The first and second operands are the same length, called the effective length. The effective length is equal to the true length or 4,096, whichever is less. Access exceptions for the first and second operands are recognized only for that portion of the operand within the effective length. When the effective length is zero, no access exceptions are recognized for the first and second operands, and no movement takes place.

As part of the execution of the instruction, the value of the true length is used to set the condition code. If the true length is 4,096 or less, including zero, then the true length and effective length are equal, and condition code 0 is set. If the true length is greater than 4,096, then the effective length is 4,096, and condition code 3 is set.

No test is made for destructive overlap, and the results in the first-operand location are unpredictable when destructive overlap exists. Operands are said to overlap destructively when the first-operand real location is used as a source after data has been moved into it.

Operands do not overlap destructively if the leftmost byte of the first operand does not coincide with any of the second-operand bytes participating in the operation other than the leftmost byte of the second operand. When an operand wraps around from location $2^{24} - 1$ (or $2^{31} - 1$ or $2^{64} - 1$) to location 0, operand bytes in locations up to and including $2^{24} - 1$ (or $2^{31} - 1$ or $2^{64} - 1$) are considered to be to the left of bytes in locations from 0 up.

In the 24-bit addressing mode, wraparound is from location $2^{24} - 1$ to location 0; in the 31-bit addressing mode, wraparound is from location $2^{31} - 1$ to location 0; and, in the 64-bit addressing mode, wraparound is from location $2^{64} - 1$ to location 0.

Special Conditions

A special-operation exception is recognized for any of the following conditions:

- DAT is off.
- The address-space control in OAC_1 designates the home-space mode, the address-space-control validity bit in OAC_1 is one, and the current PSW is in the problem state (that is, bits 40-41 of general register 0 are 11 binary, bit 47 of the register is one, and bit 15 of the current PSW is one).
- The secondary-space control, bit 37 of control register 0, is zero, and either of the following is true:
  - The A bit of the OAC for either operand is zero, and bits 16-17 of the current PSW are 10 binary.
  - The A bit of the OAC for either operand is one, and the AS bits in the same OAC are 10 binary.

  The secondary-space control is not examined for an operand that is accessed in the secondary-space mode as a result of access-register translation (that is, DAT is on, bits 16-17 of the current

PSW are 01 binary, and the access register corresponding to the operand's base register contains an ALET of 00000001 hex).

- The storage-key-removal facility is installed, the specified-access-key validity bit is one, and the corresponding specified access key is nonzero in either of the operand access controls.

When MOVE WITH OPTIONAL SPECIFICATIONS is executed in the problem state, and either the first or second operand's specified-access key (from GR0) or the implied-access key (from the PSW) is invalid, a privileged-operation exception is recognized. The validity of an access key is determined as follows:

- The specified-access key in OAC_1 is invalid if the specified-access-key control, bit 46 of general register 0, is one; and the specified-access key, bits 32-35 of the register, designates a PSW-key-mask (PKM) bit position in control register 3 that contains zero.
- The specified-access key in OAC_2 is invalid if the specified-access-key control, bit 62 of general register 0, is one; and the specified-access key, bits 48-51 of the register, designates a PKM bit position that contains zero.
- The implied-access key is invalid if both of the following conditions are true:
  - Either or both bits 46 and 62 of general register 0 are zero.
  - The PSW key, bits 8-11 of the PSW, designates a PKM bit position that contains zero.

In the supervisor state, any value for the implied- or specified-access key is valid.

Resulting Condition Code:

0 True length less than or equal to 4,096
1 --
2 --
3 True length greater than 4,096

Program Exceptions:

- Access (fetch, second operand; store first operand)
- Operation (if the move-with-optional-specifications facility is not installed)
- Privileged operation (selected PSW-key-mask bit is zero in the problem state)
- Special operation
- Transaction constraint

The priority of the recognition of exceptions and condition codes is shown in Figure 10-37.

1.-7.B	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.C.1	Operation exception.
7.C.2	Special-operation exception.
7.C.3	Privileged-operation exception.
7.D	Transaction constraint.
8.	Completion due to length zero.
9.	Access exceptions for operands.

Figure 10-37. Priority of Execution: MOVE WITH OPTIONAL SPECIFICATIONS

Programming Notes:

1. MOVE WITH OPTIONAL SPECIFICATIONS can be used in a loop to move a variable number of bytes of any length.
2. An example of moving 16 K-bytes to the home address space from the secondary address space is shown below. The first operand is accessed using the PSW key, and the second operand is accessed using key 5.

```
        LA      3,OPERAND1
        LA      5,OPERAND2
        LHI     7,16384
        LLILF   0,X'00C15083'
LOOP    MVCOS   0(3),0(5),7
        AHI     3,4096
        AHI     5,4096
        AHI     7,-4096
        BP      LOOP
```

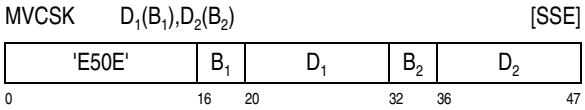
   In the 64-bit addressing mode, AGHI instructions should be substituted for the AHI instructions.

3. The performance of MOVE WITH OPTIONAL SPECIFICATIONS may be significantly slower than that of individual MOVE (MVC) instructions.
4. When bits 46-47 and 62-63 of general register 0 are all zero, MOVE WITH OPTIONAL SPECIFICATIONS uses the key and address-space control in the current PSW to access both the first and second operands.

5. In the MVCDK, MVCK, MVCP, MVCS, and MVCSK instructions, one operand is accessed using an implied key from the PSW, and the other operand is accessed using a specified key in a register. In the problem state, only the specified key is checked for validity in the PSW-key mask (PKM).

   When MVCOS is executed in the problem state, the access keys for the first and second operands are both checked for validity in the PKM, regardless of whether the keys are implied or specified.

MOVE WITH SOURCE KEY



The first operand is replaced by the second operand. The accesses to the source-operand location are performed by using the key specified in general register 1, and the accesses to the destination-operand location are performed by using the PSW key.

The first and second operands are of the same length, which is specified by bits 56-63 of general register 0. Bits 0-55 of general register 0 are ignored.

Bits 56-59 of general register 1 are used as the specified access key. Bits 0-55 and 60-63 of general register 1 are ignored.

The contents of general registers 0 and 1 are shown in Figure 10-38.

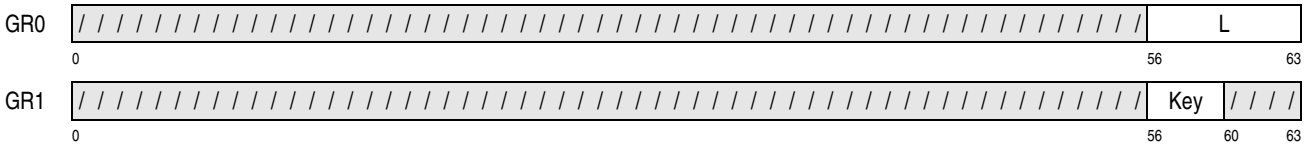


Figure 10-38. Register Contents of MOVE WITH SOURCE KEY

L specifies the number of bytes to the right of the first byte of each operand. Therefore, the length in bytes of each operand is 1-256, corresponding to a length code in L of 0-255.

The fetch accesses to the second-operand location are performed by using the key specified in general register 1, and the store accesses to the first-operand location are performed by using the PSW key.

Each of the operands is processed left to right. When the operands overlap destructively in real storage, the results in the first-operand location are unpredictable. Except for this unpredictability in the case of destructive overlap, the storage-operand-consistency rules are the same as for the MOVE (MVC) instruction.

Special Conditions

If the storage-key-removal facility is installed and the key specified in general register 1 is not zero, a special operation exception is recognized.

In the problem state, the operation is performed only if the access key specified in general register 1 is valid, that is, if the corresponding PSW-key-mask bit in control register 3 is one. Otherwise, a privileged-operation exception is recognized. In the supervisor state, any value for the specified access key is valid.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2; store, operand 1)
- Privileged operation (selected PSW-key-mask bit is zero in the problem state)
- Special operation
- Transaction constraint

The priority of the recognition of exceptions and condition codes is shown in Figure 10-39.

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.

Figure 10-39. Priority of Execution: MOVE WITH SOURCE KEY

7.A	Access exceptions for second and third instruction halfwords.
7.B	Transaction constraint.
8.	Privileged-operation exception due to selected PSW-key-mask bit being zero in the problem state.
9.	Special-operation exception due to the specified key being nonzero when the storage key removal facility is installed.
10.	Completion due to length zero.
11.	Access exceptions for operands.

Figure 10-39. Priority of Execution: MOVE WITH SOURCE KEY

Programming Notes:

1. When data is to be moved alternately in both directions between two storage areas that are fetch protected by means of different keys, then MOVE WITH SOURCE KEY and MOVE WITH DESTINATION KEY can be used while leaving the PSW key unchanged; and this may be, on most models, significantly faster than using MOVE WITH KEY along with SET PSW KEY FROM ADDRESS to change the PSW key.

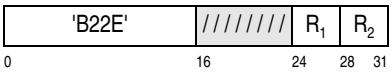
2. MOVE WITH SOURCE KEY and MOVE WITH DESTINATION KEY should be used only when movement is between storage areas having different keys. The performance of these instructions on most models may be significantly slower than that of the MOVE (MVC) instruction.

3. MOVE WITH SOURCE KEY or MOVE WITH DESTINATION KEY can be used in a loop to move a variable number of bytes as shown in the following example. In the example, the specified access key, the first-operand address, the second-operand address, and the length of each operand are assumed to be in general registers 1-4, respectively, at the beginning of the example. The length of each operand is treated as a 32-bit signed value, and a negative value is treated as zero.

```
        LTR     4,4
        BC      12,END
        AHI     4,-256
        BC      12,LAST
        LA      0,255
LOOP    MVCSK   0(2),0(3)
        LA      2,256(2)
        LA      3,256(3)
        AHI     4,-256
        BC      2,LOOP
LAST    LA      0,255(4)
        MVCSK   0(2),0(3)
END     [Any instruction]
```

PAGE IN

PGIN R_1,R_2 [RRE]



A page-in operation is performed which transfers a 4 K-byte block to the real-storage location designated by general register R_1 from the expanded-storage block designated by general register R_2.

Bits 32-63 of general register R_2 are a 32-bit unsigned binary integer called the expanded-storage-block number. This number designates the 4 K-byte block of expanded storage which is to be transferred. If the expanded-storage-block number designates an inaccessible block in expanded storage, condition code 3 is set.

The contents of general register R_1 are a real address which designates a 4 K-byte block in main storage. In the 24-bit-addressing mode, bits 40-51 designate the block, and bits 0-39 are ignored. In the 31-bit-addressing mode, bits 33-51 designate the block, and bits 0-32 are ignored. In the 64-bit-addressing mode, bits 0-51 designate the block. In all modes, bits 52-63 of the address are ignored.

Because it is a real address, the address designating the main-storage block is not subject to dynamic address translation. PAGE IN is not subject to key-controlled storage protection, but low-address protection does apply. PAGE IN is not subject to program-event recording for storage alteration.

A serialization and checkpoint-synchronization function is performed before the operation begins and again after the operation is completed.

If the page-in operation is completed with no errors, condition code 0 is set.

If the page-in operation encounters an expanded-storage data error, condition code 1 is set. For an expanded-storage data-error condition, the contents of the entire 4 K-byte block in real storage is unpredictable, but this condition does not result in the generation of invalid checking-block codes in real storage.

If the expanded-storage block is not available, that is, the block is not provided or is not currently in the configuration, then condition code 3 is set, and no other action is taken.

Operation of PAGE IN in a Multiple-CPU Configuration

The accesses to main storage and to expanded storage by PAGE IN are not necessarily single-access references and are not necessarily performed in a left-to-right direction, as observed by other CPUs and by channel programs.

See also the description under PAGE OUT.

Resulting Condition Code:

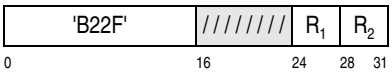
0 Page-in operation completed
1 Expanded-storage data error
2 --
3 Expanded-storage block not available

Program Exceptions:

- Addressing (block designated by general register R_1)
- Operation (if the expanded-storage facility is not installed)
- Privileged operation
- Protection (block designated by general register R_1; low-address protection)
- Secure-storage-access (block designated by general register R_1)
- Transaction constraint

PAGE OUT

PGOUT R_1,R_2 [RRE]



A page-out operation is performed which transfers a 4 K-byte block from the real-storage location designated by general register R_1 to the expanded-storage block designated by general register R_2.

Bits 32-63 of general register R_2 are a 32-bit unsigned binary integer called the expanded-storage-block number. This number designates the 4 K-byte block of expanded storage which is to be replaced. If the expanded-storage-block number designates an inaccessible block in expanded storage, condition code 3 is set.

The contents of general register R_1 are a real address which designates a 4 K-byte block in main storage. In the 24-bit-addressing mode, bits 40-51 designate the block, and bits 0-39 are ignored. In the 31-bit-addressing mode, bits 33-51 designate the block, and bits 0-32 is ignored. In the 64-bit-addressing mode, bits 0-51 designate the block. In all modes, bits 52-63 of the address are ignored.

Because it is a real address, the address designating the main-storage block is not subject to dynamic address translation. PAGE OUT is not subject to key-controlled protection.

A serialization and checkpoint-synchronization function is performed before the operation begins and again after the operation is completed.

Depending on the model, after the data has been written to the expanded-storage block, a read-back-check operation may be performed to determine whether the data was written correctly. If the read-back-check operation determines that the data has been written correctly, condition code 0 is set. If the read-back-check operation encounters an expanded-storage data error, condition code 1 is set.

Most models do not perform the read-back-check operation, and, after the page-out operation is completed, condition code 0 is set.

Regardless of whether condition code 0 or condition code 1 is set, the entire 4 K-byte block is written. Errors, if any, in the block after the block is written are

preserved. Thus, if a subsequent execution of PAGE IN addresses the same expanded-storage block, the expanded-storage data error will be detected and condition code 1 will be indicated.

If the expanded-storage block is not available, that is, the block is not provided or is not currently in the configuration, then condition code 3 is set, and no other action is taken.

Operation of PAGE OUT in a Multiple-CPU Configuration

The accesses to main storage and to expanded storage by PAGE OUT are not necessarily single-access references and are not necessarily performed in a left-to-right direction, as observed by other CPUs and by channel programs.

If two or more CPUs issue PAGE IN or PAGE OUT instructions at approximately the same instant in time, depending on the model, the operations may be performed one at a time, or the operations may be performed concurrently. Concurrent operation may occur even if the instructions address the same expanded-storage block.

When two or more PAGE OUT instructions addressing the same expanded-storage block are executed concurrently, the resulting values in the expanded-storage block for each group of bytes transferred may be from any of the instructions being executed simultaneously. The number of bytes transferred as a group depends on the model.

Similarly, for concurrent execution of a PAGE IN and a PAGE OUT instruction for the same expanded-storage block, the resulting values for each group of bytes transferred as a result of the execution of the PAGE IN instruction may be either the old or new values from the expanded-storage block.

Concurrent operation of paging instructions does not result in expanded-storage data errors.

Resulting Condition Code:

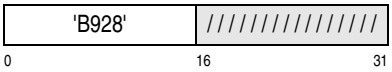
0 Page-out operation completed
1 Expanded-storage data error
2 --
3 Expanded-storage block not available

Program Exceptions:

- Addressing (block designated by general register R_1)
- Operation (if the expanded-storage facility is not installed)
- Privileged operation
- Secure-storage-access (block designated by general register R_1)
- Transaction constraint

PERFORM CRYPTOGRAPHIC KEY MANAGEMENT OPERATION

PCKMO [RRE]



A function specified by the function code in general register 0 is performed.

Bits 16-31 of the instruction are ignored.

Bit positions 57-63 of general register 0 contain the function code. Figure 10-40 on page 10-79 shows the assigned function codes. When the message-security-assist extension 13 is installed, function code 127 is valid for PERFORM CRYPTOGRAPHIC KEY MANAGEMENT OPERATION. All other function codes are unassigned. Bit 56 of general register 0 must be zero; otherwise, a specification exception is recognized. All other bits of general register 0 are ignored.

General register 1 contains the logical address of the leftmost byte of the parameter block in storage. In the 24-bit addressing mode, the contents of bit positions 40-63 of general register 1 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of general register 1 constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register 1 constitute the address.

The function codes for PERFORM CRYPTOGRAPHIC KEY MANAGEMENT OPERATION are as follows.

Code	Function	Parm. Block Size (bytes)	Data Block Size (bytes)
0	PCKMO-Query	16	—
1	PCKMO-Encrypt-DEA-Key	32	8
2	PCKMO-Encrypt-TDEA-128-Key	40	8
3	PCKMO-Encrypt-TDEA-192-Key	48	8
18	PCKMO-Encrypt-AES-128-Key	48	16
19	PCKMO-Encrypt-AES-192-Key	56	16
20	PCKMO-Encrypt-AES-256-Key	64	16
21	PCKMO-Encrypt-AES-XTS-128-Double-Key	64	16
22	PCKMO-Encrypt-AES-XTS-256-Double-Key	96	16
32	PCKMO-Encrypt-ECC-P256-Key	64	16
33	PCKMO-Encrypt-ECC-P384-Key	80	16
34	PCKMO-Encrypt-ECC-P521-Key	112	16
40	PCKMO-Encrypt-ECC-Ed25519-Key	64	16
41	PCKMO-Encrypt-ECC-Ed448-Key	96	16
118	PCKMO-Encrypt-HMAC-512-Key	96	16
122	PCKMO-Encrypt-HMAC-1024-Key	160	16
127	PCKMO-Query-Authentication-Information	V	—

Explanation:

— Not applicable

V Variable parameter block size. See each format-x parameter block for the exact size of that parameter block.

Figure 10-40. Function Codes for PERFORM CRYPTOGRAPHIC KEY MANAGEMENT OPERATION

All other function codes are unassigned.

The query function provides the means of indicating the availability of the other functions.

The query-authentication-information function provides the information that can be used by the program to authenticate the running instruction's firmware code level (IFCL) currently installed on the model.

Figure 10-41 shows the contents of general registers 0 and 1.

In the access-register mode, access register 1 specifies the address space containing the parameter block.

As observed by other CPUs and channel programs, reference to the parameter block may be multiple-access references, accesses to these storage locations are not necessarily block-concurrent, and the sequence of these accesses or references is undefined.

PCKMO-Query (Function Code 0)

The locations of the operands and addresses used by the instruction are as shown in Figure 10-41 on page 10-80.

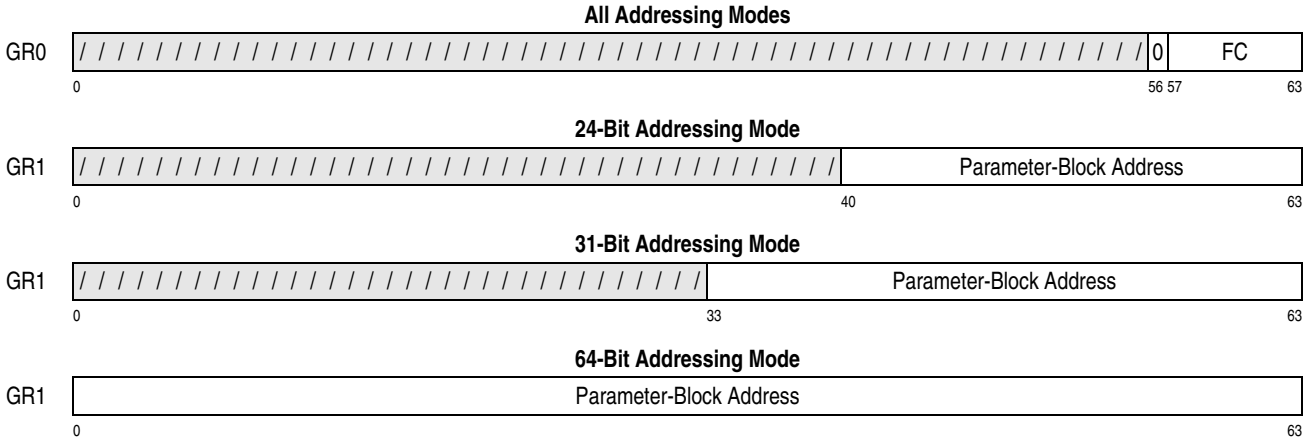


Figure 10-41. General Register Assignment for PCKMO

The parameter block used for the function has the following format:

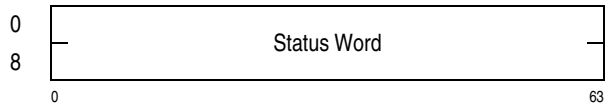

Figure 10-42. Parameter Block for PCKMO-Query

A 128-bit status word is stored in the parameter block. Bits 0-127 of this field correspond to function codes 0-127, respectively, of the PCKMO instruction. When a bit is one, the corresponding function is installed; otherwise, the function is not installed.

PCKMO-Encrypt-DEA-Key (Function Code 1)

The locations of the operands and addresses used by the instruction are as shown in Figure 10-41 on page 10-80.

The parameter block used for the function has the following format:

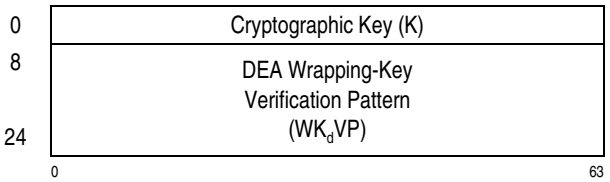

Figure 10-43. Parameter Block for PCKMO-Encrypt-DEA-Key

The 8-byte cryptographic key, K, in byte offsets 0-7 of the parameter block is encrypted using the DEA wrapping key. (See the section “Protection of Cryptographic Keys” on page 7-490 for the encryption algorithm.) The result is placed back in byte offsets 0-7 of the parameter block. The contents of the DEA wrapping-key verification-pattern register are placed in byte offsets 8-31 of the parameter block.

PCKMO-Encrypt-TDEA-128-Key (Function Code 2)

The locations of the operands and addresses used by the instruction are as shown in Figure 10-41 on page 10-80.

The parameter block used for the function has the following format:

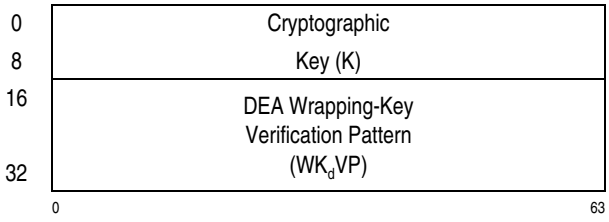

Figure 10-44. Parameter Block for PCKMO-Encrypt-TDEA-128-Key

The 16-byte cryptographic key, K, in byte offsets 0-15 of the parameter block is encrypted using the DEA wrapping key. (See the section “Protection of Cryptographic Keys” on page 7-490 for the encryption algorithm.) The result is placed back in byte offsets 0-15 of the parameter block. The contents of the DEA wrapping-key verification-pattern register are placed in byte offsets 16-39 of the parameter block.

PCKMO-Encrypt-TDEA-192-Key (Function Code 3)

The locations of the operands and addresses used by the instruction are as shown in Figure 10-41 on page 10-80.

The parameter block used for the function has the following format:

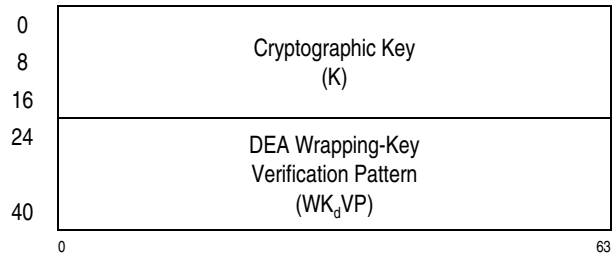

Figure 10-45. Parameter Block for PCKMO-Encrypt-TDEA-192-Key

The 24-byte cryptographic key, K, in byte offsets 0-23 of the parameter block is encrypted using the DEA wrapping key. (See the section “Protection of Cryptographic Keys” on page 7-490 for the encryption algorithm.) The result is placed back in byte offsets 0-23 of the parameter block. The contents of the DEA wrapping-key verification-pattern register are placed in byte offsets 24-47 of the parameter block.

PCKMO-Encrypt-AES-128-Key (Function Code 18)

The locations of the operands and addresses used by the instruction are as shown in Figure 10-41 on page 10-80.

The parameter block used for the function has the following format:

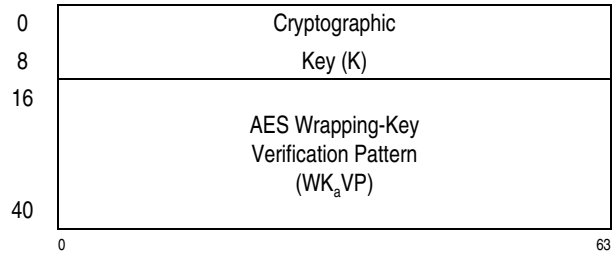

Figure 10-46. Parameter Block for PCKMO-Encrypt-AES-128-Key

The 16-byte cryptographic key, K, in byte offsets 0-15 of the parameter block is encrypted using the AES wrapping key. (See the section “Protection of Cryptographic Keys” on page 7-490 for the encryption algorithm.) The result is placed back in byte offsets 0-15 of the parameter block. The contents of the AES wrapping-key verification-pattern register are placed in byte offsets 16-47 of the parameter block.

PCKMO-Encrypt-AES-192-Key (Function Code 19)

The locations of the operands and addresses used by the instruction are as shown in Figure 10-41 on page 10-80.

The parameter block used for the function has the following format:

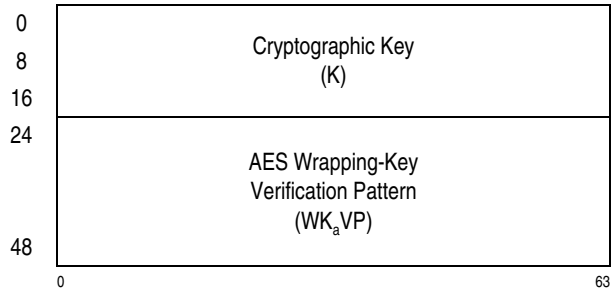

Figure 10-47. Parameter Block for PCKMO-Encrypt-AES-192-Key

The 24-byte cryptographic key, K, in byte offsets 0-23 of the parameter block is encrypted using the AES wrapping key. (See the section “Protection of Cryptographic Keys” on page 7-490 for the encryption algorithm.) The result is placed back in byte offsets 0-23 of the parameter block. The contents of the AES wrapping-key verification-pattern register are placed in byte offsets 24-55 of the parameter block.

PCKMO-Encrypt-AES-256-Key (Function Code 20)

The locations of the operands and addresses used by the instruction are as shown in Figure 10-41 on page 10-80.

The parameter block used for the function has the following format:

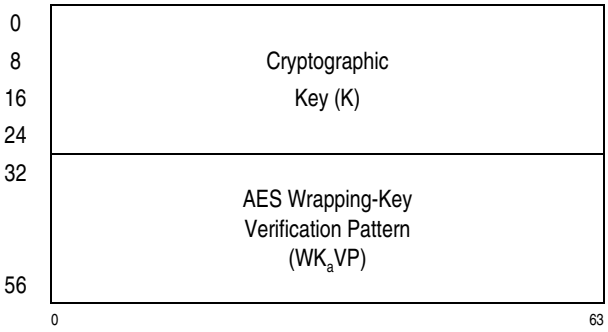

Figure 10-48. Parameter Block for PCKMO-Encrypt-AES-256-Key

The 32-byte cryptographic key, K, in byte offsets 0-31 of the parameter block is encrypted using the AES wrapping key. (See the section "Protection of Cryptographic Keys" on page 7-490 for the encryption algorithm.) The result is placed back in byte offsets 0-31 of the parameter block. The contents of the AES wrapping-key verification-pattern register are placed in byte offsets 32-63 of the parameter block.

PCKMO-Encrypt-AES-XTS-128-Double-Key (Function Code 21)

The locations of the operands and addresses used by the instruction are as shown in Figure 10-41 on page 10-80.

The parameter block used for the function has the following format:

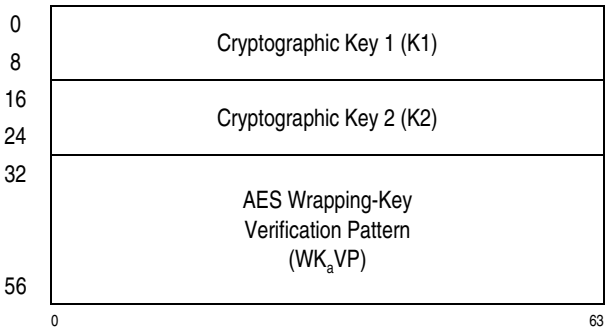

Figure 10-49. Parameter Block for PCKMO-Encrypt-AES-XTS-128-Double-Key

The 32-byte cryptographic double-key, consisting of K1 and K2, in byte offsets 0-31 of the parameter block is encrypted using the AES wrapping key. (See the section "Protection of Cryptographic Keys" on page 7-490 for the encryption algorithm.) The result is placed back in byte offsets 0-31 of the parameter block. The contents of the AES wrapping-key verification-pattern register are placed in byte offsets 32-63 of the parameter block.

PCKMO-Encrypt-AES-XTS-256-Double-Key (Function Code 22)

The locations of the operands and addresses used by the instruction are as shown in Figure 10-41 on page 10-80.

The parameter block used for the function has the following format:

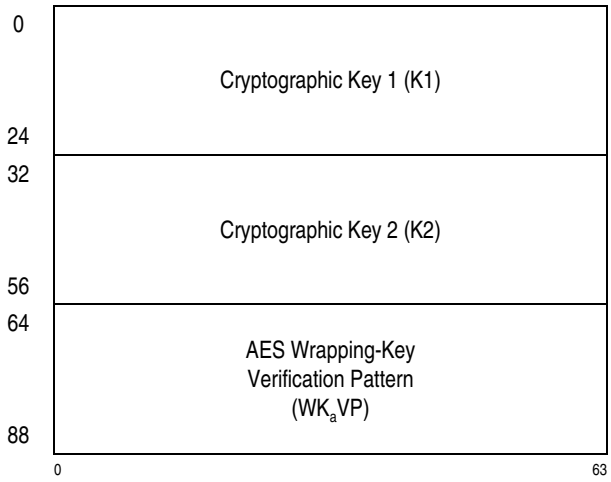

Figure 10-50. Parameter Block for PCKMO-Encrypt-AES-XTS-256-Double-Key

The 64-byte cryptographic double-key, consisting of K1 and K2, in byte offsets 0-63 of the parameter block is encrypted using the AES wrapping key. (See the section "Protection of Cryptographic Keys" on page 7-490 for the encryption algorithm.) The result is placed back in byte offsets 0-63 of the parameter block. The contents of the AES wrapping-key verification-pattern register are placed in byte offsets 64-95 of the parameter block.

PCKMO-Encrypt-ECC-P256-Key (Function Code 32)

This function is available only when message-security-assist extension 9 is installed. The locations of the operands and addresses used by the instruction are as shown in Figure 10-41 on page 10-80.

The parameter block used for the function has the following format:

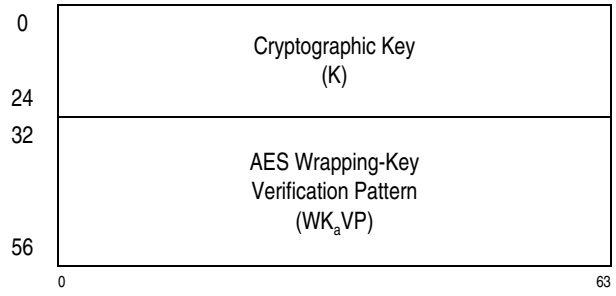

Figure 10-51. Parameter Block for PCKMO-Encrypt-ECC-P256-Key

The 32-byte cryptographic key, K, in byte offsets 0-31 of the parameter block is encrypted using the AES wrapping key. (See the section “Protection of Cryptographic Keys” on page 7-490 for the encryption algorithm.) The result is placed back in byte offsets 0-31 of the parameter block. The contents of the AES wrapping-key verification-pattern register are placed in byte offsets 32-63 of the parameter block.

PCKMO-Encrypt-ECC-P384-Key (Function Code 33)

This function is available only when message-security-assist extension 9 is installed. The locations of the operands and addresses used by the instruction are as shown in Figure 10-41 on page 10-80.

The parameter block used for the function has the following format:

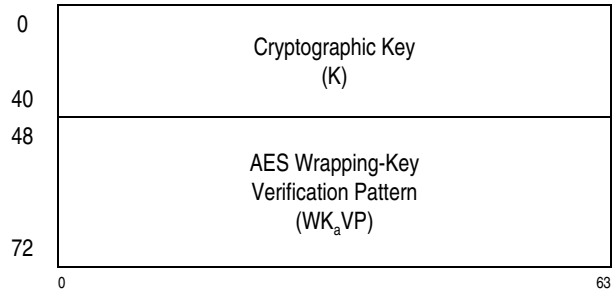

Figure 10-52. Parameter Block for PCKMO-Encrypt-ECC-P384-Key

The 48-byte cryptographic key, K, in byte offsets 0-47 of the parameter block is encrypted using the AES wrapping key. (See the section “Protection of Cryptographic Keys” on page 7-490 for the encryption algorithm.) The result is placed back in byte offsets 0-47 of the parameter block. The contents of the AES wrapping-key verification-pattern register are placed in byte offsets 48-79 of the parameter block.

PCKMO-Encrypt-ECC-P521-Key (Function Code 34)

This function is available only when message-security-assist extension 9 is installed. The locations of the operands and addresses used by the instruction are as shown in Figure 10-41 on page 10-80.

The parameter block used for the function has the following format:

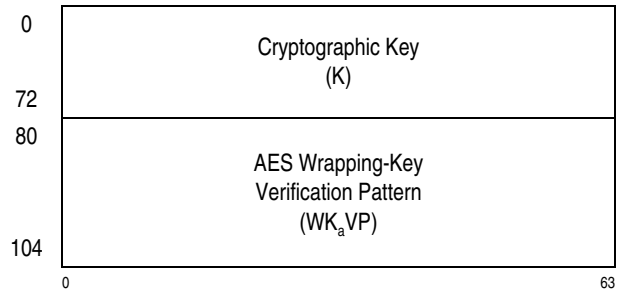

Figure 10-53. Parameter Block for PCKMO-Encrypt-ECC-P521-Key

The 521 bit cryptographic key, K, is right aligned in byte offsets 14-79 of the parameter block with padding in bytes 0 to 13 and part of byte 14. The programmer must pad with zeros in byte 14 or unpredictable results are possible when using this key. Bytes 0 to 79 are encrypted using the AES wrapping key. (See the section “Protection of Cryptographic Keys” on page 7-490 for the encryption algorithm.) The result is placed back in byte offsets 0-79 of the parameter block. The contents of the AES wrapping-key verification-pattern register are placed in byte offsets 80-111 of the parameter block.

PCKMO-Encrypt-ECC-Ed25519-Key (Function Code 40)

This function is available only when message-security-assist extension 9 is installed. The locations of the operands and addresses used by the instruction are as shown in Figure 10-41 on page 10-80.

The parameter block used for the function has the following format:

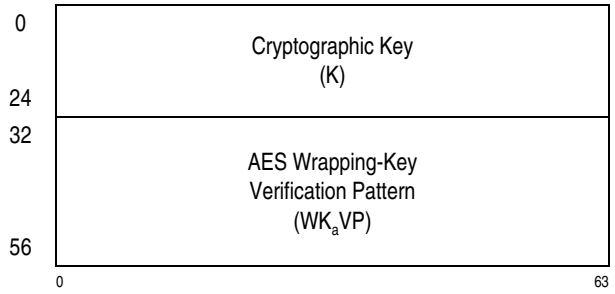

Figure 10-54. Parameter Block for PCKMO-Encrypt-ECC-Ed25519-Key

The 255 bit cryptographic key, K, is right aligned in byte offsets 0-31 of the parameter block and has a 1 bit zero pad. The programmer must use a zero for the padding or unpredictable results are possible when using this key. The whole 32 byte field is encrypted using the AES wrapping key. (See the section "Protection of Cryptographic Keys" on page 7-490 for the encryption algorithm.) The result is placed back in byte offsets 0-31 of the parameter block. The contents of the AES wrapping-key verification-pattern register are placed in byte offsets 32-63 of the parameter block.

PCKMO-Encrypt-ECC-Ed448-Key (Function Code 41)

This function is available only when message-security-assist extension 9 is installed. The locations of the operands and addresses used by the instruction are as shown in Figure 10-41 on page 10-80.

The parameter block used for the function has the following format:

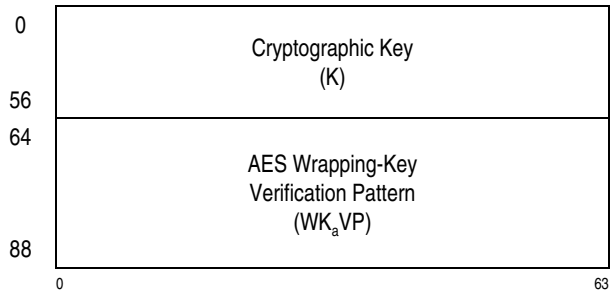

Figure 10-55. Parameter Block for PCKMO-Encrypt-ECC-Ed448-Key

Bytes 0 to 63 of the paramater block are encrypted using the AES wrapping key. (See the section "Protection of Cryptographic Keys" on page 7-490 for the encryption algorithm.) The 56-byte cryptographic key, K, is in byte offsets 8-63 of the parameter block and padding is in bytes 0-7. The result is placed back in byte offsets 0-63 of the parameter block. The contents of the AES wrapping-key verification-pattern register are placed in byte offsets 64-95 of the parameter block.

PCKMO-Encrypt-HMAC-512-Key (Function Code 118)

The locations of the operands and addresses used by the instruction are as shown in Figure 10-41 on page 10-80.

The parameter block used for the function has the following format:

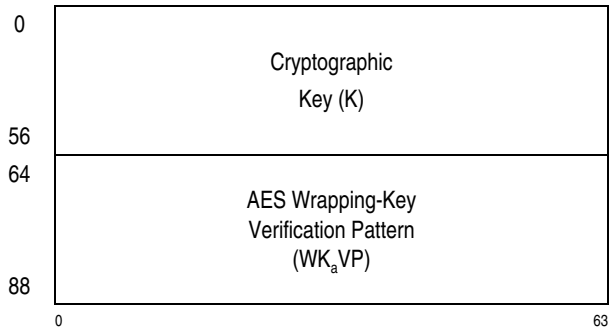

Figure 10-56. Parameter Block for PCKMO-Encrypt-HMAC-512-Key

The 64-byte cryptographic key, K, in byte offsets 0-63 of the parameter block is encrypted using the AES wrapping key. (See the section "Protection of Cryptographic Keys" on page 7-490 for the encryption algorithm.) The result is placed back in byte offsets 0-63 of the parameter block. The contents of the AES wrapping-key verification-pattern register are placed in byte offsets 64-95 of the parameter block.

PCKMO-Encrypt-HMAC-1024-Key (Function Code 122)

The locations of the operands and addresses used by the instruction are as shown in Figure 10-41 on page 10-80.

The parameter block used for the function has the following format:

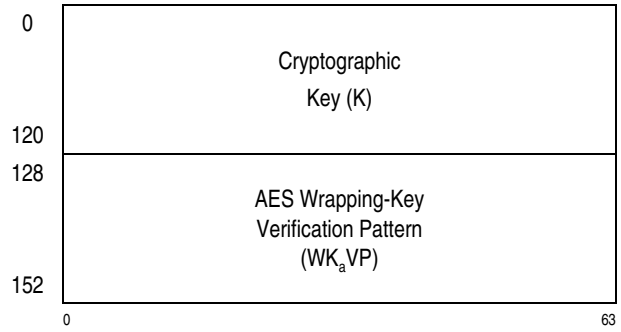

Figure 10-57. Parameter Block for PCKMO-Encrypt-HMAC-1024-Key

The 128-byte cryptographic key, K, in byte offsets 0-127 of the parameter block is encrypted using the AES wrapping key. (See the section "Protection of Cryptographic Keys" on page 7-490 for the encryption algorithm.) The result is placed back in byte offsets 0-127 of the parameter block. The contents of the AES wrapping-key verification-pattern register are placed in byte offsets 128-159 of the parameter block.

PCKMO-Query-Authentication-Information (Function Code 127)

The locations of the operands and addresses used by the instruction are as shown in Figure 10-41 on page 10-80.

The PCKMO-query-authentication-information function stores the information that can be usd by the program to authenticate the running instruction's firmware code level (IFCL) currently installed on the model into the format-0 parameter block for PCKMO-query-authentication-information. Condition code remains unchanged when execution of the PCKMO-query-authentication-information function completes.

The format-0 parameter block used for the PCKMO-query-authentication-information function has the following format:

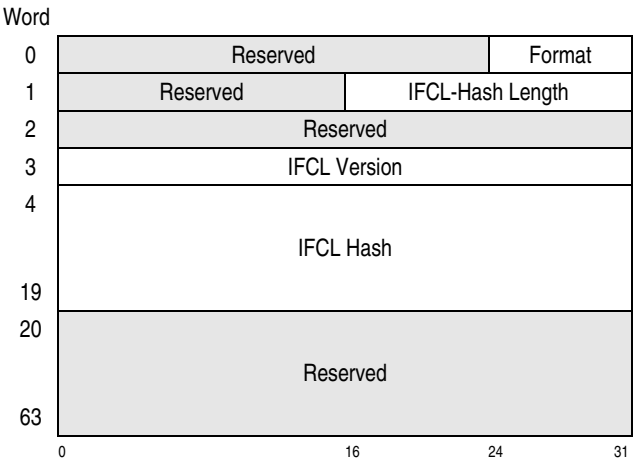

Figure 10-58. Format-0 Parameter Block for PCKMO-Query-Authentication-Information

The format-0 parameter block contains the following fields:

Reserved: Bytes 0-2 of word 0, bytes 0-1 of word 1, word 2, and words 20-63 are reserved and stored as zeros.

Format: Byte 3 of word 0 contains an 8-bit unsigned binary integer whose value specifies the format of the parameter block. A format value of zero indicates a format-0 parameter block. When a format-0 parameter block is stored, the value of this field is set to zero.

IFCL-Hash Length: Bytes 2-3 of word 1 contain a 16-bit unsigned binary integer specifying the number of bytes of the IFCL hash stored in the IFCL hash field. When the IFCL hash is less than or equal to 64 bytes, the IFCL-hash length field is set to the actual length of the IFCL hash. When the IFCL hash is larger than 64 bytes, the IFCL-hash length field is set to 64.

IFCL Version: Word 3 contains a 32-bit unsigned binary integer specifying the version number of the IFCL.

IFCL Hash: Words 4-19 contain the hash value of the IFCL. The IFCL-hash length field specifies the number of bytes that are in the IFCL hash field. The IFCL hash value is left aligned. When the IFCL hash is less than 64 bytes, it is padded with zeros on the

right. When the IFCL hash is larger than 64 bytes, only the leftmost 64 bytes of the IFCL hash are stored.

Common Operation

If the CPU is enabled to update counters in the cryptography-counter set, then instruction execution of an operation other than PCKMO-Query and PCKMO-Query-Authentication-Information also includes updating the appropriate counter.

Special Conditions

A specification exception is recognized and no other action is taken if any of the following occurs:

1. Bit 56 of general register 0 is not zero.
2. Bits 57-63 of general register 0 specify an unassigned or uninstalled function code.

Condition Code: The code remains unchanged.

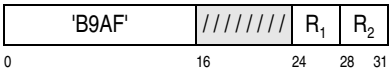
Program Exceptions:

- Access (fetch, parameter block; store, parameter block; fetch and store, cryptography counter)
- Operation (if the message-security-assist extension 3 is not installed)
- Privileged operation
- Specification
- Transaction constraint

Programming Note: Each set of PCKMO-Encrypt-DEA/TDEA-Key functions, PCKMO-Encrypt-AES-Key functions, PCKMO-Encrypt-ECC-Key functions, and PCKMO-Encrypt-HMAC-Key functions can be independently disabled by an external means. When a set is disabled, functions in the set appear as if they were not installed.

PERFORM FRAME MANAGEMENT FUNCTION

PFMF R_1,R_2 [RRE]



Subject to the controls in the first-operand register, a frame-management function is performed for the storage frame designated by the second-operand address.

The contents of general register R_1 are as follows:

Frame-management function indications: Bit positions 44-47 of general register R_1 contain the frame-management function indications (FMFI), as follows:

Reserved: Bits 44 and 45 are reserved and must contain zeros; otherwise, a specification exception is recognized.

Set-Key Control (SK): Bit 46 controls whether the storage key for each 4 K-byte block in the frame is set from bits 56-62 of general register R_1. When the SK control is zero, the keys are not set; when the SK control is one, the keys are set.

Clear-Frame Control (CF): Bit 47 controls whether the frame is set to zeros. When the CF control is zero, no clearing operation is performed. When the CF control is one, the frame is cleared to zeros.

Usage Indication (UI): Bit position 48 of general register R_1 contains the usage indication (UI). When bit 48 is zero, it indicates that the program does not anticipate immediate usage of the frame. When bit 48 is one, it indicates that program anticipates usage of the frame in the near future.

Frame-Size Code (FSC): Bits 49-51 of general register R_1 contain the frame-size code (FSC), as follows:

FSC	Meaning
0	4 K-byte frame
1	1 M-byte frame
2	2 G-byte frame
3-7	Reserved

Reference-Bit Update Mask (MR): When the set-key control, bit 46 of general register R_1, is one, bit 53 of general register R_1 controls whether updates to the reference bit in the storage key may be bypassed, as described below. When the set-key control is zero, bit 53 of general register R_1 is ignored.

Change-Bit Update Mask (MC): When the set-key control, bit 46 of general register R_1, is one, bit 54 of general register R_1 controls whether updates to the

change bit in the storage key may be bypassed. When the set-key control is zero, bit 54 of general register R_1 is ignored.

When the conditional-SSKE facility is installed, the handling of the MR and MC bits is identical to the handling of the corresponding bits of the M_3 field of the SET STORAGE KEY EXTENDED instruction (described on page 10-142), except that general register R_1 is not updated with the contents of the previous key, and the condition code is not changed. When the conditional-SSKE facility is not installed, the MR and MC bits are ignored.

Key: When the set-key control, bit 46 of general register R_1, is one, bits 56-62 of the register contain the storage key to be set for each 4 K-byte block in the frame, with the access-protection bits, fetch-protection bit, reference bit, and change bit in bit positions 56-59, 60, 61, and 62, respectively. When the set-key control is zero, bits 56-62 of general register R_1 are ignored.

Bit positions 0-31 general register R_1 are ignored. Bit positions 32-45, 55, and 63 of general register R_1 are reserved and must contain zeros. When the nonquiescing key-setting facility is not installed, bit position 52 of general register R_1 is also reserved and must contain zero. If any reserved bit position in general register R_1 does not contain zeros, a specification exception is recognized. When the nonquiescing key-setting facility is installed, bit position 52 of general register R_1 is ignored.

General register R_2 contains the real or absolute address of the storage frame upon which the frame-management function is to be performed. When the frame-size code designates a 4 K-byte block, the second-operand address is real; when the frame-size code designates a 1 M-byte or 2 G-byte block the second-operand address is absolute. The handling of the address in general register R_2 depends on the addressing mode. In the 24-bit addressing mode, the contents of bit positions 40-51 of the register, with 12 rightmost zeros appended, are the address, and bits 0-39 and 52-63 in the register are ignored. In the 31-bit addressing mode, the contents of bit positions 33-51 of the register, with 12 rightmost zeros appended, are the address, and bits 0-32 and 52-63 in the register are ignored. In the 64-bit addressing mode, the contents of bit positions 0-51 of the register, with 12 rightmost zeros appended, are the address, and bits 52-63 in the register are ignored.

The contents of the registers just described are shown in Figure 10-59.

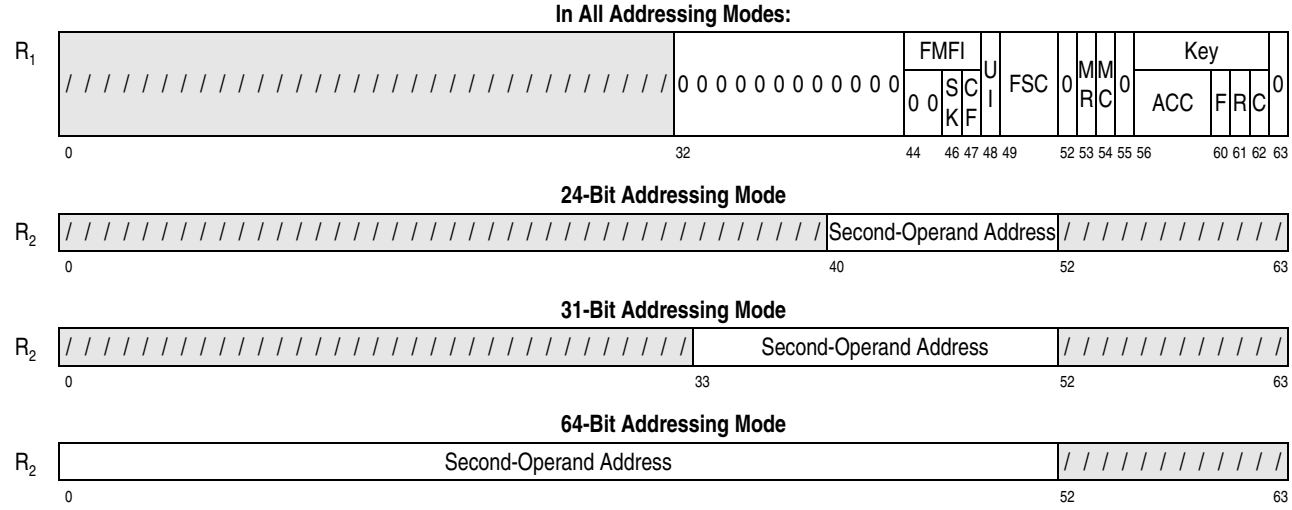


Figure 10-59. Register Contents for PERFORM FRAME-MANAGEMENT FUNCTION (Part 1 of 2)

Explanation:

ACC	Access-protection bits of the storage key
C	Change bit of the storage key
CF	Clear-frame control
F	Fetch-protection bit of the storage key
FMFI	Frame-management function indication
FSC	Frame-size code
MC	Change-bit-update mask
MR	Reference-bit-update mask
R	Reference bit of the storage key
SK	Set-key control
UI	Usage indication

Figure 10-59. Register Contents for PERFORM FRAME-MANAGEMENT FUNCTION (Part 2 of 2)

When the frame-size code is 0, the specified frame-management functions are performed for the 4 K-byte frame specified by the second operand. General register R_2 is unmodified in this case.

When the frame-size code is 1, the specified frame-management functions are performed for one or more 4 K-byte blocks within the 1 M-byte frame, beginning with the block specified by the second-operand address, and continuing to the right with each successive block up to the next 1 M-byte boundary.

When the enhanced-DAT facility 2 is installed and the frame-size code is 2, the specified frame-management functions are performed for one or more 4 K-byte blocks within the 2 G-byte frame, beginning with the block specified by the second-operand address, and continuing to the right with each successive block up to the next 2 G-byte boundary. When the enhanced-DAT facility 2 is not installed, a frame-size code of 2 is reserved.

PERFORM FRAME MANAGEMENT FUNCTION is interruptible. When the frame-size code is 1 or 2, an interruption may occur between the processing of successive 4 K-byte blocks. When both the clear-frame and set-key controls are one, an interruption may also occur between the clearing and key-setting operations for an individual 4 K-byte block.

When the frame-size code is 1 or 2, processing is as follows:

- When both the clear-frame and set-key functions are specified, both functions are completed for a 4 K-byte block before proceeding to the next block.
- When an interruption occurs (other than one that follows termination), the second-operand address in general register R_2 is updated by the number of 4 K-byte blocks completely processed, so the instruction, when reexecuted, resumes at the point of interruption.
- When the instruction completes without interruption, the second-operand address in general register R_2 is updated to the next 1 M-byte boundary (FSC=1) or 2 G-byte boundary (FSC=2).
- In any of the above cases, bit 52-63 of general register R_2 are unchanged.

When the CPU is in the 24-bit addressing mode and the frame-size code is 1, bits positions 32-39 of general register R_2 are set to zeros and bits 0-31 of the register are unchanged. When the CPU is in the 24-bit addressing mode and the frame-size code is 2, a specification exception is recognized.

When the CPU is in the 31-bit addressing mode, and the frame-size code is either 1 or 2, bit position 32 of general register R_2 is set to zero and bits 0-31 of general register R_2 are unchanged.

When the clear-frame control is one, references to main storage within the second operand may be multiple-access references and are not necessarily performed in a left-to-right direction as observed by other CPUs and by channel programs. The clear operation is not subject to key-controlled protection; however low-address protection applies regardless of whether the frame-size code designates a 4 K-byte, 1 M-byte, or 2 G-byte frame (that is, regardless of whether the second-operand address is real or absolute).

When the set-key control is one, the operation for each 4 K-byte block is similar to that described in "SET STORAGE KEY EXTENDED" on page 10-142, except that when the keys for multiple blocks are set, the condition code and the contents of general register R_1 are unchanged.

A serialization and checkpoint-synchronization function is performed before the operation begins and again after the operation is completed, except that when the seven bits of all storage keys to be set are the same as bits 56-62 of general register R_1, or when the MR and MC bits allow all the storage keys to remain unchanged, it is unpredictable whether the serialization and checkpoint-synchronization functions are performed after the operation completes. See "SET STORAGE KEY EXTENDED" on page 10-142 for details on the cases where setting of the key may be bypassed.

When the set-key control is one, and the nonquiescing key-setting facility is not installed, a quiescing operation is performed. When the set-key control is one, and the nonquiescing key-setting facility is installed, a quiescing operation is not necessarily performed. See "Storage-Key Accesses" on page 5-128 for a discussion of the effects of quiescing on key-setting instructions, and see "Quiescing" on page 5-141 for details on the quiescing operation.

Provided that there is no other access to the storage by other CPUs or the channel subsystem, the final results of the instruction reflect the specified key value, including the specified R and C values when MR and MC are zero, respectively. Subject to this constraint, it is unpredictable whether the clear-frame or the set-key operation is performed first when both of the respective controls are one. When both the clear-frame and set-key controls are one, and either the MR or MC bit is also one, and the clear operation is performed first, the storage key that is compared with bits 56-62 of general register R_1 in the set-key operation is the key following the clear operation (that is, both the R and C bits will have been set to one by the clear operation).

Before a quiescing key-setting operation is performed, transactional execution by other CPUs in the configuration is aborted with abort code 255, condition code 2. The aborting of transactional execution affects at least those CPUs accessing the locations (transactionally or nontransactionally) for which storage keys are being set. It is unpredictable whether some or all other CPUs are affected as well.

Special Conditions

A specification exception is recognized and the operation is suppressed for any of the following conditions:

- Bits 32-45, 55, or 63 of general register R_1 are not zero.
- When the nonquiescing key-setting facility is not installed, bit 52 of general register R_1 is not zero.
- The frame-size code specifies a reserved value.
- The CPU is in the 24-bit addressing mode and the frame-size code is 2.

When the storage-key-removal facility is installed and bit 46 (SK) of general register R_1 is one, a special-operation exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, low-address-protection only, operand 2, when the clear-frame control is one)
- Addressing (operand 2)
- Operation (enhanced-DAT facility not installed)
- Privileged operation
- Special operation
- Specification
- Transaction constraint

Programming Notes:

1. When PFMF is issued with the set-key control set to one, the program must ensure that no other CPU or channel subsystem is simultaneously accessing the storage designated by general register R_2. Otherwise, unpredictable results may be observed by the other CPUs and channel subsystem, including the alteration of the block designated by general register R_2. See the programming note on page 5-130 for more information.
2. It is configuration dependent whether access exceptions are recognized for the second operand when the clear-frame (CF) and set-key (SK) controls are both zero.
3. It is configuration dependent whether the second-operand address in general register R_2 is

updated when the clear-frame (CF) and set-key (SK) controls are both zero.

4. When the move-page-and-set-key facility is installed, some models also implement a performance enhancement for simultaneously clearing a frame and setting its storage key. This is likely to be the fastest way to perform this combined operation. Even though these two functions are combined, another CPU may observe the reference and change bits being set to one, before being set to their final value by the key setting operation. The CPU can invoke this mode of operation for PERFORM FRAME MANAGEMENT FUNCTION when all of the following conditions are met:

   - The set-key control (SK in R_1 bit 46) and the clear-frame control (CF in R_1 bit 47) are both one.
   - The usage indication (UI) is zero. (R_1 bit 48).
   - The reference-bit update mask (MR in R_1 bit 53) and the change-bit update mask (MC in R_1 bit 54) are both zero.

PERFORM TIMING FACILITY FUNCTION

PTFF [E]

'0104'

0 15

A timing facility function specified by the function code in general register 0 is performed. The condition code is set to indicate the outcome of the function. General register 1 contains the address of a parameter block in storage. PTFF query functions place information in the parameter block; PTFF control functions use information obtained from the parameter block.

As observed by other CPUs and channel programs, references to the parameter block may be multiple-access references, accesses to these storage locations are not necessarily block-concurrent, and the sequence of these accesses or references is undefined.

Bit positions 57-63 of general register 0 contain the function code. Figure 10-61 on page 10-91 shows the assigned function codes. Bit 56 of general register 0 must be zero; otherwise, a specification exception is recognized. All other bits of general register 0 are ignored.

General register 1 contains the logical address of the leftmost byte of the parameter block in storage. In the 24-bit addressing mode, the contents of bit positions 40-63 of general register 1 constitute the address, and the contents of bit positions 0-39 are ignored. In the 31-bit addressing mode, the contents of bit positions 33-63 of general register 1 constitute the address, and the contents of bit positions 0-32 are ignored. In the 64-bit addressing mode, the contents of bit positions 0-63 of general register 1 constitute the address.

Figure 10-60 shows the contents of the general registers just described.

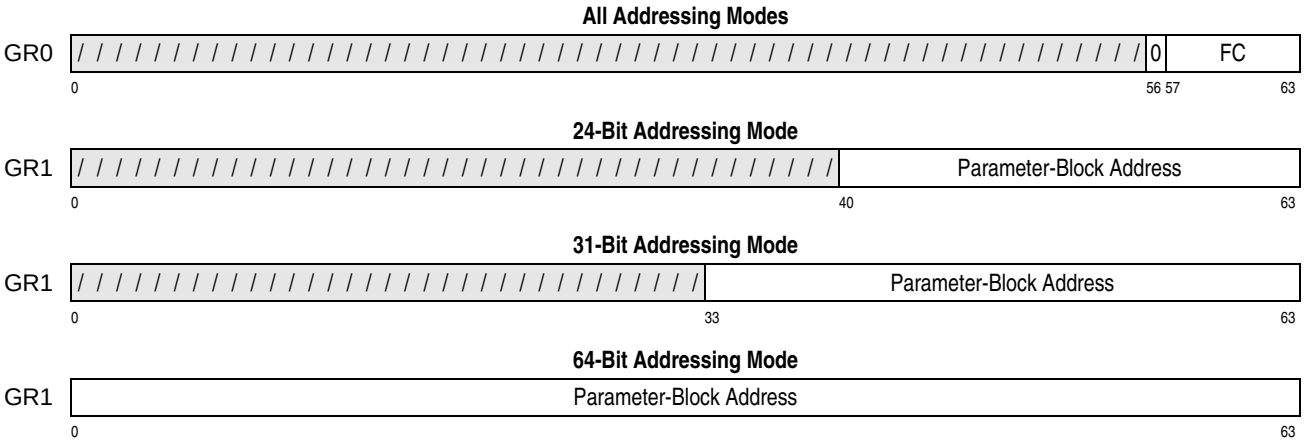

Figure 10-60. General Register Assignment for PERFORM TIMING FACILITY FUNCTION

In the access-register mode, access register 1 specifies the address space containing the parameter block.

The function codes for PERFORM TIMING FACILITY FUNCTION are as follows.

Code		Function	Parm. Block Size (bytes)	Availability
Hex	Dec			
00	0	PTFF-QAF	16	U, SM
01	1	PTFF-QTO	32	U, SM
02	2	PTFF-QSI	56	U
03	3	PTFF-QPT	8	U
04	4	PTFF-QUI	256	U, SM
05	5	PTFF-QTOU	40	U
06	6	PTFF-QTSE	16	U
0A	10	PTFF-QSIE	96	U
0D	13	PTFF-QTOUE	80	U
41	65	PTFF-STO	8	P
45	69	PTFF-STOU	8	P
49	73	PTFF-STOE	16	P
4D	77	PTFF-STOUE	16	P

Explanation:

P Privileged: Available only in the supervisor state.

SM Secure Mode: Available when operating in secure mode and non-secure mode. If this keyword is not listed, it means the function is only available in non-secure mode.

U Unprivileged: Available in both the problem state and the supervisor state

Figure 10-61. Function Codes for PERFORM TIMING FACILITY FUNCTION

All other function codes are unassigned.

The PTFF-QAF (Query Available Functions) function provides the means of indicating the availability of the other functions.

Function 0: PTFF-QAF (Query Available Functions)

The parameter block used for the function has the following format:

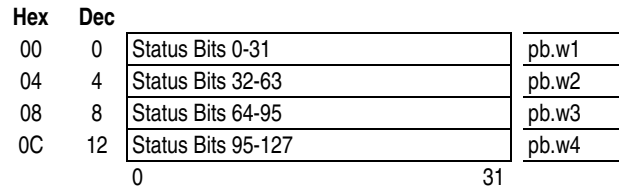

Figure 10-62. Parameter Block for PTFF-QAF (Query Available Functions)

A 128-bit field is stored in the parameter block. Bits 0-127 of this field correspond to function codes 0-127, respectively, of the PTFF instruction. When a bit is one, the corresponding function is installed; otherwise, the function is not installed. The availability of an installed function is indicated by the condition code returned by the attempted execution of the function.

Function 1: PTFF-QTO (Query TOD Offset)

The parameter block used for the function has the following format:

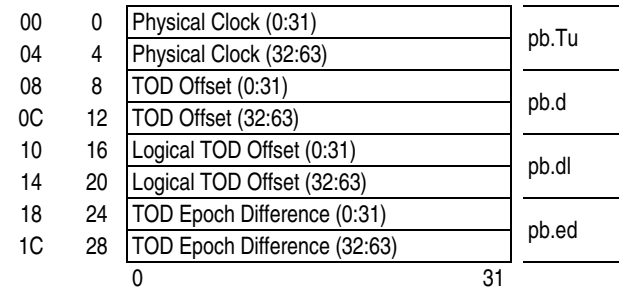

Figure 10-63. Parameter Block for PTFF-QTO (Query TOD Offset)

When the STP-hardware-based-TOD-clock-steering facility is not installed, the 64-bit physical-clock value returned (pb.Tu) is the value of the physical clock at the most recent TOD-offset-update event. When the STP-hardware-based-TOD-clock-steering facility is installed, the 64-bit physical-clock value returned is the current physical clock.

The TOD offset returned is a 64-bit signed binary integer (pb.d) that indicates the value of the TOD-offset (d). This value indicates the amount of steering

that has been applied (actually in the case of offset-based TOD-clock steering, or conceptually in the case of hardware-based TOD-clock steering) to the physical clock to form the system TOD clock. The TOD epoch difference is not included in this value.

The 64-bit logical-TOD-offset value returned (pb.dl) indicates the current value of the difference between the TOD clock and the physical clock. The value includes the TOD epoch difference. Depending on the TOD clock resolution capability of the model, a model dependent number of the low order bits of bits 32:63 may be set to zero by the machine.

The 64-bit TOD epoch difference value returned (pb.ed) is the TOD epoch difference (includes both the user-specified epoch difference and the sync-check offset). Depending on the TOD clock resolution capability of the model, a model dependent number of the low order bits of bits 32:63 may be set to zero by the machine.

Function 2: PTFF-QSI (Query Steering Information)

The parameter block used for the function has the following format:

Hex	Dec		
00	0	Physical Clock (0:31)	pb.Tu
04	4	Physical Clock (32:63)	
08	8	Old Episode Start Time (0:31)	pb.old.s
0C	12	Old Episode Start Time (32:63)	
10	16	Old Episode Base Offset (0:31)	pb.old.b
14	20	Old Episode Base Offset (32:63)	
18	24	Old Episode Fine-Steering Rate	pb.old.f
1C	28	Old Episode Gross-Steering Rate	pb.old.g
20	32	New Episode Start Time (0:31)	pb.new.s
24	36	New Episode Start Time (32:63)	
28	40	New Episode Base Offset (0:31)	pb.new.b
2C	44	New Episode Base Offset (32:63)	
30	48	New Episode Fine-Steering Rate	pb.new.f
34	52	New Episode Gross-Steering Rate	pb.new.g
		0 31	

Figure 10-64. Parameter Block for PTFF-QSI (Query Steering Information)

When the STP-hardware-based-TOD-clock-steering facility is not installed, the 64-bit physical-clock value returned (pb.Tu) is the value of the physical clock at the most recent TOD-offset-update event. When the STP-hardware-based-TOD-clock-steering facility is installed, the 64-bit physical-clock value returned is the current physical clock.

The remaining fields are the values of the old-episode and new-episode registers.

Function 3: PTFF-QPT (Query Physical Clock)

The parameter block used for the function has the following format:

Hex	Dec		
00	0	Physical Clock (0:31)	pb.Tr
04	4	Physical Clock (32:63)	
		0 31	

Figure 10-65. Parameter Block for PTFF-QPT (Query Physical Clock)

The 64-bit physical-clock value returned (pb.Tr) is the current value of the physical clock. Zeros are stored for the rightmost bit positions that are not provided by the physical clock. When the clock is running, two executions of PTFF-QPT, either on the same or different CPUs, do not necessarily return different values of the clock.

Function 4: PTFF-QUI (Query UTC Information)

The parameter block used for the function has the following format:

Hex	Dec	
00	0	UTC Information Block (UIB)
⋮	⋮	
FC	252	
		0 31

Figure 10-66. Parameter Block for PTFF-QUI (Query UTC Information)

The UIB is described in “UTC Information Block (UIB)” on page 4-59.

Function 5: PTFF-QTOU (Query TOD Offset User)

The parameter block used for the function has the following format:

Hex	Dec		
00	0	Physical Clock (0:31)	pb.Tu
04	4	Physical Clock (32:63)	
08	8	TOD Offset (0:31)	pb.d
0C	12	TOD Offset (32:63	
10	16	Logical TOD Offset (0:31)	pb.dl
14	20	Logical TOD Offset (32:63)	
18	24	TOD Epoch Difference (0:31)	pb.ed
1C	28	TOD Epoch Difference (32:63)	
20	32	TOD User Specified Epoch Difference (0:31)	pb.edu
24	36	TOD User Specified Epoch Difference (32:63)	
		0 31	

Figure 10-67. Parameter Block for PTFF-QTOU (Query TOD Offset User)

Bytes 0-31 are as defined for the PTFF query-TOD-offset function.

The 64-bit TOD user specified epoch difference value returned is the user-specified portion of the guest epoch difference for the current level of CPU execution. It does not include the sync-check offset portion of the guest epoch difference. When executed at the basic-machine or LPAR hypervisor level, this value is zero. When executed at the guest 1 level, this value is the guest epoch difference excluding the guest 1 sync-check offset portion of the guest 1 epoch difference. When executed at the guest 2 level, this value is the guest epoch difference excluding the guest 2 sync-check offset portion of the guest 2 epoch difference.

Function 6: PTFF-QTSE (Query Time-Stamp Event)

The parameter block used for the function has the following format:

Hex	Dec	
00	0	Port 0 TSE (0:31)
04	4	Port 0 TSE (32:63)
08	8	Port 1 TSE (0:31)
0C	12	Port 1 TSE (32:63)
		0 31

Figure 10-68. Parameter Block for PTFF-QTSE (Query Time-Stamp Event)

The 64-bit system-TOD-clock value at the most recent time-stamp event (TSE) for EAF port 0 is stored to bytes 0-7 of the parameter block. The 64-bit system-TOD-clock value at the most recent time-stamp event (TSE) for EAF port 1 is stored to bytes 8-15 of the parameter block.

When an EAF port is in the PPS-attachment mode, the pulse-per-second (PPS) signal causes a time-stamp event for that port.

Programming Note: When the multiple-epoch facility is installed, on rare occasions, the epoch index and epoch difference for the configuration during the execution of PTFF-QTSE may differ from the epoch index and epoch difference when the last TSE for either port occurred. It is the program's responsibility to manage such potential differences.

Function 10: PTFF-QSIE (Query Steering Information Extended)

The parameter block used for the function has the following format:

Hex	Dec		
00	0	Physical Clock (0:31)	pb.Tu
04	4	Physical Clock (32:63)	
08	8	Physical Clock (64:95)	
0C	12	Physical Clock (96:127)	
10	16	Old Episode Start Time (0:31)	pb.old.s
14	20	Old Episode Start Time (32:63)	
18	24	Old Episode Start Time (64:95)	
1C	28	Old Episode Start Time (96:127)	
20	32	Old Episode Base Offset (0:31)	pb.old.b
24	36	Old Episode Base Offset (32:63)	
28	40	Old Episode Base Offset (64:95)	
2C	44	Old Episode Base Offset (96:127)	
30	48	Old Episode Fine-Steering Rate	pb.old.f
34	52	Old Episode Gross-Steering Rate	pb.old.g
38	56	New Episode Fine-Steering Rate	pb.new.f
3C	60	New Episode Gross-Steering Rate	pb.new.g
40	64	New Episode Start Time (0:31)	pb.new.s
44	68	New Episode Start Time (32:63)	
48	72	New Episode Start Time (64:95)	
4C	76	New Episode Start Time (96:127)	
50	80	New Episode Base Offset (0:31)	pb.new.b
54	84	New Episode Base Offset (32:63)	
58	88	New Episode Base Offset (64:95)	
5C	92	New Episode Base Offset (96:127)	
		0 31	

Figure 10-69. Parameter Block for PTFF-QSIE (Query Steering Information Extended)

The PTFF-QSIE function is analogous to the PTFF-QSI function, except that the physical-clock, old-episode-start-time, old-episode-base-offset, new-episode-start-time, and new-episode-base-offset fields each contain 128 bits, rather than 64 bits.

The physical-clock, old-episode-start-time, and new-episode-start-time fields each contain a 72-bit unsigned binary integer in the rightmost bits and zeros in the leftmost 56 bits. The old-episode-base-offset and new-episode-base-offset fields each contain a 72-bit signed binary integer in the rightmost bits, and the sign bit in bit 56 is extended to the left 56 bits to form a 128-bit signed binary integer.

Programming Note: The PTFF-QSIE function is available when the multiple-epoch facility is installed in the configuration.

Function 13: PTFF-QTOUE (Query TOD Offset User Extended)

The parameter block used for the function has the following format:

Hex	Dec		
00	0	Physical Clock (0:31)	pb.Tu
04	4	Physical Clock (32:63)	
08	8	Physical Clock (64:96)	
0C	12	Physical Clock (96:127)	
10	16	TOD Offset (0:31)	pb.d
14	20	TOD Offset (32:63	
18	24	TOD Offset (64:95)	
1C	28	TOD Offset (96:127)	
20	32	Logical TOD Offset (0:31)	pb.dl
24	36	Logical TOD Offset (32:63)	
28	40	Logical TOD Offset (64:95)	
2C	44	Logical TOD Offset (96:127)	
30	48	TOD Epoch Difference (0:31)	pb.ed
34	52	TOD Epoch Difference (32:63)	
38	56	TOD Epoch Difference (64:95)	
3C	60	TOD Epoch Difference (96:127)	
40	64	TOD User Specified Epoch Difference (0:31)	pb.edu
44	68	TOD User Specified Epoch Difference (32:63)	
48	72	TOD User Specified Epoch Difference (64:95)	
4C	76	TOD User Specified Epoch Difference (96:127)	
		0 31	

Figure 10-70. Parameter Block for PTFF-QTOUE (Query TOD Offset User Extended)

The PTFF-QTOUE function is analogous to the PTFF-QTOU function, except each field is 128 bits, rather than 64 bits.

The physical-clock field contains a 72-bit unsigned binary integer in the rightmost bits, and bits 0-55 are stored as zeros. The TOD-offset, logical-TOD-offset, TOD-epoch-difference, and TOD-user-specified-epoch-difference fields each contain a 72-bit signed binary integer in the rightmost bits. The sign bit in bit 56 is extended to the left 56 bits to form a 128-bit signed binary integer.

Programming Note: The PTFF-QTOUE function is available when the multiple-epoch facility is installed in the configuration.

Function 65: PTFF-STO (Set TOD Offset)

The parameter block used for the function has the following format:

Hex	Dec		
00	0	New TOD Epoch Difference (0:31)	pb.d
04	4	New TOD Epoch Difference (32:63)	
		0 31	

Figure 10-71. Parameter Block for PTFF-STO (Set TOD Offset)

The function specifies a value that is to replace the TOD epoch difference; no new episode is scheduled and the change takes effect immediately. The function operates only on the TOD epoch difference (D), and the change takes place immediately. The function operates on the combined TOD-epoch difference (D = SCO + Du) and does not modify the sync-check offset. If the sync-check offset is nonzero, a subsequent sync-check-offset correction will modify the TOD epoch difference to reflect the amount of the correction. Depending on the TOD clock resolution capability of the model, a model dependent number of the contiguous rightmost bits of bits 32-63 may be ignored by the machine and treated as if they were zeros.

Programming Note: When the multiple-epoch facility is installed, the PTFF-STO function is deprecated, and the PTFF-STOE function should be used.

PTFF-STO provides no means by which an epoch index can be set. When the multiple-epoch facility is installed, the use of PTFF-STO may result in inconsistent values stored by SET CLOCK EXTENDED if the epoch index was previously set to a nonzero value.

At some future date, the PTFF-STO function may be removed from the architecture.

Function 69: PTFF-STOU (Set TOD Offset User)

The parameter block used for the function has the following format:

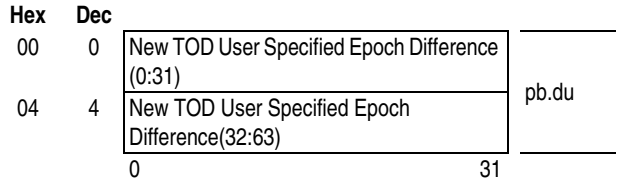

Figure 10-72. Parameter Block for PTFF-STOU (Set TOD Offset User)

The function specifies a value that is to replace the user-specified portion of the TOD epoch difference; no new episode is scheduled and the change takes effect immediately. Depending on the TOD clock resolution capability of the model, a model dependent number of the low order bits of bits 32:63 may be ignored by the machine and treated as if they were zeros.

When the multiple-epoch facility is installed, the PTFF-STOU function is deprecated, and the PTFF-STOUE function should be used.

Programming Note: At some future date, the PTFF-STOU function may be removed from the architecture.

Function 73: PTFF-STOE (Set TOD Offset Extended)

The parameter block used for the function has the following format:

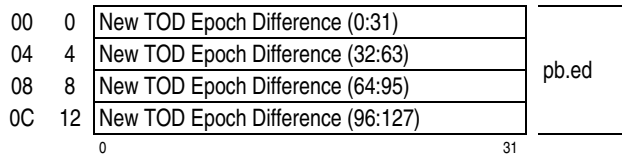

Figure 10-73. Parameter Block for PTFF-STOE (Set TOD Offset Extended)

The PTFF-STOE function is analogous to the PTFF-STO function, except that the new-TOD-epoch-difference field is 128 bits for PTFF-STOE.

The new-TOD-epoch-difference field contains a 72-bit signed binary in the rightmost bits. Bits 0-56 of the field should contain either all zeros or all ones corresponding to the sign of the new TOD epoch difference in bit 56, thus forming a 128-bit signed binary integer in the field. If a mixture of zeros and ones appear in bits 0-56, the results are unpredictable.

The function specifies a value that is to replace the TOD epoch difference; no new episode is scheduled and the change takes effect immediately. The function operates only on the TOD epoch difference (D); no new episode is scheduled, and the change takes place immediately. The function operates on the combined TOD-epoch difference (D = SCO + Du) and does not modify the sync-check offset. If the sync-check offset is nonzero, a subsequent sync-check-offset correction will modify the TOD epoch difference to reflect the amount of the correction.

Bit 127 of the new-TOD-epoch-difference field corresponds to a clock unit. Depending on the TOD-clock-resolution capability of the model, a model dependent number of the contiguous rightmost bits of bits 96-127 may be ignored by the machine and treated as if they were zeros.

Programming Note: The PTFF-STOE function is available when the multiple-epoch facility is installed in the configuration.

Function 77: PTFF-STOUE (Set TOD Offset User Extended)

The parameter block used for the function has the following format:

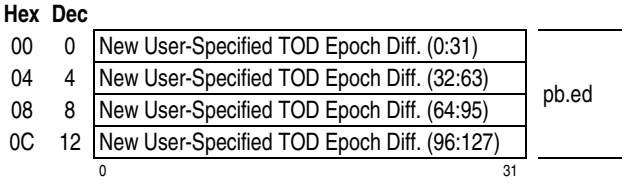

Figure 10-74. Parameter Block for PTFF-STOUE (Set TOD Offset User Extended)

The PTFF-STOUE function is analogous to the PTFF-STOU function, except that the new-TOD-epoch-difference field is 128 bits for PTFF-STOUE.

The new-user-specified-TOD-epoch-difference field contains a 72-bit signed binary in the rightmost bits.

Bits 0-56 of the field should contain either all zeros or all ones corresponding to the sign of the new user-specified TOD epoch difference in bit 56, thus forming a 128-bit signed binary integer in the field. If a mixture of zeros and ones appear in bits 0-56, the results are unpredictable.

The function specifies a value that is to replace the user-specified portion of the TOD epoch difference; no new episode is scheduled and the change takes effect immediately.

Bit 127 of the new-user-specified TOD-epoch-difference field corresponds to a clock unit. Depending on the TOD clock resolution capability of the model, a model dependent number of the contiguous rightmost bits of bits 96-127 may be ignored by the machine and treated as if they were zeros.

Programming Note: The PTFF-STOUE function is available when the multiple-epoch facility is installed in the configuration.

Special Conditions

A privileged operation exception is recognized if a PTFF control function is issued in the problem state.

A specification exception is recognized and no other action is taken if any of the following occurs:

1. Bit 56 of general register 0 is not zero.

2. Bits 57-63 of general register 0 specify an unassigned or uninstalled function code.

Resulting Condition Code:

0 Requested function performed
1 --
2 --
3 Requested function not available

Program Exceptions:

- Access (fetch, parameter block for control functions; store, parameter block for query functions)
- Operation (if the TOD-clock-steering facility instruction is not installed)
- Privileged operation (attempt to execute a PTFF control function in the problem state)
- Specification
- Transaction constraint

The priority of execution for the PTFF instruction is shown in Figure 10-75.

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Operation exception.
7.B	Transaction constraint.
8.	Specification exception due to bit 56 of general register 0 being one or bits 57-63 of general register 0 specifying an unassigned or uninstalled function code.
9.	Privileged-operation exception due to attempt to issue PTFF control function in the problem state.
10.	Condition code 3 due to a control function not available in supervisor state.
11.	Access exceptions for an access to the parameter block.
12.	Condition code 0 indicating successful completion.

Figure 10-75. Priority of Execution: PERFORM TIMING FACILITY FUNCTION (PTFF)

Programming Notes:

1. When the STP-hardware-based-TOD-clock-steering facility is not installed, the physical time (pb.Tu) returned in the parameter block for PTFF-QTO, PTFF-QTOU, and PTFF-QSI is the current value of the physical clock, but with zeros in positions to the right of the bit position incremented concurrently with each TOD-offset-update event. This value is not necessarily unique. The same value may be returned if the PTFF instruction is issued multiple times on the same CPU or issued at approximately the same time on different CPUs.

2. When the STP-hardware-based-TOD-clock-steering facility is not installed, the 64-bit value of the physical clock at the most recent TOD-offset-update event (pb.Tu) returned by PTFF-QTO, PTFF-QTOU, and PTFF-QSI may be used by the program to ensure that all events during a short routine occurred with no intervening TOD-offset-update events. This can be accomplished by issuing one of these queries at the beginning of the routine and the other at the end and reiterat-

ing if the value of pb.Tu before and the value of pb.Tu after are different.

3. When the STP-hardware-based-TOD-clock-steering facility is installed, there are no TOD-offset-update events, and pb.Tu reports the current value of the physical clock. Steering episode changes are reflected in the old and new episode start times.

4. For Query Steering Information, pb.Tu can be used to determine whether the machine is operating in the old or new episode. When pb.new.s ≤ pb.Tu, the machine is operating in the new episode, and none of the information returned by the query has changed since the most recent TOD-offset-update event. When pb.new.s > Pb.Tr, the machine is operating in the old episode, a new episode has been scheduled and has not yet taken effect. The program should avoid any dependency on the new episode values returned in this case, as it is possible the values may change again before the new episode takes effect.

5. Two or more executions of PTFF-QPT within a short period of time, either on the same or different CPUs, do not appear to step backwards, but are not necessarily unique. Thus, it is not always possible to use the values to determine the sequence of execution.

6. The Network Time Protocol (NTP) is used extensively in the Internet. A description of NTP may be found in Request for Comments (RFC) 1305. Figure 10-77 on page 10-98 shows the value of the TOD clock and NTP timestamp for 00:00:00 (0 am), UTC time, for several dates: January 1, 1900, January 1, 1972, and for that instant in time just after each of the 27 leap seconds that will have occurred through January, 2017. Each of these leap seconds is inserted in the UTC time scale beginning at 23:59:60 UTC of the day previous to the one listed and ending at 00:00:00 UTC of the day listed. Also included are values for the beginning of each year since the most recent leap second. Figure 10-76 on page 10-97 shows the values of the TOD clock and NTP timestamp for those instants just after the leftmost bit of one or the other has changed. For instants in the future, the number of leap seconds must be applied and this value is not yet known.

YYYY	MM	DD	hh mm ss	TOD Clock (Hex)				NTP Timestamp (Hex)			
1968	01	20	03:14:08.000000	7A12	0000	0000	0000	8000	0000	0000	0000
1971	05	11	11:56:53.685248	8000	0000	0000	0000	8637	BD05	AF6C	69B5*
2036	02	07	06:28:16.000000	F424	0000	0000	0000+	0000	0000	0000	0000
2042	09	17	23:53:47.370496–	0000	0000	0000	0000	0C6F	7A0B	5ED8	D36B*–

Explanation:

* Value is not exact.
\+ Leap seconds must be added to this value.
– Leap seconds must be subtracted from this value.

Figure 10-76. TOD Clock and NTP Timestamps When a Leftmost Bit Changes

Year	Month	Day	Leap Sec.	TOD Clock (Hex)	NTP Timestamp (Hex)

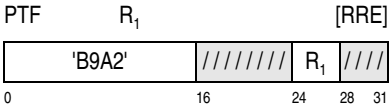
Figure 10-77. TOD Clock and NTP Timestamps

PERFORM TOPOLOGY FUNCTION



The contents of general register R_1 specify a function code in bit positions 56-63, as illustrated in Figure 10-78.

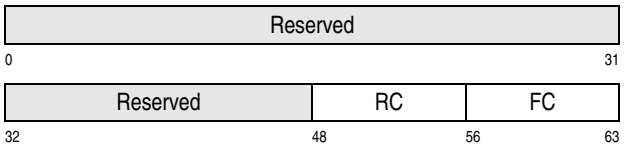


Figure 10-78. General-Register R_1 Format

The defined function codes are as follows:

FC	Meaning
0	Request horizontal polarization.
1	Request vertical polarization.
2	Check topology-change status.

Undefined function codes in the range 0-255 are reserved for future extensions.

Upon completion, if condition code 2 is set, a reason code is stored in bit positions 48-55 of general register R_1.

Bits 16-23 and 28-31 of the instruction are ignored.

Operation of Function Codes 0 and 1

When no exceptional conditions are detected, a process is initiated to place all CPUs in the configuration into the polarization specified by the function code, and condition code 0 is set. Completion of the process is asynchronous with respect to execution of the instruction and may or may not be completed when execution of the instruction completes.

Execution completes with condition code 2, and the reason code is set, for any of the following reasons:

RC	Reason
0	No reason specified.
1	The configuration is already polarized as specified by the function code.
2	A topology change is already in process

Operation of Function Code 2:

The topology-change-report-pending condition is checked. When a topology-change-report is not pending, condition code 0 is set. When a topology-change report is pending, condition code 1 is set.

A topology change is any alteration such that the contents of a SYSIB 15.1.2 would be different from the contents of the SYSIB 15.1.2 prior to the topology change.

A topology-change-report-pending condition is created when a topology-change process completes. A topology-change-report-pending condition is cleared for the configuration when any of the following is performed:

- Execution of PERFORM TOPOLOGY FUNCTION specifies function-code 2 that completes with condition code 1.
- Subsystem reset is performed.

Special Conditions

A specification exception is recognized for either of the following conditions:

- Bit positions 0-55 of general register R_1 are not zeros.
- An undefined function code is specified.

Resulting Condition Code: When the function code is 0 or 1, the condition code is set as follows:

0 Topology-change initiated
1 --
2 Request rejected
3 --

When the function code is 2, the condition code is set as follows:

0 Topology-change-report not pending
1 Topology-change report pending
2 --
3 --

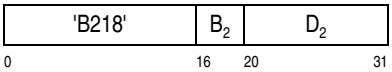
Program Exceptions:

- Operation (configuration-topology facility is not installed)
- Privileged operation
- Specification
- Transaction constraint

Programming Note: Further information on configuration topology may be found in “SYSIB 15.1.2 - 15.1.6 (Configuration Topology)” on page 10-170.

PROGRAM CALL

PC $D_2(B_2)$ [S]



A program-call number specified by the second-operand address is used in a two-level or three-level lookup to locate an entry-table entry (ETE). The pro-

gram is authorized to use the ETE when the AND of the PSW-key mask in control register 3 and the authorization key mask in the ETE is nonzero or when the CPU is in the supervisor state.

When the PC-type bit, bit 128 of the ETE, is zero, an operation called basic PROGRAM CALL is performed. When the PC-type bit is one, an operation called stacking PROGRAM CALL is performed.

Basic PROGRAM CALL, in the 24-bit or 31-bit addressing mode, loads the basic-addressing-mode bit, bits 33-62 of the updated instruction address, and the problem-state bit from the PSW into bit positions 32-63 of general register 14, and it leaves bits 0-31 of this register unchanged. In the 64-bit addressing mode, bits 0-62 of the updated instruction address and the problem-state bit are placed in bit positions 0-63 of general register 14. In any addressing mode, the PSW-key mask and PASN are placed in bit positions 32-63 of general register 3, and bits 0-31 of this register remain unchanged.

Stacking PROGRAM CALL places the entire PSW contents, except with an unpredictable PER mask, and also the PSW-key mask, PASN, SASN, and EAX in a linkage-stack program-call state entry that it forms. A called-space identification, an indication of whether the resulting addressing mode is the 64-bit mode, the numeric part of the program-call number, and the contents of general registers 0-15 and access registers 0-15 also are placed in the state entry. If the ASN-and-LX-reuse facility is installed and enabled, the PASTEIN and SASTEIN also are placed in the state entry.

For basic PROGRAM CALL, the extended-addressing-mode bit, bit 31 of the PSW, must have the same value as the entry-extended-addressing-mode bit, bit 129 of the ETE; otherwise, a special-operation exception is recognized. Basic PROGRAM CALL does not change bit 31 of the PSW and, therefore, does not switch between a basic addressing mode (the 24-bit or 31-bit mode) and the extended addressing mode (the 64-bit mode). In the 24-bit or 31-bit addressing mode, basic PROGRAM CALL sets the basic-addressing-mode bit, bit 32 of the PSW, with the value of the entry-basic-addressing-mode bit, bit 32 of the ETE, and, thus, it may switch between the 24-bit and 31-bit addressing modes. In the 64-bit addressing mode, bit 32 of the PSW remains unchanged.

Stacking PROGRAM CALL, when bit 129 of the ETE is zero, sets bit 31 of the PSW to zero and sets bit 32 of the PSW with the value of bit 32 of the ETE. When bit 129 of the ETE is one, stacking PROGRAM CALL sets bits 31 and 32 of the PSW to one. Thus, stacking PROGRAM CALL can set the 24-bit, 31-bit, or 64-bit addressing mode.

When the resulting addressing mode is the 24-bit or 31-bit mode, both basic and stacking PROGRAM CALL place bits 33-62 of the entry instruction address in the ETE, which are bits 33-62 of the ETE, with 33 leftmost and one rightmost zeros appended, in bit positions 64-127 of the PSW as the new instruction address, and they place the entry-problem-state bit, bit 63 of the ETE, in bit position 15 of the PSW as the new problem-state bit. Bits 32-63 of the entry parameter in the ETE are placed in bit positions 32-63 of general register 4, and bits 0-31 of this register remain unchanged.

When the resulting addressing mode is the 64-bit mode, both basic and stacking PROGRAM CALL place bits 0-62 of the entry instruction address, bits 0-62 of the ETE, with one rightmost zero appended, in bit positions 64-127 of the PSW, and they place bit 63 of the ETE in bit position 15 of the PSW. Bits 0-63 of the entry parameter in the ETE are placed in general register 4.

Basic PROGRAM CALL ORs the entry key mask from the ETE into the PSW-key mask in control register 3. Stacking PROGRAM CALL does the same, or it replaces the PSW-key mask with the entry key mask, as determined by the PSW-key-mask control in the ETE.

Stacking PROGRAM CALL optionally replaces the PSW key in the PSW and the EAX in control register 8 from the ETE, and it sets the address-space-control bits in the PSW, as determined by control bits in the ETE.

The ETE causes a space-switching operation to occur if it contains a nonzero ASN. When the ETE contains a zero ASN, the operation is called PROGRAM CALL to current primary (PC-cp); when the ETE contains a nonzero ASN, the operation is called PROGRAM CALL with space switching (PC-ss). When space switching is specified, the new PASN is loaded into control register 4 from the ETE, and a new primary-ASTE origin (PASTEO) is loaded into control register 5, also from the ETE. From the PASTE, a new primary ASCE (PASCE) and AX are

loaded into control registers 1 and 4, respectively. If ASN-and-LX reuse is enabled, a new primary ASTE instance number (PASTEIN) is loaded into control register 4, also from the PASTE.

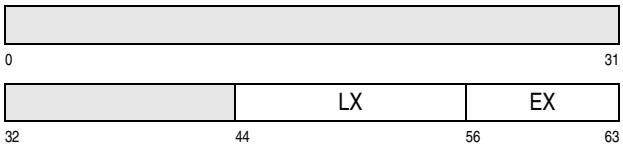
In both PC-cp and PC-ss, the SASN and secondary ASCE (SASCE) are set equal to the original PASN and PASCE, respectively, and, if ASN-and-LX reuse is enabled, the secondary ASTE instance number (SASTEIN) in control register 3 is set equal to the original PASTEIN. However, the space-switching stacking PROGRAM CALL operation may instead set the SASN and SASCE equal to the new PASN and PASCE, respectively, and, if ASN-and-LX reuse is enabled, set the SASTEIN equal to the new PASTEIN, as determined by a control bit in the ETE.

In a PC-ss to the base space of the dispatchable unit when the dispatchable unit is subspace active, bits 0-55 and 58-63 of the new PASCE are replaced by the same bits of the ASCE in the ASTE for the subspace in which the dispatchable unit last had control. This occurs before the possible setting of the SASCE equal to the PASCE.

PROGRAM CALL PC-Number Translation

The second-operand address is not used to address data; instead, the rightmost 20 or 32 bits of the address are used as a PC number divided into two fields: a linkage index (LX) and an entry index (EX). The entry index is always the rightmost eight bits of the PC number. When the ASN-and-LX-reuse is not installed or is not enabled by a one value of the ASN-and-LX-reuse control, bit 44 of control register 0, the PC number is 20 bits, and the leftmost 12 bits of the number are the linkage index. In this case, the second-operand address has the following format:

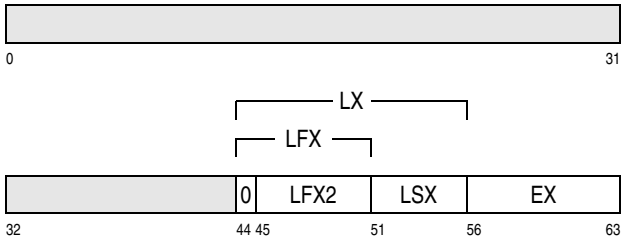
Second-Operand Address when ASN-and-LX Reuse Is Not Enabled



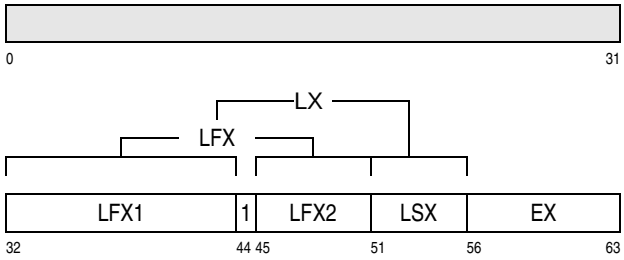
Bit 44 of the effective address has no special meaning and may be zero or one.

When the ASN-and-LX-reuse facility is installed and enabled, referred to simply by saying that ASN-and-LX reuse is enabled, the linkage index is further divided into a linkage first index (LFX) and a linkage second index (LSX). The linkage second index is always the five bits immediately on the left of the entry index. The size and format of the linkage first index depend on whether the PC number is 20 bits or 32 bits, which in turn depends on whether bit 44 of the second-operand address is zero or one, respectively. In these cases, the second-operand address has the following formats:

Second-Operand Address when ASN-and-LX Reuse Is Enabled and Bit 44 Is Zero



Second-Operand Address when ASN-and-LX Reuse Is Enabled and Bit 44 Is One



When ASN-and-LX reuse is enabled and bit 44 of the second-operand address is zero, the PC number is 20 bits, and the linkage first index is bits 44-50, or bits 45-50 (LFX2) with a zero appended on the left. Thus, the linkage first index is seven bits of which the leftmost bit is always zero. When bit 44 is one, the PC number is 32 bits, and the linkage first index is bits 45-50 (LFX2) with bits 32-43 (LFX1) appended on the left, or 18 bits, and bit 44 is not a numeric part of the PC number. However, a linkage first table can contain at most 16,384 entries, and, therefore, the leftmost four bits of the linkage first index, bits 32-35 of the second-operand address, must always be zeros; otherwise, an LFX-translation exception is recognized.

Linkage Index (LX): When ASN-and-LX reuse is not enabled, bits 44-55 of the second-operand address are the linkage index and are used to select an entry from the linkage table designated by the linkage-table designation in the primary ASTE.

Linkage First Index (LFX): When ASN-and-LX reuse is enabled and bit 44 of the second-operand address is zero, bits 44-50 of the second-operand address are the linkage first index. When ASN-and-LX reuse is enabled and bit 44 of the second-operand address is one, bits 45-50 with bits 32-43 appended on the left are the linkage first index. In either case, the linkage first index is used to select an entry from the linkage first table designated by the linkage-first-table designation in the primary ASTE.

Linkage Second Index (LSX): When ASN-and-LX reuse is enabled, bits 51-55 of the second-operand address are the linkage second index and are used to select an entry from the linkage second table designated by the linkage-first-table entry.

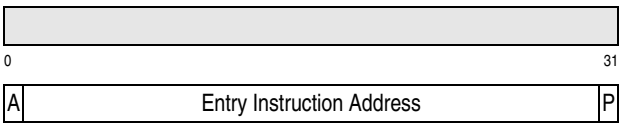
Entry Index (EX): Bits 56-63 of the second-operand address are the entry index and are used to select an entry from the entry table designated by the linkage-table entry or the linkage-second-table entry.

When the PC number is 20 bits, bits 32-43 of the second-operand address are ignored. Bits 0-31 of the second-operand address are always ignored.

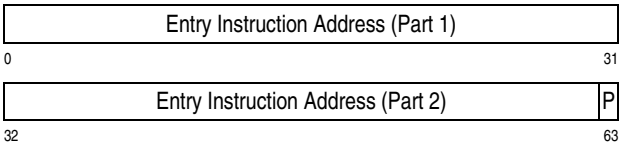
When ASN-and-LX reuse is enabled, the second word of the linkage-second-table entry used contains a linkage-second-table-entry sequence number (LSTESN). When this LSTESN is nonzero, it must be equal to an LSTESN specified in bit positions 0-31 of general register 15; otherwise, an LSTE-sequence exception is recognized. When ASN-and-LX reuse is not enabled (including when it is not installed) or the LSTESN in the linkage-second-table entry is zero, bits 0-31 of general register 15 are ignored.

The 32-byte entry-table entry (ETE) has the following format:

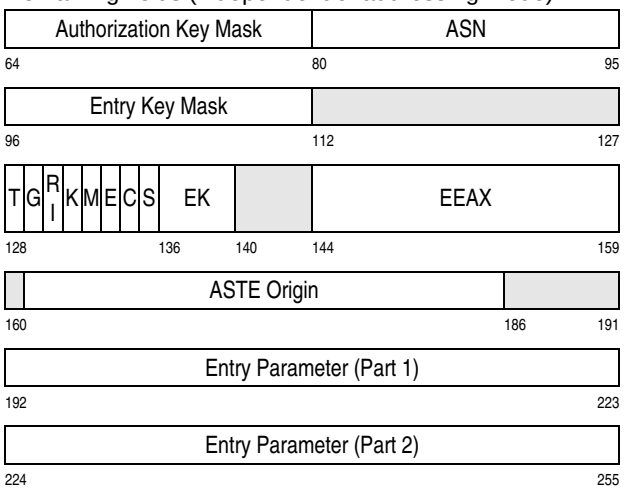
When Resulting Addressing Mode Is the 24-Bit or 31-Bit Mode



When Resulting Addressing Mode Is the 64-Bit Mode



Remaining fields (independent of addressing mode)



For basic PROGRAM CALL in the 24-bit or 31-bit addressing mode when bit 32 of the ETE (A) is zero (specifying the 24-bit mode), and for stacking PROGRAM CALL when bits 32 (A) and 129 (G) are zeros (specifying the 24-bit mode), bits 33-39 must be zeros; otherwise, a PC-translation-specification exception is recognized.

After the ETE has been fetched, if the current PSW specifies the problem state, the current PSW-key mask in control register 3 is tested against the AKM field in the ETE to determine whether the program is authorized to access this entry. The AKM and PSW-key mask are ANDed, and, if the result is zero, a privileged-operation exception is recognized. The PSW-key mask in control register 3 remains unchanged. When PROGRAM CALL is executed in the supervisor state, the AKM field is ignored.

If the result of the AND of the AKM and the PSW-key mask is not zero, or if the CPU is in the supervisor state, the execution of the instruction continues.

If bit 128 of the ETE (T) is zero, the basic PROGRAM CALL operation is specified. If bit 128 of the ETE is one, the stacking PROGRAM CALL operation is specified.

Basic PROGRAM CALL

The following operations are performed when basic PROGRAM CALL is specified.

Bit 31 of the current PSW (the extended-addressing-mode bit) must equal bit 129 (G) of the ETE; otherwise, a special-operation exception is recognized.

In the 24-bit or 31-bit addressing mode, bits 97-126 of the PSW (bits 33-62 of the updated instruction address) are placed in bit positions 33-62 of general register 14, bit 32 of the PSW (the basic-addressing-mode bit) is placed in bit position 32 of the register, and bit 15 of the PSW (the problem-state bit) is placed in bit position 63 of the register. Bits 0-31 of the register remain unchanged.

In the 64-bit addressing mode, bits 64-126 of the PSW (bits 0-62 of the updated instruction address) are placed in bit positions 0-62 of general register 14, and bit 15 of the PSW (the problem-state bit) is placed in bit position 63 of the register.

In the 24-bit or 31-bit addressing mode, bits 32 and 33-62 of the ETE (A and the EIA), with a zero appended on the right of bits 33-62, are placed in PSW bit positions 32 and 97-127, respectively (the basic-addressing-mode bit and bits 33-63 of the instruction address). In the 64-bit addressing mode, bits 0-62 of the ETE, with a zero appended on the right, are placed in PSW bit positions 64-127 (the instruction address), and PSW bit 32 remains unchanged. In any addressing mode, bit 63 of the ETE (P) is placed in PSW bit position 15 (the problem-state bit).

The PSW-key mask, bits 32-47 of control register 3, is placed in bit positions 32-47 of general register 3, and the current PASN, bits 48-63 of control register 4, is placed in bit positions 48-63 of general register 3. Bits 0-31 of general register 3 remain unchanged.

Bits 96-111 of the ETE (the EKM) are ORed with the PSW-key mask, bits 32-47 of control register 3, and the result replaces the PSW-key mask in control register 3.

In the 24-bit or 31-bit addressing mode, bits 224-255 of the ETE (bits 32-63 of the entry parameter) are loaded into bit positions 32-63 of general register 4, and bits 0-31 of the register remain unchanged. In the 64-bit addressing mode, bits 192-255 of the ETE (the entry parameter), are loaded into bit positions 0-63 of general register 4.

Stacking PROGRAM CALL

The following operations are performed when stacking PROGRAM CALL is specified.

The stacking process is performed to form a linkage-stack program-call state entry and place the following information in the state entry: current PSW (with an unpredictable PER mask), PSW-key mask, PASN, SASN, EAX, called-space identification, an indication of whether the resulting addressing mode is the 64-bit mode, numeric part of the program-call number, contents of general registers 0-15, and contents of access registers 0-15, and, if ASN-and-LX reuse is enabled, PASTEIN and SASTEIN. This is described in “Stacking Process” on page 5-85. The entry-type code in the state entry is 0001101 binary.

When bit 129 of the ETE (G) is zero, bit 31 of the PSW (the extended-addressing-mode bit) is set to zero, and bit 32 of the ETE (A) is placed in bit position 32 of the PSW (the basic-addressing-mode bit). (The addressing mode is set to the 24-bit mode if bit 32 is zero or to the 31-bit mode if bit 32 is one.) When bit 129 of the ETE is one, bits 31 and 32 of the PSW are set to one. (The 64-bit addressing mode is set.)

When the resulting addressing mode is the 24-bit or 31-bit mode, bits 33-62 of the ETE (the EIA), with 33 leftmost and one rightmost zeros appended, are placed in PSW bit positions 64-127 (the instruction address). When the resulting addressing mode is the 64-bit mode, bits 0-62 of the ETE (the EIA), with one rightmost zero appended, are placed in PSW bit positions 64-127.

Bit 63 of the ETE (P) is placed in PSW bit position 15 (the problem-state bit).

When bit 131 of the ETE (K) is zero, bits 8-11 of the PSW (the PSW key) remain unchanged. When bit 131 of the ETE is one and the storage-key-removal facility is not installed, bits 136-139 of the ETE (the EK) replace the PSW key in the PSW.

When bit 132 of the ETE (M) is zero, bits 96-111 of the ETE (the EKM) are ORed with the PSW-key mask, bits 32-47 of control register 3, and the result replaces the PSW-key mask in control register 3. When bit 132 of the ETE is one, bits 96-111 of the ETE replace the PSW-key mask in control register 3.

When bit 133 of the ETE (E) is zero, the EAX, bits 32-47 of control register 8, remains unchanged. When bit 133 of the ETE is one, bits 144-159 of the ETE (the EEAX) replace the EAX in control register 8.

When bit 134 of the ETE (C) is zero, bits 16 and 17 of the PSW (the address-space-control bits) are set to 00 binary (primary-space mode). When bit 134 of the ETE is one, the address-space-control bits in the PSW are set to 01 binary (access-register mode).

When the resulting addressing mode is the 24-bit or 31-bit mode, bits 224-255 of the ETE (bits 32-63 of the entry parameter) are loaded into bit positions 32-63 of general register 4, and bits 0-31 of this register remain unchanged. When the resulting addressing mode is the 64-bit mode, bits 192-255 of the ETE (the entry parameter), are loaded into bit positions 0-63 of general register 4.

Key-controlled protection does not apply to references to the linkage stack, but low-address protection, DAT protection, and secure-storage-access do apply.

PROGRAM CALL to Current Primary (PC-cp)

If bits 80-95 of the ETE (the ASN), are zeros, PROGRAM CALL to current primary (PC-cp) is specified, and the execution of the instruction is completed after the operations described in "PROGRAM CALL PC-Number Translation" and either "Basic PROGRAM CALL" or "Stacking PROGRAM CALL" have been performed and the following operations have been performed.

The current PASN, bits 48-63 of control register 4, is placed in bit positions 48-63 of control register 3 to become the current SASN.

The current PASCE in control register 1 is placed in control register 7 to become the current SASCE.

If ASN-and-LX reuse is enabled, the current PASTEIN, bits 0-31 of control register 4, is placed in bit positions 0-31 of control register 3 to become the current SASTEIN.

The basic PC-cp operation is depicted in parts 1-3 of Figure 10-80 on page 10-108. The stacking PC-cp operation is depicted in parts 1, 4, and 5 of the figure.

PROGRAM CALL with Space Switching (PC-ss)

If the ASN in the ETE is nonzero, PROGRAM CALL with space switching (PC-ss) is specified, and the execution of the instruction is completed after the operations described in "PROGRAM CALL PC-Number Translation" and either "Basic PROGRAM CALL" or "Stacking PROGRAM CALL" have been performed and the following operations have been performed.

Bits 80-95 of the ETE (the ASN) are placed in bit positions 48-63 of control register 4 as the new PASN.

Bits 161-185 of the ETE, with six zeros appended on the right, are used as the real address of the ASTE designated by the new PASN. An ASX-translation exception is recognized if bit 0 of the ASTE is one.

Bits 64-127 of the ASTE (the ASCE) are placed in control register 1 as the new PASCE.

Bits 32-47 of the ASTE (the AX) are placed in bit positions 32-47 of control register 4 as the new authorization index.

If ASN-and-LX reuse is enabled, bits 352-383 of the ASTE (the ASTEIN) are placed in bit positions 0-31 of control register 4 as the new PASTEIN.

Bits 33-57 of the ASTE address are placed in bit positions 33-57 of control register 5 as the new primary-ASTE origin, and zeros are placed in bit positions 32 and 58-63. Bits 0-31 of the register remain unchanged.

In basic PROGRAM CALL, or in stacking PROGRAM CALL when bit 135 of the ETE (S) is zero, the PASN existing before the PASN is replaced from the ETE is placed in bit positions 48-63 of control register 3 to become the current SASN, and the PASCE existing before the PASCE is replaced from the ASTE is placed in control register 7 to become the current SASCE. If ASN-and-LX reuse is enabled, the PASTEIN existing before the PASTEIN is replaced from the ASTE is placed in bit positions 0-31 of control register 3 to become the current SASTEIN. (The SASN and SASCE are set equal to the old PASN and PASCE, respectively, and, if ASN-and-LX reuse is enabled, the SASTEIN is set equal to the old PASTEIN.)

In stacking PROGRAM CALL when bit 135 of the ETE (S) is one, the SASN is replaced by the PASN after the PASN is replaced from the ETE, and the SASCE is replaced by the PASCE after the PASCE is replaced from the ASTE. If ASN-and-LX reuse is enabled, the SASTEIN is replaced by the PASTEIN after the PASTEIN is replaced from the ASTE. (The SASN and SASCE are set equal to the new PASN and PASCE, respectively, and, if ASN-and-LX reuse

is enabled, the SASTEIN is set equal to the new PASTEIN.)

The description in this paragraph applies to use of the subspace-group facility. After the new PASCE has been placed in control register 1 and the new primary-ASTE origin has been placed in control register 5, if (1) the subspace-group-control bit, bit 54, in the PASCE is one, (2) the dispatchable unit is subspace active, and (3) the primary-ASTE origin designates the ASTE for the base space of the dispatchable unit, then bits 0-55 and 58-63 of the PASCE are replaced by the same bits of the ASCE in the ASTE for the subspace in which the dispatchable unit last had control. This replacement occurs before a replacement of the SASCE in control register 7 by the PASCE. Further details are in "Subspace-Replacement Operations" on page 5-71.

The PC-ss operation is depicted in parts 1 and 4-6 of Figure 10-80 on page 10-108.

PROGRAM CALL Serialization

For both the PC-cp and PC-ss operations, a serialization and checkpoint-synchronization function is performed before the operation begins and again after the operation is completed. However, it is unpredictable whether or not a store into a trace-table entry or linkage-stack entry from which a subsequent instruction is fetched will be observed by the CPU that performed the store.

Special Conditions

The basic PROGRAM CALL operation can be performed successfully only when (1) the CPU is in the primary-space mode at the beginning of the operation, (2) the subsystem-linkage control, bit 0 of the linkage-table designation or linkage-first-table designation in the current primary ASN-second-table entry, is one, and (3) the extended-addressing-mode bit, bit 31 of the current PSW, equals the entry-extended-addressing-mode bit, bit 129 of the entry-table entry. Stacking PROGRAM CALL can be performed successfully only when the CPU is in the primary-space mode or access-register mode at the beginning of the operation and the subsystem-linkage control is one. In addition, PC-ss can be performed successfully only when (1) the ASN-translation control, bit 44 of control register 14, is one, (2) the storage-key-removal facility is installed and bit 131 of the entry-table-entry is zero. If any of these rules is violated, a special-operation exception is recognized.

When ASN-and-LX reuse is enabled and the LSTESN in the linkage-second-table entry is non-zero, that LSTESN must be equal to the LSTESN specified in bit positions 0-31 of general register 15; otherwise, an LSTE-sequence exception is recognized.

A stack-full or stack-specification exception may be recognized during the stacking process.

When, for PC-ss, the primary space-switch-event-control bit, bit 57 of control register 1, is one either before or after the execution of the instruction, a space-switch-event program interruption occurs after the operation is completed. A space-switch-event program interruption also occurs after the completion of a PC-ss operation if a PER event is reported.

The operation is suppressed on all addressing and protection exceptions.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch or store, except for key-controlled protection, linkage-stack entry)
- Addressing (linkage-table or linkage-first-table designation in primary ASN-second-table entry; linkage-table entry; linkage-first-table entry; linkage-second-table entry, entry-table entry; ASN-second-table entry, PC-ss only)
- ASX translation (PC-ss only)
- EX translation
- LFX translation
- LSTE sequence
- LSX translation
- LX translation
- PC-translation specification
- Privileged operation (AND of AKM and PSW-key mask is zero in the problem state)
- Secure-storage-access (linkage-table or linkage-first-table designation in primary ASN-second-table entry; linkage-table entry; linkage-first-table entry; linkage-second-table entry, entry-table entry; ASN-second-table entry, PC-ss only)
- Space-switch event (PC-ss only)
- Special operation
- Stack full (stacking PC only)
- Stack specification (stacking PC only)
- Subspace replacement (PC-ss only)
- Trace
- Transaction constraint

The priority of recognition of program exceptions for the instruction is shown in Figure 10-79.

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B	Special-operation exception due to DAT being off or the CPU being in secondary-space mode or home-space mode.
7.C	Transaction constraint.
8.A	Trace exceptions.
8.B.1	Addressing exception or secure-storage-access exception for access to linkage-table designation or linkage-first-table designation in primary ASN-second-table entry.
8.B.2	Special-operation exception due to subsystem-linkage control in linkage-table designation or linkage-first-table designation being zero. **Note:** The LFX-translation, LSX-translation, and LSTE-sequence exceptions can be recognized only if ASN-and-LX reuse is enabled, and the LX-translation exception cannot be recognized in that case.
8.B.3	LX-translation or LFX-translation exception due to linkage-table or linkage-first-table entry, respectively, being outside table.
8.B.4	Addressing exception or secure-storage-access exception for access to linkage-table or linkage-first-table entry.
8.B.5	LX-translation or LFX-translation exception due to I bit (bit 0) in linkage-table or linkage-first-table entry, respectively, being one.
8.B.6	Addressing exception or secure-storage-access exception for access to linkage-second-table entry.
8.B.7	LSX-translation exception due to I bit (bit 0) in linkage-second-table entry being one.
8.B.8	LSTE-sequence exception due to LSTE sequence number in linkage-second-table entry being nonzero and not equal to bits 0-31 of general register 15.
8.B.9	EX-translation exception due to entry-table entry being outside table.

Figure 10-79. Priority of Execution: PROGRAM CALL (Part 1 of 3)

8.B.10	Addressing exception or secure-storage-access exception for access to entry-table entry.
8.B.11	Special-operation exception due to the CPU being in access-register mode or extended-addressing-mode bit, bit 31 of PSW, not being equal to entry-extended-addressing-mode bit, bit 129 of entry-table entry (basic PC only).
8.B.12	PC-translation-specification exception due to invalid combination (bits 33-39 not zeros when resulting addressing mode is 24 bit) in entry-table entry.
8.B.13	Privileged-operation exception due to zero result from ANDing PSW-key mask and AKM in the problem state.
8.B.14.A	Special-operation exception due to the storage-key-removal facility being installed and bit 131 of the entry-table-entry being one.
8.B.14.B	Special-operation exception due to ASN-translation control, bit 44 of control register 14, being zero (PC-ss only).
8.B.15	Addressing exception or secure-storage-access exception for access to ASN-second-table entry (PC-ss only).
8.B.16	ASX-translation exception due to I bit (bit 0) in ASN-second- table entry being one (PC-ss only). **Note:** Subspace-replacement exceptions, which are not shown in detail in this figure, can occur with any priority after 8.B.16 and before 9.
8.B.17	Access exceptions (fetch) for entry descriptor of the current linkage-stack entry (stacking PC only). **Note:** Exceptions 8.B.18-8.B.23 can occur only if there is not enough remaining free space in the current linkage-stack section.
8.B.18	Stack-specification exception due to remaining-free-space value in current linkage-stack entry not being a multiple of 8.
8.B.19	Access exceptions (fetch) for second word of the trailer entry of the current section. The entry is presumed to be a trailer entry; its entry-type field is not examined (stacking PC only).
8.B.20	Stack-full exception due to forward-section validity bit in the trailer entry being zero (stacking PC only).

Figure 10-79. Priority of Execution: PROGRAM CALL (Part 2 of 3)

8.B.21	Access exceptions (fetch) for entry descriptor of the header entry of the next section (stacking PC only). This entry is presumed to be a header entry; its entry-type field is not examined.
8.B.22	Stack-specification exception due to not enough remaining free space in the next section (stacking PC only).
8.B.23	Access exceptions (store) for second word of the header entry of the next section. If there is no exception, the header is now called the current entry.
8.B.24	Access exceptions (store) for entry descriptor of the current entry and for the new state entry (stacking PC only).
9.	Space-switch event (PC-ss only).

Figure 10-79. Priority of Execution: PROGRAM CALL (Part 3 of 3)

Programming Note: The effective address from which a PC number is derived is subject to the addressing mode in the current PSW. Therefore, bits 0-39 of the effective address in the 24-bit addressing mode, and bits 0-32 in the 31-bit addressing mode, are treated as containing zeros.

PROGRAM RETURN

PR [E]

'0101'
0 15

The PSW, except for the PER-mask bit, saved in the last linkage-stack state entry is restored as the current PSW. The PER mask in the current PSW remains unchanged. The contents of general registers 2-14 and access registers 2-14 also are restored from the state entry. When the entry-type code in the entry descriptor of the state entry is 0001101 binary, indicating a program-call state entry, (1) the primary ASN (PASN), secondary ASN (SASN), PSW-key mask (PKM), and extended authorization index (EAX) in the control registers also are restored from the state entry and (2) if the ASN-and-LX-reuse facility is installed and is enabled by a one value of the ASN-and-LX-reuse control, bit 44 of control register 0, the primary ASTE instance number (PASTEIN) and secondary ASTE instance number (SASTEIN) in the control registers also are restored from the state entry. When the entry-type code is 0001100 binary, indicating a branch state entry, the current PASN, SASN, PKM, EAX, PASTEIN, and SASTEIN remain unchanged.

The last state entry is located, and information in it is restored, as described in “Unstacking Process” on page 5-88. The state entry is logically deleted from

the linkage stack, and the linkage-stack-entry address in control register 15 is replaced by the address of the next preceding state or header entry. This also is described in “Unstacking Process”.

When the state entry is a program-call state entry, it causes a space-switching operation to occur if it contains a PASN that is not equal to the current PASN. When the state entry contains a PASN that is equal to the current PASN, the operation is called PROGRAM RETURN to current primary (PR-cp); when the state entry contains a PASN that is not equal to the current PASN, the operation is called PROGRAM RETURN with space switching (PR-ss). PASN translation occurs in PR-ss. SASN translation and authorization may occur in either PR-cp or PR-ss. The terms PR-cp and PR-ss do not apply when the state entry is a branch state entry.

When the ASN-and-LX-reuse facility is installed and enabled and PASN or SASN translation occurs, the PASTEIN or SASTEIN, respectively, saved in the state entry is compared to the ASTEIN in the located ASTE.

Key-controlled protection does not apply to accesses to the linkage stack, but low-address and DAT protection do apply.

The sections “PASN Translation,” “SASN Translation,” “SASN Authorization,” and “PROGRAM RETURN Serialization” apply only when the unstacked state entry is a program-call state entry. The functions described in those sections are not performed when the state entry is a branch state entry.

The actions involving the PASTEIN and SASTEIN occur only when ASN-and-LX reuse is enabled by the ASN-and-LX reuse control in control register 0.

PASN Translation

If the new PASN is equal to the old PASN in bit positions 48-63 of control register 4, PASN translation is not performed, the PASTEIN in control register 4 remain as restored from the state entry, and the PASCE in control register 1 and primary-ASTE origin (PASTEO) in control register 5 are not changed. In this case, there is not a test of whether the new PASTEIN is equal to the old PASTEIN.

If the new PASN is not equal to the old PASN, the new PASN replaces the PASN in bit positions 48-63 of control register 4 and is translated to locate a 64-byte ASTE. The ASN table-lookup process is described in “ASN Translation” on page 3-30. The exceptions associated with ASN translation are collectively called ASN-translation exceptions. These exceptions and their priority are described in Chapter 6, “Interruptions.”

If ASN-and-LX reuse is enabled, the PASTEIN saved in bytes 180-183 of the state entry must equal the ASTEIN in bit positions 352-383 of the located ASTE; otherwise, an ASTE-instance exception is recognized.

Bits 64-127 of the ASTE are placed in control register 1 as the new PASCE.

Bits 32-47 of the ASTE are placed in bit positions 32-47 of control register 4 as the new AX. The PASN and PASTEIN in control register 4 remain as restored from the state entry.

Bits 33-57 of the ASTE address are placed in bit positions 33-57 of control register 5 as the new primary-ASTE origin, and zeros are placed in bit positions 32 and 58-63. Bits 0-31 of this register remain unchanged.

The description in this paragraph applies to use of the subspace-group facility when PASN translation has occurred. If (1) the subspace-group-control bit, bit 54, in the new PASCE is one, (2) the dispatchable unit is subspace active, and (3) the new primary-ASTE origin designates the ASTE for the base space of the dispatchable unit, then bits 0-55 and 58-63 of the new PASCE in control register 1 are replaced by the same bits of the ASCE in the ASTE for the subspace in which the dispatchable unit last had control. This replacement occurs, in the case when the new SASN is equal to the new PASN, before the SASCE is set equal to the PASCE. Further details are in “Subspace-Replacement Operations” on page 5-71.

SASN Translation

If the new SASN is equal to the new PASN, the SASCE in control register 7 is set equal to the new PASCE in control register 1. The SASTEIN, PKM, and SASN in control register 3 remain as restored from the state entry. In this case, there is not a test of whether the new SASTEIN is equal to the new PASTEIN.

If the new SASN is not equal to the new PASN, the new SASN is translated to locate a 64-byte ASTE.

If ASN-and-LX reuse is enabled, the SASTEIN saved in bytes 176-179 of the state entry must equal the ASTEIN in bit positions 352-383 of the located ASTE; otherwise, an ASTE-instance exception is recognized.

Bits 64-127 of the ASTE are placed in control register 7 as the new SASCE.

Control register 3 remains as restored from the state entry.

SASN Authorization

If the new SASN is not equal to the new PASN, the authority-table origin (ATO) from the ASTE for the new SASN is used as the base for a third table lookup. The new authorization index, bits 32-47 of control register 4, is used, after it has been checked against the authority-table length, as the index to locate the entry in the authority table. The authority-table lookup is described in “ASN Authorization” on page 3-36.

The description in this paragraph applies to use of the subspace-group facility when SASN translation and authorization have occurred. If (1) the subspace-group-control bit, bit 54, in the new SASCE is one, (2) the dispatchable unit is subspace active, and (3) the ASTE origin obtained by SASN translation designates the ASTE for the base space of the dispatchable unit, then bits 0-55 and 58-63 are replaced by the same bits of the ASCE of the ASCE in the ASTE for the subspace in which the dispatchable unit last had control. Further details are in “Subspace-Replacement Operations” on page 5-71.

PROGRAM RETURN Serialization

When the unstacked state entry is a program-call state entry, a serialization and checkpoint-synchronization function is performed before the operation begins and again after the operation is completed. However, it is unpredictable whether or not a store into a trace-table entry or linkage-stack entry from which a subsequent instruction is fetched will be observed by the CPU that performed the store.

Special Conditions

The instruction can be executed successfully only when the CPU is in the primary-space mode or access-register mode at the beginning of the operation. In addition, if ASN-translation is required for either the PASN or the SASN, it can only be performed when the ASN-translation control, bit 44 of control register 14, is one. Also, if the storage-key-removal facility is installed, bits 8-11 of the PSW to be restored must be zero. If any of these rules is violated, a special-operation exception is recognized.

A stack-empty, stack-operation, stack-specification, or stack-type exception may be recognized during the unstacking process.

If ASN-and-LX reuse is enabled, the restored PASTEIN must equal the ASTEIN in the located ASTE if PASN translation is performed, and the restored SASTEIN must equal the ASTEIN in the located ASTE if SASN translation is performed; otherwise, an ASTE-instance exception is recognized.

When, for PR-ss, the primary space-switch-event control, bit 57 of control register 1, is one either before or after the execution of the instruction, a space-switch-event program interruption occurs after the operation is completed. A space-switch-event program interruption also occurs after the completion of a PR-ss operation if a PER event is reported.

The PSW which is to be loaded by the instruction is not checked for validity before it is loaded. However, after loading, a specification exception is recognized, and a program interruption occurs, if any of bits 0, 2-4, 12, 24-30, and 33-63 of the PSW is a one, if bits 31 and 32 are zero and one, respectively, and bits 64-96 are not all zeros, if bits 31 and 32 are both zero and bits 64-103 are not all zeros, or if bits 31 and 32 are one and zero, respectively. In these cases, the operation is completed, and the resulting instruction-length code is 0. The specification exception, which in this case is listed as a program exception in this instruction, is described in “Early Exception Recognition” on page 6-9.

If a space-switch event is indicated and the PSW that was loaded by the instruction is invalid because of a reason described in the preceding paragraph, it is unpredictable whether the resulting instruction-length code is 0 or 1, or 0 or 2 if EXECUTE was used, or 0 or 3 if EXECUTE RELATIVE LONG was used.

The operation is suppressed on all addressing and protection exceptions.

Resulting Condition Code: The code is set as specified in the new PSW loaded.

Program Exceptions:

- Access (fetch and store, except key-controlled protection, linkage-stack entry)
- Addressing (authority-table entry, if SASN translation occurs)
- ASN translation (if PASN or SASN translation occurs)
- ASTE instance (if ASN-and-LX reuse is enabled and PASN or SASN translation occurs)
- Secondary authority (if SASN translation occurs)
- Secure-storage-access (authority-table entry, if SASN translation occurs)
- Space-switch event
- Special operation
- Specification
- Stack empty
- Stack operation
- Stack specification
- Stack type
- Subspace replacement (if PASN or SASN translation occurs)
- Trace
- Transaction constraint

The priority of recognition of program exceptions for the instruction is shown in Figure 10-81.

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Special-operation exception due to DAT being off or the CPU being in secondary-space mode or home-space mode.
7.B	Transaction constraint.
8.A	Trace exceptions.
8.B.1	Access exceptions (fetch) for entry descriptor of the current linkage-stack entry.
8.B.2	Stack-type exception due to current entry not being a state entry or header entry. **Note:** Exceptions 8.B.3-8.B.7 can occur only if the current entry is a header entry.
8.B.3	Stack-operation exception due to unstack-suppression bit in the header entry being one.

Figure 10-81. Priority of Execution: PROGRAM RETURN (Part 1 of 3)

8.B.4	Access exceptions (fetch) for second word of the header entry.
8.B.5	Stack-empty exception due to backward stack-entry validity bit in the header entry being zero.
8.B.6	Access exceptions (fetch) for entry descriptor of preceding entry, which is the entry designated by the backward stack-entry address in the current (header) entry.
8.B.7	Stack-specification exception due to preceding entry being a header entry.
8.B.8	Stack-type exception due to preceding entry not being a state entry.
8.B.9	Stack-operation exception due to unstack-suppression bit being one in the state entry.
8.B.10	Access exceptions (fetch) for the state entry, and access exceptions (store) for entry descriptor of the entry preceding the state entry. **Note:** Exceptions 8.B.11-8.B.15 and the event 9 can occur only if the state entry is a program-call state entry.
8.B.11.A	Special-operation exception due to the storage-key-removal facility being installed and bits 8-11 of the restored PSW are not zero.
8.B.11.B	Special-operation exception due to the ASN-translation control, bit 44 of control register 14, being zero (if PASN or SASN translation occurs).
8.B.12	ASN-translation exceptions (if PASN translation occurs).
8.B.13	ASTE-instance exception due to new PASTEIN not being equal to ASTEIN in ASN-second-table entry located by PASN translation (if ASN-and-LX reuse enabled). **Note:** Subspace-replacement exceptions for replacement of bits in the PASCE, which are not shown in detail in this figure, can occur with any priority after 8.B.13 and before 9.
8.B.14	ASN-translation exceptions (if SASN translation occurs).
8.B.15	ASTE-instance exception due to new SASTEIN not being equal to ASTEIN in ASN-second-table entry located by SASN translation (if ASN-and-LX reuse enabled).

Figure 10-81. Priority of Execution: PROGRAM RETURN (Part 2 of 3)

	Note: Subspace-replacement exceptions for replacement of bits in the SASCE, which are not shown in detail in this figure, can occur with any priority after 8.B.15 and before 9.
8.B.16	Secondary-authority exception due to authority-table entry being outside table (if SASN translation occurs).
8.B.17	Addressing exception or secure-storage-access exception for access to authority-table entry (if SASN translation occurs).
8.B.18	Secondary-authority exception due to S bit in authority-table entry being zero (if SASN translation occurs).
9.	Space-switch event (PR-ss only).
10.	Specification exception due to any PSW error of the type that causes an immediate interruption.

Figure 10-81. Priority of Execution: PROGRAM RETURN (Part 3 of 3)

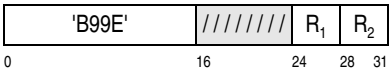
Programming Note: Because PROGRAM CALL cannot be executed successfully in the secondary-space or home-space mode, PROGRAM RETURN is not intended to load a PSW specifying one of these translation modes. PROGRAM RETURN, unlike SET ADDRESS SPACE CONTROL and SET ADDRESS SPACE CONTROL FAST, does not recognize a space-switch event because of loading a PSW that specifies the home-space mode.

PROGRAM TRANSFER

PT R_1,R_2 [RRE]

PROGRAM TRANSFER WITH INSTANCE

PTI R_1,R_2 [RRE]



Note: In this instruction definition, the name "PROGRAM TRANSFER (WITH INSTANCE)" refers to the PROGRAM TRANSFER instruction and the PROGRAM TRANSFER WITH INSTANCE instruction.

Bits 32-47 of general register R_1 are used to update the PSW key mask, and bits 48-63 of the register are used as the new SASN and may be used as the new PASN. Bits 32-63 or 0-63 of general register R_2, depending on the current addressing mode, are used as the new values for the problem-state bit, basic-addressing-mode bit, and instruction address in the current PSW. In the PROGRAM TRANSFER WITH INSTANCE operation, bits 0-31 of general register R_1 are an ASTEIN and are compared against the new value of the PASTEIN if the PASN is changed. In the PROGRAM TRANSFER operation, bits 0-31 of general register R_1 are ignored.

The format of general registers R_1 and R_2 are shown in Figure 10-82.

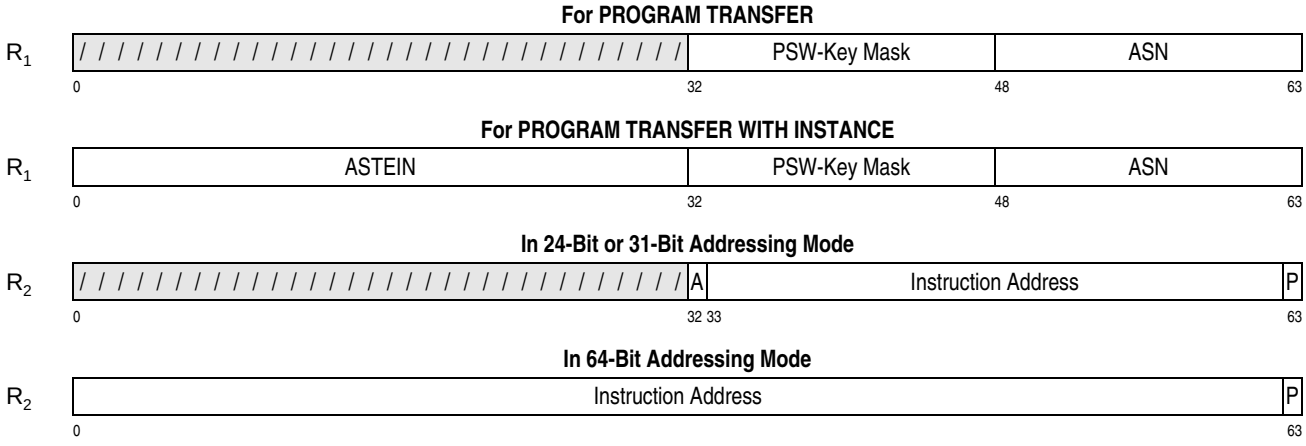


Figure 10-82. Register Contents for PROGRAM TRANSFER (WITH INSTANCE)

When the contents of bit positions 48-63 of general register R_1 are equal to the current PASN, the operation is called PROGRAM TRANSFER (WITH INSTANCE) to current primary (PT-cp or PTI-cp); when the fields are not equal, the operation is called PROGRAM TRANSFER (WITH INSTANCE) with space switching (PT-ss or PTI-ss).

The contents of general register R_2 are used to update the problem-state bit and the instruction address in the current PSW and, in the 24-bit or 31-bit addressing mode, also the basic-addressing-mode bit in the current PSW. Bit 63 of general register R_2 is placed in the problem-state bit position, PSW bit position 15, unless the operation would cause PSW bit 15 to change from one to zero (problem state to supervisor state). If such a change would occur, a privileged-operation exception is recognized.

In the 24-bit or 31-bit addressing mode, bit 32 of general register R_2 replaces the basic-addressing-mode bit, bit 32 of the current PSW, and bits 33-62 of the register, with one rightmost zero appended, replace bits 33-63 of the instruction address in the PSW, bits 97-127 of the PSW. In the 64-bit addressing mode, bits 0-62 of general register R_2, with one rightmost zero appended, replace the instruction address, and the basic-addressing-mode bit remains unchanged.

Bits 32-47 of general register R_1 are ANDed with the PSW-key mask, bits 32-47 of control register 3, and the result replaces the PSW-key mask.

In any of the PT-cp, PTI-cp, PT-ss, and PTI-ss operations, the ASN specified by bits 48-63 of general register R_1 replaces the SASN in control register 3, and the SASCE in control register 7 is replaced by the final contents of control register 1.

In the PROGRAM TRANSFER operation, if the ASN-and-LX-reuse facility is installed and is enabled by a one value of the ASN-and-LX-reuse control, bit 44 of control register 0, the SASTEIN in control register 3 is replaced by the final value of the PASTEIN in control register 4. This replacement occurs in the PROGRAM TRANSFER WITH INSTANCE operation regardless of the value of the ASN-and-LX-reuse control.

PROGRAM TRANSFER (WITH INSTANCE) to Current Primary (PT-cp or PTI-cp)

The PT-cp operation is depicted in part 1 of Figure 10-84 on page 10-121. The PTI-cp operation is depicted in part 1 of Figure 10-85 on page 10-123. The PT-cp or PTI-cp operation is completed when the common portion of the PROGRAM TRANSFER (WITH INSTANCE) operation, described above, is completed. The PASTEIN, authorization index, ASN, primary ASCE, and contents of control register 5 (primary-ASN-second-table-entry origin) are not changed by PT-cp or PTI-cp. In this case in the PTI-cp operation, there is not a test of whether the current PASTEIN equals the ASTEIN specified in bit positions 0-31 of general register R_1; the ASTEIN is ignored.

PROGRAM TRANSFER (WITH INSTANCE) with Space Switching (PT-ss or PTI-ss)

If the ASN in bit positions 48-63 of general register R_1 is not equal to the current PASN, a PROGRAM TRANSFER (WITH INSTANCE) with space switching (PT-ss or PTI-ss) operation is specified, and the ASN is translated by means of a two-level table lookup.

The PT-ss operation is depicted in parts 1 and 2 of Figure 10-84 on page 10-121. The PTI-ss operation is depicted in parts 1 and 2 of Figure 10-85 on page 10-123. The PT-ss or PTI-ss operation is completed as follows.

In PT-ss or PTI-ss, the contents of bit positions 48-63 of general register R_1 are used as an ASN, which is translated by means of a two-level table lookup.

Bits 48-57 of general register R_1 are a 10-bit AFX that is used to select an entry from the ASN first table. Bits 58-63 are a six-bit ASX that is used to select an entry from the ASN second table. The ASN table-lookup process is described in “ASN Translation” on page 3-30. The exceptions associated with ASN translation are collectively called “ASN-translation exceptions.” These exceptions and their priority are described in Chapter 6, “Interruptions.”

In PT-ss if the ASN-and-LX-reuse facility is installed and is enabled by a one value of the ASN-and-LX-reuse control, bit 44 of control register 0, the reusable-ASN bit, bit 63, in the located ASN-second-table entry (ASTE) must be zero; otherwise, a special-operation exception is recognized. In PTI-ss, regardless of the ASN-and-LX-reuse control, the controlled-ASN bit, bit 62, in the ASTE must be zero if the CPU is in the problem state at the beginning of the operation; otherwise, a special-operation exception is recognized. Also in PTI-ss, and regardless of the ASN-and-LX-reuse control and the reusable-ASN bit, the

ASTEIN in bit positions 0-31 of general register R_1 must equal the ASTEIN in bit positions 352-383 of the ASTE; otherwise, an ASTE-instance exception is recognized.

The authority-table origin from the ASN-second-table entry (ASTE) is used as the base for a third table lookup. The current authorization index, bits 32-47 of control register 4, is used, after it has been checked against the authority-table length, as the index to locate the entry in the authority table. The authority-table lookup is described in "ASN Authorization" on page 3-36.

The PT-ss or PTI-ss operation is completed by placing bits 64-127 of the ASTE in control register 1 as the new PASCE and in control register 7 as the new SASCE. The contents of bit positions 32-47 of the ASTE replace the authorization index in bit positions 32-47 of control register 4. Bits 33-57 of the ASTE address are placed in bit positions 33-57 of control register 5 as the new primary-ASTE origin, and zeros are placed in bit positions 32 and 58-63. Bits 0-31 of this register remain unchanged. The ASN, bits 48-63 of general register R_1, replaces the SASN and PASN in bit positions 48-63 of control registers 3 and 4. In PT-ss if ASN-and-LX reuse is enabled, and in PTI-ss regardless of that enablement, the ASTEIN in the ASTE replaces the SASTEIN and PASTEIN in bit positions 0-31 of control registers 3 and 4.

The description in this paragraph applies to use of the subspace-group facility. After the new PASCE has been placed in control register 1 and the new primary-ASTE origin has been placed in control register 5, if (1) the subspace-group-control bit, bit 54, in the PASCE is one, (2) the dispatchable unit is subspace active, and (3) the primary-ASTE origin designates the ASTE for the base space of the dispatchable unit, then bits 0-55 and 58-63 of the PASCE in control register 1 are replaced by the same bits of the ASCE in the ASTE for the subspace in which the dispatchable unit last had control. This replacement occurs before a replacement of the SASCE in control register 7 by the PASCE. Further details are in "Subspace-Replacement Operations" on page 5-71.

PROGRAM TRANSFER (WITH INSTANCE) Serialization

For any of the PT-cp, PTI-cp, PT-ss, and PTI-ss operations, a serialization and checkpoint-synchronization function is performed before the operation begins and again after the operation is completed. However, it is unpredictable whether or not a store into a trace-table entry from which a subsequent instruction is fetched will be observed by the CPU that performed the store.

Special Conditions

The instruction can be executed only when the CPU is in the primary-space mode and the subsystem-linkage control, bit 0 of the linkage-table designation, or linkage-first-table designation in the current primary ASN-second-table entry, is one. If the CPU is in the real mode, secondary-space mode, access-register mode, or home-space mode, or if the subsystem-linkage control is zero, a special-operation exception is recognized.

In PT-ss when ASN-and-LX reuse is enabled, the reusable-ASN bit in the ASN-second-table entry (ASTE) must be zero; otherwise, a special-operation exception is recognized. In PTI-ss, regardless of the ASN-and-LX-reuse control, a special-operation exception is recognized if the controlled-ASN bit in the ASTE is one and the CPU is in the problem state at the beginning of the operation, and an ASTE-instance exception is recognized if the ASTEIN in general register R_1 is not equal to the ASTEIN in the ASTE.

Bit 63 of general register R_2 is placed in the problem-state bit position, PSW bit position 15, unless the operation would cause PSW bit 15 to change from one to zero (problem state to supervisor state). If such a change would occur, a privileged-operation exception is recognized.

In the 24-bit or 31-bit addressing mode, the instruction is completed only if bits 32-39 of general register R_2 specify a valid combination of PSW bits 32 and 97-103. If bit 32 of general register R_2 is zero and bits 33-39 are not all zeros, a specification exception is recognized.

In addition to the above requirements, when a PT-ss or PTI-ss instruction is specified, the ASN-translation control, bit 44 of control register 14, must be one; otherwise, a special-operation exception is recognized.

When, for PT-ss or PTI-ss, the primary space-switch-event-control bit, bit 57 of register 1, is one either before or after the execution of the instruction, a space-switch-event program interruption occurs after the operation is completed. A space-switch-event

program interruption also occurs after the completion of a PT-ss or PTI-ss operation if a PER event is reported.

The operation is suppressed on all addressing exceptions.

Condition Code: The code remains unchanged.

Program Exceptions:

- Addressing (linkage-table or linkage-first-table designation in primary ASN-second-table entry; authority-table entry, PT-ss and PTI-ss only)
- ASN translation (PT-ss and PTI-ss only)
- ASTE instance (PTI-ss only)
- Operation (if ASN-and-LX-reuse facility is not installed, PTI only)
- Primary authority (PT-ss and PTI-ss only)
- Privileged operation (attempt to set the supervisor state when in the problem state)
- Secure-storage-access (linkage-table or linkage-first-table designation in primary ASN-second-table entry; authority-table entry, PT-ss and PTI-ss only)
- Space-switch event (PT-ss and PTI-ss only)
- Special operation
- Specification
- Subspace replacement (PT-ss and PTI-ss only)
- Trace
- Transaction constraint

The priority of recognition of program exceptions for the instruction is shown in Figure 10-83.

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B.1	Operation exception (PTI only, if the ASN-and-LX-reuse facility is not installed).
7.B.2	Special-operation exception due to DAT being off or the CPU being in secondary-space mode, access-register mode, or home-space mode.
7.C	Transaction constraint.

Figure 10-83. Priority of Execution: PROGRAM TRANSFER (WITH INSTANCE) (Part 1 of 2)

8.A	Trace exceptions.
8.B.1	Addressing exception or secure-storage-access exception for access to linkage-table designation or linkage-first-table designation in primary ASN-second-table entry.
8.B.2	Special-operation exception due to subsystem-linkage control in linkage-table designation or linkage-first-table designation being zero.
8.B.3	Privileged-operation exception due to attempt to set the supervisor state when in the problem state.
8.B.4	Specification exception due to invalid combination (bit 32 is zero and bits 33-39 not zeros) in general register R_2 in 24-bit or 31-bit addressing mode.
8.B.5	Special-operation exception due to the ASN-translation control, bit 44 of control register 14, being zero (PT-ss or PTI-ss only).
8.B.6	ASN-translation exceptions (PT-ss and PTI-ss only).
8.B.7	Special-operation exception due to ASN-and-LX reuse enabled and reusable-ASN bit in ASN-second-table entry being one (PT-ss only).
8.B.8	Special-operation exception due to controlled-ASN bit in ASN-second-table entry being one and CPU being in problem state at the beginning of the operation (PTI-ss only).
8.B.9	ASTE-instance exception due to ASTEIN in general register R_1 not being equal to ASTEIN in ASN-second-table entry (PTI-ss only). **Note:** Subspace-replacement exceptions, which are not shown in detail in this figure, can occur with any priority after 8.B.9 and before 9.
8.B.10	Primary-authority exception due to authority-table entry being outside table (PT-ss and PTI-ss only).
8.B.11	Addressing exception or secure-storage-access exception for access to authority-table entry (PT-ss and PTI-ss only).
8.B.12	Primary-authority exception due to P bit in authority-table entry being zero (PT-ss and PTI-ss only).
9.	Space-switch event (PT-ss and PTI-ss only).

Figure 10-83. Priority of Execution: PROGRAM TRANSFER (WITH INSTANCE) (Part 2 of 2)

Programming Notes:

1. The operation of PROGRAM TRANSFER (PT) is such that it may be used to restore the CPU to the state saved by a previous basic PROGRAM CALL operation. This restoration is accomplished by issuing PT 3,14. Though general registers 3 and 14 are not restored to their original values, the PASN, PSW-key mask, problem-state bit, and instruction address are restored, and the authorization index, PASCE, and primary-ASN-second-table-entry origin are made consistent with the restored PASN. In the 24-bit or 31-bit addressing mode, the basic-addressing-mode bit also is restored. If ASN-and-LX reuse is enabled, the PASTEIN also is made consistent with the restored PASN. Note that the SASN is not saved by PROGRAM CALL or restored by PROGRAM TRANSFER; PROGRAM TRANSFER sets the SASN equal to the restored PASN. PROGRAM TRANSFER WITH INSTANCE is the same as PROGRAM TRANSFER except that the PASTEIN is made consistent regardless of ASN-and-LX-reuse enablement.

2. With proper authority, and while being executed in a common area, PROGRAM TRANSFER (WITH INSTANCE) may be used to change the primary address space to any desired space. The secondary address space is also changed to be the same as the new primary address space.

3. Unlike the RR-format branch instructions, a value of zero in the R_2 field for PROGRAM TRANSFER (WITH INSTANCE) designates general register 0, and branching occurs.

4. A program given control by a basic PROGRAM CALL operation can use EXTRACT SECONDARY ASN AND INSTANCE to obtain the ASTEIN to be used by PROGRAM TRANSFER WITH INSTANCE to return to the calling program or by SET SECONDARY ASN WITH INSTANCE to restore its secondary address space after a change of that space. This EXTRACT SECONDARY ASN AND INSTANCE instruction should be executed while the original secondary space remains continuously the secondary space; otherwise, depending on actions by the control program, EXTRACT SECONDARY ASN AND INSTANCE may return an ASTEIN that allows return to or use of a conceptually incorrect secondary space for which the ASTEIN has been changed.

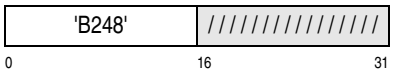
Figure 10-85. Execution of PROGRAM TRANSFER WITH INSTANCE (Part 2 of 2).

PURGE ALB

PALB [RRE]



The ART-lookaside buffer (ALB) of this CPU is cleared of entries. No change is made to the contents of addressable storage or registers.

The ALB appears cleared of its original contents beginning with the execution of the next sequential instruction. The operation is not signaled to any other CPU.

A serialization function is performed.

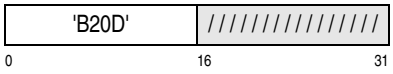
Condition Code: The code remains unchanged.

Program Exceptions:

- Privileged operation
- Transaction constraint

PURGE TLB

PTLB [S]



The translation-lookaside buffer (TLB) of this CPU is cleared of entries. No change is made to the contents of addressable storage or registers.

The TLB appears cleared of its original contents beginning with the fetching of the next sequential instruction. The operation is not signaled to any other CPU.

A serialization function is performed.

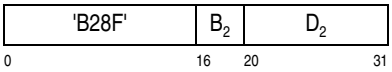
Condition Code: The code remains unchanged.

Program Exceptions:

- Privileged operation
- Transaction constraint

QUERY PROCESSOR ACTIVITY COUNTER INFORMATION

QPACI $D_2(B_2)$ [S]



Information indicating which elements of the processor-activity-instrumentation facility and processor-activity-instrumentation extension 1 are supported by the model is stored at the second-operand location.

The displacement for QUERY PROCESSOR ACTIVITY COUNTER INFORMATION is treated as a 12-bit unsigned binary integer.

The format of the information stored is illustrated in Figure 10-86 on page 10-126.

The fields of the results stored are defined as follows:

Header: Bytes 0-7 are the header of the results. The header is provided for possible future extensions to the processor-activity-instrumentation facility. The contents of the header are reserved and stored as zeros.

Cryptography-Counter-Set Support: Bytes 8-9 indicate the extent of the support for the cryptography-counter set. Bits 0-6 of bytes 8-9 are reserved and stored as zeros. Bit 7 of bytes 8-9 is stored as zero. Bits 8-15 of bytes 8-9 are an unsigned binary integer identifying the highest counter number in the set supported by the model. All counters with counter numbers less than this value are also supported. When zero is stored, no counters in the cryptography-counter set are supported by the model.

Analytics-Counter-Set Support: Bytes 10-11 indicate the extent of the support for the analytics-counter set. Bits 0-6 of bytes 10-11 are reserved and stored as zeros. Bits 7-8 of bytes 10-11 are stored as zeros. Bits 9-15 of bytes 10-11 are an unsigned binary integer identifying the highest counter number in the set supported by the model. All counters with counter numbers less than this value are also supported. When zero is stored, no counters in the analytics-counter set are supported by the model.

Reserved: Reserved bytes are stored as zeros.

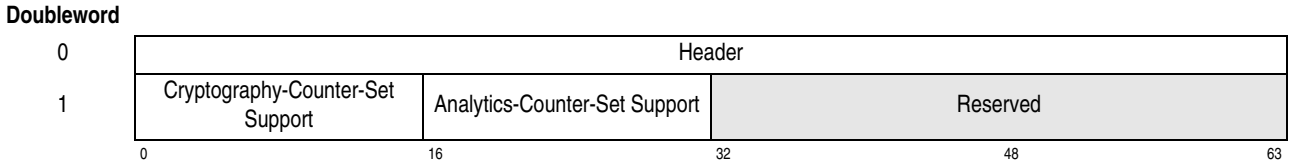


Figure 10-86. Format of QUERY PROCESSOR ACTIVITY COUNTER INFORMATION Results

The size of the information stored may be greater than two doublewords with possible future extensions.

The size of the second operand, in doublewords, is one more than the value specified in bits 60-63 of general register 0. The remaining bits of general register 0 are unassigned and should contain zeros; otherwise, the program may not operate compatibly in the future.

When the size of the second operand is large enough to contain all of the information provided by the model, then the complete information is stored to the second operand location, bits 60-63 of general register 0 are updated to contain one less than the number of doublewords needed to contain all of the information provided by the model, and condition code 0 is set. Furthermore, when the size of the second operand is greater than that necessary to provide all of the information, zeros are stored in doublewords to the right of the information.

When the size of the second operand is not large enough to contain all of the information provided by the model, then only the number of doublewords specified by the second-operand size are stored, bits 60-63 of general register 0 are updated to contain one less than the number of doublewords needed to contain all of the information provided by the model, and condition code 3 is set.

Special Conditions

The second operand must be designated on a doubleword boundary; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Complete information stored
1 --
2 --
3 Incomplete information stored

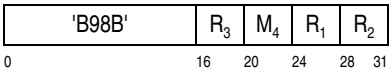
Program Exceptions:

- Access (store, second operand)
- Operation (if the processor-activity-instrumentation facility is not installed)
- Privileged operation
- Specification
- Transaction constraint

Programming Note: A program should treat each 2-byte counter-set support field as containing zeros when the facility providing the counter set is not installed, as indicated in the results of STORE FACILITY LIST EXTENDED.

RESET DAT PROTECTION

RDP $R_1,R_3,R_2[,M_4]$ [RRF-b]



The DAT-protection bit (bit 54) of the designated page-table entry is set to zero or verified to be zero. Associated TLB entries in the CPU which executes the instruction are cleared. When the local-clearing control is zero, associated TLB entries in other CPUs in the configuration may or may not be cleared asynchronously to the execution of the instruction.

Note: Associated TLB entries in the CPU which executes the instruction are always cleared, even if the designated DAT-protection bit is zero at the beginning of the instruction.

The contents of general register R_1 have the format of a segment-table entry, with only the page-table origin used. The contents of general register R_1 that are not part of the page-table origin are reserved and should contain zeros; otherwise the program may not operate compatibly in the future.

Bits 0-51 of general register R_2 have the format of bits 0-51 of a virtual address, with only the page index used. Bits 52-53 of general register R_2 are reserved for IBM use and must contain zeros; otherwise, results are unpredictable. Bits 54-63 of general register R_2 are reserved and should contain zeros; otherwise the program may not operate compatibly in the future.

If the R_3 field of the instruction is nonzero, the contents of general register R_3 have the format of an address-space-control element (ASCE) with only the table origin in bits 0-51 and the designation-type control (DT) in bits 60-61 used. These contents are used to select TLB entries to be cleared. Bits 52-59 and 62-63 of general register R_3 are ignored. If the R_3 field of the instruction is zero, the entire contents of general register R_3 are ignored, and TLB entries are cleared regardless of the ASCE used to form them.

The contents of the general registers just described are shown in Figure 10-17 .

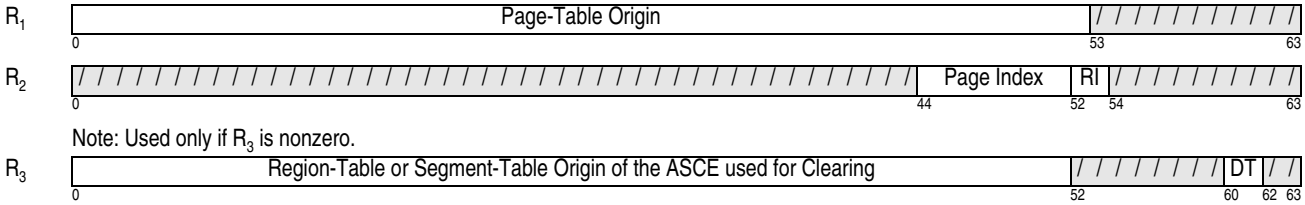


Figure 10-87. Register Contents for RESET DAT PROTECTION

The M_4 field has the following format:

The bits of the M_4 field are defined as follows:

- ***Reserved:*** Bits 0-2 are reserved. Reserved bit positions of the M_4 field are ignored but should contain zeros; otherwise, the program may not operate compatibly in the future.

- ***Local-Clearing Control (LC):*** When bit 3 of the M_4 field is one, only associated TLB entries in the local CPU are cleared. When bit 3 of the M_4 field is zero, in addition to clearing associated TLB entries in the local CPU, associated TLB entries in all CPUs of the configuration may or may not be cleared.

The page-table origin and the page index designate a page-table entry, following the dynamic-address-translation rules for page-table lookup. In the z/Architecture architectural mode, the page-table origin is treated as a 64-bit address, and the addition is performed by using the rules for 64-bit address arithmetic, regardless of the current addressing mode, which is specified by bits 31 and 32 of the current PSW. A carry out of bit position 0 as a result of the addition of the page index and page-table origin cannot occur. In the ESA/390-compatibility mode, the page-table origin and page index are treated as in the z/Architecture architectural mode. The address formed from these two components is a real or absolute address.

During this procedure, the page-table entry is not inspected for format errors, the page-frame real address contained in the entry is not checked for an addressing exception, and the DAT-protection bit is set to zero or verified to be zero, regardless of the value in the page-invalid bit.

The entire page-table entry appears to be fetched concurrently from storage as observed by other CPUs. The DAT-protection bit is examined. When the DAT-protection bit is one at the beginning of the instruction, the byte containing the DAT-protection bit is stored. When the DAT-protection bit is zero at the beginning of the instruction, it is unpredictable whether the byte containing the DAT-protection bit is stored. The fetch access to the page-table entry is subject to key-controlled protection, and the store access is subject to key-controlled protection and low-address protection.

If no exceptions are recognized, this CPU clears selected entries from its TLB. Then if the LC bit in the M_4 field is zero, this CPU may signal all CPUs in the configuration to clear selected entries from their TLBs without performing a quiescing operation. When a TLB is affected, the TLB is cleared of at least those entries for which all of the following conditions are met:

- The page-table origin in general register R_1 matches the page-table origin used to form the TLB table entry.
- The page index in general register R_2 matches the page index used to form the TLB table entry.
- Either (a) the R_3 field is zero , or (b) the table-origin and designation-type fields in general register R_3 match the table-origin and designation-type fields in the address-space-control element (ASCE) used to form the TLB table entry.
- The page-frame real address contained in the designated page-table entry matches the PFRA used to form the TLB table entry.

A serialization function is performed before the operation begins and again after the operation is completed. As is the case for all serialization operations, this serialization applies only to this CPU; other CPUs are not necessarily serialized.

Special Conditions

The instruction is suppressed on all addressing and protection exceptions.

Condition Code: The code remains unchanged.

Program Exceptions:

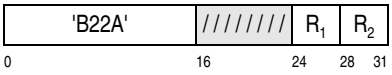
- Addressing (page-table entry)
- Privileged operation
- Operation (if the reset-DAT-protection facility is not installed)
- Protection (fetch and store, page-table entry, key-controlled protection and low-address protection)
- Secure storage access (page-table entry)
- Transaction constraint

Programming Notes:

1. A program may use CRDTE, instead of RDP, to perform the same function. However, RDP is provided to improve performance for this particular function.
2. Subsequent to executing the instruction, other CPUs in the configuration may continue to recognize a DAT-protection exception for the page corresponding to the page-table entry modified by the instruction. In this case, TLB entries corresponding to the modified PTE have not yet been cleared from the CPU which did not execute the instruction. Furthermore, in this case, the CPU which did not execute the instruction can observe the DAT-protection bit of the modified PTE being zero by fetching the PTE. The control program operating in the configuration should be aware of this potential scenario.

RESET REFERENCE BIT EXTENDED

RRBE R_1,R_2 [RRE]



The reference bit in the storage key for the 4 K-byte block that is addressed by the contents of general register R_2 is set to zero. The contents of general register R_1 are ignored.

In the 24-bit addressing mode, bits 40-51 of general register R_2 designate a 4 K-byte block in real storage, and bits 0-39 and 52-63 of the register are ignored. In the 31-bit addressing mode, bits 33-51 of general register R_2 designate a 4 K-byte block in real storage, and bits 0-32 and 52-63 of the register are ignored. In the 64-bit addressing mode, bits 0-51 of general register R_2 designate a 4 K-byte block in real storage, and bits 52-63 of the register are ignored.

Because it is a real address, the address designating the storage block is not subject to dynamic address translation. The reference to the storage key is not subject to a protection exception.

The remaining bits of the storage key, including the change bit, are not affected.

The condition code is set to reflect the state of the reference and change bits before the reference bit is set to zero.

Resulting Condition Code:

0 Reference bit zero; change bit zero
1 Reference bit zero; change bit one
2 Reference bit one; change bit zero
3 Reference bit one; change bit one

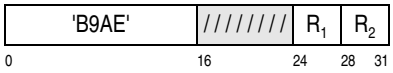
Program Exceptions:

- Addressing (address specified by general register R_2)
- Privileged operation
- Special operation (storage-key-removal facility installed)
- Transaction constraint

Programming Note: See the programming note for INSERT REFERENCE BITS MULTIPLE on page 10-31 for a discussion of differing reference bits that may be returned by IRBM, ISKE, RRBE, and RRBM for the same block of storage.

RESET REFERENCE BITS MULTIPLE

RRBM R_1,R_2 [RRE]



Beginning with the block designated by the address in general register R_2, the reference bits in the storage keys of the 64 consecutive 4 K-byte blocks are inspected and reset. For each of the 64 blocks, the reference bit is placed in an ascending bit position of general register R_1, beginning with bit position 0 of the register. Subsequent to the inspection of each reference bit, the reference bit in the storage key is reset to zero.

General register R_2 designates the first of 64 blocks in absolute storage on a 64-block (256 K-byte) boundary. In the 24-bit addressing mode, bits 40-45 of the register, with six binary zeros appended on the right, designate the first block, and bits 0-39 and 46-63 of the register are ignored. In the 31-bit addressing mode, bits 33-45 of the register, with six binary zeros appended on the right, designate the first block, and bits 0-32 and 46-63 of the register are ignored. In the 64-bit addressing mode, bits 0-45 of the register, with six binary zeros appended on the right, designate the first block, and bits 46-63 of the register are ignored.

Because it is an absolute address, the address designating the first storage block is not subject to dynamic address translation or prefixing. The references to the storage keys are not subject to protection exceptions.

The remaining bits of the storage keys are not affected.

Condition Code: The code remains unchanged.

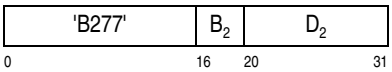
Program Exceptions:

- Addressing (address specified by general register R_2)
- Operation (reset-reference-bits-multiple facility not installed)
- Privileged operation
- Transaction constraint

Programming Note: See the programming note for INSERT REFERENCE BITS MULTIPLE on page 10-31 for a discussion of differing reference bits that may be returned by IRBM, ISKE, RRBE, and RRBM for the same block of storage.

RESUME PROGRAM

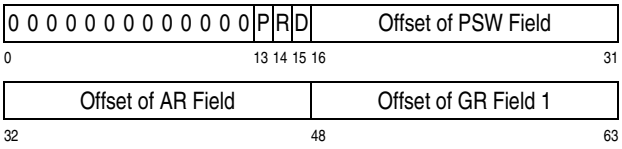
RP $D_2(B_2)$ [S]



Certain contents of the current PSW and of access register and general register B_2 are replaced from three or four corresponding fields in the second operand. The size of the PSW field in the second operand, the size or number of general-register fields in the second operand, and the offsets of the fields in the second operand are specified in a parameter list that immediately follows the instruction in the instruction address space.

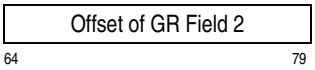
The instruction address space is the address space from which instructions are fetched. It is composed of real addresses if DAT is off.

The first 64 bits of the parameter list have the following format:



In the z/Architecture architectural mode, bits 13-15 of the parameter list further qualify the contents of the second operand, as described below. In the ESA/390-compatibility mode, if any of bits 13-15 of the parameter list is not zero, it is unpredictable whether a specification exception is recognized, or whether these bits operate as in the z/Architecture-architectural-mode definition.

When bits 14 (R) and 15 (D) of the parameter list are both one, the list is an additional 16 bits in length, as follows:



Bit 13 of the parameter list (P) specifies the size of the PSW field in the second operand. The field is eight bytes if bit 13 is zero or 16 bytes if bit 13 is one.

Bits 14 and 15 of the parameter list (R and D) provide specifications about one or two general-register fields in the second operand, as follows:

- When bit 14 is zero, then bit 15 is ignored, the general-register field 1 in the second operand is four bytes, from which bits 32-63 of general register B_2 will be replaced, there is not a general-register field 2 in the second operand, and bits 0-31 of general register B_2 will remain unchanged.
- When bit 14 is one and bit 15 is zero, then the general-register field 1 is eight bytes, from which bits 0-63 of general register B_2 will be replaced, and there is not a general-register field 2.
- When bits 14 and 15 are both one, then the general-register fields 1 and 2 are both four bytes, bits 32-63 of general register B_2 will be replaced from field 1, and bits 0-31 of the register will be replaced from field 2. (The letter “D” stands for disjoint.)

Bits 16-31 of the parameter list are an unsigned binary integer that is the offset in bytes from the beginning of the second operand to a field that has the format of an eight-byte or 16-byte PSW, depending on bit 13, and from which fields in the current PSW will be replaced. Bits 32-47 similarly are an offset to a four-byte field from which the contents of access register B_2 will be replaced. Bits 48-63 similarly are an offset to a four-byte or eight-byte field, depending on bits 14 and 15, from which bits 32-63 or 0-63, respectively, of general register B_2 will be replaced. If bits 64-79 of the parameter list exist, they similarly are an offset to a four-byte field from which bits 0-31 of general register B_2 will be replaced.

Bits 0-12 of the parameter list must be zeros; otherwise, a specification exception is recognized.

Fields in the current PSW are replaced from the corresponding fields in the PSW field in the second operand. The format of a short (eight-byte) PSW is shown in Figure 4-3 on page 4-8, and the format of a 16-byte PSW is shown in Figure 4-2 on page 4-5. The PSW fields that are replaced are shown in Figure 10-88, below.

PSW Bits	Field Name
16 and 17	Address-space control (AS)
18 and 19	Condition code (CC)
20-23	Program mask
31	Extended addressing mode (EA)
32	Basic addressing mode (BA)
64-127	Instruction address

Figure 10-88. PSW Bits Replaceable by RESUME PROGRAM

There is no test for whether bit 31 is zero in an eight-byte PSW.

The remaining fields in the PSW field in the second operand are ignored. Specifically, there is no test for whether bit 12 is one in an eight-byte PSW or zero in a 16-byte PSW.

Unassigned fields in the PSW may be assigned in the future and may then be among those restored by RESUME PROGRAM. Therefore, these fields in the PSW field in the second operand should contain zeros; otherwise, the program may not operate compatibly in the future.

When PSW bits 64-127 are replaced from an eight-byte PSW field in the second operand, they are replaced with bits 33-63 of the field, with 33 zeros appended on the left.

The fields in the second operand are fetched before the contents of access register B_2 and general register B_2 are changed.

When RESUME PROGRAM is the target of an execute-type instruction, the parameter list immediately follows the RESUME PROGRAM instruction, not the execute-type instruction.

The references to the parameter list are storage-operand fetches, not instruction fetches.

Special Conditions

The instruction is completed only if the bits 31, 32, and 64-127 that are to be placed in the current PSW are valid for placement in the PSW. If bits 31 and 32 are both zero and bits 64-103 are not all zeros, if bits 31 and 32 are zero and one, respectively, and bits 64-96 are not all zeros, if bits 31 and 32 are one and zero, respectively, or if bit 127 is one, a specification exception is recognized. A specification exception may or may not result when bit 24 in the second operand is one.

In the ESA/390-compatibility mode, the following applies:

- It is unpredictable whether a specification exception is recognized when any of bits 13-15 of the parameter list is not zero.
- It is unpredictable whether a specification exception is recognized when bit 31 of the PSW in the second operand is one.

The CPU must be in the supervisor state when the operation is to set the home-space mode; otherwise, a privileged-operation exception is recognized. When DAT is off, the values of bits 16 and 17 of the PSW field in the second operand are not tested.

When the CPU is in the home-space mode either before or after the operation, but not both before and after the operation, a space-switch-event program interruption occurs after the operation is completed if any of the following is true: (1) the primary space-switch-event control, bit 57 of the primary address-space-control element (ASCE) in control register 1, is one; (2) the home space-switch-event control, bit 57 of the home ASCE in control register 13, is one; or (3) a PER event is to be indicated.

The operation is suppressed on all addressing and protection exceptions.

Resulting Condition Code: The code is set as specified by the new condition code loaded.

Program Exceptions:

- Access (fetch, parameter list and operand 2)
- Privileged operation (attempt to set the home-space mode when in the problem state)
- Space-switch event
- Specification
- Trace
- Transaction constraint

The priority of recognition of program exceptions for the instruction is shown in Figure 10-89.

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B	Transaction constraint.
8.A	Trace exceptions.
8.B.1	Access exceptions for bits 0-63 of parameter list.
8.B.2	Specification exception due to bits 0-12 of parameter list not being all zeros.
8.B.3	Access exceptions for bits 64-79 of parameter list, if these bits exist.
8.B.4	Access exceptions for the entire second operand.
8.B.5	Privileged-operation exception due to attempt to set the home-space mode when in the problem state.
8.B.6.a	Specification exception due to invalid values in bit positions 31, 32, and 64-127 of PSW in second operand.
8.B.6.b	Specification exception may or may not occur due to a one in bit position 24 of PSW in second operand.
9.	Space-switch event.

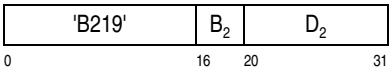
Figure 10-89. Priority of Execution: RESUME PROGRAM

Programming Notes:

1. As described in "Instruction Fetching" on page 5-125, the bytes of an instruction may be fetched piecemeal, and the instruction may be fetched multiple times for a single execution. Therefore, the results are unpredictable when instructions are fetched for execution from storage that is being changed by another CPU or a channel program. This warning is particularly applicable when RESUME PROGRAM is the target of an execute-type instruction since the execute-type instruction may be refetched in order to generate, from its second operand, the address of the parameter list used by RESUME PROGRAM. If the execute-type instruction is refetched, there is not necessarily a test for whether storage still contains either the execute-type instruction or the RESUME PROGRAM instruction.
2. The storage-operand references for RESUME PROGRAM may be multiple-access references. (See "Storage-Operand Consistency" on page 5-133.)

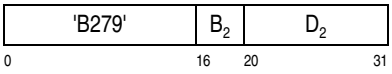
SET ADDRESS SPACE CONTROL

SAC $D_2(B_2)$ [S]



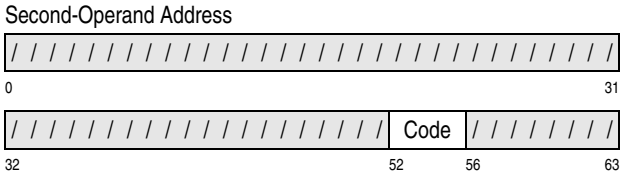
SET ADDRESS SPACE CONTROL FAST

SACF $D_2(B_2)$ [S]



Bits 52-55 of the second-operand address are used as a code to set the address-space-control bits in the PSW. The second-operand address is not used to address data; instead, bits 52-55 form the code. Bits 0-51 and 56-63 of the second-operand address are ignored. Bits 52 and 53 of the second-operand address must be zeros; otherwise, a specification exception is recognized.

The following figure summarizes the operation of SET ADDRESS SPACE CONTROL and SET ADDRESS SPACE CONTROL FAST:



Code	Name of Mode	Result in PSW Bits 16 and 17
0000	Primary space	00
0001	Secondary space	10
0010	Access register	01
0011	Home space	11
All others	Invalid	

The CPU must be in the supervisor state when the operation is to set the home-space mode; otherwise, a privileged-operation exception is recognized.

For SET ADDRESS SPACE CONTROL, a serialization and checkpoint-synchronization function is performed before the operation begins and again after the operation is completed. This function is not performed for SET ADDRESS SPACE CONTROL FAST.

Special Conditions

For SET ADDRESS SPACE CONTROL, the operation is performed only when the secondary-space control, bit 37 of control register 0, is one and DAT is on. When either the secondary-space control is zero or DAT is off, a special-operation exception is recognized. The same rules apply also to SET ADDRESS SPACE CONTROL FAST, except that whether the secondary-space control is tested is unpredictable.

When the CPU is in the home-space mode either before or after the operation, but not both before and after the operation, a space-switch-event program interruption occurs after the operation is completed if any of the following is true: (1) the primary space-switch-event control, bit 57 of the primary address-space-control element (ASCE) in control register 1, is one; (2) the home space-switch-event control, bit 57 of the home ASCE in control register 13, is one; or (3) a PER event is to be indicated.

Condition Code: The code remains unchanged.

Program Exceptions:

- Privileged operation (attempt to set the home-space mode in the problem state)
- Space-switch event
- Special operation
- Specification
- Transaction constraint

The priority of recognition of program exceptions for the instructions is shown in Figure 10-90.

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B	Special-operation exception due to DAT being off.
7.C	Special-operation exception due to the secondary-space control, bit 37 of control register 0, being zero. May be omitted for SET ADDRESS SPACE CONTROL FAST.
7.D	Transaction constraint.
8.	Privileged-operation exception due to attempt to set home-space mode when in problem state.
9.	Specification exception due to nonzero value in bit positions 52 and 53 of second-operand address.
10.	Space-switch event.

Figure 10-90. Priority of Execution: SET ADDRESS SPACE CONTROL and SET ADDRESS SPACE CONTROL FAST

Programming Notes:

1. SET ADDRESS SPACE CONTROL and SET ADDRESS SPACE CONTROL FAST are defined in such a way that the mode to be set can be placed directly in the displacement field of the instruction or can be specified from the same bit positions of a general register as those in which the mode is saved by INSERT ADDRESS SPACE CONTROL.

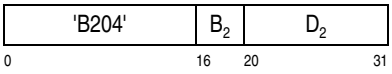
2. SET ADDRESS SPACE CONTROL FAST may provide better performance than SET ADDRESS SPACE CONTROL, depending on the model.

3. Because SET ADDRESS SPACE CONTROL FAST does not perform the serialization function, it does not cause copies of prefetched instructions to be discarded. To ensure predictable results after SET ADDRESS SPACE CONTROL FAST is used to switch to or from the home-space mode, the program must cause prefetched instructions to be discarded before an instruction is executed in a location that does not contain the same instruction in both the primary and home address spaces. The operations that cause prefetched instructions to be discarded are described in “Instruction Fetching” on page 5-125.

4. If a program stores into the instruction stream at a location following a subsequent SET ADDRESS SPACE CONTROL FAST instruction, and the SET ADDRESS SPACE CONTROL FAST instruction changes the translation mode either from or to either the access-register mode or the home-space mode, a copy of a prefetched instruction may be executed instead of the value that was stored. To avoid this situation, either SET ADDRESS SPACE CONTROL must be used instead of SET ADDRESS SPACE CONTROL FAST or some other means must be used to cause prefetched instructions to be discarded after the conceptual store occurs.

SET CLOCK

SCK $D_2(B_2)$ [S]



The current value of the TOD clock is replaced by the contents of the doubleword designated by the second-operand address, and the clock enters the stopped state.

The doubleword operand replaces the contents of the clock, as determined by the resolution of the clock. Only those bits of the operand are set in the clock that correspond to the bit positions which are updated by the clock; the contents of the remaining rightmost bit positions of the operand are ignored and are not preserved in the clock. In some models, starting at or to the right of bit position 52, the rightmost bits of the second operand are ignored, and the corresponding positions of the clock which are implemented are set to zeros. Zeros are also placed in positions to the right of bit position 63 of the clock.

After the clock value is set, the clock enters the stopped state. The clock leaves the stopped state to enter the set state and resume incrementing under control of the TOD-clock-sync control, bit 34 of control register 0, of the CPU which most recently caused the clock to enter the stopped state. When the bit is zero, the clock enters the set state at the completion of the instruction. When the bit is one, the clock remains in the stopped state until the bit is set to zero or until another CPU executes a SET CLOCK instruction affecting the clock. If an external time reference (ETR) is installed, a signal from the ETR may be used to set the set state from the stopped state. When the system is not in the interpretive-execution mode, and an external time reference (ETR) is not attached to the configuration, the TOD-clock-sync control is treated as being zero, regardless of its actual value; in this case, the clock enters the set state and resumes incrementing upon completion of the instruction.

The value of the clock is changed and the clock is placed in the stopped state only if the manual TOD-clock control of any CPU in the configuration is set to the enable-set position or the TOD-clock-control-override control, bit 42 of control register 14, is one. If the TOD-clock control of all CPUs is set to the secure position and the TOD-clock-control-override control is zero, the value and state of the clock are not changed. Whether the clock is set or remains unchanged is distinguished by condition codes 0 and 1, respectively.

When the clock is not operational, the value and state of the clock are not changed, regardless of the settings of the TOD-clock control and the TOD-clock-control-override control, and condition code 3 is set.

Special Conditions

The operand must be designated on a doubleword boundary; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Clock value set
1 Clock value secure
2 --
3 Clock in not-operational state

Program Exceptions:

- Access (fetch, operand 2)
- Privileged operation
- Specification
- Transaction constraint

Programming Notes:

1. When the TOD-clock-steering facility is installed, the use of the SET CLOCK instruction is deprecated. In this case, PTFF control functions can be used to provide equivalent function to SET CLOCK.

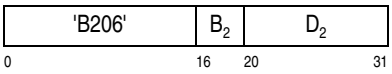
   The SET CLOCK instruction provides no means by which an epoch index can be set. When the multiple-epoch facility is installed, the use of SET CLOCK may result in inconsistent values stored by STORE CLOCK EXTENDED if the epoch index was previously set to a nonzero value. In this case, the PTFF control function PTFF-STOE (set TOD offset extended) should be used rather than SET CLOCK.

   At some future date, the SET CLOCK instruction may be removed from the architecture.

2. SET CLOCK should be issued only while all other activity on all CPUs in the configuration has been suspended. This activity should not be resumed until after the TOD clock has entered the set state.

SET CLOCK COMPARATOR

SCKC $D_2(B_2)$ [S]



The current value of the clock comparator is replaced by the contents of the doubleword designated by the second-operand address.

Only those bits of the operand are set in the clock comparator that correspond to the bit positions to be compared with the TOD clock; the contents of the remaining rightmost bit positions of the operand are ignored and are not preserved in the clock comparator.

Special Conditions

The operand must be designated on a doubleword boundary; otherwise, a specification exception is recognized.

The operation is suppressed on all addressing and protection exceptions.

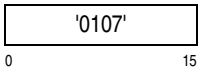
Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Privileged operation
- Specification
- Transaction constraint

SET CLOCK PROGRAMMABLE FIELD

SCKPF [E]



Bits 48-63 of general register 0 are placed in bit positions 16-31 of the TOD programmable register. Zeros are placed in bit positions 0-15 of the TOD programmable register.

Special Conditions

Bits 32-47 of general register 0 must be zeros; otherwise, a specification exception is recognized. Bits 0-31 of general register 0 are ignored.

Condition Code: The code remains unchanged.

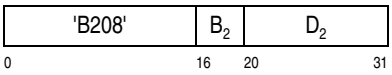
Program Exceptions:

- Privileged operation
- Specification
- Transaction constraint

Programming Note: When uniqueness of TOD-clock values obtained from processors of separate configurations is required, the values in the TOD programmable registers should be the same within each individual configuration and different from the values in any other configuration of the multiple-configuration system.

SET CPU TIMER

SPT $D_2(B_2)$ [S]



The current value of the CPU timer is replaced by the contents of the doubleword designated by the second-operand address.

Only those bits of the operand are set in the CPU timer that correspond to the bit positions to be updated; the contents of the remaining rightmost bit positions of the operand are ignored and are not preserved in the CPU timer.

Special Conditions

The operand must be designated on a doubleword boundary; otherwise, a specification exception is recognized.

The operation is suppressed on all addressing and protection exceptions.

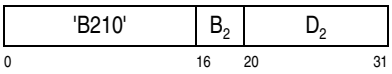
Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Privileged operation
- Specification
- Transaction constraint

SET PREFIX

SPX $D_2(B_2)$ [S]



The word at the second-operand location is fetched, and selected bits of the operand are used to form the address of an area that is tested for accessibility. If accessible, the selected bits of the second operand replace contents of the prefix register, and the ART-lookaside buffer (ALB) and translation-lookaside buffer (TLB) of this CPU are cleared of entries.

Operation in the z/Architecture Architectural Mode

Bits 1-18 of the operand with 13 zeros appended on the right and 33 zeros appended on the left are used as an absolute address of the 8 K-byte new prefix area in storage. The contents of bit positions 0 and 19-31 of the second operand are ignored. The two 4 K-byte blocks within the new prefix area are accessed; if either is not available in the configuration, an addressing exception is recognized, and the operation is suppressed. The accesses to the blocks are not subject to protection; however, the accesses may cause the reference bits for the blocks to be set to ones. If either block is a secure block, a secure-storage-access exception is recognized and the operation is suppressed.

Assuming no access exception is recognized, the contents of bit positions 33-50 of the prefix register are replaced by the contents of bit positions 1-18 of the word at the location designated by the second-operand address.

When the ultravisor-call facility is initialized, the prefix area of each CPU must be unique except for the case when the prefix address is all zeros. If an attempt is made to set a prefix area to one that is already in use, results are unpredictable.

Operation in the ESA/390-Compatibility Mode

Bits 1-19 of the operand with 12 zeros appended on the right and 33 zeros appended on the left are used as an absolute address of the 4 K-byte new prefix area in storage. The contents of bit positions 0 and 20-31 of the second operand are ignored. The 4 K-byte block within the new prefix area is accessed; if it is not available in the configuration, an addressing exception is recognized, and the operation is suppressed. The access to the block is not subject to protection; however, the access may cause the reference bit for the block to be set to one.

Assuming no access exception is recognized, the contents of bit positions 33-51 of the prefix register are replaced by the contents of bit positions 1-19 of the word at the location designated by the second-operand address.

Common Operation

The address of the prefix area is treated as a 64-bit address regardless of the addressing mode specified by the current PSW.

If the operation is completed, the new prefix is used for any interruptions following the execution of the instruction and for the execution of subsequent instructions.

The ART-lookaside buffer (ALB) and translation-lookaside buffer (TLB) are cleared of entries. The ALB and TLB appear cleared of their original contents, beginning with the fetching of the next sequential instruction.

A serialization function is performed before or after the second operand is fetched and again after the operation is completed.

Special Conditions

The second operand must be designated on a word boundary; otherwise, a specification exception is recognized.

The operation is suppressed on all addressing and protection exceptions.

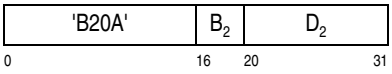
Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Addressing (new prefix area)
- Privileged operation
- Secure-storage-access (new prefix area)
- Specification
- Transaction constraint

SET PSW KEY FROM ADDRESS

SPKA $D_2(B_2)$ [S]



The four-bit PSW key, bits 8-11 of the current PSW, is replaced by bits 56-59 of the second-operand address.

The second-operand address is not used to address data; instead, bits 56-59 of the address form the new PSW key. Bits 0-55 and 60-63 of the second-operand address are ignored.

Special Conditions

In the problem state, the execution of the instruction is subject to control by the PSW-key mask in control register 3. When the bit in the PSW-key mask corresponding to the PSW-key value to be set is one, the instruction is executed successfully. When the selected bit in the PSW-key mask is zero, a privileged-operation exception is recognized. In the supervisor state, any value for the PSW key is valid.

Condition Code: The code remains unchanged.

Program Exceptions:

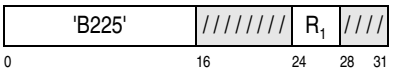
- Privileged operation (selected PSW-key-mask bit is zero in the problem state)
- Transaction constraint

Programming Notes:

1. The format of SET PSW KEY FROM ADDRESS permits the program to set the PSW key either from the general register designated by the B_2 field or from the D_2 field in the instruction itself.
2. When one program requests another program to access a location designated by the requesting program, SET PSW KEY FROM ADDRESS can be used by the called program to verify that the requesting program is authorized to make this access, provided the storage location of the called program is not protected against fetching. The called program can perform the verification by replacing the PSW key with the requesting-program PSW key before making the access and subsequently restoring the called-program PSW key to its original value. Caution must be exercised, however, in handling any resulting protection exceptions since such exceptions may cause the operation to be terminated. See TEST PROTECTION and the associated programming notes for an alternative approach to the testing of addresses passed by a calling program.

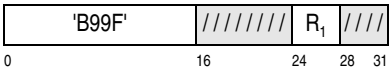
SET SECONDARY ASN

SSAR R_1 [RRE]



SET SECONDARY ASN WITH INSTANCE

SSAIR R_1 [RRE]



Note: In this instruction definition, the name "SET SECONDARY ASN (WITH INSTANCE)" refers to the SET SECONDARY ASN instruction and the SET SECONDARY ASN WITH INSTANCE instruction.

The ASN specified in bit positions 48-63 of general register R_1 replaces the secondary ASN in control register 3, and the address-space-control element corresponding to that ASN replaces the SASCE in control register 7.

The contents of bit positions 48-63 of general register R_1 are called the new ASN. For SET SECONDARY ASN WITH INSTANCE, bits 0-31 of the register are an STEIN and are compared against the new SASTEIN if the SASTEIN is not set equal to the PASTEIN, and bits 32-47 of the register are ignored. For SET SECONDARY ASN, bits 0-47 of the register are ignored.

When the new ASN is equal to the current PASN, the operation is called SET SECONDARY ASN (WITH INSTANCE) to current primary (SSAR-cp or SSAIR-cp); when the fields are not equal, the operation is called SET SECONDARY ASN (WITH INSTANCE) with space switching (SSAR-ss or SSAIR-ss). The SSAR-cp and SSAR-ss operations are depicted in Figure 10-92 on page 10-140. The SSAIR-cp and SSAIR-ss operations are depicted in Figure 10-93 on page 10-141.

SET SECONDARY ASN (WITH INSTANCE) to Current Primary (SSAR-cp or SSAIR-cp)

In the SSAR-cp or SSAIR-cp operation, the new ASN is equal to the PASN. The new ASN replaces the SASN, bits 48-63 of control register 3; the PASCE in control register 1 replaces the SASCE in control register 7.

In SSAR-cp, if the ASN-and-LX-reuse facility is installed and is enabled by a one value of the ASN-and-LX-reuse control, bit 44 of control register 0, the SASTEIN in bit positions 0-31 of control register 3 is replaced by the PASTEIN in bit positions 0-31 of con-

trol register 4. This replacement occurs in SSAIR-cp regardless of the value of the ASN-and-LX-reuse control. In SSAIR-cp, there is not a test of whether the current PASTEIN equals the ASTEIN in bit positions 0-31 of general register R_1; the ASTEIN is ignored. The operation is completed.

SET SECONDARY ASN (WITH INSTANCE) with Space Switching (SSAR-ss or SSAIR-ss)

In the SSAR-ss or SSAIR-ss operation, the new ASN is not equal to the PASN, and the new ASN is translated by means of a two-level table lookup. Bits 0-9 of the new ASN (bits 48-57 of the register) are a 10-bit AFX which is used to select an entry from the ASN first table. Bits 10-15 of the new ASN (bits 58-63 of the register) are a six-bit ASX which is used to select an entry from the ASN second table. The two-level lookup is described in "ASN Translation" on page 3-30. The exceptions associated with ASN translation are collectively called "ASN-translation exceptions." These exceptions and their priority are described in Chapter 6, "Interruptions."

In SSAR-ss, if the ASN-and-LX-reuse facility is installed and is enabled by the ASN-and-LX-reuse control in control register 0, the reusable-ASN bit, bit 63, in the located ASN-second-table entry (ASTE) must be zero; otherwise, a special-operation exception is recognized. In SSAIR-ss, regardless of the ASN-and-LX-reuse control, the controlled-ASN bit, bit 62, in the ASTE must be zero in the problem state; otherwise, a special-operation exception is recognized. Also in SSAIR-ss, and regardless of the ASN-and-LX-reuse control and the reusable-ASN bit, the ASTEIN in bit positions 0-31 of general register R_1 must equal the ASTEIN in bit positions 352-383 of the ASTE; otherwise, an ASTE-instance exception is recognized.

The ASN-second-table entry (ASTE) obtained as a result of the second lookup contains the address-space-control element and the authority-table origin and length associated with the ASN.

The authority-table origin from the ASTE is used as a base for a third table lookup. The current authorization index, bits 32-47 of control register 4, is used, after it has been checked against the authority-table length, as the index to locate the entry in the authority table. The authority-table lookup is described in "ASN Authorization" on page 3-36.

The new ASN, bits 48-63 of general register R_1, replaces the SASN, bits 48-63 of control register 3. The address-space-control element in the ASTE replaces the SASCE in control register 7. In SSAR-ss if ASN-and-LX reuse is enabled, and in SSAIR-ss regardless of that enablement, the ASTEIN in the ASTE replaces the SASTEIN in bit positions 0-31 of control register 3.

The description in this paragraph applies to use of the subspace-group facility. After the new SASCE has been placed in control register 7, if (1) the subspace-group-control bit, bit 54, in the SASCE is one, (2) the dispatchable unit is subspace active, and (3) the ASTE obtained by ASN translation is the ASTE for the base space of the dispatchable unit, then bits 0-55 and 58-63 of the SASCE are replaced by the same bits of the ASCE in the ASTE for the subspace in which the dispatchable unit last had control. Further details are in "Subspace-Replacement Operations" on page 5-71.

SET SECONDARY ASN (WITH INSTANCE) Serialization

For any of the SSAR-cp, SSAIR-cp, SSAR-ss, and SSAIR-ss operations, a serialization and checkpoint-synchronization function is performed before the operation begins and again after the operation is completed. However, it is unpredictable whether or not a store into a trace-table entry from which a subsequent instruction is fetched will be observed by the CPU that performed the store.

Special Conditions

The operation is performed only when the ASN-translation control, bit 44 of control register 14, is one and DAT is on. When either the ASN-translation-control bit is zero or DAT is off, a special-operation exception is recognized.

In SSAR-ss when ASN-and-LX reuse is enabled, the reusable-ASN bit in the ASN-second-table entry (ASTE) must be zero; otherwise, a special-operation exception is recognized. In SSAIR-ss, regardless of the ASN-and-LX-reuse control, a special-operation exception is recognized if the controlled-ASN bit in the ASTE is one and the CPU is in the problem state, and an ASTE-instance exception is recognized if the ASTEIN in general register R_1 is not equal to the ASTEIN in the ASTE.

Condition Code: The code remains unchanged.

Program Exceptions:

- Addressing (authority-table entry, SSAR-ss and SSAIR-ss only)
- ASN translation (SSAR-ss and SSAIR-ss only)
- ASTE instance (SSAIR-ss only)
- Operation (if ASN-and-LX-reuse facility is not installed, SSAIR only)
- Secondary authority (SSAR-ss and SSAIR-ss only)
- Secure-storage-access (authority-table entry, SSAR-ss and SSAIR-ss only)
- Special operation
- Subspace replacement (SSAR-ss and SSAIR-ss only)
- Trace
- Transaction constraint

The priority of recognition of program exceptions for the instruction is shown in Figure 10-91 on page 10-139.

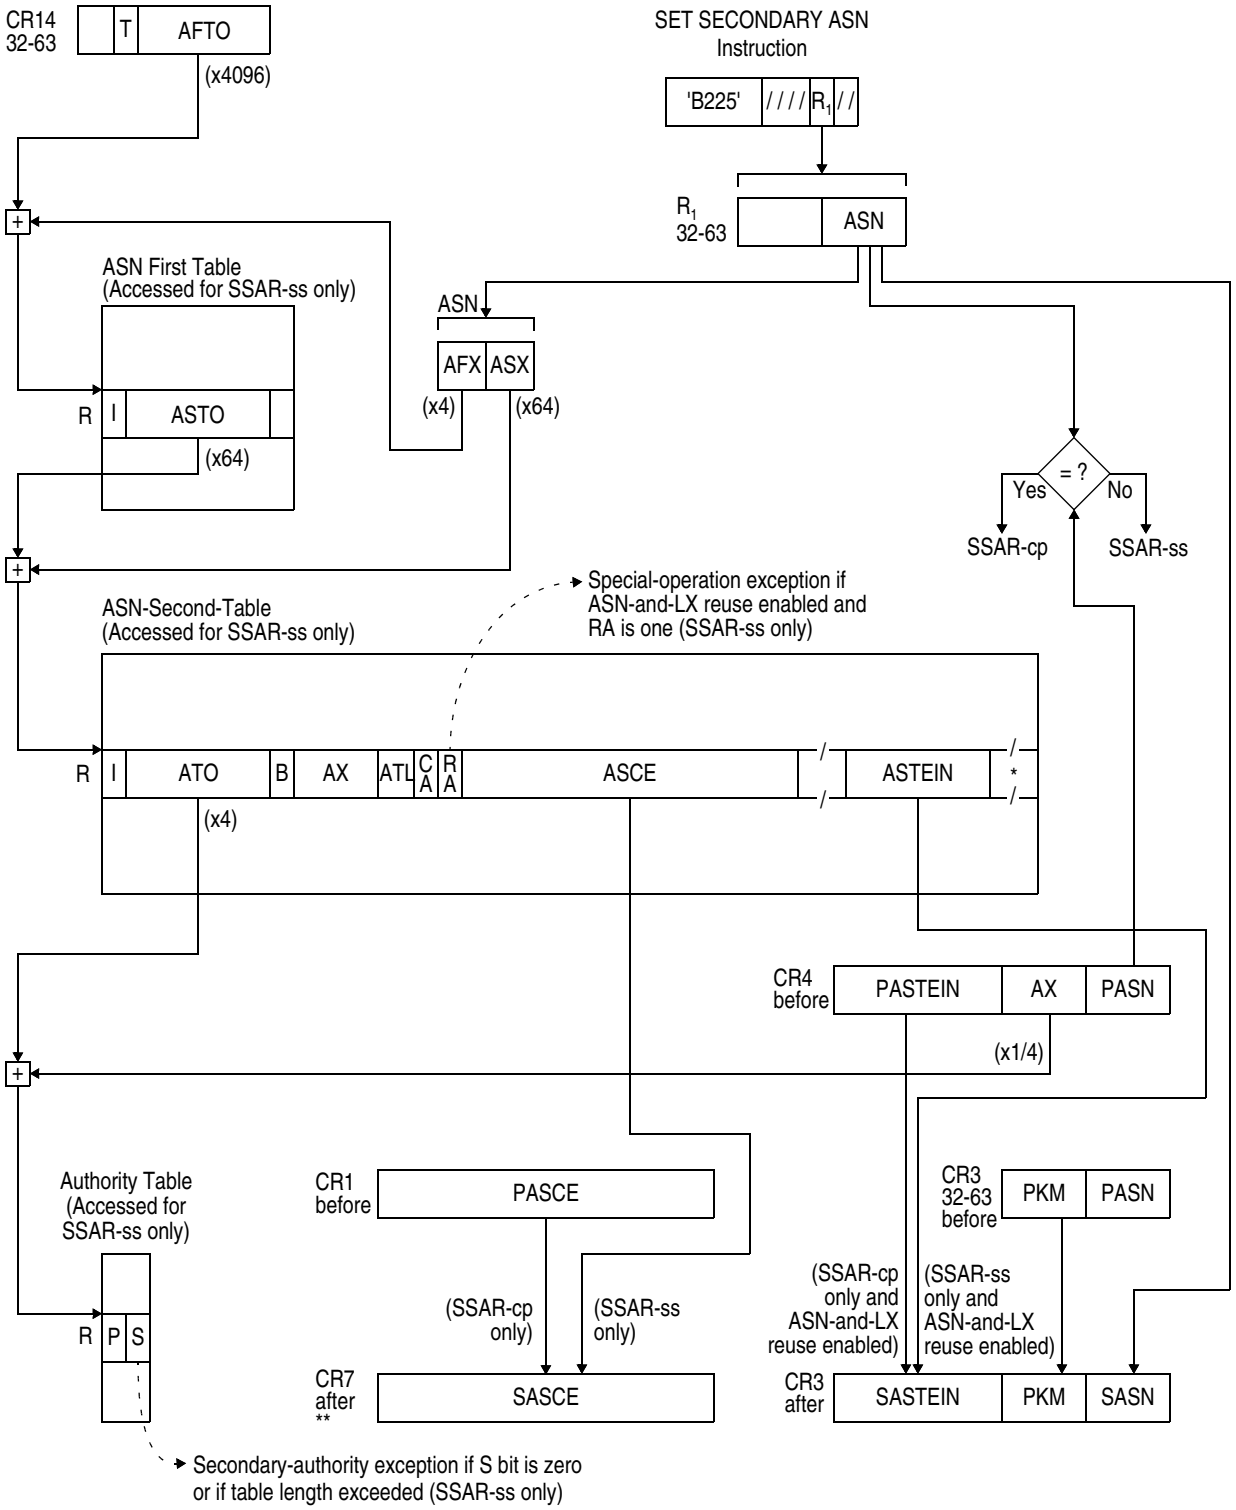
1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B.1	Operation exception (SSAIR only, if the ASN-and-LX-reuse facility is not installed).
7.B.2	Special-operation exception due to DAT being off, or the ASN-translation control, bit 44 of control register 14, being zero.
7.C	Transaction constraint.
8.A	Trace exceptions.
8.B.1	ASN-translation exceptions (SSAR-ss and SSAIR-ss only).

