	10:9	**UNUSED3** Access: RO
	8	**VECS_CTX_SWITCH_INT** Access: RO VECS context switch interrupt
	7:5	**UNUSED4** Access: RO
	4	**VECS_MI_FLUSH_DWNOTIFY** Access: RO VECS MI Flush DW Notify
	3	**VECS_ERR_INT** Access: RO VECS error interrupt

GT_INTERRUPT3_ISR - GT INTERRUPT3 STATUS REGISTER		
	2:1	**UNUSED5** Access: RO
	0	**VECS_MI_USER_INT** Access: RO VECS MI user interrupt

GTLC_PW_STAT

GTLC_PW_STAT - GTLC_PW_STAT

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	130094h

This register contains Ack and status information for power well requests.

DWord	Bit	Description
0	31:8	**RESERVED** Default Value: 000000h Access: RO Reserved
	7	**Reserved**
	6	**Reserved** Default Value: 0b Access: RO Reserved
	5	**Reserved**
	4	**Reserved** Default Value: 0b Access: RO Reserved
	3:2	**Reserved** Default Value: 00b Access: RO Reserved
	1	**ALLOWWAKEERR** Default Value: 0b Access: R/W One Clear HW set, SW cleared. When access to media or render is observed when ALLOWWAKE=0, the ALLOWWAKERR bit will be set. It will be up to SW or a power cycle to clear the ALLOWWAKEERR bit.
	0	**ALLOWWAKEACK** Default Value: 0b

GTLC_PW_STAT - GTLC_PW_STAT			
		Access:	RO
		Indicates that the allow wake request has been completed.	

GTLC_SURVIVE

GTLC_SURVIVE - GTLC_SURVIVE

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	130098h

This register contains configuration bits for modes that the PM unit should operate in.

DWord	Bit	Description
0	31:12	**RESERVED** Default Value: 00000h Access: RO Reserved
	11	**gvd_pmu_bonus1** Default Value: 0b Access: R/W gvd_pmu_bonus1_zczfwoh
	10	**gvd_pmu_bonus0** Default Value: 0b Access: R/W gvd_pmu_bonus0_zczfwoh
	9	**pmu_gvd_bonus1** Default Value: 0b Access: RO pmu_gvd_bonus1_zczfwoh
	8	**pmu_gvd_bonus0** Default Value: 0b Access: RO pmu_gvd_bonus0_zczfwoh
	7:4	**RESERVED** Default Value: 0h Access: RO Reserved

GTLC_SURVIVE - GTLC_SURVIVE

	3	**GFXCLKSTATUS** Default Value: 0b Access: RO This bit is used as a way to confirm that the GFX clocks have been turned on with bit 2. SW would normally write a one to bit2 and then poll on this bit until.
	2	**GFXCLKFORCEON** Default Value: 0b Access: R/W When this bit is set to a '1, the gvd_pmu_gfxclockstartreq_zczfwoh signal to the Punit will be forced to a one.
	1	**SPAREBIT** Default Value: 0b Access: R/W Description: Spare bit for CHV, BSW. Project: CHV, BSW
	0	**GangMediaRender** Default Value: 0b Access: R/W 0 : The media and render power wells are brought down and up independently. 1 : PM unit will treat both wells as a unit, taking well down together and up together.

GTLC_WAKE

GTLC_WAKE - GTLC_WAKE

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	130090h

GT Wake Control.
This register is used as a way for the Punit to control the GTLC Render and Media Power wells.
Writing bit 0 during normal operation may result in a hang.

