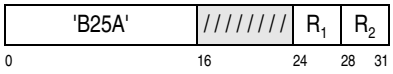
Figure 10-1. Summary of Control Instructions (Part 4 of 5)

Name	Mnemonic	Characteristics	Opcode	Page
SSF	SSF instruction format.			
ST	PER storage-alteration event.			
SU	PER store-using-real-address event.			
SW	Special-operation exception and space-switch event.			
T	Trace exceptions (which include trace table, addressing, and low-address protection).			
TE	Test-pending-external-interruption facility			
TS	TOD-clock-steering facility.			
U	Condition code is unpredictable.			
U_1	R_1 field designates an access register unconditionally.			
U_2	R_2 field designates an access register unconditionally.			
WE	Space-switch event.			
Z^1	Additional exceptions and events for PROGRAM CALL (which include ASX-translation, EX-translation, LFX-translation, LSTE-sequence, LSX-translation, LX-translation, PC-translation-specification, special-operation, stack-full, stack-specification and subspace-replacement exceptions and space-switch event).			
Z^2	Additional exceptions and events for PROGRAM TRANSFER (which include AFX-translation, ASX-translation, primary-authority, special-operation, and subspace-replacement exceptions and space-switch event).			
Z^3	Additional exceptions for SET SECONDARY ASN (which include AFX translation, ASX translation, secondary authority, special operation and subspace replacement).			
Z^4	Additional exceptions and events for PROGRAM RETURN (which include AFX-translation, ASTE-instance, ASX-translation, secondary-authority, special-operation, stack-empty, stack-operation, stack-specification, stack-type, and subspace-replacement exceptions and space-switch event).			
Z^5	Additional exceptions for BRANCH AND STACK (which include special operation, stack full, and stack specification)			
Z^6	Additional exceptions and events for PROGRAM TRANSFER WITH INSTANCE (which include AFX-translation, ASTE-instance, ASX-translation, primary-authority, special-operation, and subspace-replacement exceptions and space-switch event).			
Z^7	Additional exceptions for SET SECONDARY ASN WITH INSTANCE (which include AFX translation, ASTE instance, ASX translation, secondary authority, special operation, and subspace replacement).			

Figure 10-1. Summary of Control Instructions (Part 5 of 5)

BRANCH AND SET AUTHORITY

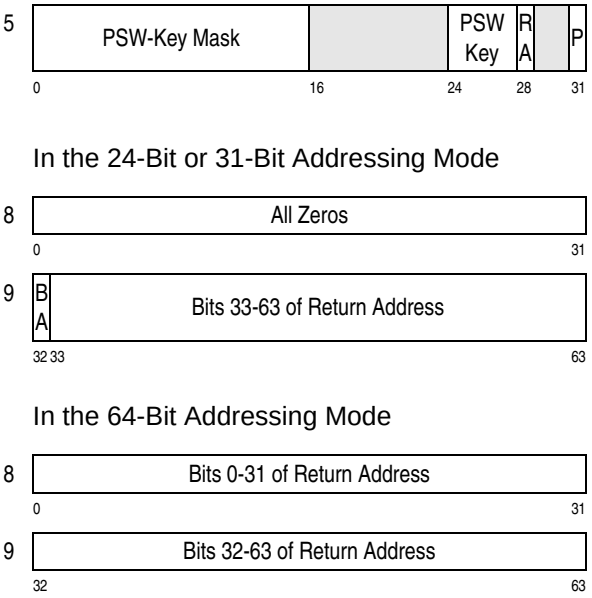
BSA R_1,R_2 [RRE]



If the dispatchable unit is in the base-authority state and the 24-bit or 31-bit addressing mode: bits 32 and 97-127 of the current PSW, the basic-addressing-mode bit and bits 33-63 of the updated instruction address, are saved in the dispatchable-unit control table (DUCT); the PSW-key mask (PKM), PSW key, and problem-state bit also are saved in the DUCT; the PKM and PSW key are replaced using the contents of general register R_1; the problem-state bit is set to one; bits 32 and 97-127 of the PSW are replaced using the contents of general register R_2; and the dispatchable unit is placed in the reduced-authority state. In the 64-bit addressing mode, the action is the same except that bits 64-127 of the current PSW are saved in the DUCT and replaced from general register R_2, and bit 32 of the PSW is neither saved nor replaced.

If the dispatchable unit is in the reduced-authority state and the 24-bit or 31-bit addressing mode: bits 32 and 97-127 of the current PSW are saved in general register R_1 if R_1 is not zero; bits 32 and 97-127 of the PSW and the PKM, PSW key, and problem-state bit are replaced by values saved in the DUCT; and the dispatchable unit is placed in the base-authority state. In the 64-bit addressing mode, the action is the same except that bits 64-127 of the current PSW are saved in general register R_1 if R_1 is not zero, those bits in the PSW are replaced from the DUCT, and bit 32 of the PSW is neither saved nor replaced.

Words 5, 8, and 9 of the DUCT are used by this instruction. The contents of those words are as follows:



The fields in words 5, 8, and 9 of the DUCT are allocated as follows:

PSW-Key Mask: Bit positions 0-15 of word 5 contain the PSW-key mask (PKM), bits 32-47 of control register 3, saved by BRANCH AND SET AUTHORITY executed in the base-authority state. The PKM is restored to control register 3 by BRANCH AND SET AUTHORITY executed in the reduced-authority state.

PSW Key: Bit positions 24-27 of word 5 contain the PSW key, bits 8-11 of the PSW, saved by BRANCH AND SET AUTHORITY executed in the base-authority state. The PSW key is restored to the PSW by BRANCH AND SET AUTHORITY executed in the reduced-authority state.

Reduced Authority (RA): Bit 28 of word 5 indicates, when zero, that the dispatchable unit associated with the DUCT is in the base-authority state or, when one, that the dispatchable unit is in the reduced-authority state. Bit 28 is set to one by BRANCH AND SET AUTHORITY executed in the base-authority state, and it is set to zero by BRANCH AND SET AUTHORITY executed in the reduced-authority state.

Problem State (P): Bit position 31 of word 5 contains the problem-state bit, bit 15 of the PSW, saved by BRANCH AND SET AUTHORITY executed in the base-authority state. The problem-state bit is restored to the PSW by BRANCH AND SET AUTHORITY executed in the reduced-authority state.

Basic Addressing Mode (BA): In the 24-bit or 31-bit addressing mode, bit position 0 of word 9 contains the basic-addressing-mode bit, bit 32 of the PSW, saved by BRANCH AND SET AUTHORITY executed in the base-authority state. The basic-addressing-mode bit is restored to the PSW from the DUCT by BRANCH AND SET AUTHORITY executed in the reduced-authority state.

Return Address: In the 24-bit or 31-bit addressing mode, bit positions 1-31 of word 9 contain bits 33-63 of the updated instruction address, bits 97-127 of the PSW, saved by BRANCH AND SET AUTHORITY executed in the base-authority state. Bits 1-31 of word 9 of the DUCT are restored to bit positions 97-127 of the PSW by BRANCH AND SET AUTHORITY executed in the reduced-authority state. In the 64-bit addressing mode, words 8 and 9 contain the updated instruction address saved by BRANCH AND SET AUTHORITY executed in the base-authority state. The contents of words 8 and 9 are restored to bit positions 64-127 of the PSW by BRANCH AND SET AUTHORITY executed in the reduced-authority state.

In the 24-bit or 31-bit addressing mode, all zeros are stored in word 8 when saving occurs in the base-authority state. In any addressing mode, all zeros are stored in bit positions 16-23, 29, and 30 of word 5 when saving occurs in the base-authority state.

All other fields in words 5, 8, and 9 remain unchanged when bit 28 of word 5 is set to zero in the reduced-authority state.

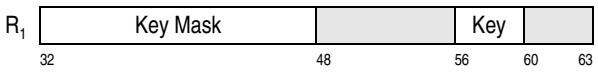
The fetch, store, and update references to the DUCT are single-access references and appear to be word concurrent as observed by other CPUs. The words of the DUCT are accessed in no particular order.

Base-Authority Operation

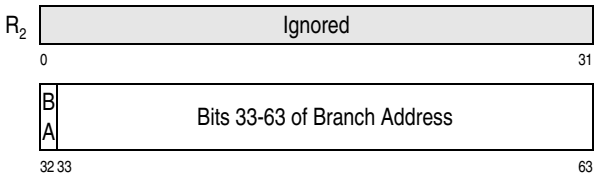
When BRANCH AND SET AUTHORITY is executed in the base-authority state, as indicated by the reduced-authority bit (RA) in the DUCT being zero, R_2 must be nonzero; otherwise, a special-operation exception is recognized. R_1 may be zero or nonzero.

The contents of bit positions 32-63 of general register R_1 and of general register R_2 when the execution of

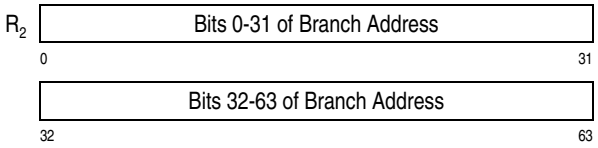
the instruction begins in the base-authority state are as follows:



In the 24-Bit or 31-Bit Addressing Mode



In the 64-Bit Addressing Mode



In any addressing mode, the contents of bit positions 0-31 of general register R_1 are ignored. In the 24-bit or 31-bit addressing mode, the contents of bit positions 0-31 of general register R_2 are ignored.

In the 24-bit or 31-bit addressing mode, PSW bits 32 and 97-127 are saved in word 9 of the DUCT, and zeros are stored in word 8. In the 64-bit addressing mode, PSW bits 64-127 are saved in words 8 and 9 of the DUCT. In any addressing mode, the PKM, the PSW key, and the problem-state bit are saved in word 5 of the DUCT, the RA bit in word 5 is set to one, and bits 16-23, 29, and 30 of word 5 are set to zeros.

Bits 56-59 of general register R_1 are placed in bit positions 8-11 of the PSW as the new PSW key. In the problem state, the new PSW key must be authorized by the PKM; otherwise, if the new PSW key is not authorized, a privileged-operation exception is recognized.

After the new PSW key has been placed in the PSW, bits 32-47 of general register R_1 are ANDed with the PKM in control register 3, and the result replaces the PKM in control register 3.

The problem-state bit in the PSW is set to one.

In the 24-bit or 31-bit addressing mode, bit 32 of general register R_2 is placed in bit position 32 of the PSW as the new basic-addressing-mode bit. A branch address is generated from bits 33-63 of general register R_2 under the control of the new basic addressing mode, and the result is placed in bit positions 64-127 of the PSW as the new instruction address.

In the 64-bit addressing mode, a branch address is generated from bits 0-63 of general register R_2 and is placed in bit positions 64-127 of the PSW as the new instruction address. Bit 32 of the PSW remains unchanged.

Bits 48-55 and 60-63 of general register R_1 may be used for future extensions and should be zeros; otherwise, the program may not operate compatibly in the future.

Reduced-Authority Operation

When BRANCH AND SET AUTHORITY is executed in the reduced-authority state, as indicated by the reduced-authority (RA) bit in the DUCT being one, R_2 must be zero; otherwise, a special-operation exception is recognized. R_1 may be zero or nonzero. The initial contents of general registers R_1 and R_2 are ignored.

If R_1 is nonzero in the 24-bit or 31-bit addressing mode, bits 32 and 97-127 of the current PSW, the basic-addressing-mode bit and bits 33-63 of the updated instruction address, are placed in bit positions 32 and 33-63, respectively, of general register R_1, and bits 0-31 of the register remain unchanged. If R_1 is nonzero in the 64-bit addressing mode, bits 64-127 of the current PSW are placed in bit positions 0-63 of general register R_1. If R_1 is zero, general register 0 remains unchanged.

In the 24-bit or 31-bit addressing mode, bit 0 of word 9 of the DUCT is placed in PSW bit position 32, and bits 1-31 of word 9, with 33 leftmost zeros appended, are placed in PSW bit positions 64-127.

In the 64-bit addressing mode, the contents of words 8 and 9 of the DUCT are placed in PSW bit positions 64-127, and bit 32 of the PSW remains unchanged.

In any addressing mode, the PKM, the PSW key, and the problem-state bit are restored from the DUCT, and the RA bit is set to zero, as previously described. There is no test for whether the restored PSW key is authorized by the restored PKM.

Special Conditions

R_2 must be nonzero in the base-authority state and zero in the reduced-authority state. If either of these rules is violated, a special-operation exception is recognized, and the operation is suppressed.

When the storage-key-removal facility is installed a special-operation exception is recognized under any of the following conditions:

- The instruction is executed in the reduced-authority state and the PSW-key value in bits 24-27 of word 5 of the DUCT is nonzero.
- The instruction is executed in the base-authority state and the PSW-key value in bits 56-59 of general register R_1 is nonzero.

In the problem state, the execution of the instruction in the base-authority state is subject to control by the PSW-key mask in control register 3. When the bit in the PSW-key mask corresponding to the PSW-key value to be set is one, the instruction is executed successfully. When the selected bit in the PSW-key mask is zero, a privileged-operation exception is recognized. In the supervisor state, any value for the PSW key is valid.

Key-controlled protection does not apply to any access made during the operation. Low-address protection does apply.

In the 24-bit or 31-bit addressing mode, the contents of word 9 of the DUCT are not checked for validity before they are loaded into the PSW. If the newly-loaded PSW contains a zero in bit position 32 and the contents of bit positions 97-103 are not zeros, then (a) the instruction is completed, (b) the resulting instruction-length code is 0, (c) a specification-exception is recognized, and (d) a program interruption occurs. The specification exception, which in this case is listed as a program exception in this instruction, is described in “Early Exception Recognition” on page 6-9.

In the ESA/390-compatibility mode, either (a) an operation exception is recognized, or (b) a special-operation exception is recognized when bit 47 of control register 0 is zero. It is unpredictable which exception is recognized.

The operation is suppressed on all addressing and protection exceptions.

Condition Code: The code remains unchanged.

Program Exceptions:

- Addressing (dispatchable-unit control table)
- Operation (in the ESA/390-compatibility mode)
- Privileged operation (selected PSW-key-mask bit is zero in the problem state, base-authority operation only)
- Protection (low-address; dispatchable-unit control table)
- Secure-storage-access (dispatchable-unit control table)
- Special operation
- Specification
- Trace
- Transaction constraint

The priority of recognition of program exceptions for the instruction is shown in Figure 10-2 on page 10-10.

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B	Transaction constraint.
7.C	Operation exception (ESA/390-compatibility mode only)
7.D	Special-operation exception due to bit 47 of control register 0 being zero (ESA/390-compatibility mode only)
8.A	Trace exceptions.
8.B	Protection exception (low-address protection) for access to dispatchable-unit control table.
8.C.1	Addressing exception or secure-storage-access exception for access to dispatchable-unit control table.
8.C.2	Special-operation exception due to R_2 being zero in the base-authority state or R_2 being nonzero in the reduced-authority state.
8.C.3	Privileged-operation exception due to selected PSW-key-mask bit being zero (base-authority operation only).
9.A	Specification exception due to bit 32 of the newly loaded PSW being zero when bits 97-103 are not all zeros (reduced-authority operation only).

Figure 10-2. Priority of Execution: BRANCH AND SET AUTHORITY (Part 1 of 2)

9.B	Special-operation exception due to PSW-key to be loaded being nonzero when the storage-key-removal facility is installed.

Figure 10-2. Priority of Execution: BRANCH AND SET AUTHORITY (Part 2 of 2)

Programming Notes:

1. BRANCH AND SET AUTHORITY can improve performance by replacing to-current-primary forms of PROGRAM TRANSFER (PT-cp) and basic (nonstacking) PROGRAM CALL (PC-cp) instructions. PT-cp and PC-cp are often used (within a single address space) to reduce the authority of the PSW-key mask (PKM) or change from supervisor state to problem state during a calling linkage made by PT-cp and then to restore the PKM authority or supervisor state during a return linkage made by PC-cp. Also, the PSW-key-setting operations of BRANCH AND SET AUTHORITY can be substituted for SET PSW KEY FROM ADDRESS instructions, and, since BRANCH AND SET AUTHORITY combines branching with PSW-key setting, it can be used to change the PSW key when branching from or to a fetch-protected program.

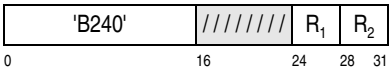
2. Only one base-authority state and one reduced-authority state are available to a dispatchable unit. Nested use of BRANCH AND SET AUTHORITY, that is, use within different subroutine levels, is not possible. The requirement that R_2 must be nonzero in the base-authority state and zero in the reduced-authority state provides detection of an attempt to use BRANCH AND SET AUTHORITY in the base-authority state when the dispatchable unit is already in the reduced-authority state because of a previous use of the instruction in the base-authority state.

3. BRANCH AND SET AUTHORITY in the base authority-state does not save an indication in the DUCT of whether the current addressing mode is the extended (64-bit) addressing mode or a basic (24-bit or 31-bit) addressing mode. The instruction, in either the base-authority state or the reduced-authority state, does not cause a switch between the extended addressing mode and a basic addressing mode. In the reduced-authority state, the contents of words 8 and 9 of the DUCT are interpreted based only on the current addressing mode. If saving occurs in the 31-bit addressing mode and then restoring occurs in the 64-bit addressing mode, bit 0 of word 9 of the DUCT will be used as an address bit instead of as the basic-addressing-mode bit. If saving occurs in the 64-bit addressing mode and then restoring occurs in the 24-bit addressing mode, an early specification exception may be recognized, after the instruction execution is completed, because bits 97-103 of the PSW may be nonzero when bit 32 is zero.

4. The instruction may be referred to as BSA-ba or BSA-ra depending on whether it is executed in the base-authority state or the reduced-authority state, respectively.

BRANCH AND STACK

BAKR R_1,R_2 [RRE]



A linkage-stack branch state entry is formed, and the current PSW, except with an unpredictable PER mask and with the addressing-mode bits and instruction address replaced from the first operand, is placed in the state entry. Subsequently, the updated instruction address in the current PSW is replaced from the second operand. Indications of the current addressing-mode bits and the new instruction address are placed in the state entry, and the PSW-key mask, PASN, SASN, EAX, and contents of general registers 0-15 and access registers 0-15 also are placed in the state entry. When the ASN-and-LX-reuse facility is installed and the ASN-and-LX-reuse control in control register 0 is one, the PASTEIN and SASTEIN also are placed in the state entry. The action associated with an operand is not performed if the R field designating the operand is zero.

When the R_1 field is nonzero, the contents of general register R_1 specify an address referred to as the return address.

When R_1 is nonzero and bit 63 of general register R_1 is zero, the return address is generated from the contents of the register under the control of the basic addressing mode specified by bit 32 of the register: 24-bit mode if bit 32 is zero, or 31-bit mode if bit 32 is one. Bit 32 of the register and the return address are substituted for the basic-addressing-mode bit, bit 32, and the updated instruction address, respectively, in the current PSW when the contents of that PSW are placed in the state entry. The extended-addressing-

mode bit, bit 31, is set to zero in the PSW that is placed in the state entry. The contents of the current PSW are not changed.

When R_1 is nonzero and bit 63 of general register R_1 is one, the return address is generated from the contents of the register under the control of the 64-bit addressing mode. Bits 0-62 of the return address, with a zero appended on the right, are substituted for the updated instruction address in the current PSW when the contents of that PSW are placed in the state entry. Bits 31 and 32 are set to one in the PSW that is placed in the state entry. The contents of the current PSW are not changed.

When the R_1 field is zero, the current PSW is placed in the state entry without any change except for an unpredictable PER mask.

Subsequently, when the R_2 field is nonzero, the instruction address in the current PSW is replaced by the branch address. The branch address is generated from the contents of general register R_2 under the control of the current addressing mode. When the R_2 field is zero, the operation is performed without branching.

The branch state entry is formed and information is placed in it as described in “Stacking Process” on page 5-85.

In the 24-bit or 31-bit addressing mode, bits 33-63 of the branch address (or of the updated instruction address if the operation is performed without branching) are placed in bit positions 33-63 of bytes 144-151 in the state entry, bit 32 of the current PSW is placed in bit position 32 of those bytes, and zeros are placed in bit positions 0-31 of the bytes.

In the 64-bit addressing mode, bits 0-62 of the branch address (or of the updated instruction address if the operation is performed without branching) are placed in bit positions 0-62 of bytes 144-151 in the state entry, and a one is placed in bit position 63 of those bytes.

The entry-type code in the state entry is 0001100 binary.

Key-controlled protection does not apply to accesses to the linkage stack, but low-address and DAT protection do apply.

Special Conditions

The CPU must be in the primary-space mode or access-register mode; otherwise, a special-operation exception is recognized.

A stack-full or stack-specification exception may be recognized during the stacking process.

The operation is suppressed on all addressing and protection exceptions.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch or store, except for key-controlled protection, linkage-stack entry)
- Special operation
- Stack full
- Stack specification
- Trace
- Transaction constraint

The priority of recognition of program exceptions for the instruction is shown in Figure 10-3 on page 10-12.

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B	Special-operation exception due to DAT being off or the CPU being in secondary-space mode or home-space mode.
7.C	Transaction constraint.
8.A	Trace exceptions (only if R_2 is nonzero).
8.B.1	Access exceptions (fetch) for entry descriptor of the current linkage-stack entry. **Note:** Exceptions 8.B.2-8.B.7 can occur only if there is not enough remaining free space in the current linkage-stack section.
8.B.2	Stack-specification exception due to remaining-free-space value in current linkage-stack entry not being a multiple of 8.

Figure 10-3. Priority of Execution: BRANCH AND STACK (Part 1 of 2)

8.B.3	Access exceptions (fetch) for second word of the trailer entry of the current section. The entry is presumed to be a trailer entry; its entry-type field is not examined.
8.B.4	Stack-full exception due to forward-section validity bit in the trailer entry being zero.
8.B.5	Access exceptions (fetch) for entry descriptor of the header entry of the next section. This entry is presumed to be a header entry; its entry-type field is not examined.
8.B.6	Stack-specification exception due to not enough remaining free space in the next section.
8.B.7	Access exceptions (store) for second word of the header entry of the next section. If there is no exception, the header is now called the current entry.
8.B.8	Access exceptions (store) for entry descriptor of the current entry and for the new state entry.

Figure 10-3. Priority of Execution: BRANCH AND STACK (Part 2 of 2)

Programming Notes:

1. Examples of the use of the BRANCH AND STACK instruction are given in Appendix A, “Number Representation and Instruction-Use Examples.”

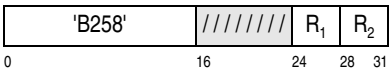
2. In no case does BRANCH AND STACK change the current addressing mode.

3. The effect when the R_1 field is zero is that the return address, which would otherwise be specified by the R_1 general register, is the address of the next sequential instruction. In this case, BRANCH AND STACK provides a program-linkage function that is comparable to the function of BRANCH AND SAVE.

4. BRANCH AND STACK with a nonzero R_1 field is intended for use at or near the entry point of a called program. The program may be called by means of BRANCH AND LINK (BALR) or BRANCH AND SAVE (BAS or BASR) from a program being executed in the 24-bit or 31-bit addressing mode, by means of BRANCH AND SAVE AND SET MODE from a program being executed in any addressing mode, or by means of a BRANCH AND SET MODE instruction located in a “glue module” and being executed in any addressing mode. In all of these cases when the nonzero R_1 field of the calling instruction is the same as the R_1 field of BRANCH AND STACK, and even when the addressing mode was changed during the calling linkage, BRANCH AND STACK correctly saves the addressing mode and return address of the calling program so that the subsequent execution of PROGRAM RETURN will return correctly to the calling program.

BRANCH IN SUBSPACE GROUP

BSG R_1,R_2 [RRE]



Provided that the current primary address space is in the subspace group, if any, associated with the current dispatchable unit, the access-list-entry token (ALET) in access register R_2 is translated by means of a special form of access-register translation (ART) to locate a destination ASN-second-table entry (DASTE). If the DASTE specifies the base space of the subspace group, the primary ASCE (PASCE) in control register 1 is replaced by the ASCE in the DASTE. If the DASTE specifies a subspace of the group, bits 0-55 and 58-63 of the PASCE are replaced by the same bits of the ASCE in the DASTE. In either case, the following actions also occur.

In the 24-bit or 31-bit addressing mode, bits 32 and 97-127 of the current PSW, the basic-addressing-mode bit and bits 33-63 of the updated instruction address, are saved in bit positions 32 and 33-63, respectively, of general register R_1, and bits 0-31 of the register remain unchanged. Subsequently, the basic-addressing-mode bit and bits 33-63 of the instruction address in the current PSW are replaced from bit positions 32-63 of general register R_2, and bits 0-31 of the register are ignored.

In the 64-bit addressing mode, bits 64-127 of the current PSW, the updated instruction address, are saved in bit positions 0-63 of general register R_1. Subsequently, the instruction address in the current PSW is replaced from bit positions 0-63 of general register R_2. Bit 32 of the PSW remains unchanged.

In any addressing mode, general register 0 remains unchanged if the R_1 field is zero.

The secondary ASCE (SASCE) in control register 7 is set equal to the new PASCE in control register 1. Also, the secondary ASN (SASN), bits 48-63 of control register 3, is set equal to the primary ASN (PASN), bits 48-63 of control register 4. If the ASN-and-LX-reuse facility is installed and is enabled by the ASN-and-LX-reuse control in control register 0, the secondary ASTEIN (SASTEIN), bits 0-31 of control register 3, is set equal to the primary ASTEIN (PASTEIN), bits 0-31 of control register 4

The current primary address space is in the subspace group for the dispatchable unit if the current primary-ASTE origin (PASTEO), bits 33-57 of control register 5, designates the ASTE for the base space of the group. The PASTEO designates the base-space ASTE if the PASTEO is equal to the base-ASTE origin (BASTEO), bits 1-25 of word 0 of the dispatchable-unit control table (DUCT). For determining whether the PASTEO equals the BASTEO, either the PASTEO may be compared to the BASTEO or the entire contents of bit positions 32-63 of control register 5 may be compared to the entire contents of word 0 of the DUCT.

Ordinary ART is described in "Access-Register-Translation Process" on page 5-60. The special ART performed by this instruction is contrasted to ordinary ART as follows:

1. The special ART is performed regardless of whether the CPU is in the access-register mode.

2. If the ALET being translated is 00000000 hex, called ALET 0, the DASTE is the ASTE for the base space. Bit 0 of the DASTE is ignored.

3. If the ALET is 00000001 hex, called ALET 1, the DASTE is the ASTE for the last subspace entered by the dispatchable unit by means of BRANCH IN SUBSPACE GROUP. That ASTE is designated by the subspace-ASTE origin (SSASTEO), bits 1-25 of word 1 of the DUCT. A special-operation exception is recognized if a subspace has not previously been entered, as indicated by an SSASTEO of all zeros. An ASTE-validity exception is recognized if bit 0 of the DASTE is one. An ASTE-sequence exception is recognized if the ASTE sequence number (ASTESN) in the DASTE does not equal the subspace ASTESN (SSASTESN) in word 3 of the DUCT. The DASTE located because of ALET 1 is considered to specify a subspace even if, due to an error, the DASTE is the ASTE for the base space. That is, there is no comparison of the SSASTEO to the BASTEO.