Figure 10-91. Priority of Execution: SET SECONDARY ASN (WITH INSTANCE) (Part 1 of 2)

8.B.2	Special-operation exception due to ASN-and-LX reuse enabled and reusable-ASN bit in ASN-second-table entry being one (SSAR-ss only).
8.B.3	Special-operation exception due to controlled-ASN bit in ASN-second-table entry being one in the problem state (SSAIR-ss only).
8.B.4	ASTE-instance exception due to ASTEIN in general register R_1 not being equal to ASTEIN in ASN-second-table entry (SSAIR-ss only). **Note:** Subspace-replacement exceptions, which are not shown in detail in this figure, can occur with any priority after 8.B.4.
8.B.5	Secondary-authority exception due to authority-table entry being outside table (SSAR-ss and SSAIR-ss only).
8.B.6	Addressing or secure-storage-access exception for access to authority-table entry (SSAR-ss and SSAIR-ss only).
8.B.7	Secondary-authority exception due to S bit in authority-table entry being zero (SSAR-ss and SSAIR-ss only).

Figure 10-91. Priority of Execution: SET SECONDARY ASN (WITH INSTANCE) (Part 2 of 2)

Programming Note: A program given control by a basic PROGRAM CALL operation can use EXTRACT SECONDARY ASN AND INSTANCE to obtain the ASTEIN to be used by PROGRAM TRANSFER WITH INSTANCE to return to the calling program or by SET SECONDARY ASN WITH INSTANCE to restore its secondary address space after a change of that space. This EXTRACT SECONDARY ASN AND INSTANCE instruction should be executed while the original secondary space remains continuously the secondary space; otherwise, depending on actions by the control program, EXTRACT SECONDARY ASN AND INSTANCE may return an ASTEIN that allows return to or use of a conceptually incorrect secondary space for which the ASTEIN has been changed.

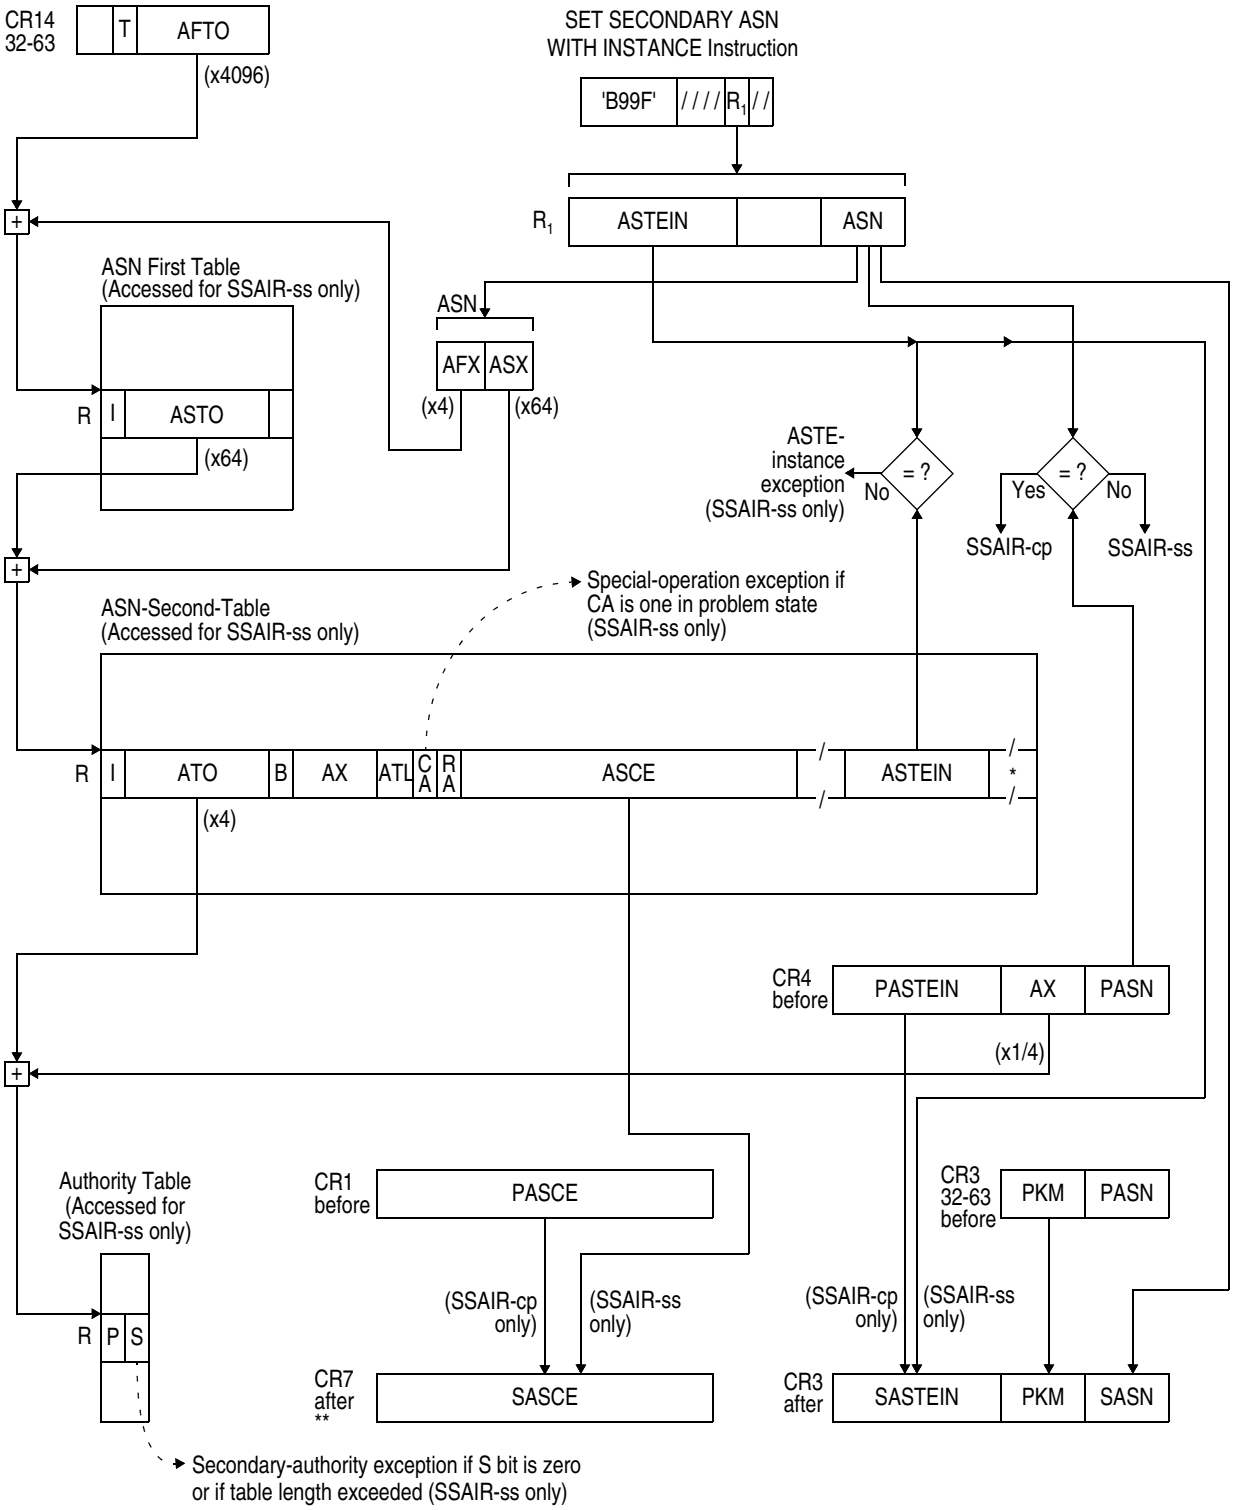


R: Address is real

*: ASTE is 64 bytes; selected fields and the last 16 bytes are not shown.

**: For SSAR-ss only, bits 0-55 and 58-63 of SASCE may be replaced from a subspace ASCE

Figure 10-92. Execution of SET SECONDARY ASN



R: Address is real

*: ASTE is 64 bytes; selected fields and the last 16 bytes are not shown.

**: For SSAIR-ss only, bits 0-55 and 58-63 of SASCE may be replaced from a subspace ASCE

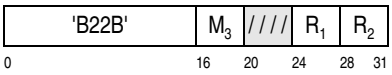
SET STORAGE KEY EXTENDED

SSKE $R_1,R_2[,M_3]$ [RRF-c]



The storage key for one or more 4 K-byte blocks is replaced by the value in the first-operand register. When the conditional-SSKE facility is installed, certain functions of the key-setting operation may be bypassed.

When the conditional-SSKE facility is not installed, or when the conditional-SSKE facility is installed and both the MR and MC bits of the M_3 field are zero, the storage key for the 4 K-byte block that is addressed by the contents of general register R_2 is replaced by bits from general register R_1. The instruction completes without changing the condition code.

When the conditional-SSKE facility is installed and either or both of the MR and MC bits are one, the access-control bits, fetch-protection bit, and, optionally, the reference bit and change bit of the storage key that is addressed by the contents of general register R_2 are compared with corresponding bits in general register R_1. If the compared bits are equal, then no change is made to the key; otherwise, selected bits of the key are replaced by the corresponding bits in general register R_1. The storage key prior to any modification is inserted in general register R_1, and the result is indicated by the condition code.

When the enhanced-DAT facility 1 is installed, the above operations may be repeated for the storage keys of multiple 4 K-byte blocks within the same 1MB block, subject to the control of the multiple-block control, described below.

The M_3 field has the following format:

The bits of the M_3 field are defined as follows:

- ***Nonquiescing Control (NQ):*** The NQ bit, bit 0 of the M_3 field, controls whether a quiescing operation is performed, as described below.

- ***Reference-Bit-Update Mask (MR):*** The MR bit, bit 1 of the M_3 field, controls whether updates to the reference bit in the storage key may be bypassed, as described below.

- ***Change-Bit-Update Mask (MC):*** The MC bit, bit 2 of the M_3 field, controls whether updates to the change bit in the storage key may be bypassed, as described below.

- ***Multiple-Block Control (MB):*** The MB bit, bit 3 of the M_3 field, controls whether the storage keys for multiple 4 K-byte blocks of storage may be set, as described in "Setting Storage Keys in Multiple 4 K-byte Blocks" on page 10-144.

When the nonquiescing key-setting facility is not installed, bit 0 of the M_3 field is ignored. When the conditional-SSKE facility is not installed, bit positions 1 and 2 of the M_3 field are ignored. When the enhanced-DAT facility 1 is not installed, bit position 3 of the M_3 field is ignored.

When the conditional-SSKE facility is installed, processing is as follows:

1. When both the MR and MC bits, bits 1 and 2 of the M_3 field, are zero, the instruction completes as though the conditional-SSKE facility was not installed. The storage key for the 4 K-byte block that is addressed by the contents of general register R_2 is replaced by bits from general register R_1, and the instruction completes without changing the condition code.

2. When either or both the MR and MC bits are one, processing is as follows:

   a. Prior to any modification, the contents of the storage key for the 4 K-byte block that is addressed by general register R_2 are placed in bit positions 48-54 of general register R_1, and bit 55 of general register R_1 is set to zero. Bits 0-47 and 56-63 of the register remain unchanged.

      If an invalid checking-block code (CBC) is detected when fetching the storage key, then (a) the entire storage key for the 4 K-byte block is replaced by bits 56-62 of general register R_1, (b) the contents of bit positions 48-55 of general register R_1 are unpredictable, and (c) the instruction completes by setting condition code 3.

b. The access-control bits and fetch-protection bit of the storage key for the designated 4 K-byte block are compared with the corresponding fields in bits 56-60 of general register R_1. If the respective fields are not equal, the entire storage key for the 4 K-byte block is replaced by bits from general register R_1, and the instruction completes by setting condition code 1.

   When the access-control and fetch-protection bits in the storage key are equal to the respective bits in general register R_1, processing continues as described below.

c. When both the MR and MC bits are one, the instruction completes by setting condition code 0. The storage key remains unchanged in this case.

d. When the MR bit is zero and the MC bit is one, then the reference bit of the storage key for the designated 4 K-byte block is compared with bit 61 of general register R_1. If the bits are equal, the instruction completes by setting condition code 0. The storage key remains unchanged in this case.

   If the bits are not equal, then either (a) the entire storage key for the designated 4 K-byte block is replaced by the bits in general register R_1, and the instruction completes by setting condition code 1; or (b) the reference bit for the storage key is replaced by bit 61 of general register R_1, the change bit for the key is unpredictable, and the instruction completes by setting condition code 2. It is unpredictable whether condition code 1 or 2 is set.

e. When the MC bit is zero and the MR bit is one, then the change bit of the storage key for the designated 4 K-byte block is compared with bit 62 of general register R_1. If the bits are equal, the instruction completes by setting condition code 0. The storage key remains unchanged in this case, except that the reference bit is unpredictable.

   If the bits are not equal, then either (a) the entire storage key for the designated 4 K-byte block is replaced by the bits in general register R_1, and the instruction completes by setting condition code 1; or (b) the change bit for the storage key is replaced by bit 62 of general register R_1, the reference bit for the key is unpredictable, and the instruction completes by setting condition code 2. It is unpredictable whether condition code 1 or 2 is set.

When the enhanced-DAT facility 1 is not installed, or when the facility is installed but the multiple-block control is zero, general register R_2 contains a real address. When the enhanced-DAT facility 1 is installed and the multiple-block control is one, general register R_2 contains an absolute address.

In the 24-bit addressing mode, bits 40-51 of general register R_2 designate a 4 K-byte block in real or absolute storage, and bits 0-39 and 52-63 of the register are ignored. In the 31-bit addressing mode, bits 33-51 of general register R_2 designate a 4 K-byte block in real or absolute storage, and bits 0-32 and 52-63 of the register are ignored. In the 64-bit addressing mode, bits 0-51 of general register R_2 designate a 4 K-byte block in real or absolute storage, and bits 52-63 of the register are ignored.

Because it is a real or absolute address, the address designating the storage block is not subject to dynamic address translation. The reference to the storage key is not subject to a protection exception.

The new seven-bit storage-key value, or selected bits thereof, is obtained from bit positions 56-62 of general register R_1. The contents of bit positions 0-55 and 63 of the register are ignored. When the conditional-SSKE facility is installed, and either or both the MR and MC bits are one, bit position 63 should contain a zero; otherwise, the program may not operate compatibly in the future.

A serialization and checkpoint-synchronization function is performed before the operation begins and again after the operation is completed, except that when the conditional-SSKE facility is installed and the resulting condition code is 0, it is unpredictable whether a serialization and checkpoint-synchronization function is performed after the operation completes.

When the nonquiescing key-setting facility is not installed, or when the facility is installed and the nonquiescing control (NQ) is zero, the following applies:

- A quiescing operation is performed.

- For any store access, by any CPU or channel program, completed to the designated 4 K-byte block either before or after the setting of the key by this instruction, the associated setting of the reference and change bits to one in the storage key for the block also is completed before or after, respectively, the execution of this instruction.

When the nonquiescing key-setting facility is installed and the NQ control is one, a quiescing operation is not necessarily performed. See "Storage-Key Accesses" on page 5-128 for a discussion the effects of quiescing on key-setting instructions, and see "Quiescing" on page 5-141 for details on the quiescing operation.

Setting Storage Keys in Multiple 4 K-byte Blocks

When the enhanced-DAT facility 1 is not installed, or when the facility is installed, but the multiple-block control is zero, the storage key for a single 4 K-byte block is set, as described above.

When the enhanced-DAT facility 1 is installed, and the multiple-block control is one, the storage keys for multiple 4 K-byte blocks within a 1 M-byte block may be set, beginning with the block specified by the second-operand address, and continuing to the right with each successive block up to the next 1 M-byte boundary. In this case, SET STORAGE KEY EXTENDED is interruptible, and processing is as follows:

- When an interruption occurs (other than one that follows termination), the leftmost bits of general register R_2 comprising the 4 K-byte block address have been updated so the instruction, when reexecuted, resumes at the point of interruption. If either or both the MR or MC bits are one, the condition code is unpredictable; otherwise, the condition code is unchanged.
- When the instruction completes without interruption, the leftmost bits of general register R_2 comprising the 4 K-byte block address have been updated to the next 1 M-byte boundary. If either or both the MR or MC bits are one, condition code 3 is set; otherwise, the condition code is unchanged.

In either of the above two cases, the following applies:

- Bits 52-63 of general register R_2 remain unchanged.
- When either or both the MR or MC bits are one, bits 48-55 of general register R_1 are unpredictable.

When multiple-block processing occurs and the R_1 and R_2 fields designate the same register, the second-operand address is placed in the register. When multiple-block processing occurs in the 24-bit or 31-bit addressing modes, the leftmost bits which are not part of the address in bit positions 32-63 of general register R_2 are set to zeros; bits 0-31 of the register are unchanged.

Before a quiescing key-setting operation is performed, transactional execution by other CPUs in the configuration is aborted with abort code 255, condition code 2. The aborting of transactional execution affects at least those CPUs accessing the locations (transactionally or nontransactionally) for which storage keys are being set. It is unpredictable whether some or all other CPUs are affected as well.

Resulting Condition Code:

When the conditional-SSKE facility is not installed, or when both the MR and MC bits of the M_3 field are zero, the condition code remains unchanged.

When the conditional-SSKE facility is installed, and either or both of the MR and MC bits are one, the condition code is set as follows:

0 Storage key not set
1 Entire storage key set
2 Partial storage key set
3 Entire storage key set; bits 48-55 of general register R_1 are unpredictable.

Program Exceptions:

- Addressing (address specified by general register R_2)
- Privileged operation
- Special operation (storage-key-removal facility is installed)
- Transaction constraint

Programming Notes:

1. The M_3 field of the instruction is considered to be optional, as indicated by the field being con-

tained within brackets [] in the assembler syntax. When the M_3 field is not specified, the assembler places zeros in that field of the instruction.

2. When setting multiple storage keys within the same 1 M-byte block to the same value, use of the multiple-block control (MB, bit 3 of the M_3 field) may yield better performance than executing separate SSKE instructions for each 4 K-byte block in the megabyte.

3. If the program does not rely on the setting of the reference bit, it may set the MR bit of the M_3 field to one, regardless of whether or not the conditional-SSKE facility is installed. Similarly, if the program does not rely on the setting of the change bit, it may set the MC bit of the M_3 field to one, regardless of whether or not the conditional-SSKE facility is installed. In these cases, the program cannot rely on the condition code or the key value returned in general register R_1. Conversely, if the program depends on accurate setting of the reference or change bit, then the MR and MC bits should be set to zero, such that reference and change bit recording are properly maintained when the conditional-SSKE facility is installed.

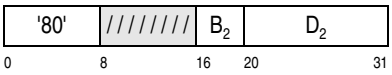
4. When SSKE is issued, the program must ensure that no channel subsystem is simultaneously altering the storage designated by general register R_2. The program also must ensure that no other CPU or channel subsystem is accessing the storage designated by general register R_2 when the nonquiescing (NQ) control is one. Otherwise, unpredictable results may be observed by the other CPUs and channel subsystem, including the alteration of the block designated by general register R_2.

5. Even when the enhanced-DAT facility 2 is installed, the multiple-block control is limited to setting keys in a 1 M-byte block; no provision is made for setting keys in a 2 G-byte block with SSKE. PERFORM FRAME MANAGEMENT FUNCTION with a set-key control of 1 and frame-size code of 2 may be used to set the keys of a 2 G-byte block. See “PERFORM FRAME MANAGEMENT FUNCTION” on page 10-86 for additional details.

6. See the programming note on page 5-130 for restrictions on the use of the nonquiescing control.

SET SYSTEM MASK

SSM $D_2(B_2)$ [SI]



Bits 0-7 of the current PSW are replaced by the byte at the location designated by the second-operand address.

Bits 8-15 of the instruction are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.

Special Conditions

When the SSM-suppression-control bit, bit 33 of control register 0, is one and the CPU is in the supervisor state, a special-operation exception is recognized.

The value to be loaded into the PSW is not checked for validity before loading. However, immediately after loading, a specification exception is recognized, and a program interruption occurs, if either (a) the contents of bit positions 0 and 2-4 of the PSW are not all zeros, or (b) in the ESA/390-compatibility mode, bit position 5 of the PSW does not contain zero. In either of these cases, the instruction is completed, and the instruction-length code is set to 2 or 3. The specification exception, which is listed as a program exception for this instruction, is described in “Early Exception Recognition” on page 6-9.

The operation is suppressed on all addressing and protection exceptions.

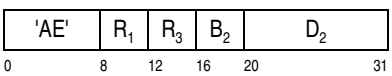
Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Privileged operation
- Special operation
- Specification
- Transaction constraint

SIGNAL PROCESSOR

SIGP $R_1,R_3,D_2(B_2)$ [RS-a]



An eight-bit order code and, if called for, a 64-bit parameter are transmitted to the CPU designated by the CPU address contained in the third operand. The result is indicated by the condition code and may be detailed by status assembled in bit positions 32-63 of the first-operand location.

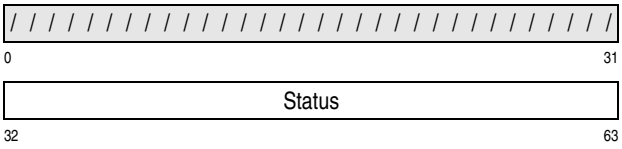
The second-operand address is not used to address data; instead, bits 56-63 of the address contain the eight-bit order code. Bits 0-55 of the second-operand address are ignored. The order code specifies the function to be performed by the addressed CPU. The assignment and definition of order codes appear in “CPU Signaling and Response” on page 4-86.

The 16-bit binary number contained in bit positions 48-63 of general register R_3 forms the CPU address. Bits 0-47 of the register are ignored. When the specified order is the set-architecture or set multithreading order, the CPU address is ignored; all CPUs in the configuration are considered to be addressed. See “CPU-Address Identification” on page 4-85 for details on the CPU address.

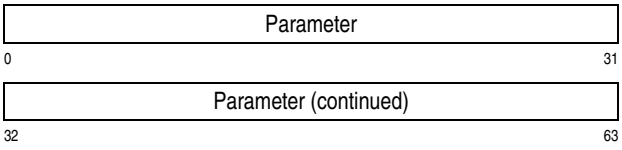
The general register containing the 64-bit parameter in bit positions 0-63 is R_1 or R_1+1, whichever is the odd-numbered register. It depends on the order code whether a parameter is provided and for what purpose it is used.

The operands just described have the following formats:

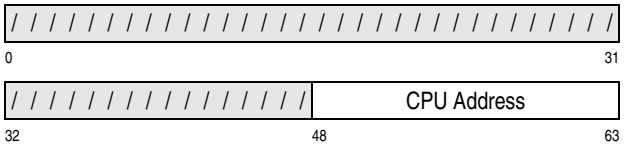
General register designated by R_1:



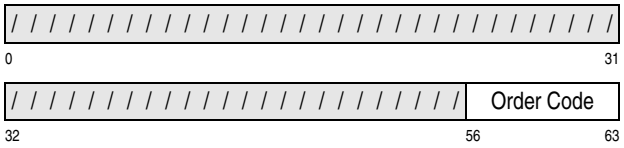
General register designated by R_1 or R_1 + 1, whichever is the odd-numbered register:



General register designated by R_3:



Second-operand address:



A serialization function is performed before the operation begins and again after the operation is completed.

When the order code is accepted and no nonzero status is returned, condition code 0 is set. When status information is generated by this CPU or returned by the addressed CPU, the status is placed in bit positions 32-63 of general register R_1, bits 0-31 of the register remain unchanged, and condition code 1 is set.

When the access path to the addressed CPU is busy, or the addressed CPU is operational but in a state where it cannot respond to the order code, condition code 2 is set.

When the addressed CPU is not operational (that is, it is not provided in the installation, it is not in the configuration, it is in any of certain customer-engineer test modes, or its power is off), condition code 3 is set.

Resulting Condition Code:

0 Order code accepted
1 Status stored
2 Busy
3 Not operational

Program Exceptions:

- Privileged operation
- Transaction constraint

Programming Notes:

1. A more detailed discussion of the condition-code settings for SIGNAL PROCESSOR is contained in “CPU Signaling and Response” on page 4-86.

2. To ensure that presently written programs will be executed properly when new facilities using additional bits are installed, only zeros should appear in the unused bit positions of the second-operand address and in bit positions 32-47 of general register R_3.

3. Certain SIGNAL PROCESSOR orders are provided with the expectation that they will be used primarily in special circumstances. Such orders may be implemented with the aid of an auxiliary maintenance or service processor, and, thus, the execution time may take several seconds. Unless all of the functions provided by the order are required, combinations of other orders, in conjunction with appropriate programming support, can be expected to provide a specific function more rapidly. The following orders are the only orders which are intended for frequent use:

   - Conditional emergency signal
   - Emergency-signal
   - External-call
   - Sense
   - Sense-running-status

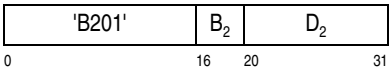
   The following orders are intended for infrequent use, and performance therefore may be much slower than for frequently used orders:

   - CPU reset
   - Initial CPU reset
   - Restart
   - Set architecture
   - Set multithreading
   - Set prefix
   - Store additional status at address
   - Store status at address
   - Start
   - Stop
   - Stop and store status

   An alternative to the set-prefix order, for faster performance when the receiving CPU is not already stopped, is the use of the emergency-signal or external-call order, followed by the execution of a SET PREFIX instruction on the addressed CPU. Clearing the TLB of entries is ordinarily accomplished more rapidly through the use of the emergency-signal or external-call order, followed by execution of the PURGE TLB instruction on the addressed CPU, than by use of the set-prefix order.

STORE BEAR

STBEAR $D_2(B_2)$ [S]



The current value of the breaking-event-address register (BEAR) is stored at the doubleword location designated by the second-operand address.

Special Conditions

The second operand must be designated on a doubleword boundary; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)
- Operation (if the BEAR-enhancement facility is not installed)
- Privileged operation
- Specification
- Transaction constraint

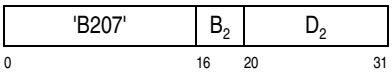
Programming Note: It is intended for a control program to use STORE BEAR within interruption-handling routines in the following manner:

1. At the beginning of the interruption-handling routine, before a breaking event can occur, STORE BEAR is issued to preserve the contents of the breaking-event-address register (BEAR) associated with the interrupted program.

2. At the end of the interruption-handling routine, LOAD BEAR is issued to restore the preserved value to the breaking-event-address register (BEAR), followed by no breaking events and issuing LOAD PSW EXTENDED (LPSWEY) to return control to the interrupted program without causing a breaking event to occur.

STORE CLOCK COMPARATOR

STCKC $D_2(B_2)$ [S]



The current value of the clock comparator is stored at the doubleword location designated by the second-operand address.

Zeros are provided for the rightmost bit positions of the clock comparator that are not compared with the TOD clock.

Special Conditions

The operand must be designated on a doubleword boundary; otherwise, a specification exception is recognized.

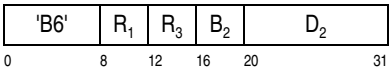
Condition Code: The code remains unchanged.

Program Exceptions:

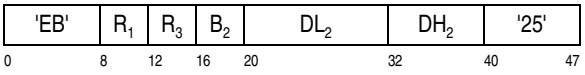
- Access (store, operand 2)
- Privileged operation
- Specification
- Transaction constraint

STORE CONTROL

STCTL $R_1,R_3,D_2(B_2)$ [RS-a]



STCTG $R_1,R_3,D_2(B_2)$ [RSY-a]



Bits of the set of control registers starting with control register R_1 and ending with control register R_3 are stored at the locations designated by the second-operand address.

For STORE CONTROL (STCTL), bits 32-63 of the control registers are stored in successive words beginning at the second-operand address, and bits 0-31 of the registers are ignored. For STORE CONTROL (STCTG), bits 0-63 of the control registers are stored in successive doublewords beginning at the second-operand address.

The storage area where the contents of the control registers are placed starts at the location designated by the second-operand address and continues through as many storage words, for STCTL, or doublewords, for STCTG, as the number of control registers specified. The contents of the control registers are stored in ascending order of their register numbers, starting with control register R_1 and continuing up to and including control register R_3, with control register 0 following control register 15. The contents of the control registers remain unchanged.

The displacement for STCTL is treated as a 12-bit unsigned binary integer. The displacement for STCTG is treated as a 20-bit signed binary integer.

Special Conditions

The second operand must be designated on a word boundary for STCTL or on a doubleword boundary for STCTG; otherwise, a specification exception is recognized.

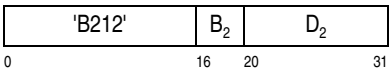
Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)
- Privileged operation
- Specification
- Transaction constraint

STORE CPU ADDRESS

STAP $D_2(B_2)$ [S]



The CPU address by which this CPU is identified in a multiprocessing configuration is stored at the halfword location designated by the second-operand address.

Special Conditions

The operand must be designated on a halfword boundary; otherwise, a specification exception is recognized.

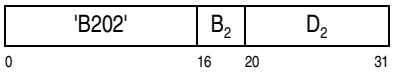
Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)
- Privileged operation
- Specification
- Transaction constraint

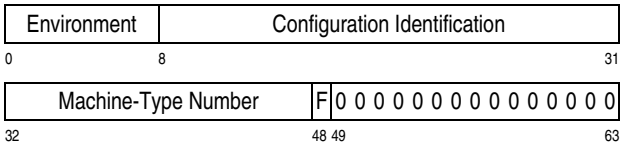
STORE CPU ID

STIDP $D_2(B_2)$ [S]



Information identifying (a) the execution environment, (b) the system serial number, (c) the machine type, and (d) the format of the response is stored at the doubleword location designated by the second-operand address. Depending on the format of the response, the CPU address, logical partition identification, or both may also be stored.

The information stored has the following format:



Environment: Bit positions 0-7 contain an indication of the environment in which the instruction was executed, as follows:

- For a program being executed by an IBM machine in a level-1 configuration (the basic machine), or for a program being executed by a level-2 configuration (in a logical partition), the environment field contains 00 hex.
- For a program being executed natively by the IBM Z Personal-Development Tool (that is, when not executed in a virtual machine running on the zPDT), the environment field contains either C1 hex or D3 hex. (See programming note 6 on page 10-151).
- For a program being executed by a level-3 configuration (a virtual machine), the environment field contains FD or FF hex, depending on the type of configuration providing the environment. A program executing in a level-3 configuration may issue DIAGNOSE, STORE FACILITY LIST EXTENDED, STORE SYSTEM INFORMATION, and SCP read-SCP-information command to determine what capabilities the host configuration provides for the level-3 configuration.

Configuration Identification: Bit positions 8-31 contain six hexadecimal digits. Depending on the environment, the rightmost of these digits may be (a) selected from some or all of the machine's physical serial number, (b) derived from either the zPDT token or the zPDT unique-identification-manager (UIM) server, or (c) assigned by the virtual machine definition.

- When executed by a level-1 configuration, bits 8-31 are stored as follows:

  – When the format bit (bit 48 of the response) is zero, bit positions 8-11 (A) contain the rightmost hexadecimal digit of the physical CPU address. When the format bit is one, bit positions 8-11 contain zeros.

  – Bit positions 12-31 (nnnnn) contain the rightmost five hexadecimal digits of the machine's physical serial number.

- When executed by a level-2 configuration, and the format bit is zero, bits 8-31 are stored as follows:

  – Bit positions 8-11 (L) contain the rightmost hexadecimal digit of the logical CPU address.

  – Bit positions 12-15 (P) contain a hexadecimal digit identifying the logical partition.

  – Bit positions 16-31 (nnnn) contain the rightmost four hexadecimal digits of the machine's physical serial number.

- When executed by a level-2 configuration, and the format bit is one, bits 8-31 are stored as follows:

  – Bit positions 8-15 contains a two hexadecimal digit user-partition identifier (UPID) which is bound to the logical partition.

  – Bit positions 16-31 (nnnn) contains the rightmost four hexadecimal digits of the system's serial number.

- When executed by a zPDT configuration, the results are similar to those defined for a level-2 configuration when the format bit is one. See programming note 6 for further details.

- When executed by a level-3 configuration, the results are similar to those defined for a level-2 configuration. However, the hypervisor can supply alternate configuration identification.

Machine-Type Number: Bit positions 32-47 contain an unsigned packed-decimal number identifying the machine type of the CPU.

Format Indication (F): Bit position 48 specifies the format of the first two hexadecimal digits of the configuration-identification field, as described above.

Reserved: Bit positions 49-63 are reserved and stored as zeros.

Special Conditions

The operand must be designated on a doubleword boundary; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)
- Privileged operation
- Specification
- Transaction constraint

Programming Notes:

1. The STORE SYSTEM INFORMATION (STSI) instruction provides more comprehensive and complete information identifying the machine, logical partition, and CPU on which the program is executing. In order to ensure world-wide unique identification of the configuration of the issuing CPU, the STSI instruction specifying SYSIB 1.1.1, 1.2.1, 2.2.1, or 3.2.2 should be used.

2. The program should allow for the possibility that the configuration-identification field may contain the hexadecimal digits A-F as well as the digits 0-9.

3. The format bit is stored as one beginning with the IBM eServer zSeries 990 and in newer models.

4. Except when executed in a level-3 configuration (that is, except when executed by a virtual machine), the value of the rightmost four or five hexadecimal digits of the configuration-identification field are equivalent to the value of the corresponding rightmost EBCDIC characters stored in the sequence-code field of the SYSIB 1.1.1 stored by STSI. When executed in a level-3 configuration, the hypervisor may provide a means by which an alternate configuration identification can be specified; however, the sequence code reported in the SYSIB 1.1.1 is that of the real machine, even when executed by a virtual machine.

   Except when executed in a level-3 configuration, the content of the machine-type-number field stored by STIDP is equivalent to the EBCDIC type field of the SYSIB 1.1.1 stored by STSI. When executed in a level-3 configuration, hypervisor features such as live guest relocation may alter machine-type number stored by STIDP to reflect the machine type corresponding to a virtual architecture level. However, the type field reported in the SYSIB 1.1.1 is that of the real machine, even when executed by a virtual machine.

5. In previous versions of the architecture, bit positions 0-7 were called the version code. Prior to z/Architecture, a nonzero version code was usually indicative of the model number and number of CPUs contained in the model.

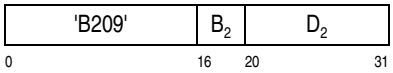
   In previous versions of the architecture, bit positions 8-31 were called the CPU-identification number. This has been renamed the configuration-identification field to more accurately represent its z/Architecture content.

6. The following applies to execution of STIDP on the IBM Z Personal-Development Tool (zPDT) or Rational Development and Test Environment for IBM Z (RD&T; for brevity the term zPDT also applies to RD&T):

   - The user-partition identifier (UPID) is associated with the Linux zPDT instance number. The zPDT instance-number field contains a value from 1-255, derived from either the zPDT token or from the unique-identification-manager (UIM) server.
   - The rightmost four hex digits of the configuration-identification field (called the serial number in zPDT documentation) contain a 16-bit binary value from 1-65,535 that is derived from the UIM server.

STORE CPU TIMER

STPT $D_2(B_2)$ [S]



The current value of the CPU timer is stored at the doubleword location designated by the second-operand address.

Zeros are provided for the rightmost bit positions that are not updated by the CPU timer.

Special Conditions

The operand must be designated on a doubleword boundary; otherwise, a specification exception is recognized.

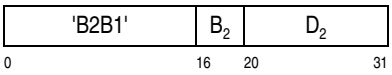
Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)
- Privileged operation
- Specification
- Transaction constraint

STORE FACILITY LIST

STFL $D_2(B_2)$ [S]



A list of bits providing information about facilities is stored in the word at real address 200. The meanings of the bits are identical to the first 32 bits stored by STORE FACILITY LIST EXTENDED. Figure 4-36, “Assigned Facility Bits” on page 4-101 shows the meanings of the assigned facility bits.

The second-operand address is ignored but should be zero to permit possible future extensions.

Key-controlled and low-address protection do not apply.

Condition Code: The code remains unchanged.

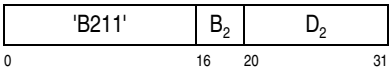
Program Exceptions:

- Privileged operation
- Transaction constraint

Programming Note: STORE FACILITY LIST stores only a 32-bit indication of facilities. STORE FACILITY LIST EXTENDED may be used to store the entire list of installed facilities.

STORE PREFIX

STPX $D_2(B_2)$ [S]



In the z/Architecture architectural mode, the contents of bit positions 33-50 of the prefix register are stored in bit positions 1-18 of the word location designated by the second-operand address, and zeros are stored in bit positions 0 and 19-31 of the word.

In the ESA/390-compatibility mode, the contents of bit positions 33-51 of the prefix register are stored in bit positions 1-19 of the word location designated by the second-operand address, and zeros are stored in bit positions 0 and 20-31 of the word.

Special Conditions

The operand must be designated on a word boundary; otherwise, a specification exception is recognized.

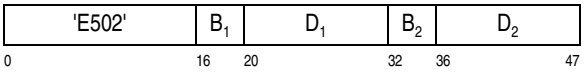
Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)
- Privileged operation
- Specification
- Transaction constraint

STORE REAL ADDRESS

STRAG $D_1(B_1),D_2(B_2)$ [SSE]



The 64-bit real or absolute address corresponding to the second-operand virtual address is stored in the doubleword at the location designated by the first-operand address.

The virtual address specified by the B_2 and D_2 fields is translated by means of the dynamic-address-translation facility, regardless of whether DAT is on or off.

DAT is performed by using an address-space-control element that depends on the current value of the address-space-control bits, bits 16 and 17 of the PSW, as shown in the following table:

PSW Bits 16 and 17	Address-Space-Control Element Used by DAT
00	Contents of control register 1
10	Contents of control register 7
01	The address-space-control element obtained by applying the access-register-translation (ART) process to the access register designated by the B_2 field
11	Contents of control register 13

ART and DAT may be performed with the use of the ART-lookaside buffer (ALB) and translation-lookaside buffer (TLB), respectively.

The resultant 64-bit real or absolute address is stored at the first-operand location.

When EDAT-1 does not apply, or when EDAT-1 does apply and the second operand is translated by means of a segment-table entry in which the STE-format control is zero, the address stored at the first-operand location is real. When EDAT-1 applies and the second operand is translated by means of a segment-table entry in which the STE-format control is one, or when EDAT-2 applies and the second operand is translated by means of a region-third-table entry in which the RTTE-format control is one, the address stored at the first-operand location is absolute.

The translated address is not inspected for boundary alignment or for addressing or protection exceptions.

The address computations for the operands are performed according to the current addressing mode, specified by bits 31 and 32 of the current PSW.

The addresses of the region-table entry or entries, if used, and of the segment-table entry and page-table entry are treated as 64-bit addresses regardless of the current addressing mode. It is unpredictable whether the addresses of these entries are treated as real or absolute addresses.

Special Conditions

The first operand must be designated on a doubleword boundary; otherwise, a specification exception is recognized.

In the ESA/390-compatibility mode, an operation exception is recognized.

The operation is suppressed on all addressing exceptions.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2, except for an addressing, secure-storage-access, or protection exception for the designated location; store, operand 1)
- Operation (in the ESA/390-compatibility mode)
- Privileged operation
- Specification
- Transaction constraint

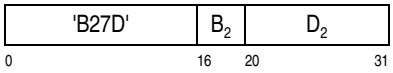
Programming Note: STORE REAL ADDRESS is contrasted to LOAD REAL ADDRESS as follows:

- In the 24-bit or 31-bit addressing mode, LOAD REAL ADDRESS (LRA) loads bits 33-63 of the real or absolute address if bits 0-32 of the address are all zeros or recognizes a special-operation exception if bits 0-32 are not all zeros. LRA in the 64-bit addressing mode, and LOAD REAL ADDRESS (LRAG) in any addressing mode, loads bits 0-63 of the real or absolute address. STORE REAL ADDRESS stores bits 0-63 of the real or absolute address in any addressing mode.

- LOAD REAL ADDRESS, for most access-exception conditions, does not recognize the conditions as exceptions but instead sets the condition code to indicate the occurrence of the conditions. STORE REAL ADDRESS recognizes all access-exception conditions as exceptions, resulting in a program interruption.

STORE SYSTEM INFORMATION

STSI $D_2(B_2)$ [S]



Depending on a function code in general register 0, either an identification of the level of the configuration executing the program is placed in general register 0 or information about a component or components of a configuration is stored in a system-information block (SYSIB). When information about a component or components is requested, the information is specified by further contents of general register 0 and by contents of general register 1. The SYSIB, if any, is designated by the second-operand address.

The machine is considered to provide one, two, or three levels of configuration. The levels are:

1. The basic machine, which is the machine as if it were operating in the basic mode.

2. A logical partition, which is provided if the machine is operating in the logically partitioned (LPAR) mode. A logical partition is provided by the LPAR hypervisor, which is a part of the machine. Basic-machine configuration information is provided even when the machine is operating in the LPAR mode.

3. A virtual machine, which is provided by a virtual-machine (VM) control program that is executed either by the basic machine or in a logical partition. A virtual machine may itself execute a VM control program that provides a higher-level (more removed from the basic machine) virtual machine, which also is considered a level-3 configuration.

The terms basic mode, LPAR mode, logical partition, hypervisor, and virtual machine, and any other terms related specifically to those terms, are not defined in this publication; they are defined in the machine manuals.

A program being executed by a level-1 configuration (the basic machine) can request information about that configuration. A program being executed by a level-2 configuration (in a logical partition) can request information about the logical partition and about the underlying basic machine. A program being executed by a level-3 configuration (a virtual machine) can request information about the virtual machine and about the one or two underlying levels; a basic machine is always underlying, and a logical partition may or may not be between the basic machine and the virtual machine. When information about a virtual machine is requested, information is provided about the configuration executing the program and about any underlying level or levels of virtual machine.

The function code determining the operation is an unsigned binary integer in bit positions 32-35 of general register 0 and is as follows:

Function Code	Information Requested
0	Current-configuration-level number
1	Information about level 1 (the basic machine)
2	Information about level 2 (a logical partition)
3	Information about level 3 (a virtual machine)
4-14	None; codes are reserved
15	Current-configuration-level information

Invalid Function Code

The level of the configuration executing the program is called the current level. The configuration level specified by a nonzero function code (other than 15) is called the specified level. When the specified level is numbered higher than the current level, then the function code is called invalid, the condition code is set to 3, and no other action (including checking) is performed. Function code 15 is invalid when the configuration-topology facility is not installed.

Valid Function Code

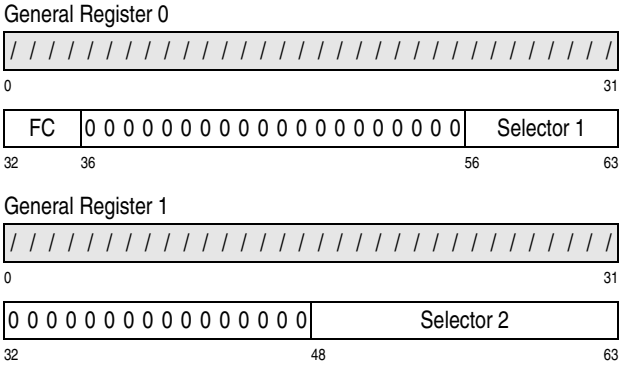
When the function code is equal to or less than the number of the current level, or 15, it is called valid. In this case, bits 36-55 of general register 0 and bits 32-47 of general register 1 must be zero; otherwise, a specification exception is recognized. Bits 0-31 of general registers 0 and 1 always are ignored.

When the function code is 0, an unsigned binary integer identifying the current configuration level (1 for basic machine, 2 for logical partition, or 3 for virtual machine) is placed in bit positions 32-35 of general register 0, the condition code is set to 0, and no further action is performed.

When the function code is valid and nonzero, general registers 0 and 1 contain additional specifications about the information requested, as follows:

- Bit positions 56-63 of general register 0 contain an unsigned binary integer, called *selector 1,* that specifies a component or components of the specified configuration.
- Bit positions 48-63 of general register 1 contain an unsigned binary integer, called *selector 2,* that specifies the type of information requested.

The contents of general registers 0 and 1 are as follows:



When the function code is valid and nonzero, information may be stored in a system-information block (SYSIB) beginning at the second-operand location. The SYSIB is 4K bytes and must begin at a 4 K-byte boundary; otherwise, a specification exception may be recognized, depending on selector 1 and selector 2 and on whether access exceptions are recognized due to references to the SYSIB (see “Special Conditions”).

Selector 1 can have values as follows:

Selector 1	Information Requested
0	None; selector is reserved
1	Information about the configuration level specified by the function code.
2	Information about one or more CPUs in the specified configuration level
3-255	None; selectors are reserved

When selector 1 is 1, selector 2 can have values as follows:

Selector 2 when Selector 1 Is 1	Information Requested
0	None; selector is reserved
1	Information about the specified configuration level
2-6	Topology information about the specified configuration level
7-65,535	None; selectors are reserved

When selector 1 is 2, selector 2 can have values as follows:

Selector 2 when Selector 1 Is 2	Information Requested
0	None; selector is reserved
1	Information about the CPU executing the program in the specified configuration level
2	Information about all CPUs in the specified configuration level
3-65,535	None; selectors are reserved

Only certain combinations of the function code, selector 1, and selector 2 are valid, as shown in Figure 10-94.

Function Code	Selector 1	Selector 2	Information Requested about
0	-	–	Current-configuration-level number
1	1	1	Basic-machine configuration
1	2	1	Basic-machine CPU
1	2	2	Basic-machine CPUs
2	2	1	Logical-partition CPU
2	2	2	Logical-partition CPUs
3	2	2	Virtual-machine CPUs
15	1	2-6	Topology information of current configuration
Explanation: – Ignored.			

Figure 10-94. Valid Function-Code, Selector-1, and Selector-2 Combinations for STORE SYSTEM INFORMATION

When the specified function-code, selector-1, and selector-2 combination is invalid (is other than as shown in Figure 10-94), or if it is valid but the requested information is not available because the specified level does not implement or does not fully implement the instruction or because a necessary part of the level is uninstalled or not initialized, and provided that an exception is not recognized (see "Special Conditions"), the condition code is set to 3. When the function code is nonzero, the combination is valid, the requested information is available, and there is no exception, the requested information is stored in a system-information block (SYSIB) at the second-operand address.

Some or all of the SYSIB may be fetched before it is stored.

A SYSIB may be identified in references by means of "SYSIB fc.s1.s2," where "fc," "s1," and "s2" are the values of a function code, selector 1, and selector 2, respectively.

Following sections describe the defined SYSIBs by means of figures and related text. In the figures, the offsets shown on the left are word values. "The configuration" refers to the configuration level specified by the function code (the configuration level about which information is requested).

Note: In the descriptions of the system-information block (SYSIB) stored by STSI, the term "CPU or core" (or briefly, "CPU/core") indicates the applicability of the text. When the multithreading facility is not installed at the selected configuration level, certain STSI functions store information relevant to logical or physical CPU attributes. When the multithreading facility is installed at the selected configuration level, these STSI functions store information relevant to logical or physical core attributes.

SYSIB 1.1.1 (Basic-Machine Configuration)

SYSIB 1.1.1 is illustrated in Figure 10-95:

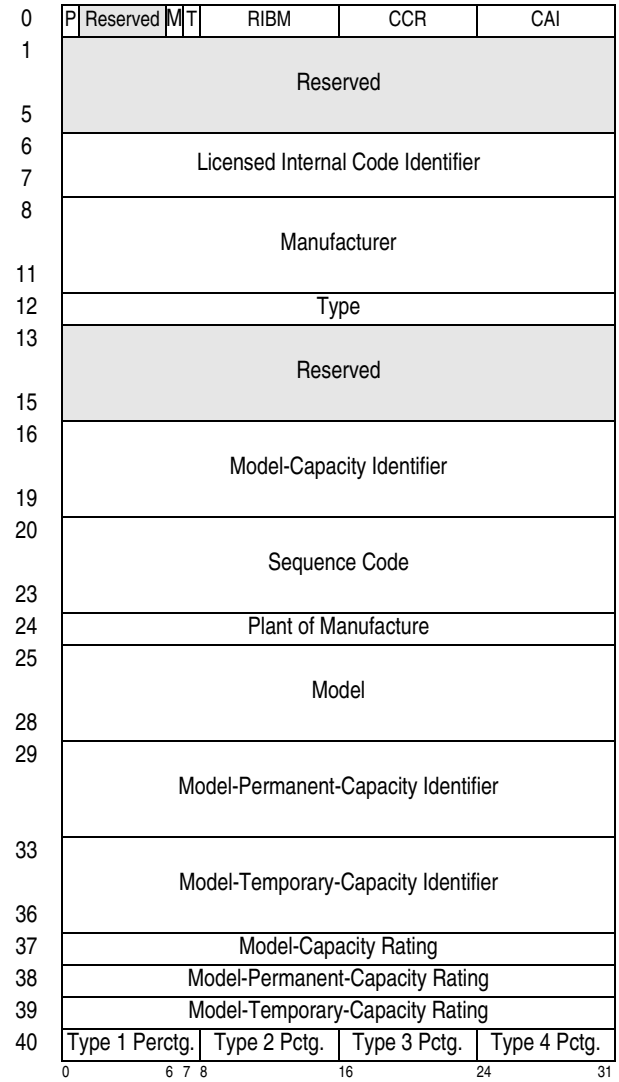


Figure 10-95. Format of the SYSIB 1.1.1 (Part 1 of 2)

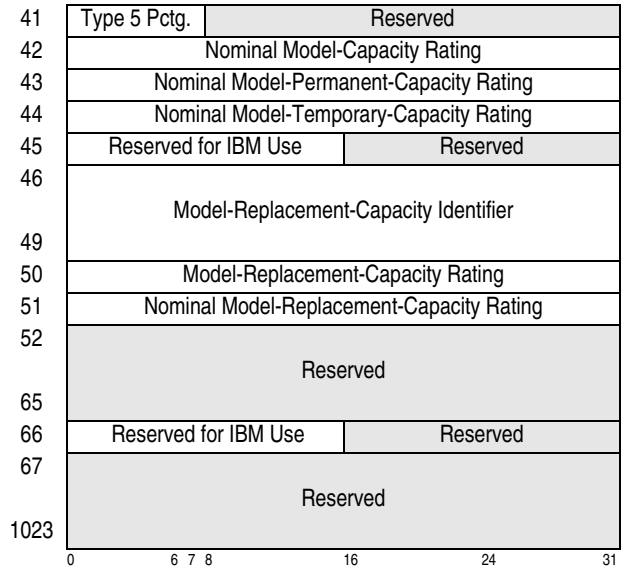

Figure 10-95. Format of the SYSIB 1.1.1 (Part 2 of 2)

Reserved: The contents of bits 1-5 of word 0, words 1-5, bits 16-31 of word 13, words 14-15, bits 8-31 of word 41, and bits 16-31 of word 45 are reserved and are stored as zeros. The contents of bits 0-15 of word 13, and words 52-63 are reserved and may be stored as zeros or unpredictable values. The contents of words 64-65 are reserved and may be stored as zeros, may remain unchanged, or may contain unpredictable values. The contents of bits 16-31 of word 66, and words 67-1023 are reserved and may be stored as zeros or may remain unchanged.

Word 0, Byte 0: Byte 0 of word 0 contains the following bit definitions:

Bit Meaning

0 When bit 0 of byte 0 (P) is one, the type-percentage bytes, located in words 40-41, are valid. When P is zero, the bytes are stored as zeros, but have no meaning.

1-5 Bits 1-5 of byte 0 are reserved and stored as zeros.

6 When bit 6 of byte 0 (M) is zero, the multithreading facility is not installed in the basic machine configuration. When M is one, the multithreading facility is installed in the basic machine configuration.

7 Bit 7 of byte 0 (T), when one, indicates that the condition represented by the CCR and CAI fields is relatively transient.

Reserved for IBM Use (RIBM): Byte 1 of word 0 , bytes 0-1 of word 45, and bytes 0-1 of word 66 are assigned to IBM internal use.

Capacity-Change Reason (CCR): When the CAI byte is nonzero, the content of byte 2 of word 0 is an 8-bit unsigned integer whose value indicates one of the following reasons which is associated with the present values contained in SYSIB 1.1.1.

CCR Capacity-Change Reason

0 Machine is running at nominal capacity.

1 The capacity change is due solely to the setting of a manual control, such as intentional power-save.

2 The capacity change is due to a machine-exception condition, such as detection of overheating.

3 The capacity change is due to a non-exception machine condition, such as concurrent service.

4 The capacity change is due to an exception condition external to the machine, such as detection of supplied power or cooling falling outside required tolerances.

5-255 Reserved.

When the CAI byte is zero, the CCR field is undefined, and stored as zero.

When multiple capacity-change reasons exist, CCR is set according to the following priority:

1a. Machine-exception condition, CCR=2.

1b. External-exception condition, CCR=4.

2. Non-exception machine condition, CCR=3.

3. Manual control, CCR=1.

Capacity-Adjustment Indication (CAI): Byte 3 of word 0, when nonzero, is an 8-bit unsigned integer whose value is in the range 1-100 and represents the aggregate position of model-dependent controls. Temporary capacity changes that affect machine performance are not included; such changes include those caused by capacity-backup (CBU), on/off-capacity-on-demand (OOCoD), capacity-planned-event (CPE), flexible capacity for cyber resiliency

(FC), and tailored fit pricing for IBM Z hardware (TFP-HW) features. When zero, the indication is not reported. When in the range 1-99, some amount of reduction is indicated. When 100, the machine is operating at its normal capacity.

Primary CPUs and all secondary-type CPUs are similarly affected.

The model-capacity rating is not affected. A change in the CAI may also reflect a change in CPU-capability fields of SYSIB 1.2.2.

Licensed Internal Code (LIC) Identifier: Words 6-7, when nonzero, indicate information about currently installed internal code. The definition of the information conveyed is model dependent. The internal code, to which the information applies, is model dependent.

Manufacturer: Words 8-11 contain the 16-character (0-9 or uppercase A-Z) EBCDIC name of the manufacturer of the configuration. The name is left justified with trailing blanks if necessary.

Type: Word 12 contains the four-character (0-9) EBCDIC type number of the configuration. (This is called the machine-type number in the definition of STORE CPU ID.)

Model-Capacity Identifier (CI): Words 16-19 contain the 16-character (0-9 or uppercase A-Z) EBCDIC model-capacity identifier of the configuration. The model-capacity identifier is left justified with trailing blanks if necessary.

Sequence Code: Words 20-23 contain the 16-character (0-9 or uppercase A-Z) EBCDIC sequence code of the configuration. The sequence code is right justified with leading EBCDIC zeros if necessary.

Plant of Manufacture: Word 24 contains the four-character (0-9 or uppercase A-Z) EBCDIC code that identifies the plant of manufacture for the configuration. The code is left justified with trailing blanks if necessary.

Model: When word 25 is not binary zeros, words 25-28 contain the 16-character (0-9 or uppercase A-Z) EBCDIC model identification of the configuration. The model identification is left justified with trailing blanks if necessary. (This is called the model number in programming note 5 on page 10-150 of STORE CPU ID.) When word 25 is binary zeros, the contents of words 16-19 represent both the model-capacity identifier and the model.

Model-Permanent-Capacity Identifier (PI): When nonzero, words 29-32 contain the 16-character (0-9 or uppercase A-Z) EBCDIC model-permanent-capacity identifier of the configuration. The identifier is left justified with trailing blanks if necessary.

Model-Temporary-Capacity Identifier (TI): When nonzero, words 33-36 contain the 16-character (0-9 or uppercase A-Z) EBCDIC model-temporary-capacity identifier of the configuration. The identifier is left justified with trailing blanks if necessary.

Model-Capacity Rating (CR): When nonzero, word 37 contains a 32-bit unsigned integer whose value is associated with the model capacity as identified by the model-capacity identifier. There is no formal description of the algorithm used to generate this integer.

Model-Permanent-Capacity Rating (PR): When nonzero, word 38 contains a 32-bit unsigned integer whose value is associated with the model-permanent capacity as identified by the model-permanent-capacity identifier. There is no formal description of the algorithm used to generate this integer.

Model-Temporary-Capacity Rating (TR): When nonzero, word 39 contains a 32-bit unsigned integer whose value is associated with the model-temporary capacity as identified by the model-temporary-capacity identifier. There is no formal description of the algorithm used to generate this integer.

Type N Pctg. Each of the byte fields in words 40-41 that is designated as a type-N percentage contains an 8-bit unsigned binary integer whose value is in the range 0-100 and represents a percentage. When nonzero, the percentage may be used to affect the use and allowed utilization of the secondary-CPUs whose CPU type corresponds to the particular byte. When a byte in this range contains a value of zero, use rules of the corresponding secondary-CPU type are not overridden. The reserved bytes in word 41 are reserved for the potential addition of new secondary CPU types.

Nominal Model-Capacity Rating (NCR): When nonzero, word 42 contains a 32-bit unsigned integer whose value is associated with the nominal model capacity as identified by the model-capacity identifier. There is no formal description of the algorithm used

to generate this integer. The NCR value equals the CR value when the CAI byte contains a value of 100. When the CAI byte is less than 100, the CR value is less than the NCR value.

Nominal Model-Permanent-Capacity Rating (NPR): When nonzero, word 43 contains a 32-bit unsigned integer whose value is associated with the nominal model-permanent capacity as identified by the model-permanent-capacity identifier. There is no formal description of the algorithm used to generate this integer. The NPR value equals the PR value when the CAI byte contains a value of 100. When the CAI byte is less than 100, the PR value is less than the NPR value.

Nominal Model-Temporary-Capacity Rating (NTR): When nonzero, word 44 contains a 32-bit unsigned integer whose value is associated with the nominal model-temporary capacity as identified by the model-temporary-capacity identifier. There is no formal description of the algorithm used to generate this integer. The NTR value equals the TR value when the CAI byte contains a value of 100. When the CAI byte is less than 100, the TR value is less than the NTR value.

Model-Replacement-Capacity Identifier (RI) : When nonzero, and the configuration type in word 12 is not one of the four listed in Figure 10-96, words 46-49 contain the 16-character (0-9 or uppercase A-Z) EBCDIC model-replacement-capacity identifier of the configuration. The identifier is left justified with trailing blanks if necessary.

When the contents of either words 48 or 49 are nonzero, and the configuration type is one of the four listed in Figure 10-96, the contents of words 46 and 47 are stored as zeros, and the contents of words 48 and 49 are unpredictable.

Configuration Type (SYSIB 1.1.1 Word 12)	Processor
3906	z14
3907	
8561	z15
8562	

Figure 10-96. Exceptions to Model-Variable-Capacity Fields

Model-Replacement-Capacity Rating (RR): When nonzero, and the configuration type in word 12 is not one of the four listed in Figure 10-96, word 50 contains a 32-bit unsigned integer whose value is associated with the model-replacement-capacity as identified by the model-replacement-capacity identifier. There is no formal description of the algorithm used to generate this integer.

When nonzero, and the configuration type is one of the four listed in Figure 10-96, the contents of word 50 are unpredictable.

Nominal Model-Replacement-Capacity Rating (NRR): When nonzero, and the configuration type in word 12 is not one of the four listed in Figure 10-96, word 51 contains a 32-bit unsigned integer whose value is associated with the nominal model-replacement-capacity as identified by the model-replacement-capacity identifier. There is no formal description of the algorithm used to generate this integer. The NRR value equals the RR value when the CAI byte contains a value of 100. When the CAI byte is less than 100, the RR value is less than the NRR value.

When nonzero, and the configuration type is one of the four listed in Figure 10-96, the contents of word 51 are unpredictable.

Worldwide Unique Identification: Taken together, the machine type, manufacturer, plant of manufacture, and sequence code allow for worldwide unique identification of the system.

Programming Notes:

1. The fields of the SYSIB 1.1.1 are similar to those of the node descriptor described in the publication *Common I/O-Device Commands and Self Description,* SA22-7204. However, the contents of the SYSIB fields may not be identical to the contents of the corresponding node-descriptor fields because the SYSIB fields:
   - Allow more characters.
   - Are more flexible regarding the type of characters allowed.
   - Provide information that is justified differently within the field.
   - May not use the same method to determine the contents of fields such as the sequence-code field.

2. The model field in a node descriptor corresponds to the content of the STSI model field and not the STSI model-capacity-identifier field.

3. The model field specifies the model of the machine (i.e., the physical model); the model-capacity identifier field specifies a token that may be used to locate a statement of capacity or performance in the System Library publication for the model.

4. Each of the four model-capacity-identifier fields specifies a token that may be used to locate a statement of capacity or performance in the System Library publication for the model.

5. Each of the four model-capacity-rating fields, corresponding one-to-one with the four model-capacity-identifier fields, specifies a numeric value that may or may not represent the actual capacity of the machine

6. The term *capacity backup* (CBU) represents a methodology by which spare capacity in a CPC can be used to replace capacity from another CPC within an enterprise, normally for a relatively limited period of time. Typically CBU is used when another CPC of the enterprise has failed, and the CPC operating under CBU rules is making up for the missing CPC's capacity. CBU is a type of temporarily-available replacement capacity.

7. The term *On/Off Capacity on Demand* (On/Off CoD) represents a methodology by which spare capacity in a CPC can be made available to increase the total capacity within an enterprise, normally for a limited period of time. For example, On/Off CoD may be used to acquire additional capacity in order to handle a workload peak. On/Off CoD is a type of temporarily-available increased capacity.

8. The content of the model-capacity identifier (CI) field corresponds to the total of all types of active capacity which is the current capacity at which the central-processing complex (CPC) is operating. It is a total of permanent capacity, temporarily-available increased capacity, temporarily-available replacement capacity, and corridor capacity.

9. The content of the model-permanent-capacity identifier (PI) corresponds to the capacity of the CPC exclusive of temporarily-available increased capacity, temporarily-available replacement capacity, and corridor capacity.

10. The content of the model-temporary-capacity identifier (TI) corresponds to the total of permanent capacity and temporarily-available increased capacity but exclusive of any temporarily-available replacement capacity and corridor capacity.

11. When the T bit in byte 0 is one, the current capacity values and identifiers are in a relatively-short period of transition and should be permitted to stabilize, that is, a result where T is zero, before any resultant action proceeds.

12. There is no facility indication defined to distinguish whether a model stores zeros, or information pertaining to installed internal code, in the licensed internal code identifier field. A program may test the licensed internal code identifier field stored, for a nonzero value, to recognize whether or not a specific machine provides the information requested.

13. The term *capacity planned event* (CPE) represents a methodology by which spare capacity in a CPC can be used to replace capacity from another CPC within an enterprise, normally for a relatively limited period of time. Typically, CPE is used when a planned outage of another CPC of the enterprise occurs. CPE is a type of temporarily-available replacement capacity.

14. The term *flexible capacity for cyber resiliency* (FC) represents a methodology by which spare capacity in a CPC can be used to replace capacity from another CPC within an enterprise, for an extended period of time. Typically, FC is used to demonstrate the capability of running enterprise workloads in an alternative data center, using the "swap and stay" methodology. Additional capacity is activated in the alternative data center, the workload is "swapped" to that data center, and then the workload "stays" active in that data center for an extended period of time. Once the workload has been swapped, an equivalent amount of capacity is deactivated in the original data center. In the advent of a real disaster, the FC record is used to provide the replacement capacity. FC is a type of temporarily-available increased capacity.

15. The term Tailored Fit Pricing for IBM Z Hardware (TFP-HW) represents a methodology by which spare capacity in a CPC can be made available

to increase the total capacity within an enterprise for a long term basis. This additional capacity is there to handle short duration workload spikes, which are too short to be regularly handled by On/Off CoD. TFP-HW is a type of corridor capacity.

16. The contents of the model-replacement-capacity identifier (RI) field corresponds to the total of permanent capacity, temporarily-available increased capacity, and temporarily-available replacement capacity, but exclusive of corridor capacity.

17. See Reference [42.] on page xxxiii for details relating to CBU, On/Off CoD, CPE, FC, and TFP-HW in the Capacity on Demand User's Guide.

SYSIB 1.2.1 (Basic-Machine CPU/Core)

SYSIB 1.2.1 is illustrated in Figure 10-97:

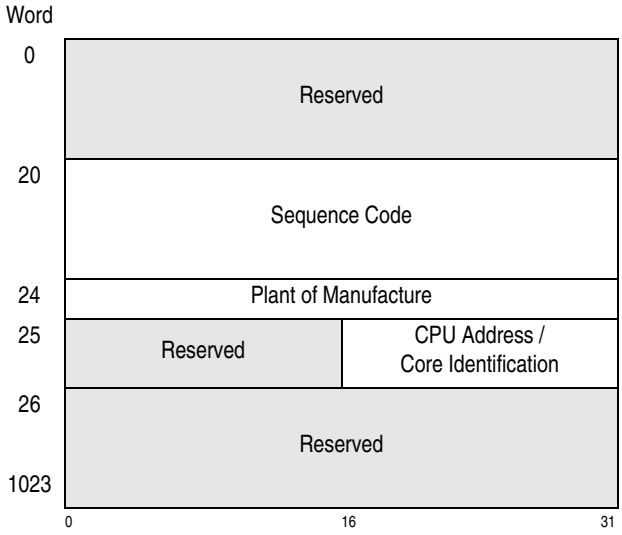

Figure 10-97. Format of the SYSIB 1.2.1

Reserved: The contents of words 0-19, bytes 0 and 1 of word 25, and words 26-63 are reserved and are stored as zeros. The contents of words 64-1023 are reserved and may be stored as zeros or may remain unchanged.

Sequence Code: Words 20-23 contain the 16-character (0-9 or uppercase A-Z) EBCDIC sequence code of the configuration. The code is right justified with leading EBCDIC zeros if necessary.

Plant of Manufacture: Word 24 contains the four-character (0-9 or uppercase A-Z) EBCDIC code that identifies the plant of manufacture for the configuration. The code is left justified with trailing blanks if necessary.

CPU Address: When the multithreading facility is not installed in the machine, bytes 2 and 3 of word 25 contain the CPU address by which this CPU is identified in a multiprocessing configuration. The CPU address is a 16-bit unsigned binary integer. The CPU address is the same as is stored by STORE CPU ADDRESS when the program is executed by a machine operating in the basic mode.

Core Identification: When multithreading is installed in the machine, bytes 2 and 3 of word 25 contain a 16-bit unsigned core identification, right justified in the field. The core ID field contains the core-ID portion of the value that would be stored by STORE CPU ADDRESS when executed by a machine operating in the basic mode; no thread ID is included.

Worldwide Unique Identification: Taken together, the machine type and manufacturer (from SYSIB 1.1.1) with the plant of manufacture and sequence code allow for worldwide unique identification of the system.

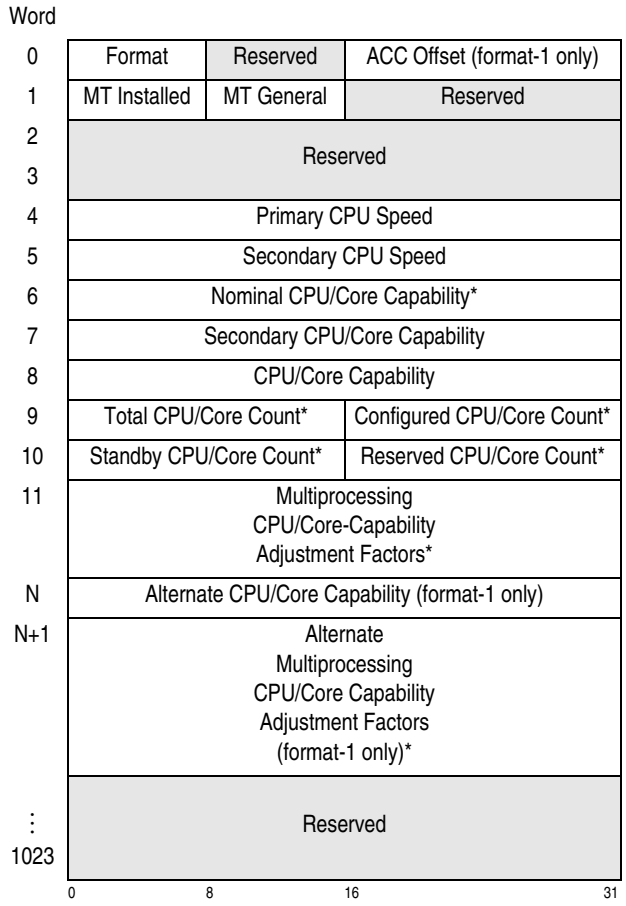
Programming Note: Multiple CPUs in the same configuration have the same sequence code, and it is necessary to use other information, such as the CPU address, to establish a unique CPU identity. The sequence code returned for a basic-machine CPU and a logical-partition CPU are identical and have the same value as the sequence code returned for the basic-machine configuration.

SYSIB 1.2.2 (Basic-Machine CPUs)

The general format of the SYSIB 1.2.2 is illustrated in Figure 10-98. Some fields may or may not be valid, as indicated by the contents of the format field in byte 0 of word zero.

When the multithreading facility is not installed (as indicated by bit 0 of word 1), fields labelled "CPU/Core" apply to a CPU. When the multithreading

facility is installed, fields labelled “CPU/Core” apply to a core.



Explanation:

* Field applies to general CPUs or to cores comprising general CPUs.

Figure 10-98. Format of the SYSIB 1.2.2

Reserved: The contents of byte 1 of word 0, bytes 2-3 of word 1, and words 2-3 are reserved and stored as zeros. When the format field contains a value of zero, bytes 2-3 of word 0 are reserved and stored as zeros.

When fewer than 64 words are needed to contain the information for all the CPUs or cores, the portion of the SYSIB following the adjustment-factor list in a format-0 SYSIB, or the alternate-adjustment-factor list in a format-1 SYSIB, up to and including word 63 are reserved and are stored as zeros. The contents of words 64-1023 are reserved and may be stored as zeros or may remain unchanged.

When 64 or more words are needed to contain the information for all the CPUs, the portion of the SYSIB following the adjustment-factor list in a format-0 SYSIB or the alternate-adjustment-factor list in a format-1 SYSIB, up to and including word 1023 are reserved and may be stored as zeros or may remain unchanged.

Format: Byte 0 of word 0 contains an 8-bit unsigned binary integer that specifies the format of SYSIB 1.2.2.

Alternate-CPU/Core-Capability Offset: When the format field has a value of one, bytes 2-3 of word 0 contain a 16-bit unsigned binary integer that specifies the offset in bytes of the alternate-CPU-capability field in the SYSIB. Zeros are stored in the rightmost two bits of the ACC offset field, thus the ACC offset is a multiple of four and designates word N in Figure 10-98.

MT Installed: When bit 0 of the MT-installed field (byte 0 of word 1) is zero, the remainder of the field and the MT-general field are not meaningful and stored as zeros. When bit 0 of the MT-installed field is one, the remainder of the field and the MT-general field are meaningful, as described below.

Bits	Meaning
0	When zero, the multithreading facility is not installed in the machine. When one, the multithreading facility is installed in the machine.
1-2	Reserved (stored as zeros).
3-7	A 5-bit unsigned integer whose value is the highest supported thread identification (TID) for a core in the machine. The value is in the range 1-31, indicating a minimum of two and a maximum of 32 CPUs per core. A specialty core may operate with this thread count .

MT General: The contents of byte 1 of word 1 are meaningful only when bit 0 of word 1 is one.

Bit	Meaning
0-2	Reserved.
3-7	A 5-bit unsigned integer whose value is the highest supported thread identification for a core comprising general CPUs. The value is in the range 0-31, indicating a minimum of one and a maximum of 32 CPUs per core.

The value is less than or equal to the value in bits 3-7 of the MT-installed field. A value of zero indicates that multithreading is not available for a general core. For a sub-capacity model, bits 3-7 of the MT-general field contain zeros.

Primary CPU/Core Speed: When not zero, word 4 contains a 32-bit unsigned binary integer whose value represents the dynamic speed of a primary CPU, encoded as the approximate number of CPU cycles per microsecond.

Secondary CPU/Core Speed: When not zero, word 5 contains a 32-bit unsigned binary integer whose value represents the dynamic speed of a secondary CPU, encoded as the approximate number of CPU cycles per microsecond.

Nominal CPU/Core Capability: Word 6, when not zero, is formatted and encoded the same as word 8, CPU capability, including that a lower value indicates a proportionally higher CPU capability.

When the CAI byte of SYSIB 1.1.1 is zero, the nominal CPU capability (word 6) is stored as zero. The nonzero value equals the word-8 value when the CAI byte of SYSIB 1.1.1 contains a value of 100. When the CAI byte of SYSIB 1.1.1 is nonzero and less than 100, the word-6 value indicates a CPU speed greater than the CPU speed indicated by the word-8 value.

Secondary CPU/Core Capability: Word 7, when not zero, is formatted and encoded the same as word 8, CPU capability, including that a lower value indicates a proportionally higher CPU capability, and specifies a secondary capability that may be applied to certain types of CPUs in the configuration.

There is no formal description of the algorithm used to generate this value, except that it is the same as the algorithm used to generate the CPU capability. The value is used as an indication of the capability of a CPU relative to the capability of other CPU models, and also relative to the capability of other CPU types within a model.

The capability value applies to each of the specialty CPUs/cores of one or more applicable CPU/core types in the configuration. That is, all CPUs in the configuration of an applicable type or types have the same capability. When the value is zero, all CPUs of any CPU type in the configuration have the same capability, as specified by the CPU capability.

The secondary CPU capability may or may not be the same value as the CPU-capability value.

The multiprocessing-CPU-capability-adjustment factors are also applicable to CPUs whose capability is specified by the secondary CPU capability.

CPU/Core Capability: Word 8 specifies the capability of one of the CPUs in the configuration.

If bits 0-8 of word 8 are zero, the word contains a 32-bit unsigned binary integer (I) in the range $1 \leq I < 2^{23}$. If bits 0-8 of word 8 are nonzero, the word contains a 32-bit binary floating point short-format number instead of an unsigned binary integer.

Regardless of encoding, the value represents the capability of one of the CPUs in the configuration, and a lower value indicates a proportionally higher CPU capability. Beyond that, there is no formal description of the algorithm used to generate this value. The value is used as an indication of the capability of the CPU relative to the capability of other CPU models.

The capability value applies to each of the general CPUs in the configuration. That is, all non-secondary CPUs in the configuration have the same capability.

Total CPU/Core Count: Bytes 0 and 1 of word 9 contain a 16-bit unsigned binary integer that specifies the total number of general CPUs or cores comprising general CPUs in the configuration. This number includes all general CPUs/cores in the configured state, the standby state, or the reserved state.

Configured CPU/Core Count: Bytes 2 and 3 of word 9 contain a 16-bit unsigned binary integer that specifies the number of general CPUs or cores comprising general CPUs that are in the configured state. A CPU/core is in the configured state when it is in the configuration and available to be used to execute programs.

Standby CPU/Core Count: Bytes 0 and 1 of word 10 contain a 16-bit unsigned binary integer that specifies the number of general CPUs or cores comprising general CPUs that are in the standby state. A CPU/core is in the standby state when it is in the configuration, is not available to be used to execute programs, and can be made available by issuing instructions to place it in the configured state.

Reserved CPU/Core Count: Bytes 2 and 3 of word 10 contain a 16-bit unsigned binary integer that specifies the number of general CPUs or cores comprising general CPUs that are in the reserved state. A CPU/core is in the reserved state when it is in the configuration, is not available to be used to execute programs, and cannot be made available by issuing instructions to place it in the configured state. (It may be possible to place a reserved CPU in the standby or configured state by means of manual actions.)

Multiprocessing CPU/Core-Capability Adjustment Factors: Beginning with bytes 0 and 1 of word 11, the SYSIB contains a series of contiguous two-byte fields, each containing a nonzero 16-bit unsigned binary integer used to form an adjustment factor (fraction) for the value contained in the CPU-capability field. Such a fraction is developed by using the value (V) of the first two-byte field according to one of the following methods:

- If V is in the range of 1 through 100, inclusive, a denominator of 100 is indicated which produces a fraction of V/100.
- If V is in the range of 101 through 255, inclusive, a denominator of 255 is indicated which produces a fraction of V/255.
- If V is in the range of 256 through 65,535, inclusive, a denominator of 65,535 is indicated which produces a fraction of V/65,535.

Thus, the fraction represented by each two-byte field is then developed by dividing the contents of a two-byte field by the indicated denominator.

The number of adjustment-factor fields is one less than the number of CPUs specified in the total-CPU-count field. The adjustment-factor fields correspond to configurations with increasing numbers of CPUs in the configured state. The first adjustment-factor field corresponds to a configuration with two CPUs in the configured state. Each successive adjustment-factor field corresponds to a configuration with a number of CPUs in the configured state that is one more than that for the preceding field.

Programming Note: The applicable MP adjustment factor is an approximation that is sensitive to the particular workload.

Alternate CPU/Core Capability: When the format field has a value of one, the location of word N is the sum of the address of the SYSIB plus the byte-offset value in the alternate-CPU-capability-offset field. If bits 0-8 of word N are zero, the word contains a 32-bit unsigned binary integer (I) in the range $0 \leq I < 2^{23}$ that specifies the announced capability of one of the CPUs in the configuration. If bits 0-8 of word N are nonzero, the word contains a 32-bit binary floating point short-format number instead of a 32-bit unsigned binary integer.

Regardless of encoding, a lower value indicates a proportionally higher CPU capacity. Beyond that, there is no formal description of the algorithm used to generate this value. The value is used as an indication of the announced capability of the CPU relative to the announced capability of other CPU models.

The alternate-capability value applies to each of the general CPUs or cores comprising general CPUs in the configuration. That is, all general CPUs/cores in the configuration have the same alternate capability.

Alternate Multiprocessing CPU/Core-Capability Adjustment Factors: When the format field has a value of one, the location of word N + 1 is the sum of the address of the SYSIB plus the byte-offset value in the alternate-CPU-capability-offset field plus four. Beginning with bytes 0 and 1 of word N + 1, the SYSIB contains a series of contiguous two-byte fields, each containing a nonzero 16-bit unsigned binary integer used to form an adjustment factor (fraction) for the value contained in the alternate-CPU-capability field. Such a fraction is developed by using the value (V) of the first two-byte field according to one of the following methods:

- If V is in the range of 1 through 100, inclusive, a denominator of 100 is indicated which produces a fraction of V/100.
- If V is in the range of 101 through 255, inclusive, a denominator of 255 is indicated which produces a fraction of V/255.
- If V is in the range of 256 through 65,535, inclusive, a denominator of 65,535 is indicated which produces a fraction of V/65,535.

Thus, the fraction represented by each two-byte field is then developed by dividing the contents of a two-byte field by the indicated denominator.

The number of alternate-adjustment-factor fields is one less than the number of CPUs specified in the

total-CPU-count field. The alternate-adjustment-factor fields correspond to configurations with increasing numbers of CPUs in the configured state. The first alternate-adjustment-factor field corresponds to a configuration with two CPUs in the configured state. Each successive alternate-adjustment-factor field corresponds to a configuration with a number of CPUs in the configured state that is one more than that for the preceding field.

SYSIB 2.2.1 (Logical-Partition CPU/Core)

SYSIB 2.2.1 is illustrated in Figure 10-99.

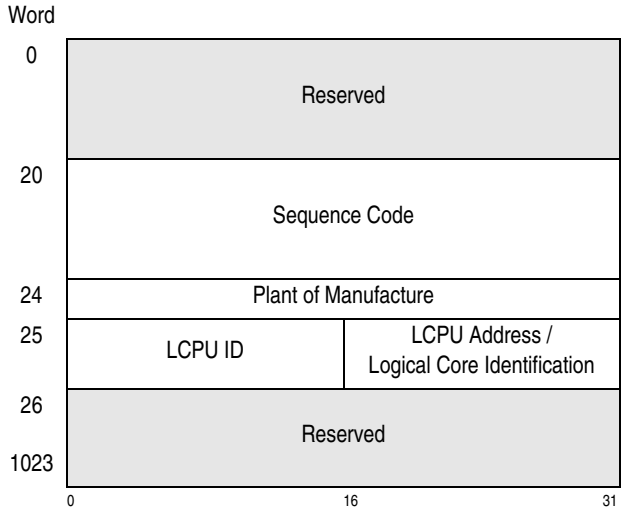


Figure 10-99. Format of the SYSIB 2.2.1

Reserved: The contents of words 0-19 and 26-63 are reserved and are stored as zeros. The contents of words 64-1023 are reserved and may be stored as zeros or may remain unchanged.

Sequence Code: Words 20-23 contain the 16-character (0-9 or uppercase A-Z) EBCDIC sequence code of the configuration. The code is right justified with leading EBCDIC zeros if necessary.

Plant of Manufacture: Word 24 contains the four-character (0-9 or uppercase A-Z) EBCDIC code that identifies the plant of manufacture for the configuration. The code is left justified with trailing blanks if necessary.

Logical-CPU ID: Bytes 0 and 1 of word 25 contain a 16-bit unsigned binary integer that can be used in conjunction with the logical-CPU address to distinguish the logical CPU from the other logical CPUs provided by the same LPAR hypervisor.

Logical-CPU Address: When the multithreading facility is not enabled in the level-2 configuration, bytes 2 and 3 of word 25 contain the logical-CPU address by which this logical CPU is identified within the level-2 configuration. The logical-CPU address is a 16-bit unsigned binary integer. The logical-CPU-address field contains the same information as is stored by STORE CPU ADDRESS when the machine is operating in the LPAR mode.

Logical-Core Identification: When the multithreading facility is enabled in the level-2 configuration, bytes 2 and 3 of word 25 contain a 16-bit unsigned core identification by which the core is identified within the configuration, right justified in the field.

Worldwide Unique Identification: Taken together, the machine type and manufacturer (from SYSIB 1.1.1) with the plant of manufacture and sequence code allow for worldwide unique identification of the system.

Programming Note: Multiple logical CPUs in the same level-2 configuration have the same logical-CPU sequence code, and it is necessary to use other information, such as the logical-CPU address, to establish a unique logical-CPU identity. The sequence code returned for a basic-machine CPU and a logical-partition CPU are identical and have the same value as the sequence code returned for the basic-machine configuration.

SYSIB 2.2.2 (Logical-Partition CPUs / Cores)

SYSIB 2.2.2 is illustrated in Figure 10-100.

When the multithreading facility is not enabled (as indicated by the PSMTID field), fields labeled with an asterisk (*) apply to a primary CPU. When the multithreading facility is enabled, fields labeled with an asterisk apply to a core comprising primary CPUs.

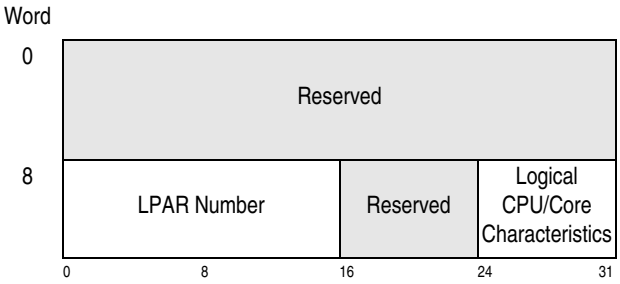

Figure 10-100. Format of the SYSIB 2.2.2 (Part 1 of 2)

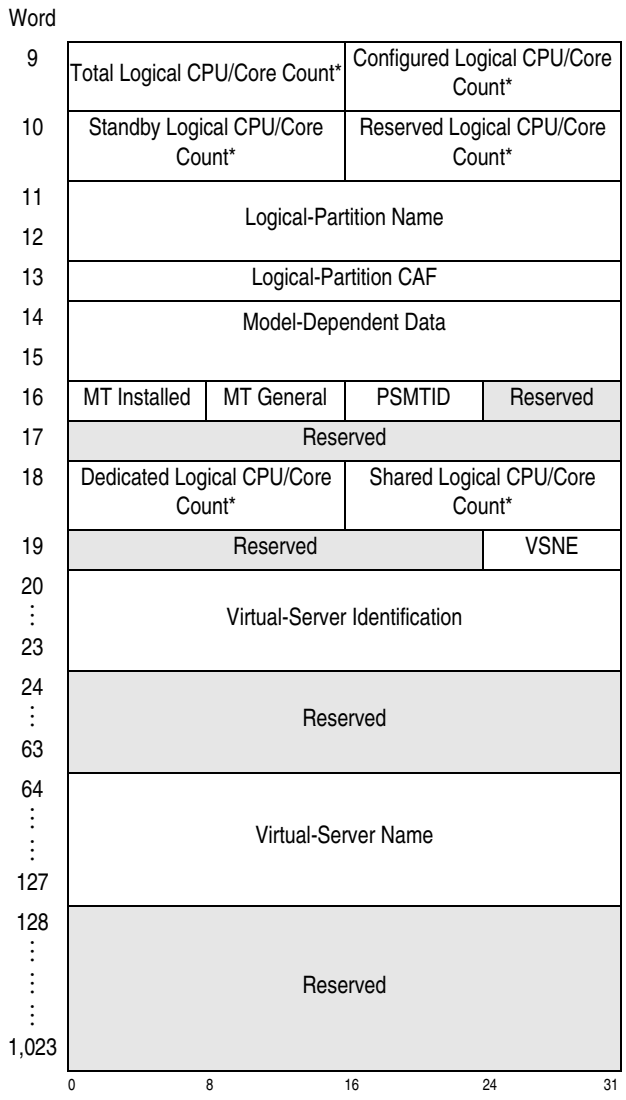

Figure 10-100. Format of the SYSIB 2.2.2 (Part 2 of 2)

Reserved: The contents of words 0-7, byte 2 of word 8, byte 3 of word 16, word 17, bytes 0-2 of word 19, and words 24-63 are reserved and are stored as zeros. When virtual-server information is not provided, the contents of byte 3 of word 19 and words 20-23 are reserved and stored as zeros, and the contents of words 64-127 are reserved and may be stored as zeros or may remain unchanged. The contents of words 128-1023 are reserved and may be stored as zeros or may remain unchanged.

Logical-Partition Number: Bytes 0 and 1 of word 8 contain a 16-bit unsigned binary integer which is the number of the level-2 configuration. This number distinguishes the configuration from all other level-2 configurations provided by the same LPAR hypervisor.

Logical-CPU/Core Characteristics: The contents of byte 3 of word 8 describe the characteristics of the logical CPUs/cores that are provided for the level-2 configuration. The bits and their meanings are as follows:

Bit Meaning

0 Dedicated: When one, bit 0 indicates that one or more of the logical CPUs/cores for this level-2 configuration are provided using level-1 CPUs/cores that are dedicated to this level-2 configuration and are not used to provide logical CPUs/cores for any other level-2 configuration. The number of logical CPUs/cores that are provided using dedicated level-1 CPUs/cores is specified by the dedicated-LCPU-count value in bytes 0 and 1 of word 18.

When zero, bit 0 indicates that none of the logical CPUs/cores for this level-2 configuration are provided using level-1 CPUs/cores that are dedicated to this level-2 configuration.

1 Shared: When one, bit 1 indicates that one or more of the logical CPUs/cores for this level-2 configuration are provided using level-1 CPUs/cores that can be used to provide logical CPUs/cores for other level-2 configurations. The number of logical CPUs/cores that are provided using shared level-1 CPUs/cores is specified by the shared-LCPU-count value in bytes 2 and 3 of word 18.

When zero, bit 1 indicates that none of the logical CPUs/cores for this level-2 configuration are provided using shared level-1 CPUs/cores.

2 Utilization Limit: When one, bit 2 indicates that the amount of use of the level-1 CPUs/cores that are used to provide the logical CPUs/cores for this level-2 configuration is limited.

When zero, bit 2 indicates that the amount of use of the level-1 CPUs/cores that are used to provide the logical CPUs/cores for this level-2 configuration is unlimited.

3-7 Reserved.

Total Logical-CPU/Core Count: Bytes 0 and 1 of word 9 contain a 16-bit unsigned binary integer that specifies the total number of primary logical CPUs/cores that are provided for this level-2 configuration. This number includes all of the logical

CPUs/cores that are in the configured state, the standby state, or the reserved state.

Configured Logical-CPU/Core Count: Bytes 2 and 3 of word 9 contain a 16-bit unsigned binary integer that specifies the number of primary logical CPUs/cores for this level-2 configuration that are in the configured state.

A logical CPU/core is in the configured state when it is in the level-2 configuration and is available to be used to execute programs.

Standby Logical-CPU/Core Count: Bytes 0 and 1 of word 10 contain a 16-bit unsigned binary integer that specifies the number of primary logical CPUs/cores for this level-2 configuration that are in the standby state.

A logical CPU/core is in the standby state when it is in the level-2 configuration, is not available to be used to execute programs, and can be made available by issuing instructions to place it in the configured state.

Reserved Logical-CPU/Core Count: Bytes 2 and 3 of word 10 contain a 16-bit unsigned binary integer that specifies the number of primary logical CPUs/cores for this level-2 configuration that are in the reserved state.

A logical CPU/core is in the reserved state when it is in the level-2 configuration, is not available to be used to execute programs, and cannot be made available by issuing instructions to place it in the configured state. (It may be possible to place the reserved CPU/core in the standby or configured state through manual actions.)

Logical-Partition Name: Words 11-12 contain the 8-character EBCDIC name of this level-2 configuration. The name is left justified with trailing blanks if necessary.

Logical-Partition Capability Adjustment Factor (CAF): Word 13 contains a 32-bit unsigned binary integer, called an adjustment factor, with a value of 1000 or less. The adjustment factor specifies the amount of the underlying level-1-configuration capability that is allowed to be used for this level-2 configuration by the LPAR hypervisor. The fraction of level-1-configuration capability is determined by dividing the CAF value by 1000.

MT Installed: When bit 0 of the MT-installed field (byte 0 of word 16) is zero, the remainder of the field and the MT-general and PSMTID fields are not meaningful and stored as zeros. When bit 0 of the MT-installed field is one, the remainder of the field and the MT-general and PSMTID fields are meaningful, as described below.

Bits	Meaning
0	When zero, the multithreading facility is not installed in the level-2 configuration. When one, the multithreading facility is installed in the level-2 configuration.
1-2	Reserved (stored as zeros).
3-7	A 5-bit unsigned integer whose value is the highest supported thread identification (TID) for a core of the level-2 configuration. The value is in the range 1-31, indicating a minimum of two and a maximum of 32 CPUs per core. A specialty core may operate with this thread count .

MT General: The contents of byte 1 of word 16 are meaningful only when bit 0 the MT-installed field is one.

Bit	Meaning
0-2	Reserved.
3-7	A 5-bit unsigned integer whose value is the highest supported thread identification for a core comprising general CPUs. The value is in the range 0-31, indicating a minimum of one and a maximum of 32 CPUs per core. The value is less than or equal to the value in bits 3-7 of the MT-installed field. A value of zero indicates that multithreading is not available for a general core. For a sub-capacity model, bits 3-7 of the MT-general field contain zeros.

Program-Specified Maximum TID (PSMTID): The contents of byte 2 of word 16 are meaningful only when bit 0 of word 16 is one.

Bits	Meaning
0-2	Reserved (stored as zeros).
3-7	When the multithreading facility is enabled in the level-2 configuration, bit positions 3-7 contain the program-specified maximum thread identification as set by the SIGNAL

PROCESSOR set-multithreading order; the value is copied from bit positions 59-63 of the SIGP parameter register. When the multithreading facility is not enabled in the level-2 configuration, bit positions 3-7 contain zeros.

Dedicated Logical-CPU Count/Core: Bytes 0 and 1 of word 18 contain a 16-bit unsigned binary integer that specifies the number of configured-state primary logical CPUs/cores for this level-2 configuration that are provided using dedicated level-1 CPUs/cores. (See the description of bit 0 of the logical-CPU-characteristics field.)

Shared Logical-CPU/Core Count: Bytes 2 and 3 of word 18 contain a 16-bit unsigned binary integer that specifies the number of configured-state primary logical CPUs/cores for this level-2 configuration that are provided using shared level-1 CPUs/cores. (See the description of bit 1 of the logical-CPU-characteristics field.)

Virtual-Server-Name Encoding (VSNE): Byte 3 of word 19 contains an 8-bit unsigned integer indicating whether virtual-server information is provided, and if so, the encoding of the virtual-server-name field in words 64-127, as follows:

Value	Meaning
0	Virtual-server information is not provided.
1	EBCDIC
2	UTF-8
3-255	Reserved.

Virtual-Server Identification: When virtual-server information is provided, words 20-23 contain a 128-bit binary universally-unique identification (UUID, also known as a *handle*) of the virtual server for this configuration. When virtual-server information is not provided, words 20-23 are stored as zeros.

Virtual-Server Name: When virtual-server information is provided, words 64-127 contain a 256-byte name of the virtual server for this configuration. The virtual-server name is left justified in the field; if the name is less than 256 bytes, the field is padded on the right with zeros. The VSNE field, byte 3 of word 19, indicates the encoding of the virtual-server-name field.

When virtual-server information is not provided, words 64-127 are reserved and may be stored as zeros or may remain unchanged.

SYSIB 3.2.2 (Virtual-Machine CPUs / Cores)

SYSIB 3.2.2 is illustrated in Figure 10-101:

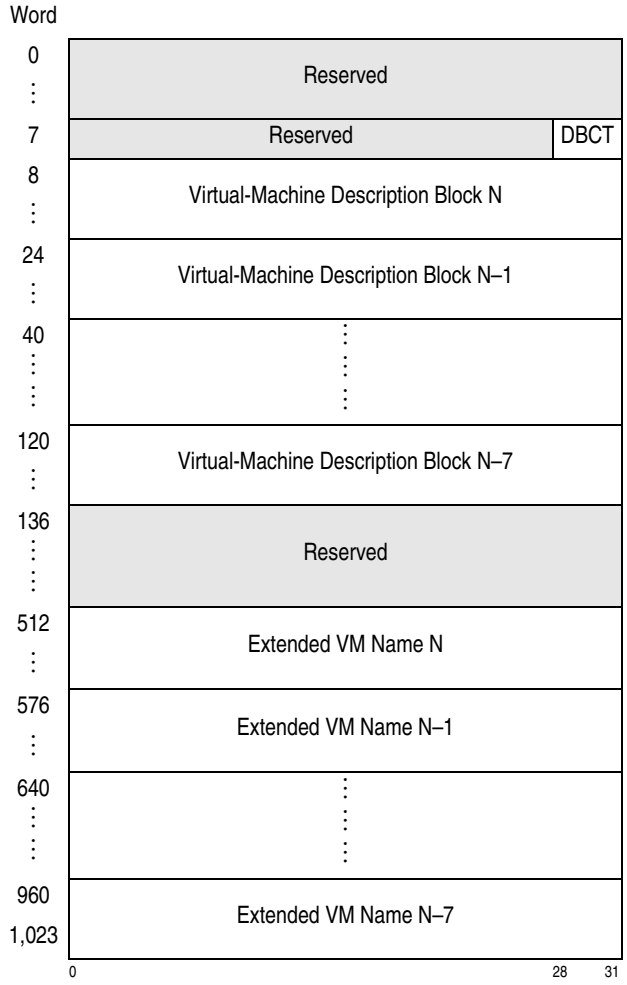

Figure 10-101. Format of the SYSIB 3.2.2

Reserved: The contents of words 0-6, bits 0-27 of word 7, and all portions of SYSIB words 8–1,023 that do not contain virtual-machine description blocks or extended virtual-machine-name blocks are reserved and are stored as zeros.

Description-Block Count (DBCT): Bits 28-31 of word 7 contain a four-bit unsigned binary integer that specifies the number (up to eight) of virtual-machine description blocks and extended-virtual-machine-name blocks that are stored in the SYSIB beginning at words 8 and 512, respectively.

Virtual-Machine Description Blocks: Depending on the number of nested level-3 configurations (if any) and their processing characteristics, from one to eight 64-byte virtual-machine description blocks are stored, beginning at word 8. The contents of the VMDB are described in the section "Virtual-Machine Description Block" on page 10-169.

When a level-3 configuration is provided by a virtual-machine control program and the control program is being executed by a level-3 configuration provided by another virtual-machine control program, the level-3 configurations are said to be "nested." Level-3 configurations can be nested in this way for several levels.

The collection of nested level-3 configurations that is in the path between a program being executed by a level-3 configuration and the basic machine is called a "level-3-configuration stack." The level-3 configurations in a stack are consecutively numbered. The level-3 configuration provided by a virtual-machine control program being executed by either a level-2 configuration or a level-1 configuration is the lowest-numbered (0) level-3 configuration in the stack. The level-3 configuration that is executing the program containing this instruction is the highest numbered (N) level-3 configuration in the stack.

If more than one virtual-machine description block is stored in words 8-135 of the SYSIB, the blocks are stored according to the following rules:

- The collection of level-3 configurations described is a contiguous subset of the total collection of level-3 configurations in the level-3-configuration stack. The subset always includes the highest-numbered level-3 configuration in the stack. One or more level-3 configurations at the bottom of the stack may not be described because the limit of eight description blocks would be exceeded.
- The highest-numbered level-3 configuration in the level-3-configuration stack is always described by the first description block in the SYSIB. The lowest-numbered level-3 configuration in the stack, of those that are included in the subset that is described, is described by the last description block in the SYSIB.

Extended VM Name(s): For each VMDB, there is a corresponding extended-VM-name field in the SYSIB 3.2.2, as shown below:

	SYSIB 3.2.2 Word Offset	
Nesting Level	VMDB	Extended VM Name
N	8	512
N–1	24	576
N–2	40	640
N–3	56	704
N–4	72	768
N–5	88	832
N–6	104	896
N–7	120	960

Figure 10-102. SYSIB 3.2.2 Offset of VMDB and Corresponding Extended-VM Name

The extended-VM-name-encoding (EVMNE) field of a VMDB indicates the encoding of the corresponding extended VM name. When the EVMNE field of a VMDB is zero, the corresponding extended-VM-name field is stored as zeros.

The extended VM name is left justified in the field; if the name is less than 256 bytes, the field is padded on the right with zeros. If the leftmost byte of the extended-VM-name field contains zeros, no extended VM name is provided for that nesting level, regardless of whether the corresponding EVMNE is nonzero.

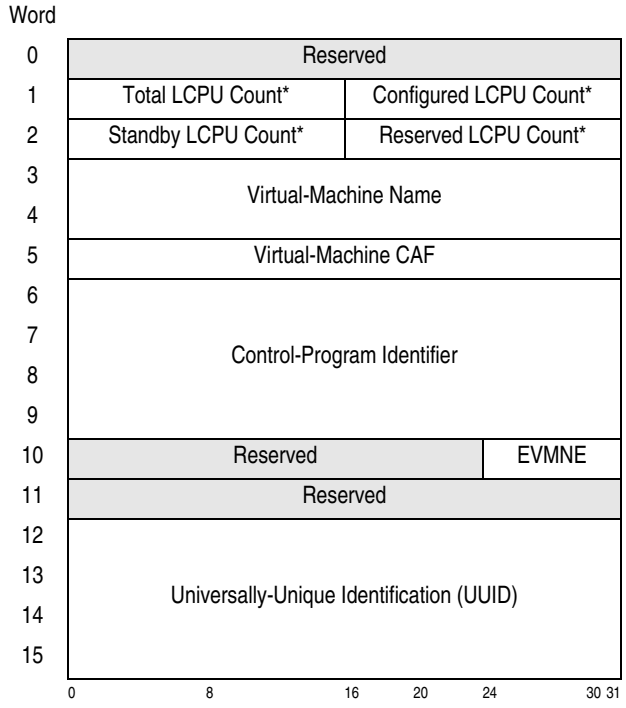
Programming Note: The highest-numbered configuration in the level-3-configuration stack that does not provide an extended VM name effectively delimits the array of extended VM names.

For example, if VMDBs for nested levels 3, 2, 1, and 0 are stored in the SYSIB, but only levels 3, 2, and 0 provide extended VM names, then extended VM names will be stored only for levels 3 and 2 (beginning at words 512 and 576, respectively). Even though the EVMNE field of the VMDB at nesting level 0 may designate a valid nonzero encoding, the extended-VM-name field for nesting-level 0 (beginning at word 704) will contain zeros.

If the configuration is not capable of providing an extended VM name, then it is assumed that the configuration is also not capable of managing extended VM names for lower-numbered nesting levels.

Virtual-Machine Description Block

The virtual-machine description block is illustrated in Figure 10-103 .



Explanation:

* Field applies to a primary CPU. The CPUs may either be general or specialty CPUs.

Figure 10-103. Virtual-Machine Descriptor Block

Reserved: The contents of word 0, bytes 0-2 of word 10, and word 11 are reserved and are stored as zeros.

Total Logical-CPU/Core Count: Bytes 0 and 1 of word 1 contain a 16-bit unsigned binary integer that specifies the total number of primary logical CPUs/cores that are provided for this level-3 configuration. This number includes all of the primary logical CPUs/cores that are in the configured state, the standby state, and the reserved state.

Configured Logical-CPU/Core Count: Bytes 2 and 3 of word 1 contain a 16-bit unsigned binary integer that specifies the number of primary logical CPUs/cores for this level-3 configuration that are in the configured state.

A logical CPU/core is in the configured state when it is in the level-3 configuration and is available to be used to execute programs.

Standby Logical-CPU/Core Count: Bytes 0 and 1 of word 2 contain a 16-bit unsigned binary integer that specifies the number of primary logical CPUs/cores for this level-3 configuration that are in the standby state.

A logical CPU/core is in the standby state when it is in the level-3 configuration, is not available to be used to execute programs, and can be made available by issuing instructions to place it in the configured state.

Reserved Logical-CPU/Core Count: Bytes 2 and 3 of word 2 contain a 16-bit unsigned binary integer that specifies the number of primary logical CPUs/cores for this level-3 configuration that are in the reserved state.

A logical CPU/core is in the reserved state when it is in the level-3 configuration, is not available to be used to execute programs, and cannot be made available by issuing instructions to place it in the configured state. (It may be possible to place the logical CPU/core in the standby or configured state through manual actions.)

Virtual-Machine Name: Words 3-4 contain the eight-character EBCDIC name of this level-3 configuration. The name is left justified with trailing blanks if necessary.

Virtual-Machine Capability Adjustment Factor (CAF): Word 5 contains a 32-bit unsigned binary integer, called an adjustment factor, with a value of 1000 or less. The adjustment factor specifies the amount of the underlying level-1-, level-2-, or level-3-configuration capability that is allowed to be used for this level-3 configuration by the virtual-machine control program. The fraction of the underlying capability is determined by dividing the CAF value by 1000.

Control-Program Identifier: Words 6-9 contain the 16-character EBCDIC identifier of the virtual-machine control program that provides this level-3 configuration. This identifier may include qualifiers such as version number and release level. The identifier is left justified with trailing blanks if necessary.

Extended VM-Name Encoding (EVMNE): Byte 3 of word 10 contains an 8-bit unsigned integer indicat-

ing whether a corresponding extended virtual-machine name is provided, and if so, the encoding of the extended-virtual-machine-name field, as follows:

Value	Meaning
0	Extended virtual-machine name is not provided
1	EBCDIC
2	UTF-8
3-255	Reserved.

When byte 3 of word 10 is zero, an extended virtual-machine name is not provided for this configuration.

Programming Note: Even if the EVMNE field is nonzero, an extended-VM name is not provided when the leftmost byte of the corresponding extended-VM-name field is zero.

Universally-Unique Identification (UUID): When the 128-bit binary value formed by words 12-15 is nonzero, the value comprises a universally-unique identification (UUID, also known as a handle) of the configuration. When words 12-15 contain all zeros, no UUID is provided.

SYSIB 15.1.2 - 15.1.6 (Configuration Topology)

SYSIBs 15.1.2 through 15.1.6 are illustrated in each have the following format:

Figure 10-104. Format of the SYSIB 15.1.2 - 15.1.6

Selector 2 specifies the MNest value to which the response is limited. STSI completes with condition code 3 for the following cases:

1. If the maximum-MNest facility is installed and selector 2 exceeds the nonzero model-dependent maximum-selector-2 value.
2. If the maximum-MNest facility is not installed and selector 2 is not specified as two.

Reserved: The contents of bytes 0-1 of word 0, byte 2 of word 2, and word 3 are reserved and are stored as zeros. The contents of words N-1023 are reserved and may be stored as zeros or may remain unchanged.

Length: Bytes 2-3 of word 0 contain a 16-bit unsigned binary integer whose value is the count of bytes of the entire SYSIB 15.1.2. The length of just the topology list is determined by subtracting 16 from the length value in bytes 2-3 of word 0. N in Figure 10-105 is determined by evaluating the formula N=Length/4.

Mag1-6: Word 1 and bytes 0-1 of word 2 constitute six one-byte fields where the content of each byte indicates the maximum number of container-type topology-list entries (TLE) or CPU-type TLEs at the corresponding nesting level. CPU-type TLEs are always found only at the Mag1 level. Additionally, the Mag1 value also specifies the maximum number of CPUs that may be represented by a container-type TLE of the Mag2 level. When the value of the nesting level is greater than one, containing nesting levels above the Mag1 level are occupied only by container-type TLEs. A dynamic change to the topology may alter the number of TLEs and the number of CPUs at the Mag1 level, but the limits represented by the values of the Mag1-6 fields do not change within a model family of machines.

The topology is a structured list of entries where an entry defines one or more CPUs or else is involved with the nesting structure. The following illustrates the meaning of the magnitude fields:

- When all CPUs of the machine are peers and no containment organization exists, other than the entirety of the central-processing complex itself, the value of the nesting level is 1, Mag1 is the only nonzero magnitude field, and the number of CPU-type TLEs stored does not exceed the Mag1 value.
- When all CPUs of the machine are subdivided into peer groups such that one level of containment exists, the value of the nesting level is 2,

Mag1 and Mag2 are the only nonzero magnitude fields, the number of container-type TLEs stored does not exceed the Mag2 value, and the number of CPU-type TLEs stored within each container does not exceed the Mag1 value.

- The Mag3-6 bytes similarly become used (proceeding in a right-to-left direction) when the value of the nesting level falls in the range 3-6.

MNest: When the maximum-MNest facility is not installed, byte 3 of word 2 specifies the nesting level of the topology to which the configuration may be extended without requiring a re-IPL. The maximum MNest value is model dependent in the range 2-6; the minimum is one. If MNest is one, there is no actual TLE nesting structure, Mag1 is the only nonzero field in the Mag1-6 range, and only CPU-type TLEs are represented in the topology list. The MNest value indicates the number of nonzero magnitude values beginning with the magnitude field at byte 1 of word 2 (Mag1), proceeding left when MNest is greater than one, and with the remaining magnitude fields stored as zeros.

The value of MNest is the maximum possible nesting. No dynamic configuration change exceeds this limit.

When the maximum-MNest facility is installed, the maximum possible nesting is indicated by other means and the MNest value in byte 3 of word 2 reflects both the requested selector-2 value and the number of nonzero magnitude values beginning with the magnitude field at byte 1 of word 2 (Mag1).

Topology List: Words of Figure 10-105 in the range 4 through N-1 specify a list of one or more topology-list entries (TLE). Each TLE is an eight-byte or sixteen-byte field; thus N is an even number of words, and a corollary is that a TLE always starts on a doubleword boundary.

Topology-List Entries: The first TLE in the topology list begins at a nesting level equal to MNest-1. The entire topology list represents the configuration of the issuer of the STSI instruction specifying SYSIB 15.1.x; no outermost container TLE entry is used as it would be redundant with the entire list, and the entire configuration. Therefore, the highest nesting level may have more than a single peer container.

Figure 10-105 illustrates the container type of TLE, and Figure 10-106 illustrates the CPU type of TLE.

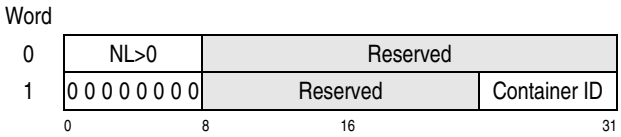


Figure 10-105. Container-Type Topology-List Entry

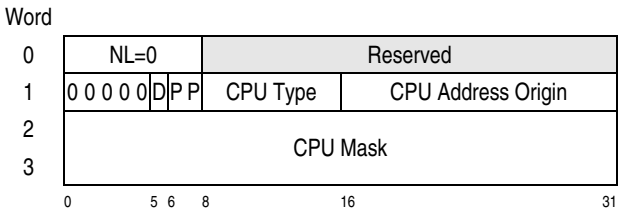

Figure 10-106. CPU-Type Topology-List Entry

Nesting Level (NL): Byte 0 of word 0 specifies the TLE nesting level.

NL	Meaning
00	The TLE is a CPU-type TLE.
01-05	The TLE is a container-type TLE. The first container-type TLE stored in a topology list or a parent container has a container-ID in the range 1-255. If sibling containers exist within the same parent, they proceed in an ascending order of container IDs, that may or may not be consecutive, to a maximum value of 255.
06-FF	Reserved

Sibling TLEs have the same value of nesting level which is equivalent to either the value of the nesting level minus one of the immediate parent TLE, or the value of MNest minus one, because the immediate parent is the topology list rather than a TLE.

Reserved, 0: For a container-type TLE, bytes 1-3 of word 0 and bytes 0-2 of word 1 are reserved and stored as zeros. For a CPU-type TLE, bytes 1-3 of word 0 and bits 0-4 of word 1 are reserved and stored as zeros.

Container ID: Byte 3 of word 1 of a container-type TLE specifies an 8-bit unsigned nonzero binary integer whose value is the identifier of the container. The container ID for a TLE is unique within the same parent container.

Fields Specific to a CPU-type TLE

The remaining fields described below are specific to a CPU-type TLE. When the multithreading facility is not installed, or when the facility is installed but not enabled, these fields describe one or more CPUs in the configuration having common topology attributes. When the multithreading facility is installed and enabled, these fields describe one or more cores in the configuration having common topology attributes; each core comprises a set of CPUs that have the same topology attributes.

Dedicated (D): Bit 5 of word 1 of a CPU-type TLE, when one, indicates that the one or more CPUs represented by the TLE are dedicated. When D is zero, the one or more CPUs of the TLE are not dedicated.

Polarization (PP): Bits 6-7 of word 1 of a CPU-type TLE specify the polarization value and, when polarization is vertical, the degree of vertical polarization also called entitlement (high, medium, low) of the corresponding CPU(s) represented by the TLE. The following values are used:

PP	Meaning
0	The one or more CPUs represented by the TLE are horizontally polarized.
1	The one or more CPUs represented by the TLE are vertically polarized. Entitlement is low.
2	The one or more CPUs represented by the TLE are vertically polarized. Entitlement is medium.
3	The one or more CPUs represented by the TLE are vertically polarized. Entitlement is high.

Polarization is only significant in a logical and virtual multiprocessing configuration that uses shared host processors and addresses how the resource assigned to a configuration is applied across the CPUs of the configuration. When horizontal polarization is in effect, each CPU of a configuration is guaranteed approximately the same amount of resource. When vertical polarization is in effect, CPUs of a configuration are classified into three levels of resource entitlement: high, medium, and low.

Both subsystem reset and successful execution of the SIGP set-architecture order specifying ESA/390 mode place a configuration and all of its CPUs into horizontal polarization. The CPUs immediately affected are those that are in the configured state. When a CPU in the standby state is configured, it acquires the current polarization of the configuration and causes a topology change of that configuration to be recognized.

A dedicated CPU is either horizontally or vertically polarized. When a dedicated CPU is vertically polarized, entitlement is always high. Thus, when D is one, PP is either 00 binary or 11 binary.

CPU Type: Byte 1 of word 1 of a CPU-type TLE specifies an 8-bit unsigned binary integer whose value is the CPU type of the one or more CPUs represented by the TLE. The CPU-type value specifies either a primary-CPU type or any one of the possible secondary-CPU types.

When the multithreading facility is installed and enabled, the TLE represents one or more cores, each CPU of which has the same CPU type.

CPU-Address Origin: When the multithreading facility is not installed, or when the facility is installed but not enabled, bytes 2-3 of word 1 of a CPU-type TLE specify a 16-bit unsigned binary integer whose value is the CPU address of the first CPU in the range of CPUs represented by the CPU mask, and whose presence is represented by the value of bit position 0 in the CPU mask. The value of a CPU-address origin is the same as that stored by the STORE CPU ADDRESS (STAP) instruction when executed on the CPU represented by bit position 0 in the CPU mask.

When the multithreading facility is installed and enabled. bytes 2-3 of word 1 specify a right-justified 16-bit unsigned binary integer whose value is the first core identification in the range of cores represented by the CPU mask, and whose presence is represented by the value of bit position 0 in the CPU mask.

The CPU-address origin is evenly divisible by 64.

CPU Mask: Words 2-3 of a CPU-type TLE specify a 64-bit mask where each bit position represents a CPU or core. When the multithreading facility is not installed, or when the facility is installed but not enabled, the following applies:

- The value of the CPU-address origin field plus a bit position in the CPU mask equals the CPU address for the corresponding CPU.
- When a CPU-mask bit is zero, the corresponding CPU is not represented by the TLE. Either the CPU is not in the configuration, or else it must be represented by another CPU-type TLE.

- When a CPU mask bit is one, the corresponding CPU has the modifier-attribute values specified by the TLE, is in the topology of the configuration, and is not present in any other TLE of the topology.

When the multithreading facility is installed and enabled, the following applies:

- The value of the CPU-address origin field plus a bit position in the CPU mask equals the core ID for the corresponding core.
- When a CPU-mask bit is zero, the corresponding core is not represented by the TLE. Either the core is not in the configuration or else must be represented by another CPU-type TLE.
- When a CPU-mask bit is one, the corresponding core and each of its CPUs has the modifier-attribute values specified by the TLE, is in the topology of the configuration, and is not present in any other TLE of the topology.

Programming Notes:

1. The following example applies when the multithreading facility is not installed, or when the facility is installed but disabled: If the CPU-address origin is a value of 64, and bit position 15 of the CPU mask is one, CPU 79 is in the configuration and has the CPU type, polarization, entitlement, and dedication as specified by the TLE.
2. The following examples apply when the multithreading facility is installed and enabled:

   A CPU-address-origin value of 0000 hex represents a set of core IDs in the range 0 to 63, 0040 hex represents a set of core IDs in the range 64 to 127, as so forth.

   If the CPU-address origin is a value of 64, and bit position 15 of the CPU mask is one, core ID 79 is in the configuration and has the CPU type, polarization, entitlement, and dedication as specified by the TLE.

   In this example, if multithreading had been enabled with a program-specified maximum thread identification of three (that is, with four threads per core, thus a TID width of 2 bits), the CPU addresses of any CPU in the core can be determined by multiplying the core ID by four (that is, shifting it left TID-width bit positions), and adding the thread ID. Thus, the CPU addresses for core 79 are 316 - 319 (013C-013F hex).

TLE Ordering: The modifier attributes that apply to a CPU-type TLE are CPU type, polarization, entitlement, and dedication. Polarization and entitlement (for vertical polarization) are taken as a single attribute, albeit with four possible values (horizontal, vertical-high, vertical-medium, and vertical-low).

A single CPU TLE is sufficient to represent as many as 64 CPUs or cores that all have the same modifier-attribute values.

When more than 64 CPUs or cores exist, or the entire range of CPU addresses are not covered by a single CPU-address origin, and the modifier attributes are constant, a separate sibling CPU TLE is stored for each CPU-address origin, as necessary, in ascending order of CPU-address origin. Each such TLE stored has at least one CPU or core represented. The collection of one or more such CPU TLEs is called a CPU-TLE set.

When multiple CPU types exist, a separate CPU-TLE set is stored for each, in ascending order of CPU type.

When multiple polarization-and-entitlement values exist, a separate CPU-TLE set is stored for each, in descending order of polarization value and degree (vertical high, medium, low, then horizontal). When present, all polarization CPU-TLE sets of a given CPU type are stored before the first CPU-TLE set of the next CPU type.

When both dedicated and not-dedicated CPUs exist, a separate CPU-TLE set is stored for each, dedicated appearing before not-dedicated.

All TLEs are ordered assuming a depth-first traversal where the sort order from major to minor is as follows:

1. CPU type
   a. Lowest CPU-type value
   b. Highest CPU-type value
2. Polarization-Entitlement
   a. Vertical high
   b. Vertical medium

   c. Vertical low

   d. Horizontal

3. Dedication (when applicable)

   a. Dedicated

   b. Not dedicated

The ordering by CPU-address origin and modifier attributes of sibling CPU TLEs within a parent container is done according to the following list, which proceeds from highest to lowest.

1. CPU-TLE set of lowest CPU-type value, vertical high, dedicated
2. CPU-TLE set of lowest CPU-type value, vertical high, not-dedicated
3. CPU-TLE set of lowest CPU-type value, vertical medium, not-dedicated
4. CPU-TLE set of lowest CPU-type value, vertical low, not-dedicated
5. CPU-TLE set of lowest CPU-type value, horizontal, dedicated
6. CPU-TLE set of lowest CPU-type value, horizontal, not-dedicated
7. CPU-TLE set of highest CPU-type value, vertical high, dedicated
8. CPU-TLE set of highest CPU-type value, vertical high, not-dedicated
9. CPU-TLE set of highest CPU-type value, vertical medium, not-dedicated
10. CPU-TLE set of highest CPU-type value, vertical low, not-dedicated
11. CPU-TLE set of highest CPU-type value, horizontal, dedicated
12. CPU-TLE set of highest CPU-type value, horizontal, not-dedicated

Other TLE Rules :

1. A container-type TLE is located at nesting levels in the range 1-5.
2. A CPU-type TLE is located at nesting level 0.
3. The number of sibling container-type TLEs in a topology list or a given parent container does not exceed the value of the magnitude byte (Mag2-6) of the nesting level corresponding to the siblings.
4. The number of CPUs represented by the one or more CPU-type TLEs of the parent container does not exceed the value of the Mag1 magnitude byte.
5. The content of a TLE is defined as follows:
   - If a TLE is a container-type TLE, the content is a list that immediately follows the parent TLE, comprised of one or more child TLEs, and each child TLE has a nesting level of one less than the nesting level of the parent TLE or topology-list end.
   - If a TLE is a CPU-type TLE, the content is one or more CPUs, as identified by the other fields of a CPU TLE.
6. When the first TLE at a nesting level is a CPU entry, the maximum nesting level 0 has been reached.

CPU Topology Overview

With the advent of the IBM z9 Enterprise Class and subsequent models, and even previously, machine organization into nodal structures has resulted in a non-uniform memory access (NUMA) behavior, sometimes also called “lumpiness”. The purpose of the SYSIB 15.1.2 and the PERFORM TOPOLOGY FUNCTION (PTF) instruction is to provide additional machine topology awareness to the program so that certain optimizations can be performed to improve cache-hit ratios and thereby improve overall performance.

The amount of host-CPU resource assigned to a multiprocessing (MP) guest configuration has generally been spread evenly across the number of configured guest CPUs. Such an even spread implies that no particular guest CPU or CPUs are entitled to any extra host-CPU provisioning than any other, arbitrarily-determined guest CPUs. This condition of the guest configuration, affecting all CPUs of the configuration, is called *horizontal polarization*.

Under horizontal polarization, assignment of a host CPU to a guest CPU is approximately the same amount of provisioning for each guest CPU. When the provisioning is not dedicated, the same host CPUs provisioning the guest CPUs also may be used

to provision guest CPUs of another guest, or even other guest CPUs of the same guest configuration. When the other guest configuration is a different logical partition, a host CPU, when active in each partition, typically must access main storage more because the cache-hit ratio is reduced by having to share the caches across multiple relocation zones. If host-CPU provisioning can alter the balance such that some host CPUs are mostly, or even exclusively, assigned to a given guest configuration, and that becomes the normal behavior, then cache-hit ratios improve, as does performance. Such an uneven spread implies that one or more guest CPUs are entitled to extra host-CPU provisioning versus other, arbitrarily-determined guest CPUs that are entitled to less host-CPU provisioning. This condition of the guest configuration, affecting all CPUs of the configuration, is called *vertical polarization*.

The architecture categorizes vertical polarization into three levels of entitlement of provisioning, high, medium, and low:

- High entitlement guarantees approximately 100% of a host CPU being assigned to a logical/virtual CPU, and the affinity is maintained as a strong correspondence between the two. With respect to provisioning of a logical partition, when vertical polarization is in effect, the entitlement of a dedicated CPU is defined to be high.
- Medium entitlement guarantees an unspecified amount of host CPU resource (one or more host CPUs) being assigned to a logical/virtual CPU, and any remaining capacity of the host CPU is considered to be slack that may be assigned elsewhere. The best case for the available slack would be to assign it as local slack if that is possible. A less-beneficial result occurs if that available slack is assigned as remote slack. (See “CPU Slack” on page 10-175 for descriptions of the two slack terms.) It is also the case that the resource percentage assigned to a logical CPU of medium entitlement is a much softer approximation as compared to the 100% approximation of a high-entitlement setting.
- Low entitlement guarantees approximately 0% of a host CPU being assigned to a logical/virtual CPU. However, if slack is available, such a logical/virtual CPU may still receive some CPU resource.

A model of nested containers using polarization is intended to provide a level of intelligence about the machine's nodal structure as it applies to the requesting configuration, so that, generally, clusters of host CPUs can be assigned to clusters of guest CPUs, thereby improving as much as possible the sharing of storage and the minimizing of different configurations essentially colliding on the same host CPUs.

Polarization and entitlement indicate the relationship of physical CPUs to logical CPUs or logical CPUs to virtual CPUs in a guest configuration, and how the capacity assigned to the guest configuration is apportioned across the CPUs that comprise the configuration. Historically, a guest configuration has been horizontally polarized. For however many guest CPUs were defined to the configuration, the host-CPU resource assigned was spread evenly across all of the guest CPUs in an equitable, non-entitled manner. It can be said that the weight of a single logical CPU in a logical partition when horizontal polarization is in effect is approximately equal to the total configuration weight divided by the number of CPUs. However, with the introduction of the 2097 and family models, it becomes imperative to be able to spread the host-CPU resource in a different manner, which is called vertical polarization of a configuration, and then the degree of provisioning of guest CPUs with host CPUs being indicated as high, medium, or low entitlement. High entitlement is in effect when a logical/virtual CPU of a vertically-polarized configuration is entirely backed by the same host CPU. Medium entitlement is in effect when a logical/virtual CPU of a vertically-polarized configuration is partially backed by a host CPU. Low entitlement is in effect when a logical/virtual CPU of a vertically-polarized configuration is not guaranteed any host-CPU resource, other than what might become available due to slack resource becoming available.

CPU Slack

Regarding slack CPU resource, there are two kinds:

- Local slack becomes available when a logical/virtual CPU of a configuration is not using all the resource to which it is entitled and such slack is then used within the configuration of that CPU. Local slack is preferred over remote slack as better hit ratios on caches are expected when the slack is used within the configuration.
- Remote slack becomes available when a logical/virtual CPU of a configuration is not using all

the resource to which it is entitled and such slack is then used outside the configuration of that CPU. Remote slack is expected to exhibit lower hit ratios on caches, but it is still better than not running a logical/virtual CPU at all.

The goal is to maximize the CPU cache hit ratios.

For a logical partition, the amount of physical-CPU resource is determined by the overall system weightings that determine the CPU resource assigned to each logical partition. For example, in a logical 3-way MP that is assigned physical-CPU resource equivalent to a single CPU, and is horizontally polarized, each logical CPU would be dispatched independently and thus receive approximately 33% physical-CPU resource. If the same configuration were to be vertically polarized, only a single logical CPU would be run and would receive approximately 100% of the assigned physical-CPU resource (high entitlement) while the remaining two logical CPUs would not normally be dispatched (low entitlement). Such resource assignment is normally an approximation. Even a low-entitlement CPU may receive some amount of resource if only to help ensure that a program does not get stuck on such a CPU.

By providing a means for a control program to indicate that it understands polarization, and to receive an indication for each CPU of its polarization and, if vertical polarization, the degree of entitlement, the control program can make more-intelligent use of data structures that are generally thought to be local to a CPU vs. available to all CPUs of a configuration. Also, such a control program can avoid directing work to any low-entitlement CPU.

The actual physical-CPU resource assigned might not constitute an integral number of CPUs, so there is also the possibility of one or more CPUs in an MP vertically-polarized configuration being entitled but not to a high degree, thereby resulting in such CPUs having either medium or low vertical entitlement.

It is possible for any remaining low-entitlement CPUs to receive some amount of host-CPU resource. For example, this may occur when such a CPU is targeted, such as via a SIGP order and slack host-CPU resource is available. Otherwise, such a logical/virtual CPU might remain in an undispatched state, even if it is otherwise capable of being dispatched.

A 2-bit polarization field is defined for the CPU-type topology-list entry (TLE) of the STORE SYSTEM INFORMATION (STSI) instruction. The degree of vertical-polarization entitlement for each CPU is indicated as high, medium, or low. The assignment is not a precise percentage but rather is somewhat fuzzy and heuristic.

In addition to vertical polarization as a means of reassigning weighting to guest CPUs, another concept exists, which is the creation and management of slack capacity (also called “white space”). Slack capacity is created under the following circumstances:

- A high-vertical CPU contributes to slack when its average utilization (AU) falls below 100 percent (100-AU).
- A medium-vertical CPU that has an assigned provisioning of M percent of a host CPU contributes to slack when its average utilization (AU) falls below M percent (M-AU > 0).
- A low-vertical CPU does not contribute to slack.
- A high-vertical CPU is not a consumer of slack.
- A medium-vertical CPU may or may not be a consumer of slack.
- A low-vertical CPU is only a consumer of slack.

Depending upon its utilization and pattern of being dispatched, a horizontally-polarized CPU can be either a contributor to slack or a consumer of it.

Programming Note: A possible examination process of a topology list is described. Before an examination of a topology list is begun, the current-TLE pointer is initialized to reference the first or top TLE in the topology list, the prior-TLE pointer is initialized to null, and then TLEs are examined in a top-to-bottom order.

As a topology-list examination proceeds, the current-TLE pointer is advanced by incrementing the current-TLE pointer by the size of the current TLE to which it points. A container-type TLE is advanced by adding eight to the current-TLE pointer. A CPU-type TLE is advanced by adding sixteen to the current-TLE pointer. The process of advancing the current-TLE pointer includes saving its value as the prior-TLE pointer just before it is incremented. TLE examination is not performed if the topology list has no TLEs.

The examination process is outlined in the following steps:

1. If the current-TLE nesting level is zero, and the prior-TLE nesting level is null or one, the current TLE represents the first CPU-type TLE of a group of one or more CPU-type TLEs. The program should perform whatever action is appropriate for when a new group of one or more CPUs is first observed. Go to step 5.

2. If the current-TLE nesting level is zero, and the prior-TLE nesting level is zero, the current TLE represents a subsequent CPU-type TLE of a group of CPU-type TLEs that represent siblings of the CPUs previously observed in steps 1 or 2. The program should perform whatever action is appropriate for when the size of an existing sibling group of one or more CPUs is increased. Go to step 5.

3. If the current-TLE nesting level is not zero, and the prior-TLE nesting level is zero, the prior TLE represents a last or only CPU-type TLE of a group of one or more CPU-type TLEs. The program should perform whatever action is appropriate for when an existing group of one or more CPUs is completed. Go to step 5.

4. Go to step 5.

   By elimination, this would be the case where the current-TLE nesting level is not zero, and the prior-TLE nesting level is not zero. If the current-TLE nesting level is less than the prior-TLE nesting level, the direction of topology-list traversal is toward a CPU-type TLE. If the current-TLE nesting level is greater than the prior-TLE nesting level, the direction of topology-list traversal is away from a CPU-type TLE. Container-type TLEs are being traversed leading to either (1) another group of CPU-type TLEs that are a separate group in the overall topology, or (2) the end of the topology list. In either case, no particular processing is required beyond advancing to the next TLE.

5. Advance to the next TLE position based upon the type of the current TLE. If the advanced current-TLE pointer is equivalent to the end of the topology list:

   a. No more TLEs of any type exist.

      b. If the prior-TLE nesting level is zero, the program should perform whatever action is appropriate for when an existing group of one or more CPUs is completed.

      c. The examination is complete.

   Otherwise go to step 1.

Special Conditions

The condition code is set to 3 if the function code in bit positions 32-35 of general register 0 is greater than the current-level number.

Bits 36-55 of general register 0 and 32-47 of general register 1 must be zero; otherwise, a specification exception is recognized.

When the function code is valid and nonzero, the following special conditions apply in an unpredictable order:

- The second operand must be designated on a 4 K-byte boundary; otherwise, a specification exception is recognized.
- If the function-code, selector-1, and selector-2 combination is invalid, or if it is valid but the requested information is not available, the condition code is set to 3.

Resulting Condition Code:

0 Requested configuration-level number placed in general register 0 or requested SYSIB information stored
1 --
2 --
3 Requested SYSIB information not available

Program Exceptions:

- Access (store, operand 2, only if function code nonzero)
- Privileged operation
- Specification
- Transaction constraint

The priority of the recognition of exceptions and condition codes is shown in Figure 10-107.

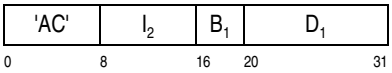
1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B	Privileged-operation exception for privileged instruction.
7.C	Transaction constraint.
8.	Condition code 3 due to function code greater than current-level number.
9.	Specification exception due to bits 36-55 of general register 0 or bits 32-47 of general register 1 not zero.
10.	Condition code 0 due to function code 0.
11.A	Specification exception due to second-operand address not designating a 4 K-byte boundary.
11.B	Condition code 3 due to invalid function-code, selector-1, and selector-2 combination or requested information not available.
12.	Access exceptions (store) for system-information block.
13.	Condition code 0 due to information stored in system-information block.

Figure 10-107. Priority of Execution: STORE SYSTEM INFORMATION

Programming Note: The storage-operand references for STORE SYSTEM INFORMATION may be multiple-access references. (See “Storage-Operand Consistency” on page 5-133.)

STORE THEN AND SYSTEM MASK

STNSM $D_1(B_1),I_2$ [SI]



Bits 0-7 of the current PSW are stored at the first-operand location. Then the contents of bit positions 0-7 of the current PSW are replaced by the logical AND of their original contents and the second operand.

Special Conditions

The operation is suppressed on addressing and protection exceptions.

Condition Code: The code remains unchanged.

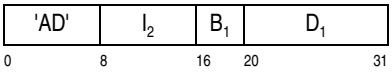
Program Exceptions:

- Access (store, operand 1)
- Privileged operation
- Transaction constraint

Programming Note: STORE THEN AND SYSTEM MASK permits the program to set selected bits in the system mask to zeros while retaining the original contents for later restoration. For example, it may be necessary that a program, which has no record of the present status, disable program-event recording for a few instructions.

STORE THEN OR SYSTEM MASK

STOSM $D_1(B_1),I_2$ [SI]



Bits 0-7 of the current PSW are stored at the first-operand location. Then the contents of bit positions 0-7 of the current PSW are replaced by the logical OR of their original contents and the second operand.

Special Conditions

The value to be loaded into the PSW is not checked for validity before loading. However, immediately after loading, a specification exception is recognized, and a program interruption occurs, if either (a) the contents of bit positions 0 and 2-4 of the PSW are not all zeros, or (b) in the ESA/390-compatibility mode, bit position 5 of the PSW does not contain zero. In either of these cases, the instruction is completed, and the instruction-length code is set to 2 or 3. The specification exception, which is listed as a program exception for this instruction, is described in “Early Exception Recognition” on page 6-9.

The operation is suppressed on addressing and protection exceptions.

Condition Code: The code remains unchanged.

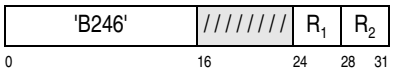
Program Exceptions:

- Access (store, operand 1)
- Privileged operation
- Specification
- Transaction constraint

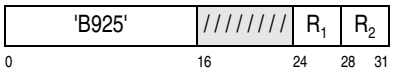
Programming Note: STORE THEN OR SYSTEM MASK permits the program to set selected bits in the system mask to ones while retaining the original contents for later restoration. For example, the program may enable the CPU for I/O interruptions without having available the current status of the external-mask bit.

STORE USING REAL ADDRESS

STURA R_1,R_2 [RRE]



STURG R_1,R_2 [RRE]



For STORE USING REAL ADDRESS (STURA), bits 32-63 of general register R_1 are stored in the word at the real-storage location addressed by the contents of general register R_2. For STORE USING REAL ADDRESS (STURG), bits 0-63 of general register R_1 are stored in the doubleword at that real-storage location.

In the 24-bit addressing mode, bits 40-63 of general register R_2 designate the real-storage location, and bits 0-39 of the register are ignored. In the 31-bit addressing mode, bits 33-63 of general register R_2 designate the real-storage location, and bits 0-32 of the register are ignored. In the 64-bit addressing mode, bits 0-63 of general register R_2 designate the real-storage location.

Because it is a real address, the address designating the storage word or doubleword is not subject to dynamic address translation.

The store-type reference to the real-storage location addressed by the contents of general register 2 appears to be a block-concurrent reference as observed by other CPUs.

Special Conditions

The contents of general register R_2 must designate a location on a word boundary for STURA or on a doubleword boundary for STURG; otherwise, a specification exception is recognized.

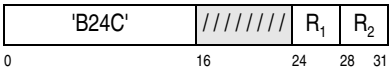
Condition Code: The code remains unchanged.

Program Exceptions:

- Addressing (address specified by general register R_2)
- Privileged operation
- Protection (store, operand 2, key-controlled protection and low-address protection)
- Secure-storage-access (address specified by general register R_2)
- Specification
- Transaction constraint

TEST ACCESS

TAR R_1,R_2 [RRE]



Note: In the ESA/390-compatibility mode when ESA extended-configuration (ESA/XC) applies, the behavior of TEST ACCESS is described in Reference [12.] on page xxxii, except that it is unpredictable whether a special-operation exception is recognized when bit position 47 of control register 0 contains zero.

The access-list-entry token (ALET) in access register R_1 is tested for exceptions recognized during access-register translation (ART). The extended authorization index (EAX) used is bits 32-47 of general register R_2. The ALET is also tested for whether it designates the dispatchable-unit access list or the primary-space access list and for whether it is 00000000 or 00000001 hex.

When R_1 is 0, the actual contents of access register 0 are used in ART, instead of the 00000000 hex that is usually used.

Bits 0-31 and 48-63 of general register R_2 are ignored.

The operation does not depend on the translation mode — bits 5, 16, and 17 of the PSW are ignored.

When the ALET specified by means of the R_1 field is other than 00000000 or 00000001 hex, the ART process is applied to the ALET. The EAX specified by means of the R_2 field is called the effective EAX, and it is the EAX which is used by ART. When a condition exists that would normally cause one of the exceptions shown in the following table, the instruction is completed by setting condition code 3.

Exception Name	Cause
ALET specification	ALET bits 0-6 not all zeros
ALEN translation	Access-list entry (ALE) outside list or invalid (bit 0 is one)
ALE sequence	ALE sequence number (ALESN) in ALET not equal to ALESN in ALE
ASTE validity	ASN-second-table entry (ASTE) invalid (bit 0 is one)
ASTE sequence	ASTE sequence number (ASTESN) in ALE not equal to ASTESN in ASTE
Extended authority	ALE private bit not zero, ALE authorization index (ALEAX) not equal to effective EAX, and secondary bit selected by effective EAX either outside authority table or zero

When ART is completed without one of the above conditions being present, the instruction is completed by setting condition code 1 or 2, depending on whether the effective access list is the dispatchable-unit access list or the primary-space access list, respectively. The effective access list is the dispatchable-unit access list if bit 7 of the ALET is zero, or it is the primary-space access list if bit 7 is one. ART, including the obtaining of the effective access-list designation, is described in "Access-Register-Translation Process" on page 5-60.

When the ALET is 00000000 hex, the instruction is completed by setting condition code 0. When the ALET is 00000001 hex, the instruction is completed by setting condition code 3.

Special Conditions

An addressing exception is recognized when the address used by ART to fetch the effective access-list designation or the ALE, ASTE, or authority-table entry designates a location which is not available in the configuration.

A secure-storage-access exception is recognized when the address used by ART to fetch the effective access-list designation or the ALE, ASTE, or authority-table entry designates a location which is a secure-storage location.

In the ESA/390-compatibility mode, it is unpredictable whether a special-operation exception is recognized when bit position 47 of control register 0 contains zero.

The operation is suppressed on all addressing exceptions.

Resulting Condition Code:

0 Access-list-entry token (ALET) is 00000000 hex
1 ALET designates the dispatchable-unit access list and does not cause exceptions in access-register translation (ART)
2 ALET designates the primary-space access list and does not cause exceptions in ART
3 ALET is 00000001 hex or causes exceptions in ART

Program Exceptions:

- Addressing (effective access-list designation, access-list entry, ASN-second-table entry, or authority-table entry)
- Secure-storage-access (effective access-list designation, access-list entry, ASN-second-table entry, or authority-table entry)
- Special operation (in the ESA/390-compatibility mode)
- Transaction constraint

The priority of recognition of program exceptions for the instruction is shown in Figure 10-108.

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B	Transaction constraint.
8.	Condition code 0 due to access-list-entry-token (ALET) being 00000000 hex.

Figure 10-108. Priority of Execution: TEST ACCESS (Part 1 of 2)

9.	Condition code 3 due to ALET being 00000001 hex or ALET bits 0-6 not being all zeros.
10.	Addressing exception or secure-storage-access exception for access to effective access-list designation.
11.	Condition code 3 due to access-list entry (ALE) being outside the list.
12.	Addressing exception or secure-storage-access exception for access to ALE.
13.	Condition code 3 due to ALE being invalid (bit 0 is 1) or access-list-entry sequence number (ALESN) in the ALET not being equal to the ALESN in the ALE.
14.	Addressing exception or secure-storage-access exception for access to ASN-second-table entry (ASTE).
15.	Condition code 3 due to ASTE being invalid (bit 0 is one) or ASTE sequence number (ASTESN) in the ALE not being equal to the ASTESN in the ASTE.
16.	Condition code 3 due to authority-table entry being outside table.
17.	Addressing exception or secure-storage-access exception for access to authority-table entry.
18.	Condition code 3 due to ALE private bit not being zero, ALE authorization index (ALEAX) not being equal to effective extended authorization index (EAX), and secondary bit selected by effective EAX being zero.
19.	Condition code 1 if ALET bit 7 is zero; otherwise, condition code 2.

Figure 10-108. Priority of Execution: TEST ACCESS (Part 2 of 2)

Programming Notes:

1. TEST ACCESS permits a called program to check whether an ALET passed from the calling program is authorized for use by means of the calling program's EAX. The calling program's EAX can be obtained from the last linkage-stack state entry by means of EXTRACT STACKED STATE. The called program can thus avoid performing an operation for the calling program, through the use of the called program's EAX, which the calling program is not authorized to perform by means of its own EAX.

2. When an ALET equal to 00000000 hex is passed during a program linkage performed by PROGRAM CALL with space switching (PC-ss), and the ALET conceptually designates the calling program's primary address space and the called program's secondary address space, the ALET must be changed to 00000001 hex before it is used by the called program. Condition code 0 of TEST ACCESS indicates a 00000000 hex ALET so that the ALET can be changed to 00000001 hex by the called program.

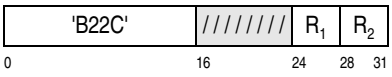
3. PROGRAM CALL to current primary (PC-cp) sets the secondary address space equal to the primary address space. PC-ss sets the secondary address space equal to the calling program's primary address space, except that stacking PC-ss sets it equal to the called program's primary address space when the secondary-ASN control in the entry-table entry used is one. In all these cases, a passed 00000001 hex ALET that conceptually designates the calling program's secondary address space is not usable by the called program, even after any transformation (unless the operation was PC-cp and the calling program's PASN and SASN are equal). This is why TEST ACCESS sets condition code 3 when the tested ALET is 00000001 hex.

4. After a PC-ss, a passed ALET that conceptually designates an entry in the primary-space access list of the calling program is not usable by the called program. This is why TEST ACCESS sets condition code 2, instead of condition code 1, when the tested ALET designates the primary-space access list.

5. The control program may manage the ASN-second-table entry in a way that causes a correctable ASTE-validity or ASTE-sequence exception situation to exist; that is, a situation which, if it were to cause a program interruption during access-register translation, would be corrected by the control program so that access-register translation could be completed successfully. In this case, the program should not use TEST ACCESS directly but should instead use a control-program service that uses TEST ACCESS and that corrects the situation, if possible, when condition code 3 is set. MVS/ESA provides the TESTART macro instruction for use instead of the direct use of TEST ACCESS.

TEST BLOCK

TB R_1,R_2 [RRE]



The storage locations and storage key of a 4 K-byte block are tested for usability, and the result of the test is indicated in the condition code. The test for usability is based on the susceptibility of the block to the occurrence of invalid checking-block code.

The block tested is addressed by the contents of general register R_2. The contents of general register R_1 are ignored.

A complete testing operation is necessarily performed only when the initial contents of bit positions 32-63 of general register 0 are zero in the 24-bit or 31-bit addressing mode, or the initial contents of bit positions 0-63 of that register are zero in the 64-bit addressing mode. In the 24-bit or 31-bit addressing mode, the contents of bit positions 32-63 of general register 0 are set to zero at the completion of the operation, and bits 0-31 of the register always are ignored and remain unchanged. In the 64-bit addressing mode, the contents of bit positions 0-63 of the register are set to zero at the completion of the operation.

If the block is found to be usable, the 4K bytes of the block are cleared to zeros, the contents of the storage key are unpredictable, and condition code 0 is set. If the block is found to be unusable, the data and the storage key are set, as far as is possible by the model, to a value such that subsequent fetches to the area do not cause a machine-check condition, and condition code 1 is set.

In the 24-bit addressing mode, bits 40-51 of general register R_2 designate a 4 K-byte block in real storage, and bits 0-39 and 52-63 of the register are ignored. In the 31-bit addressing mode, bits 33-51 of the register designate the block, and bits 0-32 and 52-63 are ignored. In the 64-bit addressing mode, bits 0-51 of the register designate the block, and bits 52-63 are ignored.

The address of the block is a real address, and the accesses to the block designated by the second-operand address are not subject to access-list-controlled, DAT, instruction-execution, or key-controlled protection. Low-address protection and secure-storage access do apply. The operation is terminated on addressing and protection exceptions. If termination occurs, the condition code and the contents of bit positions 32-63 of general register 0 are unpredictable in the 24-bit or 31-bit addressing mode, or the condition code and bits 0-63 of the register are unpredictable in the 64-bit addressing mode. The contents of the storage block and its associated storage key are not changed when these exceptions occur.

Depending on the model, the test for usability may be performed (1) by alternately storing and reading out test patterns to the data and storage key in the block or (2) by reference to an internal record of the usability of the blocks which are available in the configuration, or (3) by using a combination of both mechanisms.

In models in which an internal record is used, the block is indicated as unusable if a solid failure has been previously detected, or if intermittent failures in the block have exceeded the threshold implemented by the model. In such models, depending on the criteria, attempts to store may or may not occur. Thus, if block 0 is not usable, and no store occurs, low-address protection may or may not be indicated.

In models in which test patterns are used, TEST BLOCK may be interruptible. When an interruption occurs after a unit of operation, other than the last one, the condition code is unpredictable, and the contents of bit positions 32-63 of general register 0 may contain a record of the state of intermediate steps in the 24-bit or 31-bit addressing mode, or the contents of bit positions 0-63 may contain that record in the 64-bit addressing mode. When execution is resumed after an interruption, the condition code is ignored, but the record in general register 0 may be used to determine the resumption point.

If (1) TEST BLOCK is executed with an initial value other than zero in bit positions 32-63 of general register 0 in the 24-bit or 31-bit addressing mode or bit positions 0-63 in the 64-bit addressing mode, or (2) the interrupted instruction is resumed after an interruption with a value in bit positions 32-63 or 0-63 (depending on the addressing mode) of general register 0 or a value in the storage block or its associated storage key other than the corresponding value which was present at the time of the interruption, or (3) the block or its associated storage key is accessed by another CPU or by the channel subsystem during the execution of the instruction, then the

contents of the storage block, its associated storage key, and bit positions 32-63 or 0-63 of general register 0 are unpredictable, along with the resultant condition-code setting.

Invalid checking-block-code errors initially found in the block or encountered during the test do not normally result in machine-check conditions. The test-block function is implemented in such a way that the frequency of machine-check interruptions due to the instruction execution is not significant. However, if, during the execution of TEST BLOCK for an unusable block, that block is accessed by another CPU (or by the channel subsystem), error conditions may be reported both to this CPU and to the other CPU (or to the channel subsystem).

A serialization function is performed before the block is accessed and again after the operation is completed (or partially completed).

Resulting Condition Code:

0 Block usable
1 Block not usable
2 --
3 --

Program Exceptions:

- Addressing (fetch and store, operand 2)
- Privileged operation
- Protection (store, operand 2, low-address protection only)
- Secure-storage-access (fetch and store, operand 2)
- Transaction constraint

The priority of the recognition of exceptions and condition codes is shown in Figure 10-109.

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword.
7.B	Privileged-operation exception.
7.C	Transaction constraint.

Figure 10-109. Priority of Execution: TEST BLOCK (Part 1 of 2)

8.	Addressing exception due to block not being available in the configuration.*
9.A	Condition code 1, block not usable.
9.B	Protection exception due to low-address protection.*
9.C	Secure-storage-access exception.
10.	Condition code 0, block usable and set to zeros.

Explanation:

* The operation is terminated on addressing and protection exceptions, and the condition code may be unpredictable.

Figure 10-109. Priority of Execution: TEST BLOCK (Part 2 of 2)

Programming Notes:

1. The execution of TEST BLOCK on most models is significantly slower than that of the MOVE LONG instruction with padding; therefore, the instruction should not be used for the normal case of clearing storage.

2. The program should use TEST BLOCK at initial program loading and as part of the vary-storage-online procedure to determine if blocks of storage exist which should not be used.

3. The program should use TEST BLOCK when an uncorrected error is reported in either the data or storage key of a block. This is because in the execution of TEST BLOCK the attempt is made, as far as is possible on the model, to leave the contents of a block in a state such that subsequent prefetches or unintended references to the block do not cause machine-check conditions. The program may use the resulting condition code in this case to determine if the block can be reused. (The block could be indicated as usable if, for example, the error were an externally generated error or an indirect storage error.) This procedure should be followed regardless of whether the indirect-storage-error indication is reported.

4. The model may or may not be successful in removing the errors from a block when TEST BLOCK is executed. The program therefore should take every reasonable precaution to avoid referencing an unusable block. For example, the program should not place the page-frame real

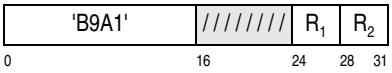
address of an unusable block in an attached and valid page-table entry.

5. On some models, machine checks may be reported for a block even though the block is not referenced by the program. When a machine check is reported for a storage-key error in a block which has been marked as unusable by the program, it is possible that SET STORAGE KEY EXTENDED may be more effective than TEST BLOCK in validating the storage key.

6. The storage-operand references for TEST BLOCK may be multiple-access references. (See “Storage-Operand Consistency” on page 5-133.)

TEST PENDING EXTERNAL INTERRUPTION

TPEI R_1,R_2 [RRE]



General register R_2 contains a mask representing one or more external-interruption subclasses to be tested for pending interruptions. The bit positions representing tested subclasses are shown in Figure 10-110. All other bits in general register R_2 are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.

Bit	External Interruption Subclass
30	Warning track
48	Malfunction alert
49	Emergency signal
50	External call

Figure 10-110. External-Interruption Subclasses and Corresponding Bit Positions in General Registers R_1 and R_2.

For the purposes of this instruction, an interruption is considered to be pending for a subclass regardless of whether the subclass is enabled in control register 0 and regardless of PSW bit 7. If an external interruption is pending for a designated subclass, the corresponding bit in general register R_1 is set to one; otherwise, the corresponding bit in general register R_1 is set to zero. All other bit positions in general register R_1 are set to zeros.

When any resulting bit position in general register R_1 contains a one, the instruction completes by setting condition code 1; otherwise, the instruction completes by setting condition code 0.

Resulting Condition Code:

0 None of the tested subclasses of external interruptions are pending, or no subclasses were tested.
1 One or more of the tested subclasses of external interruptions are pending
2 --
3 --

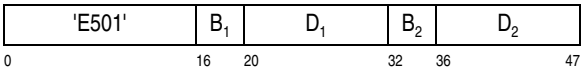
Program Exceptions:

- Operation (test-pending-external-interruption facility not installed)
- Privileged operation
- Transaction constraint

Programming Note: Unlike the TEST PENDING INTERRUPTION (TPI) instruction which is subject to the I/O-interruption subclass-mask bits in control register 6, TEST PENDING EXTERNAL INTERRUPTION does not take subclass enablement into consideration.

TEST PROTECTION

TPROT $D_1(B_1),D_2(B_2)$ [SSE]



The location designated by the first-operand address is tested for protection exceptions by using the access key specified by bits 56-59 of the second-operand address.

The second-operand address is not used to address data; instead, bits 56-59 of the address form the access key to be used in testing. Bits 0-55 and 60-63 of the second-operand address are ignored.

The first-operand address is a logical address. When the CPU is in the access-register mode (when DAT is on and PSW bits 16 and 17 are 01 binary), the first-

operand address is subject to translation by means of both the access-register-translation (ART) and the dynamic-address-translation (DAT) processes. ART applies to the access register designated by the B_1 field, and it obtains the address-space-control element to be used by DAT. When DAT is on but the CPU is not in the access-register mode, the first-operand address is subject to translation by DAT. In this case, DAT uses the address-space-control element contained in control register 1, 7, or 13 when the CPU is in the primary-space, secondary-space, or home-space mode, respectively. When DAT is off, the first-operand address is a real address not subject to translation by either ART or DAT.

When the CPU is in the access-register mode and an address-space-control element cannot be obtained by ART because of a condition that would normally cause one of the exceptions shown in the following table, the instruction is completed by setting condition code 3.

Exception Name	Cause
ALET specification	Access-list-entry-token (ALET) bits 0-6 not all zeros
ALEN translation	Access-list entry (ALE) outside list or invalid (bit 0 is one)
ALE sequence	ALE sequence number (ALESN) in ALET not equal to ALESN in ALE
ASTE validity	ASN-second-table entry (ASTE) invalid (bit 0 is one)
ASTE sequence	ASTE sequence number (ASTESN) in ALE not equal to ASTESN in ASTE
Extended authority	ALE private bit not zero, ALE authorization index (ALEAX) not equal to extended authorization index (EAX), and secondary bit selected by EAX either outside authority table or zero

When the access register contains 00000000 hex or 00000001 hex, ART obtains the address-space-control element from control register 1 or 7, respectively, without accessing the access list. When the B_1 field designates access register 0, ART treats the access register as containing 00000000 hex and does not examine the actual contents of the access register.

When ART is completed successfully, the operation is continued through the performance of DAT.

When DAT is on and the first-operand address cannot be translated because of a condition that would normally cause one of the exceptions shown in the following table, the instruction is completed by setting condition code 3.

Exception Name	Cause
ASCE type	Address-space-control element (ASCE) being used is a region-second-table designation, and bits 0-10 of first-operand address not all zeros; ASCE is a region-third-table designation, and bits 0-21 of first-operand address not all zeros; or ASCE is a segment-table designation, and bits 0-32 of first-operand address not all zeros.
Region first translation	Region-first-table entry outside table or invalid.
Region second translation	Region-second-table entry outside table or invalid.
Region third translation	Region-third-table entry outside table or invalid.
Segment translation	Segment-table entry outside table or invalid
Page translation	Page-table entry invalid

When translation of the first-operand address can be completed, or when DAT is off, the storage key for the block designated by the first-operand address is tested against the access key specified in bit positions 56-59 of the second-operand address, and the condition code is set to indicate whether store and fetch accesses are permitted, taking into consideration all applicable protection mechanisms except for instruction-execution protection. Thus, for example, if low-address protection is active and the first-operand effective address is in the range 0-511 or 4096-4607, then a store access is not permitted. Access-list-controlled protection, DAT protection, storage-protection override, and fetch-protection override also are taken into account; instruction-execution protection is not considered.

When EDAT-1 does not apply, when EDAT-1 applies but the STE-format control is zero, or when EDAT-2 applies but the RTTE-format control is zero, bits 0-4 of the storage key for the 4 K-byte block corresponding to the virtual address in the first operand are examined to determine the condition code. When EDAT-1 applies and both the STE-format and AV

controls in the STE are one, it is unpredictable whether bits 0-4 of the storage key or bits 48-52 of the segment-table entry used in the translation of the first operand are examined to determine the condition code. When EDAT-2 applies and both the RTTE-format and AV controls in the RTTE are one, it is unpredictable whether bits 0-4 of the storage key or bits 48-52 of the region-third-table entry used in the translation of the first operand are examined to determine the condition code.

The contents of storage, including the change bit, are not affected. Depending on the model, the reference bit for the first-operand address may be set to one, even for the case in which the location is protected against fetching.

Special Conditions

When the CPU is in the access-register mode, the following conditions apply:

- An addressing exception is recognized when the address used by ART to fetch the effective access-list designation or the ALE, ASTE, or authority-table entry designates a location which is not available in the configuration.
- A secure-storage-access exception is recognized when the address used by ART to fetch the effective access-list designation or the ALE, ASTE, or authority-table entry designates a location which is a secure location

When DAT is on, the following conditions apply:

- An addressing exception is recognized when the address of the region-table entry or entries, segment-table entry, or page-table entry or the operand real address after translation designates a location which is not available in the configuration.
- A secure-storage-access exception is recognized when the address of the region-table entry or entries, segment-table entry, or page-table entry or the operand real address after translation designates a location which is a secure location.

Also, a translation-specification exception is recognized when a region-table entry or the segment-table entry or page-table entry has a format error, that is, when any of the reasons 1-5 listed in “Translation-Specification Exception” on page 6-48 applies. When DAT is off, only the addressing exception due to the operand real address applies.

A secure-storage-access exception is recognized when the address used by ART to fetch the effective access-list designation or the ALE, ASTE, or authority-table entry designates a location which is a secure location or when the address used to fetch the region-table entry or entries, if any, segment-table entry, or page-table entry designates a location which is a secure location in the configuration.

For all of the above cases, the operation is suppressed.

When the storage-key-removal facility is installed and bits 56-59 of the second-operand address are nonzero, a special-operation exception is recognized.

Resulting Condition Code:

0 Fetching permitted; storing permitted
1 Fetching permitted; storing not permitted
2 Fetching not permitted; storing not permitted
3 Translation not available

Program Exceptions:

- Addressing (effective access-list designation, access-list entry, ASN-second-table entry, authority-table entry, region-table entry, segment-table entry, page-table entry, or operand 1)
- Privileged operation
- Secure-storage-access (effective access-list designation, access-list entry, ASN-second-table entry, authority-table entry, region-table entry, segment-table entry, page-table entry, or operand 1)
- Special operation
- Translation specification
- Transaction constraint

Programming Notes:

1. TEST PROTECTION permits a program to determine the protection attributes of an address passed from a calling program without incurring program exceptions. The instruction sets a condition code to indicate whether fetching or storing is permitted at the location designated by the first-operand address of the instruction. The instruction takes into consideration all of the protection mechanisms in the machine: access-list controlled, DAT, key-controlled, and low-address

protection, storage-protection override, and fetch-protection override. Additionally, since ASCE-type, region-translation, segment-translation, and page-translation-exception conditions may be a program substitute for a protection violation, these conditions are used to set the condition code rather than cause a program exception.

When the CPU is in the access-register mode, TEST PROTECTION additionally permits the program to check the usability of an access-list-entry token (ALET) in an access register without incurring program exceptions. The ALET is checked for validity (absence of an ALET-specification, ALEN-translation, and ALE-sequence-exception condition) and for being authorized for use by the program (absence of an ASTE-validity, ASTE-sequence, and extended-authority-exception condition).

2. See the programming notes under SET PSW KEY FROM ADDRESS for more details and for an alternative approach to testing the key-controlled protection attributes of addresses passed by a calling program. The approach using TEST PROTECTION has the advantage of a test which does not result in interruptions; however, the test and use are separated in time and may not be accurate if the possibility exists that the storage key of the location in question can change between the time it is tested and the time it is used.

3. In the handling of dynamic address translation, TEST PROTECTION is similar to LOAD REAL ADDRESS in that the instructions do not cause ASCE-type, region-translation, segment-translation, and page-translation exceptions. Instead, these exception conditions are indicated by means of a condition-code setting. Similarly, access-register translation sets a condition code for certain exception conditions when performed during either of the two instructions. Conditions which result in condition codes 1, 2, and 3 for LOAD REAL ADDRESS result in condition code 3 for TEST PROTECTION. The instructions also differ in several other respects. The first-operand address of TEST PROTECTION is a logical address and thus is not subject to dynamic address translation when DAT is off. The second-operand address of LOAD REAL ADDRESS is a virtual address which is always translated.

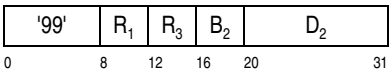
   Access-register translation applies to TEST PROTECTION only when the CPU is in the access-register mode (DAT is on), whereas it applies to LOAD REAL ADDRESS when PSW bits 16 and 17 are 01 binary regardless of whether DAT is on or off. When condition code 3 is set because of an exception condition in access-register translation, LOAD REAL ADDRESS, but not TEST PROTECTION, returns in a general register the program-interruption code assigned to the exception.

4. Condition code 3 does not necessarily indicate that the first-operand location will always be inaccessible to the program; rather it merely indicates that the current conditions prevent the instruction from determining the protection attributes of the operand. For example, in a virtual storage environment, condition code 3 may be set if the storage location has been paged out by the operating system. If the program attempts to access the location, the operating system may resolve the page-translation exception and subsequently make the location accessible to the program.

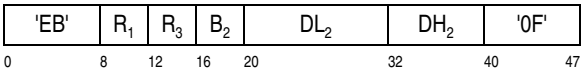
   Similarly, condition code 1 does not necessarily indicate that the address cannot ever be stored into. In an operating system that implements a Posix fork function, DAT protection is used to alert the operating system of a copy-on-write event (as described in Programming Note 1 on page 3-19). Following the operating-system resolution of the copy-on-write event, the program may be given store access to the location.

TRACE

TRACE $R_1,R_3,D_2(B_2)$ [RS-a]



TRACG $R_1,R_3,D_2(B_2)$ [RSY-a]



When explicit tracing is on (bit 63 of control register 12 is one), the second operand, which is a 32-bit word in storage, is fetched, and bit 0 of the word is examined. If bit 0 of the second operand is zero, a

trace entry is formed at the real-storage location designated by control register 12.

If explicit tracing is off (bit 63 of control register 12 is zero), or if bit 0 of the second operand is one, no trace entry is formed, and no trace exceptions are recognized.

The displacement for TRACE is treated as a 12-bit unsigned binary integer. The displacement for TRACG is treated as a 20-bit signed binary integer.

The trace entry is composed of an entry-type identifier, a count of the number of general registers whose partial or entire contents are placed in the entry, a field whose contents indicate whether the entry was formed by TRACE (TRACE) or TRACE (TRACG), selected bits of the TOD clock, the second operand, and the partial or entire contents of a range of general registers. For TRACE (TRACE), bits 16-63 of the TOD clock and bits 32-63 of the general registers are placed in the trace entry. For TRACE (TRACG), bits 1-7 of the epoch index, bits 0-79 of the clock, and bits 0-63 of the registers are placed in the entry. See "Trace Entries" on page 4-15 for further details.

The general registers are stored in ascending order of their register numbers, starting with general register R_1 and continuing up to and including general register R_3, with general register 0 following general register 15. The trace table and the trace-entry formats are described in "Tracing" on page 4-12.

When a trace entry is made, a serialization and checkpoint-synchronization function is performed before the operation begins and again after the operation is completed. However, it is unpredictable whether or not a store into a trace-table entry from which a subsequent instruction is fetched will be observed by the CPU that performed the store. Additionally, when the store-clock-fast facility is installed and the TRACE TOD-clock control in bit 32 of control register 0 is one, it is unpredictable whether explicit tracing causes serialization to be performed.

Special Conditions

A privileged-operation exception is recognized in the problem state, even when explicit tracing is off or bit 0 of the second operand is one.

The second operand must be designated on a word boundary; otherwise, a specification exception is recognized. It is unpredictable whether the specification exception is recognized when explicit tracing is off.

It is unpredictable whether access exceptions or PER zero-address-detection events are recognized for the second operand when explicit tracing is off.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Privileged operation
- Specification
- Trace
- Transaction constraint

Programming Notes:

1. Bits 1-15 of the second operand are reserved for model-dependent functions and should therefore be set to zeros.

2. When the store-clock-fast facility is not installed, or when the TOD-clock-control in bit 32 of control register 0 is zero, the entire 32-bit TRACE operand is stored in bits 64-95 of the trace entry for TRACE (TRACE) and in bits 96-127 of the trace entry for TRACE (TRACG).

3. When the store-clock-fast facility is installed and the TRACE TOD-clock control in bit 32 of control register 0 is one, the following conditions apply:

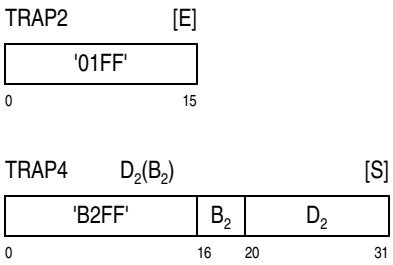
   - Two executions of the instruction do not necessarily store different values in the TOD-clock bits of the trace entry.

   - The value of the TOD clock bits stored in the trace entry does not necessarily indicate the order of operations among multiple CPUs.

   - The contents of bit positions 16-31 of the TRACE operand are stored in bits 80-95 of the trace entry for TRACE (TRACE) and in bits 112-127 of the trace entry for TRACE (TRACG).

   - Bits 64-79 of the trace entry for TRACE (TRACE) and bits 96-111 of the trace entry for TRACE (TRACG) are set to a model-dependent value.

TRAP



A trap operation is performed if the CPU is in the primary-space or access-register mode and the TRAP-enabled bit in byte 47 of the dispatchable-unit control table (DUCT) is one. Otherwise, a special-operation exception is recognized.

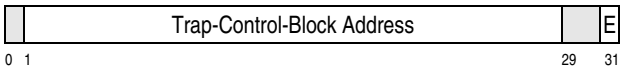
The trap operation obtains a trap-control-block address from the DUCT and then a trap-save-area address and a trap-program address from the trap control block. State information is stored in the trap save area. Then the trap-control-block address is loaded into general register 15. Finally, the current PSW is updated by setting the basic-addressing-mode bit to one (which will leave the addressing mode as either the 31-bit mode or the 64-bit mode or will change the addressing mode from the 24-bit mode to the 31-bit mode) and the address-space-control bits to zeros (primary-space mode) and by replacing the instruction address with the trap-program address. Compatibility with the ESA/390 operation of TRAP optionally is provided.

For TRAP4, the second-operand address is not used to address data; instead, bits 33-63 of the address are stored in the trap save area.

Dispatchable-Unit Control Table

Bytes 44-47 (word 10) of the dispatchable-unit-control table (DUCT) are used by this instruction. The contents of those bytes are as follows:

DUCT Bytes 44-47



The fields in bytes 44-47 of the DUCT are allocated as follows:

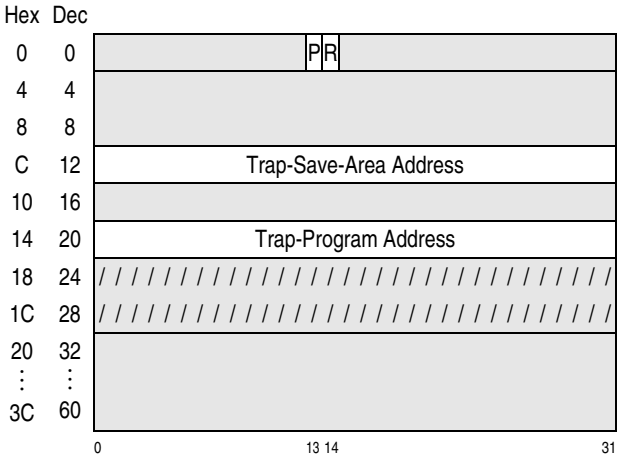
Trap-Control-Block Address: Bits 1-28, with three zeros appended on the right, form the 31-bit home virtual address of the trap control block. This address is treated as a 31-bit home virtual address regardless of the current addressing mode and regardless of the current value of the address-space-control bits. This address, with a zero appended on the left, is placed in bit positions 32-63 of general register 15 after the contents of that register have been saved in the trap save area. If the current addressing mode is the 64-bit mode, bits 0-31 of general register 15 are set to zeros.

TRAP-Enabled Bit (E): Bit 31 specifies, when one, that the trap operation is to be performed. TRAP recognizes a special-operation exception if bit 31 is zero.

Bits 0, 29, and 30 of bytes 44-47 are ignored, but they should be zeros to permit possible future extensions.

Trap Control Block

The trap control block is 64 bytes aligned on a doubleword boundary. The format of the trap control block is:



The fields in the trap control block are allocated as follows:

PSW Control (P): Bit 13 of bytes 0-3 controls the allowed value of bit 31 of the current PSW and how bits 12 and 33-127 of the current PSW are stored in the PSW-values field in the trap save area. When bit 13 is zero:

- Bit 31 of the current PSW, the extended-addressing-mode bit, must be zero; otherwise, a special-operation exception is recognized.

- A one is stored in bit position 12 of the PSW-values field even though bit 12 of the current PSW is zero.
- Bits 97-127 of the current PSW are stored in bit positions 33-63 of the PSW-values field, bits 33-96 of the current PSW are not stored, and zeros are stored in bit positions 64-127 of the PSW-values field.

When bit 13 is one:

- Bit 31 of the current PSW may be zero or one.
- Bit 12 of the current PSW is stored in bit position 12 of the PSW-values field.
- Bits 64-127 of the current PSW are stored in bit positions 64-127 of the PSW-values field.

General-Registers Control (R): Bit 14 of bytes 0-3 controls how the contents of the general registers are stored in the general-registers 0-15 field in the trap save area. When R is zero, bits 32-63 of the general registers are stored in consecutive four-byte locations beginning at the beginning of the general-registers 0-15 field, bits 0-31 of the registers are not stored, and the last 64 bytes of the general-registers 0-15 field remain unchanged. When R is one, bits 0-63 of the general registers are stored in consecutive eight-byte locations in the general-registers 0-15 field.

Trap-Save-Area Address: Bits 1-28 of bytes 12-15, with three zeros appended on the right, form the 31-bit home virtual address of the trap save area. This address is treated as a 31-bit home virtual address regardless of the current addressing mode and regardless of the current value of the address-space-control bits. Bits 0 and 29-31 of bytes 12-15 are ignored.

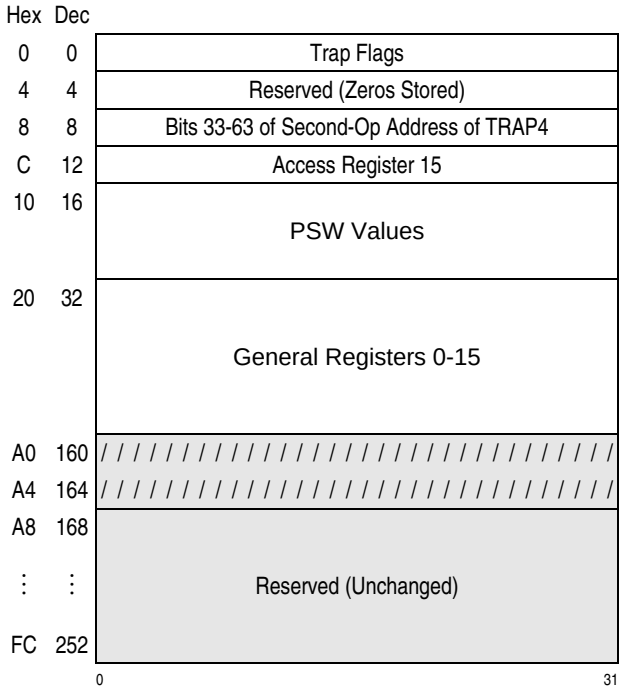
Trap-Program Address: Bits 1-31 of bytes 20-23 form the 31-bit primary virtual address of the trap program. This address is treated as a 31-bit primary virtual address regardless of the current addressing mode. Bit 0 of byte 20 is ignored.

Bit positions 0-12 and 15-31 of bytes 0-3 and bytes 4-11, 16-19, and 32-63 of the trap control block are reserved and should contain zeros. Bytes 24-31 are available for use by programming.

Trap Save Area

The trap save area is 256 bytes aligned on a double-word boundary.

The trap operation stores information into the trap save area as follows:



The fields in the trap save area are allocated as follows:

Trap Flags: Information identifying the instruction(s) causing the trap operation is stored in byte positions 0-3. The detailed format of bytes 0-3 is as follows:

Flag Bits	Meaning
0	TRAP was target of an execute-type instruction
1	TRAP is TRAP4 (not TRAP2)
2-12	Reserved, zeros stored
13-14	Instruction-length code (ILC)
15-31	Reserved, zeros stored

Bit 0 of bytes 0-3 is set to one if TRAP was the target of an execute-type instruction (EXECUTE or EXECUTE RELATIVE LONG).

Bit 1 of bytes 0-3 is set to one if TRAP is TRAP4 (not TRAP2).

Bits 13 and 14 are the instruction-length code (ILC) that specifies the length of the TRAP instruction, or the length of the execute-type instruction if TRAP was the target of an execute-type instruction.

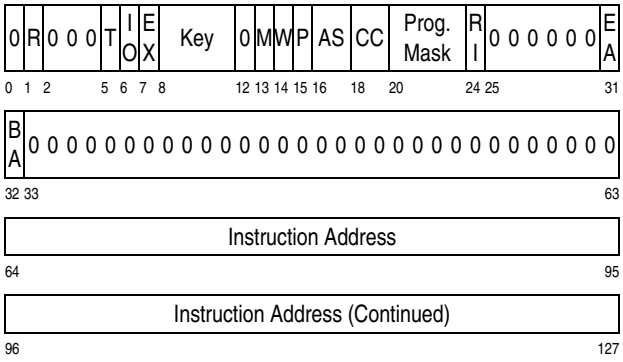
Bits 2-12 and 15-31 are reserved and are stored as zeros.

Bits 33-63 of Second-Operand Address of TRAP4: For TRAP4, bits 33-63 of the second-operand address, generated under the control of the current addressing mode and with a zero appended on the left, are stored in byte positions 8-11. Only bits 33-63 of the second-operand address are stored even when the current addressing mode is the 64-bit mode. For TRAP2, all zeros are stored in byte positions 8-11.

Access Register 15: The contents of access register 15 are stored in byte positions 12-15.

PSW Values: The following description applies when the PSW control, bit 13 of bytes 0-3 of the trap control block, is one.

Certain information from the current PSW is stored in byte positions 16-31. The PSW has the following format:



Bits 0-127 of bytes 16-31 correspond one-to-one with bits 0-127 of the PSW. For some bit positions of bytes 16-31, the corresponding PSW bits are stored. For the other bit positions of bytes 16-31, unpredictable values are stored. Information is stored in bytes 16-31 as follows:

Bits	Value
0	Zero
1	Unpredictable
2-4	Zero
5-11	Unpredictable
12	Zero
13	Unpredictable
14	Wait state (W)
15	Problem state (P)
16-17	Address-space control (AS)
18-19	Condition code (CC)
20-23	Program mask
24	Unpredictable
25-30	Zero
31	Extended addressing mode (EA)
32	Basic addressing mode (BA)
33-63	Zero
64-127	Instruction address

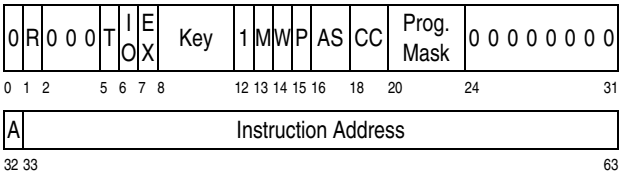
In summary, bits 0, 2-4, 12,25-30, and 33-63 are zero, bits 1, 5-11, 13, and 24 are unpredictable, and the other bits are set with variable information from the PSW.

The wait-state, problem-state, address-space-control, condition-code, program-mask, extended-addressing-mode, and basic-addressing-mode values specify the state of the CPU before the TRAP instruction was executed. The instruction-address value is the updated instruction address, which is the address of the instruction following TRAP, or the address of the instruction following the execute-type instruction if TRAP was the target of an execute-type instruction.

When the PSW control in the trap control block is zero, the operation is as described above except as follows:

- Bit 31 of the current PSW must be zero; otherwise, a special-operation exception is recognized.
- A one is stored in bit position 12 of bytes 16-31.
- Bits 97-127 of the current PSW are stored in bit positions 33-63 of bytes 16-31, bits 33-96 of the current PSW are not stored, and zeros are stored in bit positions 64-127 of bytes 16-31 (bytes 24-31).

In this case, bytes 16-23 have the format of an ESA/390 PSW, which is as follows:



General Registers 0-15: Contents of general registers 0-15 are stored in byte positions 32-159 as described in "General-Registers Control (R)" on page 10-190. When bits 32-63 or 0-63 of the general registers are stored, they are stored in ascending order of register numbers, starting with register 0 and continuing up to and including register 15.

Bytes 160-255 always remain unchanged. Bytes 168-255 are reserved. Bytes 160-167 are available for use by programming.

Special Conditions

The CPU must be in the primary-space mode or access-register mode, and bit 31 in bytes 44-47 of the dispatchable-unit control table must be one; otherwise, a special-operation exception is recognized. A special-operation exception is also recognized if the PSW control, bit 13 of bytes 0-3 of the trap control block is zero and bit 31 of the current PSW, the extended-addressing-mode bit, is one.

All protection mechanisms apply in the usual way to the accesses to the trap control block and trap save area. Access exceptions may or may not be recognized for sections of the trap control block and trap save area that are not referenced by the TRAP instruction.

The trap-program address in the trap control block is not tested before it replaces the instruction address in the PSW. An odd address will cause a specification exception to be recognized as part of the execution of the next instruction.

The operation is suppressed on all addressing and protection exceptions.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, trap control block; store, trap save area)
- Addressing (dispatchable-unit control table)
- Secure-storage-access (dispatchable-unit control table)
- Special operation
- Trace
- Transaction constraint

The priority of recognition of program exceptions for the instruction is shown in Figure 10-111.

1.-6.	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
7.A	Access exceptions for second instruction halfword (TRAP4 only).
7.B	Special-operation exception due to the CPU not being in the primary-space mode or access-register mode.
7.C.1	Addressing exception or secure-storage-access exception for access to dispatchable-unit control table.
7.C.2	Special-operation exception due to bit 31 in bytes 44-47 of dispatchable-unit control table being zero.
7.D	Transaction constraint.
8.A	Trace exceptions.
8.B.1	Access exceptions (fetch) for trap control block.
8.B.2	Special-operation exception due to PSW control in trap control block being zero and PSW bit 31 being one.
8.B.3	Access exceptions (store) for trap save area.

Figure 10-111. Priority of Execution: TRAP

Programming Notes:

1. It is intended that TRAP instructions will overlay instructions in an application program in order to give control to a trap program, which might be a program for performing fix-ups of data used by the application program, such as dates that may be a "Year-2000" problem. TRAP2 can overlay a two-byte instruction, and TRAP4 can overlay a four-byte instructions or the first four bytes of a six-byte instruction. The trap program is to simulate the overlaid instruction and perform fix-ups as appropriate, and it is then to return control to the application program.

2. The trap program can use the RESUME PROGRAM instruction to return control to the application program. For example, the trap program can restore the contents of all registers except access and general registers 15, and then, using those registers (or at least the general register) to address the trap save area, can restore the contents of those registers and also PSW fields from the trap save area. RESUME PROGRAM has control bits in its parameter list that allow it to restore PSW fields from a field having either the short format (as shown in Figure 4-3 on page 4-8) or the 16-byte format (as shown in Figure 4-2 on page 4-5) and to restore either bits 32-63 or 0-63 of a general register.

3. The trap control block and trap save area are in the home address space, and the trap program is in the primary address space. The trap-control-block address placed in general register 15 by TRAP can be useful to the trap program if (1) the primary address space and home address space are the same address space, (2) the trap control block and trap save area are at the same locations in the primary address space as in the home address space, or (3) the trap program can use access registers to access the home address space.

4. The storage-operand references for TRAP may be multiple-access references. (See “Storage-Operand Consistency” on page 5-133.)

The machine-check-handling mechanism provides extensive equipment-malfunction detection to ensure the integrity of system operation and to permit automatic recovery from some malfunctions. Equipment malfunctions and certain external disturbances are reported by means of a machine-check interruption to assist in program-damage assessment and recovery. The interruption supplies the program with information about the extent of the damage and the location and nature of the cause. Equipment malfunctions, errors, and other situations which can cause machine-check interruptions are referred to as machine checks.

Machine-Check Detection

Machine-check-detection mechanisms may take many forms, especially in control functions for arithmetic and logical processing, addressing, sequencing, and execution. For program-addressable information, detection is normally accomplished by encoding redundancy into the information in such a manner that most failures in the retention or transmission of the information result in an invalid code. The encoding normally takes the form of one or more redundant bits, called check bits, appended to a group of data bits. Such a group of data bits and the associated check bits are called a checking block. The size of the checking block depends on the model.

The inclusion of a single check bit in the checking block allows the detection of any single-bit failure within the checking block. In this arrangement, the check bit is sometimes referred to as a “parity bit.” In other arrangements, a group of check bits is included to permit detection of multiple errors, to permit error correction, or both.

For checking purposes, the contents of the entire checking block, including the redundancy, are called the checking-block code (CBC). When a CBC completely meets the checking requirements (that is, no failure is detected), it is said to be valid. When both detection and correction are provided and a CBC is not valid but satisfies the checking requirements for correction (the failure is correctable), it is said to be near-valid. When a CBC does not satisfy the checking requirements (the failure is uncorrectable), it is said to be invalid.

Correction of Machine Malfunctions

Four mechanisms may be used to provide recovery from machine-detected malfunctions: error checking and correction, CPU retry, channel-subsystem recovery, and unit deletion.

Machine failures which are corrected successfully may or may not be reported as machine-check interruptions. If reported, they are system-recovery conditions, which permit the program to note the cause of CPU delay and to keep a log of such incidents.

Error Checking and Correction

When sufficient redundancy is included in circuitry or in a checking block, failures can be corrected. For example, circuitry can be triplicated, with a voting circuit to determine the correct value by selecting two matching results out of three, thus correcting a single failure. An arrangement for correction of failures of one order and for detection of failures of a higher order is called error checking and correction (ECC). Commonly, ECC allows correction of single-bit failures and detection of double-bit failures.

Depending on the model and the portion of the machine in which ECC is applied, correction may be reported as system recovery, or no report may be given.

Uncorrected errors in storage and in the storage key may be reported, along with a failing-storage address, to indicate where the error occurred. Depending on the situation, these errors may be reported along with system recovery or with the damage or backup condition resulting from the error.

CPU Retry

In some models, information about some portion of the state of the machine is saved periodically. The

point in the processing at which this information is saved is called a checkpoint. The information saved is referred to as the checkpoint information. The action of saving the information is referred to as establishing a checkpoint. The action of discarding previously saved information is called invalidation of the checkpoint information. The length of the interval between establishing checkpoints is model-dependent. Checkpoints may be established at the beginning of each instruction or several times within a single instruction, or checkpoints may be established less frequently.

Subsequently, this saved information may be used to restore the machine to the state that existed at the time when the checkpoint was established. After restoring the appropriate portion of the machine state, processing continues from the checkpoint. The process of restoring to a checkpoint and then continuing is called CPU retry.

CPU retry may be used for machine-check recovery, to effect nullification and suppression of instruction execution when certain program interruptions occur, and in other model-dependent situations.

Effects of CPU Retry

CPU retry is, in general, performed so that there is no effect on the program. However, change bits which have been changed from zeros to ones are not necessarily set back to zeros. As a result, change bits may appear to be set to ones for blocks which would have been accessed if restoring to the checkpoint had not occurred. If the path taken by the program is dependent on information that may be changed by another CPU or by a channel program or if an interruption occurs, then the final path taken by the program may be different from the earlier path; therefore, change bits may be ones because of stores along a path apparently never taken.

During the execution of the following instructions, CPU retry may result in condition code 3 being set with possibly incorrect data having been stored in the first operand location at or to the right of the location designated by the final address in general register R_1.

- COMPRESSION CALL
- CONVERT UTF-16 TO UTF-32
- CONVERT UTF-16 TO UTF-8
- CONVERT UTF-32 TO UTF-16
- CONVERT UTF-32 TO UTF-8
- CONVERT UTF-8 TO UTF-16
- CONVERT UTF-8 TO UTF-32
- CIPHER MESSAGE
- CIPHER MESSAGE WITH AUTHENTICATION
- CIPHER MESSAGE WITH CHAINING
- CIPHER MESSAGE WITH COUNTER
- CIPHER MESSAGE WITH CIPHER FEEDBACK
- CIPHER MESSAGE WITH OUTPUT FEEDBACK
- DEFLATE CONVERSION CALL (see below for additional information)
- SORT LISTS
- TRANSLATE ONE TO ONE
- TRANSLATE ONE TO TWO
- TRANSLATE TWO TO ONE
- TRANSLATE TWO TO TWO

During the execution of the PERFORM RANDOM NUMBER OPERATION instruction's generate operation, CPU retry may result in condition code 3 being set with possibly incorrect data having been stored in the first operand location at or to the left of the rightmost byte of the first operand (that is, to the left of the location designated by the combination of general registers R_1 and $R_1 + 1$).

During the execution of DEFLATE CONVERSION CALL when the specified function is DFLTCC-CMPR or DFLTCC-XPND and the history-buffer type is circular, CPU retry may result with possibly incorrect data stored to the third-operand location.

The amount of data stored depends on the operation and the point in time at which CPU retry occurred. The amount of incorrect data stored will not exceed the minimum of (a) the length of the first operand, (b) the length of the second operand (for instructions having a second operand), and (c) the data processed in a single unit of operation of the instruction. In all cases, the storing will occur again, with correct data stored, if the instruction is executed again to continue processing the same operands.

Checkpoint Synchronization

Checkpoint synchronization consists in the following steps.

1. The CPU operation is delayed until all conceptually previous accesses by this CPU to storage have been completed, both for purposes of machine-check detection and as observed by other CPUs and by channel programs.

2. All previous checkpoints, if any, are invalidated.

3. Optionally, a new checkpoint is established.

The CPU operation is delayed until all of these actions appear to be completed, as observed by other CPUs and by channel programs.

Handling of Machine Checks during Checkpoint Synchronization

When, in the process of completing all previous stores as part of the checkpoint-synchronization action, the machine is unable to complete all stores successfully but can successfully restore the machine to a previous checkpoint, processing backup is reported.

When, in the process of completing all stores as part of the checkpoint-synchronization action, the machine is unable to complete all stores successfully and cannot successfully restore the machine to a previous checkpoint, the type of machine-check-interruption condition reported depends on the origin of the store. Failure to successfully complete stores associated with instruction execution may be reported as instruction-processing damage, or some less critical machine-check-interruption condition may be reported with the storage-logical-validity bit set to zero. A failure to successfully complete stores associated with the execution of an interruption, other than program or supervisor call, is reported as system damage.

When the machine check occurs as part of a checkpoint-synchronization action before the execution of an instruction, the execution of the instruction is nullified. When it occurs before the execution of an interruption, the interruption condition, if the interruption is external, I/O, or restart, is held pending. If the checkpoint-synchronization operation was a machine-check interruption, then along with the originating condition, either the storage-logical-validity bit is set to zero or instruction-processing damage is also reported. Program interruptions, if any, are lost.

Checkpoint-Synchronization Operations

All interruptions and the execution of certain instructions cause a checkpoint-synchronization action to be performed. The operations which cause a checkpoint-synchronization action are called checkpoint-synchronization operations and include:

- CPU reset
- All interruptions: external, I/O, machine check, program, restart, and supervisor call
- The BRANCH ON CONDITION (BCR) instruction with the M_1 and R_2 fields containing all ones and all zeros, respectively
- The instructions LOAD PSW, LOAD PSW EXTENDED, SET STORAGE KEY EXTENDED, and SUPERVISOR CALL
- All I/O instructions
- The instructions MOVE TO PRIMARY, MOVE TO SECONDARY, PROGRAM CALL, PROGRAM TRANSFER, SET ADDRESS SPACE CONTROL, and SET SECONDARY ASN, and PROGRAM RETURN when the state entry to be unstacked is a program-call state entry
- The four trace functions: branch tracing, ASN tracing, mode tracing, and explicit tracing, except that when the store-clock-fast facility is installed and the TRACE TOD-clock control in bit 32 of control register 0 is one, then it is unpredictable whether explicit tracing causes a checkpoint-synchronization action.
- PAGE IN and PAGE OUT

Programming Note: The instructions which are defined to cause the checkpoint-synchronization action invalidate checkpoint information but do not necessarily establish a new checkpoint. Additionally, the CPU may establish a checkpoint between any two instructions or units of operation, or within a single unit of operation. Thus, the point of interruption for the machine check is not necessarily at an instruction defined to cause a checkpoint-synchronization action.

Checkpoint-Synchronization Action

For all interruptions except I/O interruptions, a checkpoint-synchronization action is performed at the completion of the interruption. For I/O interruptions, a checkpoint-synchronization action may or may not be performed at the completion of the interruption. For all interruptions except program, supervisor-call, and exigent machine-check interruptions, a checkpoint-synchronization action is also performed before the interruption. The fetch access to the new PSW may be performed either before or after the first checkpoint-synchronization action. The store accesses and the changing of the current PSW associated with the interruption are performed after the first checkpoint-synchronization action and before the second.

For all checkpoint-synchronization instructions except BRANCH ON CONDITION (BCR), I/O instructions, and SUPERVISOR CALL, checkpoint-synchronization actions are performed before and

after the execution of the instruction. For BCR, only one checkpoint-synchronization action is necessarily performed, and it may be performed either before or after the instruction address is updated. For SUPERVISOR CALL, a checkpoint-synchronization action is performed before the instruction is executed, including the updating of the instruction address in the PSW. The checkpoint-synchronization action taken after the supervisor-call interruption is considered to be part of the interruption action and not part of the instruction execution. For I/O instructions, a checkpoint-synchronization action is always performed before the instruction is executed and may or may not be performed after the instruction is executed.

The four trace functions — branch tracing, ASN tracing, mode tracing, and explicit tracing — cause checkpoint-synchronization actions to be performed before the trace action and after completion of the trace action, except that when the store-clock-fast facility is installed and the TRACE TOD-clock control in bit 32 of control register 0 is one, then it is unpredictable whether checkpoint-synchronization actions are performed for explicit tracing.

Channel-Subsystem Recovery

When errors are detected in the channel subsystem, the channel subsystem attempts to analyze and recover the internal state associated with the various channel-subsystem functions and the state of the channel subsystem and various subchannels. This process, which is called channel-subsystem recovery, may result in a complete recovery or may result in the termination of one or more I/O operations and the clearing of the affected subchannels. Special channel-report-pending machine-check-interruption conditions may be generated to indicate to the program the status of the channel-subsystem recovery.

Malfunctions associated with the I/O operations, depending on the severity of the malfunction, may be reported by means of the I/O-interruption mechanism or by means of the channel-report-pending and channel-subsystem-damage machine-check-interruption conditions.

Unit Deletion

In some models, malfunctions in certain units of the system can be circumvented by discontinuing the use of the unit. Examples of cases where unit deletion may occur include the disabling of all or a portion of a cache or of a translation-lookaside buffer (TLB). Unit deletion may be reported as a degradation machine-check-interruption condition.

Handling of Machine Checks

A machine check is caused by a machine malfunction and not by data or instructions. This is ensured during the power-on sequence by initializing the machine controls to a valid state and by placing valid CBC in the CPU registers, in the storage keys, and in main storage.

Designation of an unavailable component, such as a storage location, subchannel, or I/O device, does not cause a machine-check indication. Instead, such a condition is indicated by the appropriate program or I/O interruption or condition-code setting. In particular, an attempt to access a storage location which is not in the configuration, or which has power off at the storage unit, results in an addressing exception when detected by the CPU and does not generate a machine-check condition, even though the storage location or its associated storage key has invalid CBC. Similarly, if the channel subsystem attempts to access such a location, an I/O-interruption condition indicating program check is generated rather than a machine-check condition.

A machine check is indicated whenever the result of an operation could be affected by information with invalid CBC or when any other malfunction makes it impossible to establish reliably that an operation can be, or has been, performed correctly. When information with invalid CBC is fetched but not used, the condition may or may not be indicated, and the invalid CBC is preserved.

When a machine malfunction is detected, the action taken depends on the model, the nature of the malfunction, and the situation in which the malfunction occurs. Malfunctions affecting operator-facility actions may result in machine checks or may be indicated to the operator. Malfunctions affecting certain other operations such as SIGNAL PROCESSOR may be indicated by means of a condition code or may result in a machine-check-interruption condition.

A malfunction detected as part of an I/O operation may cause a machine-check-interruption condition, an I/O-error condition, or both. I/O-error conditions

are indicated by an I/O interruption or by the appropriate condition-code setting during the execution of an I/O instruction. When the machine reports a failing-storage location detected during an I/O operation, both I/O-error and machine-check conditions may be indicated. The I/O-error condition is the primary indication to the program. The machine-check condition is a secondary indication, which is presented as system recovery together with a failing-storage address.

Certain malfunctions detected as part of I/O instructions and I/O operations are reported by means of special machine-check conditions called I/O machine-check conditions. Thus, malfunctions detected as part of an operation which is I/O related may be reported, depending on the error, in any of three ways: I/O-error condition, I/O machine-check condition, or non-I/O machine-check condition. In some cases, the definition requires the error to be reported by only one of these mechanisms; in other cases, any one, or in some cases, more than one, may be indicated.

Programming Note: Although the definition for machine-check conditions is that they are caused by machine malfunctions and not by data and instructions, there are certain unusual situations in which machine-check conditions are caused by events which are not machine malfunctions. Two examples follow:

1. In some cases, the channel-report-pending machine-check-interruption condition indicates a non-error situation. For example, this condition is generated at the completion of the function specified by RESET CHANNEL PATH.
2. Improper use of DIAGNOSE may result in machine-check conditions.

Validation

Machine errors can be generally classified as solid or intermittent, according to the persistence of the malfunction. A persistent machine error is said to be solid, and one that is not persistent is said to be intermittent. In the case of a register or storage location, a third type of error must be considered, called externally generated. An externally generated error is one where no failure exists in the register or storage location but invalid CBC has been introduced into the location by actions external to the location. For example, the value could be affected by a power transient, or an incorrect value may have been introduced when the information was placed at the location.

Invalid CBC is preserved as invalid when information with invalid CBC is fetched or when an attempt is made to update only a portion of the checking block. When an attempt is made to replace the contents of the entire checking block and the block contains invalid CBC, it depends on the operation and the model whether the block remains with invalid CBC or is replaced. An operation which replaces the contents of a checking block with valid CBC, while ignoring the current contents, is called a validation operation. Validation is used to place a valid CBC in a register or at a location which has an intermittent or externally generated error.

Validating a checking block does not ensure that a valid CBC will be observed the next time the checking block is accessed. If the failure is solid, validation is effective only if the information placed in the checking block is such that the failing bits are set to the value to which they fail. If an attempt is made to set the bits to the state opposite to that in which they fail, then the validation will not be effective. Thus, for a solid failure, validation is only useful to eliminate the error condition, even though the underlying failure remains, thereby reducing the exposure to additional reports. The locations, however, cannot be used, since invalid CBC will result from attempts to store other values at the location. For an intermittent failure, however, validation is useful to restore a valid CBC such that a subsequent partial store into the checking block will be permitted. (A partial store is a store into a checking block without replacing the entire checking block.)

When a checking block consists of multiple bytes in storage, or multiple bits in CPU registers, the invalid CBC can be made valid only when all of the bytes or bits are replaced simultaneously.

A register is automatically validated as part of the machine-check-interruption sequence after the original contents of the register are placed in the appropriate save area.

When an error occurs in a checking block, the original information contained in the checking block should be considered lost even after validation. Automatic register validation leaves the contents unpredictable.