DWord	Bit	Description
0	31:26	**RESERVED** Default Value: 00h Access: RO Reserved
	25	**RenderContextExists** Default Value: 0b Access: RO The usage is for support of s0ix, where Punit/Driver would restore the value in this bit no later than the time a '1 is written to ALLOWWAKEREQ (bit 0 of this register) during s0ix exit. SW should not write '1 to this bit during a cold boot exit or warm reset exit. CZ reset is the only thing that can clear this bit. This bit is set by HW after the first Render context save after cold boot or warm reset. SW can only write a one to this bit. If SW tries to write a zero, the previous value will be maintained.
	24	**MediaContextExists** Default Value: 0b Access: RO The usage is for support of s0ix, where Punit/Driver would restore the value in this bit no later than the time a '1 is written to ALLOWWAKEREQ (bit 0 of this register) during s0ix exit. SW should not write '1 to this bit during a cold boot exit or warm reset exit. CZ reset is the only thing that can clear this bit. This bit is set by HW after the first Media context save after cold boot or warm reset. SW can only write a one to this bit. If SW tries to write a zero, the previous value will be maintained.
	23:8	**Common No-wake Hysteresis timer for gfxstartclkreq** Default Value: 0000h

GTLC_WAKE - GTLC_WAKE

		Access: R/W New for CHV, BSW. Hysteresis timer would be used to deassert gfxclockstartreq in case of both wells being in standby and common no-wake request occurs. Counter will be incremented on 60ns interval.
	7:1	**RESERVED** Default Value: 00h Access: RO Reserved
	0	**ALLOWWAKEREQ** Default Value: 0b Access: R/W This bit is used as a way for the driver to make sure GTLC Render AND MEDIA engines do not wake while powered down. The usage is specifically with s0ix, where the driver wants to access the message channel common well (GSclk domain) and does not want the render/media wells to wake up. To remove ambiguity, this bit should be set to '1 and the ALLOWWAKEACK should be observed to the '1 before the FWAKEMEDIAREQ/FWAKERENDERREQ are set. Care must be taken to ONLY use this register prior to Gunit being powered down for S0ix or after registers have been initialized.

GT Mode Register

GT_MODE - GT Mode Register

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000 CHV, BSW
Access:	R/W
Size (in bits):	32
Trusted Type:	1
Address:	07008h
Valid Projects:	CHV, BSW

This Register is used to control the 6EU and 12EU configuration for GT. Writing 0x01FF01FF to this register enables the 6EU mode.

DWord	Bit	Description
0	31:16	**Mask** Access: WO Format: Mask[15:0] Must be set to modify corresponding bit in Bits 15:0. (All implemented bits)
	15	**EU Local Thread Checking Enable** Project: CHV, BSW Access: r/w This field configures the EU local thread checking. If enable the stateless access will be checked against the local thread's scratch space size and start address. Value / Name / Description / Project: 0h – Disable **[Default]** – EU local thread checking is disabled. – CHV, BSW 1h – Enable – EU local thread checking is enabled. – CHV, BSW
	14:13	**SFR mode** Project: CHV, BSW Access: r/w Format: U2 This field must be zero when not in GT4(SFR) configuration i.e GTB_rendermode fuse set to SFR.
	12	**Reserved** Project: CHV, BSW Access: r/w Format: PBC
	11	**16X16 Cross Slice Hash Disable for SF**

GT_MODE - GT Mode Register

Project:	CHV, BSW
Access:	r/w
Format:	U1

Description
This field allows to control pixel block hashing across slices.
Supports 16X16 pixel block hashing in the checker-board pattern irrespective of MSAA. Setting this bit disables hashing and therefore HW will send all the Pixels to both the slices.

Value	Name	Description
0h	Enable **[Default]**	16X16 Checkerboard hashing enabled across slices
1h	Disable	16X16 Checkerboard hashing disabled across slices

Programming Notes
Normal mode of operation in GT3 mode will be to use either 16x16 Hashing or 32x32 Hashing.

10 **16X16 Cross Slice Hash Disable**

Project:	CHV, BSW
Access:	r/w
Format:	U1

This field allows to control pixel block hashing across slices.

Value	Name	Description
0h	Enable **[Default]**	16X16 Checkerboard hashing enabled across slices
1h	Disable	16X16 Checkerboard hashing disabled across slices

9 **WIZ Hashing Mode High Bit**

Project:	CHV, BSW
Access:	r/w
Format:	U1

This field adds additional hashing modes in combination with the WIZ Hashing Mode field. The Value column in the table below refers to this field (high bit) and the WIZ Hashing Mode field (low bit). This field is don't care if the Hashing Disable bit is set.