4. If the ALET is other than ALET 0 and ALET 1, an ASTE is located by obtaining its origin from an access-list entry (ALE) in a way similar to ordinary ART, and the DASTE is that located ASTE. In this case, as in ordinary ART:

   - An ALET-specification exception is recognized if bits 0-6 of the ALET are not zeros.
   - An ALEN-translation exception is recognized if the ALE is outside the effective access list or bit 0 of the ALE is one.
   - An ASTE-validity exception is recognized if bit 0 of the DASTE is one.
   - An ASTE-sequence exception is recognized if the ASTE sequence number (ASTESN) in the DASTE does not equal the ASTESN in the ALE.

   The operation differs from ordinary ART in that the ALE sequence number (ALESN) in the ALE is not compared to the ALESN in the ALET, and the private bit in the ALE is treated as zero. Thus, ALE-sequence and extended-authority exceptions cannot occur.

   The fetch-only bit in the ALE is ignored.

When the ALET is other than ALET 0 and ALET 1, the special ART may be performed by using the ART-lookaside buffer (ALB).

The DASTE located due to an ALET other than ALET 0 and ALET 1 may be the ASTE for the base space of the subspace group associated with the dispatchable unit. The DASTE is the base-space ASTE if the DASTE origin (DASTEO) obtained from an ALE by ART equals the BASTEO in the DUCT. For determining whether the DASTEO equals the BASTEO, either the DASTEO may be compared to the BASTEO, or the DASTEO with one leftmost and six rightmost zeros appended may be compared to the entire contents of word 0 of the DUCT. If the DASTE is not the base-space ASTE, the DASTE is treated as the ASTE for a subspace of the dispatchable unit's subspace group provided that (1) the subspace-group bit, bit 54, in the ASCE in the DASTE is one, and (2) the DASTE does not specify the base space of another subspace group. The DASTE specifies the base space of another subspace group if the base-space bit, bit 31 of word 0 of the DASTE, is one. A

special-operation exception is recognized if either of those two provisions is not met.

If the DASTE specifies the base space of the subspace group, the PASCE in control register 1 is replaced by the ASCE in the DASTE. If the DASTE specifies a subspace, bits 0-55 and 58-63 of the PASCE are replaced by the same bits of the ASCE in the DASTE, and bits 56 and 57 of the PASCE, the storage-alteration-event bit and space-switch-event-control bit, remain unchanged.

If R_1 is nonzero in the 24-bit or 31-bit addressing mode, bits 32 and 97-127 of the current PSW, the basic-addressing-mode bit and bits 33-63 of the updated instruction address, are placed in bit positions 32 and 33-63, respectively, of general register R_1, and bits 0-31 of the register remain unchanged. If R_1 is nonzero in the 64-bit addressing mode, bits 64-127 of the current PSW, the updated instruction address, are placed in bit positions 0-63 of general register R_1. If R_1 is zero, general register 0 remains unchanged.

Whether R_2 is nonzero or zero, in the 24-bit or 31-bit addressing mode, bits 32-63 of general register R_2 specify the new basic addressing mode and designate the branch address. Bit 32 of the register specifies the new basic addressing mode and replaces bit 32 of the current PSW, and the branch address is generated from the contents of bit positions 33-63 of the register under the control of the new basic addressing mode.

When R_2 is nonzero or zero in the 64-bit addressing mode, the contents of general register R_2 designate the branch address. The branch address is generated from the contents of the register under the control of the 64-bit addressing mode. Bit 32 of the PSW remains unchanged.

Regardless of the addressing mode, the new value for the PSW is computed before general register R_1 is changed.

The secondary ASCE (SASCE) in control register 7 is set equal to the new PASCE in control register 1. The secondary ASN (SASN), bits 48-63 of control register 3, is set equal to the primary ASN (PASN), bits 48-63 of control register 4. If the ASN-and-LX-reuse facility is installed and is enabled by a one value of the ASN-and-LX-reuse control, bit 44 of control register 0, the secondary ASTEIN (SASTEIN), bits 0-31 of control register 3, is set equal to the primary ASTEIN (PASTEIN), bits 0-31 of control register 4.

If the DASTE specifies the base space, the subspace-active bit, bit 0 of word 1 of the DUCT, is set to zero, and bits 1-31 of word 1 remain unchanged. If the DASTE specifies a subspace by means of ALET 1, then (1) the subspace-active bit is set to one, (2) the SSASTEO in bit positions 1-25 of word 1 remains unchanged, and (3) bits 26-31 of word 1 either are set to zeros or remain unchanged. If the DASTE specifies a subspace by means of an ALET other than ALET 1, then (1) the subspace-active bit is set to one, (2) the DASTEO is stored in bit positions 1-25 of word 1 as the SSASTEO, (3) zeros are stored in bit positions 26-31 of word 1, and (4) the ASTESN in the DASTE is stored in word 3 of the DUCT as the SSASTESN.

The fetch, store, and update references to the DUCT are single-access references and appear to be word concurrent as observed by other CPUs. The words of the DUCT are accessed in no particular order.

The operation, since it changes a translation parameter in control register 1, causes all copies of prefetched instructions to be discarded, except when in the home-space mode.

Special Conditions

DAT must be on; otherwise, a special-operation exception is recognized. A special-operation exception is also recognized if the current primary address space is not in a subspace group associated with the current dispatchable unit, if the ALET in access register R_2 is ALET 1 but a subspace has not previously been entered by the dispatchable unit by means of BRANCH IN SUBSPACE GROUP, or if the ALET used is other than ALET 0 and ALET 1 and the destination ASTE does not specify the base space or a subspace of the subspace group.

The primary space-switch-event-control bit, bit 57 of control register 1 either before or after the operation, does not cause a space-switch-event program interruption to occur.

Key-controlled protection does not apply to any access made during the operation. Low-address protection does apply.

The operation is suppressed on all addressing and protection exceptions.

Condition Code: The code remains unchanged.

Program Exceptions:

- Addressing (dispatchable-unit control table, effective access-list designation, access-list entry, destination ASN-second-table entry)
- ALET specification
- ALEN translation
- ASTE sequence
- ASTE validity
- Protection (low-address; dispatchable-unit control table)
- Secure-storage-access (dispatchable-unit control table, effective access-list designation, access-list entry, destination ASN-second-table entry)
- Special operation
- Trace
- Transaction constraint

The priority of recognition of program exceptions for the instruction is shown in the Figure 10-4.

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B	Special-operation exception due to DAT being off.
7.C	Transaction constraint.
8.A	Trace exceptions.
8.B	Protection exception (low-address protection) for access to dispatchable-unit control table.
8.C.1	Addressing exception or secure-storage-access exception for access to dispatchable-unit control table.
8.C.2	Special-operation exception due to current primary address space not being in a subspace group associated with the current dispatchable unit (primary-ASTE origin in control register 5 not equal to base-ASTE origin in dispatchable-unit control table). **Note:** Exception 8.C.3.A can occur only if the access-list-entry token (ALET) in access register R_2 is ALET 0.

Figure 10-4. Priority of Execution: BRANCH IN SUBSPACE GROUP (Part 1 of 3)

8.C.3.A	Addressing exception or secure-storage-access exception for access to base ASTE (ASTE designated by base-ASTE origin in dispatchable-unit control table). **Note:** Exceptions 8.C.3.B.1-8.C.3.B.4 can occur only if the access-list-entry token (ALET) in access register R_2 is ALET 1.
8.C.3.B.1	Special-operation exception due to subspace-ASTE origin in dispatchable-unit control table being zero.
8.C.3.B.2	Addressing exception or secure-storage-access exception for access to subspace ASTE.
8.C.3.B.3	ASTE-validity exception due to bit 0 in subspace ASTE being one.
8.C.3.B.4	ASTE-sequence exception due to ASTE sequence number in subspace ASTE not being equal to subspace-ASTE sequence number in dispatchable-unit control table. **Note:** Exceptions 8.C.3.C.1-8.C.3.C.9 can occur only if the access-list-entry token (ALET) in access register R_2 is other than ALET 0 and ALET 1.
8.C.3.C.1	ALET-specification exception due to bits 0-6 of ALET not being all zeros.
8.C.3.C.2	Addressing exception or secure-storage-access exception for access to effective access-list designation.
8.C.3.C.3	ALEN-translation exception due to access-list entry being outside the list.
8.C.3.C.4	Addressing exception or secure-storage-access exception for access to access-list entry.
8.C.3.C.5	ALEN-translation exception due to I bit in access-list entry being one.
8.C.3.C.6	Addressing exception or secure-storage-access exception for access to destination ASTE.
8.C.3.C.7	ASTE-validity exception due to bit 0 in destination ASTE being one.
8.C.3.C.8	ASTE-sequence exception due to ASTE sequence number (ASTESN) in access-list entry not being equal to ASTESN in destination ASTE.

Figure 10-4. Priority of Execution: BRANCH IN SUBSPACE GROUP (Part 2 of 3)

8.C.3.C.9	Special-operation exception due to destination-ASTE origin not equal to base-ASTE origin in dispatchable-unit control table and (1) subspace-group bit, bit 54 in address-space-control element in destination ASTE being zero or (2) base-space bit 31, in destination ASTE being one.

Figure 10-4. Priority of Execution: BRANCH IN SUBSPACE GROUP (Part 3 of 3)

Programming Notes:

1. See the discussion of BRANCH IN SUBSPACE GROUP in "Subroutine Linkage without the Linkage Stack" on page 5-14. It is intended that there be a separate ASN-second-table entry (ASTE) for each of the base space and each subspace of a subspace group. The ASTEs for the subspaces can be "pseudo" ASTEs as described in the programming note in "Address-Space Number" on page 3-24. A subspace can contain a subset of the storage in the base space by having the DAT tables for the subspace designate a subset of the pages that are designated by the DAT tables for the base space. A dispatchable unit has access to a subspace if an access-list entry designating the ASTE for the subspace is in the primary-space or dispatchable-unit access list of the dispatchable unit.

2. BRANCH IN SUBSPACE GROUP can be used to give control from the base space to a subspace, from a subspace to another subspace, and from a subspace to the base space. The instruction can also be used to give control from the base space to the base space or from a subspace to the same subspace.

3. Since BRANCH IN SUBSPACE GROUP sets the secondary address-space-control element (ASCE) in control register 7 equal to the new primary ASCE in control register 1 (along with setting the secondary ASN in control register 3 equal to the primary ASN in control register 4), the program in an address space given control by BRANCH IN SUBSPACE GROUP does not have access to the calling program's address space by means of that address space being the secondary address space.

4. When a dispatchable unit has used BRANCH IN SUBSPACE GROUP to enter a subspace and has not subsequently used BRANCH IN SUBSPACE GROUP to return to the base space, the dispatchable unit is said to be "subspace active." When LOAD ADDRESS SPACE PARAMETERS, PROGRAM CALL, PROGRAM RETURN, PROGRAM TRANSFER, PROGRAM TRANSFER WITH INSTANCE, SET SECONDARY ASN, or SET SECONDARY ASN WITH INSTANCE places an ASCE in control register 1 as the primary ASCE or in control register 7 as the secondary ASCE, and if (1) the ASCE has the subspace-group bit on in it, (2) the dispatchable unit is subspace active, and (3) the ASCE was obtained from the ASN-second-table entry (ASTE) for the base space of the current dispatchable unit, then the instruction (any of the seven named instructions) replaces bits 0-55 and 58-63 of the ASCE in the control register with the same bits of the ASCE in the ASTE for the subspace in which the dispatchable unit last had control. Further details about the effects of the subspace-group facility on the seven named instructions are given in "Subspace-Replacement Operations" on page 5-71 and in the definitions of the instructions.

5. The use of BRANCH IN SUBSPACE GROUP (BSG) along with PROGRAM CALL (PC) and either PROGRAM TRANSFER (PT) (or PROGRAM TRANSFER WITH INSTANCE) or PROGRAM RETURN (PR) can produce results that may be unexpected. Consider the following sequence of operations:

   a. Start in the base space

   b. BSG to a subspace

   c. PC (the first PC) to an address space that is not in the subspace group.

   d. PC (the second PC) to the base space. Since the dispatchable unit is subspace active, control is given to the subspace.

   e. BSG back to the base space.

   f. PT or PR (paired with the second PC) back to the address space that is not in the subspace group.

   g. PT or PR (paired with the first PC) back to the subspace group. Since the dispatchable unit is no longer subspace active, control is given to the base space even though the first PC was issued in the subspace.

6. BRANCH IN SUBSPACE GROUP does not perform the serialization or checkpoint-synchroniza-

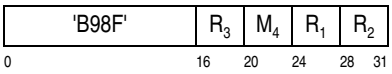
tion functions, but it does cause all copies of prefetched instructions to be discarded except when in the home-space mode.

7. Unlike the RR-format branch instructions, a value of zero in the R_2 field for BRANCH IN SUBSPACE GROUP designates general register 0, and branching occurs.

8. When the R_2 field designates access register 0, the access register is treated as containing ALET 0 regardless of the contents of the access register.

COMPARE AND REPLACE DAT TABLE ENTRY

CRDTE $R_1,R_3,R_2[,M_4]$ [RRF-b]



Note: The term “specified CPU or CPUs” has the following meaning for scope of TLBs affected by this instruction:

- When the local-clearing (LC) control in the M_4 field is zero, the term “specified CPU or CPUs” means all of the CPUs in the configuration.

- When the LC control in the M_4 field is one, the term “specified CPU or CPUs” means only the CPU executing the COMPARE AND REPLACE DAT TABLE ENTRY instruction (the local CPU). The TLBs in all other CPUs in the configuration may not be affected.

The first and second operands are compared. If they are equal, the contents of general register $R_1 + 1$ are stored at the second-operand location, and the specified CPU or CPUs in the configuration are cleared of (1) all TLB table entries of the designated type formed through the use of the replaced entry in storage, and (2) all lower-level TLB table entries formed through the use of the cleared higher-level TLB table entries. The TLB entries cleared may optionally be limited to entries formed to translate addresses in a specified address space.

If the first and second operands are unequal, the second operand is loaded at the first-operand location. However, on some models, the second operand may be fetched and subsequently stored back unchanged at the second-operand location. This update appears to be a block-concurrent interlocked-update reference as observed by other CPUs. The result of the comparison is indicated by the condition code.

The R_1 and R_2 fields each designate an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

The first operand is called the compare value and is contained in bit positions 0-63 of general register R_1. Bit positions 0-63 of general register $R_1 + 1$ are called the replacement value.

The second operand is a doubleword in storage designated by general registers R_2 and $R_2 + 1$. Bits 59-61 of general register R_2 are the designated-table type (DTT), specifying the bits in general register R_2 that form the origin of a table in storage; the DTT also specifies the bits in general register $R_2 + 1$ that are used as the effective index into the table to locate the second operand, as follows:

DTT (bits 59-61 of Reg. R_2)	Table Type	Table Origin Bits in Reg. R_2	Effective Index Bits in Reg. $R_2 + 1$
000	Page	0-52	44-51
001-011	—	—	—
100	Segment	0-51	33-43
101	Region third	0-51	22-32
110	Region second	0-51	11-21
111	Region first	0-51	0-10

When the DTT is 000 binary, the contents of bit positions 0-52 of general register R_2, with eleven zeros appended on the right, form the table origin, and bits 53-58, 62, and 63 of the register are ignored. When the DTT is 100-111 binary, the contents of bit positions 0-51 of general register R_2, with twelve zeros appended on the right, form the table origin, and bits 52-58, 62, and 63 of the register are ignored. DTT values of 001, 010, and 011 binary are invalid; a specification exception is recognized if the DTT is invalid.

Bits 0-51 of general register $R_2 + 1$ have the format of the region index, segment index, and page index of a virtual address. The part of bits 0-51 normally used by DAT to select an entry in the type of table designated by the DTT is called the effective index. The part of bits 0-51 of general register $R_2 + 1$ to the right

of the effective index is ignored. Bit positions 52-53 are reserved for IBM use and must contain zeros; otherwise, results are unpredictable. Bit positions 54-63 of general register $R_2 + 1$ are reserved and must contain zeros; otherwise, a specification exception is recognized.

If R_3 is nonzero, the contents of general register R_3 have the format of an address-space-control element with only the table origin, bits 0-51, and designation-type control (DT), bits 60 and 61, used. These contents are used to select TLB entries to be cleared. Bits 52-59, 62, and 63 of general register R_3 are ignored. If R_3 is zero, the entire contents of general register 0 are ignored, and TLB entries are cleared regardless of the ASCE used to form them.

The contents of the general registers just described are shown in Figure 10-5.

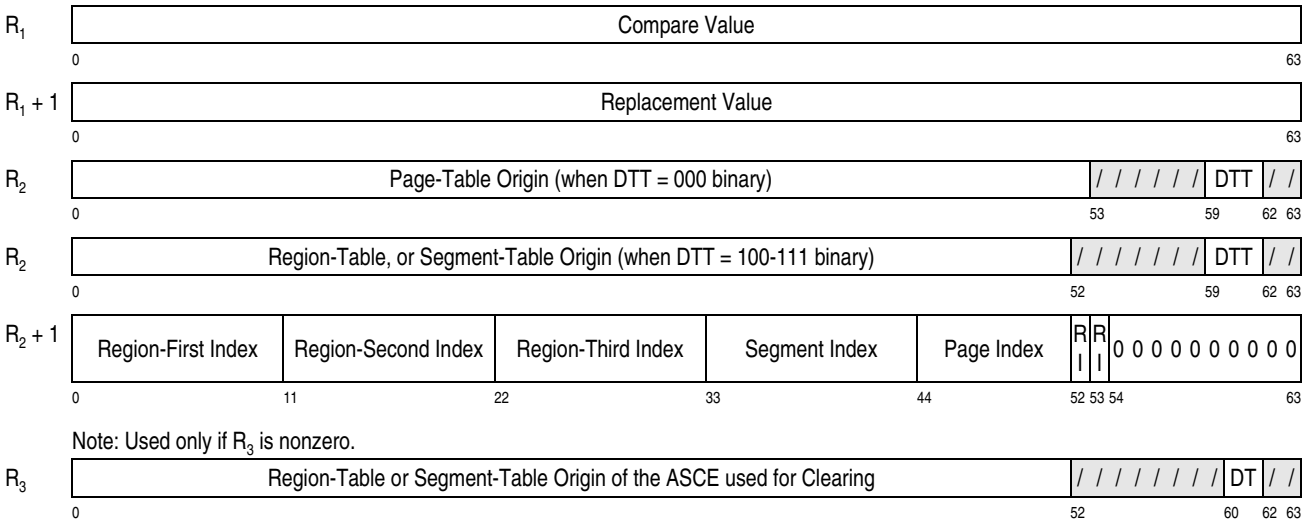


Figure 10-5. Register Contents for COMPARE AND REPLACE DAT TABLE ENTRY

The M_4 field has the following format:

The bits of the M_4 field are defined as follows:

- ***Reserved:*** Bits 0-2 are reserved. Reserved bit positions of the M_4 field are ignored but should contain zeros; otherwise, the program may not operate compatibly in the future.

- ***Local-Clearing Control (LC):*** The LC bit, bit 3 of the M_4 field controls whether only the TLB in the local CPU is cleared, or whether the TLBs in all CPUs of the configuration are cleared.

When the first and second operands are equal, the contents of general register $R_1 + 1$ are stored at the second-operand location, and the translation-lookaside buffers (TLBs) in the specified CPUs in the configuration are cleared of (1) all TLB table entries of the designated type formed through the use of the original contents of the second operand in storage (that is, the contents of the second operand before it is replaced with the replacement value), and (2) all lower-level TLB table entries formed through the use of the cleared higher-level TLB table entries. The TLB entries cleared may optionally be limited to entries formed to translate addresses in a specified address space.

Depending on the table type, the table origin in general register R_2 and effective index in general register $R_2 + 1$ designate a table entry in accordance with the rules in "Lookup in a Table Designated by an Address-Space-Control Element" on page 3-58, or "Page-Table Lookup" on page 3-62, except that a carry from bit position 0 of the resulting address is always ignored, and the index is not checked against a table-length field. The table origin is treated as a 64-bit address, and the addition is performed by using the rules for 64-bit address arithmetic, regardless of the current addressing mode specified by bits 31 and 32 of the current PSW. The address formed from these two components is a real or absolute address. The contents of the table entry are not

examined for validity, and no exception conditions are recognized due to the contents of the table entry.

The fetch and store of the table entry are performed as a block-concurrent interlocked update. The fetch access to the entry is subject to key-controlled protection, and the store access is subject to key-controlled protection and low-address protection.

A serialization function is performed before the operation begins and again after the operation is completed. As is the case for all serialization operations, this serialization applies only to this CPU; other CPUs are not necessarily serialized.

When the first and second operands are equal, this CPU clears selected entries from its TLB. In addition to the clearing of the local CPU, if the LC bit in the M_4 field is zero, all other CPUs in the configuration are signaled to clear selected entries from their TLBs. Each TLB is cleared of at least those entries for which all of the following conditions are met:

- The effective index in general register $R_2 + 1$ matches the corresponding index in the TLB table entry of type designated by the DTT field in bits 59-61 of general register R_2. If the model implements a composite TLB entry that includes the index designated by the DTT field, bits to the left of the effective index in general register $R_2 + 1$ also match any corresponding bits provided in the designated TLB table entry.
- Either the R_3 field is zero , or the table-origin and designation-type fields in general register R_3 match the table-origin and designation-type fields in the address-space-control element (ASCE) used to form the TLB table entry.

  If the R_3 field is zero, then the condition described in this step does not apply.
- If EDAT-1 applies and the entry replaced in storage is a segment-table entry, or if EDAT-2 applies and the entry replaced in storage is a region-third-table entry, the format control in the replaced entry matches that of the TLB entry.
- If the replaced entry in storage designates a lower-level translation table, the lower-level table origin in the entry matches the table-origin field in the TLB table entry.
- If EDAT-1 applies and the entry replaced in storage is a segment-table entry in which the format control is one, or if EDAT-2 applies and the entry replaced in storage is a region-third-table entry in which the format control is one, the segment-frame absolute address or region-frame absolute address, respectively, in the replaced entry matches that of the TLB entry.

Each affected TLB is also cleared of at least any lower-level TLB table entries for which all of the following conditions are met:

- The lower-level TLB table entry was formed through use of the replaced entry in storage or through use of a higher-level TLB table entry formed through use of either the replaced entry in storage or a TLB entry cleared in this process.
- Either the R_3 field is zeroor the table-origin and designation-type fields in general register R_3 match the table-origin and designation-type fields in the address-space-control element (ASCE) used to form the lower-level TLB table entry. This ASCE may be one that attached a translation path containing a higher-level table entry that attached the lower-level table entry in storage from which the lower-level TLB table entry was formed, or it may be one that made usable a higher-level TLB table entry that attached the lower-level table entry in storage from which the lower-level TLB table entry was formed. See “Formation of TLB Entries” on page 3-64 for the meaning of the terminology used here.

  If the R_3 field is zero,**,** then the condition described in this step does not apply.
- If EDAT-1 applies and the entry replaced in storage is a segment-table entry, or if EDAT-2 applies and the entry replaced in storage is a region-third-table entry, the format control in the replaced entry matches that of the TLB entry.
- If the entry in storage designates a lower-level translation table, the lower-level table origin in the entry matches the table-origin field in the TLB table entry.

When the first and second operands are equal, the execution of COMPARE AND REPLACE DAT TABLE ENTRY is not completed on the CPU which executes it until the following occurs:

1. All entries meeting the criteria specified above have been cleared from the TLB of this CPU. When the LC control in the M_4 field is one, execution of COMPARE AND REPLACE DAT TABLE

ENTRY is complete, and the following step is not performed.

2. When the LC control in the M_4 field is zero, all other CPUs in the configuration have completed any storage accesses, including the updating of the change and reference bits.

The operation does not necessarily have any effect on TLB real-space entries.

Special Conditions

A specification exception is recognized, and the operation is suppressed if any of the following is true:

- Either the R_1 or R_2 field is odd.
- The DTT field, bit positions 59-61 of general register R_2, contain 001, 010, or 011 binary.
- Bit positions 54-63 of general register $R_2 + 1$ contain nonzero values.

It is unpredictable whether a specification exception is recognized if bits 52-53 of general register $R_2 + 1$ contain nonzero values.

The operation is suppressed on all addressing and protection exceptions.

Resulting Condition Code:

0 First and second operands equal, second operand replaced by contents of general register $R_1 + 1$
1 First and second operands unequal, first operand replaced by second operand
2 --
3 --

Program Exceptions:

- Addressing (region-, segment-, or page-table entry)
- Operation (if the enhanced-DAT facility 2 is not installed)
- Privileged operation
- Protection (fetch and store, region-, segment-, or page-table entry, key-controlled protection and low-address protection)
- Secure-storage-access (region-, segment-, or page-table entry)
- Specification
- Transaction constraint

Programming Notes:

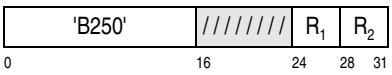
1. The selective clearing of TLB entries may be implemented in different ways, depending on the model, and, in general, more entries may be cleared than the minimum number required.
2. When clearing TLB entries associated with common segments, note that these entries may have been formed through use of address-space-control elements containing many different table origins.
3. The M_4 field of the instruction is considered to be optional, as indicated by the field being contained within brackets [ ] in the assembler syntax. When the M_4 field is not specified, the assembler places zeros in that field of the instruction.
4. The local-clearing control should be specified as one only when either of the following are true; otherwise, unpredictable results, including the presentation of a delayed-access-exception machine check, may occur.

   - The program is running in a uniprocessor configuration.
   - The program is assigned to run on a single CPU and the affinity between the program and that CPU is maintained.

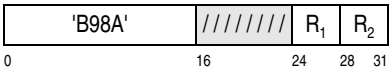
   On some models, use of COMPARE AND REPLACE DAT TABLE ENTRY specifying clearing of only the local TLB for the cases listed above may result in significant performance improvements.

COMPARE AND SWAP AND PURGE

CSP R_1,R_2 [RRE]



CSPG R_1,R_2 [RRE]



The first and second operands are compared. If they are equal, contents of general register $R_1 + 1$ are stored at the second-operand location, and a purging operation is performed. If they are unequal, the sec-

ond operand is loaded at the first-operand location. The result of the comparison is indicated in the condition code.

The R_1 field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

For COMPARE AND SWAP AND PURGE (CSP), the first operand is the contents of bit positions 32-63 of general register R_1. The second operand is a word in storage.

For COMPARE AND SWAP AND PURGE (CSPG), the first operand is the contents of bit positions 0-63 of general register R_1. The second operand is a doubleword in storage.

For both CSP and CSPG, the location of the leftmost byte of the second operand is designated by contents of general register R_2.

The purging operation applies to ART-lookaside buffers (ALBs) and translation-lookaside buffers (TLBs) in all CPUs in the configuration. Either ALBs or TLBs, or both ALBs and TLBs, may be selected for purging. All entries are cleared from the selected buffers.