Invalid CBC in Storage

The size of the checking block in storage depends on the model but is never more than 4K bytes.

When invalid CBC is detected in storage, a machine-check condition may occur; depending on the circumstances, the machine-check condition may be system damage, instruction-processing damage, or system recovery. If the invalid CBC is detected as part of the execution of a channel program, the error is reported as an I/O-error condition. When a CCW, indirect-data-address word, modified-indirect-data-address word, or data is prefetched from storage, is found to have invalid CBC, but is not used in the channel program, the condition is normally not reported as an I/O-error condition. The condition may or may not be reported as a machine-check-interruption condition. Invalid CBC detected during accesses to storage for other than CPU-related accesses may be reported as system recovery with storage error uncorrected indicated, since the primary error indication is reported by some other means.

When the storage checking block consists of multiple bytes and contains invalid CBC, special storage-validation procedures are generally necessary to restore or place new information in the checking block. Validation of storage is provided with the manual load-clear and system-reset-clear operations and is also provided as a program function. Programmed storage validation is done a block at a time, by executing the privileged instruction TEST BLOCK. Manual storage validation by clear reset validates all blocks which are available in the configuration.

A checking block with invalid CBC is never validated unless the entire contents of the checking block are replaced. An attempt to store into a checking block having invalid CBC, without replacing the entire checking block, leaves the data in the checking block (including the check bits) unchanged. Even when an instruction or a channel-program-input operation specifies that the entire contents of a checking block are to be replaced, validation may or may not occur, depending on the operation and the model.

Programming Note: Machine-check conditions may be reported for prefetched and unused data. Depending on the model, such situations may or may not be successfully retried. For example, a BRANCH AND LINK (BALR) instruction which specifies an R_2 field of zero will never branch, but on some models a prefetch of the location designated by register 0 may occur. Access exceptions associated with this prefetch will not be reported. However, if an invalid checking-block code is detected, CPU retry may be attempted. Depending on the model, the prefetch may recur as part of the retry, and thus the retry will not be successful. Even when the CPU retry is successful, the performance degradation of such a retry is significant, and system recovery may be presented, normally with a failing-storage address. To avoid continued degradation, the program should initiate proceedings to eliminate use of the location and to validate the location.

Programmed Validation of Storage

Provided that an invalid CBC does not exist in the storage key associated with a 4 K-byte block, the instruction TEST BLOCK causes the entire 4 K-byte block to be set to zeros with a valid CBC, regardless of the current contents of the storage. TEST BLOCK thus removes an invalid CBC from a location in storage which has an intermittent, or one-time, failure. However, if a permanent failure exists in a portion of the storage, a subsequent fetch may find an invalid CBC.

Invalid CBC in Storage Keys

Depending on the model, each storage key may be contained in a single checking block, or the access-control and fetch-protection bits and the reference and change bits may be in separate checking blocks.

Figure 11-1 on page 11-8 describes the action taken when the storage key has invalid CBC. The figure indicates the action taken for the case when the access-control and fetch-protection bits are in one checking block and the reference and change bits are in a separate checking block. In machines where both fields are included in a single checking block, the action taken is the combination of the actions for each field in error, except that completion is permitted only if an error in all affected fields permits completion. References to main storage to which key-controlled protection does not apply are treated as if an access key of zero is used for the reference. This includes such references as channel-program references during initial program loading and implicit references, such as interruption action and DAT-table accesses.

Type of Reference	Action Taken on Invalid CBC	
	For Access-Control and Fetch-Protection Bits	**For Reference and Change Bits**
SET STORAGE KEY EXTENDED	Complete; validate.	Complete; validate.
INSERT STORAGE KEY EXTENDED	PD; preserve.	PD; preserve.
RESET REFERENCE BIT EXTENDED	PD or complete; preserve.	PD; preserve.
INSERT VIRTUAL STORAGE KEY or TEST PROTECTION	PD; preserve.	CPF; preserve.
CPU prefetch (information not used)	CPF; preserve.	CPF; preserve.
Channel-program prefetch (information not used)	IPF; preserve.	IPF; preserve.
Fetch, nonzero access key	MC; preserve.	MC or complete; preserve.
Store[1], nonzero access key	MC[2]; preserve.	MC and preserve; or complete[3] and correct.
Fetch, zero access key[4]	MC or complete; preserve.	MC or complete; preserve.
Store[1], zero access key[2]	MC or complete; preserve.	MC and preserve; or complete[3] and correct.

Explanation:

1 CPU virtual- and logical-address store accesses are subject to DAT protection. When the DAT-protection bit is one, the location will not be changed; however, the machine may indicate a machine-check condition if the storage key or the data itself has invalid CBC.

2 The contents of the main-storage location are not changed.

3 The contents of the reference and change bits are set to ones if the “complete” action is taken.

4 The action shown for an access key of zero is also applicable to references to which key-controlled protection does not apply.

Complete The condition does not cause termination of the execution of the instruction, and, unless an unrelated condition prohibits it, the execution of the instruction is completed, ignoring the error condition. No machine- check-damage conditions are reported, but system recovery may be reported.

Correct The reference and change bits are set to ones with valid CBC.

Preserve The contents of the entire checking block having invalid CBC are left unchanged.

Validate The entire key is set to the new value with valid CBC. When the conditional-SSKE facility is installed and either or both the MR and MC bits of the M_3 field are one, condition code 3 is set when the instruction completes.

CPF Invalid CBC in the storage key for a CPU prefetch which is unused, or for instructions which do not examine the reference and change bits, may result in any of the following situations:
- The operation is completed; no machine-check condition is reported.
- The operation is completed; system recovery, with storage-key error uncorrected, is reported.
- Instruction-processing damage, with or without backup and with storage-key error uncorrected, is reported.

IPF Invalid CBC in the storage key for a channel-program prefetch which is unused may result in any of the following:
- The I/O operation is completed; no machine-check condition is reported.
- The I/O operation is completed; system recovery, with storage-key error uncorrected, is reported.

MC Same as PD for CPU references, but a channel-subsystem reference may result in the following combinations of I/O-error conditions and machine-check conditions:
- An I/O-error condition is reported; no machine-check condition is reported.
- An I/O-error condition is reported; system recovery, with or without storage-key error uncorrected, is reported.

PD Instruction-processing damage, with or without backup and with or without storage-key error uncorrected, is reported.

Note: When storage-key error uncorrected is reported, a failing storage address may or may not also be reported.

Figure 11-1. Invalid CBC in Storage Keys

Invalid CBC in Registers

When invalid CBC is detected in a CPU register, a machine-check condition may be recognized. CPU registers include the general, floating-point, floating-point-control, access, control, vector, and TOD programmable registers, the current PSW, the prefix register, the TOD clock, the CPU timer, the clock comparator, guarded-storage-control registers, and the breaking-event-address register.

When a machine-check interruption occurs, whether or not it is due to invalid CBC in a CPU register, the following actions affecting the CPU registers, other than the prefix register, the TOD clock, and the breaking-event-address register when the BEAR-enhancement facility is not installed, are taken as part of the interruption.

1. The contents of the registers are saved in assigned storage locations. Any register which is in error is identified by a corresponding validity bit of zero in the machine-check-interruption code. Malfunctions detected during register saving do not result in additional machine-check-interruption conditions; instead, the correctness of all the information stored is indicated by the appropriate setting of the validity bits.

2. Registers with invalid CBC are then changed to have valid CBC, their actual contents being unpredictable, except that in the ESA/390-compatibility mode, bits 0-31 of all control registers are predictably set to zeros.

The prefix register and the TOD clock are not stored during a machine-check interruption, have no corresponding validity bit, and are not validated. Invalid CBC associated with the prefix register cannot safely be reported by the machine-check interruption, since the interruption itself requires that the prefix value be applied to convert real addresses to the corresponding absolute addresses. Invalid CBC in the prefix register causes the CPU to enter the check-stop state immediately.

Programming Note: Prior to the advent of z/Architecture, certain older models did not perform validation of registers during a machine-check interruption. On such models, programmed validation of the registers during machine-check interruption handling was necessary.

All z/Architecture-capable processors automatically validate registers prior to presenting a machine-check interruption to the program. Therefore, any programmed validation of registers during machine-check interruption handling is superfluous.

However, regardless of the automatic register validation that occurs as a result of a machine-check interruption, the contents of the access registers, clock-comparator register, control registers, CPU-timer register, floating-point registers, floating-point-control register, general registers, guarded-storage-control registers, TOD-programmable register, breaking-event-address register, and vector registers are unpredictable following a machine-check interruption. Prior to using any of these registers or features that they control following a machine-check interruption, the program should load the register with predictable contents.

Check-Stop State

In certain situations, it is impossible or undesirable to continue operation when a machine error occurs. In these cases, the CPU may enter the check-stop state, which is indicated by the check-stop indicator.

In general, the CPU may enter the check-stop state whenever an uncorrectable error or other malfunction occurs and the machine is unable to recognize a specific machine-check-interruption condition.

The CPU always enters the check-stop state if any of the following conditions exists:

- PSW bit 13 is zero, and an exigent machine-check condition is generated.
- During the execution of an interruption due to one exigent machine-check condition, another exigent machine-check condition is detected.
- During a machine-check interruption, the machine-check-interruption code cannot be stored successfully, or the new PSW cannot be fetched successfully.
- Invalid CBC is detected in the prefix register.
- A malfunction in the receiving CPU, which is detected after accepting the order, prevents the successful completion of a SIGNAL PROCESSOR order and the order was a reset, or the

receiving CPU cannot determine what the order was. The receiving CPU enters the check-stop state.

There may be many other conditions for particular models when an error may cause check stop.

When the CPU is in the check-stop state, instructions and interruptions are not executed. The TOD clock is normally not affected by the check-stop state. The CPU timer may or may not run in the check-stop state, depending on the error and the model. The start key and stop key are not effective in this state.

The CPU may be removed from the check-stop state by CPU reset.

In a multiprocessing configuration, a CPU entering the check-stop state generates a request for a malfunction-alert external interruption to all CPUs in the configuration. Except for the reception of a malfunction alert, other CPUs and the I/O system are normally unaffected by the check-stop state in a CPU. However, depending on the nature of the condition causing the check stop, other CPUs may also be delayed or stopped, and channel subsystem and I/O activity may be affected.

System Check Stop

In a multiprocessing configuration, some errors, malfunctions, and damage conditions are of such severity that the condition causes all CPUs in the configuration to enter the check-stop state. This condition is called a system check stop. The state of the channel subsystem and I/O activity is unpredictable.

Machine-Check Interruption

A request for a machine-check interruption, which is made pending as the result of a machine check, is called a machine-check-interruption condition. There are two types of machine-check-interruption conditions: exigent conditions and repressible conditions.

Exigent Conditions

Exigent machine-check-interruption conditions are those in which damage has or would have occurred such that execution of the current instruction or interruption sequence cannot safely continue. Exigent conditions include two subclasses: instruction-processing damage and system damage. In addition to indicating specific exigent conditions, system damage is used to report any malfunction or error which cannot be isolated to a less severe report.

Exigent conditions for instruction sequences can be either nullifying exigent conditions or terminating exigent conditions, according to whether the instructions affected are nullified or terminated. Exigent conditions for interruption sequences are terminating exigent conditions. The terms “nullification” and “termination” have the same meanings as those used in Chapter 5, “Program Execution”, except that more than one instruction may be involved. Thus, a nullifying exigent condition indicates that the CPU has returned to the beginning of a unit of operation prior to the error. A terminating exigent condition means that the results of one or more instructions may have unpredictable values.

Repressible Conditions

Repressible machine-check-interruption conditions are those in which the results of the instruction-processing sequence have not been affected. Repressible conditions can be delayed, until the completion of the current instruction or even longer, without affecting the integrity of CPU operation. Repressible conditions are of three groups: recovery, alert, and repressible damage. Each group includes one or more subclasses.

A malfunction in the CPU, storage, or operator facilities which has been successfully corrected or circumvented internally without logical damage is called a recovery condition. Depending on the model and the type of malfunction, some or all recovery conditions may be discarded and not reported. Recovery conditions that are reported are grouped in one subclass, system recovery.

A machine-check-interruption condition not directly related to a machine malfunction is called an alert condition. The alert conditions are grouped in two subclasses: degradation and warning.

A malfunction resulting in an incorrect state of a portion of the system not directly affecting sequential CPU operation is called a repressible-damage condition. Repressible-damage conditions are grouped in five subclasses, according to the function affected: timing-facility damage, external damage, channel

report pending, channel-subsystem damage, and service-processor damage.

Programming Notes:

1. Even though repressible conditions are usually reported only at normal points of interruption, they may also be reported with exigent machine-check conditions. Thus, if an exigent machine-check condition causes an instruction to be abnormally terminated and a machine-check interruption occurs to report the exigent condition, any pending repressible conditions may also be reported. The meaningfulness of the validity bits depends on what exigent condition is reported.

2. Classification of damage as either exigent or repressible does not imply the severity of the damage. The distinction is whether action must be taken as soon as the damage is detected (exigent) or whether the CPU can continue processing (repressible). For a repressible condition, the current instruction can be completed before taking the machine-check interruption if the CPU is enabled for machine checks; if the CPU is disabled for machine checks, the condition can safely be kept pending until the CPU is again enabled for machine checks.

   For example, the CPU may be disabled for machine-check interruptions because it is handling an earlier instruction-processing-damage interruption. If, during that time, an I/O operation encounters a storage error, that condition can be kept pending because it is not expected to interfere with the current machine-check processing. If, however, the CPU also makes a reference to the area of storage containing the error before re-enabling machine-check interruptions, another instruction-processing-damage condition is created, which is treated as an exigent condition and causes the CPU to enter the check-stop state.

3. A repressible condition may be a floating condition. A floating repressible condition is eligible to cause an interruption on any CPU in the configuration. At the point when a CPU performs an interruption for a floating repressible condition, the condition is no longer eligible to cause an interruption on the remaining CPUs in the configuration.

Interruption Action

A machine-check interruption causes the following actions to be taken, depending on the architectural mode of the configuration.

Interruption Action in the z/Architecture Architectural Mode

An architectural-mode identification with the value 01 hex is stored at real location 163. The PSW reflecting the point of interruption is stored as the machine-check old PSW in the quadword at real location 352. The contents of other registers are stored in register-save areas at real locations 4608-4863, 4892-4895, 4900-4911, 4913-4919, 4928-5119, and in a machine-check extended save area designated by the contents of real locations 4528-4535. Additionally, the contents of the breaking-event-address register are stored in register-save area at real locations 4920-4927 when the BEAR-enhancement facility is installed. After the contents of the registers are stored in register-save areas and extended save area, depending on the model, the registers may be validated with the contents being unpredictable. A machine-check-interruption code (MCIC) of eight bytes is stored at real locations 232-239. An external-damage code may be stored at real locations 244-247, and a failing-storage address may be stored at real locations 248-255. The new PSW is fetched from real locations 480-495. In addition, a machine-check logout may have occurred.

The machine-generated addresses used to access the old and new PSW, the MCIC, extended interruption information, and the fixed-logout area are all real addresses.

The fields in assigned storage locations that are accessed during the machine-check interruption are summarized in Figure 11-2.

Information Stored (Fetched)	Starting Location*	Length in Bytes
Architectural-mode identification	163	1
Old PSW	352	16
New PSW (fetched)	480	16
Machine-check-interruption code	232	8
Register-save areas		
Floating-point registers 0-15	4608	128
General registers 0-15	4736	128

Figure 11-2. Machine-Check-Interruption Locations in the z/Architecture Architectural Mode

Information Stored (Fetched)	Starting Location*	Length in Bytes
Floating-point control register	4892	4
TOD programmable register	4900	4
CPU timer	4904	8
Clock comparator	4913	7
Breaking-event-address register	4920[1]	8
Access registers 0-15	4928	64
Control registers 0-15	4992	128
Extended interruption information		
External-damage code	244	4
Failing-storage address	248	8
Fixed-logout area	4864	16

Explanation:

* All locations are in real storage.

1 BEAR stored to locations 4920-4927 when BEAR-enhancement facility is installed.

Figure 11-2. Machine-Check-Interruption Locations in the z/Architecture Architectural Mode

When certain facilities are installed, and the machine-check-extended-save-area origin (beginning at real location 4528) is nonzero, the contents of the respective facilities' registers may be stored in the machine-check extended save area. See "Machine-Check-Extended-Save-Area Designation (MCESAD)" on page 3-83 for a description of the contents of real locations 4528-4535.

The section "Machine-Check Extended Save Area (MCESA)" on page 11-25 provides a description of the contents of the area. Depending on the facilities installed and the length of the extended save area, the following additional registers may be stored:

- Vector registers
- Guarded-storage registers

Interruption Action in the ESA/390-Compatibility Mode

An architectural-mode identification with an all zeros value is stored at real location 163. The PSW reflecting the point of interruption is stored as the short-format machine-check old PSW at real locations 48-55. The contents of other registers are stored in register save areas at real locations 216-231 and 288-511, and in a machine-check extended save area designated by the contents of real locations 212-215. After the contents of the registers are stored in register save areas and the extended save area, depending on the model, the registers may be validated with the contents being unpredictable. A failing-storage address may be stored at real locations 248-251, and an external-damage code may be stored at real locations 244-247. A machine-check-interruption code (MCIC) of eight bytes is stored at real locations 232-239. The new short-format PSW is fetched from real locations 112-119. In addition, a machine-check logout may have occurred.

The machine-generated addresses used to access the old and new PSW, the MCIC, extended interruption information, the locations containing the extended-save-area address, and the fixed-logout area are all real addresses. The extended-save-area address is an absolute address.

The fields in assigned storage locations that are accessed during the machine-check interruption are summarized in Figure 11-3.

Information Stored (Fetched)	Starting Location*	Length in Bytes
Old PSW	48	8
Architectural-mode identification	163	1
New PSW (fetched)	112	8
Extended-save-area address (fetched)	212	4
Machine-check-interruption code	232	8
Register-save areas		
CPU timer	216	8
Clock comparator	224	8
Access registers 0-15	288	64
Floating-point registers 0, 2, 4, and 6	352	32
General registers 0-15 (bits 32-63)	384	64
Control registers 0-15 (bits 32-63)	448	64
Extended interruption information		
External-damage code	244	4
Failing-storage address	248	8
Fixed-logout area	256	16

Explanation:

* All locations are in real storage.

Figure 11-3. Machine-Check-Interruption Locations in the ESA/390-compatibility Mode

When the extended-save-area control, bit 34 of control register 14, is one, and bits 1-19 of the word at real locations 212-215 are not all zeros, then other fields are stored in the machine-check extended save area. Figure 11-4 lists the fields that are stored, their

offsets within the area, and their lengths. Bytes 144-4095 of the extended save area remain unchanged.

Field	Byte Offset	Length in Bytes
Floating-point registers 0-15	0	128
Floating-point control register	128	4
Reserved (zeros stored)	132	12

Figure 11-4. Machine-Check Extended-Save-Area Locations in the ESA/390-compatibility Mode

The address of the machine-check extended save area is formed by appending 33 zeros to the left and 12 zeros to the right of bits 1-19 of the word at real locations 212-215. This address is treated as a 64-bit absolute address. If the 4096-byte block of storage at the address is not available in the configuration, storing into the extended save area is not performed.

Interruption Action: Common Actions

If the machine-check-interruption code cannot be stored successfully or the new PSW cannot be fetched successfully, the CPU enters the check-stop state.

A repressible machine-check condition can initiate a machine-check interruption only if both PSW bit 13 is one and the associated subclass mask bit, if any, in control register 14 is also one. When it occurs, the interruption does not terminate the execution of the current instruction; the interruption is taken at a normal point of interruption, and no program or supervisor-call interruptions are eliminated. If the machine check occurs during the execution of a machine function, such as a CPU-timer update, the machine-check interruption takes place after the machine function has been completed.

When the CPU is disabled for a particular repressible machine-check condition, the condition remains pending. Depending on the model and the condition, multiple repressible conditions may be held pending for a particular subclass, or only one condition may be held pending for a particular subclass, regardless of the number of conditions that may have been detected for that subclass.

When a repressible machine-check interruption occurs because the interruption condition is in a subclass for which the CPU is enabled, pending conditions in other subclasses may also be indicated by the same interruption code, even though the CPU is disabled for those subclasses. All indicated conditions are then cleared.

If a machine check which is to be reported as a system-recovery condition is detected during the execution of the interruption procedure due to a previous machine-check condition, the system-recovery condition may be combined with the other conditions, discarded, or held pending.

An exigent machine-check condition can cause a machine-check interruption only when PSW bit 13 is one. When a nullifying exigent condition causes a machine-check interruption, the interruption is taken at a normal point of interruption. When a terminating exigent condition causes a machine-check interruption, the interruption terminates the execution of the current instruction and may eliminate the program and supervisor-call interruptions, if any, that would have occurred if execution had continued. Proper execution of the interruption sequence, including the storing of the old PSW and other information, depends on the nature of the malfunction. When an exigent machine-check condition occurs during the execution of a machine function, such as a CPU-timer update, the sequence is not necessarily completed.

If, during the execution of an interruption due to one exigent machine-check condition, another exigent machine check is detected, the CPU enters the check-stop state. If an exigent machine check is detected during an interruption due to a repressible machine-check condition, system damage is reported.

When PSW bit 13 is zero, an exigent machine-check condition causes the CPU to enter the check-stop state.

Machine-check-interruption conditions are handled in the same manner regardless of whether the wait-state bit in the PSW is one or zero: a machine-check condition causes an interruption if the CPU is enabled for that condition.

Machine checks which occur while the rate control is set to the instruction-step position are handled in the same manner as when the control is set to the process position; that is, recovery mechanisms are active, and machine-check interruptions occur when allowed. Machine checks occurring during a manual operation may be indicated to the operator, may generate a system-recovery condition, may result in sys-

tem damage, or may cause a check stop, depending on the model.

Every reasonable attempt is made to limit the side effects of any machine check and the associated interruption. Normally, interruptions, as well as the progress of I/O operations, remain unaffected. The malfunction, however, may affect these activities, and, if the currently active PSW has bit 13 set to one, the machine-check interruption will indicate the total extent of the damage caused, and not just the damage which originated the condition.

Point of Interruption

The point in the processing which is indicated by the interruption and used as a reference point by the machine to determine and indicate the validity of the status stored is referred to as the point of interruption.

Because of the checkpoint capability in models with CPU retry, the interruption resulting from an exigent machine-check-interruption condition may indicate a point in the CPU processing sequence which is logically prior to the error. Additionally, the model may have some choice as to which point in the CPU processing sequence the interruption is indicated, and, in some cases, the status which can be indicated as valid depends on the point chosen.

Only certain points in the processing may be used as a point of interruption. For repressible machine-check interruptions, the point of interruption must be after one unit of operation is completed and any associated program or supervisor-call interruption is taken, and before the next unit of operation is begun.

Exigent machine-check conditions for instruction sequences are those in which damage has or would have occurred to the instruction stream. Thus, the damage can normally be associated with a point part way through an instruction, and this point is called the point of damage. In some cases, there may be one or more instructions separating the point of damage and the point of interruption, and the processing associated with one or more instructions may be damaged. When the point of interruption is a point prior to the point of damage due to a nullifiable exigent machine-check condition, the point of interruption can be only at the same points as for repressible machine-check conditions.

In addition to the point of interruption permitted for repressible machine-check conditions, the point of interruption for a terminating exigent machine-check condition may also be after the unit of operation is completed but before any associated program or supervisor-call interruption occurs. In this case, a valid PSW instruction address is defined as that which would have been stored in the old PSW for the program or supervisor-call interruption. Since the operation has been terminated, the values in the result fields, other than the instruction address, are unpredictable. Thus, the validity bits associated with fields which are due to be changed by the instruction stream are meaningless when a terminating exigent machine-check condition is reported.

When the point of interruption and the point of damage due to an exigent machine-check condition are separated by a checkpoint-synchronization function, the damage has not been isolated to a particular program, and system damage is indicated.

When an exigent machine-check-interruption condition occurs, the point of interruption which is chosen affects the amount of damage which must be indicated. An attempt is made, when possible, to choose a point of interruption which permits the minimum indication of damage. In general, the preference is the interruption point immediately preceding the error.

When all the status information stored as a result of an exigent machine-check-interruption condition does not reflect the same point, an attempt is made, when possible, to choose the point of interruption so that the instruction address which is stored in the machine-check old PSW is valid.

Machine-Check-Interruption Code

On all machine-check interruptions, a machine-check-interruption code (MCIC) is stored in the doubleword starting at real location 232. The code has the format shown in Figure 11-5.

Bits in the MCIC which are not assigned or not implemented by a particular model are stored as zeros.

Bit	Name
0	System damage (SD)
1	Instruction-processing damage (PD)
2	System recovery (SR)
4	Timing-facility damage (CD)
5	External damage (ED)
7	Degradation (DG)
8	Warning (W)
9	Channel report pending (CP)
10	Service-processor damage (SP)
11	Channel-subsystem damage (CK)
14	Backed up (B)
16	Storage error uncorrected (SE)
17	Storage error corrected (SC)
18	Storage-key error uncorrected (KE)
19	Storage degradation (DS)
20	PSW-MWP validity (WP)
21	PSW mask and key validity (MS)
22	PSW program-mask and condition-code validity (PM)
23	PSW-instruction-address validity (IA)
24	Failing-storage-address validity (FA)
25	Vector-register validity (VR)
26	External-damage-code validity (EC)
27	Floating-point-register validity (FP)
28	General-register validity (GR)
29	Control-register validity (CR)
30	Reserved for IBM use
31	Storage logical validity (ST)
32	Indirect storage error (IE)
33	Access-register validity (AR)
34	Delayed-access exception (DA)
36	Guarded-storage-registers validity (GS)
37	Breaking-event-address-register validity (BR)
42	TOD-programmable-register validity (PR)
43	Floating-point-control-register validity (FC)
44	Ancillary report (AP)
46	CPU-timer validity (CT)
47	Clock-comparator validity (CC)

Note: All other bits of the MCIC are unassigned and stored as zeros.

Figure 11-5. Machine-Check Interruption-Code Format

Subclass

Bits 0-2 and 4-11 are the subclass bits which identify the type of machine-check condition causing the interruption. At least one of the subclass bits is stored as a one. When multiple errors have occurred, several subclass bits may be set to ones.

System Damage

Bit 0 (SD), when one, indicates that damage has occurred which cannot be isolated to one or more of the less severe machine-check subclasses. When system damage is indicated, the ancillary-report bit, bit 44, is meaningful, the remaining bits in the machine-check-interruption code are not meaningful, and information stored in the register-save areas and machine-check extended-interruption fields is not meaningful.

System damage is a terminating exigent condition and has no subclass-mask bit.

Instruction-Processing Damage

Bit 1 (PD), when one, indicates that damage has occurred to the instruction processing of the CPU.

The exact meaning of bit 1 depends on the setting of the backed-up bit, bit 14. When the backed-up bit is one, the condition is called processing backup. When the backed-up bit is zero, the condition is called processing damage. These two conditions are described in “Synchronous Machine-Check-Interruption Conditions” on page 11-18.

Instruction-processing damage can be a nullifying or a terminating exigent condition and has no subclass-mask bit.

System Recovery

Bit 2 (SR), when one, indicates that malfunctions were detected but did not result in damage or have been successfully corrected. Some malfunctions detected as part of an I/O operation may result in a system-recovery condition in addition to an I/O-error condition. The presence and extent of the system-recovery capability depend on the model.

System recovery is a repressible condition. It is masked by the recovery subclass-mask bit, which is in bit position 36 of control register 14.

Programming Notes:

1. System recovery may be used to report a failing-storage address detected by a CPU prefetch or by an I/O operation.

2. Unless the corresponding validity bits are ones, the indication of system recovery does not imply storage logical validity or that the fields stored as a result of the machine-check interruption are valid.

Timing-Facility Damage

Bit 4 (CD), when one, indicates that damage has occurred to the TOD clock, CPU timer, clock comparator, or TOD programmable register, or to the CPU-timer or clock-comparator external-interruption conditions. The timing-facility-damage machine-check condition is set whenever any of the following occurs:

1. The TOD clock enters the error or not-operational state.

2. The CPU timer is damaged, and the CPU is enabled for CPU-timer external interruptions. On some models, this condition may be recognized even when the CPU is not enabled for CPU-timer interruptions. Depending on the model, the machine-check condition may be generated only as the CPU timer enters an error state. Or, the machine-check condition may be continuously generated whenever the CPU is enabled for CPU-timer interruptions, until the CPU timer is validated.

3. The clock comparator is damaged, and the CPU is enabled for clock-comparator external interruptions. On some models, this condition may be recognized even when the CPU is not enabled for clock-comparator interruptions.

Timing-facility damage may also be set along with instruction-processing damage when an instruction which accesses the TOD clock, CPU timer, or clock comparator produces incorrect results. Depending on the model, the TOD programmable register, CPU timer, or clock comparator may be validated by the interruption which reports the TOD programmable register, CPU timer, or clock comparator as invalid.

Timing-facility damage is a repressible condition. It is masked by the external-damage subclass-mask bit, which is in bit position 38 of control register 14.

Timing-facility-damage conditions for the CPU timer and the clock comparator are not recognized on most models when these facilities are not in use. The facilities are considered not in use when the CPU is disabled for the corresponding external interruptions (PSW bit 7, or the subclass-mask bits, bits 52 and 53 of control register 0, are zeros), and when the corresponding set and store instructions are not executed. Timing-facility-damage conditions that are already pending remain pending, however, when the CPU is disabled for the corresponding external interruption.

Timing-facility-damage conditions due to damage to the TOD clock are always recognized.

With TOD-clock steering, damage to the TOD clock is considered to be of such severity that it is undesirable to continue operation. When the TOD-clock-steering facility is installed, and damage has occurred to the TOD-clock-steering registers or the TOD clock and the damage is limited to a single CPU, then that CPU enters the check-stop state. If the TOD clock is in the not-operational state or error state, or when damage has occurred to the TOD-clock-steering registers or the TOD clock, and the damage affects all CPUs, then a system check stop occurs.

External Damage

Bit 5 (ED), when one, indicates that damage has occurred during operations not directly associated with processing the current instruction.

When bit 5, external damage, is one and bit 26, external-damage-code validity, is also one, the external-damage code has been stored to indicate, in more detail, the cause of the external-damage machine-check interruption. When the external damage cannot be isolated to one or more of the conditions as defined in the external-damage code, or when the detailed indication for the condition is not implemented by the model, external damage is indicated with bit 26 set to zero. The presence and extent of reporting external damage depend on the model.

External damage is a repressible condition. It is masked by the external-damage subclass-mask bit, which is in bit position 38 of control register 14.

Degradation

Bit 7 (DG), when one, indicates that continuous degradation of system performance, more serious than

that indicated by system recovery, has occurred. Degradation may be reported when system-recovery conditions exceed a machine-preestablished threshold or when unit deletion has occurred. The presence and extent of the degradation-report capability depend on the model.

Degradation is a repressible condition. It is masked by the degradation subclass-mask bit, which is in bit position 37 of control register 14.

Warning

Bit 8 (W), when one, indicates that damage is imminent in some part of the system (for example, that power is about to fail, or that a loss of cooling is occurring). Whether warning conditions are recognized depends on the model.

If the condition responsible for the imminent damage is removed before the interruption request is honored (for example, if power is restored), the request does not remain pending, and no interruption occurs. Conversely, the request is not cleared by the interruption, and, if the condition persists, more than one interruption may result from the same condition.

Warning is a repressible condition. It is masked by the warning subclass-mask bit, which is in bit position 39 of control register 14.

Channel Report Pending

Bit 9 (CP), when one, indicates that a channel report, consisting of one or more channel-report words, has been made pending, and the contents of the channel-report words describe, in further detail, the effect of the malfunction and the results of analysis or the action performed. A channel report becomes pending when one of the following conditions has occurred:

1. Channel-subsystem recovery has been completed. The channel-subsystem recovery may have been initiated with no prior notice to the program or may have been a result of a condition previously reported to the program.
2. The function specified by RESET CHANNEL PATH has been completed.

A channel report may also become pending under other conditions.

The channel-report words which make up the channel report may be cleared, one at a time, by execution of the instruction STORE CHANNEL REPORT WORD, which is described in “I/O Instructions” on page 14-1.

Bit 9 is meaningless when channel-subsystem damage is reported.

Channel report pending is a floating repressible condition. It is masked by the channel-report-pending subclass-mask bit, which is in bit position 35 of control register 14.

Service-Processor Damage

Bit 10 (SP), when one, indicates that damage has occurred to the service processor. Service-processor damage may be made pending at all CPUs in the configuration, or it may be detected independently by each CPU. The presence and extent of reporting service-processor damage depend on the model.

Service-processor damage is a repressible condition and has no subclass-mask bit.

Channel-Subsystem Damage

Bit 11 (CK), when one, indicates that an error or malfunction has occurred in the channel subsystem, or that the channel subsystem is in the check-stop state. The channel subsystem enters the check-stop state when a malfunction occurs which is so severe that the channel subsystem cannot continue, or if power is lost in the channel subsystem.

Channel-subsystem damage is a floating repressible condition and has no subclass-mask bit.

Subclass Modifiers

Bits 14 (B), 34 (DA), and 44 (AP) of the machine-check-interruption code act as modifiers to the subclass bits.

Backed Up

Bit 14 (B), when one, indicates that the point of interruption is at a checkpoint before the point of error. This bit is meaningful only when the instruction-processing-damage bit, bit 1, is also set to one. The presence and extent of the capability to indicate a backed-up condition depend on the model.

Delayed Access Exception

Bit 34 (DA), when one, indicates that an access exception was detected during a storage access

using DAT when no such exception was detected by an earlier test for access exceptions.

Bit 34 is a modifier to instruction-processing damage (bit 1) and is meaningful only when bit 1 of the machine-check-interruption code is one. When bit 1 is zero, bit 34 has no meaning. The presence and extent of reporting delayed access exception depend on the model.

Programming Note: The occurrence of a delayed access exception normally indicates that the program is using an improper procedure to update the DAT tables.

Ancillary Report

Bit 44 (AP), when one, indicates that a malfunction of a system component has occurred which has been recognized previously or which has affected the activities of multiple system elements such as CPUs and subchannels. When the malfunction affects the activities of multiple elements, an ancillary-report condition is recognized for all of the affected elements except one. This bit, when zero, indicates that this malfunction of a system component has not been recognized previously. This bit is meaningful for all conditions indicated by either the machine-check-interruption code or the external-damage code.

Depending on the model, recognition of an ancillary-report condition may not be provided, or it may not be provided for all system malfunctions. When ancillary-report recognition is not provided, bit 44 is set to zero.

Synchronous Machine-Check-Interruption Conditions

The instruction-processing damage and backed-up bits, bits 1 and 14 of the machine-check-interruption code, identify, in combination, two conditions.

Bit 1	Bit 14	Name of Condition
1	0	Processing damage
1	1	Processing backup

Processing Backup

The processing-backup condition indicates that the point of interruption is prior to the point, or points, of error. This is a nullifying exigent condition. When all of the other CPU-related-damage subclasses and modifiers of the machine-check-interruption code are zero, and certain validity bits associated with CPU status are indicated as valid, then the machine has successfully returned to a checkpoint prior to the malfunction, and no damage has yet occurred to the CPU.

The subclass bits which must be zero for no damage to have occurred are as follows:

MCIC Bit	Name
0	System damage
4	Timing-facility damage

The delayed-access-exception subclass-modifier bit, MCIC bit 34, must be zero for no damage to have occurred.

The validity bits in the machine-check-interruption code which must be one for no damage to have occurred are as follows:

MCIC Bit	Name
20	PSW MWP bits
21	PSW mask and key
22	PSW program mask and condition code
23	PSW instruction address
25	Vector registers
27	Floating-point registers
28	General registers
29	Control registers
31	Storage logical validity (result fields within current checkpoint interval)
33	Access registers
42	TOD programmable register
43	Floating-point-control register
46	CPU timer
47	Clock comparator

Programming Note: The processing-backup condition is reported rather than system recovery to indicate that a malfunction or failure stands in the way of continued operation of the CPU. The malfunction has not been circumvented, and damage would have occurred if instruction processing had continued.

Processing Damage

The processing-damage condition indicates that damage has occurred to the instruction processing of the CPU. The point of interruption is a point beyond some or all of the points of damage. Processing damage is a terminating exigent condition; therefore, the contents of result fields may be unpredictable and still indicated as valid.

Processing damage may include malfunctions in program-event recording, monitor call, tracing, access-register translation, and dynamic address translation. Processing damage causes any supervisor-call-interruption condition and program-interruption condition to be discarded. However, the contents of the old PSW and interruption-code locations for these interruptions may be set to unpredictable values.

Storage Errors

Bits 16-18 of the machine-check-interruption code are used to indicate an invalid CBC or a near-valid CBC detected in main storage or an invalid CBC in a storage key. Bit 19, storage degradation, may be indicated concurrently with bit 17. The failing-storage-address field, when indicated as valid, identifies a location within the storage checking block containing the error, or, for storage-key error uncorrected, within the block associated with the storage key. Bit 32, indirect storage error, may be set to one to indicate that the location designated by the failing-storage address is not the original source of the error.

The storage-error-uncorrected and storage-key-error-uncorrected bits do not in themselves indicate the occurrence of damage because the error detected may not have affected a result. The portion of the configuration affected by an invalid CBC is indicated in the subclass field of the machine-check-interruption code.

Storage errors detected for a channel program, when indicated as I/O-error conditions, may also be reported as system recovery. CBC errors that occur in storage or in the storage key and that are detected on prefetched or unused data for a CPU program may or may not be reported, depending on the model.

Storage Error Uncorrected

Bit 16 (SE), when one, indicates that a checking block in main storage contained invalid CBC and that the information could not be corrected. The contents of the checking block in main storage have not been changed. The location reported may have been accessed or prefetched for this CPU or another CPU or a channel program, or it may have been accessed as the result of a model-dependent storage access.

Storage Error Corrected

Bit 17 (SC), when one, indicates that a checking block in main storage contained near-valid CBC and that the information has been corrected before being used. Depending on the model, the contents of the checking block in main storage may or may not have been restored to valid CBC. The location reported may have been accessed or prefetched for this CPU or for another CPU or for a channel program, or it may have been accessed as the result of a model-dependent storage access. The presence and extent of the storage-error-correction capability depend on the model. This indication may or may not be accompanied by an indication of storage degradation, bit 19 (DS).

Storage-Key Error Uncorrected

Bit 18 (KE), when one, indicates that a storage key contained invalid CBC and that the information could not be corrected. The contents of the checking block in the storage key have not been changed. The storage key may have been accessed or prefetched for this CPU or for another CPU or for a channel program, or it may have been accessed as the result of a model-dependent storage access.

Storage Degradation

Bit 19 (DS), when one, indicates that degradation of the recovery characteristics has occurred for the 4 K-byte block reported by the failing-storage address.

Storage degradation indicates that although the associated storage error has been corrected, there are solid failures associated with the storage block (or with its associated key) that cause the correction process to take a substantial amount of time, and that if an additional error occurs in the block, the error may not be correctable or may go undetected. Thus, this bit indicates that use of the indicated block of storage should be avoided, if possible.

The indication of storage degradation has meaning only when failing-storage-address validity, MCIC bit 24, is also one. The presence and extent of reporting storage degradation depend on the model.

Because storage degradation is normally reported with system recovery, the recovery subclass mask, bit 36 of control register 14, should be set to one in order for storage degradation to be indicated.

Indirect Storage Error

Bit 32 (IE), when one, indicates that the physical main-storage location identified by the failing-storage address is not the original source of the error. Instead, the error originated in another level of the storage hierarchy and has been propagated to the current physical-storage portion of the storage hierarchy. Bit 32 is meaningful only when bit 16 or 18 (storage error uncorrected or storage-key error uncorrected) of the machine-check-interruption code is one. When bits 16 and 18 are both zeros, bit 32 has no meaning.

For errors originating outside the storage hierarchy, the attempt to store is rejected, and the appropriate error indication is presented. When an error is detected during implicit movement of information inside the storage hierarchy, the action is not rejected and reported in this manner because the movement may be asynchronous and may be initiated as the result of an attempt to access completely unrelated information. Instead, errors in the contents of the source during implicit moving of information from one portion of the storage hierarchy to another may be preserved in the target area by placing a special invalid CBC in the checking block associated with the target location. These propagated errors, when detected later, are reported as indirect storage errors. The original source of such an error may have been in a cache associated with an I/O processor or a CPU, or the error may have been the result of a data-path failure in transmitting data from one portion of the storage hierarchy to another. Additionally, a propagated error may be generated during the movement of data from one physical portion of storage to another as the result of a storage-reconfiguration action.

The presence and extent of reporting indirect storage error depend on the model.

Programming Note: See the programming notes under TEST BLOCK in Chapter 10, “Control Instructions” for the action which should be taken after storage errors are reported.

Machine-Check Interruption-Code Validity Bits

Bits 20-29, 31 33, 36, 37, 42, 43, 46, and 47 of the machine-check-interruption code are validity bits. Each bit indicates the validity of a particular field in storage. With the exception of the storage-logical-validity bit (bit 31), each bit is associated with a field stored during the machine-check interruption. When a validity bit is one, it indicates that the saved value placed in the corresponding storage field is valid with respect to the indicated point of interruption and that no error was detected when the data was stored.

When a validity bit is zero, one or more of the following conditions may have occurred: the original information was incorrect, the original information had invalid CBC, additional malfunctions were detected while storing the information, or none or only part of the information was stored. Even though the information is unpredictable, the machine attempts, when possible, to place valid CBC in the storage field and thus reduce the possibility of additional machine checks being caused.

The validity bits for the floating-point registers, general registers, control registers, access registers, vector registers, TOD programmable register, floating-point control register, CPU timer, and clock comparator indicate the validity of the saved value placed in the corresponding save area. The information in these registers after the machine-check interruption is not necessarily correct even when the correct value has been placed in the save area and the validity bit set to one. The use of the registers and the operation of the facility associated with the control registers, floating-point control register, TOD programmable register, CPU timer, and clock comparator are unpredictable until these registers are validated. (See “Invalid CBC in Registers” on page 9.)

PSW-MWP Validity

Bit 20 (WP), when one, indicates that bits 12-15 of the machine-check old PSW are correct.

PSW Mask and Key Validity

Bit 21 (MS), when one, indicates that the system mask, PSW key, and miscellaneous bits of the machine-check old PSW are correct. specifically, this bit covers bits 0-11, 16, 17, 24-30, and 33-63 of the PSW.

PSW Program-Mask and Condition-Code Validity

Bit 22 (PM), when one, indicates that the program mask and condition code of the machine-check old PSW are correct.

PSW-Instruction-Address Validity

Bit 23 (IA), when one, indicates that the addressing-mode and instruction-address bits, bits 31, 32, and 64-127, of the machine-check old PSW are correct.

Failing-Storage-Address Validity

Bit 24 (FA), when one, indicates that a correct failing-storage address has been stored at real location 248-255 (in the z/Architecture architectural mode) or real location 248-251 (in the ESA/390-compatibility mode) after a storage-error-uncorrected, storage-key-error-uncorrected, or storage-error-corrected condition has occurred. The presence and extent of the capability to identify the failing-storage location depend on the model. When no such errors are reported, that is, bits 16-18 of the machine-check-interruption code are zeros, the failing-storage address is meaningless, even though it may be indicated as valid.

Vector Register Validity

Bit 25 (VR), when one, indicates that the contents of locations 0-1023 of the machine-check extended save area reflect the correct state of the vector registers 0-31 at the point of the interruption.

Bit 25 is zero when the vector facility for z/Architecture is not installed or the machine-check extended save area address formed from the contents of real locations 4528-4535 is either invalid or all zeros.

External-Damage-Code Validity

Bit 26 (EC), when one, and provided that bit 5, external damage, is also one, indicates that a valid external-damage code has been stored in the word at real location 244. When bit 5 is zero, bit 26 has no meaning.

Floating-Point-Register Validity

In the z/Architecture architectural mode, bit 27 (FP), when one, indicates that the contents of the floating-point-register save area at real locations 4608-4735 reflect the correct state of the floating-point registers at the point of interruption. In the ESA/390-compatibility mode, bit 27 (FP), when one, indicates that the contents of the floating-point-register save area at real locations 352-383 reflect the correct state of floating-point registers 0, 2, 4, and 6 at the point of interruption.

General-Register Validity

In the z/Architecture architectural mode, bit 28 (GR), when one, indicates that the contents of the general-register save area at real locations 4736-4863 reflect the correct state of the general registers at the point of interruption. In the ESA/390-compatibility mode, bit 28 (GR), when one, indicates that the contents of the general-register save area at real locations 384-447 reflect the correct state of bits 32-63 of the general registers at the point of interruption. `

Control-Register Validity

In the z/Architecture architectural mode, bit 29 (CR), when one, indicates that the contents of the control-register save area at real locations 4992-5119 reflect the correct state of the control registers at the point of interruption. In the ESA/390-compatibility mode, bit 29 (CR), when one, indicates that the contents of the control-register save area at real locations 448-511 reflect the correct state of bits 32-63 of the control registers at the point of interruption.

Storage Logical Validity

Bit 31 (ST), when one, indicates that the storage locations, the contents of which are modified by the instructions being executed, contain the correct information relative to the point of interruption. That is, all stores before the point of interruption are completed, and all stores, if any, after the point of interruption are suppressed. When a store before the point of interruption is suppressed because of an invalid CBC, the storage-logical-validity bit may be indicated as one, provided that the invalid CBC has been preserved as invalid.

When instruction-processing damage is indicated but processing backup is not indicated, the storage-logical-validity bit has no meaning.

Storage logical validity reflects only the instruction-processing activity and does not reflect errors in the state of storage as the result of either I/O operations or the storing of the old PSW and other interruption information.

Access-Register Validity

In the z/Architecture architectural mode, bit 33 (AR), when one, indicates that the contents of the access-

register save area at real locations 4928-4991 reflect the correct state of the access registers at the point of interruption. In the ESA/390-compatibility mode, bit 33 (AR), when one, indicates that the contents of the access-register save area at real locations 288-351 reflect the correct state of the access registers at the point of interruption.

Guarded-Storage-Registers Validity

Bit 36 (GS), when one, indicates that the contents of locations 1024-1055 of the machine-check extended save area reflect the correct state of the guarded-storage registers at the point of the interruption. The guarded-storage registers are stored in the same format as that of the guarded-storage control block as shown in Figure 4-19 on page 4-68.

Bit 36 is zero when any of the following is true:

- The guarded-storage facility is not installed.
- The machine-check extended save area address formed from the contents of real locations 4528-4535 is either invalid or all zeros.
- The length characteristic (LC) in bits 60-63 of real locations 4528-4535 specifies a reserved value or a value less than 11.

Breaking-Event-Address-Register Validity

In the z/Architecture architectural mode, bit 37 (BR), when one, indicates the contents of the breaking-event-address-register save area at real locations 4920-4927 reflect the correct state of the breaking-event-address register at the point of interruption.

Bit 37 is zero when any of the following is true:

- A machine-check interruption is presented to a CPU of a configuration in the ESA/390-compatibility mode.
- The BEAR-enhancement facility is not installed.

TOD-Programmable-Register Validity

Bit 42 (PR), when one, indicates that the contents of the TOD-programmable-register save area at real locations 4900-4903 reflect the correct state of the TOD programmable register at the point of interruption.

Floating-Point-Control-Register Validity

In the z/Architecture architectural mode, bit 43 (FC), when one, indicates that the contents of the floating-point-control-register save area at real locations 4892-4895 reflect the correct state of the floating-point-control register at the point of interruption.

In the ESA/390-compatibility mode, bit 43 (XF), when one, indicates that the contents of locations 0-143 of the machine-check extended save area reflect the correct state of floating-point registers 0-15 and the floating-point-control register at the point of interruption. Bit 43 is zero when the extended-save-area control, bit 34 of control register 14, is zero, or the machine-check extended-save-area address formed from the contents of real locations 212-215 is either invalid or all zeros.

CPU-Timer Validity

In the z/Architecture architectural mode, bit 46 (CT), when one, indicates that the CPU timer is not in error and that the contents of the CPU-timer save area at real locations 4904-4911 reflect the correct state of the CPU timer at the time the interruption occurred. In the ESA/390-compatibility mode, bit 46 (CT), when one, indicates that the CPU timer is not in error and that the contents of the CPU-timer save area at real location 216-223 reflect the correct state of the CPU timer at the time the interruption occurred.

Clock-Comparator Validity

In the z/Architecture architectural mode, bit 47 (CC), when one, indicates that the clock comparator is not in error, that the contents of the clock-comparator save area at real locations 4913-4919 reflect the correct state of the clock comparator at the time the interruption occurred, and that zeros have been stored at real location 4912. In the ESA/390-compatibility mode, bit 47 (CC), when one, indicates that the clock comparator is not in error and that the contents of the clock-comparator save area at real locations 224-231 reflect the correct state of the clock comparator at the time the interruption occurred.

Programming Note: The validity bits must be used in conjunction with the subclass bits and the backed-up bit in order to determine the extent of the damage caused by a machine-check condition. No damage has occurred to the system when all of the following are true:

- The four PSW-validity bits, the seven register-validity bits, the two timing-facility-validity bits, and the storage-logical-validity bit are all ones.
- Subclass bits 0, 4, 5, 10, and 11 are zeros.
- The instruction-processing-damage bit is zero or, if one, the backed-up bit is also one.
- The delayed-access-exception bit is zero.

Machine-Check Extended Interruption Information

As part of the machine-check interruption, in some cases, extended interruption information is placed in fixed areas assigned in storage. The contents of registers associated with the CPU are placed in register-save areas. For external damage, additional information is provided for some models by storing an external-damage code. When storage error uncorrected, storage error corrected, or storage-key error uncorrected is indicated, the failing-storage address is saved.

Each of these fields has associated with it a validity bit in the machine-check-interruption code. If, for any reason, the machine cannot store the proper information in the field, the associated validity bit is set to zero.

Register-Save Areas

As part of the machine-check interruption, the current contents of the CPU registers, except for the prefix register and the TOD clock, are stored in register-save areas assigned in storage. Each of these areas has associated with it a validity bit in the machine-check-interruption code. If, for any reason, the machine cannot store the proper information in the field, the associated validity bit is set to zero.

Figure 11-6 lists the nine sets of registers and the real locations in storage where their contents are saved during a machine-check interruption in the z/Architecture architectural mode.

Locations	Registers
4608-4735	Floating-point registers 0-15
4736-4863	General registers 0-15
4892-4895	Floating-point-control register
4900-4903	TOD programmable register
4904-4911	CPU timer
4913-4919	Clock comparator
4920-4927	Breaking-event-address register[1]
4928-4991	Access registers 0-15
4992-5119	Control registers 0-15
Explanation: [1] BEAR stored to locations 4920-4927 when BEAR-enhancement facility is installed	

Figure 11-6. Register Save Areas in the z/Architecture Architectural Mode.

Figure 11-7 lists the six sets of registers and the real locations in storage where their contents are saved during a machine-check interruption in the ESA/390-compatibility mode.

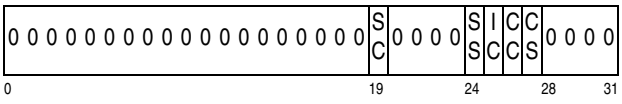
Locations	Registers
216-223	CPU timer
224-231	Clock comparator
288-351	Access registers 0-15
352-383	Floating-point registers 0, 2, 4, and 6
384-447	General registers 0-15 (bits 32-63)
448-511	Control registers 0-15 (bits 32-63)

Figure 11-7. Register Save Areas in the ESA/390-compatibility Mode.

External-Damage Code

The word at real location 244 is the external-damage code. This field, when implemented and indicated as valid, describes the cause of external damage. The field is valid only when the external-damage bit and the external-damage-code-validity bit (bits 5 and 26 in the machine-check-interruption code) are both ones. The presence and extent of reporting an external-damage code depend on the model.

The external-damage code has the following format:



ETR Sync Check (SC): Bit 19, when one, indicates that bits 32 through the rightmost incremented bit of a running clock are not in synchronism with the same bits of the ETR.

If the condition happens more than once before the interruption occurs, the condition is generated only once. The condition is generated for all CPUs in the configuration, and the condition for a CPU is cleared by the interruption taken by the CPU.

STP Sync Check (SS): Bit 24, when one, indicates that an STP-sync-check has occurred. The STP-sync-check condition is generated when the configuration is in the STP-timing mode and the timing state changes from the synchronized state to the unsynchronized or stopped state.

The machine-check condition is generated for all CPUs in the configuration, and the condition for a CPU is cleared by the interruption taken by the CPU.

Island Condition (IC): Bit 25, when one, indicates that an island condition has been detected. The island condition is generated when an attached server attempts to communicate over an STP link and both of the following conditions are detected:

- The servers have matching CTN IDs, and
- Both servers have valid stratum-1-configurations and the configurations do not match.

The island condition indicates that two separate CTNs may be operating with the same CTN ID.

The machine-check condition is generated for all CPUs in the configuration, and the condition for a CPU is cleared by the interruption taken by the CPU.

CTN Configuration Change (CC): Bit 26, when one, indicates that a CTN-configuration-change has occurred in the CTN. The conditions that cause the CTN-configuration-change condition to be generated include the following:

- A new node with a matching CTN ID has attached to this node.
- An attached node that had a matching CTN ID is no longer attached to this node
- The CTN ID for this node has changed.
- The stratum level of this node has changed, or a change in the stratum-1 or alternate-stratum-1 for the network has changed.
- STP active or maximum version number has changed.

The machine-check condition is generated for all CPUs in the configuration, and the condition for a CPU is cleared by the interruption taken by the CPU.

STP Clock Source Error (CS): Bit 27, when one, indicates that an STP-clock-source error has occurred. The STP-clock-source condition is generated when the configuration is in the STP-timing mode and the STP-clock-source state changes from the usable state to the not-usable state.

The machine-check condition is generated for all CPUs in the configuration, and the condition for a CPU is cleared by the interruption taken by the CPU.

Reserved: Bits 0-7, 10-16, 21-23, and 28-31 are reserved for future expansion and are always set to zero.

Failing-Storage Address

When storage error uncorrected, storage error corrected, or storage-key error uncorrected is indicated in the machine-check-interruption code, the associated address, called the failing-storage address, is stored at real locations 248-255(in the z/Architecture architectural mode) or 248-251 (in the ESA/390-compatibility mode). The field is valid only if the failing-storage-address validity bit, bit 24 of the machine-check-interruption code, is one.

In the case of storage errors, the failing-storage address may designate any byte within the checking block. For storage-key error uncorrected, the failing-storage address may designate any address within the block of storage associated with the storage key that is in error. When an error is detected in more than one location before the interruption, the failing-storage address may designate any of the failing locations. The address stored is an absolute address; that is, the value stored is the address that is used to reference storage after dynamic address translation and prefixing have been applied.

Machine-Check Extended Save Area (MCESA)

Machine-Check Extended Save Area in the z/Architecture Architectural Mode

In the z/Architecture architectural mode, the machine-check-extended-save-area designation (MCESAD) at real locations 4528-4535 specifies the location and size of the machine-check extended save area (MCESA). See "Machine-Check-Extended-Save-Area Designation (MCESAD)" on page 3-83 for a description of the contents of the MCESAD field. When the machine-check-extended-save-area origin (MCESAO) is nonzero, the designated area is accessible, and the length characteristic (LC) provides sufficient length, the contents of various facilities' registers are stored in the save area. A facility's registers are only stored in the MCESA when the facility is installed. The facilities accommodated by the MCESA include the following:

- Vector facility for z/Architecture
- Guarded-storage facility

When the guarded-storage facility is not installed, the length and alignment of the MCESA is 1024 bytes. When the guarded-storage facility is installed, the length characteristic (LC) in bits 60-63 of the MCESAD specifies the length and alignment of the MCESA as a power of two; an LC value of zero is treated as 10. Figure 11-8 shows the contents of the MCESA; reserved fields remain unmodified.

Offset		Content	Minimum LC
Hex	Dec		
000-1FF	0-511	Vector Registers 0-31	10
200-3FF	512-1023	Reserved	
400-407	1024-1031	Zeros	11
408-40F	1032-1039	GSD Register	
410-417	1040-1047	GSSM Register	
418-41F	1048-1055	GSEPLA Register	
420-7FF	1056-2047	Reserved	
800-FFF	2048-4095	Reserved	12

Figure 11-8. Contents of the Machine-Check Extended Save Area, Associated MCIC-Validity Bit, and Minimum Length Characteristic Required

If the minimum length required to store a facility's registers is not specified in the length code, then those registers are not stored in the MCESA.

The parameter register and additional-status-area used by the SIGNAL PROCESSOR store-additional-status-at-address order have formats identical to those of the MCESAD and MCESA, respectively. See "Store Additional Status at Address" on page 4-95 for further details.

Machine-Check Extended Save Area in the ESA/390 Compatibility Mode

In the ESA/390-compatibility mode, when the extended-save-area control, bit 34 of control register 14, is one, and bits 1-19 of real locations 212-215 are not all zeros, then, as part of a machine-check interruption, the current contents of floating-point registers 0-15 and the floating-point-control register are stored in a machine-check extended save area. The absolute address of the extended save area is obtained by appending 33 bits of zeros to the left and 12 bits of zeros to the right of bits 1-19 of real locations 212-215. Storing does not occur if the address is invalid.

The extended save area has associated with it a validity bit, bit 43, in the machine-check-interruption code. If, for any reason, the machine cannot store the proper information in the area, the associated validity bit is set to zero.

Figure 11-9 lists the fields that are stored, their offsets within the area, and their lengths. Bytes 144-4095 of the extended save area remain unchanged.

Field	Byte Offset	Length in Bytes
Floating-point registers 0-15	0	128
Floating-point control register	128	4
Reserved (zeros stored)	132	12

Figure 11-9. Machine-Check Extended-Save-Area Locations in the ESA/390-compatibility Mode

Handling of Machine-Check Conditions

Floating Interruption Conditions

An interruption condition which is made available to any CPU in a multiprocessing configuration is called a floating interruption condition. The first CPU that accepts the interruption clears the interruption condi-

tion, and it is no longer available to any other CPU in the configuration.

Floating interruption conditions include service-signal external-interruption and I/O-interruption conditions. Two machine-check-interruption conditions, channel report pending and channel-subsystem damage, are floating interruption conditions. Additionally, floating interruption conditions include STP external-damage machine-check conditions (STP Sync Check, STP Island Condition, STP CTN Configuration Error, and STP Clock Source Error) when STP machine-check floating interruptions are enabled.

Depending on the model, some machine-check-interruption conditions associated with system recovery and warning may also be floating interruption conditions.

A floating interruption is presented to the first CPU in the configuration which is enabled for the interruption condition and can accept the interruption. A CPU cannot accept the interruption when the CPU is in the check-stop state, has an invalid prefix, is performing an unending string of interruptions due to a PSW-format error of the type that is recognized early, or is in the stopped state. However, a CPU with the rate control set to instruction step can accept the interruption when the start key is activated.

Programming Note: When a CPU enters the check-stop state in a multiprocessing configuration, the program on another CPU can determine whether a floating interruption may have been reported to the failing CPU and then lost. This can be accomplished if the interruption program places zeros in the real storage locations containing old PSWs and interruption codes after the interruption has been handled (or has been moved into another area for later processing). After a CPU enters the check-stop state, the program on another CPU can inspect the old-PSW and interruption-code locations of the failing CPU. A nonzero value in an old PSW or interruption code indicates that the CPU has been interrupted but the program did not complete the handling of the interruption.

Floating Machine-Check-Interruption Conditions

Floating machine-check-interruption conditions are reset only by the manually initiated resets through the operator facilities. When a machine check occurs which prohibits completion of a floating machine-check interruption, the interruption condition is no longer considered a floating interruption condition, and system damage is indicated.

Floating I/O Interruptions

The detection of a machine malfunction by the channel subsystem, while in the process of presenting an I/O-interruption request for a floating I/O interruption, may be reported as channel report pending or as channel-subsystem damage. Detection of a machine malfunction by a CPU, while in the process of accepting a floating I/O interruption, is reported as system damage.

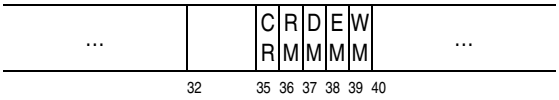
Machine-Check Masking

All machine-check interruptions are under control of the machine-check mask, PSW bit 13. In addition, some machine-check conditions are controlled by subclass masks in control register 14.

The exigent machine-check conditions (system damage and instruction-processing damage) are controlled only by the machine-check mask, PSW bit 13. When PSW bit 13 is one, an exigent condition causes a machine-check interruption. When PSW bit 13 is zero, the occurrence of an exigent machine-check condition causes the CPU to enter the check-stop state.

The repressible machine-check conditions, except channel-subsystem damage and service-processor damage, are controlled both by the machine-check mask, PSW bit 13, and by five subclass-mask bits in control register 14. If PSW bit 13 is one and one of the subclass-mask bits is one, the associated condition initiates a machine-check interruption. If a subclass-mask bit is zero, the associated condition does not initiate an interruption but is held pending. However, when a machine-check interruption is initiated because of a condition for which the CPU is enabled, those conditions for which the CPU is not enabled may be presented along with the condition which initiates the interruption. All conditions presented are then cleared.

Control register 14 contains mask bits that specify whether certain conditions can cause machine-check interruptions. It has the following format:



Bits 35-39 of control register 14 are the subclass masks for repressible machine-check conditions. In addition, bit 32 of control register 14 is initialized to one but is otherwise ignored by the machine.

Programming Note: The program should avoid, whenever possible, operating with PSW bit 13, the machine-check mask, set to zero, since any exigent machine-check condition which is recognized during this situation will cause the CPU to enter the check-stop state. In particular, the program should avoid executing I/O instructions or allowing I/O interruptions with PSW bit 13 zero.

Channel-Report-Pending Subclass Mask

Bit 35 (CM) of control register 14 controls channel-report-pending interruption conditions. This bit is initialized to zero.

Recovery Subclass Mask

Bit 36 (RM) of control register 14 controls system-recovery interruption conditions. This bit is initialized to zero.

Degradation Subclass Mask

Bit 37 (DM) of control register 14 controls degradation interruption conditions. This bit is initialized to zero.

External-Damage Subclass Mask

Bit 38 (EM) of control register 14 controls timing-facility-damage and external-damage interruption conditions. This bit is initialized to one.

Warning Subclass Mask

Bit 39 (WM) of control register 14 controls warning interruption conditions. This bit is initialized to zero.

Machine-Check Logout

As part of the machine-check interruption, some models may place model-dependent information in the fixed-logout area. In the z/Architecture architectural mode, this area is 16 bytes in length and starts at real location 4864. In the ESA/390-compatibility mode, this area is 16 bytes in length and starts at real location 256.

Summary of Machine-Check Masking

A summary of machine-check masking is given in Figure 11-10 and Figure 11-11.

Machine-Check Condition		Sub-Class Mask	Action when CPU Disabled for Subclass
MCIC Bit	Subclass		
0	System damage	-	Check stop
1	Instruction-processing damage	-	Check stop
2	System recovery	RM	Y
4	Timing-facility damage	EM	P
5	External damage	EM	P
7	Degradation	DM	P
8	Warning	WM	P
9	Channel report pending	CM	P
10	Service-processor damage	-	P
11	Channel-subsystem damage	-	P

Explanation:

-	The condition does not have a subclass mask.
P	Indication is held pending.
Y	Indication may be held pending or may be discarded.
CM	Channel-report-pending subclass mask (bit 35 of CR14).
DM	Degradation subclass mask (bit 37 of CR14).
EM	External-damage subclass mask (bit 38 of CR14).
RM	Recovery subclass mask (bit 36 of CR14).
WM	Warning subclass mask (bit 39 of CR14).

Figure 11-10. Machine-Check-Condition Masking

Bit Description	Control Register 14 Bit Position	State of Bit on Initial CPU Reset
Channel-report-pending subclass mask	35	0
Recovery subclass mask	36	0
Degradation subclass mask	37	0
External-damage subclass mask	38	1
Warning subclass mask	39	0

Manual Operation

The operator facilities provide functions for the manual operation and control of the machine. The functions include operator-to-machine communication, indication of machine status, control over the setting of the TOD clock, initial program loading, resets, and other manual controls for operator intervention in normal machine operation. A model may not implement all of the operator facilities described in this chapter.

A model may provide additional operator facilities which are not described in this chapter. Examples are the means to indicate specific error conditions in the equipment, to change equipment configurations, and to facilitate maintenance. Furthermore, controls covered in this chapter may have additional settings which are not described here. Such additional facilities and settings may be described in the appropriate System Library publication.

Most models provide, in association with the operator facilities, a console device which may be used as an I/O device for operator communication with the program; this console device may also be used to implement some or all of the facilities described in this chapter.

The operator facilities may be implemented on different models in various technologies and configurations. On some models, more than one set of physical representations of some keys, controls, and indicators may be provided, such as on multiple local or remote operating stations, which may be effective concurrently.

A machine malfunction that prevents a manual operation from being performed correctly, as defined for that operation, may cause the CPU to enter the check-stop state or give some other indication to the operator that the operation has failed. Alternatively, a machine malfunction may cause a machine-check-interruption condition to be recognized

Basic Operator Facilities

Address-Compare Controls

The address-compare controls provide a way to stop the CPU when a preset address matches the address used in a specified type of main-storage reference.

One of the address-compare controls is used to set up the address to be compared with the storage address.

© Copyright IBM Corp. 2000, 2025

Another control provides at least two positions to specify the action, if any, to be taken when the address match occurs:

1. The normal position disables the address-compare operation.
2. The stop position causes the CPU to enter the stopped state on an address match. When the control is in this setting, the test indicator is on. Depending on the model and the type of reference, pending I/O, external, and machine-check interruptions may or may not be taken before entering the stopped state.

A third control may specify the type of storage reference for which the address comparison is to be made. A model may provide one or more of the following positions, as well as others:

1. The any position causes the address comparison to be performed on all storage references.
2. The data-store position causes address comparison to be performed when storage is addressed to store data.
3. The I/O position causes address comparison to be performed when storage is addressed by the channel subsystem to transfer data or to fetch a channel-command or indirect-data-address word. Whether references to the measurement block, interruption-response block, channel-path-status word, channel-report word, subchannel-status word, subchannel-information block, and operation-request block cause a match to be indicated depends on the model.
4. The instruction-address position causes address comparison to be performed when storage is addressed to fetch an instruction. The rightmost bit of the address setting may or may not be ignored. The match is indicated only when the first byte of the instruction is fetched from the selected location (which includes fetching the target instruction of an execute-type instruction).

Depending on the model and the type of reference, address comparison may be performed on virtual, real, or absolute addresses, and it may be possible to specify the type of address.

In a multiprocessing configuration, it depends on the model whether the address setting applies to one or all CPUs in the configuration and whether an address match causes one or all CPUs in the configuration to stop.

Depending on the model, the availability of address-compare controls may be limited by the use of program-event-recording (PER) controls; PER controls include bit 1 of the PSW and all bits of control registers 9, 10, and 11. The address-compare-control limitations are as follows:

- The setting of address-compare controls may be inhibited when any PER control is nonzero. In a multi-processing configuration, the setting of address-compare controls may be inhibited on all CPUs in the configuration when any PER control is nonzero on any CPU in the configuration.
- If address-compare controls have been set on a CPU, and any PER control is set to a nonzero value, the address-compare controls may be disabled; the address-compare controls may remain disabled even if the respective PER controls are all subsequently reset to zero. In a multi-processing configuration, the address-compare controls may be disabled on all CPUs in the configuration if any PER control is set to a nonzero value in any CPU in the configuration.

Alter-and-Display Controls

The operator facilities provide controls and procedures to permit the operator to alter and display the contents of locations in storage, the storage keys, the general, floating-point, floating-point-control, vector, access, and control registers, the prefix, and the PSW.

Before alter-and-display operations may be performed, the CPU must first be placed in the stopped state. During alter-and-display operations, the manual indicator may be turned off temporarily, and the start and restart keys may be inoperative.

Addresses used to select storage locations for alter-and-display operations are real addresses. The capability of specifying logical, virtual, or absolute addresses may also be provided.

Architectural-Mode Indicator

Depending on the model, the configuration may be activated in the ESA/390 architectural mode, the

ESA/390 compatibility mode, or the z/Architecture architectural mode.

The architectural-mode indicator shows the architectural mode of operation (the ESA/390 mode, ESA/390 compatibility mode, z/Architecture mode, or some other mode) selected by the last architectural-mode-selection operation and by the last SIGNAL PROCESSOR set-architecture order or the last reset that determined the mode.

When the configuration-z/Architecture-architectural-mode (CZAM) facility is installed, the z/Architecture architectural mode is indicated.

Architectural-Mode-Selection Controls

The architectural-mode-selection controls provide for the selection of the ESA/390 architectural mode of operation, the ESA/390 compatibility mode of operation, the z/Architecture architectural mode of operation, or, possibly, some other architectural mode of operation. (When a configuration is activated in either the ESA/390 or ESA/390-compatibility mode, the z/Architecture mode is selected from the ESA/390 mode by the SIGNAL PROCESSOR set-architecture order.) Depending on the model, the architectural-mode selection may be provided as part of the IML operation or may be a separate operation.

As part of the architectural-mode-selection process, all CPUs and the associated channel-subsystem components in a particular configuration are placed in the same architectural mode.

Check-Stop Indicator

The check-stop indicator is on when the CPU is in the check-stop state. Reset operations normally cause the CPU to leave the check-stop state and thus turn off the indicator. The manual indicator may also be on in the check-stop state.

CPUs-per-Core Indicator

When the multithreading facility is installed, the CPUs-per-core indicator is provided. When the multithreading facility is not enabled, the value of this indicator is one. When the multithreading facility is enabled, the value of this indicator is one more than value of the program-specified maximum thread identification last set by the SIGNAL PROCESSOR set-multithreading order.

Operation Note: Certain operator functions are addressed to a specific CPU, designated by a CPU address. When multithreading is enabled, the CPU address includes a core identification and a thread identification as described in “CPU-Address Identification” on page 4-85. The CPUs-per-core indicator can be used to determine which format of CPU address is needed when selecting a CPU to which operator functions are addressed.

IML Controls

The IML controls provided with some models perform initial machine loading (IML), which is the loading of licensed internal code into the machine.

When the IML operation is completed, the state of the affected CPUs, channel subsystem, main storage, and operator facilities is the same as if a power-on reset had been performed, except that the value and state of the TOD clock are not changed. The contents of expanded storage may have been cleared to zeros with valid checking-block code or may have remained unchanged, depending on the model.

The IML controls are effective while the power is on.

Interrupt Key

When the interrupt key is activated, an external-interruption condition indicating the interrupt key is generated. (See “Interrupt Key” on page 6-13.)

The interrupt key is effective when the CPU is in the operating or stopped state. It depends on the model whether the interrupt key is effective when the CPU is in the load state.

Load Indicator

The load indicator is on during CCW-type initial program loading, indicating that the CPU is in the load state. The indicator goes on for a particular CPU when the load-clear, load-clear-list-directed, load-normal or load-with-dump key is activated for that CPU and the corresponding operation is started. It

goes off after the new PSW is loaded successfully. For details, see “Initial Program Loading” on page 4-83 and “Initial Program Loading” on page 17-16.

Load-Clear Key

Activating the load-clear key causes a reset operation to be performed and CCW-type initial program loading to be started by using the I/O device designated by the load-unit-address controls. Clear reset is performed on the configuration. For details, see “Resets” on page 4-75 and “Initial Program Loading” on page 4-83.

The load-clear key is effective when the CPU is in the operating, stopped, load, or check-stop state.

Load-Clear-List-Directed Key

Activating the load-clear-list-directed key causes a reset operation to be performed and list-directed initial program loading to be started using the I/O device designated by the list-directed IPL parameters. Clear reset is performed on the configuration. For details, see “Resets” on page 4-75 and “List-Directed IPL” on page 17-19.

The load-clear-list-directed key is effective when the CPU is in the operating, stopped, load, or check-stop state.

Load-Normal Key

Activating the load-normal key causes a reset operation to be performed and CCW-type initial program loading to be started by using the I/O device designated by the load-unit-address controls. Initial CPU reset is performed on the CPU for which the load-normal key was activated, CPU reset is propagated to all other CPUs in the configuration, and a subsystem reset is performed on the remainder of the configuration. For details, see “Resets” on page 4-75 and “Initial Program Loading” on page 4-83.

The load-normal key is effective when the CPU is in the operating, stopped, load, or check-stop state.

Load-Normal-List-Directed Key

Activating the load-normal-list-directed key causes a reset operation to be performed and list-directed initial program loading to be started using the I/O device designated by the list-directed IPL parameters. Initial CPU reset is performed on the CPU for which the load-normal-list-directed key was activated, CPU reset is propagated to all other CPUs in the configuration, and a subsystem reset is performed on the remainder of the configuration. For details, see “Resets” on page 4-75 and “List-Directed IPL” on page 17-19.

The load-normal-list-directed key is effective when the CPU is in the operating, stopped, load, or check-stop state.

Load-with-Dump Key

Activating the load-with-dump key causes a reset operation to be performed and list-directed initial program loading to be started by using the I/O devices designated by the list-directed IPL parameters. A store-status operation followed by an initial CPU reset is performed on the CPU for which the load-with-dump key was activated, CPU reset is propagated to all other CPUs in the configuration, and a subsystem reset is performed on the remainder of the configuration. For details, see “Resets” on page 4-75 and “List-Directed IPL” on page 17-19.

The load-with-dump key is effective when the CPU is in the operating, stopped, load, or check-stop state.

Load-Unit-Address Controls

The load-unit-address controls specify four hexadecimal digits that provide the device number used for CCW-type initial program loading. When the alternate-subchannel-set-IPL-device facility is installed the load-unit-address controls may specify an additional hexadecimal digit that provides the subchannel-set ID for CCW-type initial program loading. For details, see “Initial Program Loading” on page 4-83.

Manual Indicator

The manual indicator is on when the CPU is in the stopped state. Some functions and several manual

controls are effective only when the CPU is in the stopped state.

Power Controls

The power controls are used to turn the power on and off.

The CPUs, storage, channel subsystem, operator facilities, and I/O devices may all have their power turned on and off by common controls, or they may have separate power controls. When a particular unit has its power turned on, that unit is reset. The sequence is performed so that no instructions or I/O operations are performed until explicitly specified. The controls may also permit power to be turned on in stages, but the machine does not become operational until power on is complete.

When the power is completely turned on, an IML operation is performed on models which have an IML function. A power-on reset is then initiated (see "Resets" on page 4-75). It depends on the model whether the architectural mode of operation can be selected when the power is turned on, or whether the mode-selection controls have to be used to change the mode after the power is on.

Rate Control

A model may provide the rate control, the setting of which determines the effect of the start function and the manner in which instructions are executed.

When the rate control is provided, it has at least two positions. The normal position is the process position. Another position is the instruction-step position. When the rate control is set to the process position and the start function is performed, the CPU starts operating at normal speed. When the rate control is set to the instruction-step position and the wait-state bit is zero, one instruction or, for interruptible instructions, one unit of operation is executed, and all pending allowed interruptions are taken before the CPU returns to the stopped state. When the rate control is set to the instruction-step position and the wait-state bit is one, no instruction is executed, but all pending allowed interruptions are taken before the CPU returns to the stopped state. For details, see "CPU States" on page 4-2.

The test indicator is on while the rate control is not set to the process position.

If the setting of the rate control is changed while the CPU is in the operating or load state, the results are unpredictable.

When the rate control is not provided, the CPU operates as though the rate control was in the process position, and instruction stepping is not available.

Restart Key

Activating the restart key initiates a restart interruption. (See "Restart Interruption" on page 6-59.)

The restart key is effective when the CPU is in the operating or stopped state. The key is not effective when the CPU is in the check-stop state. It depends on the model whether the restart key is effective when any CPU in the configuration is in the load state.

The effect is unpredictable when the restart key is activated while any CPU in the configuration is in the load state. In particular, if the CPU performs a restart interruption and enters the operating state while another CPU is in the load state, operations such as I/O instructions, the SIGNAL PROCESSOR instruction, and the INVALIDATE PAGE TABLE ENTRY instruction may not operate according to the definitions given in this publication

Start Key

Activating the start key causes the CPU to perform the start function. (See "CPU States" on page 4-2.)

The start key is effective only when the CPU is in the stopped state. The effect is unpredictable when the stopped state has been entered by a reset.

Stop Key

Activating the stop key causes the CPU to perform the stop function. (See "CPU States" on page 4-2.)

The stop key is effective only when the CPU is in the operating state.

Operation Note: Activating the stop key has no effect when:

- An unending string of certain program or external interruptions occurs.
- The prefix register contains an invalid address.
- The CPU is in the load or check-stop state.

Store-Status Key

Activating the store-status key initiates a store-status operation. (See “Store Status” on page 4-84.)

The store-status key is effective only when the CPU is in the stopped state.

Operation Note: The store-status operation may be used in conjunction with a standalone dump program for the analysis of major program malfunctions. For such an operation, the following sequence would be called for:

1. Activation of the stop or system-reset-normal key
2. Activation of the store-status key (this step is unnecessary if the standalone dump program is loaded by activating the load-with-dump key)
3. Activation of the load-normal key to enter a stand-alone dump program

The system-reset-normal key must be activated in step 1 when (1) the stop key is not effective because a continuous string of interruptions is occurring, (2) the prefix register contains an invalid address, or (3) the CPU is in the check-stop state.

System-Reset-Clear Key

Activating the system-reset-clear key causes a clear-reset operation to be performed on the configuration. For details, see “Resets” on page 4-75.

The system-reset-clear key is effective when the CPU is in the operating, stopped, load, or check-stop state.

System-Reset-Normal Key

Activating the system-reset-normal key causes a CPU-reset operation and a subsystem-reset operation to be performed. In a multiprocessing configuration, a CPU reset is propagated to all CPUs in the configuration. For details, see “Resets” on page 4-75.

The system-reset-normal key is effective when the CPU is in the operating, stopped, load, or check-stop state.

Test Indicator

The test indicator is on when a manual control for operation or maintenance is in an abnormal position that can affect the normal operation of a program.

Setting the address-compare controls to the stop position or setting the rate control to the instruction-step position turns on the test indicator.

The test indicator may be on when one or more diagnostic functions under the control of DIAGNOSE are activated, or when other abnormal conditions occur.

The abnormal setting of a manual control causes the test indicator of the affected CPU to be turned on; however, in a multiprocessing configuration, the operation of other CPUs may be affected even though their test indicators are not turned on.

Depending on the model, if address-compare controls have been disabled due to bit position 1 of the PSW being set to one or any or all of control registers 9, 10, and 11 containing nonzero values, the test indicator may remain on even though the address-compare controls have been disabled.

Operation Note: If a manual control is left in a setting intended for maintenance purposes, such an abnormal setting may, among other things, result in false machine-check indications or cause actual machine malfunctions to be ignored. It may also alter other aspects of machine operation, including instruction execution, channel-subsystem operation, and the functioning of operator controls and indicators, to the extent that operation of the machine does not comply with that described in this publication.

TOD-Clock Control

When the TOD-clock control is not activated, that is, the control is set to the secure position, the state and value of the TOD clock are protected against unauthorized or inadvertent change by not permitting the

instructions SET CLOCK or DIAGNOSE to change the state or value.

When the TOD-clock control is activated, that is, the control is set to the enable-set position, alteration of the clock state or value by means of SET CLOCK or DIAGNOSE is permitted. This setting is momentary, and the control automatically returns to the secure position.

If there is more than one physical representation of the TOD-clock control, the TOD clock is secure only if all TOD-clock controls in the configuration are set to the secure position.

Wait Indicator

The wait indicator is on when the wait-state bit in the current PSW is one. Instead of a wait indicator, a model may have a means of indicating a time-averaged value of the wait-state bit.

Multiprocessing Configurations

In a multiprocessing configuration, one of each of the following keys and controls is provided for each CPU:

- Alter and display
- Interrupt
- Restart
- Start
- Stop
- Store status.

On some models, a rate control may also be provided.

On some models, the load-clear, load-clear-list-directed, load-normal, load-with-dump, and load-unit-address keys are provided for each primary CPU in the configuration. On other models, a single load-clear, load-clear-list-directed, load-normal, and load-with-dump key are provided for the entire configuration and apply to the lowest-numbered primary online CPU that is not in the check-stop state.

There need not be more than one of each of the following keys and controls in a multiprocessing configuration: address compare, IML, power, system reset clear, system reset normal, and TOD clock.

One check-stop, manual, test, and wait indicator may be provided for each CPU. A load indicator is provided only on a primary CPU. Alternatively, a single set of indicators may be switched to more than one CPU.

There need not be more than one architectural-mode and CPUs-per-core indicator in a multiprocessing configuration.

In a system capable of reconfiguration, there must be a separate set of keys, controls, and indicators in each configuration.

Multithreading Considerations

A CPU address is used to identify the CPU to which CPU-specific operator functions are directed. These CPU-specific operator functions are enumerated in the section “Multiprocessing Configurations”, above. When multithreading is enabled (that is, when the CPUs-per-core indicator is greater than one), the CPU address comprises a core identification and a thread identification, as described in “CPU-Address Identification” on page 4-85.

Some models provide a control to select the primary CPU to be started following a load operation. On such a model, when the multithreading facility is enabled prior to the load operation, the operator designates an expanded-format CPU address as described in “CPU-Address Identification” on page 4-85. However, only the core-identification portion of the designated CPU address is meaningful; the operation is always targeted to the CPU having thread identification zero of the designated core.

On models that do not provide a control to select the primary CPU to be started following a load operation, the operation is targeted to the CPU having thread identification zero in the lowest-numbered operational core.

In either case, the targeted CPU is (a) the one upon which the initial-CPU reset is performed, and (b) the CPU that is started after the load operation is completed

Input/Output (I/O)

The terms “input” and “output” are used to describe the transfer of data between I/O devices and main storage. An operation involving this kind of transfer is referred to as an I/O operation. The facilities used to control I/O operations are collectively called the channel subsystem. (I/O devices and their control units attach to the channel subsystem.) This chapter provides a brief description of the basic components and operation of the channel subsystem.

The Channel Subsystem

The channel subsystem directs the flow of information between I/O devices and main storage. It relieves CPUs of the task of communicating directly with I/O devices and permits data processing to proceed concurrently with I/O processing. The channel subsystem uses one or more channel paths as the communication link in managing the flow of information to or from I/O devices. As part of I/O processing, the channel subsystem also performs a path-management operation by testing for channel-path availability, chooses an available channel path, and initiates the performance of the I/O operation by the device.

Within the channel subsystem are subchannels. One subchannel is provided for and dedicated to each I/O device accessible to the program through the channel subsystem.

The multiple-subchannel-set facility is an optional facility. When it is installed, subchannels are partitioned into multiple subchannel sets, and each subchannel set may provide one dedicated subchannel to an I/O device. Depending on the model and the interface used, some I/O devices may only be allowed to be accessed via certain subchannel sets.

Each subchannel provides information concerning the associated I/O device and its attachment to the channel subsystem. The subchannel also provides information concerning I/O operations and other functions involving the associated I/O device. The subchannel is the means by which the channel subsystem provides information about associated I/O devices to CPUs, which obtain this information by executing I/O instructions. The actual number of subchannels provided depends on the model and the configuration; the maximum addressability is 0-65,535 in each subchannel set.

I/O devices are attached through control units to the channel subsystem by means of channel paths. Control units may be attached to the channel subsystem by more than one channel path, and an I/O device may be attached to more than one control unit. In all, an individual I/O device may be accessible to the

© Copyright IBM Corp. 2000, 2025

channel subsystem by as many as eight different channel paths via a subchannel, depending on the model and the configuration. The total number of channel paths provided by a channel subsystem depends on the model and the configuration; the maximum addressability is 0-255.

The performance of a channel subsystem depends on its use and on the system model in which it is implemented. Channel paths are provided with different data-transfer capabilities, and an I/O device designed to transfer data only at a specific rate (a magnetic-tape unit or a disk storage, for example) can operate only on a channel path that can accommodate at least this data rate.

The channel subsystem contains common facilities for the control of I/O operations. When these facilities are provided in the form of separate, autonomous equipment designed specifically to control I/O devices, I/O operations are completely overlapped with the activity in CPUs. The only main-storage cycles required by the channel subsystem during I/O operations are those needed to transfer data and control information to or from the final locations in main storage, along with those cycles that may be required for the channel subsystem to access the subchannels when they are implemented as part of non-addressable main storage. These cycles do not delay CPU programs, except when both the CPU and the channel subsystem concurrently attempt to reference the same main-storage area.

Subchannel Sets

When the multiple-subchannel-set facility is installed, subchannels are partitioned into multiple subchannel sets. There may be up to four subchannel sets, each identified by a subchannel-set identifier (SSID). When the multiple-subchannel-set facility is not installed, there is only one subchannel set with an SSID of zero. When the multiple-subchannel-set facility is not enabled, only subchannel set zero is visible to the program. See “Multiple-Subchannel-Set Facility” on page 17-34 for more information on the multiple-subchannel-set facility.

Subchannels

A subchannel provides the logical appearance of a device to the program and contains the information required for sustaining a single I/O operation. The subchannel consists of internal storage that contains information in the form of a channel-program designation, channel-path identifier, device number, count, status indications, and I/O-interruption-subclass code, as well as information on path availability and functions pending or being performed. I/O operations are initiated with a device by the execution of I/O instructions that designate the subchannel associated with the device.

Each device is accessible by means of one subchannel in each channel subsystem to which it is assigned during configuration at installation time. The device may be a physically identifiable unit or may be housed internal to a control unit. For example, in certain disk-storage devices, each actuator used in retrieving data is considered to be a device. In all cases, a device, from the point of view of the channel subsystem, is an entity that is uniquely associated with one subchannel and that responds to selection by the channel subsystem by using the communication protocols defined for the type of channel path by which it is accessible.

On some models, subchannels are provided in blocks. On these models, more subchannels may be provided than there are attached devices. Subchannels that are provided but do not have devices assigned to them are not used by the channel subsystem to perform any function and are indicated by storing the associated device-number-valid bit as zero in the subchannel-information block of the subchannel.

The number of subchannels provided by the channel subsystem is independent of the number of channel paths to the associated devices. For example, a device accessible through alternate channel paths still is represented by a single subchannel. Each subchannel is addressed by using the following:

- a 16-bit binary subchannel number
- a two-bit SSID when the subchannel-set facility is installed

After I/O processing at the subchannel has been requested by the execution of START SUBCHANNEL, the CPU is released for other work, and the channel subsystem assembles or disassembles data and synchronizes the transfer of data bytes between the I/O device and main storage. To accomplish this, the channel subsystem maintains and updates an address and a count that describe the destination or source of data in main storage. Similarly, when an I/O

device provides signals that should be brought to the attention of the program, the channel subsystem transforms the signals into status information and stores the information in the subchannel, where it can be retrieved by the program.

Attachment of Input/Output Devices

Channel Paths

The channel subsystem communicates with I/O devices by means of channel paths between the channel subsystem and control units. A control unit may be accessible by the channel subsystem by more than one channel path. Similarly, an I/O device may be accessible by the channel subsystem through more than one control unit, each having one or more channel paths to the channel subsystem.

Devices that are attached to the channel subsystem by multiple channel paths configured to a subchannel, may be accessed by the channel subsystem using any of the available channel paths. Similarly, a device having the dynamic-reconnection feature and operating in the multipath mode can be initialized to operate such that the device may choose any of the available channel paths configured to the subchannel, when logically reconnecting to the channel subsystem to continue a chain of I/O operations.

The channel subsystem may contain more than one type of channel path. Examples of channel-path types used by the channel subsystem are the ESCON I/O interface, FICON I/O interface, FICON-converted I/O interface, and IBM System/360 and System/370 I/O interface. The term “serial-I/O interface” is used to refer the ESCON I/O interface, the FICON I/O interface, and the FICON-converted I/O interface. The term “parallel-I/O interface” is used to refer to the IBM System/360 and System/370 I/O interface.

The ESCON I/O interface is described in the System Library publication *IBM Enterprise Systems Architecture/390 ESCON I/O Interface*, SA22-7202.

The FICON I/O interface is described in the ANSI standards document *Fibre Channel - Single-Byte Command Code Sets-2 (FC-SB-2)*

The IBM System/360 and System/370 I/O interface is described in the System Library publication *IBM System/360 and System/370 I/O Interface Channel to Control Unit OEMI*, GA22-6974.

Depending on the type of channel path, the facilities provided by the channel path, and the I/O device, an I/O operation may occur in one of three modes, frame-multiplex mode, burst mode, or byte-multiplex mode.

In the frame-multiplex mode, the I/O device may stay logically connected to the channel path for the duration of the execution of a channel program. The facilities of a channel path capable of operating in the frame-multiplex mode may be shared by a number of concurrently operating I/O devices. In this mode the information required to complete an I/O operation is divided into frames that may be interleaved with frames from I/O operations for other I/O devices. During this period, multiple I/O devices are considered to be logically connected to the channel path.

In the burst mode, the I/O device monopolizes a channel path and stays logically connected to the channel path for the transfer of a burst of information. No other device can communicate over the channel path during the time a burst is transferred. The burst can consist of a few bytes, a whole block of data, a sequence of blocks with associated control and status information (the block lengths may be zero), or status information that monopolizes the channel path. The facilities of the channel path capable of operating in the burst mode may be shared by a number of concurrently operating I/O devices.

Some channel paths can tolerate an absence of data transfer for about a half minute during a burst-mode operation, such as occurs when a long gap on magnetic tape is read. An equipment malfunction may be indicated when an absence of data transfer exceeds the prescribed limit.

In the byte-multiplex mode, the I/O device stays logically connected to the channel path only for a short interval of time. The facilities of a channel path capable of operating in the byte-multiplex mode may be shared by a number of concurrently operating I/O devices. In this mode, all I/O operations are split into short intervals of time during which only a segment of information is transferred over the channel path. During such an interval, only one device and its associated subchannel are logically connected to the channel path. The intervals associated with the con-

current operation of multiple I/O devices are sequenced in response to demands from the devices. The channel-subsystem facility associated with a subchannel exercises its controls for any one operation only for the time required to transfer a segment of information. The segment can consist of a single byte of data, a few bytes of data, a status report from the device, or a control sequence used for the initiation of a new operation.

Ordinarily, devices with high data-transfer-rate requirements operate with the channel path in the frame-multiplex mode, slower devices operate in the burst mode, and the slowest devices operate in the byte-multiplex mode. Some control units have a manual switch for setting the desired mode of operation.

An I/O operation that occurs on a parallel-I/O-interface type of channel path may occur in either the burst mode or the byte-multiplex mode depending on the facilities provided by the channel path and the I/O device. For improved performance, some channel paths and control units are provided with facilities for high-speed transfer and data streaming. See the *System Library publication IBM System/360 and System/370 I/O Interface Channel to Control Unit OEMI*, GA22-6974, for a description of those two facilities.

An I/O operation that occurs on a serial-I/O-interface-type of channel path may occur in either the frame-multiplex mode or the burst mode. For improved performance, some control units attaching to the serial-I/O interface provide the capability to provide sense data to the program concurrent with the presentation of unit-check status, if permitted to do so by the program. (See“Concurrent Sense” on page 17-28.)

Depending on the control unit or channel subsystem, access to a device through a subchannel may be restricted to a single channel-path type.

The modes and features described above affect only the protocol used to transfer information over the channel path and the speed of transmission. No effects are observable by CPU or channel programs with respect to the way these programs are executed.

Control Units

A control unit provides the logical capabilities necessary to operate and control an I/O device and adapts the characteristics of each device so that it can respond to the standard form of control provided by the channel subsystem.

Communication between the control unit and the channel subsystem takes place over a channel path. The control unit accepts control signals from the channel subsystem, controls the timing of data transfer over the channel path, and provides indications concerning the status of the device.

The I/O device attached to the control unit may be designed to perform only certain limited operations, or it may perform many different operations. A typical operation is moving a recording medium and recording data. To accomplish its operations, the device needs detailed signal sequences peculiar to its type of device. The control unit decodes the commands received from the channel subsystem, interprets them for the particular type of device, and provides the signal sequence required for the performance of the operation.

A control unit may be housed separately, or it may be physically and logically integrated with the I/O device, the channel subsystem, or a CPU. In the case of most electromechanical devices, a well-defined interface exists between the device and the control unit because of the difference in the type of equipment the control unit and the device require. These electromechanical devices often are of a type where only one device of a group attached to a control unit is required to transfer data at a time (magnetic-tape units or disk-access mechanisms, for example), and the control unit is shared among a number of I/O devices. On the other hand, in some electronic I/O devices, such as the channel-to-channel adapter, the control unit does not have an identity of its own.

From the programmer's point of view, most functions performed by the control unit can be merged with those performed by the I/O device. Therefore, this publication normally makes no specific mention of the control-unit function; the performance of I/O operations is described as if the I/O devices communicated directly with the channel subsystem. Reference is made to the control unit only when emphasizing a function performed by it or when describing how the sharing of the control unit among a number of devices affects the performance of I/O operations.

I/O Devices

An input/output (I/O) device provides external storage, a means of communication between data-processing systems, or a means of communication between a system and its environment. I/O devices include such equipment as magnetic-tape units, direct-access-storage devices (for example, disks), display units, typewriter-keyboard devices, printers, teleprocessing devices, and sensor-based equipment. An I/O device may be physically distinct equipment, or it may share equipment with other I/O devices.

Most types of I/O devices, such as printers, or tape devices, use external media, and these devices are physically distinguishable and identifiable. Other types are solely electronic and do not directly handle physical recording media. The channel-to-channel adapter, for example, provides for data transfer between two channel paths, and the data never reaches a physical recording medium outside main storage. Similarly, communication controllers may handle the transmission of information between the data-processing system and a remote station, and its input and output are signals on a transmission line.

In the simplest case, an I/O device is attached to one control unit and is accessible from one channel path. Switching equipment is available to make some devices accessible from two or more channel paths by switching devices among control units and by switching control units among channel paths. Such switching equipment provides multiple paths by which an I/O device may be accessed. Multiple channel paths to an I/O device are provided to improve performance or I/O availability, or both, within the system. The management of multiple channel paths to devices is under the control of the channel subsystem and the device, but the channel paths may indirectly be controlled by the program.

I/O Addressing

Four different types of I/O addressing are provided by the channel subsystem for the necessary addressing of the various components: channel-path identifiers, subchannel numbers, device numbers, and, though not visible to programs, addresses dependent on the channel-path type. When the multiple-subchannel-set facility is installed, the subchannel-set identifier (SSID) is also used in I/O addressing.

Subchannel-Set Identifier

The subchannel-set identifier (SSID) is a two-bit value assigned to each provided subchannel set.

Channel-Path Identifier

The channel-path identifier (CHPID) is a system-unique eight-bit value assigned to each installed channel path of the system. A CHPID is used to address a channel path. A CHPID is specified by the second-operand address of RESET CHANNEL PATH and used to designate the channel path that is to be reset. The channel paths by which a device is accessible are identified in the subchannel-information block (SCHIB), each by its associated CHPID, when STORE SUBCHANNEL is executed. The CHPID can also be used in operator messages when it is necessary to identify a particular channel path. A system model may provide as many as 256 channel paths. The maximum number of channel paths and the assignment of CHPIDs to channel paths depends on the system model.

Subchannel Number

A subchannel number is a 16-bit value used to address a subchannel. This value is unique within a subchannel set of a channel subsystem. The subchannel is addressed by eight I/O instructions: CANCEL SUBCHANNEL, CLEAR SUBCHANNEL, HALT SUBCHANNEL, MODIFY SUBCHANNEL, RESUME SUBCHANNEL, START SUBCHANNEL, STORE SUBCHANNEL, and TEST SUBCHANNEL. All I/O functions relative to a specific I/O device are specified by the program by designating a subchannel assigned to the I/O device. Subchannels in each subchannel set are always assigned subchannel numbers within a single range of contiguous numbers. The lowest-numbered subchannel is subchannel 0. The highest-numbered subchannel of the channel subsystem has a subchannel number equal to one less than the number of subchannels provided. A maximum of 65,536 subchannels can be provided in each subchannel set. Normally, subchannel numbers are only used in communication between the CPU program and the channel subsystem.

Device Number

Each subchannel that has an I/O device assigned to it also contains a parameter called the device number. The device number is a 16-bit value that is assigned as one of the parameters of the subchannel at the time the device is assigned to the subchannel. The device number identifies a device to the program and is unique within a subchannel set of a channel subsystem.

The device number provides a means to identify a device, independent of any limitations imposed by the system model, the configuration, or channel-path protocols. The device number is used in communications concerning the device that take place between the system and the system operator. For example, the device number is entered by the system operator to designate the input device to be used for initial program loading.

Programming Note: The device number is assigned at device-installation time and may have any value. However, the user must observe any restrictions on device-number assignment that may be required by the control program, support programs, or the particular control unit or I/O device.

Device Identifier

A device identifier is an address, not apparent to the program, that is used by the channel subsystem to communicate with I/O devices. The type of device identifier used depends on the specific channel-path type and the protocols provided. Each subchannel contains one or more device identifiers.

For a channel path of the parallel-I/O-interface type, the device identifier is called a device address and consists of an eight-bit value. For the ESCON I/O interface, the device identifier consists of a four-bit control-unit address and an eight-bit device address. For the FICON I/O interface, the device identifier consists of an eight-bit control-unit-image ID and an eight-bit device address. For the FICON-converted I/O interface, the device identifier consists of a four-bit control-unit address and an eight-bit device address.

The device address identifies the particular I/O device (and, on the parallel-I/O interface, the control unit) associated with a subchannel. The device address may identify, for example, a particular magnetic-tape drive, disk-access mechanism, or transmission line. Any number in the range 0-255 can be assigned as a device address.

For further information about the device identifier used with a particular channel-path type, see the appropriate publication for the channel-path type.

Fibre-Channel Extensions

The fibre-channel-extensions (FCX) facility is an optional facility that provides for the formation of a channel program that is composed of a transport-control word (TCW) that designates a transport-command-control block (TCCB) and a transport-status block (TSB). The TCCB includes a transport-command area (TCA) which contains a list of up to 30 I/O commands that are in the form of device-command words (DCWs).

The FCX-bidirectional-data-transfer facility is an additional and optional facility that provides support for TCW channel programs that specify both read and write operations. Whether a device recognizes bidirectional data transfers is determined by device-dependent means.

When a device does not recognize bidirectional data transfers, a TCW and its TCCB may specify either read or a write data transfers. When a device recognizes bidirectional data transfers, a TCW and its TCCB may, depending on the device, specify both read and write data transfers. For interruptions, the TSB contains the completion status and other information related to the TCW channel program in addition to the information in the IRB.

For some devices, the list of DCWs may be extended past what will fit in the TCA. For such devices, the TCA extension (TCAX) is specified and transferred as output data. Whether a device supports TCA extensions is determined by device-dependent means.

In addition to the IRB, the TSB contains the completion status and other information related to the TCW channel program.

The FCX facility provides the ability to directly or indirectly designate any or all of the TCCB, the input data storage area, and the output data storage area.

When a storage area is designated directly, the TCW specifies the location of a single, contiguous block of storage. When a storage area is designated indirectly, the TCW designates the location of a list of one or more transport-indirect-data-address words (TIDAWs). TIDAW lists and the storage area designated by each TIDAW in a list are restricted from crossing 4 K-byte boundaries

The FCX facility also provides an interrogate operation that may be initiated by the CANCEL SUBCHANNEL instruction to determine the state of an I/O operation.

I/O-Command Words

An I/O-command word specifies a command and contains information associated with the command. When the FCX facility is installed, there are two elemental forms of I/O command words which are the channel-command word (CCW) and the device-command word (DCW).

A CCW is 8-bytes in length and specifies the command to be executed. For commands that initiate certain operations the CCW also designates the storage area associated with the operation, the count of data bytes, the action to be taken when the command completes, and other options. All I/O devices recognize CCWs.

A DCW is 8-bytes in length and specifies the command to be executed. the count of data bytes, and other options. I/O devices that support FCX recognize DCWs.

Transport Command Word (TCW)

A TCW designates a transport-command-control block (TCCB) which contains a list of commands to be transported to and executed by an I/O device. The TCW also designates the storage areas for the commands in the TCCB as well as a transport-status block (TSB) to contain the status of the I/O operation.

Channel Program Organization

When the FCX facility is not installed, there is a single form of channel program which is the CCW channel program. When the FCX facility is installed, there is an additional form of channel program which is the TCW channel program. Both forms of channel programs are described below.

CCW Channel Program

A channel program that is composed of one or more CCWs is called a CCW channel program (CCP). Such a channel program contains one or more CCWs that are logically linked and arranged for sequential execution by the channel subsystem.

Figure 13-1 shows a conceptual example of a simple CCW channel program in program storage. This channel program contains 4 CCWs and specifies the transfer of data to or from contiguous areas of storage. The first CCW designates a control command and the remaining CCWs designate the transfer of data.

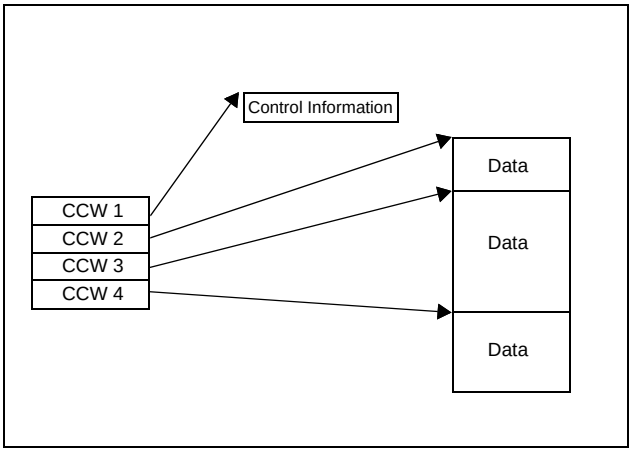

Figure 13-1. CCW Channel Program Example

TCW Channel Program

A channel program that is composed of a single TCW is called a TCW channel program. A TCW designates a transport-command-control block (TCCB) that contains from 1 to 30 DCWs.

DCWs within the TCCB are logically linked and arranged for sequential execution. For DCWs that specify control information, the TCCB also contains the control information for those commands. The TCW also designates the storage area or areas for the DCWs that specify the transfer of data from or to the device and the location of a transport-status block (TSB) for completion status. The TCCB and the storage areas for the transfer of data may be specified as either contiguous or noncontiguous storage.

Figure 13-2 shows a conceptual example of a TCW channel program in program storage. This channel program is similar to the CCW channel program in Figure 13-1. This channel program is composed of a TCW that designates a TCCB containing 4 DCWs, all of which specify the transfer of data either to or from contiguous areas of storage. The first DCW designates a control command and the remaining DCWs designate the transfer of data. The TCW also designates a TSB for completion status.

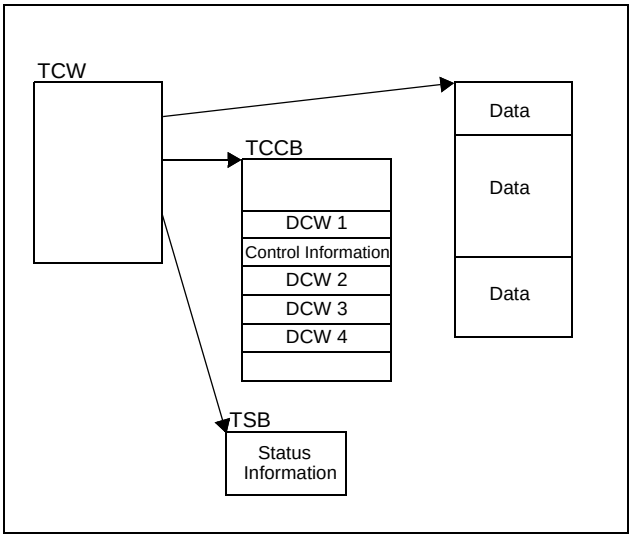

Figure 13-2. Example of TCW Channel Program Example Designating I/O

Execution of I/O Operations

I/O operations are initiated and controlled by information with four types of formats: the instruction START SUBCHANNEL, transport-command words, I/O-command words, and orders. The START SUBCHANNEL instruction is executed by a CPU and is part of the CPU program that supervises the flow of requests for I/O operations from other programs that manage or process the I/O data.

When START SUBCHANNEL is executed, parameters are passed to the target subchannel requesting that the channel subsystem perform a start function with the I/O device associated with the subchannel. The channel subsystem performs the start function by using information at the subchannel, including the information passed during the execution of the START SUBCHANNEL instruction, to find an accessible channel path to the device. Once the device has been selected, the execution of an I/O operation is accomplished by the decoding and execution of a CCW by the channel subsystem and the I/O device, for CCW channel programs, or for TCW channel programs, by transporting the TCCB to the I/O device by the channel subsystem and the decoding and execution of a DCW by the device. I/O-command words, and transport-command words.are fetched from main storage, although the modifier bits in the command code of a CCW DCW may specify device-dependent conditions for the execution of an operation at the device.

Operations peculiar to a device, such as rewinding tape or positioning the access mechanism on a disk drive, are specified by orders that are decoded and executed by I/O devices. Orders may be transferred to the device as modifier bits in the command code of a control command, may be transferred to the device as data during a control or write operation, or may be made available to the device by other means.

Start-Function Initiation

CPU programs initiate I/O operations with the instruction START SUBCHANNEL. This instruction passes the contents of an operation-request block (ORB) to the subchannel.

If the ORB specifies a CCW channel program, the contents of the ORB include the subchannel key, the address of the first CCW to be executed, and a specification of the format of the CCWs. The CCW specifies the command to be executed and the storage area, if any, to be used. If the ORB specifies a TCW channel program, the contents of the ORB include the subchannel key and the address of the TCW to be executed. The TCW designates the TCCB which contains the commands to be transported to the device for execution,the storage area or areas, if any, to be used for data transfer, and the TSB to contain the status of the I/O operation.

When the ORB contents have been passed to the subchannel, the execution of START SUBCHANNEL is complete. The results of the execution of the instruction are indicated by the condition code set in the program-status word.

When facilities become available and the ORB specifies a CCW channel program, the channel subsystem fetches the first CCW and decodes it according to the format bit specified in the ORB. If the format bit is zero, format-0 CCWs are specified. If the format bit is

one, format-1 CCWs are specified. Format-0 and format-1 CCWs contain the same information, but the fields are arranged differently in the format-1 CCW so that 31-bit addresses can be specified directly in the CCW. When facilities become available and the ORB specifies a TCW channel program, the channel subsystem fetches the designated TCW and transports the designated TCCB to the device. Storage areas designated by the TCW for the transfer of data to or from the device are 64-bit addresses.

Subchannel Operation Modes

There are two modes of subchannel operation. A subchannel enters transport mode when the FCX facility is installed and the start function is set at the subchannel as the result of the execution of a START SUBCHANNEL instruction that specifies a TCW channel program. The subchannel remains in transport mode until the start function is reset at the subchannel. At all other times, the subchannel is in command mode.

Path Management

If ORB specifies a CCW channel program and the first CCW passes certain validity tests and does not have the suspend flag specified as one or if the ORB specifies a TCW channel program and the designated TCW passes certain validity tests, the channel subsystem attempts device selection by choosing a channel path from the group of channel paths that are available for selection. A control unit that recognizes the device identifier connects itself logically to the channel path and responds to its selection.

If the ORB specifies a CCW channel program, the channel subsystem sends the command-code part of the CCW over the channel path, and the device responds with a status byte indicating whether the command can be executed. The control unit may logically disconnect from the channel path at this time, or it may remain connected to initiate data transfer.

If the ORB specifies a TCW channel program, the channel subsystem uses information in the designated TCW to transfer the TCCB to the control unit. The contents of the TCCB are ignored by the channel subsystem and only have meaning to the control unit and I/O device.

If the attempted selection does not occur as a result of either a busy indication or a path-not-operational condition, the channel subsystem attempts to select the device by an alternate channel path if one is available. When selection has been attempted on all paths available for selection and the busy condition persists, the operation remains pending until a path becomes free. If a path-not-operational condition is detected on one or more of the channel paths on which device selection was attempted, the program is alerted by a subsequent I/O interruption. The I/O interruption occurs either upon execution of the channel program (assuming the device was selected on an alternate channel path) or as a result of the execution being abandoned because path-not-operational conditions were detected on all of the channel paths on which device selection was attempted.

Channel-Program Execution

If the command is initiated at the device and command execution does not require any data to be transferred to or from the device, the device may signal the end of the operation immediately on receipt of the command code. In operations that involve the transfer of data, the subchannel is set up so that the channel subsystem will respond to service requests from the device and assume further control of the operation.

An I/O operation may involve the transfer of data to or from one storage area, designated by a single CCW or TCW or to or from a number of noncontiguous storage areas. In the latter case, generally a list of CCWs is used for the execution of the I/O operation, with each CCW designating a contiguous storage area and the CCWs are coupled by data chaining. Data chaining is specified by a flag in the CCW and causes the channel subsystem to fetch another CCW upon the exhaustion or filling of the storage area designated by the current CCW. The storage area designated by a CCW fetched on data chaining pertains to the I/O operation already in progress at the I/O device, and the I/O device is not notified when a new CCW is fetched.

Provision is made in the CCW format for the programmer to specify that, when the CCW is decoded, the channel subsystem request an I/O interruption as soon as possible, thereby notifying a CPU program that chaining has progressed at least as far as that CCW in the channel program.

To complement dynamic address translation in CPUs, CCW indirect data addressing and modified CCW indirect data addressing are provided.

When the ORB specifies a CCW channel program and CCW-indirect-data addressing is used, a flag in the CCW specifies that an indirect-data-address list is to be used to designate the storage areas for that CCW. Each time the boundary of a block of storage is reached, the list is referenced to determine the next block of storage to be used. The ORB specifies whether the size of each block of storage is 2K bytes or 4K bytes.

When the ORB specifies a CCW channel program and modified-CCW-indirect-data addressing is used, a flag in the ORB and a flag in the CCW specify that a modified-indirect-data-address list is to be used to designate the storage areas for that CCW. Each time the count of bytes specified for a block of storage is reached, the list is referenced to determine the next block of storage to be used. Unlike when indirect data addressing is used, the block may be specified on any boundary and length up to 4K, provided a data transfer across a 4 K-byte boundary is not specified.

When the ORB specifies a TCW channel progr-amand transport-indirect-data addressing is used, flags in the TCW specify whether a transport-indirect-data-address list is to be used to designate the storage areas containing the TCCB and whether a transport-indirect-data-address list is used to designate the data storage areas associated with the DCWs in the TCCB. Each time the count of bytes specified for a block of storage is reached, the corresponding transport-indirect-data-address list is referenced to determine the next storage block to be used.

CCW indirect data addressing and modified CCW indirect data addressing permit essentially the same CCW sequences to be used for a program running with dynamic address translation active in the CPU as would be used if the CPU were operating with equivalent contiguous real storage. CCW indirect data addressing permits the program to designate data blocks having absolute storage addresses up to 2^{64}-1 independent of whether format-0 or format-1 CCWs have been specified in the ORB. Modified CCW indirect data addressing permits the program to designate data blocks having absolute storage addresses up to 2^{64}-1, independent of whether format-0 or format-1 CCWs have been specified in the ORB.

In general, the execution of an I/O operation or chain of operations involves as many as three levels of participation:

1. Except for effects due to the integration of CPU and channel-subsystem equipment, a CPU is busy for the duration of the execution of START SUBCHANNEL, which lasts until the addressed subchannel has been passed the ORB contents.

2. The subchannel is busy for a new START SUB-CHANNEL from the receipt of the ORB contents until the primary interruption condition is cleared at the subchannel.

3. The I/O device is busy from the initiation of the first operation at the device until either the subchannel becomes suspended or the secondary interruption condition is placed at the subchannel. In the case of a suspended subchannel, the device again becomes busy when the execution of the suspended channel program is resumed.

Conclusion of I/O Operations

The conclusion of an I/O operation normally is indicated by two status conditions: channel end and device end. The channel-end condition indicates that the I/O device has received or provided all data associated with the operation and no longer needs channel-subsystem facilities. This condition is called the primary interruption condition, and the channel end in this case is the primary status. Generally, the primary interruption condition is any interruption condition that relates to an I/O operation and that signals the conclusion at the subchannel of the I/O operation or chain of I/O operations.

The device-end signal indicates that the I/O device has concluded execution and is ready to perform another operation. This condition is called the secondary interruption condition, and the device end in this case is the secondary status. Generally, the secondary interruption condition is any interruption condition that relates to an I/O operation and that signals the conclusion at the device of the I/O operation or chain of operations. The secondary interruption condition can occur concurrently with, or later than, the primary interruption condition.

Concurrent with the primary or secondary interruption conditions, both the channel subsystem and the I/O device can provide indications of unusual situations.

The conditions signaling the conclusion of an I/O operation can be brought to the attention of the program by I/O interruptions or, when the CPUs are dis-

abled for I/O interruptions, by programmed interrogation of the channel subsystem. In the former case, these conditions cause storing of the I/O-interruption code, which contains information concerning the interrupting source. In the latter case, the interruption code is stored as a result of the execution of TEST PENDING INTERRUPTION.

When the primary interruption condition is recognized, the channel subsystem attempts to notify the program, by means of an interruption request, that a subchannel contains information describing the conclusion of an I/O operation at the subchannel. For command-mode interruptions, the information identifies the last CCW used and may provide its residual byte count, thus describing the extent of main storage used. For transport-mode interruptions, the information identifies the current TCW and the TSB associated with the channel program that contains additional status about the I/O operation, such as residual byte count. In addition to information about the channel program, both the channel subsystem and the I/O device may provide additional indications of unusual conditions as part of either the primary or the secondary interruption condition. The information contained at the subchannel may be stored by the execution of TEST SUBCHANNEL or the execution of STORE SUBCHANNEL. This information, when stored, is called a subchannel-status word (SCSW).

Chaining When Using a CCW Channel Program

When the ORB specifies a CCW channel program, facilities are provided for the program to initiate the execution of a chain of I/O operations with a single START SUBCHANNEL instruction. When the current CCW specifies command chaining and no unusual conditions have been detected during the operation, the receipt of the device-end signal causes the channel subsystem to fetch a new CCW. If the CCW passes certain validity tests and the suspend flag is not specified as a one in the new CCW, execution of a new command is initiated at the device. If the CCW fails to pass the validity tests, the new command is not initiated, command chaining is suppressed, and the status associated with the new CCW causes an interruption condition to be generated. If the suspend flag is specified as a one and this value is valid because of a one value in the suspend control, bit 4 of word 1 of the associated ORB, execution of the new command is not initiated, and command chaining is concluded.

Execution of the new command is initiated by the channel subsystem in the same way as in the previous operation. The ending signals occurring at the conclusion of an operation caused by a CCW specifying command chaining are not made available to the program. When another I/O operation is initiated by command chaining, the channel subsystem continues execution of the channel program. If, however, an unusual condition has been detected, command chaining is suppressed, the channel program is terminated, an interruption condition is generated, and the ending signals causing the termination are made available to the program.

The suspend-and-resume function provides the program with control over the execution of a channel program. The initiation of the suspend function is controlled by the setting of the suspend-control bit in the ORB. The suspend function is signaled to the channel subsystem during channel-program execution when the suspend-control bit in the ORB is one and the suspend flag in the first CCW or in a CCW fetched during command chaining is one.

Suspension occurs when the channel subsystem fetches a CCW with the suspend flag validly (because of a one value of the suspend-control bit in the ORB) specified as one. The command in this CCW is not sent to the I/O device, and the device is signaled that the chain of commands is concluded. A subsequent RESUME SUBCHANNEL instruction informs the channel subsystem that the CCW that caused suspension may have been modified and that the channel subsystem must refetch the CCW and examine the current setting of the suspend flag. If the suspend flag is found to be zero in the CCW, the channel subsystem resumes execution of the chain of commands with the I/O device.

Chaining When Using a TCW Channel Program

When the ORB specifies a TCW channel program, facilities are also provided for the program to initiate the execution of a chain of device operations with a single START SUBCHANNEL instruction. Command chaining may be specified for those DCWs designated by a single TCW. When the current DCW specifies command chaining and no unusual conditions have been detected during the operation, recognition of the successful execution of the DCW causes the next DCW in the current TCCB to be processed.

If the next DCW passes certain validity tests, execution of a new command is initiated at the device and the DCW becomes the current DCW. If the DCW fails to pass the validity tests, the new command is not initiated, command chaining is suppressed, the channel program is terminated, and the status associated with the new DCW causes an interruption condition to be generated.

Execution of the new command is initiated in the same way as in the previous operation. The ending signals occurring at the conclusion of an operation caused by a DCW that is not the last specified DCW are not made available to the program. When another I/O operation is initiated by command chaining, execution of the channel program continues. If, however, an unusual condition has been detected, command chaining is suppressed, the channel program is terminated, an interruption condition is generated, and status is made available to the program that identifies the unusual condition.

Premature Conclusion of I/O Operations

Channel-program execution may be terminated prematurely by CANCEL SUBCHANNEL, HALT SUBCHANNEL or CLEAR SUBCHANNEL. The execution of CANCEL SUBCHANNEL causes the channel subsystem to terminate the start function at the subchannel if the channel program has not been initiated at the device. When the start function is terminated by the execution of CANCEL SUBCHANNEL, the channel subsystem sets condition code 0 in response to the CANCEL SUBCHANNEL instruction. The execution of HALT SUBCHANNEL causes the channel subsystem to issue the halt signal to the I/O device and terminate channel-program execution at the subchannel. When channel-program execution is terminated by the execution of HALT SUBCHANNEL, the program is notified of the termination by means of an I/O-interruption request. When the subchannel is in command mode, the interruption request is generated when the device presents status for the terminated operation. When the subchannel is in transport mode, the interruption request is generated immediately.If, however, the halt signal was issued to the device during command chaining after the receipt of device end but before the next command was transferred to the device, the interruption request is generated after the device has been signaled. In the latter case, the device-status field of the SCSW will contain zeros. The execution of CLEAR SUBCHANNEL clears the subchannel of indications of the channel program in execution, causes the channel subsystem to issue the clear signal to the I/O device, and causes the channel subsystem to generate an I/O-interruption request to notify the program of the completion of the clear function.

I/O Interruptions

Conditions causing I/O-interruption requests are asynchronous to activity in CPUs, and more than one condition can occur at the same time. For I/O interruptions associated with subchannels, the conditions are preserved at the subchannels until cleared by TEST SUBCHANNEL or CLEAR SUBCHANNEL, or reset by an I/O-system reset.

When an I/O-interruption condition has been recognized by the channel subsystem and indicated at the subchannel, an I/O-interruption request is made pending for the I/O-interruption subclass specified at the subchannel. The I/O-interruption subclass for which the interruption is made pending is under programmed control through the use of MODIFY SUBCHANNEL. A pending I/O interruption may be accepted by any CPU that is enabled for interruptions from its I/O-interruption subclass. Each CPU has eight mask bits, in control register 6, that control the enablement of that CPU for each of the eight I/O-interruption subclasses, with the I/O mask, bit 6 in the PSW, being the master I/O-interruption mask for the CPU.

When an I/O interruption occurs at a CPU, the I/O-interruption code is stored in real locations 184-195, and the I/O-interruption request is cleared. For I/O interruptions associated with subchannels, the I/O-interruption code identifies the subchannel for which the interruption was pending. The conditions causing the generation of the interruption request associated with the subchannel may then be retrieved from the subchannel explicitly by TEST SUBCHANNEL or by STORE SUBCHANNEL.

A pending I/O-interruption request may also be cleared by TEST PENDING INTERRUPTION when the corresponding I/O-interruption subclass is enabled but the PSW has I/O interruptions disabled. For I/O interruptions associated with subchannels, a pending I/O interruption may also be cleared by TEST SUBCHANNEL when the CPU is disabled for I/O interruptions from the corresponding I/O-interruption subclass. A pending I/O-interruption request associated with a subchannel may also be cleared by CLEAR SUBCHANNEL. Both CLEAR SUBCHAN-

NEL and TEST SUBCHANNEL clear the preserved interruption condition at the subchannel as well.

Normally, unless the interruption request is cleared by CLEAR SUBCHANNEL, the program issues TEST SUBCHANNEL to obtain subchannel information concerning the execution of the operation.

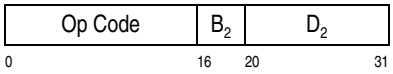
TEST SUBCHANNEL 14-21

All the I/O instructions described here are provided for the control of channel-subsystem operations. The I/O instructions are listed in Figure 14-1 on page 14-3. All of the I/O instructions are privileged instructions.

Several I/O instructions result in the channel subsystem being signaled to perform functions asynchronous to the execution of the instructions. The description of each instruction of this type contains a section, “Associated Functions,” that summarizes the asynchronous functions.

I/O-Instruction Formats

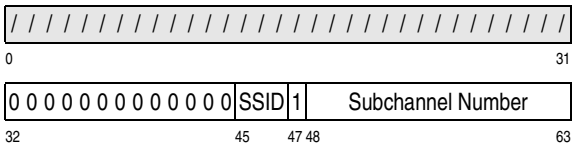
I/O instructions use the S format:



The use of the second-operand address and general registers 1 and 2 (as implied operands) depends on the I/O instruction. Figure 14-1 on page 14-3 defines which operands are used to execute each I/O instruction. In addition, detailed information regarding operand usage appears in the description of each I/O instruction.

All I/O instructions that reference a subchannel use the contents of general register 1 as an implied operand. For these I/O instructions, general register 1 contains the subsystem-identification word (SID).

When the multiple-subchannel set (MSS) facility is installed, the format of the subsystem-identification word is as follows:



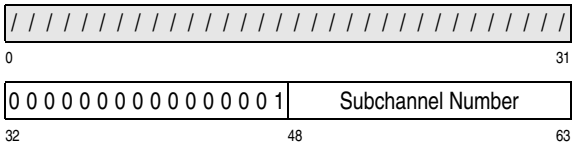
Bit positions 0-31 are ignored. Bit positions 32-44 must contain zeros and bit 47 must contain 1. (Exception conditions are listed later in the section.)

Bit positions 45-46 of general register 1 contain the subchannel-set identifier (SSID) uniquely identifying a subchannel set (SS). When the multiple-subchannel-set facility is not installed, the SSID must be equal to zero. Bit positions 48-63 of general register 1 contain the binary number of the subchannel within the specified subchannel set to be used for the function specified by the instruction**.**

(See “Multiple-Subchannel-Set Facility” on page 17-34 for more information on SSID.)

The format of the subsystem-identification word when the MSS facility is not installed is as follows:

© Copyright IBM Corp. 2000, 2025



Bit positions 48-63 of general register 1 contain the binary number of the subchannel to be used for the function specified by the instruction. Bit positions 0-31 of general register 1 are ignored and bits 32-47 specify the binary number one.

I/O-Instruction Execution

Serialization

The execution of any I/O instruction causes a serialization and checkpoint synchronization function to occur. For a definition of the serialization of CPU operations,see “CPU Serialization” on page 5-138 and “Channel-Program Serialization” on page 5-141.

Operand Access

During the execution of an I/O instruction, the order in which fields of the operand and fields of the subchannel, if applicable, are accessed is unpredictable. It is also unpredictable whether fetch accesses are made to fields of an operand or the subchannel, as applicable, when those fields are not needed to complete the execution of the I/O instruction. (See “Relation between Operand Accesses” on page 5-137.)

Condition Code

During the execution of some I/O instructions, the results of certain tests are used to set one of four condition codes in the PSW. The I/O instructions for which execution can result in the setting of the condition code are listed in Figure 14-1 on page 14-3. The condition code indicates the result of the execution of the I/O instruction. The general meaning of the condition code for I/O instructions is given below; the meaning of the condition code for a specific instruction appears in the description of that instruction.

Condition Code 0: Instruction execution produced the expected or most probable result. (See “Deferred Condition Code (CC)” on page 16-9 for a description of conditions that can be encountered subsequent to the presentation of condition code 0 that result in a nonzero deferred condition code.)

Condition Code 1: Instruction execution produced the alternate or second-most-probable result, or status conditions were present that may or may not have prevented the expected result.

Condition Code 2: Instruction execution was ineffective because the designated subchannel or channel-subsystem facility was busy with a previously initiated function.

Condition Code 3: Instruction execution was ineffective because the designated element was not operational or because some condition precluded initiation of the normal function.

In situations where conditions exist that could cause more than one nonzero condition code to be set, the priority of the condition codes is as follows:

Condition code 3 has precedence over condition codes 1 and 2.

Condition code 1 has precedence over condition code 2.

Program Exceptions

The program exceptions that the I/O instructions can encounter are access, operand, privileged-operation, and specification exceptions. Figure 14-1 on page 14-3 shows the exceptions that are applicable to each of the I/O instructions. The execution of the instruction is suppressed for privileged-operation, operand, and specification exceptions. Except as indicated otherwise in the section “Special Conditions” for each instruction, the instruction ending for access exceptions is as described in “Recognition of Access Exceptions” on page 6-49).

Instructions

The mnemonics, format, and operation codes of the I/O instructions are given in Figure 14-1 on page 14-3. The figure also indicates the conditions that can cause a program interruption and whether the condition code is set.

In the detailed descriptions of the individual instructions, the mnemonic and the symbolic operand designation for the assembler language are shown with each instruction. For START SUBCHANNEL, for example, SSCH is the mnemonic and $D_2(B_2)$ the operand designation.

Name	Mnemonic	Characteristics									Opcode	Page
CANCEL SUBCHANNEL	XSCH	S	C	P			OP	¢	GS			B276	14-3

Explanation:

*	PER zero-address-detection not recognized
¢	Causes a serialization and checkpoint synchronization function.
A	Access exceptions for logical addresses.
A^1	When the effective address is zero, it is not used to access storage, and no access exceptions can occur, except that access exceptions may occur during access-register translation.
B_2	B_2 field designates an access register in the access-register mode.
C	Condition code is set.
G1	Instruction execution includes implied use of general register 1 as a parameter.
GM	Instruction execution includes the implied use of multiple general registers: • General registers 1 and 2 for SET CHANNEL MONITOR.
GS	Instruction execution includes the implied use of general register 1 as the subsystem-identification word.
OP	Operand exception.
P	Privileged-operation exception; also, restricted from transactional execution.
S	S instruction format.
SP	Specification exception.
ST	PER storage-alteration event.

Figure 14-1. Summary of I/O Instructions

CANCEL SUBCHANNEL

XSCH [S]

The current start function, if any, is terminated at the designated subchannel if CANCEL SUBCHANNEL is applicable.

General register 1 contains a subsystem-identification word that designates the subchannel for which the current START FUNCTION, if any, is to be terminated.

If the subchannel (1) is not subchannel active, (2) is start pending, resume pending, or suspended, and (3) is performing only the start function, then the start function at the subchannel is terminated, and the subchannel is made no longer start pending, resume pending, or suspended, as appropriate. In addition, internal indications of busy are reset for the subchannel.

Condition code 0 is set to indicate that the actions described above have been taken.

If an invalid ORB field or a no-path-available condition is present for a previously initiated start function and the condition was not reported during the execu-

tion of START SUBCHANNEL, condition code 0 may be indicated for CANCEL SUBCHANNEL provided that the subchannel is not yet status pending to report the error condition; if condition code 0 is presented, no subsequent status is generated to indicate the error condition.

During the execution of CANCEL SUBCHANNEL for a transport-mode operation, the channel subsystem may be signaled to asynchronously perform the interrogate function.

Special Conditions

Condition code 1 is set, and no other action is taken, when the subchannel is status pending with any status.

Condition code 2 is set, and no other action is taken, when CANCEL SUBCHANNEL is not applicable and the subchannel is not status pending, or when conditions exist that prevent immediate determination of internal conditions for the subchannel and the CPU has determined to end the instruction. CANCEL SUBCHANNEL is not applicable when the subchannel (1) has no function specified, (2) has a function other than the start function alone specified, (3) is not resume pending, is not start pending, and is not suspended, or (4) is subchannel active.

When the subchannel is operating in transport mode and condition code 2 is set, the CPU may signal the channel subsystem to asynchronously perform the interrogate function, and end the instruction.

Condition code 3 is set, and no other action is taken, when the subchannel is not operational for CANCEL SUBCHANNEL. A subchannel is not operational for CANCEL SUBCHANNEL when the subchannel is not provided by the channel subsystem, has no valid device number assigned to it, or is not enabled.

CANCEL SUBCHANNEL can encounter the program exceptions described or listed below.

When the multiple-subchannel-set facility is not installed, bits 32-47of general register 1 must contain 0001 hex; otherwise, an operand exception is recognized.

When the multiple-subchannel-set facility is installed, bits 32-44 of general register 1 must contain zeros, bits 45-46 must contain a valid value, and bit 47 must contain the value one; otherwise, an operand exception is recognized.

Resulting Condition Code:

0 Start function canceled
1 Status pending
2 CANCEL SUBCHANNEL not applicable
3 Not operational

Program Exceptions:

- Operand
- Privileged operation
- Transaction constraint

Programming Notes:

1. The actions taken by CANCEL SUBCHANNEL are completed during the execution of the instruction.

   If condition code 0 is presented, there is no subsequent I/O interruption resulting from the terminated I/O operation. However, the device may have signaled a busy condition while the canceled operation was start pending. In this case, the device owes a no-longer-busy signal to the channel subsystem. This may result in unsolicited device-end status before the next operation is initiated at the device.

   Condition code 2 may be presented to indicate that the CPU has determined to end the instruction because the internal conditions of the specified subchannel cannot be immediately determined. Subsequent execution of STORE SUBCHANNEL may store an SCSW indicating that CANCEL SUBCHANNEL is applicable (i.e., the subchannel is performing the start function alone, is start pending, resume pending, or suspended, and is not subchannel-active). In such a case, the program can either recognize that the I/O operation has not been terminated and allow the operation to start or the program can retry CANCEL SUBCHANNEL in an attempt to terminate the start function. However, retrying CANCEL SUBCHANNEL does not guarantee that the instruction will end with condition code 0.

   In transport mode, condition code 2 may be presented to indicate that the CPU has determined to asynchronously signal the channel subsystem to perform the interrogate function, and end the

instruction. The LPUM must contain a nonzero value for the interrogate to be initiated.

2. Upon the completion of CANCEL SUBCHANNEL with condition code 0, the subchannel is ready to accept a new start function initiated by START SUBCHANNEL.

CLEAR SUBCHANNEL

CSCH [S]

The designated subchannel is cleared, the current start or halt function, if any, is terminated at the designated subchannel, and the channel subsystem is signaled to asynchronously perform the clear function at the designated subchannel and at the associated device.

General register 1 contains a subsystem-identification word (SID) that designates the subchannel to be cleared.

If a start or halt function is in progress, it is terminated at the subchannel.

The subchannel is made no longer status pending. All activity, as indicated in the activity-control field of the SCSW, is cleared at the subchannel, except that the subchannel is made clear pending. Any functions in progress, as indicated in the function-control field of the SCSW, are cleared at the subchannel, except for the clear function that is to be performed because of the execution of this instruction.

The channel subsystem is signaled to asynchronously perform the clear function. The clear function is summarized below in the section “Associated Functions” and is described in detail in “Clear Function” on page 15-14.

Condition code 0 is set to indicate that the actions described above have been taken.

Associated Functions

Subsequent to the execution of CLEAR SUBCHANNEL, the channel subsystem asynchronously performs the clear function. If conditions allow, the channel subsystem chooses a channel path and attempts to issue the clear signal to the device to terminate the I/O operation, if any. The subchannel then becomes status pending. Conditions encountered by the channel subsystem that preclude issuing the clear signal to the device do not prevent the subchannel from becoming status pending (see “Clear Function” on page 15-14).

When the subchannel becomes status pending as a result of performing the clear function, data transfer, if any, with the associated device has been terminated. The SCSW stored when the resulting status is cleared by TEST SUBCHANNEL has the clear-function bit stored as one. If the channel subsystem can determine that the clear signal was issued to the device, the clear-pending bit is stored as zero in the SCSW. Otherwise, the clear-pending bit is stored as one, and other indications are provided that describe in greater detail the condition that was encountered. (See “Interruption-Response Block” on page 16-6.)

Measurement data is not accumulated, and device-connect time is not stored in the extended-status word for the subchannel, for a start function that is terminated by CLEAR SUBCHANNEL.

Special Conditions

Condition code 3 is set, and no other action is taken, when the subchannel is not operational for CLEAR SUBCHANNEL. A subchannel is not operational for CLEAR SUBCHANNEL when the subchannel is not provided in the channel subsystem, has no valid device number assigned to it, or is not enabled.

CLEAR SUBCHANNEL can encounter the program exceptions described or listed below.

When the multiple-subchannel-set facility is not installed, bits 32-47 of general register 1 must contain 0001 hex; otherwise, an operand exception is recognized.

When the multiple-subchannel-set facility is installed, bits 32-44 of general register 1 must contain zeros, bits 45-46 must contain a valid value, and bit 47 must contain the value one; otherwise, an operand exception is recognized.

Resulting Condition Code:

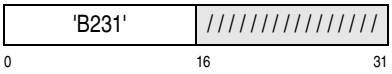
0 Function initiated
1 —
2 —
3 Not operational

Program Exceptions:

- Operand
- Privileged operation
- Transaction constraint

HALT SUBCHANNEL

HSCH [S]



The current start function, if any, is terminated at the designated subchannel, and the channel subsystem is signaled to asynchronously perform the halt function at the designated subchannel and at the associated device.

General register 1 contains a subsystem-identification word that designates the subchannel to be halted.

If a start function is in progress, it is terminated at the subchannel.

The subchannel is made halt pending, and the halt function is indicated at the subchannel.

When HALT SUBCHANNEL is executed and the designated subchannel is subchannel-and-device active and status pending with intermediate status, the status-pending indication is eliminated (see the discussion of bits 24, 25, and 28 in “Activity Control (AC)” on page 16-14). The status-pending condition is reestablished as part of the halt function (see the section “Associated Functions” below).

The channel subsystem is signaled to asynchronously perform the halt function. The halt function is summarized below in the section “Associated Functions” and is described in detail in “Halt Function” on page 15-16.

Condition code 0 is set to indicate that the actions described above have been taken.

Associated Functions

Subsequent to the execution of HALT SUBCHANNEL, the channel subsystem asynchronously performs the halt function. If conditions allow, the channel subsystem chooses a channel path and attempts to issue the halt signal to the device to terminate the I/O operation, if any. The subchannel then becomes status pending.

When the subchannel becomes status pending as a result of performing the halt function, data transfer, if any, with the associated device has been terminated. The SCSW stored when the resulting status is cleared by TEST SUBCHANNEL has the halt-function bit stored as one. If the halt signal was issued to the device, the halt-pending bit is stored as zero. Otherwise, the halt-pending bit is stored as one, and other indications are provided that describe in greater detail the condition that was encountered. (See “Interruption-Response Block” on page 16-6. and “Halt Function” on page 15-16.)

On some models, path availability is tested as part of the halt function instead of as part of the execution of the instruction. In these models, when no channel path is available for selection, the halt signal is not issued, and the subchannel is made status pending. When the status-pending condition is subsequently cleared by TEST SUBCHANNEL, the halt-pending bit is stored as one in the SCSW.

If a status-pending condition is eliminated during the execution of HALT SUBCHANNEL, then this condition is reestablished along with the other status conditions when the completion of the halt function is indicated to the program.

The halt-pending condition may not be recognized by the channel subsystem if a status-pending condition has been generated. This situation could occur, for example, when alert status is presented or generated while the subchannel is already start pending or resume pending, or when primary status is presented during the attempt to initiate the I/O operation for the first command as specified by the start function or implied by the resume function. If recognition of the status-pending condition by the channel subsystem has occurred logically prior to recognition of the halt-pending condition, the SCSW, when cleared by TEST SUBCHANNEL, has the halt-pending bit stored as one.

If measurement data is being accumulated when a start function is terminated by HALT SUBCHANNEL, the measurement data continues to be accumulated for the subchannel and reflects the extent of subchannel and device usage required, if any, while performing the currently terminated start function. The measurement data, if any, is accumulated in the measurement block for the subchannel or placed in the extended-status word, as appropriate, when the subchannel becomes status-pending with primary or secondary status. (See "Channel-Subsystem Monitoring" on page 17-1.)

Special Conditions

Condition code 1 is set, and no other action is taken, when the subchannel is status pending alone or is status pending with any combination of alert, primary, or secondary status.

Condition code 2 is set, and no other action is taken, when the subchannel is busy for HALT SUBCHANNEL. The subchannel is busy for HALT SUBCHANNEL when a halt function or clear function is already in progress at the subchannel.

Condition code 3 is set, and no other action is taken, when the subchannel is not operational for HALT SUBCHANNEL. A subchannel is not operational for HALT SUBCHANNEL when the subchannel is not provided in the channel subsystem, has no valid device number assigned to it, or is not enabled. On some models, a subchannel is also not operational for HALT SUBCHANNEL when no channel path is available for selection by the device. (See "Channel-Path Availability" on page 15-13 for a description of channel paths that are available for selection.)

HALT SUBCHANNEL can encounter the program exceptions described or listed below.

When the multiple-subchannel-set facility is not installed, bits 32-47 of general register 1 must contain 0001 hex; otherwise, an operand exception is recognized.

When the multiple-subchannel-set facility is installed, bits 32-44 of general register 1 must contain zeros, bits 45-46 must contain a valid value, and bit 47 must contain the value one; otherwise, an operand exception is recognized.

Resulting Condition Code:

0 Function initiated
1 Status pending with other than intermediate status
2 Busy
3 Not operational

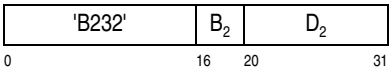
Program Exceptions:

- Operand
- Privileged operation
- Transaction constraint

Programming Note: After the execution of HALT SUBCHANNEL, the status-pending condition indicating the completion of the halt function may be delayed for an extended period of time, for example, when the device is a magnetic-tape unit executing a rewind command.

MODIFY SUBCHANNEL

MSCH $D_2(B_2)$ [S]



The information contained in the subchannel-information block (SCHIB) is placed in the program-modifiable fields at the subchannel. As a result, the program influences, for that subchannel, certain aspects of I/O processing relative to the clear, halt, resume, and start functions and certain I/O support functions.

General register 1 contains a subsystem-identification word (SID) that designates the subchannel that is to be modified as specified by certain fields of the SCHIB. The second-operand address is the logical address of the SCHIB and must be designated on a word boundary; otherwise, a specification exception is recognized.

The channel-subsystem operations that may be influenced due to placement of SCHIB information in the subchannel are:

- I/O processing (E field)
- Interruption processing (interruption parameter and ISC field)
- Path management (D, LPM, and POM fields)
- Monitoring and address-limit checking (measurement-block index, LM, and MM fields)
- Measurement-block-format control (F field)
- Extended-measurement-word-mode enable (X field)
- Concurrent-sense facility (S field)
- Measurement-block address (MBA)

Bits 0, 1, 6, and 7 of word 1, and bits 0-28 of word 6 of the SCHIB operand must be zeros, and bits 9 and 10 of word 1 must not both be ones. When the extended-I/O-measurement-block facility is installed and a format-1 measurement block is specified, bits 26-31 of word 11 must be specified as zeros. When the extended-I/O-measurement-block facility is not installed, bit 29 of word 6 must be specified as zero; otherwise, an operand exception is recognized. When the extended-I/O-measurement-word facility is not installed, or is installed but not enabled, bit 30 of word 6 must be specified as zero; otherwise, an operand exception is recognized. The remaining fields of the SCHIB are ignored and do not affect the processing of MODIFY SUBCHANNEL. (For further details, see "Subchannel-Information Block" on page 15-2.)

Condition code 0 is set to indicate that the information from the SCHIB has been placed in the program-modifiable fields at the subchannel, except that, when the device-number-valid bit (V) at the designated subchannel is zero, then condition code 0 is set, and the information from the SCHIB is not placed in the program-modifiable fields.

Special Conditions

Condition code 1 is set, and no other action is taken, when the subchannel is status pending. (See "Status Control (SC)" on page 16-17.)

Condition code 2 is set, and no other action is taken, when a clear, halt, or start function is in progress at the subchannel. (See "Function Control (FC)" on page 16-13.)

Condition code 3 is set, and no other action is taken, when the subchannel is not operational for MODIFY SUBCHANNEL. A subchannel is not operational for MODIFY SUBCHANNEL when the subchannel is not provided in the channel subsystem.

MODIFY SUBCHANNEL can encounter the program exceptions described or listed below.

In word 1 of the SCHIB, bits 0, 1, 6, and 7 must be zeros and, when the address-limit-checking facility is installed, bits 9 and 10 must not both be ones. In word 6 of the SCHIB, bits 0-28 must be zeros. Otherwise an operand exception is recognized.

When the extended-I/O-measurement-block facility is installed and a format-1 measurement block is specified, bits 26-31 of word 11 must be specified as zeros; otherwise, an operand exception is recognized. When the extended-I/O-measurement-block facility is not installed, bit 29 of word 6 must be specified as zero; otherwise, an operand exception is recognized. When the extended-I/O-measurement-word facility is not installed, or is installed but not enabled, bit 30 of word 6 must be specified as zero; otherwise, an operand exception is recognized.

When the multiple-subchannel-set facility is not installed, bits 32-47 of general register 1 must contain 0001 hex; otherwise, an operand exception is recognized.

When the multiple-subchannel-set facility is installed, bits 32-44 of general register 1 must contain zeros, bits 45-46 must contain a valid value, and bit 47 must contain the value one; otherwise, an operand exception is recognized.

The second operand must be designated on a word boundary; otherwise, a specification exception is recognized.

The execution of MODIFY SUBCHANNEL is suppressed on all addressing and protection exceptions.

Resulting Condition Code:

0 Function completed
1 Status pending
2 Busy
3 Not operational

Program Exceptions:

- Access (fetch, operand 2)
- Operand
- Privileged operation
- Specification
- Transaction constraint

Programming Notes:

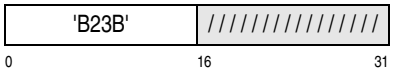
1. If a device signals I/O-error alert while the associated subchannel is disabled, the channel subsystem issues the clear signal to the device and discards the I/O-error-alert indication without generating an I/O-interruption condition.

2. If a device presents unsolicited status while the associated subchannel is disabled, that status is discarded by the channel subsystem without generating an I/O-interruption condition. However, if the status presented contains unit check, the channel subsystem issues the clear signal for the associated subchannel and does not generate an I/O-interruption condition. This should be taken into account when the program uses MODIFY SUBCHANNEL to enable a subchannel. For example, the medium on the associated device that was present when the subchannel became disabled may have been replaced, and, therefore, the program should verify the integrity of that medium.

3. It is recommended that the program inspect the contents of the subchannel by subsequently issuing STORE SUBCHANNEL when MODIFY SUBCHANNEL sets condition code 0. Use of STORE SUBCHANNEL is a method for determining if the designated subchannel was changed or not. Failure to inspect the subchannel following the setting of condition code 0 by MODIFY SUBCHANNEL may result in conditions that the program does not expect to occur.

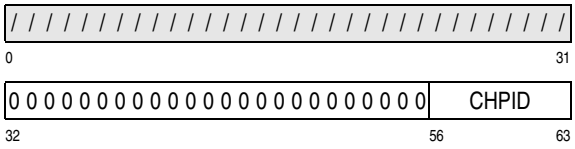
RESET CHANNEL PATH

RCHP [S]



The channel-path-reset facility is signaled to perform the channel-path-reset function on the channel path designated by the contents of general register 1.

The format of general register 1 is as follows:



Channel-Path Identifier (CHPID): Bit positions 56-63 of general register 1 contain an unsigned binary integer that designates the channel path on which the channel-path-reset function is to be performed.

Bit positions in general register 1 that are shown as zeros, are reserved and must contain zeros; otherwise, an operand exception is recognized. Bit positions 0-31 of general register 1 are ignored.

If conditions allow, the channel-path-reset facility is signaled to asynchronously perform the channel-path-reset function on the designated channel path. The channel-path-reset function is summarized below in the section “Associated Functions” and is described in detail in “Channel-Path Reset” on page 17-13.

Condition code 0 is set to indicate that the channel-path-reset facility has been signaled.

Associated Functions

Subsequent to the execution of RESET CHANNEL PATH, the channel-path-reset facility asynchronously performs the channel-path-reset function. Certain indications are reset at all subchannels that have access to the designated channel path, and the reset signal is issued on that channel path. Any I/O functions in progress at the devices are reset, but only for the channel path on which the reset signal is received. An I/O operation or chain of I/O operations taking place in the multipath mode may be able to continue to be executed on other channel paths in the multipath group, if any. (See “Channel-Path-Reset Function” on page 15-80.)

The result of performing the channel-path-reset function on the designated channel path is communicated to the program by means of a channel report (see “Channel Report” on page 17-29).

Special Conditions

Condition code 2 is set, and no other action is taken, when, on some models, the channel-path-reset facility is busy performing the channel-path-reset function for a previous execution of the RESET CHANNEL PATH instruction.

Condition code 3 is set, and no other action is taken, when, on some models, the designated channel path is not operational for the execution of RESET CHANNEL PATH. On these models, the channel path is not operational for the execution of RESET CHANNEL PATH when the designated channel path is not physically available.

If the channel-path-reset facility is busy and the designated channel path is not physically available, it depends on the model whether condition code 2 or 3 is set.

RESET CHANNEL PATH can encounter the program exceptions described or listed below.

Bit positions 32-55 of general register 1 must contain zeros; otherwise, an operand exception is recognized. Bit positions 0-31 of general register 1 are ignored.

Resulting Condition Code:

0 Function initiated
1 —
2 Busy
3 Not operational

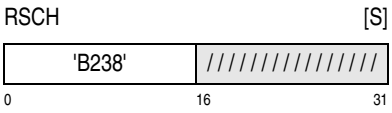
Program Exceptions:

- Operand
- Privileged operation
- Transaction constraint

Programming Notes:

1. To eliminate the possibility of a data-integrity exposure for devices that have the capability of generating unsolicited device-end status, I/O operations in progress with such devices on the channel path for which RESET CHANNEL PATH is to be executed must be terminated by the execution of either HALT SUBCHANNEL or CLEAR SUBCHANNEL. Otherwise, subsequent to receiving the reset signal, the device may present an unsolicited device end that may be interpreted by the channel subsystem as a solicited device end and cause command chaining to occur.
2. If the status-verification facility is being used and RESET CHANNEL PATH is executed without first stopping all ongoing operations associated with the channel path being reset, erroneous device-status-check conditions may be detected

RESUME SUBCHANNEL



The channel subsystem is signaled to perform the resume function at the designated subchannel.

General register 1 contains a subsystem-identification word that designates the subchannel at which the resume function is to be performed.

The subchannel is made resume pending.

Logically prior to the setting of condition code 0 and only if the subchannel is currently in the suspended state, path-not-operational conditions at the subchannel, if any, are cleared.

The channel subsystem is signaled to asynchronously perform the resume function. The resume function is summarized below in the section “Associated Functions” and is described in detail in “Start Function and Resume Function” on page 15-20

Condition code 0 is set to indicate that the actions described above have been taken.

Associated Functions

Subsequent to the execution of RESUME SUBCHANNEL, the channel subsystem asynchronously performs the resume function. Except when the subchannel is subchannel active, if the execution of RESUME SUBCHANNEL results in the setting of condition code 0, performance of the resume function causes execution of a currently suspended channel program to be resumed with the associated device, provided that the suspend flag for the current CCW has been set to zero by the program. If the suspend flag remains one, execution of the channel pro-

gram remains suspended. But, if the subchannel is subchannel active at the time the execution of RESUME SUBCHANNEL results in the setting of condition code 0, then it is unpredictable whether execution of the current program is resumed or whether it is found by the resume function that the subchannel has become suspended in the interim. The subchannel is found to be suspended by the resume function only if the subchannel is status pending with intermediate status when the resume-pending condition is recognized by the channel subsystem. (See “Start Function and Resume Function” on page 15-20.)

Special Conditions

Condition code 1 is set, and no other action is taken, when the subchannel is status pending.

Condition code 2 is set, and no other action is taken, when the resume function is not applicable. The resume function is not applicable when the subchannel (1) has any function other than the start function alone specified, (2) has no function specified, (3) is resume pending, or (4) does not have suspend control specified for the start function in progress.

Condition code 3 is set, and no other action is taken, when the subchannel is not operational for the resume function. A subchannel is not operational for the resume function if the subchannel is not provided in the channel subsystem, has no valid device number assigned to it, or is not enabled.

RESUME SUBCHANNEL can encounter the program exceptions described or listed below.

When the multiple-subchannel-set facility is not installed, bits 32-47 of general register 1 must contain 0001 hex; otherwise, an operand exception is recognized.

When the multiple-subchannel-set facility is installed, bits 32-44 of general register 1 must contain zeros, bits 45-46 must contain a valid value, and bit 47 must contain the value one; otherwise, an operand exception is recognized.

Resulting Condition Code:

0 Function initiated
1 Status pending
2 Function not applicable
3 Not operational

Program Exceptions:

- Operand
- Privileged operation
- Transaction constraint

Programming Notes:

1. When channel-program execution is resumed from the suspended state, the device views the resumption as the beginning of a new chain of commands. When the suspension of channel-program execution occurs and the device requires that certain commands be first or appear only once in a chain of commands (for example, direct-access-storage devices), the program must ensure that the appropriate commands in the proper sequence are fetched by the channel subsystem after channel-program execution is resumed. One way the program can ensure proper sequencing of commands at the device is by allowing the I/O interruption to occur for an intermediate interruption condition due to suspension.

   It is not reliable to notify the program that the subchannel is suspended by using the PCI flag in the CCW that contains the S flag because the PCI I/O interruption may occur before the subchannel is suspended. The SCSW would indicate that an I/O operation is in progress at the subchannel and device in this case.

   The suspend flag of the target CCW should be set to zero before RESUME SUBCHANNEL is executed; otherwise, it is possible that the resume-pending condition may be recognized and the CCW refetched while the suspend flag is still one, in which case the resume-pending condition would be reset, and the execution of the channel program would be suspended. If the suspend flag of the target CCW is set to zero before the execution of RESUME SUBCHANNEL, the channel program is not suspended, provided that the subchannel is not subchannel active at the time the execution of RESUME SUBCHANNEL results in the setting of condition

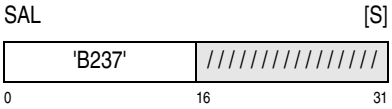
code 0. If condition code 0 is set while the subchannel is still subchannel active, it is unpredictable whether the resume-pending condition is recognized by the channel subsystem or whether it is found by the resume function that the subchannel has become suspended in the interim. The subchannel is found to be suspended by the resume function only if the subchannel is status pending with intermediate status at the time the resume-pending condition is recognized. When the subchannel is suspended, the execution of TEST SUBCHANNEL, which clears the intermediate interruption condition, also clears the indication of resume pending.

2. Some models recognize a resume-pending condition only after a CCW having an S flag validly set to one is fetched. Therefore, if a subchannel is resume pending and, during the execution of the channel program, no CCW is fetched having an S flag validly set to one, the subchannel remains resume pending until the primary interruption condition is cleared by TEST SUBCHANNEL.

3. Path availability is not tested during the execution of RESUME SUBCHANNEL. Instead, path availability is tested when the channel subsystem begins performance of the resume function.

4. The contents of the CCW fetched during performance of the resume function may be different from the contents of the same CCW when it was previously fetched and contained an S flag validly set to one.

SET ADDRESS LIMIT

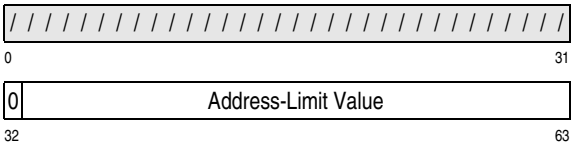


The address-limit-checking facility is signaled to use the specified address as the address-limit value, and the specified address is passed to the facility. Depending on the model, this instruction may not be provided. When this instruction is not provided, it is checked for operand exception and privileged-operation exception, and then is suppressed.

When the address-limit-checking facility is installed, the SET ADDRESS LIMIT instruction is available for use. When the address-limit-checking facility is not installed, or the FCX facility is installed, the SET ADDRESS LIMIT instruction is not provided.

General register 1 contains the absolute address to be used as the address-limit value. The specified address must be on a 64 K-byte boundary and may designate a maximum absolute storage address of 2,147,418,112 (7FFF0000 hex) regardless of whether the CPU is operating in the 24-bit, 31-bit, or 64-bit addressing mode. Bits 0-31 of general register 1 are ignored, and bit 32 must be zero.

General register 1 has the following format:



Associated Functions

The value that is used by the address-limit-checking facility when determining whether to permit or prohibit a data access is called the address-limit value. The initial address-limit value is zero. The initial address-limit value is used by the address-limit-checking facility until the facility recognizes a signal, caused by the execution of SET ADDRESS LIMIT, to use a specified address. The recognition of this specified address as the new address-limit value occurs asynchronously with respect to the execution of SET ADDRESS LIMIT.

If address-limit checking is specified for a subchannel, then whether the specified address is used by the address-limit-checking facility, when determining whether to permit or prohibit a data access, depends on whether SET ADDRESS LIMIT was executed before, during, or after the execution of START SUBCHANNEL for that subchannel. If SET ADDRESS LIMIT is executed before START SUBCHANNEL, the specified address is used by the address-limit-checking facility. If SET ADDRESS LIMIT is executed during or after the execution of START SUBCHANNEL, it is unpredictable whether the specified address is used by the address-limit-checking facility for that particular start function. For a description of the manner in which address-limit checking is performed, see “Address-Limit Checking” on page 17-27.

Special Conditions

SET ADDRESS LIMIT can encounter the program exceptions described or listed below.

The address in general register 1 must be designated on a 64K byte boundary, and bit 32 of general register 1 must be zero; otherwise, an operand exception is recognized.

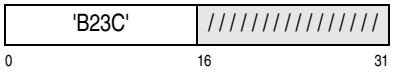
Condition Code: The code remains unchanged.

Program Exceptions:

- Operand
- Privileged operation
- Transaction constraint

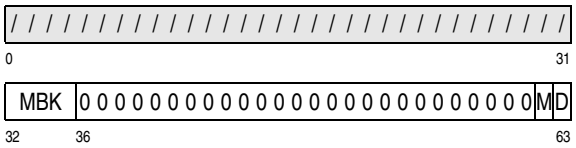
SET CHANNEL MONITOR

SCHM [S]



Each of the measurement-block-update mode and device-connect-time-measurement mode of the channel subsystem is made either active or inactive, depending on the values of the measurement-mode-control bits in general register 1. If the measurement-mode-control bit for measurement-block update is one, the measurement-block origin and measurement-block key are passed to the channel subsystem.

General register 1 has the following format:



Ignored: Bit positions 0-31 of general register 1 are ignored.

Measurement-Block Key (MBK): Bit positions 32-35 of general register 1 contain the measurement-block key. When bit 62 is one, MBK specifies the access key that is to be used by the channel subsystem when it accesses the measurement-block area and, when the extended-I/O-measurement-block facility is installed, to access format-1 measurement blocks. Otherwise, MBK is ignored.

Measurement-Block-Update Control (M): Bit 62 of general register 1 is the measurement-mode-control bit that controls the measurement-block-update mode. When bit 62 of general register 1 is one and conditions allow, the measurement-block-update facility is signaled to asynchronously make the measurement-block-update mode active. In addition, the measurement-block-origin (MBO) address in general register 2 and the measurement-block key (MBK) in general register 1 are passed to the measurement-block-update facility.

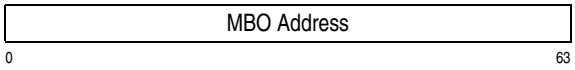
The measurement-block origin is used to determine the location of format-0 measurement blocks; the address of format-1 measurement blocks is stored at the subchannel using MODIFY SUBCHANNEL. The measurement-block key is used to access both format-0 and format-1 measurement blocks. The asynchronous functions that are performed by the measurement-block-update facility are summarized below in the section “Associated Functions” and are described in detail in “Channel-Subsystem Monitoring” on page 17-1.

When bit 62 of general register 1 is zero and conditions allow, the measurement-block-update mode is made inactive if it is active or remains inactive if it is inactive. The contents of bit positions 32-35 (MBK) of general register 1 and the contents of general register 2 are ignored.

Device-Connect-Time-Measurement Control (D): Bit 63 of general register 1 is the measurement-mode-control bit (D). When bit 63 is one and conditions allow, the device-connect-time-measurement mode is made active if it is inactive or remains active if it is active. When bit 63is zero and conditions allow, the device-connect-time-measurement mode is made inactive if it is active or remains inactive if it is inactive.

Bit positions 36-61 of general register 1 are reserved and must contain zeros; otherwise, an operand exception is recognized.

General register 2 has the following format:



Measurement-Block-Origin (MBO) Address: When bit 62 (M) of general register 1 is one, bit positions 0-63 of general register 2 contain the absolute address of the measurement-block origin (MBO), which is the beginning of the measurement-block area. The MBO address is used by the channel subsystem to locate format-0 measurement blocks. The origin of the measurement-block area must be designated on a 32-byte boundary otherwise, an operand exception is recognized. When bit 62 of general register 1 is zero, the contents of general register 2 are ignored.

If the channel-subsystem timer that is used by the channel-subsystem-monitoring facilities is in the error state, the state is reset. This happens independent of the setting of the two measurement-mode-control bits. (See "Channel-Subsystem Timing" on page 17-2 for a description of the timing facilities.)

Associated Functions

When the measurement-block-update facility is signaled (by means of SET CHANNEL MONITOR) to make the measurement-block-update mode active, the functions that are performed by the facility depend on whether or not the mode is already active when the signal is generated.

If the measurement-block-update mode is inactive when the signal is generated, the mode remains inactive until the measurement-block-update facility recognizes the signal. When the measurement-block-update facility recognizes the signal, the measurement-block-update mode is made active, and the MBK that was passed when the signal was generated is used to access all measurement blocks, and the MBO that was passed when the signal was generated is used to determine the address of format-0 measurement blocks.

If the measurement-block-update mode is active when the signal is generated, the mode remains active, and the MBK and MBO associated with the execution of a previous SET CHANNEL MONITOR instruction continue to be used to control the storing of measurement data until the measurement-block-update facility recognizes the signal. When the measurement-block-update facility recognizes the signal, the MBK and MBO associated with that signal are used instead of the MBK and MBO associated with the execution of a previous SET CHANNEL MONITOR instruction. The SET CHANNEL MONITOR instruction does not affect the measurement-block address used for format-1 measurement blocks, but the MBK associated with the signal becomes the key used to access the measurement block.

In all above cases, the measurement-block-update facility recognizes the signal during, or subsequent to, the execution of the SET CHANNEL MONITOR instruction that caused the signal to be generated and logically prior to the performance of any start function that is initiated by the subsequent execution of START SUBCHANNEL for a subchannel that is enabled for measurement by this facility. If a subchannel that is enabled for measurement by this facility already has a start function in progress when the signal is generated, it is unpredictable when measurement data for that subchannel is stored by using the MBK and MBO associated with that signal.

While the measurement-block-update mode is active, performance measurements are accumulated for subchannels that are enabled for measurement-block update. Measurements for a subchannel are either accumulated in a single 32-byte format-0 measurement block within the measurement-block area, or a 64-byte format-1 measurement block pointed to by the measurement-block address at the subchannel. A subchannel is enabled for the measurement-block-update mode by setting the measurement-block-update-enable bit to one in the SCHIB and then executing the MODIFY SUBCHANNEL instruction for that subchannel. The measurement-block-format-control bit (F) at the subchannel specifies whether a format-0 or format-1 measurement block is stored for a subchannel when the measurement-block-update mode is active and the subchannel is enabled for measurement-block updates. When the F bit is zero, the MBO and MBI are used to determine the address of the measurement block for the subchannel, and a format-0 measurement block is stored. When the F bit is one, the measurement-block-address field at the subchannel contains the address of the measurement block for the subchannel, and a format-1 measurement block is stored. The F bit and measurement-block-address field are modified using the MODIFY SUBCHANNEL instruction.

When the device-connect-time-measurement mode is active, measurements of the length of time that the device is actively communicating with the channel subsystem during the execution of a channel program are accumulated for subchannels that are enabled for device-connect-time measurement. Measurements for a subchannel are provided in the extended-status word ESW of the IRB. A subchannel

is enabled for device-connect-time-measurement mode by setting the device-connect-time-measurement-enable bit to one in the SCHIB and then executing MODIFY SUBCHANNEL for that subchannel.

For a more detailed description of the measurement-block-update mode, the format and contents of the measurement block, and the device-connect-time-measurement mode, see “Channel-Subsystem Monitoring” on page 17-1.

Special Conditions

SET CHANNEL MONITOR can encounter the program exceptions described or listed below.

Bits 36-61 of general register 1 must be zeros. When bit 62 (M) of general register 1 is one, the MBO address in general register 2 must be designated on a 32-byte boundary. When the storage-key-removal facility is installed, bits 0-3 of general register 1 must be zero. Otherwise, an operand exception is recognized.

Condition Code: The code remains unchanged.

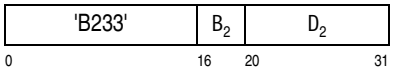
Program Exceptions:

- Operand
- Privileged operation
- Transaction constraint

Programming Note: When the channel subsystem is initialized, the measurement-block-update and device-connect-time-measurement modes are made inactive.

START SUBCHANNEL

SSCH $D_2(B_2)$ [S]



The channel subsystem is signaled to asynchronously perform the start function for the associated device, and the execution parameters that are contained in the designated ORB are placed at the designated subchannel. (See “Operation-Request Block” on page 15-24.)

General register 1 contains a subsystem-identification word that designates the subchannel to be started. The second-operand address is the logical address of the ORB and must be designated on a word boundary; otherwise, a specification exception is recognized.

The execution parameters contained in the ORB are placed at the subchannel.

When START SUBCHANNEL is executed, the subchannel is status pending with only secondary status, and the extended-status-word-format bit (L) is zero, the status-pending condition is discarded at the subchannel.

The subchannel is made start pending, and the start function is indicated at the subchannel. If the second operand designates a command-mode ORB, the subchannel remains in command mode. If the second operand designates a transport-mode ORB, the subchannel enters transport mode. When the subchannel enters transport mode, the LPUM is set to zero if no previous dedicated allegiance exists; otherwise the LPUM is not changed.

Logically prior to the setting of condition code 0, path-not-operational conditions at the subchannel, if any, are cleared.

The channel subsystem is signaled to asynchronously perform the start function. The start function is summarized below in the section “Associated Functions” and is described in detail in “Start Function and Resume Function” on page 15-20.

Condition code 0 is set to indicate that the actions described above have been taken.

Associated Functions

Subsequent to the execution of START SUBCHANNEL, the channel subsystem asynchronously performs the start function.

The contents of the ORB, other than the fields that must contain all zeros, are checked for validity. On some models, the fields of the ORB that must contain zeros are checked asynchronously, instead of during the execution of the instruction. When invalid fields are detected asynchronously, the subchannel becomes status pending with primary, secondary, and alert status and with deferred condition code 1 and program check indicated. (See “Program Check” on page 16-25.) In this situation, the I/O operation or chain of I/O operations is not initiated at the device,

and the condition is indicated by the start-pending bit being stored as one when the SCSW is cleared by the execution of TEST SUBCHANNEL. (See “Subchannel-Status Word” on page 16-7).

On some models, path availability is tested asynchronously, instead of during the execution of the instruction. When no channel path is available for selection, the subchannel becomes status pending with primary and secondary status and with deferred condition code 3 indicated. The I/O operation or chain of I/O operations is not initiated at the device, and this condition is indicated by the start-pending bit being stored as one when the SCSW is cleared by the execution of TEST SUBCHANNEL.

If conditions allow, a channel path is chosen, and execution of the channel program that is designated in the ORB is initiated. (See“Start Function and Resume Function” on page 15-20.)

Special Conditions

Condition code 1 is set, and no other action is taken, when the subchannel is status pending when START SUBCHANNEL is executed. On some models, condition code 1 is not set when the subchannel is status pending with only secondary status; instead, the status-pending condition is discarded.

Condition code 2 is set, and no other action is taken, when a start, halt, or clear function is currently in progress at the subchannel (see “Function Control (FC)” on page 16-13).

Condition code 3 is set, and no other action is taken, when the subchannel is not operational for START SUBCHANNEL. A subchannel is not operational for START SUBCHANNEL if the subchannel is not provided in the channel subsystem, has no valid device number associated with it, or is not enabled.

A subchannel is also not operational for START SUBCHANNEL, on some models, when no channel path is available for selection. On these models, the lack of an available channel path is detected as part of the START SUBCHANNEL execution. On other models, channel-path availability is only tested as part of the asynchronous start function.

START SUBCHANNEL can encounter the program exceptions described or listed below.

In word 1 of the command-mode ORB, bits 26-30 must be zeros, and, in word 2 of the command-mode ORB, bit 0 must be zero. Otherwise, on some models, an operand exception is recognized. On other models, an I/O-interruption condition is generated, indicating program check, as part of the asynchronous start function.

When the address-limit-checking facility is not installed, bit 11 of word 1 of the command-mode ORB must be zero; otherwise an operand exception is recognized.

When the storage-key-removal facility is installed, bits 0-3 of word 1 of the ORB must be zero; otherwise an operand exception is recognized.

START SUBCHANNEL can also encounter the program exceptions listed below.

When the multiple-subchannel-set facility is not installed, bits 32-47 of general register 1 must contain 0001 hex; otherwise, an operand exception is recognized.

When the multiple-subchannel-set facility is installed, bits 32-44 of general register 1 must contain zeros, bits 45-46 must contain a valid value, and bit 47 must contain the value one; otherwise, an operand exception is recognized.

The second operand must be designated on a word boundary; otherwise, a specification exception is recognized.

The execution of START SUBCHANNEL is suppressed on all addressing and protection exceptions.

Resulting Condition Code:

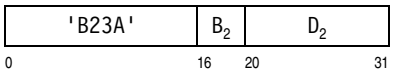
0 Function initiated
1 Status pending
2 Busy
3 Not operational

Program Exceptions:

- Access (fetch, operand 2)
- Operand
- Privileged operation
- Specification
- Transaction constraint

STORE CHANNEL PATH STATUS

STCPS $D_2(B_2)$ [S]



Depending on the model, this instruction may not be provided. When this instruction is not provided, it is checked for privileged operation exception and the instruction is suppressed by the machine

A channel-path-status word of up to 256 bits is stored at the designated location.

The second-operand address is the logical address of the location where the channel-path-status word is to be stored and must be designated on a 32-byte boundary; otherwise, a specification exception is recognized.

The channel-path-status word indicates which channel paths are actively communicating with a device at the time STORE CHANNEL PATH STATUS is executed. Bit positions 0-255 correspond, respectively, to the channel paths having the channel-path identifiers 0-255. Each of the 256 bits at the designated location is set to one, set to zero, or left unchanged, as follows:

- For all channel paths in the configuration that are actively communicating with devices at the time STORE CHANNEL PATH STATUS is executed, the corresponding bits are stored as ones.
- For all channel paths that are (1) provided in the system (PIM bit in the PMCW is one) and (2) in the configuration but not currently being used by the channel subsystem in actively communicating with devices, the corresponding bits are stored as zeros.
- For all channel paths that are not provided in the system (PIM bit in the PMCW is zero), the corresponding bits either are not stored or are stored as zeros.
- For all channel paths in the configuration that are in the channel-path-terminal state or are not physically available (the corresponding PAM bit in the PMCW is zero), the corresponding bits are stored as zeros.

Special Conditions

STORE CHANNEL PATH STATUS can encounter the program exceptions described or listed below.

The second operand must be designated on a 32-byte boundary; otherwise, a specification exception is recognized.

The execution of STORE CHANNEL PATH STATUS is suppressed on all addressing and protection exceptions.

Condition Code: The code remains unchanged.

Program Exceptions:

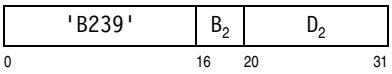
- Access (store, operand 2)
- Privileged operation
- Specification
- Transaction constraint

Programming Notes:

1. To ensure a consistent interpretation of channel-path-status-word bits, the program should, prior to the initial use of the area, store zeros at the location where the channel-path-status word is to be stored.

STORE CHANNEL REPORT WORD

STCRW $D_2(B_2)$ [S]



A CRW containing information affecting the channel subsystem is stored at the designated location.

The second-operand address is the logical address of the location where the CRW is to be stored and must be designated on a word boundary; otherwise, a specification exception is recognized.

When a malfunction or other condition affecting channel-subsystem operation is recognized, a channel report (consisting of one or more CRWs) describing the condition is made pending for retrieval and analysis by the program. The channel report contains information concerning the identity and state of a facility following the detection of the malfunction or other condition. For a description of the channel

report, the CRW, and program-recovery actions related to the channel subsystem, see “Channel-Subsystem Recovery” on page 17-29.

When one or more channel reports are pending, the instruction causes a CRW to be stored at the designated location and condition code 0 to be set. A pending CRW can only be stored by the execution of STORE CHANNEL REPORT WORD and, once stored, is no longer pending. Thus, each pending CRW is presented only once to the program.

When no channel reports are pending in the channel subsystem execution of STORE CHANNEL REPORT WORD causes zeros to be stored at the designated location and condition code 1 to be set.

Special Conditions

STORE CHANNEL REPORT WORD can encounter the program exceptions described or listed below.

The second operand must be designated on a word boundary; otherwise, a specification exception is recognized.

The execution of STORE CHANNEL REPORT WORD is suppressed on all addressing and protection exceptions.

Resulting Condition Code:

0 CRW stored
1 Zeros stored
2 —
3 —

Program Exceptions:

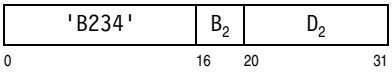
- Access (store, operand 2)
- Privileged operation
- Specification
- Transaction constraint

Programming Notes:

1. CRW overflow conditions may occur if STORE CHANNEL REPORT WORD is not executed to clear pending channel reports. If the overflow condition is encountered, one or more channel-report words have been lost. (See “Channel-Subsystem Recovery” on page 17-29 for details.)
2. A pending CRW can be cleared by any CPU in the configuration executing STORE CHANNEL REPORT WORD, regardless of whether a machine-check interruption has occurred in any CPU.

STORE SUBCHANNEL

STSCH $D_2(B_2)$ [S]



Control and status information for the designated subchannel is stored in the designated SCHIB.

General register 1 contains a subsystem-identification word that designates the subchannel for which the information is to be stored. The second-operand address is the logical address of the SCHIB and must be designated on a word boundary; otherwise, a specification exception is recognized.

When the extended-I/O-measurement-block facility is not installed, the information that is stored in the SCHIB consists of a path-management-control word, a SCSW, and three words of model-dependent information. When the extended-I/O-measurement-block facility is installed, the information that is stored in the SCHIB consists of a path-management-control word, a SCSW, the measurement-block-address field, and one word of model-dependent information. (See “Subchannel-Information Block” on page 15-2.)

The execution of STORE SUBCHANNEL does not change any information at the subchannel.

Condition code 0 is set to indicate that control and status information for the designated subchannel has been stored in the SCHIB. When the execution of STORE SUBCHANNEL results in the setting of condition code 0, the information in the SCHIB indicates a consistent state of the subchannel.

Special Conditions

Condition code 3 is set, and no other action is taken, when the designated subchannel is not operational for STORE SUBCHANNEL. A subchannel is not operational for STORE SUBCHANNEL if the subchannel is not provided in the channel subsystem.

STORE SUBCHANNEL can encounter the program exceptions described or listed below.

When the multiple-subchannel-set facility is not installed, bits 32-47 of general register 1 must contain 0001 hex; otherwise, an operand exception is recognized.

When the multiple-subchannel-set facility is installed, bits 32-44 of general register 1 must contain zeros, bits 45-46 must contain a valid value, and bit 47 must contain the value one; otherwise, an operand exception is recognized.

The second operand must be designated on a word boundary; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 SCHIB stored
1 —
2 —
3 Not operational

Program Exceptions:

- Access (store, operand 2)
- Operand
- Privileged operation
- Specification
- Transaction constraint

Programming Notes:

1. Device status that is stored in the SCSW may include device-busy, control-unit-busy, or control-unit-end indications.

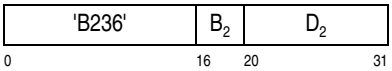
2. The information that is stored in the SCHIB is obtained from the subchannel. The STORE SUBCHANNEL instruction does not cause the channel subsystem to interrogate the addressed device.

3. STORE SUBCHANNEL may be executed at any time to sample conditions existing at the subchannel, without causing any pending status conditions to be cleared.

4. Repeated execution of STORE SUBCHANNEL without an intervening delay (for example, to determine when a subchannel changes state) should be avoided because repeated accesses of the subchannel by the CPU may delay or prohibit access of the subchannel by a channel subsystem to update the subchannel.

TEST PENDING INTERRUPTION

TPI $D_2(B_2)$ [S]



The I/O-interruption code for a pending I/O interruption at a subchannel is stored at the location designated by the second-operand address, and the pending I/O-interruption request is cleared.

The second-operand address, when nonzero, is the logical address of the location where the two-word I/O-interruption code, consisting of words 0 and 1, is to be stored. The second-operand address must be designated on a word boundary; otherwise, a specification exception is recognized.

If the second-operand address is zero, the three-word I/O-interruption code, consisting of words 0-2, is stored at real locations 184-195. In this case, low-address protection and key-controlled protection do not apply.

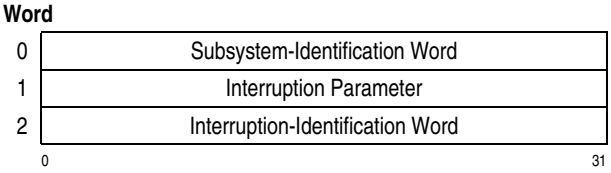
In the access-register mode when the second-operand address is zero, it is unpredictable whether access-register translation occurs for access register B_2. If the translation occurs, the resulting address-space-control element is not used; that is, the interruption code still is stored at real locations 184-195.

Pending I/O-interruption requests are accepted only for those I/O-interruption subclasses allowed by the I/O-interruption-subclass mask in control register 6 of the CPU executing the instruction. If no I/O-interruption requests exist that are allowed by control register 6, the I/O-interruption code is not stored, the second-operand location is not modified, and condition code 0 is set.

If a pending I/O-interruption request is accepted, the I/O-interruption code is stored, the pending I/O-interruption request is cleared, and condition code 1 is set. The I/O-interruption code that is stored is the same as would be stored if an I/O interruption had occurred. However, PSWs are not swapped as when an I/O-interruption occurs.

I/O-Interruption Code

The I/O-interruption code that is stored during the execution of the instruction is defined as follows:



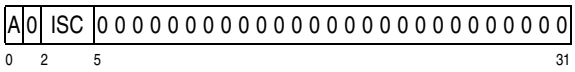
Subsystem-Identification Word (SID):
Bits 32-63 of the SID are placed in word 0.

See “I/O-Instruction Formats” in Chapter 14.

Interruption Parameter: Word 1 contains a four-byte parameter that was specified by the program and passed to the subchannel in word 0 of the ORB or the PMCW. When a device presents alert status and the interruption parameter was not previously passed to the subchannel by an execution of START SUBCHANNEL or MODIFY SUBCHANNEL, this field contains zeros.

Interruption-Identification Word: Word 2, when stored, contains the interruption-identification word, which further identifies the source of the I/O-interruption. Word 2 is stored only when the second-operand address is zero.

The interruption-identification word is defined as follows:



A bit (A)Bit 0 of the interruption-identification word specifies the type of pending I/O-interruption request that was cleared. When bit 0 is zero, the I/O-interruption request was associated with a subchannel.

I/O-Interruption Subclass (ISC): Bit positions 2-4 of the interruption-identification word contain an unsigned binary integer, in the range 0-7, that specifies the I/O-interruption subclass associated with the subchannel for which the pending I/O-interruption request was cleared.

The remaining bit positions are reserved and stored as zeros.

Special Conditions

TEST PENDING INTERRUPTION can encounter the program exceptions described or listed below.

The second operand must be designated on a word boundary; otherwise, a specification exception is recognized.

The execution of TEST PENDING INTERRUPTION is suppressed on all addressing and protection exceptions.

Resulting Condition Code:

0 Interruption code not stored
1 Interruption code stored
2 —
3 —

Program Exceptions:

- Access (store, operand 2, second-operand address nonzero only)
- Privileged operation
- Specification
- Transaction constraint

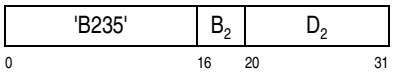
Programming Notes:

1. TEST PENDING INTERRUPTION should only be executed with a second-operand address of zero when I/O interruptions are masked off. Otherwise, an I/O-interruption code stored by the instruction may be lost if an I/O interruption occurs. The I/O-interruption code that identifies the source of an I/O interruption taken subsequent to TEST PENDING INTERRUPTION is also stored at real locations 184-195, replacing an I/O-interruption code that was stored by the instruction.

2. In the access-register mode when the second-operand address is zero, an access exception is recognized if access-register translation occurs and the access register is in error. This exception can be prevented by making the B_2 field zero or by placing 00000000 hex, 00000001 hex, or any other valid contents in the access register.

TEST SUBCHANNEL

TSCH $D_2(B_2)$ [S]



Control and status information for the subchannel is stored in the designated IRB.

General register 1 contains a subsystem-identification word that designates the subchannel for which the information is to be stored. The second-operand address is the logical address of the IRB and must be designated on a word boundary; otherwise, a specification exception is recognized.

The information that is stored in the IRB consists of a SCSW, an extended-status word, and an extended-control word. (See “Interruption-Response Block” on page 16-6.)

If the subchannel is status pending, the status-pending bit of the status-control field is stored as one. Whether or not the subchannel is status pending has an effect on the functions that are performed when TEST SUBCHANNEL is executed.

When the subchannel is status pending and TEST SUBCHANNEL is executed, information, as described above, is stored in the IRB, followed by the clearing of certain conditions and indications that exist at the subchannel as described in Figure 14-2 on page 14-21. If the subchannel is in transport mode, the clearing of these conditions, specifically the start function, places the subchannel in command mode. (See Figure 14-2 on page 14-21.) If an I/O-interruption request is pending for the subchannel, the request is cleared. Condition code 0 is set to indicate that these actions have been taken.

When the subchannel is not status pending and TEST SUBCHANNEL is executed, information (as described above) is stored in the IRB, and no conditions or indications are cleared. Condition code 1 is set to indicate that these actions have been taken.

Figure 14-2 on page 14-21 describes which conditions and indications are cleared by TEST SUBCHANNEL when the subchannel is status pending. All other conditions and indications at the subchannel remain unchanged.

Field	Subchannel Conditions*									
	Alert Status Pending		Int Status Pending		Pri Status Pending		Sec. Status Pending		Status Pending Alone	
	CM	TM	CM	TM	CM	TM	CM	TM	CM	TM
Function Control	C	C	Nc	Nm	C	C	C	C	C	C
Activity Control	Cp	Cp	Nr	Nm	Cp	Cp	Cp	Cp	Cp	Cp
Status Control	Cs	Cs	Cs	C	Cs	Cs	Cs	Cs	Cs	Cs
N Condition	C	C	Nr	Nm	C	C	C	C	C	C
Q Condition	–	C	–	C	–	C	–	C	–	C

Explanation:

–	N/A.
CM	Command-Mode Operation
TM	Transport-Mode Operation
*	Note that the rightmost column applies to status pending when it is alone. The other four status-pending conditions result in the clearing actions given. These actions apply both when a single status-pending condition occurs and when a combination of the four status-pending conditions occurs. In the combination case, all the clearing actions of the individual cases apply.
C	Cleared.
Nm	Not reset or modified by TEST SUBCHANNEL.
Cp	The resume-, start-, halt-, clear pending, and suspended conditions are cleared.
Cs	The status-pending condition is cleared.
Nc	Not changed unless function control indicates the halt function and activity control indicates suspended. If both the halt function and suspended are indicated, conditions are cleared as for status pending alone.
Nr	Not changed unless activity control indicates suspended and function control indicates the start function with or without the halt function. If the halt function is indicated, the conditions are cleared as for status pending alone. If only the start function is indicated, the resume-pending condition and the N condition are cleared.

Note: The clearing of certain subchannel conditions, places the subchannel in command mode. A subchannel in the idle state, or with the function control bits zero is considered to be in command-mode.

Figure 14-2. Conditions and Indications Cleared at the Subchannel by TEST SUBCHANNEL

Special Conditions

Condition code 3 is set, and no other action is taken, when the subchannel is not operational for TEST SUBCHANNEL. A subchannel is not operational for TEST SUBCHANNEL if the subchannel is not provided, has no valid device number associated with it, or is not enabled.

TEST SUBCHANNEL can encounter the program exceptions described or listed below.

When the multiple-subchannel-set facility is not installed, bits 32-47of general register 1 must contain 0001 hex; otherwise, an operand exception is recognized.

When the multiple-subchannel-set facility is installed, bits32-44of general register 1 must contain zeros, bits 45-46must contain a valid value, and bit 47must contain the value one; otherwise, an operand exception is recognized.

The second operand must be designated on a word boundary; otherwise, a specification exception is recognized.

When the execution of TEST SUBCHANNEL is terminated on addressing and protection exceptions, the state of the subchannel is not changed.

Resulting Condition Code:

0 IRB stored; subchannel status pending
1 IRB stored; subchannel not status pending
2 —
3 Not operational

Program Exceptions:

- Access (store, operand 2)
- Operand
- Privileged operation
- Specification

The priority of recognition of program exceptions for the instruction is shown in Figure 14-3.

1.-7	Exceptions with the same priority as the priority of program-interruption conditions for the general case.
8.A	Specification exception due to the address specified by the second operand not being on a word boundary.
8.B	Access exceptions for an access to the subchannel-status-word, extended-status-word, and extended-control-word sections of the IRB designated by the second operand.

Figure 14-3. Priority of Execution: TEST SUBCHANNEL (Part 1 of 2)

8.C	Operand exception due to an invalid field in the subsystem-identification word specified in register 1.
8.D	Access exceptions for an access to the extended-measurement-word section of the IRB designated by the second operand when the extended-I/O-measurement-word mode is enabled at the designated subchannel.

Figure 14-3. Priority of Execution: TEST SUBCHANNEL (Part 2 of 2)

Programming Notes:

1. Device status that is stored in the SCSW may include device-busy, control-unit-busy, or control-unit-end indications.

2. The information that is stored in the IRB is obtained from the subchannel. The TEST SUBCHANNEL instruction does not cause the channel subsystem to interrogate the addressed device.

3. When an I/O interruption occurs, it is the result of a status-pending condition at the subchannel, and typically TEST SUBCHANNEL is executed to clear the status. TEST SUBCHANNEL may also be executed at any other time to sample conditions existing at the subchannel.

4. Repeated execution of TEST SUBCHANNEL to determine when a start function has been completed should be avoided because there are conditions under which the completion of the start function may or may not be indicated. For example, if the channel subsystem is holding an interface-control-check (IFCC) condition in abeyance (for any subchannel) because another subchannel is already status pending, and if the start function being tested by TEST SUBCHANNEL has as the only path available for selection the channel path with the IFCC condition, then the start function may not be initiated until the status-pending condition in the other subchannel is cleared, allowing the IFCC condition to be indicated at the subchannel to which it applies.

5. Repeated execution of TEST SUBCHANNEL without an intervening delay, for example, to determine when a subchannel changes state, should be avoided because repeated accesses of the subchannel by the CPU may delay or prohibit accessing of the subchannel by the channel subsystem. Execution of TEST SUBCHANNEL

by multiple CPUs for the same subchannel at approximately the same time may have the same effect and also should be avoided.

6. The priority of I/O-interruption handling by a CPU can be modified by the execution of TEST SUBCHANNEL. When TEST SUBCHANNEL is executed and the designated subchannel has an I/O-interruption request pending, that I/O-interruption request is cleared, and the SCSW is stored, without regard to any previously established priority. The relative priority of the remaining I/O-interruption requests is unchanged.

.

Some I/O instructions specify to the channel subsystem that a function is to be performed. Collectively, these functions are referred to as the basic I/O functions. The basic I/O functions are the clear, halt, start, resume, and channel-path-reset functions.

Control of Basic I/O Functions

Information that is present at the subchannel controls how the clear, halt, resume, and start functions are

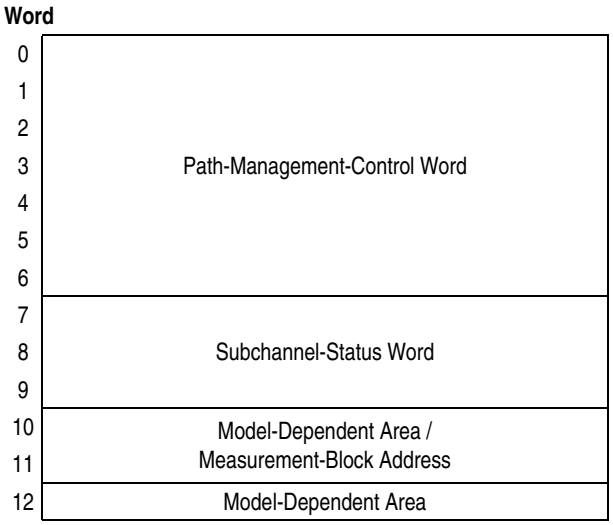
© Copyright IBM Corp. 2000, 2025

performed. This information is communicated to the program in the subchannel-information block during the execution of STORE SUBCHANNEL.

Subchannel-Information Block

The subchannel-information block (SCHIB) is the operand of the MODIFY SUBCHANNEL and STORE SUBCHANNEL instructions. The two rightmost bits of the SCHIB address are zeros, designating the SCHIB on a word boundary. The SCHIB contains three major fields: the path-management-control word (PMCW), the subchannel-status word (SCSW), and a model-dependent area. When the extended-I/O-measurement-block facility is installed the SCHIB also contains the measurement-block-address field. (Figure 15-1 on page 15-2. shows the format of the PMCW, and Figure 16-3 on page 16-8 shows the format of the command-mode SCSW and Figure 16-8 on page 16-34 shows the format of the transport-mode SCSW.)

STORE SUBCHANNEL is used to store the current PMCW, the SCSW, model-dependent data, and, when the extended-I/O-measurement-block facility is installed, the measurement-block-address field, for the designated subchannel. MODIFY SUBCHANNEL alters certain PMCW fields and, when the extended-I/O-measurement-block facility is installed, the measurement-block address in the subchannel. When the program needs to change the contents of one or more of the PMCW fields, the normal procedure is to (1) issue STORE SUBCHANNEL to obtain the current contents, (2) perform the required modifications to the PMCW field or the measurement-block-address field in main storage, and (3) issue MODIFY SUBCHANNEL to pass the new information to the subchannel. The SCHIB has the following format:



Path-Management-Control Word

Words 0-6 of the SCHIB contain the path-management-control word (PMCW). The PMCW has the format shown in Figure 15-1 on page 15-2 when the subchannel is valid (see *“Device Number Valid (V)” on page 15-4).

The format of the PMCW is as follows:

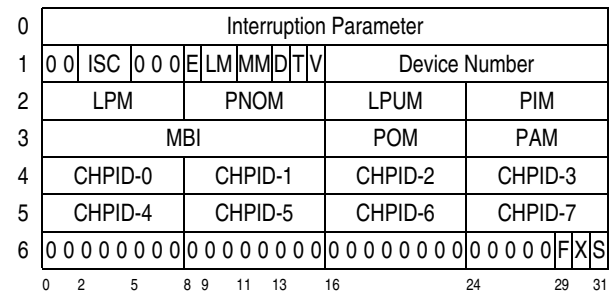


Figure 15-1. PMCW Format

Interruption Parameter: Bit positions 0-31 of word 0 contain the interruption parameter that is stored as word 1 of the interruption code. The interruption parameter can be set to any value by START SUBCHANNEL and MODIFY SUBCHANNEL. The initial value of the interruption parameter is zero.

I/O-Interruption-Subclass Code (ISC): Bits 2-4 of word 1 are an unsigned binary integer, in the range 0-7, that corresponds to the bit position of the I/O-

interruption subclass-mask bit in control register 6 of each CPU in the configuration. The setting of that mask bit in control register 6 of a CPU controls the recognition of interruption requests relating to this subchannel by that CPU (see “Priority of Interruptions” on page 16-5). The ISC can be set to any value by MODIFY SUBCHANNEL. The initial value of the ISC is zero.

Reserved: Bits 0, 1, and 5-7 of word 1 are reserved and stored as zeros by STORE SUBCHANNEL. Bits 0, 1, 6, and 7 must be zeros when MODIFY SUBCHANNEL is executed; otherwise, an operand exception is recognized. Bit 5 of word 1 is ignored when MODIFY SUBCHANNEL is executed.

Enabled (E): Bit 8 of word 1, when one, indicates that the subchannel is enabled for all I/O functions. When the E bit is zero, status presented by the device is not made available to the program, and I/O instructions other than MODIFY SUBCHANNEL and STORE SUBCHANNEL that are executed for the designated subchannel cause condition code 3 to be set. The E bit can be either zero or one when MODIFY SUBCHANNEL is executed; initially, all subchannels are not enabled; IPL causes the IPL I/O device to become enabled.

Limit Mode (LM): When the address-limit-checking facility is installed, bits 9 and 10 of word 1 define the limit mode (LM) of the subchannel. The limit mode is used by the channel subsystem when address-limit checking is invoked for an I/O operation. (See “Address-Limit Checking” on page 17-27.) Address-limit checking is under the control of the address-limit-checking-control bit that is passed to the subchannel in the operation-request block (ORB) during the execution of START SUBCHANNEL. (See “Address-Limit-Checking Control (A)” on page 15-27.) The definitions of the LM bits, whose values are used during data transfer, are as follows:

Bit 9	Bit 10	Function
0	0	Initialized value. No limit checking is performed for this subchannel.
0	1	Data address must be equal to or greater than the current address limit.
1	0	Data address must be less than the current address limit.
1	1	Reserved.

Bit positions 9 and 10 can contain any of the first three bit combinations shown above when MODIFY SUBCHANNEL is executed. Specification of the reserved bit combination in the operand causes an operand exception to be recognized when MODIFY SUBCHANNEL is executed.

When the address-limit-checking facility is not installed, bits 9-10 of word 1 may be set as described above; however, they are ignored and are not set at the specified subchannel. When bits 9-10 are not specified as described above and MODIFY SUBCHANNEL is executed, an operand exception is recognized.

Measurement-Mode Enable (MM): Bits 11 and 12 of word 1 enable the measurement-block-update mode and the device-connect-time-measurement mode, respectively, of the subchannel. These bits can have any value when MODIFY SUBCHANNEL is executed; initially, neither measurement mode is

enabled. The definition of each of these bits is as follows:

Bit
11 Measurement-Block-Update Enable:

0 Initialized value. The subchannel is not enabled for measurement-block update. Storing of measurement-block data does not occur.

1 The subchannel is enabled for measurement-block update. If the measurement-block-update mode is active, measurement data is accumulated in the measurement block at the time channel-program execution is completed or suspended at the subchannel or completed at the device, as appropriate, provided no error conditions described by subchannel logout have been detected. (See “Measurement-Block Update” on page 17-2.) If the measurement-block-update mode is inactive, no measurement-block data is stored.

Bit
12 Device-Connect-Time-Measurement Enable:

0 Initialized value. The subchannel is not enabled for device-connect-time measurement. Storing of the device-connect-time interval (DCTI) in the extended-status word (ESW) does not occur.

1 The subchannel is enabled for device-connect-time measurement. If the device-connect-time-measurement mode is active and timing facilities are provided for the subchannel, the value of the DCTI is stored in the ESW when TEST SUBCHANNEL is executed after channel-program execution is completed or suspended at the subchannel, provided no error conditions described by subchannel logout have been detected. If the device-connect-time-measurement mode is inactive, no measurement values are stored in the ESW.

The meaning of the measurement-mode-enable bits (MM), described above, applies when the timing-facility bit for the subchannel is one. When the timing-facility bit is zero, the effect of the MM bits is changed, as described below under “Timing Facility (T)” on page 15-4. (For more discussion on measurement modes, see “Measurement-Block Update” on page 17-2 and “Device-Connect-Time Measurement” on page 17-10.)