Value	Name	Description
0h	**[Default]**	8x8 Checkerboard hashing
1h		8x4 Checkerboard hashing
2h		16x4 Checkerboard hashing
3h		Reserved

Programming Notes
8x4 hashing preferred for when msaa enabled

GT_MODE - GT Mode Register

	8	**Reserved** Project: CHV, BSW Access: r/w Format: PBC
	7	**WIZ Hashing Mode** Project: CHV, BSW Access: r/w Format: U1 This field configures the Hashing mode in Windower. This field is don't care if the Hashing Disable bit is set. The WIZ Hashing Mode High Bit field is combined with this field to enable additional modes. (Project: CHV, BSW)
	6:3	**Reserved** Access: r/w Format: PBC
	2	**Reserved** Access: r/w Format: PBC
	1:0	**Reserved** Access: r/w Format: PBC

GTSCRATCH1

GTSCRATCH1 - GTSCRATCH1	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	4F100h

These (8 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation.
The use of these register is defined by software architecture.

DWord	Bit	Description
0	31:0	**GT_Scratchpad** Default Value: 00000000h Access: R/W These (36 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation. The use of these register is defined by software architecture.

GTSCRATCH2

Address:	4F104h

These (8 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation.
The use of these register is defined by software architecture.

DWord	Bit	Description
0	31:0	**GT_Scratchpad** Default Value: 00000000h Access: R/W These (36 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation. The use of these register is defined by software architecture.

GTSCRATCH3

GTSCRATCH3 - GTSCRATCH3	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	4F108h

These (8 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation.
The use of these register is defined by software architecture.

DWord	Bit	Description
0	31:0	**GT_Scratchpad** Default Value: 00000000h Access: R/W These (36 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation. The use of these register is defined by software architecture.

GTSCRATCH4

GTSCRATCH4 - GTSCRATCH4

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	4F10Ch

These (8 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation.
The use of these register is defined by software architecture.

DWord	Bit	Description
0	31:0	**GT_Scratchpad** Default Value: 00000000h Access: R/W These (36 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation. The use of these register is defined by software architecture.

GTSCRATCH5

GTSCRATCH5 - GTSCRATCH5	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	4F110h

These (8 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation.
The use of these register is defined by software architecture.

DWord	Bit	Description
0	31:0	**GT_Scratchpad** Default Value: 00000000h Access: R/W These (36 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation. The use of these register is defined by software architecture.

GTSCRATCH6

GTSCRATCH6 - GTSCRATCH6

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	4F114h

These (8 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation.
The use of these register is defined by software architecture.

DWord	Bit	Description
0	31:0	**GT_Scratchpad** Default Value: 00000000h Access: R/W These (36 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation. The use of these register is defined by software architecture.

GTSCRATCH7

GTSCRATCH7 - GTSCRATCH7	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	4F118h

These (8 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation.
The use of these register is defined by software architecture.

DWord	Bit	Description
0	31:0	**GT_Scratchpad** Default Value: 00000000h Access: R/W These (36 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation. The use of these register is defined by software architecture.

GTSCRATCH8

GTSCRATCH8 - GTSCRATCH8

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	4F11Ch

These (8 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation.
The use of these register is defined by software architecture.

DWord	Bit	Description
0	31:0	**GT_Scratchpad** Default Value: 00000000h Access: R/W These (36 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation. The use of these register is defined by software architecture.

GTSCRATCHPAD0

GTSCRATCHPAD0 - GTSCRATCHPAD0

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	130040h

GT scratchpad registers.
Scratchpad register can be R/W by both driver and GT.
One usage is that GT updates those registers before going to RC6 and reads them on RC6 exit.
Write-able and read-able from GT.
Reads do NOT rely on the register dispatch path, as dependencies could result.
Read-able and write-able from IA.
New for CHV, BSW.

DWord	Bit	Description
0	31:0	**GT_Scratch0** Default Value: 00000000h Access: R/W GT scratchpad register.