The purging operation is specified by means of bits 62 and 63 of general register R_2. When bit 62 is one, entries are cleared from ALBs. When bit 63 is one, entries are cleared from TLBs. When bits 62 and 63 both are ones, entries are cleared from ALBs and TLBs. When bits 62 and 63 both are zeros, no entries are cleared.

The handling of the address in general register R_2 is dependent on the addressing mode. For CSP in the 24-bit addressing mode, the contents of bit positions 40-61 of general register R_2, with two zeros appended on the right, constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-61 of the register, with two zeros appended on the right, constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-61 of the register, with two zeros appended on the right, constitute the address.

For CSPG in the 24-bit addressing mode, the contents of bit positions 40-60 of general register R_2, with three zeros appended on the right, constitute the address, and the contents of bit positions 0-39 and 61 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-60 of the register, with three zeros appended on the right, constitute the address, and the contents of bit positions 0-32 and 61 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-60 of the register, with three zeros appended on the right, constitute the address, and the contents of bit position 61 are ignored.

The contents of the registers just described are shown in Figure 10-6 on page 10-22 and Figure 10-7 on page 10-23. When an equal comparison occurs, the contents of bit positions 32-63 of general register R1 + 1 for CSP, or of bit positions 0-63 for CSPG, are stored at the second-operand location. The fetch of the second operand for purposes of comparison and the store into the second-operand location appear to be a block-concurrent interlocked-update reference as observed by other CPUs.

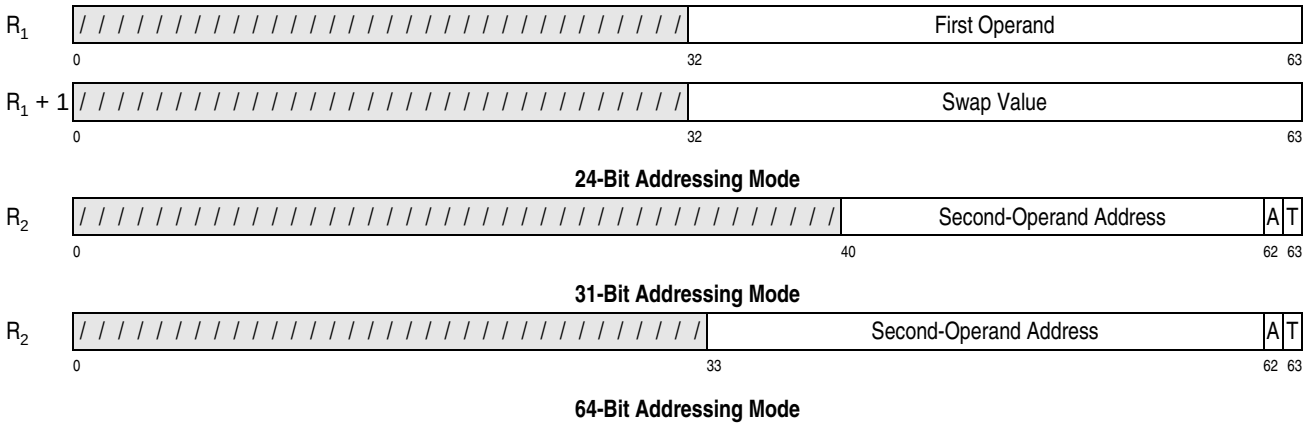


Figure 10-6. Register Contents for COMPARE AND SWAP AND PURGE (CSP) (Part 1 of 2)

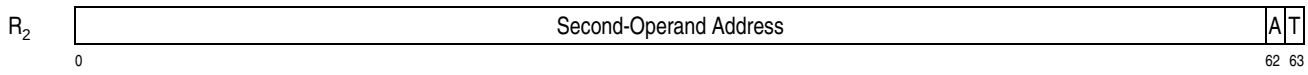

Figure 10-6. Register Contents for COMPARE AND SWAP AND PURGE (CSP) (Part 2 of 2)

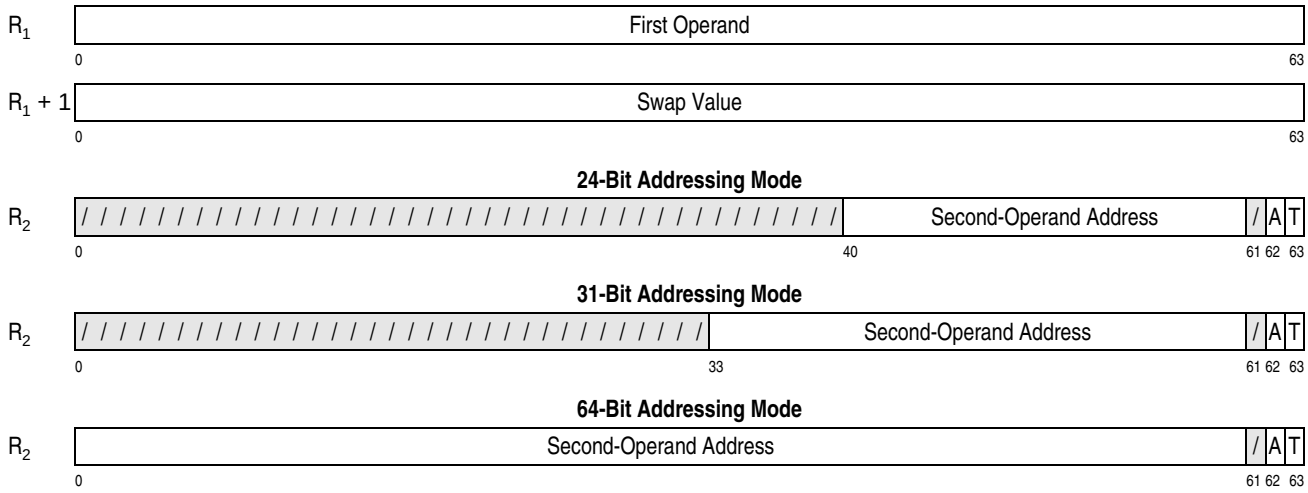

Figure 10-7. Register Contents for COMPARE AND SWAP AND PURGE (CSPG)

When the result of the comparison is unequal, the second-operand is loaded at the first-operand location, bits 0-31 of general register R_1 remain unchanged for CSP only, and the second-operand location remains unchanged. However, on some models, the second operand may be fetched and subsequently stored back unchanged at the second-operand location. This update appears to be a block-concurrent interlocked-update reference as observed by other CPUs.

A serialization function is performed before the operand is fetched and again after the operation is completed.

When an equal comparison occurs, this CPU clears entries from its ALB and TLB, as specified by bits 62 and 63 of general register R_2, and signals all CPUs in the configuration to clear the same specified entries from their ALBs and TLBs. The ALB entries that are cleared are all ALB access-list designations, access-list entries, ASN-second-table entries, and authority-table entries. The TLB entries that are cleared are all region-first-table entries, region-second-table entries, region-third-table entries, segment-table entries, page-table entries, and real-space entries.

Before the TLB purging operation, when bits 62 or 63 of general register R_2 are one, any active transactions on other CPUs in the configuration are aborted with abort code 255, condition code 2.

The execution of COMPARE AND SWAP AND PURGE is not completed on the CPU which executes it until (1) all specified entries have been cleared from the ALB and TLB of this CPU and (2) all other CPUs in the configuration have completed any storage accesses, including the updating of the change and reference bits, by using the specified ALB and TLB entries.

Special Conditions

The R_1 field must designate an even register; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 First and second operands equal, second operand replaced by contents of general register $R_1 + 1$
1 First and second operands unequal, first operand replaced by second operand
2 --
3 --

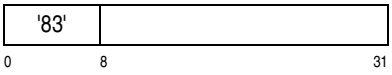
Program Exceptions:

- Access (fetch and store, operand 2)

- Operation (if DAT-enhancement facility 1 is not installed, CSPG only)
- Privileged operation
- Specification
- Transaction constraint

Programming Note: COMPARE AND SWAP AND PURGE provides a broadcast form of the PURGE ALB and PURGE TLB instructions, thus making it possible to avoid uses of SIGNAL PROCESSOR.

DIAGNOSE



The CPU performs built-in diagnostic functions, or other model-dependent functions. The purpose of the diagnostic functions is to verify proper functioning of equipment and to locate faulty components. Other model-dependent functions may include disabling of failing buffers, reconfiguration of CPUs, storage, and channel paths, and modification of control storage.

Bits 8-31 may be used as in the SI or RS formats, or in some other way, to specify the particular diagnostic function. The use depends on the model.

The execution of the instruction may affect the state of the CPU and the contents of a register or storage location, as well as the progress of an I/O operation. Some diagnostic functions may cause the test indicator to be turned on.

Resulting Condition Code: The code is unpredictable.

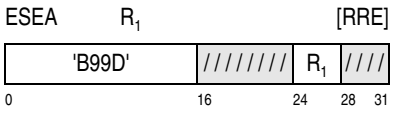
Program Exceptions:

- Privileged operation
- Transaction constraint
- Depending on the model, other exceptions may be recognized.

Programming Notes:

1. Since the instruction is not intended for problem-state-program or control-program use, DIAGNOSE has no mnemonic.
2. DIAGNOSE, unlike other instructions, does not follow the rule that programming errors are distinguished from equipment errors. Improper use of DIAGNOSE may result in false machine-check indications or may cause actual machine malfunctions to be ignored. It may also alter other aspects of system operation, including instruction execution and channel-program operation, to an extent that the operation does not comply with that specified in this publication. As a result of the improper use of DIAGNOSE, the system may be left in such a condition that the power-on reset or initial-microprogram-loading (IML) function must be performed. Since the function performed by DIAGNOSE may differ from model to model and between versions of a model, the program should avoid issuing DIAGNOSE unless the program recognizes the model number stored by STORE CPU ID.

EXTRACT AND SET EXTENDED AUTHORITY



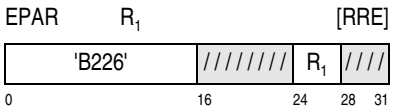
The extended authorization index (EAX), bits 32-47 of control register 8, is saved in bit positions 32-47 of the first operand, and then the EAX in control register 8 is replaced by the contents of bit positions 48-63 of the first operand. Bits 0-31 of the first operand are ignored, and bits 0-31 and 48-63 of the operand remain unchanged.

Condition Code: The code remains unchanged.

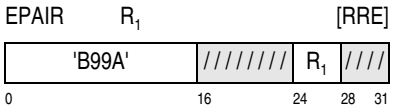
Program Exceptions:

- Privileged operation
- Transaction constraint

EXTRACT PRIMARY ASN



EXTRACT PRIMARY ASN AND INSTANCE



The 16-bit PASN, bits 48-63 of control register 4, is placed in bit positions 48-63 of general register R_1. Bits 32-47 of the general register are set to zeros.

In the EXTRACT PRIMARY ASN AND INSTANCE operation, the PASTEIN, bits 0-31 of control register 4, is placed in bit positions 0-31 of general register R_1. In the EXTRACT PRIMARY ASN operation, bits 0-31 of general register R_1 remain unchanged.

Special Conditions

The instruction must be executed with DAT on; otherwise, a special-operation exception is recognized.

In the problem state, the extraction-authority control, bit 36 of control register 0, must be one; otherwise, a privileged-operation exception is recognized. In the supervisor state, the extraction-authority-control bit is not examined.

Condition Code: The code remains unchanged.

Program Exceptions:

- Operation (if the ASN-and-LX-reuse facility is not installed, EPAIR only)
- Privileged operation (extraction-authority control is zero in the problem state)
- Special operation
- Transaction constraint

The priority of recognition of program exceptions for the instruction is shown in Figure 10-8.

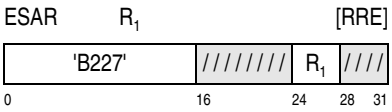
1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B.1	Operation exception if the ASN-and-LX-reuse facility is not installed (EPAIR only).

Figure 10-8. Priority of Execution: EXTRACT PRIMARY ASN (AND INSTANCE) (Part 1 of 2)

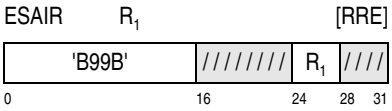
7.B.2	Special-operation exception due to DAT being off.
7.C	Transaction constraint.
8.	Privileged-operation exception due to extraction-authority control, bit 36 of control register 0, being zero in problem state.

Figure 10-8. Priority of Execution: EXTRACT PRIMARY ASN (AND INSTANCE) (Part 2 of 2)

EXTRACT SECONDARY ASN



EXTRACT SECONDARY ASN AND INSTANCE



The 16-bit SASN, bits 48-63 of control register 3, is placed in bit positions 48-63 of general register R_1. Bits 32-47 of the general register are set to zeros.

In the EXTRACT SECONDARY ASN AND INSTANCE operation, the SASTEIN, bits 0-31 of control register 3, is placed in bit positions 0-31 of general register R_1. In the EXTRACT SECONDARY ASN operation, bits 0-31 of general register R_1 remain unchanged.

Special Conditions

The instruction must be executed with DAT on; otherwise, a special-operation exception is recognized.

In the problem state, the extraction-authority control, bit 36 of control register 0, must be one; otherwise, a privileged-operation exception is recognized. In the supervisor state, the extraction-authority-control bit is not examined.

Condition Code: The code remains unchanged.

Program Exceptions:

- Operation (if the ASN-and-LX-reuse facility is not installed, ESAIR only)
- Privileged operation (extraction-authority control is zero in the problem state)
- Special operation
- Transaction constraint

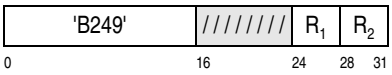
The priority of recognition of program exceptions for the instruction is shown in Figure 10-9.

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B.1	Operation exception if the ASN-and-LX-reuse facility is not installed (ESAIR only).
7.B.2	Special-operation exception due to DAT being off.
7.C	Transaction constraint.
8.	Privileged-operation exception due to extraction-authority control, bit 36 of control register 0, being zero in problem state.

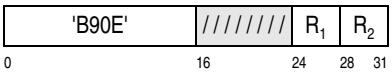
Figure 10-9. Priority of Execution: EXTRACT SECONDARY ASN (AND INSTANCE)

EXTRACT STACKED REGISTERS

EREG R_1,R_2 [RRE]



EREGG R_1,R_2 [RRE]



Contents of a set of general registers and a set of access registers that were saved in the last state entry in the linkage stack are restored to the registers. Each set of registers begins with register R_1 and ends with register R_2.

For EXTRACT STACKED REGISTERS (EREG), the contents of bit positions 32-63 of the general registers are restored, and the contents of bit positions 0-31 of the registers remain unchanged. For EXTRACT STACKED REGISTERS (EREGG), the contents of bit positions 0-63 of the general registers are restored. In either case, the contents of bit positions 0-31 of the access registers are restored.

For each of the general registers and the access registers, the registers are loaded in ascending order of their register numbers, starting with register R_1 and continuing up to and including register R_2, with register 0 following register 15. The bit positions of each register are loaded from the position in the state entry where the contents of the bit positions were saved when the state entry was created. The contents of the state entry remain unchanged.

The last state entry is located as described in “Unstacking Process” on page 5-88. The state entry remains in the linkage stack, and the linkage-stack-entry address in control register 15 remains unchanged.

Key-controlled protection does not apply to references to the linkage stack.

Special Conditions

The CPU must be in the primary-space mode, access-register mode, or home-space mode; otherwise, a special-operation exception is recognized.

A stack-empty, stack-specification, or stack-type exception may be recognized during the unstacking process.

The operation is suppressed on all addressing exceptions.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, except for protection, linkage-stack entry)
- Special operation
- Stack empty
- Stack specification
- Stack type
- Transaction constraint

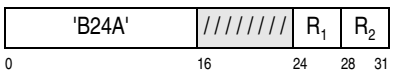
The priority of recognition of program exceptions for the instruction is shown in Figure 10-10.

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B	Special-operation exception due to DAT being off or the CPU being in secondary-space mode.
7.C	Transaction constraint.
8.	Access exceptions (fetch) for entry descriptor of the current linkage-stack entry.
9.	Stack-type exception due to current entry not being a state entry or header entry. **Note**: Exceptions 10-14 can occur only if the current entry is a header entry.
10.	Access exceptions (fetch) for second word of the header entry.
11.	Stack-empty exception due to backward stack-entry validity bit in the header entry being zero.
12.	Access exceptions (fetch) for entry descriptor of preceding entry, which is the entry designated by the backward stack-entry address in the current (header) entry.
13.	Stack-specification exception due to preceding entry being a header entry.
14.	Stack-type exception due to preceding entry not being a state entry.
15.	Access exceptions (fetch) for the selected contents of the state entry.

Figure 10-10. Priority of Execution: EXTRACT STACKED REGISTERS

EXTRACT STACKED STATE

ESTA R_1,R_2 [RRE]



Sixty-four or 128 bits of status information in the last state entry in the linkage stack are placed in the pair of general registers designated by the R_1 field. The condition code is set to indicate whether the state entry is a branch state entry or a program-call state entry.

The R_1 field designates the even-numbered register of an even-odd pair of general registers.

Bits 56-63 of general register R_2 are an unsigned binary integer that is used as a code to select the state-entry byte positions, or byte and bit positions, from which information is to be extracted, as shown in Figure 10-11.

Code (Bits 56-63 of GR R_2)	State-Entry Content	State-Entry Byte, or Byte and Bit Positions, Selected
0	PKM, SASN, EAX, and PASN	128-135
1	PSW bits 0-32 and 97-127	136-139, 140.0, and 168-175.33-63 (see text)
2	Branch address or called space and PC number	144-151
3	Modifiable area	152-159
4	PSW bits 0-127	136-143 and 168-175
5	Secondary and primary ASTEIN	176-183

Figure 10-11. EXTRACT STACKED STATE Codes and Extracted State-Entry Fields

For a code of 0, 2, or 3 in bit positions 56-63 of general register R_2, the contents of the leftmost four bytes of the eight bytes of status information are placed in bit positions 32-63 of general register R_1, and the contents of the rightmost four bytes of the status information are placed in bit positions 32-63 of general register $R_1 + 1$. The contents of bit positions 0-31 of general registers R_1 and $R_1 + 1$ remain unchanged.

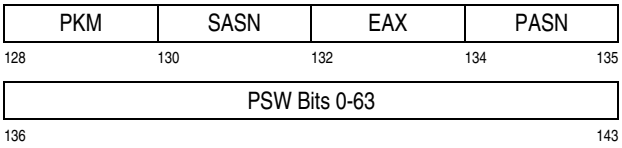
For a code of 1 in bit positions 56-63 of general register R_2, the contents of bytes 136-139 of the state entry, which are bits 0-31 of the PSW in the state entry, are placed in bit positions 32-63 of general register R_1; the contents of bit position 0 of byte 140 of the entry, which is bit 32 of that PSW, are placed in bit position 32 of general register $R_1 + 1$; and the contents of bit positions 33-63 of bytes 168-175 of the entry, which are bits 97-127 of the PSW, are placed in bit positions 33-63 of general register $R_1 + 1$. However, bit 44 of general register R_1, which corresponds to bit 12 of the PSW in the state entry, is set to one, indicating the extracted PSW is of the short-PSW format (as shown in Figure 4-3 on page 4-8). Also, if bits 0-32 of bytes 168-175 of the state entry are not all zeros, bit 63 of general register $R_1 + 1$ is set to one; otherwise, bit 63 remains with the value loaded from bit position 63 of bytes

168-175 of the state entry. The contents of bit positions 0-31 of general registers R_1 and $R_1 + 1$ remain unchanged.

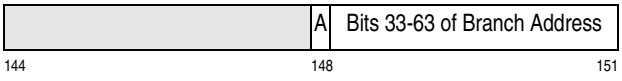
For a code of 4 in bit positions 56-63 of general register R_2, the contents of bytes 136-143 of the state entry, which are bits 0-63 of the PSW in the state entry, are placed in bit positions 0-63 of general register R_1, and the contents of bytes 168-175 of the state entry, which are bits 64-127 of that PSW, are placed in bit positions 0-63 of general register $R_1 + 1$.

Code 5 in bit positions 56-63 of general register R_2 is valid only if the ASN-and-LX-reuse facility is installed. For code 5, the contents of the leftmost four bytes of the eight bytes of status information are placed in bit positions 0-31 of general register R_1, and the contents of the rightmost four bytes of the status information are placed in bit positions 0-31 of general register $R_1 + 1$. The contents of bit positions 32-63 of general registers R_1 and $R_1 + 1$ remain unchanged.

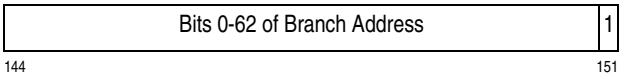
The format of byte positions 128-183 of the state entry is as follows:



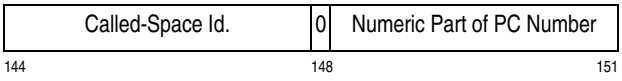
In a Branch State Entry Made in 24-Bit or 31-Bit Mode



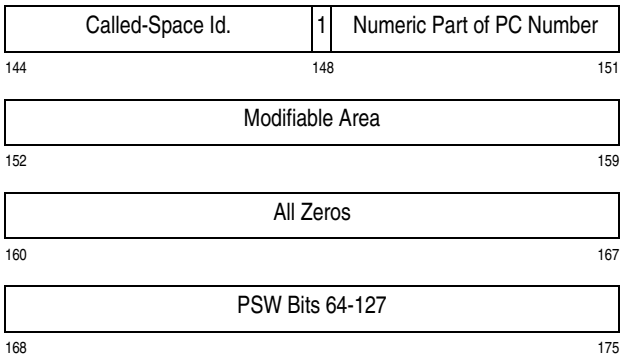
In a Branch State Entry Made in 64-Bit Mode



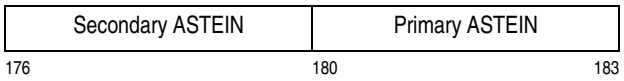
In a Program-Call State Entry Made When Resulting Mode Is 24 Bit or 31 Bit



In a Program-Call State Entry Made When Resulting Mode Is 64 Bit



If ASN-and-LX Reuse Is Enabled; otherwise Unpredictable



The contents of the state entry remain unchanged.

The last state entry is located as described in “Unstacking Process” on page 5-88. The state entry remains in the linkage stack, and the linkage-stack-entry address in control register 15 remains unchanged.

When the entry-type code in the entry descriptor of the state entry is 0001100 binary, indicating a branch state entry, the condition code is set to 0. When the entry-type code is 0001101 binary, indicating a program-call state entry, the condition code is set to 1.

Key-controlled protection does not apply to references to the linkage stack.

Bits 0-55 of general register R_2 are ignored.

Special Conditions

A specification exception is recognized when R_1 is odd or the code in bit positions 56-63 of general register R_2 is greater than 4 when the ASN-and-LX-reuse facility is not installed or is greater than 5 when the facility is installed.

The CPU must be in the primary-space mode, access-register mode, or home-space mode; otherwise, a special-operation exception is recognized.

A stack-empty, stack-specification, or stack-type exception may be recognized during the unstacking process.

The operation is suppressed on all addressing exceptions.

Resulting Condition Code:

0 Branch state entry
1 Program-call state entry
2 --
3 --

Program Exceptions:

- Access (fetch, except for protection, linkage-stack entry)
- Special operation
- Specification
- Stack empty
- Stack specification
- Stack type
- Transaction constraint

The priority of recognition of program exceptions for the instruction is shown in Figure 10-12.

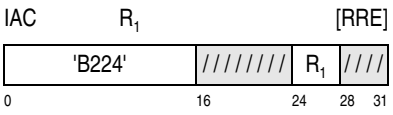
1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B	Special-operation exception due to DAT being off or the CPU being in secondary-space mode.
7.C	Transaction constraint.
8.A	Specification exception due to R_1 being odd or bits 56-63 of general register R_2 having a value greater than 4 when the ASN-and-LX-reuse facility is not installed or greater than 5 when the facility is installed.
8.B.1	Access exceptions (fetch) for entry descriptor of the current linkage-stack entry.
8.B.2	Stack-type exception due to current entry not being a state entry or header entry. **Note**: Exceptions 8.B.3-8.B.7 can occur only if the current entry is a header entry.
8.B.3	Access exceptions (fetch) for second word of the header entry.
8.B.4	Stack-empty exception due to backward stack-entry validity bit in the header entry being zero.
8.B.5	Access exceptions (fetch) for entry descriptor of preceding entry, which is the entry designated by the backward stack-entry address in the current (header) entry.
8.B.6	Stack-specification exception due to preceding entry being a header entry.
8.B.7	Stack-type exception due to preceding entry not being a state entry.
8.B.8	Access exceptions (fetch) for the selected contents of the state entry.

Figure 10-12. Priority of Execution: EXTRACT STACKED STATE (Part 1 of 2)

Figure 10-12. Priority of Execution: EXTRACT STACKED STATE (Part 2 of 2)

Programming Note: The results for a code of 1 in bit positions 56-63 of general register R_2 are intended to provide compatibility with ESA/390. However, the resulting values in bits 32-63 of general registers R_1 correspond to bits 0-31 of the short PSW (shown in Figure 4-3 on page 4-8); that is, the extracted values can indicate a stacked PSW with the extended-addressing control (bit 31) set to one, whereas an ESA/390-format PSW cannot. (It may be that only values of bits in bit positions 0-31 of the PSW are required.) Bit 63 of general register $R_1 + 1$ is set to one if the instruction address in the PSW in the state entry is larger than a 31-bit address.

INSERT ADDRESS SPACE CONTROL



The address-space-control bits, bits 16 and 17 of the current PSW, are placed in reversed order in bit positions 54 and 55 of general register R_1; that is, bit 16 is placed in bit position 55, and bit 17 is placed in bit position 54. Bits 48-53 of the register are set to zeros, and bits 0-47 and 56-63 of the register remain unchanged. The address-space-control bits are also used to set the condition code.

Special Conditions

The instruction must be executed with DAT on; otherwise, a special-operation exception is recognized.

In the problem state, the extraction-authority control, bit 36 of control register 0, must be one; otherwise, a

privileged-operation exception is recognized. In the supervisor state, the extraction-authority-control bit is not examined.

Resulting Condition Code:

0 PSW bits 16 and 17 zeros (indicating primary-space mode)
1 PSW bit 16 one and bit 17 zero (indicating secondary-space mode)
2 PSW bit 16 zero and bit 17 one (indicating access-register mode)
3 PSW bits 16 and 17 ones (indicating home-space mode)

Program Exceptions:

- Privileged operation (extraction-authority control is zero in the problem state)
- Special operation
- Transaction constraint

The priority of recognition of program exceptions for the instruction is shown in Figure 10-13.

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B	Special-operation exception due to DAT being off.
7.C	Transaction constraint.
8.	Privileged-operation exception due to extraction-authority control, bit 36 of control register 0, being zero in problem state.

Figure 10-13. Priority of Execution: INSERT ADDRESS SPACE CONTROL

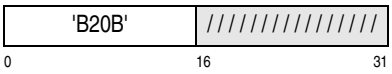
Programming Notes:

1. Bits 48-53 of general register R_1 are reserved for expansion for use with possible future facilities. The program should not depend on these bits being set to zeros.