Multipath Mode (D): Bit 13 of word 1, when one, indicates that the subchannel operates in the multipath mode when performing an I/O operation or chain of I/O operations. For proper operation in the multipath mode when more than one channel path is available for selection, the associated device must have the dynamic-reconnection feature installed and must be set up for multipath-mode operation. During performance of a start function in the multipath mode, a device is allowed to request service from the channel subsystem over any of the channel paths indicated at the subchannel as being available for selection (see *“Logical-Path Mask (LPM)” on page 15-5 and “Path-Available Mask (PAM)” on page 15-7). Bit 13, when zero, indicates that the subchannel operates in single-path mode when performing an I/O operation or chain of I/O operations. In the single-path mode, the entire start function is performed by using the channel path on which the first command of the I/O operation or chain of I/O operations was accepted by the device. The D bit can be either zero or one when MODIFY SUBCHANNEL is executed; initially, the subchannel is in the single-path mode.

Timing Facility (T): Bit 14 of word 1, when one, indicates that the channel-subsystem-timing facility is available for the subchannel and is under the control of the two measurement-mode-enable bits (MM) and SET CHANNEL MONITOR. Bit 14, when zero, indicates that the channel-subsystem-timing facility is not available for the subchannel. When bit 14 is zero, the START SUBCHANNEL count is the only measurement data that can be accumulated in the measurement block for the subchannel. Storing of the START SUBCHANNEL count is under the control of bit 11 and SET CHANNEL MONITOR, as described above under “Measurement-Mode Enable (MM)” on page 15-3. Similarly, if the T bit is zero, no device-connect-time-interval (DCTI) values can be measured for the subchannel. (See “Measurement-Block Update” on page 17-2 and “Device-Connect-Time Measurement” on page 17-10.)

Device Number Valid (V): Bit 15 of word 1, when one, indicates that the device-number field (see below) contains a valid device number and that a device associated with this subchannel may be physically installed. Bit 15, when zero, indicates that the subchannel is not valid, there is no I/O device currently associated with the subchannel, and the con-

tents of all other defined fields of the SCHIB are unpredictable.

Device Number: Bit positions 16-31 of word 1 contain the binary representation of the four-digit hexadecimal device number of the device that is associated with this subchannel. The device number is a system-unique parameter that is assigned to the subchannel and the associated device when the device is installed.

Logical-Path Mask (LPM): Bits 0-7 of word 2 indicate the logical availability of channel paths to the associated device. Each bit of the LPM corresponds one-for-one, by relative bit position, with a CHPID located in an associated byte of words 4 and 5 of the SCHIB. A bit set to one means that the corresponding channel path is logically available; a zero means the corresponding channel path is logically not available. When a channel path is logically not available, the channel subsystem does not use that channel path to initiate performance of any clear, halt, resume, or start function, except when a dedicated allegiance exists for that channel path. When a dedicated allegiance exists at the subchannel for a channel path, the logical availability of the channel path is ignored whenever a clear, halt, resume, or start function is performed. (See “Channel-Path Allegiance” on page 15-12). If the subchannel is idle, the logical availability of the channel path is ignored whenever the control unit initiates a request to present alert status to the channel subsystem. The logical availability of a channel path associated with the subchannel can be changed by setting the corresponding LPM bit in the SCHIB and then issuing MODIFY SUBCHANNEL, or by setting the corresponding LPM bit in the ORB and then issuing START SUBCHANNEL. Initially, each installed channel path is logically available.

Path-Not-Operational Mask (PNOM): Any of bits 8-15 of word 2, when one, indicates that a path-not-operational condition has been recognized on the corresponding channel path. Each bit of the PNOM corresponds one-for-one, by relative bit position, with a CHPID located in an associated byte of words 4 and 5 of the SCHIB. The channel subsystem recognizes a path-not-operational condition when, during an attempted device selection in order to perform a clear, halt, resume, or start function, the device associated with the subchannel appears not operational on a channel path that is operational for the subchannel. When a path-not-operational condition is recognized, the state of the channel path changes from operational for the subchannel to not operational for the subchannel. A channel path is operational for the subchannel if the associated device appeared operational on that channel path the last time the channel subsystem attempted device selection in order to perform a clear, halt, resume, or start function. A device appears to be operational on a channel path when the device responds to an attempted device selection. A channel path is not operational for the subchannel if the associated device appeared not operational on that channel path the last time the channel subsystem attempted device selection in order to perform a clear, halt, resume, or start function. Any of bits 8-15 of word 2, when zero, indicates that a path-not-operational condition has not been recognized on the corresponding channel path.

Initially, each of the eight possible channel paths associated with each subchannel is considered to be operational, regardless of whether the respective channel paths are installed or available; therefore, unless a path-not-operational condition is recognized during initial program loading, the PMCW, if stored, contains a PNOM of all zeros if stored prior to the execution of a CLEAR SUBCHANNEL, HALT SUBCHANNEL, RESUME SUBCHANNEL, or START SUBCHANNEL instruction.

Programming Note: The PNOM indicates those channel paths for which a path-not-operational condition has been recognized during the performance of the most recent clear, halt, resume, or start function. That is, the PNOM indicates which of the channel paths associated with the subchannel have made a transition from the operational to the not-operational state for the subchannel during the performance of the most recent clear, halt, resume, or start function. However, the transition of a channel path from the not-operational to the operational state for the subchannel is indicated in the POM. Therefore, the POM must be examined in order to determine whether any of the channel paths that are associated with a designated subchannel are operational for the subchannel.

Furthermore, while performing either a start function or a resume function, the transition of a channel path from the not-operational to the operational state for the subchannel is recognized by the channel subsystem only during the initiation sequence for the first command specified by the start function or implied by the resume function. Therefore, a channel path that is currently not operational for the subchannel can be used by the device associated with the subchannel

when reconnecting to the channel subsystem in order to continue command chaining; however, the channel subsystem does not indicate a transition of that channel path from the not-operational to the operational state for the subchannel in the POM.

POM Value and Device State before Selection Attempt		Value of Specified Bit Subsequent to Selection Attempt		
Device State[1]	POM	POM	PNOM[2]	SCSW N Bit
OP	0	1	0	0
NOP	0	0	0	0
OP	1	1	0	0
NOP	1	0	1	1[3]

Explanation:

1 Device state as it appears on the corresponding channel path.

2 Prior to the attempted device selection during the performance of either a start function or a resume function while the subchannel is suspended, the channel subsystem clears all existing path-not-operational conditions, if any, at the designated subchannel.

3 The N bit (bit 15 of word 0 of the SCSW) is indicated to the program and the N condition is cleared at the subchannel when TEST SUBCHANNEL is executed the next time the subchannel is status pending for other than intermediate status alone provided that it is not also suspended.

NOP The device is not operational on the corresponding channel path.

OP The device is operational on the corresponding channel path.

Figure 15-2. Resulting POM, PNOM, and N-Bit Values Subsequent to Selection Attempt

Last-Path-Used Mask (LPUM): Bits 16-23 of word 2 indicate the channel path that was last used for communicating or transferring information between the channel subsystem and the device. Each bit of the LPUM corresponds one-for-one, by relative bit position, with a CHPID located in an associated byte of words 4 and 5 of the SCHIB.

For a subchannel operating in command mode, each bit of the LPUM is stored as zero, except for the bit that corresponds to the channel path last used, whenever one of the following occurs:

1. The first command of a start or resume function is accepted by the device (see “Activity Control (AC)” on page 16-14).
2. The device and channel subsystem are actively communicating when the suspend function is performed for the channel program in execution.
3. Status has been accepted from the device and is recognized as an interruption condition, or a condition has been recognized that suppresses command chaining (see “Interruption Conditions” on page 16-2).
4. An interface-control-check condition has been recognized (see “Interface-Control Check” on page 16-29), and no subchannel-logout information is currently present in the subchannel.

For a subchannel operating in transport mode, each bit of the LPUM is stored as zero, except for the bit that corresponds to the channel path last used, whenever one of the following occurs:

1. The path has been selected for transporting the TCCB for the operation.
2. Status has been accepted from the device and is recognized as an interruption condition. If the accepted status is an interrogate response, the LPUM may be different than that stored with primary or secondary status or both.
3. An interface-control-check has been recognized and no subchannel-logout information is currently present in the subchannel.

The LPUM field of the PMCW contains the most recent setting. For transport-mode operations the LPUM in the subchannel is set to zeros when the start function is set and no dedicated-allegiance condition exists for the subchannel.

Path-Installed Mask (PIM): Bits 24-31 of word 2 indicate which of the channel paths 0-7 to the I/O device are physically installed. The PIM indicates the validity of the channel-path identifiers (see below) for those channel paths that are physically installed. Each bit of the PIM corresponds one-for-one, by relative bit position, with a CHPID located in an associated byte of words 4 and 5 of the SCHIB. A PIM bit stored as one indicates that the corresponding channel path is installed. A PIM bit stored as zero indicates that the corresponding channel path is not installed. The PIM always reflects the full complement of installed paths to the device, regardless of how the system is configured. Therefore, some of the channel paths indicated in the PIM may not be physically available in that configuration, as indicated by

the bit settings in the path-available mask (see below). The initial value of the PIM indicates all the physically installed channel paths to the device.

Measurement-Block Index (MBI): Bits 0-15 of word 3 form an index value used by the measurement-block-update facility when the measurement-block-update mode is active (see "SET CHANNEL MONITOR" on page 14-13.) and the subchannel is enabled for the mode (see "Measurement-Mode Enable (MM)" on page 15-3).

When the measurement-block index is used, five zero bits are appended on the right, and the result is added to the measurement-block-origin address designated by SET CHANNEL MONITOR. The calculated address, called the measurement-block address, designates the beginning of a 32-byte storage area where measurement data is stored. (See "Measurement Block" on page 17-3.) The MBI can contain any value when MODIFY SUBCHANNEL is executed; the initial value is zero.

Programming Note: The measurement-block-origin address specified by SET CHANNEL MONITOR is used as the origin address for the measurement blocks for subchannels in all subchannel sets available to the program. However, the two-byte measurement-block-index field is capable of supporting a maximum of 65,536 unique MBI values. It is the responsibility of the program to coordinate use of the measurement-block index among subchannels and subchannel sets.

Path-Operational Mask (POM): Bits 16-23 of word 3 indicate the last known operational state of the device on the corresponding channel paths. Each bit of the POM corresponds one-for-one, by relative bit position, with a CHPID located in an associated byte of words 4 and 5 of the SCHIB. If the associated device appeared operational on a channel path the last time the channel subsystem attempted device selection in order to perform a clear, halt, resume, or start function, then the channel path is operational for the subchannel, and the bit corresponding to the channel path in the POM is one. A device appears to be operational on a channel path when the device responds to an attempted device selection. A channel path is also operational for the subchannel if MODIFY SUBCHANNEL is executed and the bit corresponding to that channel path in the POM is specified as one.

If the associated device appeared not operational on a channel path the last time the channel subsystem attempted device selection in order to perform a clear, halt, resume, or start function, then the channel path is not operational for the subchannel, and the bit corresponding to the channel path in the POM is zero. A channel path is also not operational for the subchannel if MODIFY SUBCHANNEL is executed and the bit corresponding to that channel path in the POM is specified as zero.

If the device associated with the subchannel appears not operational on a channel path that is operational for the subchannel during an attempted device selection in order to perform a clear, halt, resume, or start function, then the channel subsystem recognizes a path-not-operational condition. If an SCSW is subsequently stored, then bit 15 of word 0 is one, indicating the path-not-operational condition. When a path-not-operational condition is recognized, the state of the channel path changes from operational for the subchannel to not operational for the subchannel.

When the channel path is not operational for the subchannel, a path-not-operational condition cannot be recognized. Moreover, a channel path that is not operational for the subchannel may be available for selection; if the channel subsystem chooses that channel path while performing a path-management operation, and if, during the attempted device selection, the device appears to be operational again on that channel path, then the state of the channel path changes from not operational for the subchannel to operational for the subchannel.

The POM can contain any value when MODIFY SUBCHANNEL is executed. Initially, each of the eight possible channel paths associated with each subchannel is considered to be operational, regardless of whether the respective channel paths are installed or available; therefore, unless a path-not-operational condition is recognized during initial program loading, the PMCW, if stored, contains a POM of all ones if stored prior to the execution of a CLEAR SUBCHANNEL, HALT SUBCHANNEL, RESUME SUBCHANNEL, or START SUBCHANNEL instruction.

Path-Available Mask (PAM): Bits 24-31 of word 3 indicate the physical availability of installed channel paths. Each bit of the PAM corresponds one-for-one, by relative bit position, with a CHPID located in an associated byte of words 4 and 5 of the SCHIB. A PAM bit of one indicates that the corresponding channel path is physically available for use in access-

ing the device. A PAM bit of zero indicates the channel path is not physically available for use in accessing the device. When a channel path is not physically available, it may, depending on the model and the extent of failure, be used during performance of the reset-channel-path function. A channel path that is physically available may become not physically available as a result of reconfiguring the system, or this may occur as a result of the performance of the channel-path-reset function. The initial value of the PAM reflects the set of channel paths by which the I/O device is physically accessible at the time of initialization.

Note: The change in the availability of a channel path affects all subchannels having access to that channel path. Whenever the setting of a PAM bit is referred to in conjunction with the availability status of a channel path, for brevity, reference is made in this chapter to a single PAM bit instead of to the respective PAM bits in all of the affected subchannels.

Channel-Path Identifiers (CHPIDs): Words 4 and 5 contain eight one-byte channel-path identifiers corresponding to channel paths 0-7 of the PIM. A CHPID is valid if the corresponding PIM bit is one. Each valid CHPID contains the identifier of a physical channel path to a control unit by which the associated I/O device may be accessed. A unique CHPID is assigned to each physical channel path in the system.

Different devices that are accessible by the same physical channel path have, in their respective subchannels, the same CHPID value. The CHPID value may, however, appear in each subchannel in different locations in the CHPID fields 0-7.

Subchannels that share an identical set of channel paths have the same corresponding PIM bits set to ones. The channel-path identifiers (CHPIDs) for these channel paths are the same and occupy the same respective locations in each SCHIB.

Reserved: Bits 0-28 of word 6 are reserved and are stored as zeros by STORE SUBCHANNEL. They must be zeros when MODIFY SUBCHANNEL is executed; otherwise, an operand exception may be recognized.

Measurement Block Format Control (F): When the extended-I/O-measurement-block facility is installed, bit 29 of word 6 specifies the format of the measurement block to be stored when the subchannel is enabled for the measurement-block-update mode, and measurement-block-update mode is active. The bit can contain any value when MODIFY SUBCHANNEL is executed. The initial value is zero. The definition of the bit is as follows:

Bit
29 Measurement-Block-Format Control:

0 Format-0 measurement block. Specifies that a format-0 measurement block is used when performing a measurement-block update for the subchannel. The address of the 32-byte measurement block is obtained using the MBI provided by MSCH in conjunction with the MBO provided by SCHM.

1 Format-1 measurement block. Specifies that a format-1 measurement block is used when performing a measurement-block update for the subchannel. The address of the 64-byte format-1 measurement block is provided by MSCH.

If the extended-measurement-block facility is not installed, bit 29 of word 6 of the SCHIB operand must be zero when MODIFY SUBCHANNEL is executed; otherwise, an operand exception is recognized.

Extended Measurement Word Mode Enable (X): When the extended-measurement-word facility is installed and enabled, bit 30 of word 6 enables the extended-measurement-word mode for the subchannel. Initially, the extended-measurement-word mode is not enabled. The definition of the bit is as follows:

Bit
30 Measurement-Block-Word-Mode Enable:

0 Initialized value. The subchannel is not enabled for extended-measurement-word mode. Storing of the extended-measurement word does not occur.

1 The subchannel is enabled for extended-measurement-word mode. Measurement data is stored in the extended-measurement word at the time channel-program execution is completed or suspended at the subchannel or completed at the device, as appropriate, provided no error conditions described by subchannel logout have been detected.

If the extended-measurement-word facility is not installed, or is installed but is not enabled, bit 30 of word 6 of the SCHIB operand must be zero when MODIFY SUBCHANNEL is executed; otherwise, an operand exception is recognized.

Concurrent Sense (S): Bit 31 of word 6, when one, indicates that the subchannel is in the concurrent-sense mode. When the subchannel is in command mode and concurrent-sense mode, whenever the subchannel becomes status pending with alert status, and the status byte accepted from the device contains the unit-check indication, then the channel subsystem may attempt to retrieve sense information from the associated device and place that sense information in the extended-control word.

When the subchannel is operating in transport mode, any available sense information is provided in the TSB regardless of the setting of bit 31 of word 6.

If the concurrent-sense facility is not installed, bit 31 of word 6 of the SCHIB operand must be zero when MODIFY SUBCHANNEL is executed; otherwise, an operand exception is recognized.

Subchannel-Status Word

Words 7-9 of the SCHIB contain a copy of the SCSW. The format of the SCSW is described in “Subchannel-Status Word” on page 16-7. The SCSW is stored by the execution of either STORE SUBCHANNEL or TEST SUBCHANNEL (see “STORE SUBCHANNEL” on page 14-18 and “TEST SUBCHANNEL” on page 14-21).

Model-Dependent Area/Measurement Block Address

When the extended-I/O-measurement-block facility is not installed, words 10-12 of the SCHIB contain model-dependent information.

When the extended-I/O-measurement-block facility is installed, words 10-11 are defined as the measurement-block-address field. Word 12 contains model-dependent information.

When (1) the measurement-block-update mode is active (see “SET CHANNEL MONITOR” on page 14-13), (2) the subchannel is enabled for the mode (see“Measurement-Mode Enable (MM)” on page 15-3), and (3) the format-1-measurement block is specified (see “Measurement Block Format Control (F)” on page 15-8) at the subchannel, the measurement-block-address field contains the absolute storage address of the measurement block used by the measurement-block-update facility. The measurement-block address designates the beginning of a 64-byte storage area and must be designated on 64-byte boundary. The initial value of the measurement block address is zero.

Summary of Modifiable Fields

*Figure 15-3 on page 15-10 lists the initial settings for fields in a subchannel whose device-number-valid bit is one and indicates what modifies the fields.

All of the PMCW fields contain meaningful information when STORE SUBCHANNEL is executed and the designated subchannel is idle. Subchannel fields that the channel subsystem does not modify contain valid information whenever STORE SUBCHANNEL is executed, provided that the device-number-valid bit is one. The validity of the subchannel fields that are modifiable by the channel subsystem depends on the state of the subchannel at the time STORE SUBCHANNEL is executed.

Subchannel Field	Initial Value[1]	Program Modifies by Executing	Modified by Channel Subsystem[2]
Interruption parameter	Zeros	MSCH,SSCH	No
I/O-interruption-subclass code	Zeros	MSCH	No
Enabled (E)	Zero	MSCH	No
Limit mode (LM)	Zeros	MSCH[7]	No
Measurement mode (MM)	Zeros	MSCH	Yes[3]
Multipath mode (D)	Zero	MSCH	No
Timing facility (T)	Installed value[4]	None	No
Device number valid (V)	Installed value[4]	None	No
Device number	Installed value[4]	None	No
Logical-path mask (LPM)	Path-installed-mask value	MSCH,SSCH	No
Path-not-operational mask (PNOM)	Zeros	CSCH,SSCH,RSCH[5]	Yes
Last-path-used mask (LPUM)	Zeros	CSCH	Yes
Path-installed mask (PIM)	Installed value[4]	None	No
Measurement-block index (MBI)	Zeros	MSCH	No
Path-operational mask (POM)	Ones	CSCH,MSCH,RSCH[5]	Yes
Path-available mask (PAM)	Installed values[4 6]	None	Yes[6]
Channel-path ID 0-7	Installed value$_4$	None	No
Concurrent sense (S)	ZERO	MSCH	No
Subchannel-status word (SCSW)	Zero	TSCH	Yes
Model-dependent area	*	None	*
Measurement-block-format control (F)	Zero	MSCH	No
Extended-measurement-word enable (X)	Zero	MSCH	No
Measurement-block address	Zeros	MSCH	No

Figure 15-3. Modification of Subchannel Fields (Part 1 of 2)

Explanation:

* Model dependent.

1 These fields are not meaningful if the subchannel is not valid. Initialization of a subchannel is performed when I/O-system reset occurs. (See the section "I/O-System Reset" in Chapter 17, "I/O Support Functions.") One or more of the installed-value parameters that are unmodifiable by the program may be set when the subchannel is idle. In this case, all the program-modifiable fields are set to their initialized values, and the program is notified of such a change by a channel report. (See the section "Channel-Report Word" in Chapter 17, "I/O Support Functions.")

2 Subchannel fields that are not normally modifiable by the channel subsystem may be modified as a result of dynamic configuration changes or as a result of external actions. When this occurs, the program is notified of the change by a channel report that is made pending at the time of the change.

3 When any of the following error conditions associated with the measurement-block-update mode is detected, the measurement-block-update mode is disabled by the channel subsystem (bit 11 of word 1 of the SCHIB is zero) in the affected subchannel. The device-connect-time-measurement-enable bit (bit 12 of word 1 of the SCHIB) is never modified by the channel subsystem.

- Measurement program check
- Measurement protection check
- Measurement data check
- Measurement key check

4 This information is entered when the channel-subsystem configuration is established

5 The mask is modified by the resume function only when the subchannel is in the suspended state at the time RESUME SUBCHANNEL is executed.

6 The channel subsystem may modify the PAM to reflect changes in the system configuration caused by partitioning or unpartitioning channel paths because of reconfiguration or permanent failure of part of the I/O system.

Figure 15-3. Modification of Subchannel Fields (Part 2 of 2)

Programming Notes:

1. System performance may be degraded if the LPM is not used to make channel paths for which a path-not-operational condition has been indicated in the PNOM logically not available.

2. If, during the performance of a start function, a channel path becomes not physically available because a channel-path failure has been recognized, continued performance of the start function may be precluded. That is, the program may or may not be notified, and the subchannel may remain in the subchannel-and-device-active state until cleared by the performance of the clear function.

3. If the same MBI is placed in more than one subchannel by the program, the channel-subsystem-monitoring facility updates the same locations with measurement data relating to more than one subchannel. In this case, the values stored in the measurement data are unpredictable. (See “Measurement-Block Update” on page 17-2.)

4. Modification of the I/O configuration (reconfiguration) may be accomplished in various ways depending on the model. If the reconfiguration procedure affects the physical availability of a channel path, then any change in availability can be detected by executing STORE SUBCHANNEL for a subchannel that has access to the channel path and by subsequently examining the PAM bits of the SCHIB.

5. The definitions of the PNOM, POM, and N bit are such that a path-not-operational condition is reported to the program only the first time the condition is detected by the channel subsystem after the corresponding POM bit is set to one.

   For example, if the POM bit for every channel path available for selection is one and the device appears not operational on all corresponding channel paths while the channel subsystem is attempting to initiate a start function at the device, the channel subsystem makes the subchannel status pending, with deferred condition code 3 and with the N bit stored as one. The PNOM in the SCHIB indicates the channel path or channel paths that appeared not operational, for which the corresponding POM bits have been set to zeros. The next START SUBCHANNEL causes the channel subsystem to again attempt device selection by choosing a channel path from among all of the channel paths that are available

for selection. If device selection is not successful and all channel paths available for selection have again been chosen, deferred condition code 3 is set, but the N bit in the SCSW is zero. The POM contains zeros in at least those bit positions that correspond to the channel paths that are available for selection. (See “Channel-Path Availability” on page 15-13 for a description of the term “available for selection.”) When the N bit in the SCSW is zero, the PNOM is also zero.

6. If the program is to detect path-not-operational conditions, the PNOM should be inspected following the execution of TEST SUBCHANNEL (which results in the setting of condition code zero and the valid storing of the N bit as one) and preceding the performance of another start, resume, halt, or clear function at the subchannel.

Channel-Path Allegiance

The channel subsystem establishes allegiance conditions between subchannels and channel paths. The kind of allegiance established at a subchannel for a channel path or set of channel paths depends upon the state of the subchannel, the device, and the information, if any, transferred between the channel subsystem and device. The way in which path management is handled during the performance of a clear, halt, resume, or start function is determined by the kind of allegiance, if any, currently recognized between a subchannel and a channel path.

Performing the clear function at a subchannel clears any currently existing allegiance condition in the subchannel for all channel paths.

Performing the reset-channel-path function clears all currently existing allegiances for that channel path in all subchannels.

When a channel path becomes not physically available, all internal indications of prior allegiance conditions are cleared in all subchannels having access to the designated channel path.

Note that allegiance rules do not apply for interrogate operations. An interrogate operation may be initiated and successfully complete while a subchannel is in transport mode. Furthermore, interrogate operations do not alter any allegiance conditions that may exist.

Working Allegiance

Working Allegiance for Subchannels Operating in Command Mode

A subchannel has a working allegiance for a channel path when the subchannel is operating in command mode and becomes device active on that channel path. Once a working allegiance is established, the channel subsystem maintains the working allegiance at the subchannel for the channel path until either the subchannel is no longer device active or a dedicated allegiance is recognized, whichever occurs earlier. Unless a dedicated allegiance is recognized, a working allegiance for a channel path is extended to the set of channel paths that are available for selection if the device is specified to be operating in the multipath mode (that is, the multipath-mode bit is stored as one in the SCHIB). Otherwise, the working allegiance remains only for that channel path over which the start function was initiated.

Once a working allegiance is established for a channel path or set of channel paths, the working allegiance is not changed until the subchannel is no longer device active or until a dedicated allegiance is established. If the subchannel is operating in the single-path mode, a working allegiance is maintained only for a single path.

While a working allegiance exists at a subchannel, an active allegiance can occur only for a channel path for which the working allegiance is being maintained, unless the device is specified as operating in the multipath mode. When the device is specified as operating in the multipath mode, an active allegiance may also occur for a channel path that is not available for selection if the presentation of status by the device on that channel path causes an alert interruption condition to be recognized.

A working allegiance is cleared in any subchannel having access to a channel path if the channel path becomes not physically available.

Working Allegiance for Subchannels Operating in Transport Mode

A subchannel has a working allegiance for a channel path when the subchannel is operating in transport mode, becomes start pending, and the designated TCCB is transported over that channel path to the I/O device. Once a working allegiance is established, the channel subsystem maintains the working allegiance

at the subchannel for the channel path until a busy condition is encountered or the subchannel is made status pending with primary status. The working allegiance remains only for that channel path over which the start function was initiated.

While a working allegiance exists at a subchannel that is operating in transport mode, an active allegiance can occur only for the channel path for which the working allegiance is being maintained.

A working allegiance is cleared in any subchannel having access to a channel path if the channel path becomes not physically available.

Active Allegiance

A subchannel has an active allegiance established for a channel path no later than when active communication has been initiated on that channel path with an I/O device. The subchannel can have an active allegiance to only one channel path at a time. While the subchannel has an active allegiance for a channel path, the channel subsystem does not actively communicate with that device on any other channel path. When the channel subsystem accepts a no-longer-busy indication from the device that does not cause an interruption condition, this status does not constitute the initiation of active communication. An active allegiance at a subchannel for a channel path is terminated when the channel subsystem is no longer actively communicating with the I/O device on that channel path.

A working allegiance can become an active allegiance.

Dedicated Allegiance

If a channel path is physically available (that is, if the corresponding PAM bit is one), a dedicated allegiance may be recognized for that channel path. If a channel path is not physically available, a dedicated allegiance cannot be recognized for the corresponding channel path. The channel subsystem establishes a dedicated allegiance at the subchannel for a channel path when (1) the subchannel is operating in command mode, the subchannel becomes status pending with alert status, and device status containing the unit-check indication is present but (2) concurrent-sense information is not present at the subchannel. A dedicated allegiance is maintained until the subchannel is no longer start pending (unless it becomes suspended) or resume pending following performance of the next start function, clear function, or channel-path-reset function or the next resume function if applicable. If the subchannel becomes suspended, the dedicated allegiance remains until the resume function is initiated and the subchannel is no longer resume pending. Unless a clear or channel-path-reset function is performed, the subchannel establishes a working allegiance when the dedicated allegiance ends. This occurs when the subchannel becomes device active. While a dedicated allegiance exists at a subchannel for a channel path, only that channel path is available for selection until the dedicated-allegiance condition is cleared.

Dedicated allegiance does not apply to subchannels operating in transport mode. When a subchannel operating in transport mode becomes status pending with unit check indicated, the sense information has already been transferred from the I/O device into the TSB for the I/O operation.

A dedicated allegiance can become an active allegiance. While a dedicated allegiance exists, an active allegiance can only occur for the same channel path.

A currently existing dedicated allegiance is cleared at any subchannel having access to a channel path when the channel path becomes not physically available or whenever the device appears not operational on the channel path for which the dedicated allegiance exists.

Channel-Path Availability

When a channel path is not physically available, the channel subsystem does not use the channel path to perform any of the basic I/O functions except, in some cases, the channel-path-reset function and does not respond to any control-unit-initiated requests on that same channel path. If a channel path is not physically available, the condition is indicated by the corresponding path-available-mask PAM bit being zero when STORE SUBCHANNEL is executed (see“Path-Available Mask (PAM)” on page 15-7). Furthermore, if the channel path is not physically available for the subchannel designated by STORE SUBCHANNEL, then it is not physically available for any subchannel that has a device which is accessible by that channel path.

Unless a dedicated allegiance exists at a subchannel for the channel path, a channel path becomes available for selection if it is logically available and physically available, as indicated by the bits in the LPM and PAM corresponding to the channel path being stored as ones when STORE SUBCHANNEL is executed. If a dedicated allegiance exists at a subchannel for the channel path, only that channel path is available for selection, and the setting of the corresponding LPM bit is ignored. If the channel path is currently being used and a dedicated allegiance exists at the subchannel for the channel path, selection of the device is delayed until the channel path is no longer being used.

The availability status of the eight logical paths to the associated device described in Figure 15-4 on page 15-14 is determined by the hierarchical arrangement of the corresponding bit values contained in the PIM, PAM, and LPM and by existing conditions, if any, recognized by the channel subsystem.

Value of Bit 'n'			Channel-Path Condition1	Channel-Path State
PIM	PAM	LPM		
0	0[2]	-	X	Not installed
1	0	-	X	Not physically available
1	1	0[3]	X	Not logically available
1	1	1[3]	Active	Available for selection[4]
1	1	1	Inactive	Available for selection

Explanation:

- Bit value is not meaningful.
1 If the channel path is recognized as being used in active communication with a device, the channel-path condition is described as active. Otherwise, its condition is described as inactive.
2 A PAM bit cannot have the value one when the corresponding PIM bit has the value zero.
3 If a dedicated allegiance exists to the channel path at the subchannel, the state of the bit is ignored, and the channel path is considered to be available for selection.
4 The channel path may appear to be active when a channel-path-terminal condition has been recognized.
X Condition is not meaningful.

Figure 15-4. Path condition and Path-Availability Status for PIM, PAM, and LPM Values

Control-Unit Type

In “Clear Function” on page 15-14, “Halt Function” on page 15-16, and “Start Function and Resume Function” on page 15-20, reference is made to type-1, type-2, and type-3 control units. For a description of these control-unit types, see the System Library publication *IBM System/360 and System/370 I/O Interface Channel to Control Unit OEMI*, GA22-6974. For the purposes of this definition, all control units attaching to a serial-I/O interface are considered type-2 control units.

Clear Function

Subsequent to the execution of CLEAR SUBCHANNEL, the channel subsystem performs the clear function. Performance of the clear function consists in (1) performing a path-management operation, (2) modifying fields at the subchannel, (3) issuing the clear signal to the associated device, and (4) causing the subchannel to be made status pending, indicating the completion of the clear function.

Clear-Function Path Management

A path-management operation is performed as part of the clear function in order to examine channel-path conditions for the associated subchannel and to attempt to choose an available channel path on which the clear signal can be issued to the associated device.

Channel-path conditions are examined in the following order:

1. If the channel subsystem is actively communicating or attempting to establish active communication with the device to be signaled, the channel path that is in use is chosen.

2. If the channel subsystem is in the process of accepting a no-longer-busy indication (which will not cause an interruption condition to be recognized) from the device to be signaled, and the associated subchannel has no allegiance to any channel path, the channel path that is in use is chosen.

3. If the associated subchannel has a dedicated allegiance for a channel path, that channel path is chosen.

4. If the associated subchannel has a working allegiance for one or more channel paths, one of those channel paths is chosen.

5. If the associated subchannel has no allegiance for any channel path, if a last-used channel path is indicated, and if that channel path is available for selection, that channel path is chosen. If that channel path is not available for selection, either no channel path is chosen or a channel path is chosen from the set of channel paths, if any, that are available for selection (as though no last-used channel path were indicated).

6. If the associated subchannel has no allegiance for any channel path, if no last-used channel path is indicated, and if there exist one or more channel paths that are available for selection, one of those channel paths is chosen.

If none of the channel-path conditions listed above apply, no channel path is chosen.

For item 4, for item 5 under the specified conditions, and for item 6, the channel subsystem chooses a channel path from a set of channel paths. In these cases, the channel subsystem may attempt to choose a channel path, provided that the following conditions *do not* apply:

1. A channel-path-terminal condition exists for the channel path.

2. For a parallel or ESCON channel path: Another subchannel has an active allegiance for the channel path.

   For a FICON channel path: The channel path is currently being used to actively communicate with the maximum number of subchannels that can have concurrent active communications.

3. The device to be signaled is attached to a type-1 control unit, and the subchannel for another device attached to the same control unit has an allegiance to the same channel path, unless the allegiance is a working allegiance and primary status has been accepted by that subchannel.

4. The device to be signaled is attached to a type-3 control unit, and the subchannel for another device attached to the same control unit has a dedicated allegiance to the same channel path.

Clear-Function Subchannel Modification

Path-management-control indications at the subchannel are modified during performance of the clear function. Effectively, this modification occurs after the attempt to choose a channel path, but prior to the attempt to select the device to issue the clear signal. The path-management-control indications that are modified are as follows:

1. The state of all eight possible channel paths at the subchannel is set to operational for the subchannel.

2. The last-path-used indication is reset to indicate no last-used channel path.

3. Path-not-operational conditions, if any, are reset.

Clear-Function Signaling and Completion

Subsequent to the attempt to choose a channel path and the modification of the path-management-control fields, the channel subsystem, if conditions allow, attempts to select the device to issue the clear signal. (See “Clear Signal” on page 17-12.) Conditions associated with the subchannel and the chosen channel path, if any, affect (1) whether an attempt is made to issue the clear signal, and (2) whether the attempt to issue the clear signal is successful. Independent of these conditions, the subchannel is subsequently set status pending, and the performance of the clear function is complete. These conditions and their effect on the clear function are described as follows:

No Attempt Is Made to Issue the Clear Signal: The channel subsystem does not attempt to issue the clear signal to the device if any of the following conditions exist:

1. No channel path was chosen. (See “Clear-Function Path Management” on page 15-14.)

2. The chosen channel path is no longer available for selection.

3. A channel-path-terminal condition exists for the chosen channel path.

4. For parallel and ESCON channel paths: The chosen channel path is currently being used to actively communicate with a different device.

   For FICON channel paths: The chosen channel path is currently being used to actively communicate with the maximum number of devices that can have concurrent active communications.

5. The device to be signaled is attached to a type-1 control unit, and the subchannel for another device attached to the same control unit has an allegiance to the same channel path, unless the allegiance is a working allegiance and primary status has been accepted by that subchannel.

6. The device to be signaled is attached to a type-3 control unit, and the subchannel for another device attached to the same control unit has a dedicated allegiance to the same channel path.

If any of the conditions above exist, the subchannel remains clear pending and is set status pending, and the performance of the clear function is complete.

The Attempt to Issue the Clear Signal Is Not Successful: When the channel subsystem attempts to issue the clear signal to the device, the attempt may not be successful because of the following conditions:

1. The control unit or device signals a busy condition when the channel subsystem attempts to select the device to issue the clear signal.

2. A path-not-operational condition is recognized when the channel subsystem attempts to select the device to issue the clear signal.

3. An error condition is encountered when the channel subsystem attempts to issue the clear signal.

If any of the conditions above exists and the channel subsystem either determines that the attempt to issue the clear signal was not successful or cannot determine whether the attempt was successful, the subchannel remains clear pending and is set status pending, and the performance of the clear function is complete.

The Attempt to Issue the Clear Signal Is Successful: When the channel subsystem determines that the attempt to issue the clear signal was successful, the subchannel is no longer clear pending and is set status pending, and the performance of the clear function is complete. When the subchannel becomes status pending, the I/O operation, if any, with the associated device has been terminated.

Programming Note: Subsequent to the performance of the clear function, any nonzero status, except control unit end alone, that is presented to the channel subsystem by the device is passed to the program as unsolicited alert status. Unsolicited status consisting of control unit end alone or zero status is not presented to the program.

Halt Function

Subsequent to the execution of HALT SUBCHANNEL, the channel subsystem performs the halt function. Performance of the halt function consists of (1) performing a path-management operation, (2) issuing the halt signal to the associated device, and (3) causing the subchannel to be made status pending, indicating the completion of the halt function.

Halt-Function Path Management

A path-management operation is performed as part of the halt function to examine channel-path conditions for the associated subchannel and to attempt to choose a channel path on which the halt signal can be issued to the associated device.

Channel-path conditions are examined in the following order:

1. If the channel subsystem is actively communicating or attempting to establish active communication with the device to be signaled, the channel path that is in use is chosen.

2. If the channel subsystem is in the process of accepting a no-longer-busy indication (which will not cause an interruption condition to be recognized) from the device to be signaled, and the associated subchannel has no allegiance to any channel path, the channel path that is in use is chosen.

3. If the associated subchannel has a dedicated allegiance for a channel path, that channel path is chosen.

4. If the associated subchannel has a working allegiance for one or more channel paths, one of those channel paths is chosen.

5. If the associated subchannel has no allegiance for any channel path, if a last-used channel path is indicated, and if that channel path is available for selection, that channel path is chosen. If that channel path is not available for selection, either no channel path is chosen or a channel path is chosen from the set of channel paths, if any, that are available for selection (as though no last-used channel path were indicated).

6. If the associated subchannel has no allegiance for any channel path, if no last-used channel path is indicated, and if there exist one or more channel paths that are available for selection, one of those channel paths is chosen.

If none of the channel-path conditions listed above apply, no channel path is chosen.

For item 4, for item 5 under the specified conditions, and for item 6, the channel subsystem chooses a channel path from a set of channel paths. In these cases, the channel subsystem may attempt to choose a channel path for which the following conditions *do not* apply:

1. A channel-path-terminal condition exists for the channel path.

2. For a parallel or ESCON channel path: Another subchannel has an active allegiance for the channel path.

   For a FICON channel path: The channel path is currently being used to actively communicate with the maximum number of subchannels that can have concurrent active communications.

3. The device to be signaled is attached to a type-1 control unit, and the subchannel for another device attached to the same control unit has an allegiance to the same channel path, unless the allegiance is a working allegiance and primary status has been accepted by that subchannel.

4. The device to be signaled is attached to a type-3 control unit, and the subchannel for another device attached to the same control unit has a dedicated allegiance to the same channel path.

Halt-Function Signaling and Completion

Subsequent to the attempt to choose a channel path, the channel subsystem, if conditions allow, attempts to select the device to issue the halt signal. (See “Halt Signal” on page 17-12.)

Conditions associated with the subchannel and the chosen channel path, if any, affect (1) whether an attempt is made to issue the halt signal, (2) whether the attempt to issue the halt signal is successful, and (3) whether the subchannel is made status pending to complete the halt function. These conditions and their effect on the halt function are described as follows:

No Attempt Is Made to Issue the Halt Signal: The channel subsystem does not attempt to issue the halt signal to the device if any of the following conditions exist:

1. No channel path was chosen. (See “Halt-Function Path Management” on page 15-16.)

2. The chosen channel path is no longer available for selection.

3. A channel-path-terminal condition exists for the chosen channel path.

4. The associated subchannel is status pending with other than intermediate status alone.

5. The device to be signaled is attached to a type-1 control unit, and the subchannel for another device attached to the same control unit has an allegiance to the same channel path, unless the allegiance is a working allegiance and primary status has been accepted by that subchannel.

6. The device to be signaled is attached to a type-3 control unit, and the subchannel for another device attached to the same control unit has a dedicated allegiance to the same channel path.

If the conditions described in items 3, 5, or 6 exist, the associated subchannel remains halt pending until those conditions no longer exist. When the conditions no longer exist (for the channel-path-terminal condition, when the condition no longer exists as a result of executing RESET CHANNEL PATH), the channel subsystem attempts to issue the halt signal to the device.

If any of the remaining conditions above exist, the subchannel remains halt pending and is set status pending, and the halt function is complete.

The Attempt to Issue the Halt Signal Is Not Successful: When the channel subsystem attempts to issue the halt signal to the device, the attempt may not be successful because of the following conditions:

1. The control unit or device signals a busy condition when the channel subsystem attempts to select the device to issue the halt signal.
2. A path-not-operational condition is recognized when the channel subsystem attempts to select the device to issue the halt signal.
3. An error condition is encountered when the channel subsystem attempts to issue the halt signal.

If the control unit or device signals a busy condition (item 1), the subchannel remains halt pending until the internal indication of busy is reset. When this event occurs, the channel subsystem again attempts to issue the halt signal to the device.

If any of the remaining conditions above exists and the channel subsystem either determines that the attempt to issue the halt signal was not successful or cannot determine whether the attempt was successful, then the subchannel remains halt pending and is set status pending, and the halt function is complete.

The Attempt to Issue the Halt Signal Is Successful: When the channel subsystem determines that the attempt to issue the halt signal was successful and ending status, if appropriate, has been received at the subchannel, the subchannel is no longer halt pending and is set status pending, and the halt function is complete. When the subchannel becomes status pending, the I/O operation, if any, with the associated device has been terminated. The conditions that affect the receipt of ending status at the subchannel, and the effect of the halt signal at the device are described in the following discussion.

When the subchannel is subchannel-and-device active or only device active during the performance of the halt function, the state continues until the subchannel is made status pending because (1) the device has provided ending status or (2) the channel subsystem has determined that ending status is unavailable.

When the subchannel is operating in command mode and is idle, start pending, start pending and resume pending, suspended, or suspended and resume pending, or when the halt signal is issued during command chaining after the receipt of device end but before the next command is transferred to the device, no operation is in progress at the device, and therefore no status is generated by the device as a result of receiving the halt signal. When the subchannel is neither subchannel active, nor status pending with intermediate status, and no errors are detected during the attempt to issue the halt signal to the device, an interruption condition indicating status pending alone is generated after the halt signal is issued.

When the subchannel is operating in transport mode and is start pending, an operation may or may not be in progress at the device. Regardless of whether an operation is in progress, device status is not generated.

The effect of the halt signal at the device depends partially on the subchannel operation mode, type of device, and its state. The effect of the halt signal on a device that is not active or that is performing a mechanical operation in which data is not transferred across the channel path, such as rewinding tape or positioning a disk-access mechanism, depends upon the control-unit or device model. If the device is performing a type of operation that is unpredictable in duration or in which data is transferred across the channel path, the control unit interprets the signal as one to terminate the operation. Pending status conditions at the device are not reset. When the control unit recognizes the halt signal, it immediately ceases all communication with the channel subsystem until it has reached the normal ending point. The control unit then requests selection by the channel subsystem to present any generated status.

If the subchannel is involved in the data-transfer portion of an I/O operation, data transfer is terminated during the performance of the halt function, and the device is logically disconnected from the channel path. If the halt function is addressed to a subchannel operating in command mode, performing a chain of I/O operations, and the device has already provided channel end for the current I/O operation, the channel subsystem causes the device to be discon-

nected and command chaining or command retry to be suppressed.

If the subchannel is operating in command mode, performing a chain of I/O operations with the device, and the halt signal is issued during command chaining at a point after the receipt of device end for the previous I/O operation but before the next command is transferred to the device, the subchannel is made status pending with primary and secondary status immediately after the halt signal is issued. The device-status field of the SCSW contains zeros in this case. If the halt function is addressed to a subchannel that is operating in command mode, start pending, and the halt-pending condition is recognized before initiation of the start function, initiation of the start function is not attempted, and the subchannel becomes status pending after the device has been signaled.

If the halt function is addressed to a subchannel operating in transport mode that is start pending, the halt signal is issued as follows

- If the TCCB has been transported to the I/O device for execution, the halt signal is issued and the subchannel becomes status pending.
- If the TCCB has not been transported to the I/O device, the TCCB is not transported and the subchannel becomes status pending.

When the subchannel is not performing an I/O operation with the associated device, the device is selected, and an attempt is made to issue the halt signal as the device responds. If the subchannel is in the device-active state, the subchannel does not become status pending until it receives the device-end status from the halted device. If the subchannel is neither subchannel-and-device active nor device active, the subchannel becomes status pending immediately after selecting the device and issuing the halt signal. The SCSW for the latter case has the status-pending bit set to one (see “Status-Pending (Bit 31)” on page 16-19).

The termination of an I/O operation by performing the halt function may result in two distinct interruption conditions.

The first interruption condition occurs when the device generates the channel-end condition. The channel subsystem handles this condition as it would any other interruption condition from the device, except that the command address in the associated SCSW designates the point at which the I/O operation is terminated as follows:

- When a command-mode IRB is stored, the SCSW contains the address of the last-executed CCW, plus 8, and the subchannel-status bits may reflect unusual conditions that were detected.
- When a transport-mode IRB is stored, the SCSW contains the address of the current TCW, and the subchannel-status, subchannel-extended-status, and FCX bits may reflect unusual conditions that were detected.

If the halt signal was issued before all data designated for the operation had been transferred, incorrect length is indicated, subject to the control of the SLI flag in the current CCW when the subchannel is operating in command mode. The value in the count field of the associated SCSW is unpredictable. If the halt signal was issued before all data designated for the operation had been transferred, incorrect length is not indicated, when the subchannel is operating in transport mode.

The second interruption condition occurs if device-end status was not presented with the channel-end interruption condition. In this situation, the subchannel-key, command-address, and count fields of the associated SCSW are not meaningful.

When HALT SUBCHANNEL terminates an I/O operation, the method of termination differs from that used upon exhaustion of count or upon detection of programming errors to the extent that termination by HALT SUBCHANNEL is not contingent on the receipt of a service request from the associated device.

Programming Notes:

1. When, after an operation is terminated by HALT SUBCHANNEL, the subchannel is status pending with primary, primary and secondary, or secondary status, the extent of data transferred as described by the count field is unpredictable.
2. When the path that is chosen by the path-management operation has a channel-path-terminal condition associated with it, the halt function remains pending until the condition no longer exists. Until the condition is cleared, the associated subchannel cannot be used to perform I/O operations, even if other channel paths become

available for selection. CLEAR SUBCHANNEL can be executed to terminate the halt-pending condition and make the subchannel usable.

Start Function and Resume Function

The start and resume functions initiate I/O operations as described below. The start function applies to subchannels operating in either command mode or transport mode. The resume function applies only to subchannels operating in command mode.

Subsequent to the execution of START SUBCHANNEL and RESUME SUBCHANNEL, the channel subsystem performs the start and resume functions, respectively, to initiate an I/O operation with the associated device. Performance of a start or resume function consists of: (1) performing a path-management operation, (2) performing an I/O operation or chain of I/O operations with the associated device, and (3) causing the subchannel to be made status pending, indicating the completion of the start function. (Completion of a start function is described in "I/O Interruptions" on page 16-1.) The start function initiates the execution of a channel program that is designated in the ORB, which in turn is designated as the operand of START SUBCHANNEL, in contrast to the resume function that initiates the execution of a suspended channel program, if any, beginning at the CCW that caused suspension; otherwise, the resume function is performed as if it were a start function (see "Resume-Pending (Bit 20)" on page 16-14).

Start-Function and Resume-Function Path Management

A path-management operation is performed by the channel subsystem during the performance of either a start or a resume function to choose an available channel path that can be used for device selection to initiate an I/O operation with that device. The actions taken are as follows:

1. If the subchannel is currently start pending and device active, the start function remains pending at the subchannel until the secondary status for the previous start function has been accepted from the associated device and the subchannel is made start pending alone. When the status is accepted and does not describe an alert interruption condition, the subchannel is not made status pending, and the performance of the pending start function is subsequently initiated. If the status describes an alert interruption condition, the subchannel becomes status pending with secondary and alert status, the pending start function is not initiated, deferred condition code 1 is set, and the start-pending bit remains one. If the subchannel is currently start pending alone, the performance of the start function is initiated as described below.
2. If a dedicated allegiance exists at the subchannel for a channel path, the channel subsystem chooses that path for device selection. If a busy condition is encountered while attempting to select the device and a dedicated allegiance exists at the subchannel, the start function remains pending until the internal indication of busy is reset for that channel path. When the internal indication of busy is reset, the performance of the pending start function is initiated on that channel path.
3. If no channel path is available for selection and no dedicated allegiance exists in the subchannel for a channel path, a channel path is not chosen.
4. If all channel paths that are available for selection have been tried and one or more of them are being used to actively communicate with other devices, or, alternatively, if the channel subsystem has encountered either a control-unit-busy or a device-busy condition on one or more of those channel paths, or a combination of those conditions on one or more of those channel paths, the start function remains pending at the subchannel until a channel path, control unit, or device, as appropriate, becomes available.
5. If (1) the start function is to be initiated on a channel path with a device attached to a type-1 control unit and (2) no other device is attached to the same control unit whose subchannel has either a dedicated allegiance to the same channel path or a working allegiance to the same channel path where primary status has not been received for that subchannel, then that channel path is chosen if it is available for selection; otherwise, that channel path is not chosen. If, however, another channel path to the device is available for selection and no allegiances exist as described above, that channel path is chosen. If no other channel path is available for selection,

the start or resume function, as appropriate, remains pending until a channel path becomes available.

6. If the device is attached to a type-3 control unit, and if at least one other device is attached to the same control unit whose subchannel has a dedicated allegiance to the same channel path, another channel path that is available for selection may be chosen, or the start function remains pending until the dedicated allegiance for the other device is cleared.

7. If a channel path has been chosen and a busy indication is received during device selection to initiate the execution of the first command of a pending CCW channel program or to transport the TCCB of a pending TCW channel program, the channel path over which the busy indication is received is not used again for that device or control unit (depending on the device-busy or control-unit-busy indication received) until the internal indication of busy is reset.

8. If, during an attempt to select the device in order to initiate the execution of the first command specified for the start or implied for the resume function for a CCW channel program, or to initiate the transportation of the TCCB for the start function for a TCW channel program, (as described in action 7 above), the channel subsystem receives a busy indication, it performs one of the following actions:

   a. If the device is specified to be operating in the multipath mode and the busy indication received is device busy, then the start or resume function remains pending until the internal indication of busy is reset. (See “Multipath Mode (D)” on page 15-4.)

   b. If the device is specified to be operating in the multipath mode and the busy indication received is control unit busy, or if the device is specified to be operating in the single-path mode, the channel subsystem attempts selection of the device by choosing an alternate channel path that is available for selection and continues the path-management operation until either the start or the resume function is initiated or selection of the device has been attempted on all channel paths that are available for selection. If the start or resume function has not been initiated by the channel subsystem after all channel paths available for selection have been chosen, the start or resume function remains pending until the internal indication of busy is reset.

   c. If the subchannel has a dedicated allegiance, then action 2 on page 20 applies.

9. When, during the selection attempt to transfer the first command for a CCW channel program, or to transport the TCCB for a TCW channel program, the device appears not operational and the corresponding channel path is operational for the subchannel, a path-not-operational condition is recognized, and the state of the channel path changes at the subchannel from operational for the subchannel to not operational for the subchannel (see “Path-Not-Operational Mask (PNOM)” on page 15-5). The path-not-operational conditions at the subchannel, if any, are preserved until the subchannel next becomes clear pending, start pending, or resume pending (if the subchannel was suspended), at which time the path-not-operational conditions are cleared. If, however, the corresponding channel path is not operational for the subchannel, a path-not-operational condition is not recognized. When the device appears not operational during the selection attempt to transfer the first command or TCCB on a channel path that is available for selection, one of the following actions occurs:

   a. If a dedicated allegiance exists for that channel path, then it is the only channel path that is available for selection; therefore, further attempts to initiate the start or resume function are abandoned, and an interruption condition is recognized.

   b. If no dedicated allegiance exists and there are alternate channel paths available for selection that have not been tried, one of those channel paths is chosen to attempt device selection and transfer the first command for a CCW channel program, or the TCCB for a TCW channel program.

   c. If no dedicated allegiance exists, no alternate channel paths are available for selection that have not been tried, and the device has appeared operational on at least one of the channel paths that were tried, the start or resume function remains pending at the subchannel until a channel path, a control unit,

or the device, as appropriate, becomes available.

d. If no dedicated allegiance exists, no alternate channel paths are available for selection that have not been tried, and the device has appeared not operational on all channel paths that were tried, further attempts to initiate the start or resume function are abandoned, and an interruption condition is recognized.

10. When the subchannel is active and an I/O operation is to be initiated with a device, all device selections occur according to the LPUM indication if the multipath mode is not specified at the subchannel. For example, if command chaining is specified for a CCW channel program, the channel subsystem transfers the first and all subsequent commands describing a chain of I/O operations over the same channel path.

Interrogate Function

Subsequent to the execution of CANCEL SUBCHANNEL for a subchannel operating in transport mode, the channel subsystem performs the interrogate function. Performance of the interrogate function consists of (1) transporting the designated interrogate TCCB to the I/O device, (2) storing the interrogate TSB, and (3) causing the subchannel to become intermediate status pending with interrogate-complete status indicated.

All storage accesses used to perform the interrogate operation are made as if a storage-access key of zero is used. However, accesses are still subject to secure-storage-access exception checking.

Interrogate-Function Path Management

The same channel path that was used to transport the TCCB for the I/O operation being interrogated is used for the interrogate function.

Interrogate TCCB Transportation and Completion

Subsequent to determining the channel path, the channel subsystem, if conditions allow, attempts to transport the interrogate TCCB. Conditions associated with the subchannel, the interrogate TCCB, and the chosen channel path, if any, affect (1) whether an attempt is made to transport the interrogate TCCB, (2) whether the attempt to transport the interrogate TCCB is successful, and (3) whether the interrogate TSB is stored. These conditions and their effect on the interrogate function are described as follows:

No Attempt Is Made to Transport the Interrogate TCCB: The channel subsystem does not transport the interrogate TCCB if any of the following conditions exists:

- The subchannel is status pending with primary status indicated.
- The subchannel is idle or device active only.
- The TCCB for the I/O operation being interrogated has not been transported to the device.
- Another interrogate function is already in progress on the channel path for the I/O device.
- The interrogate-TCW-address field of the TCW for the I/O operation being interrogated contains zeros.
- The channel subsystem doesn't have the resources to process the interrogate.

The Attempt to Transport the Interrogate TCCB or Store the Interrogate TSB is Unsuccessful: When the channel subsystem attempts to transport the interrogate TCCB, the attempt may not be successful if any of the following conditions exists:

- The interrogate-TCW address designated by the TCW of the I/O operation being interrogated designates an unavailable storage location or does not designate the interrogate TCW on a 64-byte boundary.
- The TCCB-TIDA flag is one in the flags field of the interrogate TCW and the TCCB-address field in the interrogate TCW does not designate the first TIDAW on a quadword boundary.
- The interrogate-TSB address designated by the TCW of the I/O operation being interrogated designates an unavailable storage location or does not designate the interrogate TSB on a doubleword boundary.

If any of the above conditions is true, the subchannel is made status pending with program check and

interrogate-failed status indicated in the subchannel-extended-status field of the IRB.

The attempt to transport the interrogate TCCB is also not successful when a device-detected program check is recognized. In this case, interrogate-failed status is also indicated in the subchannel-extended-status field of the IRB.

If the interrogate TCCB has been sent and the corresponding interrogate response is not received within a model-dependent amount of time, an interface-control check is recognized with interrogate-failed status indicated in the subchannel-extended-status field of the IRB.

The Attempt to Transport the Interrogate TCCB is Successful: When the channel subsystem determines that the attempt to transport the interrogate TCCB was successful and the interrogate data has been received at the subchannel before the completion of the I/O operation being interrogated, the interrogate data is stored into the interrogate TSB, and the subchannel is made status pending with intermediate status and interrogate-complete status indicated. The status related to the operation being interrogated remains unchanged.

When the channel subsystem determines that the operation being interrogated has completed before the interrogate data has been received at the subchannel, the channel subsystem waits until the interrogate data is received. When received, the interrogate data is stored into the interrogate TSB, and the subchannel is made status pending with primary status indicated. The status related to the operation being interrogated is unchanged.

Execution of I/O Operations

After a channel path is chosen, the channel subsystem, if conditions allow, initiates the execution of an I/O operation with the associated device. Execution of additional I/O operations may follow the initiation and execution of the first I/O operation.

For subchannels operating in command mode, the channel subsystem can execute seven types of commands: write, read, read backward, control, sense, sense ID, and transfer in channel. Each command, except transfer in channel, initiates a corresponding I/O operation. Except for periods when channel-program execution is suspended at the subchannel (see “Suspension of CCW Channel-Program Execution” on page 15-73), the subchannel is active from the acceptance of the first command until the primary interruption condition is recognized at the subchannel. If the primary interruption condition is recognized before the acceptance of the first command, the subchannel does not become active. Normally, the primary interruption condition is caused by the channel-end signal or, in the case of command chaining, the channel-end signal for the last CCW of the chain. (See “Primary Interruption Condition” on page 16-4.) The device is active until the secondary interruption condition is recognized at the subchannel. Normally, the secondary interruption condition is caused by the device-end signal or, in the case of command chaining, the device-end signal for the last CCW of the chain. (See “Secondary Interruption Condition” on page 16-5.)

For subchannels operating in transport mode, the channel subsystem can transport six types of commands for execution: write, read, control, sense, sense ID, and interrogate. Each command initiates a corresponding device operation. When one or more commands are transported to the I/O device in a TCCB, the subchannel remains start pending until primary status is presented.

Programming Notes:

In the single-path mode, all transfers of commands, data, and status for the I/O operation or chain of I/O operations occur on the channel path over which the first command was transferred to the device.

When the device has the dynamic-reconnection feature installed, an I/O operation or chain of I/O operations may be performed in the multipath mode. To operate in the multipath mode, MODIFY SUBCHANNEL must have been previously executed for the subchannel with bit 13 of word 1 of the SCHIB specified as one. (See “Multipath Mode (D)” on page 15-4.) In addition, the device must be set up for the multipath mode by the execution of certain model-dependent commands appropriate to that type of device. The general procedures for handling multipath-mode operations are as follows:

1. Setup
    a. A set-multipath-mode type of command must be successfully executed by the device on each channel path that is to be a member of

the multipath group being set up; otherwise, the multipath mode of operation may give unpredictable results at the subchannel. If, for any reason, one or more physically available channel paths to the device are not included in the multipath group, these channel paths must not be available for selection while the subchannel is operating in the multipath mode. A channel path can be made not available for selection by having the corresponding LPM bit set to zero either in the SCHIB prior to the execution of MODIFY SUBCHANNEL or in the ORB prior to the execution of START SUBCHANNEL.

b. When a set-multipath-mode type of command is transferred to a device, only a single channel path must be logically available in order to avoid alternate channel-path selection for the execution of that start function; otherwise, device-busy conditions may be detected by the channel subsystem on more than one channel path, which may cause unpredictable results for subsequent multipath-mode operations. This type of setup procedure should be used whenever the membership of a multipath group is changed.

2. Leaving the Multipath Mode

   To leave the multipath mode and continue processing in the single-path mode, either of the following two procedures may be used:

   a. A disband-multipath-mode type of command may be executed for any channel path of the multipath group. This command must be followed by either (1) the execution of MODIFY SUBCHANNEL with bit 13 of word 1 of the SCHIB specified as zero, or (2) the specification of only a single channel path as logically available in the LPM. A start function must not be performed at a subchannel operating in the multipath mode with multiple channel paths available for selection while the device is operating in single-path mode; otherwise, unpredictable results may occur at the subchannel for that function or subsequent start functions.

   b. A resign-multipath-mode type of command is executed on each channel path of the multipath group (the reverse of the setup described in item 1 on page 23). This command must be followed by either (1) the execution of MODIFY SUBCHANNEL with bit 13 of word 1 of the SCHIB specified as zero, or (2) the specification of only a single channel path as logically available in the LPM. No start function may be performed at a subchannel operating in the multipath mode with multiple channel paths available for selection while the device is operating in single-path mode; otherwise, unpredictable results may occur at the subchannel for that or subsequent start functions.

Blocking of Data

Data recorded by an I/O device is divided into blocks. The length of a block depends on the device; for example, a block can be a card, a line of printing, or the information recorded between two consecutive gaps on magnetic tape.

The maximum amount of information that can be transferred in one I/O operation is one block. An I/O operation is terminated when the associated main-storage area is exhausted or the end of the block is reached, whichever occurs first. For some operations, such as writing on a magnetic-tape unit or at an inquiry station, blocks are not defined, and the amount of information transferred is controlled only by the program.

Operation-Request Block

The operation-request block (ORB) is the operand of START SUBCHANNEL. The ORB specifies the parameters to be used in controlling that particular start function. These parameters include the interruption parameter, the subchannel key, the address of first CCW or the TCW, operation-control bits, priority-control numbers, and a specification of the logical availability of channel paths to the designated device.

The contents of the ORB are placed at the designated subchannel during the execution of START SUBCHANNEL, prior to the setting of condition code 0. If the execution will result in a nonzero condition code, the contents of the ORB are not placed at the designated subchannel.

The two rightmost bits of the ORB address must be zeros, placing the ORB on a word boundary; otherwise, a specification exception is recognized.

When the fibre-channel-extensions (FCX) facility is installed, the channel-program-type control (B) (word 1, bit 13) of the ORB specifies the type of channel program that is designated by the ORB. When B is zero, the ORB designates a CCW channel program. When the B is one, the ORB designates a TCW channel program. Only I/O-devices that support FCX recognize TCW channel programs.

If the contents of an ORB that designates a CCW channel program are placed at the designated subchannel during the execution of START SUBCHANNEL, the subchannel remains in command mode. Thus, such an ORB is also known as a command-mode ORB. If the contents of an ORB that designates a TCW channel program are placed at the designated subchannel during execution of START SUBCHANNEL, the subchannel enters transport mode. Thus, such an ORB is also known as a transport-mode ORB.

Command-Mode ORB

This section describes the command-mode ORB. The term operation-request block (ORB), in this section, means an ORB in which bit 13 of word 1 (the channel-program-type control (B)) is zero.

The format of the command-mode ORB is as follows when the ORB-format facility is not installed:

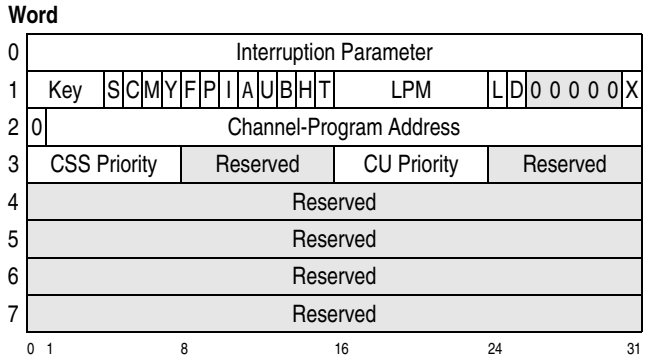

Figure 15-5. Command-Mode Operation-Request Block

The fields in the command-mode ORB are defined as follows:

Interruption Parameter: Bits 0-31 of word 0 are preserved unmodified in the subchannel until replaced by a subsequent START SUBCHANNEL or MODIFY SUBCHANNEL instruction. These bits are placed in word 1 of the interruption code when an I/O interruption occurs and when an interruption request is cleared by the execution of TEST PENDING INTERRUPTION.

Subchannel Key: Bits 0-3 of word 1 form the subchannel key for all fetching of CCWs, IDAWs, MIDAWS, and output data and for the storing of input data associated with the start function initiated by START SUBCHANNEL. This key is matched with a storage key during these storage references. For details, see the section “Key-Controlled Protection” on page 3-11.

When the storage-key-removal facility is installed, bits 0-3 of word one must be zero in the ORB when START SUBCHANNEL is executed; otherwise, an operand exception is recognized.

Suspend Control (S): Bit 4 of word 1 controls the performance of the suspend function for the channel program designated in the ORB. The setting of the S bit applies to all CCWs of the channel program designated by the ORB (see “Commands and Flags for CCWs” on page 15-75).

When bit 4 is one, suspend control is specified, and channel-program suspension occurs when a suspend flag set to one is detected in a CCW. When bit 4 is zero, suspend control is not specified, and the presence of a suspend flag set to one in any CCW of the channel program causes a program-check condition to be recognized.

Streaming-Mode Control (C): Bit 5 of word 1 controls streaming-mode enablement for subchannels configured to FICON-converted-I/O-interface channel paths during performance of the specified start function. When bit 5 is zero, the streaming mode is enabled at the subchannel. When bit 5 is one, the streaming mode is disabled at the subchannel. Bit 5 is meaningful only for subchannels configured to FICON-converted-I/O-interface channel paths and is ignored for subchannels configured to other channel-path types.

When the streaming mode is enabled, the channel path considers the first command of the designated channel program to be in progress at the associated device when the channel path receives the indication that the command has been accepted at the device. In addition, the channel path's acceptance of status, under certain conditions, is recognized by the channel path without receiving acknowledgement of status acceptance from the device.

When the streaming mode is not enabled, the channel path does not consider the first command of the designated channel program to be in progress at the associated device until the appropriate channel-path response, indicating that the device-command response or status has been accepted at the channel path, is sent to the device. In addition, when the device sends status to the channel path, the channel path's acceptance of that status is not recognized at the channel path until the channel path's confirmation of acceptance is received and acknowledged by the device.

Modification Control (M): Bit 6 of word 1 specifies whether modification control is required for the channel program. When bit 6 is zero, modification control is specified. When bit 6 is one, modification control is not specified.

When modification control is specified, the channel subsystem forces command synchronization with the addressed I/O device each time a command is executed and the previously executed command has the PCI and chain-command flags set to one and the chain-data and suspend flags set to zero. When this condition is recognized, the channel subsystem signals a synchronization request to the I/O device for the current command. The channel subsystem temporarily suspends command chaining and does not fetch (or refetch) the next command-chained CCW until after normal ending status is received for the synchronizing command.

When modification control is not specified, then command synchronization is not required, and the channel subsystem may transfer commands to the I/O device without waiting for status.

The M bit is meaningful only for subchannels configured to FICON-I/O-interface or FICON-converted-I/O-interface channel paths and is ignored for other subchannels configured to other channel-path types.

Programming Notes:

1. For FICON-I/O-interface and FICON-converted-I/O-interface channel paths, modification control provides the capability to optimize dynamically modified channel programs that use the PCI flag in the CCW to initiate channel-program modification. Specifically, it allows the program to delay the channel-subsystem fetching and transferring of commands until after status is received for the command following the command with the PCI bit set. This increases the likelihood that a program-controlled interruption will be accepted by a CPU and acted upon by the program that dynamically modifies one or more command-chained CCWs that follow the synchronizing command.

   In order to increase the probability that any dynamically modified CCWs are fetched after their modification and not prior to their modification, the modifying program should be executed as soon as possible following the CPU's acceptance of the program-controlled interruption. Additionally, the program should minimize the periods during which the configured CPUs are disabled for I/O interruptions.

   For channel paths other than FICON-I/O-interface or FICON-converted-I/O-interface channel paths, command synchronization is implicit in the signaling protocol between the channel subsystem and the I/O device; therefore no explicit programming action is required to force command synchronization. Regardless, the program should still attempt to accept and process program-controlled interruptions for these channel-path types in as timely a manner as possible for the same reason as stated above.

2. In order to allow the channel subsystem to optimize the execution of channel programs for FICON-I/O-interface or FICON-converted-I/O-interface channel paths, use of the modification-control facility is discouraged except for channel programs that require dynamic modification.

Synchronization Control (Y): Bit 7 of word 1 specifies whether synchronization control is required for the channel program. When bit 7 is zero and the prefetch-control bit, bit 9 of word 1, is one, synchronization control is specified. When bit 7 is one and bit 9 is one, synchronization control is not specified.

When synchronization control is specified, the channel subsystem forces command synchronization with the addressed I/O device whenever the current command in execution describes an input operation and the next CCW to be fetched describes an output operation. When this condition is recognized, the channel subsystem signals a synchronization request to the I/O device when the input command is transferred. The transfer of the output command is held pending at the subchannel until normal ending status, signaling the completion of the performance of the input operation by the I/O device, is received. Upon receipt of the ending status, the channel sub-

system fetches (or refetches) the data associated with the output command and transfers it to the I/O device.

When synchronization control is not specified, the channel subsystem may transfer commands of the channel program without awaiting status that would signal the completion of the I/O operation for each command.

The Y bit is meaningful only when the subchannel is configured to FICON-I/O-interface or FICON-converted-I/O-interface channel paths and the prefetch-control bit, bit 9 of word 1, is one. The Y bit is ignored for subchannels configured to other channel-path types and when the prefetch-control bit is zero.

CCW-Format Control (F): Bit 8 of word 1 specifies the format of the channel-command words (CCWs) that make up the channel program designated by the channel-program-address field. When bit 8 of word 1 is zero, format-0 CCWs are specified. When bit 8 is one, format-1 CCWs are specified. (See "Channel-Command Word" on page 15-31 for the definition of the CCW formats.)

Prefetch Control (P): Bit 9 of word 1 specifies whether or not unlimited prefetching of CCWs is allowed for the channel program. When bit 9 is one, unlimited prefetching of CCWs is allowed. (Unlimited prefetching of data, IDAWs, and MIDAWs, associated with the current and prefetched CCWs is always allowed.) It is model dependent whether prefetching is actually performed.

When bit 9 of word 1 is zero, no prefetching is allowed, except in the case of data chaining on output, where the prefetching of one CCW describing a data area is allowed. When bit 9 of word 1 is zero, the synchronization-control bit, bit 7 of word 1, is ignored.

Additional controls may limit the scope of prefetching.

Initial-Status-Interruption Control (I): Bit 10 of word 1 specifies whether or not the channel subsystem must verify to the program that the device has accepted the first command associated with a start or resume function. When the I bit is specified as one in the ORB, then, when the subchannel becomes active, indicating that the first command has been accepted for this start or resume function, the Z bit (see "Zero Condition Code (Z)" on page 16-12) is set to one at this subchannel, and the subchannel becomes status pending with intermediate status.

If the subchannel does not become active — for example, when the device signals channel end immediately upon receiving the first command, command chaining is not specified in the CCW, and command retry is not signaled — the command-accepted condition (Z bit set to one) is not generated; instead, the subchannel becomes status pending with primary status. Intermediate status may also be indicated in this case when the command is accepted if the first CCW contained the PCI flag set to one.

Address-Limit-Checking Control (A): When the address-limit-checking facility is installed, bit 11 of word 1 specifies whether or not address-limit checking is specified for the channel program. When this bit is zero, no address-limit checking is performed for the execution of the channel program, independent of the setting of the limit-mode bits in the subchannel (see "Limit Mode (LM)" on page 15-3). When this bit is one, address-limit checking is allowed for the channel program, subject to the setting of the limit-mode bits in the subchannel.

When the address-limit-checking facility is not installed, the address-limit-checking-control bit (A) must be zero in the ORB when START SUBCHANNEL is executed; otherwise, an operand exception is recognized.

Suppress-Suspended-Interruption Control (U): Bit 12 of word 1, when one, specifies that the channel subsystem is to suppress the generation of an intermediate interruption condition due to suspension if the subchannel becomes suspended. When bit 12 is zero, the channel subsystem generates an intermediate interruption condition whenever the subchannel becomes suspended during the execution of the channel program.

Channel-Program Type Control (B): Bit 13 of word 1 specifies the type of channel program that is designated by the channel-program-address field. When bit 13 is zero, the channel-program-address field designates a CCW channel program. When bit 13 is one, the channel-program-address field designates a TCW channel program. If the FCX facility is not installed and this bit is one, an operand exception or program-check exception is recognized.

Bit 13 also designates the layout of the ORB. When bit 13 is zero, a command-mode ORB is specified. When bit 13 is one, a transport-mode ORB is specified.

Format-2-IDAW Control (H):
Bit 14 of word 1 specifies the format of IDAWs for CCWs that specify indirect data addressing. When bit 14 of word 1 is one, format-2 (64-bit data address) IDAWs are provided for all CCWs that have the IDAW flag set to one in the CCW. When bit 14 of word 1 is zero, format-1 (31-bit data address) IDAWs are provided for all CCWs that have the IDAW flag set to one in the CCW.

Programming Note: Format-2 IDAWs and MIDAWs provide the only means by which data can be transferred directly between an I/O device and storage locations with addresses greater than 2G bytes.

2K-IDAW Control (T): Bit 15 of word 1 specifies the main-storage block size for format-2-IDAW data areas. Bit 15 is meaningful only when bit 14 (format-2 IDAW control) is one and is ignored when bit 14 is zero. When bit 15 of word 1 is one, all format-2 IDAWs designate 2 K-byte storage blocks. When bit 15 of word 1 is zero, all format-2 IDAWs designate 4 K-byte storage blocks.

Logical-Path Mask (LPM): Bits 16-23 of word 1 are preserved unmodified in the subchannel and specify to the channel subsystem which of the logical paths 0-7 are to be considered logically available, as viewed by the program. A bit setting of one means that the corresponding channel path is logically available; a zero specifies that the corresponding channel path is logically not available. If a channel path is specified by the program as being logically not available, the channel subsystem does not use that channel path to perform clear, halt, resume, or start functions when requested by the program, except when a dedicated-allegiance condition exists for that channel path. If a dedicated-allegiance condition exists, the setting of the LPM is ignored, and a resume, start, halt, or clear function is performed by using the channel path having the dedicated allegiance.

Incorrect-Length-Suppression Mode (L): When bit 8 of word 1 is one, then bit 24 of word 1, when one, specifies the incorrect-length-suppression mode. When the subchannel is in this mode when an immediate operation occurs (that is, when a device signals the channel-end condition during initiation of the command) and the current CCW contains a nonzero value in bit positions 16-31, indication of an incorrect-length condition is suppressed.

When bit 8 of word 1 is one, then bit 24 of word 1, when zero, specifies the incorrect-length-indication mode. When the subchannel is in this mode when an immediate operation occurs (that is, when a device signals the channel-end condition during initiation of the command) and the current CCW contains a nonzero value in bit positions 16-31, indication of an incorrect-length condition is recognized. Command chaining is suppressed unless the SLI flag in the CCW is one and the chain-data flag is zero.

When bit 8 of word 1 is zero, the value of bit 24 is ignored by the channel subsystem, and the subchannel is in the incorrect-length-suppression mode.

Modified-CCW-Indirect-Data-Addressing Control (D) : When the modified-CCW-indirect-data-addressing facility is installed, bit 25 of word 1 specifies whether the channel program may include CCWs that specify modified-CCW-indirect-data-address lists. When bit 25 of word 1 is one, the channel program may include CCWs that specify lists of quadwords each called a modified-CCW-indirect-data-address word (MIDAW). When bit 25 of word 1 is zero, the channel program may not include CCWs that specify modified-CCW-indirect-data-address lists.

When the modified-CCW-indirect-data-addressing facility is not installed, the modified-CCW-indirect-data-addressing control must be zero in the ORB when START SUBCHANNEL is executed; otherwise, an operand exception is recognized.

ORB-Extension Control (X): Bit 31 of word 1 specifies whether the ORB is extended. When bit 31 of word 1 is zero, the ORB consists of words 0-2, and words 3-7 are ignored. When bit 31 of word 1 is one, the ORB consists of words 0-7. Words 0 and 1 are described above. Words 2-7 are described below.

Reserved: Bits 26-30 of word 1 are reserved for future use and must be set to zeros. Bit 31 of word 1 must be zero if the ORB-extension facility is not installed. Otherwise, an operand exception or program-check condition is recognized.

Channel-Program Address: Bits 1-31 of word 2 specify the absolute address of the first CCW in main storage. Bit 0 of word 2 must be zero; otherwise, either an operand exception or a program-check condition is recognized. If format-0 CCWs are specified by bit 8 of word 1, then bits 1-7 of word 2 also must

be zeros; otherwise, a program-check condition is recognized.

The three rightmost bits of the channel-program address must be zeros, designating the CCW on a doubleword boundary; otherwise, a program-check condition is recognized.

If the channel-program address designates a location protected against fetching or designates a location outside the storage of the particular configuration, the start function is not initiated at the device. In this situation, the subchannel becomes status pending with primary, secondary, and alert status.

Channel-Subsystem (CSS) Priority: When bit 31 (X) of word 1 of the ORB is one, byte 0 of word 3 contains an unsigned binary integer, called the channel-subsystem-priority number, that is assigned to the designated subchannel and used to order the selection of subchannels when either a start function or a resume function is to be initiated for one or more subchannels that are start pending or resume pending.

The specified channel-subsystem-priority number can be any number in the range of 0 to 255. The numbers 0 and 255 designate the lowest and highest priorities, respectively.

Depending on the model and the configuration:

1. Fewer than 256 priority levels may be provided. For such models, the ORB-specified priority number may be ignored, and an alternative priority number may be implicitly assigned to the subchannel when the subchannel becomes start pending.
2. When bit 31 (X) of word 1 of the ORB is zero, an implicit priority number is assigned to the subchannel.

See “Channel-Subsystem-I/O-Priority Facility” on page 17-33 for details about how the priority number is assigned for both of these cases.

Control-Unit (CU) Priority: When bit 31 (X) of word 1 of the ORB is one, byte 2 of word 3 contains an unsigned binary integer, called the control-unit-priority number, that specifies, for an associated control unit attached by a FICON channel path, the priority level that is applied at the associated control unit for all I/O operations associated with the start function.

The specified control-unit-priority number can be any integer in the range of 1 to 255. The numbers 1 and 255 designate the lowest and highest priorities, respectively. The number 0 designates that no priority is assigned to the I/O operations associated with the start function. The handling of I/O operations when the priority number is 0 depends on the control-unit model.

Also depending on the control-unit model, fewer than 255 priority levels may be supported by the control unit. See the control-unit's System Library publication for additional information regarding the range of priority numbers supported and how this priority number is used.

The specified control-unit-priority number is ignored if any of the following conditions exists:

1. Bit 31 (X) of word 1 is zero. In this case, a control-unit-priority number of 0 is transmitted in the associated outbound frames.
2. The designated subchannel is not associated with a control unit configured to a FICON channel path.
3. The associated control unit does not provide prioritized performance of I/O operations. In this case, the control-unit-priority number in the associated outbound frames is ignored at the control unit.
4. The channel-subsystem model does not provide for the transmission of the control-unit-priority number.
5. The channel-subsystem-I/O-priority facility is not operational due to an operator action.

Reserved: All fields in the ORB that are defined as either "0" or "Reserved" must contain zeros when START SUBCHANNEL is executed; otherwise, either an operand exception or a program-check condition is recognized.

Programming Notes:

1. Bit positions of the ORB that presently are specified to contain zeros may in the future be assigned for the control of new functions.
2. The interruption parameter may contain any information, but ordinarily the information is of

significance to the program handling the I/O interruption.

Transport-Mode ORB

This section describes the transport-mode ORB. The term operation-request block (ORB), in this section, means an ORB in which bit 13 of word 1 (the channel-program-type control (B)) is one.

The format of the transport-mode ORB is as follows:

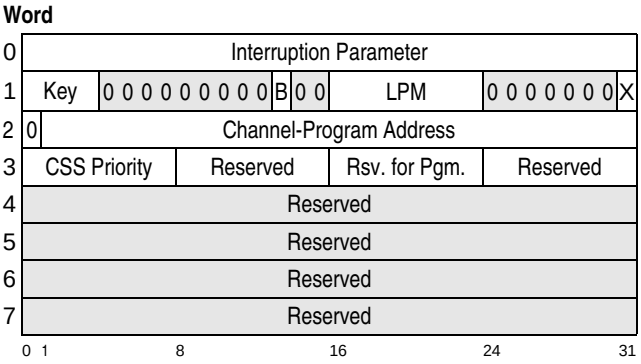

Figure 15-6. Transport-Mode Operation-Request Block

The fields in the transport-mode ORB are defined as follows:

Interruption Parameter: This field has the same meaning as in the ORB that designates a CCW channel program. See “Interruption Parameter” on page 15-2.

Subchannel Key: Bits 0-3 of word 1 form the subchannel key for all fetching of TCWs, TCCBs, TIDAWs, and output data and for the storing of input data associated with the start function initiated by START SUBCHANNEL. This key is matched with a storage key during these storage references. For details, see the section “Key-Controlled Protection” on page 3-11.

All storage accesses to the TSB are made as if the subchannel key is zero, but secure-storage-access exceptions still apply.

When the storage-key-removal facility is installed, bits 0-3 of word one must be zero in the ORB when START SUBCHANNEL is executed; otherwise, an operand exception is recognized.

Reserved: All fields in the ORB that are defined as either “0” or “Reserved” must contain zeros when START SUBCHANNEL is executed; otherwise, either an operand exception or a program-check condition is recognized.

Channel-Program Type Control (B): This bit has the same meaning as in the ORB that designates a CCW channel program. For the transport-mode ORB, the value of this bit is one. See “Channel-Program Type Control (B)” on page 15-27.

Logical-Path Mask (LPM): Bits 16-23 of word 1 are preserved unmodified in the subchannel and specify to the channel subsystem which of the logical paths 0-7 are to be considered logically available, as viewed by the program. A bit setting of one means that the corresponding channel path is logically available; a zero specifies that the corresponding channel path is logically not available. If a channel path is specified by the program as being logically not available, the channel subsystem does not use that channel path to perform clear, halt, or start functions when requested by the program.

If the LPM specifies a channel path that does not support FCX, either an operand-exception or a program check may be recognized.

ORB-Extension Control (X): This field has the same meaning as in the ORB that designates a CCW channel program. See “ORB-Extension Control (X)” on page 15-28.

Channel-Program Address: Bits 1-31 of word 2 specify the absolute address of the TCW in main storage. Bit 0 of word 2 must be zero; otherwise, either an operand exception or a program-check condition is recognized.

The six rightmost bits of the channel-program address must be zeros, designating the TCW on a 64-byte boundary; otherwise, a program-check condition is recognized.

If the channel-program address designates a location protected against fetching or designates a location outside the storage of the particular configuration, the start function is not initiated at the device. In this situation, the subchannel becomes status pending with primary, secondary, and alert status.

Channel-Subsystem (CSS) Priority: This field has the same meaning as in the ORB that designates a CCW channel program. See “Channel-Subsystem (CSS) Priority” on page 15-29

Reserved for Program Use (Rsv. for Pgm.): Byte 2 of word 3 is reserved for program use and is not checked or used by the channel subsystem.

Programming Note: See the programming notes on page 29.

Channel-Command Word

The channel-command word (CCW) specifies the command to be executed and, for commands initiating certain I/O operations, it designates the storage area associated with the operation, the action to be taken whenever transfer to or from the area is completed, and other options.

A channel program consists of one or more CCWs that are logically linked such that they are fetched and executed by the channel subsystem in either a sequential or a nonsequential order. Sequential (contiguous) CCWs are linked by the use of the chain-data and chain-command flags, and nonsequential (noncontiguous) CCWs are linked by a CCW specifying the transfer-in-channel command.

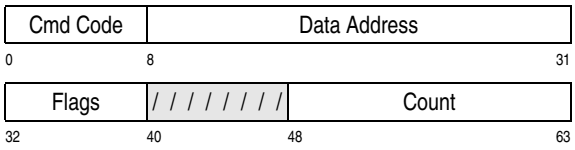
As each CCW is executed, it is recognized as the current CCW. A CCW becomes current (1) when it is the first CCW of a channel program and has been fetched, (2) when, during command chaining, the new CCW is logically fetched, or (3) when, during data chaining, the new CCW takes over control of the I/O operation (see “Data Chaining” on page 15-61). When chaining is not specified, a CCW is no longer current after TEST SUBCHANNEL clears the start-function bit in the subchannel.

The location of the first CCW of the channel program is designated in the ORB that is the operand of START SUBCHANNEL. The first CCW is fetched subsequent to the execution of the instruction. The format of the CCWs fetched by the channel subsystem is specified by bit 8 of word 1 of the ORB. Each additional CCW in the channel program is obtained when the CCW is needed. Fetching of the CCWs by the channel subsystem does not affect those locations in main storage.

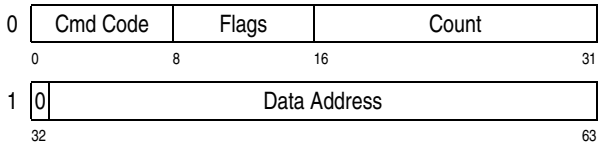
CCWs have either of two different formats, format 0 or format 1. The two formats do not differ in the information contained in the CCW, but they do differ in the size of the address and the arrangement of fields within the CCW.

The formats are defined as follows:

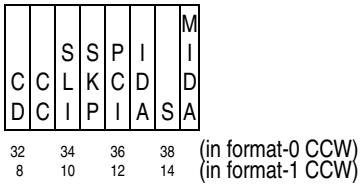
Format-0 CCW



Format-1 CCW



Flags



Format-0 CCWs can be located anywhere in the first 2^{24} (16M) bytes of absolute storage, and format-1 CCWs can be located anywhere in the first 2^{31} (2G) bytes of absolute storage.

If indirect data addressing is specified and the format-2-IDAW-control bit is zero in the ORB associated with the CCW, then:

1. Bits 30 and 31 (format 0) or 62 and 63 (format 1) of the CCW must be zeros, designating a word boundary,
2. Bit 0 of the first entry of the indirect-data-address list must be zero.
3. The MIDA flag must be zero.

If indirect data addressing is specified and the format-2-IDAW-control bit is one in the ORB associated with the CCW, bits 29-31 (format 0) or bits 61-63 (format 1) of the CCW must be zeros, designating a doubleword boundary.

If modified indirect data addressing is specified, then:

1. The modified-CCW-indirect-data-addressing-control bit in the ORB must be one.

2. Bits 28-31 (format 0) or bits 60-63 (format 1) of the CCW must be zeros, designating a quadword boundary.

3. The CCW SKP and IDA flags must be zero.

4. The MIDAW count field must be greater than zero.

5. The combination of the MIDAW count and data-address fields must not specify the transfer of data across a 4 K-byte boundary, unless skipping is in effect for the MIDAW.

6. Reserved bits in the first entry of the modified-CCW-indirect-data-address list must be zero.

When any of these requirements is not met, a program-check condition may be recognized (see "CCW Indirect Data Addressing" on page 15-66 and "Modified CCW Indirect Data Addressing" on page 15-68). Detection of this condition during data chaining causes the I/O device to be signaled to conclude the operation. When a failure to meet these requirements is detected during command chaining or subsequent to the execution of START SUBCHANNEL, the new operation is not initiated, and an interruption condition is generated.

The contents of bit positions 40-47 of a format-0 CCW are ignored.

The fields in the CCWs are defined as follows:

Command Code: Bits 0-7 (both formats) specify the operation to be performed.

Data Address: Bits 8-31 (format 0) or bits 33-63 (format 1) designate a location in absolute storage. The designated location is the first location referred to in the area designated by the CCW. Bit 32 of a format-1 CCW must be zero; otherwise, a program-check condition is recognized. If a byte count of zero is specified, this field is not checked.

When the MIDA flag is one, the data-address field must designate an absolute storage location that is on a quadword boundary; otherwise, a program-check condition is recognized.

See "CCW Indirect Data Addressing" on page 15-66 and "Modified CCW Indirect Data Addressing" on page 15-68 for information about the specification of data addresses greater than 2G bytes.

Chain-Data (CD) Flag: Bit 32 (format 0) or bit 8 (format 1), when one, specifies chaining of data. The bit causes the storage area designated by the next CCW to be used with the current I/O operation. When the CD flag is one in a CCW, the chain-command and suppress-length-indication flags (see below) are ignored.

Chain-Command (CC) Flag: Bit 33 (format 0) or bit 9 (format 1), when one, and when the CD flag and S flag are both zeros, specifies chaining of commands. The bit causes the operation specified by the command code in the next CCW to be initiated upon the normal completion of the current operation.

Suppress-Length-Indication (SLI) Flag: Bit 34 (format 0) or bit 10 (format 1) controls whether an incorrect-length condition is to be indicated to the program. When this bit is one and the CD flag is zero, the incorrect-length indication is suppressed. When both the CC and SLI flags are ones and the CD flag is zero, command chaining takes place, regardless of the presence of an incorrect-length condition. This bit should be specified in *all* CCWs where suppression of the incorrect-length indication is desired.

Skip (SKP) Flag: Bit 35 (format 0) or bit 11 (format 1), when one, specifies the suppression of transfer of information to storage during a read, read-backward, sense ID, or sense operation. This bit must be zero when the MIDA flag is one; otherwise, a program-check condition is recognized.

Program-Controlled-Interruption (PCI) Flag: Bit 36 (format 0) or bit 12 (format 1), when one, causes the channel subsystem to generate an intermediate interruption condition when the CCW containing the bit takes control of the I/O operation. When the PCI flag bit is zero, normal operation takes place.

Indirect-Data-Address (IDA) Flag: Bit 37 (format 0) or bit 13 (format 1), when one, specifies indirect data addressing. This bit must be zero when the MIDA flag is one; otherwise, a program-check condition is recognized.

Suspend (S) Flag: Bit 38 (format 0) or bit 14 (format 1), when one, specifies suspension of channel-program execution. When valid, it causes channel-program execution to be suspended prior to the execution of the CCW containing the S flag. A one value of the S flag is valid when bit 4 of word 1 of the associated ORB is one.

Modified-Indirect-Data-Address (MIDA) Flag: Bit 39 (format 0) or bit 15 (format 1), when one, specifies modified indirect data addressing. This bit must be zero when the modified-CCW-indirect-data-addressing-control bit in the ORB is zero, the CCW IDA flag is one, the CCW SKP flag is one, or the channel paths associated with the subchannel do not support modified CCW indirect data addressing; otherwise, a program-check condition is recognized.

Count: Bits 48-63 (format 0) or bits 16-31 (format 1) specify the number of bytes in the storage area designated by the CCW.

Transport Control Word

The transport-control word (TCW) specifies a transport-command-control block (TCCB) whose contents are to be transported to the I/O device for processing. The TCCB contains one or more device-command words (DCWs) and associated options. For a DCW that specifies a command which initiates the transfer of data (with the exception of control data contained within the TCCB), the TCW designates one or more storage areas where the data is located.

When a TCW specifies bidirectional data transfer and the designated DCWs specify write data transfers for storage areas that overlap with the storage areas for read data transfers, the results are unpredictable.

When START SUBCHANNEL is issued specifying a transport-mode ORB, the TCW designated by the ORB becomes the current TCW, the subchannel becomes start pending, and the TCCB designated by the TCW is transported to the I/O device for execution. The TCW remains the current TCW until TEST SUBCHANNEL clears the start-function indication in the subchannel.

The TCW is a 64-byte control block that is designated on a 64-byte boundary. For all operations, except for the interrogate operation, accesses to the TCW by the channel subsystem are made using the subchannel storage-access key specified in the ORB. For interrogate operations, fetch accesses to the interrogate TCW by the channel subsystem are made as if a subchannel storage-access key of zero is used and are subject to secure-storage-access protections. The channel subsystem does not make any store accesses to a TCW.

The format of the TCW is as follows:

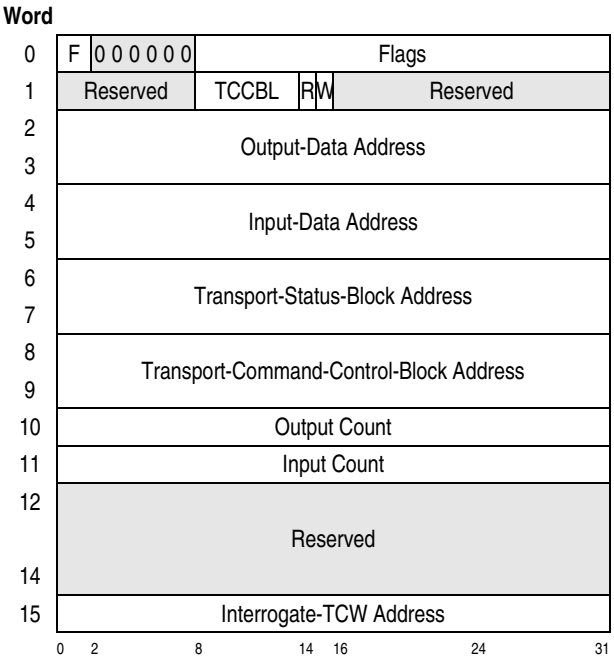


Figure 15-7. Transport-Control Word (TCW)

Format (F): Bits 0-1 of word 0 form the TCW-format that contains a 2-bit unsigned integer value that defines the layout of the TCW. The value of this field must be zero, otherwise a program-check condition is recognized.

Reserved: Bits 2-7 of word 0 are reserved and must be zeros, otherwise a program-check condition is recognized.

Bytes 0 and 2-3 of word 1 and words 12-14 are reserved and not checked. These fields are reserved for future extensions. Programs which place nonzero values in these fields may not operate compatibly on future models.

Flags: Bytes 1-3 of word 0 contain information about the TCW. The meaning of each flag bit is as follows:

Bit	***Meaning***
0-4	Reserved. Bits 0-4 are reserved and must be zero, otherwise a program-check condition is recognized.
5	Input transport-indirect-data addressing (TIDA): When bit 5 is zero and bit 14 of word 1 (the R-bit) is one, the input-data-

address field designates the absolute address of the input location. When bit 5 is one and the R-bit is one, the input-data-address field designates the absolute address of a transport-indirect-data-address word (TIDAW) or the first TIDAW in a list of TIDAWs that designates the input storage location or locations, respectively.

When the R-bit is zero, bit 5 has no meaning.

6 Transport-command-control-block TIDA: When bit 6 is zero, the transport-command-control-block-address field designates the absolute address of the transport-command-control block for the TCW. When bit 6 is one, the transport-command-control-block-address field designates the absolute address of a TIDAW or list of TIDAWs that designates the location or locations, respectively, of the transport-command-control block for the TCW.

7 Output TIDA: When bit 7 is zero and bit 15 of word 1 (the W-bit) is one, the output-data-address field designates an output location in absolute storage. When bit 7 is one and the W-bit is one, the output-data-address field designates the absolute address of a TIDAW or list of TIDAWs that designates the output storage location or locations, respectively.

When the W-bit is zero, bit 7 has no meaning.

8-9 TIDAW format: Bits 8-9 form a 2-bit encoded field that specifies the format of TIDAWs designated by the TCW. This field must contain zeros, otherwise a program-check condition is recognized.

10-23 Reserved. Bits 10-23 are reserved and must be zero, otherwise a program-check condition is recognized.

Transport-Command-Control-Block Length (TCCBL): Bits 8-13 of word 1, with two zeros appended on the right, specify the unsigned integer whose value, when added to 20 for unidirectional data transfers or when added to 24 for bidirectional data transfers, specifies the length of the TCCB in bytes. This field, before having 20 added to it for unidirectional data transfers or before having 24 added to it for bidirectional data transfers, must specify a length that is between 12 and 244 inclusive, otherwise a program-check condition is recognized.

Note: The TCCBL is based on the FCP additional command length and does not include the TCA header (16 bytes), and the transport-count (4 bytes) in the TCA trailer for unidirectional data transfers, nor does it include the write count (4 bytes) and read count (4 bytes) in the TCA trailer for bidirectional data transfers.

Read Operations (R): When bit 14 of word 1 is one, the input count (word 11) is valid and contains a nonzero value, indicating the number of bytes to be transferred into main storage.

Write Operations (W): When bit 15 of word 1 is one, the output count (word 10) is valid and contains a nonzero value, indicating the number of bytes to be transferred from main storage.

If the R-bit and W-bit are both one and the device does not support bidirectional data transfer, and flags bit 10 is zero, a program-check condition is recognized.

If the W-bit is one and the TCW is an interrogate TCW, a program-check condition is recognized.

Output-Data Address: When bit 15 of word 1 (the W-bit) is one and bit 7 of the flags field (the output-TIDA flag) is zero, words 2-3 designate the 64-bit output location in absolute storage. When the W-bit is one and the output-TIDA flag is one, words 2-3 designate the 64-bit location in absolute storage of a TIDAW or list of TIDAWs that designate the output storage location or locations.

When the W-bit is one and the output-TIDA flag is one, words 2-3 must designate a storage location that is on a quadword boundary, otherwise a program-check condition is recognized.

When the W-bit is zero, words 2-3 have no meaning and are ignored.

Input-Data Address: When the bit 14 of word 1 (the R-bit) is one and bit 5 of the flags field (the input-TIDA flag) is zero, words 4-5 designate the 64-bit input location in absolute storage. When the R-bit is one and the input-TIDA flag is one, words 4-5 desig-

nate the location in absolute storage of a TIDAW or list of TIDAWs that designate the input storage location(s).

When the R-bit is one and the input-TIDA flag is one, words 4-5 must designate a storage location that is on a quadword boundary, otherwise a program-check condition is recognized.

When the R-bit is zero, words 4-5 have no meaning and are ignored.

Transport-Status-Block Address: Words 6-7 designate the 64-bit location in absolute storage of the transport-status block for the TCW.

Words 6-7 must designate a storage location on a doubleword boundary, otherwise a program-check condition is recognized.

Transport-Command-Control-Block Address: If the transport-command-control-block-TIDA bit (bit 6 of the flags field) is zero, words 8-9 designate 64-bit location in absolute storage of the transport-command-control block. When the transport-command-control-block-TIDA bit is zero, the transport-command-control block is specified to reside in a contiguous area of storage. If the transport-command-control-block-TIDA bit is one, words 8-9 designate the 64-bit location in absolute storage of a TIDAW or list of TIDAWs that designate the location in absolute storage of the transport-command-control block. When the transport-command-control-block-TIDA bit is one, the transport-command-control block may be specified to reside in noncontiguous areas of storage.

When the transport-command-control-block-TIDA flag is zero, words 8-9 should designate a storage location on a doubleword boundary, otherwise, degradation of performance is possible.

When the transport-command-control-block-TIDA flag is one:

- Words 8-9 must designate a storage location on a quadword boundary, otherwise a program-check condition is recognized.
- The transport-command-control-block-address and transport-command-control-block-length fields must not specify a list of TIDAWs that cross a 4 K-byte boundary, otherwise a program-check condition is recognized.
- The TIDAW-transfer-in-channel (TTIC) bit should be zero in all specified TIDAWs, otherwise degradation of performance is possible.
- The first TIDAW should designate the TCCB on a doubleword boundary; otherwise, degradation of performance is possible.

.

Output Count: When bit 15 of word 1 (the W-bit) is one, word 10 contains the unsigned integer total count of output bytes for the TCW.

When the W-bit is one and word 10 contains zeros, a program-check condition is recognized.

When the W-bit is one:

- The output-count value, rounded upwards to the nearest multiple of 4, plus 4, should equal the value in the transport-count field in the associated TCCB for unidirectional data transfers or the value in the write-count field in the associated TCCB for bidirectional transfer, otherwise this may lead to a device-detected-program-check condition being recognized.
- The output-count value should equal the sum of the following, otherwise this may lead to a device-detected-program-check condition being recognized.
  - The sum of count field values in all of the DCWs that specify a write command.
  - The sum of the count field values in all of the transport-command DCWs that specify the transfer of transport-command-meta information (TCMI) plus the size of the reserved fields in the TCMI. (Note that the size of a TCMI reserved field may be zero. See “Transport-Command DCW” on page 15-42.)
  - The count of any inserted padding and CBC bytes when flags bit 7 (the output-TIDA bit) is one as follows:
    - Four bytes for the CBC information for every TIDAW designated by the output-address field for which the insert-CBC flag bit is one.
    - The count of padding bytes added for every TIDAW designated by the output-address field for which the insert-CBC

flag bit is one. (See “Transport Indirect Data Addressing” on page 15-70.)

When the W-bit is zero, word 10 is ignored.

Input Count: When bit 14 of word 1 (the R-bit) is one, word 11 contains the unsigned integer total count of input bytes for the TCW.

When the R-bit is one and word 11 contains zeros, a program-check condition is recognized.

When the R-bit is one:

- The input-count value, rounded upwards to the nearest multiple of 4, plus 4, should equal the value in the transport-count field in the associated TCCB for unidirectional transfer or the value in the read-count field in the associated TCCB for bidirectional transfer, otherwise this may lead to a device-detected-program-check condition being recognized.
- The input-count value should equal the sum of count fields in all of the DCWs that specify a read-type command in the associated TCCB and any such DCWs specified in a TCA extension, otherwise this may lead to a device-detected-program-check condition being recognized.

When the R-bit is zero, word 11 is ignored.

Interrogate-TCW Address: When a START SUBCHANNEL designates a TCW, word 15 of the TCW is not checked. When a CANCEL SUBCHANNEL designates a subchannel that is start pending for a TCW channel program and is not status pending, bits 1-31 of word 15 of the TCW designated by START SUBCHANNEL specify the 31-bit location in absolute storage of the interrogate-TCW that is used to initiate an interrogate operation for the subchannel. If word 15 contains zeros when CANCEL SUBCHANNEL is issued, an interrogate operation is not initiated.

When CANCEL SUBCHANNEL is issued, bit 0 of word 15 must be zero, otherwise a program-check condition is recognized with interrogate-failed status indicated. When CANCEL SUBCHANNEL is issued and bits 1-31 of word 15 do not contain zeros, bits 1-31 of word 15 must designate a storage location on a 64-byte boundary, otherwise a program-check condition is recognized with interrogate-failed status indicated.

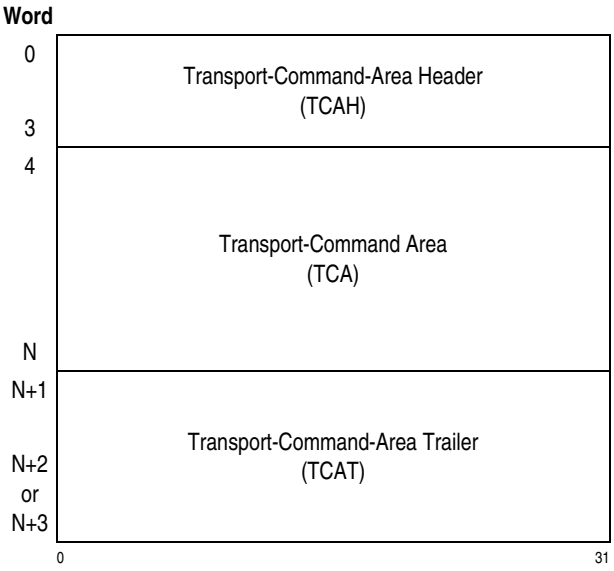
Transport-Command-Control Block

The transport-command-control block (TCCB) is variable in length, contains header and trailer information, and from 1 to 30 device-command words (DCWs) that are logically linked such that they are executed by the control unit in a sequential manner.

A TCCB may reside as a single block of contiguous storage or it may reside as multiple blocks of noncontiguous storage. The TCCB-TIDA flag specifies whether the TCCB resides in contiguous storage. When the flag is zero, the TCW designates a contiguous TCCB. When the flag is one, the TCW designates one or more TIDAWs that designate the location of the TCCB in noncontiguous storage.

The transport-command-control block is designated on a doubleword boundary and has a maximum length of 264 bytes. For non-interrogate operations, fetch accesses to the TCCB by the channel subsystem are made using the subchannel storage-access key specified in the ORB. For interrogate operations, fetch accesses to the interrogate TCCB by the channel subsystem are made as if a storage-access key of zero is used and are subject to secure storage protection. The channel subsystem does not make any store accesses to a TCCB nor does it examine its contents.

The format of the TCCB is as follows:



Explanation:

The offset of the last word of the TCCB is N+2 for unidirectional data transfers and N+3 for bidirectional data transfers.

Figure 15-8. Transport-Command-Control Block (TCCB)

Transport-Command-Area Header

The transport-command-area header (TCAH) is a 16-byte control block that contains information about the transport-command area and the operations described therein. The TCAH has the following format:

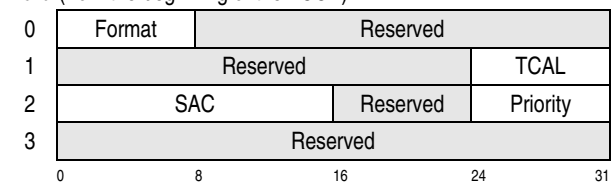


Figure 15-9. Transport-Command-Area Header (TCAH)

Format Control: Byte 0 of word 0 is the TCCB format control. The value of this field must be 7F hex, otherwise a device-detected-program-check is recognized.

Reserved: Byte 1 of word 0 is reserved and must contain zeros, otherwise a device-detected-program-check condition may be recognized. Bytes 2-3 of word 0, bytes 0-2 of word 1, byte 2 of word 2, and bytes 0-3 of word 3 are reserved and should contain zeros, otherwise the channel program may not operate compatibly in the future.

Transport-Command-Area Length (TCAL): Byte 3 of word 1 specifies an 8-bit unsigned integer whose value, when reduced by 12, specifies the length of the TCA in bytes. The specified value must be a nonzero multiple of 4 that is between 20 and 252, inclusive, otherwise a device-detected-program-check condition may be recognized.

Service-Action Code (SAC): Bytes 0-1 of word 2 contain an unsigned integer value that must be either 1FFE hex or 1FFF hex. The meanings of these values is device dependent.

Priority: Byte 3 of word 2 contains the 8-bit unsigned binary integer priority value for the TCCB. A value of zero indicates that no priority has been assigned. Valid priority values range from 1, the lowest priority, to 255, the highest priority.

Transport-Command Area

The transport-command area (TCA) is a variable-length area that contains from 1 to 30 device-command words (DCWs). The length of the TCA is an in integral number of words.

For DCWs that specify control data, the TCA also contains the control data associated with the commands. Each DCW that specifies control data, reduces the maximum-DCW capacity by one or more DCWs, depending on the size of the command-associated data.

For DCWs that specify input or output data, the TCW specifying the TCCB designates the associated storage area or areas (see “Input-Data Address” on page 15-34 and “Output-Data Address” on page 15-34) and the DCW designates the count of bytes to transfer.

For some devices, the list of DCWs may be extended past what will fit in the TCA. For such devices, the TCA extension (TCAX) is specified and transferred as if it were output data; however, the TCAX is treated as a logical continuation of the TCA instead of transfer data. (See “Transport-Command-Area Extension” on page 15-45.) A TCAX is specified by the transfer-TCA-extension DCW. (See “Transfer-TCA-Extension DCW” on page 15-44.)

Whether a device supports TCA extensions is determined by device-dependent means.

The maximum size of the TCA is 240 bytes. The TCA has the following format:

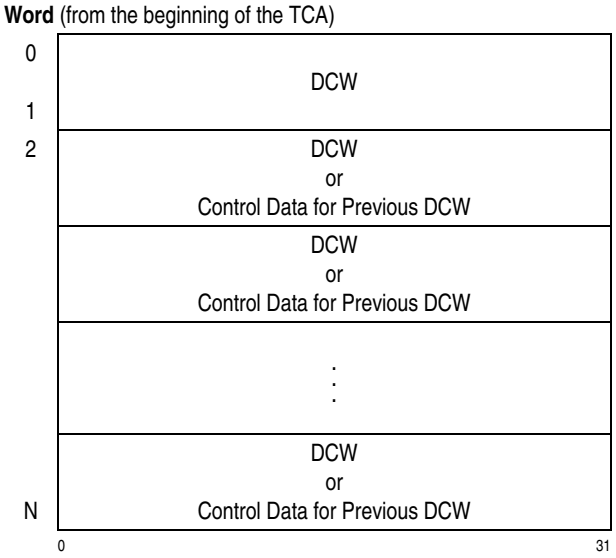

Figure 15-10. Transport-Command Area (TCA)

Device-Command Word

A device-command word (DCW) specifies a command to be executed. For commands initiating certain I/O operations, it designates the count of bytes on which the operation is performed, the action to be taken whenever transfer to or from storage is completed, and other options. The storage area or areas associated with a DCW data-transfer operation are designated, depending on the operation specified by the command, by the input-data-address field or the output-data-address field of the TCW that designates the transport-control-block containing the DCW. Whether the input-data-address field or the output-data-address field of the TCW designates the storage directly or indirectly, by use of a TIDAW list, is specified by the input-TIDA and output-TIDA flags in the TCW, respectively.

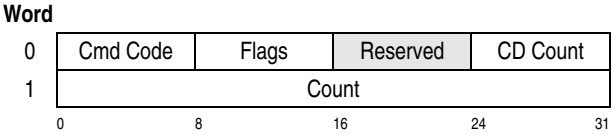
For commands initiating control operations, the associated data immediately follows the command. If this data is not a multiple of 4 bytes, the field immediately following the data begins on the next word boundary that immediately follows the last byte of specified data. In the TCA, this field will be either the next DCW, if additional DCWs are specified, or the transport-command-area trailer, if additional DCWs are not specified. When the DCW is in a transport-command-area extension (TCAX), this field will be one of the following:

- The next DCW when additional DCWs are specified.
- The TCAX reserved area when present, and additional DCWs are not specified.
- The end of the TCAX when the TCAX reserved area is not present and additional DCWs are not specified.

As each DCW starts execution at the I/O device and while it is executing, it is recognized as the current DCW. A DCW becomes current when it is the first DCW of a channel program and has been selected by the I/O device for execution or when, during command chaining, a subsequent chained DCW takes over control of the operation and begins execution at the I/O device.

The first DCW to be executed is at offset zero of the TCA in the TCCB. Each additional DCW in the channel program is also in the TCA and is used when the DCW is needed by the I/O device.

The DCW is an 8-byte control block that is designated on a word boundary. The format of the DCW is as follows:



Flags:

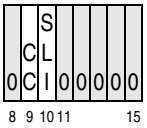


Figure 15-11. Device-Command Word (DCW)

Command Code : Bits 0-7 of word 0 specify the operation to be performed.

Whether a command is valid is device dependent and dependent on the value of the service-action-code field in the TCAH.

Reserved: Bits 8, 11-15, and 16-23 of word 0 are reserved and should contain zeros, otherwise the channel program may not operate compatibly in the

future. When the FCX-incorrect-length-indication facility is not installed or the device does not support incorrect-length indication, bit 10 of word 0 is reserved and should contain zero, otherwise the channel program may not operate compatibly in the future.

Chain-Command (CC) Flag: Bit 9 of word 0, when one, specifies the chaining of commands. When one, the bit causes the operation specified by the next DCW to be initiated upon normal completion of the current DCW. When the control-data count is zero, the next DCW immediately follows the DCW in the TCA or TCAX. When the control-data count is not zero, the next DCW immediately follows the control-data, rounded to a word boundary, specified for the DCW.

If bit 9 of word 0 is one in a DCW whose offset, plus 8, plus its control-data-count value leaves less than 8 bytes in the TCA and a TCAX is not specified, a device-detected-program-check condition may be recognized.

If bit 9 of word 0 is one in a DCW whose offset, plus 8, plus its control-data-count value leaves less than 8 bytes in the TCAX, a device-detected-program-check condition may be recognized.

If bit 9 of word 0 is zero in a DCW whose offset, plus 8, plus its control-data-count value leaves greater than 3 bytes remaining in the TCA, a device-detected-program-check condition may be recognized.

Note: When the chain-command flag is one, the next DCW location in the TCA or TCAX is determined by adding eight and the value in the CD-count field to the location of the current DCW and rounding upwards to the nearest word boundary. If the chain-command flag is one in a DCW in a TCA, the next DCW location is past the end of the TCA, and a TCAX is specified, the next DCW is at the beginning of the TCAX.

Suppress-Length-Indication (SLI) Flag: When the FCX-incorrect-length-indication facility is installed and the device supports incorrect-length indication, bit 10 of word 0 controls whether an incorrect-length condition is to be indicated to the program when the condition is recognized for the DCW in control as follows:

- When the SLI flag is one, incorrect-length indication is suppressed. When both the CC and SLI flags are ones, command chaining takes place, regardless of the presence of an incorrect-length condition. This bit should be specified as one in *all* DCWs where suppression of the incorrect-length indication is desired.
- When the SLI flag is not one, processing of the TCA is terminated (command-chaining is terminated) and the subchannel is made status pending with incorrect length indicated in the subchannel status.

When an incorrect-length condition exists for a DCW and the SLI flag in the DCW is set to zero, data transfer occurs as follows for read operations:

- If the DCW count is greater than the amount of data available at the device for the command, the data available at the device is transferred.
- If the DCW count is less than the amount of data available at the device for the command, only an amount of data equal to the DCW count is transferred

When an incorrect-length condition exists for a DCW and the SLI flag in the DCW is set one, data transfer occurs as follows for read operations:

- If the DCW count is greater than the amount of data available at the device for the command and the DCW chain-command (CC) flag is one, the following occurs in order:
  1) The data available at the device is transferred.
  2) Pad bytes of zeros are transferred until the total amount transferred is equal to the DCW count.
- If the DCW count is greater than the amount of data available at the device for the command and the DCW chain-command (CC) flag is zero, the following occurs in order:
  1) The data available at the device is transferred
  2) Depending on the device, either data transfer is terminated or pad bytes of zeros are transferred until the total

amount transferred is equal to the DCW count.

- If the DCW count is less than the amount of data available at the device for the command, only an amount of data equal to the DCW count is transferred

When an incorrect-length condition exists for a DCW, data transfer occurs as follows for write operations regardless of the setting of the SLI flag:

- If the DCW count is greater than the amount of data required by the device for the command and the DCW chain-command (CC) flag is one, the following occurs in order:

  1) The data required by the device is transferred.

  2) Data continues to be transferred until the total amount transferred is equal to the DCW count. Data not required by the device is discarded.

- If the DCW count is greater than the amount of data required by the device for the command and the DCW chain-command (CC) flag is zero, the following occurs in order:

  1) The data required by the devices is transferred.

  2) Data continues to be transferred until the next intermediate CBC is specified to be inserted or until the total amount transferred is equal to the DCW count. Data not required by the device is discarded.

- For write operations, if the DCW count is less than the amount of data required by the device for the command, only the amount of data specified by the DCW count is transferred.

Whether a device supports the suppression of incorrect-length indication is determined by device-dependent means.

Control-Data (CD) Count: When the command-code field specifies a command that requires control data, the data for the command immediately follows the DCW and byte 3 of word 0 specifies the length of the data, in bytes. If the command code specifies a command that requires control data and byte 3 of word 0 specifies a control-data count that is less than required for the command a unit-check condition is recognized. If the command code specifies a command that requires control data and byte 3 of word 0 contains zero or contains a value that specifies data past the end of the TCA or past the end of the specified TCAX, a device-detected-program-check condition is recognized.

Count: Word 1 specifies the 32-bit unsigned integer count of bytes in the storage area designated by the TCW for this DCW.

Transport-Command-Area Trailer

The transport-command-area trailer (TCAT) contains additional information about the TCCB. When uni-directional data transfer is specified (either the R-bit or the W-bit is set to one) or no data transfer is specified (both the R-bit and W-bit in the TCW are set to zero), the TCAT is two words in length. When bidirectional data transfer is specified (both the R-bit and the W-bit in the TCW are set to one), the TCAT is three words in length. The TCAT has the following format:

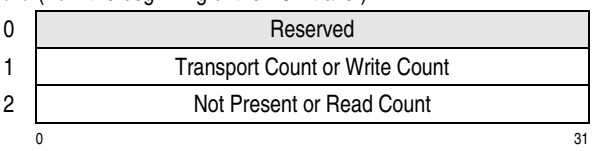

Figure 15-12. Transport-Command-Area Trailer (TCAT)

Reserved: Word 0 is reserved and not checked.

Transport Count: When uni-directional data transfer is specified, word 1 is the transport count and specifies the 32-bit unsigned integer count of total data to be transferred.

When a read operation is specified (the TCW R-bit is one), the value in the transport-count field in the TCAT is determined as follows, otherwise a device-detected-program-check condition may be recognized:

- The count field values in the DCWs that each specify a read-type command are summed.
- The sum is rounded upwards to the nearest multiple of 4.
- The rounded sum is increased by 4 giving the transport-count value.

When a read operation is specified, the transport-count value should be equal to the value in the TCW input-count field, rounded upwards to the next multiple of 4, plus 4, otherwise a device-detected-program-check condition may be recognized.

When a write operation is specified (the W-bit in the TCW is one), the value in the transport-count field in the TCAT is determined as follows, otherwise a device-detected-program-check condition may be recognized:

- The count field values in the DCWs that each specify a write command are summed.
- The count field values in all of the transport-command DCWs that specify the transfer of transport-command-meta information (TCMI) plus the size of the reserved fields in the TCMI are added to the sum. (Note that the size of a TCMI reserved field may be zero. See “Transport-Command DCW” on page 15-42.)
- The total of the counts of any TIDAW-specified CBC bytes and padding bytes (see “Transport Indirect Data Addressing” on page 15-70) is added to the sum.
- The sum is rounded upwards to the nearest multiple of 4.
- The rounded sum is increased by 4 giving the transport-count value.

When a write operation is specified, the transport-count value should be equal to the value in TCW output-count field, rounded upwards to the next multiple of 4, plus 4, otherwise a device-detected-program-check condition may be recognized.

When neither a read nor a write operation is specified (both the W-bit and R-bit in the TCW are zero), the transport count value should be zero, otherwise this may lead to a device-detected-program-check condition being recognized.

Write Count: When bidirectional data transfer is specified, word 1 is the write count and specifies the 32-bit unsigned integer count of total output data to be transferred. The value in the write-count field in the TCAT is determined as follows, otherwise a device-detected-program-check condition may be recognized:

- The count field values in the DCWs that each specify a write command are summed.
- The count field values in all of the transport-command DCWs that specify the transfer of transport-command-meta information (TCMI) plus the size of the reserved fields in the TCMI are added to the sum. (Note that the size of a TCMI reserved field may be zero. See “Transport-Command DCW” on page 15-42.)
- The total of the counts of any TIDAW-specified CBC bytes and padding bytes (see “Transport Indirect Data Addressing” on page 15-70) is added to the sum.
- The sum is rounded upwards to the nearest multiple of 4.
- The rounded sum is increased by 4 giving the transport-count value.

The write-count value should be equal to the value in TCW output-count field, rounded upwards to the next multiple of 4, plus 4, otherwise a device-detected-program-check condition may be recognized.

Read Count: When uni-directional data transfer is specified the read count field is not present. When a bidirectional data transfer is specified, word 2 is the read count and specifies the 32-bit unsigned integer count of total input data to be transferred. The value in the read-count field in the TCAT is determined as follows, otherwise a device-detected-program-check condition may be recognized:

- The count field values in the DCWs that each specify a read-type command are summed.
- The sum is rounded upwards to the nearest multiple of 4.
- The rounded sum is increased by 4 giving the transport-count value.

The read-count value should be equal to the value in the TCW input-count field, rounded upwards to the next multiple of 4, plus 4, otherwise a device-detected-program-check condition may be recognized.

Programming Note: The following table summarizes the determination of the TCW input-count, output-

count, and the TCCB transport count values for unidirectional data transfers:

Operation	TCW Input Count	TCW Output Count	TCAT Transport Count
Input operation (TCW R-bit is 1)	Sum of DCW count values in the TCA.	n/a	Sum of DCW count values in TCA, rounded to four,[2] plus four[2]
Output operation (TCW W-bit is 1), TIDAWs not used (TCW output-TIDA flag is 0)	n/a	Sum of DCW count values in TCA.	Sum of DCW count values in TCA, rounded to four,[2] plus four[2]
Output operation (TCW W-bit is 1), TIDAWs used (TCW output-TIDA flag is 1)	n/a	Sum of DCW count values in TCA and TCAX plus the size of the reserved areas in any specified TCMIs[3], plus total of TIDAW-specified CBC and padding bytes [1]	Sum of DCW count values in TCA and TCAX, plus the size of the reserved areas in any specified TCMIs[3], plus total of TIDAW-specified CBC and padding bytes,[1] rounded to four,[2] plus four[2]

Explanation:

1 See the description of the insert-CBC control in "Flags" on page 15-70.

2 The channel subsystem adds a CBC word to the end of the last data transported. Up to 3 padding bytes are added after the last data transported to ensure the added CBC word is on a word boundary.

3 Because of alignment requirements, the size of the reserved area in a TCMI is either 0 or 4.

Figure 15-13. Determination of the TCAT Transport Count, TCW Input Count, and TCW Output Count for Uni-Directional Data Transfers

The following table summarizes the determination of the TCW input-count, output-count, and the TCCB read and write count values for bidirectional data transfers:

Operation	TCW Input Count	TCW Output Count	TCAT Read Count	TCAT Write Count
Input operation (TCW R-bit is 1) and output operation (TCW W-bit is 1), TIDAWs not used (TCW output-TIDA flag is 0)	Sum of read DCW count values in the TCA and TCAX.	Sum of write DCW count values in the TCA, plus count values in DCWs that specify the transfer of TCMI	Sum of read DCW count values in the TCA and TCAX, rounded to four,[2] plus four[2]	Sum of write DCW count values in the TCA, plus count values in DCWs that specify the transfer of TCMI, rounded to four,[2] plus four[2]
Input operation (TCW R-bit is 1) and output operation (TCW W-bit is 1), TIDAWs used (TCW output-TIDA flag is 1)	Sum of read DCW count values in the TCA and TCAX.	Sum of write DCW count values in the TCA and TCAX, plus count values in DCWs that specify the transfer of TCMI, plus the size of the reserved areas in any specified TCMIs[3], plus total of TIDAW-specified CBC and padding bytes.[1]	Sum of read DCW count values in the TCA and TCAX, rounded to four,[2] plus four[2]	Sum of write DCW count values in the TCA and TCAX, plus count values in DCWs that specify the transfer of TCMI, plus the size of the reserved areas in any specified TCMIs[3], plus total of TIDAW-specified CBC and padding bytes,[1] rounded to four,[2] plus four[2]

Explanation:

1 See the description of the insert-CBC control in "Flags" on page 15-70.

2 The channel subsystem adds a CBC word to the end of the last data transported. Up to 3 padding bytes are added after the last data transported to ensure the added CBC word is on a word boundary.

3 Because of alignment requirements, the size of the reserved area in a TCMI is either 0 or 4.

Figure 15-14. Determination of the TCAT Transport Count, TCW Input Count, TCAT Read Count, and TCAT Write Count for Bidirectional Data Transfers

Transport-Command DCW

A transport-command DCW specifies a transport command that performs a device-support function associated with transport-mode operations. (See "Command Code" on page 15-57.) A transport-command DCW may specify control data and may also specify the transfer of transport-command-meta information (TCMI).

When a transport-command DCW specifies the transfer of TCMI to a device, the TCMI is transferred as output data. The size of the TCMI is command-

dependent and is a multiple of 4. Furthermore, the TCMI may be extended by 4 reserved bytes when all of the following are true:

- The size of the TCMI is an even multiple of 4.
- TIDAWs are used to specify the output storage areas.
- The insert-CBC flag is one in the last TIDAW used to specify the storage containing the TCMI.
- The chain-command bit is one in the transport-command DCW that specifies the TCMI.
- A subsequent DCW specifies the transfer of a TCMI or output data.

Note that when a transport command specifies the transfer of a TCMI to a device and the TCMI is extended by 4 reserved bytes because all of the preceding conditions are met, the 4 reserved bytes are not included in the data-count value in the transport-command DCW but are included in the following:

- The count value in the last TIDAW used to specify the storage containing the TCMI.
- The output-count value in the TCW.
- The transport-count value in the associated TCCB for unidirectional data transfers or the write-count value in the associated TCCB for bidirectional transfer.

The following summarizes the transport-command DCWs and identifies the specific TCMI that may be transferred to the device:

Transport-Command DCW	Transport-Command-Meta Information (TCMI)	Page
Transfer-CBC-Offset Block TCOB_	CBC-Offset Block (COB)	15-43
Transfer-TCA Extension (TTE)	TCA Extension (TCAX)	15-44
Interrogate	(none)	15-46
Explanation: (none) - The transport-command DCW does not transfer TCMI.		

Figure 15-15. Summary of Transport-Command DCWs

Transfer-CBC-Offset-Block DCW

For write operations, the transfer-CBC-offset-block (TCOB) DCW specifies that a CBC-offset block (COB) is transported to the device. The content of the TCOB DCW is as follows:

- The command code contains the transfer-CBC-offset-block command which is a value of 60 hex.
- The chain-command flag is one.
- When the CD-count is not zero, the COB immediately follows the TCOB DCW in the TCA and the CD-count specifies the number of CBC offsets in the COB multiplied by 4.
- When the CD-count is zero, the COB is specified as TCMI in the output data, the location of the COB is specified by the output-data-address field in the TCW, and the count field specifies the number of CBC offsets in the COB multiplied by 4.

The incorrect-length condition is not recognized for the transfer-CBC-offset-block command regardless of whether the FCX-incorrect-length-indication facility is installed and supported by the device.

When a TCOB DCW is used, a device-detected program check is recognized when any of the following conditions exist:

- A TCOB DCW is specified and a write operation is not specified (that is, the W-bit in the TCW is zero).
- A TCOB DCW is the only DCW in the TCA. (That is the chain-command flag in the TCOB DCW is zero.)
- A TCOB DCW is not the first DCW in the TCA.
- More than one TCOB DCW is specified
- The control-data-count field and the count field in the TCOB DCW both contain the value zero or both contain a value that is nonzero.
- The control-data-count field contains the value zero, the count field contains a value that is nonzero, but the value in the count field is not a multiple of 4.
- The count field contains the value zero, the control-data-count field contains a value that is nonzero, but the value in the control-data-count field is not a multiple of 4.

When a TCOB is used that specifies the COB in the output data, the following must be true; otherwise, a device-detected program check may be recognized:

- The output-TIDA flag (flags bit 7) in the TCW must be one.
- The insert-CBC control must be set to one in the last or only TIDAW that is used to transfer the COB when the transfer of a TCAX or output data or both is also specified.
- When there is an odd number of CBC offsets in the COB, the total of the count fields in the TIDAWs used to the transfer the COB must specify the number of CBC offsets in the COB multiplied by 4. When there is an even number of CBC offsets in the COB, the total of the count fields in the TIDAWs used to the transfer the COB must specify the number of CBC offsets in the COB multiplied by 4, plus 4.

Whether a device recognizes the TCOB command is determined by device-dependent means.

CBC-Offset Block

The CBC-offset block (COB) is a variable-length control block that contains a list of 4-byte entries, each of which identifies the offset of a CBC specified by a TIDAW to be inserted in the output data. When the COB is specified in the output data, the offset of the CBC inserted by the TIDAW that specifies the transfer of the COB is not included in the COB.

Accesses to a CBC-offset block by the channel subsystem are treated as if a storage-access key of zero is used but are subject to secure storage protection.

The COB has the following format:

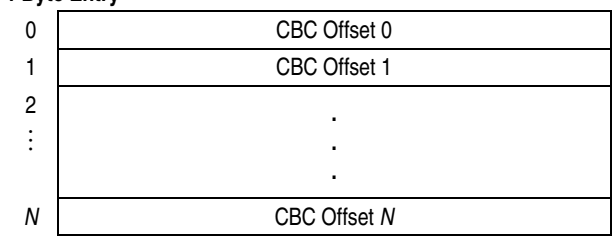

Figure 15-16. CBC-Offset Block (COB)

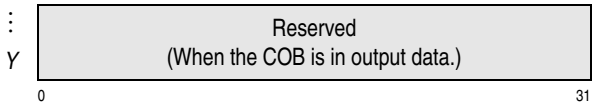


Explanation:

- The size of the COB is 4(*N*+1) when the COB is specified in the TCA. (There is no reserved field for this case.)
- The size of the COB is 4(*Y*+1) when the COB is specified in the output data, where *Y* is an even number that is equal to either *N* or *N*+1.

Figure 15-16. CBC-Offset Block (COB) (Continued)

CBC Offsets: Entries 0 through *N* contain CBC offsets. Each CBC offset is a 4-byte field containing a 32-bit unsigned integer value that specifies the relative offset, from the beginning of the output-data area, to a CBC that is specified to be inserted by a TIDAW. When a COB is in the TCA, the beginning of the output-data area is specified by the output-data-address field of the TCW. When a COB is in the output-data, the output-data area begins immediately after the COB.

Reserved: When a COB is specified in the TCA, or a COB is specified in the output data and there is an odd number of CBC offsets in the COB, there are no reserved bytes.

When a COB is specified in the output data and there is an even number of CBC offsets in the COB, the 4 bytes immediately following the last CBC offset are reserved and should contain zeros, otherwise unpredictable results may result.

See “Transport-Command DCW” on page 15-42 for the handling of reserved bytes when calculating the DCW count, TIDAW count, TCCB write-count (for bidirectional transfers) and TCCB transport count (for unidirectional data transfers).

Programming Note: When a device indicates that it supports the TCOB command and TIDAWs are used that specify insert-CBC, a TCOB and COB should be used; otherwise, unpredictable results or errors may result.

Transfer-TCA-Extension DCW

The transfer-TCA-extension (TTE) DCW specifies that the TCA is logically extended in the output data and that the TCA extension (TCAX) is transported to the device. The content of the TTE DCW is as follows:

- The command code contains the transfer-TCA-extension command which is the value of 50 hex.
- The chain-command flag is set to one.
- The CD-count is zero.
- The count specifies the length of the TCAX as a multiple of 4.

The incorrect-length condition is not recognized for the transfer-TCA-extension command regardless of whether the FCX-incorrect-length-indication facility is installed and supported by the device.

When a TTE DCW is used, a device-detected program check is recognized when any of the following conditions exist:

- When a TCOB DCW is not specified, the TTE DCW is not the first DCW in the TCA. When a TCOB DCW is specified, the TTE DCW is not the second DCW in the TCA.
- The TTE DCW is specified and a write operation is not specified (that is, the W-bit in the TCW is zero).
- The chain-command flag in the TTE DCW is zero.
- More than one TTE DCW is specified
- The control-data-count field in the TTE DCW does not contain zero.
- The count field contains less than 8 or a value that is not a multiple of 4.
- Any of the following are true for the TCA:
  - The TCA does not contain at least one DCW that is not a transport-command DCW.
  - The TCA contains one or more DCWs that are not transport-command DCWs and the chain-command flag in the last DCW of the TCA is zero.

Whether a device recognizes the TTE command is determined by device-dependent means.

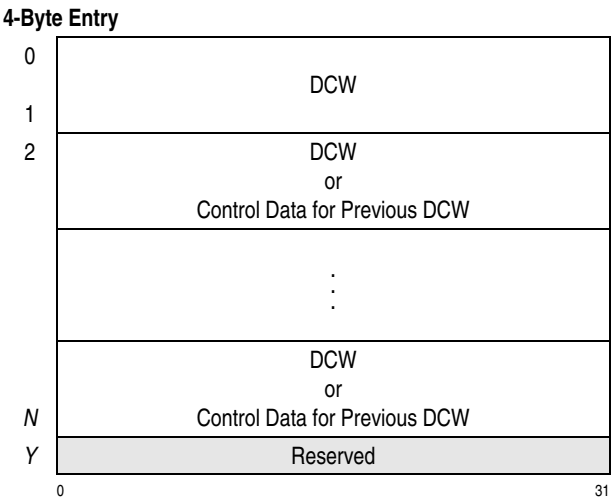
Transport-Command-Area Extension

The transport-command-area extension (TCAX) is a variable-length area that is the logical continuation of the TCA. At a minimum, the TCAX contains one DCW. The length of the TCAX is an integral multiple of 4 and is specified by the TTE DCW.

For DCWs that specify control data, the TCAX also contains the control data associated with the commands.

For DCWs that specify input or output data, the associated TCW designates the associated storage area or areas (see “Input-Data Address” on page 15-34 and “Output-Data Address” on page 15-34) and the DCW designates the count of bytes to transfer.

The maximum size of the TCAX is device dependent. The TCAX has the following format:



Explanation:

The size of the TCAX is 4(*Y*+1), where *Y* is an even number that is equal to either *N* or *N*+1.

Figure 15-17. Transport-Command Area Extension (TCAX)

Device-Command Word (DCW) or Control Data for Previous DCW: For information about DCWs and control data, see “Device-Command Word” on page 15-38.

Reserved: When the last information in the TCAX is a DCW, the end of the DCW defines the end of the meaningful information in the TCAX. When the last information in the TCAX is control data and the control data ends on a 4-byte boundary, the end of the control data defines the end of the meaningful information in the TCAX. When the last information in the TCAX is control data and the control data does not end on a 4-byte boundary, padding bytes are appended to the control data to reach a 4-byte

boundary and the end of the padding bytes define the end of the meaningful information in the TCAX.

When the size of the meaningful information in the TCAX divided by four is an odd number, there are no reserved bytes; otherwise, the four bytes immediately following the meaningful information in the TCAX are reserved and should contain zeros, otherwise unpredictable results may result.

See “Transport-Command DCW” on page 15-42 for the handling of reserved bytes when calculating the DCW count, TIDAW count, TCAT write-count (for bidirectional transfers) and TCAT transport count (for unidirectional data transfers).

Interrogate TCCB

The interrogate TCCB is a TCCB that specifies a service-action code value of 1FFF hex, contains a TCA that is at least 8 bytes in length that specifies an interrogate DCW, and may specify a read operation.

Any data that immediately follows the interrogate DCW and is specified by a nonzero CD-count in the interrogate DCW is transported to the device and may be written to a device-dependent log. Any input data that is specified by the interrogate TCW is device-dependent data and is transferred from the I/O device.

Accesses to the interrogate TCCB by the channel subsystem are treated as if a storage-access key of zero is used but are subject to secure storage protection.

The format of the interrogate TCA is as follows:

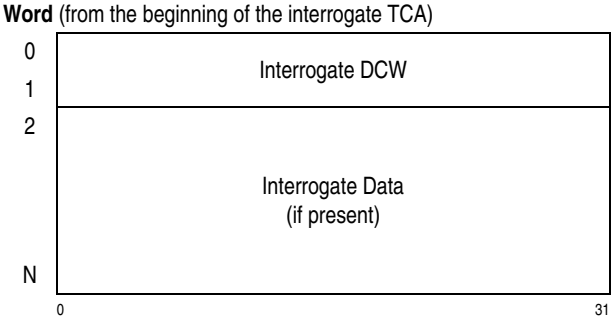


Figure 15-18. Interrogate Transport-Command Area (TCA)

Interrogate DCW

Words 0 and 1 of the interrogate TCA contain a DCW that specifies an interrogate operation. The content of the interrogate DCW is as follows:

- The command code contains the interrogate command which is a value of 40 hex.
- The CD-count field must contain a value that is not greater than 232, otherwise a device-detected-program-check condition is recognized with interrogate-failed status indicated in the subchannel-extended-status field of the IRB.
- With the exceptions of the command code, SLI flag, count and CD-count fields, all other fields in the DCW must contain zeros, otherwise a device-detected-program-check condition is recognized with interrogate-failed status indicated in the subchannel-extended-status field of the IRB.

The incorrect-length condition is not recognized for the interrogate command regardless of whether the FCX-incorrect-length-indication facility is installed and supported by the device.

Interrogate Data

If the CD-count of the interrogate DCW is greater than zero, interrogate data is specified. Since interrogate data is for device-dependent logging purposes only, interrogate data that is incorrectly specified does not cause any exception condition to be recognized. The interrogate data has the following format:

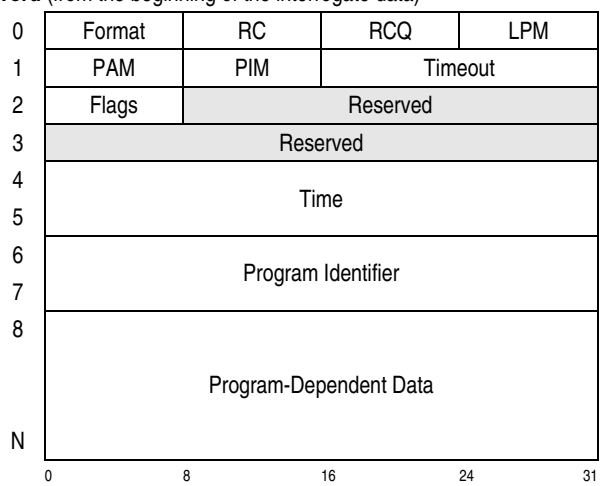

Figure 15-19. Interrogate Data

Format: Byte 0 of word 0 contains the unsigned integer value that defines the layout of the interrogate

data. The value of this field should be zero, otherwise the I/O device may not recognize the layout of the interrogate data

Reason Code (RC): Byte 1 of word 0 contains the unsigned integer value that indicates the reason the interrogate operation was initiated. The following values may be specified. The meaning of RC values is as follows:

Value	*Meaning*
0	Interrogate reason not specified.
1	Timeout: Program-detected timeout for the operation being interrogated.
2-255	Reserved.

Reason-Code Qualifier (RCQ): Byte 2 of word 0 contains the unsigned integer value that indicates additional information about the reason the interrogate operation was initiated.

When the reason-code field contains the value one, the meaning of RCQ values are as follows:

Value	*Meaning*
0	Interrogate reason qualifier not specified.
1	Primary: The timeout was specified by the primary program.
2	Secondary: The timeout was specified by a secondary program.
3-255	Reserved.

When the reason-code field does not contain the value one, the reason-code-qualifier field has no meaning.

Logical-Path Mask (LPM): Byte 3 of word 0 contains the LPM that was used when the operation being interrogated was initiated by START SUBCHANNEL.

Path-Available Mask (PAM): Byte 0 of word 1 contains the value of the PAM at the time the interrogate operation is initiated.

Path-Installed Mask (PIM): Byte 1 of word 1 contains the value of the PAM at the time the interrogate operation is initiated.

Timeout: When the RC field contains the value one or two, bytes 2-3 of word 1 contain the timeout interval used by the designated program, in unsigned integer seconds.

Flags: Byte 0 of word 2 contains information about the interrogate. The meaning of each flag bit is as follows:

Bit	*Meaning*
0	Multipath mode: This bit has the same setting as the multipath-mode bit (D) at the time the interrogate operation is initiated.
1	Program path recovery: The interrogate is issued during path recovery by the program.
2	Critical: The device is a critical device for the program.
3-7	Reserved.

Reserved: Bytes 1-3 of word 2 and word 3 are reserved.

Time: Words 4-5 contain the time the interrogate operation was initiated.

Program Identifier: Words 6-7 identify the program initiating the interrogate operation. The content of this field is program dependent.

Program-Dependent Data: Words 8-N contain program-dependent information.

Programming Notes:

1. It is assumed that the program will specify the value in the time field as UTC in the same form as the TOD clock.
2. If the interrogate operation does not complete within a model-dependent amount of time, an interface-control check condition is recognized, terminating the I/O operation being interrogated.
3. If a timeout value is specified and the timeout value is less than a device-dependent minimum, the I/O device may not write the interrogate data into its log.

Transport Status Block

When the TSB-valid bit in the IRB is one, the transport-status block (TSB) for the I/O operation may contain additional information about the completion of the associated TCW channel program. When the interrogate-complete (Q) bit in the IRB is one, the interrogate TSB may contain interrogate data.

The TSB is 64 bytes in length and is allocated on a doubleword boundary. Accesses to the TSB by the channel subsystem are treated as if a storage-access key of zero is used but are subject to secure storage protection.

The format of the TSB is as follows:

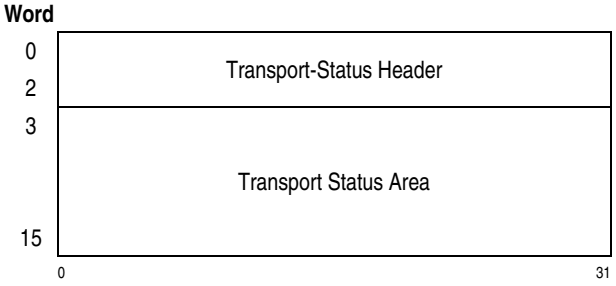

Figure 15-20. Transport-Status Block

Transport-Status Header (TSH)

The transport-status header is a 12-byte control block that contains information about the transport status. The format of the TSH is as follows:

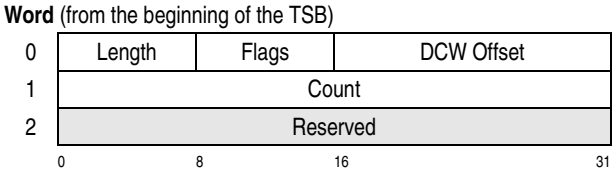

Figure 15-21. Transport-Status Header (TSH)

Length: Byte 0 of word 0 contains the unsigned binary integer length, in bytes, of the status information stored in the TSB. This length includes the TSH and the transport-status area (TSA), if present. If this value is less than 64, the difference between the length value and 64 specifies the number of bytes, at the end of the TSB, that are not used, have no meaning, and may or may not be stored.

Flags: Byte 1 of word 0 contains information about the TSB. The meaning of each flag bit is as follows.:

Bit	***Meaning***
0	DCW-offset field valid. When bit 0 is one, the DCW-offset field contains a DCW-offset value. When bit 0 is zero, the DCW-offset field has no meaning.
1	Count field valid. When bit 1 is one, the count field contains a count value. When bit 1 is zero, the count field has no meaning.
2	Cache miss. When flag bits 5-7 specify an I/O-status TSA and bit 2 is one, one or more I/O-device cache misses occurred during the I/O operation. When flag bits 5-7 specify an I/O-status TSA and bit 2 is zero, no cache misses occurred. When flag bits 5-7 do not specify an I/O-status TSA, bit 2 is reserved.
3	Time fields valid. When flag bits 5-7 specify an I/O-status TSA and bit 3 is one, the device-time, defer-time, queue-time, device-busy-time, and device-active-only time fields in the I/O-status TSA contain time information. When flag bits 5-7 specify an I/O-status TSA and bit 3 is zero, the contents of the device-time, defer-time, queue-time, device-busy-time, and device-active-only time fields in the I/O-status TSA have no meaning. When flag bits 5-7 do not specify an I/O-status TSA, bit 3 is reserved.
4	Reserved.
5-7	TSA format. Bits 5-7 form a 3-bit unsigned integer that indicates the layout of the TSA as follows:

Value	***Meaning***
0	TSA contents have no meaning: The other fields of the TSA do not contain meaningful data.
1	I/O-Status TSA: The TSA contains ending status in addition to ending status in the IRB for the I/O operation.
2	Device-detected-program-check TSA: The TSA contains information describing the reason for

the device-detected program check

3 Interrogate TSA: The TSA contains interrogate response information

4-7 Reserved.

DCW Offset: When bit 0 of the flags field (the DCW-offset-field-valid bit) is one and the DCW-offset value is less than the size of the TCA, bytes 2-3 of word 0 contain the byte offset, from the beginning of the TCA to the DCW either partially or completely executed when the TSB is stored. When bit 0 of the flags field is one and the DCW-offset value is greater than or equal than the size of the TCA, the value in bytes 2-3 of word 0 minus the size of the TCA is the offset, from the beginning of the TCAX to the DCW either partially or completely executed when the TSB is stored.

If the channel program cannot be completed, this offset identifies the DCW for which processing could not be completed. Additional information in the IRB and TSB may be used for recovery purposes. When bit 0 of the flags field is zero, bytes 2-3 of word 0 have no meaning.

Count: When bit 1 of the flags field (the count-field-valid bit) is one, word 1 contains the residual count for the DCW designated by the DCW-offset field.

Reserved: Word 2 is reserved and contains zeros.

Programming Note: If the program sets the length and flags fields to zeros before initiating an operation, the program can determine whether the TSB contains meaningful information after the operation completes by checking that both the length and flags field contain nonzero values.

I/O-Status TSA

When the TSA-format field in the TSH contains one, the TSA has the following format:

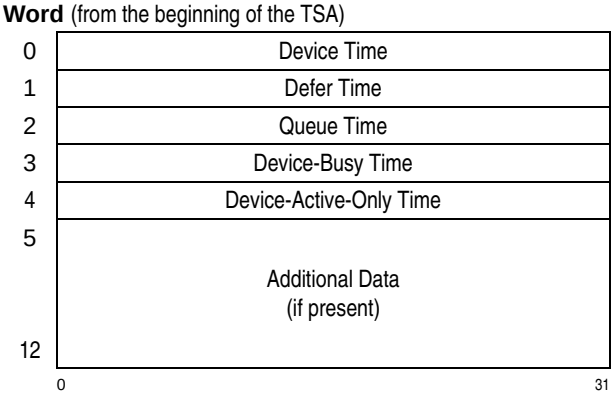

Figure 15-22. I/O-Status Transport-Status Area (TSA)

Device Time: When bit 3 of the flags field in the TSH (the time-fields-valid flag) is one, word 0 contains the 32-bit unsigned integer total count of time intervals between when the I/O device received the information in the TCCB until the I/O device returned the information in the TSB. The resolution of the device time is such that bit 31 corresponds to one microsecond.

When bit 3 of the flags field in the TSH (the time-fields-valid flag) is zero, the contents of word 0 have no meaning.

Defer Time: When bit 3 of the flags field in the TSH (the time-fields-valid flag) is one, word 1 contains the 32-bit unsigned integer total count of time intervals that the I/O operation was temporarily delayed by the I/O device to perform device-dependent operations or other operations not associated with the current channel program. The resolution of the defer time is such that bit 31 corresponds to one microsecond.

When bit 3 of the flags field in the TSH (the time-fields-valid flag) is zero, the contents of word 1 have no meaning.

Queue Time: When bit 3 of the flags field in the TSH (the time-fields-valid flag) is one, word 2 contains the 32-bit unsigned integer total count of timer intervals that the I/O operation or portions of the operation were queued at the control unit while waiting for operations not associated with the current operation to complete. The resolution of the queue

time is such that bit 31 corresponds to one microsecond.

When bit 3 of the flags field in the TSH (the time-fields-valid flag) is zero, the contents of word 2 have no meaning.

Device-Busy Time: When bit 3 of the flags field in the TSH (the time-fields-valid flag) is one, word 3 contains the 32-bit unsigned integer total count of time intervals that the I/O device was busy attempting to initiate a command. The resolution of the device-busy time is such that bit 31 corresponds to one microsecond.

When bit 3 of the flags field in the TSH (the time-fields-valid flag) is zero, the contents of word 3 have no meaning.

Device-Active-Only Time: When bit 3 of the flags field in the TSH (the time-fields-valid flag) is one, word 4 contains the 32-bit unsigned integer total count of time between the time that the channel-end condition existed and the time that the channel-end and device-end conditions were recognized by the device. The resolution of the device-active time is such that bit 31 corresponds to one microsecond.

When bit 3 of the flags field in the TSH (the time-fields-valid flag) is zero, the contents of word 4 have no meaning.

Additional Data: When the length field in the TSH contains a value greater than 32, additional data has been provided by the I/O device. The count of meaningful additional-data bytes in this field is determined by subtracting 32 from the value in the length field.

When unit check is included in the device status, any additional data provided is sense data. When unit check is not included in the device status, any additional data provided is device dependent.

Device-Detected-Program-Check TSA

When the TSA-format field in the TSH contains two, the TSA has the following format:

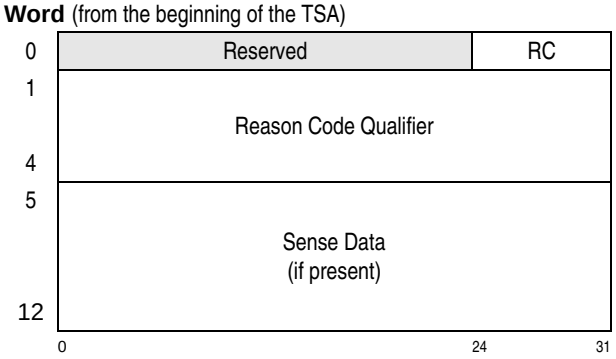

Figure 15-23. Device-Detected-Program-Check Transport-Status Area (TSA)

Reserved: Bytes 0-2 of word 0 are reserved and have no meaning.

Reason Code (RC): Byte 3 of word 0 contains an 8-bit unsigned integer code that indicates the primary reason for the device-detected program check. The meaning of each reason code value is as follows:

Value	*Meaning*
0	No information: Byte 3 has no meaning.
1	TCCB transport failure: An invalid CBC was detected by the I/O device while transporting the TCCB. The reason-code-qualifier (RCQ) field contains additional information.
2	Invalid CBC detected on output data: An invalid CBC was detected while transferring output data. The RCQ field contains additional information.
3	Incorrect TCCB length specification: The RCQ field contains additional information.
4	TCAH specification error: The RCQ field contains additional information. When a TCAH specification error is recognized, pre-existing allegiance conditions are not cleared.
5	DCW specification error: There is an error with the DCW designated by the

DCW-offset field in the TSH. The RCQ field contains additional information.

6 Transfer-direction specification error: The command specified by the DCW designated by the DCW-offset field in the TSH specifies a direction of data transfer that disagrees with the transfer direction specified in the TCW, or both the read-operation (R) and write-operation (W) bits in the TCW are set to one and the device does not support bidirectional data transfers. The RCQ field contains additional information.

7 Transport-count specification error: The RCQ field contains additional information.

8 Two I/O operations active: While an I/O operation is active at the device a second non-interrogate TCCB has been transported to the device for execution. The RCQ field has no meaning.

9 CBC-offset specification error: One or more CBC offsets in the CBC-offset block indicate that a CBC is at a location that is not recognized by the device or is not recognized for the designated DCW. The RCQ field contains additional information.

10-255 Reserved.

For a summary of the meanings of reason-code values and their associated reason-code-qualifier values see Figure 15-24 on page 15-54.

Reason Code Qualifier (RCQ): Words 1-4 may contain additional information about the reason for the device-detected program check as follows.

When the RC field contains the value one, only byte 0 of the RCQ field has meaning. For this case, byte 0 of the RCQ field contains an 8-bit unsigned integer code that further describes the condition indicated by the RC field and the meaning of each RCQ value is as follows:

Value Meaning

0 No additional information.

1 TCCB transport size error: The value of the TCCBL field of the TCW that was sent to the I/O device is not equivalent to the count of bytes actually transported for the TCCB.

2 TCCB CBC error: An invalid CBC was detected while transferring the TCCB.

3-255 Reserved.

When the RC field contains the value two, only words 0-1 of the RCQ field have meaning as follows:

Value Meaning

0 Word 0 contains the 32-bit unsigned integer offset of the first output-data byte for which the invalid CBC was detected.

1 Word 1 contains the 32-bit unsigned integer offset of the last byte of the last output-data word for which the invalid CBC was detected.

When the RC field contains the value three, only byte 0 of the RCQ field has meaning. For this case, byte 0 of the RCQ field contains an 8-bit unsigned integer code that further describes the condition indicated by the RC field and the meaning of each RCQ value is as follows:

Value Meaning

0 No additional information.

1 The value specified by the TCAL field is not 8 greater than the value specified by the TCCBL field in the TCW for the operation.

2 The value specified by the TCAL field is less than 20 or greater than 252.

3-255 Reserved.

When the RC field contains the value four, only byte 0 of the RCQ field has meaning. For this case, byte 0 of the RCQ field contains an 8-bit unsigned integer code that further describes the condition indicated by the RC field and the meaning of each RCQ value is as follows:

Value Meaning

0 No additional information.

1 Format-field specification error: The format field contains an unrecognized

value. See “Format Control” on page 15-37.

2 Reserved-field specification error: A reserved field in the TCAH does not contain zeros.

3 Service-action-code-field specification error: The service-action-code field in the TCAH contains an unrecognized value or a value that is incorrect for command specified by the DCW designated by the DCW-offset field in the TSH. See “Service-Action Code (SAC)” on page 15-37.

4-255 Reserved.

When the RC field contains the value five, only byte 0 of the RCQ field has meaning. For this case, byte 0 of the RCQ field contains an 8-bit unsigned integer code that further describes the condition indicated by the RC field and the meaning of each RCQ value is as follows:

Value ***Meaning***

0 No additional information.

1 Reserved-field specification error: A reserved field in the DCW does not contain zeros.

2 Flags-field command-chaining specification error: Either of the following is true:

- The chain-command flag is one and the offset of the next DCW is such that all or part of the next DCW extends past the end of the TCA or TCAX.
- The chain-command flag is zero and more than 3 unused bytes remain in the TCA or TCAX (excluding the TCAX reserved field).
- The DCW is the last DCW in the TCA, a TCAX is not specified, and the chain-command flag is one.
- The DCW is the last DCW in the TCAX and the chain-command flag is one.

See “Chain-Command (CC) Flag” on page 15-39.

3 Control-data-count-field specification error: The CD-count field specifies control data past the end of the TCA or TCAX.

See “Control-Data (CD) Count” on page 15-40.

4 TCOB location error: The TCOB DCW is not the first DCW in the TCA

5 TCOB duplication error: More than one TCOB DCW is specified.

6 TCOB multiple-count error: The control-data-count field and the count field in the TCOB DCW both specify the value zero or both specify a nonzero value.

7 TCOB direction error: A TCOB DCW is specified and the write-operation (W) in the TCW is zero.

8 TCOB chaining error: The chain-command bit in the TCOB DCW is zero.

9 TCOB count-specification error: Either of the following is true:

- The count field in the TCOB is zero, the control-data-count field in the TCOB DCW is nonzero, and the control-data-count field in the TCOB specifies a value that is not an even multiple of four
- The control-data-count field in the TCOB is zero, the count field in the TCOB DCW is nonzero, and the count field in the TCOB specifies a value that is not an even multiple of four,

10 TTE location error: Either of the following is true:

- A TCOB DCW is not specified and the TTE DCW is not the first DCW in the TCA.
- A TCOB DCW is specified and the TTE DCW specified is not the second DCW in the TCA.

11 TTE duplication error: More than one TTE DCW is specified.

12 TTE CD-count specification error: The control-data-count field in the TTE DCW specifies a value that is not zero.

13 TTE count specification error: The count field in the TTE DCW specifies a value that is less than 8 or a value that is not a multiple of 4.

14 TTE direction error: A TTE DCW is specified and the write-operation (W) in the TCW is zero.

15 TTE chaining error: The chain-command bit in the TTE DCW is zero.

16 TCAX specification error: A TTE DCW is specified and any of the following is true:

- The TCA does not contain at least one DCW that specifies the transfer of data (that is, at least one DCW that is not a transport-command DCW).
- The TCA contains one or more DCWs that specify the transfer of data and the chain-command flag in the last DCW of the TCA is zero.

17-255 Reserved.

When the RC field contains the value six, only byte 0 of the RCQ field has meaning. For this case, byte 0 of the RCQ field contains an 8-bit unsigned integer code that further describes the condition indicated by the RC field and the meaning of each RCQ value is as follows:

Value Meaning

0 No additional information.

1 Read-direction specification error: The DCW specifies an input operation, but the R-bit in the TCW used to transport the TCCB is zero.

2 Write-direction specification error: The DCW specifies an output operation, a TCOB operation, or a TTE operation, but the W-bit in the TCW used to transport the TCCB is zero.

3 Read-write-conflict specification error: Both the R-bit and the W-bit are one in the TCW used to transport the TCCB and the device does not support bidirectional data transfers.

4-255 Reserved.

When the RC field contains the value seven, only byte 0 of the RCQ field has meaning. For this case, byte 0 of the RCQ field contains an 8-bit unsigned integer code that further describes the condition indicated by the RC field and the meaning of each RCQ value is as follows:

Value Meaning

0 No additional information.

1 Read-count specification error: The specified read-count value is incorrect for any of the following reason:

- For unidirectional data transfers, the TCAT transport-count specifies a value that is not equivalent to the TCW input-count value. See “Transport Count” on page 15-40.
- For bidirectional data transfers, the TCAT read-count is not equivalent to the TCW input-count value. See “Read Count” on page 15-41.
- For unidirectional data transfers, the TCAT transport-count is not equivalent to the total count of bytes specified by the DCWs in the TCA and TCAX (when specified) that specify read operations**.**
- For bidirectional data transfers, the TCAT read-count is not equivalent to the total count of bytes specified by the DCWs in the TCA and in the TCAX (when specified), that specify read operations.

2 Write-count specification error: The specified write-count value is incorrect for any of the following reason:

- For unidirectional data transfers, the TCAT transport-count specifies a value that is not equivalent to the TCW output-count value. See “Transport Count” on page 15-40.
- For bidirectional data transfers, the TCAT write-count is not equivalent to

the TCW output-count value. See “Write Count” on page 15-41.

- For unidirectional data transfers, the TCAT transport-count is not equivalent to the total count of bytes specified by the DCWs in the TCA and TCAX (when specified) that specify write operations.
- For bidirectional data transfers, the TCAT write-count is not equivalent to the total count of bytes specified by the DCWs in the TCA and TCAX that specify write operations, the transfer of a COB, and the transfer of a TCAX.

3-255 Reserved.

When the RC field contains the value nine, only words 1 of the RCQ field has meaning as follows:

Value Meaning

0 Word 0 contains the 32-bit unsigned integer byte offset of the first CBC-offset entry in the COB that specifies a CBC offset that is not at a location that is recognized by the device or is not recognized for the DCW

Sense Data: When the length field in the TSH contains a value greater than 32, sense data has been provided by the I/O device. The count of meaningful sense-data bytes in this field is determined by subtracting 32 from the value in the length field.

Summary of Reason Codes and Associated Reason-Code Qualifiers

Figure 15-24 on page 15-54 provides a summary of the device-detected-program-check RC values and the meanings of their associated RCQ values.

Reason Code Value	**Meaning**	
0	No information.	
1	TCCB Transport Failure.	
	Reason-Code Qualifier Byte 0 Value	**Meaning**
	0	No additional information.
	1	TCCB transport size error
	2	TCCB CBC error.
2	Invalid CBC detected on output data.	
	Reason-Code Qualifier	**Meaning**
	Word 0 Value:	Offset of first output-data byte for which the invalid CBC was detected.
	Word 1 Value:	Offset of last output-data byte for which the invalid CBC was detected.
3	Incorrect TCCB length specification.	
	Reason-Code Qualifier Byte 0 Value	**Meaning**
	0	No additional information.
	1	TCCB TCAL field value not 8 greater than TCW TCCBL field value.
	2	TCCB TCAL field value is less than 20 or greater than 252.
4	TCAH specification error.	
	Reason-Code Qualifier Byte 0 Value	**Meaning**
	0	No additional information.
	1	TCCB format field specification error.
	2	TCCB reserved field specification error.
	3	TCCB service-action-code field specification error.

Figure 15-24. Summary of Reason-Code (RC) and Reason-Code-Qualifier (RCQ) Values in the Device-Detected-Program-Check TSA (Part 1 of 2)

Reason Code Value	Meaning	
5	DCW specification error.	
	Reason-Code Qualifier Byte 0 Value	**Meaning**
	0	No additional information.
	1	DCW reserved field specification error.
	2	DCW flags field command-chaining specification error.
	3	DCW control-data-count field specification error.
	4	TCOB location error
	5	TCOB duplication error
	6	TCOB multiple-count error
	7	TCOB direction error
	8	TCOB chaining error
	9	TCOB count-specification error
	10	TTE location error.
	11	TTE duplication error.
	12	TTE CD-count specification error.
	13	TTE count specification error.
	14	TTE direction error.
	15	TTE chaining error.
	16	TCAX specification error.
6	Transfer-direction specification error.	
	Reason-Code Qualifier Byte 0 Value	**Meaning**
	0	No additional information.
	1	Read-direction specification error.
	2	Write-direction specification error.
	3	Read-write conflict error.
7	Transport-count specification error.	
	Reason-Code Qualifier Byte 0 Value	**Meaning**
	0	No additional information.
	1	Read-count specification error.
	2	Write-count specification error.
8	Two I/O operations active.	
	Reason-Code Qualifier	No additional information.
9	CBC-offset-specification error.	
	Reason-Code Qualifier	No additional information.
	Word 0 Value:	Offset of first CBC-offset entry that specifies a CBC offset that is not at a location that is recognized.

Explanation:

- Reason-code values and reason-code-qualifier values that have no meaning do not appear in this summary.
- Portions of the reason-code-qualifier field that have no meaning for a specific reason code do not appear in this summary.

Figure 15-24. Summary of Reason-Code (RC) and Reason-Code-Qualifier (RCQ) Values in the Device-Detected-Program-Check TSA (Part 2 of 2)

Interrogate TSA

When the TSA-format field in the TSH contains three, the TSA has the following format:

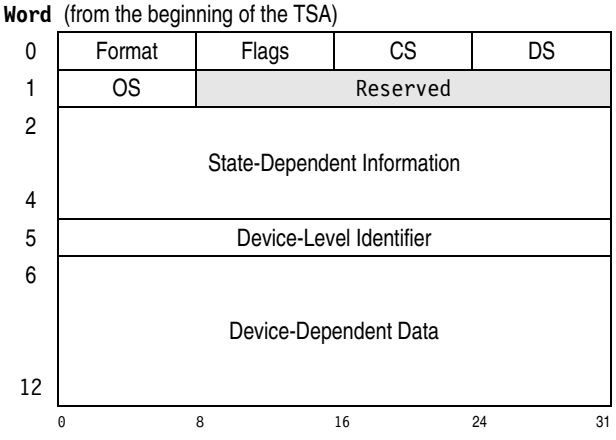

Figure 15-25. Interrogate Transport-Status Area (TSA)

Format: Byte of word 0 contains the unsigned integer value that defines the layout of the interrogate TSA. If the value of this field is not one, the contents of the interrogate TSA are meaningless.

Flags: Byte 1 of word 0 contains information about the interrogate TSA. The meaning of each flag bit is as follows.:

Bit	*Meaning*
0	Control-unit-state valid: When bit 0 is one, the control-unit-state field contains meaningful information. When bit 0 is zero, the control-unit-state field has no meaning.
1	Device-state valid: When bit 1 is one, the device-state field contains meaningful information. When bit 1 is zero, the device-state field has no meaning
2	Operation-state valid: When bit 2 is one, the operation-state field contains meaningful information. When bit 2 is zero, the operation-state field has no meaning.
3-7	Reserved.

Control-Unit State (CS): Byte 2 of word 0 contains an 8-bit unsigned integer that indicates a current state of the control unit for the I/O device. The meaning of each value is as follows:

Value	*Meaning*
0	Busy: The control unit is busy and the device-dependent-data field may contain additional information about the busy state.
1	Recovery: The control unit is performing a recovery process and the device-dependent-data field may contain additional information about the recovery state.
2	Interrogate maximum: The control unit is executing the maximum number of interrogate operations that it supports
3-127	Reserved.
128-255	Device-dependent meanings.

Device State (DS): Byte 3 of word 0 contains an 8-bit unsigned integer that indicates a current state of the I/O device. The meaning of this byte is

Value	*Meaning*
0	Path-group identification: The state-dependent-information field contains information identifying a path group.
1	Long busy: The device is in a long-busy state. The meaning of long busy is device dependent and the device-dependent-data field may contain additional information about the long-busy state.
2	Recovery: The device is performing a recovery process and the device-dependent-data field may contain additional information about the recovery state.
3-127	Reserved.
128-255	Device-dependent meanings.

Operation State (OS): Byte 0 of word 1 contains an 8-bit unsigned integer that indicates whether an I/O operation is present at the device and, when present, the state of the operation. The meaning of this byte is as follows:

Value	*Meaning*
0	No I/O operation is present.

1 An I/O operation is present and executing.

2 An I/O operation is present and waiting for completion of an I/O operation that was initiated by another configuration.

3 An I/O operation is present and waiting for completion of an I/O operation that was initiated for the same device extent.

4 An I/O operation is present and waiting to perform a device-dependent operation.

5-127 Reserved.

128-255 Device-dependent meanings.

State-Dependent Information: Words 2-4 may contain state-dependent information. Whether this field has meaning is designated by the CS, DS, and OS fields.

The contents of this field are device dependent. When the device places one or more bytes in this field, they are left justified.

Device-Level Identifier: Word 5 contains a device-dependent token that identifies the implementation level of the device.

Device-Dependent Data: Words 6-12 contain device-dependent information. Whether this field has meaning is designated by the CS, DS, and OS fields.

When the device places one or more bytes in this field, they are left justified.

Note:

1. An interrogate TSA is stored only in a TSB designated by an interrogate TCW.
2. If a program-check condition is recognized for an interrogate TCCB, a device-detect-program-check TSA is stored in the TSB designated by the interrogate TCW.

Command Code

For CCW channel programs, the command code, bit positions 0-7 of the CCW, specifies to the channel subsystem and the I/O device the operation to be performed. For TCW channel programs, the command code, bit positions 0-7 of the DCW, specifies to the I/O device the operation to be performed.

With the exception of transport commands, the two rightmost bits or, when these bits are zeros, the four rightmost bits of the command code identify the operation to the channel subsystem. The channel subsystem distinguishes among the following operations:

- Control
- Output forward (write)
- Input forward (read, sense, sense ID)
- Input backward (read backward)
- Branching (transfer in channel)
- Interrogate
- Transport

For CCW channel programs, the channel subsystem ignores the leftmost four bits of the command code in a format-0 CCW that specifies transfer-in-channel. In a format-1 CCW that specifies transfer in channel, all bits of the command code are decoded by the channel subsystem.

For CCW channel programs, commands that initiate I/O operations (write, read, read backward, control, sense, and sense ID) cause all eight bits of the command code to be transferred to the control unit.

In command codes that initiate I/O operations, the leftmost bit positions contain modifier bits. The modifier bits specify to the device how the command is to be executed. They may, for example, cause the device to compare data received during a write operation with data previously recorded, and they may specify such attributes as recording density and parity. For the control command, the modifier bits may contain the order code specifying the control function to be performed. The meaning of the modifier bits depends on the type of I/O device and is specified in the System Library publication for the device.

The command-code assignment is listed in Figure 15-26 on page 15-58. The symbol x indicates

that the bit position is ignored; the symbol m identifies a modifier bit.

Code	Command
x x x x 0 0 0 0	Invalid
m m m m m m 0 1	Write[1]
m m m m m m 1 0	Read[1]
m m m m 1 1 0 0	Read Backward[2]
m m m m m m 1 1	Control
m m m m 0 1 0 0	Sense
1 1 1 0 0 1 0 0	Sense ID
x x x x 1 0 0 0	Transfer in channel[3]
0 0 0 0 1 0 0 0	Transfer in channel[4]
m m m m 1 0 0 0	Invalid[5]
0 1 m m 0 0 0 0	Transport[6]

Explanation:

m Modifier bit
x Ignored
1 May designate control data in DCWs.
2 CCW only
3 Format-0 CCW
4 Format-1 CCW
5 Format-1 CCW with any of bits 0-3 nonzero
6 DCW only

Figure 15-26. Command-Code Assignment

Whenever the channel subsystem detects an invalid command code during the initiation of command execution for a CCW channel program, the program-check-interruption condition is generated, and channel-program execution is terminated. The command code is ignored during data chaining, unless it specifies transfer in channel.

Whenever an I/O device detects an invalid command code while executing the commands in a TCCB, a device-detected-program-check condition is recognized and channel-program execution is terminated.

Designation of Storage Area

For CCW channel programs, the main-storage area associated with an I/O operation is defined by one or more CCWs. A CCW defines an area by specifying the address of the first byte to be transferred and the number of consecutive bytes contained in the area. The address of the first byte of data to be transferred is specified either directly in the data-address field of the CCW or indirectly in an indirect-data-address word (IDAW) or modified-indirect-data-address word (MIDAW) designated by the data-address field of the CCW. The number of bytes contained in the storage area is specified in the count field.

For TCW channel programs the main-storage area associated with an I/O operation is designated by a TCW. A TCW designates an area by specifying the address of the first byte to be transferred and the number of consecutive bytes contained in the area. The address of the first byte of data to be transferred for input operations is specified either directly in the input-data-address field of the TCW or indirectly by a transport-indirect-data-address word (TIDAW) designated by the input-data-address field of the TCW. The number of bytes contained in the storage area for input operations is specified in the input-count field. The address of the first byte of data to be transferred for output operations is specified either directly in the output-data-address field of the TCW or indirectly by a TIDAW designated by the output-data-address field of the TCW. The number of bytes contained in the storage area for output operations is specified in the output-count field. In this case, the actual number of bytes in the storage area is determined by subtracting the number of any inserted padding or CBC bytes from the output-count field value. The address of the first byte of data to be transferred into the TSB is specified in the TSB-address field of the TCW. The number of bytes contained in the storage area for the TSB is dependent on the status being returned and is a maximum of 64.

In general, for write, read, control, and sense operations, storage locations are used in ascending order of addresses. As information is transferred to or from main storage, the address from the appropriate address field is incremented, and the count from the associated count field is decremented. For command-mode operations, the read-backward operation places data in storage in a descending order of addresses, and both the count and the address are decremented. When the associated count reaches zero, the storage area defined by the CCW is exhausted.

When a subchannel is operating in transport mode, the channel subsystem may take advantage of performance optimizations and access storage locations in a non-sequential order within the storage area or areas designated by the current TCW. When a transport-mode operation is concluded, the transfer of specified data, as indicated by information in the I/O-status TSB, is complete.

Any main-storage location available to the start function can be used in the transfer of data to or from an I/O device, provided that the location is not protected against that type of reference. Format-0 CCWs can be located in any available part of the first 2^{24} (16M) bytes of absolute storage, and format-1 CCWs and TCWs can be located in any available part of the first 2^{31} (2G) bytes of absolute storage, provided that, in both cases, the location is not protected against a fetch-type reference. When the channel subsystem attempts to refer to a protected location, the protection-check condition is generated, and the device is signaled to terminate the operation.

A main-storage location is available if it is available in the configuration and access to the location is not prevented by the address-limit-checking facility. CCWs, TCWs, ISDs, TSBs, and the data they address reside in main-storage locations. If a main-storage location is not available, it is said to have an invalid address

If the channel subsystem refers to a location that is not available, the program-check condition is generated. When the first CCW or TCW designated by the channel-program address is at an unavailable location, the start function is not initiated at the device, the status portion of the SCSW is updated with the program-check indication, the subchannel becomes status pending with primary, secondary, and alert status, and deferred condition code 1 is indicated. An invalid data address, as well as any invalid CCW address detected on chaining or subsequent to the execution of START SUBCHANNEL, causes the channel subsystem to signal the device to conclude the operation, if and when the device requests or offers a byte of data or status at the invalid address. In this situation, the subchannel is made status pending with program check indicated in the subchannel status, and the device status is a function of the status received from the device. The program-check condition causes command chaining and command retry to be suppressed.

During an output operation, the channel subsystem may fetch data from main storage before the time the I/O device requests the data. Any number of bytes specified by the current CCW or TCW may be prefetched and buffered.

When data chaining during an output operation for a CCW channel program, the channel subsystem may fetch one CCW describing a data area at any time during the execution of the current CCW. If unlimited prefetching is allowed by the setting of the prefetch-control bit in the ORB CCW channel program, any number of CCWs, IDAWs, and MIDAWs and the associated data may be prefetched by the channel subsystem. When the I/O operation uses data or CCWs from locations near the end of the available storage, such prefetching may cause the channel subsystem to refer to locations that do not exist. Invalid addresses detected during prefetching do not affect the performance of the I/O operation and do not cause error indications until the operation actually attempts to use the information. If the operation is concluded by the I/O device or by the execution of HALT SUBCHANNEL or CLEAR SUBCHANNEL before the invalid information is needed, the condition is not brought to the attention of the program.

The count field in the CCW can specify any number of bytes up to 65,535. In format-0 CCWs, the count field is always nonzero unless the command code specifies transfer in channel, in which case the count field is ignored. In format-1 CCWs, the count field may contain the value zero unless data chaining is specified or the CCW is fetched while data chaining. Whenever (1) the count field in a format-1 CCW is zero, (2) data chaining is either not specified or not in effect, and (3) data transfer is requested by the device, the device is signaled to stop, and the I/O operation is terminated. The channel subsystem sets the incorrect-length condition if the SLI flag is not one in the CCW. No data is transferred. If the device does not request data transfer, the operation proceeds to the normal ending point.

If a zero byte count is contained in a format-0 CCW that does not specify transfer in channel, or if a zero byte count is contained in a format-1 CCW that specifies data chaining or was fetched while data chaining, a program-check condition is recognized, and the subchannel is made status pending with combinations of primary, secondary, and alert status as a function of the state of the subchannel and the status received from the device.

The input-count and output-count fields in the TCW can specify any number of bytes up to 2^{32} - 8. For input operations, the input-count field is always nonzero; otherwise, a program-check condition is recognized. For output operations, the output-count field is always nonzero; otherwise, a program-check condition is recognized.

Note: For a description of the storage area associated with a CCW when indirect data addressing is

used, see “CCW Indirect Data Addressing” on page 15-66. For a description of the storage area associated with a TCW when indirect data addressing is used, see “Transport Indirect Data Addressing” on page 15-70.

Programming Notes:

1. Since a format-1 CCW with a count of zero is valid, the program can use the CCW count field to specify that no data be transferred to the I/O device. If the device requests a data transfer, the device is signaled to terminate data transfer. If the SLI and chain-command flags are also specified as ones, and no unusual conditions are encountered subsequent to signaling the device to terminate data transfer, the new operation is initiated upon receipt of device end from the device.

2. If the subchannel is in the incorrect-length-suppression mode, the chain-data flag in the current CCW is zero, and the operation is performed as an immediate operation, then incorrect length is not indicated, regardless of the setting of the SLI flag.

   If the subchannel is in the incorrect-length-indication mode, if the chain-data flag in the current CCW is zero, and if the operation is performed as an immediate operation, then incorrect length is indicated if the count field of the current CCW specifies a nonzero value, unless suppressed by the SLI flag of the CCW; incorrect length is not indicated, however, if the count field of the CCW specifies a value of zero.

   If a new CCW that has a count field of zero is fetched during data chaining or if a CCW is fetched with the chain-data flag set to one and a count field of zero, a program-check condition is recognized by the channel subsystem.

3. Since the channel-subsystem may access storage in a non-sequential manner while a subchannel is operating in transport mode, the results may be unpredictable if the program accesses the input storage area or areas designated by a TCW before primary status is indicated.

CCW Channel Program Chaining

When the channel subsystem has completed the transfer of information specified by a CCW, it can continue performing the start function by fetching a new CCW. Such fetching of a new CCW is a form of chaining, and the CCWs belonging to such a sequence are said to be chained.

Chaining takes place between CCWs located in successive doubleword locations in storage. It proceeds in an ascending order of addresses; that is, the address of the new CCW is obtained by adding 8 to the address of the current CCW. Two chains of CCWs located in noncontiguous storage areas can be coupled for chaining purposes by a transfer-in-channel command. All CCWs in a chain apply to the I/O device that is associated with the subchannel designated by the original START SUBCHANNEL instruction.

Two types of chaining are provided for CCWs: Chaining is controlled by the chain-data (CD) and chain-command (CC) flags in conjunction with the suppress-length-indication (SLI) flag in the CCW. These flags specify the action to be taken by the channel subsystem upon the exhaustion of the current CCW and upon receipt of ending status from the device, as shown in Figure 15-27 on page 15-61.

The specification of chaining is effectively propagated through a transfer-in-channel command. When, in the process of chaining, a transfer-in-channel command is fetched, the CCW designated by the transfer-in-channel command is used for the type of chaining specified in the CCW preceding the transfer-in-channel command.

The CD and CC flags are ignored in a format-0 CCW specifying the transfer-in-channel command. In a format-1 CCW specifying the transfer-in-channel com-

mand, the CD and CC flags must be zeros; otherwise, a program-check condition is recognized.

Flags in Current CCW			Action at the Subchannel upon Exhaustion of Count or Receipt of Channel End						
			Immediate Operation				Non-immediate Operation		
			Incorrect-Length-Suppression Mode[1]		Incorrect-Length-Indication Mode		Count Exhausted		Count Not Exhausted and CE Received
CD	CC	SLI	CCW Count≠0	CCW Count=0	CCW Count≠0	CCW Count=0	CE Not Received	CE Received	
0	0	0	End, NIL	End, NIL	End, IL	End, NIL	Stop, IL	End, NIL	End, IL
0	0	1	End, NIL	End, NIL	End, NIL	End, NIL	Stop, NIL	End NIL,	End, NIL
0	1	0	CC	CC	End, IL	CC	Stop, IL	CC	End, IL
0	1	1	CC	CC	CC	CC	Stop, CC	CC	CC
1	-	-	End, NIL	PC	End, IL	PC	CD	*	End IL

Explanation:

-	The selected bit is ignored and may be either zero or one.
*	These situations cannot validly occur. When data chaining is specified, the new CCW takes control of the operation after transferring the last byte of data designated by the current CCW, but before the next request for data or status transfer from the device. The new CCW (which cannot contain a count of zero unless a program-check condition is also recognized) is in control of the operation
1	The count field must contain a nonzero value when format-0 CCWs are specified; otherwise, the operation is terminated with a program-check condition.
CC	Command chaining is performed by the channel subsystem upon receipt of device end.
CD	The chain-data flag causes the channel subsystem to immediately fetch a new CCW for the same operation. The operation continues unless the CCW thus fetched has a count field of zero, in which case the operation is terminated with a program-check condition.
CE	Channel end from the device that indicates end of block.
End	Operation is terminated.
IL	Incorrect length is indicated with the subsequent interruption condition generated at the subchannel.
NIL	Incorrect length is not indicated with the subsequent interruption condition generated at the subchannel.
PC	These situations cannot validly occur. The channel subsystem recognizes a program-check condition when a CCW is fetched that has the chain-data flag set to one and a count field of zero.
STOP	Device is signaled to terminate data transfer, but subchannel remains subchannel active until channel end is received.

Figure 15-27. Subchannel Chaining Action

Programming Note: When bit 9 of word 1 of the ORB is one, unlimited prefetching of chained CCWs (including CCWs linked by a transfer-in-channel command) by the channel subsystem is permitted. When prefetching is allowed by the ORB, no modification of the channel program should be performed after START SUBCHANNEL is executed and before the primary interruption condition for the operation has been received unless the subchannel is currently suspended and is not resume pending.

Data Chaining

During data chaining, the new CCW fetched by the channel subsystem defines a new storage area for the original I/O operation. If the channel path is of the parallel-I/O-interface type, the performance of the operation at the I/O device is not affected. If the channel path is of the serial-I/O-interface type, then the performance of the operation at the I/O device either is not affected or, depending on the device model, may be terminated with unit-check status. When the operation at the I/O device is not affected and all data designated by the current CCW has been transferred to main storage or to the device, data chaining causes the operation to continue, using the storage area designated by the new CCW. The contents of the command-code field of the new CCW are ignored, unless they specify transfer in channel.

Data chaining is considered to occur immediately after the last byte of data designated by the current CCW has been transferred to main storage or to the device. When the last byte of the data transfer has been placed in main storage or accepted by the device, the new CCW takes over the control of the operation. If the device sends channel end after

exhausting the count of the current CCW but before transferring any data to or from the storage area designated by the new CCW, the SCSW associated with the concluded operation pertains to the new CCW.

If programming errors are detected in the new CCW or during its fetching, the error indication is generated, and the device is signaled to conclude the operation when it attempts to transfer data designated by the new CCW. If the device signals the channel-end condition before transferring any data designated by the new CCW, program check or protection check is indicated in the SCSW associated with the termination. The contents of the SCSW pertain to the new CCW unless the address of the new CCW is invalid, the location is protected against fetching, or programming errors are detected in an intervening transfer-in-channel command. A data address referring to a nonexistent or protected area causes an error indication only after the I/O device has attempted to transfer data to or from the invalid location.

Data chaining during an input operation causes the new CCW to be fetched when all data designated by the current CCW has been placed in main storage. On an output operation, the channel subsystem may fetch the new CCW from main storage before data chaining occurs. Any programming errors in the prefetched CCW, however, do not affect the performance of the operation until all data designated by the current CCW has been transferred to the I/O device. If the device concludes the operation before all data designated by the current CCW has been transferred, the conditions associated with the prefetched CCW are not indicated to the program. Unlimited prefetching is allowed under the control of the prefetch bit specified in the ORB. (See “Prefetch Control (P)” on page 15-27.) When unlimited prefetching is not allowed and an output operation is specified, only one CCW describing a data area may be prefetched. If a prefetched CCW specifies transfer in channel, only one more CCW may be fetched before the exhaustion of the current CCW.

Programming Notes:

1. If the ORB does not specify unlimited prefetching, no prefetching of CCWs is performed, except in the case of data chaining on an output operation where one CCW describing a data area may be prefetched at a time.

   If the ORB for the I/O operation specifies that prefetching is allowed, any number of CCWs, IDAWs, and MIDAWs and the associated data areas may be prefetched and buffered in the channel subsystem.

   The same actions for signaling errors and terminating operations take place when unlimited prefetching is allowed by the ORB as when it is not allowed. However, when unlimited prefetching is specified and an error condition is detected, both the channel subsystem and the program must recognize that the points of termination at the channel subsystem and at the I/O device may be different in terms of the channel command in execution at the point of error. The channel subsystem indicates the point of termination at the channel subsystem by storing the appropriate CCW address in word 1 of the subchannel-status word and the point of termination at the device by storing the secondary-CCW address in word 4 of the format-0 extended-status word.

   When prefetching has been specified in the ORB, the result of modifications to CCWs after START SUBCHANNEL has been executed or after self-describing channel programs have been used is unpredictable. (See note 2 for the definition of self-describing channel programs.)

2. Data chaining may be used to rearrange information as it is transferred between main storage and an I/O device. Data chaining permits blocks of information to be transferred to or from noncontiguous areas of storage, and, when used in conjunction with the skipping function, data chaining allows the program to place in main storage specified portions of a block of data.

   When, during an input operation, the program specifies data chaining to a location in which data has been placed under the control of the current CCW, the channel subsystem, in fetching the next CCW, fetches the new contents of the location. This is true even if the location contains the last byte transferred under the control of the current CCW. When a channel program data-chains to a CCW placed in storage by the CCW specifying data chaining, the input block is said to be self-describing. A self-describing block contains one or more CCWs that designate storage locations and counts for subsequent data in the same input block.

   The use of self-describing blocks is equivalent to the use of unchecked data. An I/O data-transfer

malfunction that affects validity of a block of information is signaled only at the completion of data transfer. The error condition normally does not prematurely terminate or otherwise affect the performance of the operation. Thus, there is no assurance that a CCW read as data is valid until the operation is completed. If the CCW thus read is in error, use of the CCW in the current operation may cause subsequent data to be placed at wrong locations in main storage with resultant destruction of its contents, subject only to the control of the protection key and the address-limit-checking facility, if used.

3. When, during data chaining, a device transfers data by using the data-streaming feature, an overrun or chaining-check condition may be recognized when a small byte-count value is specified in the CCW. The minimum acceptable number of bytes that can be specified varies as a function of the system model and system activity.

Command Chaining

During command chaining, the new CCW fetched by the channel subsystem specifies a new I/O operation. The channel subsystem fetches the new CCW upon the receipt of the device-end signal for the current operation. If the new CCW does not have its S flag set to one and no unusual conditions are detected, the channel subsystem initiates the new operation. The presence of the S flag set to one or unusual conditions causes command chaining to be suppressed. When command chaining takes place, the completion of the current operation does not cause an I/O interruption, and the count indicating the amount of data transferred during the current operation is not made available to the program. For operations involving data transfer, the new command always applies to the next block of data at the device.

Command chaining takes place and the new operation is initiated only if no unusual conditions have been detected in the current operation. In particular, the channel subsystem initiates a new I/O operation by command chaining upon receipt of a status byte containing only the following bit combinations: (1) device end, (2) device end and status modifier, (3) device end and channel end, and (4) device end, channel end, and status modifier. In the first two cases, channel end is signaled before device end, with all other status bits zeros. If a condition such as attention, unit check, unit exception, incorrect length, program check, or protection check has occurred, the sequence of operations is concluded, and the status associated with the current operation causes an interruption condition to be generated. The new CCW in this case is not fetched. The incorrect-length condition does not suppress command chaining if the current CCW has the SLI flag set to one.

An exception to sequential chaining of CCWs occurs when the I/O device presents the status-modifier condition with the device-end signal or channel-end and device-end signals. When command chaining is specified and no unusual conditions have been detected, or when command retry has been previously signaled and an immediate retry could not be performed, the combination of status-modifier and device-end bits causes the channel subsystem to alter the sequential execution of CCWs. If command chaining was specified, status modifier and device end cause the channel subsystem to fetch and chain to the CCW whose main-storage address is 16 higher than that of the CCW that specified chaining. If command retry was previously signaled and immediate retry could not be performed, the status causes the channel subsystem to command chain to the CCW whose storage address is 8 higher than that of the CCW for which retry was initially signaled.

When both command and data chaining are specified, the first CCW associated with the operation specifies the operation to be performed, and the last CCW specifies whether another operation follows.

Programming Note: Command chaining makes it possible for the program to initiate transfer of multiple blocks of data by issuing a single START SUBCHANNEL instruction. It also permits a subchannel to be set for execution of other commands, such as positioning the disk-access mechanism, and for data-transfer operations without interference by the program at the end of each operation. Command chaining, in conjunction with the status-modifier condition, permits the channel subsystem to modify the normal sequence of operations in response to signals provided by the I/O device.

TCW Channel Program Chaining

When the I/O device has completed a control operation or the transfer of information specified by a DCW, the device can continue by executing the next DCW that is specified. Such execution of a new DCW is a form of command chaining, and the DCWs belonging to such a sequence are said to be chained.

Command chaining is controlled by the DCW chain-command (CC) flag in the DCW. This flag specifies the action to be taken upon the exhaustion of the current DCW. Chaining takes place between successive DCWs within the TCA. When a TCAX is specified, chaining also takes place between the last DCW in the TCA and the first DCW in the TCAX, and between successive DCWs within the TCAX.

When a TCCB is transported to an I/O device and selected by the device for processing, the first DCW in the TCA becomes the current DCW and is executed by the device. When the current DCW specifies command chaining and no unusual conditions have been detected during the operation, the completion of the current DCW causes the next DCW to become the current DCW and be executed by the device. The TCA offset of the next DCW is determined by adding 8, plus the value of the control-data (CD) count field of the DCW, to the TCA offset of the current DCW and rounding upwards to the next word boundary. If a TCAX is specified and the offset of the next DCW is past the end of the TCA, chaining continues with the first DCW of the TCAX whose TCAX offset is determined by subtracting the TCA length from the calculated offset. Thus, command chaining proceeds in ascending order of TCA offsets and then TCAX offsets when a TCAX is specified.

During command chaining, the new DCW executed by the device specifies a new I/O command. When command chaining takes place, the completion of the execution of the current command does not cause an I/O interruption, and the count indicating the amount of data transferred during the current operation is not made available to the program. For operations involving data transfer, the new command always applies to the next block of data at the device.

Command chaining takes place and the new command is initiated only if no unusual conditions have been detected in the execution of the current command. In particular, the I/O device initiates a new I/O operation by command chaining upon successful completion of the current command. If a condition such as attention, unit check, unit exception, or incorrect length has occurred, the sequence of operations is concluded, and the status associated with the current operation causes an interruption condition to be generated. The new DCW in this case is not executed.

Command chaining makes it possible for the program to initiate transfer of multiple blocks of data by issuing a single START SUBCHANNEL instruction. It also permits a subchannel to be set for execution of other commands, such as positioning the disk-access mechanism, and for data-transfer operations without interference by the program at the end of each operation. For command-mode operations, command chaining, in conjunction with the status-modifier condition, permits the channel subsystem to modify the normal sequence of operations in response to signals provided by the I/O device

Skipping

Skipping causes the suppression of main-storage references during an I/O operation. It is defined only for read, read-backward, sense-ID, and sense operations. Skipping is controlled by the skip flag, which can be specified individually for each CCW, MIDAW, or TIDAW. When the skip flag is one, skipping occurs; when it is zero, normal operation takes place. The setting of the skip flag is ignored in all other operations.

Skipping affects only the handling of information by the channel subsystem. The operation at the I/O device proceeds normally, and information is transferred. The channel subsystem keeps updating the count but does not place the information in main storage. Chaining is not precluded by skipping. In the case of CCW data chaining, normal operation is resumed if the skip flag in the new CCW is zero.

No checking for invalid or protected data addresses takes place during skipping.

Programming Note: Skipping, when combined with CCW data chaining, MIDAWs, and TIDAWs, permits the program to place in main storage specified portions of a block of information from an I/O device.

Program-Controlled Interruption

The program-controlled-interruption (PCI) function permits the program to cause an I/O interruption during the performance of an I/O operation. The function is controlled by the PCI flag of the CCW. Neither the value of the PCI flag nor the associated interruption request affects the performance of the current operation.

The value of the PCI flag can be one either in the first CCW designated for the current start or resume func-

tion or in a CCW fetched during chaining. If the PCI flag is one in a CCW that has become current, the subchannel becomes status pending with intermediate status, and an I/O-interruption request is generated. The point at which the subchannel becomes status pending depends on the progress of the current start or resume function as follows:

1. If the PCI flag is one in the first CCW associated with a start function or a resume function, the subchannel becomes status pending with intermediate status only after the command has been accepted.
2. If the PCI flag is one in a CCW that has become current while data chaining, the subchannel becomes status pending with intermediate status after all data designated by the preceding CCW has been transferred.
3. If the PCI flag is one in a CCW that has become current while command chaining, the subchannel becomes status pending with intermediate status as that CCW becomes current.

In all cases, if the subchannel is enabled for I/O interruptions, the point of interruption depends on the current activity in the system and may be delayed. No predictable relationship exists between the point at which the interruption request is generated because of the PCI flag and the extent to which data transfer has been completed to or from the area designated by the CCW. However, all the fields within the SCSW pertain to the same instant.

An intermediate interruption condition that is made pending because of a PCI flag remains pending during chaining if not cleared by TEST SUBCHANNEL or CLEAR SUBCHANNEL. If another CCW containing a PCI flag that is one becomes current prior to the clearing of the intermediate interruption condition, only one interruption condition is preserved.

An intermediate interruption may occur while the subchannel is subchannel-and-device active with the operation specified by the CCW causing the intermediate interruption condition or with the operation specified by a CCW that has subsequently become current. If the intermediate interruption condition is not cleared prior to the conclusion of the operation or chain of operations, the condition is indicated together with the primary interruption condition at the conclusion of the operation or chain of operations. The intermediate interruption condition may be cleared by TEST SUBCHANNEL while the subchannel is subchannel active.

If the SCSW stored by TEST SUBCHANNEL indicates that the subchannel is status pending with intermediate status and the operation or chain of operations has not been concluded (that is, the activity-control field indicates subchannel-and-device active or suspended), then the CCW-address field contains an address that is 8 higher than the address of the most recent CCW to become current and have a PCI flag that is one, or the CCW-address field contains an address that is 8 higher than the address of a CCW that has subsequently become current. Unless the SCSW also contains the primary-status bit set to one, the device-status field contains zeros, and the count is unpredictable.

Subchannel-status conditions other than PCI may be indicated when the SCSW is stored. If the subchannel is not also status pending with primary status, these conditions may or may not be indicated again. If the subchannel-status condition is detected while prefetching and the operation or chain of operations is concluded before the condition affects an operation, the condition is reset and is not indicated when the subchannel subsequently becomes status pending with primary status. If the subchannel-status condition affects an operation, the condition is indicated when the subchannel becomes status pending with primary status.

If the program-controlled-interruption condition remains pending until the operation or chain of operations is concluded at the subchannel, a single interruption request exists. When TEST SUBCHANNEL is subsequently executed, the status-control field of the SCSW stored indicates both the primary interruption condition and the intermediate interruption condition, and the PCI bit of the subchannel-status field is one.

The value of the PCI flag is inspected in every CCW except for those CCWs that specify the transfer-in-channel command. The PCI flag is ignored during initial program loading.

Programming Notes:

1. The program-controlled interruption provides a means of alerting the program to the progress of chaining during an I/O operation. It permits programmed dynamic main-storage allocation.

2. A CCW with a PCI flag set to one may, if retried because of command retry, cause multiple PCI interruptions to occur. (See “Command Retry” on page 15-77.)

Indirect Storage Addressing

Indirect-storage addressing (ISA) allows for storage areas designated by a channel program to be specified in noncontiguous storage. Depending on the model, more than one form of ISA facility may be installed as follows:

- CCW-indirect-data (see “CCW Indirect Data Addressing” on page 15-66) addressing is installed in all models.
- Modified-CCW-indirect-data (see “Modified CCW Indirect Data Addressing” on page 15-68) addressing may also be installed in a model.
- TCW-indirect-data-addressing (see “Transport Indirect Data Addressing” on page 15-70) may also be installed in a model.