GTSCRATCHPAD1

GTSCRATCHPAD1 - GTSCRATCHPAD1

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	130044h

GT scratchpad registers.
Scratchpad register can be R/W by both driver and GT.
One usage is that GT updates those registers before going to RC6 and reads them on RC6 exit.
Write-able and read-able from GT.
Reads do NOT rely on the register dispatch path, as dependencies could result.
Read-able and write-able from IA.
New for CHV, BSW.

DWord	Bit	Description
0	31:0	**GT_Scratch1** Default Value: 00000000h Access: R/W GT scratchpad register.

GTSCRATCHPAD2

GTSCRATCHPAD2 - GTSCRATCHPAD2

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	130048h

GT scratchpad registers.
Scratchpad register can be R/W by both driver and GT.
One usage is that GT updates those registers before going to RC6 and reads them on RC6 exit.
Write-able and read-able from GT.
Reads do NOT rely on the register dispatch path, as dependencies could result.
Read-able and write-able from IA.
New for CHV, BSW.

DWord	Bit	Description
0	31:0	**GT_Scratch2** Default Value: 00000000h Access: R/W GT scratchpad register.

GTSCRATCHPAD3

GTSCRATCHPAD3 - GTSCRATCHPAD3

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	13004Ch

GT scratchpad registers.
Scratchpad register can be R/W by both driver and GT.
One usage is that GT updates those registers before going to RC6 and reads them on RC6 exit.
Write-able and read-able from GT.
Reads do NOT rely on the register dispatch path, as dependencies could result.
Read-able and write-able from IA.
New for CHV, BSW.

DWord	Bit	Description
0	31:0	**GT_Scratch3** Default Value: 00000000h Access: R/W GT scratchpad register.

GTSCRATCHPAD4

GTSCRATCHPAD4 - GTSCRATCHPAD4

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	130050h

GT scratchpad registers.
Scratchpad register can be R/W by both driver and GT.
One usage is that GT updates those registers before going to RC6 and reads them on RC6 exit.
Write-able and read-able from GT.
Reads do NOT rely on the register dispatch path, as dependencies could result.
Read-able and write-able from IA.
New for CHV, BSW.

DWord	Bit	Description
0	31:0	**GT_Scratch4** Default Value: 00000000h Access: R/W GT scratchpad register.

GTSCRATCHPAD5

GTSCRATCHPAD5 - GTSCRATCHPAD5

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	130054h

GT scratchpad registers.
Scratchpad register can be R/W by both driver and GT.
One usage is that GT updates those registers before going to RC6 and reads them on RC6 exit.
Write-able and read-able from GT.
Reads do NOT rely on the register dispatch path, as dependencies could result.
Read-able and write-able from IA.
New for CHV, BSW.

DWord	Bit	Description
0	31:0	**GT_Scratch5** Default Value: 00000000h Access: R/W GT scratchpad register.

GTSCRATCHPAD6

GTSCRATCHPAD6 - GTSCRATCHPAD6

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	130058h

GT scratchpad registers.
Scratchpad register can be R/W by both driver and GT.
One usage is that GT updates those registers before going to RC6 and reads them on RC6 exit.
Write-able and read-able from GT.
Reads do NOT rely on the register dispatch path, as dependencies could result.
Read-able and write-able from IA.
New for CHV, BSW.

DWord	Bit	Description
0	31:0	**GT_Scratch6** Default Value: 00000000h Access: R/W GT scratchpad register.

GTSCRATCHPAD7

GTSCRATCHPAD7 - GTSCRATCHPAD7

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	13005Ch

GT scratchpad registers.
Scratchpad register can be R/W by both driver and GT.
One usage is that GT updates those registers before going to RC6 and reads them on RC6 exit.
Write-able and read-able from GT.
Reads do NOT rely on the register dispatch path, as dependencies could result.
Read-able and write-able from IA.
New for CHV, BSW.

DWord	Bit	Description
0	31:0	**GT_Scratch7** Default Value: 00000000h Access: R/W GT scratchpad register.