2. INSERT ADDRESS SPACE CONTROL and SET ADDRESS SPACE CONTROL are defined to operate on the seventh byte of a general register so that the address-space-control bits can be saved in the same general register as the PSW key, which is placed in the eighth byte of general register 2 by INSERT PSW KEY.

INSERT PSW KEY

IPK [S]



The four-bit PSW-key, bits 8-11 of the current PSW, is inserted in bit positions 56-59 of general register 2, and bits 60-63 of that register are set to zeros. Bits 0-55 of general register 2 remain unchanged.

Special Conditions

In the problem state, the extraction-authority control, bit 36 of control register 0, must be one; otherwise, a privileged-operation exception is recognized. In the supervisor state, the extraction-authority-control bit is not examined.

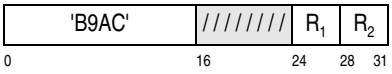
Condition Code: The code remains unchanged.

Program Exceptions:

- Privileged operation (extraction-authority control is zero in the problem state)
- Transaction constraint

INSERT REFERENCE BITS MULTIPLE

IRBM R_1,R_2 [RRE]



Beginning with the block designated by the address in general register R_2, the reference bits in the storage keys of the 64 consecutive 4 K-byte blocks are inspected. For each of the 64 blocks, the reference bit is placed in an ascending bit position of general register R_1, beginning with bit position 0 of the register.

General register R_2 designates the first of 64 blocks in absolute storage on a 64-block (256 K-byte) boundary. In the 24-bit addressing mode, bits 40-45 of the register, with six binary zeros appended on the right, designate the first block, and bits 0-39 and

46-63 of the register are ignored. In the 31-bit addressing mode, bits 33-45 of the register, with six binary zeros appended on the right, designate the first block, and bits 0-32 and 46-63 of the register are ignored. In the 64-bit addressing mode, bits 0-45 of the register, with six binary zeros appended on the right, designate the first block, and bits 46-63 of the register are ignored.

Because it is an absolute address, the address designating the first storage block is not subject to dynamic address translation or prefixing. The references to the storage keys are not subject to protection exceptions.

Condition Code: The code remains unchanged.

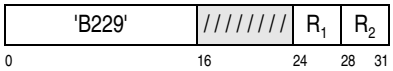
Program Exceptions:

- Addressing (address specified by general register R_2)
- Operation (insert-reference-bits-multiple facility not installed)
- Privileged operation
- Transaction constraint

Programming Note: The reference bits provided by the INSERT REFERENCE BITS MULTIPLE instruction provide the control program with a substantially accurate census of the reference bits inspected by the instruction. However, depending on the model, the results returned by the instruction may differ from those provided by the RESET REFERENCE BITS MULTIPLE instruction for the same blocks of storage. Similarly, the results returned by INSERT REFERENCE BITS MULTIPLE may differ from those provided by a series of 64 INSERT STORAGE KEY EXTENDED or RESET REFERENCE BIT EXTENDED instructions for the same blocks of storage.

INSERT STORAGE KEY EXTENDED

ISKE R_1,R_2 [RRE]



The storage key for the block that is addressed by the contents of general register R_2 is inserted in general register R_1.

In the 24-bit addressing mode, bits 40-51 of general register R_2 designate a 4 K-byte block in real storage, and bits 0-39 and 52-63 of the register are ignored. In the 31-bit addressing mode, bits 33-51 of general register R_2 designate a 4 K-byte block in real storage, and bits 0-32 and 52-63 of the register are ignored. In the 64-bit addressing mode, bits 0-51 of general register R_2 designate a 4 K-byte block in real storage, and bits 52-63 of the register are ignored.

The address designating the storage block, being a real address, is not subject to dynamic address translation. The reference to the storage key is not subject to a protection exception.

The seven-bit storage key is inserted in bit positions 56-62 of general register R_1, and bit 63 is set to zero. The contents of bit positions 0-55 of the register remain unchanged.

Special Conditions

When the storage-key-removal facility is installed, a special-operation exception is recognized.

Condition Code: The code remains unchanged.

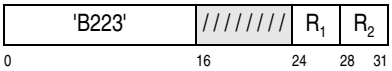
Program Exceptions:

- Addressing (address specified by general register R_2)
- Privileged operation
- Special operation (storage-key-removal facility installed)
- Transaction constraint

Programming Note: See the programming note for INSERT REFERENCE BITS MULTIPLE on page 10-31 for a discussion of differing reference bits that may be returned by IRBM, ISKE, RRBE, and RRBM for the same block of storage.

INSERT VIRTUAL STORAGE KEY

IVSK R_1,R_2 [RRE]



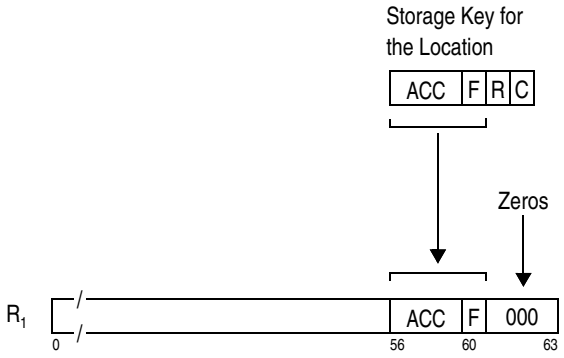
The storage key for the location designated by the virtual address in general register R_2 is inserted in general register R_1.

Selected bits of general register R_2 are used as a virtual address. In the 24-bit addressing mode, the address is specified by bits 40-63 of the register, and bits 0-39 are ignored. In the 31-bit addressing mode, the address is specified by bits 33-63, and bits 0-32 is ignored. In the 64-bit addressing mode, the address is specified by bits 0-63 of the register.

The address is a virtual address and is subject to the address-space-control bits, bits 16 and 17 of the current PSW. The address is treated as a primary virtual address in the primary-space mode, as a secondary virtual address in the secondary-space mode, as an AR-specified virtual address in the access-register mode, or as a home virtual address in the home-space mode. The reference to the storage key is not subject to a protection exception.

Bits 0-4 of the storage key, which are the access-control bits and the fetch-protection bit, are placed in bit positions 56-60 of general register R_1, with bits 61-63 set to zeros. The contents of bit positions 0-55 of the register remain unchanged. The change and reference bits in the storage key are not inspected. The change bit is not affected by the operation. The reference bit, depending on the model, may or may not be set to one as a result of the operation.

The following diagram shows the storage key and the register positions just described.



Special Conditions

The instruction must be executed with DAT on; otherwise, a special-operation exception is recognized.

In the problem state, the extraction-authority control, bit 36 of control register 0, must be one; otherwise, a privileged-operation exception is recognized. In the supervisor state, the extraction-authority-control bit is not examined.

When the storage-key-removal facility is installed, a special-operation exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (except for protection, address specified by general register R_2)
- Privileged operation (extraction-authority control is zero in the problem state)
- Special operation
- Transaction constraint

The priority of recognition of program exceptions for the instruction is shown in Figure 10-14.

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B	Special-operation exception due to DAT being off.
7.C	Transaction constraint.
8.	Privileged-operation exception due to extraction-authority control, bit 36 of control register 0, being zero.
9.	Special-operation exception when the storage-key-removal facility is installed.
10.	Access exceptions (except for protection) for address specified by general register R_2.

Figure 10-14. Priority of Execution: INSERT VIRTUAL STORAGE KEY

Programming Notes:

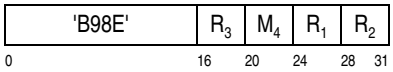
1. Since all bytes in a 4 K-byte block are associated with the same page and the same storage key, bits 52-63 of general register R_2 essentially are ignored. Similarly, since all bytes in a 1 M-byte block are associated with the same segment, bits 44-51 of general register R_2 may also be ignored when EDAT-1 applies and the STE-format is one

and the control program ensures the access-control and fetch-protection bits are identical in each of the 256 storage keys for the segment. Similarly, since all bytes in a 2 G-byte block are associated with the same region, bits 33-51 of general register R_2 may also be ignored when EDAT-2 applies and the RTTE-format is one and the control program ensures the access-control and fetch-protection bits are identical in each of the 524,288 storage keys for the region.

2. In the access-register mode, access register 0 designates the primary address space regardless of the contents of access register 0.

INVALIDATE DAT TABLE ENTRY

IDTE $R_1,R_3,R_2[,M_4]$ [RRF-b]



Note: The term “specified CPU or CPUs” has the following meaning for scope of TLBs affected by this instruction:

- When the local-TLB-clearing facility is not installed, or when the facility is installed and the local-clearing-control (LC) bit in the M_4 field is zero, the term “specified CPU or CPUs” means all of the CPUs in the configuration.
- When the local-TLB-clearing facility is installed and the LC bit in the M_4 field is one, the term “specified CPU or CPUs” means only the CPU executing the IDTE instruction (the local CPU). The TLBs in all other CPUs in the configuration may not be affected.

When the clearing-by-ASCE-option bit, bit 52 of general register R_2, is zero, an operation called the invalidation-and-clearing operation is performed, as follows. The designated region-table entry or segment-table entry in storage, or a range of entries beginning with the designated entry, is invalidated, and the translation-lookaside buffers (TLBs) in the specified CPU or CPUs in the configuration are cleared of (1) all TLB table entries of the designated type formed through the use of the invalidated entry or entries in storage, and (2) all lower-level TLB table entries formed through the use of the cleared higher-level TLB table entries. The TLB entries cleared may optionally be limited to entries formed to translate addresses in a specified address space.

When the clearing-by-ASCE-option bit is one, an operation called the clearing-by-ASCE operation is performed, as follows. The operation does not perform any invalidation of DAT-table entries in storage, but it does clear, from the TLBs in all CPUs in the configuration, all region-first-table entries, region-second-table entries, region-third-table entries, segment-table entries and page-table entries formed to translate addresses in a specified address space.

The two operations are described separately below, before the section “Common Operation.”

The M_4 field has the following format:

The bits of the M_4 field are defined as follows:

- ***Reserved:*** Bits 0-1 of the M_4 field are ignored but should contain zeros; otherwise, the program may not operate compatibly in the future.
- ***Format-Control Summary (FS):*** When EDAT-2 applies, bit 2 of the M_4 field is the format-control summary (FS) for the invalidation-and-clearing operation. Bit 2 of the M_4 field is ignored for the clearing-by-ASCE operation and when EDAT-2 does not apply.

  The format-control summary applies when the designation type (DT), bits 60-61 of the general register R_1, is 00 or 01 binary; when the DT in general register R_1 is 10 or 11 binary, the format-control summary is ignored. The meaning of the FS bit is as follows:

Value	Meaning
0	The format control is not known to be one in all of the table entries designated by the effective invalidation index and additional-entry count.
1	The format control is one in all of the table entries designated by the effective invalidation index and additional-entry count.

- ***Local-Clearing Control (LC):*** When the local-TLB-clearing facility is installed, the LC bit, bit 3 of the M_4 field, controls whether only the TLB in the local CPU is cleared or whether the TLBs in all CPUs of the configuration are cleared. When

the local-TLB-clearing facility is not installed, bit 3 of the M_4 field is ignored.

Invalidation-and-Clearing Operation

When bit 52 of general register R_2, the clearing-by-ASCE-option bit, is zero, the invalidation-and-clearing operation is specified.

The contents of general register R_1 have the format of an address-space-control element with only the table origin, bits 0-51, and designation-type control (DT), bits 60 and 61, used. The table origin designates the DAT table in which one or more entries are to be invalidated, and DT specifies the type of that table.

Bits 52-59, 62, and 63 of general register R_1 are ignored.

Bits 0-43 of general register R_2 have the format of the region index and segment index of a virtual address. The part of bits 0-43 normally used by DAT to select an entry in the type of table designated by general register R_1 is called the effective invalidation index.

Bits 60 and 61 of general register R_1 specify a table type and an effective invalidation index as follows:

Bits 60 and 61 of Reg. R_1	Table Type	Effective Invalidation Index in Reg. R_2
11	Region first table	Region first index (bits 0-10)
10	Region second table	Region second index (bits 11-21)
01	Region third table	Region third index (bits 22-32)
00	Segment table	Segment index (bits 33-43)

The part of bits 0-43 of general register R_2 to the left (if any) and to the right of the effective invalidation index is ignored.

The table origin in general register R_1 and the effective invalidation index designate a DAT-table entry to be invalidated. Bits 53-63 of general register R_2 are an unsigned binary integer specifying the number of additional table entries to be invalidated. Therefore, the number of entries to be invalidated is 1-2,048, corresponding to a value of bits 53-63.

Bits 44-49 of general register R_2 must be zeros; otherwise, a specification exception is recognized. It is unpredictable if a specification exception is recognized if bits 50 and 51 of general register R_2 contain nonzero values.

If R_3 is nonzero, the contents of general register R_3 have the format of an address-space-control element with only the table origin, bits 0-51, and designation-type control (DT), bits 60 and 61, used. These contents are used to select TLB entries to be cleared. Bits 52-59, 62, and 63 of general register R_3 are ignored. If R_3 is zero, the entire contents of general register 0 are ignored, and TLB entries are cleared regardless of the ASCE used to form them.

The contents of the general registers just described are shown in Figure 10-15.

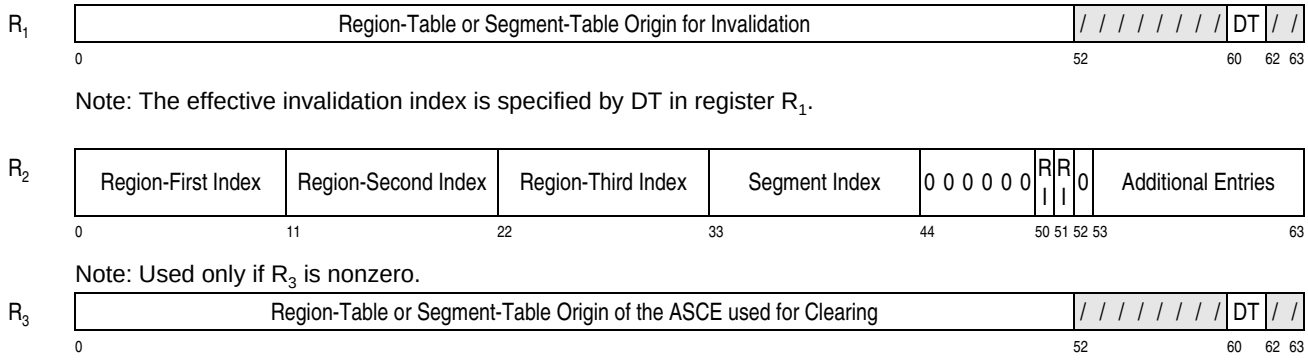


Figure 10-15. Register Contents for INVALIDATE DAT TABLE ENTRY Invalidation-and-Clearing Operation (Bit 52 of GR R_2 Is Zero)

The table origin in general register R_1 and effective invalidation index in general register R_2 designate a table entry in accordance with the rules in "Lookup in a Table Designated by an Address-Space-Control Element" on page 3-58, except that a carry from bit position 0 of the resulting address is always ignored, and the index is not checked against a table-length field. The table origin is treated as a 64-bit address, and the addition is performed by using the rules for 64-bit address arithmetic, regardless of the current addressing mode specified by bits 31 and 32 of the current PSW. The address formed from these two components is a real or absolute address. The invalid bit, bit 58, of this doubleword is set to one. During this procedure, the entry is not checked for a format error or for whether the origin, in the entry, of the next-lower-level table would cause an addressing or secure-storage-access exception. The table-type field in the entry is ignored. If the DT field in bits 60-61 of general register R_1 designates a segment-table entry, the common-segment bit in the entry is ignored. If EDAT-2 applies and the DT field designates a region-third-table entry, the common-region bit in the entry is ignored.

The entire table entry is fetched concurrently from storage. Subsequently, the byte containing the invalid bit is stored. The fetch access to the entry is subject to key-controlled protection, and the store access is subject to key-controlled protection and low-address protection.

If bits 53-63 of general register R_2 are not all zeros, the setting of the invalid bit to one in a region-table or segment-table entry is repeated by adding one to the previously used value of the effective invalidation index, and this is done as many times as are specified by bits 53-63. A carry out of the leftmost bit position of the effective invalidation index is ignored, and wraparound in the table occurs in this case. The contents of general register R_2 remain unchanged.

A serialization function is performed before the operation begins and again after the operation is completed. As is the case for all serialization operations, this serialization applies only to this CPU; other CPUs are not necessarily serialized.

After it has set an invalid bit to one, this CPU clears selected entries from its TLB. Then if the local-TLB-clearing facility is not installed, or if the facility is installed and LC bit in the M_4 field is zero, this CPU signals all other CPUs in the configuration to clear selected entries from their TLBs. Each affected TLB is cleared of at least those entries for which all of the following conditions are met:

- The effective invalidation index in general register R_2 matches the corresponding index in the TLB table entry of type designated by the DT field in bits 60-61 of general register R_1. If the model implements a composite TLB entry that includes the index designated by the DT field, bits to the left of the effective index in general register R_2 also match any corresponding bits provided in the designated TLB table entry. Note that when multiple table entries are invalidated due to bits 53-63 of general register R_2, then the effective invalidation index is incremented, a carry out of the leftmost bit position of the index is lost, and TLB region- or segment-table entries

are cleared for each value of the index so obtained.

- Either the R_3 field is zero, or the table-origin and designation-type fields in general register R_3 match the table-origin and designation-type fields in the address-space-control element (ASCE) used to form the TLB table entry.

  If the R_3 field is zero, then the condition described in this step does not apply.

- If the entry invalidated in storage designates a lower-level translation table, the lower-level table origin in the invalidated entry matches the table-origin field in the TLB table entry.

Each affected TLB is also cleared of at least any lower-level TLB table entries for which all of the following conditions are met:

- The lower-level TLB table entry was formed through use of an entry invalidated in storage or through use of a higher-level TLB table entry formed through use of either an entry invalidated in storage or a TLB entry cleared in this process.
- Either the R_3 field is zero or the table-origin and designation-type fields in general register R_3 match the table-origin and designation-type fields in the address-space-control element (ASCE) used to form the lower-level TLB table entry. This ASCE may be one that attached a translation path containing a higher-level table entry that attached the lower-level table entry in storage from which the lower-level TLB table entry was formed, or it may be one that made usable a higher-level TLB table entry that attached the lower-level table entry in storage from which the lower-level TLB table entry was formed. See “Formation of TLB Entries” on page 3-64 for the meaning of the terminology used here.

  If the R_3 field is zero, then the condition described in this step does not apply.

- If the entry invalidated in storage designates a lower-level translation table, the lower-level table origin in the invalidated entry matches the table-origin field in the TLB table entry.

Programming Notes:

1. Setting the format-control summary to one may provide improved performance on certain models.
2. When the designation type (DT), bits 60-61 of general register R_1, is 00 binary, the format-control summary applies to the segment-table entries being invalidated. When the DT in general register R_1 is 01 binary, the format-control summary applies to the region-third-table entries being invalidated.
3. The program should only set the format-control summary to one if it can ensure that format control (bit 53 of the table entry) is one in all of the table entries being invalidated. If the format-control summary is set to one, but the format control is not one in all of the table entries being invalidated, incomplete purging of the TLB may occur, resulting in unpredictable results from DAT.
4. The M_4 field of the instruction is considered to be optional, as indicated by the field being contained within brackets [ ] in the assembler syntax. When the M_4 field is not specified, the assembler places zeros in that field of the instruction.

Storing in the region- or segment-table entry and the clearing of TLB entries may or may not occur if the invalid bit is already one in the region- or segment-table entry.

When multiple entries are invalidated, clearing of TLB entries may be delayed until all entries have been invalidated.

Clearing-by-ASCE Operation

When bit 52 of general register R_2, the clearing-by-ASCE-option bit, is one, the clearing-by-ASCE operation is specified.

The contents of general register R_3 have the format of an address-space-control element with only the table origin, bits 0-51, and designation-type control (DT), bits 60 and 61, used. These contents are used to select TLB entries to be cleared. Bits 52-59, 62, and 63 of general register R_3 are ignored. R_3 may be zero or nonzero, that is, any general register, including register 0, may be designated.

Bits 44-49 of general register R_2 must be zeros; otherwise, a specification exception is recognized. It is

unpredictable if a specification exception is recognized if bits 50 and 51 of general register R_2 do not contain zero values.

The contents of general register R_1 and of bit positions 0-43 and 53-63 of general register R_2 are ignored.

The contents of the general registers just described are shown in Figure 10-16.

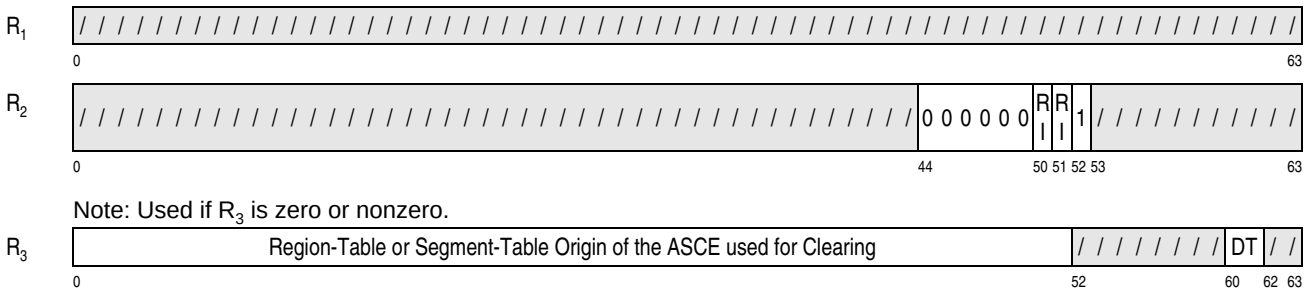

Figure 10-16. Register Contents for INVALIDATE DAT TABLE ENTRY Clearing-by-ASCE Operation (Bit 52 of GR R2 Is One)

The TLBs of the specified CPU or CPUs in the configuration are cleared at all levels of at least those entries for which the table-origin and designation-type fields in general register R_3 match the table-origin and designation-type fields in the address-space-control element (ASCE) used to form the entry. This ASCE is the one used in the translation during which the entry was formed. See "Formation of TLB Entries" on page 3-64 for the meaning of the terminology used here.

When the clearing-by-ASCE-option bit (bit 52 of general register R_2) is one, the format-control summary bit (bit 2 of the M_4 field) is ignored.

Common Operation

The execution of INVALIDATE DAT TABLE ENTRY is not completed on the CPU which executes it until the following occur:

1. All entries meeting the criteria specified above have been cleared from the TLB of this CPU. When the local-TLB-clearing facility is installed and the LC bit in the M_4 field is one, execution of INVALIDATE DAT TABLE ENTRY is complete at this point and the following step is not performed.
2. When the local-TLB-clearing facility is not installed, or when the facility is installed and the LC bit in the M_4 field is zero, all other CPUs in the configuration have completed any storage accesses, including the updating of the change and reference bits, by using TLB entries corresponding to the specified parameters.

Before the TLB purging operation, transactional execution by other CPUs in the configuration is aborted with abort code 255, condition code 2. The aborting of transactional execution affects at least those CPUs accessing the locations (transactionally or nontransactionally) for which TLB entries are being cleared. It is unpredictable whether some or all other CPUs are affected as well.

The operations do not necessarily have any effect on TLB real-space entries.

Special Conditions

Bits 44-49 of general register R_2 must be zeros; otherwise, a specification exception is recognized.

It is unpredictable whether a specification exception is recognized if bits 44-49 of general register R_2 contain non-zero values.

The operation is suppressed on all addressing and protection exceptions (invalidation-and-clearing operation only).

Resulting Condition Code: The code is unpredictable.

Program Exceptions:

- Addressing (invalidated region- or segment-table entry, invalidation-and-clearing operation only).
- Operation (if the DAT-enhancement facility 1 is not installed)
- Privileged operation
- Protection (fetch and store, region- or segment-table entry, key-controlled protection and low-address protection; invalidation-and-clearing operation only).
- Secure-storage-access (invalidated region- or segment-table entry, invalidation-and-clearing operation only)
- Specification
- Transaction constraint

Programming Notes:

1. The selective clearing of TLB entries may be implemented in different ways, depending on the model, and, in general, more entries may be cleared than the minimum number required. When the invalidation-and-clearing operation is performed, some models may clear all TLB entries when the effective invalidation index is not a segment index or may clear an entry regardless of the page-table origin in the entry. When that operation or the clearing-by-ASCE operation is performed, some models may clear a TLB entry regardless of the designation-type field in general register R_3. When either operation is performed, other models may clear precisely the minimum number of entries required. Therefore, in order for a program to operate on all models, the program should not take advantage of any properties obtained by a less selective clearing on a particular model.

2. When using the clearing-by-ASCE operation to clear TLB entries associated with common segments, note that these entries may have been formed through use of address-space-control elements containing many different table origins.

The following notes apply when the invalidation-and-clearing operation is specified.

3. The clearing of TLB entries may make use of the page-table origin in a segment-table entry. Therefore, if the segment-table entry, when in the attached state, ever contained a page-table origin that is different from the current value, copies of entries containing the previous values may remain in the TLB.

4. INVALIDATE DAT TABLE ENTRY cannot be safely used to update a shared location in main storage if the possibility exists that another CPU or a channel program may also be updating the location.

5. The address of the DAT-table entry for INVALIDATE DAT TABLE ENTRY is a 64-bit address, and the address arithmetic is performed by following the normal rules for 64-bit address arithmetic, with wraparound at 2^{64} - 1. Also, offset and length fields are not used. Contrast this with implicit translation and the translations for LOAD REAL ADDRESS and STORE REAL ADDRESS, all of which may result either in wraparound or in an addressing exception when a carry occurs out of bit position 0 and which indicate an exception condition when the designated entry does not lie within its table. Accordingly, the DAT tables should not be specified to wrap from maximum storage locations to location 0, and the first designated entry and all additional entries specified by bits 53-63 of general register R_2 should lie within the designated table.

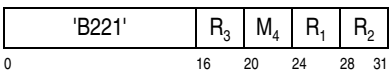
6. When the local-TLB-clearing facility is installed, the local-clearing control should be specified as one when the ASCE used to form the TLB entries being cleared has been attached only to the CPU on which the IDTE instruction is executed (for example, if the program is running on a uniprocessor). Otherwise, unpredictable results, including the presentation of a delayed-access-exception machine check, may occur.

   On some models, use of INVALIDATE DAT TABLE ENTRY specifying clearing of only the local TLB for the cases listed above may result in significant performance improvements.

7. The M_4 field of the instruction is considered to be optional, as indicated by the field being contained within brackets [ ] in the assembler syntax. When the M_4 field is not specified, the assembler places zeros in that field of the instruction.

INVALIDATE PAGE TABLE ENTRY

IPTE $R_1,R_2[,R_3[,M_4]]$ [RRF-a]



Note: The term “specified CPU or CPUs” has the following meaning for scope of TLBs affected by this instruction:

- When the local-TLB-clearing facility is not installed, or when the facility is installed and the local-clearing-control (LC) bit in the M_4 field is zero, the term “specified CPU or CPUs” means all of the CPUs in the configuration.
- When the local-TLB-clearing facility is installed and the LC bit in the M_4 field is one, the term “specified CPU or CPUs” means only the CPU executing the IPTE instruction (the local CPU). The TLBs in all other CPUs in the configuration may not be affected.