Indirect-Storage Designator (ISD)

Each ISA facility description includes the definition of a facility-unique indirect-storage designator (ISD) that is used to specify a block of storage to the channel subsystem. Thus, a list of ISDs may be used to designate noncontiguous storage blocks. How the location and size of a storage block are specified and whether the specification of the storage block has boundary restrictions, size restrictions, or both is dependent on the method of ISA used. The following ISDs may be used as follows:

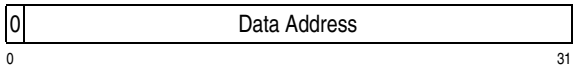
- Format-1 and format-2 indirect-data-address word (IDAW). See “CCW Indirect Data Addressing” on page 15-66.
- Modified-indirect-data-address word (MIDAW), when the modified-CCW-indirect-data-addressing facility is installed. See “Modified CCW Indirect Data Addressing” on page 15-68.
- Transport-indirect-data-address word (TIDAW), when the fibre-channel-extensions (FCX) facility is installed. See “Transport Indirect Data Addressing” on page 15-70.

CCW Indirect Data Addressing

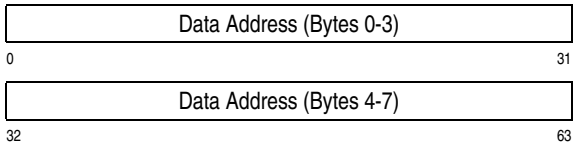
CCW indirect data addressing permits a single channel-command word to control the transfer of data that spans noncontiguous 2 K-byte or 4 K-byte blocks in main storage. The use of CCW indirect data addressing also allows the program to designate data addresses above 16M bytes when using format-0 CCWs or above 2G bytes when using format-1 CCWs. CCW indirect data addressing is specified by a flag in the CCW which, when one, indicates that the data address is not used to directly address data. Instead, the address points to a list of words or doublewords, called indirect-data-address words (IDAWs), each of which contains an absolute address designating a data area in main storage.

IDAWs have either of two formats, called format 1 and format 2, as determined by the format-2-IDAW control, bit 14 of word 1 of the ORB associated with the channel program being executed. When the format-2-IDAW control is zero, the IDAW is format 1 and is a word containing a 31-bit address. When the control is one, the IDAW is format 2 and is a doubleword containing a 64-bit address. The IDAW formats are as follows:

Format-1 IDAW



Format-2 IDAW



Bit 0 (format 1) is reserved for future use and must be zero; otherwise, a program-check condition may be recognized, as described below.

A format-1 IDAW designates a data area within a 2 K-byte block of main storage and is capable of addressing storage in the range of 0 to 2^{31} - 1.

A format-2 IDAW designates a data area within a 2 K-byte or 4 K-byte block of main storage, as determined by the 2K-IDAW control, bit 15 of word 1 of the ORB associated with the channel program being executed, and is capable of addressing storage in the range of 0 to 2^{64} - 1. When the 2K-IDAW-control bit is zero, each format-2 IDAW of the designated channel

program designates a 4 K-byte block of main storage. When the 2K-IDAW-control bit is one, each format-2 IDAW designates a 2 K-byte data-area block. All IDAWs associated with the designated channel program must have the same IDAW format, and all of those IDAWs specify the same size of storage block.

When the indirect-data-addressing bit in the CCW is one, the data-address field of the CCW designates the location of the first IDAW to be used for data transfer for the command. Additional IDAWs, if needed for completing the data transfer for the CCW, are in successive locations in storage. The number of IDAWs required for a CCW is determined by the IDAW format as specified in the ORB, by the count field of the CCW, and by the data address in the initial IDAW. When, for example, (1) the ORB specifies format-2 IDAWs with 4 K-byte blocks, (2) the CCW count field specifies 8K bytes, and (3) the first IDAW designates a location in the middle of a 4 K-byte block, then three IDAWs are required.

The IDAW designated by the CCW can designate any location. Data is then transferred, for read, write, control, sense ID, and sense commands, to or from successively higher storage locations or, for a read-backward command, to successively lower storage locations, until a 2 K-byte block boundary (format-1 or format-2 IDAW) or a 4 K-byte block boundary (format-2 IDAW) is reached. The control of data transfer is then passed to the next IDAW. The second and any subsequent IDAWs must designate, depending on the command, the first byte, or the last byte for read backward, of a 2 K-byte block (format-1 or format-2 IDAW) or a 4 K-byte block (format-2 IDAW). Thus, for read, write, control, sense ID, and sense commands, such format-1 IDAWs must have zeros in bit positions 21-31, and such format-2 IDAWs must have zeros in bit positions 53-63 (2 K-byte blocks) or 52-63 (4 K-byte blocks). For a read-backward command, such format-1 IDAWs must have ones in bit positions 21-31, and such format-2 IDAWs must have ones in bit positions 53-63 (2 K-byte blocks) or 52-63 (4 K-byte blocks). If any of these rules is violated, a program-check condition is recognized.

Except for the unique restrictions on the designation of the data address by the IDAW, all other actions taken for the data address, such as for protected storage and invalid addresses, and the actions taken for data prefetching are the same as when indirect data addressing is not used.

IDAWs pertaining to the current CCW or a prefetched CCW may be prefetched. The number of IDAWs that can be prefetched cannot exceed that required to satisfy the count in the CCW that points to the IDAWs. An IDAW takes control of data transfer when the last byte has been transferred for the previous IDAW. The same actions take place as with data chaining regarding when an IDAW takes control of data transfer during an I/O operation. That is, when the count for the CCW has not reached zero, a new IDAW takes control of the data transfer when the last byte has been transferred for the previous IDAW for that CCW, even in situations where (1) channel end, (2) channel end and device end, or (3) channel end, device end, and status modifier are received prior to the transfer of any data bytes pertaining to the new IDAW.

A prefetched IDAW does not take control of an I/O operation if the count in the CCW has reached zero with the transfer of the last byte of data for the previous IDAW for that CCW. Program or access errors detected in prefetched IDAWs are not indicated to the program until the IDAW takes control of data transfer. However, when the channel subsystem detects an invalid CBC on the contents of a prefetched IDAW or its associated key, the condition may be indicated to the program, when detected, before the IDAW takes control of data transfer. For a description of the indications provided when an invalid CBC is detected on the contents of an IDAW or its associated key, see “Channel-Control Check” on page 16-29.

Bits 1-31 (format 1) or bits 0-63 (format 2) designate the absolute storage location of the first byte to be used in the data transfer. When format-1 IDAWs are specified, the channel subsystem forms a 64-bit absolute main-storage address by appending 33 zero bits on the left of bit 1.

When the IDAW flag of the CCW is set to one and any of the following conditions occurs:

1. Format-1 IDAWs are specified in the ORB, and the address in the CCW does not designate the first IDAW on a word boundary,
2. Format-2 IDAWs are specified in the ORB, and the address in the CCW does not designate the first IDAW on a doubleword boundary,
3. The address in the CCW designates a storage location that is not physically available,

4. Access to the storage location specified by the address in the CCW is prohibited by protection, or

5. Bit 0 (format 1 only) of the first IDAW is not zero,

then, depending on the model, one of the following two actions is taken independent of the setting of the skip flag (if condition 5 above is true, action 2 must be taken).

1. The above conditions are checked before initiating the operation at the device. If any of these conditions is recognized, initiation of the I/O operation does not occur, and the subchannel is made status pending with primary, secondary, and alert status.

2. The operation is initiated at the device prior to checking for these conditions. If the device attempts to transfer data, the device is signaled to terminate the I/O operation, and the subchannel is made status pending with primary, secondary, and alert status as a function of the subchannel state and the status presented by the device.

Modified CCW Indirect Data Addressing

Modified CCW indirect data addressing (MIDA) permits a single channel-command word to control the transfer of up to 65,535 bytes of data that spans noncontiguous blocks in main storage. Each block of main storage to be transferred may be specified on any boundary and length up to 4K bytes, provided the specified block does not cross a 4 K-byte boundary. The use of modified CCW indirect data addressing requires that the program designate 64-bit data addresses.

Modified CCW indirect data addressing is controlled by a flag in the ORB and specified by a flag in the CCW which, when both are one, indicates that the CCW data address is not used to directly address data. Instead, the address points to a contiguous list of up to 256 quadwords called modified-indirect-data-address words (MIDAWs), each of which contains flags, a byte count, and a 64-bit address designating a data area in absolute storage.

Use of modified CCW indirect data addressing may be restricted to certain channel-path types. If the MIDA flag in the CCW is one, specifying the use of modified CCW indirect data addressing, and the subchannel is associated with channel paths that do not support modified CCW indirect data addressing, a program check is recognized.

The MIDAW begins on a quadword boundary and has the following format:

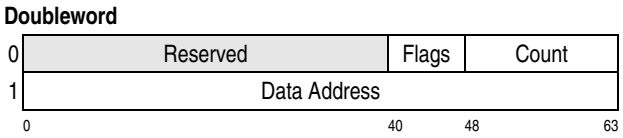


Figure 15-28. Modified-Indirect-Data-Address Word (MIDAW)

Reserved : Bits 0-39 of the MIDAW are reserved for future use and must be zero; otherwise, a program-check condition may be recognized.

Flags : Bits 40-47 of the MIDAW contain an 8-bit flag field. The meaning of each flag bit is as follows. Bits not shown are reserved.

Bit Meaning

40 Last MIDAW: Bit 40, when one, specifies that the MIDAW is the last in the contiguous list of MIDAWs.

41 Skip: Bit 41, when one, specifies the suppression of transfer of information to main storage during a read, read-backward, sense ID, or sense operation, thus specifying that skipping is in effect. When the operation is not read, read-backward, sense ID, or sense, bit 41 is ignored and skipping is not in effect

When skipping is in effect, no checking for invalid or protected data addresses takes place.

42 Data-transfer-interruption control: Bit 42, when one, specifies that a program-check be recognized when the device attempts to transfer data.

Count : Bits 48-63 of the MIDAW specify the number of bytes in the storage area designated by the data-address field. The count value must not be zero; otherwise a program-check condition is recognized. When skipping is in effect, the count value may be in the range of 1 - 65,535. When skipping is not in effect, the count value, in conjunction with the data address, must not specify the transfer of data that crosses a 4K-block boundary; otherwise, a program-

check condition is recognized. When the count value causes the total data transfer count to exceed that specified in the CCW count field, a program-check condition is recognized.

Data Address : Bits 64-127 of the MIDAW designate the 64-bit address of a location in absolute storage which is the first byte of information to be transferred. If the count field specifies zero, this field is not checked.

When modified CCW indirect data addressing is specified, the data-address field of the CCW designates the location of the first MIDAW to be used for data transfer for the CCW command. Additional MIDAWs, if needed for completing the data transfer for the CCW, are fetched from successive locations in storage. The number of MIDAWs required for a CCW is determined by the count field of the CCW in relation to the count fields in the list of MIDAWs designated by the CCW. The list must not cross a 4 K-byte boundary.

If a list of two or more MIDAWs is designated for a read operation, it is unpredictable in which order the MIDAW data addresses are used to transfer information into main storage. Thus, if two or more MIDAWs in a MIDAW list designate overlapping storage areas, the results are unpredictable.

MIDAWs that specify the transfer of data (MIDAWs for which skipping is not in effect) may specify a transfer count in the range of 1 - 4096 bytes, provided the MIDAW does not specify a data transfer that crosses a 4 K-byte boundary; MIDAWs that specify the suppression of the transfer of data (MIDAWs for which skipping is in effect) may specify a skip count in the range of 1 - 65,535 bytes. The total number of bytes that can be transferred or skipped or both by a single MIDAW list is limited by the CCW count field, which is a maximum of 65,535 bytes. The sum of the count fields in all of the MIDAWs in the list designated by the CCW should equal the value in the count field of the CCW; otherwise, a program-check condition may be recognized.

The MIDAW designated by the CCW can designate any location. When the MIDAW skip flag is zero and the CCW specifies the read, write, control, sense ID, or sense command, data is then transferred to or from successively higher storage locations until the number of bytes specified by the MIDAW count field have been transferred. When the MIDAW skip flag is zero and the CCW specifies the read backwards command, data is then transferred to successively lower storage locations until the number of bytes specified by the MIDAW count field have been transferred. When the MIDAW skip flag is one and the CCW specifies the read, sense ID, or sense command, skipping occurs to successively higher storage locations until the number of bytes specified by the MIDAW count field have been skipped. When the MIDAW skip flag is one and the CCW specifies the read backwards command, skipping occurs to successively lower storage locations until the number of bytes specified by the MIDAW count field have been skipped.

When the specified number of bytes have been transferred or skipped and the CCW specifies a subsequent MIDAW, the control of data transfer is then passed to the next MIDAW in the list. Like the MIDAW designated by the CCW, subsequent MIDAWs may designate any location and any length, provided the MIDAW does not specify a data transfer that crosses a 4 K-byte boundary; otherwise, a program-check condition is recognized.

Except for the unique restriction on designating a valid combination of data address and count by a MIDAW and the resulting behavior when the data-transfer-interruption control is one, all other actions taken for data addresses specified by a MIDAW, such as for protected storage and invalid addresses, and the actions taken for data prefetching, are the same as when modified CCW indirect data addressing is not used.

MIDAWs pertaining to the current CCW or a prefetched CCW may be prefetched. The number of MIDAWs that can be prefetched cannot exceed that required to satisfy the count in the CCW that designates the MIDAWs. Any MIDAWs that are prefetched for a CCW and are not used are discarded.

Similar to when CCW data chaining occurs, the action of transferring control from one MIDAW to the next is transparent to any attached device. A MIDAW takes control of data transfer when the last byte specified by the previous MIDAW has been transferred, even in situations where (1) channel end, (2) channel end and device end, or (3) channel end, device end, and status modifier are received prior to the transfer of any data bytes pertaining to the new MIDAW.

A prefetched MIDAW does not take control of an I/O operation if the count in the CCW has reached zero with the transfer of the last byte of data for the previ-

ous MIDAW. Program or access errors detected in prefetched MIDAWs are not indicated to the program until the MIDAW takes control of data transfer, even if an attempt had been made to prefetch that data. However, when the channel subsystem detects an invalid CBC on the contents of a prefetched MIDAW or its associated key, the condition may be indicated to the program, when detected, before the MIDAW takes control of data transfer. For a description of the indications provided when an invalid CBC is detected on the contents of a MIDAW or its associated key, see "Channel-Control Check" on page 16-29.

When a CCW specifies a MIDAW list and either the address in the CCW designates a storage location that is not physically available or the address designates a storage location to which access is prohibited by protection, then, depending on the model, one of the following two actions is taken:

- The above conditions are checked before initiating the operation at the device. If any of these conditions is recognized, initiation of the I/O operation does not occur, and the subchannel is made status pending with primary, secondary, and alert status.
- The operation is initiated at the device prior to checking for these conditions. If the device attempts to transfer data, the device is signaled to terminate the I/O operation, and the subchannel is made status pending with primary, secondary, and alert status as a function of the subchannel state and the status presented by the device.

Transport Indirect Data Addressing

When a designated subchannel is operating in transport mode, transport indirect data addressing (TIDA) may be used. TIDA permits a TCW to specify the transfer of data from noncontiguous blocks in main storage or to specify the transfer-command-control block (TCCB) in noncontiguous blocks of storage or both.

The use of transport indirect data addressing is controlled by flags in the TCW as follows:

When the input-TIDA flag is one in the TCW, the TCW input-data address is not used to directly address data. Instead, the TCW input-data address points to a list of quadwords called transport-indirect-data-address words (TIDAWs), each of which contains flags, a byte count, and a 64-bit address designating a data area in absolute storage.

When the output-TIDA flag is one in the TCW, the TCW output-data address is not used to directly address data. Instead, the TCW output-data address points to a list of TIDAWs, each of which designates a data area in absolute storage.

When the transport-command-control-block-TIDA flag is one in the TCW, the TCW transport-command-control-block address is not used to directly address a TCCB. Instead, the TCW transport-command-control-block address points to a list of TIDAWs, each of which designates a portion of the TCCB in absolute storage.

A list of one or more TIDAWs is called a transport-indirect-data-addressing list (TIDAL).

Unless otherwise specified, TIDAWs may designate a block of main storage on any boundary and length up to 4K bytes, provided the specified block does not cross a 4 K-byte boundary.

A TIDAW begins on a quadword boundary and has the following format:

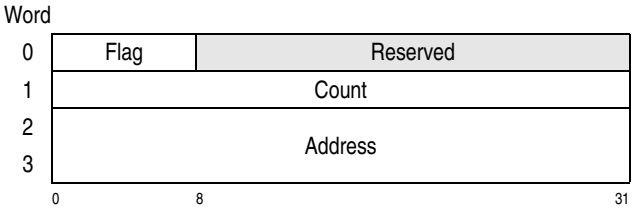

Figure 15-29. Transport-Indirect-Data-Address Word (TIDAW)

Flags : Bits 0-7 of word 0 contain an 8-bit flag field. The meaning of each flag bit is as follows. Bits not described below are reserved.

Bit	Meaning
0	Last TIDAW: Bit 0, when one, specifies that the TIDAW is the last in the contiguous list of TIDAWs.
1	Skip: Bit 1, when one, specifies the suppression of transfer of information to main storage during an input operation, thus specifying that skipping is in effect.

When the operation is an output operation, bit 1 is ignored and skipping is not in effect. When the TIDAW is being used to transport a TCCB, bit 1 is ignored and assumed to be zero.

When skipping is in effect, no checking for invalid or protected data addresses takes place.

2 Data-transfer-interruption control: Bit 2, when one, specifies that a program-check be recognized when the TIDAW is the current TIDAW.

3 TIDAW-transfer-in-channel (TTIC): Bit 3, when one, specifies that the TIDAW is not used to transfer data or TCCB storage. Instead, the address field designates the address of the next TIDAW to be used for the transfer of data. If bit 3 is one and the address field designates a TIDAW in which bit 3 is one, a program-check condition is recognized. If bit 3 is one and any other TIDAW flag bits are one, a program-check condition is recognized.

4 Insert-CBC control: Bit 4, when one, specifies that the following occurs when an output operation is specified and all of the data specified by the TIDAW has been transferred:

- If the count of data bytes transferred is not a multiple of 4, up to 3 padding bytes are transferred to make the total count of data bytes, plus the count of padding bytes, a multiple of 4.
- A word of CBC information is generated and transferred to the device.

Bit 4 has no meaning for the following cases:

- When the TIDAW is being used for an input data transfer.
- When the TIDAW is being used for an output data transfer and the last-TIDAW flag, bit 0, is one.
- When the TIDAW is in a TIDAW list designated by the TCCB-address field of the TCW.

5-7 Reserved: Bits 5-7 are reserved and must be zero, otherwise a program-check condition is recognized.

Reserved: Bits 8-31 are reserved for future use and must be zero; otherwise, a program-check condition may be recognized.

Count : Bits 32-63 specify the number of bytes to be transferred. When skipping is in effect, the count value may be in the range of 1 through 2^{32}-8 for a TIDAW. When skipping is not in effect and the TTIC flag, bit 3, is zero, the count value, in conjunction with the data address, must not specify the transfer of data that crosses a 4 K-byte block boundary; otherwise, a program-check condition is recognized.

When a TIDAW is in the TIDAW list designated by the input-address field in the TCW, the count value specified in the TIDAW in which the last-TIDAW flag is one and the input-count value specified in the TCW must both decrement to zero for the same byte transferred, otherwise a program-check condition is recognized.

When a TIDAW is in the TIDAW list designated by the output-address field in the TCW, the count value specified in the TIDAW in which the last-TIDAW flag is one and the output-count value specified in the TCW must both decrement to zero for the same byte transferred, otherwise a program-check condition is recognized.

When a TIDAW is in the TIDAW list designated by the TCCB-address field in the TCW, the following are true:

- The count value specified in the TIDAW in which the last-TIDAW flag is one and the count of bytes specified by the TCCB-length field in the TCW must both decrement to zero for the same byte transferred, otherwise a program-check condition is recognized.
- If the TIDAW specifies the TCCB to cross a 4 K-byte boundary, a program-check condition is recognized.
- If the specified count value is zero or is not evenly divisible by four, a program-check condition is recognized.

When the TTIC flag is zero, the count field must not be zero, otherwise a program-check condition is recognized. When the TTIC flag is one, the count field

must be zero, otherwise a program-check condition is recognized.

Address : Bits 64-127 of the TIDAW designate the 64-bit address of a location in absolute storage. When the TTIC flag is zero, this is the location of the first byte of information to be transferred. When the TTIC flag is one, this is the location of the next TIDAW to be used and must specify an address on a quadword boundary, otherwise a program-check condition is recognized.

Input TIDAL: When transport indirect data addressing is specified for input (the input-TIDA flag in the TCW is one), the input-address field of the TCW designates the location of the first TIDAW to be used for data transfer for the first DCW in the associated TCCB that specifies a data transfer command. Additional TIDAWs, if needed for completing the data transfer for the DCW or subsequent DCWs, are fetched from successive locations in storage. The number of TIDAWs required for an input TIDAL is variable and is a function of the following factors:

- The total number of bytes being transferred as specified by the input-count field in the TCW.
- The number of noncontiguous fragments that compose the data being transferred.
- The number of 4 K-byte boundaries within those fragments.

The input TIDAL must not cross a 4 K-byte boundary, otherwise a program-check condition is recognized.

If a list of two or more TIDAWs is designated for an input operation, it is unpredictable in which order the TIDAW data addresses are used to transfer information into main storage. Thus, if two or more TIDAWs in a TIDAW list designate overlapping storage areas, the results are unpredictable.

Output TIDAL: When transport indirect data addressing is specified for output (the output-TIDA flag in the TCW is one), the output-address field of the TCW designates the location of the first TIDAW to be used for data transfer for the first DCW in the associated TCCB that specifies a data transfer command. Additional TIDAWs, if needed for completing the data transfer for the DCW or subsequent DCWs, are fetched from successive locations in storage. The number of TIDAWs required for a TCW is determined by the output-count field of the TCW. The number of TIDAWs required for an output TIDAL is variable and is a function of the following factors:

- The total number of bytes being transferred as specified by the output-count field in the TCW.
- The number of noncontiguous fragments that compose the data being transferred.
- The number of 4 K-byte boundaries within those fragments.

The output TIDAL must not cross a 4 K-byte boundary, otherwise a program-check condition is recognized.

TCCB TIDAL: When transport indirect data addressing is specified for the TCCB (the transport-command-control-block-TIDA flag in the TCW is one), the transport-command-control-block-address field of the TCW designates the location of the first TIDAW to be used to designate the storage location of the TCCB. Additional TIDAWs, if needed for completing the TCCB, are fetched from successive locations in storage. The number of TIDAWs required for a TCCB TIDAL is variable and is a function of the following factors:

- The total number of bytes being transferred as specified by the TCCB-length field in the TCW.
- The number of noncontiguous fragments that compose the data being transferred.
- The number of 4 K-byte boundaries within those fragments.

The TCCB TIDAL must not cross a 4 K-byte boundary, otherwise a program-check condition is recognized.

Additional Information

TIDAWs that specify the transfer of data (TIDAWs for which skipping is not in effect) may specify a transfer count in the range of 1 through 4096 bytes, provided the TIDAW does not specify a data transfer that crosses a 4 K-byte boundary.

TIDAWs that specify the suppression of the transfer of data may specify a skip count in the range of 1 through 2^{32}-8.

The total number of bytes that can be transferred or skipped or both by a single TIDAL is limited by the

TCW count field that applies to the TIDAL, which may be a maximum of 2^{32}-8 bytes. If a TIDAL does not specify the same number of data bytes to be transferred as the count in the TCW for the TIDAL, or does not specify the same number of data bytes to transferred as that specified by the associated TCCB, a program-check condition may be recognized.

A TIDAW can designate any location. When the TIDAW skip flag is zero and a DCW specifies the read, write, control, sense ID, or sense command, data is then transferred to or from successively higher storage locations until the number of bytes specified by the TIDAW count field have been transferred. When the TIDAW skip flag is one and a DCW specifies the read, sense ID, or sense command, skipping occurs to successively higher storage locations until the number of bytes specified by the TIDAW count field have been skipped.

When the specified number of bytes have been transferred or skipped and the TCW and DCW specify a subsequent TIDAW, the control of data transfer is then passed to the next TIDAW in the list. Like the TIDAW designated by the TCW, subsequent TIDAWs may designate any location and any length, provided the TIDA does not specify a data transfer that crosses a 4 K-byte boundary; otherwise, a program-check condition is recognized.

Except for the unique restriction on designating a valid combination of data address and count by a TIDAW, and the resulting behavior when the data-transfer-interruption control is one, all other actions taken for data addresses specified by a TIDAW, such as for protected storage and invalid addresses, and the actions taken for data prefetching, are the same as when transport indirect data addressing is not used.

TIDAWs pertaining to the current TCW may be prefetched. The number of TIDAWs that can be prefetched cannot exceed that required to satisfy the associated count in the TCW that designates the TIDAWs. Any TIDAWs that are prefetched for a TCW and are not used are discarded.

The action of transferring control from one TIDAW to the next is transparent to any attached device. A TIDAW takes control of data transfer when the last byte specified by the previous TIDAW has been transferred, this may occur even in situations where (1) channel end, (2) channel end and device end, or (3) channel end, device end, and status modifier are received prior to the transfer of any data bytes pertaining to the new TIDAW.

Program or access errors when fetching or prefetching TIDAWs are indicated to the program when detected. For output operations, this may preclude transporting the TCCB to the I/O device.

When the channel subsystem detects an invalid CBC on the contents of a prefetched TIDAW or its associated key, the condition may be indicated to the program, when detected, before the TIDAW takes control of data transfer. For a description of the indications provided when an invalid CBC is detected on the contents of a TIDAW or its associated key, see “Channel-Control Check” on page 16-29.

When a TCW specifies a TIDAL and either the address in the TCW designates a storage location that is not physically available or the address designates a storage location to which access is prohibited by protection, then, depending on the model, one of the following two actions is taken:

- The above conditions are checked before initiating the operation at the device. If any of these conditions is recognized, initiation of the I/O operation does not occur, and the subchannel is made status pending with primary, secondary, and alert status.
- The operation is initiated at the device prior to checking for these conditions. If the device attempts to transfer data, the device is signaled to terminate the I/O operation, and the subchannel is made status pending with primary, secondary, and alert status as a function of the subchannel state and any status presented by the device.

Suspension of CCW Channel-Program Execution

The suspend function, when used in conjunction with RESUME SUBCHANNEL, provides the program with a means to stop and restart the execution of a channel program. The initiation of the suspend function is controlled by the setting of the suspend control, bit 4 of word 1 of the command-mode ORB. The suspend function is signaled when suspend control has been specified for the subchannel in the ORB and a CCW containing an S flag set to one becomes the current CCW. The flag can be indicated either in the first

CCW of the channel program or in a CCW fetched while command chaining. The S flag is not valid and causes a program-check condition to be recognized if (1) the ORB contains the suspend-control bit set to zero, or (2) the CCW is fetched while data chaining (see “Data Chaining” on page 15-61, concerning the handling of programming errors detected during data chaining).

Upon recognition of the suspend function, suspension of channel-program execution occurs when the CCW becomes current (see “Channel-Command Word” on page 15-31, for a definition of when a CCW becomes current). If suspension occurs during command chaining, the device is signaled that command chaining is no longer in effect.

RESUME SUBCHANNEL signals that the CCW that caused channel-program suspension may have been modified, that the CCW must be refetched, and that the contents of the CCW must be examined to determine the settings of the flags. If the S flag is one, execution of that CCW does not occur. If the CCW is valid and the S flag in the CCW is zero, execution is initiated (see “RESUME SUBCHANNEL” on page 14-10 and “Start Function and Resume Function” on page 15-20).

When a valid CCW that contains an S flag validly set to one becomes the current CCW during command chaining and the resume-pending condition is not recognized, the suspend function is performed and causes the following actions to occur in the order given:

1. The device is signaled that the chain of operations has been concluded.
2. Channel-program execution is suspended at the subchannel; all prefetched IDAWs, MIDAWs, CCWs, and data are discarded; and the subchannel is set up such that the resume function can be performed when the subchannel is next recognized to be resume pending.
3. If the measurement-block-update mode is active and the subchannel is enabled for the mode, the accrued values of the measurement data, including the start-subchannel and sample count, are added to the accumulated values in the measurement block for the subchannel. The start-subchannel count is the only measurement data that is updated in the measurement block if the channel-subsystem-timing facility is not available for the subchannel. (See “Channel-Subsystem Monitoring” on page 17-1 for more information.)

   If a measurement-check condition is detected during the measurement-block update, the channel program is terminated at the subchannel. The subchannel is made status pending with primary, secondary, and alert status, the device-status and subchannel-status fields are set to zero, and one of the measurement-check conditions is indicated in the extended-status flags of the format-0 ESW. The subchannel is not placed in the suspended state. (See “Subchannel-Control Field” on page 16-12.)
4. The subchannel is placed in the suspended state.
5. If the subchannel is not resume pending at this point, the intermediate interruption condition due to suspension is recognized if the suppress-suspended-interruption bit of the ORB is zero; otherwise, the resume function is performed.

When a valid CCW that contains an S flag validly set to one becomes the current CCW during command chaining and the resume-pending condition is recognized, the resume function is performed instead of the suspend function.

When the first CCW of a channel program contains an S flag validly set to one and the resume-pending condition is not recognized, the suspend function is performed and causes the following actions to occur in the order given:

1. Channel-program execution is suspended prior to the selection of the device.
2. The subchannel is set up such that the resume function can be performed when the subchannel is next recognized to be resume pending.
3. If the measurement-block-update mode is active and the subchannel is enabled for the mode, the SSCH+RSCH count is incremented, and the accrued function-pending time (a function of the setting of the timing-facility bit) is added to the accumulated value in the measurement block for the subchannel.

   If a measurement-check condition is detected during the measurement-block update, the channel program is not started at the subchannel. The subchannel is made status pending with primary, secondary, and alert status. Deferred condition

code one is set, and the start-pending bit remains set to one. The device-status and subchannel-status fields are set to zero, and one of the measurement-check conditions is indicated in the extended-status flags of the format-0 ESW. The subchannel is not placed in the suspended state. (See “Subchannel-Control Field” on page 16-12.)

4. The subchannel is placed in the suspended state.

5. If the subchannel is not resume pending at this point, the subchannel is made status pending with intermediate status due to suspension if the suppress-suspended-interruption-control bit of the ORB is zero; otherwise, the resume function is performed.

When the first CCW of a channel program contains an S flag validly set to one and the resume-pending condition is recognized, the resume function is performed instead of the suspend function.

Programming Notes:

1. The execution of MODIFY SUBCHANNEL and START SUBCHANNEL completes with condition code 2 set if the designated subchannel is suspended. The start function is indicated at the subchannel while the subchannel is in the suspended state.

2. In certain situations, normal resumption of the execution of a channel program that has been suspended may not be desired. Normal termination of the suspended channel-program execution may be accomplished by:

   a. Executing HALT SUBCHANNEL and designating the subchannel.

   b. Modifying the CCWs in storage such that, when channel-program execution is resumed, the command transferred to the device is a control command with all modifier bits specified as zeros (no-operation) and with the chain-command flag specified as zero; and then executing RESUME SUBCHANNEL.

   c. When an IRB indicates measurement check along with zero device status, zero subchannel status, and status pending with primary, secondary, and alert status, it may indicate that the measurement check was detected during an attempt to place the subchannel into the suspended state.

3. If the suspended interruption is suppressed, the N condition and DCTI values applicable to the preceding subchannel-active period are not made available to the program. The execution of RESUME SUBCHANNEL when the subchannel is in the suspended state causes path-not-operational conditions and the N condition to be reset to zeros. Path-not-operational conditions and the N condition are not reset when RESUME SUBCHANNEL is executed and the designated subchannel is not in the suspended state.

Commands and Flags for CCWs

Figure 15-30 on page 15-75 lists the command codes for the seven CCW commands and indicates which flags are defined for each command. Except for a format-1 CCW specifying transfer in channel, the flags are ignored for all commands for which they are not defined. The flags are reserved in a format-1 CCW specifying transfer in channel and must be zeros.

Name	Code	Flags
Write	M M M M M M 0 1	CD CC SLI PCI IDA MIDA
Read	M M M M M M 1 0	CD CC SLI SK PCI IDA MIDA
Read backward	M M M M 1 1 0 0	CD CC SLI SK PCI IDA MIDA
Control	M M M M M M 1 1	CD CC SLI PCI IDA MIDA
Sense	M M M M 0 1 0 0	CD CC SLI SK PCI IDA MIDA
Sense ID	1 1 1 0 0 1 0 0	CD CC SLI SK PCI IDA MIDA
Transfer in Channel	X X X X 1 0 0 0	(See note below)

Explanation:

CC	Chain command
CD	Chain data
IDA	Indirect data addressing
M	Modifier bit
MIDA	Modified indirect data addressing
PCI	Program-controlled interruption
S	Suspend
SK	Skip
SLI	Suppress-length indication
X	Ignored in a format-0 CCW; must be zero in a format-1 CCW
Note:	Flags are ignored in a format-0 transfer-in-channel CCW and must be zeros in a format-1 transfer-in-channel CCW.

Figure 15-30. Command Codes and Flags for CCWs

All flags have individual significance, except for the following cases:

- The CC and SLI flags are ignored when the CD flag is set to one, and, for output forward operations the SK flag is ignored.
- The presence of the SLI flag is ignored for immediate operations involving format-0 CCWs, in which case the incorrect-length indication is suppressed regardless of the setting of the flag.
- The incorrect-length indication may be suppressed for immediate operations when executing a format-1 CCW, depending on the incorrect-length-suppression mode.
- The PCI flag is ignored during initial program loading. All flags, except the PCI flag, are ignored when the S flag is one.
- The MIDA flag is mutually exclusive from both the IDA and SKP flags. If the IDA or SKP flag is specified and the MIDA flag is specified, a program-check condition is recognized.

Programming Notes:

1. A malfunction that affects the validity of data transferred in an I/O operation is signaled at the end of the operation by means of unit check or channel-data check, depending on whether the device (control unit) or the channel subsystem detected the error. In order to make use of the checking facilities provided in the system, data read in an input operation should not be used until the end of the operation has been reached and the validity of the data has been checked. Similarly, on writing, the copy of data in main storage should not be destroyed until the program has verified that no malfunction affecting the transfer and recording of data was detected.
2. An error condition may be recognized and the I/O operation terminated when 256 or more chained commands are executed with a device and none of the executed commands result in the transfer of any data. When this condition is recognized, program check is indicated.
3. All CCWs that require suppression of incorrect-length indications must use the SLI flag.

Commands and Flags for DCWs

Figure 15-31 on page 15-76 lists the command codes for the eight DCW commands and indicates which flags are defined for each command.

Name	Code	DCW Flags
Write	m m m m m m 0 1	CC SLI
Read	m m m m m m 1 0	CC SLI
Control	m m m m m m 1 1	CC SLI
Sense	m m m m 0 1 0 0	CC SLI
Sense ID	1 1 1 0 0 1 0 0	CC SLI
Interrogate	0 1 0 0 0 0 0 0	
Transport COB	0 1 1 0 0 0 0 0	CC SLI[1]
Transfer TCAX	0 1 0 1 0 0 0 0	CC SLI[1]

Explanation:

CC	Chain command
m	Modifier bit.
SLI	Suppress-length indication
1	Incorrect-length condition not recognized for this command; the SLI flag is ignored

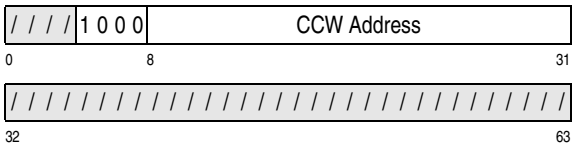
Figure 15-31. Command Codes and Flags for DCWs

Branching in CCW Channel Programs

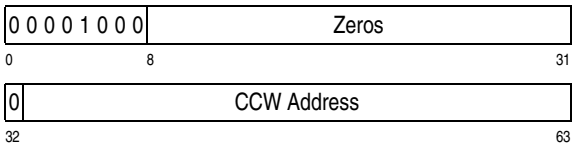
The channel subsystem provides two methods to modify the normal sequential execution of the CCWs in a channel program. One is the transfer-in-channel (TIC) command (described in “Transfer in Channel” on page 15-77), which can be used to loop back to a previously executed CCW, or to connect discontiguous segments of the channel program. The other method, which uses the status-modifier device-status bit (described in the publication *ESA/390 Common I/O-Device Commands*, SA22-7204), allows conditions at the device to cause the channel to bypass the next CCW in the channel program.

Transfer in Channel

Format-0 TIC CCW



Format-1 TIC CCW



The next CCW is fetched from the location in absolute main storage designated by the data-address field of the CCW specifying transfer in channel. The transfer-in-channel command does not initiate any I/O operation, and the I/O device is not signaled of the execution of the command. The purpose of the transfer-in-channel command is to provide chaining between CCWs not located in adjacent doubleword locations in an ascending order of addresses. The command can occur in both data and command chaining.

Bits 29-31 (format 0) or bits 61-63 (format 1) of a CCW that specifies the transfer-in-channel command must be zeros, designating a CCW on a doubleword boundary. Furthermore, a CCW specifying transfer in channel may not be fetched from a location designated by an immediately preceding transfer in channel. When either of these errors is detected or when an invalid address is designated in the transfer-in-channel command, the program-check condition is generated. When a CCW that specifies the transfer-in-channel command designates a CCW at a location protected against fetching, the protection-check condition is generated. Detection of these errors during data chaining causes the operation at the I/O device to be terminated and an interruption condition to be generated, while during command chaining it causes only an interruption condition to be generated.

The contents of the second half of the format-0 CCW, bit positions 32-63, are ignored. Similarly, the contents of bit positions 0-3 of the format-0 CCW are ignored.

Bit positions 0-3 and 8-32 of the format-1 CCW must contain zeros; otherwise, a program-check condition is generated.

Command Retry

The channel subsystem has the capability to perform command retry, a procedure that causes a command to be retried without requiring an I/O interruption. This retry is initiated by the control unit presenting either of two status-bit combinations by means of a special sequence. When immediate retry can be performed, it presents a channel-end, unit-check, and status-modifier status-bit combination, together with device end. When immediate retry cannot be performed, the presentation of device end is delayed until the control unit is prepared. When device end is presented alone, the previous command is transferred again. If device end is accompanied by status modifier, command retry is not performed, and the channel subsystem command-chains to the CCW following the one for which command retry was signaled (for information on status modifier, see the publication *ESA/390 Common I/O-Device Commands*, SA22-7204). When the channel subsystem is not capable of performing command retry due to an error condition, or when any status bit other than device end or device end and status modifier accompanies the requested command-retry initiation, the retry is suppressed, and the subchannel becomes status pending. The SCSW stored by TEST SUBCHANNEL contains the status provided by the I/O device.

Programming Note: The following possible results of a command retry must be anticipated by the program:

1. A CCW containing a PCI may, if retried because of command retry, cause multiple PCI interruptions to occur.
2. If a CCW used in an operation is changed before that operation has been successfully completed, the results are unpredictable.

Concluding I/O Operations before Initiation

Subsequent to the execution of START SUBCHANNEL or RESUME SUBCHANNEL for a command-mode operation and before the first command is accepted, the start function can be ended at the subchannel by CANCEL SUBCHANNEL, CLEAR SUBCHANNEL, or HALT SUBCHANNEL.

Subsequent to the execution of START SUBCHANNEL for a transport-mode operation, the start function may be ended at the subchannel by CANCEL SUBCHANNEL, CLEAR SUBCHANNEL, or HALT SUBCHANNEL before the TCCB is transported.

For both command-mode and transport-mode operations, if the I/O operation is ended by CANCEL SUBCHANNEL, there is no subsequent interruption condition from the I/O operation, and the subchannel is available for the initiation of another start function. However, the device may have signaled a busy condition while the canceled operation was start pending. In this case, the device owes a no-longer-busy signal to the channel subsystem. This may result in unsolicited device-end status before the next operation is initiated at the device. (See also "Clear Function" on page 15-14 and "Halt Function" on page 15-16.)

Concluding I/O Operations during Initiation

After the designated subchannel has been determined to be in a state such that START SUBCHANNEL can be executed, certain tests are performed on the validity of the information specified by the program and on the logical availability of the associated device. This testing occurs during or subsequent to the execution of START SUBCHANNEL and during command chaining and command retry.

A data-transfer operation is initiated at the subchannel and device only when no programming or equipment errors are detected by the channel subsystem and when the device responds with zero status during the initiation sequence. When the channel subsystem detects or the device signals any unusual condition during the initiation of a command-mode I/O operation, the command is said to be not accepted. When the channel subsystem detects or the device signals any unusual condition during the initiation of a transport-mode I/O operation, the I/O-operation initiation is said to be not accepted. For these cases, the subchannel becomes status pending with primary, secondary, and alert status. Deferred condition code 1 is set, and the start-pending bit remains set to one.

Conditions that preclude the initiation of an I/O operation are detailed in the SCSW stored by TEST SUBCHANNEL. In this situation, the device is not started, no interruption conditions are generated subsequent to TEST SUBCHANNEL, and the subchannel is idle. The device is immediately available for the initiation of another operation, provided the command was not rejected because of the busy or not-operational condition.

When an unusual condition causes a command to be not accepted during the initiation of a command-mode I/O operation by command chaining or command retry, an interruption condition is generated, and the subchannel becomes status pending with combinations of primary, secondary, and alert status as a function of the status signaled by the device. The status describing the condition remains at the subchannel until cleared by TEST SUBCHANNEL. The conditions are indicated to the program by means of the corresponding status bits in the SCSW. A path-not-operational condition recognized during command chaining is signaled to the program by means of an interface-control-check indication. The new I/O operation at the device is not started.

START SUBCHANNEL is executed independent of its associated device. Tests on most program-specified information, on device availability and unit status, and on most error conditions are performed subsequent to the execution of START SUBCHANNEL. When any conditions are detected that preclude the performance of the start function, an interruption condition is generated by the channel subsystem and placed at the subchannel, causing it to become status pending.

Immediate Conclusion of Command-Mode I/O Operations

During the initiation of an I/O operation, the device can accept the command and signal the channel-end condition immediately upon receipt of the command code. An I/O operation causing the channel-end condition to be signaled during the initiation sequence is called an *immediate operation*. Status generated by the device for the immediate command, when command chaining is not specified and command retry is not signaled, causes the subchannel to become status pending with combinations of primary, secondary, intermediate, and alert status as a result of information specified in the ORB and CCW and status presented by the device. If the immediate operation is

the first operation of the channel program, deferred condition code 1 is set and accompanies the status indications. If intermediate status is indicated, the indication can occur only as a result of the CCW having the PCI flag set to one (see “Program-Controlled Interruption” on page 15-64).

Whenever command chaining is specified after an immediate operation and no unusual conditions have been detected during the operation, or when command retry occurs for an immediate operation, an interruption condition is not generated. The subsequent commands in the chain are handled normally, and, usually, the channel-end condition for the last CCW generates a primary interruption condition. If device end is signaled with channel end, a secondary interruption condition is also generated.

Whenever immediate completion of an I/O operation is signaled, no data has been transferred to or from the device, and the data address in the CCW is not checked for validity. If the subchannel is in the incorrect-length-suppression mode, incorrect length is not indicated to the program, and command chaining is performed when specified. If the subchannel is in the incorrect-length-indication mode, incorrect length and command chaining are under control of the SLI and chain-command flags. The conditions that cause the incorrect-length indication to be suppressed are summarized in Figure 15-27 on page 15-61.

Programming Note: I/O operations for which the entire operation is specified in the command code may be performed as immediate operations. Whether the command is executed as an immediate operation depends on the operation and type of device.

Concluding I/O Operations During Data Transfer

When the subchannel has been passed the contents of an ORB, the subchannel is said to be start pending. When a command-mode I/O operation has been initiated and the command has been accepted, the subchannel becomes subchannel-and-device active. When a transport-mode I/O operation has been initiated, the subchannel remains start pending while the TCCB is transported and executed. The subchannel remains in the respective state unless (1) the channel subsystem detects an equipment malfunction, (2) the operation is concluded by the execution of CLEAR SUBCHANNEL or HALT SUBCHANNEL, or (3) status that causes a primary interruption condition to be recognized (usually channel end) is accepted from the device.

When CCW command chaining and command retry are not specified or when chaining is suppressed because of unusual conditions, the status that is recognized as primary status causes the operation at the subchannel to be concluded and an interruption condition to be generated. The status bits in the associated SCSW indicate primary status and the unusual conditions, if any. The device can present status that is recognized as primary status at any time after the initiation of the I/O operation, and the presentation of status may occur before any data has been transferred.

For operations not involving data transfer, the device normally controls the timing of the channel-end condition. The duration of data-transfer operations may be variable and may be controlled by the device or the channel subsystem.

Excluding equipment errors and the execution of the CLEAR SUBCHANNEL, HALT SUBCHANNEL, and RESET CHANNEL PATH instructions, the channel subsystem signals the device to conclude the performance of an I/O operation during data transfer whenever any of the following conditions occurs:

- The storage areas designated for the operation are exhausted or filled.
- A program-check condition is detected.
- A protection-check condition is detected.
- A CCW chaining-check condition is detected.
- A channel-control-check condition is detected that does not affect the control of the I/O operation.

The first of these conditions occurs when the channel subsystem has decremented the count to zero in the last CCW or current TCW associated with the operation. A count of zero indicates that the channel subsystem has transferred all information specified by the I/O operation. The other four conditions are due to errors and cause premature conclusion of data transfer. In either case, the conclusion is signaled in response to a service request from the device and causes data transfer to cease. If the device has no blocks defined for the operation (such as writing on

magnetic tape), it concludes the operation and presents channel-end status.

For command-mode operations, the device can control the duration of an operation and the timing of channel end by blocking of data. On certain operations for which blocks are defined (such as reading on magnetic tape), the device does not present channel-end status until the end of the block is reached, regardless of whether the device has been previously signaled to conclude data transfer.

Checking for the validity of the CCW data address is performed only as data is transferred to or from main storage. When the initial data address in the CCW is invalid, no data is transferred during the operation, and the device is signaled to conclude the operation in response to the first service request. On writing, devices such as magnetic-tape units request the first byte of data before any mechanical motion is started, and, if the initial data address is invalid, the operation is terminated by the channel subsystem before the recording medium has been advanced. However, since the operation has been initiated at the device, the device presents channel-end status, causing the channel subsystem to recognize a primary interruption condition. Subsequently, the device also presents device-end status, causing the channel subsystem to recognize a secondary interruption condition. Whether a block at the device is advanced when no data is transferred depends on the type of device.

Checking for the validity of main-storage addresses of the TCCB is performed before attempting to transport the TCCB to the I/O device. When an applicable address is invalid, a program check condition is recognized and no data is transferred during the operation nor is there any communication with the I/O device. After the TCCB has been transported to the device, the operation is considered initiated at the device and subsequent checks for the validity of main-storage addresses are performed either as information is transferred to or from main storage or as information is prefetched, as specified by the applicable TCW reference to storage (directly or indirectly by a TIDAW). If a main-storage address is found to be invalid after the operation has been initiated at the device, the device presents channel-end status, causing the channel subsystem to recognize a primary interruption condition. Subsequently, the device may also present device-end status, causing the channel subsystem to recognize a secondary interruption condition. Whether a block at the device is advanced when no data is transferred depends on the type of device.

When CCW command chaining takes place, the subchannel is in the subchannel-and-device-active state from the time the first I/O operation is initiated at the device until the device presents channel-end status for the last I/O operation of the chain. The subchannel remains in the device-active state until the device presents the device-end status for the last I/O operation of the chain.

Any unusual conditions cause CCW command chaining to be suppressed and a primary interruption condition to be generated. The unusual conditions can be detected by either the channel subsystem or the device, and the device can provide the indications with channel end, control unit end, or device end. When the channel subsystem is aware of the unusual condition by the time the channel-end status for the operation is accepted, the chain is ended as if the operation during which the condition occurred were the last operation of the chain. The device-end status is recognized as a secondary interruption condition whether presented together with the channel-end status or separately. If the device presents unit check or unit exception together with either control unit end or device end as status that causes the channel subsystem to recognize the primary interruption condition, then the subchannel-and-device-active state of the subchannel is terminated, and the subchannel is made status pending with primary, secondary, and alert status. Intermediate status may also be indicated if an intermediate interruption condition previously existed at the subchannel for the initial-status-interruption condition or the PCI condition and that condition still remains pending at the subchannel. The channel-end status that was presented to the channel subsystem previously when command chaining was signaled is not made available to the program.

Channel-Path-Reset Function

Subsequent to the execution of RESET CHANNEL PATH, the channel-path-reset function is performed. The performance of the function consists of: (1) issuing the reset signal on the designated channel path and (2) causing a channel report to be made pending, indicating the completion of the channel-path-reset function.

Channel-Path-Reset-Function Signaling

The channel subsystem issues the reset signal on the designated channel path. As part of this operation, the following actions are taken:

1. All internal indications associated with control-unit-busy, device-busy, and allegiance conditions for the designated channel path are reset. These indications are reset at all subchannels that have access to the designated channel path.The reset function has no other effect on subchannels, including those having I/O operations in progress.

2. If the channel path fails to respond properly to the reset signal (see “I/O-System Reset” on page 17-13 for a detailed description) or, because of a malfunction, the reset signal could not be issued, the channel path is made physically not available at each applicable subchannel.

3. If an I/O operation is in progress at the device and the device is actively communicating on the channel path in the performance of that I/O operation when the reset signal is received on that channel path, the I/O operation is reset, and the control unit and device immediately terminate current communication with the channel subsystem. (To avoid possible misinterpretation of unsolicited device-end status, programming measures can be taken as described in programming note 2 on page 82.)

4. If an I/O operation is in progress in the multipath mode at the device and the device is not currently communicating over the channel path in the performance of that I/O operation when the reset signal is received, then the I/O operation may or may not be reset depending on whether another channel path is available for selection in the same multipath group for the device. If there is at least one other channel path in the multipath group for the device that is available for selection, the I/O operation is not reset. However, the channel path on which the system reset is received is removed from the current set of channel paths that form the multipath group. If the channel path on which the reset signal is received is the only channel path of a multipath group, or if the device is operating in the single-path mode, the I/O operation is reset.

5. The channel-path-reset function causes I/O operations to be terminated at the device as described above; however, I/O operations are *never* terminated at the subchannel by the channel-path-reset function.

If an I/O operation is in progress at the subchannel and the channel path designated for the performance of the channel-path-reset function is being used for that I/O operation, the subchannel may or may not accurately reflect the progress of the I/O operation up to that instant. The subchannel remains in the state that exists at the time the channel-path-reset function is performed until the state is changed because of some action taken by the program or by the device.

Channel-Path-Reset-Function-Completion Signaling

After the reset signal has been issued and an attempt has been made to issue the reset signal, or after it has been determined that the reset signal cannot be issued, the channel-path-reset function is completed. (See “Reset Signal” on page 17-12.)

As a result of the channel-path-reset function being performed, a channel report is made pending (see “Channel-Subsystem Recovery” on page 17-29)

to report the results. If the channel path responds properly to the system-reset signal, the channel report indicates that the channel path has been initialized and is physically available for use. If the reset signal was issued but either the channel path failed to respond properly or the channel path was already not physically available at each subchannel having access to the channel path, the channel report indicates that the channel path has been initialized but is not physically available for use. If, because of a malfunction or because the designated channel path is not in the configuration, the reset signal could not be issued, the channel report indicates that the channel path has not been initialized and is not physically available for use.

Programming Notes:

1. If an I/O operation is in progress in the multipath mode when the channel-path-reset function is performed on a channel path of the multipath group, it is possible for the I/O operation to be

continued on a remaining channel path of the group.

2. When the performance of the channel-path-reset function causes the I/O operation at the device to be reset, unsolicited device-end status presented by the device, if any, may be erroneously interpreted by the channel subsystem to be chaining status and thus cause the channel subsystem to continue the chain of commands. If this situation occurs, then the device-end status is not made available to the program, and the device is selected again by the channel subsystem; however, the device may interpret the initiation sequence as the beginning of a new channel program instead of as command chaining. This possibility can be avoided by issuing CLEAR SUBCHANNEL or HALT SUBCHANNEL, designating the affected subchannels, prior to issuing RESET CHANNEL PATH.
3. The performance of the channel-path-reset function may, on some models, cause overruns to occur on other channel paths.

Even though reset is signaled on the designated channel path, by one or more devices may not have been reset because of a malfunction at a control unit or a malfunction at the physical channel path to the control unit.

When an I/O operation or sequence of I/O operations initiated by the execution of START SUBCHANNEL is ended, the channel subsystem and the device generate status conditions. The generation of these conditions can be brought to the attention of the program by means of an I/O interruption or by means of the execution of the TEST PENDING INTERRUPTION instruction. (During certain abnormal situations, these conditions can be brought to the attention of the program by means of a machine-check interruption. See “Channel-Subsystem Recovery” on page 17-29 for details.)

The status conditions, as well as an address and a count indicating the extent of the operation sequence, are presented to the program in the form

© Copyright IBM Corp. 2000, 2025

of a subchannel-status word (SCSW). The SCSW is stored in an interruption-response block (IRB) during the execution of TEST SUBCHANNEL. When a transport-mode IRB is stored, additional information describing the status of the operation is also stored in the transport-status block.

Normally an I/O operation is being performed until the device signals primary interruption status. Primary interruption status can be signaled during initiation of an I/O operation, or later. An I/O operation can be terminated by the channel subsystem performing a clear or halt function when it detects an equipment malfunction, a program check, a chaining check, a protection check, or an incorrect-length condition, or by performing a clear, halt, or channel-path-reset function as a result of the execution of CLEAR SUBCHANNEL, HALT SUBCHANNEL, or RESET CHANNEL PATH, respectively.

I/O interruptions provide a means for the CPU to change its state in response to conditions that occur at I/O devices or subchannels. These conditions can be caused by the program, by the channel subsystem, or by an external event at the device.

Interruption Conditions

The conditions causing requests for I/O interruptions to be initiated are called I/O-interruption conditions. When an interruption condition is recognized by the channel subsystem, it is indicated at the appropriate subchannel. The subchannel is then said to be status pending. The subchannel becoming status pending causes the channel subsystem to generate an I/O-interruption request. An I/O-interruption request can be brought to the attention of the program only once.

An I/O-interruption request remains pending until it is accepted by a CPU in the configuration, is withdrawn by the channel subsystem, or is cleared by means of the execution of TEST PENDING INTERRUPTION, TEST SUBCHANNEL, or CLEAR SUBCHANNEL, or by means of subsystem reset. When a CPU accepts an interruption request and stores the associated interruption code, the interruption request is cleared. When the pending interruption is cleared by the execution of TEST PENDING INTERRUPTION, the subchannel remains status pending until the associated interruption condition is cleared when TEST SUBCHANNEL or CLEAR SUBCHANNEL is executed or when the subchannel is reset.

An I/O-interruption condition is normally cleared by means of the execution of TEST SUBCHANNEL. If TEST SUBCHANNEL is executed, designating a subchannel that has an I/O-interruption request pending, both the interruption request and the interruption condition at the subchannel are cleared. The interruption request and the interruption condition can also be cleared by CLEAR SUBCHANNEL.

A device-end status condition generated by the I/O device and presented following the conclusion of the last I/O operation of a start function is reset at the subchannel by the channel subsystem without generating an I/O-interruption condition or I/O-interruption request if the subchannel is currently start pending and if the status contains device end either alone or accompanied by control unit end. If any other status bits accompany the device-end status bit, then the channel subsystem generates an I/O-interruption request with deferred condition code 1 indicated.

When an I/O operation is terminated because of an unusual condition detected by the channel subsystem during the command-initiation sequence, status describing the interruption condition is placed at the subchannel, causing it to become status pending. If the unusual condition is detected by the device, the device-status field of the associated SCSW identifies the condition.

When command chaining takes place, the generation of status by the device does not cause an interruption, and the status is not made available to the program.

When the channel subsystem detects any of the following interruption conditions, it initiates a request for an I/O interruption without necessarily communicating with, or having received the status byte from, the device:

- A programming error associated with the contents of the ORB passed to the subchannel by the previous execution of START SUBCHANNEL
- A suspend flag set to one in the first CCW fetched that initiates a CCW channel program execution for either START SUBCHANNEL or RESUME SUBCHANNEL, and suppress suspended interruption not specified in the command-mode ORB.

- A programming error associated with the first CCW, TCW, TIDAW, TCCB fetch, data fetch**,** IDAW, or MIDAW.

These interruption conditions from the subchannel, except for the suspended condition, can be accompanied by other subchannel-status indications, but the device-status indications are all stored as zeros.

The channel subsystem issues the clear signal to the device when status containing unit check is presented to a subchannel that is disabled or when the device is not associated with any subchannel. However, if the presented status does not contain unit check, the status is accepted by the channel subsystem and discarded without causing the subchannel to become status pending.

An interruption condition caused by the device may be accompanied by multiple device-status conditions. Furthermore, more than one interruption condition associated with the same device can be accepted by the channel subsystem without an intervening I/O interruption. As an example, when the channel-end condition is not cleared at the device by the time device end is generated, both conditions may be cleared at the device concurrently and indicated in the SCSW together. Alternatively, channel-end status may have been previously accepted at the subchannel, and an I/O interruption may have occurred; however, the associated status-pending condition may not have been cleared by TEST SUBCHANNEL by the time device-end status was accepted at the subchannel. In this situation, the device-end status may be merged with the channel-end status without causing an additional I/O interruption. Whether an interruption condition may be merged at the subchannel with other existing interruption conditions depends upon whether the interruption condition is unsolicited or solicited.

Unsolicited Interruption Condition: An unsolicited interruption condition is any interruption condition that is unrelated to the performance of a clear, halt, resume, interrogate, or start function. An unsolicited interruption condition is identified at the subchannel as alert status. An unsolicited interruption condition can be generated only when the subchannel is not device active.

The subchannel and device status associated with an unsolicited interruption condition is never merged with that of any currently existing interruption condition. If the subchannel is currently status pending, the unsolicited interruption condition is held in abeyance in either the channel subsystem or the device, as appropriate, until the status-pending condition has been cleared. Whenever the subchannel is idle and zero status is presented by the device, the status is discarded.

Solicited Interruption Condition: A solicited interruption condition is any interruption condition generated as a direct consequence of performing or attempting to perform a clear, halt, resume, interrogate, or start function. Solicited interruption conditions include any interruption condition generated while the subchannel is either subchannel-and-device active or device active. When the subchannel is operating in transport mode, solicited interruption conditions can be generated when the subchannel is start pending. The subchannel and device status associated with a solicited interruption condition may be merged at the subchannel with that of another currently existing solicited interruption condition. Figure 16-1 on page 16-4 describes the interruption

condition that results from any combination of bits in the status-control field of the SCSW.

Status-Control Field	Status-Control-Bit Combinations															
Alert	1	1	1	1	1	1	1	1	0	0	0	0	0	0	0	0
Primary	0	1	1	1	1	0	0	0	1	1	1	1	0	0	0	0
Secondary	0	0	1	1	0	1	1	0	0	1	1	0	1	1	0	0
Intermediate	0	0	0	1	1	0	1	1	0	0	1	1	0	1	1	0
Status pending	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
Resulting interruption condition	E	S	S	S	S	S	-	S	S	S	S	S	S	-	S	S

Explanation:

-	Combination does not occur.
E	Unsolicited or solicited interruption condition.
S	Solicited interruption condition.
0	Indicates the bit stored as zero.
1	Indicates the bit stored as one.

Figure 16-1. Interruption Condition for Status-Control-Bit Combinations

Intermediate Interruption Condition

An intermediate interruption condition is a solicited interruption condition that indicates that an event has occurred for which the program had previously requested notification. An intermediate interruption condition is described by any of, or any combination of the following:

- solicited subchannel status
- the Z bit
- the subchannel-suspended condition
- the Q bit

An intermediate interruption condition can occur only after it has been requested by the program through the use of flags in the ORB, CCW**,** or a CANCEL SUBCHANNEL for a subchannel operating in transport mode that requests an interrogate operation. Depending on the state of the subchannel, the performance or suspension of the I/O operation continues, unaffected by the setting of the intermediate-status bit.

An intermediate interruption condition can be indicated only together with one of the following indications:

1. Subchannel active
2. Status pending with primary status alone
3. Status pending with primary status together with alert status or secondary status or both
4. Suspended
5. Interrogate-complete (Q-bit)

If only the intermediate-status bit and the status-pending bit of the status-control field are ones during the execution of TEST SUBCHANNEL, the device-status field is zero.

Primary Interruption Condition

A primary interruption condition is a solicited interruption condition that indicates the performance of the start function is completed at the subchannel. A primary interruption condition is described by the SCSW stored as a result of the execution of TEST SUBCHANNEL while the subchannel is status pending with primary status. Once the primary interruption condition is indicated at the subchannel, the channel subsystem is no longer actively participating in the I/O operation by transferring commands or data. When a subchannel is status pending with a primary interruption condition, the execution of any of the following instructions results in the setting of a nonzero condition code: HALT SUBCHANNEL, MODIFY SUBCHANNEL, RESUME SUBCHANNEL, and START SUBCHANNEL. Once the primary interruption condition is cleared by the execution of TEST SUBCHANNEL, the subchannel accepts the START

SUBCHANNEL instruction. (See “START SUBCHANNEL” on page 14-15)

Secondary Interruption Condition

A secondary interruption condition is a solicited interruption condition that normally indicates the completion of an I/O operation at the device. A secondary interruption condition is also generated by the channel subsystem if the start function is terminated because a solicited alert interruption condition is recognized prior to initiating the first I/O operation at the device. A secondary interruption condition is described by the SCSW stored as a result of the execution of TEST SUBCHANNEL while the subchannel is status pending with secondary status. Once the channel subsystem has accepted status from the device that causes a secondary interruption condition to be recognized, the start function is completed at the device.

Alert Interruption Condition

An alert interruption condition is either a solicited interruption condition that indicates the occurrence of an unusual condition in a halt, resume, or start function or an unsolicited interruption condition that describes a condition unrelated to the performance of a halt, resume, or start function. An alert interruption condition is described by the SCSW stored as a result of the execution of TEST SUBCHANNEL while the subchannel is status pending with alert status. An alert interruption condition may be generated by either the channel subsystem or the device. Nonzero alert status is always brought to the attention of the program.

Priority of Interruptions

All requests for an I/O interruption are asynchronous to any activity in any CPU, and interruption requests associated with more than one subchannel can exist at the same time. The priority of interruptions is controlled by two types of mechanisms — one establishes within the channel subsystem the priority among interruption requests from subchannels associated with the same I/O-interruption subclass, and another establishes within a given CPU the priority among requests from subchannels of different I/O-interruption subclasses. The channel subsystem requests an I/O interruption only after it has established priority among requests from its subchannels. The conditions responsible for the I/O-interruption requests associated with subchannels are preserved at the subchannels until cleared by a CPU's execution of TEST SUBCHANNEL or CLEAR SUBCHANNEL or I/O-system reset is performed.

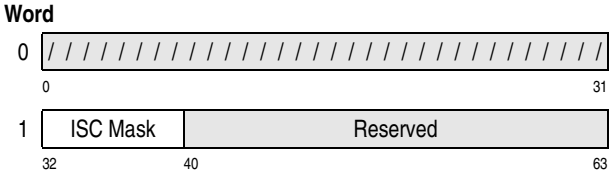
The assignment of priority among requests for interruption from subchannels of the same I/O-interruption subclass is in the order that the need for interruption is recognized by the channel subsystem. The order of recognition by the channel subsystem is a function of the type of interruption condition and the type of channel path. For the parallel-I/O-interface type of channel path, the order depends on the electrical position of the device on the channel path to which it is attached. (A device's electrical position on the parallel-I/O interface is not related to its device address.)

The assignment of priority among requests for interruption from subchannels of different I/O-interruption subclasses is made by the CPU according to the numerical value of the I/O-interruption subclass codes (with zero having highest priority), in conjunction with the I/O-interruption-subclass mask in control register 6. The numerical value of the I/O-interruption-subclass code directly corresponds to the bit position in the I/O-interruption-subclass mask in control register 6 of a CPU. If, in any CPU, an I/O-interruption-subclass-mask bit is zero, then all subchannels having an I/O-interruption-subclass code numerically equal to the associated position in the mask register are said to be masked off in the respective CPU. Therefore, a CPU accepts the highest-priority I/O-interruption request from a subchannel that has the lowest-numbered I/O-interruption subclass code that is not masked off by a corresponding bit in control register 6 of that CPU. When the highest-priority interruption request is accepted by a CPU, it is cleared so that the interruption request is not accepted by any other CPU in the configuration.

The priority of interruption handling can be modified by the execution of either TEST SUBCHANNEL or CLEAR SUBCHANNEL. When either of these instructions is executed and the designated subchannel has an interruption request pending, that interruption request is cleared, without regard to any previous established priority. The relative priority of the remaining interruption requests is unchanged.

Programming Notes:

1. The I/O-interruption subclass mask is in control register 6, which has the following format:



2. Control register 6 is set to all zeros during initial CPU reset.

Interruption Action

An I/O interruption can occur only when the I/O-interruption-subclass-mask bit associated with the subchannel is one and the CPU is enabled for I/O interruptions.

The interruption occurs at the completion of a unit of operation (see "Point of Interruption" on page 5-24). If the channel subsystem establishes the priority among requests for interruption from subchannels while the CPU is disabled for I/O interruptions, the interruption occurs immediately after the completion of the instruction enabling the CPU and before the next instruction is executed, provided that the I/O-interruption subclass-mask bit associated with the subchannel is one. Alternatively, if the channel subsystem establishes the priority among requests for interruption from subchannels while the I/O-interruption-subclass-mask bit is zero for each subchannel that is status pending, the interruption occurs immediately after the completion of the instruction that sets at least one of the I/O-interruption-subclass-mask bits to one, provided that the CPU is also enabled for I/O interruptions. This interruption is associated with the highest-priority I/O-interruption request, as established by the CPU.

If the channel subsystem has not established the priority among requests for interruption from the subchannels by the time the interruption is allowed, the interruption does not necessarily occur immediately after the completion of the instruction enabling the CPU. A delay can occur regardless of how long the interruption condition has existed at the subchannel.

The interruption causes the current PSW to be stored as the input/output old PSW at real locations 368-383and causes the I/O-interruption code associated with the interruption to be stored at real locations 184-195 of the CPU allowing the interruption. Subsequently, a new input/output PSW is loaded from real locations 496-511and processing resumes in the CPU state indicated by that PSW. The subchannel causing the interruption is identified by the interruption code.

The I/O-interruption code has the following format when it is stored. The code is described in "TEST PENDING INTERRUPTION" on page 14-19.

Hex.		
B8	184	Subsystem-Identification Word
BC	188	I/O-Interruption Parameter
C0	192	I/O-Interruption-Identification Word

Programming Note: The I/O-interruption subclass code for all subchannels is set to zero by I/O-system reset. It may be set to any of the values 0-7 by the execution of MODIFY SUBCHANNEL. (The operation of the instruction is described in "MODIFY SUBCHANNEL" on page 14-7.)

Interruption-Response Block

The interruption-response block (IRB) is the operand of TEST SUBCHANNEL. The two rightmost bits of the IRB address are zeros, designating the IRB on a word boundary. The IRB contains three major fields: the subchannel-status word, the extended-status word, and the extended-control word. When the extended-I/O-measurement-word mode is enabled at the subchannel, the IRB contains a fourth major field, the extended-measurement word.

IRB Format

The format of the IRB stored depends upon the subchannel status. The status present at the subchannel when a TEST SUBCHANNEL instruction is executed determines whether a command-mode IRB or transport-mode IRB is stored. Bit 11 of word 0 of the IRB

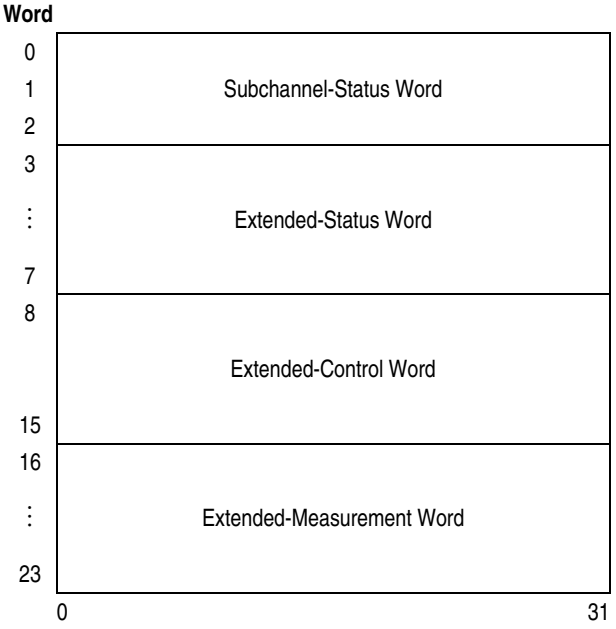
is the IRB-format control bit (X). When an IRB is stored with X set to zero, a command-mode IRB is stored. (See “Command-Mode SCSW” on page 16-8.) When an IRB is stored with X set to one, a 3-bit format field is defined. (See “Format (FMT)” on page 16-35.) The format of the IRB is specified according to the table below:

Subchannel Mode	Subchannel Status	Bit (X)	FMT	IRB Mode Stored
Command mode	Any subchannel status or combination of status	0	N	Command mode
Transport mode	Status-pending alone with halt function	1	Y-0	Transport mode
	Status-pending alone with clear function	0	N	Command mode
	Primary status with or without any other status combination	1	Y-0	Transport mode
	Secondary status alone	0	N	Command mode
	Intermediate status	1	Y-0	Transport mode
	Alert status with secondary, without primary or intermediate status	0	N	Command mode

Explanation:
N: Format field is not defined.
Y-0: Format field is defined and its value is 0.

Figure 16-2. Summary of IRB Format as Function of Subchannel Status

The general layout of the IRB is as follows:



The length of the subchannel-status and extended-status words is 12 bytes and 20 bytes, respectively. The length of the extended-control word is 32 bytes. When the extended-control bit, bit 14 of word 0 of the SCSW, is zero, words 8-15 of the interruption-response block may or may not be stored. The length of the extended-measurement word is 32 bytes. When the conditions for storing the extended-measurement word are not met (see “Extended-Measurement Word” on page 16-56), words 16-23 of the interruption-response block may or may not be stored.

Subchannel-Status Word

The subchannel-status word (SCSW) provides to the program indications describing the status of a subchannel and its associated device. When a transport-mode IRB is stored, additional information describing the status of the operation and the associated device may also be stored in the transport-status block associated with the operation. If performance of a halt, resume, or start function has occurred, the SCSW may describe the conditions under which the operation was concluded.

The SCSW is stored when TEST SUBCHANNEL is executed and the designated subchannel is operational. The SCSW is placed in words 0-2 of the IRB that is designated as the TEST SUBCHANNEL operand. When STORE SUBCHANNEL is executed, the SCSW is stored in words 7-9 of the subchannel-information block (described in “Subchannel-Information Block” on page 15-2).

Figure 16-3 on page 16-8 shows the summary and contents of the command-mode SCSW.

Command-Mode SCSW

The format of a command-mode SCSW is as follows:

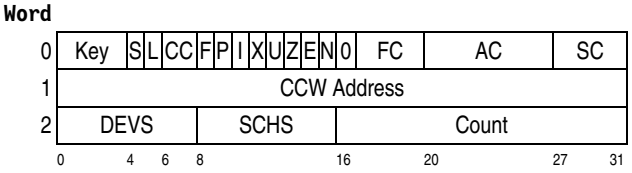


Figure 16-3. Command-Mode SCSW Format

Bits	Name
Word 0	
0-3	Subchannel Key
4	Suspend control (S)
5	ESW format (L)
6-7	Deferred condition code (CC)
8	CCW Format (F)
9	Prefetch (P)
10	Initial-status interruption control (I)
11	IRB-format control (X)
12	Suppressed-suspended interruption (U)
13	Zero condition (Z)
14	Extended control (E)
15	Path not operational (N)
16	Reserved
17-19	**Function Control (FC)**
17	Start function
18	Halt function
19	Clear function
20-26	**Activity Control (AC)**
20	Resume pending
21	Start pending
22	Halt pending
23	Clear pending
24	Subchannel active
25	Device active
26	Suspended
27-31	**Status Control (SC)**
27	Alert status
28	Intermediate status
29	Primary status
30	Secondary status
31	Status pending
Word 1	
0-31	**CCW Address**
Word 2	
0-7	**Device Status (DEVS)**
0	Attention
1	Status modifier
2	Control-unit end
3	Busy
4	Channel end
5	Device end
6	Unit check
7	Unit exception
8-15	**Subchannel Status (SCHS)**
8	Program-controlled interruption
9	Incorrect length
10	Program check
11	Protection check
12	Channel-data check
13	Channel-control check
14	Interface-control check
15	Chaining check
16-31	**Count**

Figure 16-4. Command-Mode SCSW

The contents of the subchannel-status word (SCSW) depend on the state of the subchannel when the SCSW is stored. Depending on the state of the subchannel and the device, the specific fields of the SCSW may contain (1) information pertaining to the last operation, (2) information unrelated to the performance of an operation, (3) zeros, or (4) meaningless values. The following descriptions indicate when an SCSW field contains meaningful information for a command-mode IRB.

Subchannel Key

When the start-function bit, bit 17 of word 0, is one, bit positions 0-3 of word 0 contain the access key used during performance of the associated start function. These bits are identical with the key specified in bit positions 0-3 of word 1 of the ORB. The subchannel key is meaningful only when the start-function bit, bit 17 of word 0, is one.

Suspend Control (S)

When the start-function bit, bit 17 of word 0, is one, bit 4 of word 0, when one, indicates that the suspend function can be initiated at the subchannel. Bit 4 is meaningful only when bit 17 is one. If bit 17 is one and bit 4 is one, channel-program execution can be suspended if the channel subsystem recognizes an S flag set to one in a CCW. If bit 4 is zero, channel-program execution cannot be suspended, and, if an S flag set to one in a CCW is encountered, a program-check condition is recognized.

Extended-Status-Word Format (L)

When the status-pending bit, bit 31 of word 0, is one, bit 5 of word 0, when one, indicates that a format-0 ESW has been stored. A format-0 ESW is stored when an interruption condition containing any of the following indications is cleared by TEST SUBCHANNEL:

Channel-data check
Channel-control check
Interface-control check
Measurement-block-program check
Measurement-block-data check
Measurement-block-protection check
Path verification required
Authorization check
Extended subchannel logout pending

The extended-status-word-format bit is meaningful whenever the subchannel is status pending. The extended-status information that is used to form a format-0 ESW is cleared at the subchannel by TEST SUBCHANNEL or CLEAR SUBCHANNEL.

Deferred Condition Code (CC)

When the start-function bit, bit 17 of word 0, is one and the status-pending bit, bit 31 of word 0, is also one, bits 6 and 7 of word 0 indicate the general reason that the subchannel was status pending when TEST SUBCHANNEL or STORE SUBCHANNEL was executed. The deferred condition code is meaningful when the subchannel is status pending with any combination of status and only when the start-function bit of the function-control field in the SCSW is one. The meaning of the deferred condition code for each value when the subchannel is status pending is given in Figure 16-5 on page 16-11.

The deferred condition code, if not zero, is used to indicate whether conditions have been encountered that preclude the subchannel becoming subchannel-and-device active while the subchannel is either start pending or suspended.

Deferred Condition Code 0: A normal I/O interruption has taken place.

Deferred Condition Code 1: Status is present in the SCSW that was presented by the associated device or generated by the channel subsystem subsequent to the setting of condition code 0 for START SUBCHANNEL or RESUME SUBCHANNEL. If only the alert-status bit and the status-pending bit of the status-control field of the SCSW are ones, the status present is not related to the execution of a channel program. If the intermediate-status bit, the primary-status bit, or both are ones, then the status is related to the execution of the channel program specified by the most recently executed START SUBCHANNEL instruction or implied by the most recently executed RESUME SUBCHANNEL instruction. (See “Immediate Conclusion of Command-Mode I/O Operations” on page 15-78.) If the secondary-status bit is one and the primary-status bit is zero, the status present is related to the channel program specified by the START SUBCHANNEL instruction or implied by the RESUME SUBCHANNEL instruction that preceded the most recently executed START SUBCHANNEL instruction.

Deferred Condition Code 2: This code does not occur and is reserved for future use.

Deferred Condition Code 3: An attempted device selection has occurred, and the device appeared not operational on all of the channel paths that were available for selection of the device.

A device appears not operational when it does not respond to a selection attempt by the channel subsystem. This occurs when the control unit is not provided in the system, when power is off in the control unit, or when the control unit has been logically switched off the channel path. The not-operational state is also indicated when the control unit is provided and is capable of attaching the device, but the device has not been installed and the control unit is not designed to recognize the device being selected as one of its attached devices. (See also "I/O Addressing" on page 13-5.)

A deferred condition code 3 also can be set by the channel subsystem if no channel paths to the device are available for selection. (See Figure 16-5 on page 16-11.)

Programming Notes:

1. If, during performance of a start function, the I/O device being selected is not installed or has been logically removed from the control unit, but the associated control unit is operational and the control unit recognizes the I/O device being selected as one of its I/O devices, the control unit, depending upon the model, either fails to recognize the address of the I/O device or considers the I/O device to be not ready. In the former case, a path-not-operational condition is recognized, subject to the setting of the path-operational mask. (See "Path-Operational Mask (POM)" on page 15-7.) In the latter case, the not-ready condition is indicated when the control unit responds to the selection and indicates unit check whenever the not-ready state precludes successful initiation of the operation at the I/O device. In this case, unit-check status is indicated in the SCSW, the subchannel becomes status pending with primary, secondary, and alert status, and with deferred condition code 1 indicated. (See the publication *ESA/390 Common I/O-Device Commands*, SA22-7204, for a description of unit-check status.) Refer to the System Library publication for the control unit to determine how the condition is indicated.
2. The deferred condition code is 1, and the status-control field contains the status-pending and intermediate-status bits or the status-pending, intermediate-status, and alert-status bits as ones when HALT SUBCHANNEL has been executed and the designated subchannel is suspended and status pending with intermediate status. If the alert-status bit is one, then subchannel-logout information was generated as a result of attempting to issue the halt signal to the device.

Bit 6	Bit 7	Status Control[1]	Meaning
0	0	A I P S X A I P – X A – P S X A – P – X – I P S X – I P – X – I – – X – – P S X – – P – X	Normal I/O Interruption
0	1	A I P S X A I P – X A I – – X[2] A – P S X A – P – X A – – S X A – – – X – I P S X – I P – X – I – – X[2] – – P S X – – P – X – – – S X[3] – – – – X[3] [2]	Either an immediate operation, with chaining not specified, has ended normally, or the setting of some status condition precluded the initiation or resumption of a requested I/O operation at the device.
1	0	Reserved	Reserved
1	1	– – P S X – I P S X	The device is not operational on any available path or, if a dedicate-allegiance condition exists, the device is not operational on the path to which the dedicated-allegiance is owed.

Explanation:

– Bit is zero.
[1] The allowed combinations of status-control-bit settings when the start-function bit is one in the function-control field.
[2] The condition is encountered after the execution of HALT SUBCHANNEL when the subchannel is currently suspended
[3] The condition is encountered after the execution of HALT SUBCHANNEL when the subchannel is currently start pending.
A Alert status.
I Intermediate status.
P Primary status.
S Secondary status.
X Status pending.

Figure 16-5. Deferred-Condition-Code Meaning for Status-Pending Subchannel

CCW Format (F)

When the start-function bit, bit 17 of word 0, is one, bit 8 of word 0 indicates the format of the CCWs associated with an I/O operation. The format bit is meaningful only when bit 17 is one. If bit 8 of word 0 is zero, format-0 CCWs are indicated. If it is one, format-1 CCWs are indicated. (See “Channel-Command Word” on page 15-31 for the description of the two CCW formats.)

Prefetch (P)

When the start-function bit, bit 17 of word 0, is one, bit 9 of word 0 indicates whether or not unlimited prefetching of CCWs, IDAWs, MIDAWS, and associ-

ated data is allowed. The prefetch bit is meaningful only when bit 17 is one. If bit 9 is zero, prefetching of one CCW describing a data area is allowed during output-data-chaining operations and is not allowed during any other operations. If bit 9 is one, unlimited prefetching of CCWs, IDAWs, MIDAWS, and associated data is allowed. It is model dependent whether prefetching is actually performed for any or all of the CCWs, IDAWs, MIDAWS, and associated data that comprise the CCW channel program.

Initial-Status-Interruption Control (I)

When the start-function bit, bit 17 of word 0, is one, bit 10 of word 0, when one, indicates that the channel subsystem is to generate an intermediate interruption condition if the subchannel becomes subchannel active (see "Initial-Status-Interruption Control (I)" on page 15-27). Bit 10 of word 0, when zero, indicates that the subchannel becoming subchannel active is not to cause an intermediate interruption condition to be generated.

The program requests the intermediate interruption condition by means of the command-mode ORB. An I/O interruption that results from that request may be due to the channel subsystem performing either a start function or a resume function. (See "Zero Condition Code (Z)" on page 16-12 for details of the indication given by the channel subsystem when the intermediate interruption condition is cleared by TEST SUBCHANNEL.)

Address-Limit-Checking Control (A)

When the address-limit-checking facility is installed and the start-function bit, bit 17 of word 0, is one, bit 11 of word 0, when one, indicates that the channel subsystem has been requested by the program to perform address-limit checking, subject to the setting of the limit mode at the subchannel (see "Address-Limit-Checking Control (A)" on page 15-27). The address-limit-checking-control bit is meaningful only when bit 17 is one.

IRB-Format Control (X)

Bit 11 of word 0 is the IRB-format control bit (X). The value of this bit is zero for the command-mode IRB. See Figure 16-2 on page 16-7.

Suppress-Suspended Interruption (U)

When the start-function bit, bit 17 of word 0, is one, bit 12 of word 0, when one, indicates that the channel subsystem has been requested by the program to suppress the generation of a subchannel-suspended interruption condition when the subchannel is suspended (see "Suppress-Suspended-Interruption Control (U)" on page 15-27). When bit 12 is zero, the channel subsystem generates an intermediate interruption condition whenever the subchannel is suspended during the execution of the associated channel program. The suppress-suspended-interruption bit is meaningful only when bit 17 is one.

Subchannel-Control Field

The following subchannel-control-information descriptions apply to the subchannel-control field, bits 13-31 of word 0 of the SCSW.

Zero Condition Code (Z)

Bit 13 of word 0, when one, indicates that the subchannel has become subchannel active and the channel subsystem has recognized an initial-status-interruption condition at the subchannel. The Z bit is meaningful only when the intermediate-status bit, bit 28 of word 0, and the start-function bit, bit 17 of word 0, are both ones.

If the initial-status-interruption-control bit, bit 10 of word 1 of the command-mode ORB, is one when START SUBCHANNEL is executed, then the subchannel becoming subchannel active causes the subchannel to be made status pending with intermediate status indicating the initial-status-interruption condition. The initial-status-interruption condition remains at the subchannel until the intermediate interruption condition is cleared by the execution of TEST SUBCHANNEL or CLEAR SUBCHANNEL. If the initial-status-interruption-control bit of the command-mode ORB is zero when START SUBCHANNEL is executed, then the subchannel becoming subchannel active does not cause an intermediate interruption condition to be generated, and the initial-status-interruption condition is not recognized.

Extended Control (E)

Bit 14 of word 0, when one, indicates that model-dependent information or concurrent-sense information is stored in the extended-control word (ECW). When bit 14 is zero, the contents of words 0-7 of the ECW, if stored, are unpredictable. The E bit is meaningful whenever the subchannel is status pending with alert status either alone or together with primary status, secondary status, or both.

Programming Note: During the execution of TEST SUBCHANNEL, the storing of words 0-7 of the ECW is a model-dependent function subject to the setting of bit 14 as described above. Therefore, the program should always provide sufficient storage to accommodate the storing of at least a 64-byte IRB or, when the extended-I/O-measurement-word mode is enabled at the subchannel, a 96-byte IRB.

Path Not Operational (N)

Bit 15 of word 0, when one, indicates that the N condition has been recognized by the channel subsystem. The N condition, in turn, indicates that one or more path-not-operational conditions have been recognized. The channel subsystem recognizes a path-not-operational condition when, during an attempted device selection in order to perform a clear, halt, resume, or start function, the device associated with the subchannel appears not operational on a channel path that is operational for the subchannel. A channel path is operational for the subchannel if the associated device appeared operational on that channel path the last time the channel subsystem attempted device selection in order to perform a clear, halt, resume, or start function. A channel path is not operational for the subchannel if the associated device appeared not operational on that channel path the last time the channel subsystem attempted device selection in order to perform a clear, halt, resume, or start function. A device appears to be operational on a channel path when the device responds to an attempted device selection.

The N bit is meaningful whenever the status-control field contains any of the indications listed below and at least one basic I/O function is also indicated at the subchannel:

- Status pending with any combination of primary, secondary, or alert status
- Status pending alone
- Status pending with intermediate status when the subchannel is also suspended

The N condition is reset whenever the execution of TEST SUBCHANNEL results in the setting of condition code 0 and the N bit is meaningful as described above.

Notes:

1. A path-not-operational condition does not imply a malfunctioning channel path. A malfunctioning channel path causes the generation of an error indication, such as interface-control check.
2. When a path-not-operational condition has been recognized and the subchannel subsequently becomes status pending with only intermediate status, the path-not-operational condition (a) continues to be recognized until the subchannel becomes status pending with primary status or becomes suspended and (b) is indicated by storing the path-not-operational bit as a one during the execution of TEST SUBCHANNEL. When a path-not-operational condition has been recognized and the channel-program execution subsequently becomes suspended, the path-not-operational condition does not remain pending if channel-program execution is subsequently resumed. Instead, the old indication is lost, and the path-not-operational indication, if any, pertains to the attempt by the channel subsystem to resume channel-program execution.

Function Control (FC)

The function-control field indicates the basic I/O functions that are indicated at the subchannel. This field may indicate the acceptance of as many as two functions. The function-control field is contained in bit positions 17-19 of the first word of the SCSW. The function-control field is meaningful at an installed subchannel whenever the subchannel is valid (see “Device Number Valid (V)” on page 15-4). The function-control field contains all zeros whenever both the activity- and status-control fields contain all zeros. The meaning of the individual bits is as follows:

Start Function (Bit 17): When one, bit 17 indicates that a start function has been requested and is either pending or in progress at the subchannel. A start function is requested by the execution of START SUBCHANNEL. A start function is indicated at the subchannel when condition code 0 is set during the execution of START SUBCHANNEL. The start-function indication is cleared at the subchannel when TEST SUBCHANNEL is executed and the subchannel is either status pending alone or status pending with any combination of alert, primary, or secondary status. The start-function indication is also cleared at the subchannel during the execution of CLEAR SUBCHANNEL.

Halt Function (Bit 18): When one, bit 18 indicates that a halt function has been requested and is either pending or in progress at the subchannel. A halt function is requested by the execution of HALT SUBCHANNEL. A halt function is indicated at the subchannel when condition code 0 is set for HALT SUBCHANNEL. The halt-function indication is cleared at the subchannel when the next status-pending condition that occurs is cleared by the execution of TEST SUBCHANNEL. The next status-pending condition depends on the state of the subchannel when HALT SUBCHANNEL is executed. If the subchannel is subchannel active when HALT SUBCHANNEL is executed, then the next status-pending condition is status pending with at least primary status indicated. If the subchannel is device active when HALT SUBCHANNEL is executed, then the next status-pending condition is status pending with at least secondary status indicated. If the subchannel is suspended and status pending with intermediate status when HALT SUBCHANNEL is executed, then the next status-pending condition is status pending with intermediate status. If the subchannel is idle when HALT SUBCHANNEL is executed, then the next status-pending condition is status pending alone. The halt-function indication is also cleared at the subchannel during the execution of CLEAR SUBCHANNEL. In normal operations, this function is indicated together with bit 17; that is, there is a start function either pending or in progress that is to be halted.

Clear Function (Bit 19): When one, bit 19 indicates that a clear function has been requested and is either pending or in progress at the subchannel. A clear function is requested by the execution of CLEAR SUBCHANNEL. A clear function is indicated at the subchannel when condition code 0 is set for CLEAR SUBCHANNEL (see "CLEAR SUBCHANNEL" on page 14-5). The clear-function indication is cleared at the subchannel when the resulting status-pending condition is cleared by TEST SUBCHANNEL.

Activity Control (AC)

The activity-control field is contained in bit positions 20-26 of the first word of the SCSW. This field indicates the current progress of a basic I/O function previously accepted at the subchannel. By using the contents of this field, the program can determine the degree of completion of the basic I/O function. The activity-control field is meaningful at an installed subchannel whenever the subchannel is valid (see "Device Number Valid (V)" on page 15-4). However, if an IFCC or CCC condition is detected during the performance of a basic I/O function and that function is indicated as pending, I/O operations may or may not have been performed at the device. The activity-control bits are defined as follows:

Bit	Meaning
20	Resume pending
21	Start pending
22	Halt pending
23	Clear pending
24	Subchannel active
25	Device active
26	Suspended

When an SCSW is stored that has the status-pending bit of the status-control field zero and all zeros in the activity-control field, the subchannel is said to be idle or in the idle state.

Note: All conditions that are represented by the bits in the function-control field and by the resume-pending, start-pending, halt-pending, clear-pending, subchannel-active, and suspended bits in the activity-control field are reset at the subchannel when TEST SUBCHANNEL is executed and the subchannel is (1) status pending alone, (2) status pending with primary status, (3) status pending with alert status, or (4) status pending with intermediate status and is also suspended.

Resume-Pending (Bit 20): When one, bit 20 indicates that the subchannel is resume pending. The channel subsystem may or may not be in the process of performing the start function. The subchannel becomes resume pending when condition code 0 is set for RESUME SUBCHANNEL. The point at which the subchannel is no longer resume pending is a function of the subchannel state existing when the resume-pending condition is recognized and the state of the device if channel-program execution is resumed.

If the subchannel is in the suspended state when the resume-pending condition is recognized, the CCW that caused the suspension is refetched, the setting of the suspend flag is examined, and one of the following actions is taken by the channel subsystem:

1. If the CCW suspend flag is one, the device is not selected, the subchannel is no longer resume pending, and the channel-program execution remains suspended.

2. If the CCW suspend flag is zero, the channel subsystem attempts to resume channel-program execution by performing a modified start function. The resumption of channel-program execution appears to the device as the initiation of a new channel-program execution. The resume function causes the channel subsystem to perform the path-management operation as if a new start function were being initiated, using the ORB parameters previously passed to the subchannel by START SUBCHANNEL with the exception that the channel-program address is the address of the CCW that caused the suspension of the channel-program execution.

   The subchannel remains resume pending when, during the performance of the start function, the channel subsystem (1) determines that it is not possible to attempt to initiate the I/O operation for the first command, (2) determines that an attempt to initiate the I/O operation for the first command does not result in the command being accepted, or (3) detects an IFCC or CCC condition and is unable to determine whether the first command has been accepted. (See "Start Function and Resume Function" on page 15-20.)

   The subchannel is no longer resume pending when any of the following events occurs:

   a. While performing the start function, the subchannel becomes subchannel-and-device active or device active only, or the first command is accepted with channel-end and device-end initial status and the CCW does not specify command chaining.

   b. CLEAR SUBCHANNEL is executed.

   c. TEST SUBCHANNEL clears any combination of primary, secondary, and alert status or clears the status-pending condition alone.

   d. TEST SUBCHANNEL clears intermediate status while the subchannel is suspended.

   e. CANCEL SUBCHANNEL is executed with a resulting condition code 0.

If the subchannel is not in the suspended state when the resume-pending condition is recognized, the CCW suspend flag of the most recently fetched CCW, if any, is examined, and one of the following actions is taken by the channel subsystem:

1. If a CCW has not been fetched or the suspend flag of the most recently fetched CCW is zero, the subchannel is no longer resume pending, and the resume function is not performed.

2. If the suspend flag of the most recently fetched CCW is one, the subchannel is no longer resume pending, and the CCW is refetched. The subchannel proceeds with channel-program execution if the suspend flag of the refetched CCW is zero. The subchannel suspends channel-program execution if the suspend flag of the refetched CCW is one.

Some models recognize a resume-pending condition only after a CCW having an S flag validly set to one is fetched. Therefore, if a subchannel is resume pending and, during the execution of the channel program, no CCW is fetched that has an S flag validly set to one, the subchannel remains resume pending until the primary interruption condition is cleared by TEST SUBCHANNEL.

Start-Pending (Bit 21): When one, bit 21 indicates that the subchannel is start pending. The channel subsystem may or may not be in the process of performing the start function. The subchannel becomes start pending when condition code 0 is set for START SUBCHANNEL. The subchannel remains start pending when, during the performance of the start function, the channel subsystem (1) determines that it is not possible to attempt to initiate the I/O operation for the first command, (2) determines that an attempt to initiate the I/O operation for the first command does not result in the command being accepted, or (3) detects an IFCC or CCC condition and is unable to determine whether the first command has been accepted. (See "Start Function and Resume Function" on page 15-20.)

The subchannel becomes no longer start pending when any of the following occurs:

1. While performing the start function, the subchannel becomes subchannel-and-device active or device active only, or the first command is accepted with channel-end and device-end initial status and the CCW does not specify command chaining.

2. The subchannel becomes suspended because of a suspend flag validly set to one in the first CCW.

3. CLEAR SUBCHANNEL is executed.

4. TEST SUBCHANNEL clears any combination of primary, secondary, and alert status or clears the status-pending condition alone.

5. CANCEL SUBCHANNEL is executed with a resulting condition code 0.

Halt-Pending (Bit 22): When one, bit 22 indicates that the subchannel is halt pending. The channel subsystem may or may not be in the process of performing the halt function. The subchannel becomes halt pending when condition code 0 is set for HALT SUBCHANNEL. The subchannel remains halt pending when, during the performance of the halt function, the channel subsystem (1) determines that it is not possible to attempt to issue the halt signal to the device, (2) determines that the attempt to issue the halt signal to the device is not successful, or (3) detects an IFCC or CCC condition and is unable to determine whether the halt signal is issued to the device. (See "Halt Function" on page 15-16.)

The subchannel is no longer halt pending when any of the following occurs:

1. While performing the halt function, the channel subsystem determines that the halt signal has been issued to the device.

2. CLEAR SUBCHANNEL is executed.

3. TEST SUBCHANNEL clears any combination of primary, secondary, and alert status or clears the status-pending condition alone.

4. TEST SUBCHANNEL clears intermediate status while the subchannel is suspended.

Clear-Pending (Bit 23): When one, bit 23 indicates that the subchannel is clear pending. The channel subsystem may or may not be in the process of performing the clear function. The subchannel becomes clear pending when condition code 0 is set for CLEAR SUBCHANNEL. The subchannel remains clear pending when, during performance of the clear function, the channel subsystem (1) determines that it is not possible to attempt to issue the clear signal to the device, (2) determines that the attempt to issue the clear signal to the device is not successful, or (3) detects an IFCC or CCC condition and is unable to determine whether the clear signal is issued to the device. (See "Clear Function" on page 15-14.)

The subchannel is no longer clear pending when either of the following occurs:

1. While performing the clear function, the channel subsystem determines that the clear signal has been issued to the device.

2. TEST SUBCHANNEL clears the status-pending condition alone.

Subchannel Active (Bit 24): When one, bit 24 indicates that the subchannel is subchannel active. A subchannel is said to be subchannel active when an I/O operation is currently being performed at the subchannel. The subchannel becomes subchannel active when the first command is accepted and the start function or resume function is not immediately concluded at the subchannel. (See "Immediate Conclusion of Command-Mode I/O Operations" on page 15-78.)

The subchannel is no longer subchannel active when any of the following occurs:

1. The subchannel becomes suspended.

2. The subchannel becomes status pending with primary status.

3. CLEAR SUBCHANNEL is executed.

4. The device appears not operational during performance of a halt function.

The subchannel does not become subchannel active during performance of the function specified by either a HALT SUBCHANNEL or a CLEAR SUBCHANNEL instruction.

Device Active (Bit 25): When one, bit 25 indicates that the subchannel is device active. A subchannel is said to be device active when an I/O operation is currently in progress at the associated device. The subchannel becomes device active when the first command is accepted.

The subchannel is no longer device active when any of the following occurs:

1. The subchannel becomes suspended.

2. The subchannel becomes status pending with secondary status.

3. CLEAR SUBCHANNEL is executed.

4. The device appears not operational during performance of a halt function.

If the subchannel is not start pending or if the status accepted from the device also describes an alert condition, the subchannel becomes status pending with secondary status. After the status has been accepted from the device, the device is capable of accepting a command for performing a new I/O operation. If the subchannel is start pending and the status is device end or device end with control unit end, then the channel subsystem discards the status and performs the start function for the new channel program. (See“Start Function and Resume Function” on page 15-20) In this situation, the subchannel does not become status pending with the secondary interruption condition, and the status is not made available to the program.

The subchannel does not become device active during performance of the functions specified by either a HALT SUBCHANNEL or a CLEAR SUBCHANNEL instruction.

Suspended (Bit 26): When one, bit 26 indicates that the subchannel is suspended. A subchannel is said to be suspended when channel-program execution is currently suspended. The subchannel becomes suspended as part of the suspend function. (See “Suspension of CCW Channel-Program Execution” on page 15-73.)

The subchannel is no longer suspended when any of the following occurs:

1. As part of the resume function following the execution of RESUME SUBCHANNEL when the subchannel becomes subchannel-and-device active or device active only, or the first command is accepted for channel-end and device-end initial status, with or without status modifier, and the CCW does not specify command chaining.
2. CLEAR SUBCHANNEL is executed.
3. TEST SUBCHANNEL clears any combination of primary, secondary, and alert status or clears the status-pending condition alone.
4. TEST SUBCHANNEL clears intermediate status while the halt function is specified.
5. CANCEL SUBCHANNEL is executed with a resulting condition code 0.

Programming Note: When an SCSW is stored by STORE SUBCHANNEL or TEST SUBCHANNEL following CLEAR SUBCHANNEL but prior to the subchannel becoming status pending, and the subchannel-active bit, bit 24 of word 0, is stored as zero, this does not mean that data transfer has stopped for the device. The program cannot determine whether data transfer has stopped until the subchannel becomes status pending as a result of performing the clear function.

Status Control (SC)

The status-control field is contained in bit positions 27-31 of the first word of the SCSW. This field provides the program with a summary-level indication of the interruption condition described by either subchannel or device status, the Z bit, or, in the case of the subchannel-suspended interruption, the suspended bit, bit 26. More than one summary indication may be signaled as a result of existing conditions at the subchannel. Whenever the subchannel is enabled (see “Enabled (E)” on page 15-3) and at least bit 31 is one, the subchannel is said to be status pending. Whenever the subchannel is disabled, the subchannel is not made status pending. Bit 31 of SCSW word 0 is meaningful at an installed subchannel whenever the subchannel is valid (see “Device Number Valid (V)” on page 15-4); bits 27-30 are meaningful when bit 31 is one. The status-control bits are defined as follows:

Alert Status (Bit 27): When one (and when the status-pending bit is also one), bit 27 indicates an alert interruption condition exists. In such a case, the subchannel is said to be status pending with alert status. An alert interruption condition is recognized when alert status is present at the subchannel. Alert status may be subchannel status or device status. Alert status is status generated by either the channel subsystem or the device under any of the following conditions:

- The subchannel is idle (activity-control bits 20-26 and status-control bit 31 are zeros).
- The subchannel is start pending, and the status condition precludes initiation of the I/O operation.
- The subchannel is subchannel-and-device active, and the status condition has suppressed command chaining or would have suppressed command chaining if chaining had been specified (see “CCW Channel Program Chaining” on page 15-60).
- The subchannel is subchannel-and-device active, command chaining is not specified, the

execution of the channel program has just been concluded, and the status presented by the device is attempting to alter the sequential execution of commands (see the publication *ESA/390 Common I/O-Device Commands*, SA22-7204, for more information on the use of status modifier to alter the sequential execution of commands).

- The subchannel is device active only, and the status presented by the device is other than device end, control unit end, or device end and control unit end.
- The subchannel is suspended (bit 26 is one).

If the subchannel is start pending when an alert interruption condition is recognized, the subchannel becomes status pending with alert status, deferred condition code 1 is set, the start-pending bit remains one, and the performance of the pending I/O operation is not initiated.

When TEST SUBCHANNEL is executed and stores an SCSW with the alert-status bit and the status-pending bit as ones in the IRB, the alert interruption condition is cleared at the subchannel. The alert interruption condition is also cleared during the execution of CLEAR SUBCHANNEL.

Whenever alert status is present at the subchannel, it is brought to the attention of the program. Examples of alert status include attention, device end (which signals a transition from the not-ready to the ready state), incorrect length, program check, and unit check.

Intermediate Status (Bit 28): When one (and when the status-pending bit is also one), bit 28 indicates an intermediate interruption condition exists. In such a case, the subchannel is said to be status pending with intermediate status. Intermediate status can be indicated when the Z bit (of the subchannel-control field), the suspended bit (of the activity-control field), or the PCI bit (of the subchannel-status field) is one.

When the initial-status-interruption-control bit is one in the command-mode ORB, the subchannel becomes status pending with intermediate status (the Z bit indicated) only after the subchannel is subchannel active. If the subchannel does not become subchannel active, the Z condition is not generated.

When suspend control is specified and the generation of an intermediate interruption condition due to suspension is not suppressed in the command-mode ORB, then the subchannel can become status pending with intermediate status due to suspension if a CCW becomes current that contains the suspend flag set to one. When the suspend flag is specified in the first CCW of a channel program, channel-program execution is suspended, and the subchannel becomes status pending with intermediate status (the suspended bit indicated) before the command in the first CCW is transferred to the device. When the suspend flag is specified in a CCW fetched during command chaining, then channel-program execution is suspended, and the subchannel becomes status pending with intermediate status (the suspended bit is indicated), only after the execution of the preceding CCW is complete.

When the PCI flag is specified in a CCW, the generation of an intermediate interruption condition due to PCI depends on whether the CCW is the first CCW of the channel program. When the PCI flag is specified in the first CCW of a channel program, the subchannel becomes status pending with intermediate status (the PCI bit indicated) only after initial status is received for the first CCW of the channel program indicating the command has been accepted. When the PCI flag is specified in a CCW fetched while chaining, the subchannel becomes status pending with intermediate status (the PCI bit indicated) only after the execution of the preceding CCW is complete. If chaining occurs before an interruption condition containing PCI is cleared by TEST SUBCHANNEL, the condition is carried over to the next CCW. This carry-over occurs during both data and command chaining, and, in either case, the condition is propagated through the transfer-in-channel command.

If the subchannel is status pending with intermediate status when HALT SUBCHANNEL is executed, the intermediate interruption condition remains at the subchannel, but the interruption request, if any, is withdrawn, and the subchannel becomes no longer status-pending. The subchannel remains no longer status pending until performance of the halt function has ended. The subchannel then becomes status pending with intermediate status indicated (possibly together with any combination of primary, secondary, and alert status).

When TEST SUBCHANNEL is executed and stores an SCSW with the intermediate-status bit and the

status-pending bit as ones in the IRB, the intermediate interruption condition is cleared at the subchannel. The intermediate interruption condition is also cleared at the subchannel during the execution of CLEAR SUBCHANNEL.

Primary Status (Bit 29): When one (and when the status-pending bit is also one), bit 29 indicates a primary interruption condition exists. In such a case, the subchannel is said to be status pending with primary status. A primary interruption condition is a solicited interruption condition that indicates the completion of the start function at the subchannel. The primary interruption condition is described by the SCSW stored. When an I/O operation is terminated by HALT SUBCHANNEL but the halt signal is not issued to the device because the device appeared not operational, the subchannel is made status pending with primary status (and secondary status) with both the subchannel-status field and the device-status field set to zero.

When TEST SUBCHANNEL is executed and stores an SCSW with the primary-status bit and the status-pending bit as ones in the IRB, the primary interruption condition is cleared at the subchannel. The primary interruption condition is also cleared at the subchannel during the execution of CLEAR SUBCHANNEL.

Secondary Status (Bit 30): When one (and when the status-pending bit is also one), bit 30 indicates a secondary interruption condition exists. In such a case, the subchannel is said to be status pending with secondary status. A secondary interruption condition is a solicited interruption condition that normally indicates the completion of the I/O operation at the device. The secondary interruption condition is described by the SCSW stored.

When an I/O operation is terminated by HALT SUBCHANNEL but the halt signal is not issued to the device because the device appeared not operational, the subchannel is made status pending with secondary status (and primary status if the subchannel is also subchannel active) with zeros for subchannel and device status.

When TEST SUBCHANNEL is executed and stores an SCSW with the secondary-status bit as one in the IRB, the secondary interruption condition is cleared at the subchannel. The secondary interruption condition is also cleared at the subchannel during the execution of CLEAR SUBCHANNEL.

Status-Pending (Bit 31): When one, bit 31 indicates that the subchannel is status pending and that information describing the cause of the interruption condition is available to the program. The subchannel becomes status pending whenever intermediate, primary, secondary, or alert status is generated. When HALT SUBCHANNEL is executed, designating a subchannel that is idle, the subchannel becomes status pending subsequent to performance of the halt function to notify the program that the halt function has been completed. When TEST SUBCHANNEL is executed, thus storing an SCSW with the status-pending bit as one in the IRB, the status-pending condition is cleared at the subchannel. The status-pending condition is also cleared at the subchannel during the execution of CLEAR SUBCHANNEL. When CLEAR SUBCHANNEL is executed and the designated subchannel is operational, the subchannel becomes status pending subsequent to performance of the clear function to notify the program that the clear function has been completed.

Note: The status-pending bit, in conjunction with the remaining bits of the status-control field, indicates the type of status condition. For example, if bits 29 and 31 are ones, the subchannel is status pending with primary status. Alternatively, if only bit 31 is one, then the subchannel is said to be status pending or status pending alone. If only bit 31 is one in the status-control field, the settings of all bits in the subchannel-status and device-status fields are unpredictable. If bit 31 is not one, then the remaining bits of the status-control field are not meaningful.

CCW-Address Field

Bits 1-31 of word 1 form an absolute address. The address indicated is a function of the subchannel state when the SCSW is stored, as indicated in Figure 16-6 on page 16-20. When the subchannel-status field indicates channel-control check, channel-data check, or interface-control check, the CCW-address field is usable for recovery purposes if the CCW-address field-validity flag in the ESW is one.

Programming Note: When a CCW address, either detected in the channel-program address (see “Channel-Program Address” on page 15-28) or generated during chaining, would cause the channel subsystem to fetch a CCW from a location greater than $2^{24} - 1$ while format-0 CCWs are specified for the operation, the invalid address is stored in the CCW-address field of the SCSW without truncation.

If the invalid address causes the channel subsystem, while chaining, to fetch a CCW from a location greater than 2^{31} - 1 while format-1 CCWs are specified for the operation, the rightmost 31 bits of the invalid address are stored in the CCW-address field.

Subchannel State[1]	CCW Address[2]
Start pending (UUUU0/AIPSX)[3]	Unpredictable
Start pending and device active (UUUU0/AIPSX)[3]	Unpredictable
Subchannel-and-device active (UUUU0/AIPSX)[3]	Unpredictable
Device active only (UUUU0/AIPSX)	Unpredictable
Suspended (YYYYY/AIPSX)[3]	See note 1
Status pending (10001/AIPSX) because of unsolicited alert status from the device while the subchannel was start pending[3]	Channel-program address + 8
Status pending (0Y111/AIPSX) because the device appeared not operational on all paths[3]	Channel-program address + 8
Status pending (10011/AIPSX) because of solicited alert status from the device while the subchannel was start pending and device active[3]	Channel-program address + 8
Status pending (10111/AIPSX) because of solicited alert status generated by the channel subsystem while the subchannel was start pending[3] or start pending and device active[3]	See note 2
Status pending (01001/AIPSX) for the program-controlled-interruption condition while the subchannel was subchannel-and-device active[3]	CCW + 8 of the CCW that contained the last recognized PCI, or 8 higher than a CCW that has subsequently become current
Status pending (01001/AIPSX) for the initial-status-interruption condition while the subchannel was subchannel-and-device active[3]	CCW + 8 of the CCW causing the intermediate interruption condition, or a CCW that has subsequently become current
Status pending (1Y1Y1/AIPSX); termination occurred because of program check caused by one of the following conditions:[3]	
Bit 24 of word 1 of the ORB set to one; incorrect-length-indication-suppression facility not installed	Channel-program address + 8
Unused bits in ORB not set to zeros	Channel-program address + 8
Invalid CCW-address specification in transfer in channel (TIC)	Address of TIC + 8
Invalid CCW-address specification in the channel-program address in the ORB	Channel-program address + 8[4]

Figure 16-6. (Part 1 of 4) CCW Address as Function of Subchannel State

Subchannel State[1]	CCW Address[2]
Invalid CCW address in TIC	Address of TIC + 8
Invalid CCW address in the channel-program address in the ORB	Channel-program address + 8[4]
Invalid CCW address while chaining	Invalid CCW address + 8
Invalid command code	Address of invalid CCW + 8[5]
Invalid count	Address of invalid CCW + 8[5]
Invalid IDAW-address or MIDAW-address specification	Address of invalid CCW + 8[5]
Invalid IDAW or MIDAW address in CCW	Address of invalid CCW + 8[5]
Invalid IDAW address while sequentially fetching IDAWs or invalid MIDAW address while sequentially fetching MIDAWs	Address of current CCW + 8
Invalid data-address specification, format 1	Address of invalid CCW + 8[5]
Invalid data address in a CCW	Address of invalid CCW + 8[5]
Invalid data address while sequentially accessing storage	Address of current CCW + 8
Invalid data address in IDAW or MIDAW	Address of current CCW + 8
Invalid IDAW or MIDAW specification	Address of current CCW + 8
Invalid CCW, format 0 or 1, for a CCW other than a TIC	Address of invalid CCW + 8[5]
Invalid suspend flag – CCW fetched during data chaining has suspend flag set to one	Address of invalid CCW + 8
Invalid suspend flag – CCW has suspend flag set to one, but suspend control was not specified in the ORB	Address of invalid CCW + 8
Invalid MIDA flag – CCW has MIDA flag set to one, but modified-CCW-indirect-data addressing was not specified in the ORB	Address of invalid CCW + 8
Invalid MIDA flag – CCW has MIDA flag set to one and either the skip flag or the IDA flag or both are set to one	Address of invalid CCW + 8
Invalid CCW, format 1, for a TIC	Address of TIC + 8
Invalid sequence – two TICs	Address of second TIC + 8
Invalid sequence – 256 or more CCWs without data transfer	Address of 256th CCW + 8
Status pending (1Y1Y1/AIPSX); termination occurred because of protection check detected as follows:[3]	
On a CCW access	Address of protected CCW + 8[5]
On data or an IDAW or a MIDAW access	Address of current CCW + 8

Figure 16-6. (Part 2 of 4) CCW Address as Function of Subchannel State

Subchannel State[1]	CCW Address[2]
Status pending (1Y1Y1/AIPSX); termination occurred because of chaining check[3]	Address of current CCW + 8
Status pending (YY1Y1/AIPSX); termination occurred under count control[3]	Address of current CCW + 8[6]
Status pending (1Y1Y1/AIPSX); operation prematurely terminated by the device because of alert status[3]	Address of current CCW + 8[6]
Status pending (YYYY1/AIPSX) after termination by HALT SUBCHANNEL and the activity-control-field bits indicated below set to ones:	
Status pending alone	Unpredictable
Start pending[3]	Unpredictable
Device active and start pending[3]	Unpredictable
Device active	Unpredictable
Subchannel active and device active[3]	CCW + 8 of the last-executed CCW
Suspended	CCW + 8 of CCW causing suspension
Suspended and resume pending	Unpredictable
Status pending (00001/AIPSX) after termination by CLEAR SUBCHANNEL	Unpredictable
Status pending (YY1Y1/AIPSX); operation completed normally at the subchannel[3]	CCW + 8 of the last-executed CCW[6]
Status pending (00011/AIPSX)	Unpredictable
Status pending (10001/AIPSX)	Unpredictable
Status pending (00001/AIPSX)	Unpredictable
Status pending (1Y111/AIPSX); command chaining suppressed because of alert status other than channel-control check or interface-control check[3]	Address of current CCW + 8[6]
Status pending (1YYY1/AIPSX) because of alert status for channel-control check or interface-control check[3]	See note 3[6]
Status pending (1Y1Y1/AIPSX) because of channel-data check[3]	See note 3[6]

Figure 16-6. (Part 3 of 4) CCW Address as Function of Subchannel State

Explanation:

[1] The meaning of the notation used in this column is as follows:

A Alert status
I Intermediate status
P Primary status
S Secondary status
X Status Pending

The possible combination of status-control-bit settings is shown to the left of the "/" symbol by the use of these symbols:

0 Corresponding condition is not indicated
1 Corresponding condition is indicated
U Unpredictable. The corresponding condition is not meaningful when the subchannel is not status pending.
Y The corresponding condition is not significant and is indicated as a function of the subchannel state.

[2] A CCW becomes current when (1) it is the first CCW of a channel program and has been fetched, (2) while command chaining, the previous CCW is no longer current and the new CCW has been fetched, or (3) in the case of data chaining, the new CCW takes over control of the I/O operation (see the section "Data Chaining" in Chapter 15, "Basic I/O Functions"). If chaining is not specified or is suppressed, a CCW is no longer current and becomes the last-executed CCW when secondary status has been accepted by the channel subsystem. During command chaining, a CCW is no longer current when device-end status has been accepted or, in the case of data chaining, when the last byte of data for that CCW has been accepted.

[3] The subchannel may also be resume pending.

[4] The stored address is the channel-program address (in the ORB) + 8 even though it is either invalid or protected.

[5] The stored address is the address of the current CCW + 8 even though it is either invalid or protected.

[6] Incorrect length is indicated as a function of the setting of the suppress-length-indication flag in the current CCW (see the section "Channel-Command Word" in Chapter 15, "Basic I/O Functions").

Notes:

1. Unless the subchannel is also resume pending, the address stored is the address of the CCW that caused suspension, plus 8. Otherwise, the address stored is unpredictable.

2. The address of the CCW is given as a function of the alert status indicated. For example, if a program-check or protection-check condition is recognized, the CCW address stored is the same as for the entry for program check or protection check, respectively, in this table. Alternatively, if alert status for interface-control check or channel-control check is indicated, the CCW address stored is either the channel-program address (in the ORB) + 8 or invalid as specified by the field-validity flags in the subchannel logout. If alert status for path-verification required is indicated, the CCW address stored is the channel-program address (in the ORB) + 8.

3. Bit 21 of the subchannel-logout information, when stored as one, indicates that the address is CCW + 8 of the last-fetched CCW if the command for the CCW has not been accepted by the device. If the command has been accepted by the device at the time the error condition is recognized, then the address stored is the address of the CCW + 8 of the last-executed CCW.

Figure 16-6. (Part 4 of 4) CCW Address as Function of Subchannel State

Device-Status Field

Device-status conditions are generated by the I/O device and are presented to the channel subsystem over the channel path. The timing and causes of these conditions for each type of device are specified in the System Library publication for the device. The device-status field is meaningful whenever the subchannel is status pending with any combination of primary, secondary, intermediate, or alert status. Whenever the subchannel is status pending with intermediate status alone, the device-status field is zero. When the subchannel-status field indicates channel-control check, channel-data check, or interface-control check, the device-status field is usable for recovery purposes if the device-status field-validity flag in the ESW is one. When the subchannel is status pending with deferred condition code 3 indicated, the contents of the device-status field are not meaningful.

If, within a system, the I/O device is accessible from more than one channel path, status related to channel-subsystem-initiated operations in the single-path mode (solicited status) is signaled over the initiating channel path. Devices operating in the multipath mode may signal solicited status over any channel path that belongs to the same path group as the initiating channel path. The handling of conditions not associated with I/O operations (unsolicited alert status), such as attention, unit exception, and device end due to transition from the not-ready to the ready state, depends on the type of device and condition and is specified in the System Library publication for the device.

The channel subsystem does not modify the status bits received from the I/O device. These bits appear in the SCSW as received over the channel path. For more information on the status bits received from the I/O device, see the publication *ESA/390 Common I/O-Device Commands*, SA22-7204.

Subchannel-Status Field

Subchannel-status conditions are detected and indicated in the SCSW by the channel subsystem. Except for the conditions caused by equipment malfunctioning, they can occur only while the channel subsystem is involved with the performance of a halt, resume, or start function. The subchannel-status field is meaningful whenever the subchannel is status pending with any combination of primary, secondary, intermediate, or alert status. Individual bits contained in the subchannel-status field may be unpredictable even when the subchannel-status field is meaningful. When the subchannel is status pending with deferred condition code 3 indicated, the contents of the subchannel-status field are not meaningful.

Program-Controlled Interruption

An intermediate interruption condition is generated after a CCW with the program-controlled-interruption (PCI) flag set to one becomes the current CCW. The I/O interruption due to the PCI flag may be delayed an unpredictable amount of time because of masking of the interruption request or other activity in the system. (See “Program-Controlled Interruption” on page 15-64.) When the channel subsystem recognizes an alert interruption condition due to either a channel-control-check condition or an interface-control-check condition, then any previously existing intermediate interruption condition caused by a PCI flag in a CCW may or may not be recognized by the channel subsystem.

Detection of the PCI condition does not affect the progress of the I/O operation.

Incorrect Length

Incorrect length occurs when the number of bytes contained in the storage areas assigned for the I/O operation is not equal to the number of bytes requested or offered by the I/O device. Incorrect length is indicated for one of the following reasons:

Long Block on Input: During a read, read-backward, or sense operation, the device attempted to transfer one or more bytes to main storage after the assigned main-storage areas were filled, or the device indicated that more data could have been transferred if the count had been larger. The extra bytes have not been placed in main storage. The count in the SCSW is zero.

Long Block on Output: During a write or control operation, the device requested one or more bytes from the channel subsystem after the assigned main-storage areas were exhausted, or the device indicated that more data could have been transferred if the count had been larger. The count in the SCSW is zero.

Short Block on Input: The number of bytes transferred during a read, read-backward, or sense opera-

tion is insufficient to fill the main-storage areas assigned to the operation. The count in the SCSW is not zero.

Short Block on Output: The device terminated a write or control operation before all information contained in the assigned main-storage areas was transferred to the device. The count in the SCSW is not zero.

The incorrect-length indication is suppressed when the current CCW has the SLI flag set to one and the CD flag set to zero. The indication does not occur for operations rejected during the initiation sequence. The indication also does not occur for immediate operations when the count field is nonzero and the subchannel is in the incorrect-length-suppression mode. The incorrect-length indication is not meaningful when the count field of the SCSW is not meaningful.

Presence of the incorrect-length condition suppresses command chaining unless the SLI flag in the CCW is one or unless the condition occurs in an immediate operation when the subchannel is in the incorrect-length-suppression mode.

Program Check

Program check occurs when programming errors are detected by the channel subsystem. The condition can be due to the following causes:

Invalid CCW-Address Specification: The channel-program address (CPA) or the transfer-in-channel command does not designate the CCW on a doubleword boundary, or bit 0 of the CPA or bit 32 of a format-1 CCW specifying the transfer-in-channel command is not zero.

Invalid CCW Address: The channel subsystem has attempted to fetch a CCW from a main-storage location that is not available. An invalid CCW address can occur because the program has designated an invalid address in the channel-program-address field of the command-mode ORB or in the transfer-in-channel command or because, on chaining, the channel subsystem attempts to fetch a CCW from an unavailable location. A main-storage location is unavailable when any of the following conditions is detected:

1. The absolute CCW address does not correspond to a physical location.
2. Format-0 CCWs are specified in the ORB, and the absolute CCW address is greater than $2^{24} - 1$.
3. Format-1 CCWs are specified in the ORB, and the absolute CCW address is greater than $2^{31} - 1$

Invalid Command Code: There are zeros in the four rightmost bit positions of the command code in the CCW designated by the CPA or in a CCW fetched on command chaining. The command code is not tested for validity during data chaining.

Invalid Count, Format 0: A CCW, which is other than a CCW specifying transfer in channel, contains zeros in bit positions 48-63.

Invalid Count, Format 1: A CCW that specifies data chaining or a CCW fetched while data chaining contains zeros in bit positions 16-31.

Invalid IDAW-Address or MIDAW-Address Specification: Indirect data addressing or modified indirect data addressing is specified, and any of the following conditions is detected:

1. The ORB specifies format-1 IDAWs, the CCW specifies indirect data addressing, and the contents of the data-address field in the CCW do not designate the first IDAW on a word boundary; that is, bits 30 and 31 (format-0 CCW) or 62 and 63 (format-1 CCW) are not zeros.
2. The ORB specifies format-2 IDAWs, the CCW specifies indirect data addressing, and the contents of the data-address field in the CCW do not designate the first IDAW on a doubleword boundary; that is, bits 29-31 (format-0 CCW) or 61-63 (format-1 CCW) are not zeros.
3. The ORB specifies modified-CCW-indirect-data addressing, the CCW specifies modified-indirect-data addressing, and the contents of the data-address field in the CCW do not designate the first MIDAW on a quadword boundary.

Invalid IDAW or MIDAW Address: The channel subsystem has attempted to fetch an IDAW or MIDAW from a main-storage location that is not available. An invalid IDAW or MIDAW address can occur because the program has designated an invalid address in a CCW that specifies indirect data addressing or modified indirect data addressing, or because the channel subsystem, on sequentially fetching IDAWs or MIDAWs, attempts to fetch from

an unavailable location. A main-storage location is unavailable when any of the following conditions is detected:

1. The absolute IDAW or MIDAW address does not correspond to a physical location.
2. Format-0 CCWs are specified in the ORB, and the absolute IDAW or MIDAW address is greater than 2^{24} - 1.
3. Format-1 CCWs are specified in the ORB, and the absolute IDAW or MIDAW address is greater than 2^{31} - 1.

Invalid Data-Address Specification: Bit 32 of a format-1 CCW is not zero.

Invalid Data Address: When any of the following conditions is detected, an invalid data address is recognized by the channel subsystem.

1. Use of the data address has caused the channel subsystem to attempt to wrap from the maximum storage address to zero.
2. Use of the data address has caused the channel subsystem to attempt to wrap from zero to the maximum storage address during a read-backward operation.
3. The channel subsystem has attempted to transfer data to a storage location that is unavailable.

An invalid data address can occur because the program has designated an unavailable location in a CCW or in an IDAW or MIDAW, or because the channel subsystem, on sequentially accessing storage, attempted to access an unavailable location. A main-storage location is unavailable when any of the following conditions is detected:

1. The absolute address of the location does not correspond to a physical location.
2. Format-0 CCWs are specified in the ORB, indirect data addressing is not specified in the CCW, and the absolute address is greater than 2^{24} - 1.
3. Format-1 CCWs are specified in the ORB, indirect data addressing is not specified in the CCW, and the absolute address is greater than 2^{31} - 1.
4. Format-1 IDAWs are specified in the ORB, indirect data addressing is specified in the CCW, and the absolute address is greater than 2^{31} - 1.
5. When the address-limit-checking facility is installed, the absolute address is outside the addressing range specified by SET ADDRESS LIMIT, and the limit mode at the subchannel is active.

Note: The maximum storage address is determined as a function of the CCW and IDAW formats used or MIDAWs used. When neither an IDAW nor a MIDAW is used, the maximum storage address is a function of the CCW format specified, as follows:

1. When 24-bit (format 0) CCWs are specified, the maximum storage address recognized by the channel subsystem is 2^{24} - 1.
2. When 31-bit (format 1) CCWs are specified, the maximum storage address recognized by the channel subsystem is 2^{31} - 1.

When an IDAW is used, the maximum storage address is a function of the IDAW format specified, as follows:

1. When 31-bit (format 1) IDAWs are specified, the maximum storage address recognized by the channel subsystem is 2^{31} - 1.
2. When 64-bit (format 2) IDAWs are specified, the maximum storage address recognized by the channel subsystem is 2^{64} - 1

When a MIDAW is used, the maximum storage address recognized by the channel subsystem is 2^{64} - 1.

Invalid IDAW or MIDAW Specification: When any of the following conditions is detected, an invalid IDAW specification is recognized by the channel subsystem:

1. Bit 0 of a format-1 IDAW is not zero.
2. A second or subsequent format-1 IDAW does not designate the location of the beginning byte of a 2 K-byte block or, for read-backward operations, the location of the ending byte of a 2 K-byte block.
3. A second or subsequent format-2 IDAW does not designate the location of the beginning byte of a 2 K-byte or 4 K-byte block, as required by the 2K-IDAW control in the ORB, or, for read-backward operations, the location of the ending byte of a 2 K-byte or 4 K-byte block.

When bit 0 of a format-1 IDAW is not zero, the subchannel is made status pending with program-check indicated only after the I/O device attempts to transfer data, just as when an invalid data address that refers to a nonexistent data area is detected. If the device ends the operation prior to the transfer of data, no error condition is reported. See “CCW Indirect Data Addressing” in Chapter 15 for additional information about the reporting of program-check conditions.

When any of the following conditions is detected, an invalid MIDAW specification is recognized by the channel subsystem:

1. One or more bits defined as reserved in the MIDAW are not zero.
2. The MIDAW count field contains zeros.
3. The combination of the MIDAW data-address and count fields specify data addresses that cross a 4 K-byte block boundary, unless skipping is in effect for the MIDAW.
4. The MIDAW in control has its last-MIDAW flag set to zero and the sum of the count values of the previous MIDAWs in the MIDAW list (MIDAL) and the MIDAW in control is greater than or equal to the count value in the CCW.
5. The MIDAW in control has its last-MIDAW flag set to one and the sum of the count values in the previous MIDAWs in the MIDAL and the MIDAW in control do not equal the count value in the CCW.
6. The MIDAW in control is a second or subsequent MIDAW whose address is on a 4 K-byte boundary.

Invalid CCW, Format 1: A CCW specifying transfer in channel does not contain zeros in bit positions 0-3 and 8-31 .

Invalid Suspend Flag: A format-0 or format-1 CCW fetched during data chaining, other than a CCW specifying transfer in channel, does not contain a zero in bit position 38 or 14, respectively. A CCW other than a CCW specifying transfer in channel does not contain a zero in bit position 38 for a format-0 CCW or bit position 14 for a format-1 CCW, and suspend control was not specified by bit 4 of word 1 of the ORB.

Invalid MIDA Flag: When any of the following conditions is detected, an invalid MIDA flag condition is recognized by the channel subsystem.

1. Bit 39 (format 0) or bit 15 (format 1) of the CCW is one, specifying modified CCW indirect data addressing; however, modified CCW indirect data addressing was not specified by bit 25 of word 1 of the ORB.
2. Bit 39 (format 0) or bit 15 (format 1) of the CCW is one, specifying modified CCW indirect data addressing, and bit 35 (format 0) or bit 11 (format 1) of the CCW is one, specifying skip.
3. Bit 39 (format 0) or bit 15 (format 1) of the CCW is one, specifying modified CCW indirect data addressing, and bit 37 (format 0) or bit 13 (format 1) of the CCW is one, specifying indirect data addressing.
4. Bit 39 (format 0) or bit 15 (format 1) of the CCW is one, specifying modified CCW indirect data addressing, and the designated subchannel is not associated with channel paths that support modified CCW indirect data addressing.

Invalid ORB Format: One or more reserved bit positions in the operation-request block (ORB) is not zero. (See “Operation-Request Block” on page 15-24 for more information.) If the incorrect-length-indication-suppression facility is not installed, then bit 24 of word 1 of the command-mode ORB must also be zero.

Invalid Sequence: The channel subsystem has fetched two successive CCWs both of which specify transfer in channel, or, depending on the model, a sequence of 256 or more CCWs with command chaining specified was executed by the channel subsystem and did not result in the transfer of any data to or from an I/O device.

Detection of the program-check condition during the initiation of an operation at the device causes the operation to be suppressed and the subchannel to be made status pending with primary, secondary, and alert status. When the condition is detected after the I/O operation has been initiated at the device, the device is signaled to conclude the operation the next

time the device requests or offers a byte of data or status. In this situation, the subchannel is made status pending as a function of the status received from the device. The program-check condition causes command chaining and command retry to be suppressed.

Protection Check

Protection check occurs when the channel subsystem attempts a storage access that is prohibited by the protection or secure storage mechanism. Protection applies to the fetching of CCWs, IDAWs, MIDAWs, and output data and to the storing of input data. The subchannel key provided in the ORB is used as the access key for storage accesses associated with an I/O operation.

Detection of the protection-check condition during the fetching of the first CCW, IDAW, or MIDAW causes the operation to be suppressed and the subchannel to be made status pending with primary, secondary, and alert status. When protection check is detected after the I/O operation has been initiated at the device, the device is signaled to conclude the operation after the available data logically prior to the protection check has been transferred. However, if an access violation occurs when the channel subsystem is in the process of fetching either a new IDAW, MIDAW, or a new CCW while data chaining, and if the device signals the channel-end condition before transferring any data designated by the new CCW, IDAW or MIDAW, then the status is accepted, and the subchannel becomes status pending with primary and alert status and with protection check indicated. Other indications may accompany the protection-check indication as a function of the operation specified by the CCW, the status received from the device, and the current state of the subchannel. The protection-check condition causes command chaining and command retry to be suppressed.

Channel-Data Check

Channel-data check indicates that an uncorrected storage error has been detected in regard to data, contained in main storage, that is currently used in the performance of an I/O operation. The condition may be indicated when detected, even if the data is not used when prefetched. Channel-data check is indicated when data or the associated key has an invalid checking-block code (CBC) in main storage when that data is referenced by the channel subsystem.

On an input operation, when the channel subsystem attempts to store less than a complete checking block, and invalid CBC is detected on the checking block in storage, the contents of the location remain unchanged and with invalid CBC. On an output operation, whenever channel-data check is indicated, no bytes from the checking block with invalid CBC are transferred to the device.

During a storage access, the maximum number of bytes that can be transferred is model dependent. If a channel-data-check condition is recognized during that storage access, the number of bytes transferred to or from storage may not be detectable by the channel subsystem. Consequently, the number of bytes transferred to or from storage may not be correctly reflected by the residual count. However, the residual count that is stored in the SCSW, when used in conjunction with the storage-access code and the CCW address, designates a byte location within the block of main storage in which the channel-data-check condition was recognized.

A condition indicated as channel-data check causes the current operation, if any, to be terminated. The subchannel becomes status pending with primary and alert status, or with primary, secondary, and alert status, as a function of the status received from the device. The count and address fields of the SCSW stored by TEST SUBCHANNEL pertain to the operation terminated. The extended-status-word-format bit is one, and subchannel-logout information is stored in the ESW, when TEST SUBCHANNEL is executed.

Whenever the channel-data-check condition pertains to prefetched data, the failing-storage-address-validity flag, bit 6 of the ERW, is one. An address of a location within the checking block for which the channel-data-check condition is generated is stored in the ESW failing-storage-address field.

Uncorrectable storage or key errors detected on prefetched data while the subchannel is start pending cause the operation to be canceled before initiation at the device. In this case, the subchannel is made status pending with primary, secondary, and alert status, with channel-data check indicated, and with the ESW failing-storage address stored.

Whenever channel-data check is indicated, no measurement data for the subchannel is stored.

Channel-Control Check

Channel-control check is caused by any machine malfunction affecting channel-subsystem controls. The condition includes invalid CBC on a CCW, an IDAW, a MIDAW, or the respective associated key. The condition may be indicated when an invalid CBC is detected on a prefetched CCW, IDAW, MIDAW, or the respective associated key, even if that CCW, IDAW, or MIDAW is not used.

Channel-control check may also indicate that an error has been detected in the information transferred to or from main storage during an I/O operation. However, when this condition is detected, the error has occurred inboard of the channel path: in the channel subsystem or in the path between the channel subsystem and main storage.

Detection of the channel-control-check condition causes the current operation, if any, to be terminated immediately. The subchannel is made status pending with primary and alert status or with primary, secondary, and alert status as a function of the type of termination, the current subchannel state, and the device status presented, if any. When the channel subsystem recognizes a channel-control-check condition, any previously existing intermediate interruption condition caused by a PCI flag in a CCW may or may not be recognized by the channel subsystem. The count and data-address fields of the SCSW stored by TEST SUBCHANNEL pertain to the operation terminated. The extended-status-word-format bit is one, and subchannel-logout information is stored in the ESW, when TEST SUBCHANNEL is executed.

Whenever the channel-control-check condition pertains to an invalid CBC detected on a prefetched CCW, a prefetched IDAW, a prefetched MIDAW, or the key associated with the prefetched CCW, the prefetched IDAW, or the prefetched MIDAW, an extended-report word with bit 6 set to one, and the failing-storage address, are stored in the ESW when TEST SUBCHANNEL is executed.

Channel-control-check conditions encountered while prefetching when the subchannel is start pending cause the operation to be canceled before initiation at the device. In this case, the subchannel is made status pending with primary, secondary, and alert status, with channel-control check indicated, and with a failing-storage address that will be stored in the ESW.

If a subchannel is halt pending and the channel subsystem encounters a channel-control-check condition while performing the halt function for that subchannel, the subchannel remains halt pending unless the channel subsystem can determine that the halt signal was issued. The subchannel remains halt pending even if the channel subsystem was attempting to issue the halt signal and is unable to determine if the halt signal was issued.

If a subchannel is start pending or resume pending and the channel subsystem encounters a channel-control-check condition while performing the start function for that subchannel, the subchannel remains start pending or resume pending unless the channel subsystem can determine that the first command was accepted. The subchannel remains start pending or resume pending even if the channel subsystem was attempting to initiate the I/O operation for the first command and is unable to determine if the command was accepted. If the channel subsystem is unable to determine whether the first command was accepted, the subchannel is made status pending with at least alert and primary status.

In some situations in which a channel-subsystem malfunction exists, the channel-control-check condition may be reported as a machine-check condition.

Whenever channel-control check is indicated, no measurement data for the subchannel is stored.

Programming Note: If the status-control field of the SCSW indicates that the subchannel is status pending with alert status but the field-validity flags of the SCSW indicate that the device-status field is not usable for error-recovery purposes, the program should (1) assume that the channel-control-check condition occurred while the channel subsystem was accepting alert status from the device and (2) take the appropriate action for alert status, even though the status itself has been lost.

Interface-Control Check

Interface-control check indicates that an invalid signal has occurred on the channel path. The condition is detected by the channel subsystem and usually indicates malfunctioning of an I/O device. Interface-control check can occur for any of the following reasons:

1. A data or status byte received from a device while the subchannel is subchannel-and-device

active or device active has an invalid checking-block code.

2. The status byte received from a device while the subchannel is idle, start pending, suspended, or halt pending has an invalid checking-block code.
3. A device responded with an address other than the address designated by the channel subsystem during initiation of an operation.
4. During command chaining, the device appeared not operational.
5. A signal from an I/O device either did not occur or occurred at an invalid time or had an invalid duration.
6. The channel subsystem recognized the I/O-error-alert condition (see "I/O-Error Alert (A)" on page 16-50).
7. ESW bit 26, indicating device-status check, is set to one.

Detection of an interface-control check during a CCW-type IPL I/O operation on a machine that retries IPL I/O operations on an alternate channel path causes the channel subsystem to terminate operations on the current channel path and to retry the IPL I/O operation on another logically-available channel path to the designated device, if one is available, without causing the subchannel to become status-pending. (See "CCW-type IPL" on page 17-17 for additional information.) In all other cases and when an interface-control check has been detected for a CCW-type IPL operation on all logically-available channel paths to the designated device, detection of the interface-control-check condition causes the current operation, if any, to be terminated immediately, and the subchannel is made status pending with alert status, primary and alert status, secondary and alert status, or primary, secondary, and alert status as a function of the type of termination, the current subchannel state, and the device status presented, if any. When the channel subsystem recognizes an interface-control-check condition, any previously existing intermediate interruption condition caused by a PCI flag in a CCW may or may not be recognized by the channel subsystem. The extended-status-word-format bit is one, and subchannel-logout information is stored in the ESW, when TEST SUBCHANNEL is executed.

If a subchannel is halt pending and the channel subsystem encounters an interface-control-check condition while performing the halt function for that subchannel, the subchannel remains halt pending unless the channel subsystem can determine that the halt signal was issued. The subchannel remains halt pending even if the channel subsystem was attempting to issue the halt signal and is unable to determine if the halt signal was issued.

If a subchannel is start pending or resume pending and the channel subsystem encounters an interface-control-check condition while performing the start function for that subchannel, the subchannel remains start pending or resume pending unless the channel subsystem can determine that the first command was accepted. The subchannel remains start pending or resume pending even if the channel subsystem was attempting to initiate the I/O operation for the first command and is unable to determine if the command was accepted. If the channel subsystem is unable to determine whether the first command was accepted, the subchannel is made status pending with at least alert and primary status.

If, while initiating a signaling sequence with the channel subsystem for the purpose of presenting status or transferring data, the device presents an address with invalid parity, the error condition is not made available to the program since the identity of the device and associated subchannel are unknown.

Whenever interface-control check is indicated, no measurement data for the subchannel is stored.

Programming Note: If the status-control field of the SCSW indicates that the subchannel is status pending with alert status but the field-validity flags of the SCSW indicate that the device-status field is not usable for error-recovery purposes, the program should (1) assume that the interface-control-check condition occurred while the channel subsystem was accepting alert status from the device and (2) take the appropriate action for alert status, even though the status itself has been lost.

Chaining Check

Chaining check is caused by channel-subsystem overrun during data chaining on input operations. The condition occurs when the I/O-data rate is too high for the particular resolution of data addresses. Chaining check cannot occur on output operations.

Detection of the chaining-check condition causes the I/O device to be signaled to conclude the operation. It causes command chaining to be suppressed.

Count Field

Bit positions 16-31 of word 2 contain the residual count. The count is to be used in conjunction with the original count specified in the last CCW and, depending upon existing conditions (see Figure 16-7 on page 16-32), indicates the number of bytes transferred to or from the area designated by the CCW. The count field is meaningful whenever the subchannel is status pending with primary status that consists of either (1) device status only or (2) device status together with subchannel status of incorrect length only, PCI only, or both.

In Figure 16-7 on page 16-32, the contents of the count field are listed for all cases where the subchannel is start pending, subchannel-and-device active, device active, suspended, or status pending.

Subchannel State[1]	Count[2]
Start pending (UUUU0/AIPSX)[2]	Not meaningful[3]
Start pending and status pending (10YY1/AIPSX)[2]	Not meaningful[3]
Start pending and status pending (00111/AIPSX) because the device appeared not operational on all paths[2]	Not meaningful[3]
Start pending and device active (UUUU0/AIPSX)[2]	Not meaningful[3]
Suspended (YYYYY/AIPSX)[2]	Not meaningful[3]
Subchannel-and-device active (UUUU0/AIPSX)[2]	Not meaningful[3]
Device active (UUUU0/AIPSX)	Not meaningful[3]
Status pending (01001/AIPSX) because of program-controlled-interruption condition or initial-status interruption	Not meaningful[3]
Status pending (1Y1Y1/AIPSX); termination occurred because of:[2]	
Program check	Not meaningful[3]
Protection check	Not meaningful[3]
Chaining check	Not meaningful[3]
channel-control check	See note 1
Interface-control check	Not meaningful[3]
Channel-data check	See note 2
Status pending (YY1Y1/AIPSX); termination occurred under count control[2]	Correct
Status pending (Y0011/AIPSX)[2]	Not meaningful[3]
Status pending (1Y1Y1/AIPSX)[2]	Correct; residual count of last used CCW
Status pending (1Y111/AIPSX); command chaining suppressed because of alert status[2]	Correct; residual count of last used CCW
Status pending (YYYY1/AIPSX); after termination by HALT SUBCHANNEL[2]	Unpredictable
Status pending (00001/AIPSX); after termination by CLEAR SUBCHANNEL	Not meaningful[3]
Status pending (YY1Y1/AIPSX); operation completed normally at the subchannel[2]	Correct; indicates the residual count
Status pending (1Y111/AIPSX); command chaining terminated because of alert status[2]	Correct; original count of CCW specifying the new I/O operation
Status pending (10001/AIPSX) because of alert status	Not meaningful[3]

Figure 16-7. (Part 1 of 2) Contents of Count Field in SCSW

Explanation:

[1] In situations where more than a single condition exists because of, for example, alert status that is described by program check and unit check, the entry appearing first in the table takes precedence.

The meaning of the notation used in this column is as follows:

A Alert status
I Intermediate status
P Primary status
S Secondary status
X Status Pending

The allowed combinations of status-control-bit settings is shown to the left of the "/" symbol by the use of these symbols:

0 Corresponding condition is not indicated
1 Corresponding condition is indicated
U Unpredictable. The corresponding condition is not meaningful when the subchannel is not status pending.
Y The corresponding condition is not significant and is indicated as a function of the subchannel state.

[2] The subchannel may also be resume pending.

[3] The contents of the count field are not meaningful because the count field is not valid when the SCSW is stored and the subchannel is in the given state.

Notes:

1. The count is unpredictable unless IDAW/MIDAW check is indicated, in which case the count may not correctly reflect the number of bytes transferred to or from main storage but will (when used in conjunction with the CCW address) designate a byte location within the page in which the channel-control-check condition was recognized.
2. During a storage access, the maximum number of bytes that can be stored by a channel subsystem is model dependent. If a channel-data-check condition is recognized during that access, the number of bytes transferred to or from storage may not be detectable by the channel subsystem. Consequently, the number of bytes transferred to or from storage may not be correctly reflected by the residual count. However, the residual count that is stored when used in conjunction with the storage-access code and the CCW address designates a byte location within the page in which the channel-data-check condition was recognized.

Figure 16-7. (Part 2 of 2) Contents of Count Field in SCSW

Transport-Mode SCSW

The format of a transport-mode SCSW is as follows:

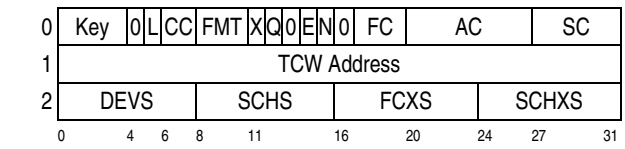

Figure 16-8. Transport-Mode SCSW Format

Figure 16-9 on page 16-34 shows the summary and contents of the transport-mode SCSW:

Bits	Name
Word 0	
0-3	Subchannel Key
4	Reserved
5	ESW format (L)
6-7	Deferred condition code (CC)
8-10	Format (FMT)
11	IRB-Format control (X)
12	Interrogate-complete (Q)
13	Reserved
14	Extended control (E)
15	Path not operational (N)
16	Reserved
17-19	**Function Control (FC)**
17	Start function
18	Halt function
19	Clear function
20-26	**Activity Control (AC)**
20	Reserved
21	Start pending
22	Halt pending
23	Clear pending
24	Reserved
25	Device active
26	Reserved

Figure 16-9. Transport-Mode SCSW

Bits	Name
27-31	**Status Control (SC)**
27	Alert status
28	Intermediate status
29	Primary status

25-31	Subchannel-Extended-Status Qualifier (SESQ)

Figure 16-9. Transport-Mode SCSW (Continued)

The following descriptions indicate when an SCSW field contains meaningful information for a transport-mode IRB.

Subchannel Key
This bit has the same meaning as in the command mode SCSW. (See “Subchannel Key” on page 16-9)**.**

Reserved
SCSW bits 4, 13, 16, 20, 24, and 26 of word 0, bit 0 of word 1, and bits 8 and 16-22 of word 2 are reserved and stored as zeros.

Extended-Status-Word Format (L)
This bit has the same meaning as in the command-mode SCSW. (See “Extended-Status-Word Format (L)” on page 16-9)**.**

Deferred Condition Code (CC)
This field has the same meaning as in the command-mode SCSW. (See “Deferred Condition Code (CC)” on page 16-9).

Format (FMT)
Bits 8-10 of word 0 are the IRB-format field that contains a 3-bit, unsigned integer whose value specifies the layout of the IRB, when the IRB-format control bit (X), is set to one.

FMT	Description
0	Transport-Mode IRB
1-7	Reserved

IRB-Format Control (X)
Bit 11 of word 0 is the IRB-format control bit. The value of this bit is one for the transport-mode IRB. (See Figure 16-2 on page 16-7).

Interrogate Complete (Q)
Bit 12 of word 0 is the interrogate-complete bit (Q). When one, Q indicates that the interrogate operation has completed successfully, and the subchannel is made status-pending with intermediate interruption status. If the pending intermediate interruption condition has not been cleared by TEST SUBCHANNEL by the time the primary interruption condition for the original interrogated operation is presented at the subchannel, both conditions may be merged and indicated together in the SCSW.

Subchannel-Control Field

The subchannel-control information is contained in bit positions 13-31 of the first word of the SCSW.

Extended Control (E)
Bit 14 of word 0, when one, indicates that model-dependent information is stored in the extended-control word (ECW). When bit 14 is zero, the contents of words 0-7 of the ECW are unpredictable. The E bit is meaningful whenever the subchannel is status pending with alert status either alone or together with primary status, secondary status, or both. The concurrent sense information has no meaning when a transport-mode IRB is stored.

Path Not Operational (N)
This bit has the same meaning as in the command-mode SCSW. See “Path Not Operational (N)” on page 16-13**.**

Function Control (FC)
The function-control field indicates the basic I/O functions that are indicated at the subchannel. This field may indicate the acceptance of as many as two functions. The function-control field is contained in bit positions 17-19 of the first word of the SCSW. The function-control field is meaningful at an installed subchannel whenever the subchannel is valid (see “Function Control (FC)” on page 16-13). The function-control field contains all zeros whenever both the activity- and status-control fields contain all zeros. The meaning of the individual bits is as follows:

Start Function (Bit 17): This bit has the same meaning as in the command-mode SCSW. (See “Start Function (Bit 17)” on page 16-13)**.**

Halt Function (Bit 18): When one, bit 18 indicates that a halt function has been requested and is either pending or in progress at the subchannel. A halt function is requested by the execution of HALT SUBCHANNEL. A halt function is indicated at the subchannel when condition code 0 is set for HALT SUBCHANNEL. The halt-function indication is cleared at the subchannel when the next status-pending condition that occurs is cleared by the execution of TEST SUBCHANNEL. The next status-pending condition depends on the state of the subchannel when HALT SUBCHANNEL is executed. If the subchannel is start pending or device active when HALT SUBCHANNEL is executed, then the

next status-pending condition is status pending with at least primary status indicated. The halt-function indication is also cleared at the subchannel during the execution of CLEAR SUBCHANNEL.

Clear Function (Bit 19): This bit has the same meaning as in the command-mode SCSW. (See "Clear Function (Bit 19)" on page 16-14)**.**

Activity Control (AC)

The activity-control field is contained in bit positions 20-26 of word 0 of the SCSW. The activity-control field is meaningful at an installed subchannel whenever the subchannel is valid (see "Device Number Valid (V)" on page 15-4). However, if an IFCC or CCC condition is detected during the performance of a basic I/O function and that function is indicated as pending, I/O operations may or may not have been performed at the device. The activity-control bits are defined as follows:

Bit	Meaning
20	Reserved
21	Start pending
22	Halt pending
23	Clear pending
24	Reserved
25	Device active
26	Reserved

Start Pending (Bit 21): This bit has the same meaning as in the command-mode SCSW with the exception that the subchannel remains start pending until a primary interruption condition is generated. (See "Start-Pending (Bit 21)" on page 16-15)**.**

Halt Pending (Bit 22): This bit has the same meaning as in the command-mode SCSW. (See "Halt-Pending (Bit 22)" on page 16-16)**.**

Clear Pending (Bit 23): This bit has the same meaning as in the command-mode SCSW. (See "Clear-Pending (Bit 23)" on page 16-16)**.**

Device Active (Bit 25): When one, bit 25 indicates that the subchannel is device active. A subchannel is said to be device active when an I/O operation is currently in progress at the associated device. The subchannel becomes device active, only when primary status is presented without secondary.

Status Control (SC)

The status-control field is contained in bit positions 27-31 of word 0 of the SCSW. This field provides the program with a summary-level indication of the interruption condition described by either subchannel or device status or the Q bit. More than one summary indication may be signaled as a result of existing conditions at the subchannel. Whenever the subchannel is enabled (see "Enabled (E)" on page 15-3) and at least bit 31 is one, the subchannel is said to be status pending. Whenever the subchannel is disabled, the subchannel is not made status pending. Bit 31 of SCSW word 0 is meaningful at an installed subchannel whenever the subchannel is valid (see "Device Number Valid (V)" on page 15-4); bits 27-30 are meaningful when bit 31 is one.The status-control bits are defined as follows:

Alert Status (Bit 27): This bit has the same meaning as in the command-mode SCSW with the exception that a command-mode IRB is stored when alert status is presented with secondary status. (See "Alert Status (Bit 27)" on page 16-17).

Intermediate Status (Bit 28): Intermediate status can be indicated when the interrogate operation associated with the TCW is completed, and the Q-bit (interrogate-complete) is one.

Primary Status (Bit 29): This bit has the same meaning as in the command-mode SCSW. (See "Primary Status (Bit 29)" on page 16-19).

Secondary Status (Bit 30): This bit has the same meaning as in the command-mode SCSW. (See "Secondary Status (Bit 30)" on page 16-19).

Status Pending (Bit 31): This bit has the same meaning as in the command-mode SCSW. (See "Status-Pending (Bit 31)" on page 16-19).

TCW Address Field

Bits1-31 of word 1 form an absolute address of a TCW. The TCW address indicated is the address of the current TCW when the subchannel becomes pending with primary interruption. When the subchannel-status field indicates channel-control check, channel-data check, program check or interface-control check, the TCW-address field is usable for recov-

ery purposes if the TCW-address field-validity flag in the ESW is one.

Subchannel State	TCW Address
Start pending (UUUU0/AIPSX)	Unpredictable
Start pending and device active (UUUU0/AIPSX)	Unpredictable
Subchannel-and-device active (UUUU0/AIPSX)	N/A
Device active only (UUUU0/AIPSX)	Unpredictable
Suspended (YYYYY/AIPSX)	N/A
Status pending (10001/AIPSX) because of unsolicited alert status from the device while the subchannel was start pending	Address of current TCW[3]
Status pending (0Y111/AIPSX) because the device appeared not operational on all paths	Address of current TCW[3]
Status pending (10011/AIPSX) because of solicited alert status from the device while the subchannel was start pending and device active	Address of current TCW[3]
Status pending (10111/AIPSX) because of solicited alert status generated by the channel subsystem while the subchannel was start pending or start pending and device active	See note 2
Status pending (01001/AIPSX) for the program-controlled-interruption condition while the subchannel was subchannel-and-device active	N/A
Status pending (01001/AIPSX) for the initial-status-interruption condition while the subchannel was subchannel-and-device active	N/A
Status pending (01001/AIPSX) for the intermediate/interrogate	Address of current TCW[2]
Status pending (1Y1Y1/AIPSX); termination occurred because of program check caused by one of the following conditions:	
Bit 24 of word 1 of the ORB set to one; incorrect-length-indication-suppression facility not installed	N/A
Unused bits in ORB not set to zeros	Address of current TCW[2]
Invalid TCW-address specification in the channel-program address in the ORB	Address of invalid TCW
Invalid TCW address in the channel-program address in the ORB	Address of invalid TCW
Invalid TCW address while DCW data chaining	N/A
Invalid TCW count or TIDAW count	Address of invalid TCW[4]
Invalid TIDAW-address specification	Address of invalid TCW[4]
Invalid TIDAW address in TCW	Address of invalid TCW[4]
Invalid TIDAW address while sequentially fetching TIDAWs	N/A
Invalid data-address specification	Address of invalid TCW[4]
Invalid data address in a TCW	Address of invalid TCW[4]
Invalid data address while sequentially accessing storage	Address of current TCW
Invalid data address in TIDAW	Address of current TCW
Invalid TIDAW	Address of current TCW

Figure 16-10. (Part 1 of 3) TCW Address as Function of Subchannel State

Subchannel State	TCW Address
Invalid TSB-address specification	Address of current TCW
Invalid TSB address	Address of current TCW
Invalid TCCB address specification	Address of current TCW
Invalid TCCB address	Address of current TCW
Device-detected program checks	Address of current TCW
Status pending (1Y1Y1/AIPSX); termination occurred because of protection check detected as follows:	
On a TCW access	Address of protected TCW[4]
On data or an TIDAW access	Address of current TCW
Status pending (1Y1Y1/AIPSX); termination occurred because of chaining check	N/A
Status pending (YY1Y1/AIPSX); termination occurred under count control	Address of current TCW
Status pending (1Y1Y1/AIPSX); operation prematurely terminated by the device because of alert status	Address of current TCW[3]
Status pending (YYYY1/AIPSX) after termination by HALT SUBCHANNEL and the activity-control-field bits indicated below set to ones:	
Status pending alone	Unpredictable
Start pending	Unpredictable
Device active and start pending	Unpredictable
Device active	Unpredictable
Status pending (00001/AIPSX) after termination by CLEAR SUBCHANNEL	Unpredictable
Status pending (YY1Y1/AIPSX); operation completed normally at the subchannel	Address of current TCW
Status pending (00011/AIPSX)	Unpredictable
Status pending (10001/AIPSX)	Unpredictable
Status pending (00001/AIPSX)	Unpredictable
Status pending (1Y111/AIPSX); command chaining suppressed because of alert status other than channel-control check or interface-control check	N/A
Status pending (1YYY1/AIPSX) because of alert status for channel-control check or interface-control check	See note 3
Status pending (1Y1Y1/AIPSX) because of channel-data check	Address of current TCW
Status pending (1Y1Y1/AIPSX) because of channel-subsystem retry failed	Address of current TCW

Explanation:

[1] The meaning of the notation used in this column is as follows:
- A Alert status
- I Intermediate status
- P Primary status
- S Secondary status
- X Status Pending

Figure 16-10. (Part 2 of 3) TCW Address as Function of Subchannel State (Continued)

Subchannel State	TCW Address
The possible combination of status-control-bit settings is shown to the left of the "/" symbol by the use of these symbols: 0 Corresponding condition is not indicated 1 Corresponding condition is indicated U Unpredictable. The corresponding condition is not meaningful when the subchannel is not status pending. Y The corresponding condition is not significant and is indicated as a function of the subchannel state.	
[2] A TCW becomes current when start subchannel is issued, specifying a transport-mode ORB, and the instruction completes with condition code 0.	
[3] Command-mode IRB may be stored depending on the current subchannel status	
[4] The stored address is the address of the current TCW even though it is either invalid or protected.	
[5] Not applicable	

Notes:

1. The address stored is unpredictable.
2. The address of the TCW is given as a function of the alert status indicated.
3. Bit 21 of the subchannel-logout information, when stored as one, indicates that the address is the address of the current TCW.

Figure 16-10. (Part 3 of 3) TCW Address as Function of Subchannel State (Continued)

Device-Status Field

The device-status field is contained in bit positions 0-7 of word 2 of the SCSW. Each bit of the device-status field has the same meaning as in the command-mode SCSW. See "Device-Status Field" on page 16-24 for details.

Subchannel-Status Field

The subchannel-status field is contained in bit positions 8-15 of word 2 of the SCSW. Subchannel-status conditions are detected and indicated in the SCSW by the channel subsystem. Except for the conditions caused by equipment malfunctioning, they can occur only while the channel subsystem is involved with the performance of a halt or start function. The subchannel-status field is meaningful whenever the subchannel is status pending with any combination of primary, secondary, intermediate, or alert status. When the subchannel is status pending with deferred condition code 3 indicated, the contents of the subchannel-status field are not meaningful. The following subchannel-status conditions are described:

Incorrect Length

Incorrect length occurs when the number of bytes contained in the storage areas assigned for the I/O operation is not equal to the number of bytes requested or offered by the I/O device.

When the FCX-incorrect-length-indication facility is not installed and an incorrect-length condition is detected, the processing of the transport-mode channel program is terminated with program-check status.

When the FCX-incorrect-length-indication facility is installed, the device supports incorrect-length indication, incorrect-length-indication is not being suppressed, and an incorrect-length condition is detected, incorrect length is indicated for one of the following reasons:

Long Block on Input: During a read or sense operation, the device attempted to transfer one or more bytes to main storage after the assigned main-storage areas were filled, or the device indicated that more data could have been transferred if the count had been larger. The extra bytes have not been placed in main storage. The count in the TSB header (TSH) is zero.

Long Block on Output: During a write operation, the device requested one or more bytes from the channel subsystem after the assigned main-storage areas were exhausted, or the device indicated that more data could have been transferred if the count had been larger. The count in the TSH is zero.

Short Block on Input: The number of bytes transferred during a read or sense operation is insufficient to fill the main-storage areas assigned to the operation. The count in the TSH is not zero.

Short Block on Output: The device terminated a write before all of the information contained in the assigned main-storage areas was transferred to the device. The count in the TSH is not zero.

The incorrect-length indication is suppressed when the current DCW has the SLI flag set to one. The incorrect-length indication is not meaningful when the count field of the TSH is not meaningful.

Presence of the incorrect-length condition suppresses command chaining unless the SLI flag in the DCW is one.

Program Check

Program check occurs when programming errors are detected by the channel subsystem. For a transport-mode operation, programming errors may also be detected by the I/O device and are reported as program checks. When a program check condition is recognized, additional information may be available in the "Subchannel-Extended-Status Qualifier (SESQ)" section of the subchannel-extended-status field when a program check is indicated.

Whenever the program-check condition pertains to the fetching of data, the failing-storage-address validity flag, bit 6 of the ERW, is one. An address of a location within the checking block for which the program-check condition is generated is stored in the ESW failing-storage-address field.

A program check condition can be due to any of the following reasons:

Invalid TCW Specification: When any of the following conditions is detected, an invalid TCW specification is recognized:

1. A reserved field that is checked for zeros in the TCW does not contain zeros.
2. A nonzero value is specified in the TCW format field.
3. The read and write bits in the TCW are both one, bit 10 of the TCW flags field is zero, and either or both of the following are true.
   - The FCX-bidirectional-data-transfer facility is not installed.
   - The specified device does not support bidirectional data transfers.
4. The TCCB-length field in a TCW specifies a length that is less than 12 or greater than 244.

Invalid TCW-Address Specification: An invalid TCW address specification can occur because the TCW address is not designated on a 64-byte boundary.

Invalid TCW Address: The channel-subsystem has attempted to fetch a TCW from a main-storage location that is not available. An invalid TCW address can occur because the program has designated an invalid address in the channel-program-address field of the transport-mode ORB, when the B-bit (channel-program-type control), is one. A main-storage location is unavailable when the absolute TCW address does not correspond to a physical location.

Invalid TCW Counts: When any of the following conditions is detected by the channel subsystem, an invalid TCW byte count is recognized:

1. The write-bit is one in the TCW and the value in the TCW output-count field is zero.
2. The read-bit is one in the TCW and the value in the TCW input-count field is zero.

Invalid TSB-Address Specification: An invalid transport-status-block address specification can occur if the content of the transport-status-block-address field specified in the TCW does not designate a storage location on a doubleword boundary.

Invalid TSB Address: The channel-subsystem has attempted to store a TSB to a main-storage location that is not available. An invalid transport-status-block address can occur because the program has designated an unavailable location in a TCW, or the channel-subsystem has attempted to store the transport status to a main-storage location that is not available. A main-storage location is unavailable when the absolute address of the location does not correspond to a physical location.

Invalid TCCB Address: The channel-subsystem has attempted to fetch a TCCB from a main-storage location that is not available. An invalid transport-command-control-block address can occur because

the program has designated an unavailable location in a TCW, or has specified a transport-command-control-block address and a length which caused a list of TIDAW to cross a 4 K-byte when the transport-command-control-block-TIDA flag in the TCW is one. A main-storage location is unavailable when the absolute address of the location does not correspond to a physical location. ***Invalid TIDAW-Address Specification:*** Transport-indirect data addressing is specified, and any of the following conditions is detected:

1. A write operation is requested, the output-TIDA flag in a TCW is one, and the contents of the output-data-address field in the TCW do not designate a storage location on a quadword boundary.
2. A read operation is requested, the input-TIDA flag in a TCW is one, and the contents of the input-data-address field in the TCW do not designate a storage location on a quadword boundary.
3. The transport-command-control-block-TIDA flag in the TCW is one, and the contents of the transport-command-control-block-address do not designate a storage location on a quadword boundary.

Invalid Data Address: An invalid data address can occur because the program has designated an unavailable location specified by a TCW or a TIDAW. When any of the following conditions is detected, an invalid data address is recognized by the channel subsystem.

1. The channel-subsystem has attempted to access a main-storage location that is not available. A main-storage location is unavailable when the absolute address of the location does not correspond to a physical location.
2. The channel subsystem, on sequentially accessing storage for a data fetch or data store, attempted to access an unavailable location.
3. Use of the data address has caused the channel subsystem to attempt to wrap from the maximum storage address to zero.

Invalid TIDAW Specification: When the use of TIDAW is specified, an invalid TIDAW specification is recognized when any of the following conditions is detected by the channel subsystem:

1. Any of the bits defined as reserved in the TIDAW are not zero.
2. The TIDAW-transfer-in-channel flag (TTIC) in a TIDAW is one, and one or more other flag bits are also one.
3. The TTIC points to a TIDAW in which the TTIC flag is one.
4. The TIDAW count field contains zeros when the TTIC flag is zero.
5. The combination of a TIDAW data-address and count fields specify data that crosses a 4 K-byte block boundary, when skipping is not in effect.
6. The count value specified in the TIDAW in which the last-TIDAW flag is one and the value for either input-count or output-count specified in a TCW did not both decrement to zero for the same byte of data transferred.
7. For a read operation only, the TIDAW in control has its data-transfer-interruption control flag set to one when data transfer was attempted by the device.
8. The TIDAW is in the TIDAW list designated by the TCCB-address field in the TCW and the count field of the TIDAW contains either a value that is zero or a value that is not evenly divisible by four.

Invalid TIDAW Address: The channel-subsystem has attempted to fetch a TIDAW from a main-storage location that is not available. An invalid TIDAW address can occur because the program has designated an invalid address in a TCW that specifies TIDAW addressing, or because the channel subsystem, on sequentially fetching TIDAWs, attempts to fetch from an unavailable location. A main-storage location is unavailable when the absolute address of the location does not correspond to a physical location.***Storage-Requests Limit Exceeded:*** The use of TIDAWs is specified, and the model-dependent maximum number of storage requests required to satisfy the transfer of a block of data has been reached.

Max Data-Count Exceeded: The model-dependent maximum count of data for a single transport-control area (TCA) has been reached or exceeded for the current operation.

Device-Detected Program Check: Device-detected program checks are errors detected during a transport-mode operation by the I/O device and the channel-subsystem is requested to present a program-check condition. When a device-detected-program-check condition is recognized, additional information is available in the subchannel-extended status field, and the TSB is stored with a transport-status-area format of two. (See device-detected-program check in chapter 15.)

Protection Check

Protection check occurs when the channel subsystem attempts a storage access that is prohibited by the protection mechanism. A protection check condition is indicated as a result of a storage operation that detects any of the following errors:

1. Protection applies to the fetching of TCW.
2. Protection applies to the fetching of TCCB.
3. Protection applies to the fetching of TIDAWs.
4. Protection applies to the fetching of output data.
5. Protection applies to the storing of input data.

The subchannel key provided in the transport-mode ORB is used as the access key for storage accesses associated with an I/O operation except for the TSB store.

Detection of the protection-check condition during the fetching of a TCW, TCCB, or a TIDAW would cause the operation to be suppressed and the subchannel to be made status pending with primary, secondary, and alert status. When protection check is detected after the I/O operation has been initiated at the device, the device may be signaled to conclude the operation. Other indications may accompany the protection-check indication as a function of the operation specified by the TCW, the status received from the device, on a read operation, and the current state of the subchannel. The protection-check condition may or may not causes the execution of subsequent DCWs in a TCCB to be suppressed.

Whenever the protection-check condition pertains to the fetching of data, the failing-storage-address validity flag, bit 6 of the ERW, is one. An address of a location within the checking block for which the protection-check condition is generated is stored in the ESW failing-storage-address field.

Additional information may be available in the “Subchannel-Extended-Status Qualifier (SESQ)” section of the subchannel-extended-status field when a protection check condition check is indicated.

Channel-Data Check

Channel-data check indicates that an uncorrected storage error has been detected in regard to data, contained in main storage, that is currently used in the performance of an I/O operation. Channel-data check is indicated when data has an invalid checking-block code (CBC) in main storage when that data is referenced by the channel subsystem.

On an input operation, when the channel subsystem attempts to store less than a complete checking block, and invalid CBC is detected on the checking block in storage, the contents of the location remain unchanged and with invalid CBC. On an output operation, whenever channel-data check is indicated, no bytes from the checking block with invalid CBC are transferred to the device.

During a storage access, the maximum number of bytes that can be transferred is model dependent. If a channel-data-check condition is recognized during that storage access, the number of bytes transferred to or from storage may not be detectable by the channel subsystem. Consequently, the number of bytes transferred to or from storage may not be correctly reflected by the residual count. When a channel-data-check condition is recognized during a storage access, the channel subsystem stores the address where the storage exception is encountered.

A condition indicated as channel-data check causes the current operation, if any, to be terminated. The subchannel becomes status pending with primary, secondary and alert status, as a function of the status received from the device. The TCW address field of the SCSW stored by TEST SUBCHANNEL pertain to the operation terminated. The extended-status-word-format bit is one, and subchannel-logout information is stored in the ESW, when TEST SUBCHANNEL is executed.

Whenever the channel-data-check condition pertains to the fetching of data, the failing-storage-address-validity flag, bit 6 of the ERW, is one. An address of a location within the checking block for which the channel-data-check condition is generated is stored in the ESW failing-storage-address field.

Uncorrectable storage or key errors detected during data access causes the operation to be terminated. In this case the subchannel is made status pending with primary, secondary, and alert status, with channel-data check indicated, and with the ESW failing-storage address stored.

Whenever channel-data check is indicated, no measurement data for the subchannel is stored. The transport-status block may or may not be stored. Additional information may be available in the "Subchannel-Extended-Status Qualifier (SESQ)" section of the subchannel-extended-status field.

Channel-Control Check

Channel-control check is caused by any machine malfunction affecting channel-subsystem controls. The condition may be indicated when an invalid CBC is detected on a TCW, TIDAW, TCCB, TSB, or the respective associated key.

Channel-control check may also indicate that an error has been detected in the information transferred to or from main storage during an I/O operation. However, when this condition is detected, the error has occurred inboard of the channel path: in the channel subsystem or in the path between the channel subsystem and main storage.

Detection of the channel-control-check condition causes the current operation, if any, to be terminated immediately. The subchannel is made status pending with primary and alert status or with primary, secondary, and alert status as a function of the type of termination, the current subchannel state, and the device status presented, if any. When the channel subsystem recognizes a channel-control-check condition, any previously existing intermediate interruption condition may or may not be recognized by the channel subsystem.

Whenever the channel-control-check condition pertains to an invalid CBC detected on fetching a TCW or a TCCB, or a TIDAW or storing a TSB, an extended-report word with bit 6 set to one, and the failing-storage address, are stored in the ESW when TEST SUBCHANNEL is executed.

Channel-control-check conditions encountered while fetching when the subchannel is start pending cause the operation to be terminated. In this case, the subchannel is made status pending with primary, secondary, and alert status, with channel-control check indicated, and with a failing-storage address that is stored in the ESW.

If a subchannel is halt pending and the channel subsystem encounters a channel-control-check condition while performing the halt function for that subchannel, the subchannel remains halt pending unless the channel subsystem can determine that the halt signal was issued. The subchannel remains halt pending even if the channel subsystem was attempting to issue the halt signal and is unable to determine if the halt signal was issued.

If a subchannel is start pending and the channel subsystem encounters a channel-control-check condition while performing the start function for that subchannel, the subchannel is made status pending with at least alert and primary status.

In some situations in which a channel-subsystem malfunction exists, the channel-control-check condition may be reported as a machine-check condition.

Whenever channel-control check is indicated, no measurement data for the subchannel is stored. The transport-status block may or may not be stored. Additional information may be available in the "Subchannel-Extended-Status Qualifier (SESQ)" section of the subchannel-extended-status field.

Interface-Control Check

Interface-control check indicates that an invalid signal has occurred on the channel path. The condition is detected by the channel subsystem and usually indicates malfunctioning of an I/O device. Interface-control check can occur for any of the following reasons:

1. A data or status byte received from a device has an invalid checking-block code.
2. A signal from an I/O device either did not occur or occurred at an invalid time.
3. ESW bit 26, indicating device-status check, is set to one.
4. A failed interrogate function or a recovery operation.
5. The TCW residual count did not match the residual count in the response from the device.

When the channel subsystem recognizes an interface-control-check condition, any previously existing

intermediate interruption condition may or may not be recognized by the channel subsystem. The extended-status-word-format bit is one, and subchannel-logout information is stored in the ESW, when TEST SUBCHANNEL is executed.

If a subchannel is halt pending and the channel subsystem encounters an interface-control-check condition while performing the halt function for that subchannel, the subchannel remains halt pending unless the channel subsystem can determine that the halt signal was issued. The subchannel remains halt pending even if the channel subsystem was attempting to issue the halt signal and is unable to determine if the halt signal was issued.

If a subchannel is start pending and the channel subsystem encounters an interface-control-check condition while performing the start function for that subchannel, the subchannel is made status pending with at least alert and primary status.

Whenever interface-control check is indicated, no measurement data for the subchannel is stored. The transport-status block may or may not be stored. Additional information may also be available in the "Subchannel-Extended-Status Qualifier (SESQ)" section of the subchannel-extended-status field.

Channel-Subsystem Retry Failed

Channel-subsystem retry failed indicates that internal channel-subsystem conditions exist that prevent the fetching of the TCCB, a TIDAW, or data. The channel subsystem retried the fetch and the retry failed.

FCX-Status Field

The FCX-status field is contained in bit positions 16-23 of word 2 of the SCSW. This field contains channel specific status information returned by the I/O device.

TSB Valid (Bit 23): Bit 23, when set to one, indicates that additional status information for the I/O operation designated by the subchannel is available in the transport-status block. When zero, the contents of the transport-status block do not contain any additional status information for the completed I/O operation.

Subchannel-Extended-Status Field

The subchannel-extended-status field is contained in bit positions 24-31 of word 2 of the SCSW. This field may contain information used to further qualify the reason for any the following conditions, when indicated in the subchannel-status: interface-control check, channel-control check, channel-data check, program check, and protection check. If none of these bits are active in the subchannel-status byte, the fields of the subchannel-extended-status contain no meaningful information. When more than one condition is indicated, the interface-control check takes priority over the other conditions.

Interrogate Failed (F): Bit 24 is the interrogate-failed operation bit. When set to one, the F bit indicates that an interrogate operation failed because of a program check, channel-control check, or interface-control check.

Subchannel-Extended-Status Qualifier (SESQ): Bits 25-31 are the subchannel-extended-status qualifier and contain an unsigned integer value. When the subchannel-status field indicates program check, interface-control check, protection check, data check, or channel-control check, bits 25-31 may contain additional information as follows:

Value	Description	IFCC	CCC	CDC	PGC	PTC	
0	No status available for the exception condition indicated.	X	X	X	X	X	
1	Storage-request limit exceeded, a model-dependent number of storage requests has been exceeded for the requested block of data.	-	-	-	X	-

IFCC	Interface-control check
CCC	Channel-control check
CDC	Channel-data check
PGC	Program check
PTC	Protection check

Footnotes:

a	The failing-storage-address (FSA) field in the ESW is valid and contains the address of the TIDAW which was determined to be invalid.
b	The FSA field is valid and contains the address of the current TCW.
c	The FSA field is valid and contains the address of the TSB designated by the current TCW.
d	The FSA field is valid and contains the address of the TCCB designated (directly or indirectly) by the TCW.
e	The FSA field is valid and contains the address of the TIDAW for which the exception was detected.
f	The FSA field is valid and contains the address of the input or output data designated (directly or indirectly) by the TCW.
Note:	If the FSA field is valid for any SESQ value other than those identified by footnotes a-f, the FSA field contains the address of the current TCW.

Figure 16-11. Subchannel-Extended Status Qualifiers (Continued)

Extended-Status Word

The extended-status word (ESW) provides additional information to the program about the subchannel and its associated device. The ESW is placed in words 3-7 of the IRB designated by the second operand of TEST SUBCHANNEL when TEST SUBCHANNEL is executed and the subchannel designated is operational. If the subchannel is status pending or status pending with any combination of primary, secondary, intermediate, or alert status (except as noted in the next paragraph) when TEST SUBCHANNEL is executed, the ESW may have any of the following types of extended-status format:

Format 0 Subchannel logout in word 0, an ERW in word 1, a failing-storage address or zeros in words 2 and 3, and a secondary-CCW address or zeros in word 4.

Format 1 Zeros in bytes 0, 2, and 3 of word 0, the LPUM in byte 1 of word 0, an ERW in word 1, and zeros in words 2-4.

Format 2 Zeros in byte 0, the LPUM in byte 1, and the device-connect time in bytes 2 and 3 of word 0; an ERW in word 1; zeros in words 2-4.

Format 3 Zeros in byte 0, the LPUM in byte 1, and unpredictable values in bytes 2 and 3 of word 0; an ERW in word 1; zeros in words 2-4.

Words 0-4 of the ESW contain unpredictable values if any of the following conditions is met:

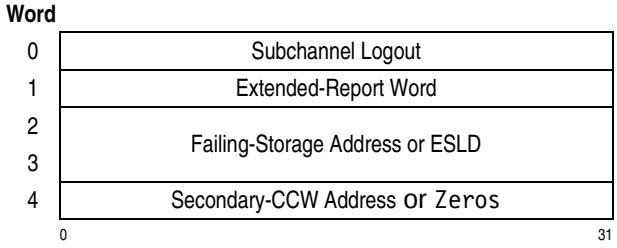
1. The subchannel is not status pending.
2. The subchannel is status pending alone, and the extended-status-word-format bit is zero.
3. The subchannel is status pending with intermediate status alone for other than the intermediate interruption condition due to suspension.

The type of extended-status format stored depends upon conditions existing at the subchannel at the time TEST SUBCHANNEL is executed. The conditions under which each of the types of formats is stored are described in the remainder of this section.

Extended-Status Format 0

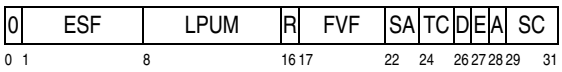
The ESW stored by TEST SUBCHANNEL is a format-0 ESW when the extended-status-word-format bit, bit 5 of word 0 of the SCSW, is one and the subchannel is status pending with any combination of status as defined in Figure 16-12 on page 16-51. In this case, subchannel-logout information and an ERW are stored in the extended-status word. Subchannel logout provides detailed model-independent information relating to a subchannel and describing equipment errors detected by the channel subsystem. The information is provided to aid the recovery of an I/O operation, a device, or both. Whenever subchannel logout is provided, the error conditions relate only to the subchannel reporting the error. If I/O operations involving other subchannels have been affected by the error condition, those subchannels also provide similar subchannel-logout information. An extended-report word provides additional information relating to the cause of the malfunction.

A format-0 ESW has the following format:



Subchannel Logout

The subchannel logout has the following format:



Extended-Status Flags (ESF): Any of bits 1-7, when one, specifies that an error-check condition has been detected by the channel subsystem. The following indications are provided in the ESF field:

Key Check. Bit 1, when one, indicates that the channel subsystem, when accessing data, when attempting to update the measurement block, or when attempting to fetch either a CCW, an IDAW, MIDAW, TCW, TCCB, TIDAW, or when accessing a TSB, has detected an invalid checking-block code (CBC) on the associated storage key. The channel-data-check bit, bit 12 of word 2 of the

SCSW, the measurement-block data-check bit, bit 3 of word 0 of the ESW, the CCW-check bit, bit 5 of word 0 of the ESW, or the IDAW/MIDAW-check bit, bit 6 of word 0 of the ESW, identifies the source of the key error.

Note: This condition may be indicated to the program when an invalid checking-block code on a key is detected but the data, CCW, IDAW, TIDAW, or MIDAW then is not used after being prefetched. In this case, the failing-storage-address-validity bit, bit 6 of the ERW, is one, indicating that the address of a location within the storage block having the key is stored in words 2 and 3 of the ESW.

Measurement-Block Program Check. Bit 2, when one, indicates that the channel subsystem, in attempting to update the measurement block, has either detected an invalid absolute address when combining the measurement-block origin with the measurement-block index for this subchannel or has detected an invalid measurement-block address at the subchannel.

Measurement-Block Data Check. Bit 3, when one, indicates that a malfunction has been detected involving the data of the measurement block in main storage. (See "Measurement Block" on page 17-3.) Measurement-block data check is indicated when the measurement block is updated and an invalid checking-block code (CBC) is detected on the storage used to contain the measurement data or on the associated key. When invalid CBC on the associated key is detected, the key-check bit, bit 1 of the ESF field, is also stored as one.

Measurement-Block Protection Check. Bit 4, when one, indicates that the channel subsystem, when attempting to update the measurement block, has been prohibited from accessing the measurement block because the storage key does not match the measurement-block key (see "Measurement Block" on page 17-3.) The key provided by SET CHANNEL MONITOR is used for the access of storage associated with measurement-block-update operations (see "SET CHANNEL MONITOR" on page 14-13.).

Note: Whenever any of the measurement-check conditions is indicated by bits 2-4, the channel subsystem sets the subchannel measurement-block-update-enable bit to zero, disabling the storing of measurement data for the subchannel (see "Measurement-Mode Enable (MM)" on page 15-3).

CCW Check. When a command-mode IRB is stored, bit 5, when one, indicates that an invalid CBC on the contents of the CCW or its associated key has been detected. When either of these conditions is detected, the I/O operation is terminated, the subchannel becomes status pending with primary and alert status, the extended-status-word-format bit in the SCSW is stored as one, and channel-control check is indicated in the subchannel-status field. The subchannel also becomes status pending with secondary status as a function of the type of termination or status received from the device. When invalid CBC on the associated key is detected, the key-check bit, bit 1 of the ESF field, is also stored as one.

When a transport-mode IRB is stored, bit 5 is reserved and set to zero.

Note: This condition may be indicated to the program when an invalid checking-block code on a prefetched CCW is detected but the CCW is not used. In this case, the failing-storage-address-validity bit, bit 6 of the ERW, is one, indicating that the address of a location having the invalid CBC is stored in words 2 and 3 of the ESW.

IDAW/MIDAW Check. When a command-mode IRB is stored, bit 6, when one, indicates that an invalid CBC on the contents of an IDAW or MIDAW or its associated key has been detected. When either of these conditions is detected, the I/O operation is terminated with the device, the subchannel becomes status pending with primary and alert status, the extended-status-word-format bit in the SCSW is one, and channel-control check is indicated in the subchannel-status field. The subchannel also becomes status pending with secondary status as a function of the type of termination or status received from the device. When invalid CBC on the associated key is detected, the key-check bit, bit 1 of the ESF field, is also one.

When a transport-mode IRB is stored, bit 6 is reserved and set to zero.

Note: This condition may be indicated to the program when an invalid checking-block code on the contents of a prefetched IDAW or MIDAW is detected but the IDAW or MIDAW is not used. In this case, the failing-storage-address-validity bit,

bit 6 of the ERW, is one, indicating that the address of a location having the invalid CBC is stored in words 2 and 3 of the ESW. Detection of a channel-data-check condition does not cause the CCW-check and IDAW/MIDAW-check bits to be stored as ones.

Reserved. Bit 7 is stored as zero.

Last-Path-Used Mask (LPUM): Bits 8-15 indicate the channel path that was last used for communicating or transferring information between the channel subsystem and the device. When a command-mode IRB is stored, the bit corresponding to the channel path in use is set whenever any of the following occurs:

1. The first command of a start-subchannel function is accepted by the device (see “Activity Control (AC)” on page 16-14).
2. The device and channel subsystem are actively communicating when the channel subsystem performs the suspend function for the channel program in execution.
3. The channel subsystem accepts status from the device that is recognized as an interruption condition, or a condition has been recognized that suppresses command chaining (see “Interruption Conditions” on page 16-2).
4. The channel subsystem recognizes an interface-control-check condition (see “Interface-Control Check” on page 16-29), and no subchannel-logout information is currently present at the subchannel.

When a transport-mode IRB is stored, each bit of the LPUM is stored as zero, except for the bit that corresponds to the channel path last used, whenever one of the following occurs:

1. The path has been selected for transporting the TCCB for the operation.
2. The channel subsystem accepts status from the device that is recognized as an interruption condition. If the accepted status is an interrogate response, the LPUM may be different than that stored with primary or secondary status, or both.
3. The channel subsystem recognizes an interface-control-check condition (see “Interface-Control Check” on page 16-29), and no subchannel-logout information is currently present at the subchannel.

The LPUM field contains the most recent setting and is valid whenever the ESW contains information in one of the formats 0-3 (see “Extended-Status Word” on page 16-47) and the SCSW is stored. When subchannel-logout information is present in the ESW, a zero LPUM-field-validity flag indicates that the LPUM setting is not consistent with the other subchannel-logout indications.

Ancillary Report (R): Bit 16, when one, indicates that a malfunction of a system component has occurred that has been recognized previously or that has affected the activities of multiple subchannels. When the malfunction affects the activities of multiple subchannels, an ancillary-report condition is recognized for all of the affected subchannels except one. This bit, when zero, indicates that this malfunction of a system component has not been recognized previously. This bit is meaningful only when a channel-control check, channel-data check, or an interface-control check is indicated in bit positions 12-14 of word 2 of the SCSW.

Depending on the model, recognition of an ancillary-report condition may not be provided or it may not be provided for all system malfunctions that effect subchannel activity. When ancillary-report recognition is not provided, bit 16 is set to zero

Field-Validity Flags (FVF): Bits 17-21 indicate the validity of the information stored in the corresponding fields of either the SCSW or the extended-status word. When the validity bit is one, the corresponding field has been stored and is usable for recovery purposes. When the validity bit is zero, the corresponding field is not usable.

This bit-significant field has meaning when channel-data check, channel-control check, or interface-control check is indicated in the SCSW. When these checks are not indicated, this field, as well as the termination-code and sequence-code fields, has no meaning. Furthermore, when these checks are not indicated, the last-path-used-mask, device-status, and the TCW address or the CCW-address fields are all valid. The fields are defined as follows:

17 Last-path-used mask
18 Termination code
19 Sequence code
20 Device status

21 CCW address or TCW address

Storage-Access Code (SA): Bits 22-23 indicate the type of storage access that was being performed by the channel subsystem at the time of error. The SA field pertains only to the access of storage for the purpose of fetching or storing data during the performance of an I/O operation. This encoded field has meaning only when channel-data check, channel-control check, or interface-control check is indicated in the subchannel status. The access-code assignments are as follows:

00 Access type unknown
01 Read
10 Write
11 Read backward for a command-mode operation.

Termination Code (TC): Bits 24 and 25 indicate the type of termination that has occurred. This encoded field has meaning only when channel-data check, channel-control check, or interface-control check is indicated in the SCSW. The types of termination are as follows:

00 Halt signal issued
01 Stop, stack, or normal termination
10 Clear signal issued
11 Reserved

When at least one channel check is indicated in the SCSW but the termination-code-field-validity flag is zero, it is unpredictable which, if any, termination has been signaled to the device. If more than one channel-check condition is indicated in the SCSW, the device may have been signaled one or more termination codes that are the same or different. In this situation, if the termination-code-field-validity flag is one, the termination code indicates the most severe of the terminations signaled to the device. The termination codes, in order of increasing severity, are: stop, stack, or normal termination (01); halt signal issued (00); and clear signal issued (10)

Device-Status Check (D): When the status-verification facility is installed, bit 26, when one, indicates that the subchannel logout in the ESW resulted from the channel subsystem detecting device status that had valid CBC but that contained a combination of bits that was inappropriate when the status byte was presented to the channel subsystem. When the device-status-check bit is one, the interface-control-check status bit is set to one. If, additionally, bit 20 of the subchannel-logout field has been stored as one, then the status byte in error has been stored in the device-status field of the SCSW. If the status-verification facility is not installed, bit 26 is stored as zero.

Secondary Error (E): Bit 27, when one, indicates that a malfunction of a system component that may or may not have been directly related to any activity involving subchannels or I/O devices has occurred. Subsequent to this occurrence, the activity related to this subchannel and the associated I/O device was affected and caused the subchannel to be set status pending with either channel-control check or interface-control check.

I/O-Error Alert (A): Bit 28, when one, indicates that subchannel logout in the ESW resulted from the signaling of I/O-error alert. The I/O-error-alert signal indicates that the control unit or device has detected a malfunction that must be reported to the channel subsystem. The channel subsystem, in response, issues a clear signal and, except as described in the next paragraph, causes interface-control check to be set and extended-status-format-0 (logout) information to be stored in the ESW.

When I/O-error alert is signaled and the subchannel has previously been set disabled or no subchannel is associated with the device, the clear signal is issued to the device, and the I/O-error-alert indication is ignored by the channel subsystem.

Sequence Code (SC): When a command-mode IRB is stored, bits 29-31 identify the I/O sequence in progress at the time of error. The sequence code pertains only to I/O operations initiated by the execution of START SUBCHANNEL or RESUME SUBCHANNEL. This encoded field has meaning only when channel-data check, channel-control check, or interface-control check is indicated in the SCSW.

When a transport-mode IRB is stored, and the validity bit corresponding to the sequence-code field is one, bits 29-31 are stored as zeros.

The sequence-code assignments are:

000 Reserved

001 A nonzero command byte has been sent by the channel subsystem, but a response has not yet been analyzed by the channel subsystem. This code is set during the initiation sequence.

010 The command has been accepted by the device, but no data has been transferred.

011 At least one byte of data has been transferred between the channel subsystem and the device. This code may be used when the channel path is in an idle or polling state.

100 The command in the current CCW (1) has not yet been sent to the device, (2) was sent but not accepted by the device, or (3) was sent and accepted but command-retry status was presented. This code is set when any of the following conditions occurs:

1. The command address is updated during command chaining or during the initiation of a start function or resume function at the device.
2. During the initiation sequence, the status includes attention, control unit end, unit check, unit exception, busy, status modifier (without channel end and device end), or device end (without channel end).
3. Command retry is signaled.
4. The channel subsystem interrogates the device in the process of clearing an interruption condition.
5. The channel subsystem signals the conclusion of the chain of operations to the device during command chaining while performing the suspend function.

101 The command in the current CCW has been accepted, but data transfer is unpredictable. This code applies from the time a device is logically connected to a channel path until the time it is determined that a new sequence code applies. This code may also be used when the channel subsystem places a channel path in the polling or idle state and it is impossible to determine that code 010 or 011 applies. It may also be used at other times when a channel path cannot distinguish between code 010 or 011.

110 Reserved.

111 Reserved.

Figure 16-12 on page 16-51 defines the relationship between indications provided as subchannel-logout data and the appropriate SCSW bits.

Subchannel-Logout Condition Indicated	Logout Condition for SCSW Indication of[1]		
	CDC	CCC	IFCC
Key check	V	V	-
Measurement-block-program check[2]	-	-	-
Measurement-block-data check[2]	-	-	-
Measurement-block-protection check[2]	-	-	-
CCW check	-	V	-
IDAW/MIDAW check	-	V	-
Last-path-used mask[3]	V	V	V
Field-validity flags	V	V	V
Termination code[3]	V	V	V
Device-status check	-	-	V
Secondary error	-	V	V
I/O-error alert	-	-	V
Sequence code[3]	V	V	V

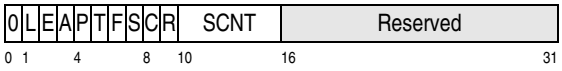
Explanation:

- No relationship.
1 When more than one SCSW indication is signaled, the subchannel-logout conditions that are valid are the logical OR for each of the respective SCSW indications.
2 Only one measurement-block check may be indicated in a specific subchannel logout.
3 This field has a field-validity flag.
CCC Channel-control check.
CDC Channel-data check.
IFCC Interface-control check.
V Bit setting valid.

Figure 16-12. Relationship Between Subchannel-Logout Data and SCSW Bits

Extended-Report Word

The extended-report word (ERW) provides information to the program describing specific conditions that may exist at the device, subchannel, or channel subsystem. The ERW is stored whenever the extended-status word is stored. When the extended-status-word-format bit, bit 5 of word 0 of the SCSW, and the extended-control bit, bit 14 of word 0 of the SCSW, are both zeros, the ERW contains all zeros. When the extended-status-word-format bit or the extended-control bit or both are ones, the ERW has the following format:



Request Logging Only (L) : Bit 1, when one, requests that the program only record information about the condition that caused the extended-status word to be stored.

Extended-Subchannel-Logout Pending (E): Bit 2, when one, and when the extended-status-word-format bit, bit 5 of word 0 of the SCSW, is also one, indicates that an extended-subchannel logout is pending and that words 2-3 of the ESW contain the extended-subchannel-logout descriptor.

Bit 2 is set to zero when bit 6 is set to one.

When an ERW is stored with bits 2 and 6 both set to zero, zeros are stored in words 2 and 3 of the ESW.

Authorization Check (A): Bit 3, when one, indicates that the start or resume function was terminated because the channel subsystem has been placed in the isolated state in which pending I/O operations are not initiated and I/O operations currently being performed either are in the process of being terminated or have been terminated.

Path Verification Required (P): Bit 4, when one, indicates that the program must verify the identity of the device. The LPUM, when valid, indicates the channel path for which device verification is to be performed. When a valid LPUM is not available, the identity of the device must be verified for each available channel path.

Channel-Path Timeout (T): Bit 5, when one, indicates that, during a signaling sequence, an appropriate signal from the device did not occur within a predetermined time interval. Bit 5 is meaningful when the extended-status-word-format bit, bit 5 of word 0 of the SCSW, and the interface-control-check bit, bit 14 of word 2 of the SCSW, are both ones.

Failing-Storage-Address Validity (F): Bit 6, when one, and when the extended-status-word-format bit, bit 5 of word 0 of the SCSW, is also one, indicates that the channel subsystem has detected an invalid CBC on a CCW, a data location, an IDAW, a MIDAW, a TCW, TCCB, a TIDAW, a TSB or on the respective associated key and has stored, in words 2 and 3 of the ESW, the absolute address of a location associated with the invalid CBC.

Bit 6 is set to zero when bit 2 is set to one.

When an ERW is stored with bits 2 and 6 both set to zero, zeros are stored in words 2 and 3 of the ESW.

Concurrent Sense (S) : When a command-mode IRB is stored, bit 7, when one, indicates that the concurrent-sense facility has placed sense information accepted from the device in the extended-control word and has stored a value, in bit positions 10-15 of the ERW, that specifies the number of sense bytes that have been stored in the extended-control word. When bit 7 is one, bit 14 of word 0 of the SCSW is also one.

When a transport-mode IRB is stored, bit 7 is reserved and set to zero.

Concurrent-Sense Count (SCNT): When bit 7 is one, bit positions 10-15 contain a value, in the range 1-32, that specifies the number of sense bytes stored into the extended-control word by the concurrent-sense facility. When bit 7 is zero, bit positions 10-15 contain zeros.

Secondary-CCW-Address Validity (C): When a command-mode IRB is stored, bit 8, when one, and when the extended-status-word-format bit, bit 5 of word 0 of the SCSW, is also one, indicates that the channel subsystem has detected an error condition that precludes the continued performance of an I/O operation. When prefetching applies (bit 9 of word 1 of the ORB is one) and certain error conditions identified by channel-control check, channel-data check, or interface-control check are recognized by the channel subsystem, situations may exist where the termination point of execution of the channel program differs between the channel subsystem and the I/O device. To properly identify the termination points, bit 8 is set to one, and a second CCW address (secondary-CCW address) is provided in the ESW and designates the last CCW executed at the device. When the validity bit is zero for the previously mentioned errors, the channel subsystem was unable to determine the termination point of the control-unit execution, and the secondary-CCW-address field contains zeros.

Bit 8 is not set to one unless the program has permitted prefetching by setting the prefetch-control bit, bit 9 of word 1 of the ORB, to one for the channel program in execution.

When a transport-mode IRB is stored, bit 8 is reserved and set to zero.

Failing-Storage-Address Format (R): Bit 9 indicates the format of the failing-storage address when the failing-storage-address validity bit, bit 6 of the ERW, is one. When bit 6 is zero, bit 9 is not meaningful and is stored as zero. When bit 6 is one and bit 9 is zero, a format-1 failing-storage address is stored in words 2 and 3 of the ESW. When bit 6 is one and bit 9 is one, a format-2 failing-storage address is stored in words 2 and 3. See "Failing-Storage Address" below for a description of format-1 and format-2 addresses.