GTT Cache Enable

GTT_CACHE_EN - GTT Cache Enable

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000 CHV, BSW
Size (in bits):	32
Address:	04024h

Enable GTT Cache for respective client(s), A0: Must program/observed this to all 0 due to Big Pages Bug 1898112

DWord	Bit	Description
0	31:0	**GTT Cache Enable for CS** Access: R/W Enable GTT Caching for all the client(s) below: 31: BLIT Engine (overrides individual enables of the units) 30: VEBX Engine (overrides individual enables of the units) 29: MFX Engine (overrides individual enables of the units) 28: GFX Engine (overrides individual enables of the units) 27-15: Reserved 14: VMCunit 13: VLFunit 12: BLBunit 11: VFWunit 10: VEOunit 9: HIZunit 8: RCZunit 7: RCCunit 6: ISCunit 5: DCunit 4: MTunit 3: SOLunit 2: VFunit 1: RSunit 0: CSunit

GTTMMADR_LSB

GTTMMADR_LSB - GTTMMADR_LSB

Register Space:	PCI: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000004
Size (in bits):	32
Address:	00010h

Gfx Memory Mapped Address Range. This is the base
address for all memory mapped registers and GTT table.
This register requests allocation for the combined Graphics Translation Table Modification Range and Memory Mapped Range. For the Global GTT, this range is defined as a memory BAR in graphics device config space. It is an alias into which software is required to write Page Table Entry values (PTEs). Software may read PTE values from the global Graphics Translation Table (GTT). PTEs cannot be written directly into the global GTT memory area.
GTTMMADR comprises of 2 regions, GTT and MMADR. Prior to this feature it had a max size of 4M with 2M MMADR + {0,1M, 2M} GTT. Now GTTMMADR will have a max size of 16M.GTTMMADR = 2M MMADR + 6M rsvd + {0, 2M, 4M, 8M} GTT.GTTMMADR will be 16M aligned.

DWord	Bit	Description
0	31:24	**MBA_LSB** Default Value: 00h Access: R/W Memory Base Address (MBA): Set by the OS, these bits correspond to address signals [35:24].16MB combined for MMIO and Global GTT table aperture (2MB for MMIO, 6MB reserved and 8 MB for GTT).
	23:4	**Reserved** Default Value: 00000h Access: RO RSVD:Hardwired to 0 to indicate at least 4MB address range.
	3	**Reserved** Default Value: 0b Access: RO Prefetchable Memory (PREFMEM): Hardwired to 0to prevent prefetching.
	2:1	**MEMTYP** Default Value: 10b Access: RO Memory Type (MEMTYP):

GTTMMADR_LSB - GTTMMADR_LSB		
		00: To indicate 32 bit base address 01: Reserved 10: To indicate 64 bit base address 11: Reserved
	0	**Reserved**

GTTMMADR_MSB

GTTMMADR_MSB - GTTMMADR_MSB

Register Space:	PCI: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	00014h

Default Value:	0x00000070
Size (in bits):	32
Address:	182030h

Gunit Configuration bits.

DWord	Bit	Description
0	31	**GT_IOSFSB_P_READ_POLICY** Default Value: 0b Access: R/W During an SOIx flow, the Punit must read Gunit registers. 0 (Default) : Allow IOSF SB P reads. Note : Punit knows when appropriate times are to issue IOSF SB P reads. 1 : Abort IOSF SB P reads. Note : This default is the opposite of the IOSF SB polarity bit 12_0008h[31]. Note : For CHV, BSW, this policy register will applies to new PM endpoint (which includes the new PM endpoint).
	30:16	**SPARE15** Default Value: 0000h Access: R/W Spare register bits for future use
	15	**SB_Doorbellprevention** Default Value: 0b Access: R/W 0 (default) : IOSF P to IOSF SB doorbell registers can be accesses by IOSF SB and IOSF SBp. Note : This should never occur during normal operation. 1 : IOSF SB and IOSF SBp accesses targeting the IOSF P to IOSF SB doorbell registers are aborted.
	14	**SPARE1** Default Value: 0b Access: R/W Spare register bits for future use
	13	**Reserved**