The designated page-table entries are invalidated, and the translation-lookaside buffers (TLBs) in the specified CPU or CPUs in the configuration are cleared of the associated entries.

The contents of general register R_1 have the format of a segment-table entry, with only the page-table origin used. The contents of general register R_2 have the format of a virtual address, with only the page index used. The contents of fields that are not part of the page-table origin or page index are ignored.

When the IPTE-range facility is not installed, or when the R_3 field is zero, the single page-table entry designated by the first and second operands is invalidated.

When the IPTE-range facility is installed and the R_3 field is nonzero, bits 56-63 of general register R_3 contain an unsigned binary integer specifying the count of additional page-table entries to be invalidated. Therefore, the number of page-table entries to be invalidated is 1-256, corresponding to a value of 0-255 in bits 56-63 of the register. Bits 0-55 of the register should be set to zero; otherwise, the program may not operate compatibly in the future.

When the IPTE-range facility is installed in the z/Architecture architectural mode, it is unpredictable whether it is installed in the ESA/390-compatibility mode.

The contents of the general registers just described are shown in Figure 10-17 .

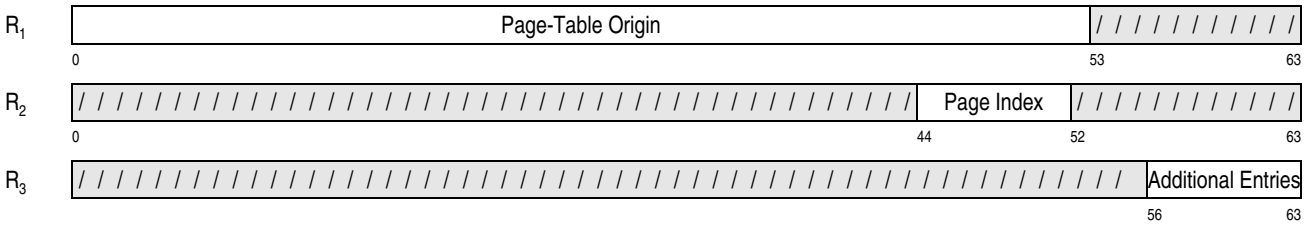


Figure 10-17. Register Contents for INVALIDATE PAGE TABLE ENTRY

When the IPTE-range facility is not installed, the R_3 field is ignored but should contain zeros; otherwise, the program may not operate compatibly in the future.

The M_4 field has the following format:

The bits of the M_4 field are defined as follows:

- ***Reserved:*** Bits 0-2 are reserved. Reserved bit positions of the M_4 field are ignored but should contain zeros; otherwise, the program may not operate compatibly in the future.
- ***Local-Clearing Control (LC):*** When the local-TLB-clearing facility is installed, the LC bit, bit 3 of the M_4 field, controls whether only the TLB in the local CPU is cleared or whether the TLBs in all CPUs of the configuration are cleared. When the local-TLB-clearing facility is not installed, bit 3 of the M_4 field is reserved.

The page-table origin and the page index designate a page-table entry, following the dynamic-address-translation rules for page-table lookup. In the z/Architecture architectural mode, the page-table origin is treated as a 64-bit address, and the addition is performed by using the rules for 64-bit address arithmetic, regardless of the current addressing mode, which is specified by bits 31 and 32 of the current PSW. A carry out of bit position 0 as a result of the addition of

the page index and page-table origin cannot occur. In the ESA/390-compatibility mode, it is unpredictable whether the page-table origin and page index are treated as in the z/Architecture architectural mode, or the page-table origin is treated as a 31-bit address and the page-table index is multiplied by four (as in the ESA/390 architectural mode). The address formed from these two components is a real or absolute address.

The page-invalid bit of this page-table entry is set to one. During this procedure, the page-table entry is not inspected for whether the page-invalid bit is already one or for format errors. Additionally, the page-frame real address contained in the entry is not checked for an addressing exception. In the z/Architecture architectural mode, the page-invalid bit is bit 53 of the doubleword PTE. In the ESA/390-compatibility mode, it is unpredictable whether the page invalid bit is bit 53 of the doubleword PTE or bit 21 of the word PTE.

When the IPTE-range facility is installed and the R_3 field is nonzero, the instruction is interruptible, and processing is as follows:

1. The invalidation process described above is repeated for each subsequent entry in the page table until either the number of additional entries specified in bits 56-63 of general register R_3 have been invalidated or an interruption occurs.

2. The page-index in bits 44-51 of general register R_2 is incremented by the number of page-table entries that were invalidated; a carry out of bit position 44 of general register R_2 is ignored.

3. The additional-entry count in bits 56-63 of general register R_3 is decremented by the number of page-table entries that were invalidated.

Therefore, whenthe IPTE-range facility is installed, the R_3 field is nonzero, and an interruption occurs (other than one that causes termination), general registers R_2 and R_3 have been updated, so that the instruction, when reexecuted, resumes at the point of interruption.

When the IPTE-range facility is not installed, or when the R_3 field is zero, the contents of registers R_2, and R_3 remain unchanged.

For each page-table entry that is invalidated, the entire page-table entry appears to be fetched concurrently from storage as observed by other CPUs. Subsequently, the byte containing the page-invalid bit is stored. The fetch access to each page-table entry is subject to key-controlled protection, and the store access is subject to key-controlled protection and low-address protection.

A serialization function is performed before the operation begins and again after the operation is completed. As is the case for all serialization operations, this serialization applies only to this CPU; other CPUs are not necessarily serialized.

If no exceptions are recognized, this CPU clears selected entries from its TLB. Then if the local-TLB-clearing facility is not installed, or if the facility is installed and LC bit in the M_4 field is zero, this CPU signals all CPUs in the configuration to clear selected entries from their TLBs. For each page-table entry invalidated, each affected TLB is cleared of at least those entries that have been formed using all of the following:

- The page-table origin specified by general register R_1
- The page index specified by general register R_2
- The page-frame real address contained in the designated page-table entry

When the local-TLB-clearing facility is installed in the z/Architecture architectural mode, it is unpredictable whether the facility is installed in the ESA/390-compatibility mode.

The execution of INVALIDATE PAGE TABLE ENTRY is not completed on the CPU which executes it until the following occur:

1. All page-table entries corresponding to the specified parameters have been invalidated.

2. All entries corresponding to the specified parameters have been cleared from the TLB of this CPU. When the local-TLB-clearing facility is installed and the LC bit in the M_4 field is one, the execution of INVALIDATE PAGE TABLE entry is complete at this point and the following step is not performed.

3. When the local-TLB-clearing facility is not installed, or when the facility is installed and LC bit in the M_4 field is zero, all other CPUs in the configuration have completed any storage

accesses, including the updating of the change and reference bits, by using TLB entries corresponding to the specified parameters.

Before the TLB purging operation, transactional execution by other CPUs in the configuration is aborted with abort code 255, condition code 2. The aborting of transactional execution affects at least those CPUs accessing the locations (transactionally or nontransactionally) for which TLB entries are being cleared. It is unpredictable whether some or all other CPUs are affected as well.

Special Conditions

When the IPTE-range facility is installed, the R_3 field is nonzero, and the page index in general register R_2 plus the additional-entry count in general register R_3 is greater than 255, a specification exception is recognized.

The unit of operation is suppressed on all addressing and protection exceptions.

Condition Code: The code remains unchanged.

Program Exceptions:

- Addressing (page-table entry)
- Privileged operation
- Protection (fetch and store, page-table entry, key-controlled protection, and low-address protection)
- Secure-storage-access (page-table entry)
- Specification
- Transaction constraint

Programming Notes:

1. The selective clearing of entries may be implemented in different ways, depending on the model, and, in general, more entries may be cleared than the minimum number required. Some models may clear all entries which contain the page-frame real addresses obtained from the page-table entries in storage. Others may clear all entries which contain the designated page index (or indices), and some implementations may clear precisely the minimum number of entries required. Therefore, in order for a program to operate on all models, the program should not take advantage of any properties obtained by a less selective clearing on a particular model.

2. The clearing of TLB entries may make use of the page-frame real addresses in the page-table entries. Therefore, if the page-table entries, when in the attached state, ever contained page-frame real addresses that are different from the current values, copies of entries containing the previous values may remain in the TLB.

3. INVALIDATE PAGE TABLE ENTRY cannot be safely used to update a shared location in main storage if the possibility exists that another CPU or a channel program may also be updating the location.

4. When the IPTE-range facility is installed and the R_3 field is nonzero, the following applies:

   a. All of the page-table entries to be invalidated must reside in the same page table. A specification exception is recognized if the page index in general register R_1 plus the additional-entry count in general register R_3 is greater than the maximum page index of 255.

   b. The number of page-table entries that are invalidated by INVALIDATE PAGE TABLE ENTRY may vary from one execution to another.

   c. The instruction cannot be used for situations where the program must rely on uninterrupted execution of the instruction. Similarly, the program should normally not use INVALIDATE PAGE TABLE ENTRY to invalidate a page-table entry, the page-frame-real address of which designates the 4 K-byte block containing the instruction or of an execute-type instruction that executes the IPTE.

   d. Further programming notes concerning interruptible instructions are included in “Interruptible Instructions” on page 5-24.

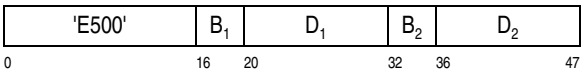
5. When the local-TLB-clearing facility is installed, the local-clearing control should be specified as one when the ASCE used to form the TLB entries being cleared has been attached only to the CPU on which the IPTE instruction is executed (for example, if the program is running on a uniprocessor). Otherwise, unpredictable results, including the presentation of a delayed-access-exception machine check, may occur.

On some models, use of INVALIDATE PAGE TABLE ENTRY specifying clearing of only the local TLB for the cases listed above may result in significant performance improvements.

6. The R_3 and M_4 fields of the instruction are considered to be optional, as indicated by the fields being contained within brackets [ ] in the assembler syntax. When either field is not specified, the assembler places zeros in the corresponding field of the instruction. When the M_4 field is coded but the R_3 field is not required, a zero should be coded to designate the place of the third operand.

LOAD ADDRESS SPACE PARAMETERS

LASP $D_1(B_1),D_2(B_2)$ [SSE]



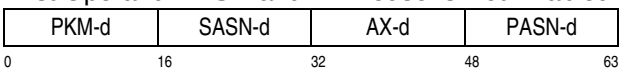
The first operand contains values to be loaded into control registers 3 and 4, including a secondary ASN (SASN) and a primary ASN (PASN), and, possibly, a secondary ASTE instance number (SASTEIN) and a primary ASTE instance number (PASTEIN). Execution of the instruction consists in performing four major steps: PASN translation, SASN translation, SASN authorization, and control-register loading. Each of these steps may or may not be performed, depending on the outcome of certain tests and on the setting of bits 61-63 of the second-operand address. The first three of these steps, when performed and successful, obtain additional values, that are loaded into control registers 1, 5, and 7. When the first three steps are not successful when performed, no control registers are changed, and the reason is indicated in the condition code.

When the ASN-and-LX-reuse facility is not installed, or is installed but is not enabled by a one value of the ASN-and-LX-reuse control, bit 44 of control register 0, the first operand is a doubleword containing a PSW-key mask (PKM), a SASN, an authorization index (AX), and a PASN. When the ASN-and-LX-reuse facility is installed and enabled, the first operand is two consecutive doublewords containing those four values and also a SASTEIN and a PASTEIN.

The primary ASN may be translated by means of the ASN-translation tables to obtain a primary-ASTE (PASTE) origin (PASTEO) and, from the PASTE, a primary ASCE (PASCE). The secondary ASN may be translated by means of the ASN-translation tables to obtain a secondary ASCE (SASCE). If the first operand is two doublewords and PASN or SASN translation occurs, the ASTEIN in the located ASTE is checked for being equal to the PASTEIN or SASTEIN, respectively, in the first operand. An authority check for ensuring that the new AX is authorized to establish the new SASN can be prevented when SASN translation occurs, or it can be required and cause SASN translation even when SASN translation would not otherwise occur. The new AX, which is placed in a control register and is used in SASN authorization if that occurs, is the old AX if PASN translation has not occurred or is the AX in the located PASTE otherwise. However, in either of these cases, the new AX may be the AX specified in the first operand.

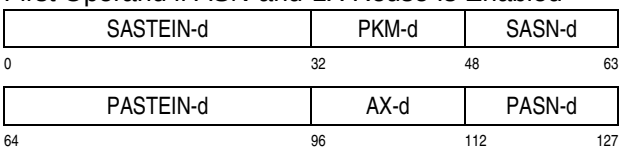
A doubleword first operand has the following format:

First Operand if ASN-and-LX Reuse Is Not Enabled



A two-doubleword first operand has the following format:

First Operand if ASN-and-LX Reuse Is Enabled



The “d” stands for designated value and is used to distinguish these fields from other fields with similar names which are referred to in the definition. The current contents of the corresponding fields in the control registers are referred to as SASTEIN-old, PKM-old, SASN-old, etc. The updated contents of the control registers are referred to as SASTEIN-new, PKM-new, SASN-new, etc.

The second-operand address is not used to address data; instead, the rightmost three bits are used to control portions of the operation. The remainder of

the second-operand address is ignored. Bits 61-63 of the second-operand address are used as follows:

Bit	Function Specified in Second-Operand Address	
	When Bit Is Zero	**When Bit Is One**
61	ASN translation performed only when new ASN and old ASN are different.	ASN translation performed.*
62	AX associated with new PASN used.	AX in first operand used.
63	SASN authorization performed.*	SASN authorization not performed.

Explanation:

* SASN translation and SASN authorization are performed only when SASN-d is not equal to PASN-d. When SASN-d is equal to PASN-d, the SASCE is set equal to the PASCE, the SASTEIN is set equal to the PASTEIN (if ASN-and-LX reuse is enabled), and no authorization is performed.

The operation of LOAD ADDRESS SPACE PARAMETERS is depicted in Figure 10-21 on page 10-50.

Note: In the following sections, the actions involving the PASTEIN and SASTEIN occur only if the ASN-and-LX-reuse facility is installed and is enabled by the ASN-and-LX-reuse control in control register 0.

PASN Translation and Related Processing

In the PASN-translation process, the PASN-d is translated by means of the ASN first table and the ASN second table. The PASTEO resulting from PASN translation replaces the PASTEO in control register 5. The ASCE in the located ASTE replaces the PASCE in control register 1. When bit 62 of the second-operand address is zero, the AX in the ASTE replaces the AX in control register 4. When bit 62 is one, AX-d replaces the AX in the control register. When ASN-and-LX reuse is enabled, PASTEIN-d is compared to the ASTEIN in the ASTE, and, when equal, replaces the PASTEIN in control register 4.

When bit 61 of the second-operand address is one, PASN translation is always performed. When bit 61 is zero, PASN translation is performed only if PASN-d is not equal to PASN-old. When bit 61 is zero and PASN-d is equal to PASN-old, the PASCE-old, PASTEO-old, and PASTEIN-old are left unchanged in the control registers and become the PASCE-new, PASTEO-new, and PASTEIN-new, respectively. In this case, if bit 62 is zero, then the AX-old is left unchanged in the control register and becomes the AX-new, or, if bit 62 is one, AX-new is set equal to AX-d.

The PASN translation follows the normal rules for ASN translation, except that the invalid bits, bit 0 in the ASN-first-table entry and bit 0 in the ASTE, when ones, do not result in an ASN-translation exception. When either of the invalid bits is one, condition code 1 is set. Condition code 1 is also set if PASN translation occurs, the ASN-and-LX-reuse facility is enabled, and PASTEIN-d is not equal to the ASTEIN in the ASTE. When a reason for setting condition code 1 does not exist and either the current primary space-switch-event-control bit in control register 1 is one or the space-switch-event-control bit in the ASTE is one, a space-switch event does not occur; instead, condition code 3 is set. When condition code 1 or 3 is set, the control registers remain unchanged.

The contents of the AX, ASCE, and ASTEIN fields in the ASTE which is accessed as a result of the PASN translation are referred to as AX-p, ASCE-p, and ASTEIN-p, respectively. The origin of the ASTE is referred to as PASTEO-p.

The description in this paragraph applies to use of the subspace-group facility. After ASCE-p has been obtained, if (1) the subspace-group-control bit, bit 54 in ASCE-p, is one, (2) the dispatchable unit is subspace active, and (3) PASTEO-p designates the ASTE for the base space of the dispatchable unit, then a copy of ASCE-p, called ASCE-rp, is made, and bits 0-55 and 58-63 of ASCE-rp are replaced by the same bits of the ASCE in the ASTE for the subspace in which the dispatchable unit last had control. Further details are in “Subspace-Replacement Operations” on page 5-71. If bit 0 in the subspace ASTE is one, or if the ASTE sequence number (ASTESN) in the subspace ASTE does not equal the subspace ASTESN in the dispatchable-unit control table, an exception is not recognized; instead, condition code 1 is set, and the control registers remain unchanged.

SASN Translation and Related Processing

In the SASN-translation process, the SASN-d is translated by means of the ASN first table and the ASN second table. The ASCE field obtained from the ASTE subsequently replaces the secondary ASCE (SASCE) in control register 7. When ASN-and-LX reuse is enabled, SASTEIN-d is compared to the

ASTEIN in the ASTE, and, when equal, replaces the SASTEIN in control register 3.

SASN translation is performed only when, but not necessarily when, SASN-d is not equal to PASN-d. When SASN-d is equal to PASN-d, SASCE-new and SASTEIN-new are set equal to PASCE-new and PASTEIN-new, respectively. In this case, there is not a test of whether SASTEIN-d is equal to PASTEIN-d; SASTEIN-d is ignored. When SASN-d is not equal to PASN-d and is equal to SASN-old, bit 61 (force ASN translation) is zero, and bit 63 (skip SASN authorization) is one, SASN translation is not performed, and SASCE-old and SASTEIN-old become SASCE-new and SASTEIN-new, respectively. In this case, there is not a test of whether SASTEIN-d is equal to SASTEIN-old; SASTEIN-d is ignored.

SASN translation is performed in each of the following cases:

- SASN-d is not equal to PASN-d or SASN-old.
- SASN-d is not equal to PASN-d but is equal to SASN-old, and either bit 61 (force ASN translation) of the second-operand address is one or bit 63 (skip secondary authority test) of that address is zero. (The translation must be performed when bit 63 is zero in order to obtain the ATO and ATL from the SASTE.)

The SASN translation follows the normal rules for ASN translation, except that the invalid bits, bit 0 in the ASN-first-table entry and bit 0 in the ASTE, when ones, do not result in an ASN-translation exception. When either of the invalid bits is one, condition code 2 is set. Condition code 2 is also set if SASN translation occurs, the ASN-and-LX-reuse facility is enabled, and SASTEIN-d is not equal to the ASTEIN in the ASTE. When condition code 2 is set, the control registers remain unchanged.

The contents of the ASCE, ATO, ATL and ASTEIN fields in the ASTE which is accessed as a result of the SASN translation are referred to as ASCE-s, ATO-s, ATL-s, and ASTEIN-s, respectively. The origin of the ASTE is referred to as SASTEO-s.

The description in this paragraph applies to use of the subspace-group facility. After ASCE-s has been obtained, if (1) the subspace-group-control bit, bit 54 in ASCE-s, is one, (2) the dispatchable unit is subspace active, and (3) SASTEO-s designates the ASTE for the base space of the dispatchable unit, then a copy of ASCE-s, called ASCE-rs, is made, and bits 0-55 and 58-63 of ASCE-rs are replaced by the same bits of the ASCE in the ASTE for the subspace in which the dispatchable unit last had control. Further details are in “Subspace-Replacement Operations” on page 5-71. If bit 0 in the subspace ASTE is one, or if the ASTE sequence number (ASTESN) in the subspace ASTE does not equal the subspace ASTESN in the dispatchable-unit control table, an exception is not recognized; instead, condition code 2 is set, and the control registers remain unchanged.

SASN Authorization

SASN authorization is performed when bit 63 of the second-operand address is zero and SASN-d is not equal to PASN-d; it is performed in this case regardless of whether SASN-d is equal to SASN-old. When SASN-d is equal to PASN-d or when bit 63 of the second-operand address is one, SASN authorization is not performed.

SASN authorization is performed by using ATO-s, ATL-s, and the intended value for AX-new. When bit 62 of the second-operand address is zero and PASN translation was performed, the intended value for AX-new is AX-p. When bit 62 of that address is zero and PASN translation was not performed, the AX is not changed, and AX-new is the same as AX-old. When bit 62 of that address is one, the intended value for AX-new is AX-d. SASN authorization follows the rules for secondary authorization as described in “ASN-Authorization Process” on page 3-37. If the SASN is not authorized (that is, the authority-table length is exceeded, or the selected bit is zero), condition code 2 is set, and none of the control registers is updated.

Control-Register Loading

When the PASN-translation and SASN-translation functions and related functions, and the SASN-authorization functions and subspace-replacement operations, if called for in the instruction execution, are performed without encountering any exceptions or exception conditions, the execution is completed by replacing the contents of control registers 1, 3, 4, 5, and 7 with the new values, and condition code 0 is set. The control registers are loaded as follows.

The PSW-key-mask, bits 32-47, and SASN, bits 48-63, in control register 3 are replaced by the contents of the PKM-d and SASN-d fields of the first operand.

If ASN-and-LX reuse is enabled, the SASTEIN, bits 0-31, in control register 3 is replaced as follows:

- When SASN translation is performed, by SASTEIN-d.
- When SASN translation is not performed because SASN-d is equal to PASN-d, by PASTEIN-new.
- When SASN translation is not performed because (1) SASN-d is not equal to PASN-d but is equal to SASN-old, (2) bit 61 (force ASN translation) of the second-operand address is zero, and (3) bit 63 (skip secondary authority test) of the second-operand address is one, the SASTEIN remains unchanged.

When ASN-and-LX reuse is not enabled, bits 0-31 of control register 3 always remain unchanged.

The PASN, bits 48-63 of control register 4, is replaced by the PASN-d of the first operand. If ASN-and-LX reuse is enabled, the PASTEIN, bits 0-31 of control register 4, is replaced by the PASTEIN-d of the first operand; otherwise, bits 0-31 of the register remain unchanged.

The authorization index, bits 32-47 of control register 4, is replaced as follows:

- When bit 62 of the second-operand address is one, by AX-d.
- When bit 62 of the second-operand address is zero and PASN translation is performed, by AX-p.
- When bit 62 of the second-operand address is zero and PASN translation is not performed, the authorization index remains unchanged.

The primary address-space-control element (PASCE) in control register 1 and the primary-ASN-second-table-entry origin (PASTEO) in control register 5 are replaced as follows:

- When PASN translation is performed, the PASCE in control register 1 is replaced by the ASCE-p obtained as a result of PASN translation, except that it is replaced by ASCE-rp if a subspace-replacement operation was performed on ASCE-p. Also, the PASTEO in control register 5 is replaced by PASTEO-p. The PASTEO-p is placed in bit positions 33-57 of control register 5, and zeros are placed in bit positions 32 and 58-63. Bits 0-31 of the register remain unchanged.
- When PASN translation is not performed, the contents of control registers 1 and 5 remain unchanged.

The secondary address-space-control element (SASCE) in control register 7 is replaced as follows:

- When SASN-d equals PASN-d, by the new contents of control register 1, the PASCE. The new contents may be PASCE-old, ASCE-p, or ASCE-rp.
- When SASN translation is performed, by ASCE-s, or by ASCE-rs if a subspace-replacement operation was performed on ASCE-s.

When SASN-d does not equal PASN-d and SASN translation is not performed, the SASCE remains unchanged.

Other Condition-Code Settings

When PASN translation is called for and cannot be completed because bit 0 is one in either the ASN-first-table entry or the ASTE, or if it can be completed but (1) ASN-and-LX reuse is enabled and PASTEIN-d does not equal the ASTEIN in the ASTE or (2) a subspace-replacement-exception condition exists due to bit 0 or the ASTE sequence number in the subspace ASTE during a subspace-replacement operation on the ASCE-p, condition code 1 is set, and the control registers are not changed.

When PASN translation is called for and completed and any required PASTEIN-d comparison and subspace-replacement operations on the ASCE-p are also completed, and then either (1) the current primary space-switch-event-control bit, bit 57 of control register 1, is one or (2) the space-switch-event-control bit in the ASTE designated by PASTEO-p is one, condition code 3 is set, and the control registers are not changed.

When SASN translation is called for and the translation cannot be completed because bit 0 is one in either the ASN-first-table entry or the ASTE, or if it can be completed but (1) ASN-and-LX reuse is enabled and SASTEIN-d does not equal the ASTEIN in the ASTE, (2) a subspace-replacement-exception

condition exists due to bit 0 or the ASTE sequence number in the subspace ASTE during a subspace-replacement operation on the ASCE-s, or (3) SASN authorization is called for and the SASN is not authorized, or condition code 2 is set, and the control registers are not changed.

Special Conditions

The instruction can be executed only when the ASN-translation control, bit 44 of control register 14, is one. If the ASN-translation-control bit is zero, a special-operation exception is recognized.

The first operand must be designated on a doubleword boundary; otherwise, a specification exception is recognized.

In the ESA/390-compatibility mode, one of the following exceptions is recognized: (a) an operation exception, (b) a privileged-operation exception when the CPU is in the problem state, (c) a special-operation exception when bit 44 of control register 14 is zero, or (d) a specification exception when the first operand is not on a doubleword boundary. It is unpredictable which exception is recognized.

The operation is suppressed on all addressing and protection exceptions.

Figure 10-20 on page 10-49 and Figure 10-18 on page 10-46 summarize the functions of the instruction.

Resulting Condition Code:

0 Translation and authorization complete; parameters loaded
1 Primary ASN or subspace not available; parameters not loaded
2 Secondary ASN not available or not authorized, or secondary subspace not available; parameters not loaded
3 Space-switch event specified; parameters not loaded

Program Exceptions:

- Access (fetch, operand 1)
- Addressing (ASN-first-table entry, ASN-second-table entry, authority-table entry, dispatchable-unit control table)
- Operation (in the ESA/390-compatibility mode)
- Privileged operation
- Secure-storage-access (ASN-first-table entry, ASN-second-table entry, authority-table entry, dispatchable-unit control table)
- Special operation
- Specification
- Transaction constraint

The priority of recognition of program exceptions for the instruction is shown in Figure 10-18.

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second and third instruction halfwords.
7.B.1	Privileged-operation exception.
7.B.2	Special-operation exception due to the ASN-translation control, bit 44 of control register 14, being zero.
7.C	Transaction constraint.
7.D	Operation exception (in the ESA/390-compatibility mode)
8.	Specification exception.
9.	Access exceptions for the first operand.
10.	PASN translation and related processing (when performed).
10.1	Addressing exception or secure-storage-access exception for access to ASN-first-table entry.
10.2	Condition code 1 due to I bit (bit 0) in ASN-first-table entry being one.
10.3	Addressing exception or secure-storage-access exception for access to ASN-second-table entry.
10.4	Condition code 1 due to (1) I bit (bit 0) in ASN-second-table entry (ASTE) being one or (2) ASN-and-LX reuse enabled and primary ASTE instance number (PASTEIN) in first operand not being equal to ASTEIN in ASTE.