Failing-Storage Address

Words 2 and 3 of the extended-status contain a 24-, 31-, or 64-bit absolute address. When the failing-storage-address-validity flag, bit 6 of the ERW, is one, words 2 and 3 contain either a format-1 failing-storage address or a format-2 failing-storage address. When bit 6 is one**,** the failing-storage-address field designates a byte location within the invalid checking block associated with an invalid CBC for a CCW, data location, IDAW, MIDAW, TCW, TCCB, TIDAW, TSB, or their respective associated key.

When a transport-mode IRB is stored, and the failing-storage-address validity flag, bit 6 of the ERW, is one, the failing-storage address contains the absolute address associated with the reported failing condition.

When an error condition is detected and a command-mode IRB is stored, the form of the address stored in words 2 and 3 depends on the format-2-IDAW control, bit 14 of word 1 of the ORB, and on the MIDA control, bit 25 of word 1 of the ORB, as follows:

1. When the format-2-IDAW control is zero, specifying that word IDAWs containing 31-bit addresses are used, and the modified-CCW-indirect-data-addressing-control is zero, a format-1 address is stored, and the failing-storage-address-format bit, bit 9 of the ERW, is stored as zero.
2. When either the format-2-IDAW control is one, specifying that doubleword IDAWs containing 64-bit addresses are used, or the modified-CCW-indirect-data-addressing-control is one, or both are one, a format-2 address is stored, and the failing-storage-address-format bit is stored as one.

When an error condition is detected and a transport-mode IRB is stored, a format-2 failing-storage address is stored. A format-2 failing-storage address is stored for a transport-mode IRB when a program-check, protection check, channel-data check or channel-control check condition is indicated by the subchannel status.

When a format-1 address is stored, bits 1-31 of word 2 form the address associated with the reported error condition, and bit 0 of word 2 and all of word 3 are stored as zeros. When a format-2 address is stored, bits 0-31 of word 2 followed by bits 0-31 of word 3 form the 64-bit address associated with the reported error condition.

Extended-Subchannel-Logout Descriptor (ESLD)

When the extended-status-word-format (L) bit, bit 5 of SCSW word 0, is one and the extended-subchannel-logout pending (E) flag, bit 2 of the ERW, is one, an extended-subchannel-logout descriptor is provided in words 2-3 of the ESW. The ESLD identifies the logout and the channel path for which the extended-subchannel logout is pending.

Secondary-CCW Address

When the subchannel-status field indicates channel-control check, channel-data check, or interface-control check and the secondary-CCW-address-validity flag, bit 8 of word 1, is one, bits 1-31 of word 4 form an absolute address of the last CCW executed by the I/O device at the point the reported check condition caused channel-program termination. When provided, the secondary-CCW address may be used for recovery purposes. When the secondary-CCW-address-validity flag is zero, this field contains zeros.

When a transport-mode IRB is stored and the subchannel-status field indicates channel-control check, channel-data check, or interface-control check, word 4 is reserved and contains zeros.

Extended-Status Format 1

The ESW stored by TEST SUBCHANNEL is a format-1 ESW when all of the following conditions are met:

1. The extended-status-word-format bit, bit 5 of word 0 of the SCSW, is zero.

2. The subchannel status-control field has the status-pending bit, bit 31 of word 0 of the SCSW, set to one, together with:

   a. The primary-status bit, bit 29 of word 0 of the SCSW, alone,

   b. The primary-status bit and other status-control bits, or

   c. The intermediate-status bit, bit 28 of word 0 of the SCSW, and the suspended bit, bit 26 of word 0 of the SCSW.

3. At least one of the following conditions is indicated:

   a. The device-connect-time-measurement mode is inactive.

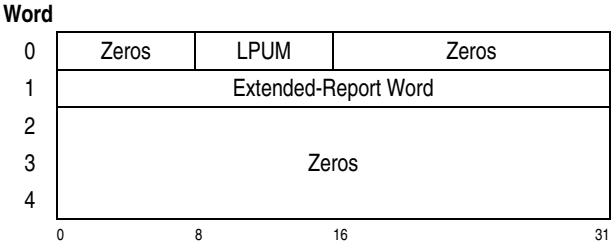
   b. The channel-subsystem-timing facility is not available for the subchannel.

   c. The subchannel is not enabled for the device-connect-time-measurement mode.

Zeros are stored in bytes 0, 2, and 3 of word 0, and the LPUM is stored in byte 1 of word 0; an ERW is stored in word 1; zeros are stored in words 2-4.

The device-connect-time-measurement mode is made inactive when SET CHANNEL MONITOR is executed and bit 31 of general register 1 is zero.

A format-1 ESW has the following format:



Last-Path-Used Mask (LPUM): For a definition of the LPUM, see “Last-Path-Used Mask (LPUM)” on page 16-49.

Extended-Report Word (ERW): For a definition of the ERW, see “Extended-Report Word” on page 16-51.

Extended-Status Format 2

The ESW stored by TEST SUBCHANNEL is a format-2 ESW when all of the following conditions are met:

1. The extended-status-word-format bit, bit 5 of word 0 of the SCSW, is zero.

2. The channel-subsystem-timing facility is available for the subchannel.

3. The subchannel is enabled for the device-connect-time-measurement mode.

4. The device-connect-time-measurement mode is active.

5. The subchannel status-control field has the status-pending bit, bit 31 of word 0 of the SCSW, set to one, together with:

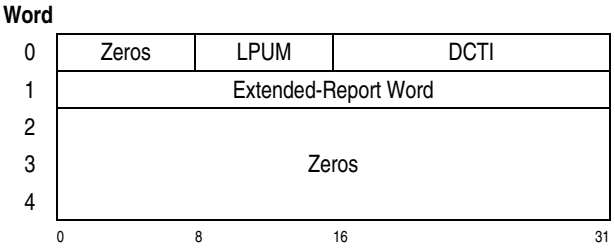
   a. The primary-status bit, bit 29 of word 0 of the SCSW, alone,

   b. The primary-status bit and other status-control bits, or

   c. The intermediate-status bit, bit 28 of word 0 of the SCSW, and the suspended bit, bit 26 of word 0 of the SCSW.

Zeros are stored in byte 0 of word 0, the LPUM is stored in byte 1 of word 0, and the device-connect time is stored in bytes 2 and 3 of word 0; an ERW is stored in word 1; zeros are stored in words 2-4.

A format-2 ESW has the following format:



Last-Path-Used Mask (LPUM): For a definition of the LPUM, see “Last-Path-Used Mask (LPUM)” on page 16-49.

Device-Connect-Time Interval (DCTI): Bit positions 16-31 contain the binary count of time increments accumulated by the channel subsystem during

the time that the channel subsystem and the device were actively communicating and the subchannel was subchannel active for a command-mode operation, or start pending for a transport-mode operation. The time increment of the DCTI is 128 microseconds.

If the above conditions for the storing of the DCTI value in the ESW are met but the device-connect-time-measurement mode was made active by SET CHANNEL MONITOR subsequent to the execution of START SUBCHANNEL for this subchannel, the DCTI value stored is greater than or equal to zero and less than or equal to the correct DCTI value.

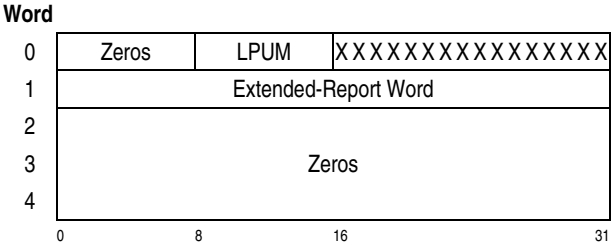
Note: The DCTI value stored in the ESW is the same as that used to update the corresponding measurement-block data for the subchannel if the measurement-block-update mode is in use for the subchannel. If the measurement-block-update mode for the channel subsystem is active and the subchannel is enabled for the device-connect-time-measurement mode but no DCTI value is stored in the ESW (because of the presence of subchannel-logout information), or if the DCTI is zero, then nothing is added to the corresponding measurement-block data.

Extended-Report Word (ERW): For a definition of the ERW, see "Extended-Report Word" on page 16-51.

Extended-Status Format 3

The ESW stored by TEST SUBCHANNEL is a format-3 ESW when the extended-status-word-format bit, bit 5 of word 0 of the SCSW, is zero and the subchannel is status pending with (1) secondary status, alert status, or both when primary status is not also present, or (2) intermediate status when the subchannel is not suspended. Zeros are stored in byte 0 of word 0, and the LPUM is stored in byte 1 of word 0. Bytes 2 and 3 of word 0 contain unpredictable values; an ERW is stored in word 1; zeros are stored in words 2-4.

A format-3 ESW has the following format:



Last-Path-Used Mask (LPUM): For a definition of the LPUM, see "Last-Path-Used Mask (LPUM)" on page 16-49.

An "X" in the format indicates the bit may be zero or one.

Extended-Report Word (ERW): For a definition of the ERW, see "Extended-Report Word" on page 16-51.

Figure 16-13 on page 16-56 summarizes the conditions at the subchannel under which each type of information is stored in the ESW.

Subchannel Conditions When IRB is stored						Extended-Status Word (ESW), Word 0

Explanation:

-	Defined to be not meaningful when X is zero.
*	Bits may be zeros or ones.
/	Information not relevant in this situation.
A	Alert status.
D	Accumulated device-connect-time-interval (DCTI) value stored in bytes 2 and 3.
I	Intermediate status.
L	Extended-status-word format.
M	Last-path-used mask (LPUM) stored in byte 1.
P	Primary status.
R	Subchannel-logout information stored in word 0.
S	Secondary status.
U	No format defined.
X	Status pending.
Z	Bits are stored as zeros.

Figure 16-13. Information Stored in ESW

Extended-Control Word

The extended-control word, which is words 8-15 of an interruption-response block (see "Interruption-Response Block" on page 16-6), provides additional information to the program describing conditions that may exist at the channel subsystem, subchannel, or device. The extended-control (E) bit, bit 14 of word 0 of the SCSW, when one, indicates that model-dependent information or concurrent-sense information has been stored in the extended-control word.

The information provided in the extended-control word is as follows:

SCSW Bits 5	SCSW Bits 14	ERW Bit 7	ERW Bits 10-15	ECW Words 0-7
0	0	0	Zeros	Unpredictable[1]
0	1	0	([5])	([5])
0	1	1	([3])	Concurrent-sense information[4]
1	0	0	Zeros	Unpredictable[1]
1	1	0	Zeros	Model-dependent information[2]
1	1	1	([3])	Concurrent-sense information[4]

Explanation:

1. If stored, the value of these words is unpredictable.
2. Unused bits in the model-dependent information are stored as zeros.
3. Bit positions 10-15 contain a value equal to the number of sense bytes returned.
4. Unused bytes in the concurrent-sense information are stored as zeros.
5. The combination of SCSW bit 5 as 0, SCSW bit 14 as one, and ERW bit 7 as zero does not occur.

Extended-Measurement Word

The extended-measurement word (EMW) provides I/O measurement information to the program for the most recent start or resume operation performed at the subchannel. When the extended-I/O-measurement-word facility is installed and enabled, the EMW is conditionally stored in words 16-23 of the IRB designated by the second operand of TEST SUBCHANNEL when TEST SUBCHANNEL is executed. The EMW is stored by TEST SUBCHANNEL when all of the following conditions are met:

1. The extended-status-word-format (L) bit (bit 5, word 0 of the SCSW) is zero.
2. The channel-subsystem-timing facility is available for the subchannel, as indicated by the timing facility bit (T) at the subchannel.
3. The extended-I/O-measurement-word-mode enable bit (X) at the subchannel is one.

4. The subchannel status-control field has the status-pending bit (bit 31, word 0 of the SCSW) set to one, together with:

   a. The primary-status bit (bit 29, word 0 of the SCSW) alone, or

   b. The primary-status bit and other status-control bits, or

   c. The secondary-status bit (bit 29, word 0 of the SCSW) alone, or

   d. The intermediate-status bit (bit 28, word 0 of the SCSW) and the suspended bit (bit 26, word 0 of the SCSW).

Words 16-23 of the IRB contain unpredictable values when the extended-I/O-measurement-word facility is installed and enabled but the conditions listed above are not met.

When the extended-I/O-measurement-word facility is not installed, or the facility is installed but not enabled, words 16-23 of the IRB are not accessed by the channel subsystem.

The format of the extended-measurement word is shown below:

Word	
0	Device-Connect Time
1	Function-Pending Time
2	Device-Disconnect Time
3	Control-Unit-Queuing Time
4	Device-Active-Only Time
5	Device-Busy Time
6	Initial Command Response Time
7	Reserved
	0 31

Each field in the EMW, when valid, contains a 32 bit binary count in which each increment of the count represents a value of 0.5 microseconds. A value of 00000000 hex represents a time period of zero seconds; the maximum value of FFFFFFFF hex represents approximately 35.79 minutes.

The accuracy of each of the measurement fields stored by the measurement facility is undefined and may vary depending on the resolution of timers implemented at the channel subsystem, the types of channels used to perform the operation, the capabilities of control units accessed during the operation, and the overall length of the I/O operation that was performed. The maximum value of FFFFFFFF hex is stored if a counter overflows; the program is not alerted when an overflow occurs.

Device-Connect Time: Bit positions 0-31 of word 0 contain the measured device-connect time for the operation. The device-connect time is the sum of the time intervals measured whenever the device is logically connected to a channel path while the subchannel is subchannel active for a command-mode operation, or start-pending for a transport-mode operation, and the device is actively communicating with the channel path, as defined in the section “Device-Connect Time” on page 17-4.

Function-Pending Time: Bit positions 0-31 of word 1 contain the SSCH- or RSCH-function-pending time for the operation. Function-pending time is the time interval between acceptance of the start function (or resume function if the subchannel is in the suspended state) at the subchannel and acceptance of the first command associated with the initiation or resumption of channel-program execution at the device, as defined in the section “Function-Pending Time” on page 17-5.

Device-Disconnect Time: Bit positions 0-31 of word 2 contain the device-disconnect time for the operation. Device-disconnect time is the sum of the time intervals measured whenever the device is logically disconnected from the channel subsystem while the subchannel is subchannel-active for a command-mode operation, or start-pending for a transport-mode operation, as defined in the section “Device-Disconnect Time” on page 17-5.

Control-Unit-Queuing Time : Bit positions 0-31 of word 3 contain the control-unit-queuing time for the operation. Control-unit-queuing time is the sum of the time intervals measured by the control unit whenever the device is logically disconnected from the channel subsystem during an I/O operation while the device is busy with an operation initiated from a different system, as defined in the section “Control-Unit-Queuing Time” on page 17-5.

Device-active-only time: Bit positions 0-31 of word 4 contain the device-active-only time for the operation. For a command-mode operation, device-active-only time is the sum of the time intervals when the subchannel is device-active but not subchannel-active at the end of an I/O operation or chain of I/O

operations initiated by a start function or resume function, as defined in section “Device-Active-Only Time” on page 17-6. When a transport-mode IRB is stored, device-active-only time is the sum of the times that the I/O device was active executing device command and the time interval between when channel-end and device-end status were presented.

Device-busy time: Bit positions 0-31 of word 5 contain the device-busy time for the operation. When a command-mode IRB is stored, the device-busy time is the sum of the time intervals when the device is found to be device busy during an attempt to initiate a start function or resume function at the subchannel, as defined in the section “Device-Busy Time” on page 17-6. When a transport-mode IRB is stored, device-busy time is the sum of the times that the I/O device was busy attempting to initiate a command and the device busy time accumulated by the channel subsystem.

Initial Command Response Time: Bit positions 0-31 of word 6 contain the initial-command-response time for the operation. When a command-mode IRB is stored, initial-command-response time for an operation is the time interval beginning from when the first command of the channel program is sent to the device until the device indicates it has accepted the command. When a transport-mode IRB is stored, the initial-command-response time, is the time interval difference between when a TCCB is sent to the I/O device until the response is received from the I/O device, minus the time from when the control unit receives the TCCB until the channel subsystem receives the response from the control unit.

The I/O support functions are those functions of the channel subsystem that are not directly related to the initiation or control of I/O operations. The following I/O support functions are described in this chapter:

- Channel-subsystem monitoring
- Signals and resets
- Externally initiated functions
- Status verification
- Address-limit checking
- Configuration alert
- Incorrect-length-indication suppression
- Concurrent sense
- Channel-subsystem recovery
- I/O-priority facility
- Restore-subchannel facility
- Multiple-subchannel-set facility

Channel-Subsystem Monitoring

Monitoring facilities are provided in the channel subsystem so that the program can retrieve measured values on performance for a designated subchannel. The use of these facilities is under program control by means of the execution of the SET CHANNEL MONITOR instruction and the MODIFY SUBCHANNEL instruction.

The principal components of the channel-subsystem-monitoring facilities are the channel-subsystem-timing facility, measurement-block-update facility, and device-connect-time-measurement facility. The measurement-block-update facility and device-connect-time-measurement facility both use the channel-subsystem-timing facility but otherwise are logically distinct and operate independent of one another.

© Copyright IBM Corp. 2000, 2025

Other components of the channel-subsystem-monitoring facilities are the control-unit-queuing-measurement facility, the control-unit-defer-time facility, the device-active-only-measurement facility, the initial-command-response-measurement facility, the extended-I/O-measurement-block facility, and the extended-I/O-measurement-word facility. These enhance the measurements of the measurement-block-update facility if they are available as described in later sections, where each of the facilities that constitute the channel-subsystem-monitoring facilities is described in this chapter.

Channel-Subsystem Timing

The channel-subsystem-timing facility provides the channel subsystem with the capability of measuring the elapsed time required for performing several different phases of the processing of a start function initiated by START SUBCHANNEL. These elapsed-time measurements are used by both the measurement-block-update facility and the device-connect-time-measurement facility to provide subchannel performance information to the program.

While every channel subsystem has a channel-subsystem-timing facility, it may or may not be provided for use with all subchannels. Subchannels for which the facility is provided have the timing-facility bit, bit 14 of word 1, stored as one in the associated subchannel-information block. (See “Timing Facility (T)” on page 15-4.) If the channel-subsystem-timing facility is not provided for the subchannel, the subchannel's timing-facility bit is stored as zero.

Subchannels that do not have the channel-subsystem-timing facility provided are those for which the characteristics of the associated device, the manner in which it is attached to the channel subsystem, or the channel-subsystem resources required to support the device are such that use of the channel-subsystem-timing facility is precluded.

The channel-subsystem-timing facility consists of at least one channel-subsystem timer and the associated logic and storage required for computing and recording the elapsed-time intervals for use by the two measurement facilities. The aspects of the channel-subsystem-timing facility that are of importance to the program are described below.

Channel-Subsystem Timer

Each channel-subsystem timer is a binary counter that is not accessible to the program. The channel-subsystem timer provides a minimum timer resolution of 128 microseconds. A timer resolution of 1.0 microseconds is provided when FICON-I/O-interface channel paths are supported. When incrementing the channel-subsystem timer causes a carry out of the leftmost bit position, the carry is ignored, and counting continues from zero. No indications are generated as a result of the overflow.

Just as every CPU has access to a TOD clock, every channel subsystem has access to at least one channel-subsystem timer. When multiple channel-subsystem timers are provided, synchronization among these timers is also provided, creating the effect that all the timing facilities of the channel subsystem share a single timer. Synchronization among these timers may be supplied either through some TOD clock or independently by the channel subsystem.

If the TOD clocks are not synchronized, the elapsed times measured by the channel-subsystem-timing facility may have unpredictable values for some or all of the subchannels, depending on the model and on the particular channel-subsystem timer and the way the associated devices are physically attached to the system. The values are unpredictable for those devices attached to the system by separately configurable channel paths whose associated CPU TOD clocks are not synchronized.

Synchronization: If either the measurement-block-update mode or the device-connect-time-measurement mode is active and any of the channel-subsystem timers is found to be out of synchronization, a channel-subsystem-timer-sync check is recognized, and a channel report is generated to alert the program (see “Channel-Subsystem Recovery” on page 17-29). If neither of these modes is active, the lack of synchronization is not recognized.

Measurement-Block Update

The measurement-block-update facility provides the program with the capability of accumulating performance information for subchannels that are enabled for the measurement-block-update mode when the measurement-block-update mode is active. A subchannel is enabled for the measurement-block-update mode by setting bit 11 of word 1 of the SCHIB operand to one and then issuing MODIFY SUB-

CHANNEL. The measurement-block-update mode is made active by the execution of SET CHANNEL MONITOR when bit 62 of general register 1 is one.

When the measurement-block-update mode is active and the subchannel is enabled for the measurement-block-update mode, information is accumulated in a measurement block associated with the subchannel. A measurement block is either a 32-byte area (format-0 measurement block) or a 64-byte area (format-1 measurement block) in main storage that is associated with a subchannel for the purpose of accumulating measurement data.

For format-0 measurement blocks, the program specifies a contiguous area of absolute storage, referred to as the measurement-block area, and subdivides this area into 32-byte blocks, one block for each subchannel for which measurement data is to be accumulated. The measurement-block-update facility uses the measurement-block index contained at the subchannel in conjunction with the measurement-block origin established by the execution of SET CHANNEL MONITOR to compute the absolute address of the measurement block associated with a subchannel.

For format-1 measurement blocks, the program provides a 64-byte contiguous area of absolute storage for the subchannel. The measurement-block-update facility uses the measurement-block address provided by the MSCH instruction to access the measurement block.

Measurement data is stored in the measurement block associated with the subchannel each time an I/O operation or chain of I/O operations initiated by a START SUBCHANNEL instruction or RESUME SUBCHANNEL instruction is suspended or is completed at the device. The completion of an I/O operation or chain of I/O operations at the device is normally determined when secondary status is accepted from the device.

The measurement data accumulated in the format-0 and format-1 measurement blocks by the measurement-block-update facility is described in the following section, “Measurement Block”.

Measurement Block

A measurement block is either a 32-byte area (format-0 measurement block) at a location designated by the program by its use of a measurement-block-origin address in conjunction with the measurement-block index, or a 64-byte area (format-1 measurement block) at a location designated by the measurement-block address provided in the SCHIB during the execution of the MODIFY SUBCHANNEL instruction.

The measurement block contains the accumulated values of the measurement data described below. When the measurement-block-update mode is active and the subchannel is enabled for measurement-block update, the measurement-block-update facility accumulates the values for the measurement data that accrue during the performance of an I/O operation or chain of I/O operations initiated by START SUBCHANNEL.

When the I/O operation or chain of I/O operations is suspended or completed and no error condition is encountered, the accrued values are added to the accumulated values in the measurement block for that subchannel. If an error condition is detected and subchannel-logout information is stored in the extended-status word (ESW), the accrued values are not added to the accumulated values in the measurement block for the subchannel, and the two count fields in the measurement block are not incremented.

If (1) any of the accrued time values is detected to exceed the internal storage provided for containing these values, (2) the control unit cannot provide an accurate queuing time or defer time for the current operation, or (3) the channel subsystem successfully recovers from certain error conditions, none of the accrued values is added to the measurement block for the subchannel, and the sample count in the measurement block is not incremented, but the SSCH+RSCH count in the block is incremented.

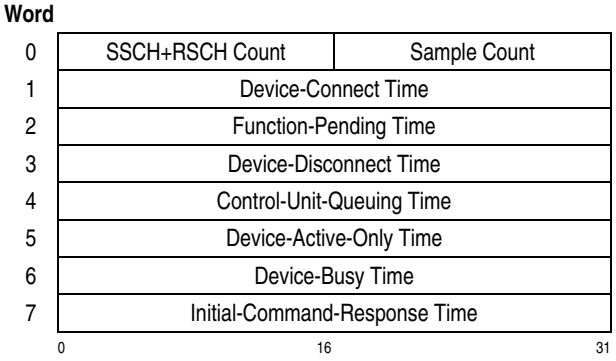
References to the measurement block by the measurement-block-update facility, in order to accumulate measurement data at the suspension or completion of an I/O function, are single-access references and appear to be word concurrent as observed by CPUs.

The measurement-block-update facility updates all fields in the measurement block that are required to be updated for a suspended I/O operation prior to putting the subchannel into the suspended state. The measurement-block-update facility updates all fields in the measurement block that are required to be updated for a completed I/O operation prior to making the subchannel status pending with secondary status or, if the subchannel is start pending for a sub-

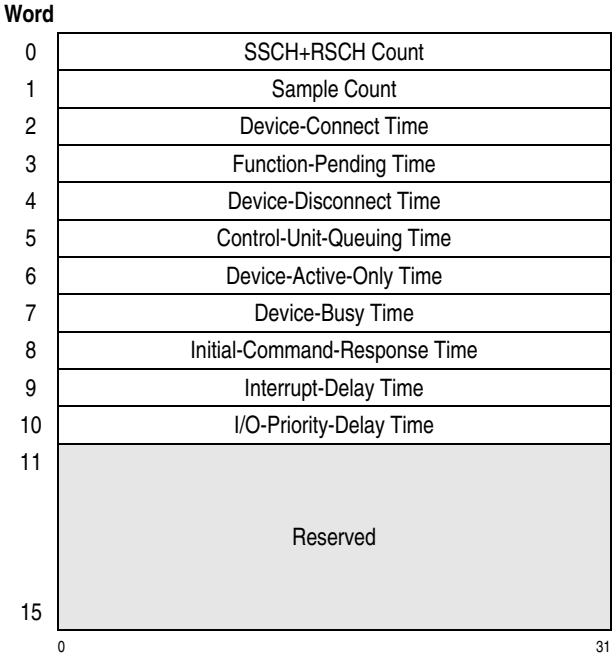
sequent operation, prior to initiating the start function.

A format-0 measurement block is stored when the measurement-block-format-control bit at the subchannel is zero; a format-1 measurement block is stored when the measurement-block-format-control bit at the subchannel is one.

The format-0 measurement block has the following format:



The format-1 measurement block has the following format:



SSCH+RSCH Count: Bits 0-15 of word 0 in the format-0 measurement block and bits 0-31 of word 0 in the format-1 measurement block are used as a binary counter. During the performance of a start function for which measurement-block update is active, when (1) the secondary status condition is recognized or (2) the suspend function is performed, the counter is incremented by one, and the measurement data is stored. The counter wraps around from the maximum value to 0. The program is not alerted when counter overflow occurs.

If the measurement-block-update mode is active and the subchannel is enabled for measuring, the SSCH+RSCH count is incremented even when the lack of measured values for an individual start function precludes the updating of the remaining fields of the measurement block or when the timing-facility bit for the subchannel is zero. The SSCH+RSCH count is not incremented if the measurement-block-update mode is inactive, if the subchannel is not enabled for the measurement-block update, or if subchannel-logout information has been generated for the start function.

Sample Count: Bits 16-31 of word 0 in the format-0 measurement block and bits 0-31 of word 1 in the format-1 measurement block are used as a binary counter. When the time-accumulation fields following word 0 of the format-0 measurement block or following word 1 of the format-1 measurement block are updated, the counter is incremented by one. On some models, certain conditions may prevent the measurement-block-update facility from obtaining the accrued values of the measurement data for an individual start function, even when the measurement-block-update mode is active and the subchannel is enabled for that mode. The control unit may also signal that it was not able to accumulate an accurate queuing time. In these situations, the sample-count field is not incremented.

The counter wraps around from the maximum value to 0. The program is not alerted when counter overflow occurs. This field is not updated if the channel-subsystem-timing facility is not provided for the subchannel.

The System Library publication for the system model specifies the conditions, if any, that preclude the updating of the sample count and time-accumulation fields of the measurement block.

Device-Connect Time: Bit positions 0-31 of word 1 in the format-0 measurement block and bit positions 0-31 of word 2 in the format-1 measurement block contain the accumulation of measured device-connect-time intervals. The device-connect-time interval

(DCTI) is the sum of the time intervals measured whenever the device is logically connected to a channel path while the subchannel is subchannel active and the device is actively communicating with the channel path. The device-connect time does not include the intervals when a device is logically connected to a channel path but is not actively communicating with the channel. The device reports the accumulation of time intervals when the device is logically connected but not actively communicating with the channel path as control-unit-defer time. The control-unit-defer time is not included in the device-connect-time measurement but, instead, is added to the accrued device-disconnect-time measurement for the operation.

The time intervals are stored using a resolution of 128 microseconds. The accumulated value is modulo approximately 152.71 hours, and the program is not alerted when an overflow occurs. This field is not updated if (1) the channel-subsystem-timing facility is not provided for the subchannel, (2) the measurement-block-update mode is inactive, or (3) any of the time values accrued for the current start function has been detected to exceed the internal storage in which it was accrued.

Accumulation of device-connect-time intervals for a subchannel and storing this data in the ESW are not affected by whether the measurement-block-update mode is active. (See “Device-Connect-Time Measurement” on page 17-10.)

Function-Pending Time: Bit positions 0-31 of word 2 in the format-0 measurement block and bit positions 0-31 of word 3 in the format-1 measurement block contain the accumulated SSCH- and RSCH-function-pending time. Function-pending time is the time interval between acceptance of the start function (or resume function if the subchannel is in the suspended state) at the subchannel and acceptance of the first command associated with the initiation or resumption of channel-program execution at the device.

When channel-program execution is suspended because of a suspend flag in the first CCW of a channel program, the suspension occurs prior to transferring the first command to the device. In this case, the function-pending time accumulated up to that point is added to the value in the function-pending-time field of the measurement block. Function-pending time is not accrued while the subchannel is suspended. Function-pending time begins to be accrued again, in this case, when RESUME SUBCHANNEL is subsequently executed while the designated subchannel is in the suspended state.

The function-pending-time interval is stored using a resolution of 128 microseconds. The accumulated value is modulo approximately 152.71 hours, and the program is not alerted when an overflow occurs. This field is not updated if the channel-subsystem-timing facility is not provided for the subchannel.

Device-Disconnect Time: Bit positions 0-31 of word 3 in the format-0 measurement block and bit positions 0-31 of word 4 in the format-1 measurement block contain the accumulated device-disconnect time. Device-disconnect time is the sum of the time intervals measured whenever the device is logically disconnected from the channel subsystem while the subchannel is subchannel active. The device-disconnect time also includes the sum of control-unit-defer-time intervals reported by the device during the I/O operation.

Device-disconnect time is not accrued while the subchannel is in the suspended state. Device-disconnect time begins to be accrued again, in this case, on the first device disconnection after channel-program execution has been resumed at the device (the subchannel is again subchannel active).

The device-disconnect-time interval is stored using a resolution of 128 microseconds. The accumulated value is modulo approximately 152.71 hours; the program is not alerted when an overflow occurs. This field is not updated if the channel-subsystem-timing facility is not provided for the subchannel.

The device-disconnect time does not include the interval between the primary status condition and the secondary status condition at the end of an I/O operation when the subchannel is no longer subchannel active but the I/O device is active. If the channel subsystem provides the device-active-only measurement facility, this time is accumulated in the device-active-only-time field of the measurement block.

Control-Unit-Queuing Time: Bit positions 0-31 of word 4 in the format-0 measurement block and bit positions 0-31 of word 5 in the format-1 measurement block contain the accumulated control-unit-queuing time. Control-unit-queuing time is the sum of the time intervals measured by the control unit whenever the device is logically disconnected from the channel subsystem during an I/O operation while the

device is busy with an operation initiated from a different system.

Control-unit-queuing time is not accrued while the subchannel is in the suspended state. Control-unit-queuing time may be accrued for the channel program after the subchannel becomes subchannel active following a successful resumption.

The control-unit-queuing-time field is updated such that bit 31 represents 128 microseconds. The accumulated value is modulo approximately 152.71 hours; the program is not alerted when an overflow occurs. This field is not updated if the channel-subsystem-timing facility is not provided for the subchannel or if the control unit does not provide a queuing time.

Device-Active-Only Time: Bit positions 0-31 of word 5 in the format-0 measurement block and bit positions 0-31 of word 6 in the format-1 measurement block contain the accumulated device-active-only time. Device-active-only time is the sum of the time intervals when the subchannel is device active but not subchannel active at the end of an I/O operation or chain of I/O operations initiated by a start function or resume function.

Device-active-only time is not accumulated when the subchannel is device active during periods when the subchannel is active; such time is accumulated as device-connect time or device-disconnect time, as appropriate.

The device-active-only-time field is updated such that bit 31 represents 128 microseconds. The accumulated value is modulo approximately 152.71 hours; the program is not alerted when an overflow occurs. This field is not updated if the channel-subsystem-timing facility is not provided for the subchannel.

Device-Busy Time: When the extended-I/O-measurement-block facility is installed, bit positions 0-31 of word 6 in the format-0 measurement block, and bit positions 0-31 of word 7 in the format-1 measurement block contain the accumulated device-busy time. Device-busy time is the sum of the time intervals when the subchannel is device busy during an attempt to initiate a start function or resume function at the subchannel.

The device-busy-time field is updated such that bit 31 represents 128 microseconds. The accumulated value is modulo approximately 152.71 hours; the program is not alerted when an overflow occurs. This field is not updated if the channel-subsystem-timing facility is not provided for the subchannel.

Initial-Command-Response Time: Bit positions 0-31 of word 7 in the format-0 measurement block, and bit positions 0-31 of word 8 in the format-1 measurement block contain the accumulated initial-command-response time for the subchannel.

The initial-command-response time for a start or resume function is the time interval beginning from when the first command of the channel program is sent to the device until the device indicates it has accepted the command.

The initial-command-response time is stored at a resolution of 128 microseconds. The accumulated value is modulo approximately 152.71 hours; the program is not alerted when an overflow occurs.

This field is not updated if the channel-subsystem-timing facility is not provided for the subchannel or if the initial-command-response-measurement facility is not installed.

Control-Unit-Defer Time: Control-unit-defer time is the sum of the time intervals measured by the control unit whenever the device is logically connected to the channel subsystem during an I/O operation but is not actively communicating with the channel because of device-dependent delays in channel-program execution. The control-unit-defer time is not stored in the measurement block as a separate measurement field but is used in the calculation of device-connect-time measurement and device-disconnect-time measurement for an operation.

Control-unit-defer time, if provided by a control unit, is accrued while the device is logically connected to the channel. The time is reported to the channel when channel-end status is presented that causes a device disconnection or terminates the I/O operation. Control-unit-defer time is subtracted from the device-connect-time measurement and is added to the device-disconnect-time measurement reported for the operation.

Interrupt-Delay Time: When the interrupt-delay-measurement facility is installed, bit positions 0-31 of word 9 in the format-1 measurement block contain the accumulated interrupt-delay time for the subchannel. Interrupt-delay time is the time interval from when a subchannel is made status pending with pri-

mary status to when the status is cleared by TSCH. When the interrupt-delay-measurement facility is not installed, bit positions 0-31 of word 9 in the format-1 measurement block are not updated and contain zeros.

The interrupt-delay time is accumulated in the measurement block when a measurement-block update is performed on a subsequent SSCH since the interrupt-delay time is not known when the measurement block is updated for the current SSCH. Consequently, the interrupt-delay time contains the accumulated interrupt-delay time for SSCH operations completed prior to the last completed SSCH operation.

The interrupt-delay time is stored using a resolution of 128 microseconds. The accumulated value is modulo approximately 152.71 hours and the program is not alerted when an overflow occurs. This field is not updated if the channel-subsystem-timing facility is not provided for the subchannel.

I/O-Priority-Delay Time: Bit positions 0-31 of word 10 in the format-1 measurement block contain the accumulated I/O-priority-delay time for the subchannel. The I/O-priority-delay time is that portion of the queue time that can be attributed to delay due to I/O-priority management performed by the control unit. The measurement applies only to TCW I/O operations and is reported in the additional data area of the TSB according to device-dependent definition. If the control unit does not support I/O-priority management or if there is no I/O-priority delay, bit positions 0-31 of word 10 in the format-1 measurement block are not updated.

The I/O-priority-delay time is stored using a resolution of 128 microseconds. The accumulated value is modulo approximately 152.71 hours, and the program is not alerted when an overflow occurs. This field is not updated if the channel-subsystem-timing facility is not provided for the subchannel.

Programming Note: This time is a direct measurement of the effect of the software setting I/O priorities for the I/O executed at the control unit for all I/O devices. Times will vary depending if priorities are kept low for some work. Software uses the time to validate the correctness of the algorithms used for I/O priority management.

Reserved: The remaining words of the measurement block, along with any words associated with facilities that are not provided by the channel subsystem or the subchannel, are reserved for future use. They are not updated by the measurement-block-update facility.

Programming Note: It is possible for the program to fetch a portion of a measurement block immediately prior to, or during, a measurement block update by the measurement-block-update facility. To ensure that a consistent measurement block is fetched, the program should not fetch measurement data for a subchannel during the time from when a start or resume function is initiated at the subchannel until the operation is suspended or completes with secondary status.

Measurement-Block Format

The measurement block is stored as either a format-0 measurement block or a format-1 measurement block. The format-0 measurement block is a 32-byte area (format-0 measurement block) at a location designated by the program using the measurement-block origin in conjunction with the measurement-block index. The format-1 measurement block is a 64-byte area (format-1 measurement block) at a location designated by the measurement-block address provided in the SCHIB during the execution of the MODIFY SUBCHANNEL instruction. The measurement-block-format-control bit at the subchannel indicates whether a format-0 or format-1 measurement block is stored when measurement-block-update mode is active and enabled at the subchannel.

Measurement-Block Origin

The measurement-block origin is the beginning of the measurement-block area in main storage, used to store format-0 measurement blocks. The absolute address of the measurement-block origin, specified on a 32-byte boundary, is passed in general register 2 to the measurement-block-update facility when SET CHANNEL MONITOR is executed with bit 62 of general register 1 set to one.

Measurement-Block Address

The measurement-block address is set at the subchannel through the execution of MODIFY SUBCHANNEL. The measurement block address specifies the absolute address of the beginning of the 64-byte area to be used for accumulating format-1 measurement-block parameters for that subchannel.

Programming Note: The initial value of the measurement-block address is zero. The program is

responsible for setting the measurement-block address to the proper value prior to enabling the subchannel for the measurement-block-update mode for format-1 measurement blocks and making the mode active.

Measurement-Block Key

Bits 32-35 of general register 1 form the four-bit access key to be used for subsequent measurement-block updates when SET CHANNEL MONITOR causes the measurement-block-update mode to be made active. The measurement-block key is passed to the measurement-block-update facility whenever the measurement-block-update mode is made active. The key is used for format-0 and format-1 measurement block updates.

Measurement-Block Index

The measurement-block index is set in the subchannel through the execution of MODIFY SUBCHANNEL. The measurement-block index specifies which 32-byte measurement block, relative to the measurement-block origin, is to be used for accumulating the format-0 measurement-block parameters for that subchannel. The location of the format-0 measurement block of a subchannel is computed by the measurement-block-update facility by appending five rightmost zeros to the measurement-block index of the subchannel and adding the result to the measurement-block origin. The result is the absolute address of the 32-byte format-0 measurement block for that subchannel. When the computed measurement-block address exceeds $2^{31}1$, a measurement-block program-check condition is recognized, and measurement-block updating does not occur for the preceding subchannel-active period.

Programming Note: The initial value of the measurement-block index is zero. The program is responsible for setting the measurement-block index to the proper value prior to enabling the subchannel for the measurement-block-update mode and making the mode active. To ensure predictable results for the measured parameters in the measurement block, each subchannel for which measured parameters are to be accumulated must have a different value for its measurement-block index.

Measurement-Block-Update Mode

The measurement-block-update mode is made active by the execution of SET CHANNEL MONITOR with bit 62 of general register 1 set to one. If bit 62 of general register 1 is zero when SET CHANNEL MONITOR is executed, the mode is made inactive. When the measurement-block-update mode is inactive, no measurement values are accumulated in main storage. When the measurement-block-update mode is made active, the contents of general register 2 are passed to the measurement-block-update facility as the absolute address of the measurement-block origin and is used to calculate the address of format-0 measurement blocks. The measurement-block origin is not used for format-1 measurement blocks. The MBK is also passed to the measurement-block-update facility as the access key to be used when updating either format-0 or format-1 measurement blocks for each subchannel. When the measurement-block-update mode is active, the measurement-block-update facility accumulates measurements in individual measurement blocks for subchannels whose measurement-block-update-enable bit is one. (See the section “Measurement Block” on page 17-3 for a description of the measured parameters.)

If the measurement-block-update mode is already active when SET CHANNEL MONITOR is executed, the values for the measurement-block origin and measurement-block key that are used for a subchannel enabled for measuring by the measurement-block-update facility are dependent upon whether SET CHANNEL MONITOR is executed prior to, during, or subsequent to the execution of START SUBCHANNEL for that subchannel. If SET CHANNEL MONITOR is executed prior to START SUBCHANNEL, the current measurement-block origin and measurement-block key are in control. If SET CHANNEL MONITOR is executed during or subsequent to execution of START SUBCHANNEL, it is unpredictable whether the measurement-block origin and measurement-block key that are in control are old or current.

Measurement-Block-Format Control

Bit 29, word 6, of the SCHIB is the measurement-block-format-control bit. This bit provides the capability of specifying whether a format-0 or format-1 measurement block is stored on a subchannel basis. The initial value of the bit is zero. When MODIFY SUBCHANNEL is executed with the measurement-block-format-control bit in the SCHIB operand set to one, the format-1 measurement block is specified for the subchannel. If the measurement-block-update mode is active and enabled at the subchannel, the measurement-block-update facility stores a format-1 measurement-block for the subchannel, starting with

the next START SUBCHANNEL issued to that subchannel. Similarly, if MODIFY SUBCHANNEL is executed with measurement-block-format-control bit of the SCHIB operand set to zero by the program, the measurement-block-update facility stores a format-0 measurement-block for the subchannel, starting with the next START SUBCHANNEL issued to that subchannel.

Measurement-Block-Update Enable

Bit 11 of word 1 of the SCHIB is the measurement-block-update-enable bit. This bit provides the capability of controlling the accumulation of measurement-block parameters on a subchannel basis. The initial value of the enable bit is zero. When MODIFY SUBCHANNEL is executed with the enable bit set to one in the SCHIB, the subchannel is enabled for the measurement-block-update mode. If the measurement-block-update mode is active, the measurement-block-update facility accumulates measurement-block parameters for the subchannel, starting with the next START SUBCHANNEL issued to that subchannel. Conversely, if MODIFY SUBCHANNEL is executed with bit 11 of word 1 of the SCHIB operand set to zero by the program, the subchannel is disabled for the measurement-block-update mode, and no additional measurement-block parameters are accumulated for that subchannel.

Control-Unit-Queuing Measurement

The control-unit-queuing-measurement facility allows the channel subsystem to accept queuing times from control units and, in conjunction with the measurement-block-update facility, to accumulate those times in the measurement block.

The System Library publication for the control-unit model specifies its ability to supply queuing time. If a control-unit model is capable of supplying queuing time, the publication specifies the conditions that prevent the control unit from accumulating an accurate control-unit-queuing time.

Control-Unit-Defer Time

The control-unit-defer-time facility allows the channel subsystem to accept defer times from control units and, in conjunction with the measurement-block-update facility, to modify the device-connect and device-disconnect times reported in the measurement block to reflect the defer time. The control-unit-defer time is subtracted from the device-connect-time measurement and is added to the device-disconnect-time measurement reported for an I/O operation.

The System Library publication for the control-unit model specifies its ability to supply defer time. If a control-unit model is capable of supplying defer time, the publication specifies the conditions that prevent the control unit from accumulating an accurate control-unit-defer time.

Device-Active-Only Measurement

The device-active-only-measurement facility permits the channel subsystem to report the times that the device is disconnected between primary status and secondary status at the end of an I/O operation or chain of I/O operations.

The measurement-block updates are performed at the time that secondary status is accepted from the I/O device, in order that the device-active time between primary status and secondary status can be reported.

If the subchannel is start pending when secondary status is accepted from the I/O device and the measurement-block update is to be performed, the measurement-block update is performed prior to performing the start function. If measurement-block errors occur, they are reported to the program along with the secondary status instead of performing the start function.

Initial-Command-Response Measurement

The initial-command-response-measurement facility allows the channel subsystem to calculate initial-command-response time for I/O operations and, in conjunction with the measurement-block-update facility, to accumulate those times in the measurement block. The initial-command-response time is accumulated in word 7 of the measurement block.

Time-Interval-Measurement Accuracy

On some models, when time intervals are to be measured and condition code 0 is set for START SUBCHANNEL (or RESUME SUBCHANNEL in the case of a suspended subchannel), a period of latency may occur prior to the initiation of the function-pending time measurement. The System Library publication for the system model specifies the mean latency value and variance for each of the measured time intervals.

Programming Notes:

1. Excessive delays may be encountered by the channel subsystem when attempting to update measurement data if the program is concurrently accessing the same measurement-block area. A programming convention should ensure that the storage block designated by SET CHANNEL MONITOR is made read-only while the measurement-block-update mode is active.

2. To ensure that programs written to support measurement functions are executed properly, the program should initialize all the measurement blocks to zeros prior to making the measurement-block-update mode active. Only zeros should appear in the reserved and unused words of the measurement blocks.

3. When the incrementing of an accumulated value causes a carry to be propagated out of bit position 0, the carry is ignored, and accumulating continues from zero on.

Device-Connect-Time Measurement

The device-connect-time-measurement facility provides the program with the capability of retrieving the length of time that a device is actively communicating with the channel subsystem while executing a channel program. The measured length of time that the device spends actively communicating on a channel path during the execution of a channel program is called the device-connect-time interval (DCTI). Control-unit-defer time is not included in the DCTI.

If timing facilities are provided for the subchannel, the DCTI value is passed to the program in the extended-status word (ESW) at the completion of the operation when the primary-status condition is cleared by TEST SUBCHANNEL and when TEST SUBCHANNEL clears an intermediate-status condition alone while the subchannel is suspended. The DCTI value passed in the ESW pertains to the previous subchannel-active period. The passing of the DCTI in the ESW is under program control by the SET CHANNEL MONITOR device-connect-time-measurement mode-control bit and the corresponding enable bit in the subchannel. However, the DCTI value is not stored in the ESW if the I/O function initiated by START SUBCHANNEL is terminated because of an error condition that is described by subchannel logout. See the section “Extended-Status Format 0” on page 16-47. In this case, the extended-status bit (L) of the SCSW is stored as one, indicating that the ESW contains logout information describing the error condition. See the section “Extended-Status Word” on page 16-47 for the description of the logout information. If the accrued DCTI value exceeded 8.388608 seconds during the previous subchannel-active period, then the maximum value (FFFF hex) is passed in the ESW.

Device-Connect-Time-Measurement Mode

The device-connect-time-measurement mode is made active by the execution of SET CHANNEL MONITOR when bit 63 of general register 1 is one. If bit 63 of general register 1 is zero when SET CHANNEL MONITOR is executed, the mode is made inactive, and DCTIs are not passed to the program. When timing facilities are provided for the subchannel, the device-connect-time-measurement mode is active, and the subchannel is enabled for the mode, the DCTI value is passed to the program in the ESW stored when TEST SUBCHANNEL (1) clears the primary-interruption condition with no logout information indicated in the SCSW (extended-status-word-format bit is zero) or (2) clears the intermediate-status condition alone while the subchannel is suspended.

If a start function is currently being executed with a subchannel enabled for the device-connect-time-measurement mode when SET CHANNEL MONITOR makes this mode active for the channel subsystem, the value of the DCTI stored under the appropriate conditions may be zero, a partial result, or the full and correct value, depending on the model and the progress of the start function at the time the mode was activated.

Provision of the DCTI value in the measurement-block area is not affected by whether the device-connect-time-measurement mode is active.

Device-Connect-Time-Measurement Enable

Bit 12 of word 1 of the SCHIB is the device-connect-time measurement-mode-enable bit. This bit provides the program with the capability of selectively controlling the storing of DCTI values for a subchannel when the device-connect-time-measurement mode is active. The initial value of the enable bit is zero. When this enable bit is one in the SCHIB and MODIFY SUBCHANNEL is executed, the subchan-

nel is enabled for the device-connect-time-measurement mode. If the device-connect-time-measurement mode is active, the device-connect-time-measurement facility begins providing DCTI values for the subchannel, starting with the next START SUBCHANNEL issued to the subchannel. In this situation, the DCTI values are provided in the ESW (see the section “Extended-Status Format 2” on page 16-54). Similarly, if MODIFY SUBCHANNEL is executed with bit 12 of word 1 of the SCHIB operand set to zero by the program, the subchannel is disabled for the device-connect-time-measurement mode, and no further DCTI values are passed to the program for that subchannel.

Extended Measurement Word

The extended-I/O-measurement-word facility provides the program with the capability of retrieving measurement information for a channel program. The measurement information is stored into the extended-measurement word (EMW) in the Interruption Response Block when the extended-measurement-word enable bit is one at the subchannel. See the section “Extended-Measurement Word” on page 16-56 in Chapter 16, “I/O Interruptions,” for the description of the extended-measurement word.

When the extended-measurement-word is enabled for the subchannel, measurement values are passed to program in the EMW when TEST SUBCHANNEL clears a primary-status condition, secondary-status condition alone, or an intermediate-status condition alone while the subchannel is suspended. The measurement values stored in the EMW pertain to the previous subchannel-active and device-active period. Measurement values are not stored in the EMW if the I/O function initiated by START SUBCHANNEL is terminated because of an error condition that is described by subchannel logout (see the section “Extended-Status Format 0” on page 16-47). In this case, the extended-status bit (L) of the SCSW is stored as one, indicating that the ESW contains logout information describing the error condition. See the section “Extended-Status Word” on page 16-47. for the description of the logout information. If any of the accrued measurement values exceeded the maximum value capable of being measured during the previous subchannel-active and device-active period, then the maximum value is stored for that value in the EMW.

Extended-Measurement-Word Enable

Bit 30 of word 6 of the SCHIB is the extended-measurement-word enable bit. This bit provides the program with the capability of selectively controlling the storing of measurement values for a subchannel. The initial value of the enable bit is zero. When this enable bit is one in the SCHIB and MODIFY SUBCHANNEL is executed, the subchannel is enabled for the extended-measurement-word and the extended-measurement-word facility begins providing measurement values for the subchannel starting with the next START SUBCHANNEL issued to the subchannel. Similarly, if MODIFY SUBCHANNEL is executed with bit 30, word 6, of the SCHIB operand set to zero by the program, the subchannel is disabled for the extended-measurement-word and no further measurement values are passed to the program for that subchannel.

Signals and Resets

During system operation, it may become necessary to terminate an I/O operation or to reset either the I/O system or a portion of the I/O system. (The I/O system consists of the channel subsystem plus all of the attached control units and devices.) Various signals and resets are provided for this purpose. Three signals are provided for the channel subsystem to notify an I/O device to terminate an operation or perform a reset function or both. Two resets are provided to cause the channel subsystem to reinitialize certain information contained either at the I/O device or at the channel subsystem.

Signals

The request that the channel subsystem initiate a signaling sequence is made by one of the following:

1. The program's issuance of the CLEAR SUBCHANNEL, HALT SUBCHANNEL, or RESET CHANNEL PATH instruction
2. The I/O device's signaling of I/O-error alert
3. The channel subsystem itself, upon detecting certain error conditions or equipment malfunctions

The three signals are the halt signal, the clear signal, and the reset signal.

Halt Signal

The halt signal is provided so the channel subsystem can terminate an I/O operation. The halt signal is issued by the channel subsystem as part of the halt function performed subsequent to the execution of HALT SUBCHANNEL. The halt signal is also issued by the channel subsystem when certain error conditions are encountered.

For the parallel-I/O-interface type of channel path, the halt signal results in the channel subsystem using the interface-disconnect sequence control defined in the System Library publication *IBM System/360 and System/370 I/O Interface Channel to Control Unit OEMI*, GA22-6974.

For the ESCON-I/O-interface type of channel path, the halt signal results in the channel subsystem using the cancel function defined in the System Library publication *IBM Enterprise Systems Architecture/390 ESCON I/O Interface*, SA22-7202.

For the FICON-I/O-interface type of channel path and the subchannel is operating in command-mode, the halt signal results in the channel subsystem using the cancel function defined in the ANSI standards document *Fibre Channel - Single-Byte Command Code Sets-2 (FC-SB-2).*

For the FICON-I/O-interface type of channel path with the subchannel is operating in transport mode, the halt signal results in the channel subsystem using the transport-mode abort-sequence function.

Clear Signal

The clear signal is provided so the channel subsystem can terminate an I/O operation and reset status and control information contained at the device. The clear signal is issued as part of the clear function performed subsequent to the execution of CLEAR SUBCHANNEL. The clear signal is also issued by the channel subsystem when certain error conditions or equipment malfunctions are detected by the I/O device or the channel subsystem.

For the parallel-I/O-interface type of channel path, the clear signal results in the channel subsystem using the selective-reset sequence control defined in the System Library publication *IBM System/360 and System/370 I/O Interface Channel to Control Unit OEMI*, GA22-6974.

For the ESCON-I/O-interface type of channel path, the clear signal results in the channel subsystem using the selective-reset function defined in the System Library publication *IBM Enterprise Systems Architecture/390 ESCON I/O Interface*, SA22-7202.

For the FICON-I/O-interface type of channel path and the subchannel is operating in command-mode, the clear signal results in the channel subsystem using the selective-reset function defined in the ANSI standards document *Fibre Channel - Single-Byte Command Code Sets-2 (FC-SB-2).*

For the FICON-I/O-interface type of channel path with the subchannel is operating in transport mode, the clear signal results in the channel subsystem using the selective-reset function.

When the subchannel is operating in command mode, if an I/O operation is in progress at the device and the device is actively communicating over a channel path in the performance of that I/O operation when a clear signal is received on that channel path, the device disconnects from that channel path upon receiving the clear signal. Data transfer and any operation using the facilities of the control unit are immediately concluded, and the I/O device is not necessarily positioned at the beginning of a block. Mechanical motion not involving the use of the control unit, such as rewinding magnetic tape or positioning a disk-access mechanism, proceeds to the normal stopping point, if possible. The device may appear busy until termination of the mechanical motion or the inherent cycle of operation, if any, whereupon it becomes available. Status information in the device and control unit is reset, but an interruption condition may be generated upon the completion of any mechanical operation.

Reset Signal

The reset signal is provided so the channel subsystem can reset all I/O devices on a channel path. The reset signal is issued by the channel subsystem as part of the channel-path-reset function performed subsequent to the execution of RESET CHANNEL PATH. The reset signal is also issued by the channel subsystem as part of the I/O-system-reset function.

For the parallel-I/O-interface type of channel path, the reset signal results in the channel subsystem using the system-reset sequence control defined in the System Library publication *IBM System/360 and*

System/370 I/O Interface Channel to Control Unit OEMI, GA22-6974.

For the ESCON-I/O-interface type of channel path, the reset signal results in the channel subsystem using the system-reset function defined in the System Library publication *IBM Enterprise Systems Architecture/390 ESCON I/O Interface*, SA22-7202.

For the FICON-I/O-interface type of channel path, the reset signal results in the channel subsystem using the system-reset function defined in the ANSI standards document *Fibre Channel - Single-Byte Command Code Sets-2 (FC-SB-2)*.

Resets

Two resets are provided so the channel subsystem can reinitialize certain information contained at either the I/O device or the channel subsystem. The request that the channel subsystem initiate one of the reset functions is made by one of the following:

1. The program's issuance of the RESET CHANNEL PATH instruction
2. The operator's activation of a system-reset-clear or system-reset-normal key or a load-clear or load-normal key
3. The channel subsystem itself upon detecting certain error conditions or equipment malfunctions

The resets are channel-path reset and I/O-system reset.

Channel-Path Reset

The channel-path-reset facility provides a mechanism to reset certain indications that pertain to a designated channel path at all associated subchannels. Channel-path reset occurs when the channel subsystem performs the channel-path-reset function initiated by RESET CHANNEL PATH. (See “RESET CHANNEL PATH” on page 14-9.) All internal indications of dedicated allegiance, control unit busy, and device busy that pertain to the designated channel path are cleared in all subchannels, and reset is signaled on that channel path.

The receipt of the reset signal by control units attached to that channel path causes all operations in progress and all status, mode settings, and allegiance, pertaining to that channel path, of the control unit and its attached devices to be reset. (See also the description of the system-reset-signal actions in “I/O-System Reset” on page 17-13.)

The results of the channel-path-reset function on the designated channel path are communicated to the program by means of a subsequent machine-check-interruption condition generated by the channel subsystem (see “Channel-Subsystem Recovery” on page 17-29).

I/O-System Reset

The I/O-system-reset function is performed when the channel subsystem is powered on, when initial program loading is initiated manually (see “Initial Program Loading” on page 17-16), and when the system-reset-clear or system-reset-normal key is activated. The I/O-system-reset function cannot be initiated under program control; it must be initiated manually. I/O-system reset may fail to complete due to malfunctions detected at the channel subsystem or on a channel path. I/O-system reset is performed as part of subsystem reset, which also resets all floating interruption requests, including pending I/O interruptions. (See “Subsystem Reset” on page 4-81.) Detailed descriptions of the effects of I/O-system reset on the various components of the I/O system appear later in this chapter.

I/O-system reset provides a means for placing the channel subsystem and its attached I/O devices in the initialized state. I/O-system reset affects only the channel-subsystem configuration in which it is performed, including all channel-subsystem components configured to that channel subsystem. I/O-system reset has no effect on any system components that are not part of the channel-subsystem configuration that is being reset. The effects of I/O-system reset on the configured components of the channel subsystem are described in the following sections.

Channel-Subsystem State: I/O-system reset causes the channel subsystem to be placed in the initialized state, with all the channel-subsystem components in the states described in the following sections. All operations in progress are terminated and reset, and all indications of prior conditions are reset. These indications include status information, interruption conditions (but not pending interruptions), dedicated-allegiance conditions, pending channel reports, and all internal information regarding prior conditions and operations. In the initialized state, the channel subsystem has no activity in progress and is

ready to perform the initial-program-loading (IPL) function or respond to I/O instructions, as described in “I/O Instructions” on page 14-1.

Control Units and Devices: I/O-system reset causes a reset signal to be sent on all configured channel paths, including those which are not physically available (as indicated by the PAM bit being zero) because of a permanent error condition detected earlier. When the reset signal is received by a control unit, control-unit functions in progress, control-unit status, control-unit allegiance, and control-unit modes for the resetting channel path are reset. Device operations in progress, device status, device allegiance, and the device mode for the resetting channel path are also reset. Control-unit and device mode, allegiance, status, and I/O functions in progress for other channel paths are not affected.

For devices that are operating in the single-path mode, an operation can be in progress for, at most, one channel path. Therefore, if the reset signal is received on that channel path, the operation in progress is reset. Devices that have the dynamic-reconnection feature and are operating in the multipath mode, however, have the capability to establish an allegiance to a group of channel paths during an I/O operation, where all the channel paths of the path group are configured to the same channel subsystem. If an operation is in progress for a device that is operating in the multipath mode and the reset signal is received on one of the channel paths of that path group, then the operation in progress is reset for the resetting channel path only. Although the operation in progress cannot continue on the resetting channel path, it can continue on the other channel paths of the path group, subject to the following restrictions:

1. If the device is actively communicating with the channel subsystem on a channel path when it receives the reset signal on that channel path, then the operation is reset unconditionally, regardless of path groups.

2. If the operation is in progress in the multipath mode but the path group consists only of the resetting path, then the operation is reset.

3. Except as noted in item 2, if the operation in progress is currently in a disconnected state (device not actively communicating with the channel subsystem) or is active on another channel path of a path group, system reset has no effect upon the continued performance of the operation.

A control unit is completely reset after the reset signal has been received on all its channel paths, provided no new activity is initiated at the control unit between the receipt of the first and last reset signal. “Completely reset” means that the current operation, if any, at the control unit is terminated and that control-unit allegiance, control-unit status, and the control-unit mode, if any, are reset.

An I/O device is completely reset after the reset signal has been received on all channel paths of all control units by which the device is accessible, provided no new activity is initiated at the device between the receipt of the first and last reset signal. “Completely reset” means that the current operation, if any, at the device is terminated and that device allegiance, device status, and the device mode are reset.

In summary, system reset always causes an operation in progress to be reset for the channel path on which the reset signal is received. If the resetting channel path is the only channel path for which the operation is in progress, then the operation is completely reset. If a device is actively communicating on a channel path over which the reset signal is received, then the operation in progress is unconditionally and completely reset.

The reset signal is not received by control units and devices on channel paths from which the control unit has been partitioned. A control unit is partitioned from a channel path by means of an enable/disable switch on the control unit for each channel path by which it is accessible. Multi-tagged, unsolicited status, if any, remains pending at the control unit for such a channel path in this case. However, from the point of view of the program, the control unit and device appear to be completely reset if the reset signal is received by the control unit on all the channel paths by which it is currently accessible.

The resultant reset state of individual control units and devices is described in the System Library publication for the control unit.

Channel Paths: I/O-system reset causes a reset signal to be sent on all configured channel paths and causes the channel subsystem to be placed in the reset and initialized state, as described in the previous sections. As a result of these actions, all communication between the channel subsystem and its

attached control units and devices is terminated and the components reset, and all configured channel paths are made quiescent or are deconfigured.

Subchannels: I/O-system reset causes all operations on all subchannels to be concluded. Status information, all interruption conditions (but not pending interruptions), dedicated-allegiance conditions, and internal indications regarding prior conditions and operations in all subchannels are reset, and all valid subchannels are placed in the initialized state.

In the initialized state, the subchannel parameters of all valid subchannels are set to their initial values. The initial values of the following subchannel parameters are zeros:

- Interruption parameter
- I/O-interruption-subclass code (ISC)
- Enabled
- Limit mode when the address-limit-checking facility is installed
- Measurement mode
- Multipath mode
- Path-not-operational mask
- Last-path-used mask
- Measurement-block index
- Concurrent sense

The initial values of the following subchannel parameters are assigned as part of the installation procedure for the device associated with each valid subchannel:

- Timing facility
- Device number
- Logical-path mask (same value as path-installed mask)
- Path-installed mask
- Path-available mask
- Channel-path ID 0-7

The values assigned may depend upon the particular system model and the configuration; dependencies, if any, are described in the System Library publication for the system model. Programming considerations may further constrain the values assigned.

The initial value of the path-operational mask is all ones.

The device-number-valid bit is one for all subchannels having an assigned I/O device.

The initial value of the model-dependent area of the subchannel-information block is described in the System Library publication for the system model.

The initial value of the subchannel-status word and extended-status word is all zeros.

The initialized state of the subchannel is the state specified by the initial values for the subchannel parameters described above. The description of the subchannel parameters can be found in “Subchannel-Information Block” on page 15-2, “Subchannel-Status Word” on page 16-7, and “Extended-Status Word” on page 16-47.

Channel-Path-Reset Facility: I/O-system reset causes the channel-path-reset facility to be reset. A channel-path-reset function initiated by RESET CHANNEL PATH, either pending or in progress, is overridden by I/O-system reset. The machine-check-interruption condition, which normally signals the completion of a channel-path-reset function, is not generated for a channel-path-reset function that is pending or in progress at the time I/O-system reset occurs.

Address-Limit-Checking Facility: When the address-limit-checking facility is installed, I/O-system reset causes the address-limit-checking facility to be reset. The address-limit value is initialized to all zeros and validated.

Channel-Subsystem-Monitoring Facilities: I/O-system reset causes the channel-subsystem-monitoring facilities to be reset. The measurement-block-update mode and the device-connect-time-measurement mode, if active, are made inactive. The measurement-block origin and the measurement-block key are both initialized to zeros and validated.

Pending Channel Reports: I/O-system reset causes pending channel reports to be reset.

Channel-Subsystem Timer: I/O-system reset does not necessarily affect the contents of the channel-subsystem timer. In models that provide channel-subsystem-timer checking, I/O-system reset may cause the channel-subsystem timer to be validated.

Pending I/O Interruptions: I/O-system reset does not affect pending I/O interruptions. However, during subsystem reset, I/O interruptions are cleared concurrently with the performance of I/O-system reset. (See “Subsystem Reset” on page 4-81.)

Area Affected	Effect on I/O-System Reset[1]
Channel-subsystem state	Reset and initialized
Control units and devices	Reset
Channel paths	Quiescent
Subchannels	Reset and initialized
Interruption parameter	Zeros[2]
I/O-interruption-subclass code (ISC)	Zeros[2]
Enabled bit	Zero[2]
Address-limit-mode bits[4]	Zeros[2]
Timing-facility bit	Installed value[2]
Multipath-mode bit	Zero[2]
Measurement-mode bits	Zeros[2]
Device-number-valid bit	Installed value[2]
Device number	Installed value[2]
Logical-path mask	Equal to path-installed mask value[2]
Path-not-operational mask	Zeros[2]
Last-path-used mask	Zeros[2]
Path-installed mask	Installed value[2]
Measurement-block index	Zeros[2]
Path-operational mask	Ones[2]
Path-available mask	Installed value[2 3]
Channel-path ID 0-7	Installed value[2]
Concurrent-sense bit	Zero[2]
Subchannel-status word	Zeros[2]
Extended-status word	Zeros[2]
Model-dependent area	Model dependent[2]
Channel-path-reset facility	Reset
Address-limit-checking facility[4]	Reset and initialized
Address-limit value	Zeros[2]
Channel-subsystem-monitoring facility	Reset and initialized
Measurement-block-update mode	Inactive[2]
Device-connect-time-measurement mode	Inactive[2]
Measurement-block origin	Zeros[2]
Measurement-block key	Zeros[2]
Pending channel-report words	Cleared
Channel-subsystem timer	Unchanged/validated

Explanation:

1 For a detailed description of the effect of I/O-system reset on each area, see the text.
2 Initialized value.
3 Also subject to model-dependent configuration controls, if any.
4 When the FCX facility is not installed.

Figure 17-1. Summary of I/O-System-Reset Actions

Externally Initiated Functions

I/O-system reset, which is an externally initiated function, is described in "I/O-System Reset" on page 17-13.

Initial Program Loading

Initial program loading (IPL) provides a manual means for causing a program to be read from a designated device and for initiating the execution of that program.

Some models may provide additional controls and indications relating to IPL; this additional information is specified in the System Library publication for the model.

There are two types of IPL: CCW-type IPL and list-directed IPL. CCW-type IPL is provided by all machine configurations. List-directed IPL may be provided, depending on the model.

CCW-type IPL

CCW-type IPL is initiated manually by setting the load-unit-address controls to a four-digit number to designate an input device and by subsequently activating the load-clear or load-normal key.

When the configuration-z/Architecture-architectural-mode (CZAM) facility is not installed, activating the load-clear or load-normal key sets the architectural mode to the ESA/390 mode (or ESA/390 compatibility mode). When the CZAM facility is installed, activating the load-clear or load-normal key leaves the architectural mode unchanged (that is, it remains in the z/Architecture architectural mode).

Activating the load-clear key causes a clear reset to be performed on the configuration.

Activating the load-normal key causes an initial CPU reset to be performed on this CPU, CPU reset to be propagated to all other CPUs in the configuration, and a subsystem reset to be performed on the remainder of the configuration.

In the loading part of the operation, after the resets have been performed, this CPU enters the load state. This CPU does not necessarily enter the stopped state during performance of the reset. The load indicator is on while the CPU is in the load state.

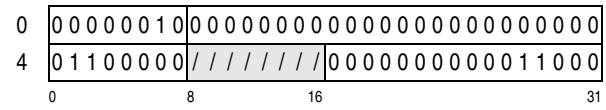
Subsequently, if conditions allow, a read operation is initiated from the designated input device and associated subchannel. The read operation is performed as if a START SUBCHANNEL instruction were executed that designated (1) the subchannel corresponding to the device number specified by the load-unit-address controls and (2) a command-mode ORB containing all zeros, except for a byte of all ones in the logical-path-mask field.

Figure 17-2 illustrates the ORB parameters used by the channel subsystem for a CCW-type IPL.

ORB			
Word	**Bit(s)**	**Field**	**Value**
0	0-31	Interruption parameter	Zeros
1	0-3	Key: Subchannel key	Zeros
1	4	S: Suspend control	0
1	5	C: Streaming-mode control	0
1	6	M: Modification control	0
1	7	Y: Synchronization control	0
1	8	F: CCW-format control	0
1	9	P: Prefetch control	0
1	10	I: Initial-status-interruption control	0
1	11	A: Address-limit-checking control	0
1	12	U: Suppress-suspended-interruption control	0
1	13	B: Channel-program-type control	0
1	14	H: IDAW control	0
1	15	T: 2K-IDAW control	0
1	16-23	LPM: Logical Path Mask	Ones
1	24	L: Incorrect-length-suppression-mode control	0
1	25	D: Modified-CCW-IDA control	0
1	31	X: ORB-extension control	0
2	1-31	CCW Address (absolute address)	Zeros

Figure 17-2. ORB Parameters Used in a CCW-Type IPL

The first CCW to be executed is not fetched from storage. Instead, the effect is as if an implied format-0 CCW, beginning in absolute location 0 and having the following detailed format, were executed:



In the illustration above, the CCW specifies a read command with the modifier bits zeros, a data address of 0, a byte count of 24, the chain-command flag one, the suppress-incorrect-length-indication flag one, the chain-data flag zero, the skip flag zero, the program-controlled-interruption (PCI) flag zero, the indirect-data-address (IDA) flag zero, and the suspend flag zero. The CCW fetched, as a result of command chaining, from location 8 or 16, as well as any subsequent CCW in the IPL sequence, is interpreted the same as a CCW in any I/O operation, except that any PCI flags that are specified in the IPL channel program are ignored.

At the time the subchannel is made start pending for the IPL read, it is also enabled, which ensures proper handling of subsequent status from the device by the channel subsystem and facilitates subsequent I/O operations using the IPL device. (Except for the sub-

channel used by the IPL I/O operation, each subchannel must first be made enabled by MODIFY SUBCHANNEL before it can accept a start function or any status from the device.)

When the IPL subchannel becomes status pending for the last operation of the IPL channel program, no I/O-interruption condition is generated. Instead, the subsystem ID is stored in absolute locations 184-187, zeros are stored in absolute locations 188-191, and the subchannel is cleared of the pending status as if TEST SUBCHANNEL had been executed but without storing information usually stored in an IRB. If the subchannel-status field that would normally have been stored is all zeros and the device-status field that would normally have been stored contains only the channel-end indication, with or without the device-end indication, the IPL I/O operation is considered to be completed successfully. If the device-end status for the IPL I/O operation is provided separately after channel-end status, it causes an I/O-interruption condition to be generated.

If an interface-control check is detected during execution of the IPL channel program, some models may re-initiate the same channel program on another channel path. The other path chosen is any logically-available channel path to the designated device on which the IPL channel program has not previously been initiated during the current IPL operation. (See programming note 6 on page 17-19 for additional information.)

When the IPL I/O operation is completed successfully, a new PSW is loaded from absolute locations 0-7. When the configuration-z/Architecture-architectural-mode (CZAM) facility is not installed, the CPU is in the ESA/390 architectural mode (or ESA/390 compatibility mode), and absolute locations 0-7 have the format of an ESA/390 PSW (in which case, bit 31 of the new PSW must be zero). When the CZAM facility is installed, the CPU is in the z/Architecture architectural mode, and absolute locations 0-7 have the short-PSW format shown in Figure 4-3 on page 4-8 (in which case, bit 31 of the new PSW is the extended-addressing bit).

If the PSW loading is successful and no malfunctions are recognized that preclude the completion of IPL, then the CPU leaves the load state, and the load indicator is turned off. If the rate control is set to the process position, the CPU enters the operating state, and CPU operation proceeds under control of the new PSW. If the rate control is set to the instruction-step position, the CPU enters the stopped state, with the manual indicator on, after the new PSW has been loaded.

If the IPL I/O operation or the PSW loading is not completed successfully, the CPU remains in the load state, and the load indicator remains on.

IPL does not complete when any of the following occurs

- No subchannel contains a valid device number equal to the IPL device number specified by the load-unit-address controls.
- A malfunction is detected in the CPU, main storage, or channel subsystem that precludes the completion of IPL.
- Unsolicited alert status is presented by the device subsequent to the subchannel becoming start pending for the IPL read and before the IPL subchannel becomes subchannel active. The IPL read operation is not initiated in this case.
- There were no available channel paths to the IPL device.
- On every available channel path to the IPL device, either the IPL device appeared not operational or an interface-control check was detected.
- The IPL device presented a status byte containing indications other than channel end, device end, status modifier, control unit end, control unit busy, device busy, or retry status during the IPL I/O operation. Whenever control unit end, control unit busy, or device busy is presented in the status byte, normal path-management actions are taken.
- A subchannel-status indication other than PCI was generated during the IPL I/O operation, except that on some models, detection of an interface-control check may cause the I/O operation to be retried on another available channel path to the IPL device.
- The PSW loaded from absolute locations 0-7 has a PSW-format error of the type that is recognized early.

Except in the cases of no corresponding subchannel for the device number entered or a machine malfunction, the subsystem ID of the IPL device is stored in

absolute locations 184-187; otherwise, the contents of these locations are unpredictable. In all cases of unsuccessful IPL, the contents of absolute locations 0-7 are unpredictable.

Subsequent to a successful IPL, the subchannel parameters contain the normal values as if an actual START SUBCHANNEL had been executed, designating the ORB as described above.

Programming Notes:

1. The information read and placed at absolute locations 8-15 and 16-23 may be used as CCWs for reading additional information during the IPL I/O operation: the CCW at location 8 may specify reading additional CCWs elsewhere in storage, and the CCW at location 16 may specify the transfer-in-channel command, causing transfer to these CCWs.

2. The status-modifier bit has its normal effect during the IPL I/O operation, causing the channel subsystem to fetch and chain to the CCW whose address is 16 higher than that of the current CCW. This applies also to the initial chaining that occurs after completion of the read operation specified by the implicit CCW.

3. The PSW that is loaded at the completion of the IPL operation may be provided by the first eight bytes of the IPL I/O operation or may be placed at absolute locations 0-7 by a subsequent CCW.

4. Activating the load-normal key implicitly specifies the use of the first 24 bytes of main storage and the eight bytes at absolute locations 184-191. Since the remainder of the IPL program may be placed in any part of storage below the 2 G-byte boundary, it is possible to preserve such areas of storage as may be helpful in debugging or recovery. The IPL program should not be placed in the low 512 bytes of storage since that area is reserved as described in a programming note under “Compatibility between z/Architecture and ESA/390” on page 1-42. When the load-clear key is activated, the IPL program starts with a cleared machine in a known state, except that information on external storage remains unchanged.

5. When the PSW at absolute location 0 has bit 14 set to one, the CPU is placed in the wait state after the IPL operation is completed. At that point, the load and manual indicators are off, and the wait indicator is on.

6. When the program receives control after the machine leaves the load state during IPL, the last-path-used mask (LPUM) in the subchannel-information block (SCHIB) for the IPL device should be saved. The program should use this saved LPUM as the logical-path mask (LPM) in the ORB until the program reaches the point in its initialization where it has the ability to process and recover from interface-control checks, and verify that all of the channel paths associated with the subchannel are connected to the same device.

   When multiple paths are associated with the subchannel of the IPL device, it is possible that miscabling of one or more of the paths can cause the program initialization to proceed on different devices. This affects the integrity of the IPL process. The program should ensure that all paths are connected to the same device, but this typically is not possible before program initialization completes. Thus the use of the saved LPUM ensures that all I/O operations to the IPL device during program initialization are executed on the same device, allowing postponement of the checking of the paths.

   Using the saved LPUM also helps to ensure that the channel subsystem will not select a path on which errors would prevent completion of the program initialization, since the path indicated in the LPUM has demonstrated its functionality. On some models, using the saved LPUM also ensures that the path selection will not re-select a path on which an interface-control check was detected while the machine was in the load state.

7. Because the CCW-format control (bit 8 of word 1 in the implied ORB) used during the IPL I/O operation is zero, the CCWs are limited to format-0 CCWs with 24-bit addresses. However, the IPL process may read in additional CCWs that specify indirect addressing using IDAWs. Because the IDAW control (bit 14 of word 1 in the implied ORB) is zero, the IDAWs are limited to format-1 IDAWs with 31-bit addresses. Therefore, the IPL process can read into (or write from) any location below the 2 G-byte boundary.

List-Directed IPL

List-directed IPL supports the use of I/O devices which are not accessed by CCWs, except for ECKD

load devices when the secure-IPL-from-ECKD-load-device facility is installed. List-directed IPL may be provided for a logical partition or virtual machine, depending on the model and the amount of memory available to the logical partition or virtual machine. The terms logical partition and virtual machine are not defined in this publication. The term logical partition is defined in the System Library publications. The term virtual machine is defined in the virtual-machine product manuals.

List-directed IPL is initiated by activating the load-clear-list-directed, load-normal-list-directed, or load-with-dump key. Prior to activating either of these keys, the list-directed-IPL parameters are entered using a model-dependent console. List-directed-IPL parameters include the following information:

- Information which identifies the I/O device from which a program is to be loaded. This I/O device is referred to as the load device.
- Information which identifies a location on a load device from which a program will be loaded.
- Information to be used by the program which will be loaded from the load device.

The list-directed-IPL parameters required by a specific machine and the means by which they are entered are specified in the System Library publications.

After the list-directed-IPL parameters have been entered, the load-clear-list-directed, load-normal-list-directed, or load-with-dump key for a particular CPU is activated. In the description which follows, the term "this CPU" refers to the CPU in the configuration for which the load-clear-list-directed key was activated.

Activating the load-clear-list-directed or load-normal-list-directed key causes an initial CPU reset to be performed on this CPU, CPU reset to be propagated to all other CPUs in the configuration, and a subsystem reset to be performed on the non-CPU elements of the configuration. In addition, activating the load-clear-list-directed key causes a clear reset to be performed on all of the CPUs in the configuration.

Activating the load-with-dump key causes obtaining a dump-save area, a store-status operation, and a memory-save function to be performed on this CPU when not IPLing from an ECKD load device. When IPLing from an ECKD load device, activation of the load-with-dump key causes obtaining a dump-save area, and may cause a store-status operation, a memory-save function, and a storage-key-save function to be performed on this CPU based on the setting of various controls (see store-status-on-load facility). Subsequently, an initial-CPU-reset operation is performed on this CPU, CPU reset is propagated to all other CPUs in the configuration, and a subsystem reset is performed on the remainder of the configuration.

In the loading part of the operation, after the resets have been performed, the operations listed below are performed.

- If the rate control is not in the process position, it is forced into the process position.
- If the list-directed IPL operation was initiated by activating the load-with-dump key, the contents of a model-dependent number of contiguous logical-partition or virtual-machine storage locations (and the corresponding storage keys) starting with absolute location 0 are stored in a model-dependent dump-save area. The data stored includes the contents of all storage locations (and storage keys) into which the program will be loaded from the load device. See Programming Note 4 for additional information.
- The program to be loaded from the load device is loaded into logical-partition or virtual-machine storage at the locations specified on the load device.
- A system IPL-parameter block (SIPB) used by the machine during list-directed IPL is placed in storage in the format shown in Figure 17-3 on page 17-21. The SIPB is also known as the IPL-parameter-information block (IPIB). The absolute address of the first word of the system IPL-parameter block is stored in absolute address locations 20-23. When the secure-IPL facility is installed in the z/Architecture architectural mode. an XML document is not present; otherwise, the presence of an XML document is model dependent. If an XML document is present, it contains the system IPL parameters and it immediately follows the last byte of the system IPL-parameter block. (See Reference [22.] on page xxxii for information regarding XML.) When the IPL-Information-Report (IPLIR), bit 2 of word 2 of the system IPL-parameter block , is one, an IPL-information-report block (IIRB) containing the IPL information report immediately follows the last

byte of the system IPL-parameter block (instead of an XML document) and is aligned on a doubleword boundary; otherwise, an IIRB containing the system IPL information report is not present.

System-IPL-Parameter Block (SIPB):

The system-IPL-parameter block (SIPB) has the following format:

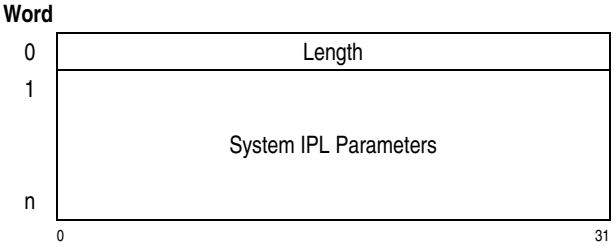


Figure 17-3. System-PL-Parameter Block (SIPB)

Bits 0-31 of word 0 of the system-IPL-parameter block contains a length field. The length field contains a 32-bit binary number representing the number of bytes occupied by the system IPL-parameter block. When the secure-IPL facility is installed in the z/Architecture architectural mode, the system-IPL-parameter block length field must contain a value that is multiple of 8-bytes to ensure the IPL-information-report block (IIRB) immediately follows the last byte of the system IPL-parameter block and is aligned on a doubleword boundary. Words 1 through n contain the system IPL parameters.

IPL Information Report Block

The IPL-information-report block (IIRB) contains information used to locate various IPL records and to report the results of signature verification of one or more secure components of the load device. IIRB is generated by the machine loader after DIAGNOSE x'0308' functions are used to update the system IPL-parameter block. The generated IIRB is stored immediately following the system IPL-parameter block by the machine loader and is aligned on a doubleword boundary.

The IPL-information-report block has the following format:

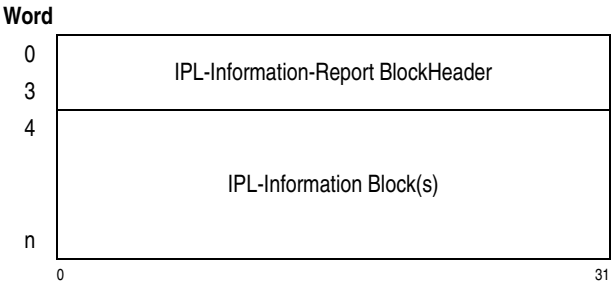

Figure 17-4. IPL-Information-Report Block

The IPL-information-report block contains an IPL-information-report block header, followed by one or more IPL-information blocks.

The IPL-information-report block header has the following format:

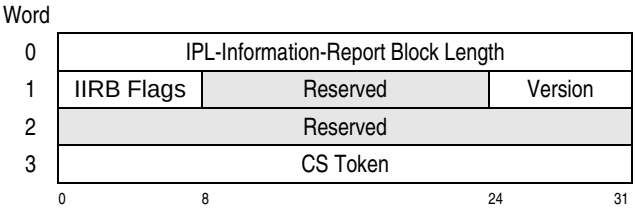

Figure 17-5. IPL-Information-Report BlockHeader

The IPL-information-report block header contains the following fields:

IPL-Information-Report Block Length: Word 0 contains a 32-bit unsigned binary integer specifying the number of bytes in the IIRB. Byte 0 of word 0 must be zero to indicate XML file is not present following the system IPL-parameter block and to limit the length to a maximum of 16-Megabytes; otherwise, an error is reported.

IIRB Flags: Byte 0 of word 1 contains a flag field defined as follows:

Bit	Meaning
0	Verification-certificates obtained from the certificate-store (VCFCS). This flag is set to 1 when the certificate-store (CS) facility (SCP Info byte 134, bit 5 stored by the SCLP read SCP information command) is installed and the verification-certificates (VCs) are obtained from the certificate-store (CS).
1-7	Reserved.

Version: Bits 24-31 of word 1 contain an 8-bit unsigned binary integer specifying the version number of the IPL-information-report block. This field is set to zero.

CS Token: Word 3 contains a 32-bit unsigned binary integer specifying the version of the certificate-store (CS) for the current configuration whose verification-certificates (VCs) were used to verify the signed binary codes of the current IPL-load-device. This field is meaningful when the VCFCS flag (bit 0 of IIRB Flags field in the IPL-information-report block header) is set to one.

IPL-Information Blocks

One or two IPL-information blocks follow the IPL-information-report block header. The first type of IPL-information block identifies an IPL-verification-certificate list. A second type of IPL-information block identifies an IPL-device-component list.

Each IPL-information block contains a common header followed by one or more specific types of IPL-information block entries.

The IPL-information-block header has the following format:

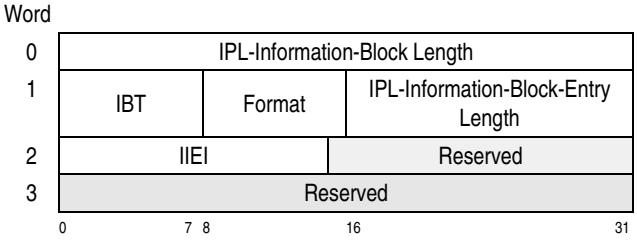

Figure 17-6. IPL-Information-*Block Header*

The IPL-information block header contains the following fields:

IPL-Information-Block Length: Word 0 contains a 32-bit unsigned binary integer specifying the number of bytes in the IPL-information block.

IPL-Information-Block Type (IBT): Byte 0 of word 1 contains a value that specifies the format of the specific IPL-information-block type. Each list that is valid based on the valid IBT field values must be stored in ascending order of the valid IBT field values; otherwise, legacy code may not work properly. The IBT field values are defined as follows:

Value	Meaning
0	Reserved.
1	The IPL-information block specifies a format-0 IPL-verification-certificate list. This value is valid when secure-IPL facility (SCP Info byte 136, bit 1 stored by the SCLP read SCP information command) is installed.
2	The IPL-information block specifies a format-0 IPL-device-component list. This value is valid when secure-IPL facility (SCP Info byte 136, bit 1 stored by the SCLP read SCP information command) is installed.
3	The IPL-information block specifies a format-1 IPL-verification-certificate list. This value is valid when the VCFCS flag (bit 0 of IIRB Flags field in the IPL-Information-Report Block Header") is set to one.
4-255	Reserved.

Programming Note: When the IPL-information block identifying an IPL-verification-certificate list is created from the firmware-embedded-certificates repository, format-1 IPL-verification-certificate list (IBT 3) is not present in the IIRB. That is, only format-0 IPL-verification-certificate list (IBT 1) and IPL-device-component list (IBT 2) are stored in the IIRB. Also, when format-1 IPL-verification-certificate list (IBT 3) is present, the program may ignore format-0 IPL-verification-certificate list (IBT 1) since the same information is included in format-1 IPL-verification-certificate list (IBT 3).

Format: Byte 1 of word 1 contains an 8-bit unsigned binary integer specifying the format of the IPL-information block.

IPL-Information-Block-Entry Length: Bytes 2-3 of word 1 contain a 16-bit unsigned binary integer specifying the number of bytes in each entry of the IPL-information block.

IPL-Information Error indicators (IIEI): Bytes 0-1 of word 2 contain a 16-bit flag field. This field is only valid when the IPL-Information-Block Type (IBT) is set to two and the secure-IPL-code-loading-attributes facility is installed. If the value contained is not zero, it indicates conditions were detected by the machine

loader that will cause the IPL to terminate if enforce-mode secure-IPL is performed.

IPL-Verification-Certificate List

Note: The IPL-verification certificate was previously named the IPL-signature certificate.

The IPL-information block identifying an IPL-verification-certificate list is created from a single source; that is, an IPL-verification-certificate list must not be created using certificates from multiple sources such as the certificate-store and the firmware-embedded-certificates repository.

The IPL-information block identifying an IPL-verification-certificate list has the following format:

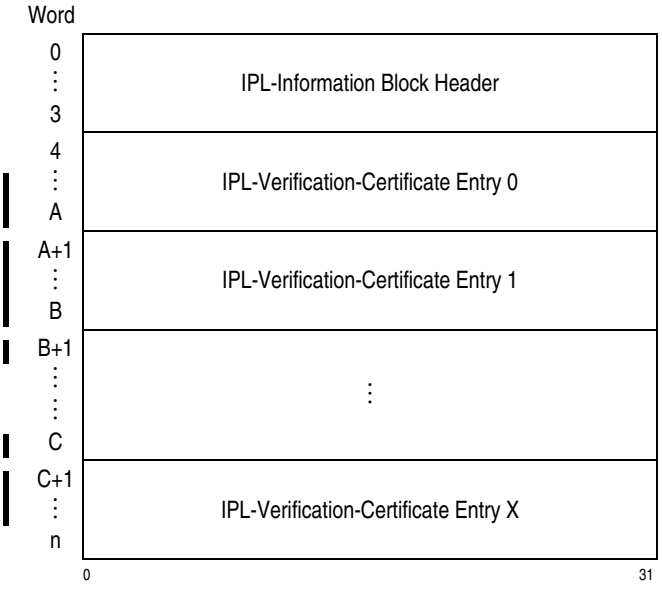

Figure 17-7. IPL-Information *Block for IPL-Verification-Certificate List*

IPL-Verification-Certificate Entry

The format-0 IPL-verification-certificate entry has the following format:

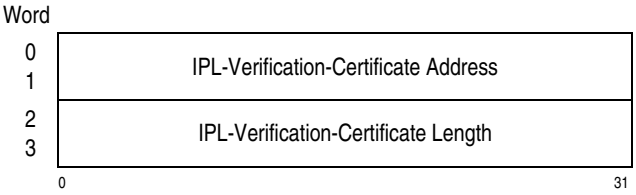

Figure 17-8. IPL-Verification-Certificate Entry

The format-1 IPL-verification-certificate entry has the following format:

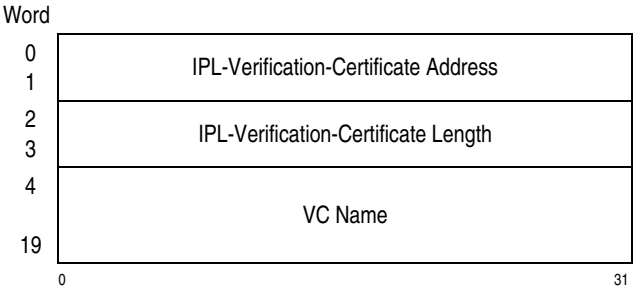

Figure 17-9. Format-1 IPL-Verification-Certificate Entry

The IPL-verification-certificate entry contains the following fields:

IPL-Verfication-Certificate Address: Words 0-1 contain a 64-bit absolute storage location of an X.509 certificate.

IPL-Verfication-Certificate Length: Words 2-3 contain a 64-bit unsigned binary integer specifying the number of bytes in an X.509 certificate.

VC Name: Words 4-19 contain a 64-byte name of the verification-certificate (VC) as it appears on the SE. The VC name is in EBCDIC character format, left justified with padding on the right in EBCDIC blanks using character set 1134 and code page 500.

IPL-Device-Component List

The IPL-information block identifying an IPL-device-component list has the following format:

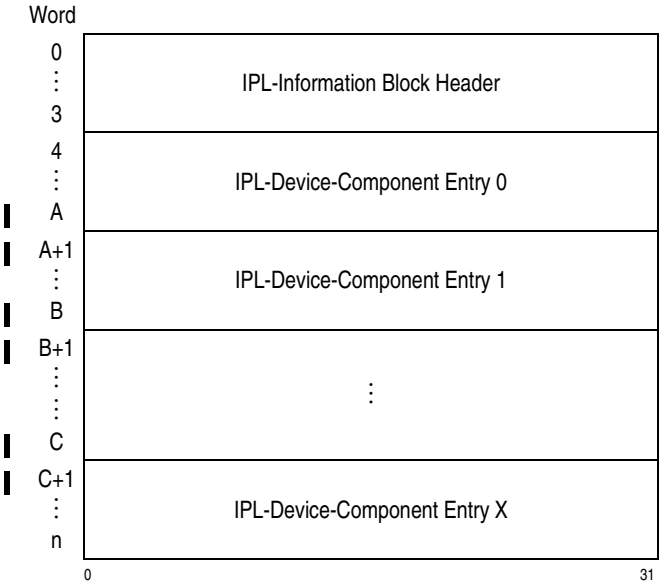

Figure 17-10. IPL-Information *Blockfor IPL-Device-Component List*

IPL-Device-Component Entry

The IPL-device-component entry has the following format:

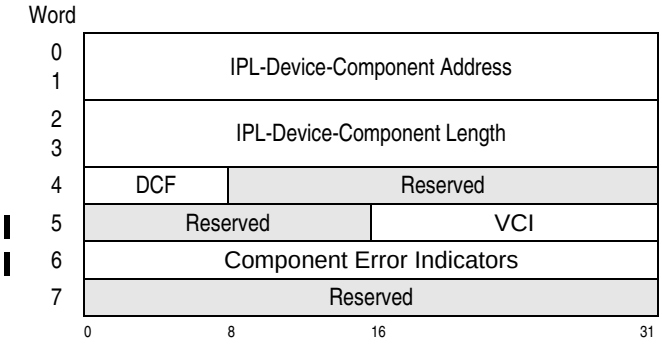

Figure 17-11. IPL-Device-Component Entry

The IPL-device-component entry contains the following fields:

IPL-Device-Component Address: Words 0-1 contain a 64-bit absolute storage location of the binary code of a component.

IPL-Device-Component Length: Words 2-3 contain a 64-bit unsigned binary integer specifying the number of bytes in the binary code of a component.

IPL-Device-Component Flags (DCF): Byte 0 of word 4 contains a flag field defined as follows:

Bit	Meaning
0	Signed Component (SC). When bit 0 is one, the binary code of the component is signed. When bit 0 is zero, the binary code of the component is not signed.
1	Component-Signature-Verified (CSV). When bit 1 is one, the component signature verification is successful. When bit 1 is zero, the component signature verification is not successful. CSV bit is meaningful only when SC bit is set to one. When SC bit is set to zero, CSV bit should also be set to zero.
2-7	Reserved.

IPL-Verification-Certificate Index (VCI): Bytes 2-3 of word 5 contain a 16-bit unsigned binary integer specifying the index of the IPL-verification-certificate entry containing the X.509 certificate that was used to verify this signed component. This field is meaningful only when both SC and CSV bits are set to one, indicating that the binary code of the component is both signed and verified using the verification-certificate from the IPL-verification-certificate entry with the VCI index.

Component Error Indicators: Word 6 contains a 32-bit flag field. This field is only valid when the secure-IPL-code-loading-attributes facility is installed. If the value contained is not zero, it indicates conditions were detected by the machine loader that will cause the IPL to terminate if enforce-mode secure IPL is performed.

After processing the system-IPL-parameter block (SIPB), the machine loader continues with the rest of the list-directed IPL processing as described below.

If no errors occur during the operations listed above, then if a subchannel is associated with the IPL-device, the subsystem-identification word is stored in absolute locations 184-187; otherwise zeros are stored in absolute locations 184-187. Additionally, zeros are stored in absolute locations 188-191, and a new PSW is loaded from absolute locations 0-7.

When the configuration-z/Architecture-architectural-mode (CZAM) facility is not installed, the CPU is in the ESA/390 architectural mode (or ESA/390 compatibility mode), and absolute locations 0-7 have the format of an ESA/390 PSW (in which case, bit 31 of the new PSW must be zero). When the CZAM facility is installed, the CPU is in the z/Architecture architectural mode, and absolute locations 0-7 have the short-PSW format shown in Figure 4-3 on page 4-8 (in which case, bit 31 of the new PSW is the extended-addressing bit).

If the PSW loading is successful and if no malfunctions are recognized which preclude execution of the program which was loaded from the load device, then operation proceeds under control of the new PSW.

If errors occur during the operations listed above, or if the PSW loading is not successful, then this CPU remains in the operating state. See the appropriate System Library publications for additional information.

When list-directed IPL was initiated by activating the load-clear-list-directed key or the load-normal-list-directed key, the state of the machine resources at the time when the loaded program is initiated is the same as it was immediately after the clear reset was performed except as indicated below. For a description of the state of the machine resources immediately after the clear reset was performed, see “Resets” on page 4-75.

- This CPU is in the operating state. The contents of the ALB and TLB for this CPU are unpredictable.
- The PSW for this CPU is set from the contents of absolute storage locations 0-7. When the CZAM facility is not installed, the CPU is in the ESA/390 architectural mode (or ESA/390 compatibility mode), and absolute locations 0-7 have the format of an ESA/390 PSW (in which case, bit 31 of the new PSW must be zero). When the CZAM facility is installed, the CPU is in the z/Architecture architectural mode, and absolute locations 0-7 have the short-PSW format shown in Figure 4-3 on page 4-8 (in which case, bit 31 of the new PSW is the extended-addressing bit).
- Main storage locations into which the program was loaded from the load device contain the program which was loaded, except for absolute storage locations 20-23 and 184-191. Absolute storage locations 20-23 contain the absolute address of the system IPL-parameter block; storage locations starting with this absolute address contain the system IPL-parameter block, immediately followed by an XML document containing the same system IPL parameters or IIRB containing the IPL information report (if present). If a subchannel is associated with the IPL device, then absolute storage locations 184-187 contain the subsystem-identification word for the IPL-device and absolute storage locations 188-191 contain zeros; otherwise, absolute storage locations 184-191 contain zeros. The contents of all other storage locations are unpredictable.
- The ACC and F bits of the storage keys associated with all main storage locations are set to zero. The R and C bits of the storage keys associated with the first 4 K-byte block of storage, the blocks of storage containing the XML document or IIRB (if present), and IPL-parameter list, and the blocks of storage containing the loaded program are set to one. The R and C bits of the storage keys associated with all other blocks of storage are unpredictable.
- The TOD clock is unaffected by initial-program loading.

When list-directed IPL was initiated by activating the load-with-dump key, the state of the machine resources when control is passed to the loaded program is as follows:

- The I/O system has been reset.
- The state of all CPUs in the configuration except for this CPU is the same as it was immediately after the CPUs were reset.
- This CPU is in the operating state. The contents of all registers, the ALB, and the TLB for this CPU are unpredictable.
- The PSW for this CPU is set from the contents of absolute storage locations 0-7. When the CZAM facility is not installed, the CPU is in the ESA/390 architectural mode (or ESA/390 compatibility mode), and absolute locations 0-7 have the format of an ESA/390 PSW (in which case, bit 31 of the new PSW must be zero). When the CZAM facility is installed, the CPU is in the z/Architecture architectural mode, and absolute locations 0-7 have the short-PSW format shown in

Figure 4-3 on page 4-8 (in which case, bit 31 of the new PSW is the extended-addressing bit).

- The contents of all main storage locations which were not stored in the model-dependent dump-save area are unchanged from the time when the load-with-dump key was activated.
- The contents of all main storage locations which were stored in the model-dependent dump-save area are unpredictable except as follows:
  - Main storage locations into which the program was loaded from the load device contain the program which was loaded, except for absolute storage locations 20-23.
  - Absolute storage locations 20-23 contain the absolute address of the system IPL-parameter block; storage locations starting with the absolute address indicated by the contents of absolute addresses 20-23 contain the system IPL-parameter block, which is immediately followed by an XML document containing the system IPL parameters or IIRB containing the IPL information report (if present).
  - If a subchannel is associated with the IPL device, then absolute storage locations 184-187 contain the subsystem-identification word for the IPL-device and absolute storage locations 188-191 contain zeros; otherwise, absolute storage locations 184-191 contain zeros.
- The storage keys associated with the blocks of main storage which were stored in the model-dependent dump-save area are unpredictable. The storage keys associated with all other blocks of main storage are in the same state as they were immediately after the CPUs were reset.
- The TOD clock is unaffected by initial-program loading.

List-directed IPL does not complete if any of the following occurs:

- A malfunction is detected in the CPU, channel subsystem, or main storage which precludes the completion of IPL.
- The list-directed IPL parameters did not contain sufficient information to identify the load device or the program on the load device.
- An I/O device designated by the list-directed-IPL parameters is not in the machine configuration.
- The I/O device designated by the list-directed-IPL parameters is a CCW-type device and is not supported by list-directed IPL.
- The I/O device appeared not operational.
- The amount of storage in the logical partition or virtual machine is insufficient to allow list-directed IPL to complete.
- The PSW to be loaded from locations 0-7 has a PSW-format error of the type that is recognized early.

Programming Notes:

1. The executable portion of the program loaded during list-directed IPL should be located in absolute storage starting at absolute storage locations 8192 and higher. This is necessary in order to avoid use of the architecturally assigned storage locations. See “Assigned Storage Locations” on page 3-74.
2. When the address indicated by storage locations 20-23 is above 16 MB, it is necessary for the machine to be in 31-bit addressing mode in order to access the IPL-parameter list and XML document or IIRB (if present).
3. When list-directed IPL is initiated by activation of the load-clear-list-directed key, the program loaded from the load device is typically an operating-system loader. In this case, the load device may also contain the operating system to be loaded by the operating-system loader. See the applicable operating-system manuals for additional information.
4. When list-directed IPL is initiated by activation of the load-with-dump key, the contents of storage which are affected by the IPL operation are stored in a model-dependent dump-save area so that they can be retrieved by the program which was loaded from the load device. When secure-IPL from ECKD device facility is installed, the associated storage keys are also saved. The program loaded from the load device is typically an O/S-specific system dump program which stores the retrieved data onto a dump device. This process ensures that the contents of storage affected by the IPL operation are preserved for analysis during subsequent debug operations.

See the applicable operating system manuals for additional information.

Reconfiguration of the I/O System

Reconfiguration of the I/O system is handled in a model-dependent manner. For example, changes may be made under program control, by using the model-dependent DIAGNOSE instruction; or manually, by using system-operator configuration controls; or by using a combination of DIAGNOSE and manual controls. The method used depends on the system model. The System Library publication for the system model specifies how the changes are made. The partitioning of channel paths because of reconfiguration is indicated by the setting of the PAM bits in the SCHIB stored when STORE SUBCHANNEL is executed (see "Path-Available Mask (PAM)" on page 15-7).

Status Verification

The status-verification facility provides the channel subsystem with a means of indicating that a device has presented a device-status byte that has valid CBC but that contained a combination of bits that was inappropriate when the status byte was presented to the channel subsystem. The indication provided to the program in the ESW by the channel subsystem is called device-status check. When the channel subsystem recognizes a device-status-check condition, an interface-control-check condition is also recognized. For a summary of the status combinations considered to be appropriate or inappropriate, see the System Library publications *IBM Enterprise Systems Architecture/390 ESCON I/O Interface*, SA22-7202, and *IBM System/360 and System/370 I/O Interface Channel to Control Unit OEMI*, GA22-6974, and the ANSI standards document *Fibre Channel - Single-Byte Command Code Sets-2 (FC-SB-2)*.

Address-Limit Checking

The address-limit-checking facility may be installed on a model and when installed provides a storage-protection mechanism for I/O data accesses to storage that augments key-controlled protection. The address-limit-checking facility is not installed when the FCX facility is installed. When address-limit checking is used, absolute storage is divided into two parts by a program-controlled address-limit value. I/O data accesses can then be optionally restricted to only one of the two parts of absolute storage by the limit mode at each subchannel. The address-limit constraint applies at a higher priority than key-controlled protection, that is, I/O data accesses to the part of main storage that is protected by address-limit checking are prevented even when the subchannel key is zero or matches the key in storage. Address-limit checking does not apply to the fetching of CCWs, IDAWs and MIDAWs.

The address-limit-checking facility consists of the following elements:

- The I/O instruction SET ADDRESS LIMIT.
- The limit mode at each subchannel.
- The address-limit-checking-control bit in the ORB.

The execution of SET ADDRESS LIMIT passes the contents of general register 1 to the address-limit-checking facility to be used as the address-limit value. Bits 32 and 48-63of general register 1 must be zeros to designate a valid absolute address on a 64 K-byte boundary; otherwise, an operand exception is recognized, and the execution of the instruction is suppressed.

The limit mode at each subchannel indicates the manner in which address-limit checking is to be performed. The limit mode is set by placing the desired value in bit positions 9 and 10 of word 1 in the SCHIB and executing MODIFY SUBCHANNEL. The settings of these bits in the SCHIB have the following meanings:

00 No limit checking (initialized value).

01 Data address must be equal to or greater than the current address limit.

10 Data address must be less than the current address limit.

11 Reserved. This combination of limit-mode bits causes an operand exception to be recognized when MODIFY SUBCHANNEL is executed.

The address-limit-checking-control bit, bit 11 of word 1 of the ORB, specifies whether address-limit checking is to be used for the start function that is accepted when the execution of START SUBCHANNEL causes the contents of the ORB to be passed to the subchannel. If the address-limit-checking-control bit is zero when the contents of the ORB are passed, address-limit checking is not specified for that start function. If the bit is one, address-limit checking is specified and is under the control of the current address limit and the current setting of the limit mode at the subchannel.

During the performance of the start function, an attempt to access an absolute storage location for data that is protected by an address limit (either high or low) is recognized as an address-limit violation, and the access is not allowed. A program-check condition is recognized, and channel-program execution is terminated, just as when an attempt is made to access an invalid address.

Configuration Alert

The configuration-alert facility provides a detection mechanism for devices that are not associated with a subchannel in the configuration. The configuration-alert facility notifies the program, by means of a channel report, that a device which is not associated with a subchannel has attempted to communicate with the program.

Each device must be assigned to a subchannel during an installation procedure; otherwise, the channel subsystem is unable to generate an I/O-interruption condition for the device. This is because the I/O-interruption code contains the subchannel number that identifies the particular device causing the I/O-interruption condition. When a device that is not associated with a subchannel attempts to communicate with the channel subsystem, the configuration-alert facility generates a channel report in which the unassociated device is identified. For a description of the means by which the program is notified of a pending channel report and how the information in the channel report is retrieved, see “Channel Report” on page 17-29.

Incorrect-Length-Indication Suppression

The incorrect-length-indication-suppression facility allows the indication of incorrect length for immediate operations to be suppressed in the same manner when using format-1 CCWs as when using format-0 CCWs. When the incorrect-length-indication-suppression facility is installed, bit 24 of word 1 of the ORB specifies whether the channel subsystem is to suppress the indication of incorrect length for an immediate operation when format-1 CCWs are used or whether this indication will remain under the control of the SLI flag of the current CCW (as is the case for CCWs not executed as immediate operations). This bit provides the capability for a channel program to operate in the same manner regarding the indication of incorrect length regardless of whether format-0 or format-1 CCWs are used.

Concurrent Sense

The concurrent-sense facility provides a mechanism whereby sense information that is provided by the device can be presented by the channel subsystem to the program in the same command-mode IRB that contains the unit-check indication when the subchannel is in the concurrent-sense mode. The concurrent-sense mode is made active at a subchannel for which the concurrent-sense facility is applicable when MODIFY SUBCHANNEL is executed and bit 31 of word 6 of the SCHIB operand is set to one. The concurrent-sense facility is applicable to subchannels that are operating in command-mode and are associated with channel paths by which the channel subsystem can attempt to retrieve sense information from the device without requiring program intervention.

The concurrent-sense facility is not applicable when a subchannel is operating in transport mode. When a transport-mode IRB is presented that contains the unit-check indication, the associated sense information is found in the TSB for the associated TCW channel program. Therefore, the concurrent sense facility is not necessary with FCX.

Channel-Subsystem Recovery

The channel subsystem provides various methods for extensive detection of malfunctions and other conditions to ensure the integrity of channel-subsystem operation and to achieve automatic recovery of some malfunctions.

The method used to report a particular malfunction or other condition is dependent upon the severity of the malfunction or other condition and the degree to which the malfunction or other condition can be isolated. A malfunction or other condition in the channel subsystem may be indicated to the program by information being stored by one of the following methods:

1. Information is provided in the IRB describing a condition that has been recognized by either the channel subsystem or device that must be brought to the attention of the program. Generally, this information is made available to the program by the execution of TEST SUBCHANNEL, which is usually executed in response to the occurrence of an I/O interruption. (See “Interruption Action” on page 16-6, for a definition of the information stored, as well as “Interruptions” on page 6-1.)

2. Information is provided in a channel report describing a machine malfunction affecting the identified facility associated with the channel-subsystem. This information is made available to the program by the execution of STORE CHANNEL REPORT WORD, which is usually executed in response to the occurrence of a machine-check interruption. (See “Machine-Check Handling” on page 11-1 for a description of the machine-check-interruption mechanism and the contents of the machine-check-interruption code.)

3. Information is provided in a channel report describing a malfunction or other condition affecting a collection of channel-subsystem facilities. This information is made available to the program as indicated in item 2.

4. Information is provided in the machine-check-interruption code (MCIC) describing a malfunction affecting the continued operational integrity of the channel subsystem. (See “Channel-Subsystem Damage” on page 11-17.)

5. Information is provided in the MCIC describing a malfunction affecting the continued operational integrity of a process or of the system. (See “Instruction-Processing Damage” on page 11-15 and “System Damage” on page 11-15.)

Channel reports are used to report malfunctions or other conditions only when the use of the I/O-interruption facility is not appropriate and in preference to reporting channel-subsystem damage, instruction-processing damage, or system damage.

Channel Report

When a malfunction or other condition affecting elements of the channel subsystem has been recognized, a channel report is generated. The performance of recovery actions by the program or by external means may be required to gain recovery from the error condition. The channel report indicates the source of the channel report and the recovery state to the extent necessary for determining the proper recovery action. A channel report consists of one or more channel-report words (CRWs) that have been generated from an analysis of the malfunction or other condition. The inclusion of two or more CRWs within a channel report is indicated by the chaining flag being stored as one in all of the CRWs of the channel report except the last one in the chain.

When a channel report is made pending by the channel subsystem for retrieval and analysis by the program (by means of the execution of STORE CHANNEL REPORT WORD), a malfunction or other condition that affects the normal operation of one or more of the channel-subsystem facilities has been recognized. If the channel report that is made pending is an initial channel report, a machine-check-interruption condition is generated that indicates one or more CRWs are pending at the channel subsystem. A channel report is initial either if it is the first channel report to be generated after the most recent I/O-system reset or if no previously generated reports are pending and the last STORE CHANNEL REPORT WORD instruction that was executed resulted in the setting of condition code 1, indicating that no channel report was pending. When the machine-check interruption occurs and bit 9 of the machine-check-interruption code (channel report pending) is one, a channel report is pending. If the program clears the first CRW of a channel report before the associated machine-check interruption has occurred, some models may reset the machine-

check-interruption condition, and the associated machine-check interruption does not occur. A machine-check interruption indicating that a channel report is pending occurs only if the machine-check mask (PSW bit 13) and the channel-report-pending subclass mask, bit 3 of control register 14, are both ones.

If the channel report that is made pending is not an initial channel report, a machine-check-interruption condition is not generated. The CRW that is presented to the program in response to the first STORE CHANNEL REPORT WORD instruction that is executed after a machine-check interruption may or may not be part of the initial channel report that caused the machine-check condition to be generated. A pending channel-report word is cleared by any CPU executing STORE CHANNEL REPORT WORD, regardless of whether a machine-check interruption has occurred in any CPU. If a CRW is not pending and STORE CHANNEL REPORT WORD is executed, condition code 1 is set, and zeros are stored at the location designated by the second-operand address. During the execution of STORE CHANNEL REPORT WORD as a result of receiving a machine-check interruption, condition code 1 may be set, and zeros may be stored because (1) the related channel report has been cleared by another CPU or (2) a malfunction occurred during the generation of a channel report. In the latter case, if, during a subsequent attempt, a valid channel report can be made pending, an additional machine-check-interruption condition is generated.

When a channel report consists of multiple chained CRWs, they are presented to the program in the same order that they are placed in the chain by the channel subsystem as a result of consecutive executions of STORE CHANNEL REPORT WORD. If, for example, the first CRW of a chain is presented to the program as a result of executing STORE CHANNEL REPORT WORD, the CRW that is presented as a result of the next execution of STORE CHANNEL REPORT WORD is the second CRW of the same chain and not a CRW that is part of another channel report.

Channel reports are not presented to the program in any special order, except for channel reports whose first or only CRW indicates the same reporting-source code and the same reporting-source ID. These channel reports are presented to the program in the same order that they are generated by the channel subsystem, but they are not necessarily presented consecutively. For example, suppose the channel subsystem generates channel reports A, B, and C, in that order. The first CRW of channel reports B and C indicates the same reporting-source code and the same reporting-source ID. Channel report B is presented to the program before channel report C is presented, but channel report A may be presented after channel report B and before channel report C.

Programming Notes:

1. The information that is provided in a single CRW may be made obsolete by another CRW that is subsequently generated for the same channel-subsystem facility. Therefore, the information that is provided in one channel report should be interpreted in light of the information provided by all of the channel reports that are pending at a given instant.

2. A machine-check-interruption condition is not always generated when a channel report is made pending. The conditions that result in a machine-check-interruption condition being generated are described earlier in this section.

3. After a machine-check interruption has occurred with bit 9 of the machine-check-interruption code set to one, STORE CHANNEL REPORT WORD should be issued repeatedly until all of the pending channel reports have been cleared and condition code 1 has been set.

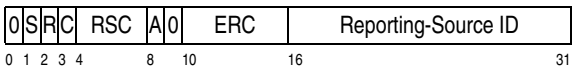
4. A CRW-overflow condition can occur if the program does not issue successive STORE CHANNEL REPORT WORD instructions in a timely manner after the machine-check interruption occurs.

5. The number of CRWs that can be pending at the same time is model dependent. During the existence of an overflow condition, CRWs that would have otherwise been made pending are lost and are never presented to the program.

Channel-Report Word

The channel-report word (CRW) provides information to the program that can be used to facilitate the recovery of an I/O operation, a device, or some element of the channel subsystem, such as a channel path or subchannel.

The format of the CRW is as follows:



Solicited CRW (S): Bit 1, when one, indicates a solicited CRW. A CRW is considered by the channel subsystem to be solicited if it is made pending as the direct result of some action that is taken by the program. When bit 1 is zero, the CRW is unsolicited and has been made pending as the result of an action taken by the channel subsystem that is independent of the program.

Overflow (R): Bit 2, when one, indicates that a CRW-overflow condition has been recognized since this CRW became pending and that one or more CRWs have been lost. This bit is one in the CRW that has most recently been set pending when the overflow condition is recognized. When bit 2 is zero, a CRW-overflow condition has not been recognized.

A CRW that is part of a channel report is not made pending, even though the overflow condition does not exist, if an overflow condition prevented a previous CRW of that report from being made pending.

Chaining (C): Bit 3, when one, and when the overflow flag is zero, indicates chaining of associated CRWs. Chaining of CRWs is indicated whenever a malfunction or other condition is described by more than a single CRW. The chaining flag is zero if the channel report is described by a single CRW or if the CRW is the last CRW of a channel report.

The chaining flag is not meaningful if the overflow bit, bit 2, is one.

Reporting-Source Code (RSC): Bits 4-7 identify the channel-subsystem facility that is associated with the channel report. Some facilities are further identified in the reporting-source-identification field (see below). The following combinations of bits identify the facilities:

Bits				
4	**5**	**6**	**7**	**Facility**
0	0	1	0	Monitoring facility
0	0	1	1	Subchannel
0	1	0	0	Channel Path
1	0	0	1	Configuration-alert facility
1	0	1	1	Channel subsystem

All other bit combinations in the reporting-source-code field are reserved.

Ancillary Report (A): Bit 8, when one, indicates that a malfunction of a system component has occurred that was recognized previously or which has affected the activity of multiple channel-subsystem facilities. When the malfunction affects the activity of multiple channel-subsystem facilities, an ancillary-report condition is recognized for all of the affected facilities except one. This bit, when zero, indicates that this malfunction of a system component was not recognized previously. This bit is meaningful for all channel reports.

Depending on the model, recognition of an ancillary-report condition may not be provided, or it may not be provided for all system malfunctions that affect channel-subsystem facilities. When ancillary-report recognition is not provided, bit 8 is set to zero.

Error-Recovery Code (ERC): Bits 10-15, when zero, indicate that the channel subsystem has error information regarding the channel-subsystem facility identified in the reporting-source code, and that the program can now request that information. Otherwise, bit positions 10-15 contain the error-recovery code that defines the recovery state of the channel-subsystem facility identified in the reporting-source code. This field, when used in conjunction with the reporting-source code, can be used by the program to determine whether the identified facility has already been recovered and is available for use or whether recovery actions are still required. The following error-recovery codes are defined:

Bits						
10	**11**	**12**	**13**	**14**	**15**	**State**
0	0	0	0	0	0	Event-information pending
0	0	0	0	0	1	Available
0	0	0	0	1	0	Initialized
0	0	0	0	1	1	Temporary error
0	0	0	1	0	0	Installed parameters initialized
0	0	0	1	0	1	Terminal
0	0	0	1	1	0	Permanent error with facility not initialized
0	0	0	1	1	1	Permanent error with facility initialized
0	0	1	0	0	0	Installed parameters modified
0	0	1	0	1	0	Installed parameters restored[1]

Explanation:

[1]. Installed-parameters restored is presented only if reporting of the installed-parameters-restored CRW is enabled in the restore-subchannel facility.

All other bit combinations in the error-recovery-code field are reserved.

The specific meaning of each error-recovery code depends on the particular reporting-source code that accompanies it in a CRW. The error-recovery codes are defined as follows:

Event-Information Pending: Event information for the identified facility is available for retrieval by the program. This CRW does not indicate the state of the identified facility.

Available: The identified facility is in the same state that the program would expect if the CRW had not been generated.

Initialized: The identified facility is in the same state that existed immediately following the I/O-system reset that was part of the most recent system IPL.

Temporary Error: The identified facility is not operating in a normal manner or has recognized the occurrence of an abnormal event. It is expected that subsequent actions either will restore the facility to normal operation or will record the appropriate information describing the abnormal event.

Installed Parameters Initialized: This state is the same as the initialized state, except that one or more parameters that are associated with the facility and that are not modifiable by the program may have been changed.

On some models that do not implement the restore-subchannel facility, or in the absence of enablement by the program of reporting of the installed-parameters-restored CRW by the restore-subchannel facility, the installed-parameters-initialized CRW may be reported as a result of the channel subsystem's recovery of the facility designated by the reporting-source ID.

Terminal: The identified facility is in a state such that an operation that was in progress can neither be completed nor terminated in the normal manner.

Permanent Error with Facility Not Initialized: The identified facility is in a state of malfunction, and the channel subsystem has not caused a reset function to be performed for that facility.

Permanent Error with Facility Initialized: The identified facility is in a state of malfunction, and the channel subsystem has caused or may have caused a reset function to be performed for that facility.

Installed Parameters Modified: One or more parameters of the specified facility have been changed.

Installed Parameters Restored: This state is the same as the initialized state, except that one or more parameters that are associated with the facility and that are not modifiable by the program may have been changed from their most recent values back to their initialized values a result of the channel subsystem's recovery of the facility.

Reporting-Source ID (RSID): Bit positions 16-31 contain the reporting-source ID, which may, depending upon the condition that caused the channel report and the reporting-source code, either further identify the affected channel-subsystem facility or provide additional information describing the condition that caused the channel report. The RSID field has the following format as a function of the bit settings of the reporting-source code.

Reporting-Source Code				Reporting-Source ID Bits 16-31			
4	**5**	**6**	**7**				
0	0	1	0	0000	0000	0000	0000
0	0	1	1	xxxx	xxxx	xxxx	xxxx
0	0	1	1	0000	0000	00ss	0000
0	1	0	0	0000	0000	yyyy	yyyy
1	0	0	1	0000	0000	yyyy	yyyy
1	0	1	1	0000	0000	0000	0000

Note:

xxxx	**xxxx**	**xxxx**	**xxxx**	Subchannel Number
ss				Subchannel-set ID when the MSS facility is installed and the CRW is chained immediately following a CRW for a subchannel.
yyyy	**yyyy**			Channel-path ID (CHPID)

When the MSS facility is installed an additional CRW is chained to every channel report for subchannels. The content of this chained CRW is identical to the original CRW except for the RSID field. In this chained CRW, bit positions 10-11 of the RSID field contain the SSID identifying the subchannel set.

Restore-Subchannel Facility

The restore-subchannel facility may be available on a model implementing z/Architecture. This facility provides the means for the channel subsystem to recover a damaged subchannel and report the recovery to the program by means of a CRW. When the facility is installed and reporting of the installed-parameters-restored CRW is enabled in the restore-subchannel facility, the channel subsystem may recover the damaged subchannel and make a CRW pending that indicates installed-parameters restored. When the facility is installed and reporting of the installed-parameters-restored CRW is not enabled, the channel subsystem may recover the damaged subchannel and make a CRW pending that indicates installed-parameters initialized.

In some models that do not implement the restore-subchannel facility, the channel subsystem may nevertheless recover a damaged subchannel, and make a CRW pending that indicates installed-parameters initialized.

Extended-Subchannel-Logout Facility

When the extended-subchannel-logout facility is installed and enabled, all fibre-channel (FC) channel paths can create extended-subchannel logouts, under applicable error conditions, and generate I/O interruptions that indicate such a logout is pending retrieval. The extended-subchannel logouts are stored in and retrieved from a model-dependent number of extended-subchannel-logout buffers associated with each channel path supported by the facility.

When TEST SUBCHANNEL for a subchannel that specifies an FC channel path stores an interruption-response block (IRB) containing a format-0 ESW in which the extended-subchannel-logout-pending (E) bit is 1, an extended-subchannel logout is pending for the specified subchannel. Words 2-3 of the format-0 ESW contain the extended-subchannel-logout descriptor (ESLD) that identifies the logout and the channel path for which the logout is pending.

If all of the buffers for a given channel contain pending extended-subchannel logouts, the logouts will remain pending for a model-dependent time interval. If, during that time interval, a subsequent condition occurs that warrants a new extended-subchannel logout, that logout is not made and is lost. If the time interval has been exceeded and the program has not used the ESLD to retrieve a pending logout, the logout may be removed from the buffer or the buffer may be reused to contain a subsequent logout. When a logout is removed from a buffer and the buffer is not reused, the ESLD is no longer recognized as a valid logout identifier. When a buffer is reused, the ESLD may be recognized as a valid logout identifier albeit for a logout different from the logout for which the original I/O interruption was generated.

Channel-Subsystem-I/O-Priority Facility

The channel-subsystem-I/O-priority facility provides a means by which the program can establish a priority relationship, at the channel subsystem, among the subchannels that are placed into the start-pending state when START SUBCHANNEL is executed and condition code 0 is indicated. For I/O-subchannels that are configured to fibre-channel channel paths (FICON and FICON-converted channel paths), it also provides a means by which the program can establish a priority relationship for I/O operations at the fibre-channel-attached control units.

The program assigns the desired channel-subsystem priority and control-unit priority by specifying the desired priority numbers in the ORB extension when START SUBCHANNEL is executed.

The channel-subsystem-priority number specified in the ORB is used by the channel subsystem to determine the order in which start-pending and resume-pending subchannels are selected when the channel subsystem attempts to initiate a start function or a resume function. See the section “Start Function and Resume Function” on page 15-20 for details about these functions. In general, I/O subchannels that are in the start-pending or resume-pending state and have a higher priority number are selected for start-function or resume-function initiation by the channel subsystem before start-pending or resume-pending subchannels that have a lower priority number. The specific priority selection algorithm used by the channel subsystem for this purpose depends on the model. Additionally, the channel subsystem also applies a fairness selection algorithm in conjunction with the priority selection algorithm when selecting

I/O subchannels. The specific fairness selection algorithm also depends on the model. For all models, the channel-subsystem priority and fairness selection algorithms are always applied to I/O subchannels that are either start pending or resume pending. Some models may also apply both algorithms to subchannels that are either clear pending or halt pending. See a model's System-Library publication for a description of the priority and fairness selection algorithms that the model provides and whether these algorithms are also applied to clear-pending or halt-pending subchannels.

The control-unit-priority number specified in the ORB is used by control units attached to fibre-channel channel paths in order to determine the priority of the execution of CCWs at the control unit. See “Control-Unit (CU) Priority:” on page 15-29 for additional information.

Number of Channel-Subsystem-Priority Levels

Depending on the model, fewer than 256 channel-subsystem-priority levels may be provided by the channel subsystem. Each priority level that the model provides is designated by an eight-bit unsigned binary integer. The lowest provided channel-subsystem-priority level is designated by the integer 0, and each succeeding higher priority level is designated by the next-higher sequential integer. For example, if the model provides 16 priority levels, they are numbered 0-15, respectively, from the lowest priority level to the highest priority level.

Multiple-Subchannel-Set Facility

The multiple-subchannel-set (MSS) facility increases the maximum number of subchannels that can be configured to a program. When the MSS facility is not provided, a single set of subchannels, in the range 0-65,535 may be provided for a program. When the MSS facility is provided, a maximum of four sets of subchannels may be provided for a program. Each subchannel set provides from one to 64K subchannels in the range 0 to-65,535. A two-bit unsigned binary integer, in the range of 0-3, called the subchannel-set identifier (SSID) is used to specify each provided subchannel set. The default subchannel set for a program is SSID 0. The initialized state of the MSS facility is disabled, in this state the MSS facility functions are not provided to programs executing in logical partitions.

When the MSS facility is provided, a subchannel is specified by a unique address formed by the concatenation of:

1. The subchannel-set identifier (SSID) of the subchannel-image set to which the designated subchannel-image is configured,
2. The subchannel number of the subchannel-image being accessed.

HFP Arithmetic

HFP Number Representation

A hexadecimal-floating-point (HFP) number consists of a sign bit, a hexadecimal fraction, and an unsigned seven-bit binary integer called the characteristic. The characteristic represents a signed exponent and is obtained by adding 64 to the exponent value (excess-64 notation). The range of the characteristic is 0 to 127, which corresponds to an exponent range of -64 to +63. The magnitude of an HFP number is the product of its fraction and the number 16 raised to the power of the exponent that is represented by its characteristic. The number is positive or negative depending on whether the sign bit is zero or one, respectively.

The fraction of an HFP number is treated as a hexadecimal number because it is considered to be multiplied by a number which is a power of 16. The name, fraction, indicates that the radix point is assumed to be immediately to the left of the leftmost fraction digit.

When an HFP operation would cause the result exponent to exceed 63, the characteristic wraps around from 127 to 0, and an HFP-exponent-overflow condition exists. The result characteristic is then too small by 128. When an operation would cause the exponent to be less than -64, the characteristic wraps around from 0 to 127, and an HFP-exponent-underflow condition exists. The result characteristic is then too large by 128, except that a zero characteristic is produced when a true zero is forced.

A true zero is an HFP number with a zero characteristic and zero fraction. A true zero may arise as the normal result of an arithmetic operation because of the particular magnitude of the operands. For HFP operations, the result is forced to be a positive true zero when:

1. An HFP exponent underflow occurs and the HFP-exponent-underflow mask bit in the PSW is zero.
2. The result fraction of a normalized or unnormalized addition or subtraction operation is zero and the HFP-significance mask bit in the PSW is zero.
3. The operand of the CONVERT FROM FIXED instruction is zero.
4. The dividend in the DIVIDE instruction has a zero fraction.
5. The operand of the HALVE, LOAD FP INTEGER, or SQUARE ROOT instruction has a zero fraction.
6. One or both operands of a multiplication operation has a zero fraction.

© Copyright IBM Corp. 2000, 2025

7. The operand of the DECIMAL SCALE AND CONVERT TO HFP or DECIMAL SCALE AND CONVERT AND SPLIT TO HFP (described in Chapter 25, “Vector Decimal Instructions”) instruction is zero.

When a program interruption for HFP exponent underflow occurs, a true zero is not forced; instead, the fraction and sign remain correct, and the characteristic is too large by 128. When a program interruption for HFP significance occurs, the fraction remains zero, the sign is positive, and the characteristic remains correct.

The sign of a sum, difference, product, quotient, square root, the result of CONVERT FROM FIXED, or the result of LOAD FP INTEGER with a zero fraction is positive. The sign for a zero fraction resulting from other HFP operations is established from the operand sign, the same as for nonzero fractions.

Normalization

A quantity can be represented with the greatest precision by an HFP number of a given fraction length when that number is normalized. A normalized HFP number has a nonzero leftmost hexadecimal fraction digit. If one or more leftmost fraction digits are zeros, the number is said to be unnormalized.

Unnormalized numbers are normalized by shifting the fraction left, one digit at a time, until the leftmost hexadecimal digit is nonzero and reducing the characteristic by the number of hexadecimal digits shifted. A number with a zero fraction cannot be normalized; either its characteristic remains unchanged or its characteristic is made zero when the result is forced to be a true zero.

Addition and subtraction with extended operands, as well as the MULTIPLY, DIVIDE, CONVERT FROM FIXED, HALVE, LOAD FP INTEGER, and SQUARE ROOT operations, are performed only with normalization. Addition and subtraction with short or long operands may be specified as either normalized or unnormalized. For all other operations, the result is produced without normalization.

With unnormalized operations, leftmost zeros in the result fraction are not eliminated. The result may or may not be in normalized form, depending upon the original operands.

In both normalized and unnormalized operations, the initial operands need not be in normalized form. The operands for multiply, divide, and square-root operations are normalized before the arithmetic process. For other normalized operations, normalization takes place when the intermediate arithmetic result is changed to the final result.

When the intermediate result of addition, subtraction, or rounding causes the fraction to overflow, the fraction is shifted right by one hexadecimal-digit position, and the value one is supplied to the vacated leftmost digit position. The fraction is then truncated to the final result length, while the characteristic is increased by one. This adjustment is made for both normalized and unnormalized operations.

Figure 18-1 on page 18-3 summarizes, for all instructions producing HFP results, the handling of zero results and whether normalization occurs for nonzero results.

Programming Note: Up to three leftmost bits of the fraction of a normalized number may be zeros, since the nonzero test applies to the entire leftmost hexadecimal digit.

HFP Data Formats

HFP numbers have a 32-bit (short) format, a 64-bit (long) format, or a 128-bit (extended) format. Numbers in the short and long formats may be designated as operands both in storage and in the floating-point registers, whereas operands having the extended format are designated in floating-point register pairs, except for DECIMAL SCALE AND CONVERT TO HFP (extended) and VECTOR CONVERT HFP TO SCALED DECIMAL (extended), where they are designated in 128-bit vector registers.

In all formats, the first bit (bit 0) is the sign bit (S). The next seven bits are the characteristic. In the short and long formats, the remaining bits constitute the fraction, which consists of six or 14 hexadecimal digits, respectively.

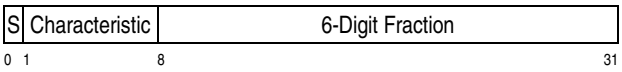
Explanation:

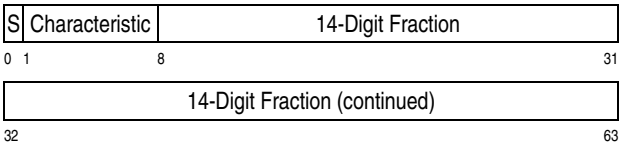
- Not applicable.
1 Floating-point-support instruction.
2 Vector-decimal instruction.
Y/N When the HFP-significance mask bit (PSW bit 23) is zero, a true zero is forced. When the HFP-significance mask bit is one, the characteristic remains unchanged, and a program interruption for HFP significance occurs.

Figure 18-1. Normalization and Zero Handling for Instructions with HFP Results

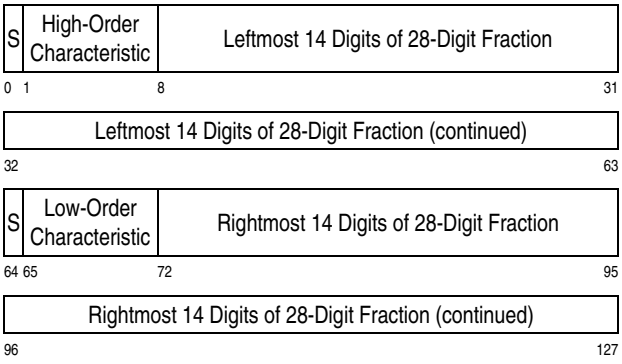
HFP Short Format



HFP Long Format



HFP Extended Format



An extended HFP number has a 28-digit fraction and consists of two long HFP numbers that are called the high-order and low-order parts. The high-order part may be any long HFP number. The fraction of the high-order part contains the leftmost 14 hexadecimal digits of the 28-digit fraction. The characteristic and sign of the high-order part are the characteristic and sign of the extended HFP number. If the high-order part is normalized, the extended number is considered normalized. The fraction of the low-order part contains the rightmost 14 digits of the 28-digit fraction. The sign and characteristic of the low-order part of an extended operand are ignored.

When a result is generated in the extended format and placed in a floating-point register pair or combined into a single vector register, the sign of the low-order part is made the same as that of the high-order part, and, unless the result is a true zero, the low-order characteristic is made 14 less than the high-order characteristic. When the subtraction of 14 would cause the low-order characteristic to become less than zero, the characteristic is made 128 greater than its correct value. (Thus, the subtraction is performed modulo 128.) HFP exponent underflow is indicated only when the high-order characteristic underflows.

When an extended result is made a true zero, both the high-order and low-order parts are made a true zero.

The range covered by the magnitude (M) of a normalized HFP number depends on the format.

In the short format:

$16^{-65} \le M \le (1 - 16^{-6}) \times 16^{63}$

In the long format:

$16^{-65} \le M \le (1 - 16^{-14}) \times 16^{63}$

In the extended format:

$16^{-65} \le M \le (1 - 16^{-28}) \times 16^{63}$

In all formats, approximately:

$5.4 \times 10^{-79} \le M \le 7.2 \times 10^{75}$

Although the final result of an HFP operation has six hexadecimal fraction digits in the short format, 14 fraction digits in the long format, and 28 fraction digits in the extended format, intermediate results have one additional hexadecimal digit on the right. This digit is called the guard digit. The guard digit may increase the precision of the final result because it participates in addition, subtraction, and comparison operations and in the left shift that occurs during normalization.

The entire set of HFP operations with normalized results is available for short, long, and extended operands in register-register versions; and for short and long operands in register-storage versions. Most instructions generate a result that has the same format as the source operands, except that there are multiplication operations which can generate a long product from short operands or an extended product from long operands. Other exceptions are instructions which convert operands from one floating-point format to another or between floating-point and fixed-point (binary-integer) formats.

Programming Notes:

1. In the absence of an HFP exponent overflow or HFP exponent underflow, the long HFP number constituting the low-order part of an extended result correctly expresses the value of the low-order part of the extended result when the characteristic of the high-order part is 14 or higher. This applies also when the result is a true zero. When the high-order characteristic is less than 14 but the number is not a true zero, the low-

order part, when considered as a long HFP number, does not express the correct characteristic value.

2. The entire fraction of an extended result participates in normalization. The low-order part alone may or may not appear to be a normalized long HFP number, depending on whether the 15th digit of the normalized 28-digit fraction is nonzero or zero.

Instructions

The HFP instructions and their mnemonics and operation codes are listed in Figure 18-2 on page 18-5. The figure indicates, in the column labeled "Characteristics", the instruction format, when the condition code is set, the instruction fields that designate access registers, and the exceptional conditions in operand designations, data, or results that cause a program interruption.

All HFP instructions are subject to the AFP-register-control bit, bit 45 of control register 0. The AFP-register-control bit must be one when an AFP register is specified as an operand location; otherwise, an AFP-register data exception, DXC 1, is recognized.

Mnemonics for the HFP instructions have an R as the last letter when the instruction is in the RR, RRE, or RRF format. Certain letters are used for HFP instructions to represent operand-format length and normalization, as follows:

F Thirty-two-bit fixed point
G Sixty-four-bit fixed point
D Long normalized
E Short normalized
U Short unnormalized
W Long unnormalized
X Extended normalized

Note: In the detailed descriptions of the individual instructions, the mnemonic and the symbolic operand designation for the assembler language are shown with each instruction. For a register-to-register operation using COMPARE (short), for example, CER is the mnemonic and R_1,R_2 the operand designation.

Programming Notes:

1. The following additional HFP instructions are available when the HFP-multiply-and-add/subtract facility is installed:
   - MULTIPLY AND ADD (MAD, MADR, MAE, MAER)
   - MULTIPLY AND SUBTRACT (MSD, MSDR, MSE, MSER)
2. The following additional HFP instructions are available when the HFP-unnormalized-extensions facility is installed:
   - MULTIPLY AND ADD UNNORMALIZED (MAY, MAYH, MAYHR, MAYL, MAYLR, MAYR)
   - MULTIPLY UNNORMALIZED (MY, MYH, MYHR, MYL, MYLR, MYR)

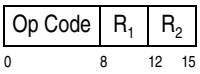
Figure 18-2. Summary of HFP Instructions (Part 4 of 4)

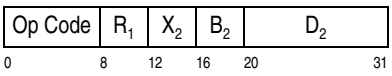
ADD NORMALIZED

Mnemonic1 R_1,R_2 [RR]



Mnemonic1	Op Code	Operands
AER	'3A'	Short HFP
ADR	'2A'	Long HFP
AXR	'36'	Extended HFP

Mnemonic2 $R_1,D_2(X_2,B_2)$ [RX-a]



Mnemonic2	Op Code	Operands
AE	'7A'	Short HFP
AD	'6A'	Long HFP

The second operand is added to the first operand, and the normalized sum is placed at the first-operand location.

Addition of two HFP numbers consists in characteristic comparison, fraction alignment, and signed fraction addition. The characteristics of the two operands are compared, and the fraction accompanying the smaller characteristic is aligned with the other fraction by a right shift, with its characteristic increased by one for each hexadecimal digit of shift until the two characteristics agree.

When a fraction is shifted right during alignment, the leftmost hexadecimal digit shifted out is retained as a guard digit. The fraction that is not shifted is considered to be extended with a zero in the guard-digit position. When no alignment shift occurs, both operands are considered to be extended with zeros in the guard-digit position. The fractions with signs are then added algebraically to form a signed intermediate sum.

The intermediate-sum fraction consists of seven (short format), 15 (long format), or 29 (extended format) hexadecimal digits, including the guard digit, and a possible carry. If a carry is present, the sum is shifted right one digit position so that the carry becomes the leftmost digit of the fraction, and the characteristic is increased by one.

If the addition produces no carry, the intermediate-sum fraction is shifted left as necessary to eliminate any leading hexadecimal zero digits resulting from the addition, provided the fraction is not zero. Zeros are supplied to the vacated rightmost digits, and the characteristic is reduced by the number of hexadecimal digits of shift. The fraction thus normalized is then truncated on the right to six (short format), 14 (long format), or 28 (extended format) hexadecimal

digits. In the extended format, a characteristic is generated for the low-order part, which is 14 less than the high-order characteristic.

The sign of the sum is determined by the rules of algebra, unless all digits of the intermediate-sum fraction are zero, in which case the sign is made plus.

An HFP-exponent-overflow exception exists when a carry from the leftmost position of the intermediate-sum fraction would cause the characteristic of the normalized sum to exceed 127. The operation is completed by making the result characteristic 128 less than the correct value, and a program interruption for HFP exponent overflow occurs. The result is normalized, and the sign and fraction remain correct. For extended results, the characteristic of the low-order part remains correct.

An HFP-exponent-underflow exception exists when the characteristic of the normalized sum would be less than zero and the fraction is not zero. If the HFP-exponent-underflow mask bit in the PSW is one, the operation is completed by making the result characteristic 128 greater than the correct value, and a program interruption for HFP exponent underflow occurs. The result is normalized, and the sign and fraction remain correct. If the HFP-exponent-underflow mask bit in the PSW is zero, a program interruption does not occur; instead, the operation is completed by making the result a positive true zero. For extended results, HFP exponent underflow is not recognized when the low-order characteristic is less than zero but the high-order characteristic is equal to or greater than zero.

The result fraction is zero when the intermediate-sum fraction, including the guard digit, is zero. With a zero result fraction, the action depends on the setting of the HFP-significance mask bit in the PSW. If the HFP-significance mask bit in the PSW is one, no normalization occurs, the intermediate and final result characteristics are the same, and a program interruption for HFP significance occurs. If the HFP-significance mask bit in the PSW is zero, the program interruption does not occur; instead, the result is made a positive true zero.

For AXR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Result is zero
1 Result is less than zero
2 Result is greater than zero
3 --

Program Exceptions:

- Access (fetch, operand 2 of AE and AD only)
- Data with DXC 1, AFP register
- HFP exponent overflow
- HFP exponent underflow
- HFP significance
- Specification (AXR only)
- Transaction constraint

Programming Notes:

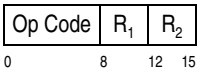
1. An example of the use of the ADD NORMALIZED instruction (AE) is given in Appendix A.

2. Interchanging the two operands in an HFP addition does not affect the value of the sum.

3. The ADD NORMALIZED instruction normalizes the sum but not the operands. Thus, if one or both operands are unnormalized, precision may be lost during fraction alignment.

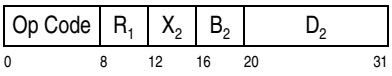
ADD UNNORMALIZED

Mnemonic1 R_1,R_2 [RR]



Mnemonic1	Op Code	Operands
AUR	'3E'	Short HFP
AWR	'2E'	Long HFP

Mnemonic2 $R_1,D_2(X_2,B_2)$ [RX-a]



Mnemonic2	Op Code	Operands
AU	'7E'	Short HFP
AW	'6E'	Long HFP

The second operand is added to the first operand, and the unnormalized sum is placed at the first-operand location.

The execution of ADD UNNORMALIZED is identical to that of ADD NORMALIZED, except that:

1. When no carry is present after the addition, the intermediate-sum fraction is truncated to the proper result-fraction length without a left shift to eliminate leading hexadecimal zeros and without the corresponding reduction of the characteristic.
2. HFP exponent underflow cannot occur.
3. The guard digit does not participate in the recognition of a zero result fraction. A zero result fraction is recognized when the fraction (that is, the intermediate-sum fraction, excluding the guard digit) is zero.

Resulting Condition Code:

0 Result fraction zero
1 Result less than zero
2 Result greater than zero
3 --

Program Exceptions:

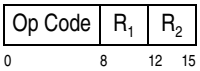
- Access (fetch, operand 2 of AU and AW only)
- Data with DXC 1, AFP register
- HFP exponent overflow
- HFP significance
- Transaction constraint

Programming Notes:

1. An example of the use of the ADD UNNORMALIZED instruction (AU) is given in Appendix A.
2. Except when the result is made a true zero, the characteristic of the result of ADD UNNORMALIZED is equal to the greater of the two operand characteristics, increased by one if the fraction addition produced a carry, or set to zero if HFP exponent overflow occurred.

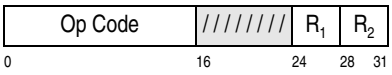
COMPARE

Mnemonic1 R_1,R_2 [RR]



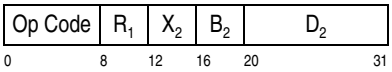
Mnemonic1	Op Code	Operands
CER	'39'	Short HFP
CDR	'29'	Long HFP

Mnemonic2 R_1,R_2 [RRE]



Mnemonic2	Op Code	Operands
CXR	'B369'	Extended HFP

Mnemonic3 $R_1,D_2(X_2,B_2)$ [RX-a]



Mnemonic3	Op Code	Operands
CE	'79'	Short HFP
CD	'69'	Long HFP

The first operand is compared with the second operand, and the condition code is set to indicate the result.

The comparison is algebraic and follows the procedure for normalized subtraction, except that the difference is discarded after setting the condition code and both operands remain unchanged. When the difference, including the guard digit, is zero, the operands are equal. When a nonzero difference is positive or negative, the first operand is high or low, respectively.

An HFP-exponent-overflow, HFP-exponent-underflow, or HFP-significance exception cannot occur.

For CXR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Operands equal
1 First operand low
2 First operand high
3 --

Program Exceptions:

- Access (fetch, operand 2 of CE and CD only)
- Data with DXC 1, AFP register
- Specification (CXR only)
- Transaction constraint

Programming Notes:

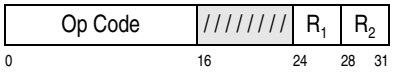
1. Examples of the use of the COMPARE instruction (CDR) are given in Appendix A.

2. An exponent inequality alone is not sufficient to determine the inequality of two operands with the same sign, because the fractions may have different numbers of leading hexadecimal zeros.

3. Numbers with zero fractions compare equal even when they differ in sign or characteristic.

CONVERT FROM FIXED

Mnemonic R_1,R_2 [RRE]



Mnemonic	Op Code	Operands
CEFR	'B3B4'	32-bit binary-integer operand, short HFP result
CDFR	'B3B5'	32-bit binary-integer operand, long HFP result
CXFR	'B3B6'	32-bit binary-integer operand, extended HFP result
CEGR	'B3C4'	64-bit binary-integer operand, short HFP result
CDGR	'B3C5'	64-bit binary-integer operand, long HFP result
CXGR	'B3C6'	64-bit binary-integer operand, extended HFP result

The fixed-point second operand is converted to the HFP format, and the normalized result is placed at the first-operand location.

A nonzero result is normalized. A zero result is made a positive true zero.

The second operand is a signed binary integer that is located in the general register designated by R_2. A 32-bit operand is in bit positions 32-63 of the register.

The result is normalized and rounded toward zero (truncated) before it is placed at the first-operand location.

For CXFR and CXGR, the R_1 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

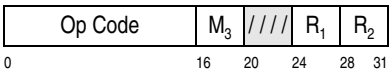
Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC 1, AFP register
- Specification (CXFR and CXGR)
- Transaction constraint

CONVERT TO FIXED

Mnemonic R_1,M_3,R_2 [RRF-e]



Mnemonic	Op Code	Operands
CFER	'B3B8'	Short HFP operand, 32-bit binary-integer result
CFDR	'B3B9'	Long HFP operand, 32-bit binary-integer result
CFXR	'B3BA'	Extended HFP operand, 32-bit binary-integer result
CGER	'B3C8'	Short HFP operand, 64-bit binary-integer result
CGDR	'B3C9'	Long HFP operand, 64-bit binary-integer result
CGXR	'B3CA'	Extended HFP operand, 64-bit binary-integer result

The HFP second operand is rounded to an integer value and then converted to the fixed-point format. The result is placed at the first-operand location.

The result is a signed binary integer that is placed in the general register designated by R_1. For instructions that produce a 32-bit result, the result replaces bits 32-63 of the register, and bits 0-31 of the register remain unchanged.

The second operand is rounded to an integer value by rounding as specified by the modifier in the M_3 field:

M_3	Effective Rounding Method
0	Round toward 0
1	Round to nearest with ties away from 0
4	Round to nearest with ties to even
5	Round toward 0
6	Round toward +∞
7	Round toward -∞

For details on rounding see the section “Rounding Methods” on page 9-14.

A modifier other than 0, 1, or 4-7 is invalid.

The sign of the result is the sign of the second operand, except that a zero result has a plus sign.

If the rounded result would have a value exceeding the range that can be represented in the result format, the largest (in magnitude) representable num-

ber of the same sign as the source is placed at the target location, and condition code 3 is set.

HFP exponent underflow is not recognized because small values are rounded to one (with the appropriate sign) or to zero, depending on the rounding mode.

The M_3 field must designate a valid modifier; otherwise, a specification exception is recognized. For CFXR and CGXR, the R_2 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Source was zero
1 Source was less than zero
2 Source was greater than zero
3 Special case

Program Exceptions:

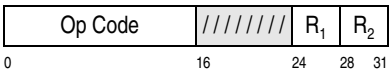
- Data with DXC 1, AFP register
- Specification
- Transaction constraint

DIVIDE

Mnemonic1 R_1,R_2 [RR]

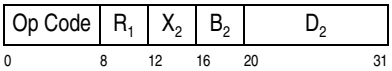
Mnemonic1	Op Code	Operands
DER	'3D'	Short HFP
DDR	'2D'	Long HFP

Mnemonic2 R_1,R_2 [RRE]



Mnemonic2	Op Code	Operands
DXR	'B22D'	Extended HFP

Mnemonic3 $R_1,D_2(X_2,B_2)$ [RX-a]



Mnemonic3	Op Code	Operands
DE	'7D'	Short HFP
DD	'6D'	Long HFP

The first operand (the dividend) is divided by the second operand (the divisor), and the normalized quotient is placed at the first-operand location. No remainder is preserved.

HFP division consists in characteristic subtraction and fraction division. The operands are first normalized to eliminate leading hexadecimal zeros. The difference between the dividend and divisor characteristics of the normalized operands, plus 64, is used as the characteristic of an intermediate quotient.

All dividend and divisor fraction digits participate in forming the fraction of the intermediate quotient. The intermediate-quotient fraction can have no leading hexadecimal zeros, but a right shift of one digit position may be necessary, with this causing an increase of the characteristic by one. The fraction is then truncated to the proper result-fraction length.

An HFP-exponent-overflow exception exists when the characteristic of the final quotient would exceed 127 and the fraction is not zero. The operation is completed by making the result characteristic 128 less than the correct value, and a program interruption for HFP exponent overflow occurs. The result is normalized, and the sign and fraction remain correct. If, for extended results, the low-order characteristic would also exceed 127, it too is decreased by 128.

An HFP-exponent-underflow exception exists when the characteristic of the final quotient would be less than zero and the fraction is not zero. If the HFP-exponent-underflow mask bit in the PSW is one, the operation is completed by making the result characteristic 128 greater than the correct value, and a program interruption for HFP exponent underflow occurs. The result is normalized, and the sign and fraction remain correct. If the HFP-exponent-underflow mask bit in the PSW is zero, a program interruption does not occur; instead, the operation is completed by making the result a positive true zero. For extended results, HFP exponent underflow is not recognized when the low-order characteristic is less than zero but the high-order characteristic is equal to or greater than zero.

HFP exponent underflow does not occur when the characteristic of an operand becomes less than zero during normalization of the operands or when the intermediate-quotient characteristic is less than zero, as long as the final quotient can be represented with the correct characteristic.

When the divisor fraction is zero, an HFP-divide exception is recognized. This includes the case of division of zero by zero.

When the dividend fraction is zero but the divisor fraction is nonzero, the quotient is made a positive true zero. No HFP exponent overflow or HFP exponent underflow occurs.

The sign of the quotient is the exclusive or of the operand signs, except that the sign is always plus when the quotient is made a positive true zero.

For DXR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

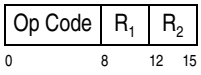
Program Exceptions:

- Access (fetch, operand 2 of DE and DD only)
- Data with DXC 1, AFP register
- HFP divide
- HFP exponent overflow
- HFP exponent underflow
- Specification (DXR only)
- Transaction constraint

Programming Note: Examples of the use of the DIVIDE instruction (DER) are given in Appendix A.

HALVE

Mnemonic R_1,R_2 [RR]



Mnemonic	Op Code	Operands
HER	'34'	Short HFP
HDR	'24'	Long HFP

The second operand is divided by 2, and the normalized quotient is placed at the first-operand location.

The fraction of the second operand is shifted right one bit position, placing the contents of the rightmost bit position in the leftmost bit position of the guard digit, and a zero is supplied to the leftmost bit position of the fraction. The intermediate result, including the guard digit, is then normalized, and the final result is truncated to the proper length.

An HFP-exponent-underflow exception exists when the characteristic of the final result would be less than zero and the fraction is not zero. If the HFP-exponent-underflow mask bit in the PSW is one, the operation is completed by making the result characteristic 128 greater than the correct value, and a program interruption for HFP exponent underflow occurs. The result is normalized, and the sign and fraction remain correct. If the HFP-exponent-underflow mask bit in the PSW is zero, a program interruption does not occur; instead, the operation is completed by making the result a positive true zero.

When the fraction of the second operand is zero, the result is made a positive true zero, and no HFP exponent underflow occurs.

The sign of the result is the same as that of the second operand, except that the sign is always plus when the quotient is made a positive true zero.

Condition Code: The code remains unchanged.

Program Exceptions:

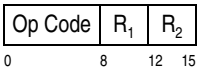
- Data with DXC 1, AFP register
- HFP exponent underflow
- Transaction constraint

Programming Notes:

1. An example of the use of the HALVE instruction (HDR) is given in Appendix A.
2. With short and long operands, the halve operation is identical to a divide operation with the number 2 as divisor. Similarly, the result of HDR is identical to that of MD or MDR with one-half as a multiplier, and the result of HER is identical to that of MEE or MEER with one-half as a multiplier.

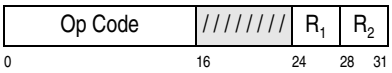
LOAD AND TEST

Mnemonic1 R_1,R_2 [RR]



Mnemonic1	Op Code	Operands
LTER	'32'	Short HFP
LTDR	'22'	Long HFP

Mnemonic2 R_1,R_2 [RRE]



Mnemonic2	Op Code	Operands
LTXR	'B362'	Extended HFP

The second operand is placed at the first-operand location, and its sign and magnitude are tested to determine the setting of the condition code. The condition code is set the same as for a comparison of the second operand with zero.

For short and long operands, the second operand is placed unchanged in the first-operand location.

For extended operands, the high-order sign and the entire fraction of the source are placed unchanged in the result, and the low-order sign is set equal to the high-order sign. If the extended-operand fraction is nonzero, the high-order characteristic is placed unchanged in the result high-order characteristic, and the low-order characteristic is set to 14 less than the high-order characteristic, modulo 128. If the extended-operand fraction is zero, the result is made a true zero with the same sign as the source (the high-order and low-order sign bits of the result are the same as the high-order sign bit of the source).

For LTXR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Result is zero
1 Result is less than zero
2 Result is greater than zero
3 --

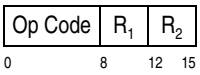
Program Exceptions:

- Data with DXC 1, AFP register
- Specification (LTXR only)
- Transaction constraint

Programming Note: When, for LTER and LTDR, the same register is designated as the first-operand and second-operand location, the operation is equivalent to a test without data movement.

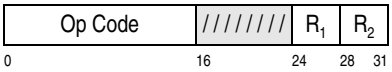
LOAD COMPLEMENT

Mnemonic1 R_1,R_2 [RR]



Mnemonic1	Op Code	Operands
LCER	'33'	Short HFP
LCDR	'23'	Long HFP

Mnemonic2 R_1,R_2 [RRE]



Mnemonic2	Op Code	Operands
LCXR	'B363'	Extended HFP

The second operand is placed at the first-operand location with the sign bit inverted.

The sign bit is inverted even if the operand is zero. For all operand lengths, the source fraction is placed unchanged in the result.

For short and long operands, the source characteristic is placed unchanged in the result.

For extended operands, the low-order sign is set equal to the high-order sign. If the extended-operand fraction is nonzero, the high-order characteristic is placed unchanged in the result high-order characteristic, and the low-order characteristic is set to 14 less than the high-order characteristic, modulo 128. If the extended-operand fraction is zero, the result is made a true zero with the sign inverted from the source (the high-order and low-order sign bits of the result are inverted from the high-order sign bit of the source).

For LCXR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Resulting Condition Code:

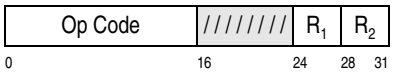
0 Result is zero
1 Result is less than zero
2 Result is greater than zero
3 --

Program Exceptions:

- Data with DXC 1, AFP register
- Specification (LCXR only)
- Transaction constraint

LOAD FP INTEGER

Mnemonic R_1,R_2 [RRE]



Mnemonic	Op Code	Operands
FIER	'B377'	Short HFP
FIDR	'B37F'	Long HFP
FIXR	'B367'	Extended HFP

The second operand is truncated (rounded toward zero) to an integer value in the same floating-point format, and the normalized result is placed at the first-operand location.

A nonzero result is normalized. A zero result is made a positive true zero.

For FIXR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC 1, AFP register
- Specification (FIXR only)
- Transaction constraint

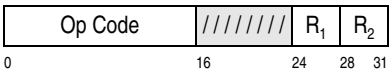
Programming Notes:

1. LOAD FP INTEGER truncates (rounds toward zero) an HFP number to an integer value. These integers, which remain in the HFP format, should not be confused with binary integers, which use a fixed-point format.

2. If the HFP operand has a large enough exponent so that it is already an integer, the result value remains the same, except that an unnormalized operand is normalized, and an operand with a zero fraction is changed to a positive true zero.

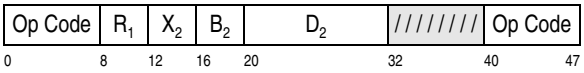
LOAD LENGTHENED

Mnemonic1 R_1,R_2 [RRE]



Mnemonic1	Op Code	Operands
LDER	'B324'	Short HFP operand 2, long HFP operand 1
LXDR	'B325'	Long HFP operand 2, extended HFP operand 1
LXER	'B326'	Short HFP operand 2, extended HFP operand 1

Mnemonic2 $R_1,D_2(X_2,B_2)$ [RXE]



Mnemonic2	Op Code	Operands
LDE	'ED24'	Short HFP operand 2, long HFP operand 1
LXD	'ED25'	Long HFP operand 2, extended HFP operand 1
LXE	'ED26'	Short HFP operand 2, extended HFP operand 1

The second operand is extended to a longer format, and the result is placed at the first-operand location.

For all operand lengths, the source fraction is extended with zeros and placed in the result. The sign bit of the result is set the same as the sign of the source even when the result is made a true zero.

For long results, the source characteristic is placed unchanged in the result.

For extended results, the low-order sign is set equal to the high-order sign. If the fraction is nonzero, the source characteristic is placed unchanged in the result high-order characteristic, and the low-order characteristic is set to 14 less than the high-order characteristic, modulo 128. If the fraction is zero, the result is made a true zero with the same sign as the source (the high-order and low-order sign bits of the result are the same as the sign bit of the source).

For LXD, LXDR, LXE, and LXER, the R_1 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

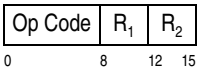
Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2 of LDE, LXE, and LXD only)
- Data with DXC 1, AFP register
- Specification (LXE, LXER, LXD, LXDR)
- Transaction constraint

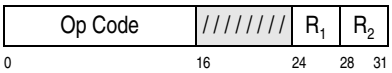
LOAD NEGATIVE

Mnemonic1 R_1,R_2 [RR]



Mnemonic1	Op Code	Operands
LNER	'31'	Short HFP
LNDR	'21'	Long HFP

Mnemonic2 R_1,R_2 [RRE]



Mnemonic2	Op Code	Operands
LNXR	'B361'	Extended HFP

The second operand is placed at the first-operand location with the sign bit made one.

The sign bit is made one even if the operand is zero. For all operand lengths, the source fraction is placed unchanged in the result.

For short and long operands, the source characteristic is placed unchanged in the result.

For extended operands, the low-order sign is set equal to the high-order sign. If the extended-operand fraction is nonzero, the high-order characteristic is placed unchanged in the result high-order characteristic, and the low-order characteristic is set to 14 less than the high-order characteristic, modulo 128. If the extended-operand fraction is zero, the result is made a negative true zero (the high-order and low-order sign bits of the result are set to one).

For LNXR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Resulting Condition Code:

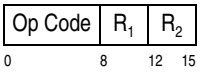
0 Result is zero
1 Result is less than zero
2 --
3 --

Program Exceptions:

- Data with DXC 1, AFP register
- Specification (LNXR only)
- Transaction constraint

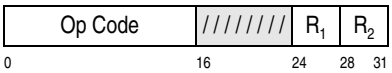
LOAD POSITIVE

Mnemonic1 R_1,R_2 [RR]



Mnemonic1	Op Code	Operands
LPER	'30'	Short HFP
LPDR	'20'	Long HFP

Mnemonic2 R_1,R_2 [RRE]



Mnemonic2	Op Code	Operands
LPXR	'B360'	Extended HFP

The second operand is placed at the first-operand location with the sign bit made zero.

For all operand lengths, the sign bit is made zero, and the source fraction is placed unchanged in the result.

For short and long operands, the source characteristic is placed unchanged in the result.

For extended operands, the low-order sign is set equal to the high-order sign. If the extended-operand fraction is nonzero, the high-order characteristic is placed unchanged in the result high-order characteristic, and the low-order characteristic is set to 14 less than the high-order characteristic, modulo 128. If the extended-operand fraction is zero, the result is made a positive true zero (the high-order and low-order sign bits of the result are set to zero).

For LPXR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Resulting Condition Code:

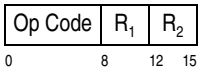
0 Result is zero
1 --
2 Result is greater than zero
3 --

Program Exceptions:

- Data with DXC 1, AFP register
- Specification (LPXR only)
- Transaction constraint

LOAD ROUNDED

Mnemonic1 R_1,R_2 [RR]

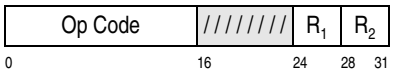


Mnemonic1	Op Code	Operands
LEDR	'35'	Long HFP operand 2, short HFP operand 1
LDXR	'25'	Extended HFP operand 2, long HFP operand 1

The above mnemonics are alternatives to the following older mnemonics that are less descriptive of operand lengths:

LRER	'35'	Long HFP operand 2, short HFP operand 1
LRDR	'25'	Extended HFP operand 2, long HFP operand 1

Mnemonic2 R_1,R_2 [RRE]



Mnemonic2	Op Code	Operands
LEXR	'B366'	Extended HFP operand 2, short HFP operand 1

The second operand is rounded to a shorter format, and the result is placed at the first-operand location.

Rounding consists in adding a one to the leftmost bit position of the second operand that is to be dropped and propagating any carry through the fraction. The sign of the second operand is ignored, and addition is performed as if the fraction were positive.

If rounding causes a carry out of the leftmost hexadecimal digit position of the fraction, the fraction is shifted right one digit position so that the carry becomes the leftmost digit of the fraction, and the characteristic is increased by one.

The intermediate fraction is then truncated to the proper result-fraction length. For LEDR and LEXR, the result replaces the leftmost 32 bits of the target register, and the rightmost 32 bit positions of the target register remain unchanged. For LDXR, the 64-bit result is placed in a floating-point register, not a floating-point register pair.

The sign of the result is the same as the sign of the second operand. There is no normalization to eliminate leading zeros.

An HFP-exponent-overflow exception exists when shifting the fraction right would cause the characteristic to exceed 127. The operation is completed by making the result characteristic 128 less than the correct value, and a program interruption for HFP exponent overflow occurs. The result is normalized, and the sign and fraction remain correct.

HFP-exponent-underflow and HFP-significance exceptions cannot occur.

For LDXR (or LRDR) and LEXR, the R_2 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

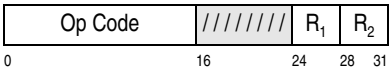
Program Exceptions:

- Data with DXC 1, AFP register
- HFP exponent overflow
- Specification (LDXR, LEXR, LRDR)
- Transaction constraint

Programming Note: The sign of the rounded result is the same as the sign of the operand, even when the result is zero.

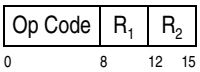
MULTIPLY

Mnemonic1 R_1,R_2 [RRE]



Mnemonic1	Op Code	Operands
MEER	'B337'	Short HFP

Mnemonic2 R_1,R_2 [RR]

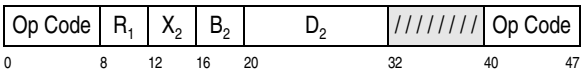


Mnemonic2	Op Code	Operands
MDR	'2C'	Long HFP
MXR	'26'	Extended HFP
MDER	'3C'	Short HFP multiplier and multiplicand, long HFP product
MXDR	'27'	Long HFP multiplier and multiplicand, extended HFP product

The above mnemonic MDER is an alternative to the following older mnemonic that is less descriptive of operand lengths:

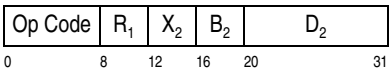
MER	'3C'	Short HFP multiplier and multiplicand, long HFP product

Mnemonic3 $R_1,D_2(X_2,B_2)$ [RXE]



Mnemonic3	Op Code	Operands
MEE	'ED37'	Short HFP

Mnemonic4 $R_1,D_2(X_2,B_2)$ [RX-a]



Mnemonic4	Op Code	Operands
MD	'6C'	Long HFP
MDE	'7C'	Short HFP multiplier and multiplicand, long HFP product
MXD	'67'	Long HFP multiplier and multiplicand, extended HFP product

The above mnemonic MDE is an alternative to the following older mnemonic that is less descriptive of operand lengths:

ME	'7C'	Short HFP multiplier and multiplicand, long HFP product

The normalized product of the second operand (the multiplier) and the first operand (the multiplicand) is placed at the first-operand location.

Multiplication of two HFP numbers consists in exponent addition and fraction multiplication. The operands are first normalized to eliminate leading hexadecimal zeros. The sum of the characteristics of the normalized operands, less 64, is used as the characteristic of the intermediate product.

The fraction of the intermediate product is the exact product of the normalized operand fractions. If the intermediate-product fraction has one leading hexadecimal zero digit, the fraction is shifted left one digit position, bringing the contents of the guard-digit position into the rightmost position of the result fraction, and the intermediate-product characteristic is reduced by one. The fraction is then truncated to the proper result-fraction length.

For MDE and MDER, the multiplier and multiplicand fractions have six hexadecimal digits; the product fraction has the full 14 digits of the long format, with the two rightmost fraction digits always zeros. For MEE and MEER, the multiplier and multiplicand fractions have six digits, and the final product fraction is truncated to six digits; the result, as for all short-format results, replaces the leftmost 32 bits of the target register, and the rightmost 32 bit positions of the target register remain unchanged.

For MD and MDR, the multiplier and multiplicand fractions have 14 digits, and the final product fraction is truncated to 14 digits. For MXD and MXDR, the multiplier and multiplicand fractions have 14 digits, with the multiplicand occupying the high-order part of the first operand; the final product fraction contains 28 digits and is an exact product of the operand fractions. For MXR, the multiplier and multiplicand fractions have 28 digits, and the final product fraction is truncated to 28 digits.

An HFP-exponent-overflow exception exists when the characteristic of the final product would exceed 127 and the fraction is not zero. The operation is completed by making the result characteristic 128 less than the correct value, and a program interruption for HFP exponent overflow occurs. The result is normalized, and the sign and fraction remain correct. If, for extended results, the low-order characteristic would also exceed 127, it too is decreased by 128.

HFP exponent overflow is not recognized when the intermediate-product characteristic is initially 128 but is brought back within range by normalization.

An HFP-exponent-underflow exception exists when the characteristic of the final product would be less than zero and the fraction is not zero. If the HFP-exponent-underflow mask bit in the PSW is one, the operation is completed by making the result characteristic 128 greater than the correct value, and a program interruption for HFP exponent underflow occurs. The result is normalized, and the sign and fraction remain correct. If the HFP-exponent-underflow mask bit in the PSW is zero, a program interruption does not occur; instead, the operation is completed by making the result a positive true zero. For extended results, HFP exponent underflow is not recognized when the low-order characteristic is less than zero but the high-order characteristic is equal to or greater than zero.

HFP exponent underflow does not occur when the characteristic of an operand becomes less than zero during normalization of the operands, as long as the final product can be represented with the correct characteristic.

If either or both operand fractions are zero, the result is made a positive true zero, and no HFP exponent overflow or HFP exponent underflow occurs.

The sign of the product is the exclusive or of the operand signs, except that the sign is always plus when the result is made a true zero.

The R_1 field for MXD, MXDR, and MXR, and the R_2 field for MXR must designate valid floating-point-register pairs. Otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

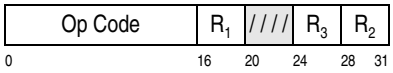
- Access (fetch, operand 2 of MDE, MEE, MD, and MXD only)
- Data with DXC 1, AFP register
- HFP exponent overflow
- HFP exponent underflow
- Specification (MXD, MXDR, MXR)
- Transaction constraint

Programming Notes:

1. An example of the use of the MULTIPLY instruction (MDR) is given in Appendix A.
2. Interchanging the two operands in an HFP multiplication does not affect the value of the product.

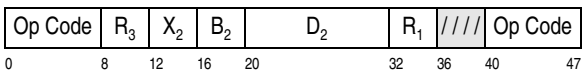
MULTIPLY AND ADD

Mnemonic1 R_1,R_3,R_2 [RRD]



Mnemonic1	Op Code	Operands
MAER	'B32E'	Short HFP
MADR	'B33E'	Long HFP

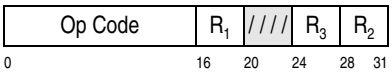
Mnemonic2 $R_1,R_3,D_2(X_2,B_2)$ [RXF]



Mnemonic2	Op Code	Operands
MAE	'ED2E'	Short HFP
MAD	'ED3E'	Long HFP

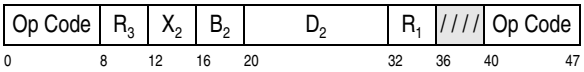
MULTIPLY AND SUBTRACT

Mnemonic1 R_1,R_3,R_2 [RRD]



Mnemonic1	Op Code	Operands
MSER	'B32F'	Short HFP
MSDR	'B33F'	Long HFP

Mnemonic2 $R_1,R_3,D_2(X_2,B_2)$ [RXF]



Mnemonic2	Op Code	Operands
MSE	'ED2F'	Short HFP
MSD	'ED3F'	Long HFP

The third operand is multiplied by the second operand, and then the first operand is added to or subtracted from the product. The sum or difference is placed at the first-operand location. The MULTIPLY AND ADD and MULTIPLY AND SUBTRACT operations may be summarized as:

$op_1 = op_3 \bullet op_2 \pm op_1$

The third and second HFP operands are multiplied, forming an intermediate product, and the first operand is then added (or subtracted) algebraically to (or from) the intermediate product, forming an intermediate result. The exponent and fraction of the intermediate product and intermediate result are maintained exactly. The intermediate result, if nonzero, is normalized and truncated to the operand format and then placed at the first-operand location.

The sign of the result is determined by the rules of algebra, unless the intermediate-result fraction is zero, in which case the result is made a positive true zero.

An HFP-exponent-overflow exception exists when the characteristic of the normalized result would exceed 127 and the fraction is not zero. The operation is completed by making the result characteristic 128 less than the correct value, and a program interruption for HFP exponent overflow occurs. The result is normalized, and the sign and fraction remain correct.

HFP exponent overflow is not recognized on intermediate values, provided the normalized result can be represented with the correct characteristic.

An HFP-exponent-underflow exception exists when the characteristic of the normalized result would be less than zero and the fraction is not zero. If the HFP-exponent-underflow mask bit in the PSW is one, the operation is completed by making the result characteristic 128 greater than the correct value, and a program interruption for HFP exponent underflow occurs. The result is normalized, and the sign and fraction remain correct. If the HFP-exponent-underflow mask bit in the PSW is zero, a program interruption does not occur; instead, the operation is completed by making the result a positive true zero.

HFP exponent underflow is not recognized on input operands and intermediate values, provided the normalized result can be represented with the correct characteristic.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2 of MAE, MAD, MSE, MSD)
- Data with DXC 1, AFP register
- HFP exponent overflow
- HFP exponent underflow
- Operation (if the HFP multiply-add/subtract facility is not installed)
- Transaction constraint

Programming Note: MULTIPLY AND ADD (SUBTRACT) differs from MULTIPLY followed by ADD (SUBTRACT) NORMALIZED in the following ways:

1. The product is maintained to full precision, and overflow and underflow are not recognized on the product.

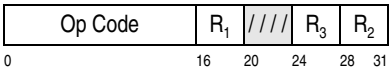
2. The HFP-significance exception is not recognized for MULTIPLY AND ADD (SUBTRACT).

3. ADD (SUBTRACT) NORMALIZED maintains only a single guard digit and does not prenormalize input operands; thus, in some cases, an unnormalized input operand may cause loss of precision in the result. MULTIPLY AND ADD (SUBTRACT) maintains the entire intermediate sum (difference), which is normalized before the truncation operation is performed; thus, unnormalized operands do not cause any additional loss of precision.

4. On most models, the execution time of MULTIPLY AND ADD (SUBTRACT) is less than the combined execution time of MULTIPLY followed by ADD (SUBTRACT) NORMALIZED. The performance of MULTIPLY AND ADD (SUBTRACT) may be severely degraded in the case of unnormalized input operands.

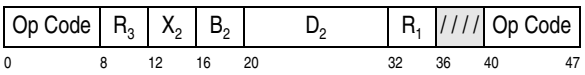
MULTIPLY AND ADD UNNORMALIZED

Mnemonic1 R_1,R_3,R_2 [RRD]



Mnemonic1	Op Code	Operands
MAYR	'B33A'	Long HFP sources, extended HFP result
MAYHR	'B33C'	Long HFP sources, high-order part of extended HFP result
MAYLR	'B338'	Long HFP sources, low-order part of extended HFP result

Mnemonic2 $R_1,R_3,D_2(X_2,B_2)$ [RXF]



Mnemonic2	Op Code	Operands
MAY	'ED3A'	Long HFP sources, extended HFP result
MAYH	'ED3C'	Long HFP sources, high-order part of extended HFP result
MAYL	'ED38'	Long HFP sources, low-order part of extended HFP result

The second and third HFP operands are multiplied, forming an intermediate product; the first operand (addend) is then added algebraically to the intermediate product to form an intermediate sum; the intermediate-sum fraction is truncated on the left or on the right, if need be, to form an intermediate extended result. All (or a part) of the intermediate extended result is placed in the floating-point-register pair (or floating-point register) designated by the R_1 field. The operands, intermediate values, and results are not normalized to eliminate leading hexadecimal zeros.

The MULTIPLY AND ADD UNNORMALIZED operations may be summarized as:

$t_1 \leftarrow op_3 \bullet op_2 + op_1$

Multiplication of two HFP numbers consists in exponent addition and fraction multiplication. The sum of the characteristics of the second and third operands, less 64, is used as the characteristic of the high-

order part of the intermediate product; this value is independent of whether the result fraction is zero. The characteristic of the intermediate product is maintained correctly and does not wrap.

In all cases, the second- and third-operand fractions have 14 digits; the intermediate-product fraction contains 28 digits and is an exact product of the operand fractions. The intermediate-product fraction is not inspected for leading hexadecimal zero digits and is used without shifting in the subsequent addition.

In all cases, the first operand is located in the floating-point register designated by the R_1 field and the first-operand fraction has 14 digits.

Addition of two HFP numbers consists in characteristic comparison, fraction alignment, and signed fraction addition. The characteristics of the intermediate product and the addend are compared. If the characteristics are equal, no alignment is required. If the characteristic of the addend is smaller than the characteristic of the product, the fraction of the addend is aligned with the product fraction by a right shift, with its characteristic increased by one for each hexadecimal digit of shift. If the characteristic of the addend is larger than the characteristic of the product, the fraction of the addend is aligned with the product fraction by a left shift, with its characteristic decreased by one for each hexadecimal digit of shift. Shifting continues until the two characteristics agree. All hexadecimal digits shifted out are preserved and participate in the subsequent addition.

After alignment, the fractions with signs are then added algebraically to form a signed intermediate sum. The fraction of the intermediate sum is maintained exactly. The intermediate-sum fraction is not inspected for leading hexadecimal zero digits and is not shifted. Only those 28 hexadecimal digits of the intermediate-sum fraction which are aligned with the 28 hexadecimal digits of the intermediate-product fraction are used as the fraction of the intermediate extended-result.

The high-order characteristic of the intermediate extended result is set to the characteristic of the intermediate product, modulo 128. The low-order characteristic of the intermediate extended result is set to 14 less than the high-order characteristic, modulo 128. Wrap-around of the characteristic is independent of whether the result fraction is zero.

The sign of the result is determined by the rules of algebra, unless the entire intermediate-sum fraction is zero, in which case the sign of the result is made positive.

For MAY and MAYR, the entire intermediate extended result is placed in the floating-point register-pair designated by the R_1 field; the R_1 field may designate either the lower-numbered or higher-numbered register of a floating-point-register pair. For MAYH and MAYHR, the high-order part of the intermediate extended result is placed in the floating-point register designated by the R_1 field and the low-order part is discarded. For MAYL and MAYLR, the low-order part of the intermediate extended result is placed in the floating-point register designated by the R_1 field and the high-order part is discarded.

HFP-exponent-overflow and HFP-exponent-underflow exceptions are not recognized. Characteristics of the intermediate extended result wrap-around modulo 128 and no exception is reported.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2 of MAYH, MAY, and MAYL only)
- Data with DXC 1, AFP register
- Operation (if the HFP-unnormalized-extensions facility is not installed)
- Transaction constraint

Programming Notes:

1. While performance of MULTIPLY AND ADD may be severely degraded for the case of unnormalized input operands, this is not the case for MULTIPLY AND ADD UNNORMALIZED.

2. MULTIPLY AND ADD UNNORMALIZED can be used to efficiently perform multiple precision arithmetic on numbers of any arbitrary size. This is accomplished by organizing the numbers into big digits of 52 bits each, with each big digit maintained as an integer in the HFP long format. Using a radix of 2^{52} and big digits which can hold up to 56 bits provides a redundant representation. This redundant representation permits multiplication and addition using a “carry save” technique and permits maximum utilization of the floating-point pipeline.

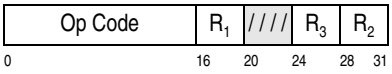
3. By setting the multiplier to an integer value of 1 with the proper characteristic, the multiplicand can be scaled by any power of 16 and then added to the addend. This permits, for example, adding the "carry" from one stage of a multiplication to the "sum" of the next stage to the left. In the same manner, the "sum" of one stage can be scaled to be added to the "carry" of the stage to the right.

4. In the first round of a multiply and accumulate, the step of clearing the accumulated value to zero, may be avoided by using the MULTIPLY UNNORMALIZED instead of MULTIPLY AND ADD UNNORMALIZED.

5. For additional notes concerning the unnormalized operations see the programming notes under the MULTIPLY UNNORMALIZED instruction.

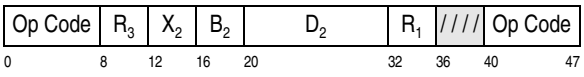
MULTIPLY UNNORMALIZED

Mnemonic1 R_1,R_3,R_2 [RRD]



Mnemonic1	Op Code	Operands
MYR	'B33B'	Long HFP multiplier and multiplicand, extended HFP product
MYHR	'B33D'	Long HFP multiplier and multiplicand, high-order part of extended HFP product
MYLR	'B339'	Long HFP multiplier and multiplicand, low-order part of extended HFP product

Mnemonic2 $R_1,R_3,D_2(X_2,B_2)$ [RXF]



Mnemonic2	Op Code	Operands
MY	'ED3B'	Long HFP multiplier and multiplicand, extended HFP product
MYH	'ED3D'	Long HFP multiplier and multiplicand, high-order part of extended HFP product
MYL	'ED39'	Long HFP multiplier and multiplicand, low-order part of extended HFP product

The second and third HFP operands are multiplied, forming an intermediate product, which, in turn, is used to form an intermediate extended result. All (or a part) of the intermediate extended result is placed in the floating-point-register pair (or floating-point register) designated by the R_1 field. The operands, intermediate values, and results are not normalized to eliminate leading hexadecimal zeros.

Multiplication of two HFP numbers consists in exponent addition and fraction multiplication. The sum of the characteristics of the second and third operands, less 64, is used as the characteristic of the high-order part of the intermediate product; this value is independent of whether the result fraction is zero. The characteristic of the intermediate product is maintained correctly and does not wrap.

The high-order characteristic of the intermediate extended result is set to the characteristic of the intermediate product, modulo 128. The low-order characteristic of the intermediate extended result is set to 14 less than the high-order characteristic, modulo 128. Wrap-around of the characteristic is independent of whether the result fraction is zero.

In all cases, the second- and third-operand fractions have 14 digits; the intermediate-product fraction contains 28 digits and is an exact product of the operand fractions. The intermediate-product fraction is not inspected for leading hexadecimal zero digits and is used without shifting as the fraction of the intermediate extended result.

The sign of the result is the exclusive or of the operand signs, including the case when the result fraction is zero.

For MY and MYR, the entire intermediate extended result is placed in the floating-point-register pair designated by the R_1 field. For MYH and MYHR, the high-order part of the intermediate extended result is placed in the floating-point register designated by the R_1 field and the low-order part is discarded. For MYL and MYLR, the low-order part of the intermediate extended result is placed in the floating-point register designated by the R_1 field and the high-order part is discarded.

HFP-exponent-overflow and HFP-exponent-underflow exceptions are not recognized. Characteristics of the intermediate extended result wrap-around modulo 128 and no exception is reported.

The R_1 field for MY and MYR must designate a valid floating-point-register pair. Otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2 of MYH, MY, and MYL only)
- Data with DXC 1, AFP register
- Operation (if the HFP-unnormalized-extensions facility is not installed)
- Specification (MY and MYR)
- Transaction constraint

Programming Notes:

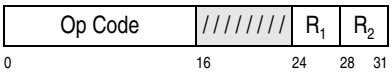
1. The formal definition of Long HFP numbers is in terms of a 14-digit fraction and a signed exponent in “excess-64 notation”. But, without change in function, these numbers can also be described as having a 14-digit integer and a signed exponent in “excess-78 notation”. When using the unnormalized instructions, the programmer may find it more convenient to consider these values in the later terms rather than the former. Thus, in these terms, MULTIPLY UNNORMALIZED multiplies two 14-digit integers to produce a 28-digit integer result. The characteristic of the low-order part is the sum of the operand characteristics less 78 and the high-order characteristic is set 14 larger than the low-order part. When considered as described above, MULTIPLY UNNORMALIZED provides the exact 28-digit integer product of two 14-digit integers.

2. Rather than using MY (or MYR) to provide the entire 28-digits in a floating-point-register pair, the programmer may find it more convenient to issue two separate instructions, MYH and MYL (or MYHR and MYLR), to place the high-order part and low-order part in any floating-point register. It is expected that on most machines, the performance of these two approaches is essentially the same.

3. The MULTIPLY UNNORMALIZED instruction format designates three operand locations and can be used to produce a product without overlaying the source operands. In many cases this saves an extra load.

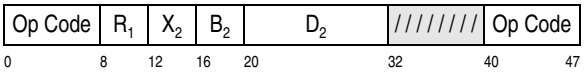
SQUARE ROOT

Mnemonic1 R_1,R_2 [RRE]



Mnemonic1	Op Code	Operands
SQER	'B245'	Short HFP
SQDR	'B244'	Long HFP
SQXR	'B336'	Extended HFP

Mnemonic2 $R_1,D_2(X_2,B_2)$ [RXE]



Mnemonic2	Op Code	Operands
SQE	'ED34'	Short HFP
SQD	'ED35'	Long HFP

The normalized and rounded square root of the second operand is placed at the first-operand location.

When the fraction of the second operand is zero, the sign and characteristic of the second operand are ignored, and the operation is completed by placing a positive true zero at the first-operand location.

If the second operand is less than zero, an HFP-square-root exception is recognized.

If the second operand is normalized and greater than zero, the characteristic, fraction, and sign of the result are produced as follows:

- The result characteristic is one-half of the sum of the operand characteristic and either 64, if the operand characteristic is even, or 65, if it is odd.
- If the operand characteristic is odd, the operand fraction is shifted right one digit position, the rightmost digit entering the guard-digit position.
- An intermediate-result fraction is produced by computing without rounding the square root of the operand fraction, after any right shift as described. The intermediate-result fraction consists of the 29 most significant hexadecimal digits of the square-root result in the extended format, 15 in the long format, or seven in the short format, where all three formats include a guard digit on the right.
- A one is added to the leftmost bit of the guard digit of the intermediate result, any carry is prop-

agated to the left, and the guard digit is dropped to produce the result fraction.

- The result sign is made plus.

If the second operand is unnormalized and greater than zero, the operand is first normalized. The operation then proceeds as for normalized operands.

For SQXR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2 of SQE and SQD only)
- Data with DXC 1, AFP register
- HFP square root
- Specification (SQXR only)
- Transaction constraint

Programming Notes:

1. The use of the SQUARE ROOT instruction with short operands (SQER) is illustrated by the examples in the following table:

Operand (hex)	Decimal Value	Result (hex)	Decimal Value
42 190000	25.0	41 500000	5.0
40 400000	0.250	40 800000	0.50
40 800000	0.50	40 B504F3	0.7071...
41 800000	8.0	41 2D413D	2.8284...

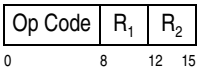
2. The result fraction is correctly normalized without any further left or right shifts of the intermediate-result fraction and without any further exponent adjustment. Rounding cannot cause a carry out of the leftmost digit.

3. Although a characteristic greater than 127 or less than zero may temporarily be generated during the operation, the result characteristic is always within the representable range, and no HFP exponent overflow or underflow occurs.

   Specifically, the smallest nonzero operand in the long format consists of a one bit, preceded on the left by 63 zeros. This operand is an unnormalized number with a value of 16^{-78}, and its square root is 16^{-39}. The normalized representation of this result has a characteristic of 26 (decimal). Similarly, the square root of the largest representable operand has a characteristic of 96 (decimal). The instruction, therefore, cannot produce a nonzero result with a characteristic outside the range of 26 to 96.

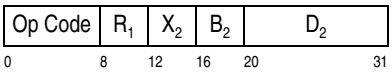
SUBTRACT NORMALIZED

Mnemonic1 R_1,R_2 [RR]



Mnemonic1	Op Code	Operands
SER	'3B'	Short HFP
SDR	'2B'	Long HFP
SXR	'37'	Extended HFP

Mnemonic2 $R_1,D_2(X_2,B_2)$ [RX-a]



Mnemonic2	Op Code	Operands
SE	'7B'	Short HFP
SD	'6B'	Long HFP

The second operand is subtracted from the first operand, and the normalized difference is placed at the first-operand location.

The execution of SUBTRACT NORMALIZED is identical to that of ADD NORMALIZED, except that the second operand participates in the operation with its sign bit inverted.

For SXR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Resulting Condition Code:

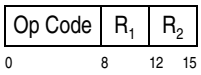
0 Result is zero
1 Result is less than zero
2 Result is greater than zero
3 --

Program Exceptions:

- Access (fetch, operand 2 of SE and SD only)
- Data with DXC 1, AFP register
- HFP exponent overflow
- HFP exponent underflow
- HFP significance
- Specification (SXR only)
- Transaction constraint

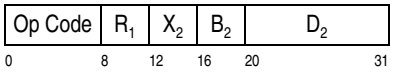
SUBTRACT UNNORMALIZED

Mnemonic1 R_1,R_2 [RR]



Mnemonic1	Op Code	Operands
SUR	'3F'	Short HFP
SWR	'2F'	Long HFP

Mnemonic2 $R_1,D_2(X_2,B_2)$ [RX-a]



Mnemonic2	Op Code	Operands
SU	'7F'	Short HFP
SW	'6F'	Long HFP

The second operand is subtracted from the first operand, and the unnormalized difference is placed at the first-operand location.

The execution of SUBTRACT UNNORMALIZED is identical to that of ADD UNNORMALIZED, except that the second operand participates in the operation with its sign bit inverted.

Resulting Condition Code:

0 Result fraction zero
1 Result less than zero
2 Result greater than zero
3 --

Program Exceptions:

- Access (fetch, operand 2 of SU and SW only)
- Data with DXC 1, AFP register
- HFP exponent overflow
- HFP significance
- Transaction constraint

Binary-Floating-Point Facility

The binary-floating-point (BFP) facility provides instructions to operate on binary (radix-2) floating-point data.

BFP provides a number of important advantages over hexadecimal floating point (HFP):

- Greater precision and exponent range (except for numbers in the short format where HFP has the greater range).
- Automatic rounding to the nearest value for all arithmetic operations. There are directed-rounding options that may be used instead.
- Special entities of “infinity” and “Not-a-Number” (NaN), which are accepted and handled by arithmetic operations in a reasonable fashion. They provide better defaults for exponent overflow and invalid operations (such as division of zero by zero). This allows most programs to continue running without hiding such errors and without using specialized exception handlers.
- Exponent underflow gives “subnormal” numbers as the default, which provides more consistent results than the abrupt result of zero produced by the HFP instructions.
- The greater exponent range makes exponent overflow and underflow in correctly written programs very unlikely, so that programmers may often be able to ignore these conditions.
- Both mask and flag bits are provided for all IEEE exceptions. The mask bits enable or disable interruptions. When interruptions are disabled, the flag bits keep track of exceptions during execution so that warning messages may be issued.
- Programs can be migrated from and to workstations and other systems using different architectures and still give consistent results, provided that floating-point operations on the other sys-

© Copyright IBM Corp. 2000, 2025

tems also conform to ANSI/IEEE Standard 754-2008 (see Reference [20.] on page xxxii). This does not mean, however, that bit-wise compatible results can be guaranteed, because the standard allows implementation flexibility, especially in the presence of exceptions.

Programming Note: The bit representation of the BFP data formats in storage is defined to be left-to-right in a manner that is uniform for all numeric operands in the z/Architecture architecture. Although the format diagrams in ANSI/IEEE Standard 754-2008 appear to use the same left-to-right bit sequence, the standard only defines the meaning of the bits without specifying how they appear in storage; the storage arrangement is left to the implementation. Several implementations in fact use other sequences; this may affect programs which are dependent on the bit representation of floating-point data in storage.

Floating-Point-Control (FPC) Register

The floating-point-control (FPC) register is a 32-bit register that contains mask bits, flag bits, a data-exception code, and two rounding-mode fields. The FPC register is described in the section "Floating-Point-Control (FPC) Register" on page 9-9. An overview of the FPC register is shown in Figure 9-5 on page 9-9. Details are shown in Figure 9-6 on page 9-9, Figure 9-7 on page 9-10, and in Figure 9-8 on page 9-10. (In Figure 9-6 on page 9-9, the abbreviations "IM" and "SF" are based on the terms "interruption mask" and "status flag," respectively.)

The bits of the FPC register are often referred to as, for example, FPC 1.0, meaning bit 0 of byte 1 of the register.

BFP Arithmetic

BFP Data Formats

Binary-floating-point data may be represented in any of following formats: tiny, short, long, or extended.

BFP Tiny Format

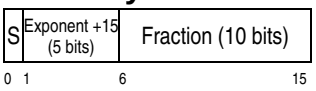

Figure 19-1. BFP Tiny Format (2 bytes)

BFP Short Format

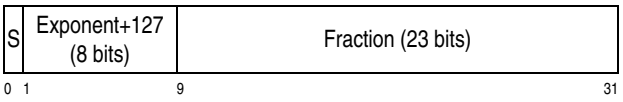

Figure 19-2. BFP Short Format (4 bytes)

When an operand in the BFP short format is loaded into a floating-point register, it occupies the left half of the register, and the right half remains unchanged.

BFP Long Format

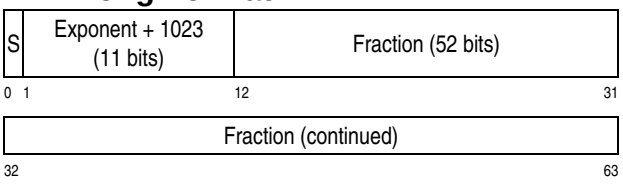

Figure 19-3. BFP Long Format (8 bytes)

When an operand in the BFP long format is loaded into a floating-point register, it occupies the entire register.

BFP Extended Format

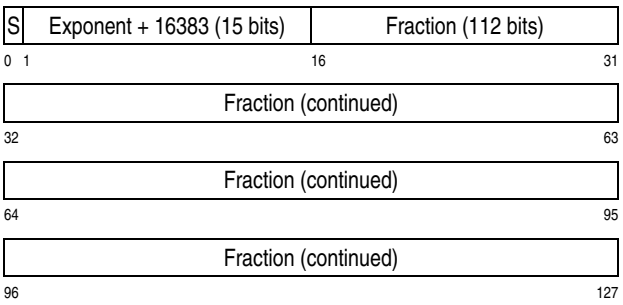

Figure 19-4. BFP Extended Format (16 bytes)

An operand in the BFP extended format occupies a register pair. The sign and biased exponent are in the leftmost 16 bits of the lower-numbered register of the pair and are followed by the leftmost 48 bits of the fraction. The rightmost 64 bits of the fraction are in the higher-numbered register of the pair.

The properties of the four formats are tabulated in Figure 19-5 on page 19-3.

Property	Format			
	Tiny	Short	Long	Extended
Format length (bits)	16	32	64	128
Biased-exponent length (bits)	5	8	11	15
Fraction length (bits)	10	23	52	112
Precision (p)	11	24	53	113
Maximum left-units-view (LUV) exponent (Emax)	15	127	1023	16383
Minimum left-units-view (LUV) exponent (Emin)	-14	-126	-1022	-16382
Left-units-view (LUV) bias	15	127	1023	16383
Nmax	$(1-2^{-11})x2^{16}$	$(1-2^{-24})x2^{128}$ $\approx 3.4x10^{38}$	$(1-2^{-53})x2^{1024}$ $\approx 1.8x10^{308}$	$(1-2^{-113})x2^{16384}$ $\approx 1.2x10^{4932}$
Nmin	$1.0x2^{-14}$	$1.0x2^{-126}$ $\approx 1.2x10^{-38}$	$1.0x2^{-1022}$ $\approx 2.2x10^{-308}$	$1.0x2^{-16382}$ $\approx 3.4x10^{-4932}$
Dmin	$1.0x2^{-24}$	$1.0x2^{-149}$ $\approx 1.4x10^{-45}$	$1.0x2^{-1074}$ $\approx 4.9x10^{-324}$	$1.0x2^{-16494}$ $\approx 6.5x10^{-4966}$

Explanation:

≈ Value is approximate.
Dmin Smallest (in magnitude) representable subnormal number.
Nmax Largest (in magnitude) representable finite number.
Nmin Smallest (in magnitude) representable normal number.