GU_CTL0 - GU_CTL0

12	**CMDperCLK_ECO** Default Value: 0b Access: R/W 0(default): GSA command per clock supported. 1: A GAM write followed by a read command cannot dispatch in consecutive clocked.
11	**Reserved**
10:9	**SPARE2** Default Value: 00b Access: R/W Spare bits for future use
8	**RESERVED** Default Value: 0b Access: RO Reserved
7	**IOSFP_DCR_Policy** Default Value: 0b Access: R/W IOSF Primary Data Credit Policy. 0 (default) : IOSF Primary data credits reflect data buffer depth. 1: IOSF Primary infinite data credits for both posted and non-posted data is advertised. Credit accounting (and flow control) will rely on cmd credits only.
6:4	**IOSFP_PCRD** Default Value: 111b Access: R/W IOSF Primary Credit AdvertisementNumber of posted command (and data credits/4) will advertize.
3	**SPARE3** Default Value: 0b Access: R/W Spare bits for future use
2	**Reserved**
1	**Reserved**
0	**PFI_Snoop_Override** Default Value: 0b

GU_CTL0 - GU_CTL0

Access:	R/W

0 : Observe GAM snoop/non-snoop indications.
1 : Force all GAM requests to snoop.

Hardware Status Mask Register

HWSTAM - Hardware Status Mask Register

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0xFFFFFFFF
Access:	R/W, RO
Size (in bits):	32
Trusted Type:	1
Address:	02098h
Address:	12098h-1209Bh
Name:	Hardware Status Mask Register
ShortName:	HWSTAM_VCSUNIT0
Address:	1A098h-1A09Bh
Name:	Hardware Status Mask Register
ShortName:	HWSTAM_VECSUNIT
Address:	1C098h-1C09Bh
Name:	Hardware Status Mask Register
ShortName:	HWSTAM_VCSUNIT1
Address:	22098h-2209Bh
Name:	Hardware Status Mask Register
ShortName:	HWSTAM_BCSUNIT

The HWSTAM register has the same format as the Interrupt Control Registers. The bits in this register are mask bits that prevent the corresponding bits in the Interrupt Status Register from generating a Hardware Status Write (PCI write cycle). Any unmasked interrupt bit (HWSTAM bit set to 0) will allow the Interrupt Status Register to be written to the ISR location (within the memory page specified by the Hardware Status Page Address Register) when that Interrupt Status Register bit changes state.

Programming Notes

- To write the interrupt to the HWSP, the corresponding IMR bit must also be clear (enabled).
- At most 1 bit can be unmasked at any given time.

DWord	Bit	Description
0	31:0	**Hardware Status Mask Register Value** Default Value: FFFFFFFFh Format: Array of Masks Refer to the Interrupt Control Register section for bit definitions. Reserved bits are RO.

Hardware Status Page Address Register

HWS_PGA - Hardware Status Page Address Register

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Trusted Type:	1

Address:	02080h-02083h
Name:	Hardware Status Page Address Register
ShortName:	HWS_PGA_RCSUNIT

Address:	12080h-12083h
Name:	Hardware Status Page Address Register
ShortName:	HWS_PGA_VCSUNIT0

Address:	1A080h-1A083h
Name:	Hardware Status Page Address Register
ShortName:	HWS_PGA_VECSUNIT

Address:	1C080h-1C083h
Name:	Hardware Status Page Address Register
ShortName:	HWS_PGA_VCSUNIT1

Address:	22080h-22083h
Name:	Hardware Status Page Address Register
ShortName:	HWS_PGA_BCSUNIT

Description	Project
This register is used to program the 4 KB-aligned System Memory address of the Hardware Status Page used to report hardware status into (typically cacheable) System Memory.	
The address in this register is translated using the Global GTT in memory. The mapping type of the GTT entry determines the snoop nature of the transaction to memory.	CHV, BSW

DWord	Bit	Description
0	31:12	**Address** Format: GraphicsAddress[31:12] This field is used by SW to specify Bits 31:12 of the 4 KB-aligned System Memory address of the 4 KB page known as the Hardware Status Page. The Global GTT is used to map this page from the graphics virtual address to physical address.