Figure 10-18. Priority of Execution: LOAD ADDRESS SPACE PARAMETERS (Part 1 of 3)

10.5	Addressing exception or secure-storage-access exception for access to dispatchable-unit control table.
10.6	Addressing exception or secure-storage-access exception for access to subspace ASN-second-table entry.
10.7	Condition code 1 due to I bit (bit 0) in subspace ASN-second-table entry being one.
10.8	Condition code 1 due to subspace ASN-second-table-entry sequence number (SSASTESN) in dispatchable-unit control table not being equal to ASTESN in subspace ASN-second-table entry.
10.9	Condition code 3 due to either the old or new space-switch-event-control bit being one.
11.	SASN translation and related processing (when performed).
11.1	Addressing exception or secure-storage-access exception for access to ASN-first-table entry.
11.2	Condition code 2 due to I bit (bit 0) in ASN-first-table entry being one.
11.3	Addressing exception or secure-storage-access exception for access to ASN-second-table entry.
11.4	Condition code 2 due to (1) I bit (bit 0) in ASN-second-table entry (ASTE) being one or (2) ASN-and-LX reuse enabled and secondary ASTE instance number (SASTEIN) in first operand not being equal to ASTEIN in ASTE.
12.A	Execution of secondary authorization (when performed).
12.A.1	Condition code 2 due to authority-table entry being outside table.
12.A.2	Addressing exception or secure-storage-access exception for access to authority-table entry.
12.A.3	Condition code 2 due to S bit in authority-table entry being zero.
12.B.1	Addressing exception or secure-storage-access exception for access to dispatchable-unit control table.
12.B.2	Addressing exception or secure-storage-access exception for access to subspace ASN-second-table entry.
12.B.3	Condition code 2 due to I bit (bit 0) in subspace ASN-second-table entry being one.

Figure 10-18. Priority of Execution: LOAD ADDRESS SPACE PARAMETERS (Part 2 of 3)

12.B.4	Condition code 2 due to subspace ASN-second-table-entry sequence number (SSASTESN) in dispatchable-unit control table not being equal to ASTESN in subspace ASN-second-table entry.

Figure 10-18. Priority of Execution: LOAD ADDRESS SPACE PARAMETERS (Part 3 of 3)

Programming Notes:

1. Bits 61 and 63 in the second-operand address are intended primarily to provide improved performance for those cases where the associated action is unnecessary.

   When bit 61 is set to zero, the action of the instruction is based on the assumption that the current values for PASCE-old, PASTEO-old, and AX-old are consistent with PASN-old and that SASCE-old is consistent with SASN-old. When this is not the case, bit 61 should be set to one.

   Bit 63, when one, eliminates the SASN-authorization test. The program may be able to determine in certain cases that the SASN is authorized, either because of prior use or because the AX being loaded is authorized to access all address spaces.

2. The SASN-translation and SASN-authorization steps are not performed when SASN-d is equal to PASN-d. This is consistent with the action in SET SECONDARY ASN to current primary (SSAR-cp), which does not perform the translation or ASN authorization.

3. The storage-operand references for LOAD ADDRESS SPACE PARAMETERS may be multiple-access references. (See “Storage-Operand Consistency” on page 5-133.)

4. See Figure 10-19 on page 10-47 for a listing of abbreviations used in this instruction description.

First-Operand Bit Positions when ASN-and-LX Reuse Not Enabled	Abbreviation
0-15	PKM-d
16-31	SASN-d
32-47	AX-d
48-63	PASN-d

Figure 10-19. Summary of Abbreviations for LOAD ADDRESS SPACE PARAMETERS (Part 1 of 2)

First-Operand Bit Positions when ASN-and-LX Reuse Enabled	Abbreviation
0-31	SASTEIN-d
32-47	PKM-d
48-63	SASN-d
64-95	PASTEIN-d
96-111	AX-d
112-127	PASN-d

Control-Register Number.Bit	Abbreviation for	
	Previous Contents	Subsequent Contents
1.0-63	PASCE-old	PASCE-new
3.0-31	SASTEIN-old	SASTEIN-new
3.32-47	PKM-old	PKM-new
3.48-63	SASN-old	SASN-new
4.0-31	PASTEIN-old	PASTEIN-new
4.32-47	AX-old	AX-new
4.48-63	PASN-old	PASN-new
5.33-57	PASTEO-old	PASTEO-new
7.0-63	SASCE-old	SASCE-new

Field in ASN-Second-Table Entry	Abbreviation Used for the Field When Accessed as Part of	
	PASN Translation	SASN Translation
1-29	-	ATO-s
32-47	AX-p	-
48-59	-	ATL-s
64-127	ASCE-p[1]	ASCE-s[1]
352-383	ASTEIN-p	ASTEIN-s

Explanation:

- The field is not used in this case.

[1] ASCE-rp is formed from ASCE-p, and ASCE-rs is formed from ASCE-s, by a subspace-replacement operation.

Figure 10-19. Summary of Abbreviations for LOAD ADDRESS SPACE PARAMETERS (Part 2 of 2)

PASN-d Equals PASN-old	Second-Operand-Address Bits[1]		PASN Translation Performed	Result Field						
	61	62		PASCE-new	AX-new	PASTEO-new	PKM-new	SASN-new	PASN-new	PASTEIN-new
Yes	0	0	No	PASCE-old	AX-old	PASTEO-old	PKM-d	SASN-d	PASN-d	PASTEIN-old
Yes	0	1	No	PASCE-old	AX-d	PASTEO-old	PKM-d	SASN-d	PASN-d	PASTEIN-old
Yes	1	0	Yes	ASCE-p[2]	AX-p	PASTEO-p	PKM-d	SASN-d	PASN-d	PASTEIN-d
Yes	1	1	Yes	ASCE-p[2]	AX-d	PASTEO-p	PKM-d	SASN-d	PASN-d	PASTEIN-d
No	-	0	Yes	ASCE-p[2]	AX-p	PASTEO-p	PKM-d	SASN-d	PASN-d	PASTEIN-d
No	-	1	Yes	ASCE-p[2]	AX-d	PASTEO-p	PKM-d	SASN-d	PASN-d	PASTEIN-d

Figure 10-20. Summary of Actions: LOAD ADDRESS SPACE PARAMETERS (Part 1 of 2).

SASN-d Equals PASN-d	SASN-d Equals SASN-old	Second-Operand-Address Bits[1]		SASN Translation Performed	SASN Authorization Performed[3]	Result Field	
		61	63			SASCE-new	SASTEIN-new
Yes	-	-	-	No	No	PASCE-new	PASTEIN-new
No	Yes	0	1	No	No	SASCE-old	SASTEIN-old
No	Yes	1	1	Yes	No	ASCE-s[4]	SASTEIN-d
No	Yes	-	0	Yes	Yes	ASCE-s[4]	SASTEIN-d
No	No	-	1	Yes	No	ASCE-s[4]	SASTEIN-d
No	No	-	0	Yes	Yes	ASCE-s[4]	SASTEIN-d

Explanation:

- Action in this case is the same regardless of the outcome of this comparison or of the setting of this bit.

[1] Second-operand-address bits:
- 61: Force ASN translation.
- 62: Use AX from first operand.
- 63: Skip secondary authority test.

[2] PASCE-new is ASCE-rp (a copy of ASCE-p except with bits 0-55 and 58-63 replaced from the ASCE in the subspace ASTE), if subspace replacement is performed.

[3] SASN authorization is performed using ATO-s, ATL-s, and AX-new.

[4] SASCE-new is ASCE-rs (a copy of ASCE-s except with bits 0-55 and 58-63 replaced from the ASCE in the subspace ASTE), if subspace replacement is performed.

Figure 10-20. Summary of Actions: LOAD ADDRESS SPACE PARAMETERS (Part 2 of 2).

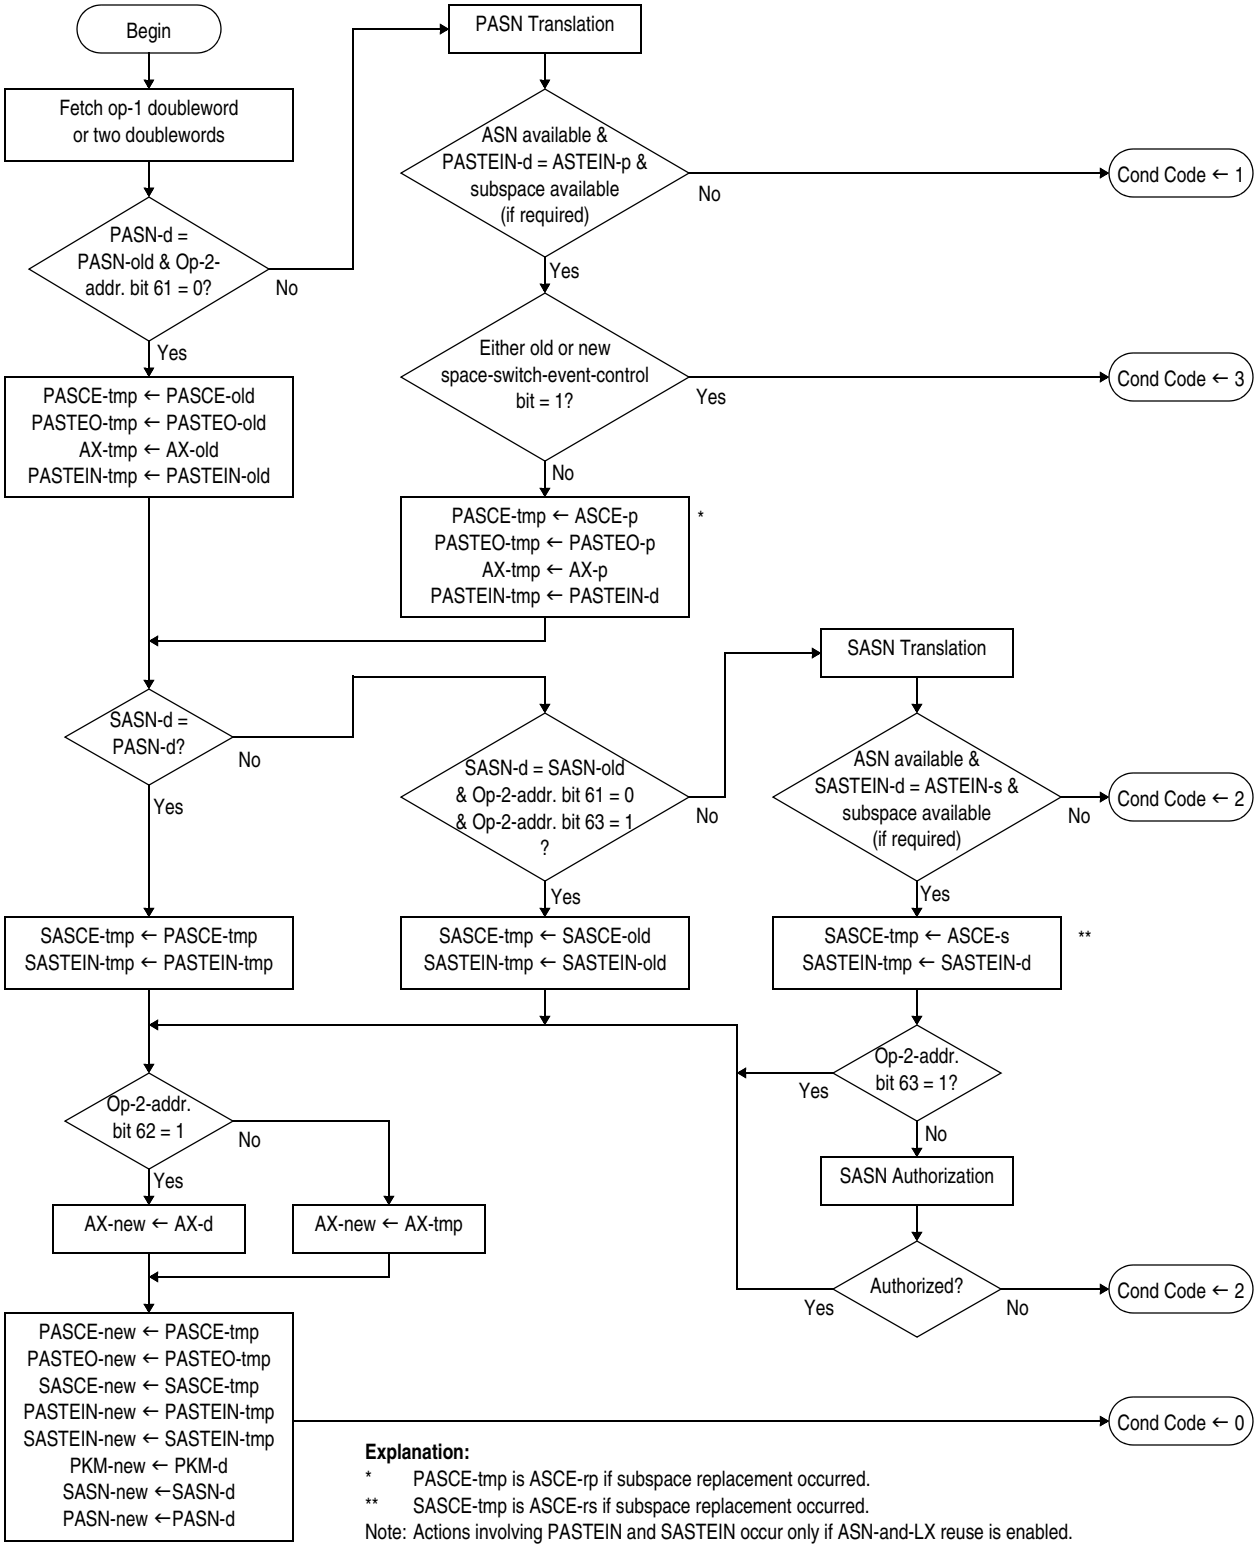


Figure 10-21. Execution of LOAD ADDRESS SPACE PARAMETERS

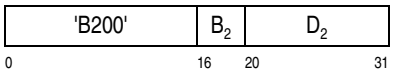
LOAD BEAR

LBEAR $D_2(B_2)$ [S]



The current value of the breaking-event-address register (BEAR) is replaced by the contents of the doubleword designated by the second-operand address.

Special Conditions

The second operand must be designated on a doubleword boundary; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Operation (if the BEAR-enhancement facility is not installed)
- Privileged operation
- Specification
- Transaction constraint

Programming Notes:

1. The reset value of 0000000000000001 hex may be loaded into the breaking-event-address register. This may occur when the control program initiates a dispatchable unit.

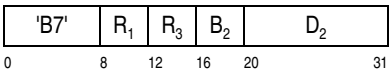
2. It is intended for a control program to use LOAD BEAR within interruption-handling routines in the following manner:

   a. At the beginning of the interruption-handling routine, before a breaking event can occur, STORE BEAR is issued to preserve the contents of the breaking-event-address register (BEAR) associated with the interrupted program.

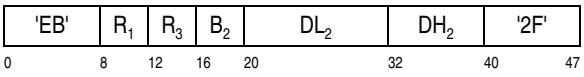
   b. At the end of the interruption-handling routine, LOAD BEAR is issued to restore the preserved value to the breaking-event-address register (BEAR), followed by no breaking events and issuing LOAD PSW EXTENDED (LPSWEY) to return control to the interrupted program without causing a breaking event to occur.

LOAD CONTROL

LCTL $R_1,R_3,D_2(B_2)$ [RS-a]



LCTLG $R_1,R_3,D_2(B_2)$ [RSY-a]



Bit positions of the set of control registers starting with control register R_1 and ending with control register R_3 are loaded from storage beginning at the location designated by the second-operand address and continuing through as many locations as needed.

For LOAD CONTROL (LCTL), bit positions 32-63 of the control registers are loaded from successive words beginning at the second-operand address, and bits 0-31 of the registers remain unchanged. For LOAD CONTROL (LCTLG), bit positions 0-63 of the control registers are loaded from successive doublewords beginning at the second-operand address. The control registers are loaded in ascending order of their register numbers, starting with control register R_1 and continuing up to and including control register R_3, with control register 0 following control register 15.

The information loaded into the control registers becomes active when instruction execution has ended.

The displacement for LCTL is treated as a 12-bit unsigned binary integer. The displacement for LCTLG is treated as a 20-bit signed binary integer.

Special Conditions

The second operand must be designated on a word boundary for LCTL or on a doubleword boundary for LCTLG; otherwise, a specification exception is recognized.

Attempted execution of LCTLG in the ESA/390-compatibility mode results in an operation exception being recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Operation (LCTLG, in the ESA/390-compatibility mode)
- Privileged operation
- Specification
- Transaction constraint

Programming Notes:

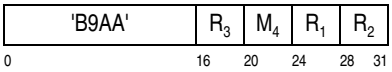
1. To ensure that existing programs operate correctly if and when new facilities using additional control-register positions are defined, only zeros should be loaded in unassigned control-register positions.

2. Loading of control registers on some models may require a significant amount of time. This is particularly true for changes in significant parameters.

   For example, the TLB may be cleared of entries as a result of changing or enabling the program-event-recording parameters in control registers 9-11. Where possible, the program should avoid unnecessary loading of control registers. In loading control registers 9-11, most models attempt to optimize for the case when the bits of control register 9 are zeros.

LOAD PAGE TABLE ENTRY ADDRESS

LPTEA R_1,R_3,R_2,M_4 [RRF-b]



General register R_2 contains a virtual address that is processed by means of dynamic address translation to locate a page-table entry, the 64-bit real or absolute address of which is returned in general register R_1. The M_4 field contains a value designating the effective address-space-control element (ASCE) that is used by DAT, as shown in the following table:

M_4 Field (binary)	Effective Address-Space-Control Element Used by DAT
0000	Contents of control register 1
0001	The address-space-control element obtained by applying the access-register-translation (ART) process to the access register designated by the R_2 field.
0010	Contents of control register 7
0011	Contents of control register 13
0100	The address-space-control element corresponding to the current address-space-control bits, bits 16 and 17 of the PSW.

When the M_4 field contains 0001 binary, or when the M_4 field contains 0100 binary and bits 16-17 of the PSW contain 01 binary, then access-register translation precedes, as is normal, the dynamic address translation.

The R_3 field is ignored but should be zero to permit possible future extensions.

The virtual address specified by the R_2 field is translated by means of dynamic-address translation, regardless of whether DAT is on or off. ART and DAT may be performed with the use of the ART-lookaside buffer (ALB) and translation-lookaside buffer (TLB), respectively. The DAT process completes upon locating the page-table entry. The contents of the page-table entry are not examined for format errors, the I bit is not examined to determine whether the page is invalid, and the page-frame real address is not fetched.

Virtual address computation is performed according to the addressing mode specified by bits 31 and 32 of the current PSW.

The addresses of the region-table entry or entries, if used, and of the segment-table entry and page-table entry are treated as 64-bit addresses, regardless of the current addressing mode. It is unpredictable whether the addresses of these entries are treated as real or absolute addresses.

If the DAT process successfully locates the page-table entry, the 64-bit real or absolute address of the entry is placed in general register R_1, and the condition code is set as follows:

- When EDAT-1 does not apply, the condition code is set based on the DAT-protection bit (P) of the segment-table entry used in the translation. Con-

dition code 0 is set when the P bit is zero; condition code 1 is set when the P bit is one.

- When EDAT-1 applies, the condition code is set based on all of the DAT-protection bits encountered in the translation. If the DAT-protection bit is zero in the segment-table entry and the DAT-protection bits are zero in any and all region-table entries used in the translation, condition code 0 is set. If the DAT-protection bit is one in any region- or segment-table entry used in the translation, condition code 1 is set.

When EDAT-1 applies and the DAT process successfully locates a valid segment-table entry in which the STE-format control is one, bits 0-60 of the segment-table entry address are placed in bit positions 0-60 of general register R_1, bit 61 of the register is set to the logical OR of the DAT-protection bit in the segment-table entry and any region-table entries used in the translation, bits 62-63 of the register are set to zeros, and the instruction completes by setting condition code 2.

When EDAT-2 applies and the DAT process successfully locates a valid region-third-table entry in which the RTTE-format control is one, bits 0-60 of the region-third-table entry address are placed in bit positions 0-60 of general register R_1, bit 61 of the register is set to the logical OR of the DAT-protection bit in the region-third-table entry and any higher-level region-table entries used in the translation, bits 62-63 of the register are set to zeros, and the instruction completes by setting condition code 2.

When a condition exists that would normally cause one of the exceptions shown in Figure 10-22, processing is as follows:

1. General register R_1 is updated as follows:

   a. Bits 0-60 of the table-entry address are placed in bit positions 0-60 of the register.

   b. When EDAT-1 does not apply, bit 61 of the register is set to zero. When enhanced DAT applies, bit 61 is set to the logical OR of the DAT-protection bits in all valid region-table entries used in the translation; if the DAT process does not require region-table entries, or if no valid region-table entries are encountered, bit 61 is set to zero.

   c. The expected table-type bits are placed in bit positions 62-63 of the register. When the region table or segment table containing the invalid entry is directly designated by the address-space-control element, then the expected table-type bits are those contained in the designation-type control (DT) in the ASCE. Otherwise, the expected table-type bits are one less than the value of those bits in the next-higher-level table.

2. The instruction is completed by setting condition code 2.

Exception Name	Cause	Code (hex)	Expected TT Bits
Region first translation	Invalid bit is one in the region-first-table entry selected by the RFX portion of the virtual address.	0039	11
Region second translation	Invalid bit is one in the region-second-table entry selected by the RSX portion of the virtual address.	003A	10
Region third translation	Invalid bit is one in the region-third-table entry selected by the RTX portion of the virtual address.	003B	01
Segment translation	Invalid bit is one in the segment-table entry selected by the SX portion of the virtual address.	0010	00

Figure 10-22. LPTEA Exception Conditions Causing CC2

When a condition exists that would normally cause one of the exceptions shown in Figure 10-23, (1) the interruption code assigned to the exception is placed in bit positions 48-63 of general register R_1, and bits

0-47 of the register are set to zeros; and (2) the instruction is completed by setting condition code 3.

Exception Name	Cause	Code (hex)
ALET specification	ALET bits 0-6 not all zeros.	0028
ALEN translation	ALE outside list or I bit is one.	0029
ALE sequence	ALESN in ALET not equal to ALESN in ALE.	002A
ASTE validity	ASTE I bit is one.	002B
ASTE sequence	ASTESN in ALE not equal to ASTESN in ASTE.	002C
Extended authority	ALE P bit not zero, ALEAX not equal to EAX, and secondary bit selected by EAX either outside authority table or zero.	002D
ASCE type	ASCE is a region-second-table designation, and bits 0-10 of virtual address not all zeros; ASCE is a region-third-table designation, and bits 0-21 of virtual address not all zeros; or ASCE is a segment-table designation, and bits 0-32 of virtual address not all zeros.	0038
Region first translation	Region-first-table entry selected by RFX portion of virtual address outside table.	0039
Region second translation	Region-second-table entry selected by RSX portion of virtual address outside table.	003A
Region third translation	Region-third-table entry selected by RTX portion of virtual address outside table.	003B
Segment translation	Segment-table entry selected by SX portion of virtual address outside table.	0010

Figure 10-23. LPTEA Exception Conditions Causing CC3

Special Conditions

If the M_4 field contains any value other than 0000-0100 binary, a specification exception is recognized.

The address-space-control element used in the translation must not be a real-space designation; otherwise, a special-operation exception is recognized. The exception due to the address-space-control element has priority 9 in Figure 6-8 on page 6-54.

An addressing exception or secure-storage-access exception is recognized when the address used by ART to fetch the effective access-list designation, the access-list entry, the address-space-second-table entry, or the authority-table entry designates a location which is not available in the configuration or the security marking does not allow for access. An addressing exception or secure-storage-access exception is also recognized when the address used by DAT to fetch a region-table entry or the segment-table entry designates a location which is not available in the configuration or the security marking does not allow for access.

A carry out of bit position 0 as a result of the addition done to compute the address of a region-table entry or the segment-table entry may be ignored or may result in an addressing exception.

A translation-specification exception is recognized if an accessed region-table entry or the segment-table entry has a zero I bit and a format error.

The operation is suppressed on all addressing exceptions.

In the ESA/390-compatibility mode, an operation exception is recognized.

Resulting Condition Code:

0 PTE address returned; P bit is 0 in all DAT-table entries examined
1 PTE address returned; P bit is 1 in any DAT-table entry examined
2 Invalid bit is one in the region- or segment-table entry; EDAT-1 applies, a valid STE was located, and STE FC is 1; or EDAT-2 applies, a valid RTTE was located, and RTTE FC is 1
3 Exception condition exists

Program Exceptions:

- Addressing (effective access-list designation, access-list entry, ASN-second-table entry, authority-table entry, region-table entry, or segment-table entry)
- Operation (DAT-enhancement facility 2 not installed or in the ESA/390-compatibility mode)
- Privileged operation
- Secure-storage-access (effective access-list designation, access-list entry, ASN-second-table entry, authority-table entry, region-table entry, or segment-table entry)

- Special operation
- Specification
- Transaction constraint
- Translation specification

Programming Notes:

1. An addressing exception is not recognized if the page-table-entry address returned in general register R_1 is not available in the configuration.

2. A secure-storage-access exception is not recognized if the page-table-entry address returned in general register R_1 designates a secure page.

3. When EDAT-1 applies, the STE-format control is one, and no other exception conditions apply, the address of the segment-table entry is placed in general register R_1, and condition code 2 is set. This effectively performs a *load-segment-table-entry-address* function, although no such instruction is defined.

   However, because condition code 2 is also used to indicate an invalid region-table entry or segment-table entry, all of the following conditions must exist in order to assume that the located table entry is a valid STE:

   a. Bit positions 62-63 of general register R_1 must contain 00 binary.

   b. Bit position 58 of the table entry designated by bits 0-60 of general register R_1 must contain zero (indicating a valid table entry).

   c. The table-type field in bit positions 60-61 of the table entry designated by bits 0-60 of general register R_1 must contain 00 binary (designating a segment-table entry).

   The following program fragment illustrates this determination when only EDAT-1 applies. If no branch is taken, then the address in general register 1 is that of a segment-table entry in which the STE-format control is one:

```
      LPTEA  1,0,2,4
      BRC    8,PTE_WITH_NEITHER_STE_NOR_RTE_PROT
      BRC    4,PTE_WITH_PROTECTED_STE_OR_RTE
      BRC    1,EXCEPTION_EXISTS
      TMLL   1,X'0003'
      JNZ    EXCEPTION_EXISTS
      NILL   1,X'FFF8'
      LURAG  10,1
      TMLL   10,X'0020'
      JO     EXCEPTION_EXISTS
```

4. When EDAT-2 applies, the RTTE-format control is one, and no other exception conditions apply, the address of the region-third-table entry is placed in general register R_1, and condition code 2 is set. This effectively performs a *load-region-third-table-entry-address* function, although no such instruction is defined.