Figure 19-5. Summary of BFP Data Formats

Biased Exponent

For each format, the bias that is used to allow all exponents to be expressed as unsigned numbers is shown in the Figure 19-5 on page 19-3. Biased exponents are similar to the characteristics of the HFP format, except that special meanings are attached to biased exponents of all zeros and all ones, which are discussed in the section “Classes of BFP Data” on page 19-4.

Significand

In each format, the binary point of a BFP number is considered to be to the left of the leftmost fraction bit. To the left of the binary point there is an implied unit bit, which is considered to be one for normal numbers and zero for zeros and subnormal numbers. The fraction with the implied unit bit appended on the left is the *significand* of the number.

The value of a normal BFP number is the significand multiplied by the radix 2 raised to the power of the unbiased exponent. The value of a subnormal BFP number is the significand multiplied by the radix 2 raised to the power of the minimum exponent.

A value of one in the rightmost bit position of the significand in each format is sometimes referred to as one ulp (unit in the last place).

Values of Nonzero Numbers

The values of nonzero numbers in the various formats are shown in Figure 19-6.

Number Class	Format	Value
Normal	Tiny	$\pm 2^{e-15}x(1.f)$
	Short	$\pm 2^{e-127}x(1.f)$
	Long	$\pm 2^{e-1023}x(1.f)$
	Extended	$\pm 2^{e-16383}x(1.f)$
Subnormal	Tiny	$\pm 2^{-14}x(0.f)$
	Short	$\pm 2^{-126}x(0.f)$
	Long	$\pm 2^{-1022}x(0.f)$
	Extended	$\pm 2^{-16382}x(0.f)$

Explanation:

e Biased exponent (shown in decimal).
f Fraction (in binary).

Figure 19-6. Values of Nonzero Numbers

Programming Note: ANSI/IEEE Standard 754-2008 specifies minimum requirements for the extended format but does not include details. The BFP extended format meets these requirements, far exceeding them in the area of precision.

Classes of BFP Data

There are six classes of BFP data, which include numeric and related nonnumeric entities. Each data item consists of a sign, an exponent, and a significand. The exponent is biased such that all biased exponents are nonnegative unsigned numbers and the minimum biased exponent is zero. The significand consists of an explicit fraction and an implicit unit bit to the left of the binary point. The sign bit is zero for plus and one for minus.

All nonzero finite numbers permitted by a given format have a unique BFP representation. There are no unnormalized numbers, which numbers might allow multiple representations for the same values, and there are no unnormalized arithmetic operations. Tiny numbers of a magnitude below the minimum normal number in a given format are represented as *subnormal* numbers, but those values are also represented uniquely. The implied unit bit of a normal number is one, and that of a subnormal number or a zero is zero.

The six classes of BFP data are summarized in Figure 19-7 on page 19-4.

Data Class	Sign	Biased Exponent	Unit Bit*	Fraction
Zero	±	0	0	0
Subnormal numbers	±	0**	0	Not 0
Normal numbers	±	Not 0, not all ones	1	Any
Infinity	±	All ones	—	0
Quiet NaN	±	All ones	—	F0=1, Fr=any
Signaling NaN	±	All ones	—	F0=0, Fr≠0

Explanation:

—	Does not apply.
*	The unit bit is implied.
**	The biased exponent is treated arithmetically as if it had the value one.
F0	Leftmost bit of fraction.
Fr	Remaining bits of fraction.
NaN	Not-a-number.

Figure 19-7. Classes of BFP Data

The instruction TEST DATA CLASS may be used to determine the class of a BFP operand.

Zeros

Zeros have a biased exponent of zero and a zero fraction. The implied unit bit is zero. A +0 is distinct from -0, except that comparison treats them as equal.

Subnormal Numbers

Subnormal numbers are numbers which are smaller than the smallest normal number and greater than zero in magnitude. They have a biased exponent of zero and a nonzero fraction. The biased exponent is treated arithmetically as if it were one, which causes the exponent to be the minimum exponent. The implied unit bit is zero. (In ANSI/IEEE Standard 754-1985, subnormal numbers were called “denormalized numbers”.)

Normal Numbers

Normal numbers have a biased exponent greater than zero but less than all ones. The implied unit bit is one, and the fraction may have any value. (In some early documentation, normal numbers were called “normalized numbers”.)

Infinities

An infinity is represented by a biased exponent of all ones and a zero fraction. Infinities can participate in most arithmetic operations and give a consistent result, usually infinity. In comparisons, +∞ compares greater than any finite number, and -∞ compares less than any finite number.

Signaling and Quiet NaNs

A NaN (not-a-number) entity is represented by a biased exponent of all ones and a nonzero fraction. NaNs are produced in place of a numeric result after an invalid operation when there is no interruption. NaNs may also be used by the program to flag special operands, such as the contents of an uninitialized storage area.

There are two types of NaNs, signaling and quiet. A signaling NaN (SNaN) is distinguished from the corresponding quiet NaN (QNaN) by the leftmost fraction bit: zero for the SNaN and one for the QNaN. A special QNaN is supplied as the default result for an IEEE-invalid-operation exception; it has a plus sign and a leftmost fraction bit of one, with the remaining fraction bits being set to zeros.

Normally, QNaNs are just propagated during computations so that they will remain visible at the end. An

SNaN operand causes an IEEE-invalid-operation exception. If the IEEE-invalid-operation mask (FPC 0.0) is zero, the result is the corresponding QNaN, which is produced by setting the leftmost fraction bit to one, and the IEEE-invalid-operation flag (FPC 1.0) is set to one. If the IEEE-invalid-operation mask (FPC 0.0) is one, the operation is suppressed, and a data exception for IEEE-invalid operation occurs.

Where applicable, the propagation of NaNs is illustrated in the action figure for an instruction.

Programming Notes:

1. The program can generate and assign meanings to any nonzero fraction values of a NaN. The CPU propagates those values unchanged, except that an SNaN is changed to the corresponding QNaN if the IEEE-invalid-operation mask bit is zero, and conversion to a narrower format may truncate significant bits on the right.

2. ANSI/IEEE Standard 754-2008 requires SNaNs to signal the invalid-operation exception for the arithmetic, comparison, and conversion operations that are part of the standard, but it makes it an implementation option whether copying an SNaN without a change of format signals the exception. In the appendix, the standard also makes it an implementation option whether SNaNs should signal the invalid-operation exception for the recommended functions of copying the sign, taking the absolute value, reversing the sign, and testing the data class of a datum.

   The above functions generally correspond to the instructions LOAD, LOAD COMPLEMENT, LOAD NEGATIVE, LOAD POSITIVE, and TEST DATA CLASS. These instructions do not signal the invalid-operation exception but, instead, treat SNaNs like any other data; giving an exception would be disruptive when the intention is to include SNaNs. TEST DATA CLASS does not give an exception since it is the instruction with which to test for the presence of SNaNs.

3. LOAD AND TEST signals the invalid-operation exception when the operand is an SNaN. This instruction, in conjunction with the above instructions, gives the program the choice of either option permitted by ANSI/IEEE Standard 754-2008.

4. Load-type instructions which change the precision signal the invalid-operation exception when the operand is an SNaN, as this is required by ANSI/IEEE Standard 754-2008.

BFP-Format Conversion

BFP format conversion is described in the section "IEEE Same-Radix Format Conversion" on page 9-23.

BFP Rounding

BFP rounding is described in the section "IEEE Rounding" on page 9-13.

BFP Comparison

BFP comparison is described in the section "IEEE Comparison" on page 9-24.

Remainder

The instruction DIVIDE TO INTEGER produces two floating-point results, an exact integer quotient and the corresponding remainder. The remainder is defined as follows:

Let

a = Dividend
b = Divisor
q = Exact quotient (a÷b)
r = Remainder

in the selected floating-point format. Then

$r = a - b \bullet n$

where n is an integer. If q is an integer, then n equals q. Otherwise, n is obtained by rounding q according to a final-quotient-rounding method.

When the final-quotient-rounding method is round to nearest with ties to even or round toward zero, the remainder is exact for any finite dividend and any nonzero divisor. The remainder cannot overflow.

If the integer quotient has a value that lies outside the range of the operand format, a scaled result is provided.

In certain cases where the number of bits in the integer quotient exceeds or may exceed the maximum number of bits provided in the precision of the operand format, partial results are produced, and more than one execution of the instruction is required to obtain the final result; this may be done with a simple instruction loop.

Partial results are produced when the precise quotient is not an integer and the two integers closest to this precise quotient cannot both be represented exactly in the precision of the quotient. This situation exists when the precise quotient is greater than 2^P, where P is the precision of the operand format, and the remainder is not zero. When the remainder is zero, then the quotient is an integer, and the number of bits required to represent the quotient is never more than the precision of the target.

Programming Note: The remainder result of DIVIDE TO INTEGER with a final-quotient-rounding method of round to nearest with ties to even corresponds to the *Remainder* function in ANSI/IEEE Standard 754-2008. This function is similar to the *MOD* function found in some languages and to the mathematical *modulo* function, but they are not the same. They differ in the definition of n:

Remainder	n is q rounded to nearest with ties to even.
modulo	n is q rounded toward -∞.
MOD	n is q rounded toward 0.

Another important difference is that implementations of modulo and MOD may put range restrictions on the result because they may simply use the DIVIDE instruction and accept its range restrictions.

The MOD definition provides an exact result, as does Remainder, but the modulo definition may result in rounding errors.

The differences between the various methods may be illustrated by the simple example of computing a divided by b to obtain an integer quotient n, where a is a series of integers, and b is +4 or -4. Figure 19-8 shows the results for the three definitions.

	a																	
	-8	-7	-6	-5	-4	-3	-2	-1	-0	+0	+1	+2	+3	+4	+5	+6	+7	+8

b=-4: n	+2	+1	+1	+1	+1	0	0	0	0	-1	-1	-1	-1	-2	-2	-2	-2	
r	0	-3	-2	-1	0	-3	-2	-1	0	-3	-2	-1	0	-3	-2	-1	0	

Explanation:

a	Dividend.
b	Divisor.
n	Integer quotient.
r	Result (Remainder, MOD, or modulo).

Figure 19-8. Comparison of Remainder with MOD and Modulo

The result of Remainder lies in the range of zero to one-half the divisor, inclusive, in magnitude. A zero result is defined to have the sign of the dividend. A zero divisor is invalid.

The modulo and MOD results can both be computed from the Remainder result; the reverse may not be true, because of rounding errors and, depending on the implementation, range restrictions.

An extreme example of the rounding error that can occur with the modulo definition is the following, where the result is restricted to two significant decimal digits:

modulo(0.01,-95) = -94.99, which rounds to -95

Remainder(0.01,-95) = 0.01

The properly rounded modulo result is completely wrong since it is equal to the divisor instead of being smaller in magnitude. The Remainder result is exact and can be used to compute the theoretical result of modulo.

Remainder is included as an arithmetic operation because of its usefulness in argument reduction when computing elementary transcendental functions. Thus, SIN(X) can be computed to full precision for any value of X in degrees by first reducing the argument to Remainder(X,360).

IEEE Exceptions

The IEEE exceptions for the BFP instructions are described in the section “IEEE Exceptions” on page 9-18.

Summary of Rounding And Range Actions

Figure 19-9 summarizes the BFP rounding and range actions.

Range of v	Case	Nontrap Result (r) when Effective Rounding Method Is					
		To Nearest with ties to even	**To Nearest with ties away from 0[3]**	**Toward 0**	**Toward +∞**	**Toward -∞**	**Prepare for shorter precision**
v < -Nmax, g < -Nmax	Overflow	-∞[1]	-∞[1]	-Nmax	-Nmax	-∞[1]	-Nmax

Figure 19-9. Action for R(v): Rounding and Range Function (Part 1 of 2)

Range of v	Case	Nontrap Result (r) when Effective Rounding Method Is					
		To Nearest with ties to even	**To Nearest with ties away from 0[3]**	**Toward 0**	**Toward +∞**	**Toward -∞**	**Prepare for shorter precision**
v < -Nmax, g = -Nmax	Normal	-Nmax	-Nmax	-Nmax	-Nmax	–	-Nmax
-Nmax ≤ v ≤ -Nmin	Normal	g	g	g	g	g	g
-Nmin < v ≤ -Dmin	Tiny	d*	d*	d	d	d*	d
-Dmin < v < -Dmin/2	Tiny	-Dmin	-Dmin	-0	-0	-Dmin	-Dmin
v = -Dmin/2	Tiny	-0	-Dmin	-0	-0	-Dmin	-Dmin
-Dmin/2 < v < 0	Tiny	-0	-0	-0	-0	-Dmin	-Dmin
v = 0	Exact zero difference[2]	+0	+0	+0	+0	-0	+0
0 < v < +Dmin/2	Tiny	+0	+0	+0	+Dmin	+0	+Dmin
v = +Dmin/2	Tiny	+0	+Dmin	+0	+Dmin	+0	+Dmin
+Dmin/2 < v < +Dmin	Tiny	+Dmin	+Dmin	+0	+Dmin	+0	+Dmin
+Dmin ≤ v < +Nmin	Tiny	d*	d*	d	d*	d	d
+Nmin ≤ v ≤ +Nmax	Normal	g	g	g	g	g	g
+Nmax < v, g = +Nmax	Normal	+Nmax	+Nmax	+Nmax	–	+Nmax	+Nmax
+Nmax < v, +Nmax < g	Overflow	+∞[1]	+∞[1]	+Nmax	+∞[1]	+Nmax	+Nmax

Explanation:

– This situation cannot occur.

* The rounded value, in the extreme case, may be Nmin. In this case, the exceptions are underflow, inexact and incremented.

[1] The nontrap result r is considered to have been incremented.

[2] The exact-zero-difference case applies only to ADD, SUBTRACT, MULTIPLY AND ADD, and MULTIPLY AND SUBTRACT. For all other BFP operations, a zero result is detected by inspection of the source operands without use of the R(v) function.

[3] The rounding mode is used for converts to NNP-data-type 1.

d The denormalized value. The value derived when the precise intermediate value (v) is rounded to the format of the target, including both precision and bounded exponent range. Except as explained in note *, this is a subnormal number.

g The precision-rounded value. The value derived when the precise intermediate value (v) is rounded to the precision of the target, but assuming an unbounded exponent range.

v Precise intermediate value. This is the value, before rounding, assuming unbounded precision and an unbounded exponent range. For LOAD ROUNDED, v is the source value (a).

Dmin Smallest (in magnitude) representable subnormal number in the target format.

Nmax Largest (in magnitude) representable finite number in the target format.

Nmin Smallest (in magnitude) representable normal number in the target format.

Explanation:

–	The results do not depend on this condition or mask bit.
[1]	This condition is true by virtue of the state of some condition to the left of this column.
[2]	The IEEE-inexact-exception control (XxC) is defined only if the floating-point extension facility is installed.
Ψ	Scale factor. For overflow, $\Psi = 2^{+\alpha}$. For underflow, $\Psi = 2^{-\alpha}$. The unsigned scaling exponent (α) depends on the type of operation and operand format. For all BFP operations except LOAD ROUNDED, α depends on the target format and is 192 for short, 1536 for long, and 24576 for extended. For LOAD ROUNDED, α depends on the source format, and is 512 for long and 8192 for extended.
g	The precision-rounded value. The value derived when the precise intermediate value (v) is rounded to the precision of the target, but assuming an unbounded exponent range.
r	Nontrap result as defined in Part 1 of this figure.
v	Precise intermediate value. This is the value, before rounding, assuming unbounded precision and unbounded exponent range.
PIDc(h)	Program interruption for data exception, condition c, with DXC of h in hex. See Figure 19-11 on page 19-11.
SFo	IEEE overflow flag, FPC 1.2.
SFu	IEEE underflow flag, FPC 1.3.
SFx	IEEE inexact flag, FPC 1.4.
T(x)	The value x is placed at the target operand location.
Tw(x)	The scaled result x is placed at the target operand location. For all operations except BFP LOAD ROUNDED, the scaled result is in the format and length of the target and rounded to the precision of the target. For LOAD ROUNDED, the scaled result is in the format and length of the source, but rounded to the precision of the target.

Figure 19-9. Action for R(v): Rounding and Range Function (Part 2 of 2)

Result Figures

Concise descriptions of the results produced by many of the BFP instructions are made by means of figures which contain columns and rows representing all possible combinations of BFP data class for the source operands of an instruction. The information shown at the intersection of a row and a column is one or more symbols representing the result or results produced for that particular combination of source-operand data classes. Explanations of the symbols used are contained in each figure. In many cases, the explanation of a particular result is in the form of a cross reference to another figure. In many cases, the information shown at the intersection consists of several symbols separated by commas. All such results are produced unless one of the results is a program interruption. In the case of a program interruption, the operation is suppressed or completed as shown in Figure 19-11 on page 19-11.

Data-Exception Codes (DXC) and Abbreviations

Figure 19-10 shows IEEE exceptions and flag abbreviations that are used in the result figures, and it explains the symbols “Xi:” and “Xz:” that are used in the figures. Bits 0-4 (i, z, o, u, and x) of the eight-bit data-exception code (DXC) in byte 2 of the FPC register are trap flags and correspond to the same bits in bytes 0 and 1 of the register (IEEE masks and IEEE flags). The trap flag for an exception, instead of the IEEE flag, is set to one when an interruption for the exception is enabled by the corresponding IEEE mask bit. Bit 5 of byte 2 (y) is used in conjunction with bit 4, inexact (x), to indicate that the result has been incremented in magnitude.

Exception		FPC IEEE Mask Bit	IEEE Flag	
Name	**Abbr.**		**FPC Bit**	**Abbr.**
IEEE invalid operation	Xi[1]	0.0	1.0	SFi
IEEE division by zero	Xz[2]	0.1	1.1	SFz
IEEE overflow	Xo	0.2	1.2	SFo
IEEE underflow	Xu	0.3	1.3	SFu
IEEE inexact	Xx	0.4	1.4	SFx

Explanation:

1 The symbol “Xi:” followed by a list of results in a figure indicates that, when FPC 0.0 is zero, then instruction execution is completed by setting SFi (FPC 1.0) to one and producing the indicated results; and when FPC 0.0 is one, then instruction execution is suppressed, the data exception code (DXC) is set to 80 hex, and a program interruption for a data exception occurs.

2 The symbol “Xz:” followed by a list of results in a figure indicates that, when FPC 0.1 is zero, then instruction execution is completed by setting SFz (FPC 1.1) to one and producing the indicated results; and when FPC 0.1 is one, then instruction execution is suppressed, the data exception code (DXC) is set to 40 hex, and a program interruption for a data exception occurs.

Figure 19-10. IEEE Exception and Flag Abbreviations

Figure 19-11 on page 19-11 shows the various DXCs that can be indicated, the associated instruction endings, and abbreviations that are used for the DXCs in the result figures. (The abbreviation “PID” stands for “program interruption for a data exception.”)

Abbr.	DXC (Hex)	Data-Exception-Code Name	Instruction Ending
PIDx	08	IEEE inexact and truncated	Complete
PIDy	0C	IEEE inexact and incremented	Complete
PIDu	10	IEEE underflow, exact	Complete, scale exponent
PIDux	18	IEEE underflow, inexact and truncated	Complete, scale exponent
PIDuy	1C	IEEE underflow, inexact and incremented	Complete, scale exponent
PIDo	20	IEEE overflow, exact	Complete, scale exponent
PIDox	28	IEEE overflow, inexact and truncated	Complete, scale exponent
PIDoy	2C	IEEE overflow, inexact and incremented	Complete, scale exponent
PIDz	40	IEEE division by zero	Suppress
PIDi	80	IEEE invalid operation	Suppress

Figure 19-11. IEEE Data-Exception Codes (DXC) and Abbreviations

Instructions

The BFP instructions and their mnemonics and operation codes are listed in Figure 19-12 on page 19-12.

The figure indicates, in the column labeled “Characteristics”, the instruction format, when the condition code is set, the instruction fields that designate access registers, and the exceptional conditions in operand designations, data, or results that cause a program interruption.

All BFP instructions are subject to the AFP-register-control bit, bit 45 of control register 0. For the BFP instructions to be executed successfully, the AFP-register-control bit must be one; otherwise, a BFP-instruction data exception, DXC 2, is recognized.

Mnemonics for the BFP instructions are distinguished from the corresponding HFP instructions by a B in the mnemonic. Mnemonics for the BFP instructions have an R as the last letter or the letter next to the last letter when the instruction is in the RRE or RRF format. Mnemonics for the BFP instructions have an A as the last letter when the instruction is an alternate instruction, which uses additional modifier fields not available to the original instruction. Certain letters are used for BFP instructions to represent operand-format length, as follows:

F Thirty-two-bit signed fixed point
G Sixty-four-bit signed fixed point
LF Thirty-two-bit unsigned fixed point
LG Sixty-four-bit unsigned fixed point
D Long
E Short
X Extended

Note: In the detailed descriptions of the individual instructions, the mnemonic and the symbolic operand designation for the assembler language are shown with each instruction. For a register-to-register operation using COMPARE (short), for example, CEBR is the mnemonic and R_1,R_2 the operand designation.

Programming Note: The floating-point extension facility includes the following BFP features:

- The following new BFP instructions are added:
  - CONVERT FROM LOGICAL (CXLFBR, CDLFBR, CELFBR, CXLGBR, CDLGBR, and CELGBR).
  - CONVERT TO LOGICAL (CLFXBR, CLFDBR, CLFEBR, CLGXBR, CLGDBR, and CLGEBR)
- One new value of the effective rounding method field is assigned to support the round to prepare for shorter precision rounding method for CONVERT TO FIXED, DIVIDE TO INTEGER, and LOAD FP INTEGER
- An IEEE-inexact-exception control (XxC) is added to CONVERT TO FIXED and LOAD FP INTEGER.

- An effective rounding method field and an IEEE-inexact-exception control (XxC) are added to CONVERT FROM FIXED and LOAD ROUNDED.

Explanation:

¤[7]	Restricted from transactional execution when the effective allow-floating-point-operation control is zero.
¤[9]	Restricted in the constrained transactional-execution mode; a transaction-constraint program exception may be recognized.
A	Access exceptions for logical addresses.
B_2	B_2 field designates an access register in the access-register mode.
C	Condition code is set.
Db	BFP-instruction data exception.
F	Floating-point extension facility
N	Instruction is new in z/Architecture as compared to ESA/390.
RRD	RRE instruction format.
RRE	RRE instruction format.
RRF	RRF instruction format.
RXE	RXE instruction format.
RXF	RXF instruction format.
SP	Specification exception.
Xi	IEEE invalid-operation data exception.
Xo	IEEE overflow data exception.
Xu	IEEE underflow data exception.
Xx	IEEE inexact data exception.
Xz	IEEE division-by-zero data exception.

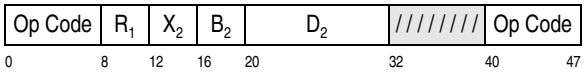
Figure 19-12. Summary of BFP Instructions (Part 3 of 3)

ADD

Mnemonic1 R_1,R_2 [RRE]

Mnemonic1	Op Code	Operands
AEBR	'B30A'	Short BFP
ADBR	'B31A'	Long BFP
AXBR	'B34A'	Extended BFP

Mnemonic2 $R_1,D_2(X_2,B_2)$ [RXE]



Mnemonic2	Op Code	Operands
AEB	'ED0A'	Short BFP
ADB	'ED1A'	Long BFP

The second operand is added to the first operand, and the sum is placed at the first-operand location.

If both operands are finite numbers, they are added algebraically, forming an intermediate sum. The intermediate sum, if nonzero, is rounded to the operand format according to the current BFP rounding mode. The sum is then placed at the result location.

The sign of the sum is determined by the rules of algebra. This also applies to a result of zero:

- If the result of rounding a nonzero intermediate sum is zero, the sign of the zero result is the sign of the intermediate sum.
- If the sum of two operands with opposite signs is exactly zero, the sign of the result is plus in all rounding methods except round toward -∞, in which method the sign is minus.
- The sign of the sum x plus x is the sign of x, even when x is zero.

If one operand is an infinity and the other is a finite number, the result is that infinity. If both operands are infinities of the same sign, the result is the same infinity. If the two operands are infinities of opposite signs, an IEEE-invalid-operation exception is recognized.

See Figure 19-14 on page 19-16 for a detailed description of the results of this instruction. (Figure 19-13 is referred to by Figure 19-14.)

For AXBR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Result is zero
1 Result is less than zero
2 Result is greater than zero
3 Result is a NaN

IEEE Exceptions:

- Invalid operation
- Overflow
- Underflow
- Inexact

Program Exceptions:

- Access (fetch, operand 2 of AEB and ADB only)
- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Specification (AXBR only)
- Transaction constraint

Programming Note: Interchanging the two operands in a BFP addition does not affect the value of the sum when the result is numeric. This is not true, however, when both operands are QNaNs, in which case the result is the first operand; or when both operands are SNaNs and the IEEE-invalid-operation mask bit in the FPC register is zero, in which case the result is the QNaN derived from the first operand.

Value of Result (r)	Condition Code
r=0	0
r<0	1
r>0	2

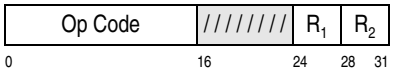
Explanation:

*	The SNaN is converted to the corresponding QNaN before it is placed at the target operand location.
ccn	Condition code is set to n.
ccrs	Condition code is set according to the resultant sum. See Figure 19-13 on page 19-15.
dNaN	Default NaN.
Dn	Subnormal number.
Nn	Normal number.
R(v)	Rounding and range action is performed on the value v. See Figure 19-9 on page 19-7.
Rezd	Exact zero-difference result. See Figure 19-9 on page 19-7.
T(x)	The value x is placed at the target operand location.
Xi:	IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.

Figure 19-14. Results: ADD

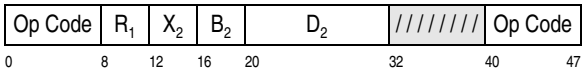
COMPARE

Mnemonic1 R_1,R_2 [RRE]



Mnemonic1	Op Code	Operands
CEBR	'B309'	Short BFP
CDBR	'B319'	Long BFP
CXBR	'B349'	Extended BFP

Mnemonic2 $R_1,D_2(X_2,B_2)$ [RXE]



Mnemonic2	Op Code	Operands
CEB	'ED09'	Short BFP
CDB	'ED19'	Long BFP

The first operand is compared with the second operand, and the condition code is set to indicate the result.

If both operands are finite numbers, the comparison is algebraic and follows the procedure for BFP subtraction, except that the difference is discarded after setting the condition code, and both operands remain unchanged. If the difference is exactly zero with either sign, the operands are equal; this includes zero operands (so +0 equals -0). If a nonzero difference is positive or negative, the first operand is high or low, respectively.

+∞ compares greater than any finite number, and all finite numbers compare greater than -∞. Two infinity operands of like sign compare equal.

Numeric comparison is exact, and the condition code is determined for finite operands as if range and precision were unlimited. No overflow or underflow exception can occur.

If either or both operands are QNaNs and neither operand is an SNaN, the comparison result is unordered, and condition code 3 is set.

If either or both operands are SNaNs, an IEEE-invalid-operation exception is recognized. If the IEEE invalid-operation mask bit is one, a program interruption for a data exception with DXC 80 hex (IEEE invalid operation) occurs. If the IEEE-invalid-operation mask bit is zero, the IEEE-invalid-operation flag bit is set to one, and instruction execution is completed by setting condition code 3.

See Figure 19-15 on page 19-18 for a detailed description of the results of this instruction.

For CXBR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Operands equal
1 First operand low
2 First operand high
3 Operands unordered

IEEE Exceptions:

- Invalid operation

Program Exceptions:

- Access (fetch, operand 2 of CEB and CDB only)
- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Specification (CXBR only)
- Transaction constraint

Programming Notes:

1. COMPARE may be used to implement those comparisons which are required by ANSI/IEEE Standard 754-2008 to not recognize an exception when the result is unordered due to a QNaN.

2. ANSI/IEEE Standard 754-2008 requires that it be possible to compare BFP operands in different formats. To accomplish this, LOAD LENGTHENED may be used before COMPARE to convert the shorter operand to the same format as the longer.

First Operand (a) Is	Results for COMPARE (a:b) when Second Operand (b) Is							
	-∞	**-Fn**	**-0**	**+0**	**+Fn**	**+∞**	**QNaN**	**SNaN**
-∞	cc0	cc1	cc1	cc1	cc1	cc1	cc3	Xi: cc3
-Fn	cc2	C(a:b)	cc1	cc1	cc1	cc1	cc3	Xi: cc3
-0	cc2	cc2	cc0	cc0	cc1	cc1	cc3	Xi: cc3
+0	cc2	cc2	cc0	cc0	cc1	cc1	cc3	Xi: cc3
+Fn	cc2	cc2	cc2	cc2	C(a:b)	cc1	cc3	Xi: cc3
+∞	cc2	cc2	cc2	cc2	cc2	cc0	cc3	Xi: cc3
QNaN	cc3	cc3	cc3	cc3	cc3	cc3	cc3	Xi: cc3
SNaN	Xi: cc3	Xi: cc3	Xi: cc3	Xi: cc3	Xi: cc3	Xi: cc3	Xi: cc3	Xi: cc3

Explanation:

ccn Condition code is set to n.
C(a:b) Basic compare results. See Figure 19-16.
Fn Finite nonzero number (includes both subnormal and normal).
Xi: IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.

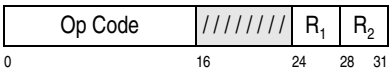
Figure 19-15. Results: COMPARE

Relation of Value (a) to Value (b)	Condition Code for C(a:b)
a=b	0
a<b	1
a>b	2

Figure 19-16. Basic Compare Results

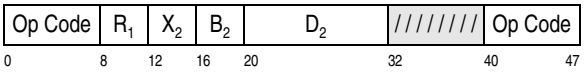
COMPARE AND SIGNAL

Mnemonic1 R_1,R_2 [RRE]



Mnemonic1	Op Code	Operands
KEBR	'B308'	Short BFP
KDBR	'B318'	Long BFP
KXBR	'B348'	Extended BFP

Mnemonic2 $R_1,D_2(X_2,B_2)$ [RXE]



Mnemonic2	Op Code	Operands
KEB	'ED08'	Short BFP
KDB	'ED18'	Long BFP

The first operand is compared with the second operand, and the condition code is set to indicate the result. The operation is the same as for COMPARE except that QNaN operands cause an IEEE-invalid-operation exception to be recognized. Thus, QNaN operands are treated as if they were SNaNs.

See Figure 19-17 on page 19-19 for a detailed description of the results of this instruction.

For KXBR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Operands equal
1 First operand low
2 First operand high
3 Operands unordered

IEEE Exceptions:

- Invalid operation

Program Exceptions:

- Access (fetch, operand 2 of KEB and KDB only)
- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Specification (KXBR only)
- Transaction constraint

Programming Notes:

1. COMPARE AND SIGNAL may be used to implement those comparisons which are required by ANSI/IEEE Standard 754-2008 to recognize an exception when the result is unordered due to a QNaN.

2. ANSI/IEEE Standard 754-2008 requires that it be possible to compare BFP operands in different formats. To accomplish this, LOAD LENGTHENED may be used before COMPARE AND SIGNAL to convert the shorter operand to the same format as the longer.

First Operand (a) Is	Results for COMPARE AND SIGNAL (a:b) when Second Operand (b) Is						
	-∞	**-Fn**	**-0**	**+0**	**+Fn**	**+∞**	**NaN**

+∞	cc2	cc2	cc2	cc2	cc2	cc0	Xi: cc3
NaN	Xi: cc3	Xi: cc3	Xi: cc3	Xi: cc3	Xi: cc3	Xi: cc3	Xi: cc3

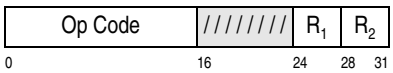
Explanation:

ccn Condition code is set to n.
C(a:b) Basic compare results. See Figure 19-16 on page 19-18
Fn Finite nonzero number (includes both subnormal and normal).
Xi: IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.

Figure 19-17. Results: COMPARE AND SIGNAL

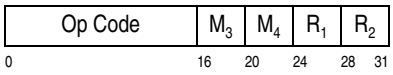
CONVERT FROM FIXED

Mnemonic1 R_1,R_2 [RRE]



Mnemonic1	Op Code	Operands
CEFBR	'B394'	32-bit binary-integer operand, short BFP result
CDFBR	'B395'	32-bit binary-integer operand, long BFP result
CXFBR	'B396'	32-bit binary-integer operand, extended BFP result
CEGBR	'B3A4'	64-bit binary-integer operand, short BFP result
CDGBR	'B3A5'	64-bit binary-integer operand, long BFP result
CXGBR	'B3A6'	64-bit binary-integer operand, extended BFP result

Mnemonic2 R_1,M_3,R_2,M_4 [RRF-e]



Mnemonic2	Op Code	Operands
CEFBRA	'B394'	32-bit binary-integer operand, short BFP result
CDFBRA	'B395'	32-bit binary-integer operand, long BFP result
CXFBRA	'B396'	32-bit binary-integer operand, extended BFP result
CEGBRA	'B3A4'	64-bit binary-integer operand, short BFP result
CDGBRA	'B3A5'	64-bit binary-integer operand, long BFP result
CXGBRA	'B3A6'	64-bit binary-integer operand, extended BFP result

The fixed-point second operand is converted to the BFP format, and the result is placed at the first-operand location.

The second operand is a signed binary integer that is located in the general register designated by R_2. A 32-bit operand is in bit positions 32-63 of the register.

When the floating-point extension facility is installed, the converted result is rounded by rounding as specified by the modifier in the M_3 field:

M_3	Effective Rounding Method
0	According to current BFP rounding mode
1	Round to nearest with ties away from 0
3	Round to prepare for shorter precision
4	Round to nearest with ties to even
5	Round toward 0

6 Round toward +∞
7 Round toward -∞

An M_3 modifier other than 0, 1, or 3-7 is invalid. The M_3 field must designate a valid modifier; otherwise, a specification exception is recognized.

When the M_3 modifier field is zero, rounding is controlled by the current BFP rounding mode specified in the FPC register. When the field is not zero, rounding is performed as specified by the modifier, regardless of the current BFP rounding mode.

When the floating-point extension facility is not installed and bits 16-19 of the instruction contain a value of zero, the converted result is rounded according to the current BFP rounding mode. When the floating-point extension facility is not installed and bits 16-19 of the instruction contain a nonzero value, it is undefined whether a specification exception is recognized or an unpredictable rounding method is performed.

When the floating-point extension facility is installed, bit 1 of the M_4 field is the IEEE-inexact-exception control (XxC). Bits 0, 2, and 3 are ignored. If XxC is zero, recognition of IEEE-inexact exception is not suppressed; if XxC is one, recognition of IEEE-inexact exception is suppressed.

When the floating-point extension facility is not installed and if bits 20-23 of the instruction are zeros, recognition of IEEE-inexact exception is not suppressed; when the floating-point extension facility is not installed and if bits 20-23 of the instruction contain a nonzero value, then it is unpredictable whether recognition of IEEE-inexact exception is suppressed.

See Figure 19-18 on page 19-21 for a detailed description of the results of this instruction.

For CXFBR, CXFBRA, CXGBR, and CXGBRA, the R_1 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Inexact (CEFBR, CEFBRA, CDGBR, CDGBRA, CEGBR, CEGBRA)

Program Exceptions:

- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Specification
- Transaction constraint

Programming Note: Unassigned bits in the M_4 field are reserved for future extensions and should be set to zeros; otherwise the program may not operate compatibly in the future.

Instruction	Results for Instructions with a Single Operand (a) when Operand (a) Is							
	-∞	**-Fn**	**-0**	**+0**	**+Fn**	**+∞**	**QNaN**	**SNaN**
CONVERT FROM FIXED	–	Rf(a)	–	T(+0)	Rf(a)	–	–	–
LOAD AND TEST	T(-∞)	T(a)	T(-0)	T(+0)	T(a)	T(+∞)	T(a)	Xi: T(a*)
LOAD LENGTHENED	T(-∞)	T(a)[1]	T(-0)	T(+0)	T(a)[1]	T(+∞)	T(a)[1]	Xi: T(a*)[1]
LOAD ROUNDED	T(-∞)	R(a)	T(-0)	T(+0)	R(a)	T(+∞)	T(a)[2]	Xi: T(a*)[2]
SQUARE ROOT	Xi: T(dNaN)	Xi: T(dNaN)	T(-0)	T(+0)	R($\sqrt{a}$)	T(+∞)	T(a)	Xi: T(a*)

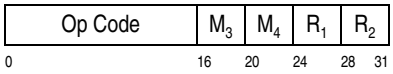
Explanation:

– This situation cannot occur.
* The SNaN is converted to the corresponding QNaN before it is placed at the target operand location.
[1] The operand is extended to the longer format by appending zeros on the right before it is placed at the target operand location.
[2] The NaN is shortened to the target format by truncating the rightmost bits.
dNaN Default NaN.
Fn Finite nonzero number (includes both subnormal and normal).
R(v) Rounding and range action is performed on the value v. See Figure 19-9 on page 19-9.
Rf(a) The value a is converted to the precise intermediate value floating-point number v, and then action R(v) is performed.
T(x) The value x is placed in the target operand location.
Xi: IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.

Figure 19-18. Results: Single-Operand Instructions

CONVERT FROM LOGICAL

Mnemonic R_1,M_3,R_2,M_4 [RRF-e]



Mnemonic	Op Code	Operands
CELFBR	'B390'	32-bit binary-integer operand, short BFP result
CDLFBR	'B391'	32-bit binary-integer operand, long BFP result
CXLFBR	'B392'	32-bit binary-integer operand, extended BFP result
CELGBR	'B3A0'	64-bit binary-integer operand, short BFP result
CDLGBR	'B3A1'	64-bit binary-integer operand, long BFP result
CXLGBR	'B3A2'	64-bit binary-integer operand, extended BFP result

The fixed-point second operand is converted to the BFP format, and the result is placed at the first-operand location.

The second operand is an unsigned binary integer that is located in the general register designated by R_2. A 32-bit operand is in bit positions 32-63 of the register.

The converted result is rounded by rounding as specified by the modifier in the M_3 field:

M_3	Effective Rounding Method
0	According to current BFP rounding mode
1	Round to nearest with ties away from 0
3	Round to prepare for shorter precision
4	Round to nearest with ties to even
5	Round toward 0
6	Round toward +∞
7	Round toward -∞

An M_3 modifier other than 0, 1, or 3-7 is invalid.

When the M_3 modifier field is zero, rounding is controlled by the current BFP rounding mode specified in the FPC register. When the field is not zero, rounding is performed as specified by the modifier, regardless of the current BFP rounding mode.

The M_3 field must designate a valid modifier; otherwise, a specification exception is recognized. For CXLFBR and CXLGBR, the R_1 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

Bit 1 of the M_4 field is the IEEE-inexact-exception control (XxC). Bits 0, 2, and 3 are ignored. If XxC is

zero, recognition of IEEE-inexact exception is not suppressed; if XxC is one, recognition of IEEE-inexact exception is suppressed.

The result always has a plus sign.

See Figure 19-18 on page 19-21 for a detailed description of the results of this instruction.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Inexact (CELFBR, CDLGBR, CELGBR)

Program Exceptions:

- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Operation (if the floating-point extension facility is not installed)
- Specification
- Transaction constraint

Programming Notes:

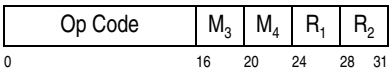
1. Unassigned bits in the M_4 field are reserved for future extensions and should be set to zeros; otherwise the program may not operate compatibly in the future
2. Using either the round toward 0 or the round toward -∞ rounding method produces the same result.

CONVERT TO FIXED

Mnemonic1 R_1,M_3,R_2 [RRF-e]

Mnemonic1	Op Code	Operands
CFEBR	'B398'	Short BFP operand, 32-bit binary-integer result
CFDBR	'B399'	Long BFP operand, 32-bit binary-integer result
CFXBR	'B39A'	Extended BFP operand, 32-bit binary-integer result
CGEBR	'B3A8'	Short BFP operand, 64-bit binary-integer result
CGDBR	'B3A9'	Long BFP operand, 64-bit binary-integer result
CGXBR	'B3AA'	Extended BFP operand, 64-bit binary-integer result

Mnemonic2 R_1,M_3,R_2,M_4 [RRF-e]



Mnemonic2	Op Code	Operands
CFEBRA	'B398'	Short BFP operand, 32-bit binary-integer result
CFDBRA	'B399'	Long BFP operand, 32-bit binary-integer result
CFXBRA	'B39A'	Extended BFP operand, 32-bit binary-integer result
CGEBRA	'B3A8'	Short BFP operand, 64-bit binary-integer result
CGDBRA	'B3A9'	Long BFP operand, 64-bit binary-integer result
CGXBRA	'B3AA'	Extended BFP operand, 64-bit binary-integer result

The BFP second operand is rounded to an integer value and then converted to the fixed-point format. The result is placed at the first-operand location.

The result is a signed binary integer that is placed in the general register designated by R_1. For instructions that produce a 32-bit result, the result replaces bits 32-63 of the register, and bits 0-31 of the register remain unchanged.

If the second operand is a finite number, it is rounded to an integer value by rounding as specified by the modifier in the M_3 field:

M_3	Effective Rounding Method
0	According to current BFP rounding mode
1	Round to nearest with ties away from 0
3	Round to prepare for shorter precision
4	Round to nearest with ties to even
5	Round toward 0
6	Round toward +∞
7	Round toward -∞

An M_3 modifier other than 0, 1, or 3-7 is invalid. If the floating-point extension facility is not installed, an M_3 modifier of 3 is also invalid.

When the M_3 modifier field is zero, rounding is controlled by the current BFP rounding mode specified in the FPC register. When the field is not zero, rounding is performed as specified by the modifier, regardless of the current BFP rounding mode.

The sign of the result is the sign of the second operand, except that a zero result has a plus sign.

When the floating-point extension facility is installed, bit 1 of the M_4 field is the IEEE-inexact-exception control (XxC). Bits 0, 2, and 3 are ignored. If XxC is zero, recognition of IEEE-inexact exception is not suppressed; if XxC is one, recognition of IEEE-inexact exception is suppressed.

When the floating-point extension facility is not installed and if bits 20-23 of the instruction are zeros, recognition of IEEE-inexact exception is not suppressed; when the floating-point extension facility is not installed and if bits 20-23 of the instruction contain a nonzero value, it is unpredictable whether recognition of IEEE-inexact exception is suppressed.

See Figure 19-19 for a detailed description of the results of this instruction.

Figure 19-19. Results: CONVERT TO FIXED

Operand (a)	Is n Inexact (n≠a)	Inv.-Op. Mask (FPC 0.0)	IEEE Inexact Exception Control (XxC)	Inexact Mask (FPC 0.4)	Is n Incre-mented (|n|>|a|)	Results
NaN	–	1	–	–	–	PIDi(80)

Explanation:

–	The results do not depend on this condition or mask bit.
1	This condition is true by virtue of the state of some condition to the left of this column.
2	The n=MP condition only applies to CFDBR, CFDBRA, CFXBR, CFXBRA, CGXBR. and CGXBRA.
3	Floating-point extension facility is installed and XxC bit in the M_4 field is 1.
4	Bit 21 of the instruction is 0, regardless of whether the floating-point extension facility is installed.
†	Result differs from DFP CONVERT TO FIXED. The DFP instruction combines two cases as it does not recognize inexact for this case and does not test the inexact mask.
ccn	Condition code is set to n.
f	The value n converted to a fixed-point result.
n	The value derived when the source value (a) is rounded to a floating-point integer using the effective rounding method.
MN	Maximum negative number representable in the target fixed-point format.
MP	Maximum positive number representable in the target fixed-point format.
PIDc(h)	Program interruption for data exception, condition c, with DXC of h in hex. Figure 19-11 on page 19-11.
SFi	IEEE invalid-operation flag, FPC 1.0.
SFx	IEEE inexact flag, FPC 1.4.
T(x)	The value x is placed at the target operand location.

Figure 19-19. Results: CONVERT TO FIXED

If the M_3 field designates any of the following invalid modifier values: 2 and 8-15, then a specification exception is recognized. When the floating-point extension facility is not installed, if the M_3 field designates the invalid value 3, it is undefined whether a specification exception is recognized or an unpredictable rounding method is performed.

For CFXBR, CFXBRA, CGXBR and CGXBRA, the R_2 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Source was zero
1 Source was less than zero
2 Source was greater than zero
3 Special case

IEEE Exceptions:

- Invalid operation
- Inexact

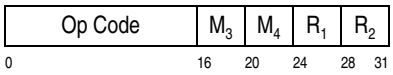
Program Exceptions:

- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Specification
- Transaction constraint

Programming Note: Unassigned bits in the M_4 field are reserved for future extensions and should be set to zeros; otherwise the program may not operate compatibly in the future.

CONVERT TO LOGICAL

Mnemonic R_1,M_3,R_2,M_4 [RRF-e]



Mnemonic	Op Code	Operands
CLFEBR	'B39C'	Short BFP operand, 32-bit binary-integer result
CLFDBR	'B39D'	Long BFP operand, 32-bit binary-integer result
CLFXBR	'B39E'	Extended BFP operand, 32-bit binary-integer result
CLGEBR	'B3AC'	Short BFP operand, 64-bit binary-integer result
CLGDBR	'B3AD'	Long BFP operand, 64-bit binary-integer result
CLGXBR	'B3AE'	Extended BFP operand, 64-bit binary-integer result

The BFP second operand is rounded to an integer value and then converted to the fixed-point format. The result is placed at the first-operand location.

The result is an unsigned binary integer that is placed in the general register designated by R_1. For instructions that produce a 32-bit result, the result replaces bits 32-63 of the register, and bits 0-31 of the register remain unchanged.

If the second operand is a finite number, it is rounded to an integer value by rounding as specified by the modifier in the M_3 field:

M_3	Effective Rounding Method
0	According to current BFP rounding mode
1	Round to nearest with ties away from 0
3	Round to prepare for shorter precision
4	Round to nearest with ties to even
5	Round toward 0
6	Round toward +∞
7	Round toward -∞

An M_3 modifier other than 0, 1, or 3-7 is invalid.

When the M_3 modifier field is zero, rounding is controlled by the current BFP rounding mode specified in the FPC register. When the field is not zero, rounding is performed as specified by the modifier, regardless of the current BFP rounding mode.

Bit 1 of the M_4 field is the IEEE-inexact-exception control (XxC). Bits 0, 2, and 3 are ignored. If XxC is zero, recognition of IEEE-inexact exception is not suppressed; if XxC is one, recognition of IEEE-inexact exception is suppressed.

The M_3 field must designate a valid modifier; otherwise, a specification exception is recognized. For CLFXBR and CLGXBR, the R_2 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

See Figure 19-20 for a detailed description of the results of this instruction.

Resulting Condition Code:

0 Source was zero
1 Source was less than zero
2 Source was greater than zero
3 Special case

IEEE Exceptions:

- Invalid operation
- Inexact

Program Exceptions:

- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Operation (if the floating-point extension facility is not installed)
- Specification
- Transaction constraint

Programming Note: Unassigned bits in the M_4 field are reserved for future extensions and should be set to zeros; otherwise the program may not operate compatibly in the future.

Operand (a)	Is n Inexact (n≠a)	Inv.-Op. Mask (FPC 0.0)	IEEE Inexact Exception Control (XxC)	Inexact Mask (FPC 0.4)	Is n Incremented (|n|>|a|)	Results

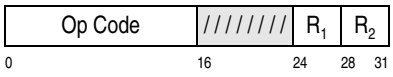
Explanation:

– The results do not depend on this condition or mask bit.
[1] This condition is true by virtue of the state of some condition to the left of this column.
† Result differs from DFP CONVERT TO LOGICAL. The DFP instruction combines two cases as it does not recognize inexact for this case and does not test the inexact mask.
ccn Condition code is set to n.
f The value n converted to a fixed-point result.
n The value derived when the source value (a) is rounded to a floating-point integer using the effective rounding method.
MU Maximum unsigned number representable in the target fixed-point format.
PIDc(h) Program interruption for data exception, condition c, with DXC of h in hex. Figure 19-11 on page 19-11.
SFi IEEE invalid-operation flag, FPC 1.0.
SFx IEEE inexact flag, FPC 1.4.
T(x) The value x is placed at the target operand location.

Figure 19-20. Results: CONVERT TO LOGICAL

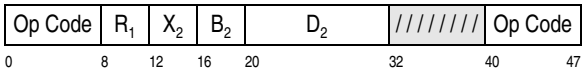
DIVIDE

Mnemonic1 R_1,R_2 [RRE]



Mnemonic1	Op Code	Operands
DEBR	'B30D'	Short BFP
DDBR	'B31D'	Long BFP
DXBR	'B34D'	Extended BFP

Mnemonic2 $R_1,D_2(X_2,B_2)$ [RXE]



Mnemonic2	Op Code	Operands
DEB	'ED0D'	Short BFP
DDB	'ED1D'	Long BFP

The first operand (the dividend) is divided by the second operand (the divisor), and the quotient is placed at the first-operand location. No remainder is preserved.

If the divisor is nonzero and both the dividend and divisor are finite numbers, the first operand is divided by the second operand to form an intermediate quotient. The intermediate quotient, if nonzero, is rounded to the target format according to the current BFP rounding mode.

When the dividend is a finite number and the divisor is infinity, the result is zero.

The sign of the quotient, if the quotient is numeric, is the exclusive or of the operand signs. This includes the sign of a zero or infinite quotient.

If the divisor is zero but the dividend is a finite number, an IEEE-division-by-zero exception is recognized. If the dividend and divisor are both zero, or if both are infinity, regardless of sign, an IEEE-invalid-operation exception is recognized.

See Figure 19-21 on page 19-27 for a detailed description of the results of this instruction.

For DXBR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Dividend (a)	Results for DIVIDE (a÷b) when Divisor (b) Is							
	-∞	**-Fn**	**-0**	**+0**	**+Fn**	**+∞**	**QNaN**	**SNaN**

Explanation:

*	The SNaN is converted to the corresponding QNaN before it is placed at the target operand location.
Fn	Finite nonzero number (includes both subnormal and normal).
R(v)	Rounding and range action is performed on the value v. See Figure 19-9 on page 19-7.
T(x)	The value x is placed at the target operand location.
Xi:	IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.
Xz:	IEEE division-by-zero exception. The results shown are produced only when FPC 0.1 is zero.

Figure 19-21. Results: DIVIDE

IEEE Exceptions:

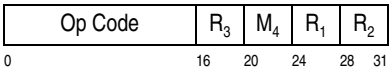
- Invalid operation
- Division by zero
- Overflow
- Underflow
- Inexact

Program Exceptions:

- Access (fetch, operand 2 of DEB and DDB only)
- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Specification (DXBR only)
- Transaction constraint

DIVIDE TO INTEGER

Mnemonic R_1,R_3,R_2,M_4 [RRF-b]



Mnemonic	Op Code	Operands
DIEBR	'B353'	Short BFP
DIDBR	'B35B'	Long BFP

The first operand (the dividend) is divided by the second operand (the divisor). An integer quotient in BFP form is produced and placed at the third-operand location. The remainder replaces the dividend at the first-operand location. The first, second, and third operands must be in different registers. The condition code indicates whether partial or final results have been produced.

The remainder result is

$r = a - b \bullet n$

where a is the dividend, b the divisor, and n an integer obtained by rounding the precise quotient

$q = a \div b.$

The first-operand result is r with the sign determined by the above expression. The third-operand result is n with a sign that is the exclusive or of the dividend and divisor signs.

If the precise quotient is not an integer and the two integers closest to this precise quotient cannot both be represented exactly in the precision of the quotient, then a partial quotient and partial remainder are formed. (In all other cases, a final quotient and final remainder are formed.) This partial quotient n and the corresponding partial remainder

$r = a - b \bullet n$

are used as the results. The sign of a partial remainder is the same as the sign of the dividend. The sign of a partial quotient is the exclusive or of the dividend and divisor signs.

If the remainder is zero, then the precise quotient is an integer and can be represented exactly in the precision of the quotient.

The M_4 field, called the modifier field, specifies rounding of the final quotient. This rounding is called the “final-quotient-rounding method” as contrasted to the “current BFP rounding mode” specified by the BFP rounding-mode bits in the FPC register. The final quotient is rounded according to the final-quotient-rounding method. The final-quotient-rounding method affects only the final quotient; partial quotients are rounded toward zero.

Since the partial quotient is rounded toward zero, the partial remainder is always exact. For the final-quotient-rounding methods of round toward 0, round to nearest with ties to even, and round to nearest with ties away from 0, the final remainder is exact. For the final-quotient-rounding methods of round toward $+\infty$ and round toward $-\infty$, the final remainder may not be exact.

The final quotient is rounded to an integer by rounding as specified by the modifier in the M_4 field:

M_4	Final-Quotient-Rounding Method
0	According to current BFP rounding mode
1	Round to nearest with ties away from 0
3	Round to prepare for shorter precision
4	Round to nearest with ties to even
5	Round toward 0
6	Round toward $+\infty$
7	Round toward $-\infty$

When the floating-point extension facility is installed, a modifier of 2 and 8-15 is invalid. If the floating-point extension facility is not installed, a modifier of 2-3 and 8-15 is invalid.

When the modifier field is zero, rounding of the final quotient is controlled by the current BFP rounding mode specified in the FPC register. When the field is not zero, rounding is performed as specified by the modifier, regardless of the current BFP rounding mode.

Underflow is recognized only on the final remainder, not on the partial remainder.

For the final-quotient-rounding methods of round toward +∞, round toward -∞, and round to prepare for shorter precision, the final remainder may not be exact. When, in these cases, the final remainder is inexact, it is rounded according to the current BFP rounding mode specified in the FPC register.

The sign of a zero quotient is the exclusive or of the divisor and dividend signs.

A zero remainder has the sign of the dividend.

See Figure 19-22 on page 19-29 for a detailed description of the results of this instruction.

If the quotient exponent is greater than the largest exponent that can be represented in the operand format, the correct remainder or partial remainder still is produced, and the third-operand result is the correct value, but with the exponent reduced by 192 or 1536 for short or long operands, respectively. The condition code indicates this out-of-range condition.

If the M_4 field designates any of the following invalid modifier values: 2 and 8-15, then a specification exception is recognized. When the floating-point extension facility is not installed, if the M_4 field designates the invalid value 3, it is undefined whether a specification exception is recognized or an unpredictable rounding method is performed.

The R_1, R_2, and R_3 fields must designate different registers; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Remainder final; normal quotient
1 Remainder final; quotient overflow or NaN
2 Remainder partial; normal quotient
3 Remainder partial; quotient overflow

IEEE Exceptions:

- Invalid operation
- Underflow
- Inexact

Yes	No	Final	No	Yes	–	1	No[1]	No	T(r,n), cc0, PIDx(08)
Yes	No	Final	No	Yes	–	1	No[1]	Yes	T(r,n), cc0, PIDy(0C)
No	Yes	Final	No[1]	No[1]	–	–	No	–	T(r,n), cc0
No	Yes	Final	No[1]	No[1]	–	–	Yes	–	T(r, n÷Ψ), cc1
No	No	Partial	–[2]	No[1]	–	–	No	–	T(r,n), cc2
No	No	Partial	–[2]	No[1]	–	–	Yes	–	T(r, n÷Ψ), cc3

Explanation:

–	The results do not depend on this condition or mask bit.
[1]	This condition is true by virtue of the state of some condition to the left of this column. That is, when $\|q\| < 2^P$, there cannot be a quotient overflow; the cases of remainder is zero, tiny, or inexact are mutually exclusive; and when r is exact, it is not incremented.
[2]	Underflow is not recognized for a partial remainder.
#	Each entry of this column is derived from the entries of the two left columns, and helps determine the specific rounding method used in some columns on the right and determine the resulting condition code setting.
Ψ	Scale factor. For overflow, $\Psi = 2^{+\alpha}$. For underflow, $\Psi = 2^{-\alpha}$. The unsigned scaling exponent (α) depends on the operand format and is 192 for short and 1536 for long.
|q|	The absolute value of q, where q is the precise intermediate value of a÷b before rounding, assuming unbounded precision and unbounded exponent range.
cc0	Condition code is set to 0 (remainder final; normal quotient).
cc1	Condition code is set to 1 (remainder final; quotient overflow).
cc2	Condition code is set to 2 (remainder partial; normal quotient).
cc3	Condition code is set to 3 (remainder partial; quotient overflow).
n	Integer quotient. n = q, rounded toward 0 for partial results and rounded according to the final-quotient-rounding method for final results. The sign of the integer quotient, including the cases of partial and final, scaled value, and zero, is the exclusive or of the signs of the dividend (a) and divisor (b).
r	Remainder. r = a-b•n. A partial remainder is always exact; no rounding is necessary. The sign of a partial remainder is always the same as the sign of the dividend (a). A final remainder is rounded according to the current BFP rounding mode (if necessary) specified in the FPC register. The sign of a zero remainder is the same as the sign of the dividend (a). The sign of a nonzero final remainder is determined by the rules of algebra.
P	Precision of the operand, which depends on the target format: P = 24 for short and 53 for long.
PIDc(h)	Program interruption for data exception, condition c, with DXC of h in hex. See Figure 19-11 on page 19-11.
SFi	IEEE invalid-operation flag, FPC 1.0.
SFu	IEEE underflow flag, FPC 1.3.
SFx	IEEE inexact flag, FPC 1.4.
T(r,n)	Results r (the remainder) and n (the integer quotient) are placed in target operands 1 and 3, respectively.

Figure 19-22. Results: DIVIDE TO INTEGER (Part 2 of 2)

Program Exceptions:

- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Specification
- Transaction constraint

Programming Notes:

1. The Remainder operation, as defined in ANSI/IEEE Standard 754-2008, is produced by issuing DIVIDE TO INTEGER in an iterative loop, with the M_4 field set to 4.

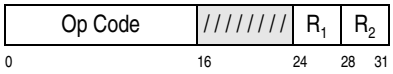
2. The rounding specifications of round to nearest with ties to even, round toward 0, and round toward -∞ permit the instruction to be used directly to produce the Remainder, MOD, and modulo functions, respectively.

3. When DIVIDE TO INTEGER is used in an iterative loop, all quotients are produced in BFP format but may be considered as portions of a multiple-precision fixed-point number.

4. In the case when the resulting remainder is subnormal, ANSI/IEEE Standard 754-2008 requires that if traps are implemented and the underflow mask is one, then an underflow trap must occur. To accomplish this, DIVIDE TO INTEGER recognizes underflow on the final remainder but not on the partial remainder. Since in all cases when underflow exists on the partial remainder it will also exist on the final remainder, recognizing underflow on only the final remainder avoids two underflow traps to be reported for what ANSI/IEEE Standard 754-2008 considers a single Remainder operation.

LOAD AND TEST

Mnemonic R_1,R_2 [RRE]



Mnemonic	Op Code	Operands
LTEBR	'B302'	Short BFP
LTDBR	'B312'	Long BFP
LTXBR	'B342'	Extended BFP

The second operand is placed at the first-operand location, and its sign and magnitude are tested to determine the setting of the condition code. The condition code is set the same as for a comparison of the second operand with zero.

The second operand is placed unchanged at the first-operand location. If the second operand is an SNaN, an IEEE-invalid-operation exception is recognized; if there is no interruption, the result is the corresponding QNaN.

See Figure 19-18 on page 19-21 for a detailed description of the results of this instruction.

For LTXBR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Result is zero
1 Result is less than zero
2 Result is greater than zero
3 Result is a NaN

IEEE Exceptions:

- Invalid operation

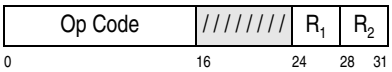
Program Exceptions:

- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Specification (LTXBR only)
- Transaction constraint

Programming Note: LOAD AND TEST signals invalid operation when the operand is an SNaN. TEST DATA CLASS may be used to test an operand if signaling is not desired.

LOAD COMPLEMENT

Mnemonic R_1,R_2 [RRE]



Mnemonic	Op Code	Operands
LCEBR	'B303'	Short BFP
LCDBR	'B313'	Long BFP
LCXBR	'B343'	Extended BFP

The second operand is placed at the first-operand location with the sign bit inverted.

The sign bit is inverted even if the operand is zero. The rest of the second operand is placed unchanged at the first-operand location. The sign is inverted for any operand, including a QNaN or SNaN, without causing an IEEE exception.

For LCXBR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Result is zero
1 Result is less than zero
2 Result is greater than zero
3 Result is a NaN

IEEE Exceptions: None.

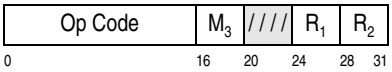
Program Exceptions:

- Data with DXC 2, BFP instruction
- Specification (LCXBR only)
- Transaction constraint

Programming Note: LOAD COMPLEMENT does not signal invalid operation when the operand is an SNaN. LOAD AND TEST may be used in conjunction with this instruction if signaling is desired.

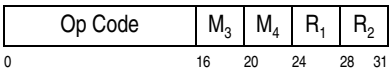
LOAD FP INTEGER

Mnemonic1 R_1,M_3,R_2 [RRF-e]



Mnemonic1	Op Code	Operands
FIEBR	'B357'	Short BFP
FIDBR	'B35F'	Long BFP
FIXBR	'B347'	Extended BFP

Mnemonic2 R_1,M_3,R_2,M_4 [RRF-e]



Mnemonic2	Op Code	Operands
FIEBRA	'B357'	Short BFP
FIDBRA	'B35F'	Long BFP
FIXBRA	'B347'	Extended BFP

The second operand is rounded to an integer value in the same floating-point format, and the result is placed at the first-operand location.

The second operand, if a finite number, is rounded to an integer value as specified by the modifier in the M_3 field:

M_3	Effective Rounding Method
0	According to current BFP rounding mode
1	Round to nearest with ties away from 0
3	Round to prepare for shorter precision
4	Round to nearest with ties to even
5	Round toward 0
6	Round toward +∞
7	Round toward -∞

An M_3 modifier other than 0, 1, or 3-7 is invalid. If the floating-point extension facility is not installed, an M_3 modifier of 3 is also invalid.

When the M_3 modifier field is zero, rounding is controlled by the current BFP rounding mode in the FPC register. When the field is not zero, rounding is performed as specified by the modifier, regardless of the current BFP rounding mode.

In the absence of an interruption, if the second operand is an infinity or a QNaN, the result is that operand; if the second operand is an SNaN, the result is the corresponding QNaN.

The sign of the result is the sign of the second operand, even when the result is zero.

When the floating-point extension facility is installed, bit 1 of the M_4 field is the IEEE-inexact-exception control (XxC). Bits 0, 2, and 3 are ignored. If XxC is zero, recognition of IEEE-inexact exception is not suppressed; if XxC is one, recognition of IEEE-inexact exception is suppressed.

When the floating-point extension facility is not installed and if bits 20-23 of the instruction are zeros, recognition of IEEE-inexact exception is not suppressed; when the floating-point extension facility is not installed and if bits 20-23 of the instruction contain a nonzero value, it is unpredictable whether recognition of IEEE-inexact exception is suppressed.

See Figure 19-23 on page 19-33 for a detailed description of the results of this instruction.

If the M_3 field designates any of the following invalid modifier values: 2 and 8-15, then a specification exception is recognized. When the floating-point extension facility is not installed, if the M_3 field designates the invalid value 3, it is undefined whether a specification exception is recognized or an unpredictable rounding method is performed.

For FIXBR and FIXBRA, the R fields must designate valid floating-point-register pairs. Otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Invalid operation
- Inexact

Program Exceptions:

- Data with DXC 2, BFP instruction

- Data with DXC for IEEE exception
- Specification
- Transaction constraint

Programming Notes:

1. LOAD FP INTEGER rounds a BFP number to an integer value. These integers, which remain in the BFP format, should not be confused with binary integers, which have a fixed-point format.
2. If the BFP operand is a finite number with a large enough exponent so that it is already an integer, the result value remains the same.
3. Unassigned bits in the M_4 field are reserved for future extensions and should be set to zeros; otherwise the program may not operate compatibly in the future.

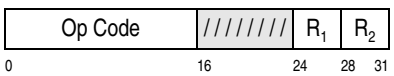
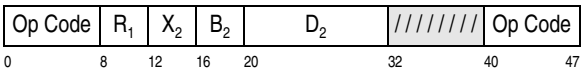
LOAD LENGTHENED

Mnemonic1 R_1,R_2 [RRE]



Mnemonic1	Op Code	Operands
LDEBR	'B304'	Short BFP operand 2, long BFP operand 1
LXDBR	'B305'	Long BFP operand 2, extended BFP operand 1
LXEBR	'B306'	Short BFP operand 2, extended BFP operand 1

Mnemonic2 $R_1,D_2(X_2,B_2)$ [RXE]



Mnemonic2	Op Code	Operands
LDEB	'ED04'	Short BFP operand 2, long BFP operand 1
LXDB	'ED05'	Long BFP operand 2, extended BFP operand 1
LXEB	'ED06'	Short BFP operand 2, extended BFP operand 1

The second operand is converted to a longer format, and the result is placed at the first-operand location.

When the second operand is a finite number, the value of the second operand is placed in the target format. The exponent of the second operand is converted to the corresponding exponent in the result format, and the fraction is extended by appending zeros on the right.

If the second operand is an infinity, the result is an infinity of the same sign. If the second operand is an SNaN, an IEEE-invalid-operation exception is recognized; if there is no interruption, the result is the corresponding QNaN with the fraction extended.

The sign of the result is the same as the sign of the source.

See Figure 19-18 on page 19-21 for a detailed description of the results of this instruction.

For LXDB, LXDBR, LXEB, and LXEBR, the R_1 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions:

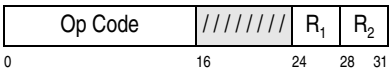
- Invalid operation

Program Exceptions:

- Access (fetch, operand 2 of LDEB, LXEB, and LXDB only)
- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Specification (LXEB, LXEBR, LXDB, LXDBR)
- Transaction constraint

LOAD NEGATIVE

Mnemonic R_1,R_2 [RRE]



Mnemonic	Op Code	Operands
LNEBR	'B301'	Short BFP
LNDBR	'B311'	Long BFP
LNXBR	'B341'	Extended BFP

The second operand is placed at the first-operand location with the sign bit made one.

The sign bit is made one even if the operand is zero. The rest of the second operand is placed unchanged at the first-operand location. The sign is set for any operand, including a QNaN or SNaN, without causing an IEEE exception.

For LNXBR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Result is zero
1 Result is less than zero
2 --
3 Result is a NaN

IEEE Exceptions: None.

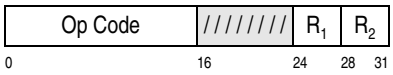
Program Exceptions:

- Data with DXC 2, BFP instruction
- Specification (LNXBR only)
- Transaction constraint

Programming Note: LOAD NEGATIVE does not signal invalid operation when the operand is an SNaN. LOAD AND TEST may be used in conjunction with this instruction if signaling is desired.

LOAD POSITIVE

Mnemonic R_1,R_2 [RRE]



Mnemonic	Op Code	Operands
LPEBR	'B300'	Short BFP
LPDBR	'B310'	Long BFP
LPXBR	'B340'	Extended BFP

The second operand is placed at the first-operand location with the sign bit made zero.

The sign bit is made zero, and the rest of the second operand is placed unchanged at the first-operand location. The sign is set for any operand, including a QNaN or SNaN, without causing an IEEE exception.

For LPXBR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Result is zero
1 --
2 Result is greater than zero
3 Result is a NaN

IEEE Exceptions: None.

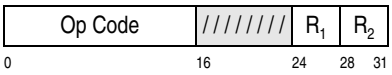
Program Exceptions:

- Data with DXC 2, BFP instruction
- Specification (LPXBR only)
- Transaction constraint

Programming Note: LOAD POSITIVE does not signal invalid operation when the operand is an SNaN. LOAD AND TEST may be used in conjunction with this instruction if signaling is desired.

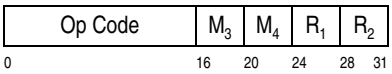
LOAD ROUNDED

Mnemonic1 R_1,R_2 [RRE]



Mnemonic1	Op Code	Operands
LEDBR	'B344'	Long BFP source, short BFP target, short or long BFP result
LDXBR	'B345'	Extended BFP source, long BFP target, long or extended BFP result
LEXBR	'B346'	Extended BFP source, short BFP target, short or extended BFP result

Mnemonic2 R_1,M_3,R_2,M_4 [RRF-e]



Mnemonic2	Op Code	Operands
LEDBRA	'B344'	Long BFP source, short BFP target, short or long BFP result
LDXBRA	'B345'	Extended BFP source, long BFP target, long or extended BFP result
LEXBRA	'B346'	Extended BFP source, short BFP target, short or extended BFP result

The second operand, in the format of the source, is rounded to the precision of the target, and the result is placed at the first-operand location.

When the floating-point extension facility is installed, the second operand, if a finite number, is rounded by rounding as specified by the modifier in the M_3 field:

M_3	Effective Rounding Method
0	According to current BFP rounding mode
1	Round to nearest with ties away from 0
3	Round to prepare for shorter precision
4	Round to nearest with ties to even
5	Round toward 0
6	Round toward $+\infty$
7	Round toward $-\infty$

An M_3 modifier other than 0, 1, or 3-7 is invalid. The M_3 field must designate a valid modifier; otherwise, a specification exception is recognized.

When the M_3 modifier field is zero, rounding is controlled by the current BFP rounding mode specified in the FPC register. When the field is not zero, rounding is performed as specified by the modifier, regardless of the current BFP rounding mode.

When the floating-point extension facility is not installed and bits 16-19 of the instruction contain a value of zero, the second operand is rounded according to the current BFP rounding mode. When the floating-point extension facility is not installed and bits 16-19 of the instruction contain a nonzero value, it is undefined whether a specification exception is recognized or an unpredictable rounding method is performed.

In the absence of IEEE-trap action for overflow or underflow, the result is in the format and length of the target. However, when an IEEE overflow or an IEEE underflow is recognized and the corresponding mask bit is one, the operation is completed by producing a scaled result in the same format and length as the source but rounded to the precision of the target. For LEDBR, LEDBRA, LEXBR and LEXBRA, the result has at most 23 significand fraction bits; for LDXBR and LDXBRA, the result has at most 52 significand fraction bits.

A short-format result replaces the leftmost 32 bits of the target register, and the rightmost 32 bit positions of the target register remain unchanged. A long-format result is placed in a floating-point register, and the other register of the floating-point register pair, if any, remains unchanged. An extended-format result is placed in a floating-point register pair.

The sign of the result is the same as the sign of the second operand.

When the floating-point extension facility is installed, bit 1 of the M_4 field is the IEEE-inexact-exception control (XxC). Bits 0, 2, and 3 are ignored. If XxC is zero, recognition of IEEE-inexact exception is not suppressed; if XxC is one, recognition of IEEE-inexact exception is suppressed.

When the floating-point extension facility is not installed and if bit 21 of the instruction is zero, recognition of IEEE-inexact exception is not suppressed; when the floating-point extension facility is not installed and if bit 21 of the instruction is one, then it is unpredictable whether recognition of IEEE-inexact exception is suppressed.

See Figure 19-18 on page 19-21 for a detailed description of the results of this instruction.

For LDXBR, LDXBRA, LEXBR, and LEXBRA, the R_1 and R_2 fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Invalid operation
- Overflow
- Underflow
- Inexact

Program Exceptions:

- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Specification
- Transaction constraint

Programming Notes:

1. The sign of the rounded result is the same as the sign of the operand, even when the result is zero.

2. The R_1 field for LDXBR, LDXBRA, LEXBR, and LEXBRA must designate a valid floating-point-register pair since in certain cases the result is in the extended format. In normal operation for LDXBR, LDXBRA, LEXBR and LEXBRA, the result format is long or short, respectively, and this result replaces the leftmost 32 bits or 64 bits of the target-register pair. However, when an IEEE overflow or an IEEE underflow is recognized and the corresponding mask bit is one, the operation is completed by placing a result in the extended format at the target location. Thus, the program must take into account the fact that these instructions sometimes update both registers of the pair.

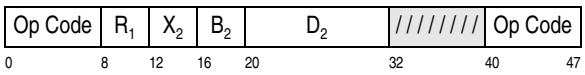
3. Unassigned bits in the M_4 field are reserved for future extensions and should be set to zeros; otherwise the program may not operate compatibly in the future

MULTIPLY

Mnemonic1 R_1,R_2 [RRE]

Mnemonic1	Op Code	Operands
MEEBR	'B317'	Short BFP
MDBR	'B31C'	Long BFP
MXBR	'B34C'	Extended BFP
MDEBR	'B30C'	Short BFP multiplier and multiplicand, long BFP product
MXDBR	'B307'	Long BFP multiplier and multiplicand, extended BFP product

Mnemonic2 $R_1,D_2(X_2,B_2)$ [RXE]



Mnemonic2	Op Code	Operands
MEEB	'ED17'	Short BFP
MDB	'ED1C'	Long BFP
MDEB	'ED0C'	Short BFP multiplier and multiplicand, long BFP product
MXDB	'ED07'	Long BFP multiplier and multiplicand, extended BFP product

The product of the second operand (the multiplier) and the first operand (the multiplicand) is placed at the first-operand location.

The two BFP operands, if finite numbers, are multiplied, forming an intermediate product. For MDEB, MDEBR, MXDB, and MXDBR, the intermediate product is converted to the longer target format; the result cannot overflow or underflow and is exact. For MDB, MDBR, MEEB, MEEBR, and MXBR, the result is rounded to the operand format according to the current BFP rounding mode. For MEEB and MEEBR, the result, as for all short-format results, replaces the leftmost 32 bits of the target register, and the rightmost 32 bit positions of the target register remain unchanged.

The sign of the product, if the product is numeric, is the exclusive or of the operand signs. This includes the sign of a zero or infinite product.

If one operand is a zero and the other an infinity, an IEEE-invalid-operation exception is recognized.

See Figure 19-24 on page 19-38 for a detailed description of the results of this instruction.

The R_1 field for MXDB, MXDBR, and MXBR, and the R_2 field for MXBR, must designate valid floating-point-register pairs. Otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Invalid operation
- Overflow (MDB, MDBR, MEEB, MEEBR, MXBR)
- Underflow (MDB, MDBR, MEEB, MEEBR, MXBR)
- Inexact (MDB, MDBR, MEEB, MEEBR, MXBR)

Program Exceptions:

- Access (fetch, operand 2 of MDEB, MEEB, MDB, and MXDB only)
- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Specification (MXDB, MXDBR, MXBR)
- Transaction constraint

Programming Note: Interchanging the two operands in a BFP multiplication does not affect the value of the product when the result is numeric. This is not true, however, when both operands are QNaNs, in which case the result is the first operand; or when both operands are SNaNs and the IEEE-invalid-operation mask bit in the FPC register is zero, in which case the result is the QNaN derived from the first operand.

First Operand (a) Is	Results for MULTIPLY (a•b) when Second Operand (b) Is							
	-∞	**-Fn**	**-0**	**+0**	**+Fn**	**+∞**	**QNaN**	**SNaN**
-∞	T(+∞)	T(+∞)	Xi: T(dNaN)	Xi: T(dNaN)	T(-∞)	T(-∞)	T(b)	Xi: T(b*)
-Fn	T(+∞)	R(a•b)	T(+0)	T(-0)	R(a•b)	T(-∞)	T(b)	Xi: T(b*)
-0	Xi: T(dNaN)	T(+0)	T(+0)	T(-0)	T(-0)	Xi: T(dNaN)	T(b)	Xi: T(b*)
+0	Xi: T(dNaN)	T(-0)	T(-0)	T(+0)	T(+0)	Xi: T(dNaN)	T(b)	Xi: T(b*)
+Fn	T(-∞)	R(a•b)	T(-0)	T(+0)	R(a•b)	T(+∞)	T(b)	Xi: T(b*)
+∞	T(-∞)	T(-∞)	Xi: T(dNaN)	Xi: T(dNaN)	T(+∞)	T(+∞)	T(b)	Xi: T(b*)
QNaN	T(a)	T(a)	T(a)	T(a)	T(a)	T(a)	T(a)	Xi: T(b*)
SNaN	Xi: T(a*)	Xi: T(a*)	Xi: T(a*)	Xi: T(a*)	Xi: T(a*)	Xi: T(a*)	Xi: T(a*)	Xi: T(a*)

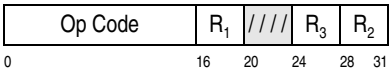
Explanation:

*	The SNaN is converted to the corresponding QNaN before it is placed at the target operand location.
dNaN	Default NaN.
Fn	Finite nonzero number (includes both subnormal and normal).
R(v)	Rounding and range action is performed on the value v. See Figure 19-9 on page 19-7.
T(x)	The value x is placed at the target operand location.
Xi:	IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.

Figure 19-24. Results: MULTIPLY

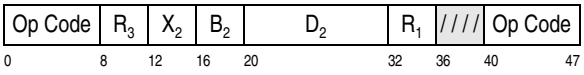
MULTIPLY AND ADD

Mnemonic1 R_1,R_3,R_2 [RRD]



Mnemonic1	Op Code	Operands
MAEBR	'B30E'	Short BFP
MADBR	'B31E'	Long BFP

Mnemonic2 $R_1,R_3,D_2(X_2,B_2)$ [RXF]



Mnemonic2	Op Code	Operands

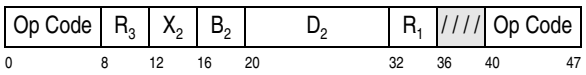
MSDBR	'B31F'	Long BFP

Mnemonic2 $R_1,R_3,D_2(X_2,B_2)$ [RXF]



Mnemonic2	Op Code	Operands
MSEB	'ED0F'	Short BFP
MSDB	'ED1F'	Long BFP

The third operand is multiplied by the second operand, and then the first operand is added to or subtracted from the product. The sum or difference is placed at the first-operand location. The MULTIPLY AND ADD and MULTIPLY AND SUBTRACT operations may be summarized as:

$op_1 = op_3 \bullet op_2 \pm op_1$

When the operands are finite numbers, the third and second BFP operands are multiplied, forming an intermediate product, and the first operand is then added (or subtracted) algebraically to (or from) the intermediate product, forming an intermediate sum. The intermediate sum, if nonzero, is rounded to the operand format according to the current BFP rounding mode and then placed at the first-operand location. The exponent and fraction of the intermediate product are maintained exactly; rounding and range checking occur only on the intermediate sum.

See Figure 19-25 for a detailed description of the results of MULTIPLY AND ADD. The results of MUL-

Third Operand (a) Is	Results, Part 1, for MULTIPLY AND ADD (a•b+c) when Second Operand (b) Is

Explanation:

*	The SNaN is converted to the corresponding QNaN before it is placed at the target operand location.
dNaN	Default NaN.
Fn	Finite nonzero number (includes both subnormal and normal).
P(x)	The value x is passed to Part 2 of this figure.
R(v)	Rounding and range action is performed on the value v. See Figure 19-9 on page 19-7.
Rezd	Exact zero-difference result. See Figure 19-9 on page 19-7.
T(x)	The value x is placed at the target operand location.
Xi:	IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.

Figure 19-25. Results: MULTIPLY AND ADD (Part 2 of 2)

TIPLY AND SUBTRACT are the same, except that the first operand, if numeric, participates in the operation with its sign bit inverted. When the first operand is a NaN, it participates in the operation with its sign bit unchanged.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Invalid operation
- Overflow
- Underflow
- Inexact

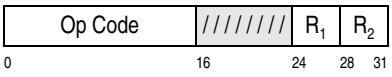
Program Exceptions:

- Access (fetch, operand 2 of MAEB, MADB, MSEB, MSDB)
- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Transaction constraint

Programming Note: MULTIPLY AND ADD and MULTIPLY AND SUBTRACT produce a precise intermediate value, and a single rounding operation is performed after the addition or subtraction. This definition is consistent with the Power architecture, and, in certain applications, can be used to great advantage, especially in algorithms used in math libraries.

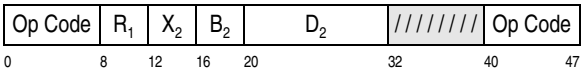
SQUARE ROOT

Mnemonic1 R_1,R_2 [RRE]



Mnemonic1	Op Code	Operands
SQEBR	'B314'	Short BFP
SQDBR	'B315'	Long BFP
SQXBR	'B316'	Extended BFP

Mnemonic2 $R_1,D_2(X_2,B_2)$ [RXE]



Mnemonic2	Op Code	Operands
SQEB	'ED14'	Short BFP
SQDB	'ED15'	Long BFP

The square root of the second operand is placed at the first-operand location.

The result rounded according to the current BFP rounding mode is placed at the first-operand location.

If the second operand is a positive finite number, the result is the square root of that number with a plus sign. If the operand is a zero of either sign, the result is a zero of the same sign. If the operand is +∞, the result is +∞.

If the second operand is less than zero, an IEEE-invalid-operation exception is recognized.

See Figure 19-18 on page 19-21 for a detailed description of the results of this instruction.

For SQXBR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions:

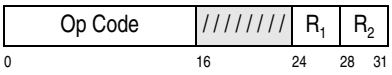
- Invalid operation
- Inexact

Program Exceptions:

- Access (fetch, operand 2 of SQEB and SQDB only)
- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Specification (SQXBR only)
- Transaction constraint

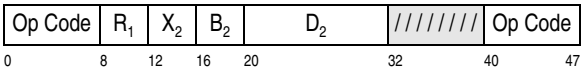
SUBTRACT

Mnemonic1 R_1,R_2 [RRE]



Mnemonic1	Op Code	Operands
SEBR	'B30B'	Short BFP
SDBR	'B31B'	Long BFP
SXBR	'B34B'	Extended BFP

Mnemonic2 $R_1,D_2(X_2,B_2)$ [RXE]



Mnemonic2	Op Code	Operands
SEB	'ED0B'	Short BFP
SDB	'ED1B'	Long BFP

The second operand is subtracted from the first operand, and the difference is placed at the first-operand location.

The execution of SUBTRACT is identical to that of ADD, except that the second operand, if numeric, participates in the operation with its sign bit inverted. When the second operand is a NaN, it participates in the operation with its sign bit unchanged. See Figure 19-14 on page 19-16 for the detailed results of ADD.

For SXBR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Result is zero
1 Result is less than zero
2 Result is greater than zero
3 Result is a NaN

IEEE Exceptions:

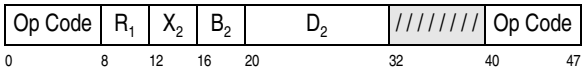
- Invalid operation
- Overflow
- Underflow
- Inexact

Program Exceptions:

- Access (fetch, operand 2 of SEB and SDB only)
- Data with DXC 2, BFP instruction
- Data with DXC for IEEE exception
- Specification (SXBR only)
- Transaction constraint

TEST DATA CLASS

Mnemonic $R_1,D_2(X_2,B_2)$ [RXE]



Mnemonic	Op Code	Operands
TCEB	'ED10'	Short BFP
TCDB	'ED11'	Long BFP
TCXB	'ED12'	Extended BFP

The class and sign of the first operand are examined to select one bit from the second-operand address. Condition code 0 or 1 is set according to whether the selected bit is zero or one, respectively.

The second-operand address is not used to address data; instead, the rightmost 12 bits of the address, bits 52-63, are used to specify 12 combinations of BFP data class and sign. Bits 0-51 of the second-operand address are ignored.

As shown in Figure 19-26, BFP operands are divided into six classes: zero, normal number, subnormal number, infinity, quiet NaN, and signaling NaN.

One or more of the second-operand-address bits may be set to one. If the second-operand-address bit corresponding to the class and sign of the first operand is one, condition code 1 is set; otherwise, condition code 0 is set.

BFP Operand Class	Bit Used when Sign Is +	Bit Used when Sign Is -
Zero	52	53
Normal number	54	55
Subnormal number	56	57
Infinity	58	59
Quiet NaN	60	61
Signaling NaN	62	63

Figure 19-26. Second-Operand-Address Bits for TEST DATA CLASS

Operands, including SNaNs and QNaNs, are examined without causing an IEEE exception.

For TCXB, the R_1 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Selected bit is 0 (no match)
1 Selected bit is 1 (match)
2 --
3 --

IEEE Exceptions: None.

Program Exceptions:

- Data with DXC 2, BFP instruction
- Specification (TCXB only)
- Transaction constraint

Programming Notes:

1. TEST DATA CLASS provides a way to test an operand without risk of an exception or setting the IEEE flags.

2. The bits used to specify the combinations of data class and sign are not all the same for BFP and DFP. Specifically, DFP TEST DATA CLASS uses bits 54 and 55 for subnormal number, and bits 56 and 57 for normal number.

Decimal-Floating-Point Facility

The decimal-floating-point (DFP) facility provides instructions to operate on decimal (radix-10) floating-point data. The facility was designed in cooperation with the IEEE floating-point working group.

Additionally, this facility was designed to support a common library for various systems. This facility in both the z/architecture and Power architectures supports the same data formats, the same rounding methods, the same functions, and the same exceptions.

DFP has a number of important characteristics:

© Copyright IBM Corp. 2000, 2025

- It produces results consistent with decimal arithmetic as taught in elementary school.
- It recognizes the quantum of a finite number, maintains quantum information through arithmetic operations, and provides special operations to extract, compare, and adjust the quantum.
- It provides greater exponent range than hexadecimal-floating-point (HFP) and binary-floating-point (BFP) while maintaining comparable precision.
- It provides greater precision and better space efficiency than provided by the decimal-arithmetic instructions and the packed-decimal format as described in Chapter 8, “Decimal Instructions.”
- It supports IEEE flags, exceptions, and special entities of “infinity” and “Not-a-Number” (NaN).
- It supports eight automatic rounding methods. For DFP computational instructions, an explicit rounding method can be specified in a modifier field in the instruction.
- It facilitates production of DFP results with a precision other than any supported format precision and with the effect of single rounding.
- It provides operations for conversion between fixed-point and DFP formats.
- It provides operations for conversion between packed-decimal and DFP formats.
- It provides three-operand nondestructive arithmetic operations by permitting different target-operand registers from source-operand registers.

The DFP facility uses the same 16 floating-point registers as those used by HFP and BFP. A set of radix-independent floating-point-support instructions can be used to load, store, or change the sign of a DFP operand. These instructions are defined in Chapter 9, “Floating-Point Overview and Support Instructions.”

The DFP facility uses the same floating-point-control (FPC) register as that used by BFP. The bits of the FPC register are often referred to as, for example, FPC1.0, meaning bit 0 of byte 1 of the register. The description of the FPC register, including the DFP-rounding-mode field, and the instructions that operate on the FPC register are provided in Chapter 9, “Floating-Point Overview and Support Instructions.”

The DFP computational model, a high-level overview of the computational steps, is described in the section “IEEE Computational Operations” of Chapter 9, “Floating-Point Overview and Support Instructions.” Detailed definitions of rounding methods and IEEE exceptions supported by DFP are also described in the section.

DFP Arithmetic

Finite Floating-Point Number

A finite floating-point number has three components: a sign, an exponent, and a significand. The magnitude of a finite number is the product of significand multiplied by the radix raised to the power of the exponent. The number is positive or negative depending on whether the sign bit is zero or one, respectively.

Cohort

Finite decimal-floating-point (DFP) numbers are not necessarily normalized; that is, the leftmost significand digit may be zero. This allows some values to have multiple representations; each with a different combination of the significand and the exponent. The set of different representations for a value of the same sign is called a cohort; and each representation in a cohort is called a cohort member. A positive zero and a negative zero have the same value but are in different cohorts.

Quantum

For a DFP finite number, the magnitude of a value of one in the rightmost digit position of the significand is called the quantum. Each cohort member of a cohort uses a different quantum to represent the same value. Regardless of whether the left-units view or right-units view is taken, the quantum of a cohort member is the same.

Preferred Quantum

For operations that produce a DFP result, when, in the absence of a trap overflow or a trap underflow, the delivered value is a finite number, a value, called the preferred quantum, is defined to select a cohort member to represent the delivered value. The preferred quantum for each of these operations is shown in Figure 20-4 on page 20-10. When the delivered value is exact, the preferred quantum depends on the

operation. When the delivered value is inexact, the preferred quantum is the smallest quantum of the cohort members, unless otherwise stated.

Scaled Preferred Quantum

For operations that produce a DFP result, when a trap overflow or a trap underflow occurs, a scaled preferred quantum is used to select a cohort member to represent the delivered value. The scaled preferred quantum is obtained by scaling the preferred quantum using the same scale factor as that used to obtain the delivered value.

Delivered Quantum

Normally, when the delivered value is a finite number, the result is selected from the cohort for the delivered value in the target format. However, in case of a trap overflow or trap underflow for LOAD ROUNDED, the result is selected from a subset of the cohort for the delivered value in the source format. This subset of the cohort consists of cohort members that have the number of DFP significand digits equal to or less than the precision of the target format.

In the absence of a trap overflow or trap underflow, if the delivered value is a finite number, the cohort member with the quantum closest to the preferred quantum is selected.

In case of a trap overflow or trap underflow, the cohort member with the quantum closest to the scaled preferred quantum is selected.

Special Quantum-Handling Operations

Special operations are provided to handle the quantum: COMPARE BIASED EXPONENT can be used to compare two quanta; EXTRACT BIASED EXPONENT can be used to determine the quantum of a finite number; and QUANTIZE can be used to adjust the quantum of a finite number.

Programming Notes:

1. Many financial applications and commercial databases use scaled integer representation of decimal data. Calculations are carried out by using integer arithmetic and scaling factors are tracked separately; the scaling factor is often an attribute of a column in the database. This computational model can be supported by DFP by allowing the integer part of decimal data to map into the significand with a right-units view and the scaling factor to map into the quantum.
2. The term coefficient is used in some other documents to mean an integer value in significand; that is, significand in right-units view.

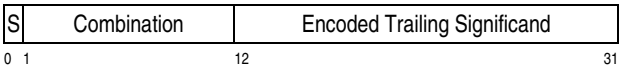
DFP Data Formats

Decimal-floating-point data may be represented in any of three data formats: short, long, or extended.

The contents of each data format represent encoded information. Special codes are assigned to distinguish finite numbers from NaNs and infinities.

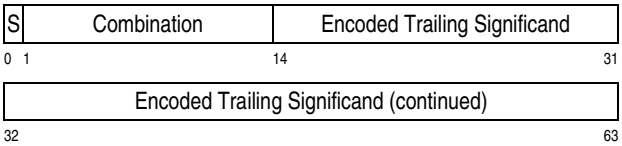
For finite numbers, a biased exponent is used in the format. For each format, a different bias is used for right-units-view (RUV) exponents from that for left-units-view (LUV) exponents. The biased exponents are unsigned numbers and all biases are shown in Figure 20-3 on page 20-6. The biased exponent is encoded with the leftmost digit (LMD) of the significand in the combination field. The remaining digits of the significand are encoded in the encoded trailing-significand field.

DFP Short Format



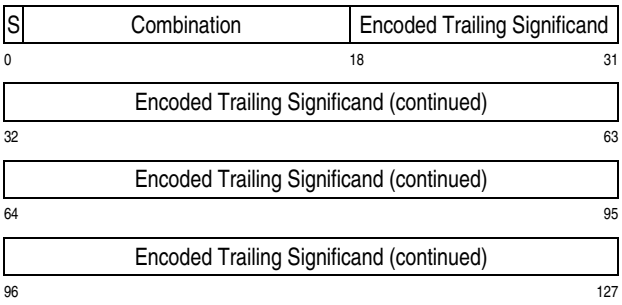
When an operand in the DFP short format is loaded into a floating-point register, it occupies the left half of the register, and the right half remains unchanged.

DFP Long Format



When an operand in the DFP long format is loaded into a floating-point register, it occupies the entire register.

DFP Extended Format



An operand in the DFP extended format occupies a register pair. The leftmost 64 bits occupy the entire lower-numbered register of the pair and the rightmost 64 bits occupy the entire higher-numbered register.

The properties of the three formats are tabulated in Figure 20-3 on page 20-6.

Sign

The sign bit is in bit 0 of each format, and is zero for plus and one for minus.

Combination

For finite numbers, this field contains the biased exponent and the leftmost digit of the significand; for NaNs and infinities, this field contains codes to identify them.

When bits 1-5 of the format are in the range of 00000 - 11101, the operand is a finite number. The two leftmost bits of the biased exponent and the leftmost digit of the significand are encoded in bits 1-5 of the format. Bit 6 through the end of the combination field contain the rest of the biased exponent.

When bits 1-5 of the format field are 11110, the operand is an infinity. All bits in the combination field to the right of bit 5 of the format constitute the reserved field for infinity. A nonzero value in the reserved field is accepted in a source infinity; the reserved field is set to zero in a resultant infinity.

When bits 1-5 of the format are 11111, the operand is a NaN and bit 6, called the SNaN bit, further distinguishes QNaN from SNaN. If bit 6 is zero, then it is QNaN; otherwise, it is SNaN. All bits in the combination field to the right of bit 6 of the format constitute the reserved field for NaN. A nonzero value in the reserved field is accepted in a source NaN; the reserved field is set to zero in a resultant NaN.

Figure 20-1 summarizes the encoding and layout of the combination field. In the figure, the biased exponent of a finite number is the concatenation of two parts: (1) two leftmost bits are derived from bits 1-5 of the format, and (2) the remaining bits in the combination field. For example, if the combination field of the DFP short format contains 10101010101 binary, it represents a biased exponent of 10010101 binary and a leftmost significand digit of 5.

Bits 1 2 3 4 5	Bit 6	Type	Biased Exponent	LMD

Figure 20-1. The Combination Field

Bits 1 2 3 4 5	Bit 6	Type	Biased Exponent	LMD
11111	1	SNaN[2]	--	--

Explanation:

--	Not applicable.
|	Concatenation.
[1]	All bits in the combination field to the right of bit 5 of the format constitute the reserved field for infinity.
[2]	All bits in the combination field to the right of bit 6 of the format constitute the reserved field for NaN.
LMD	Leftmost digit of the significand.
m	Bit 6 is a part of the remaining biased exponent.
RBE	Remaining biased exponent. It includes all bits in the combination field to the right of bit 5 of the format.
r	Bit 6 is a reserved bit for infinity.

Figure 20-1. The Combination Field (Continued)

Encoded Trailing Significand

This field contains an encoded decimal number, which represents digits in the trailing significand. The trailing significand contains all significand digits, except the leftmost digit. For infinities, nonzero trailing-significand digits are accepted in a source infinity; all trailing-significand digits in a resultant infinity are set to zeros, unless otherwise stated. For NaNs, this field contains diagnostic information called the payload.

The encoded trailing-significand field is a multiple of 10-bit blocks called declets. The number of declets depends on the format. Each declet represents three decimal digits in a 10-bit value. This is described in the section, “Densely Packed Decimal (DPD)” on page 20-58.

Values of Finite Numbers

The values of finite numbers in the various formats are shown in Figure 20-2.

Format	Value	
	Left-Units View	Right-Units View
Short	$\pm 10^{e-95} \times (d_0.d_1d_2...d_6)$	$\pm 10^{e-101} \times (d_0d_1d_2...d_6)$
Long	$\pm 10^{e-383} \times (d_0.d_1d_2...d_{15})$	$\pm 10^{e-398} \times (d_0d_1d_2...d_{15})$
Extended	$\pm 10^{e-6143} \times (d_0.d_1d_2...d_{33})$	$\pm 10^{e-6176} \times (d_0d_1d_2...d_{33})$

Explanation:

$d_0.d_1d_2...d_{p-1}$	Significand in left-units view. The decimal point is to the immediate right of the leftmost digit and d_i is a decimal digit, where $0 \le i \le (p - 1)$ and p is the format precision.
$d_0d_1d_2...d_{p-1}$	Significand in right-units view. The decimal point is to the right of the rightmost digit and d_i is a decimal digit, where $0 \le i \le (p - 1)$ and p is the format precision.
e	Biased exponent.

Figure 20-2. Values of Finite Numbers

Programming Note: The RUV exponent, Q, is related to the LUV exponent, E, as follows: Q = E - p + 1, where p is the format precision.

Significand

Hereafter, the term significand is used to mean the following:

1. For finite numbers, the significand contains all trailing significand digits padded on the left with the leftmost digit of significand derived from the combination field.
2. For infinities and NaNs, the significand contains all trailing significand digits padded on the left with a zero digit.

DFP Significant Digits

For a finite number, the DFP significant digits begin with the leftmost nonzero significand digit and end with the rightmost significand digit.

For a finite number, the number of DFP significant digits is the difference of subtracting the number of leading zeros from the format precision. The number of leading zeros is the number of zeros in the significand to the left of the leftmost nonzero digit.

Programming Note: The number of DFP significant digits of the value zero is zero.

Property	Format		
	Short	Long	Extended
Format length (bits)	32	64	128
Combination length (bits)	11	13	17
Encoded Trailing significand length (bits)	20	50	110
Precision (p)	7	16	34
Maximum left-units-view (LUV) exponent (Emax)	96	384	6144
Minimum left-units-view (LUV) exponent (Emin)	-95	-383	-6143
Left-units-view (LUV) bias	95	383	6143
Maximum right-units-view (RUV) exponent (Qmax)	90	369	6111
Minimum right-units-view (RUV) exponent (Qmin)	-101	-398	-6176
Right-units-view (RUV) bias	101	398	6176
Maximum biased exponent	191	767	12,287
Nmax	$(10^7 - 1) \times 10^{90}$	$(10^{16} - 1) \times 10^{369}$	$(10^{34} - 1) \times 10^{6111}$
Nmin	1×10^{-95}	1×10^{-383}	1×10^{-6143}
Dmin	1×10^{-101}	1×10^{-398}	1×10^{-6176}

Explanation:

Dmin Smallest (in magnitude) subnormal number.
Nmax Largest (in magnitude) normal number.
Nmin Smallest (in magnitude) normal number,

Figure 20-3. Summary of DFP Formats

Canonical Declets

The trailing significand digits in a DFP data format are encoded by representing three decimal digits with a 10-bit declet. Of the 1024 possible declets, 1000 canonical declets are produced in resultant DFP operands, and 24 noncanonical declets are not produced as DFP results. Both canonical and noncanonical declets are accepted in source DFP operands. The encoding of a canonical declet or noncanonical declet is described in the section, "Densely Packed Decimal (DPD)" on page 20-58.

DFP Canonical Data

A finite number is canonical when all declets are canonical declets.

An infinity is canonical when the reserved field is zero and all digits in the trailing significand are zeros.

A NaN is canonical when the reserved field is zero and all declets are canonical declets.

Programming Note: To ensure compatibility with future extensions and interchangeability between software routines, only DFP canonical data should be used.

Classes of DFP Data

There are six classes of DFP data: zero, subnormal number, normal number, infinity, signaling NaN, and quiet NaN. The zero, subnormal number, and normal number data classes are collectively called finite numbers. The instruction TEST DATA CLASS may be used to determine the class of a DFP operand.

Zeros

Zeros have a zero significand and any representable value in the biased exponent. A +0 is distinct from a -0 and zeros with different biased exponents are distinct, except that comparison treats them as equal.

Subnormal Numbers

Subnormal numbers are numbers which are smaller than Nmin and larger than zero in magnitude.

Normal Numbers

Normal numbers are numbers whose magnitude is between Nmin and Nmax inclusively.

Infinities

An infinity is represented by 11110 binary in bits 1-5 of the data format. Infinities can participate in most arithmetic operations and give a consistent result, usually infinity. In comparisons, +∞ compares greater than any finite number, and -∞ compares less than any finite number. All +∞ are compared equal and all -∞ are compared equal.

Signaling and Quiet NaNs

A NaN (Not-a-Number) is represented by 11111 binary in bits 1-5 of the data format. NaNs are produced in place of a numeric result after an invalid operation when there is no interruption. NaNs may also be used by the program to flag special operands, such as the contents of an uninitialized storage area.

There are two types of NaNs, signaling and quiet. A signaling NaN (SNaN) is distinguished from a quiet NaN (QNaN) by bit 6, the SNaN bit, of the data format: zero for the QNaN and one for the SNaN. A special QNaN, called the default QNaN, is supplied as the nontrap result for an IEEE-invalid-operation exception; it has a plus sign, and the SNaN bit, the reserved field, and the payload are set to zeros.

Normally, source QNaNs are canonicalized to become the resultant QNaN that has the same sign and payload as the source during operations so that they will remain visible at the end. (See the section “Canonicalization” on page 20-7 for details.) An SNaN operand causes an IEEE invalid-operation exception, unless otherwise stated. When the exception is recognized for a SNaN, the nontrap result is the corresponding QNaN**,** which is produced by setting the SNaN bit in the source SNaN to zero and then the converted QNaN is canonicalized, and the IEEE-invalid-operation flag (FPC 1.0) is set to one.

Where applicable, the propagation of NaNs is illustrated in the action figure for an instruction.

Canonicalization

For operations that are defined to produce a DFP result, the result placed at the target operand location is canonical, unless otherwise stated.

Programming Notes:

1. The following instructions may produce a noncanonical infinity as the result:

   - INSERT BIASED EXPONENT
   - LOAD LENGTHENED
   - LOAD ROUNDED
   - SHIFT SIGNIFICAND LEFT
   - SHIFT SIGNIFICAND RIGHT

   Infinities produced as a DFP result have the reserved field set to zero and have canonical declets in the encoded trailing-significand field. However, the infinity produced by the above instructions does not necessarily have zeros in all digits in the trailing significand. Such an infinity is not canonical.

2. Only canonical operands should be used, as it is possible that some libraries or software routines reject noncanonical operands.

3. Except for INSERT BIASED EXPONENT, if only canonical source operands are used, the result is canonical. INSERT BIASED EXPONENT may produce a noncanonical result even if all source operands are canonical. Special precautions should be taken to avoid producing a noncanonical result from INSERT BIASED EXPONENT.

DFP-Format Conversion

DFP format conversion is described in the section “IEEE Same-Radix Format Conversion” of Chapter 9, “Floating-Point Overview and Support Instructions.”

DFP Rounding

DFP rounding is described in the section “IEEE DFP Rounding” of Chapter 9, “Floating-Point Overview and Support Instructions.”

DFP Comparison

DFP comparison is described in the section “IEEE Comparison” of Chapter 9, “Floating-Point Overview and Support Instructions.”

DFP Formatting Instructions

A set of instructions are provided to compose and decompose DFP data. These instructions do not recognize any IEEE exceptions. They are:

- CONVERT FROM PACKED
- CONVERT FROM SIGNED PACKED
- CONVERT FROM UNSIGNED PACKED
- CONVERT FROM ZONED
- CONVERT TO PACKED
- CONVERT TO SIGNED PACKED
- CONVERT TO UNSIGNED PACKED
- CONVERT TO ZONED
- EXTRACT BIASED EXPONENT
- INSERT BIASED EXPONENT
- SHIFT SIGNIFICAND LEFT
- SHIFT SIGNIFICAND RIGHT

Conversion of data between character strings in an external format and the DFP format may be performed in several steps. At certain steps, for finite numbers, the significand is kept in the packed-decimal format and the biased exponent in the fixed-point format. See Chapter 8, “Decimal Instructions,” for a detailed description of the zoned and packed-decimal formats.

It takes 17 packed-decimal digits to hold the 16 significand digits and one sign of a long DFP format; it takes 35 packed-decimal digits for an extended DFP format. To facilitate the conversion, the significand is divided into pieces and only one piece contains the sign. Each piece fits into a register or a register pair, and each piece is converted separately. To support this piecemeal conversion, two formats, signed-packed-decimal and unsigned-packed-decimal, are used to hold the pieces.

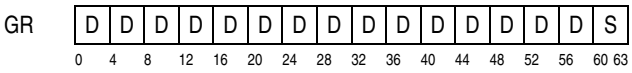
To facilitate the conversion between packed-decimal format data in memory and the DFP format, the CONVERT FROM PACKED and CONVERT TO PACKED instructions are provided. It takes up to 9 bytes to hold the 16 significand digits and one sign digit of a long DFP format. It takes up to 18 bytes to hold the 34 significand digits and one sign digit for an extended DFP format. Any unused digits in a packed-decimal format operand of CONVERT FROM PACKED must be zero.

For a zoned-decimal format, it takes 16 bytes to hold the 16 significand digits and one sign digit of a long DFP format; it takes 34 bytes for an extended DFP format. To facilitate the conversion, the CONVERT FROM ZONED and CONVERT TO ZONED instructions are provided.

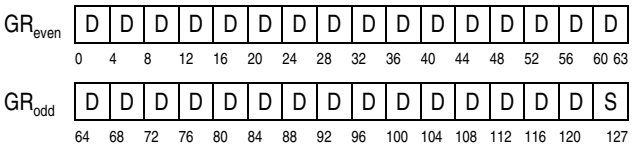
Signed-Packed-Decimal Format

In the signed-packed-decimal format, each byte contains two 4-bit decimal digits (D), except for the rightmost byte, which contains a 4-bit sign (S) to the right of a 4-bit decimal digit.

When a signed-packed-decimal operand resides in a general register (GR), the operand is 64 bits (15 digits and sign), as shown below.



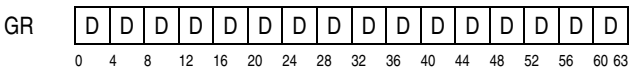
When a signed-packed-decimal operand resides in a general-register pair, the leftmost 64 bits of the operand occupy the even-numbered register of the pair and the rightmost 64 bits occupy the odd-numbered register, as shown below.



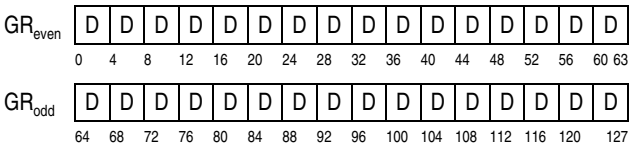
Unsigned-Packed-Decimal Format

In the unsigned-packed-decimal format, each byte contains two 4-bit decimal digits (D) and there is no sign.

When an unsigned-packed-decimal operand resides in a general register, the operand is 64 bits (16 digits), as shown below.



When an unsigned-packed-decimal operand resides in a general-register pair, the leftmost 64 bits of the operand occupy the even-numbered register of the pair and the rightmost 64 bits occupy the odd-numbered register, as shown below.



Zoned-Decimal Format

In the unsigned zoned-decimal format, each byte contains two fields, a zone field in the leftmost four bit positions and a decimal digit in the rightmost four bit positions. The signed zoned-decimal format is similar to the unsigned zoned-decimal format except that the zone field of the rightmost byte instead contains a 4-bit sign. A zoned-decimal operand is a storage operand. See “Zoned Format” on page 8-1 for more details.

IEEE Exceptions

The IEEE exceptions for the DFP instructions are described in the section “IEEE Exceptions” on page 9-18. This also includes the quantum exception.

Summary of Preferred Quantum

Figure 20-4 summarizes all preferred quanta.

Operations	Delivered value	Preferred Quantum
ADD	Exact	The smaller quantum of the two source operands†
	Inexact	The smallest quantum of cohort members
CONVERT FROM FIXED	Exact	One†
	Inexact	The smallest quantum of cohort members
CONVERT FROM LOGICAL	Exact	One†
	Inexact	The smallest quantum of cohort members
CONVERT FROM PACKED	—	One
CONVERT FROM SIGNED PACKED	—	One
CONVERT FROM UNSIGNED PACKED	—	One
CONVERT FROM ZONED	—	One
DIVIDE	Exact	The quantum of the dividend divided by the quantum of the divisor†
	Inexact	The smallest quantum of cohort members
INSERT BIASED EXPONENT	—	The quantum corresponds to the requested biased exponent
LOAD AND TEST	—	The quantum of the source operand
LOAD FP INTEGER	Exact	The larger value of one and the quantum of the source operand
	Inexact	One
LOAD LENGTHENED	Exact*	The quantum of the source operand
LOAD ROUNDED	Exact	The quantum of the source operand†
	Inexact	The smallest quantum of cohort members
PERFORM FLOATING POINT OPERATION (DPQC=0)‡	Exact	The largest quantum of cohort members†
	Inexact	The smallest quantum of cohort members
PERFORM FLOATING POINT OPERATION (DPQC=1)‡	Exact	One†
	Inexact	The smallest quantum of cohort members
MULTIPLY	Exact	The product of the quanta of the two source operands†
	Inexact	The smallest quantum of cohort members
QUANTIZE	Exact	The requested quantum
	Inexact	The requested quantum
REROUND	Exact	See the instruction description
	Inexact	The quantum that corresponds to the requested significance
SHIFT SIGNIFICAND LEFT	—	The quantum of the source operand
SHIFT SIGNIFICAND RIGHT	—	The quantum of the source operand
SUBTRACT	Exact	The smaller quantum of the two source operands†
	Inexact	The smallest quantum of cohort members

Explanation:

* This is true due to a condition to the left of the column.
— For these operations, the concept of exact result or inexact result does not apply.
† If the delivered value cannot be represented with the preferred quantum, it is represented with the quantum closest to the preferred quantum.
‡ Applicable only when the operation-type code is 01 hex (PFPO Convert Floating-Point Radix).
DPQC DFP preferred quantum control.

Explanation:

—	This situation cannot occur.
*	The rounded value, in the extreme case, may be Nmin. In this case, the exceptions are underflow, inexact and incremented.
[1]	The nontrap result r is considered to have been incremented.
d	The value derived when the precise intermediate value (v) is rounded to the format of the target, including both precision and bounded exponent range. Except as explained in note *, this is a subnormal number.
g	The precision-rounded value. The value derived when the precise intermediate value (v) is rounded to the precision of the target, but assuming an unbounded exponent range.
v	Precise intermediate value. This is the value, before rounding, assuming unbounded precision and an unbounded exponent range. For LOAD ROUNDED, v is the source value.
EZD	Exact zero difference. The case applies only to ADD and SUBTRACT. For all other DFP operations, a zero result is detected by inspection of the source operands without use of the R(v) function.
Dmin	Smallest (in magnitude) representable subnormal number in the target format**.**
Nmax	Largest (in magnitude) representable finite number in the target format.
Nmin	Smallest (in magnitude) representable normal number in the target format**.**
RNTA	Round to nearest with ties away from 0.
RNTE	Round to nearest with ties to even.
RNTZ	Round to nearest with ties toward 0.
RA	Round away from 0.
RFS	Round to prepare for shorter precision.
RM	Round toward -∞.
RP	Round toward +∞.
RZ	Round toward 0.

Explanation:

— The results do not depend on this condition or mask bit.

[1] This condition is true by virtue of the state of some condition to the left of this column.

[2] The quantum exception mask bit and the quantum exception control are defined only when the floating-point extension facility is installed.

[3] This column specifies whether a QX is recognized by considering all columns to the left of this column and the existence of the quantum exception condition. The specification in this column does not include the effects of the quantum-exception mask bit and the quantum-exception control.

Ψ Scale factor. For overflow, $\Psi=2^{+\alpha}$. For underflow, $\Psi=2^{-\alpha}$. The unsigned scaling exponent (α) depends on the type of operation and operand format. For all DFP operations except LOAD ROUNDED, α depends on the target format and is 576 for long, and 9216 for extended. For LOAD ROUNDED, α depends on the source format and is 192 for long and 3072 for extended.

g The precision-rounded value. The value derived when the precise intermediate value (v) is rounded to the precision of the target, but assuming an unbounded exponent range.

r Nontrap result as defined in Part 1 of this figure.

v Precise intermediate value. This is the value, before rounding, assuming unbounded precision and unbounded exponent range.

PIDc(h) Program interruption for data exception, condition c, with DXC of h in hex. See Figure 20-8 on page 20-16.

PIDq(04) DXC 04 is defined only when the floating-point extension facility is installed.

QX Quantum exception. This exception is defined only when the floating-point extension facility is installed.

SFo IEEE overflow flag, FPC 1.2.

SFq Quantum-exception status flag, FPC 1.5. This flag is defined only when the floating-point extension facility is installed

SFu IEEE underflow flag, FPC 1.3.

SFx IEEE inexact flag, FPC 1.4.

T(x) The value x is placed at the target operand location.

Tw(x) The scaled result x is placed at the target operand location. For all DFP operations except LOAD ROUNDED, the scaled result is in the format and length of the target and rounded to the precision of the target. For LOAD ROUNDED, the scaled result is in the format and length of the source, but rounded to the precision of the target.

Explanation:

— The results do not depend on this condition or mask bit.

[1] This condition is true by virtue of the state of some condition to the left of this column.

[2] The quantum exception mask bit and the quantum exception control are defined only when the floating-point extension facility is installed.

[3] This column specifies whether a QX is recognized by considering all columns to the left of this column and the existence of the quantum exception condition. The specification in this column does not include the effects of the quantum-exception mask bit and the quantum-exception control.

Ψ Scale factor. For overflow, $\Psi=2^{+\alpha}$. For underflow, $\Psi=2^{-\alpha}$. The unsigned scaling exponent (α) depends on the type of operation and operand format. For all DFP operations except LOAD ROUNDED, α depends on the target format and is 576 for long, and 9216 for extended. For LOAD ROUNDED, α depends on the source format and is 192 for long and 3072 for extended.

g The precision-rounded value. The value derived when the precise intermediate value (v) is rounded to the precision of the target, but assuming an unbounded exponent range.

r Nontrap result as defined in Part 1 of this figure.

v Precise intermediate value. This is the value, before rounding, assuming unbounded precision and unbounded exponent range.

PIDc(h) Program interruption for data exception, condition c, with DXC of h in hex. See Figure 20-8 on page 20-16.

PIDq(04) DXC 04 is defined only when the floating-point extension facility is installed.

QX Quantum exception. This exception is defined only when the floating-point extension facility is installed.

SFo IEEE overflow flag, FPC 1.2.

SFq Quantum-exception status flag, FPC 1.5. This flag is defined only when the floating-point extension facility is installed

SFu IEEE underflow flag, FPC 1.3.

SFx IEEE inexact flag, FPC 1.4.

T(x) The value x is placed at the target operand location.

Tw(x) The scaled result x is placed at the target operand location. For all DFP operations except LOAD ROUNDED, the scaled result is in the format and length of the target and rounded to the precision of the target. For LOAD ROUNDED, the scaled result is in the format and length of the source, but rounded to the precision of the target.

Figure 20-6. (Part 3 of 3) Rounding and Range Actions

Result Figures

Concise descriptions of the results produced by many of the DFP instructions are made by means of figures which contain columns and rows representing all possible combinations of DFP data class for the source operands of an instruction. The information shown at the intersection of a row and a column is one or more symbols representing the result or results produced for that particular combination of source-operand data classes. Explanations of the symbols used are contained in each figure. In many cases, the explanation of a particular result is in the form of a cross-reference to another figure. In many cases, the information shown at the intersection consists of several symbols separated by commas. All such results are produced unless one of the results is a program interruption. In the case of a program interruption, the operation is suppressed or completed as shown in Figure 20-8 on page 20-16.

Data-Exception Codes (DXC) and Abbreviations

Figure 20-7 shows IEEE exceptions and flag abbreviations that are used in the result figures, and it explains the symbols “Xi:” and “Xz:” that are used in the figures. Bits 0-4 (i,z,o,u,x) of the eight-bit data-exception code (DXC) in byte 2 of the FPC register are trap flags and correspond to the same bits in bytes 0 and 1 of the register (IEEE masks and IEEE flags). The trap flag for an exception, instead of the IEEE flag, is set to one when an interruption for the exception is enabled by the corresponding IEEE mask bit. Bit 5 (y) of byte 2 is used in conjunction with bit 4, inexact (x), to indicate that the result has been incremented in magnitude.

When the floating-point extension facility is installed, bit 5 of DXC also has a second meaning. When DXC bits 0-4 are zero, DXC bit 5 is the quantum-exception trap flag and corresponds to the quantum-exception mask IMq and its status flag SFq.

Figure 20-8 on page 20-16 shows the various DXCs that can be indicated, the associated instruction endings, and abbreviations that are used for the DXCs in the result figures. (The abbreviation “PID” stands for “program interruption for a data exception.”)

Exception		FPC IEEE Mask bit	IEEE Flag	
Name	Abbr.		FPC Bit	Abbr.
IEEE invalid operation	Xi[1]	0.0	1.0	SFi
IEEE division by zero	Xz[2]	0.1	1.1	SFz
IEEE overflow	Xo	0.2	1.2	SFo
IEEE underflow	Xu	0.3	1.3	SFu
IEEE inexact	Xx	0.4	1.4	SFx
Quantum-exception	Xq	0.5	1.5	SFq

Explanation:

1 The symbol “Xi:” followed by a list of results in a figure indicates that, when FPC 0.0 is zero, then instruction execution is completed by setting SFi (FPC 1.0) to one and producing the indicated results; and when FPC 0.0 is one, then instruction execution is suppressed, the data exception code (DXC) is set to 80 hex, and a program interruption for a data exception occurs.

2 The symbol “Xz:” followed by a list of results in a figure indicates that, when FPC 0.1 is zero, then instruction execution is completed by setting SFz (FPC 1.1) to one and producing the indicated results; and when FPC 0.1 is one, then instruction execution is suppressed, the data exception code (DXC) is set to 40 hex, and a program interruption for a data exception occurs.

Figure 20-7. IEEE Exception and Flag Abbreviations

Abbr.	DXC (hex)	Data-Exception-Code Name	Instruction Ending
PIDq	04	Quantum exception	Complete
PIDx	08	IEEE inexact and truncated	Complete
PIDy	0C	IEEE inexact and incremented	Complete
PIDu	10	IEEE underflow, exact	Complete, wrap exponent
PIDux	18	IEEE underflow, inexact and truncated	Complete, wrap exponent
PIDuy	1C	IEEE underflow, inexact and incremented	Complete, wrap exponent
PIDo	20	IEEE overflow, exact	Complete, wrap exponent
PIDox	28	IEEE overflow, inexact and truncated	Complete, wrap exponent
PIDoy	2C	IEEE overflow, inexact and incremented	Complete, wrap exponent
PIDz	40	IEEE division by zero	Suppress
PIDi	80	IEEE invalid operation	Suppress

Figure 20-8. IEEE Data-Exception Codes (DXC) and Abbreviations

Instructions

The Decimal-Floating-Point (DFP) instructions and their mnemonics and operation codes are listed in Figure 20-9 on page 20-17.

The figure indicates, in the column labeled "Characteristics," the instruction format, when the condition code is set, and the exceptional conditions in operand designations, data, or results that cause a program interruption.

All DFP instructions are subject to the AFP-register-control bit, bit 45 of control register 0. For the DFP instructions to be executed successfully, the AFP-register-control bit must be one; otherwise, a DFP-instruction data exception, DXC 3, is recognized.

Mnemonics for the DFP instructions are distinguished from corresponding HFP or BFP instructions by a T in the mnemonic. Mnemonics for the DFP instructions have an R as the last letter or the letter next to the last letter when the instruction is in the RRE or RRF format. Mnemonics for the DFP instructions have an A as the last letter when the instruction is an alternate instruction, which uses additional modifier fields not available to the original instruction. Certain letters are used for DFP instructions to represent operand format and operand-format length, as follows:

E Short
F Thirty-two-bit fixed point
G Sixty-four-bit fixed point
D Long
P Packed
X Extended
Z Zoned

Note: In the detailed descriptions of the individual instructions, the mnemonic and the symbolic operand designation for the assembler language are shown with each instruction. For a register-to-register operation using COMPARE (long), for example, CDTR is the mnemonic and R_1,R_2 the operand designation.

Programming Notes:

1. The floating-point extension facility includes the following:

   - The following new DFP instructions:
     – CONVERT FROM FIXED (CXFTR, CDFTR)
     – CONVERT FROM LOGICAL (CXLGTR, CDLGTR, CXLFTR, CDLFTR)
     – CONVERT TO FIXED (CFXTR, CFDTR)
     – CONVERT TO LOGICAL (CLGXTR, CLGDTR, CLFXTR, CLFDTR)
   - All reserved values in the effective rounding method field and a quantum-exception control (XqC) are assigned for LOAD FP INTEGER, LOAD ROUNDED, QUANTIZE, and REROUND.
   - All reserved values in the effective rounding method field are assigned for CONVERT TO FIXED.
   - An IEEE-inexact-exception control (XxC) is added to CONVERT TO FIXED and LOAD ROUNDED.
   - An effective rounding method field and a quantum-exception control (XqC) are added to ADD, DIVIDE, MULTIPLY, and SUBTRACT.
   - An effective rounding method field, an IEEE-inexact-exception control (XxC), and a quantum-exception control (XqC) are added to CONVERT FROM FIXED.

2. The following instructions are available when the DFP-zoned-conversion facility is installed:
   - CONVERT FROM ZONED (CDZT, CXZT)
   - CONVERT TO ZONED (CZDT, CZXT)

3. The following instructions are available when the DFP-packed-conversion facility is installed:
   - CONVERT FROM PACKED (CDPT, CXPT)
   - CONVERT TO PACKED (CPDT, CPXT)

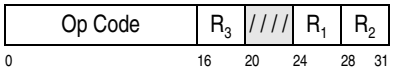
S	S instruction format.			
SP	Specification exception.			
ST	PER storage-alteration event.			
TF	Decimal-Floating-Point facility.			
Xi	IEEE invalid-operation data exception.			
Xo	IEEE overflow data exception.			
Xq	Quantum data exception (if the floating-point extension facility is installed).			
Xu	IEEE underflow data exception.			
Xx	IEEE inexact data exception.			
Xz	IEEE division-by-zero data exception.			
ZF	DFP zoned-conversion facility.			

Figure 20-9. Summary of Decimal Instructions (Part 3 of 3)

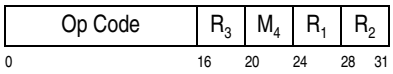
ADD

Mnemonic1 R_1,R_2,R_3 [RRF-a]



Mnemonic1	Op Code	Operands
ADTR	'B3D2'	Long DFP
AXTR	'B3DA'	Extended DFP

Mnemonic2 R_1,R_2,R_3,M_4 [RRF-a]



Mnemonic2	Op Code	Operands
ADTRA	'B3D2'	Long DFP
AXTRA	'B3DA'	Extended DFP

The third operand is added to the second operand, and the sum is placed at the first-operand location.

If both operands are finite numbers, they are added algebraically, forming an intermediate sum. The intermediate sum, if nonzero, is rounded to the operand format and the rounded value is then placed at the result location.

When the floating-point extension facility is installed, the intermediate sum is rounded by rounding as specified by the modifier in the M_4 field:

M_4	Effective Rounding Method
0	According to the current DFP rounding mode
1	Round to nearest with ties away from 0
2	According to the current DFP rounding mode
3	Round to prepare for shorter precision

M_4	Effective Rounding Method
4	Round to nearest with ties to even
5	Round toward 0
6	Round toward +∞
7	Round toward -∞
8	Round to nearest with ties to even
9	Round toward 0
10	Round toward +∞
11	Round toward -∞
12	Round to nearest with ties away from 0
13	Round to nearest with ties toward 0
14	Round away from 0
15	Round to prepare for shorter precision

When the modifier field is zero or two, rounding is controlled by the current DFP rounding mode specified in the FPC register. When the field is 1, or 3-15, rounding is performed as specified by the modifier, regardless of the current DFP rounding mode.

If the modifier field is 0 or 8-15, the quantum-exception control (XqC) is one and recognition of the quantum exception is suppressed; if the modifier field is 1-7, the quantum-exception control is zero and recognition of the exception is not suppressed.

When the floating-point extension facility is not installed, no quantum exception is recognized. If bits 20-23 of the instruction contain a value of zero, the intermediate sum is rounded according to the current DFP rounding mode; if bits 20-23 of the instruction contain a nonzero value, it is unpredictable which rounding method is performed.

The sign of the sum is determined by the rules of algebra. This also applies to a result of zero, as follows:

- If the result of rounding a nonzero intermediate sum is zero, the sign of the zero result is the sign of the intermediate sum.
- If the sum of two operands with opposite signs is exactly zero, the sign of the result is plus in all rounding methods except round toward -∞, in which method the sign is minus.
- The sign of the sum x plus x is the sign of x, even when x is zero.

If one operand is an infinity and the other is a finite number, the result is an infinity with the sign of the source infinity. If both operands are infinities of the same sign, the result is an infinity with the same sign. If the two operands are infinities of opposite signs, an IEEE-invalid-operation exception is recognized.

When the delivered value is exact, the preferred quantum is the smaller quantum of the two source operands; when the delivered value is inexact, the preferred quantum is the smallest quantum.

The result placed at the first-operand location is canonical.

See Figure 20-11 on page 20-21 for a detailed description of the results of this instruction. (Figure 20-10 is referred to by Figure 20-11.)

For AXTR and AXTRA, the R fields designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Result is zero
1 Result is less than zero
2 Result is greater than zero
3 Result is a NaN

IEEE Exceptions:

- Invalid operation
- Overflow
- Underflow
- Inexact
- Quantum (if the floating-point extension facility is installed)

Program Exceptions:

- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation (if the DFP facility is not installed)
- Specification (AXTR and AXTRA only)
- Transaction constraint

Value of Result (r)	Condition code
r = 0	0
r < 0	1
r > 0	2

Figure 20-10. Condition Code for Resultant Sum

Programming Notes:

1. Interchanging the two operands in a DFP addition does not affect the value of the sum when the result is numeric. This is not true, however, when both operands are QNaNs; or when both operands are SNaNs and the IEEE invalid-operation mask bit in the FPC register is zero, in these cases, the result is the canonical QNaN derived from the second operand.
2. For ADD or SUBTRACT, when the delivered value is inexact, the preferred quantum is the smallest quantum which is the same quantum as that closest to the smaller quantum of the two source operands.

Explanation:

*	The SNaN is converted to the corresponding QNaN before it is placed at the target operand location.
ccn	Condition code is set to n.
ccrs	Condition code is set according to the resultant sum. See Figure 20-10 on page 20-20.
dNaN	Default NaN.
Nn	Normal number.
R(v)	Rounding and range action is performed on the value v. See Figure 20-5 on page 20-11. The result is canonical**.**
Rezd	Exact zero-difference result. See Figure 20-5 on page 20-11.
Dn	Subnormal number.
T(x)	The canonical result x is placed at the target operand location.
Xi:	IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.

Figure 20-11. Results: ADD

COMPARE

Mnemonic R_1,R_2 [RRE]

Mnemonic	Op Code	Operands
CDTR	'B3E4'	Long DFP
CXTR	'B3EC'	Extended DFP

The first operand is compared with the second operand, and the condition code is set to indicate the result.

If both operands are finite numbers, the comparison is algebraic and follows the procedure for DFP subtraction, except that the difference is discarded after setting the condition code, and both operands remain unchanged. If the difference is exactly zero with either sign, the operands are equal; this includes zero operands (so +0 equals -0). If a nonzero difference is positive or negative, the first operand is high or low, respectively.

+∞ compares greater than any finite number, and all finite numbers compare greater than -∞. Two infinity operands of like sign compare equal.

Numeric comparison is exact, and the condition code is determined for finite operands as if range and precision were unlimited. No overflow or underflow exception can occur.

If either or both operands are QNaNs and neither operand is an SNaN, the comparison result is unordered, and condition code 3 is set.

If either or both operands are SNaNs, an IEEE-invalid-operation exception is recognized. If the IEEE invalid-operation mask bit is one, a program interruption for a data exception with DXC 80 hex (IEEE invalid operation) occurs. If the IEEE-invalid-operation mask bit is zero, the IEEE-invalid-operation flag bit is set to one, and instruction execution is completed by setting condition code 3.

See Figure 20-12 on page 20-22 for a detailed description of the results of this instruction.

For CXTR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

First Operand (a) is	Results for COMPARE (a:b) when Second Operand (b) is							
	-∞	-Fn	-0	+0	+Fn	+∞	QNaN	SNaN
-∞	cc0	cc1	cc1	cc1	cc1	cc1	cc3	Xi: cc3

a < b	1
a > b	2

Figure 20-13. Basic Compare Results

Resulting Condition Code:

0 Operands equal
1 First operand low
2 First operand high
3 Operands unordered

IEEE Exceptions:

- Invalid operation

Program Exceptions:

- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation (if the DFP facility is not installed)
- Specification (CXTR only)
- Transaction constraint

COMPARE AND SIGNAL

Mnemonic R_1,R_2 [RRE]

Mnemonic	Op Code	Operands
KDTR	'B3E0'	Long DFP
KXTR	'B3E8'	Extended DFP

The first operand is compared with the second operand, and the condition code is set to indicate the result. The operation is the same as for COMPARE except that QNaN operands cause an IEEE-invalid-operation exception to be recognized. Thus QNaN operands are treated as if they were SNaNs.

See Figure 20-14 on page 20-23 for a detailed description of the results of this instruction.

For KXTR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Operands equal
1 First operand low
2 First operand high
3 Operands unordered

IEEE Exceptions:

- Invalid operation

Program Exceptions:

- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation (if the DFP facility is not installed)
- Specification (KXTR only)
- Transaction constraint

First Operand (a) is	Results for COMPARE AND SIGNAL (a:b) when Second Operand (b) is						
	-∞	-Fn	-0	+0	+Fn	+∞	NaN
-∞	cc0	cc1	cc1	cc1	cc1	cc1	Xi: cc3

+∞	cc2	cc2	cc2	cc2	cc2	cc0	Xi: cc3
NaN	Xi: cc3	Xi: cc3	Xi: cc3	Xi: cc3	Xi: cc3	Xi: cc3	Xi: cc3

Explanation:

ccn	Condition code is set to n.
C(a:b)	Basic compare results. See Figure 20-13**.**
Fn	Nonzero finite number (includes both subnormal and normal).
Xi:	IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.

Figure 20-14. Results: COMPARE AND SIGNAL

COMPARE BIASED EXPONENT

Mnemonic R_1,R_2 [RRE]

Mnemonic	Op Code	Operands
CEDTR	'B3F4'	Long DFP
CEXTR	'B3FC'	Extended DFP

The biased exponent of the first operand is compared with the biased exponent of the second operand, and the condition code is set to indicate the result.

This operation is performed for any second operand, including an infinity, QNaN, or SNaN, without causing an IEEE exception.

See Figure 20-15 on page 20-24 for a detailed description of the results of this instruction.

For CEXTR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Biased exponents equal
1 First-operand biased exponent low
2 First-operand biased exponent high
3 Unordered

IEEE Exceptions: None.

Program Exceptions:

- Data with DXC 3, DFP instruction
- Operation (if the DFP facility is not installed)
- Specification (CEXTR only)
- Transaction constraint

First operand (a) is	Result for COMPARE BIASED EXPONENT when second operand (b) is			
	F	∞	QNaN	SNaN
F	C(e_a:e_b)	cc3	cc3	cc3
∞	cc3	cc0	cc3	cc3
QNaN	cc3	cc3	cc0	cc0
SNaN	cc3	cc3	cc0	cc0

Explanation:

C(e_a:e_b) Biased-exponent compare results. See Figure 20-16 on page 20-24.
ccn Condition code is set to n.
F All finite numbers, including zeros.

Figure 20-15. Results: COMPARE BIASED EXPONENT

Relation of value e_a to value e_b	Condition Code for C(e_a:e_b)
$e_a = e_b$	cc0
$e_a < e_b$	cc1
$e_a > e_b$	cc2

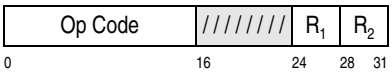
Explanation:

ccn Condition code is set to n.
e_a Biased exponent of the first operand
e_b Biased exponent of the second operand

Figure 20-16. Biased-Exponent Compare Results

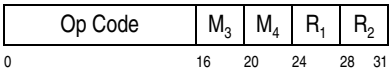
CONVERT FROM FIXED

Mnemonic R_1,R_2 [RRE]



Mnemonic	Op Code	Operands
CDGTR	'B3F1'	64-bit binary-integer source, long DFP result
CXGTR	'B3F9'	64-bit binary-integer source, extended DFP result

Mnemonic2 R_1,M_3,R_2,M_4 [RRF-e]



Mnemonic2	Op Code	Operands
CDGTRA	'B3F1'	64-bit binary-integer source, long DFP result
CXGTRA	'B3F9'	64-bit binary-integer source, extended DFP result
CDFTR	'B951'	32-bit binary-integer source, long DFP result
CXFTR	'B959'	32-bit binary-integer source, extended DFP result

The fixed-point second operand is converted to the DFP format, and the result is placed at the first-operand location.

The second operand is a signed binary integer that is located in the general register designated by R_2. A 32-bit operand is in bit positions 32-63 of the register.

The converted result is rounded and then the rounded value is placed at the first-operand location.

When the floating-point extension facility is installed, the converted result is rounded by rounding as specified by the modifier in the M_3 field:

M_3	Effective Rounding Method
0	According to the current DFP rounding mode
1	Round to nearest with ties away from 0
2	According to the current DFP rounding mode
3	Round to prepare for shorter precision
4	Round to nearest with ties to even
5	Round toward 0
6	Round toward +∞
7	Round toward -∞
8	Round to nearest with ties to even
9	Round toward 0
10	Round toward +∞
11	Round toward -∞
12	Round to nearest with ties away from 0

M_3	Effective Rounding Method
13	Round to nearest with ties toward 0
14	Round away from 0
15	Round to prepare for shorter precision

When the modifier field is zero or two, rounding is controlled by the current DFP rounding mode specified in the FPC register. When the field is 1, or 3-15, rounding is performed as specified by the modifier, regardless of the current DFP rounding mode.

If the modifier field is 0 or 8-15, the quantum-exception control (XqC) is one and recognition of the quantum exception is suppressed; if the modifier field is 1-7, the quantum-exception control is zero and recognition of the exception is not suppressed.

When the floating-point extension facility is not installed, no quantum exception is recognized. If bits 16-19 of the instruction contain a value of zero, the converted result is rounded according to the current DFP rounding mode; if bits 16-19 of the instruction contain a nonzero value, it is unpredictable which rounding method is performed.

When the delivered value is exact, the preferred quantum is one; when the delivered value is inexact, the preferred quantum is the smallest quantum.

The result placed at the first-operand location is canonical.

See Figure 20-24 on page 20-42 for a detailed description of the results of this instruction.

When the floating-point extension facility is installed, bit 1 of the M_4 field is the IEEE-inexact-exception control (XxC), and bits 0, 2, and 3 are ignored. If XxC is zero, recognition of IEEE-inexact exception is not suppressed; if XxC is one, recognition of the exception is suppressed.

When the floating-point extension facility is not installed, and if bits 20-23 of the instruction are zeros, then recognition of IEEE-inexact exception is not suppressed; if bits 20-23 of the instruction contain a nonzero value, it is unpredictable whether recognition of IEEE-inexact exception is suppressed.

For CXGTR, CXGTRA, and CXFTR, the R_1 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

An operation exception is recognized if the DFP facility is not installed. For CDFTR and CXFTR, the operation exception is also recognized if the floating-point extension facility is not installed.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Inexact (CDGTR and CDGTRA only)
- Quantum (CDGTR and CDGTRA only, if the floating-point extension facility is installed)

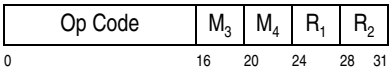
Program Exceptions:

- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation (if the DFP facility is not installed)
- Specification (CXGTR, CXGTRA, and CXFTR only)
- Transaction constraint

Programming Note: Unassigned bits in the M_4 field are reserved for future extensions and should be set to zeros; otherwise, the program may not operate compatibly in the future.

CONVERT FROM LOGICAL

Mnemonic R_1,M_3,R_2,M_4 [RRF-e]



Mnemonic	Op Code	Operands
CDLGTR	'B952'	64-bit binary-integer source, long DFP result
CXLGTR	'B95A'	64-bit binary-integer source, extended DFP result
CDLFTR	'B953'	32-bit binary-integer source, long DFP result
CXLFTR	'B95B'	32-bit binary-integer source, extended DFP result

The fixed-point second operand is converted to the DFP format, and the result is placed at the first-operand location.

The second operand is an unsigned binary integer that is located in the general register designated by R_2. A 32-bit operand is in bit positions 32-63 of the register.

The converted result is rounded to an integer value by rounding as specified by the modifier in the M_3 field:

M_3	Effective Rounding Method
0	According to the current DFP rounding mode
1	Round to nearest with ties away from 0
2	According to the current DFP rounding mode
3	Round to prepare for shorter precision
4	Round to nearest with ties to even
5	Round toward 0
6	Round toward +∞
7	Round toward -∞
8	Round to nearest with ties to even
9	Round toward 0
10	Round toward +∞
11	Round toward -∞
12	Round to nearest with ties away from 0
13	Round to nearest with ties toward 0
14	Round away from 0
15	Round to prepare for shorter precision

When the modifier field is zero or two, rounding is controlled by the current DFP rounding mode specified in the FPC register. When the field is 1, or 3-15, rounding is performed as specified by the modifier, regardless of the current DFP rounding mode.

If the modifier field is 0 or 8-15, the quantum-exception control (XqC) is one and recognition of the quantum exception is suppressed; if the modifier field is 1-7, the quantum-exception control is zero and recognition of the exception is not suppressed.

Bit 1 of the M_4 field is the IEEE-inexact-exception control (XxC). Bits 0, 2, and 3 are ignored. If XxC is zero, recognition of IEEE-inexact exception is not suppressed; if XxC is one, recognition of the exception is suppressed.

The result always has a plus sign.

When the delivered value is exact, the preferred quantum is one; when the delivered value is inexact, the preferred quantum is the smallest quantum.

The result placed at the first-operand location is canonical.

See Figure 20-24 on page 20-42 for a detailed description of the results of this instruction.

For CXLGTR and CXLFTR, the R_1 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Inexact (CDLGTR only)
- Quantum (CDLGTR only)

Program Exceptions:

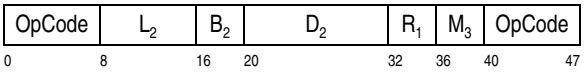
- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation (if the floating-point extension facility is not installed)
- Specification (CXLGTR and CXLFTR only)
- Transaction constraint

Programming Notes:

1. Unassigned bits in the M_4 field are reserved for future extensions and should be set to zeros; otherwise, the program may not operate compatibly in the future.
2. Using either the round toward 0 or the round toward -∞ rounding method produces the same result; using either the round away from 0 or the round toward +∞ rounding method produces the same result.

CONVERT FROM PACKED

Mnemonic $R_1,D_2(L_2,B_2),M_3$ [RSL-b]



Mnemonic	Op Code	Operands
CDPT	'EDAE'	Packed source, long DFP result
CXPT	'EDAF'	Packed source, extended DFP result

The second operand in the packed-decimal format is converted to the DFP format, and the result is placed at the first-operand location.

The preferred quantum is one, and the delivered value is always represented with the preferred quantum.

The result placed at the first-operand location is canonical.

For CXPT the length in bytes of the second operand is 1-18, corresponding to a length code in L_2 of 0-17. For CDPT the length in bytes of the second operand is 1-9, corresponding to a length code in L_2 of 0-8. See Figure 20-17 for valid L_2 values along with the corresponding number of digits converted.

The M_3 field has the following format:

The bits of the M_3 field are defined as follows:

- **Sign-Control (S):** Bit 0 of the M_3 field is the sign control (S). When the S bit is zero, the second operand does not have a sign field and the sign bit of the DFP first-operand result is set to zero.

  When the S bit is one, the second operand contains a sign field in the rightmost four bit positions of the rightmost byte. The sign bit of the DFP first-operand result is set to zero when the sign field of the second operand indicates a positive value, or when the ignore-sign-digit control is one. The sign bit of the DFP first-operand result is set to one when the sign field of the second operand indicates a negative value and the ignore-sign-digit control is zero.

- **Reserved:** Bits 1-2 of the M_3 field are reserved.

- **Ignore-Sign-Digit Control (I):** Bit 3 of the M_3 field is the ignore-sign-digit control (I). When the I bit is zero, no special action is taken. When the I bit is one, the sign field of the second operand is ignored, it is not checked for invalid digits, and the sign bit of the DFP first-operand result is set to zero. When the S-bit is zero, the I bit is ignored.

Special Conditions

When an invalid digit or sign code is detected in the second operand, or an unused digit is not zero, a general-operand data exception is recognized. If the sign control and the ignore-sign-digit control are one, no sign code checking is performed on the sign digit.

A specification exception is recognized, and the operation is suppressed, when any of the following is true.

- For CDPT, the L_2 field is greater than 8
- For CXPT, the R_1 field designates an invalid floating-point-register pair, or the L_2 field is greater than 17

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (Fetch operand 2)
- Data with DXC 0, general operand
- Data with DXC 3, DFP instruction
- Operation (if the DFP packed-conversion facility is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. Depending on the model, for CXPT, when the L_2 field specifies 16 or 17 (meaning 32-34 digits), performance may be significantly worse than if shorter lengths are specified.

2. When trying to convert 16 packed digits and a sign digit for CDPT, a L_2 value of 8 should be used and the S bit in the M_3 field should be set to one. When trying to convert 34 packed digits and a sign digit for CXPT an L_2 value of 17 should be used and the S bit in the M_3 field should be set to one. In both of these cases, bits 0-3 of the first byte of the second operand should be zero; otherwise, a general-operand data exception will occur.

L_2	S=0	S=1
0	2	1
1	4	3
2	6	5
3	8	7
4	10	9
5	12	11
6	14	13
7	16	15
For CDPT only:		
8	16*	16*
CXPT only below		
8	18	17
9	20	19
10	22	21
11	24	23
12	26	25
13	28	27

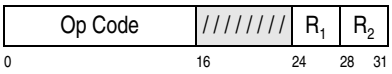
Figure 20-17. Valid L_2 Values for Signed and Unsigned Digit Combinations

L_2	S=0	S=1
14	30	29
15	32	31
16	34	33
17	34*	34*
Explanation: * Unused digits must be zero.		

Figure 20-17. Valid L_2 Values for Signed and Unsigned Digit Combinations

CONVERT FROM SIGNED PACKED

Mnemonic R_1,R_2 [RRE]



Mnemonic	Op Code	Operands
CDSTR	'B3F3'	64-bit signed-packed-decimal source in GR, long DFP result
CXSTR	'B3FB'	128-bit signed-packed-decimal source in GRs, extended DFP result

The second operand in the signed-packed-decimal format is converted to the DFP format, and the result is placed at the first-operand location.

The second operand is located in the general register or general-register pair designated by R_2.

The preferred quantum is one, and the delivered value is always represented with the preferred quantum.

The result placed at the first-operand location is canonical.

When an invalid digit or sign code is detected in the second operand, a general-operand data exception is recognized.

For CXSTR, the R_1 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized. Also, the R_2 field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

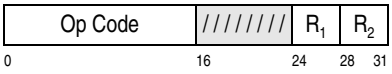
IEEE Exceptions: None.

Program Exceptions:

- Data with DXC 0, general operand
- Data with DXC 3, DFP instruction
- Operation (if the DFP facility is not installed)
- Specification (CXSTR only)
- Transaction constraint

CONVERT FROM UNSIGNED PACKED

Mnemonic R_1,R_2 [RRE]



Mnemonic	Op Code	Operands
CDUTR	'B3F2'	64-bit unsigned-packed-decimal source in GR, long DFP result
CXUTR	'B3FA'	128-bit unsigned-packed-decimal source in GRs, extended DFP result

The second operand in the unsigned-packed-decimal format is converted to the DFP format with a positive sign, and the result is placed at the first-operand location.

The second operand is located in the general register or general-register pair designated by R_2.

The preferred quantum is one, and the delivered value is always represented with the preferred quantum.

The result placed at the first-operand location is canonical.

When an invalid digit code is detected in the second operand, a general-operand data exception is recognized.

For CXUTR, the R_1 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized. Also, the R_2 field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions: None.

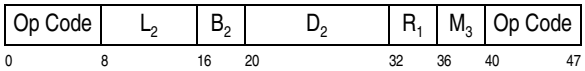
Program Exceptions:

- Data with DXC 0, general operand
- Data with DXC 3, DFP instruction

- Operation (if the DFP facility is not installed)
- Specification (CXUTR only)
- Transaction constraint

CONVERT FROM ZONED

Mnemonic $R_1,D_2(L_2,B_2),M_3$ [RSL-b]



Mnemonic	Op Code	Operands
CDZT	'EDAA'	Zoned source, long DFP result
CXZT	'EDAB'	Zoned source, extended DFP result

The second operand in the zoned format is converted to the DFP format, and the result is placed at the first-operand location.

The preferred quantum is one, and the delivered value is always represented with the preferred quantum.

The result placed at the first-operand location is canonical.

The length in bytes of the second operand is 1-34 for CXZT, corresponding to a length code in L_2 of 0-33. The length in bytes of the second operand is 1-16 for CDZT, corresponding to a length code in L_2 of 0-15.

The M_3 field has the following format:

The bits of the M_3 field are defined as follows:

- **Sign-Control (S):** Bit 0 of the M_3 field is the sign control (S). When zero, the second operand does not have a sign field and the sign bit of the DFP first-operand result is set to zero. When one, the second operand is signed. That is, the leftmost four bit positions of the rightmost byte are a sign. The sign bit of the DFP first-operand result is set to zero when the sign field indicates a positive value and one when the sign field indicates a negative value.
- **Reserved:** Bits 1-3 of the M_3 field are ignored.

Special Conditions:

When an invalid digit or sign code is detected in the second operand, a general-operand data exception is recognized.

A specification exception is recognized, and the operation is suppressed, when any of the following is true.

- For CDZT, the L_2 field is greater than or equal to 16.
- For CXZT, the R_1 field designates an invalid floating-point-register pair, or the L_2 field is greater than or equal to 34.

Condition Code: The code remains unchanged.

Program Exceptions:

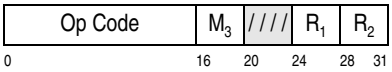
- Access (Fetch operand 2)
- Data with DXC 0, general operand
- Data with DXC 3, DFP instruction
- Operation (if the DFP zoned-conversion facility is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. When an ASCII second operand is specified, bit 0 of the M_3 field must be zero, otherwise a general-operand data exception is recognized. That is, a sign value of 0011 binary is not a valid sign.
2. Depending on the model, for CXZT, when the L_2 field specifies 32 or 33 (meaning 33 or 34 digits), performance may be significantly worse than if shorter lengths are specified.
3. Bits 1-3 of the M_3 field should be set to zeros, otherwise the program may not operate compatibly in the future.

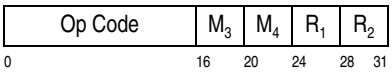
CONVERT TO FIXED

Mnemonic1 R_1,M_3,R_2 [RRF-e]



Mnemonic1	Op Code	Operands
CGDTR	'B3E1'	Long DFP source, 64-bit binary-integer result
CGXTR	'B3E9'	Extended DFP source, 64-bit binary-integer result

Mnemonic2 R_1,M_3,R_2,M_4 [RRF-e]



Mnemonic2	Op Code	Operands
CGDTRA	'B3E1'	Long DFP source, 64-bit binary-integer result
CGXTRA	'B3E9'	Extended DFP source, 64-bit binary-integer result
CFDTR	'B941'	Long DFP source, 32-bit binary-integer result
CFXTR	'B949'	Extended DFP source, 32-bit binary-integer result

The DFP second operand is rounded to an integer value and then converted to the fixed-point format. The result is placed at the first-operand location.

The result is a signed binary integer that is placed in the general register designated by R_1. A 32-bit result replaces bits 32-63 of the register, and bits 0-31 of the register remain unchanged.

If the second operand is numeric and finite, it is rounded to an integer value by rounding as specified by the modifier in the M_3 field:

M_3	Effective Rounding Method
0	According to the current DFP rounding mode
1	Round to nearest with ties away from 0
2	According to the current DFP rounding mode
3	Round to prepare for shorter precision
4	Round to nearest with ties to even
5	Round toward 0
6	Round toward +∞
7	Round toward -∞
8	Round to nearest with ties to even
9	Round toward 0
10	Round toward +∞
11	Round toward -∞
12	Round to nearest with ties away from 0
13	Round to nearest with ties toward 0
14	Round away from 0
15	Round to prepare for shorter precision

When the modifier field is zero, rounding is controlled by the current DFP rounding mode specified in the FPC register. When the field is 8-15, rounding is performed as specified by the modifier, regardless of the current DFP rounding mode.

When the floating-point extension facility is installed and if the modifier field is 2, rounding is controlled by the current DFP rounding mode specified in the FPC register; if the field is 1, or 3-7, rounding is performed as specified by the modifier, regardless of the current DFP rounding mode.

When the floating-point extension facility is not installed, and if the M_3 modifier field is 1-7, it is unpredictable which rounding method is performed.

The sign of the result is the sign of the second operand, except that a zero result has a plus sign.

This operation performs a functionally-constrained rounding. Neither overflow nor underflow condition can occur.

When the floating-point extension facility is installed, bit 1 of the M_4 field is the IEEE-inexact-exception control (XxC), and bits 0, 2, and 3 are ignored. If XxC is zero, recognition of IEEE-inexact exception is not suppressed; if XxC is one, recognition of the exception is suppressed.

When the floating-point extension facility is not installed, and if bits 20-23 of the instruction are zeros, then recognition of IEEE-inexact exception is not suppressed; if bits 20-23 of the instruction contain a nonzero value, it is unpredictable whether recognition of IEEE-inexact exception is suppressed.

See Figure 20-18 for a detailed description of the results of this instruction.

For CGXTR, CGXTRA, and CFXTR, the R_2 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

An operation exception is recognized if the DFP facility is not installed. For CFDTR, CFXTR, CGDTRA, and CGXTRA, the operation exception is also recognized if the floating-point extension facility is not installed.

Resulting Condition Code:

0 Source was zero
1 Source was less than zero
2 Source was greater than zero
3 Special case

IEEE Exceptions:

- Invalid operation
- Inexact

Program Exceptions:

- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation
- Specification (CGXTR, CGXTRA, and CFXTR only)
- Transaction constraint

Programming Note: Unassigned bits in the M_4 field are reserved for future extensions and should be set to zeros; otherwise, the program may not operate compatibly in the future.

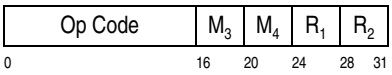
Explanation:

—	The results do not depend on this condition or mask bit.
[1]	This condition is true by virtue of the state of some condition to the left of this column.
[2]	XxC is defined only when the floating-point extension facility is installed.
ccn	Condition code is set to n.
†	Result differs from BFP CONVERT TO FIXED. The BFP instruction recognizes inexact for this case and takes different actions depending on the inexact mask. The DFP implementation is intended to be more in keeping with the spirit of the IEEE standard.
f	The value n converted to a fixed-point result.
n	The value derived when the source value (b) is rounded to a floating-point integer using the effective rounding method.
MN	Maximum negative number representable in the target fixed-point format.
MP	Maximum positive number representable in the target fixed-point format.
PIDc(h)	Program interruption for data exception, condition c, with DXC of h in hex. Figure 20-8 on page 20-16
SFi	IEEE invalid-operation flag, FPC 1.0.
SFx	IEEE inexact flag, FPC 1.4.
T(x)	The value x is placed at the target operand location

Figure 20-18. Results: CONVERT TO FIXED

CONVERT TO LOGICAL

Mnemonic R_1,M_3,R_2,M_4 [RRF-e]



Mnemonic	Op Code	Operands
CLGDTR	'B942'	Long DFP source, 64-bit binary-integer result
CLGXTR	'B94A'	Extended DFP source, 64-bit binary-integer result
CLFDTR	'B943'	Long DFP source, 32-bit binary-integer result
CLFXTR	'B94B'	Extended DFP source, 32-bit binary-integer result

The DFP second operand is rounded to an integer value and then converted to the fixed-point format. The result is placed at the first-operand location.

The result is an unsigned binary integer that is placed in the general register designated by R_1. A 32-bit result replaces bits 32-63 of the register, and bits 0-31 of the register remain unchanged.

If the second operand is numeric and finite, it is rounded to an integer value by rounding as specified by the modifier in the M_3 field:

M_3	Effective Rounding Method
0	According to the current DFP rounding mode
1	Round to nearest with ties away from 0
2	According to the current DFP rounding mode
3	Round to prepare for shorter precision
4	Round to nearest with ties to even
5	Round toward 0
6	Round toward +∞
7	Round toward -∞
8	Round to nearest with ties to even
9	Round toward 0
10	Round toward +∞
11	Round toward -∞
12	Round to nearest with ties away from 0
13	Round to nearest with ties toward 0
14	Round away from 0
15	Round to prepare for shorter precision

When the modifier field is zero or two, rounding is controlled by the current DFP rounding mode specified in the FPC register. When the field is 1, or 3-15, rounding is performed as specified by the modifier, regardless of the current DFP rounding mode.

This operation performs a functionally-constrained rounding. Neither overflow nor underflow condition can occur.

Bit 1 of the M_4 field is the IEEE-inexact-exception control (XxC). Bits 0, 2, and 3 are ignored. If XxC is zero, recognition of IEEE-inexact exception is not suppressed; if XxC is one, recognition of the exception is suppressed.

See Figure 20-19 for a detailed description of the results of this instruction.

For CLGXTR and CLFXTR, the R_2 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Source was zero
1 Source was less than zero
2 Source was greater than zero
3 Special case

IEEE Exceptions:

- Invalid operation

Figure 20-19. Results: CONVERT TO LOGICAL

CONVERT TO PACKED

Mnemonic $R_1,D_2(L_2,B_2),M_3$ [RSL-b]

Mnemonic	Op Code	Operands
CPDT	'EDAC'	Long DFP source, packed result
CPXT	'EDAD'	Extended DFP source, packed result

The significand digits of the DFP first operand and the sign bit of the first operand are converted to the packed format. The exponent in the combination field is ignored. The specified number of rightmost bytes of packed digits are placed at the second-operand location.

If there are not enough significand digits to fill all of the packed bytes, zero digits are appended to the significand as leftmost digits.

The number of bytes containing rightmost significand digits of the converted first operand is specified by L_2. The length in bytes of the second operand is 1-18 for

CPXT, corresponding to a length code in L_2 of 0-17. The length in bytes of the second operand is 1-9 for CPDT, corresponding to a length code in L_2 of 0-8.

The M_3 field has the following format:

The bits of the M_3 field are defined as follows:

- **Sign Control (S):** Bit 0 of the M_3 field is the sign control (S). When S is zero, the second operand does not have a sign field. When S is one, the second operand has a sign field. That is, the rightmost four bit positions of the rightmost byte are a sign.
- **Reserved:** Bit 1 of the M_3 field is reserved and should be zero.
- **Plus-Sign-Code Control (P):** Bit 2 of the M_3 field is the plus-sign-code control (P). When P is zero, the plus sign is encoded as 1100 binary. When P is one, the plus sign is encoded as 1111 binary. When the S bit is zero, the P bit is ignored.
- **Force-Plus-Zero Control (F)**: Bit 3 of the M_3 field is the force-plus-zero control (F). When F is zero and a signed value of negative zero results, no action is taken. When F is one and the absolute value of the result placed in the second operand location is zero, the result is set to indicate a positive zero with the sign code specified by the P bit. When the S bit is zero, the F bit is ignored.

Special Conditions

The operation is performed for any first operand, including an infinity, QNaN, or SNaN, without causing an IEEE exception.

If the first operand is an infinity or a NaN, a zero digit is appended as the leftmost digit (LMD) of the significand, thereby conceptually forming the effective significand to be converted. The specified number of rightmost effective significand digits and the sign bit are converted to the packed format, the result is placed at the second-operand location, and execution completes with condition code 3.

For any type of first operand, including an infinity and a NAN, when one or more leftmost nonzero digits of the significand are lost because the second operand field is too short, the result is obtained by ignoring the overflow digits, condition code 3 is set, and, if the decimal-overflow mask bit is one, a program interruption for decimal overflow occurs. The operand lengths alone are not an indication of overflow; nonzero digits must have been lost during the operation.

A specification exception is recognized, and the operation is suppressed, when any of the following is true.

- For CPDT, the L_2 field is greater than 8.
- For CPXT, the R_1 field designates an invalid floating-point-register pair, or the L_2 field is greater than 17.

Resulting Condition Code:

0 Source is zero
1 Source is not special and is less than zero
2 Source is not special and is greater than zero
3 Source is special which is infinity, QNaN, SNaN, or a partial result

Program Exceptions:

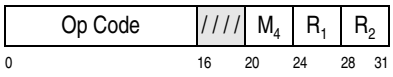
- Access (Store operand 2)
- Data with DXC 3, DFP instruction
- Decimal overflow
- Operation (if the DFP packed-conversion facility is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. If the number of significant digits of a significand exceeds the specified number, one or more leftmost digits of the significand are ignored except for the detection of a decimal overflow exception.
2. A completion with condition code 0 indicates that the absolute value of the first operand is zero.

CONVERT TO SIGNED PACKED

Mnemonic R_1,R_2,M_4 [RRF-d]



Mnemonic	Op Code	Operands
CSDTR	'B3E3'	Long DFP source, 64-bit signed packed-decimal result in GR
CSXTR	'B3EB'	Extended DFP source, 128-bit signed-packed-decimal result in GRs

Rightmost significand digits of the DFP second operand are converted to the signed-packed-decimal format, and the result is placed at the first-operand location.

For CSDTR, the rightmost 15 digits in the trailing significand and the sign bit of the second operand are converted to a 64-bit result (15 4-bit decimal digits and a 4-bit sign); for CSXTR, the rightmost 31 digits in the trailing significand and the sign bit of the second operand are converted to a 128-bit result (31 4-bit decimal digits and a 4-bit sign). The sign of the result is the sign of the second operand.

Bit 3 of the M_4 field is the plus sign-code selection bit. When the bit is zero, the plus sign is encoded as 1100; when the bit is one, the plus sign is encoded as 1111. Bits 0-2 are ignored.

The result is placed in the general register or general-register pair designated by R_1.

This operation is performed for any second operand, including an infinity, QNaN, or SNaN, without causing an IEEE exception.

For CSXTR, the R_2 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized. Also, the R_1 field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions: None.

Program Exceptions:

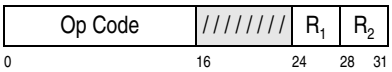
- Data with DXC 3, DFP instruction
- Operation (if the DFP facility is not installed)
- Specification (CSXTR only)
- Transaction constraint

Programming Notes:

1. See also the programming note under CONVERT FROM FIXED.
2. The sign code 1100 is the preferred plus sign in IBM Z products, and 1111 is the preferred plus sign in IBM i products.

CONVERT TO UNSIGNED PACKED

Mnemonic R_1,R_2 [RRE]



Mnemonic	Op Code	Operands
CUDTR	'B3E2'	Long DFP source, 64-bit unsigned-packed-decimal result in GR
CUXTR	'B3EA'	Extended DFP source, 128-bit unsigned-packed-decimal result in GRs

Rightmost significand digits of the DFP second operand are converted to the unsigned-packed-decimal format, and the result is placed at the first-operand location.

For CUDTR, 16 significand digits of the second operand are converted to a 64-bit result (16 4-bit decimal digits). If the second operand is an infinity or NaN, the 15 digits in the trailing significand are padded with a zero digit on the left to form a 16 significand digits.

For CUXTR, the rightmost 32 digits in the trailing significand of the second operand are converted to a 128-bit result (32 4-bit decimal digits).

The result is placed in the general register or general-register pair designated by R_1.

This operation is performed for any second operand, including an infinity, QNaN, or SNaN, without causing an IEEE exception.

For CUXTR, the R_2 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized. Also, the R_1 field designates an even-odd pair of general registers and must designate an even-numbered register; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions: None.

Program Exceptions:

- Data with DXC 3, DFP instruction
- Operation (if the DFP facility is not installed)
- Specification (CUXTR only)
- Transaction constraint

CONVERT TO ZONED

Mnemonic $R_1,D_2(L_2,B_2),M_3$ [RSL-b]

Mnemonic	Op Code	Operands
CZDT	'EDA8'	Long DFP source, zoned result
CZXT	'EDA9'	Extended DFP source, zoned result

The specified number of rightmost significand digits of the DFP first operand and the sign bit of the first operand are converted to the zoned format, and the result is placed at the second-operand location. The exponent in the combination field is ignored.

The number of rightmost significand digits of the first operand to be converted is specified by L_2. The length in bytes of the second operand is 1-34 for CZXT, corresponding to a length code in L_2 of 0-33, meaning 1-34 digits. The length in bytes of the second operand is 1-16 for CZDT, corresponding to a length code in L_2 of 0-15, meaning 1-16 digits.

The M_3 field has the following format:

The bits of the M_3 field are defined as follows:

- **Sign Control (S):** Bit 0 of the M_3 field is the sign control (S). When S is zero, the second operand does not have a sign field, and the zone field is set as determined by the Z bit. When S is one, the second operand has a sign field. That is, the leftmost four bit positions of the rightmost byte are a sign.
- **Zone Control (Z):** Bit 1 of the M_3 field is the zone control (Z). When Z is zero, each zone field of the second operand is stored as 1111 binary, except that the zone field of the rightmost byte is set to the sign when the S bit is one. When Z is one, each zone field of the second operand is stored as 0011 binary, except that the zone field of the rightmost byte is set to the sign when the S bit is one.
- **Plus-Sign-Code Control (P):** Bit 2 of the M_3 field is the plus-sign-code control (P). When P is zero, the plus sign is encoded as 1100 binary. When P is one, the plus sign is encoded as 1111 binary.

  When the S bit is zero, the P bit is ignored and assumed to be zero. The zone of the rightmost digit is set as determined by the Z bit.
- **Force-Plus-Zero Control (F)**: Bit 3 of the M_3 field is the force-plus-zero control (F). When F is zero, no action is taken. When F is one and the absolute value of the result placed at the second-operand location is zero, the sign of the result is set to indicate a plus value with the sign code specified by the P bit.

  When the S bit is zero, the F bit is ignored and assumed to be zero.

Special Conditions

The operation is performed for any first operand, including an infinity, QNaN, or SNaN, without causing an IEEE exception.

If the first operand is an infinity or a NaN, a zero digit is assumed to be the leftmost digit (LMD) of the significand, thereby conceptually forming the effective significand to be converted. The specified number of rightmost effective-significand digits and the sign bit are converted to the zoned format, the result is placed at the second-operand location, and execution completes with condition code 3.

For any type of first operand, including an infinity, and a NaN, when one or more leftmost nonzero digits of the significand are lost because the second-operand field is too short, the result is obtained by ignoring the overflow digits, condition code 3 is set, and, if the decimal-overflow mask bit is one, a program interruption for decimal overflow occurs. The operand lengths alone are not an indication of overflow; nonzero digits must have been lost during the operation.

A specification exception is recognized, and the operation is suppressed, when any of the following is true:

- For CZDT, the L_2 field is greater than or equal to 16, meaning 17 or more digits.
- For CZXT, the R_1 field designates an invalid floating-point-register pair, or the L_2 field is greater than or equal to 34, meaning 35 or more digits.

Resulting Condition Code:

0 Source is zero
1 Source is less than zero
2 Source is greater than zero
3 Infinity, QNaN, SNaN, Partial result

Program Exceptions:

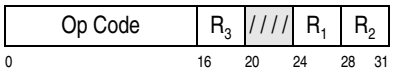
- Access (Store operand 2)
- Data with DXC 3, DFP instruction
- Decimal overflow
- Operation (if the DFP zoned-conversion facility is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. An ASCII zoned-decimal operand may be stored as signed when the S bit is one. This is entirely up to the program as ASCII representations are usually unsigned and positive with no concept of a rightmost zone being used as a sign.
2. If the number of significant digits of a significand exceeds the specified number, one or more leftmost digits of the significand are ignored.
3. Depending on the model, for CZXT, when the L_2 field specifies 32 or 33 (meaning 33 or 34 digits), performance may be significantly worse than if shorter lengths are specified.
4. A completion with condition code 0 indicates that the absolute value of the first operand is zero.

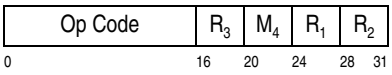
DIVIDE

Mnemonic1 R_1,R_2,R_3 [RRF-a]



Mnemonic1	Op Code	Operands
DDTR	'B3D1'	Long DFP
DXTR	'B3D9'	Extended DFP

Mnemonic2 R_1,R_2,R_3,M_4 [RRF-a]



Mnemonic2	Op Code	Operands
DDTRA	'B3D1'	Long DFP
DXTRA	'B3D9'	Extended DFP

The second operand (the dividend) is divided by the third operand (the divisor), and the quotient is placed at the first-operand location. No remainder is preserved.

If divisor is nonzero and both the dividend and divisor are finite numbers, the second operand is divided by the third operand to form an intermediate quotient. The intermediate quotient, if nonzero, is rounded to the target format and the rounded value is then placed at the first-operand location.

When the floating-point extension facility is installed, the intermediate quotient is rounded by rounding as specified by the modifier in the M_4 field:

M_4	Effective Rounding Method
0	According to the current DFP rounding mode
1	Round to nearest with ties away from 0
2	According to the current DFP rounding mode
3	Round to prepare for shorter precision
4	Round to nearest with ties to even
5	Round toward 0
6	Round toward +∞
7	Round toward -∞
8	Round to nearest with ties to even
9	Round toward 0
10	Round toward +∞
11	Round toward -∞
12	Round to nearest with ties away from 0
13	Round to nearest with ties toward 0
14	Round away from 0
15	Round to prepare for shorter precision

When the modifier field is zero or two, rounding is controlled by the current DFP rounding mode specified in the FPC register. When the field is 1, or 3-15, rounding is performed as specified by the modifier, regardless of the current DFP rounding mode.

If the modifier field is 0 or 8-15, the quantum-exception control (XqC) is one and recognition of the quantum exception is suppressed; if the modifier field is 1-

7, the quantum-exception control is zero and recognition of the exception is not suppressed.

When the floating-point extension facility is not installed, no quantum exception is recognized. If bits 20-23 of the instruction contain a value of zero, the intermediate quotient is rounded according to the current DFP rounding mode; if bits 20-23 of the instruction contain a nonzero value, it is unpredictable which rounding method is performed.

When the dividend is a finite number and the divisor is infinity, then a value of zero with zero significand and zero biased exponent is produced.

The sign of the quotient, if the quotient is numeric, is the exclusive or of the operand signs. This includes the sign of a zero or infinite quotient.

When the delivered value is exact, the preferred quantum is the quantum of the dividend divided by the quantum of the divisor; when the delivered value is inexact, the preferred quantum is the smallest quantum.

The result placed at the first-operand location is canonical.

If the divisor is zero but the dividend is nonzero and finite, an IEEE-division-by-zero exception is recognized. If the dividend and divisor are both zero, or if both are infinite, regardless of sign, an IEEE-invalid-operation exception is recognized.

See Figure 20-20 on page 20-38 for a detailed description of the results of this instruction.

For DXTR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Invalid operation
- Division by zero
- Overflow
- Underflow
- Inexact
- Quantum (if the floating-point extension facility is installed)

Program Exceptions:

- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation (if the DFP facility is not installed)
- Specification (DXTR and DXTRA only)
- Transaction constraint

Dividend (b) is	Results for DIVIDE (b ÷ c) when divisor (c) is							
	-∞	**-Fn**	**-0**	**+0**	**+Fn**	**+∞**	**QNaN**	**SNaN**
-∞	Xi: T(dNaN)	T(+∞)	T(+∞)	T(-∞)	T(-∞)	Xi: T(dNaN)	T(c)	Xi: T(c*)
-Fn	T(+zt)	R(b÷c)	Xz: T(+∞)	Xz: T(-∞)	R(b÷c)	T(-zt)	T(c)	Xi: T(c*)
-0	T(+zt)	T(+0)	Xi: T(dNaN)	Xi: T(dNaN)	T(-0)	T(-zt)	T(c)	Xi: T(c*)
+0	T(-zt)	T(-0)	Xi: T(dNaN)	Xi: T(dNaN)	T(+0)	T(+zt)	T(c)	Xi: T(c*)
+Fn	T(-zt)	R(b÷c)	Xz: T(-∞)	Xz: T(+∞)	R(b÷c)	T(+zt)	T(c)	Xi: T(c*)
+∞	Xi: T(dNaN)	T(-∞)	T(-∞)	T(+∞)	T(+∞)	Xi: T(dNaN)	T(c)	Xi: T(c*)
QNaN	T(b)	T(b)	T(b)	T(b)	T(b)	T(b)	T(b)	Xi: T(c*)
SNaN	Xi: T(b*)	Xi: T(b*)	Xi: T(b*)	Xi: T(b*)	Xi: T(b*)	Xi: T(b*)	Xi: T(b*)	Xi: T(b*)

Explanation:

*	The SNaN is converted to the corresponding QNaN before it is placed at the target operand location.
dNaN	Default NaN.
Fn	Nonzero finite number (includes both subnormal and normal numbers).
R(x)	Rounding and range action is performed on the value x. See Figure 20-5 on page 20-11. The result is canonical.
T(x)	The canonical result x is placed at the target operand location.
Xi:	IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.
Xz:	IEEE division-by-zero exception. The results shown are produced only when FPC 0.1 is zero.
zt	A value of zero with zero significand and zero biased exponent.

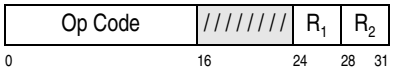
Figure 20-20. Results: DIVIDE

Programming Note: For DIVIDE, when the delivered value is inexact, the preferred quantum is the smallest quantum which is not always the same quantum as that closest to the quantum of the dividend divided by the quantum of the divisor.

For example, with the short data format, when 5000001×10^{-7} is divided by 400×10^{0}, the smallest quantum for the delivered value is 1×10^{-9}. However, the quantum that is closest to the quantum of the dividend divided by the quantum of the divisor is 1×10^{-7}.

EXTRACT BIASED EXPONENT

Mnemonic R_1,R_2 [RRE]



Mnemonic	Op Code	Operands
EEDTR	'B3E5'	Long DFP source, 64-bit binary-integer result
EEXTR	'B3ED'	Extended DFP source, 64-bit binary-integer result

The biased exponent of the DFP second operand is placed at the first-operand location.

When the second operand is a finite number, the biased exponent of the second operand is placed at the first-operand location. When the second operand is an infinity, QNaN, or SNaN, a special value is placed at the first-operand location.

The result is a 64-bit signed binary integer that is placed in the general register designated by R_1.

This operation is performed for any second operand, including an infinity, QNaN, or SNaN, without causing an IEEE exception.

See Figure 20-21 for a detailed description of the results of this instruction.

Second-operand data	First-operand value
Finite number	e
Infinity	-1
QNaN	-2
SNaN	-3
Explanation: e Biased exponent	

Figure 20-21. Results: EXTRACT BIASED EXPONENT

For EEXTR, the R_2 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

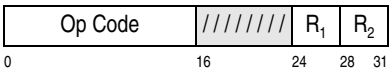
IEEE Exceptions: None.

Program Exceptions:

- Data with DXC 3, DFP instruction
- Operation (if the DFP facility is not installed)
- Specification (EEXTR only)
- Transaction constraint

EXTRACT SIGNIFICANCE

Mnemonic R_1,R_2 [RRE]



Mnemonic	Op Code	Operands
ESDTR	'B3E7'	Long DFP source, 64-bit binary-integer result
ESXTR	'B3EF'	Extended DFP source, 64-bit binary-integer result

The number of DFP significant digits of the DFP second operand is placed at the first-operand location.

When the second operand is a finite number, the result is set to the number of DFP significant digits of the second operand. When the second operand is an infinity, QNaN, or SNaN, the result is set to -1, -2, or -3, respectively.

The result is a 64-bit signed binary integer that is placed in the general register designated by R_1.

See Figure 20-22 for a detailed description of the results of this instruction.

Second-operand data	First-operand value
Nonzero finite number	NSD
Zero	0
Infinity	-1
QNaN	-2
SNaN	-3
Explanation: NSD The number of DFP significant digits of the second operand.	

Figure 20-22. Results: EXTRACT SIGNIFICANCE

This operation is performed for any second operand, including an infinity, QNaN, or SNaN, without causing an IEEE exception.

For ESXTR, the R_2 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

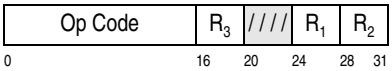
IEEE Exceptions: None.

Program Exceptions:

- Data with DXC 3, DFP instruction
- Operation (if the DFP facility is not installed)
- Specification (ESXTR only)
- Transaction constraint

INSERT BIASED EXPONENT

Mnemonic R_1,R_3,R_2 [RRF-b]



Mnemonic	Op Code	Operands
IEDTR	'B3F6'	Long DFP
IEXTR	'B3FE'	Extended DFP

A DFP operand is produced by combining the requested biased exponent with the sign bit and the significand of the DFP third operand, and the result is placed in the first-operand location.

The value of the requested biased exponent is a 64-bit signed binary integer and is located in the general register designated by R_2.

When the value of the requested biased exponent is in the range between zero and the maximum biased exponent, inclusively, for the target format, the result is a finite number. The biased exponent of the result is set to the value of the requested biased exponent; the significand of the result is set to the significand of the third operand. If the third operand is an infinity or NaN, the significand of the third operand contains the digits in the trailing significand of the third operand padded with a zero digit on the left.

When the value of the requested biased exponent is -1, the result is an infinity. The reserved field of the result is set to zero; the trailing significand of the result is set to the trailing significand of the third operand.

When the value of the requested biased exponent is equal to -2, less than -3, or greater than the maximum biased exponent for the target format, the result is a QNaN; when the value of the requested biased exponent is -3, the result is an SNaN. When a NaN is produced as the result, the reserved field of the result is set to zero, and the trailing significand of the result is set to the trailing significand of the third operand.

The sign of the result is the same as the sign of the third operand.

The preferred quantum is the quantum that corresponds to the requested biased exponent. If the delivered value is a finite number, it is always represented with the preferred quantum.

The result placed at the first-operand location is canonical, except for infinity. When the result is an infinity, if all digits in the trailing significand of the third operand are zeros, then the result is a canonical infinity; otherwise, the result is an infinity that has the reserved field set to zero, canonical declets in the encoded trailing-significand field, and some nonzero digits in the trailing significand.

See Figure 20-23 for a detailed description of the results of this instruction.

This operation is performed for any requested biased exponent and any third operand without causing an IEEE exception.

For IEXTR, the R_1 and R_3 fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions: None.

Program Exceptions:

- Data with DXC 3, DFP instruction
- Operation (if the DFP facility is not installed)
- Specification (IEXTR only)
- Transaction constraint

Programming Note: Infinities produced as DFP results have the reserved field set to zero and have canonical declets in the encoded trailing-significand

Value (b) in second operand	Results[1] for INSERT BIASED EXPONENT when third operand (c) is			
	F	∞	QNaN	SNaN
b > MBE	T(QNaN)	T(QNaN)	T(QNaN)	T(QNaN)
MBE ≥ b ≥ 0	T(F)	T(F^2)	T(F^2)	T(F^2)
b = -1	N(∞)	N(∞)	N(∞)	N(∞)
b = -2	T(QNaN)	T(QNaN)	T(QNaN)	T(QNaN)
b = -3	T(SNaN)	T(SNaN)	T(SNaN)	T(SNaN)
b ≤ -4	T(QNaN)	T(QNaN)	T(QNaN)	T(QNaN)

Explanation:

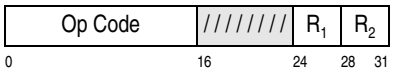
1 The sign of the result is the same as the sign of the third operand.
2 The leftmost digit of the significand is zero.
F All finite numbers, including zeros.
MBE Maximum biased exponent for the target format.
N(∞) The result is a canonical infinity if all digits in the trailing significand of the third operand are zeros; otherwise, the resultant infinity has the reserved field set to zero, canonical declets in the encoded trailing-significand field, and some nonzero digits in the trailing significand.
T(x) The canonical result x is placed at the target operand location.

Figure 20-23. Results: INSERT BIASED EXPONENT

field. An infinity is not considered canonical unless all digits in the trailing significand are zeros.

LOAD AND TEST

Mnemonic R_1,R_2 [RRE]



Mnemonic	Op Code	Operands
LTDTR	'B3D6'	Long DFP
LTXTR	'B3DE'	Extended DFP

The second operand is placed at the first-operand location, and its sign and magnitude are tested to determine the setting of the condition code. The condition code is set the same as for a comparison of the second operand with zero.

The second operand is canonicalized before it is placed at the first-operand location. If the second operand is an SNaN, an IEEE-invalid-operation exception is recognized; if there is no interruption, the result is the corresponding QNaN**.**

The preferred quantum is the quantum of the second operand. If the delivered value is a finite number, it is always represented with the preferred quantum.

The result placed at the first-operand location is canonical.

See Figure 20-24 for a detailed description of the results of this instruction.

For LTXTR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Result is zero
1 Result is less than zero
2 Result is greater than zero
3 Result is a NaN

IEEE Exceptions:

- Invalid operation

Program Exceptions:

- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation (if the DFP facility is not installed)
- Specification (LTXTR only)
- Transaction constraint

Instruction	Results for some instructions with a single operand (b) when second operand (b) is							
	-∞	**-Fn**	**-0**	**+0**	**+Fn**	**+∞**	**QNaN**	**SNaN**

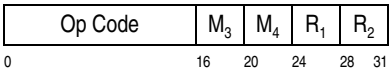
Explanation:

—	The results do not depend on this condition.
*	The SNaN is converted to the corresponding QNaN before it is placed at the target operand location.
1	The operand is extended to the longer format by appending zeros on the left before it is placed at the target operand location.
2	The operand is shortened to the target format by truncating the leftmost digits.
Fn	Nonzero finite number (includes both subnormal and normal).
N(±∞)	The resultant infinity has the reserved field set to zero and has canonical declets in the encoded trailing-significand field. The result is not considered canonical unless all digits in the trailing significand are zeros.
R(v)	Rounding and range action is performed on the value v. See Figure 20-5 on page 20-11. The result is canonical.
Rf(b)	The value b is converted to the exact floating-point number v, and then action R(v) is performed. The result is canonical.
T(x)	The canonical result x is placed at the target operand location.
Xi:	IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.
XiC	IEEE-invalid-operation-exception control, bit 0 of the M_4 field.

Figure 20-24. Results: Some Single-Operand Instructions

LOAD FP INTEGER

Mnemonic R_1,M_3,R_2,M_4 [RRF-e]



Mnemonic	Op Code	Operands
FIDTR	'B3D7'	Long DFP
FIXTR	'B3DF'	Extended DFP

The second operand is rounded to an integer value in the same floating-point format, and the result is placed at the first-operand location.

The second operand, if a finite number, is rounded to an integer value as specified by the modifier in the M_3 field:

M_3	Effective Rounding Method
0	According to the current DFP rounding mode
1	Round to nearest with ties away from 0
2	According to the current DFP rounding mode
3	Round to prepare for shorter precision
4	Round to nearest with ties to even
5	Round toward 0
6	Round toward +∞
7	Round toward -∞
8	Round to nearest with ties to even
9	Round toward 0
10	Round toward +∞
11	Round toward -∞
12	Round to nearest with ties away from 0
13	Round to nearest with ties toward 0
14	Round away from 0
15	Round to prepare for shorter precision

When the modifier field is zero, rounding is controlled by the current DFP rounding mode specified in the FPC register. When the field is 8-15, rounding is performed as specified by the modifier, regardless of the current DFP rounding mode.

When the floating-point extension facility is installed and if the modifier field is 2, rounding is controlled by the current DFP rounding mode specified in the FPC register; if the field is 1, or 3-7, rounding is performed as specified by the modifier, regardless of the current DFP rounding mode. If the modifier field is 0 or 8-15, the quantum-exception control (XqC) is one and recognition of the quantum exception is suppressed; if the modifier field is 1-7, the quantum-exception con-

trol is zero and recognition of the exception is not suppressed.

When the floating-point extension facility is not installed, no quantum exception is recognized. If the M_3 modifier field is 1-7, it is unpredictable which rounding method is performed.

In the absence of an interruption, if the second operand is an infinity, the result is the canonical infinity; if the second operand is a QNaN, the result is the canonicalized source QNaN that has the same sign and payload as the source; if the second operand is an SNaN, the result is the corresponding QNaN.

The sign of the result is the sign of the second operand, even when the result is zero.

Bit 1 of the M_4 field is the IEEE-inexact-exception control (XxC). Bits 0, 2, and 3 are ignored.

When the result differs in value from the second operand, if XxC is zero, an IEEE-inexact exception is recognized. If XxC one, then no IEEE-inexact exception is recognized.

This operation performs a functionally-constrained rounding. Neither overflow nor underflow condition can occur.

When the delivered value is exact, the preferred quantum is the larger value of one and the quantum of the second operand; when the delivered value is inexact, the preferred quantum is one. If the delivered value is a finite number, it is always represented with the preferred quantum.

The result placed at the first-operand location is canonical.

See Figure 20-25 on page 20-43 for a detailed description of the results of FIDTR and FIXTR.

When the floating-point extension facility is installed, if the quantum of the delivered finite number is not equal to the quantum of the second operand and if XqC is zero, then a quantum exception is recognized.

For FIXTR, the R fields must designate valid floating-point-register fields; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Invalid operation
- Inexact
- Quantum (if the floating-point extension facility is installed)

Program Exceptions:

- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation (if the DFP facility is not installed)
- Specification (FIXTR only)
- Transaction constraint

SNaN	No[1]	—	—	—	—	—	—	1	PIDi(80)

Explanation:

—	The results do not depend on this condition or mask bit.
*	The SNaN is converted to the corresponding QNaN before it is placed at the target operand location.
1	This condition is true by virtue of the state of some condition to the left of this column.
2	XqC is defined only if the floating-point extension facility is installed.
n	The value derived when the source value, b, is rounded to an integer using the effective rounding method.
Fn	Finite nonzero number (includes both subnormal and normal).
PIDc(h)	Program interruption for data exception, condition c, with DXC of h in hex. See Figure 20-8 on page 20-16.
PIDq(04)	Program interruption for data exception, quantum-exception condition q, with DXC of 04 in hex. It is defined only if the floating-point extension facility is installed.
Q	Quantum of the second operand.
SFi	IEEE invalid-operation flag, FPC 1.0.
SFq	Quantum exception flag, FPC 1.5. The flag is defined only if the floating-point extension facility is installed.
SFx	IEEE inexact flag, FPC 1.4.
T(x)	The canonical result x is placed at the target operand location. The result, when it is a finite number, is always represented with the preferred quantum.

Figure 20-25. Results: LOAD FP INTEGER

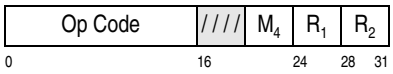
Programming Notes:

1. Unassigned bits in the M_4 field are reserved for future extensions and should be set to zeros; otherwise, the program may not operate compatibly in the future.
2. If the DFP source operand is numeric with a quantum of at least one so that it is already an integer, the result value and quantum remain the same. Other numeric DFP source operands that are integers with a quantum less than one are

converted to the same value with a quantum of one.

LOAD LENGTHENED

Mnemonic R_1,R_2,M_4 [RRF-d]



Mnemonic	Op Code	Operands
LDETR	'B3D4'	Short DFP source, long DFP result
LXDTR	'B3DC'	Long DFP source, extended DFP result

The second operand is converted to a longer format, and the result is placed at the first-operand location.

Bit 0 of the M_4 field controls the handling of SNaN and infinity, and is called the IEEE-invalid-operation-exception control (XiC). Bits 1-3 are ignored. When XiC is zero, recognition of IEEE-invalid-operation exception is not suppressed; when XiC is one, recognition of the exception is suppressed.

When the second operand is a finite number, the value of the second operand is placed in the target format.

When the second operand is an infinity, if XiC is zero, the result is the canonical infinity for the target format; if XiC is one, the result is the source infinity with the reserved field of the target format being set to zero, the trailing significand being extended by appending zeros on the left, and all declets in the encoded trailing-significand field being canonicalized.

When the second operand is a QNaN, the result is the canonicalized source QNaN with the payload extended by appending zeros on the left.

When the second operand is an SNaN, if XiC is zero, an invalid-operation exception is recognized and the nontrap result is the corresponding QNaN with the payload extended by appending zeros on the left; if XiC is one, no invalid-operation exception is recognized, and the result is the canonicalized source SNaN with the payload extended by appending zeros on the left.

The sign of the result is the same as the sign of the second operand.

The delivered value is always exact and the preferred quantum is the quantum of the second operand.

When XiC is zero, the result placed at the first-operand location is canonical. When XiC is one, the result is canonical, except for infinity. See the detailed description above for producing an infinity when XiC is one.

See Figure 20-24 on page 20-42 for a detailed description of the results of this instruction.

For LXDTR, the R_1 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Invalid operation

Program Exceptions:

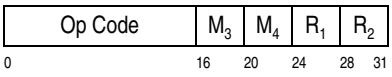
- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation (if the DFP facility is not installed)
- Specification (LXDTR only)
- Transaction constraint

Programming Notes:

1. Unassigned bits in the M_4 field are reserved for future extensions and should be set to zeros; otherwise, the program may not operate compatibly in the future.
2. The equivalent operations of LOAD LENGTHENED (short to long) in the Power architecture do not recognize the invalid-operation exception for both BFP and DFP. The equivalent operations of LOAD LENGTHENED in z/Architecture do recognize the exception for BFP. The IEEE-invalid-operation-exception control (XiC) is provided for compatibility.
3. Infinities produced as DFP results have the reserved field set to zero and have canonical declets in the encoded trailing-significand field. An infinity is not considered canonical unless all digits in the trailing significand are zeros.

LOAD ROUNDED

Mnemonic R_1,M_3,R_2,M_4 [RRF-e]



Mnemonic	Op Code	Operands
LEDTR	'B3D5'	Long DFP source, short DFP target, short or long DFP result
LDXTR	'B3DD'	Extended DFP source, long DFP target, long or extended DFP result

The second operand, in the format of the source, is rounded to the precision of the target, and the result is placed at the first-operand location.

The second operand, if it is a finite number, is rounded as specified by the modifier in the M_3 field:

M_3	Effective Rounding Method
0	According to the current DFP rounding mode
1	Round to nearest with ties away from 0
2	According to the current DFP rounding mode
3	Round to prepare for shorter precision
4	Round to nearest with ties to even
5	Round toward 0
6	Round toward +∞
7	Round toward -∞
8	Round to nearest with ties to even
9	Round toward 0
10	Round toward +∞
11	Round toward -∞
12	Round to nearest with ties away from 0
13	Round to nearest with ties toward 0
14	Round away from 0
15	Round to prepare for shorter precision

When the modifier field is zero, rounding is controlled by the current DFP rounding mode specified in the FPC register. When the field is 8-15, rounding is performed as specified by the modifier, regardless of the current DFP rounding mode.

When the floating-point extension facility is installed and if the modifier field is 2, rounding is controlled by the current DFP rounding mode specified in the FPC register; if the field is 1, or 3-7, rounding is performed as specified by the modifier, regardless of the current DFP rounding mode. If the modifier field is 0 or 8-15, the quantum-exception control (XqC) is one and recognition of the quantum exception is suppressed; if the modifier field is 1-7, the quantum-exception control is zero and recognition of the exception is not suppressed.

When the floating-point extension facility is not installed, no quantum exception is recognized. If the M_3 modifier field is 1-7, it is unpredictable which rounding method is performed.

Bit 0 of the M_4 field controls the handling of SNaN and infinity, and is called the IEEE-invalid-operation-exception control (XiC). When XiC is zero, recognition of IEEE-invalid-operation exception is not suppressed; when XiC is one, recognition of IEEE-invalid-operation exception is suppressed.

When the floating-point extension facility is installed, bit 1 of the M_4 field is the IEEE-inexact-exception control (XxC), and bits 2-3 are ignored. If XxC is zero, recognition of IEEE-inexact exception is not suppressed; if XxC is one, recognition of the exception is suppressed.

When the floating-point extension facility is not installed, and if bits 21-23 of the instruction are zeros, then recognition of IEEE-inexact exception is not suppressed; if bits 21-23 of the instruction contain a nonzero value, it is unpredictable whether recognition of IEEE-inexact exception is suppressed.

In the absence of a trap overflow or trap underflow, the result is in the format and length of the target. However, when a trap overflow or trap underflow occurs, the operation is completed by producing a scaled result in the same format and length as the source but rounded to the precision of the target. In this case, the result is selected from a subset of the cohort for the delivered value in the source format. This subset of the cohort consists of cohort members that have the number of DFP significand digits equal to or less than the precision of the target format. For LEDTR, the result has at most seven DFP significant digits; for LDXTR, the result has at most 16 DFP significant digits.

When the second operand is an infinity, if XiC is zero, the result is the canonical infinity for the target format; if XiC is one, the result is the source infinity with the reserved field of the target format being set to zero, the trailing significand being shortened by removing leftmost digits, and declets corresponding to the shortened trailing significand being canonicalized.

When the second operand is a QNaN, the result is the canonicalized source QNaN with the payload shortened by removing leftmost digits.

When the second operand is an SNaN, if XiC is zero, an invalid-operation exception is recognized and the nontrap result is the corresponding QNaN with the payload shortened by removing leftmost digits; if XiC is one, no invalid-operation exception is recognized, and the result is the canonicalized source SNaN with the payload shortened by removing leftmost digits.

The sign of the result is the same as the sign of the second operand.

When the delivered value is exact, the preferred quantum is the quantum of the second operand; when the delivered value is inexact, the preferred quantum is the smallest quantum.

When XiC is zero, the result placed at the first-operand location is canonical. When XiC is one, the result is canonical, except for infinity. See the detailed description above for producing an infinity when XiC is one.

See Figure 20-24 on page 20-42 for a detailed description of the results of this instruction.

For LDXTR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Invalid operation
- Overflow
- Underflow
- Inexact
- Quantum (if the floating-point extension facility is installed)

Program Exceptions:

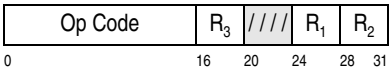
- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation (if the DFP facility is not installed)
- Specification (LDXTR only)
- Transaction constraint

Programming Notes:

1. LOAD ROUNDED and the round-to-prepare-for-shorter-precision rounding method can be used to simulate a DFP operation with the precision of a shorter format and with the effect of single rounding. The round-to-prepare-for-shorter-precision rounding method is used by the operation, and the desirable rounding method is used by the subsequent LOAD ROUNDED instruction.
2. Unassigned bits in the M_4 field are reserved for future extensions and should be set to zeros; otherwise, the program may not operate compatibly in the future.
3. The equivalent operation of LOAD ROUNDED (long to short) in the Power architecture does not recognize the invalid-operation exception. IEEE-invalid-operation-exception control (XiC) is provided for compatibility.
4. Infinities produced as DFP results have the reserved field set to zero and have canonical declets in the encoded trailing-significand field. An infinity is not considered canonical unless all digits in the trailing significand are zeros.
5. In case of a trap overflow or a trap underflow, the number of DFP significand digits of the delivered result is limited to the precision of the target format. For example, when the source operand is 75958100 X 10^{369} and is represented with the quantum of 10^{369}, execution of LEDTR using the round-away-from-0 rounding method produces a value of 7595810 X 10^{178} with the delivered quantum of 10^{178} as the trap overflow result.

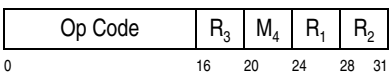
MULTIPLY

Mnemonic1 R_1,R_2,R_3 [RRF-a]



Mnemonic2	Op Code	Operands
MDTR	'B3D0'	Long DFP
MXTR	'B3D8'	Extended DFP

Mnemonic2 R_1,R_2,R_3,M_4 [RRF-a]



Mnemonic2	Op Code	Operands
MDTRA	'B3D0'	Long DFP
MXTRA	'B3D8'	Extended DFP

The product of the second operand (the multiplicand) and the third operand (the multiplier) is placed at the first-operand location.

If both source operands are finite numbers, they are multiplied to form an intermediate product. The intermediate product is rounded to the target format and the rounded value is then placed at the first-operand location.

When the floating-point extension facility is installed, the intermediate product is rounded by rounding as specified by the modifier in the M_4 field:

M_4	Effective Rounding Method
0	According to the current DFP rounding mode
1	Round to nearest with ties away from 0
2	According to the current DFP rounding mode
3	Round to prepare for shorter precision
4	Round to nearest with ties to even
5	Round toward 0
6	Round toward +∞
7	Round toward -∞
8	Round to nearest with ties to even
9	Round toward 0
10	Round toward +∞
11	Round toward -∞
12	Round to nearest with ties away from 0
13	Round to nearest with ties toward 0
14	Round away from 0
15	Round to prepare for shorter precision

When the modifier field is zero or two, rounding is controlled by the current DFP rounding mode specified in the FPC register. When the field is 1, or 3-15, rounding is performed as specified by the modifier, regardless of the current DFP rounding mode.