HWS_PGA - Hardware Status Page Address Register

		Programming Notes If the Per-Process Virtual Address Space and Exec List Enable bit is set, HW requires that the status page is programmed to allow for the context switch status to be reported.
	11:0	**Reserved** Format: MBZ

HCP CABAC Status

HCP_CABAC_STATUS - HCP CABAC Status

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0x00000000
Size (in bits):	32
Trusted Type:	1
Address:	1E904h

HCP CABAC status.

DWord	Bit	Description
0	31:12	**Reserved** Format: MBZ
	11	**Temporal Direction Motion Vector Out-of-Bound Error** Default Value: 0 Access: RO Format: U1 This flag indicates motion vectors calculated from the Temporal Direct Motion vector is larger than the allowed range.
	10:7	**Reserved** Format: MBZ
	6	**Motion Vector Delta SE** Default Value: 0 Access: RO Format: U1 This flag indicates out-of-bound motion vector delta SEs coded in the bit-stream.
	5	**Delta QP SE** Default Value: 0 Access: RO Format: U1 This flag indicates leading-one overflow during CABAC decode of cu_qp_delta_abs.
	4	**Residual Error** Default Value: 0 Access: RO

HCP_CABAC_STATUS - HCP CABAC Status

		Format: U1 This flag indicates out-of-bound absolute coefficient level SEs coded in the bit-stream.
	3	**Slice and Error** Default Value: 0 Access: RO Format: U1 This flag indicates a pre-mature end to the slice or an inconsistent end of slice on the last Ctb of a slice.
	2:1	**Reserved** Format: MBZ
	0	**Ctb Concealment Flag** Default Value: 0 Access: RO Format: U1 Each pulse from this flag indicates one Ctb is concealed by the HCP.

HCP Decode Status

HCP_DEC_STATUS - HCP Decode Status

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	1E900h

HCP Decode status.

DWord	Bit	Description
0	31:18	**Number of Ctbs Concealed** Default Value: 0 Format: U14 This 16-bit field indicates the number of Ctbs concealed during the decoding of the current frame. This field is cleared with the HCP_PIPE_MODE_SELECT command.
	17	**Frame Dec Active** Default Value: 0 Format: U1 This flag indicates that the decoder hardware is actively decoding a picture.
	16	**Indirect Bitstream ObjectAccess Upper Bound Error** Default Value: 0 Format: U1 This flag indicates that the upper bound bit-stream address was reached.
	15:0	**Bit-stream Error Flags** Default Value: 0 Format: U16 This 16-bit field indicates the number of bit stream errors detected for each bit field indicated in the CABAC Status register.

HCP Picture Checksum cIdx0

HCP_PICTURE_CHECKSUM_CIDX0 - HCP Picture Checksum cIdx0

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	1E91Ch

- The HCP Picture Checksum cIdx0 register reports the 32-bit unsigned picture checksum for cIdx=0 calculated by the HCP hardware and whose algorithm is defined in Annex D of the HEVC standard specification.
- This calculated value is updated at the end of the frame.

DWord	Bit	Description
0	31:0	**Picture checksum cIdx0** Default Value: 0 Format: U32

HCP Picture Checksum cIdx1

HCP_PICTURE_CHECKSUM_CIDX1 - HCP Picture Checksum cIdx1

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	1E920h

- The HCP Picture Checksum cIdx1 register reports the 32-bit unsigned picture checksum for cIdx=1 calculated by the HCP hardware and whose algorithm is defined in Annex D of the HEVC standard specification.
- This calculated value is updated at the end of the frame.

DWord	Bit	Description
0	31:0	**Picture checksum cIdx1** Default Value: 0 Format: U32

HCP Picture Checksum cIdx2

HCP_PICTURE_CHECKSUM_CIDX2 - HCP Picture Checksum cIdx2

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	1E924h

- The HCP Picture Checksum cIdx2 register reports the 32-bit unsigned picture checksum for cIdx=2 calculated by the HCP hardware and whose algorithm is defined in Annex D of the HEVC standard specification.
- This calculated value is updated at the end of the frame.