   However, because condition code 2 is also used to indicate an invalid region-table entry, all of the following conditions must exist in order to assume that the located table entry is a valid RTTE:

   a. Bit positions 62-63 of general register R_1 must contain 00 binary.

   b. Bit position 58 of the table entry designated by bits 0-60 of general register R_1 must contain zero (indicating a valid table entry).

   c. The table-type field in bit positions 60-61 of the table entry designated by bits 0-60 of general register R_1 must contain 01 binary (designating a region-third-table entry).

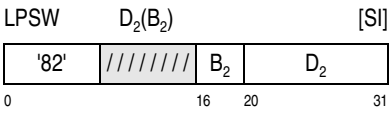
   The following program fragment continues the fragment in programming note 3, illustrating this determination when EDAT-2 applies. If no branch is taken, then the address in general register 1 is that of a region-third-table entry in which the RTTE-format control is one:

```
* Further check for EDAT-2
      TMLL   10,X'000C
      JZ     VALID_F1_STE
* Must be valid F1 RTTE
```

5. When condition code 2 is set as a result of locating a valid segment-table entry in which the STE-format control is one, bit 61 of general register R_1 indicates whether DAT protection applies to the segment. Similarly, when condition code 2 is set as a result of locating a valid region-third-table entry in which the RTTE-format control is one, bit 61 of general register R_1 indicates whether DAT protection applies to the region.

6. When EDAT-1 does not apply, only the STE is examined in determining whether condition code 0 or 1 is set. When EDAT applies, all DAT-table entries used in the translation may be examined in determining whether condition code 0 or 1 is to be set.

LOAD PSW



The current PSW is replaced by a 16-byte PSW formed from the contents of the doubleword at the location designated by the second-operand address. Figure 4-3 on page 4-8 illustrates the contents of the second operand.

Bits 8-15 of the instruction are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.

Bit 12 of the doubleword must be one; otherwise, depending on the model, a specification exception may be recognized and the operation suppressed.

Bits 0-11, 13-32, and 33-63 of the doubleword are placed in bit positions 0-11, 13-32, and 97-127 of the current PSW, respectively. Bits 33-96 of the current PSW are set to zeros.

Bit 12 of the doubleword is inverted and then placed in bit 12 of the current PSW. This applies in the z/Architecture architectural mode and in the ESA/390-compatibility mode.

A serialization and checkpoint-synchronization function is performed before or after the operand is fetched and again after the operation is completed.

Special Conditions

The operand must be designated on a doubleword boundary; otherwise, a specification exception is recognized. A specification exception may be recognized if bit 12 of the operand is zero, depending on the model.

If the storage-key-removal facility is installed, a special-operation exception is recognized if the key value in bits 8-11 of the operand is nonzero.

The other PSW fields which are to be loaded by the instruction are not checked for validity before they are loaded, except for the optional checking of bit 12. However, immediately after loading, a specification exception is recognized, and a program interruption occurs, when any of the following is true for the newly loaded PSW:

- Any of bits 0, 2-4, 12, or 25-30 is a one.
- In the ESA/390-compatibility mode, bit 5 of the PSW is one.
- Bit 24 is one (recognition of this condition is optional)
- Bits 31 and 32 are both zero, and bits 97-103 are not all zeros.
- Bits 31 and 32 are one and zero, respectively.
- In the ESA/390-compatibility mode, bit 31 is one (recognition of this condition is unpredictable).

In these cases, the operation is completed, and the resulting instruction-length code is 0.

The test for a specification exception after the PSW is loaded is described in “Early Exception Recognition” on page 6-9.

The operation is suppressed on all addressing and protection exceptions.

Resulting Condition Code: The code is set as specified in the new PSW loaded.

Program Exceptions:

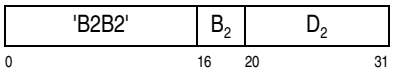
- Access (fetch, operand 2)
- Privileged operation
- Special operation
- Specification
- Transaction constraint

Programming Note: The second operand of LOAD PSW has the short-PSW format (shown in Figure 4-3 on page 4-8), which is similar to that of an ESA/390-mode PSW (that is, bit 12 of the operand must be 1). When bit 12 of the second operand is zero, a specification exception is recognized, either during the execution of the instruction, or when the instruction completes and the new PSW becomes active.

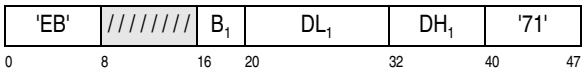
However, unlike the ESA/390-format PSW in which bit 31 must be zero, bit 31 of the short PSW may be either zero or one in the z/Architecture architectural mode. In the ESA/390-compatibility mode, bit 5 must be zero and it is unpredictable whether bit 31 must be zero.

LOAD PSW EXTENDED

LPSWE $D_2(B_2)$ [S]



LPSWEY $D_1(B_1)$ [SIY]



For LOAD PSW EXTENDED (LPSWE), the current PSW is replaced by the contents of the 16-byte second operand. For LOAD PSW EXTENDED (LPSWEY), the current PSW is replaced by the contents of the 16-byte first operand. Figure 4-2 on page 4-5 illustrates the contents of the second operand for LPSWE and the contents of the first operand for LPSWEY.

For LOAD PSW EXTENDED (LPSWEY), bits 8-15 of the instruction are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.

Note: Bit 12 of the storage operand is placed unchanged into bit 12 of the current PSW. This applies in the z/Architecture architecture mode and in the ESA/390-compatibility mode.

A serialization and checkpoint-synchronization function is performed before or after the operand is fetched and again after the operation is completed.

A breaking event occurs as part of completing LOAD PSW EXTENDED (LPSWE) and does not occur as part of completing LOAD PSW EXTENDED (LPSWEY).

Special Conditions

The operand must be designated on a doubleword boundary; otherwise, a specification exception is recognized.

It is unpredictable whether LOAD PSW EXTENDED is supported in the ESA/390-compatibility mode. If the instruction is not supported, attempted execution results in an operation exception being recognized.

If the storage-key-removal facility is installed, a special-operation exception is recognized if the key value in bits 8-11 of the storage operand is nonzero.

The other PSW fields which are to be loaded by the instruction are not checked for validity before they are loaded. However, immediately after loading, a specification exception is recognized, and a program interruption occurs, when any of the following is true for the newly loaded PSW:

- Any of the unassigned bits (0, 2-4, 25-30, or 33-63) is a one.
- In the ESA/390-compatibility mode, bit 5 of the PSW is one.
- Bit 12 is a one.
- Bit 24 is one (recognition of this condition is optional)
- Bits 31 and 32 are zero and one, respectively, and bits 64-96 are not all zeros.
- Bits 31 and 32 are both zero, and bits 64-103 are not all zeros.
- Bits 31 and 32 are one and zero, respectively.
- In the ESA/390-compatibility mode, bit 31 is one (recognition of this condition is unpredictable).

In these cases, the operation is completed, and the resulting instruction-length code is zero.

The test for a specification exception after the PSW is loaded is described in “Early Exception Recognition” on page 6-9.

The operation is suppressed on all addressing and protection exceptions.

Resulting Condition Code: The code is set as specified in the new PSW loaded.

Program Exceptions:

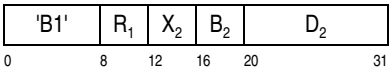
- Access (fetch, operand 2)
- Operation (LPSWEY, if the BEAR-enhancement facility is not installed)
- Privileged operation
- Special operation
- Specification
- Transaction constraint

Programming Note: It is intended for a control program to use LOAD PSW EXTENDED (LPSWEY) within interruption-handling routines in the following manner:

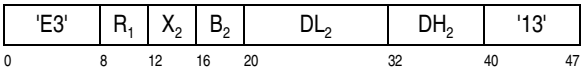
1. At the beginning of the interruption-handling routine, before a breaking event can occur, STORE BEAR is issued to preserve the contents of the breaking-event-address register (BEAR) associated with the interrupted program.
2. At the end of the interruption-handling routine, LOAD BEAR is issued to restore the preserved value to the breaking-event-address register (BEAR), followed by no breaking events and issuing LOAD PSW EXTENDED (LPSWEY) to return control to the interrupted program without causing a breaking event to occur.

LOAD REAL ADDRESS

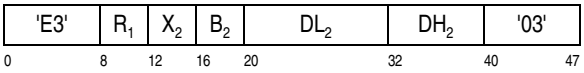
LRA $R_1,D_2(X_2,B_2)$ [RX-a]



LRAY $R_1,D_2(X_2,B_2)$ [RXY-a]



LRAG $R_1,D_2(X_2,B_2)$ [RXY-a]



For LOAD REAL ADDRESS (LRA, LRAY) in the 24-bit or 31-bit addressing mode, if bits 0-32 of the 64-bit real or absolute address corresponding to the second-operand virtual address are all zeros, bits 32-63 of the real or absolute address are placed in bit positions 32-63 of general register R_1, and bits 0-31 of the register remain unchanged. If bits 0-32 of the real or absolute address are not all zeros, a special-operation exception is recognized.

For LRA or LRAY in the 64-bit addressing mode, and for LOAD REAL ADDRESS (LRAG) in any addressing mode, the 64-bit real or absolute address corresponding to the second-operand virtual address is placed in general register R_1.

When EDAT-1 does not apply, or when EDAT-1 applies but the second operand is translated by means of a segment-table entry in which the STE-format control is zero, the address placed in general register R_1 is real. When EDAT-1 applies and the second operand is translated by means of a segment-table entry in which the STE-format control is one, or when EDAT-2 applies and the second operand is translated by means of a region-third-table entry in which the RTTE-format control is one, the address placed in general register R_1 is absolute.

The virtual address specified by the X_2, B_2, and D_2 fields is translated by means of the dynamic-address-translation facility, regardless of whether DAT is on or off.

The displacement for LRA is treated as a 12-bit unsigned binary integer. The displacement for LRAY and LRAG is treated as a 20-bit signed binary integer.

DAT is performed by using an address-space-control element that depends on the current value of the address-space-control bits, bits 16 and 17 of the PSW, as shown in Figure 10-24.

PSW Bits 16 and 17	Address-Space-Control Element Used by DAT
00	Contents of control register 1
01	The address-space-control element obtained by applying the access-register-translation (ART) process to the access register designated by the B_2 field
10	Contents of control register 7
11	Contents of control register 13

Figure 10-24. Address-Space Control used by LOAD REAL ADDRESS

ART and DAT may be performed with the use of the ART-lookaside buffer (ALB) and translation-lookaside buffer (TLB), respectively.

The virtual-address computation is performed according to the current addressing mode, specified by bits 31 and 32 of the current PSW.

The addresses of the region-table entry or entries, if used, and of the segment-table entry and page-table entry, if used, are treated as 64-bit addresses regardless of the current addressing mode. It is unpredictable whether the addresses of these entries are treated as real or absolute addresses.

Condition code 0 is set when both ART, if applicable, and DAT can be completed and a special-operation

exception is not recognized, that is, when an address-space-control element can be obtained, the entry in each DAT table lies within the table and has a zero I bit, and, for LRA or LRAY in the 24-bit or 31-bit addressing mode, bits 0-32 of the resulting real or absolute address are zeros. The translated address is not inspected for boundary alignment or for addressing or protection exceptions.

When PSW bits 16 and 17 are 01 binary and an address-space-control element cannot be obtained because of a condition that would normally cause one of the exceptions shown in Figure 10-25, (1) the interruption code assigned to the exception is placed in bit positions 48-63 of general register R_1, bit 32 of this register is set to one, bits 33-47 are set to zeros, and bits 0-31 remain unchanged, and (2) the instruction is completed by setting condition code 3.

Exception Name	Cause	Code (Hex)
ALET specification	Access-list-entry-token (ALET) bits 0-6 not all zeros	0028
ALEN translation	Access-list entry (ALE) outside list or invalid (bit 0 is one)	0029
ALE sequence	ALE sequence number (ALESN) in ALET not equal to ALESN in ALE	002A
ASTE validity	ASN-second-table entry (ASTE) invalid (bit 0 is one)	002B
ASTE sequence	ASTE sequence number (ASTESN) in ALE not equal to ASTESN in ASTE	002C
Extended authority	ALE private bit not zero, ALE authorization index (ALEAX) not equal to extended authorization index (EAX), and secondary bit selected by EAX either outside authority table or zero	002D

Figure 10-25. Handling of ART-Related Exceptions for LOAD REAL ADDRESS

When ART is completed normally, the operation is continued through the performance of DAT.

When the segment-table entry is outside the table and bits 0-32 of the real or absolute address of the entry are all zeros, bits 32-63 of the entry address are placed in bit positions 32-63 of general register R_1, bits 0-31 of the register remain unchanged, and the instruction completes by setting condition code 3. If bits 0-32 of the address are not all zeros, the result is as described in the section "DAT-Related Exceptions for LOAD REAL ADDRESS" on page 10-60.

When the I bit in the segment-table entry is one, the following applies:

- For LRA or LRAY in the 64-bit addressing mode or for LRAG in any addressing mode, the 64-bit real or absolute address of the segment-table entry is placed in general register R_1, and the instruction is completed by setting condition code 1.
- For LRA or LRAY in the 24-bit or 31-bit addressing mode, the following applies:
  - If bits 0-32 of the address of the segment-table entry are all zeros, bits 32-63 of the real or absolute address of the segment-table entry are placed in bits 32-63 of general register R_1, bits 0-31 of the register remain unchanged, and the instruction is completed by setting condition code 1.
  - If bits 0-32 of the address of the segment-table entry are not all zeros, the result is as described in the section "DAT-Related Exceptions for LOAD REAL ADDRESS", below.

When the I bit in the page-table entry is one, the following applies:

- For LRA or LRAY in the 64-bit addressing mode or for LRAG in any addressing mode, the 64-bit real or absolute address of the page-table entry is placed in general register R_1, and the instruction is completed by setting condition code 2.
- For LRA or LRAY in the 24-bit or 31-bit addressing mode, the following applies:
  - If bits 0-32 of the address of the page-table entry are all zeros, bits 32-63 of the real or absolute address of the page-table entry are placed in bits 32-63 of general register R_1, bits 0-31 of the register remain unchanged, and the instruction is completed by setting condition code 2.
  - If bits 0-32 of the address of the page-table entry are not all zeros, the result is as described in the section "DAT-Related Exceptions for LOAD REAL ADDRESS", below.

A segment-table-entry or page-table-entry address placed in general register R_1 is real or absolute in

accordance with the type of address that was used during the attempted translation.

DAT-Related Exceptions for LOAD REAL ADDRESS

If a condition exists that would normally cause one of the exceptions shown in the Figure 10-26, (1) the interruption code assigned to the exception is placed in bit positions 48-63 of general register R_1, bit 32 of this register is set to one, bits 33-47 are set to zeros, and bits 0-31 remain unchanged, and (2) the instruction is completed by setting condition code 3.

Exception Name	Cause	Code (Hex)
ASCE type	Address-space-control element (ASCE) being used is a region-second-table designation, and bits 0-10 of virtual address not all zeros; ASCE is a region-third-table designation, and bits 0-21 of virtual address not all zeros; or ASCE is a segment-table designation, and bits 0-32 of virtual address not all zeros.	0038
Region first translation	Region-first-table entry selected by region-first-index portion of virtual address outside table or invalid.	0039
Region second translation	Region-second-table entry selected by region-second-index portion of virtual address outside table or invalid.	003A
Region third translation	Region-third-table entry selected by region-third-index portion of virtual address outside table or invalid.	003B
Segment translation	Segment-table entry selected by segment-index portion of virtual address outside table (for all instructions and all addressing modes, but only when bits 0-32 of entry address not all zeros); or segment-table entry invalid (LRA and LRAY only, and only in 24-bit or 31-bit addressing mode when bits 0-32 of entry address not all zeros).	0010
Page translation	Page-table entry selected by page-index portion of virtual address invalid (LRA and LRAY only, and only in 24-bit or 31-bit addressing mode when bits 0-32 of entry address not all zeros).	0011

Figure 10-26. Handling of DAT-Related Exceptions for LOAD REAL ADDRESS

Special Conditions

In the ESA/390-compatibility mode, an operation exception is recognized.

A special-operation exception is recognized when, for LRA or LRAY in the 24-bit or 31-bit addressing mode, bits 0-32 of the resultant 64-bit real or absolute address are not all zeros.

An addressing exception is recognized when the address used by ART to fetch the effective access-list designation or the ALE, ASTE, or authority-table entry designates a location which is not available in the configuration or when the address used to fetch the region-table entry or entries, if any, segment-table entry, or page-table entry designates a location which is not available in the configuration.

A secure-storage-access exception is recognized when the address used by ART to fetch the effective access-list designation or the ALE, ASTE, or authority-table entry designates a location which is a secure location or when the address used to fetch the region-table entry or entries, if any, segment-table entry, or page-table entry designates a location which is a secure location in the configuration.

A translation-specification exception is recognized when an accessed region-table entry or the segment-table entry or page-table entry has a zero I bit and a format error, that is, when any of the reasons 1-5 listed in “Translation-Specification Exception” on page 6-48 applies.

A carry out of bit position 0 as a result of the addition done to compute the address of a region-table entry or the segment-table entry may be ignored or may result in an addressing exception.

The operation is suppressed on all addressing exceptions.

Resulting Condition Code:

0 Translation available
1 Segment-table entry invalid (I bit one) for LRAG, or for LRA and LRAY in 64-bit addressing mode, or for LRA and LRAY in 24-bit or 31-bit addressing mode and bits 0-32 of the entry address are all zeros
2 Page-table entry invalid (I bit one) for LRAG, or for LRA and LRAY in 64-bit addressing mode, or for LRA and LRAY in 24-bit or 31-bit addressing

mode and bits 0-32 of the entry address are all zeros

3 Address-space-control element not available, region-table entry outside table or invalid (I bit one), segment-table entry outside table, or, for LRA and LRAY only, and only in 24-bit or 31-bit addressing mode when bits 0-32 of entry address not all zeros, segment-table entry or page-table entry invalid (I bit one)

Program Exceptions:

- Addressing (effective access-list designation, access-list entry, ASN-second-table entry, authority-table entry, region-table entry, segment-table entry, or page-table entry)
- Operation (LRAY, if the long-displacement facility is not installed; LRA, LRAY, LRAG, in the ESA/390-compatibility mode)
- Privileged operation
- Secure-storage-access (effective access-list designation, access-list entry, ASN-second-table entry, authority-table entry, region-table entry, segment-table entry, or page-table entry)
- Special operation (LRA, LRAY only)
- Transaction constraint
- Translation specification

Programming Notes:

1. Caution must be exercised in the use of LOAD REAL ADDRESS in a multiprocessing configuration. Since INVALIDATE DAT TABLE ENTRY or INVALIDATE PAGE TABLE ENTRY may set I bits in storage to one before causing the corresponding entries in TLBs of other CPUs to be cleared, the simultaneous execution of LOAD REAL ADDRESS on this CPU and either INVALIDATE DAT TABLE ENTRY or INVALIDATE PAGE TABLE ENTRY on another CPU may produce inconsistent results. Because LOAD REAL ADDRESS may access the tables in storage, the region-table entries, segment-table entry or page-table entry may appear to be invalid (condition codes 3, 1, or 2, respectively) even though the corresponding TLB entry has not yet been cleared, and the TLB entry may remain in the TLB until the completion of INVALIDATE DAT TABLE ENTRY or INVALIDATE PAGE TABLE ENTRY on the other CPU. There is no guaranteed limit to the number of instructions which may be executed between the completion of LOAD REAL ADDRESS and the TLB being cleared of the entry.

   The above cautions for using LOAD REAL ADDRESS also apply when COMPARE AND SWAP AND PURGE or COMPARE AND REPLACE DAT TABLE ENTRY is used to explicitly set the invalid bit in a DAT-table entry.

2. Figure 10-27 on page 10-61 summarizes the resulting contents of general register R_1 and the condition code.

Exception/Cause/ Entry-Address Size or Resultant- Address Size	**General Register R_1 Contents and Condition Code**

Explanation:

EA1 Bits 0-31 of the entry address.
EA2 Bit 32 of the entry address.
EA3 Bits 33-47 of the entry address.
EA4 Bits 48-63 of the entry address.
RA1 Bits 0-31 of the resultant real or absolute address.
RA2 Bit 32 of the resultant real or absolute address.
RA3 Bits 33-47 of the resultant real or absolute address.
RA4 Bits 48-63 of the resultant real or absolute address.
U Unchanged.

Figure 10-27. Summary of Results: LOAD REAL ADDRESS

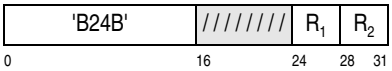
3. When the instruction completes with condition code 3, the following applies:

   – Only the rightmost 32 bits of general register R_1 are meaningful, regardless of the addressing mode or instruction executed. The program can determine whether the rightmost bits of general register R_1 contain the address of a DAT-table entry or a program-interruption code based on whether bit 32 of the register is zero or one, respectively.

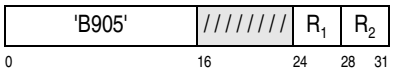
   – In order to correctly use a DAT-table-entry address returned in general register R_1 in the 64-bit addressing mode, the leftmost 32 bits of the register must be set to zeros.

LOAD USING REAL ADDRESS

LURA R_1,R_2 [RRE]



LURAG R_1,R_2 [RRE]



For LOAD USING REAL ADDRESS (LURA), the word at the real-storage location addressed by the contents of general register R_2 is placed in bit positions 32-63 of general register R_1, and the contents of bit positions 0-31 remain unchanged. For LOAD USING REAL ADDRESS (LURAG), the doubleword at that real-storage location is placed in bit positions 0-63 of general register R_1.

In the 24-bit addressing mode, bits 40-63 of general register R_2 designate the real-storage location, and bits 0-39 of the register are ignored. In the 31-bit addressing mode, bits 33-63 of general register R_2 designate the real-storage location, and bits 0-32 of the register are ignored. In the 64-bit addressing mode, bits 0-63 of general register R_2 designate the real-storage location.

Because it is a real address, the address designating the storage word or doubleword is not subject to dynamic address translation.

Special Conditions

The contents of general register R_2 must designate a location on a word boundary for LURA or on a doubleword boundary for LURAG; otherwise, a specification exception is recognized.

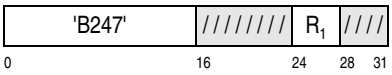
Condition Code: The code remains unchanged.

Program Exceptions:

- Addressing (address specified by general register R_2)
- Privileged operation
- Protection (fetch, operand 2, key-controlled protection)
- Secure-storage-access (address specified by general register R_2)
- Specification
- Transaction constraint

MODIFY STACKED STATE

MSTA R_1 [RRE]



The contents of bit positions 32-63 of the pair of general registers designated by the R_1 field are placed in the modifiable area, byte positions 152-159, of the last state entry in the linkage stack.

The R_1 field designates the even-numbered register of an even-odd pair of general registers.

The last state entry is located as described in “Unstacking Process” on page 5-88. The state entry remains in the linkage stack, and the linkage-stack-entry address in control register 15 remains unchanged.

Key-controlled protection does not apply to the references to the linkage stack, but low-address and DAT protection do apply.

Special Conditions

A specification exception is recognized when R_1 is odd.

The CPU must be in the primary-space mode, access-register mode, or home-space mode; otherwise, a special-operation exception is recognized.

A stack-empty, stack-specification, or stack-type exception may be recognized during the unstacking process.

The operation is suppressed on all addressing and protection exceptions.

The priority of recognition of program exceptions for the instruction is shown in Figure 10-28 on page 10-64.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch and store, except for key-controlled protection, linkage-stack entry)
- Special operation
- Specification
- Stack empty

- Stack specification
- Stack type
- Transaction constraint

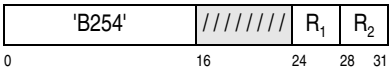
1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B	Special-operation exception due to DAT being off or the CPU being in secondary-space mode.
7.C	Transaction constraint.
8.A	Specification exception due to R_1 being odd.
8.B.1	Access exceptions (fetch) for entry descriptor of the current linkage-stack entry.
8.B.2	Stack-type exception due to current entry not being a state entry or header entry. **Note**: Exceptions 8.B.3-8.B.7 can occur only if the current entry is a header entry.
8.B.3	Access exceptions (fetch) for second word of the header entry.
8.B.4	Stack-empty exception due to backward stack-entry validity bit in the header entry being zero.
8.B.5	Access exceptions (fetch) for entry descriptor of preceding entry, which is the entry designated by the backward stack-entry address in the current (header) entry.
8.B.6	Stack-specification exception due to preceding entry being a header entry.
8.B.7	Stack-type exception due to preceding entry not being a state entry.
8.B.8	Access exceptions (store) for the modifiable area of the state entry.

Figure 10-28. Priority of Execution: MODIFY STACKED STATE

Programming Note: The modifiable area can be obtained from the last linkage-stack state entry by means of EXTRACT STACKED STATE.

MOVE PAGE

MVPG R_1,R_2 [RRE]



The first operand is replaced by the second operand and, optionally, the storage key associated with the 4K-byte block of storage designated by the first operand is set. The first and second operands both are 4K bytes on 4 K-byte boundaries. The results are indicated in the condition code. The accesses to the first-operand location or the second-operand location, but not to both locations, may be performed by using the key specified in general register 0; otherwise, the accesses to an operand location are performed by using the PSW key.

The location of the leftmost byte of the first operand and second operand is designated by the contents of general registers R_1 and R_2, respectively.

The handling of the addresses in general registers R_1 and R_2 depends on the addressing mode. In the 24-bit addressing mode, the contents of bit positions 40-51 of a general register, with 12 rightmost zeros appended, are the address, and bits 0-39 and 52-63 in the register are ignored. In the 31-bit addressing mode, the contents of bit positions 33-51 of a general register, with 12 rightmost zeros appended, are the address, and bits 0-32 and 52-63 in the register are ignored. In the 64-bit addressing mode, the contents of bit positions 0-51 of a general register, with 12 rightmost zeros appended, are the address, and bits 52-63 in the register are ignored.

Bits 51-53 of general register 0 contain the key-function control (KFC) which is used to determine how

the supplied storage key in bits 56-62 will be used or set.

KFC	Meaning
0	The PSW key is used for accessing both operands. The reference (R) and change (C) bits of the storage key associated with the 4K-byte block of storage designated by the first operand are set.
1	The PSW key is used for store accesses to the first operand and the supplied ACC key (bits 56-59 of general register 0) is used for fetch accesses to the second operand. The reference (R) and change (C) bits of the storage key associated with the 4K-byte block of storage designated by the first operand are set.
2	The supplied ACC key (bits 56-59 of general register 0) is used for store accesses to the first operand and the PSW key is used for fetch accesses to the second operand. The reference (R) and change (C) bits of the storage key associated with the 4K-byte block of storage designated by the first operand are set.
3	Reserved
4	Key-controlled protection does not apply to the first operand. The PSW key is used for fetch accesses to the second operand. The storage key associated with the 4K-byte block of storage designated by the first operand is set to the full key supplied in bits 56-62 of general register 0.
5	Key-controlled protection does not apply to the first operand. The PSW key is used for fetch accesses to the second operand. The storage key associated with the 4K-byte block of storage designated by the first operand is set as follows: the access-control bits (ACC) and fetch-protection bit (F) are copied from the storage key of the second operand and the reference bit (R) and change bit (C) use the value supplied in bits 61-62 of general register 0.
6-7	Reserved

When the move-page-and-set-key facility is not installed, KFC values of 4 and 5 are also reserved. If a reserved value is specified, a specification exception is recognized.