If the modifier field is 0 or 8-15, the quantum-exception control (XqC) is one and recognition of the quantum exception is suppressed; if the modifier field is 1-7, the quantum-exception control is zero and recognition of the exception is not suppressed.

When the floating-point extension facility is not installed, no quantum exception is recognized. If bits 20-23 of the instruction contain a value of zero, the intermediate product is rounded according to the current DFP rounding mode; if bits 20-23 of the instruction contain a nonzero value, it is unpredictable which rounding method is performed.

The sign of the product, if the product is numeric, is the exclusive or of the operand signs. This includes the sign of a zero or infinite product.

When the delivered value is exact, the preferred quantum is the product of the quanta of the two source operands; when the delivered value is inexact, the preferred quantum is the smallest quantum.

The result placed at the first-operand location is canonical.

See Figure 20-26 on page 20-49 for a detailed description of the results of this instruction.

If one source operand is a zero and the other an infinity, an IEEE-invalid-operation exception is recognized

For MXTR and MXTRA, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Invalid operation
- Overflow
- Underflow
- Inexact
- Quantum (if the floating-point extension facility is installed)

Program Exceptions:

- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation (if the DFP facility is not installed)
- Specification (MXTR and MXTRA only)
- Transaction constraint

Programming Notes:

1. Interchanging the two operands in a DFP multiplication does not affect the value of the product when the result is numeric. This is not true, however, when both operands are QNaNs. in which case the result is the canonical QNaN derived from the second operand; or when both operands are SNaNs and the IEEE invalid-operation

Multiplicand (b) is	Results for MULTIPLY (b • c) when multiplier (c) is							
	-∞	-Fn	-0	+0	+Fn	+∞	QNaN	SNaN
-∞	T(+∞)	T(+∞)	Xi: T(dNaN)	Xi: T(dNaN)	T(-∞)	T(-∞)	T(c)	Xi: T(c*)
-Fn	T(+∞)	R(b • c)	T(+0)	T(-0)	R(b • c)	T(-∞)	T(c)	Xi: T(c*)
-0	Xi: T(dNaN)	T(+0)	T(+0)	T(-0)	T(-0)	Xi: T(dNaN)	T(c)	Xi: T(c*)
+0	Xi: T(dNaN)	T(-0)	T(-0)	T(+0)	T(+0)	Xi: T(dNaN)	T(c)	Xi: T(c*)
+Fn	T(-∞)	R(b • c)	T(-0)	T(+0)	R(b • c)	T(+∞)	T(c)	Xi: T(c*)
+∞	T(-∞)	T(-∞)	Xi: T(dNaN)	Xi: T(dNaN)	T(+∞)	T(+∞)	T(c)	Xi: T(c*)
QNaN	T(b)	T(b)	T(b)	T(b)	T(b)	T(b)	T(b)	Xi: T(c*)
SNaN	Xi: T(b*)	Xi: T(b*)	Xi: T(b*)	Xi: T(b*)	Xi: T(b*)	Xi: T(b*)	Xi: T(b*)	Xi: T(b*)

Explanation:

*	The SNaN is converted to the corresponding QNaN before it is placed at the target operand location.
dNaN	Default NaN.
Fn	Nonzero finite number (includes both subnormal and normal).
R(v)	Rounding and range action is performed on the value v. See Figure 20-5 on page 20-11. The result is canonical.
T(x)	The canonical result x is placed at the target operand location.
Xi:	IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.

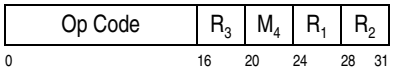
Figure 20-26. Results: MULTIPLY

mask bit in the FPC register is zero, in which case the result is the canonical QNaN derived from the second operand.

2. For MULTIPLY, when the delivered value is inexact, the preferred quantum is the smallest quantum which is the same quantum as that closest to the product of the quanta of the two source operands.

QUANTIZE

Mnemonic R_1,R_3,R_2,M_4 [RRF-b]



Mnemonic	Op Code	Operands
QADTR	'B3F5'	Long DFP
QAXTR	'B3FD'	Extended DFP

The third operand is rounded to a requested quantum, and the result is placed at the first-operand location.

The requested quantum is the quantum of the second operand.

When both the second and third operands are finite numbers, if the quantum of the third operand is equal to or larger than the requested quantum, the value of the third operand with the requested quantum is placed at the first-operand location. If the quantum of the third operand is smaller than the requested quantum, the third operand is rounded to the requested quantum by rounding as specified by the modifier in the M_4 field, and the result with the requested quantum is placed at the first-operand location.

M_4	Effective Rounding Method
0	According to the current DFP rounding mode
1	Round to nearest with ties away from 0
2	According to the current DFP rounding mode
3	Round to prepare for shorter precision
4	Round to nearest with ties to even
5	Round toward 0
6	Round toward +∞
7	Round toward -∞
8	Round to nearest with ties to even
9	Round toward 0
10	Round toward +∞
11	Round toward -∞
12	Round to nearest with ties away from 0
13	Round to nearest with ties toward 0
14	Round away from 0
15	Round to prepare for shorter precision

When the modifier field is zero, rounding is controlled by the current DFP rounding mode specified in the FPC register. When the field is 8-15, rounding is performed as specified by the modifier, regardless of the current DFP rounding mode.

When the floating-point extension facility is installed and if the modifier field is 2, rounding is controlled by the current DFP rounding mode specified in the FPC

register; if the field is 1, or 3-7, rounding is performed as specified by the modifier, regardless of the current DFP rounding mode. If the modifier field is 0 or 8-15, the quantum-exception control (XqC) is one and recognition of the quantum exception is suppressed; if the modifier field is 1-7, the quantum-exception control is zero and recognition of the exception is not suppressed.

When the floating-point extension facility is not installed, no quantum exception is recognized. If the M_4 modifier field is 1-7, it is unpredictable which rounding method is performed.

The sign of the result, if numeric, is the same as the sign of the third operand.

This operation performs a functionally-constrained rounding, and does not recognize an underflow exception. No overflow condition can occur.

The preferred quantum is the requested quantum. If the delivered value is a finite number, it is always represented with the preferred quantum.

The result placed at the first-operand location is canonical.

See Figure 20-27 on page 20-51 for a detailed description of the results of this instruction.

An invalid-operation exception is recognized when the resultant value cannot be represented in the target format with the requested quantum. When the invalid-operation exception is recognized, and if the exception is disabled, the result is the default QNaN.

An IEEE inexact exception is recognized when the result differs in value from the third operand,

When the floating-point extension facility is installed, if the quantum of the delivered finite number is not equal to the quantum of the third operand and if XqC is zero, then a quantum exception is recognized.

For QAXTR, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged*.*

IEEE Exceptions:

- Invalid operation
- Inexact
- Quantum (if the floating-point extension facility is installed)

Program Exceptions:

- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation (if the DFP facility is not installed)
- Specification (QAXTR only)
- Transaction constraint

When second operand (b) is	Result for QUANTIZE when third operand (c) is							
	-∞	-Fn	-0	+0	+Fn	+∞	QNaN	SNaN

SNaN	Xi: T(b*)	Xi: T(b*)	Xi: T(b*)	Xi: T(b*)	Xi: T(b*)	Xi: T(b*)	Xi: T(b*)	Xi: T(b*)

Explanation:

*	The SNaN is converted to the corresponding QNaN before it is placed at the target operand location.
dNaN	Default NaN.
E(0)	The value zero with the quantum of operand b is placed at the target operand location.
Fn	Finite nonzero number (includes both subnormal and normal).
Q(b:c)	See Figure 20-28.
T(x)	The canonical result x is placed at the target operand location.
Xi:	IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.

Figure 20-27. Results: QUANTIZE

Relation[1]	Is $\|Vc\| > (10^p - 1) \times 10^{Qb}$?	Result for Q(b:c)
$10^{Qb} < 10^{Qc}$	Yes	Xi: T(dNaN)
	No	L(c)
$10^{Qb} = 10^{Qc}$		T(c)
$10^{Qb} > 10^{Qc}$		Rq(c)

Explanation:

[1]	The quantum of the second operand and the third operand is 10^{Qb} and 10^{Qc}, respectively.
dNaN	Default NaN.
p	Format precision.
Qb	The right-units-view exponent of the second operand (b).
Qc	The right-units-view exponent of the third operand (c).
|Vc|	The absolute value of the third operand (c).
L(c)	The third operand (c) is represented with the requested quantum. The result is represented with the preferred quantum and is canonical.
Rq(c)	The third operand (c) is rounded to the requested quantum. The result is represented with the preferred quantum and is canonical.
T(x)	The canonical result x is placed at the target operand location. The result, when it is a finite number, is represented with the preferred quantum and is canonical.
Xi:	IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.

Figure 20-28. Results: Q(b:c)

Programming Notes:

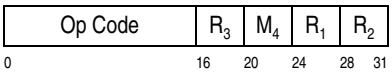
1. When the third operand is larger than $(10^p - 1) \times 10^{Qb}$ in magnitude, an invalid-operation exception is recognized, where p is the format precision and 10^{Qb} is the requested quantum.

   The expression, $(10^p - 1) \times 10^{Qb}$, specifies the largest magnitude that can be represented with the requested quantum in the format. A value larger than $(10^p - 1) \times 10^{Qb}$ in magnitude will have more than p digits when the value is represented with the requested quantum.

2. When both source operands are finite numbers, an invalid-operation exception can occur only if the requested quantum is smaller than the quantum of the third operand; and an inexact exception can occur only if the requested quantum is larger than the quantum of the third operand.

REROUND

Mnemonic R_1,R_3,R_2,M_4 [RRF-b]



Mnemonic	Op Code	Operands
RRDTR	'B3F7'	Long DFP
RRXTR	'B3FF'	Extended DFP

The third operand is rounded to the requested significance, and the result is placed at the first-operand location.

The requested significance, which specifies a number of DFP significant digits, is an unsigned binary integer and is in bit positions 58-63 of general register R_2. The contents of bit positions 0-57 of general register R_2 are ignored.

When the third operand is a finite number, if the requested significance is zero, then the value of the third operand with the original quantum is placed at the first-operand location.

When the third operand is a finite number, if the requested significance is nonzero, and if the number of DFP significant digits of the third operand is equal to or less than the requested significance, then the value of the third operand with the original quantum is placed at the first-operand location.

When the third operand is a finite number, if the requested significance is nonzero, and if the number of DFP significant digits of the third operand is greater than the requested significance, then the third operand is rounded to the requested significance, and the result with the requested significance is placed at the first-operand location.

The third operand is rounded to the requested significance by rounding as specified by the modifier in the M_4 field:

M_4	Effective Rounding Method
0	According to the current DFP rounding mode
1	Round to nearest with ties away from 0
2	According to the current DFP rounding mode
3	Round to prepare for shorter precision
4	Round to nearest with ties to even
5	Round toward 0
6	Round toward +∞
7	Round toward -∞
8	Round to nearest with ties to even
9	Round toward 0
10	Round toward +∞
11	Round toward -∞
12	Round to nearest with ties away from 0
13	Round to nearest with ties toward 0
14	Round away from 0
15	Round to prepare for shorter precision

When the modifier field is zero, rounding is controlled by the current DFP rounding mode specified in the FPC register. When the field is 8-15, rounding is performed as specified by the modifier, regardless of the current DFP rounding mode.

When the floating-point extension facility is installed and if the modifier field is 2, rounding is controlled by the current DFP rounding mode specified in the FPC register; if the field is 1, or 3-7, rounding is performed as specified by the modifier, regardless of the current DFP rounding mode. If the modifier field is 0 or 8-15, the quantum-exception control (XqC) is one and recognition of the quantum exception is suppressed; if the modifier field is 1-7, the quantum-exception control is zero and recognition of the exception is not suppressed.

When the floating-point extension facility is not installed, no quantum exception is recognized. If the M_4 modifier field is 1-7, it is unpredictable which rounding method is performed.

The sign of the result, if numeric, is the same as the sign of the third operand.

This operation performs a functionally-constrained rounding, and does not recognize an underflow exception. No overflow condition can occur.

When the delivered value is exact, if the requested significance is zero, or if the requested significance is nonzero and the number of DFP significant digits of the third operand is equal to or less than the requested significance, then the preferred quantum is the quantum of the third operand. When the delivered value is exact, if the requested significance is nonzero and the number of DFP significant digits of the third operand is greater than the requested significance, then the preferred quantum is the quantum that corresponds to the requested significance.

When the delivered value is inexact, the preferred quantum is the quantum that corresponds to the requested significance.

If the delivered value is a finite number, it is always represented with the preferred quantum.

The result placed at the first-operand location is canonical.

See Figure 20-29 for a detailed description of the results of this instruction.

Significance Comparison	Is $\|Rp(c)\| > (10^k-1) \times 10^{Qmax}$?	Results for REROUND when the Third Operand (c) is							
		-∞	-Fn	-0	+0	+Fn	+∞	QNaN	SNaN
k = 0	--	T(-∞)	T(c)	T(c)	T(c)	T(c)	T(+∞)	T(c)	Xi: T(c*)
k ≠ 0; k > m	--	T(-∞)	T(c)	T(c)	T(c)	T(c)	T(+∞)	T(c)	Xi: T(c*)
k ≠ 0; k = m	--	T(-∞)	T(c)	--	--	T(c)	T(+∞)	T(c)	Xi: T(c*)
k ≠ 0; k < m	No	T(-∞)	Rp(c)	--	--	Rp(c)	T(+∞)	T(c)	Xi: T(c*)
	Yes	T(-∞)	Xi:T(dNaN)	--	--	Xi:T(dNaN)	T(+∞)	T(c)	Xi: T(c*)

Explanation:

--	Not applicable.
*	The SNaN is converted to the corresponding QNaN and placed at the target operand location.
dNaN	Default NaN.
Fn	Nonzero finite numbers (includes both subnormal and normal).
k	The requested significance.
m	Number of DFP significant digits in the third operand (c).
Qmax	Maximum right-units-view exponent.
Rp(c)	The third operand (c) is rounded to the requested significance. The result is canonical and is represented with the preferred quantum.
|Rp(c)|	The absolute value of Rp(c).
T(x)	The canonical result x is placed at the target operand location. The result is canonical and, when it is a finite number, is represented with the preferred quantum.
Xi:	IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.

Figure 20-29. Results: REROUND

An invalid-operation exception is recognized when the resultant value cannot be represented in the target format with the requested significance. When the invalid-operation exception is recognized, and if the exception is disabled, the result is the default QNaN.

When an invalid-operation exception is recognized, the IEEE inexact exception is not recognized.

In the absence of an invalid-operation exception, if the result differs in value from the third operand, an IEEE inexact exception is recognized.

When the floating-point extension facility is installed, if the quantum of the delivered finite number is not equal to the quantum of the third operand and if XqC is zero, then a quantum exception is recognized.

For RRXTR, the R_1 and R_3 fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Invalid operation
- Inexact
- Quantum (if the floating-point extension facility is installed)

Program Exceptions:

- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation (if the DFP facility is not installed)
- Specification (RRXTR only)
- Transaction constraint

Programming Notes:

1. REROUND and the round-to-prepare-for-shorter-precision rounding method can be used to simulate a DFP operation with a precision other than any supported format precision and with the effect of single rounding. The round-to-prepare-for-shorter-precision rounding method is used by the operation, and the desirable round-

ing method is used by the subsequent REROUND instruction.

2. When the rounded intermediate value is larger than $(10^k - 1) \times 10^{Qmax}$ in magnitude, an invalid-operation exception is recognized, where k is the requested significance and 10^{Qmax} is the largest quantum for the format.

   The expression, $(10^k - 1) \times 10^{Qmax}$, specifies the largest magnitude that can be represented with the requested significance in the format. A value larger than $(10^p - 1) \times 10^{Qb}$ in magnitude will have a quantum larger than 10^{Qmax} when the value is represented with the requested significance.

SHIFT SIGNIFICAND LEFT

Mnemonic $R_1,R_3,D_2(X_2,B_2)$ [RXF]

Mnemonic	Op Code	Operands
SLDT	'ED40'	Long DFP
SLXT	'ED48'	Extended DFP

The significand of the third operand is shifted left the number of digits specified by the second-operand address, and the result is placed at the first-operand location.

Digits shifted out of the leftmost digit are lost. Zeros are supplied to the vacated positions on the right. The sign of the result is the same as the sign of the third operand.

For a finite number, all digits in the significand participate in the shift and the result is a finite number with the same biased exponent as the third operand and the shifted significand. For an infinity, all digits in the trailing significand participate in the shift, and the result is an infinity with the shifted trailing significand and a zero in the reserved field of the format. For a QNaN or SNaN, all digits in the payload participate in the shift and the result is a QNaN or SNAN, respectively, with the shifted payload and a zero in the reserved field of the format.

The second-operand address is not used to address data; its rightmost six bits indicate the number of digit positions to be shifted. The remainder of the address is ignored.

The preferred quantum is the quantum of the third operand. If the delivered value is a finite number, it is always represented with the preferred quantum.

The result placed at the first-operand location is canonical, except for infinity. When the result is an infinity, if all digits in the trailing significand of the result are zeros, then the result is canonical; otherwise, the result is an infinity that has the reserved field set to zero, canonical declets in the encoded trailing-significand field, and some nonzero digits in the trailing significand.

This operation is performed for any second operand, including an infinity, QNaN, or SNaN, without causing an IEEE exception.

For SLXT, the R_1 and R_3 fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions: None.

Program Exceptions:

- Data with DXC 3, DFP instruction
- Operation (if the DFP facility is not installed)
- Specification (SLXT only)
- Transaction constraint

Programming Note: Infinities produced as DFP results have the reserved field set to zero and have canonical declets in the encoded trailing-significand field. An infinity is not considered canonical unless all digits in the trailing significand are zeros.

SHIFT SIGNIFICAND RIGHT

Mnemonic $R_1,R_3,D_2(X_2,B_2)$ [RXF]

Mnemonic	Op Code	Operands
SRDT	'ED41'	Long DFP
SRXT	'ED49'	Extended DFP

The significand of the third operand is shifted right the number of digits specified by the second-operand address, and the result is placed at the first-operand location.

Digits shifted out of the rightmost digit are lost. Zeros are supplied to the vacated positions on the left. The sign of the result is the same as the sign of the third operand.

For a finite number, all digits in the significand participate in the shift and the result is a finite number with the same biased exponent as the third operand and the shifted significand. For an infinity, all digits in the trailing significand participate in the shift, and the result is an infinity with the shifted trailing significand and a zero in the reserved field of the format. For a QNaN or SNaN, all digits in the payload participate in the shift and the result is a QNaN or SNaN, respectively, with the shifted payload and a zero in the reserved field of the format.

The second-operand address is not used to address data; its rightmost six bits indicate the number of digit positions to be shifted. The remainder of the address is ignored.

The preferred quantum is the quantum of the third operand. If the delivered value is a finite number, it is always represented with the preferred quantum.

The result placed at the first-operand location is canonical, except for infinity. When the result is an infinity, if all digits in the trailing significand of the result are zeros, then the result is canonical; otherwise, the result is an infinity that has the reserved field set to zero, canonical declets in the encoded trailing-significand field, and some nonzero digits in the trailing significand.

This operation is performed for any second operand, including an infinity, QNaN, or SNaN, without causing an IEEE exception.

For SRXT, the R_1 and R_3 fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions: None.

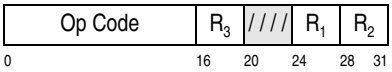
Program Exceptions:

- Data with DXC 3, DFP instruction
- Operation (if the DFP facility is not installed)
- Specification (SRXT only)
- Transaction constraint

Programming Note: Infinities produced as DFP results have the reserved field set to zero and have canonical declets in the encoded trailing-significand field. An infinity is not considered canonical unless all digits in the trailing significand are zeros.

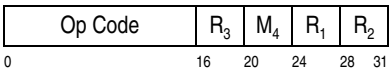
SUBTRACT

Mnemonic1 R_1,R_2,R_3 [RRF-a]



Mnemonic1	Op Code	Operands
SDTR	'B3D3'	Long DFP
SXTR	'B3DB'	Extended DFP

Mnemonic2 R_1,R_2,R_3,M_4 [RRF-a]



Mnemonic2	Op Code	Operands
SDTRA	'B3D3'	Long DFP
SXTRA	'B3DB'	Extended DFP

The third operand is subtracted from the second operand, and the difference is placed at the first-operand location.

The execution of SUBTRACT is identical to that of ADD, except that the third operand, if numeric, participates in the operation with its sign bit inverted. When the third operand is a NaN, it participates in the operation with its sign bit unchanged. See Figure 20-11 on page 20-21 for the detailed results of ADD.

When the delivered value is exact, the preferred quantum is the smaller quantum of the two source operands; when the delivered value is inexact, the preferred quantum is the smallest quantum.

The result placed at the first-operand location is canonical.

For SXTR and SXTRA, the R fields must designate valid floating-point-register pairs; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Result is zero
1 Result is less than zero
2 Result is greater than zero

3 Result is a NaN

IEEE Exceptions:

- Invalid operation
- Overflow
- Underflow
- Inexact
- Quantum (if the floating-point extension facility is installed)

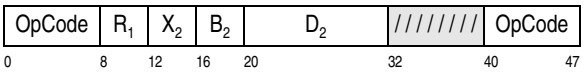
Program Exceptions:

- Data with DXC 3, DFP instruction
- Data with DXC for IEEE exception
- Operation (if the DFP facility is not installed)
- Specification (SXTR and SXTRA only)
- Transaction constraint

Programming Note: See the programming notes for ADD.

TEST DATA CLASS

Mnemonic $R_1,D_2(X_2,B_2)$ [RXE]



Mnemonic	*Op Code*	*Operands*
TDCET	'ED50'	Short DFP
TDCDT	'ED54'	Long DFP
TDCXT	'ED58'	Extended DFP

The class and sign of the first operand are examined to select one bit from the second-operand address. Condition code 0 or 1 is set according to whether the selected bit is zero or one, respectively.

The second-operand address is not used to address data; instead, the rightmost 12 bits of the address, bits 52-63, are used to specify 12 combinations of data class and sign. Bits 0-51 of the second-operand address are ignored.

As shown in Figure 20-30, DFP operands are divided into six classes: zero, subnormal, normal, infinity, quiet NaN, and signaling NaN:

One or more of the second-operand-address bits may be set to one. If the second-operand-address bit corresponding to the class and sign of the first operand is one, condition code 1 is set; otherwise, condition code 0 is set.

DFP data class	Bit used when sign is +	Bit used when sign is -
Zero	52	53
Subnormal	54	55
Normal	56	57
Infinity	58	59
Quiet NaN	60	61
Signaling NaN	62	63

Figure 20-30. Second-Operand-Address Bits for TEST DATA CLASS

Operands, including SNaNs and QNaNs, are examined without causing an IEEE exception.

For TDCXT, the R_1 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Selected bit is 0 (no match)
1 Selected bit is 1 (match)
2 --
3 --

IEEE Exceptions: None.

Program Exceptions:

- Data with DXC 3, DFP instruction
- Operation (if the DFP facility is not installed)
- Specification (TDCXT only)
- Transaction constraint

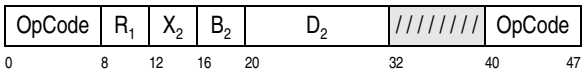
Programming Notes:

1. TEST DATA CLASS provides a way to test an operand without risk of an exception or setting the IEEE flags.

2. The bits used to specify the combinations of data class and sign are not all the same for BFP and DFP. Specifically, BFP TEST DATA CLASS uses bits 54 and 55 for normal number, and bits 56 and 57 for subnormal number.

TEST DATA GROUP

Mnemonic $R_1,D_2(X_2,B_2)$ [RXE]



Mnemonic	Op Code	Operands
TDGET	'ED51'	Short DFP
TDGDT	'ED55'	Long DFP
TDGXT	'ED59'	Extended DFP

The group and sign of the first operand are examined to select one bit from the second-operand address. Condition code 0 or 1 is set according to whether the selected bit is zero or one, respectively.

The second-operand address is not used to address data; instead, the rightmost 12 bits of the address, bits 52-63, are used to specify 12 combinations of data group and sign. Bits 0-51 of the second-operand address are ignored.

TEST DATA GROUP is used to determine whether a finite number is safe. A finite number is safe if the exponent is neither maximum nor minimum, and the leftmost significand digit is zero.

Figure 20-31 on page 20-58 shows the data groups and the bit assignment. There are six data groups: safe zero, zero with extreme exponent, nonzero with extreme exponent, safe nonzero, nonzero leftmost significand digit with nonextreme exponent, and special. The special group is defined for infinity and NaN. Depending on the model, subnormal with nonextreme exponent may be placed in the nonzero-with-extreme-exponent group or the safe-nonzero group.

One or more of the second-operand-address bits may be set to one. If the second-operand-address bit corresponding to the group and sign of the first operand is one, condition code 1 is set; otherwise, condition code 0 is set.

Operands, including SNaNs and QNaNs, are examined without causing an IEEE exception.

For TDGXT, the R_1 field must designate a valid floating-point-register pair; otherwise, a specification exception is recognized.

Resulting Condition Code:

0 Selected bit is 0 (no match)
1 Selected bit is 1 (match)
2 --
3 --

IEEE Exceptions: None.

Program Exceptions:

- Data with DXC 3, DFP instruction
- Operation (if the DFP facility is not installed)
- Specification (TDGXT only)
- Transaction constraint

Programming Notes:

1. TEST DATA GROUP provides a way to test an operand without risk of an exception or setting the IEEE flags.

2. TEST DATA GROUP can be issued after an operation that produces a DFP result to quickly determine if the result is safe. For DFP results that are finite numbers, the result is safe if using a wider data format by the operation would have produced the same value and quantum. A safe result has two important characteristics: (1) the exponent is neither the maximum exponent nor the minimum exponent, and (2) the leftmost significand digit is zero.

3. TEST DATA GROUP may be used to test whether a nonzero finite number is safe by setting bits 58 and 59 of the second-operand address to ones.

4. TEST DATA GROUP may be used to test whether a nonzero finite number has reached the limit of the format precision but not the limit of the format range by setting bits 60 and 61 of the second-operand address to ones.

5. Subnormal with nonextreme exponent may be grouped with either the nonzero-with-extreme-exponent group or the safe-nonzero group. The

program shouldn't depend on which group subnormal with nonextreme exponent is in.

DFP Operand	Exponent	LMD	Data Group	Bit used when sign is +	Bit used when sign is –
Zero	Nonextreme	z[1]	Safe zero	52	53
	Extreme	z[1]	Zero with extreme exponent	54	55
Nonzero finite	Extreme	--	Nonzero with extreme exponent	56	57
	Nonextreme	z	Safe nonzero	58	59
	Nonextreme	nz	Nonzero leftmost significand digit with nonextreme exponent	60	61
Infinity or NaN	na	na	Special	62	63

Explanation:

--	The result does not depend on this condition.
1	This condition is true by virtue of the condition to the left of this column.
Extreme	Maximum right-units-view (RUV) exponent, Qmax, or minimum right-units-view (RUV) exponent, Qmin.
Nonextreme	Qmax < right-units-view (RUV) exponent < Qmin.
LMD	Leftmost significand digit.
na	Not applicable.
nz	Nonzero.
z	Zero.

Figure 20-31. Second-Operand-Address Bits for TEST DATA GROUP

Densely Packed Decimal (DPD)

Decimal-to-DPD Mapping

The mapping of a 3-digit decimal number (000 - 999) to a 10-bit value, called a declet is shown in Figure 20-32 on page 20-59. The DPD entries are shown in hexadecimal. The first two digits of the decimal number are shown in the leftmost column and the third digit along the top row. The table is split into two halves, with the right half being a continuation of the left half.

DPD-to-Decimal Mapping

The mapping of the 10-bit declet to a 3-digit decimal number is shown in Figure 20-33 on page 20-60. The 10-bit declet value is split into a 6-bit index shown in the left column and a 4-bit index shown along the top row, both represented in hexadecimal. The values marked with an asterisk are results mapped from noncanonical declets and are explained further in section "Canonical Declets" on page 20-6.

Chapter 21. Vector Overview and Support Instructions

Overview 21-1
Vector Registers and Controls 21-2
  Vector Enablement Control 21-2
Vector Storage Accesses 21-2
Saturating Arithmetic 21-2
Instructions 21-2
  VECTOR BIT PERMUTE 21-5
  VECTOR BLEND 21-5
  VECTOR GATHER ELEMENT 21-6
  VECTOR GENERATE BYTE MASK 21-6
  VECTOR GENERATE ELEMENT MASKS . . 21-7
  VECTOR GENERATE MASK 21-7
  VECTOR LOAD 21-8
  VECTOR LOAD AND REPLICATE 21-8
  VECTOR LOAD BYTE REVERSED ELEMENT 21-9
  VECTOR LOAD BYTE REVERSED ELEMENT AND REPLICATE 21-9
  VECTOR LOAD BYTE REVERSED ELEMENT AND ZERO 21-10
  VECTOR LOAD BYTE REVERSED ELEMENTS 21-11
  VECTOR LOAD ELEMENT 21-11
  VECTOR LOAD ELEMENT IMMEDIATE . . 21-12
  VECTOR LOAD ELEMENTS REVERSED . 21-12
  VECTOR LOAD GR FROM VR ELEMENT . 21-13
  VECTOR LOAD LOGICAL ELEMENT AND ZERO 21-13
  VECTOR LOAD MULTIPLE 21-14
  VECTOR LOAD RIGHTMOST WITH LENGTH 21-15
  VECTOR LOAD TO BLOCK BOUNDARY . 21-15
  VECTOR LOAD VR ELEMENT FROM GR . 21-16
  VECTOR LOAD VR FROM GRS DISJOINT 21-16
  VECTOR LOAD WITH LENGTH 21-17
  VECTOR MERGE HIGH 21-17
  VECTOR MERGE LOW 21-17
  VECTOR PACK 21-18
  VECTOR PACK SATURATE 21-18
  VECTOR PACK LOGICAL SATURATE 21-19
  VECTOR PERMUTE 21-20
  VECTOR PERMUTE DOUBLEWORD IMMEDIATE 21-20

Overview

The vector facility provided in the z/Architecture architectural mode provides fixed-sized vectors ranging from one to sixteen elements. For most instructions, all of the data contained in a vector is operated on by the instructions defined in this facility. Some instructions only operate on a subset of the elements within a vector. If a vector is made up of multiple elements, each element is processed in parallel with the others. Instruction completion does not occur until processing of all elements is complete.

Vector Registers and Controls

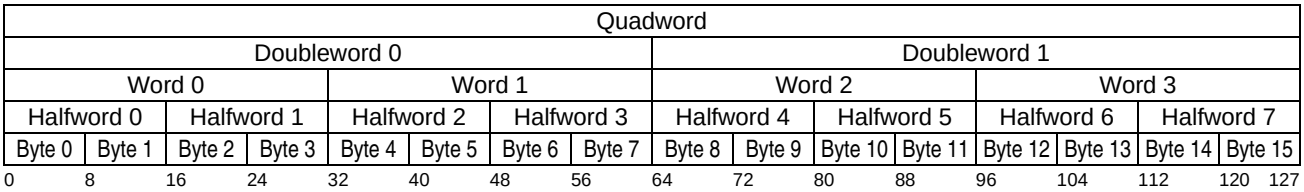

Figure 21-1. Vector Register Element Representations

A vector register with byte, halfword, word, doubleword or quadword size elements, contains 16, 8, 4, 2 or 1 elements of equal size respectively. When there are multiple elements in the vector register the elements are indexed from left to right starting at element zero.

Vector Enablement Control

The vector instructions should only be used if both the vector enablement control (bit 46) and the AFP-register-control (bit 45) in control register zero are set to one. If the vector facility for z/Architecture is installed and a vector instruction is executed without the vector enablement control set, a data exception with DXC FE hex is recognized. If bit 45 of control register zero is not also set to one, it is unpredictable if a data exception is recognized. If the vector facility for z/Architecture is not installed, an operation exception is recognized.

Programming Note: When a control program initially enables the vector facility for z/Architecture for a task, which may occur in response to a data exception with DXC FE, it should ensure that newly enabled full vector registers as well as the rightmost portions of vector registers that overlap with any enabled floating-point registers are zeroed.

Vector Storage Accesses

All vector data appears in storage in the same left-to-right sequence as all other data formats. Bits of a data format that are numbered 0-7 constitute the byte in the leftmost (lowest-numbered) byte location in storage, bits 8-15 form the byte in the next sequential location, and so on. (See also “Storage Addressing” on page 3-2.)

Saturating Arithmetic

Some vector operations perform saturating operations. Saturation for signed binary integers means that if there is an overflow, the result is set to the largest positive number; if there is an underflow, the result is set to the largest negative number. Saturation for unsigned binary integers means that if there is an overflow, the result is set to the largest representable number; if there is an underflow, the result is set to zero.

Instructions

All vector instructions, defined in chapters 21-25, have a field in bits 36-39 of the instruction labeled as RXB. This field contains the most significant bit for each of the vector register designated operands. Bits for register designations not specified by the instruction are reserved and should be set to zero; otherwise the program may not operate compatibly in the future.

The bits are defined as follows:

Bit	MSB of Vector Register in Instruction Bits
36	8-11
37	12-15
38	16-19
39	32-35

Programming Note: It is assumed that the assembler will set these bits whenever a vector register designation greater than 15 is specified.

Unless otherwise specified, all operands are vector-register operands. A “V” in the assembler syntax designates a vector operand.

Many instructions have an extended-mnemonic section which describes recommended extended mnemonics and their corresponding machine assembler syntax.

Programming Notes:

1. The assembler will set a bit of the RXB field to zero when the corresponding vector register of the instruction is specified as 0-15, and to one when the corresponding vector register is 16-31.

2. The vector-enhancements facility 2 provides the following additional instructions to handle load and store of elements or arrays of elements in the little endian format:

   - VECTOR LOAD BYTE REVERSED ELEMENTS (VLBR)
   - VECTOR LOAD ELEMENTS REVERSED (VLER)
   - VECTOR LOAD BYTE REVERSED ELEMENT AND ZERO (VLLEBRZ)
   - VECTOR LOAD BYTE REVERSED ELEMENT (VLEBRH, VLEBRF, VLEBRG)
   - VECTOR LOAD BYTE REVERSED ELEMENT AND REPLICATE (VLBRREP)
   - VECTOR STORE BYTE REVERSED ELEMENTS (VSTBR)
   - VECTOR STORE ELEMENTS REVERSED (VSTER)
   - VECTOR STORE BYTE REVERSED ELEMENT (VSTEBRH, VSTEBRF, VSTEBRG)

3. The vector-enhancements facility 3 provides the following additional instructions:

   - VECTOR BLEND (VBLEND)
   - VECTOR GENERATE ELEMENT MASKS (VGEM)

4. The vector-enhancements facility 3 adds support for doubleword elements to the following instructions:

   - VECTOR UNPACK HIGH (VUPH)
   - VECTOR UNPACK LOGICAL HIGH (VUPLH)
   - VECTOR UNPACK LOW (VUPL)
   - VECTOR UNPACK LOGICAL LOW (VUPLL)

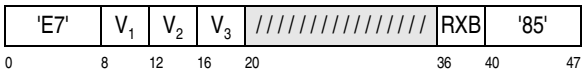
Figure 21-2. Summary of Vector Support Instructions (Part 3 of 3)

VECTOR BIT PERMUTE

VBPERM V_1,V_2,V_3 [VRR-c]



A source vector is created from the concatenation of the second operand followed by 128 binary zeros. The byte-sized elements of the third operand contain unsigned integers which are used to select bits from the source vector to create a halfword result which is placed in bits 48 to 63 of the first operand, other halfwords are set to zero. Each bit of the halfword result is selected from the source vector by the corresponding byte in the third operand.

If the same register is used to designate the first operand as either the second or third operands, the original source value is used throughout the operation with no intermediate updates.

Condition Code: The code remains unchanged.

Program Exceptions:

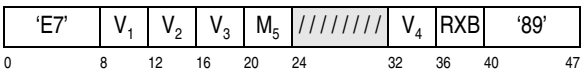
- Data with DXC FE, Vector Instruction
- Operation (if the vector-enhancements facility 1 is not installed)
- Transaction constraint

Programming Note: The fact that the source vector contains 128 bits of zeros following the second operand and permits the permuted bits to be selected from a 256-bit quantity using a single index register. Assume the 256-bit quantity is in vector registers 0 and 1, the indicies are in vector register 2, and each byte of vector register 3 contains the value 128. The following code sequence selects sixteen bits from the 256-bit quantity.

```
VBPERM   v4,v0,v2
VX       v2,v2,v3
VBPERM   v5,v1,v2
VO       v4,v4,v5
```

VECTOR BLEND

VBLEND V_1,V_2,V_3,V_4,M_5 [VRR-d]



For each element in the fourth operand, if bit 0 of the element is zero, the corresponding element from the third operand is placed in the corresponding element of the first operand; and if bit 0 of the element is one, the corresponding element from the second operand is placed in the corresponding element of the first operand. Fourth-operand element bits other than bit 0 are ignored.

The M_5 field specifies the element size control (ES). The ES control specifies the size of the elements in

the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_5	Element Size
0	Byte
1	Halfword
2	Word
3	Doubleword
4	Quadword
5-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

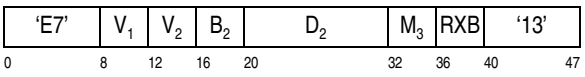
- Data with DXC FE, Vector Instruction
- Operation (if the vector-enhancements facility 3 is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

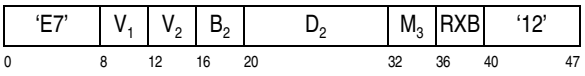
Extended Mnemonic	Base Mnemonic
VBLENDB V_1,V_2,V_3,V_4	VBLEND $V_1,V_2,V_3,V_4,0$
VBLENDH V_1,V_2,V_3,V_4	VBLEND $V_1,V_2,V_3,V_4,1$
VBLENDF V_1,V_2,V_3,V_4	VBLEND $V_1,V_2,V_3,V_4,2$
VBLENDG V_1,V_2,V_3,V_4	VBLEND $V_1,V_2,V_3,V_4,3$
VBLENDQ V_1,V_2,V_3,V_4	VBLEND $V_1,V_2,V_3,V_4,4$

VECTOR GATHER ELEMENT

VGEF $V_1,D_2(V_2,B_2),M_3$ [VRV]



VGEG $V_1,D_2(V_2,B_2),M_3$ [VRV]



The element-sized second operand replaces the specified element of the first operand indexed by the M_3 field. The remaining elements are left unchanged. If the M_3 field specifies a value greater than the highest numbered element in the first operand, of the specified element size, a specification exception is recognized.

For VGEF the elements in all operands are 4-bytes in size; for VGEG the elements in all operands are 8-bytes in size.

The second-operand address is generated by adding the unsigned binary integer value from the element in vector-register V_2 indexed by the M_3 field with the address in the B_2 register along with the D_2 value.

The displacement for VECTOR GATHER ELEMENT is treated as a 12-bit unsigned integer.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

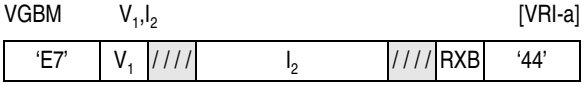
Programming Notes:

1. The VECTOR GATHER ELEMENT instruction can be used to perform a load when doing scalar computation in vector registers and the address resides in a vector register. However, depending on the model, performance may be better if address computations are done in general registers.

2. For VGEF care must be taken to ensure that the values in the second operand elements are unsigned. Otherwise, when running in 64-bit addressing mode program behavior might not be as expected.

VECTOR GENERATE BYTE MASK

VGBM V_1,I_2 [VRI-a]



For each bit in the second operand, if the bit is one, all bit positions in the corresponding byte element of the first operand are set to ones. If the bit is zero, all bit positions in the corresponding byte element of the first operand are set to zeros.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

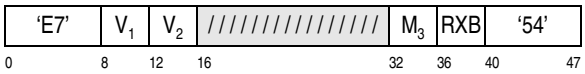
Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
VZERO	V_1	VGBM	V_1,0
VONE	V_1	VGBM	V_1,X'FFFF'

Programming Note: VECTOR GENERATE BYTE MASK is the preferred method for setting a vector register to all zeros or ones.

VECTOR GENERATE ELEMENT MASKS

VGEM V_1,V_2,M_3 [VRR-a]



The second operand contains a quadword element 0, the leftmost bits of which form a mask of bits corresponding to the elements of the first operand. For each bit of the mask; if the bit is one, all bit positions in the corresponding element of the first operand are set to ones; if the bit is zero, all bit positions in the corresponding element of the first operand are set to zeros.

The mask consists of bits from the quadword element 0 of the second operand where byte-size elements use bits 0-15, halfword-size elements use bits 0-7, word-size elements use bits 0-3, doubleword-size elements use bits 0-1, and quadword-size elements use bit 0. Bits other than leftmost bits consisting of mask bits of quadword element 0 of the second operand for the specified element size are ignored.

The M_3 field specifies the element size control (ES). The ES control specifies the size of the elements in the first operand. If a reserved value is specified, a specification exception is recognized.

M_3	Element Size	Mask Bits in V_2
0	Byte	0-15
1	Halfword	0-7
2	Word	0-3
3	Doubleword	0-1
4	Quadword	0
5-15	Reserved	N/A

Condition Code: The code remains unchanged.

Program Exceptions:

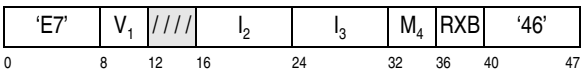
- Data with DXC FE, Vector Instruction
- Operation (if the vector-enhancements facility 3 is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
VGEMB	V_1,V_2	VGEM	V_1,V_2,0
VGEMH	V_1,V_2	VGEM	V_1,V_2,1
VGEMF	V_1,V_2	VGEM	V_1,V_2,2
VGEMG	V_1,V_2	VGEM	V_1,V_2,3
VGEMQ	V_1,V_2	VGEM	V_1,V_2,4

VECTOR GENERATE MASK

VGM V_1,I_2,I_3,M_4 [VRI-b]



For each element in the first operand a bit mask is generated. The mask consists of bits set to one starting at the bit position specified by the unsigned integer value in I_2 and ending with the bit position specified by the unsigned integer value in I_3 all other bit positions are set to zero. Only the number of bits needed to represent all of the bit positions for the specified element size are used from the I_2 and I_3 fields, other bits are ignored. If the bit position in the I_2 field is greater than the bit position in the I_3 field, the range of bits wraps at the maximum bit position for the specified element size.

The M_4 field specifies the element size control (ES). The ES control specifies the size of the elements in

the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_4	Element Size
0	Byte
1	Halfword
2	Word
3	Doubleword
4-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

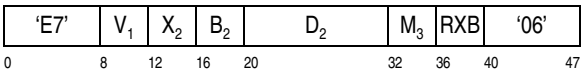
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

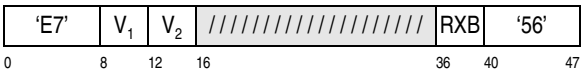
Extended Mnemonic		Base Mnemonic	
VGMB	V_1,I_2,I_3	VGM	$V_1,I_2,I_3,0$
VGMH	V_1,I_2,I_3	VGM	$V_1,I_2,I_3,1$
VGMF	V_1,I_2,I_3	VGM	$V_1,I_2,I_3,2$
VGMG	V_1,I_2,I_3	VGM	$V_1,I_2,I_3,3$

VECTOR LOAD

VL $V_1,D_2(X_2,B_2)[,M_3]$ [VRX]



VLR V_1,V_2 [VRR-a]



The 128-bit second operand is placed unchanged in the first-operand location.

The displacement for VL is treated as a 12-bit unsigned integer.

For VL the M_3 field contains a 4-bit unsigned binary integer specifying the alignment of the second operand. Reserved values should not be specified; otherwise, the program may not operate compatibly in the future.

M_3	Alignment Hint
0	No alignment indicated
1-2	Reserved
3	Doubleword aligned
4	Quadword aligned
5-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

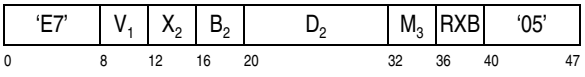
- Access (fetch, operand 2 for VL)
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

Programming Notes:

1. If the alignment of the address specified by the second operand is known to be either on a doubleword or quadword boundary and alignment hint is set to 3 or 4 respectively, performance may be improved on some models. If the alignment of the second operand is not on a doubleword or quadword boundary, or is unknown, the alignment hint should be set to 0.
2. Setting the alignment hint to a non-zero value that doesn't correspond to the alignment of the second operand may reduce performance on some models.

VECTOR LOAD AND REPLICATE

VLREP $V_1,D_2(X_2,B_2),M_3$ [VRX]



The element-sized second operand is replicated into all elements of the first operand.

The M_3 field specifies the element size control (ES). The ES control specifies the size of the elements in

the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_3	Element Size
0	Byte
1	Halfword
2	Word
3	Doubleword
4-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

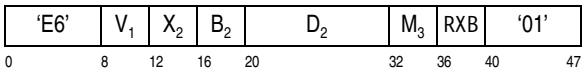
- Access (fetch, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

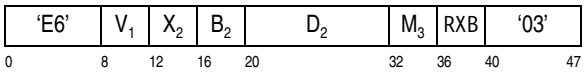
Extended Mnemonic		Base Mnemonic	
VLREPB	$V_1,D_2(X_2,B_2)$	VLREP	$V_1,D_2(X_2,B_2),0$
VLREPH	$V_1,D_2(X_2,B_2)$	VLREP	$V_1,D_2(X_2,B_2),1$
VLREPF	$V_1,D_2(X_2,B_2)$	VLREP	$V_1,D_2(X_2,B_2),2$
VLREPG	$V_1,D_2(X_2,B_2)$	VLREP	$V_1,D_2(X_2,B_2),3$

VECTOR LOAD BYTE REVERSED ELEMENT

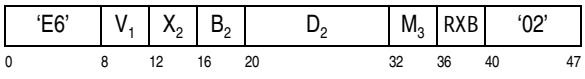
VLEBRH $V_1,D_2(X_2,B_2),M_3$ [VRX]



VLEBRF $V_1,D_2(X_2,B_2),M_3$ [VRX]



VLEBRG $V_1,D_2(X_2,B_2),M_3$ [VRX]



The element-sized second operand replaces the first-operand element, indexed by the M_3 field, with the left-to-right sequence of bytes reversed. The remaining elements are left unchanged. If the M_3 field specifies a value greater than the highest numbered element in the first operand, of the specified element size, a specification exception is recognized.

The displacement for VECTOR LOAD BYTE REVERSED ELEMENT is treated as a 12-bit unsigned integer.

For VLEBRH the elements are halfword sized. For VLEBRF the elements are word sized. For VLEBRG the elements are doubleword sized.

Condition Code: The code remains unchanged.

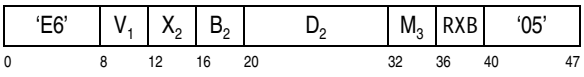
Program Exceptions:

- Access (fetch, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector enhancements facility 2 is not installed)
- Specification
- Transaction constraint

Programming Note: No byte-sized element are supported by this instruction as the result would be same as VLEB.

VECTOR LOAD BYTE REVERSED ELEMENT AND REPLICATE

VLBRREP $V_1,D_2(X_2,B_2),M_3$ [VRX]



The element-sized second operand is loaded and replicated into all elements of the first operand with the left-to-right sequence of bytes reversed within the elements.

The M_3 field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_3	Element Size
0	Reserved
1	Halfword
2	Word
3	Doubleword
4-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

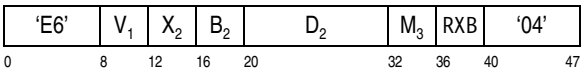
- Access (fetch, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector enhancements facility 2 is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic	Base Mnemonic
VLBRREPH $V_1,D_2(X_2,B_2)$	VLBRREP $V_1,D_2(X_2,B_2),1$
VLBRREPF $V_1,D_2(X_2,B_2)$	VLBRREP $V_1,D_2(X_2,B_2),2$
VLBRREPG $V_1,D_2(X_2,B_2)$	VLBRREP $V_1,D_2(X_2,B_2),3$

VECTOR LOAD BYTE REVERSED ELEMENT AND ZERO

VLLEBRZ $V_1,D_2(X_2,B_2),M_3$ [VRX]



An element, of the size specified by the M_3 field, is loaded from the second-operand location in storage and placed into an element in the first-operand vector register, with the left-to-right sequence of bytes reversed within that element. When the M_3 value is in the range 1-3, the unsigned element-sized second operand is placed in the rightmost sub-element or element of the leftmost doubleword element of the vector-register specified first operand with the left-to-right sequence of the bytes reversed. When the M_3 value is 6 the unsigned 4-byte second operand is placed in word 0 of the vector-register specified first operand, with its byte order reversed.

The displacement for VLLEBRZ is treated as a 12-bit unsigned integer.

The M_3 field specifies the size of the element to be loaded. If a reserved value is specified, a specification exception is recognized.

M_3	Element Size
0	Reserved
1	Halfword
2	Word
3	Doubleword
4-5	Reserved
6	Word - Left Aligned
7-15	Reserved

The illustration below shows the resulting register content of this instruction:

Operand 2[a]

0	1	[2]	[3]	[[4]]	[[5]]	[[6]]	[[7]]

Operand 1[b]

M_3=3	7	6	5	4	3	2	1	0	Z	Z	Z	Z	Z	Z	Z	Z
M_3=2	Z	Z	Z	Z	3	2	1	0	Z	Z	Z	Z	Z	Z	Z	Z
M_3=1	Z	Z	Z	Z	Z	Z	1	0	Z	Z	Z	Z	Z	Z	Z	Z
M_3=6	3	2	1	0	Z	Z	Z	Z	Z	Z	Z	Z	Z	Z	Z	Z

a. only the number of bytes corresponding to the element size specified by M_3 are accessed.
b. a 'Z' in the table denotes a byte with the value of zero.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector enhancements facility 2 is not installed)
- Specification
- Transaction constraint

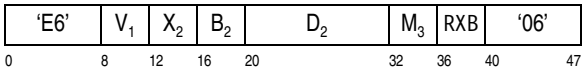
Extended Mnemonics:

Extended Mnemonic	Base Mnemonic
VLLEBRZH $V_1,D_2(X_2,B_2)$	VLLEBRZ $V_1,D_2(X_2,B_2),1$
VLLEBRZF $V_1,D_2(X_2,B_2)$	VLLEBRZ $V_1,D_2(X_2,B_2),2$
VLLEBRZG $V_1,D_2(X_2,B_2)$	VLLEBRZ $V_1,D_2(X_2,B_2),3$
VLLEBRZE $V_1,D_2(X_2,B_2)$	VLLEBRZ $V_1,D_2(X_2,B_2),6$
LDRV $V_1,D_2(X_2,B_2)$	VLLEBRZ $V_1,D_2(X_2,B_2),3$
LERV $V_1,D_2(X_2,B_2)$	VLLEBRZ $V_1,D_2(X_2,B_2),6$

Programming Note: This instruction is similar to VECTOR LOAD LOGICAL ELEMENT AND ZERO but is useful for operating on data in storage in the little endian format.

VECTOR LOAD BYTE REVERSED ELEMENTS

VLBR $V_1,D_2(X_2,B_2),M_3$ [VRX]



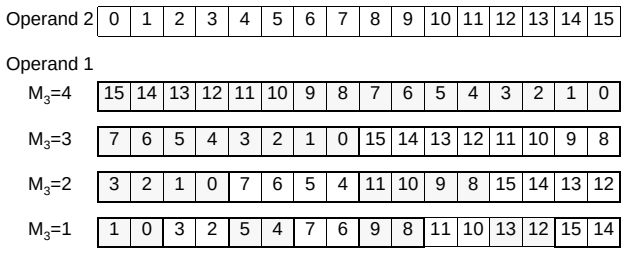
The 16-byte second operand is loaded into the first-operand location. For each element of the second operand, the left-to-right sequence of the bytes is reversed and placed into the corresponding first-operand element location.

The displacement for VLBR is treated as a 12-bit unsigned integer.

The M_3 field specifies the size of the element to be loaded. If a reserved value is specified, a specification exception is recognized.

M_3	Element Size
0	Reserved
1	Halfword
2	Word
3	Doubleword
4	Quadword
5-15	Reserved

The illustration below shows the resulting byte position of this instruction:



Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector enhancements facility 2 is not installed)
- Specification
- Transaction constraint

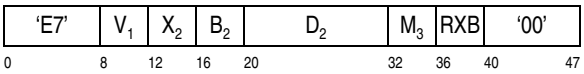
Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
VLBRH	$V_1,D_2(X_2,B_2)$	VLBR	$V_1,D_2(X_2,B_2),1$
VLBRF	$V_1,D_2(X_2,B_2)$	VLBR	$V_1,D_2(X_2,B_2),2$
VLBRG	$V_1,D_2(X_2,B_2)$	VLBR	$V_1,D_2(X_2,B_2),3$
VLBRQ	$V_1,D_2(X_2,B_2)$	VLBR	$V_1,D_2(X_2,B_2),4$

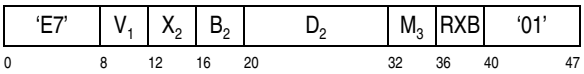
Programming Note: This instruction is similar to the VECTOR LOAD but is useful for operating on data in storage in the little endian format.

VECTOR LOAD ELEMENT

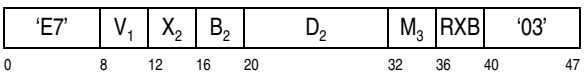
VLEB $V_1,D_2(X_2,B_2),M_3$ [VRX]



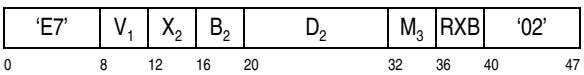
VLEH $V_1,D_2(X_2,B_2),M_3$ [VRX]



VLEF $V_1,D_2(X_2,B_2),M_3$ [VRX]



VLEG $V_1,D_2(X_2,B_2),M_3$ [VRX]



The element-sized second operand replaces the specified element of the first operand indexed by the M_3 field. The remaining elements are left unchanged. If the third operand specifies a value greater than the highest numbered element in the first operand, of the specified element size, a specification exception is recognized.

The displacement for VECTOR LOAD ELEMENT is treated as a 12-bit unsigned integer.

For VLEB the elements are byte sized. For VLEH the elements are halfword sized. For VLEF the elements are word sized. For VLEG the elements are doubleword sized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Programming Note: For VLEB a specification is not recognized since the third operand cannot designate an index greater than the number of elements.

VECTOR LOAD ELEMENT IMMEDIATE

VLEIB V_1,I_2,M_3 [VRI-a]

VLEIH V_1,I_2,M_3 [VRI-a]

VLEIF V_1,I_2,M_3 [VRI-a]

VLEIG V_1,I_2,M_3 [VRI-a]

The signed binary integer second operand is sign extended, if necessary, and replaces the specified element of the first operand. The remaining elements are left unchanged. The M_3 field specifies the element index of the first operand for the second operand to replace. For VLEIB, only bits 8-15 of the second operand are placed into the byte element; bits 0-7 are ignored. If the third operand specifies a value greater than the highest numbered element in the first operand, of the specified element size, a specification exception is recognized.

For VLEIB the elements are byte sized. For VLEIH the elements are halfword sized. For VLEIF the elements are word sized. For VLEIG the elements are doubleword sized.

Condition Code: The code remains unchanged.

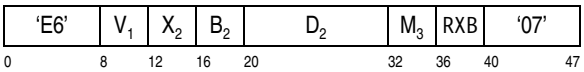
Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Programming Note: For VLEIB a specification is not recognized since the third operand cannot designate an index greater than the number of elements.

VECTOR LOAD ELEMENTS REVERSED

VLER $V_1,D_2(X_2,B_2),M_3$ [VRX]



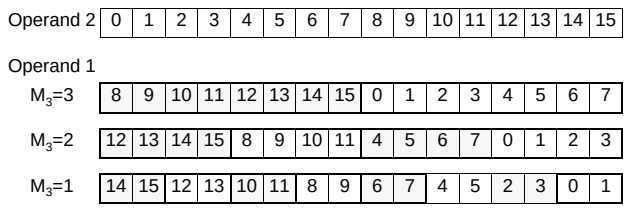
The 16-byte second operand is loaded into the first-operand location. The left-to-right sequence of the elements is reversed when loading into the vector register. The bytes within the elements themselves are not reversed.

The displacement for VLER is treated as a 12-bit unsigned integer.

The M_3 field specifies the size of the element to be loaded. If a reserved value is specified, a specification exception is recognized.

M_3	Element Size
0	Reserved
1	Halfword
2	Word
3	Doubleword
4-15	Reserved

The illustration below shows the resulting byte position of this instruction:



Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector enhancements facility 2 is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
VLERH	$V_1,D_2(X_2,B_2)$	VLER	$V_1,D_2(X_2,B_2),1$
VLERF	$V_1,D_2(X_2,B_2)$	VLER	$V_1,D_2(X_2,B_2),2$
VLERG	$V_1,D_2(X_2,B_2)$	VLER	$V_1,D_2(X_2,B_2),3$

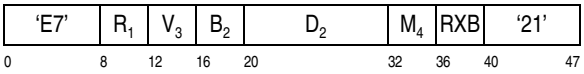
Programming Notes:

1. VECTOR LOAD BYTE REVERSED ELEMENTS with an M_3 value of 4 can be used to reverse the elements when the elements are byte-sized.

2. This instruction is useful in the context of large precision arithmetic.

VECTOR LOAD GR FROM VR ELEMENT

VLGV $R_1,V_3,D_2(B_2),M_4$ [VRS-c]



The element of the third operand indexed by the second-operand address is placed in the first-operand location. The third operand is a vector register. The first operand is a general register. If the index specified by the second-operand address is greater than the highest numbered element in the third operand, of the specified element size, the result in the first operand is unpredictable.

If the vector register element is smaller than a doubleword, the element is right aligned in the 64-bit general register and zeros fill the remaining bits.

The second-operand address is not used to address data; instead the rightmost 12 bits of the address are used to specify the index of an element within the third operand.

The M_4 field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_4	Element Size
0	Byte
1	Halfword
2	Word
3	Doubleword
4-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

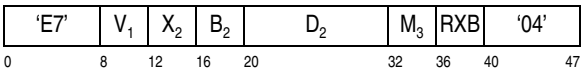
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
VLGVB	$R_1,V_3,D_2(B_2)$	VLGV	$R_1,V_3,D_2(B_2),0$
VLGVH	$R_1,V_3,D_2(B_2)$	VLGV	$R_1,V_3,D_2(B_2),1$
VLGVF	$R_1,V_3,D_2(B_2)$	VLGV	$R_1,V_3,D_2(B_2),2$
VLGVG	$R_1,V_3,D_2(B_2)$	VLGV	$R_1,V_3,D_2(B_2),3$

VECTOR LOAD LOGICAL ELEMENT AND ZERO

VLLEZ $V_1,D_2(X_2,B_2),M_3$ [VRX]



When the M_3 value is in the range of 0-3, the unsigned element-sized second operand is placed in the rightmost sub-element or element of the leftmost doubleword element of the vector-register specified first operand. When the vector-enhancements facility 1 is installed and the M_3 value is 6 the unsigned element-sized second operand is placed in the leftmost sub-element of the leftmost doubleword element of the vector-register specified first operand. The bit positions of all other elements are set to zero. The element size is determined by the ES value in the M_3 field.

The displacement for VLLEZ is treated as a 12-bit unsigned binary integer.

The M_3 field specifies the element size control (ES). The ES control specifies the size of the element in the vector register operands. If a reserved value is specified, a specification exception is recognized. When the vector-enhancements facility 1 is not installed the M_3 value of 6 is also reserved.

M_3	Element Size
0	Byte
1	Halfword
2	Word
3	Doubleword
4-5	Reserved
6	Word - Left Aligned
7-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

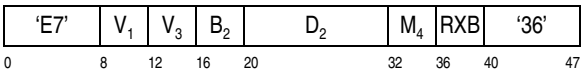
Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
VLLEZB	$V_1,D_2(X_2,B_2)$	VLLEZ	$V_1,D_2(X_2,B_2),0$
VLLEZH	$V_1,D_2(X_2,B_2)$	VLLEZ	$V_1,D_2(X_2,B_2),1$
VLLEZF	$V_1,D_2(X_2,B_2)$	VLLEZ	$V_1,D_2(X_2,B_2),2$
VLLEZG	$V_1,D_2(X_2,B_2)$	VLLEZ	$V_1,D_2(X_2,B_2),3$
VLLEZLF	$V_1,D_2(X_2,B_2)$	VLLEZ	$V_1,D_2(X_2,B_2),6$

Programming Note: This instruction can be used for loading scalar values into vector registers.

VECTOR LOAD MULTIPLE

VLM $V_1,V_3,D_2(B_2)[,M_4]$ [VRS-a]



The set of vector registers starting with the first operand vector register designation and ending with the third operand vector register designation are loaded from storage beginning at the location specified by the second-operand address and continuing through as many locations as needed.

The vector registers are loaded in ascending order of their register numbers starting with the first operand vector register designation and continuing up to and including the third operand vector register designation. If the third operand vector register designation is less than the first operand vector register designation, a specification exception is recognized. The number of registers to be loaded is at most sixteen. If a range of more than sixteen registers is specified, a specification exception is recognized.

The displacement for VLM is treated as a 12-bit unsigned binary number.

The M_4 field contains a 4-bit unsigned binary integer specifying the alignment of the second operand. Reserved values should not be specified; otherwise, the program may not operate compatibly in the future.

M_4	Alignment Hint
0	No alignment indicated
1-2	Reserved
3	Doubleword aligned
4	Quadword aligned
5-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Programming Notes:

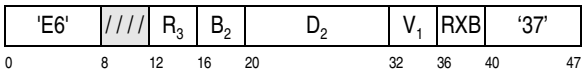
1. If the first operand vector register designation and the third operand vector register designation specify the same vector register only 16-bytes are loaded.
2. If the alignment of the address specified by the second operand is known to be either on a doubleword or quadword boundary and alignment hint is set to 3 or 4 respectively, performance may be improved on some models. If the align-

ment of the second operand is not on a doubleword or quadword boundary, or is unknown, the alignment hint should be set to 0.

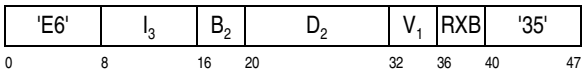
3. Setting the alignment hint to a non-zero value that doesn't correspond to the alignment of the second operand may reduce performance on some models.

VECTOR LOAD RIGHTMOST WITH LENGTH

VLRLR $V_1,R_3,D_2(B_2)$ [VRS-d]



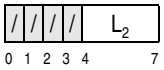
VLRL $V_1,D_2(B_2),I_3$ [VSI]



Proceeding from left to right, the specified number of bytes from the second-operand location are placed in the first operand location.

For VLRLR, bits 32-63 of the general-register specified third operand contain an unsigned integer value that when subtracted from fifteen represents the index of the first byte of the vector register to load. If the third operand contains a value greater than or equal to fifteen, all bytes of the first operand are loaded. Bits 0-31 of the third operand are ignored.

For VLRL, the I_3 field has the following format:



The bits of the I_3 field are defined as follows:

- ***Reserved:*** Bits 0-3 are reserved and must contain zeros. Otherwise, a specification exception is recognized.
- ***Operand 2 Length Code(L2):*** Bits 4-7 contain an unsigned integer value that when subtracted from fifteen represents the index of the first byte of the vector register to load. If the L_2 field contains a value equal to fifteen, all bytes of the first operand are loaded.

Zeros are placed in any bytes of the first operand that are not loaded from the second operand. Access exceptions are only recognized for the bytes of the second operand that are loaded from storage.

The displacement is a 12-bit unsigned integer.

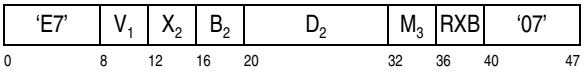
Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector-packed-decimal facility for z/Architecture is not installed)
- Specification (VLRL only)
- Transaction constraint

VECTOR LOAD TO BLOCK BOUNDARY

VLBB $V_1,D_2(X_2,B_2),M_3$ [VRX]



The single vector-register first operand is loaded starting at the zero indexed byte element with bytes from the second operand. If a boundary condition is encountered, the rest of the first operand is unpredictable. Access exceptions are not recognized for second-operand locations beyond the specified boundary. If no boundary is encountered, all byte elements of the first operand are loaded with data from storage.

The displacement for VLBB is treated as a 12-bit unsigned integer.

The M_3 field specifies a code indicating the boundary at which the second operand ends. If a reserved value is specified, a specification exception is recognized.

Code	Boundary
0	64 Byte
1	128 Byte
2	256 Byte
3	512 Byte

Code	Boundary
4	1 K-byte
5	2 K-Byte
6	4 K-Byte
7-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

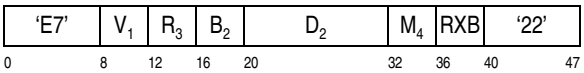
- Access (fetch, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. In certain circumstances, data may be loaded past the block boundary. However, this will only occur if there are no access exceptions on that data. The program should not depend on the unpredictable data being loaded by a particular model.
2. This instruction can be used for loading null-terminated character data without crossing a page, segment, or region boundary unnecessarily.
3. If a block size code equal to the cache line size of the processor is specified, performance may be improved due to the fact that subsequent accesses will be aligned.
4. The LOAD COUNT TO BLOCK BOUNDARY instruction may be used with the same specified boundary to obtain a count of the number of bytes loaded.

VECTOR LOAD VR ELEMENT FROM GR

VLVG $V_1,R_3,D_2(B_2),M_4$ [VRS-b]



The third operand of size specified by the ES value in the M_4 field is placed into the element of the first operand indexed by the second-operand address. The third operand is a general register. The first operand is a vector register. If the index, specified by the second-operand address, is greater than the highest numbered element in the first operand, of the specified element size, it is unpredictable which element, if any, is replaced.

For element sizes less than doubleword the rightmost bits of the third operand are used.

The second operand is not used to address data; instead the rightmost 12 bits of the address are used to specify the index of an element within the first operand.

The M_4 field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_4	Element Size
0	Byte
1	Halfword
2	Word
3	Doubleword
4-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

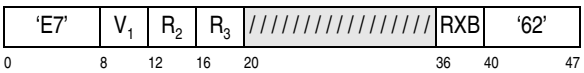
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
VLVGB	$V_1,R_3,D_2(B_2)$	VLVG	$V_1,R_3,D_2(B_2),0$
VLVGH	$V_1,R_3,D_2(B_2)$	VLVG	$V_1,R_3,D_2(B_2),1$
VLVGF	$V_1,R_3,D_2(B_2)$	VLVG	$V_1,R_3,D_2(B_2),2$
VLVGG	$V_1,R_3,D_2(B_2)$	VLVG	$V_1,R_3,D_2(B_2),3$

VECTOR LOAD VR FROM GRS DISJOINT

VLVGP V_1,R_2,R_3 [VRR-f]



The general register specified second operand is placed unchanged into bit positions 0-63 of the first operand. The general register specified third operand is placed unchanged into bit positions 64-127 of the first operand.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

VECTOR LOAD WITH LENGTH

VLL $V_1,R_3,D_2(B_2)$ [VRS-b]

Proceeding from left to right, bytes of the first operand are loaded from the second-operand location. The third operand (in bits 32-63 of general register R_3) contains a 32-bit unsigned integer that represents the highest indexed byte to load. If the third operand contains a value greater than or equal to the highest byte index of the vector, all bytes of the first operand are loaded. Zeros are placed in any bytes that are not loaded.

Access exceptions are only recognized for the bytes of the second operand that are loaded from storage.

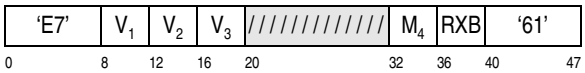
Condition Code: The code remains unchanged.

Program Exceptions:

- Access (fetch, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

VECTOR MERGE HIGH

VMRH V_1,V_2,V_3,M_4 [VRR-c]



Proceeding from left to right, the elements in the leftmost half of the second operand are placed into the even indexed elements of the first operand. Proceeding from left to right, the elements in the leftmost half of the third operand are placed into the odd indexed elements of the first operand. The elements in the low order half of the second and third operands are ignored.

If the same register is used to designate the first operand as either the second or third operands the source value is used throughout the operation with no intermediate updates.

The M_4 field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_4	**Element Size**
0	Byte
1	Halfword
2	Word
3	Doubleword
4-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		**Base Mnemonic**	
VMRHB	V_1,V_2,V_3	VMRH	$V_1,V_2,V_3,0$

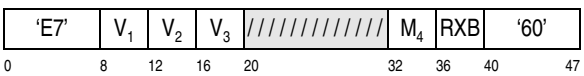
VMRHG	V_1,V_2,V_3	VMRH	$V_1,V_2,V_3,3$

VECTOR MERGE LOW

VMRL V_1,V_2,V_3,M_4 [VRR-c]



Proceeding from left to right, the elements in the rightmost half of the second operand are placed into the even indexed elements of first operand. Proceeding from left to right, the elements in the rightmost half of the third operand are placed into the odd indexed elements of the first operand. The elements in the high order half of the second and third operands are ignored.

If the same register is used to designate the first operand as either the second or third operands the source value is used throughout the operation with no intermediate updates.

The M_4 field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_4	Element Size
0	Byte
1	Halfword
2	Word
3	Doubleword
4-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

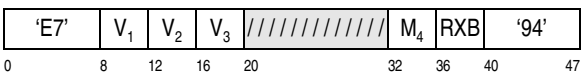
VMRLF	V_1,V_2,V_3	VMRL	$V_1,V_2,V_3,2$
VMRLG	V_1,V_2,V_3	VMRL	$V_1,V_2,V_3,3$

VECTOR PACK

VPK V_1,V_2,V_3,M_4 [VRR-c]



A source vector is created from the concatenation of the vector register-specified second operand followed by the vector-register-specified third operand. In a left to right fashion, each element in the source vector is reduced in size by half. The rightmost half of each element of the source vector is placed into the corresponding element of the vector-register-specified first operand.

If the same register is used to designate the first operand as either the second or third operands the source value is used throughout the operation with no intermediate updates.

The M_4 field specifies the element size control (ES). The ES control specifies the size of the elements in the second and third operands. The first operand contains elements half the size of those specified by the ES control. If a reserved value is specified, a specification exception is recognized.

M_4	Element Size
0	Reserved
1	Halfword
2	Word
3	Doubleword
4-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

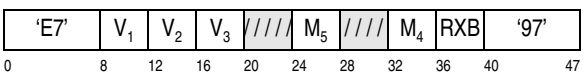
VECTOR PACK SATURATE

VPKS V_1V_2,V_3,M_4,M_5 [VRR-b]



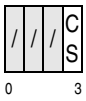
A source vector is created from the concatenation of the second operand followed by the third operand. In a left to right fashion each signed element in the source vector is reduced in size by half and placed in the corresponding element of the first operand. If the element in the source vector is outside of the allowable range of the target element, the target element is set to the maximum value in the target format in the direction of the overflow.

If the same register is used to designate the first operand as either the second or third operands, the original source value is used throughout the operation with no intermediate updates.

The M_4 field specifies the element size control (ES). The ES control specifies the size of the elements in the second and third operands. The first operand contains elements half the size of those specified by the ES control. If a reserved value is specified, a specification exception is recognized.

M_4	Element Size
0	Reserved
1	Halfword
2	Word
3	Doubleword
4-15	Reserved

The M_5 field has the following format:



The bits of the M_5 field are defined as follows:

- ***Reserved:*** Bits 0, 1, and 2 are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.
- ***Condition Code Set (CS):*** If bit 3 is 0, the code remains unchanged. If the bit is one, the code is set as described below.

Resulting Condition Code: When bit 3 of the M_5 field is one, the condition code is set as follows:

0 No saturation
1 At least one but not all elements saturated
2 --
3 Saturation on all elements

When bit 3 of the M_5 field is zero, the code remains unchanged.

Program Exceptions:

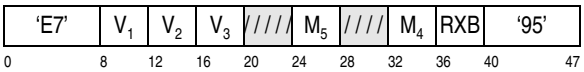
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
VPKSH	V_1,V_2,V_3	VPKS	$V_1,V_2,V_3,1,0$
VPKSF	V_1,V_2,V_3	VPKS	$V_1,V_2,V_3,2,0$
VPKSG	V_1,V_2,V_3	VPKS	$V_1,V_2,V_3,3,0$
VPKSHS	V_1,V_2,V_3	VPKS	$V_1,V_2,V_3,1,1$
VPKSFS	V_1,V_2,V_3	VPKS	$V_1,V_2,V_3,2,1$
VPKSGS	V_1,V_2,V_3	VPKS	$V_1,V_2,V_3,3,1$

VECTOR PACK LOGICAL SATURATE

VPKLS V_1V_2,V_3,M_4,M_5 [VRR-b]



A source vector is created from the concatenation of the second operand followed by the third operand. In a left to right fashion, each unsigned integer element in the source vector is reduced in size by half and placed in the corresponding element in the first operand. If the magnitude of the element in the source vector is greater than the largest magnitude representable in the target element, the target element is set to the largest representable magnitude value.

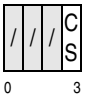
If the same register is used to designate the first operand as either the second or third operands, the original source value is used throughout the operation with no intermediate updates.

The M_4 field specifies the element size control (ES). The ES control specifies the size of the elements in the second and third operands. The first operand contains elements half the size of those specified by

the ES control. If a reserved value is specified, a specification exception is recognized.

M_4	Element Size
0	Reserved
1	Halfword
2	Word
3	Doubleword
4-15	Reserved

The M_5 field has the following format:



The bits of the M_5 field are defined as follows:

- ***Reserved:*** Bits 0, 1, and 2 are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.
- ***Condition Code Set (CS):*** If bit 3 is 0, the code remains unchanged. If the bit is one, the code is set as described below.

Resulting Condition Code: When bit 3 of the M_5 field is one, the condition code is set as follows:

0 No saturation
1 At least one but not all elements saturated
2 --
3 Saturation on all elements

When bit 3 of the M_5 field is zero, the code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
VPKLSH	V_1,V_2,V_3	VPKLS	$V_1,V_2,V_3,1,0$
VPKLSF	V_1,V_2,V_3	VPKLS	$V_1,V_2,V_3,2,0$

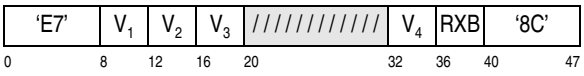
VECTOR PERMUTE

VPERM V_1,V_2,V_3,V_4 [VRR-e]



A source vector is created from the concatenation of the second operand followed by the third operand. The byte element of the source vector indexed by the five least significant bits of each byte element of the fourth operand is placed into the byte element of the first operand corresponding to the byte element in the fourth operand.

If the same register is used to designate the first operand as either the second, third, or fourth operands the original source value is used throughout the operation with no intermediate updates.

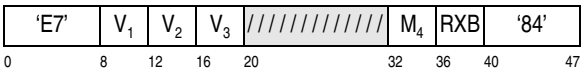
Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

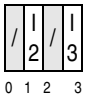
VECTOR PERMUTE DOUBLEWORD IMMEDIATE

VPDI V_1V_2,V_3,M_4 [VRR-c]



The first, second and third operands consist of double word elements. Bit 1 of the M_4 field is the index which selects which doubleword of the second operand is placed into the zero indexed doubleword of the first operand. Bit 3 of the M_4 field is the index which selects which doubleword of the third operand is placed in the doubleword element with index one of the first operand.

The M_4 field has the following format:



The bits of the M_4 field are defined as follows:

- ***Reserved:*** Bits 0 and 2 are reserved and should be zeros; otherwise, the program may not operate compatibly in the future.
- ***Second Operand Index (I2):*** Bit 1 provides the index of the doubleword in the second operand to be placed in the first operand.
- ***Third operand index (I3):*** Bit 3 provides the index of the doubleword in the third operand to be placed in the first operand.

If the same register is used to designate the first operand as either the second or third operands, the original source value is used throughout the operation with no intermediate updates.

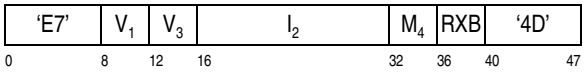
Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

VECTOR REPLICATE

VREP V_1,V_3,I_2,M_4 [VRI-c]



The element of the third operand indexed by the unsigned integer in I_2 is replicated across all elements of the first operand. If the value of the unsigned integer in I_2 is greater than the highest element number in the third operand, of the specified element size, a specification exception is recognized.

The M_4 field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_4	Element Size
0	Byte
1	Halfword
2	Word
3	Doubleword
4-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

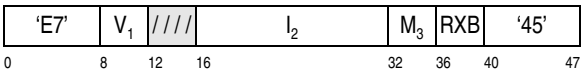
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
VREPB	V_1,V_3,I_2	VREP	$V_1,V_3,I_2,0$
VREPH	V_1,V_3,I_2	VREP	$V_1,V_3,I_2,1$
VREPF	V_1,V_3,I_2	VREP	$V_1,V_3,I_2,2$
VREPG	V_1,V_3,I_2	VREP	$V_1,V_3,I_2,3$

VECTOR REPLICATE IMMEDIATE

VREPI V_1,I_2,M_3 [VRI-a]



The signed integer immediate value in I_2 is sign extended, if necessary, and replicated across all elements of the first operand. If the element size is less than a halfword, only bits 8 through 15 of the I_2 field are used; bits zero through seven are ignored.

The M_3 field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_3	Element Size
0	Byte
1	Halfword
2	Word
3	Doubleword
4-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

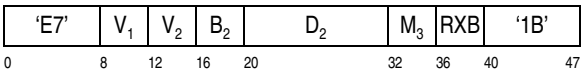
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

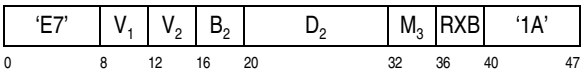
Extended Mnemonic		Base Mnemonic	
VREPIB	V_1,I_2	VREPI	$V_1,I_2,0$
VREPIH	V_1,I_2	VREPI	$V_1,I_2,1$
VREPIF	V_1,I_2	VREPI	$V_1,I_2,2$
VREPIG	V_1,I_2	VREPI	$V_1,I_2,3$

VECTOR SCATTER ELEMENT

VSCEF $V_1,D_2(V_2,B_2),M_3$ [VRV]



VSCEG $V_1,D_2(V_2,B_2),M_3$ [VRV]



The element of the first operand designated by the M_3 field is placed unchanged into the second-operand location. If the third operand specifies a value greater than the highest numbered element in the first operand, of the specified element size, a specification exception is recognized.

For VSCEF the elements are 4-bytes in size; for VSCEG the elements are 8-bytes in size.

The second-operand address is generated by adding the unsigned binary integer value from the element in vector-register V_2 indexed by the M_3 field with the address in the B_2 register along with the D_2 value.

The displacement for VECTOR SCATTER ELEMENT is treated as a 12-bit unsigned integer.

Condition Code: The code remains unchanged.

Program Exceptions:

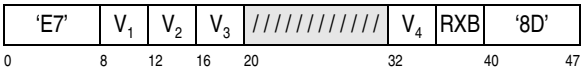
- Access (store, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Programming Notes:

1. The VECTOR SCATTER ELEMENT instruction can be used to perform a store when doing scalar computation in vector registers and the address resides in a vector register. However, depending on the model, performance may be better if address computations are done in general registers.
2. For VSCEF care must be taken to ensure that the values in the second operand elements are unsigned. Otherwise, when running in 64-bit addressing mode program behavior might not be as expected.

VECTOR SELECT

VSEL V_1,V_2,V_3,V_4 [VRR-e]



For each bit in the fourth operand that contains a zero, the corresponding bit from the third operand is placed in the corresponding bit of the first operand. For each bit in the fourth operand that contains a one, the corresponding bit from the second operand is placed in the corresponding bit of the first operand.

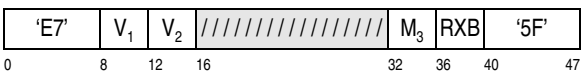
Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

VECTOR SIGN EXTEND TO DOUBLEWORD

VSEG V_1,V_2,M_3 [VRR-a]



The leftmost bit of the rightmost element-sized subelement of each doubleword of the second operand is replicated across all bit positions of all other elements in the doubleword. The result is placed in the corresponding doubleword of the first operand.

The M_3 field specifies the element size control (ES). The ES control specifies the size of the element in each doubleword of the second operand. If a reserved value is specified, a specification exception is recognized.

M_3	Element Size
0	Byte
1	Halfword
2	Word
3-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
VSEGB	V_1,V_2	VSEG	$V_1,V_2,0$
VSEGH	V_1,V_2	VSEG	$V_1,V_2,1$
VSEGF	V_1,V_2	VSEG	$V_1,V_2,2$

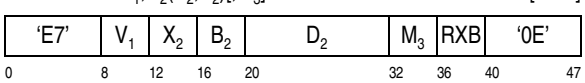
Programming Notes:

1. This instruction allows for a value to be sign extended after being loaded with VECTOR LOAD LOGICAL ELEMENT AND ZERO.

2. To sign extend to smaller element sizes the VECTOR UNPACK instructions can be used.

VECTOR STORE

VST $V_1,D_2(X_2,B_2)[,M_3]$ [VRX]



The 128-bit value in the first operand is stored to the storage location specified by the second operand.

The displacement for VST is treated as a 12-bit unsigned integer.

The M_3 field specifies an alignment hint (AH). The AH control specifies the alignment of the first byte of the second operand. Reserved values should not be specified; otherwise, the program may not operate compatibly in the future.

M_3	Alignment Hint
0	No alignment indicated
1-2	Reserved
3	Doubleword aligned
4	Quadword aligned
5-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

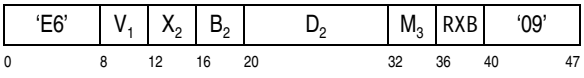
Programming Notes:

1. If the alignment of the address specified by the second operand is known to be either on a doubleword or quadword boundary and alignment hint is set to 3 or 4 respectively, performance may be improved on some models. If the alignment of the second operand is not on a doubleword or quadword boundary, or is unknown, the alignment hint should be set to 0.

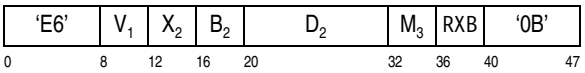
2. Setting the alignment hint to a non-zero value that doesn't correspond to the alignment of the second operand may reduce performance on some models.

VECTOR STORE BYTE REVERSED ELEMENT

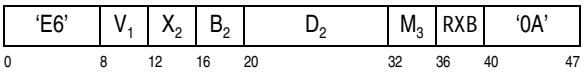
VSTEBRH $V_1,D_2(X_2,B_2),M_3$ [VRX]



VSTEBRF $V_1,D_2(X_2,B_2),M_3$ [VRX]



VSTEBRG $V_1,D_2(X_2,B_2),M_3$ [VRX]



The first-operand element, indexed by the M_3 field, is stored into the element-sized second-operand. The left-to-right sequence of bytes within the elements is reversed when storing into the storage location. If the M_3 field specifies a value greater than the highest numbered element in the first operand, of the specified element size, a specification exception is recognized.

The displacement for VECTOR STORE BYTE REVERSED ELEMENT is treated as a 12-bit unsigned integer.

For VSTEBRH the elements are halfword sized. For VSTEBRF the elements are word sized. For VSTEBRG the elements are doubleword sized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector enhancements facility 2 is not installed)
- Specification
- Transaction constraint

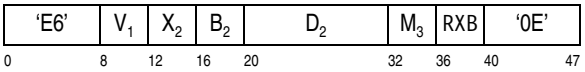
Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
STERV	$V_1,D_2(X_2,B_2)$	VSTEBRF	$V_1,D_2(X_2,B_2),0$
STDRV	$V_1,D_2(X_2,B_2)$	VSTEBRG	$V_1,D_2(X_2,B_2),0$

Programming Note: No byte-sized element version of this instruction exists as it would deliver the same result as VSTEB.

VECTOR STORE BYTE REVERSED ELEMENTS

VSTBR $V_1,D_2(X_2,B_2),M_3$ [VRX]



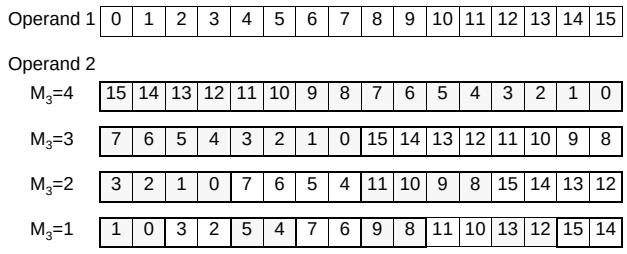
The first operand is stored into the 16-bytes second operand. For each element of the first operand, the left-to-right sequence of bytes is reversed as that element is placed into the corresponding element of the 16-byte storage.

The displacement for VSTBR is treated as a 12-bit unsigned integer.

The M_3 field specifies the size of the element to be stored. If a reserved value is specified, a specification exception is recognized.

M_3	Element Size
0	Reserved
1	Halfword
2	Word
3	Doubleword
4	Quadword
5-15	Reserved

The illustration below shows the resulting byte position of this instruction:



Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector enhancements facility 2 is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
VSTBRH	$V_1,D_2(X_2,B_2)$	VSTBR	$V_1,D_2(X_2,B_2),1$
VSTBRF	$V_1,D_2(X_2,B_2)$	VSTBR	$V_1,D_2(X_2,B_2),2$
VSTBRG	$V_1,D_2(X_2,B_2)$	VSTBR	$V_1,D_2(X_2,B_2),3$
VSTBRQ	$V_1,D_2(X_2,B_2)$	VSTBR	$V_1,D_2(X_2,B_2),4$

Programming Note: This instruction is similar to the VECTOR STORE but is useful for operating on data in storage in the little endian format.

VECTOR STORE ELEMENT

VSTEB $V_1,D_2(X_2,B_2),M_3$ [VRX]

VSTEH $V_1,D_2(X_2,B_2),M_3$ [VRX]

VSTEF $V_1,D_2(X_2,B_2),M_3$ [VRX]

VSTEG $V_1,D_2(X_2,B_2),M_3$ [VRX]

The element of the first operand designated by the M_3 field is placed unchanged into the second-operand location. If the third operand specifies a value greater than the highest numbered element in the first operand, of the specified element size, a specification exception is recognized. For VSTEB a specification is not recognized since the third operand cannot designate an index greater than the number of elements.

The displacement for VECTOR STORE ELEMENT is treated as a 12-bit unsigned integer.

For VSTEB the elements are byte sized. For VSTEH the elements are halfword sized. For VSTEF the elements are word sized. For VSTEG the elements are doubleword sized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

VECTOR STORE ELEMENTS REVERSED

VSTER $V_1,D_2(X_2,B_2),M_3$ [VRX]

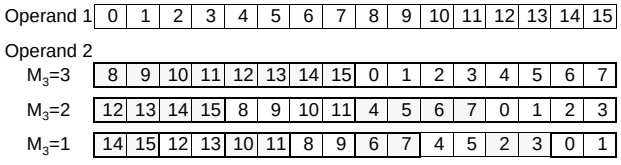
The first operand is stored into the 16-byte second operand. The left-to-right sequence of the elements is reversed when storing into the storage location.

The displacement for VSTER is treated as a 12-bit unsigned integer.

The M_3 field specifies the size of the element to be stored. If a reserved value is specified, a specification exception is recognized.

M_3	Element Size
0	Reserved
1	Halfword
2	Word
3	Doubleword
4-15	Reserved

The illustration below shows the resulting byte position of this instruction:



Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)
- Data with DXC FE, Vector Instruction

- Operation (if the vector enhancements facility 2 is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
VSTERH	$V_1,D_2(X_2,B_2)$	VSTER	$V_1,D_2(X_2,B_2),1$
VSTERF	$V_1,D_2(X_2,B_2)$	VSTER	$V_1,D_2(X_2,B_2),2$
VSTERG	$V_1,D_2(X_2,B_2)$	VSTER	$V_1,D_2(X_2,B_2),3$

Programming Notes:

1. VECTOR STORE BYTE REVERSED ELEMENTS with an M_3 value of 4 can be used to reverse the elements when the elements are byte-sized.
2. This instruction is useful in the context of large precision arithmetic.

VECTOR STORE MULTIPLE

VSTM $V_1,V_3,D_2(B_2)[,M_4]$ [VRS-a]

The set of vector registers starting with the first operand vector register designation and ending with the third operand vector register designation are placed in the storage area beginning at the location specified by the second-operand address and continuing through as many locations as needed.

The contents of bit positions 0-127 of the vector registers are stored in successive 16-byte fields beginning at the second-operand address.

The vector registers are stored in the ascending order of their register numbers, starting with the first operand vector register designation and continuing up to and including the third operand vector register designation. If the third operand vector register designation is less than the first operand vector register designation, a specification exception is recognized. The number of registers to be stored is at most sixteen. If a range of more than sixteen registers is specified, a specification exception is recognized.

The displacement for VSTM is treated as a 12-bit unsigned binary number.

The M_4 field specifies an alignment hint (AH). The AH control specifies the alignment of the first byte of the second operand. Reserved values should not be specified; otherwise, the program may not operate compatibly in the future.

M_4	Alignment Hint
0	No alignment indicated
1-2	Reserved
3	Doubleword aligned
4	Quadword aligned
5-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

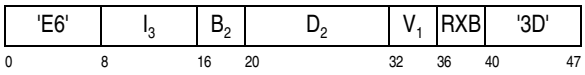
Programming Notes:

1. If the first operand vector register designation and the third operand vector register designation specify the same vector register only 16-bytes are stored.
2. If the alignment of the address specified by the second operand is known to be either on a doubleword or quadword boundary and alignment hint is set to 3 or 4 respectively, performance may be improved on some models. If the alignment of the second operand is not on a doubleword or quadword boundary, or is unknown, the alignment hint should be set to 0.
3. Setting the alignment hint to a non-zero value that doesn't correspond to the alignment of the second operand may reduce performance on some models.

VECTOR STORE RIGHTMOST WITH LENGTH

VSTRLR $V_1,R_3,D_2(B_2)$ [VRS-d]

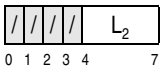
VSTRL $V_1,D_2(B_2),I_3$ [VSI]



Proceeding from left to right, the specified number of rightmost bytes from the first operand are stored at the second-operand location.

For VSTRLR, bits 32-63 of the general register specified third operand contain an unsigned integer value that when subtracted from fifteen represents the index of the first byte of the vector register to store. If the third operand contains a value greater than or equal to fifteen, all bytes of the first operand are stored. Bits 0-31 of the third operand are ignored.

For VSTRL, the I_3 field has the following format:



The bits of the I_3 field are defined as follows:

- ***Reserved:*** Bits 0-3 are reserved and must contain zeros. Otherwise, a specification exception is recognized.
- ***Operand 2 Length Code(L2):*** Bits 4-7 contain an unsigned integer value that when subtracted from fifteen represents the index of the first byte of the vector register to store. If the L_2 field contains a value equal to fifteen, all bytes of the first operand are stored.

Access exceptions are only recognized on bytes stored.

The displacement is treated as a 12-bit unsigned integer.

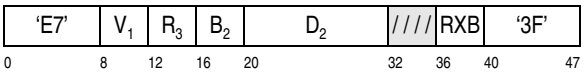
Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector-packed-decimal facility for z/Architecture is not installed)
- Specification (VSTRL only)
- Transaction constraint

VECTOR STORE WITH LENGTH

VSTL $V_1,R_3,D_2(B_2)$ [VRS-b]



Proceeding from left to right, bytes from the first operand are stored at the second-operand location. Bits 32-63 of the general register specified third operand contain a 32-bit unsigned integer containing a value that represents the highest indexed byte to store. If the third operand contains a value greater than or equal to the highest byte index of the vector, all bytes of the first operand are stored.

Access exceptions are only recognized on bytes stored.

The displacement for VECTOR STORE WITH LENGTH is treated as a 12-bit unsigned integer.

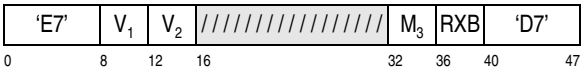
Condition Code: The code remains unchanged.

Program Exceptions:

- Access (store, operand 2)
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

VECTOR UNPACK HIGH

VUPH V_1V_2,M_3 [VRR-a]



The elements of the leftmost half of the vector-register second operand are sign extended and placed into double-sized elements in the first operand. The rightmost half of the second operand are ignored.

If the same register is used to designate the first operand as the second operand the original source value is used throughout the operation with no intermediate updates.

The M_3 field specifies the element size control (ES). The ES control specifies the size of the elements in the second operand. The first operand contains elements twice the size of those specified by the ES

control. If a reserved value is specified, a specification exception is recognized. When the vector-enhancements facility 3 is not installed, the M_3 value of 3 is also reserved.

M_3	Element Size
0	Byte
1	Halfword
2	Word
3	Doubleword
4-15	Reserved

Condition Code: The code remains unchanged.

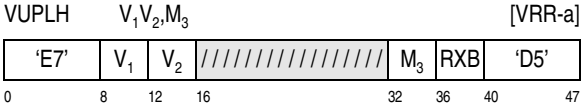
Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
VUPHB	V_1,V_2	VUPH	$V_1,V_2,0$
VUPHH	V_1,V_2	VUPH	$V_1,V_2,1$
VUPHF	V_1,V_2	VUPH	$V_1,V_2,2$
VUPHG	V_1,V_2	VUPH	$V_1,V_2,3$

VECTOR UNPACK LOGICAL HIGH



The elements of the leftmost half of the second operand are zero extended and placed into double-sized elements in the first operand. The rightmost half of the second operand is ignored.

If the same register is used to designate the first operand as the second operand the original source value is used throughout the operation with no intermediate updates.

The M_3 field specifies the element size control (ES). The ES control specifies the size of the elements in the second operand. The first operand contains elements double the size of those specified in the ES control. If a reserved value is specified, a specification exception is recognized. When the vector-enhancements facility 3 is not installed, the M_3 value of 3 is also reserved.

M_3	Element Size
0	Byte
1	Halfword
2	Word
3	Doubleword
4-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Integer Divide Exception Handling

The vector instructions recognize an integer divide exception as described in “Vector-Exception Code”

© Copyright IBM Corp. 2000, 2025

on page 6-20 which are subject to additional control fields in the vector instruction that can mask reporting. When a vector instruction is executed and an integer divide exception condition is recognized, instruction execution is suppressed for all elements, except that the floating-point-control register is updated with the VXC. The index in the VXC is always the index of the source element that caused the exception. If vector-processing exception conditions exist for multiple elements, the exception of the lowest-indexed source element is recognized.

Instructions

Many instructions have an extended mnemonic section which describe recommended extended mnemonics and their corresponding machine assembler syntax.

Unless otherwise specified all operands are vector-register operands. A “V” in the assembler syntax designates a vector operand.

Programming Notes:

1. The vector-enhancements facility 2 provides the following shift features:

   - The following additional instructions are provided:
     – VECTOR SHIFT LEFT DOUBLE BY BIT (VSLD)
     – VECTOR SHIFT RIGHT DOUBLE BY BIT (VSRD)
   - The behavior for different per byte element shift amount has been defined for the following instrucctions:
     – VECTOR SHIFT LEFT (VSL)
     – VECTOR SHIFT RIGHT LOGICAL (VSRL)

2. The vector-enhancements facility 3 provides the following additional instructions:

   - VECTOR DIVIDE (VD)
   - VECTOR DIVIDE LOGICAL (VDL)
   - VECTOR EVALUATE (VEVAL)
   - VECTOR REMAINDER (VR)
   - VECTOR REMAINDER LOGICAL (VRL)

3. The vector-enhancements facility 3 adds support for doubleword elements to the following instructions:

   - VECTOR MULTIPLY AND ADD EVEN (VMAE)
   - VECTOR MULTIPLY AND ADD LOGICAL EVEN (VMALE)
   - VECTOR MULTIPLY AND ADD ODD (VMAO)
   - VECTOR MULTIPLY AND ADD LOGICAL ODD (VMALO)
   - VECTOR MULTIPLY EVEN (VME)
   - VECTOR MULTIPLY LOGICAL EVEN (VMLE)
   - VECTOR MULTIPLY ODD (VMO)
   - VECTOR MULTIPLY LOGICAL ODD (VMLO)

4. The vector-enhancements facility 3 adds support for doubleword and quadword elements to the following instructions:

   - VECTOR MULTIPLY AND ADD LOW (VMAL)
   - VECTOR MULTIPLY AND ADD HIGH (VMAH)
   - VECTOR MULTIPLY AND ADD LOGICAL HIGH (VMALH)
   - VECTOR MULTIPLY HIGH (VMH)
   - VECTOR MULTIPLY LOGICAL HIGH (VMLH)
   - VECTOR MULTIPLY LOW (VML)

5. The vector-enhancements facility 3 adds support for quadword elements to the following instructions:

   - VECTOR AVERAGE (VAVG)
   - VECTOR AVERAGE LOGICAL (VAVGL)
   - VECTOR ELEMENT COMPARE (VEC)
   - VECTOR ELEMENT COMPARE LOGICAL (VECL)
   - VECTOR COMPARE EQUAL (VCEQ)
   - VECTOR COMPARE HIGH (VCH)
   - VECTOR COMPARE HIGH LOGICAL (VCHL)
   - VECTOR COUNT LEADING ZEROS (VCLZ)
   - VECTOR COUNT TRAILING ZEROS (VCTZ)
   - VECTOR LOAD COMPLEMENT (VLC)
   - VECTOR LOAD POSITIVE (VLP)
   - VECTOR MAXIMUM (VMX)
   - VECTOR MAXIMUM LOGICAL (VMXL)
   - VECTOR MINIMUM (VMN)
   - VECTOR MINIMUM LOGICAL (VMNL)

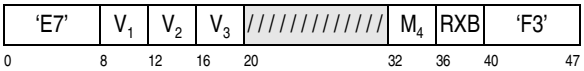
Explanation:

¤7	Restricted from transactional execution when the effective allow-floating-point-operation control is zero.
¤9	Restricted in the constrained transactional-execution mode; a transaction-constraint program exception may be recognized.
C	Condition code set.
C*	Condition code optionally set.
Dv	Vector-instruction data exception
SP	Specification exception.
V1	Vector-enhancements facility 1
V2	Vector-enhancements facility 2
V3	Vector-enhancements facility 3
VF	Vector facility for z/Architecture
VRI	VRI instruction format
VRR	VRR instruction format
VRS	VRS instruction format
Xd	Integer divide vector-processing exception.

Figure 22-1. Summary of Vector Integer Instructions (Part 2 of 2)

VECTOR ADD

VA V_1,V_2,V_3,M_4 [VRR-c]



The contents of each element of the second operand are added to the contents of each corresponding element of the third operand and the resulting sum or sums are placed in the first operand. Each element is treated as a signed binary integer of size specified by the element size control in the M_4 field.

When there is an overflow, the result is obtained by allowing any carry into the sign-bit position and ignoring any carry out of the sign-bit position.

No fixed point overflow exceptions are recognized.

The M_4 field specifies the element size control (ES). The ES control specifies the size of the element or elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_4	Element Size
0	Byte
1	Halfword
2	Word
3	Doubleword
4	Quadword
5-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

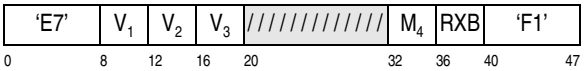
Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
VAB	V_1,V_2,V_3	VA	$V_1,V_2,V_3,0$
VAH	V_1,V_2,V_3	VA	$V_1,V_2,V_3,1$
VAF	V_1,V_2,V_3	VA	$V_1,V_2,V_3,2$
VAG	V_1,V_2,V_3	VA	$V_1,V_2,V_3,3$
VAQ	V_1,V_2,V_3	VA	$V_1,V_2,V_3,4$

Programming Note: The same results are obtained if the contents of each element contain unsigned binary integers.

VECTOR ADD COMPUTE CARRY

VACC V_1,V_2,V_3,M_4 [VRR-c]



The contents of each element of the second operand are added to the contents of each corresponding element of the third operand. If the addition of two elements results in a carry out of bit zero, a value of one is placed in the corresponding element of the first operand. If there is no carry out of bit zero, a value of zero is placed in the corresponding element of the first operand. Each element is treated as an unsigned binary integer of size specified by the element size in the M_4 field.

The M_4 field specifies the element size control (ES). The ES control specifies the size of the element or elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_4	Element Size
0	Byte
1	Halfword
2	Word
3	Doubleword
4	Quadword
5-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

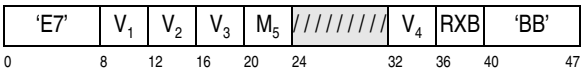
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
VACCB	V_1,V_2,V_3	VACC	$V_1,V_2,V_3,0$
VACCH	V_1,V_2,V_3	VACC	$V_1,V_2,V_3,1$
VACCF	V_1,V_2,V_3	VACC	$V_1,V_2,V_3,2$
VACCG	V_1,V_2,V_3	VACC	$V_1,V_2,V_3,3$
VACCQ	V_1,V_2,V_3	VACC	$V_1,V_2,V_3,4$

VECTOR ADD WITH CARRY

VAC V_1,V_2,V_3,V_4,M_5 [VRR-d]



The contents of the second operand are added to the third operand to form an intermediate quadword sum. Subsequently, the rightmost bit of the fourth operand

concatenated with 127 bits of zero on its left are added to the intermediate sum and the resulting sum is placed in the first operand. All bits except for the rightmost bit position of the fourth operand are ignored. Each operand is treated as a 128-bit unsigned binary integer.

When there is an overflow, the result is obtained by allowing any carry into the leftmost-bit position and ignoring any carry out of the leftmost-bit position.

No fixed point overflow exceptions are recognized.

The M_5 field must contain a value of 4; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

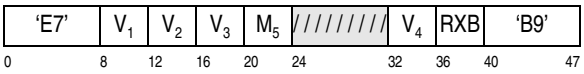
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
VACQ	V_1,V_2,V_3,V_4	VAC	$V_1,V_2,V_3,V_4,4$

VECTOR ADD WITH CARRY COMPUTE CARRY

VACCC V_1,V_2,V_3,V_4,M_5 [VRR-d]



The contents of the second operand are added to the third operand to form an intermediate quadword sum. Subsequently, the rightmost bit of the fourth operand concatenated with 127 bits of zero on its left are added to the intermediate sum. All bits except for the rightmost bit position of the fourth operand are ignored. If the addition results in a carry out of the leftmost bit, a value of one is placed in the first operand. If there is no carry out of the leftmost bit, a value of zero is placed in the first operand. Each operand is treated as a 128-bit unsigned binary integer.

The M_5 field must contain a value of 4; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

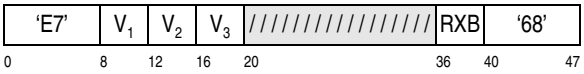
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
VACCCQ	V_1,V_2,V_3,V_4	VACCC	$V_1,V_2,V_3,V_4,4$

VECTOR AND

VN V_1,V_2,V_3 [VRR-c]



The AND of the second and third operands is placed in the first operand.

The connective AND is applied to the operands bit by bit. The contents of a bit position in the result are set to one if the corresponding bit positions in both operand contain ones; otherwise, the result bit is set to zero.

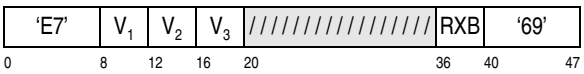
Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

VECTOR AND WITH COMPLEMENT

VNC V_1,V_2,V_3 [VRR-c]



The AND of the second operand and the bit-wise complement of the third operand is placed in the first operand.

The connective AND is applied to the second operand and bit-wise complemented third operand bit by bit. The contents of a bit position in the result are set to one if the corresponding bit positions in the second operand contains a one and the third operand contains a zero; otherwise, the result bit is set to zero.

Condition Code: The code remains unchanged.

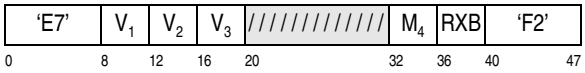
Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

Programming Note: This instruction is useful for zeroing out bits under a mask.

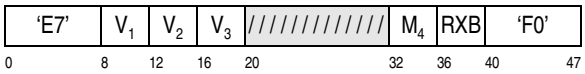
VECTOR AVERAGE

VAVG V_1,V_2,V_3,M_4 [VRR-c]



VECTOR AVERAGE LOGICAL

VAVGL V_1,V_2,V_3,M_4 [VRR-c]



The average of the corresponding elements of the second and third operands is placed in the corresponding element of the first operand.

For VECTOR AVERAGE, each element of the second operand and the corresponding element of the third operand are sign extended by one bit. The elements are then added together along with an additional value of one. The sum is then shifted right by one bit to produce an element sized result in the corresponding element of the first operand.

For VECTOR AVERAGE LOGICAL, each element of the second operand and the corresponding element of the third operand are extended by one bit by appending a zero on the left. The elements are then added together along with an additional value of one. The sum is then shifted right by one bit to produce an element sized result in the corresponding element of the first operand.

The M_4 field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized. When the vector-enhancements facility 3 is not installed, the M_4 value of 4 is also reserved.

M_4	Element Size
0	Byte
1	Halfword
2	Word
3	Doubleword
4	Quadword
5-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

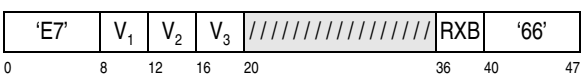
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
VAVGB	V_1,V_2,V_3	VAVG	$V_1,V_2,V_3,0$
VAVGH	V_1,V_2,V_3	VAVG	$V_1,V_2,V_3,1$
VAVGF	V_1,V_2,V_3	VAVG	$V_1,V_2,V_3,2$
VAVGG	V_1,V_2,V_3	VAVG	$V_1,V_2,V_3,3$
VAVGQ	V_1,V_2,V_3	VAVG	$V_1,V_2,V_3,4$
VAVGLB	V_1,V_2,V_3	VAVGL	$V_1,V_2,V_3,0$
VAVGLH	V_1,V_2,V_3	VAVGL	$V_1,V_2,V_3,1$
VAVGLF	V_1,V_2,V_3	VAVGL	$V_1,V_2,V_3,2$
VAVGLG	V_1,V_2,V_3	VAVGL	$V_1,V_2,V_3,3$
VAVGLQ	V_1,V_2,V_3	VAVGL	$V_1,V_2,V_3,4$

VECTOR CHECKSUM

VCKSM V_1,V_2,V_3 [VRR-c]



The word-sized elements from the second operand are added together one-by-one along with the element in word one of the third operand. The sum is placed in word one of the first operand. Zeros are placed in word elements 0, and 2-3 of the first operand. The word-sized elements are all treated as 32-

bit unsigned binary integers. After each addition of an element, a carry out of bit position 0 of the sum is added to bit position 31 of the result in word element one of the first operand.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

Programming Notes:

1. The contents of the third operand should contain zero at the start of a checksum computation algorithm.

2. A16-bit checksum is used in, for example, the TCP/IP application. The following program can be executed after a 32-bit checksum has been computed:

   ```
   VERLLF   V2,V1,16(0)
   VAF      V2,V1,V2
   ```

   The halfword in element 2 will contain the 16-bit checksum.

VECTOR ELEMENT COMPARE

VEC V_1,V_2,M_3 [VRR-a]

VECTOR ELEMENT COMPARE LOGICAL

VECL V_1,V_2,M_3 [VRR-a]

The single element of specified size of the first and second operands are compared and the result is indicated in the condition code.

The elements compared are treated as signed binary integers for VEC and unsigned binary integers for VECL.

The index of the element that is being compared is dependent on the size of the element being compared. Figure 22-2 specifies what element is compared for each element size.

Element Size	Element Index
Byte	7
Halfword	3
Word	1
Doubleword	0
Quadword	0

Figure 22-2. Element Sizes and Indexes

The M_3 field specifies the element size control (ES). The ES control specifies the size of the element in the vector register operands. If a reserved value is specified, a specification exception is recognized. When the vector-enhancements facility 3 is not installed, the M_3 value of 4 is also reserved.

M_3	Element Size
0	Byte
1	Halfword
2	Word
3	Doubleword
4	Quadword
5-15	Reserved

Resulting Condition Code:

0 Operand elements equal
1 First operand element low
2 First operand element high
3 --

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
VECB	V_1,V_2	VEC	$V_1,V_2,0$

VECLQ	V_1,V_2	VECL	$V_1,V_2,4$

VECTOR COMPARE EQUAL

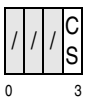
VCEQ V_1,V_2,V_3,M_4,M_5 [VRR-b]

The unsigned binary integer elements of the second operand are compared with the corresponding unsigned binary integer elements of the third operand. If the element in the second operand is equal to the element in the third operand, all of the bit positions of the corresponding element in the first operand are set to ones; otherwise they are all set to zeros.

The M_4 field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized. When the vector-enhancements facility 3 is not installed, the M_4 value of 4 is also reserved.

M_4	Element Size
0	Byte
1	Halfword
2	Word
3	Doubleword
4	Quadword
5-15	Reserved

The M_5 field has the following format:



The bits of the M_5 field are defined as follows:

- ***Reserved:*** Bits 0, 1, and 2 are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.
- ***Condition Code Set (CS):*** If bit 3 is 0, the code remains unchanged. If the bit is one, the code is set as described below.

Resulting Condition Code:

When bit 3 of the M_5 field is one, the condition code is set as follows:

0 All elements equal
1 At least one, but not all elements equal
2 --
3 No element equal

When bit 3 of the M_5 field is zero, the code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

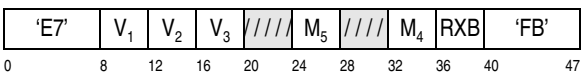
VCEQGS	V_1,V_2,V_3	VCEQ	$V_1,V_2,V_3,3,1$
VCEQQS	V_1,V_2,V_3	VCEQ	$V_1,V_2,V_3,4,1$

Programming Note: Depending on the model, setting the condition code may result in reduced performance.

VECTOR COMPARE HIGH

VCH V_1,V_2,V_3,M_4,M_5 [VRR-b]



The signed elements of the second operand are compared to the corresponding signed elements of

the third operand. If the element in the second operand is greater than the element in the third operand, all of the bit positions of the corresponding element in the first operand are set to ones; otherwise, they are all set to zeros.

The M_4 field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized. When the vector-enhancements facility 3 is not installed, the M_4 value of 4 is also reserved.

M_4	Element Size
0	Byte
1	Halfword
2	Word
3	Doubleword
4	Quadword
5-15	Reserved

The M_5 field has the following format:

The bits of the M_5 field are defined as follows:

- ***Reserved:*** Bits 0, 1, and 2 are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.
- ***Condition Code Set (CS):*** If bit 3 is 0, the code remains unchanged. If the bit is one, the code is set as described below.

Resulting Condition Code:

When bit 3 of the M_5 field is one, the condition code is set as follows:

0 All elements high
1 Some elements high
2 --
3 No element high

When bit 3 of the M_5 field is zero, the code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

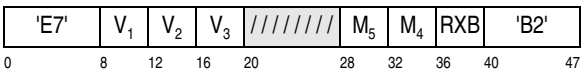
VCTZQ	V_1,V_2	VCTZ	$V_1,V_2,4$

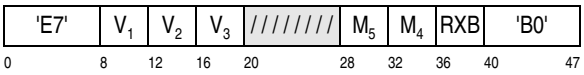
VECTOR DIVIDE

VD V_1,V_2,V_3,M_4,M_5 [VRR-c]



VECTOR DIVIDE LOGICAL

VDL V_1,V_2,V_3,M_4,M_5 [VRR-c]



The contents of each element of the second operand (the dividend) are divided by the contents of each corresponding element of the third operand (the divisor). The quotient or quotients are placed at the corresponding elements in the first-operand location. No remainder is preserved.

For VECTOR DIVIDE, the elements are treated as signed binary integers. For VECTOR DIVIDE LOGICAL, the elements are treated as unsigned binary integers.

If the divisor is zero and the integer-divide control (IDC) in the M_5 field is zero, an integer divide vector-processing exception is recognized and the instruction execution is suppressed. If the divisor is zero and the IDC bit is one, recognition of an integer divide vector-processing exception is suppressed and the result is zero.

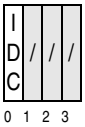
The sign of the quotient is determined by the rules of algebra, except that a zero quotient is always positive.

For VECTOR DIVIDE, if the divisor is negative one and the dividend is the negative maximum value of the specified size; if the IDC bit is zero, the instruction execution is suppressed and an integer divide vector-processing exception is recognized; if the IDC bit is one, recognition of an integer divide vector-processing exception is suppressed and the result is zero.

The M_4 field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_4	Element Size
0-1	Reserved
2	Word
3	Doubleword
4	Quadword
5-15	Reserved

The M_5 field has the following format:



The bits of the M_5 field are:

- ***Integer-Divide Control (IDC):*** Bit 0 of the M_5 field is the integer-divide control (IDC) bit. If the IDC is zero, recognition of an integer divide vector-processing exception is not suppressed; if IDC is one, recognition of an integer divide vector-processing exception is suppressed.
- ***Reserved:*** Bits 1-3 are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector-enhancements facility 3 is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for integer divide exception and element index

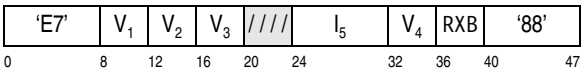
VECTOR EVALUATE

VEVAL V_1,V_2,V_3,V_4,I_5 [VRI-k]



Bits of the second, third, and fourth operand vectors are combined by logical operations specified by the fifth operand, and the results are placed in the first operand vector.

The fifth operand is an unsigned binary integer that specifies a boolean operation to be performed on the three source operands.

For each bit in the source operands, the value from the second, third, and fourth operands are concatenated to form a 3-bit index. The index is used to select the corresponding bit from the fifth operand. The value of the selected bit is placed in the corresponding bit position of the first operand.

Figure 22-3 summarizes the encoding and layout of bits 0-7 of the fifth operand. Bits 0-4 contain the row index and bits 5-7 contain an column index to locate a boolean operation.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector-enhancements facility 3 is not installed)
- Transaction constraint

Programming Notes:

1. Boolean logical functions which can be provided using existing vector instructions are not described in Figure 22-3 on page 22-14 and it is recommended to use existing vector instructions for such boolean logical functions .
2. Only unique instances of boolean functions are described in Figure 22-3 on page 22-14 and possible redundant entries have been omitted.

Explanation:

≡	The entry is a duplicate function of an existing vector instruction.
‡	The entry is a duplicate of another entry in the table for a boolean operation with a different order of A, B, C.
A	Represents a bit from the content of second operand.
AND	Boolean AND function.
B	Represents a bit from the content of third operand.
C	Represents a bit from the content of fourth operand.
MAJOR	Boolean MAJOR function.
	A three-input boolean operation that returns a value of 1 when two or three of its inputs are 1, and 0 otherwise.
MINOR	Boolean MINOR function.
	A three-input boolean operation that returns a value of 1 when zero or one of its inputs are 1, and 0 otherwise.
NAND	Boolean NAND function.
NOR	Boolean NOR function.
NOT	Boolean NOT function.
OR	Boolean OR function.
SEL	Select function (Condition(C_i), Select1(S_1), Select2(S_2)).
	If condition C_i is TRUE the returned result is S_1 else returned result is S_2.
XOR	Boolean EXCLUSIVE OR function.
NXOR	Boolean NOT of EXCLUSIVE OR function.

Figure 22-3. Boolean operations (Part 2 of 2).

VECTOR EXCLUSIVE OR

VX V_1,V_2,V_3 [VRR-c]

The EXCLUSIVE OR of the second and third operands is placed at the first-operand location.

The connective EXCLUSIVE OR is applied to the operands bit by bit. The contents of a bit position in the result are set to one if the bits in the corresponding bit positions in the two operands are unlike; otherwise, the result bit is set to zero.

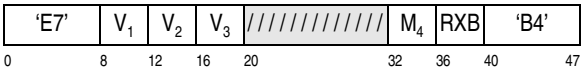
Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

VECTOR GALOIS FIELD MULTIPLY SUM

VGFM V_1,V_2,V_3,M_4 [VRR-c]



Each element of the second operand is multiplied in a Galois field with the corresponding element of the third operand. The Galois field has an order of two. This multiplication is similar to standard binary multiplication, but instead of adding the shifted multiplicand it is exclusive ORed. The resulting even-odd pairs of double element-sized products are exclusive ORed with each other and placed in the corresponding double-wide element of the first operand.

The M_4 field specifies the element size control (ES). The ES control specifies the size of the elements in vector register operands two and three; the elements in the first operand are twice the size of those specified by the ES control. If a reserved value is specified, a specification exception is recognized.

M_4	Element Size
0	Byte
1	Halfword
2	Word
3	Doubleword
4-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

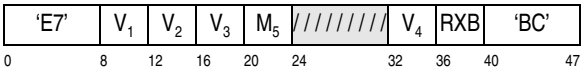
VECTOR GALOIS FIELD MULTIPLY SUM AND ACCUMULATE

VGFMA V_1,V_2,V_3,V_4,M_5 [VRR-d]



Each element of the second operand is multiplied in a Galois field with the corresponding element of the third operand. The Galois field has an order of two. This multiplication is similar to standard binary multiplication, but instead of adding the shifted multiplicand it is exclusive ORed. The resulting even-odd pairs of double element-sized products are exclusive ORed with each other and exclusive ORed with the corresponding double-wide element of the fourth operand. The results are placed in the double-wide elements of the first operand.

The M_5 field specifies the element size control (ES). The ES control specifies the size of the elements in vector register operands two and three; the elements in the first and fourth operand are twice the size of those specified by the ES control. If a reserved value is specified, a specification exception is recognized.

M_5	Element Size
0	Byte
1	Halfword
2	Word
3	Doubleword
4-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

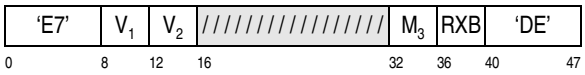
VECTOR LOAD COMPLEMENT

VLC V_1,V_2,M_3 [VRR-a]



The two's complement of each element in the second operand is placed in the corresponding element in the first operand. The operands are treated as signed binary integers.

When there is an overflow, the result is obtained by allowing any carry into the sign bit position and ignoring any carry out of the sign-bit position.

The M_3 field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized. When the vector-enhancements facility 3 is not installed, the M_3 value of 4 is also reserved.

M_3	Element Size
0	Byte
1	Halfword
2	Word
3	Doubleword
4	Quadword
5-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

VECTOR MAXIMUM

VMX V_1,V_2,V_3,M_4 [VRR-c]

VECTOR MAXIMUM LOGICAL

VMXL V_1,V_2,V_3,M_4 [VRR-c]

Each element of the second operand is compared to the corresponding element of the third operand. The greater of the two values is placed into the corresponding element of the first operand. If the operands are equal the value of both elements is placed in the corresponding element of the first operand.

For VECTOR MAXIMUM the operands are treated as signed integer elements. For VECTOR MAXIMUM LOGICAL the operands are treated as unsigned integer elements.

The M_4 field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized. When the vector-enhancements facility 3 is not installed, the M_4 value of 4 is also reserved.

M_4	Element Size

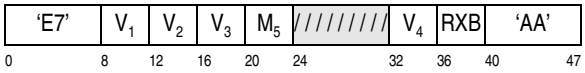
VECTOR MULTIPLY AND ADD LOW

VMAL V_1,V_2,V_3,V_4,M_5 [VRR-d]



The integer elements of the second operand are multiplied by the corresponding integer elements of the third operand producing a double element-sized intermediate product. This intermediate product is then added to the corresponding element of the fourth operand. The least significant half of the resulting sum is placed into the corresponding element of the first operand.

The M_5 field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized. When the vector-enhancements facility 3 is not installed, the M_5 values of 3 and 4 are also reserved.

M_5	Element Size
0	Byte
1	Halfword
2	Word
3	Doubleword
4	Quadword
5-15	Reserved

Condition Code: The code remains unchanged.

VMLQ	V_1,V_2,V_3	VML	$V_1,V_2,V_3,4$

Programming Notes:

1. The results from VML are the same if the elements are treated as unsigned binary integers or signed binary integers.
2. VECTOR MULTIPLY LOW is analogous to MULTIPLY SINGLE in chapter 7.
3. The extended mnemonic VMLHW is not VMLH because that would conflict with VECTOR MULTIPLY LOW

VECTOR MULTIPLY EVEN

VME V_1,V_2,V_3,M_4 [VRR-c]

VECTOR MULTIPLY LOGICAL EVEN

VMLE V_1,V_2,V_3,M_4 [VRR-c]

The even indexed elements of the second operand are multiplied with the corresponding even indexed elements of the third operand and the resulting double element width product is placed into the corresponding even and odd indexed element pair of the first operand. The odd elements of the second and third operands are ignored.

For VECTOR MULTIPLY EVEN the elements are treated as signed binary integers. For VECTOR MULTIPLY LOGICAL EVEN the elements are treated as unsigned binary integers.

The M_4 field specifies the element size control (ES). The ES control specifies the size of the elements in vector register operands two and three; the elements in the first operand are twice the size of those specified by the ES control. If a reserved value is specified, a specification exception is recognized. When the vector-enhancements facility 3 is not installed, the M_4 value of 3 is also reserved.

M_4	Element Size
0	Byte

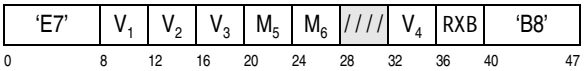
VMLOB	V_1,V_2,V_3	VMLO	$V_1,V_2,V_3,0$
VMLOH	V_1,V_2,V_3	VMLO	$V_1,V_2,V_3,1$
VMLOF	V_1,V_2,V_3	VMLO	$V_1,V_2,V_3,2$
VMLOG	V_1,V_2,V_3	VMLO	$V_1,V_2,V_3,3$

VECTOR MULTIPLY SUM LOGICAL

VMSL V_1,V_2,V_3,V_4,M_5,M_6 [VRR-d]



The even indexed unsigned integer elements of the second and third operands are multiplied to create a double element wide first intermediate result. The odd indexed elements of the second and third operands are multiplied together to create a double element wide second intermediate result. The first and second double-element-wide intermediate results are each shifted to the left by the values specified in the M_6 field and then added together along with the corresponding double-wide even-odd element pair value in the fourth operand and the corresponding even-odd element pair sums are placed in the first operand. Any carry outs or overflows from the additions are ignored.

The M_5 field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_5	Element Size
0-2	Reserved
3	Doubleword
4-15	Reserved

The M_6 field has the following format:

The bits of the M_6 field are defined as follows:

- ***Even Shift Indication (ES):*** When bit 0 is one, the first intermediate result is shifted left one bit before the addition; when bit 0 is zero shifting of the first intermediate result is not performed.
- ***Odd Shift Indication (OS):*** When bit 1 is one, the second intermediate result is shifted left one bit before the addition; when bit 1 is zero shifting of the second intermediate result is not performed.
- ***Reserved:*** Bits 2 and 3 are reserved and should be zeros; otherwise, the program may not operate compatibly in the future.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction

- Operation (vector-enhancements facility 1 not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

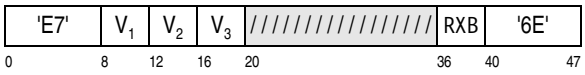
Extended Mnemonic		Base Mnemonic	
VMSLG	V_1,V_2,V_3,V_4,M_6	VMSL	$V_1,V_2,V_3,V_4,3,M_6$

Programming Notes:

1. On some models when a doubleword element size is specified, if the most significant eight bits of the elements in the second and third operands are nonzero performance may be significantly reduced. When the vector-enhancement facility 3 is installed, performance is not reduced if the most significant 8 bits are nonzero.
2. The primary intended use of this instruction is as a building block for software implementation of larger multiplications.
3. The shift controls in the M_6 field may be used for software implementations of squaring of large binary numbers.

VECTOR NAND

VNN V_1,V_2,V_3 [VRR-c]



The NAND of the second and third operands is placed in the first operand.

The connective NAND is applied to the operands bit-by-bit. The contents of a bit position in the result are set to zero if the corresponding bit positions in both source operands contain ones; otherwise, the result bit is set to one.

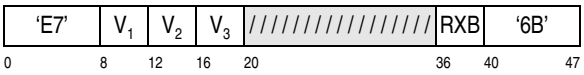
Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (vector-enhancements facility 1 not installed)
- Transaction constraint

VECTOR NOR

VNO V_1,V_2,V_3 [VRR-c]



The NOR of the second and third operands is placed at the first-operand location.

The connective NOR is applied to the operand bit by bit. The contents of a bit position in the result are set to one if the corresponding bit in both operands contains zero; otherwise, the result bit is set to zero.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

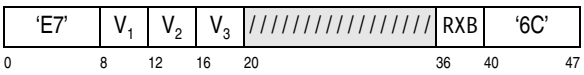
Programming Note: VNO can be used to provide the functionality of a bit-wise NOT operation by specifying the same vector-register for V_2 and V_3.

Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
VNOT	V_1,V_2	VNO	V_1,V_2,V_2

VECTOR NOT EXCLUSIVE OR

VNX V_1,V_2,V_3 [VRR-c]



The complement of the EXCLUSIVE OR of the second and third operands is placed at the first-operand location.

The connective EXCLUSIVE OR and complementation is applied to the operands bit-by-bit. The contents of a bit position in the result are set to zero if the bits in the corresponding bit positions in the two source operands are unlike; otherwise, the result bit is set to one.

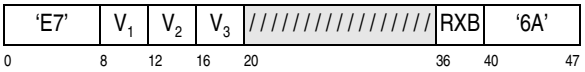
Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (vector-enhancements facility 1 not installed)
- Transaction constraint

VECTOR OR

VO V_1,V_2,V_3 [VRR-c]



The OR of the second and third operands is placed at the first-operand location.

The connective OR is applied to the operand bit by bit. The contents of a bit position in the result are set to one if the corresponding bit in one or both operands contains a one; otherwise, the result bit is set to zero.

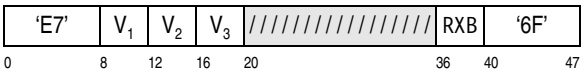
Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

VECTOR OR WITH COMPLEMENT

VOC V_1,V_2,V_3 [VRR-c]



The OR of the second operand and the bit-wise complement of the third operand is placed in the first operand.

The connective OR is applied to the second operand and bit-wise complemented third operand bit-by-bit. The contents of a bit position in the result are set to zero if the corresponding bit positions in the second operand contains a zero and the third operand contains a one; otherwise, the result bit is set to one.

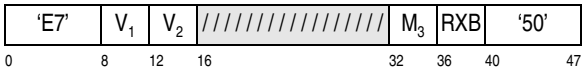
Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (vector-enhancements facility 1 not installed)
- Transaction constraint

VECTOR POPULATION COUNT

VPOPCT V_1,V_2,M_3 [VRR-a]



For each element of the second operand the count of the number of bits that are one is stored in the corresponding element of the first operand. Each element in the result contains an binary integer.

The M_3 field specifies the element size control (ES). The ES control specifies the size of the element in the vector register operands. If a reserved value is specified, a specification exception is recognized. If the vector enhancement facility 1 is not installed the values 1-3 are reserved.

M_3	Element Size
0	Byte
1	Halfword
2	Word
3	Doubleword
4-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

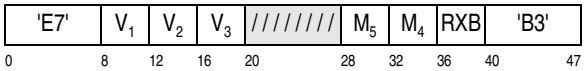
Extended Mnemonics:

Extended Mnemonic	Base Mnemonic
VPOPCTB V_1,V_2	VPOPCT $V_1,V_2,0$
VPOPCTH V_1,V_2	VPOPCT $V_1,V_2,1$
VPOPCTF V_1,V_2	VPOPCT $V_1,V_2,2$
VPOPCTG V_1,V_2	VPOPCT $V_1,V_2,3$

Programming Note: To count all of the ones in a vector register, a VECTOR SUM ACROSS instruction may be used.

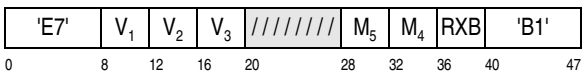
VECTOR REMAINDER

VR V_1,V_2,V_3,M_4,M_5 [VRR-c]



VECTOR REMAINDER LOGICAL

VRL V_1,V_2,V_3,M_4,M_5 [VRR-c]



The contents of each element of the second operand (the dividend) are divided by the contents of each corresponding element of the third operand (the divisor). The remainder or remainders are placed at the corresponding elements in the first-operand location. No quotient is preserved.

For VECTOR REMAINDER, the elements are treated as signed binary integers. For VECTOR REMAINDER LOGICAL, the elements are treated as unsigned binary integers.

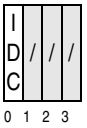
The remainder has the same sign as the dividend, except that a zero remainder is always positive.

If the divisor is zero and the integer-divide control (IDC) in the M_5 field is zero, an integer divide vector-processing exception is recognized and the instruction execution is suppressed. If the divisor is zero and the IDC bit is one, recognition of an integer divide vector-processing exception is suppressed and the result is zero.

The M_4 field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_4	Element Size
0-1	Reserved
2	Word
3	Doubleword
4	Quadword
5-15	Reserved

The M_5 field has the following format:



The bits of the M_5 field are:

- ***Integer-Divide Control (IDC):*** Bit 0 of the M_5 field is the integer-divide control (IDC) bit. If the IDC is zero, recognition of an integer divide vector-processing exception is not suppressed; if IDC is one, recognition of an integer divide vector-processing exception is suppressed.
- ***Reserved:*** Bits 1-3 are reserved and should contain zeros; otherwise, the program may not operate compatibly in the future.

Condition Code: The code remains unchanged.

Program Exceptions:

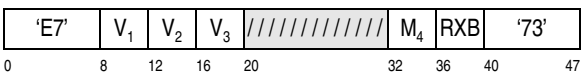
- Data with DXC FE, Vector Instruction
- Operation (if the vector-enhancements facility 3 is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for integer divide exception and element index

Extended Mnemonics:

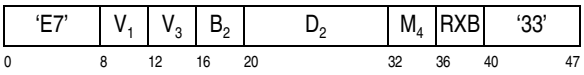
Extended Mnemonic		Base Mnemonic	
VRF	V_1,V_2,V_3,M_5	VR	$V_1,V_2,V_3,2,M_5$
VRG	V_1,V_2,V_3,M_5	VR	$V_1,V_2,V_3,3,M_5$
VRQ	V_1,V_2,V_3,M_5	VR	$V_1,V_2,V_3,4,M_5$
VRLF	V_1,V_2,V_3,M_5	VRL	$V_1,V_2,V_3,2,M_5$
VRLG	V_1,V_2,V_3,M_5	VRL	$V_1,V_2,V_3,3,M_5$
VRLQ	V_1,V_2,V_3,M_5	VRL	$V_1,V_2,V_3,4,M_5$

VECTOR ELEMENT ROTATE LEFT LOGICAL

VERLLV V_1,V_2,V_3,M_4 [VRR-c]



VERLL $V_1,V_3,D_2(B_2),M_4$ [VRS-a]



For VERLLV, each element in the second operand is rotated left by the number of bits specified in the corresponding element of the third operand modulo the element size in bits. For VERLL, each element in the third operand is rotated left by the number of bits specified by the second-operand address, modulo the number of bits in the specified element size. Each bit shifted out of the leftmost bit position of the element reenters in the rightmost bit position of the element. The result is placed in the corresponding element in the first operand.

For VERLL, The displacement is treated as a 12-bit unsigned integer.

For VERLL, The second-operand address is not used to address data; its rightmost bits indicate the number of bit positions to be rotated. The remainder of the address is ignored.

The M_4 field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_4	Element Size
0	Byte
1	Halfword
2	Word
3	Doubleword
4-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

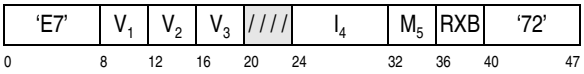
Programming Note: Although the rotate amount is defined to be an unsigned integer of the number of bits necessary to specify a full rotate left amount for an element, a negative value may be encoded which effectively specifies a rotate-right amount.

Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
VERLLVB	V_1,V_2,V_3	VERLLV	$V_1,V_2,V_3,0$
VERLLVH	V_1,V_2,V_3	VERLLV	$V_1,V_2,V_3,1$
VERLLVF	V_1,V_2,V_3	VERLLV	$V_1,V_2,V_3,2$
VERLLVG	V_1,V_2,V_3	VERLLV	$V_1,V_2,V_3,3$
VERLLB	$V_1,V_3,D_2(B_2)$	VERLL	$V_1,V_3,D_2(B_2),0$
VERLLH	$V_1,V_3,D_2(B_2)$	VERLL	$V_1,V_3,D_2(B_2),1$
VERLLF	$V_1,V_3,D_2(B_2)$	VERLL	$V_1,V_3,D_2(B_2),2$
VERLLG	$V_1,V_3,D_2(B_2)$	VERLL	$V_1,V_3,D_2(B_2),3$

VECTOR ELEMENT ROTATE AND INSERT UNDER MASK

VERIM V_1,V_2,V_3,I_4,M_5 [VRI-d]



Each element of the second operand is rotated left by the number of bits specified by the fourth operand. Each bit shifted out of the leftmost bit position of the element reenters in the rightmost bit position of the element. The third operand contains a mask in each element. For each bit in the third operand that is one, the corresponding bit of the rotated elements in the second operand replaces the corresponding bit in the first operand. For each bit in the third operand that is zero, the corresponding bit of the first operand remains unchanged. Except for the case when the first operand is the same as either the second or third operand, the second and third operands remain unchanged.

The fourth operand is an unsigned binary integer specifying the number of bits to rotate each element in the second operand by. If the value is larger than the number of bits in the specified element size, the value is reduced modulo the number of bits in the element.

The M_5 field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_5	Element Size
0	Byte
1	Halfword
2	Word

M_5	Element Size
3	Doubleword
4-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
VERIMB	V_1,V_2,V_3,I_4	VERIM	$V_1,V_2,V_3,I_4,0$
VERIMH	V_1,V_2,V_3,I_4	VERIM	$V_1,V_2,V_3,I_4,1$
VERIMF	V_1,V_2,V_3,I_4	VERIM	$V_1,V_2,V_3,I_4,2$
VERIMG	V_1,V_2,V_3,I_4	VERIM	$V_1,V_2,V_3,I_4,3$

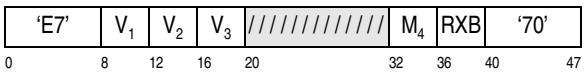
Programming Notes:

1. A combination of VERIM and VGM may be used to accomplish the full functionality of ROTATE AND INSERT SELECTED BITS in Chapter 7.

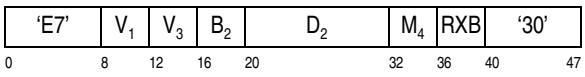
2. Although the bits of the I_4 field are defined to contain an unsigned binary integer specifying the number of bits to rotate each element left, a negative value may be coded which effectively specifies a rotate-right amount.

VECTOR ELEMENT SHIFT LEFT

VESLV V_1,V_2,V_3,M_4 [VRR-c]



VESL $V_1,V_3,D_2(B_2),M_4$ [VRS-a]



For VESLV, each element in the second operand is shifted left by the number of bits specified in the corresponding element in the third operand modulo the number of bits in an element. For VESL, each element in the third operand is shifted left by the number of bits specified by the second-operand address modulo the number of bits in the specified element size. Bits shifted out of bit 0 of each element are lost and zeros are supplied to the vacated bit positions to the right of each element. The result is placed in the first operand.

For VESL, the displacement is treated as a 12-bit unsigned integer.

For VESL, the second-operand address is not used to address data; its rightmost bits indicate the number of bit positions to be shifted. The leftmost bits of the address are ignored.

The M_4 field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_4	Element Size
0	Byte
1	Halfword
2	Word
3	Doubleword
4-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Programming Note: The same results are obtained if the second operand contains either signed or unsigned binary integers.

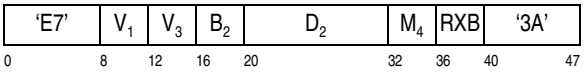
VECTOR ELEMENT SHIFT RIGHT ARITHMETIC

VESRAV V_1,V_2,V_3,M_4 [VRR-c]

VESRA $V_1,V_3,D_2(B_2),M_4$ [VRS-a]



For VESRAV, each element in the second operand is shifted right by the number of bits specified in the corresponding element of the third operand modulo the number of bits in the specified element size. For VESRA, each element in the third operand is shifted right by the number of bits specified in the second-operand address modulo the number of bits in the specified element size. The result is placed in the corresponding element of the first operand with the vacated bits replaced with the original high order bit of each element.

For VESRA, the displacement is treated as a 12-bit unsigned integer.

For VESRA, the second-operand address is not used to address data; its rightmost bits indicate the number of bit positions to be shifted. The leftmost bits of the address are ignored.

The M_4 field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_4	Element Size

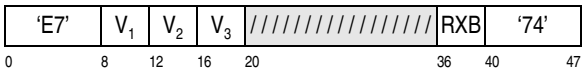
VECTOR SHIFT LEFT

VSL V_1,V_2,V_3 [VRR-c]



Each byte-sized element of the second operand is shifted left by the number of bits specified by the unsigned binary integer in bits 5-7 of the corresponding byte-sized element of the third operand. For all bytes other than the rightmost byte, the vacated bit positions are supplied by the leftmost bits of the adjacent byte on the right. For the rightmost byte, zeros are supplied to the vacated bit positions. For all bytes other than the leftmost byte, bits which are shifted out and not supplied to the byte on the left are lost. For the leftmost byte, bits shifted out are lost. If the vector-enhancements facility 2 is not installed and all shift amounts specified by all bytes of the third operand are not equal, then the result is unpredictable. The result is placed in the first operand.

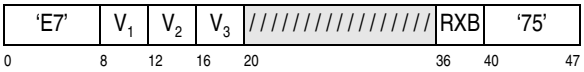
Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

VECTOR SHIFT LEFT BY BYTE

VSLB V_1,V_2,V_3 [VRR-c]



The second operand is shifted left by the number of bytes specified by the unsigned integer in bits 1-4 of byte element seven of the third operand. Bits shifted out of bit 0 are lost and zeros are supplied to the vacated bit positions to the right. The result is placed in the first operand.

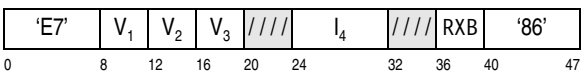
Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

VECTOR SHIFT LEFT DOUBLE BY BIT

VSLD V_1,V_2,V_3,I_4 [VRI-d]



A double-wide source vector is created by concatenating the second operand followed by the third operand. Bits 5-7 of the fourth operand contain an unsigned binary integer that specifies the start index of the 128 consecutive bits from the source vector which are placed into the first operand vector register.

If bits 0-4 of the fourth operand are non zero, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector-enhancements facility 2 is not installed)
- Transaction constraint
- Specification

Programming Note: The illustration below shows an example:

Operand 2	01	23	45	67	89	AB	CD	EF	FE	DC	BA	98	76	54	32	1 0
Operand 3	F0	E1	D2	C3	B4	A5	96	87	78	69	5A	4B	3C	2D	1E	0 A

Operand 4 = 4

Operand 1	12	34	56	78	9A	BC	DE	FF	ED	CB	A9	87	65	43	21	0 F

VECTOR SHIFT LEFT DOUBLE BY BYTE

VSLDB V_1,V_2,V_3,I_4 [VRI-d]

A double-wide source vector of byte elements is created by concatenating the second operand followed by the third operand. Bits 4-7 of the fourth operand contain an unsigned binary integer that specifies the starting index of sixteen consecutive bytes from the source vector which are placed into vector register V_1. Bits 0-3 of the fourth operand should contain zeros; otherwise the results are unpredictable.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

VECTOR SHIFT RIGHT ARITHMETIC

VSRA V_1,V_2,V_3 [VRR-c]

Each byte-sized element of the second operand is shifted right by the number of bits specified by the unsigned binary integer in bits 5-7 of the corresponding byte-sized element of the third operand. For all bytes other than the lefttmost byte, the vacated bit positions are supplied by the rightmost bits of the adjacent byte on the left. For the leftmost byte, bits equal to bit 0 of the leftmost byte are supplied to the vacated bit positions. For all bytes other than the rightmost byte, bits which are shifted out and not supplied to the byte on the right are lost. For the rightmost byte, bits shifted out are lost. If the vector-enhancements facility 2 is not installed and all shift amounts specified by all bytes of the third operand are not equal, then the result is unpredictable. The result is placed in the first operand.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

VECTOR SHIFT RIGHT ARITHMETIC BY BYTE

VSRAB V_1,V_2,V_3 [VRR-c]

The second operand is shifted right by the number of bytes specified by the unsigned integer in bits 1-4 of byte seven of the third operand. Bits shifted out of bit 127 are lost, and bits equal to bit zero are supplied to the vacated bit positions to the left. The result is placed in the first operand.

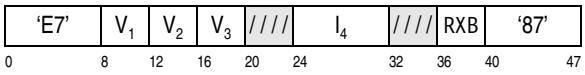
Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

VECTOR SHIFT RIGHT DOUBLE BY BIT

VSRD V_1,V_2,V_3,I_4 [VRI-d]



A double-wide source vector is created by concatenating the second operand followed by the third operand. Bits 5-7 of the fourth operand contain an unsigned binary integer that subtracted from 128 specifies the start index of the 128 consecutive bits from the source vector which are placed into the first operand vector register.

If bits 0-4 of the fourth operand are non zero, a specification exception is recognized.

Condition Code: The code remains unchanged.

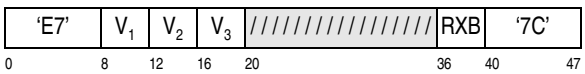
Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector-enhancements facility 2 is not installed)
- Transaction constraint
- Specification

Programming Note: This instruction is intended to extract arbitrary length data elements not on a byte boundary into SIMD elements for parallel processing.

VECTOR SHIFT RIGHT LOGICAL

VSRL V_1,V_2,V_3 [VRR-c]



Each byte element of the second operand is shifted right by the number of bits specified by the unsigned binary integer in bits 5-7 of the corresponding byte-sized element of the third operand. For all bytes other than the lefttmost byte, the vacated bit positions are supplied by the rightmost bits of the adjacent byte on the left. For the leftmost byte, zeros are supplied to the vacated bit positions. For all bytes other than the rightmost byte, bits which are shifted out and not supplied to the byte on the right are lost. For the rightmost byte, bits shifted out are lost. If the vector-enhancements facility 2 is not installed and all shift amounts specified by all bytes of the third operand are not equal, then the result is unpredictable. The result is placed in the first operand.

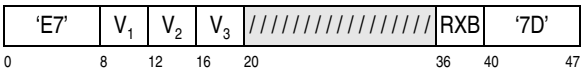
Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

VECTOR SHIFT RIGHT LOGICAL BY BYTE

VSRLB V_1,V_2,V_3 [VRR-c]



The second operand is shifted right by the number of bytes specified by the unsigned integer in bits 1-4 of byte element seven of the third operand. Bits shifted out of bit 127 are lost and zeros are supplied to the vacated bit positions to the left. The result is placed in the first operand.

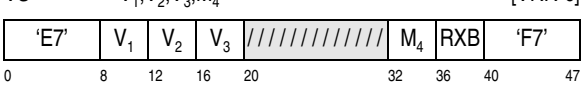
Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

VECTOR SUBTRACT

VS V_1,V_2,V_3,M_4 [VRR-c]



The contents of each element of the third operand are subtracted from the contents of each corresponding element of the second operand and the resulting difference is placed in the corresponding element of the first operand. Each element is treated as a signed binary integer specified by the element size control in the M_4 field.

When there is an overflow, the result is obtained by allowing any carry into the sign-bit position and ignoring any carry out of the sign-bit position.

The M_4 field specifies the element size control (ES). The ES control specifies the size of the element or elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_4	Element Size
0	Byte
1	Halfword
2	Word
3	Doubleword
4	Quadword
5-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

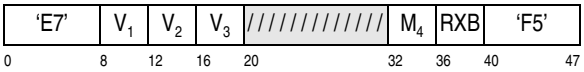
Programming Note: The same results are obtained if the contents of each element contain unsigned binary integers.

Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
VSB	V_1,V_2,V_3	VS	$V_1,V_2,V_3,0$
VSH	V_1,V_2,V_3	VS	$V_1,V_2,V_3,1$
VSF	V_1,V_2,V_3	VS	$V_1,V_2,V_3,2$
VSG	V_1,V_2,V_3	VS	$V_1,V_2,V_3,3$
VSQ	V_1,V_2,V_3	VS	$V_1,V_2,V_3,4$

VECTOR SUBTRACT COMPUTE BORROW INDICATION

VSCBI V_1,V_2,V_3,M_4 [VRR-c]



The contents of each element of the third operand are subtracted from the contents of each corresponding element of the second operand. An indication of borrow is placed in the corresponding element of the first operand.

If the resulting subtraction results in a carry out of bit zero, a value of one is placed in the corresponding element of the first operand; otherwise, a value of zero is placed in the corresponding element of the first operand. The operands are treated as unsigned binary integers of size specified by the element size control in the M_4 field.

The M_4 field specifies the element size control (ES). The ES control specifies the size of the element or elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_4	Element Size
0	Byte
1	Halfword
2	Word
3	Doubleword
4	Quadword
5-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

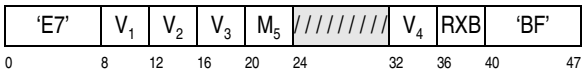
Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
VSCBIB	V_1,V_2,V_3	VSCBI	$V_1,V_2,V_3,0$
VSCBIH	V_1,V_2,V_3	VSCBI	$V_1,V_2,V_3,1$
VSCBIF	V_1,V_2,V_3	VSCBI	$V_1,V_2,V_3,2$

Extended Mnemonic		Base Mnemonic	
VSCBIG	V_1,V_2,V_3	VSCBI	$V_1,V_2,V_3,3$
VSCBIQ	V_1,V_2,V_3	VSCBI	$V_1,V_2,V_3,4$

VECTOR SUBTRACT WITH BORROW INDICATION

VSBI V_1,V_2,V_3,V_4,M_5 [VRR-d]



A subtraction is performed by adding the contents of the second operand with the bitwise complement of the third operand along with a borrow indication from the rightmost bit position of the fourth operand and the result is placed in the first operand. All bit positions to the left of the rightmost bit position of the fourth operand are ignored. Each operand is treated as an unsigned binary integer.

When there is an overflow, the result is obtained by allowing any carry into the leftmost-bit position and ignoring any carry out of the leftmost-bit position.

No fixed point overflow exceptions are recognized.

The M_5 field must contain a value of 4; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

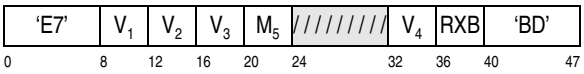
- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
VSBIQ	V_1,V_2,V_3,V_4	VSBI	$V_1,V_2,V_3,V_4,4$

VECTOR SUBTRACT WITH BORROW COMPUTE BORROW INDICATION

VSBCBI V_1,V_2,V_3,V_4,M_5 [VRR-d]



A subtraction is performed by adding the contents of the second operand with the bitwise complement of the third operand along with a borrow indication from the rightmost bit of the fourth operand. All bit positions to the left of the rightmost bit position of the fourth operand are ignored. If the addition results in a carry out of the leftmost bit, a value of one is placed in the first operand. If there is no carry out of the leftmost bit, a value of zero is placed in the first operand. Each operand is treated as an unsigned binary integer.

The M_5 field must contain a value of 4; otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
VSBCBIQ	V_1,V_2,V_3,V_4	VSBCBI	$V_1,V_2,V_3,V_4,4$

Programming Note: VECTOR SUBTRACT WITH BORROW COMPUTE BORROW INDICATION in conjunction with VECTOR SUBTRACT WITH BORROW INDICATION can be used to perform subtractions on values with a precision greater than a quadword.

VECTOR SUM ACROSS DOUBLEWORD

VSUMG V_1,V_2,V_3,M_4 [VRR-c]

The four halfword or two word sub-elements in each of the doubleword elements of the second operand are summed and then added to the corresponding rightmost sub-element of the corresponding doubleword of the third operand. The full-precision intermediate-sum is extended on the left with zeros to a doubleword and the results are placed in the corresponding doubleword of the first operand.

The M_4 field specifies the element size control (ES). The ES control specifies the size of the sub-elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_4	Element Size
0	Reserved
1	Halfword
2	Word
3-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
VSUMGH	V_1,V_2,V_3	VSUMG	$V_1,V_2,V_3,1$
VSUMGF	V_1,V_2,V_3	VSUMG	$V_1,V_2,V_3,2$

VECTOR SUM ACROSS QUADWORD

VSUMQ V_1,V_2,V_3,M_4 [VRR-c]

The two doubleword elements or four word elements of the second operand are added together along with the corresponding rightmost word or doubleword element of the third operand. The full-precision intermediate-sum is extended on the left with zeros to a quadword and the result is placed in the first operand.

The M_4 field specifies the element size control (ES). The ES control specifies the size of the sub-elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_4	Element Size
0-1	Reserved
2	Word
3	Doubleword
4-15	Reserved

Condition Code: The code remains unchanged.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
VSUMQF	V_1,V_2,V_3	VSUMQ	$V_1,V_2,V_3,2$
VSUMQG	V_1,V_2,V_3	VSUMQ	$V_1,V_2,V_3,3$

VECTOR SUM ACROSS WORD

VSUM V_1,V_2,V_3,M_4 [VRR-c]

The two halfword elements or four byte elements of each word element of the second operand are added together along with the corresponding rightmost sub-element of each word in the third operand. The full-precision intermediate-sum is extended on the left with zeros to a word and the result is placed in the corresponding word element of the first operand.

The M_4 field specifies the element size control (ES). The ES control specifies the size of the sub-elements

in the vector register operand. If a reserved value is specified, a specification exception is recognized.

M_4	Element Size
0	Byte
1	Halfword
2-15	Reserved

Condition Code: The code remains unchanged.

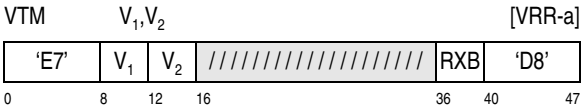
Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
VSUMB	V_1,V_2,V_3	VSUM	$V_1,V_2,V_3,0$
VSUMH	V_1,V_2,V_3	VSUM	$V_1,V_2,V_3,1$

VECTOR TEST UNDER MASK



The second operand contains a mask. The bits in the mask correspond one for one with the bits of the first operand. A mask bit of one indicates that the first-operand bit is to be tested. When a mask bit is zero, the first operand bit is ignored. When all first-operand bits thus selected are zero, condition code 0 is set. Condition code 0 is also set when the mask is all zeros. When the selected bits are all ones, condition code 3 is set; otherwise, condition code 1 is set.

Resulting Condition Code:

0 Selected bits all zeros; or all mask bits zero
1 Selected bits a mix of zeros and ones
2 --
3 Selected bits all ones

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Transaction constraint

Chapter 23. Vector String Instructions

Vector String Facility 23-1
Instructions 23-1
VECTOR FIND ANY ELEMENT EQUAL. . . . 23-2
VECTOR FIND ELEMENT EQUAL 23-3
VECTOR FIND ELEMENT NOT EQUAL 23-4
VECTOR ISOLATE STRING 23-5
VECTOR STRING RANGE COMPARE 23-6
VECTOR STRING SEARCH 23-8

Vector String Facility

The vector string facility provides instructions to accelerate the processing of strings of character data.

Instructions

All of the instructions except for VECTOR ISOLATE STRING have the ability to produce an index to a character element within a vector. This index is always placed in the rightmost bits of the leftmost doubleword of the vector. This index will often be used in scalar computation for address generation and will need to be transferred to a general register. If an element index is needed the index will have to be shifted right by the appropriate number of bits.

Unless otherwise specified, all operands are vector-register operands. A “V” in the assembler syntax designates a vector operand.

Each instruction has an Extended Mnemonic section which describe recommended extended mnemonics and their corresponding machine assembler syntax.

Programming Notes:

1. For all instructions that optionally set the condition code, performance may be degraded if the condition code is set.
2. The following additional instruction is available when the vector-enhancements facility 2 is installed:
   - VECTOR STRING SEARCH (VSTRS)

Name	Mnemonic	Characteristics							Opcode	Page
VECTOR FIND ANY ELEMENT EQUAL	VFAE	VRR-b	C*	VF	¤[7,9]	SP	Dv		E782	23-2

VECTOR FIND ANY ELEMENT EQUAL

VFAE $V_1,V_2,V_3,M_4[,M_5]$ [VRR-b]

Proceeding from left to right, each element of the second operand is compared for equality with every element of the third operand. A first intermediate result is created from this comparison with an indication for each element in the second operand if the element was equal to any element in the third operand.

If the invert-result (IN) flag in the M_5 field is one, then each indication in the first intermediate result is inverted.

If the zero-search (ZS) flag in the M_5 field is one, each element in the second operand is also compared with zeros and a second intermediate result is created with an indication for each element if that element is equal to zero. If the ZS flag is zero, the second intermediate result contains all false indications.

If the result-type (RT) flag is zero, for each of the two intermediate results, the index of the lowest indexed true result is obtained. The index is then converted to a byte index by multiplying by the number of bytes in an element. The minimum of the indices obtained from the two intermediate results is then computed. If no true result is found in either intermediate result, a final index equal to the number of bytes in the vector is produced. The index is placed into byte seven of the first operand; all other bytes of the first operand are set to zero.

If the RT flag in the M_5 field is one, for each element in the second operand, if the indication in the first intermediate result is true, the bit positions of the corresponding element in first operand are set to ones. If the first intermediate result element contains a false indication the bit positions of the corresponding element in the first operand are set to zero. No indication of true results in the second intermediate value are indicated in the first operand.

The M_4 field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_4	Element Size
0	Byte
1	Halfword
2	Word
3-15	Reserved

The M_5 field has the following format:

The bits of the M_5 field are defined as follows:

- ***Invert Result (IN):*** If bit 0 is zero, the operation proceeds using the comparison indication values in the first intermediate result. If one, the operation proceeds with the comparison indication values in the first intermediate result inverted.
- ***Result Type (RT):*** If bit 1 is zero, a byte index is stored into byte seven of the first operand and zeros are stored in all other elements. If bit 1 is one, each resulting element is a bit-vector.
- ***Zero Search (ZS):*** If bit 2 is one, each element of the second operand is also compared for equality with zero.
- ***Condition Code Set (CS):*** If bit 3 is zero, the condition code is not set and remains unchanged. If one, the condition code is set as specified in the resulting condition code section below.

Resulting Condition Code:

If the CS-bit is zero, the code remains unchanged.

If the CS-bit is one, the code is set as follows:

0 If the ZS-bit is one, there are no true indications in a lower indexed element in the first intermediate result than a true indication in the second intermediate result. That is, there were no matching elements before an element containing zero in the second operand.
1 At least one indication in the first intermediate result is true. All indications in the second intermediate result are false. That is, there was at

least one match in the second operand and, if the ZS-bit is one, no zero matches.

2 If the ZS-bit is one and at least one indication in the first intermediate result is true with a lower index than a true indication in the second intermediate result.

3 All indications in the first intermediate and second intermediate results are false.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		Base Mnemonic
VFAEB	$V_1,V_2,V_3[,M_5]$	VFAE V_1,V_2,V_3,0[,M_5]
VFAEH	$V_1,V_2,V_3[,M_5]$	VFAE V_1,V_2,V_3,1[,M_5]
VFAEF	$V_1,V_2,V_3[,M_5]$	VFAE V_1,V_2,V_3,2[,M_5]
VFAEBS	$V_1,V_2,V_3[,M_5]$	VFAE V_1,V_2,V_3,0,([M_5 | X'1')
VFAEHS	$V_1,V_2,V_3[,M_5]$	VFAE V_1,V_2,V_3,1,([M_5 | X'1')
VFAEFS	$V_1,V_2,V_3[,M_5]$	VFAE V_1,V_2,V_3,2,([M_5 | X'1')
VFAEZB	$V_1,V_2,V_3[,M_5]$	VFAE V_1,V_2,V_3,0,([M_5 | X'2')
VFAEZH	$V_1,V_2,V_3[,M_5]$	VFAE V_1,V_2,V_3,1,([M_5 | X'2')
VFAEZF	$V_1,V_2,V_3[,M_5]$	VFAE V_1,V_2,V_3,2,([M_5 | X'2')
VFAEZBS	$V_1,V_2,V_3[,M_5]$	VFAE V_1,V_2,V_3,0,([M_5 | X'3')
VFAEZHS	$V_1,V_2,V_3[,M_5]$	VFAE V_1,V_2,V_3,1,([M_5 | X'3')
VFAEZFS	$V_1,V_2,V_3[,M_5]$	VFAE V_1,V_2,V_3,2,([M_5 | X'3')

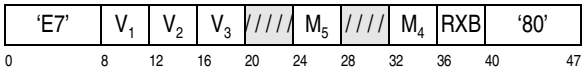
Programming Notes:

1. If the RT flag is zero, a byte index is always stored into the first operand for any element size. For example, if the specified element size is halfword and the halfword with index 2 compared equal, a byte index of 4 would be stored.

2. If the CS bit is one, conditions codes 0 and 2 can only be set if the ZS-bit is one.

VECTOR FIND ELEMENT EQUAL

VFEE $V_1,V_2,V_3,M_4[,M_5]$ [VRR-b]



Proceeding from left to right, the elements of the second operand are compared with the corresponding elements of the third operand and optionally with zero.

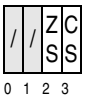
If two elements are equal, the byte index of the first byte of the leftmost equal element is placed in byte seven of the first operand. Zeros are stored in the remaining bytes of the first operand. If no bytes are found to be equal, or are equal to zero if the zero search (ZS) bit is one, an index equal to the number of bytes in the vector is stored in byte seven of the first operand. Zeros are stored in the remaining bytes.

If the ZS bit is one in the M_5 field, each element in the second operand is also compared for equality with zero. If a zero element is found in the second operand before any other elements of the second and third operands are found to be equal, the byte index of the first byte of the element found to be zero is stored in byte seven the first operand and zeros are stored in all other byte locations. If the condition-code-set (CS) flag is one, the condition code is set to zero.

The M_4 field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_4	Element Size
0	Byte
1	Halfword
2	Word
3-15	Reserved

The M_5 field has the following format:



The bits of the M_5 field are defined as follows:

- ***Reserved:*** Bits 0-1 are reserved and must be zero. Otherwise, a specification exception is recognized.
- ***Zero Search (ZS):*** If bit 2 is one, each element of the second operand is also compared for equality with zero.

- ***Condition Code Set (CS):*** If bit 3 is zero, the condition code remains unchanged. If one, the condition code is set as specified in the following section.

Resulting Condition Code:

If the CS-bit is zero, the code remains unchanged.

If the CS-bit is one, the code is set as follows:

0 If the ZS-bit is one, in the second operand there were no equal comparisons in an element with an index less than an element whose contents are zero.
1 Comparison detected a match between the second and third operands in some element. If the ZS-bit is one, there were no zero comparisons in the second operand.
2 If the ZS-bit is one, there was a match between the second and third operands with a lower index than a match with zero in the second operand.
3 No elements compared equal. Additionally, if the ZS-bit is one, no elements contain zero.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

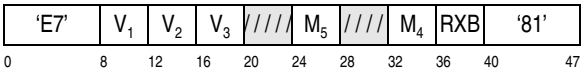
Extended Mnemonic		Base Mnemonic	
VFEEB	$V_1,V_2,V_3[,M_5]$	VFEE	$V_1,V_2,V_3,0[,M_5]$
VFEEH	$V_1,V_2,V_3[,M_5]$	VFEE	$V_1,V_2,V_3,1[,M_5]$
VFEEF	$V_1,V_2,V_3[,M_5]$	VFEE	$V_1,V_2,V_3,2[,M_5]$
VFEEBS	V_1,V_2,V_3	VFEE	$V_1,V_2,V_3,0,1$
VFEEHS	V_1,V_2,V_3	VFEE	$V_1,V_2,V_3,1,1$
VFEEFS	V_1,V_2,V_3	VFEE	$V_1,V_2,V_3,2,1$
VFEEZB	V_1,V_2,V_3	VFEE	$V_1,V_2,V_3,0,2$
VFEEZH	V_1,V_2,V_3	VFEE	$V_1,V_2,V_3,1,2$
VFEEZF	V_1,V_2,V_3	VFEE	$V_1,V_2,V_3,2,2$
VFEEZBS	V_1,V_2,V_3	VFEE	$V_1,V_2,V_3,0,3$
VFEEZHS	V_1,V_2,V_3	VFEE	$V_1,V_2,V_3,1,3$
VFEEZFS	V_1,V_2,V_3	VFEE	$V_1,V_2,V_3,2,3$

Programming Notes:

1. A byte index is always stored into the first operand for any element size. For example, if the specified element size is halfword and the 2nd indexed halfword compared equal, a byte index of 4 would be stored.
2. Depending on the model, VECTOR FIND ELEMENT EQUAL may have better performance than VECTOR FIND ANY EQUAL when searching for a single character by replicating the character across all elements of the third operand.

VECTOR FIND ELEMENT NOT EQUAL

VFENE $V_1,V_2,V_3,M_4[,M_5]$ [VRR-b]



Proceeding from left to right, the elements of the second operand are compared with the corresponding elements of the third operand and optionally with zeros. The elements of the second and third operands are treated as unsigned binary integers.

If two elements are not equal, the byte index of the leftmost not-equal element is placed in byte seven of the first operand and zeros are stored to all other bytes. If the condition code set (CS) bit in the M_5 field is one, the condition code is set to indicate which operand was greater. If all elements were equal, a byte index equal to the vector size is placed in byte seven of the first operand and zeros are placed in all other byte locations and if the CS bit is one, condition code 3 is set.

If the zero search (ZS) bit is one in the M_5 field, each element in the second operand is also compared for equality with zero. If a zero element is found in the second operand with a lower index than any other element of the second operand found to be unequal, the byte index of the first byte of the element found to be zero is stored in byte seven of the first operand. Zeros are stored in all other bytes and condition code 0 is set.

The M_4 field specifies the element size control (ES). The ES control specifies the size of the elements in

the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_4	Element Size
0	Byte
1	Halfword
2	Word
3-15	Reserved

The M_5 field has the following format:

The bits of the M_5 field are defined as follows:

- ***Reserved:*** Bits 0 and 1 are reserved and must be zero, otherwise a specification exception is recognized.
- ***Zero Search (ZS):*** If bit 2 is one, each element of the second operand is also compared for equality with zero.
- ***Condition Code Set (CS):*** If bit 3 is zero, the condition code is not set and remains unchanged. If one, the condition code is set as specified in the following section.

Resulting Condition Code:

If the CS-bit is zero, the code remains unchanged.

If the CS-bit is one, the code is set as follows:

0 If the ZS-bit is one, comparison detected a zero element in both operands in a lower indexed element than any unequal compares.
1 An element mismatch was detected and the element in the second operand is less than the element in the third operand.
2 An element mismatch was detected and the element in the second operand is greater than the element in the third operand.
3 All elements compared equal, and if the ZS-bit is one, no zero elements were found in the second operand.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

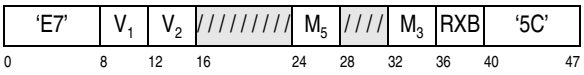
VECTOR ISOLATE STRING

VISTR $V_1,V_2,M_3[,M_5]$ [VRR-a]



Proceeding from left to right, the elements of the second operand are compared with zero. The elements of the second operand are treated as unsigned binary integers. If a zero comparison is not found, the element is copied into the corresponding element of the first operand. If a zero comparison is found, comparison stops and the corresponding element and all elements to the right in the first operand are set to zero.

The M_3 field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_3	Element Size
0	Byte
1	Halfword
2	Word
3-15	Reserved

The M_5 field has the following format:

The bits of the M_5 field are defined as follows:

- ***Reserved:*** Bits 0-2 are reserved and must be zero, otherwise a specification exception is recognized.
- ***Condition Code Set (CS):*** If bit 3 is zero, the condition code is not set and remains unchanged. If one, the condition code is set as specified in the following section.

Resulting Condition Code:

If the CS-bit is zero, the code remains unchanged.

If the CS-bit is one, the code is set as follows:

0 A zero element was found in the second operand
1 --
2 --
3 All elements of the second operand are nonzero

VECTOR STRING RANGE COMPARE

VSTRC $V_1,V_2,V_3,V_4,M_5[,M_6]$ [VRR-d]

Proceeding from left to right, the elements of the second operand are compared to ranges specified by values in even-odd element pairs of the third and fourth operands and, optionally, against an element containing zero. The element in the second and third operand are treated as unsigned binary integers.

The elements of the third and fourth operands form range comparisons to which are applied to elements of the second operand. The even-odd pairs of elements in the third operand define values for the limits of the ranges. The corresponding even-odd pair of elements in the fourth operand contain control information to specify the comparison to be done with each value in the third operand. A range comparison is said to be true if the comparisons on both elements in the even-odd pair are true.

Each element in the second operand is compared against every range specified by the even-odd element pairs in the third and fourth operands. A first intermediate result is created from this comparison with an indication for each element in the second operand if the element was contained in any of the specified ranges.

If the invert-result (IN) flag in the M_6 field is one, then each indication in the first intermediate result is inverted.

If the zero-search (ZS) flag in the M_6 field is one, each element in the second operand is also compared with zeros and a second intermediate result is created with an indication for each element if that element is equal to zero. If the ZS flag is zero the second intermediate result contains all false indications.

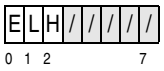
If the result-type (RT) flag is zero, for each of the two intermediate results, the index of the lowest indexed true result is obtained. The index is then converted to a byte index by multiplying by the number of bytes in an element. The minimum of the indices obtained from the two intermediate results is then computed. If no true result is found in either intermediate result, a final index equal to the number of bytes in the vector

is produced. The index is placed into byte seven of the first operand; all other bytes of the first operand are set to zero.

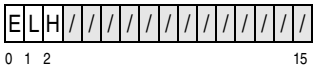
If the RT flag in the M_6 field is one, for each element in the second operand, if the indication in the first intermediate result is true, the bit positions of the corresponding element in first operand are set to ones. If the first intermediate result element contains a false indication the bit positions of the corresponding element in the first operand are set to zero. No indication of true results in the second intermediate value are indicated in the first operand.

The fourth operand elements have the following format:

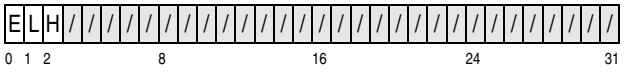
If ES equals 0:



If ES equals 1:



If ES equals 2:



The bits in the fourth operand elements are defined as follows:

- ***Equal (E):*** When one, a comparison for equality is made.
- ***Low (L):*** When one, a less than comparison is performed.
- ***High (H):*** When one, a greater than comparison is performed.
- All other bits are reserved and should be zero to ensure future compatibility.

The control bits may be used in any combination. If none of the bits are set, the comparison will always produce a false result. If all of the bits are set, the comparison will always produce a true result.

The M_5 field specifies the element size control (ES). The ES control specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_5	Element Size
0	Byte
1	Halfword
2	Word
3-15	Reserved

The M_6 field has the following format:

The bits of the M_6 field are defined as follows:

- ***Invert Result (IN):*** If bit 0 is zero, the operation proceeds using the comparison indication values in the first intermediate result. If one, the operation proceeds with the comparison indication values in the first intermediate result inverted.
- ***Result Type (RT):*** If bit 1 is zero, a byte index is stored into byte seven of the first operand and zeros are stored in all other elements. If bit 1 is one, each resulting element is a bit-vector.
- ***Zero Search (ZS):*** If bit 2 is one, each element of the second operand is also compared for equality with zero.
- ***Condition Code Set (CS):*** If bit 3 is zero, the condition code is not set and remains unchanged. If one, the condition code is set as specified in the following section.

Resulting Condition Code:

If the CS-bit is zero, the code remains unchanged.

If the CS-bit is one, the code is set as follows:

0 If the ZS-bit is one, there are no true indications in a lower indexed element in the first intermediate result than a true indication in the second intermediate result. That is, there were no matching elements before an element containing zero in the second operand.

1 At least one indication in the first intermediate result is true. All indications in the second intermediate result are false. That is, there was at

least one match in the second operand and, if the ZS-bit is one, no zero matches.
2 If the ZS-bit is one and at least one indication in the first intermediate result is true with a lower index than a true indication in the second intermediate result.
3 All indications in the first intermediate and second intermediate results are false.

Program Exceptions:

VSTRCZB	$V_1,V_2,V_3,V_4[,M_6]$	VSTRC V_1,V_2,V_3,V_4,0$[,M_6]$|X'2')
VSTRCZH	$V_1,V_2,V_3,V_4[,M_6]$	VSTRC V_1,V_2,V_3,V_4,1$[,M_6]$|X'2')
VSTRCZF	$V_1,V_2,V_3,V_4[,M_6]$	VSTRC V_1,V_2,V_3,V_4,2$[,M_6]$|X'2')
VSTRCZBS	$V_1,V_2,V_3,V_4[,M_6]$	VSTRC V_1,V_2,V_3,V_4,0$[,M_6]$|X'3')
VSTRCZHS	$V_1,V_2,V_3,V_4[,M_6]$	VSTRC V_1,V_2,V_3,V_4,1$[,M_6]$|X'3')
VSTRCZFS	$V_1,V_2,V_3,V_4[,M_6]$	VSTRC V_1,V_2,V_3,V_4,2$[,M_6]$|X'3')

Programming Notes:

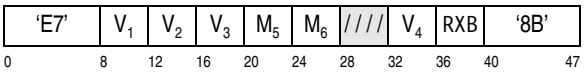
1. To create a comparison that is a range with only one bound, either place that comparison in both the even and odd elements of the pair in the third and fourth operands or place the operand in a single element of the pair with the comparison needed in the corresponding element of the fourth operand, and set the other element in the fourth operand to have all three control bits set.

2. To create a comparison for equality place the same value in the even-odd pair in the third operand. The corresponding even-odd element pair in the fourth operand should contain elements with only a one in the EQ bit.

3. If all available ranges are not needed, the control bits in the fourth operand should all be zero for the elements in the unneeded range. The corresponding elements in the third operand are ignored.

VECTOR STRING SEARCH

VSTRS $V_1,V_2,V_3,V_4,M_5,[M_6]$ [VRR-d]



The substring specified in the third operand is searched for in the second operand. The length of the substring in the third operand is dependent on the zero-search (ZS) flag in the M_6 field. When the ZS flag is zero, the length in bytes is specified as an unsigned binary integer in bits 56-63 of the fourth operand. When the ZS flag is one, the length in bytes is specified by the smaller of, the unsigned binary integer in bits 56-63 of the fourth operand, or the number of leftmost bytes of the third operand that contain nonzero values (from 0 to 16). See Figure 23-2 and Figure 23-3 for the dataflow of the instruction.

If the zero search (ZS) flag in the M_6 field is one and a zero element is contained in the third operand at a position less than the length specified by the fourth operand, then the position of the leftmost byte of the zero element is used as the length of the substring. If the ZS flag is zero, then the length specified in the fourth operand is used.

A first intermediate result is computed as the leftmost byte position in the second operand where the elements, left to right, of the substring are matching the elements in the second operand for the length of the substring. If such a position exists, then a full match exists. Otherwise, the longest partial string, left to right, of the substring matching the rightmost elements of the second operand is computed as the intermediate result. If such a match is found, it is called a partial match. Otherwise, there is no match and the intermediate result is 16.

If the zero search (ZS) flag in the M_6 is one and the index of the first substring matching position is greater than the position of the leftmost byte of the leftmost zero element in the second operand then the match is ignored.

If a non-ignored match is found, then the starting position in bytes of the match in the second operand is stored in byte element seven of the first operand

else a value of 16 is stored. All other bytes of the first operand are set to zero.

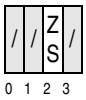
Byte element seven of the fourth operand specifies the length of the substring in bytes and must be in the range of 0-16. Other values will result in an unpredictable result.

The M_5 field specifies the size of the elements in the vector register operands. If a reserved value is specified, a specification exception is recognized.

M_5	Element Size
0	Byte
1	Halfword
2	Word
3-15	Reserved

If the M_5 field specifies a halfword or word element size and the length of the substring in bytes is not a multiple of this element size, then results are unpredictable .

The M_6 field has the following format:



The bits of the M_6 field are defined as follows:

- ***Reserved:*** Bits 0,1,3 are reserved and must be zero; otherwise, a specification exception is recognized.
- ***Zero Search (ZS):*** If bit 2 is one, the position of the leftmost zero byte element marks the string length.

Resulting Condition Code:

0 No match or partial match of the substring was found, and either the ZS flag is zero or no zero byte was detected in the second operand.
1 No match of the substring was found, and the ZS flag is one and a zero byte was detected in the second operand.
2 A full match was found.
3 A partial match was found but no full match.

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector enhancements facility 2 for the z/Architecture is not installed)
- Specification
- Transaction constraint

Extended Mnemonics:

Extended Mnemonic		Base Mnemonic	
VSTRSB	$V_1,V_2,V_3,V_4[,M_6]$	VSTRS	$V_1,V_2,V_3,V_4,0\ [,M_6]$
VSTRSH	$V_1,V_2,V_3,V_4[,M_6]$	VSTRS	$V_1,V_2,V_3,V_4,1\ [,M_6]$
VSTRSF	$V_1,V_2,V_3,V_4[,M_6]$	VSTRS	$V_1,V_2,V_3,V_4,2\ [,M_6]$
VSTRSZB	V_1,V_2,V_3,V_4	VSTRS	$V_1,V_2,V_3,V_4,0,\ 2$

VSTRSZF	V_1,V_2,V_3,V_4	VSTRS	$V_1,V_2,V_3,V_4,2,\ 2$

Programming Notes:

1. In accordance to C11 and Java programming language standard a zero length substring is recognized as a full match.
2. If the ZS flag is one and a zero byte was detected in the second operand, then there can not be a partial match as the end of the string has been reached.
3. For proper usage, if the M_5 field specifies a halfword size then bit 63 of the fourth operand must be zero, and if the M_5 field specifies a word size then bits 62 and 63 of the fourth operand must both be zero.

The vector facility for z/Architecture provides support for short-format, long-format, and extended format binary-floating-point (BFP) operations. Numerically, the results in each element are the same as would occur as if an instruction in Chapter 19 was used to compute the result. Some instructions have different result figures noting changes due to different exception handling described below.

IEEE Exception Handling

When a vector instruction is executed and a trapping IEEE exception condition is encountered, instruction execution is suppressed for all elements, except that the floating-point-control register is updated with the VXC. The index in the VXC is always the index of the source element that caused the trapping exception except for one special case in VECTOR LOAD LENGTHENED (see the programming note on page 24-27). If trapping vector-processing exception conditions exist for multiple elements, the exception of the lowest-indexed source element is recognized.

When either a trapping IEEE overflow or IEEE underflow exception occur concurrently on the same element with a trapping IEEE inexact exception, only the IEEE overflow or IEEE underflow exception is recognized.

When a vector instruction is executed, no trapping IEEE exceptions are encountered on any elements, and a non-trapping IEEE exception condition is encountered on an element, the flag bit for that exception is set in the floating-point-control (FPC) register and the IEEE defined default value is placed in the corresponding element of the target operand. If multiple elements have non-trapping IEEE exception conditions then each element sets the flag bit in the FPC register and the defined default values are placed in the corresponding elements of the target operand.

Result Figures

Concise descriptions of the results produced by many of the vector floating point instructions are made by means of figures which contain columns and rows representing all possible combinations of data class for the source operand elements of an instruction. The information shown at the intersection of a row and a column is one or more symbols representing the result or results produced for that particular combination of source-operand element data classes. Explanations of the symbols used are contained in each figure. In many cases, the explanation of a particular result is in the form of a cross reference to another figure. In many cases, the information shown at the intersection consists of several

© Copyright IBM Corp. 2000, 2025

symbols separated by commas. All such results are produced unless one of the results for an element is a program interruption. In the case of a program interruption on any element, the operation is suppressed.

Figure 24-1, “IEEE Exception and Flag Abbreviations” on page 24-2 shows IEEE exceptions and flag abbreviations that are used in the result figures.

Exception		FPC IEEE Mask Bit	IEEE Flag	
Name	Abbr.		FPC Bit	Abbr.
IEEE invalid operation	Xi[1]	0.0	1.0	SFi
IEEE division by zero	Xz[2]	0.1	1.1	SFz
IEEE overflow	Xo	0.2	1.2	SFo
IEEE underflow	Xu	0.3	1.3	SFu
IEEE inexact	Xx	0.4	1.4	SFx

Explanation:

1 The symbol “Xi:” followed by a list of results in a figure indicates that, when FPC 0.0 is zero, then instruction execution is completed by setting SFi (FPC 1.0) to one and producing the indicated results; and when FPC 0.0 is one, then instruction execution is suppressed, if the element is the leftmost element upon which an exception is recognized the vector interrupt code (VIC) in the vector exception code (VXC) is set to 1 hex, the VIX is set to the index of the element recognizing the exception, and a program interruption for a vector-processing exception occurs.

2 The symbol “Xz:” followed by a list of results in a figure indicates that, when FPC 0.1 is zero, then instruction execution is completed by setting SFz (FPC 1.1) to one and producing the indicated results; and when FPC 0.1 is one, then instruction execution is suppressed if the element is the leftmost element upon which an exception is recognized the vector interrupt code (VIC) in the vector exception code (VXC) is set to 2 hex, the VIX is set to the index of the element recognizing the exception, and a program interruption for a data exception occurs.

Figure 24-1. IEEE Exception and Flag Abbreviations

Instructions

Each instruction has an Extended Mnemonic section which describes recommended extended mnemonics and their corresponding machine assembler syntax. Not all assemblers may provide these mnemonics.

Most vector floating-point instructions have a single element control bit. If this bit is set to one, indicating only one element is to be executed, performance may be improved on some models. When the single element control bit is set the bit positions of all other elements besides the zero indexed element are unpredictable A mnemonic with the initial V replaced with a W indicates the instruction will only operate on a single element.

Programming Note: When the vector-enhancements facility 2 is installed, the following instructions are extended to provide conversion between BFP short format and word sized integer:

- VECTOR FP CONVERT FROM FIXED
- VECTOR FP CONVERT FROM LOGICAL
- VECTOR FP CONVERT TO FIXED
- VECTOR FP CONVERT TO LOGICAL

To distinguish which functions are provided, alternative names and mnemonics are assigned to these instructions.

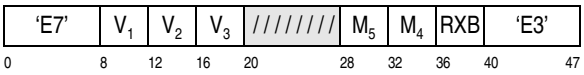
Figure 24-2. Summary of Vector Floating-Point Instructions

VECTOR FP ADD

VFA V_1,V_2,V_3,M_4,M_5 [VRR-c]



The floating-point element or elements of the third operand are added to the corresponding floating-point element or elements of the second operand. The results are placed in the corresponding elements of the first operand. The size of the operand elements is determined by the floating-point-format control in the M_4 field. The operand elements all are treated as BFP numbers of the specified format.

If the corresponding elements of both operands are finite numbers, they are added algebraically, forming an intermediate sum. The intermediate sum, if nonzero, is rounded to the operand format according to the current BFP rounding mode. The sum is then placed at the result location.

The sign of the sum is determined by the rules of algebra. This also applies to a result of zero:

- If the result of rounding a nonzero intermediate sum is zero, the sign of the zero result is the sign of the intermediate sum.
- If the sum of two operand elements with opposite signs is exactly zero, the sign of the result is plus in all rounding methods except round toward -∞, in which method the sign is minus.
- The sign of the sum x plus x is the sign of x, even when x is zero.

If one operand element is an infinity and the other is a finite number, the result is that infinity. If both operand elements are infinities of the same sign, the result is the same infinity. If the two operand elements are infinities of opposite signs, an IEEE-invalid-operation exception is recognized.

See Figure 24-3 on page 24-5 for detailed information on the results for each element.

The M_4 field specifies the floating-point format. The floating-point format determines the size of the elements within the vector register operands. If a reserved value is specified, a specification exception is recognized. If the vector-enhancements facility 1 is not installed the values 2 and 4 are reserved.

M_4	Floating-Point Format
0-1	Reserved
2	Short format
3	Long format
4	Extended format
5-15	Reserved

The M_5 field has the following format:

The bits of the M_5 field are defined as follows:

- ***Single-Element-Control (S):*** If bit 0 is set to one, the operation takes place only on the zero-indexed element in the vector. In the absence of a trapping exception condition, the bit positions of all other elements in the first operand vector are unpredictable . If bit 0 is set to zero, the operation occurs on all elements in the vector.
- ***Reserved:*** Bits 1 to 3 are reserved and must be zero. Otherwise, a specification exception is recognized.

Condition Code: The code remains unchanged.

IEEE Exceptions:

- Invalid Operation
- Overflow
- Underflow
- Inexact

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

Explanation:

*	The SNaN is converted to the corresponding QNaN before it is placed at the target operand element location.
dNaN	Default NaN.
Dn	Subnormal number.
Nn	Normal number.
R(v)	Rounding and range action is performed on the value v. See Figure 24-4 on page 24-6.
Rezd	Exact zero-difference result. See Figure 24-4 on page 24-6.
T(x)	The value x is placed at the target operand element location if no trapping exceptions on other elements.
Xi:	IEEE invalid-operation exception. The results shown are produced only when FPC 0.0 is zero.

Explanation:

– This situation cannot occur.

* The rounded value, in the extreme case, may be Nmin. In this case, the exceptions are underflow, inexact and incremented.

[1] The nontrap result r is considered to have been incremented.

[2] The exact-zero-difference case applies only to VECTOR FP ADD, VECTOR FP SUBTRACT, VECTOR FP MULTIPLY AND ADD, and VECTOR FP MULTIPLY AND SUBTRACT. For all other vector BFP operations, a zero result is detected by inspection of the source operand elements without use of the R(v) function.

[3] The rounding mode is used for converts to NNP-data-type 1.

d The denormalized value. The value derived when the precise intermediate value (v) is rounded to the format of the target, including both precision and bounded exponent range. Except as explained in note *, this is a subnormal number.

g The precision-rounded value. The value derived when the precise intermediate value (v) is rounded to the precision of the target, but assuming an unbounded exponent range.

v Precise intermediate value. This is the value, before rounding, assuming unbounded precision and an unbounded exponent range. For VECTOR LOAD ROUNDED, v is the source value (a).

Dmin Smallest (in magnitude) representable subnormal number in the target format.

Nmax Largest (in magnitude) representable finite number in the target format.

Nmin Smallest (in magnitude) representable normal number in the target format.

Figure 24-4. Action for R(v): Rounding and Range Function (Part 1 of 2)

Case	Is r Inexact (r≠v)	Overflow Mask (FPC 0.2)	Underflow Mask (FPC 0.3)	IEEE Inexact Exception Control (XxC)[2]	Inexact Mask (FPC 0.4)	Results
Overflow	Yes[1]	0	–	1	–	T(r), SFo←1
Overflow	Yes[1]	0	–	0	0	T(r), SFo←1, SFx←1
Overflow	Yes[1]	0	–	0	1	PIV(5)
Overflow	Yes[1]	1	–	–	–	PIV(3)
Normal	No	–	–	–	–	T(r)
Normal	Yes	–	–	1	–	T(r)
Normal	Yes	–	–	0	0	T(r), SFx←1
Normal	Yes	–	–	0	1	PIV(5)
Tiny	No	–	0	–	–	T(r)
Tiny	No	–	1	–	–	PIV(4)
Tiny	Yes	–	0	1	–	T(r), SFu←1
Tiny	Yes	–	0	0	0	T(r), SFu←1, SFx←1
Tiny	Yes	–	0	0	1	PIV(5)
Tiny	Yes	–	1	–	–	PIV(4)

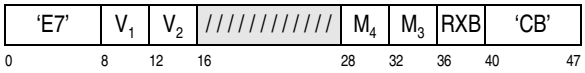
Explanation:

–	The results do not depend on this condition or mask bit.
1	This condition is true by virtue of the state of some condition to the left of this column.
2	If no XxC is defined for an instruction it is assumed to be zero.
r	Nontrap result as defined in Part 1 of this figure.
v	Precise intermediate value. This is the value, before rounding, assuming unbounded precision and unbounded exponent range.
PIV(h)	Program interruption for vector-processing exception, with VXC containing the element index and a VIC of h in hex.
SFo	IEEE overflow flag, FPC 1.2.
SFu	IEEE underflow flag, FPC 1.3.
SFx	IEEE inexact flag, FPC 1.4.
T(x)	The value x is placed at the target operand element location.

Figure 24-4. Action for R(v): Rounding and Range Function (Part 2 of 2)

VECTOR FP COMPARE SCALAR

WFC V_1,V_2,M_3,M_4 [VRR-a]



The zero-indexed floating-point element of the first operand is compared with the zero-indexed floating-point element of the second operand, and the condition code is set to indicate the result. The operand elements are all treated as BFP numbers of the specified format.

If both operand elements are finite numbers, the comparison is algebraic and follows the procedure for BFP subtraction, except that the difference is discarded after setting the condition code, and both operand elements remain unchanged. If the difference is exactly zero with either sign, the operand elements are equal; this includes zero operand elements (so +0 equals -0). If a nonzero difference is positive or negative, the first operand element is high or low, respectively.

+∞ compares greater than any finite number, and all finite numbers compare greater than -∞. Two infinity operand elements of like sign compare equal.

Numeric comparison is exact, and the condition code is determined for finite operand elements as if range and precision were unlimited. No overflow or underflow exception can occur.

If either or both operand elements are QNaNs and neither operand element is an SNaN, the comparison result is unordered, and condition code 3 is set.

If either or both operand elements are SNaNs, an IEEE-invalid-operation exception is recognized. If the IEEE invalid-operation mask bit is one, a program

interruption for a vector-processing exception with a VXC indicating an IEEE invalid-operation occurs. If the IEEE-invalid-operation mask bit is zero, the IEEE-invalid-operation flag bit is set to one, and instruction execution is completed by setting condition code 3.

See Figure 19-15, “Results: COMPARE” on page 19-18 for a detailed description of the results of this instruction substituting the first operand element for (a) and the second operand element for (b).

The M_3 field specifies the floating-point format. The floating-point format determines the size of the elements within the vector register operands. If a reserved value is specified, a specification exception is recognized. If the vector-enhancements facility 1 is not installed the values 2 and 4 are reserved.

M_3	Floating-Point Format
0-1	Reserved
2	Short format
3	Long format
4	Extended format
5-15	Reserved

The M_4 field must be zero otherwise a specification exception is recognized.

Resulting Condition Code:

0 Operand elements equal
1 First operand element low
2 First operand element high
3 Operand elements unordered

IEEE Exceptions:

- Invalid operation

Program Exceptions:

- Data with DXC FE, Vector instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

Extended Mnemonics:

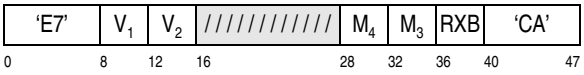
Extended Mnemonic		Base Mnemonic	
WFCSB	V_1,V_2	WFC	$V_1,V_2,2,0$
WFCDB	V_1,V_2	WFC	$V_1,V_2,3,0$
WFCXB	V_1,V_2	WFC	$V_1,V_2,4,0$

Programming Notes:

1. VECTOR FP COMPARE SCALAR may be used to set a condition code to be used by a subsequent branch for program control flow.
2. VECTOR FP COMPARE SCALAR may be used to implement those comparisons which are required by ANSI/IEEE Standard 754-2008 to not recognize an exception when the result is unordered due to a QNaN.

VECTOR FP COMPARE AND SIGNAL SCALAR

WFK V_1,V_2,M_3,M_4 [VRR-a]



The zero-indexed first operand floating-point element is compared with the zero-indexed second operand floating-point element, and the condition code is set to indicate the result. The operand elements are all treated as BFP numbers of the specified format. The operation is the same as for VECTOR FP COMPARE SCALAR except that QNaN operand elements cause an IEEE-invalid-operation exception to be recognized. Thus, QNaN operand elements are treated as if they were SNaNs.

See Figure 19-17, “Results: COMPARE AND SIGNAL” on page 19-19 for a detailed description of the results of this instruction substituting the first operand element for (a) and the second operand element for (b).

The M_3 field specifies the floating-point format. The floating-point format determines the size of the elements within the vector register operands. If a reserved value is specified, a specification exception

is recognized. If the vector-enhancements facility 1 is not installed the values 2 and 4 are reserved.

M_3	Floating-Point Format
0-1	Reserved
2	Short format
3	Long format
4	Extended format
5-15	Reserved

The M_4 field must be zero otherwise a specification exception is recognized.

Resulting Condition Code:

0 Operand elements equal
1 First operand element low
2 First operand element high
3 Operand elements unordered

IEEE Exceptions:

- Invalid operation

Program Exceptions:

- Data with DXC FE, Vector Instruction
- Operation (if the vector facility for z/Architecture is not installed)
- Specification
- Transaction constraint
- Vector processing with VXC for IEEE exception and element index

Extended Mnemonics:

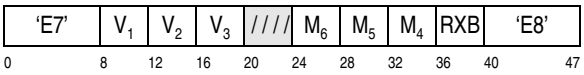
Extended Mnemonic		Base Mnemonic	
WFKSB	V_1,V_2	WFK	$V_1,V_2,2,0$
WFKDB	V_1,V_2	WFK	$V_1,V_2,3,0$
WFKXB	V_1,V_2	WFK	$V_1,V_2,4,0$

Programming Notes:

1. VECTOR FP COMPARE AND SIGNAL SCALAR may be used to set a condition code to be used by a subsequent branch for program control flow.
2. VECTOR FP COMPARE AND SIGNAL SCALAR may be used to implement those comparisons which are required by ANSI/IEEE Standard 754-2008 to recognize an exception when the result is unordered due to a QNaN.

VECTOR FP COMPARE EQUAL

VFCE V_1,V_2,V_3,M_4,M_5,M_6 [VRR-c]



The floating-point element or elements of the second operand are compared for equality with the corresponding element or elements of the third operand. If equal, the bits of the corresponding element in the first operand are set to all ones, otherwise the bits are set to all zeros. The size of the operand elements is determined by the floating-point-format control in the M_4 field. The second and third operand elements are treated as BFP numbers of the specified format.

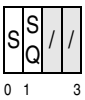
If any of the elements in the second or third operands used in the comparison are SNaNs, an IEEE invalid-operation exception is recognized. If the vector-enhancements facility 1 is installed and the signal-if-QNaN (SQ) control is one and any of the elements in the second or third operands used in the comparison are QNaNs, an IEEE invalid-operation exception is also recognized. If the IEEE invalid-operation mask bit is one, a program interruption with VXC set for IEEE invalid-operation and the corresponding element index occurs and the operation is suppressed. If the IEEE invalid-operation mask bit is zero, the bits of the corresponding element in the first operand are set to zeros and the IEEE invalid-operation flag bit is set in the FPC register.

See Figure 24-5 on page 24-11 for a detailed description of the results for each element.

The M_4 field specifies the floating-point format. The floating-point format determines the size of the elements within the vector register operands. If a reserved value is specified, a specification exception is recognized. If the vector-enhancements facility 1 is not installed the values 2 and 4 are reserved.

M_4	Floating-Point Format
0-1	Reserved
2	Short format
3	Long format
4	Extended format
5-15	Reserved

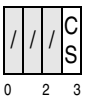
The M_5 field has the following format:



The bits of the M_5 field are defined as follows:

- ***Single-Element-Control (S):*** If bit 0 is set to one, the operation takes place only on the zero-indexed element in the vector. In the absence of a trapping exception condition, the bit positions of all other elements in the first operand vector are unpredictable . The values of all other elements in the second and third operands are ignored. If bit 0 is set to zero, the operation occurs on all elements in the vector.
- ***Signal-on-QNaN (SQ):*** If bit 1 is set to one, a QNaN in any element of the second or third operands will signal an IEEE invalid-operation exception. If bit 1 is set to zero a QNaN will not signal an IEEE invalid-operation exception.
- ***Reserved:*** Bits 2, 3, and if the vector-enhancements facility 1 is not installed, bit 1 are reserved and must be zero. Otherwise, a specification exception is recognized.

The M_6 field has the following format:



The bits of the M_6 field are defined as follows:

- ***Reserved:*** Bits 0, 1, and 2 are reserved and must be zero. Otherwise, a specification exception is recognized.
- ***Condition Code Set (CS):*** If bit 3 is 0, the code remains unchanged. If the bit is one, the code is set as described below.