Bit 54 of general register 0 is a destination-reference-intention bit, and bit 55 is a condition-code-option bit. Bits 48-50 of general register 0 must be zeros; otherwise, a specification exception is recognized. Bits 0-47 and 63 of general register 0 are ignored. When the move-page-and-set-key facility is not installed, bits 60-62 are also ignored.

The contents of the registers just described are shown in Figure 10-29.

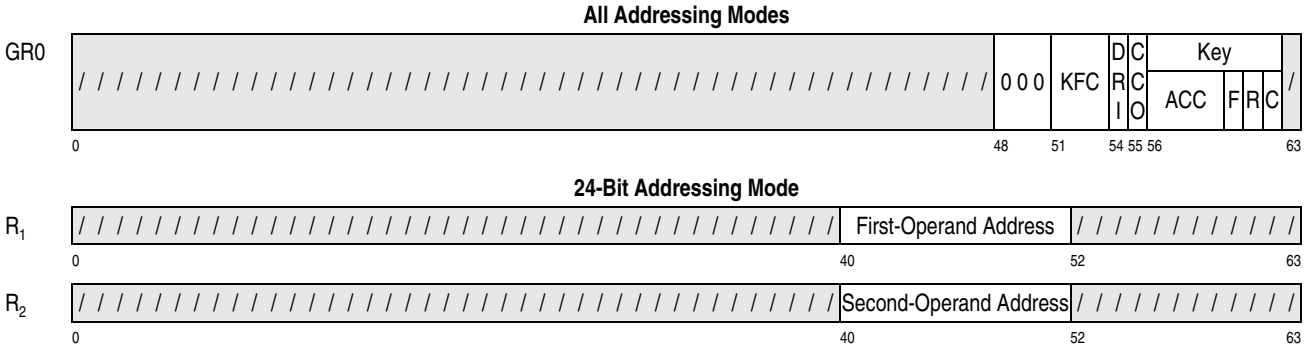


Figure 10-29. Register Contents for MOVE PAGE (Part 1 of 2)

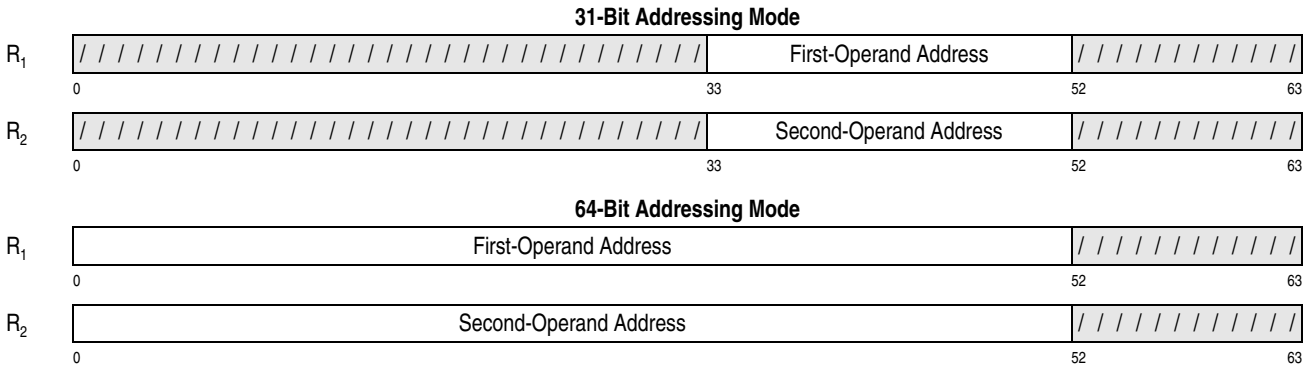


Explanation:

CCO Condition-code-option bit.
DRI Destination-reference-intention bit.
Key Specified access key.
KFC Key-function control.

Figure 10-29. Register Contents for MOVE PAGE (Part 2 of 2)

When 4K bytes have been moved, condition code 0 is set.

When a page-translation-exception condition exists, the exception is not recognized if the condition-code-option bit, bit 55 in general register 0, is one; instead, condition code 1 or 2 is set. Condition code 1 is set if a page-translation-exception condition exists for the first operand and not for the second operand. Condition code 2 is set if a page-translation-exception condition exists for the second operand, regardless of whether the condition exists for the first operand.

When the KFC value is 4 or 5 and the real or absolute addresses (possibly after DAT) of the first and second operands are the same, it is model dependent if an operand exception is recognized.

When an access exception can be recognized for both operands, it is unpredictable for which operand an exception is recognized. If one of the exceptions is a page-translation exception that would cause condition code 1 or 2 to be set, it is unpredictable whether the access exception for the other operand is recognized or condition code 1 or 2 is set.

When the instruction completes by setting condition codes 1 or 2, and a PER zero-address-detection condition also exists for either the first or second operand, it is unpredictable whether the zero-address-detection condition is recognized.

The references to main storage are not necessarily single-access references and are not necessarily performed in a left-to-right direction, as observed by other CPUs and by channel programs.

When the storage key is set on the first operand block (KFC values of 4 or 5), a quiescing operation is not necessarily performed. See “Storage-Key Accesses” on page 5-128 for a discussion of the effects of quiescing on key-setting instructions, and see “Quiescing” on page 5-141 for details on the quiescing operation.

When the KFC value is 4 or 5, serialization and checkpoint-synchronization functions are performed before the operation begins and again after the operation is completed.

Special Conditions

In the problem state, when the KFC value is 1 or 2, the operation is performed only if the access key specified in general register 0 is valid, that is, if the corresponding PSW-key-mask bit in control register 3 is one. Otherwise, a privileged-operation exception is recognized. In the supervisor state, any value for the specified access key is valid.

When the KFC value is 0, the access key in general register 0 is not tested for validity and a priviliged-operation exception is not recognized. In the problem state, when the move-page-and-set-key facility is

installed and the KFC value is 4 or 5, a privleged-operation exception is recognized.

In the problem state, when the KFC value is 3 and the access key in general register 0 is not permitted by the PSW-key mask, it is unpredictable whether a specification exception or a privileged-operation exception is recognized.

KFC values of 6 or 7 always result in a specification exception.

If the storage-key-removal facility is installed and either bit 52 or bit 53 in general register is one and the access key specified in general register 0 is non-zero, a special-operation exception is recognized.

In the ESA/390-compatibility mode, an operation exception is recognized when the configuration is not also operating in the ESA/extended-configuration (ESA/XC) mode . See Reference [12.] on page xxxii for details on ESA/XC.

Resulting Condition Code:

0 Data moved and, optionally, key is set
1 Condition-code-option bit one, page-table entry for first operand invalid, and page-table entry for second operand valid
2 Condition-code-option bit one and page-table entry for second operand invalid
3 --

Program Exceptions:

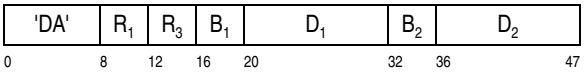
- Access (fetch, operand 2; store, operand 1)
- Operand
- Operation (in the ESA/390 compatibility mode when not in ESA/XC mode)
- Privileged operation (access key specified, and selected PSW-key-mask bit is zero in the problem state; KFC values of 4 or 5 in the problem state)
- Special operation
- Specification
- Transaction constraint

Programming Notes:

1. MOVE PAGE, or a loop of MOVE PAGE instructions that moves multiple pages, may provide, on most models, better performance than a MOVE LONG instruction or a loop of MOVE (MVC) instructions that performs the same function. Whether MOVE PAGE provides better performance depends on control-program specifications and the method by which the control program handles page-translation exceptions.
2. The destination-reference-intention bit should be set to one when there is an intention to reference the first operand by means of an instruction other than MOVE PAGE. The bit may allow the control program to process a page-translation exception more efficiently.
3. On most models where the move-page-and-set-key facility is installed and it is desired to both move a page of data and copy or set its key, then using MVPG with KFC values of 4 or 5 will provide better performance compared to a separate move operation followed by a SET STORAGE KEY EXTENDED or PERFORM FRAME MANAGE FUNCTION.
4. When KFC values of 4 or 5 are used, another CPU might briefly observe the reference and change bits being set to one for the first operand block, before being set to their final value by the key setting operation.
5. The condition code set by the instruction normally need not be examined if the condition-code-option bit is zero or if DAT is off.
6. See the definitions of real locations 162 and 168-175 under “Assigned Storage Locations” in Chapter 3, “Storage” for a description of information stored during a program interruption due to a DAT-related translation exception recognized by MOVE PAGE.

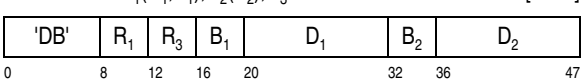
MOVE TO PRIMARY

MVCP $D_1(R_1,B_1),D_2(B_2),R_3$ [SS-d]



MOVE TO SECONDARY

MVCS $D_1(R_1,B_1),D_2(B_2),R_3$ [SS-d]



The first operand is replaced by the second operand. One operand is in the primary address space, and the other is in the secondary address space. The accesses to the operand in the primary space are performed by using the PSW key; the accesses to the operand in the secondary space are performed by using the key specified by the third operand.

The addresses of the first and second operands are virtual, one operand address being translated by means of the primary address-space-control element and the other by means of the secondary address-space-control element. Operand-address translation is performed in the same way when the address-space-control bits in the current PSW specify either the primary-space mode or the secondary-space mode.

For MOVE TO PRIMARY, movement is to the primary space from the secondary space. The first-operand address is translated by using the primary address-space-control element, and the second-operand address is translated by using the secondary address-space-control element.

For MOVE TO SECONDARY, movement is to the secondary space from the primary space. The first-operand address is translated by using the secondary address-space-control element, and the second-operand address is translated by using the primary address-space-control element.

Bit positions 56-59 of general register R_3 are used as the secondary-space access key. Bit positions 0-55 and 60-63 of the register are ignored.

General register R_1 contains an unsigned binary integer called the true length. In the 24-bit or 31-bit addressing mode, the true length is in bit positions 32-63 of the register, and the contents of bit positions 0-31 of the register are ignored. In the 64-bit addressing mode, the true length is in bit positions 0-63 of the register.

The contents of the general registers just described are shown in Figure 10-30.

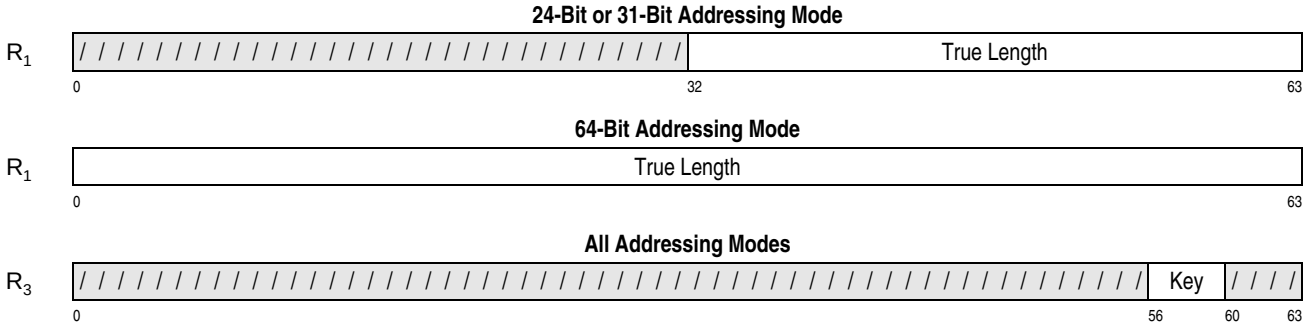


Figure 10-30. Register Contents of MOVE TO PRIMARY and MOVE TO SECONDARY

The first and second operands are the same length, called the effective length. The effective length is equal to the true length or 256, whichever is less. Access exceptions for the first and second operands are recognized only for that portion of the operand within the effective length. When the effective length is zero, no access exceptions are recognized for the first and second operands, and no movement takes place.

Each storage operand is processed left to right. The storage-operand-consistency rules are the same as for MOVE (MVC), except that when the operands overlap in real storage, the use of the common real-storage locations is not necessarily recognized.

As part of the execution of the instruction, the value of the true length is used to set the condition code. If the true length is 256 or less, including zero, the true length and effective length are equal, and condition code 0 is set. If the true length is greater than 256, the effective length is 256, and condition code 3 is set.

For both MOVE TO PRIMARY and MOVE TO SECONDARY, a serialization and checkpoint-synchronization function is performed before the operation begins and again after the operation is completed.

Special Conditions

Since the secondary space is accessed, the operation is performed only when the secondary-space control, bit 37 of control register 0, is one and DAT is on. When any of the following conditions are true a special-operation exception is recognized:

- When either the secondary-space control is zero or DAT is off.
- When the address-space-control bits in the current PSW specify the access-register or home-space mode.
- When the storage-key-removal facility is installed and the key specified in R_3 is nonzero.

In the problem state, the operation is performed only if the secondary-space access key is valid, that is, if the corresponding PSW-key-mask bit in control register 3 is one. Otherwise, a privileged-operation exception is recognized. In the supervisor state, any value for the secondary-space access key is valid.

Resulting Condition Code:

0 True length less than or equal to 256
1 --
2 --
3 True length greater than 256

Program Exceptions:

- Access (fetch, primary virtual address, operand 2, MVCS; fetch, secondary virtual address, operand 2, MVCP; store, secondary virtual address, operand 1, MVCS; store, primary virtual address, operand 1, MVCP)
- Privileged operation (selected PSW-key-mask bit is zero in the problem state)
- Special operation
- Transaction constraint

The priority of the recognition of exceptions and condition codes is shown in Figure 10-31.

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second and third instruction halfwords.

Figure 10-31. Priority of Execution: MOVE TO PRIMARY and MOVE TO SECONDARY (Part 1 of 2)

7.B	Special-operation exception due to the secondary-space control, bit 37 of control register 0, being zero, to DAT being off, or to the CPU being in the access-register or home-space mode.
7.C	Transaction constraint.
8.	Privileged-operation exception due to selected PSW-key-mask bit being zero in the problem state.
9.	Special-operation exception due to the specified key being nonzero when the storage key removal facility is installed.
10.	Completion due to length zero.
11.	Access exceptions for operands.

Figure 10-31. Priority of Execution: MOVE TO PRIMARY and MOVE TO SECONDARY (Part 2 of 2)

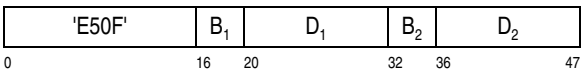
Programming Notes:

1. MOVE TO PRIMARY and MOVE TO SECONDARY can be used in a loop to move a variable number of bytes of any length. See the programming note under MOVE WITH KEY.

2. MOVE TO PRIMARY and MOVE TO SECONDARY should be used only when movement is between different address spaces. The performance of these instructions on most models may be significantly slower than that of MOVE WITH KEY, MOVE (MVC), or MOVE LONG. In addition, the definition of overlapping operands for MOVE TO PRIMARY and MOVE TO SECONDARY is not compatible with the more precise definitions for MOVE (MVC), MOVE WITH KEY, and MOVE LONG.

MOVE WITH DESTINATION KEY

MVCDK $D_1(B_1),D_2(B_2)$ [SSE]



The first operand is replaced by the second operand. The accesses to the destination-operand location are performed by using the key specified in general register 1, and the accesses to the source-operand location are performed by using the PSW key.

The first and second operands are of the same length, which is specified by bits 56-63 of general register 0. Bits 0-55 of general register 0 are ignored.

Bits 56-59 of general register 1 are used as the specified access key. Bits 0-55 and 60-63 of general register 1 are ignored.

The contents of general registers 0 and 1 are shown in Figure 10-32.

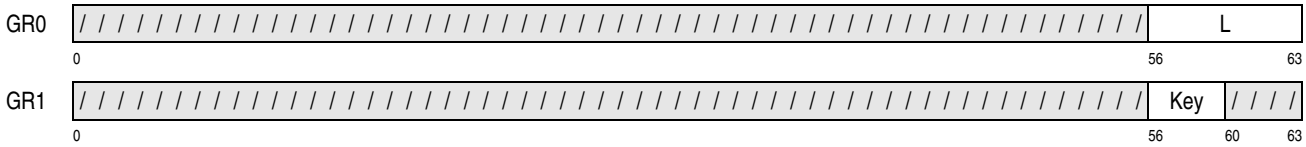


Figure 10-32. Register Contents of MOVE WITH DESTINATION KEY

L specifies the number of bytes to the right of the first byte of each operand. Therefore, the length in bytes of each operand is 1-256, corresponding to a length code in L of 0-255.

The fetch accesses to the second-operand location are performed by using the PSW key, and the store accesses to the first-operand location are performed by using the key specified in general register 1.

Each of the operands is processed left to right. When the operands overlap destructively in real storage, the results in the first-operand location are unpredictable. Except for this unpredictability in the case of destructive overlap, the storage-operand-consistency rules are the same as for the MOVE (MVC) instruction.

Special Conditions

If the storage-key-removal facility is installed and the key specified in general register 1 is not zero, a special operation exception is recognized.

In the problem state, the operation is performed only if the access key specified in general register 1 is valid, that is, if the corresponding PSW-key-mask bit in control register 3 is one. Otherwise, a privileged-operation exception is recognized. In the supervisor state, any value for the specified access key is valid.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2; store, operand 1)
- Privileged operation (selected PSW-key-mask bit is zero in the problem state)
- Special operation
- Transaction constraint

The priority of the recognition of exceptions and condition codes is shown in Figure 10-33.

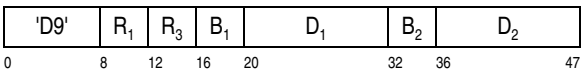
1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second and third instruction halfwords.
7.B	Transaction constraint.
8.	Privileged-operation exception due to selected PSW-key-mask bit being zero in the problem state.
9.	Special-operation exception due to the specified key being nonzero when the storage key removal facility is installed.
10.	Completion due to length zero.
11.	Access exceptions for operands.

Figure 10-33. Priority of Execution: MOVE WITH DESTINATION KEY

Programming Note: See the programming notes for the MOVE WITH SOURCE KEY instruction.

MOVE WITH KEY

MVCK $D_1(R_1,B_1),D_2(B_2),R_3$ [SS-d]



The first operand is replaced by the second operand. The fetch accesses to the second-operand location are performed by using the key specified in the third

operand, and the store accesses to the first-operand location are performed by using the PSW key.

Bit positions 56-59 of general register R_3 are used as the source access key. Bit positions 0-55 and 60-63 of the register are ignored.

General register R_1 contains an unsigned binary integer called the true length. In the 24-bit or 31-bit addressing mode, the true length is in bit positions 32-63 of the register, and the contents of bit positions 0-31 of the register are ignored. In the 64-bit addressing mode, the true length is in bit positions 0-63 of the register.

The contents of the general registers just described are shown in Figure 10-34.

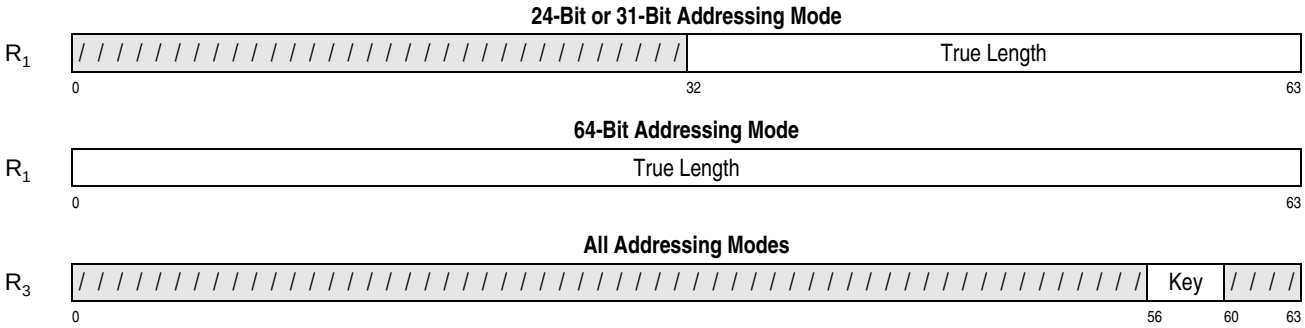


Figure 10-34. Register Contents of MOVE WITH KEY

The first and second operands are of the same length, called the effective length. The effective length is equal to the true length or 256, whichever is less. Access exceptions for the first and second operands are recognized only for that portion of the operand within the effective length. When the effective length is zero, no access exceptions are recognized for the first and second operands, and no movement takes place.

Each storage operand is processed left to right. When the storage operands overlap, the result is obtained as if the operands were processed one byte at a time and each result byte were stored immediately after the necessary operand byte was fetched. The storage-operand-consistency rules are the same as for the MOVE (MVC) instruction.

As part of the execution of the instruction, the value of the true length is used to set the condition code. If the true length is 256 or less, including zero, the true length and effective length are equal, and condition code 0 is set. If the true length is greater than 256, the effective length is 256, and condition code 3 is set.

Special Conditions

If the storage-key-removal facility is installed and the key specified in general register 1 is not zero, a special operation exception is recognized.

In the problem state, the operation is performed only if the source access key is valid, that is, if the corresponding PSW-key-mask bit in control register 3 is one. Otherwise, a privileged-operation exception is recognized. In the supervisor state, any value for the source access key is valid.

Resulting Condition Code:

0 True length less than or equal to 256
1 --
2 --
3 True length greater than 256

Program Exceptions:

- Access (fetch, operand 2; store, operand 1)
- Privileged operation (selected PSW-key-mask bit is zero in the problem state)
- Special operation
- Transaction constraint

The priority of the recognition of exceptions and condition codes is shown in Figure 10-35.

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.

Figure 10-35. Priority of Execution: MOVE WITH KEY (Part 1 of 2)

7.A	Access exceptions for second and third instruction halfwords.
7.B	Transaction constraint.
8.	Privileged-operation exception due to selected PSW-key-mask bit being zero in the problem state.
9.	Special operation exception due to storage key removal facility being installed and specified key being nonzero.
10.	Completion due to length zero.
11.	Access exceptions for operands.

Figure 10-35. Priority of Execution: MOVE WITH KEY (Part 2 of 2)

Programming Notes:

1. MOVE WITH KEY can be used in a loop to move a variable number of bytes of any length, as follows:

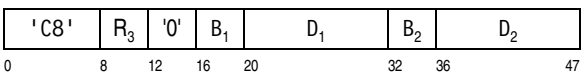
```
LOOP    MVCK  D1(R1,B1),D2(B2),R3
        BC    8,END
        AHI   B1,256
        AHI   B2,256
        AHI   R1,-256
        B     LOOP
END     [Any instruction]
```

   The above program is for execution in the 24-bit or 31-bit addressing mode. In the 64-bit addressing mode, AGHI instructions should be substituted for the AHI instructions.

2. The performance of MOVE WITH KEY on most models may be significantly slower than that of the MOVE (MVC) and MOVE LONG instructions. Therefore, MOVE WITH KEY should not be used if the keys of the source and the target are the same.

MOVE WITH OPTIONAL SPECIFICATIONS

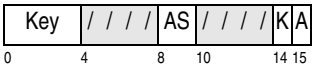
MVCOS $D_1(B_1),D_2(B_2),R_3$ [SSF]



The first operand is replaced by the second operand. Bits in general register 0 determine the address-space-control modes and protection keys that are used to access the first and second operands.

The addresses of the first and second operands are virtual.

Bits 32-47 of general register 0 contain the operand-access control for the first operand (OAC_1), and bits 48-63 of general register 0 contain the operand-access control for the second operand (OAC_2). The operand-access control has the following format.



Specified-Access Key (Key): Bits positions 0-3 contain the specified-access key that is used to access the operand if the specified-access-key validity bit (K) is one; otherwise, the specified-access key is ignored.

Specified-Address-Space Control (AS): Bit positions 8-9 contain the address-space control that is used to access the operand when the specified-address-space-control validity bit (A) is one; otherwise, the specified-address-space control is ignored. The meaning of bits 8-9 is identical to that of the address-space control in bits 16-17 of the PSW.

Specified-Access-Key Validity Bit (K): Bit 14 controls whether the PSW key or the specified-access key is used to access the operand. When the K bit is zero, the PSW key is used. When the K bit is one, the specified-access key is used.

Specified-Address-Space-Control Validity Bit (A): Bit 15 controls whether the address-space control in the current PSW or the address-space control in the specified-ASC is used to access the operand. When the A bit is zero, the address-space control in the current PSW is used. When the A bit is one, the specified-address-space control is used.

Bits 0-31 of general register 0 are ignored. Bits 4-7 and 10-14 of both operand-access controls (that is, bits 36-39, 42-45, 52-55, and 58-61 of general register 0) are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.

General register R_3 contains an unsigned binary integer called the true length. In the 24-bit or 31-bit addressing mode, the true length is in bit positions

32-63 of the register, and the contents of bit positions 0-31 of the register are ignored. In the 64-bit addressing mode, the true length is in bit positions 0-63 of the register.

The contents of the general registers just described are shown in Figure 10-36.

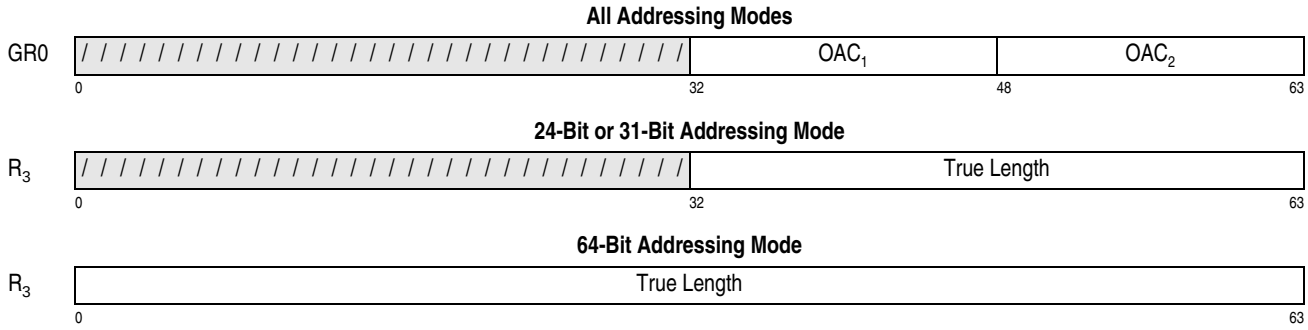


Figure 10-36. Register Contents for MOVE WITH OPTIONAL SPECIFICATIONS