DWord	Bit	Description
0	31:0	**Picture checksum cIdx2** Default Value: 0 Format: U32

HDR

HDR - HDR

Register Space:	PCI: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	0000Ch

Header Type

DWord	Bit	Description
0	31:24	**RESERVED** Default Value: 00h Access: RO Reserved
	23	**MULTI_FUNCTION_STATUS** Default Value: 0b Access: RO MFUNC: Integrated graphics is a single function
	22:16	**HEADER_CODE** Default Value: 00h Access: RO HDR: Indicates a type 0 configuration space header format
	15:0	**RESERVED** Default Value: 0000h Access: RO Reserved

HEVC Local APIC Retry Vector

HEVC_LAPIC_RETRY_VECT - HEVC Local APIC Retry Vector

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Address:	0D594h
Valid Projects:	CHV, BSW

Holds the 4 last retry interrupt vectors. Retries are errors in hardware and are not expected. No interrupt is actually retried, and the interrupt stimulus will be lost if a retry occurs. The system will hang eventually. A 2-bit counter (starting at reset value of 0) is used to point to the slot/byte location from which to load the next retry vector (into the 4 available slots) in sequence. This means if a 5th retry vector shows up, it will be loaded into slot 0 again (as the counter wraps around), over-writing the retry vector which existed there in slot_0.

DWord	Bit	Description
0	31:24	**Vector Slot 3** Format: U8
	23:16	**Vector Slot 2** Format: U8
	15:8	**Vector Slot 1** Format: U8
	7:0	**Vector Slot 0** Format: U8

HS Invocation Counter

HS_INVOCATION_COUNT - HS Invocation Counter	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000, 0x00000000
Access:	R/W
Size (in bits):	64
Trusted Type:	1
Address:	02300h

This register stores the number of patch objects processed by the HS unit. E.g., A PATCHLIST_2 topology with 6 vertices would cause this counter to increment by 3 (there are 3 2-vertex patch objects in that topology).This register is part of the context save and restore.

DWord	Bit	Description
0	63:32	**HS Invocation Count UDW** Number of patch objects processed by the HS stage. Updated only when HS Enable and HS Statistics Enable are set in 3DSTATE_HS
	31:0	**HS Invocation Count LDW** Number of patch objects processed by the HS stage. Updated only when HS Enable and HS Statistics Enable are set in 3DSTATE_HS

IA Vertices Count

IA_VERTICES_COUNT - IA Vertices Count	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000, 0x00000000
Access:	R/W
Size (in bits):	64
Trusted Type:	1
Address:	02310h
Valid Projects:	

This register stores the count of vertices processed by VF. This register is part of the context save and restore.

DWord	Bit	Description
0	63:32	**IA Vertices Count Report UDW** Total number of vertices fetched by the VF stage. This count is updated for every input vertex as long as Statistics Enable is set in VF_STATE (see the Vertex Fetch Chapter in the 3D Volume.)
	31:0	**IA Vertices Count Report LDW** Total number of vertices fetched by the VF stage. This count is updated for every input vertex as long as Statistics Enable is set in VF_STATE (see the Vertex Fetch Chapter in the 3D Volume.)

IDLE Messaging Register for Blitter Engine

MSG_IDLE_BCS - IDLE Messaging Register for Blitter Engine

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	16
Address:	0800Ch

Message registers have bit-wise masking applied for writes. The register consists of 16 bits of data in [15:0], and 16 bits of corresponding masks in [31:16]. In order to set bit0, for example, the data would be 0x0001_0001. In order to clear bit0, for example, the data would be 0x0001_0000. Note that mask bit is the data bit offset + 16. Message registers are protected from non-GT writes via the Message Channel.

DWord	Bit	Description
0	15:6	**Reserved** Access: RO
	5	**Flush and Block Acknowledgement** Access: R/W Flush and Block Acknowledgement 1'b0 : Not flushed and blocked <default> 1'b1 : Unit has flushed and blocked its pipeline
	4	**Preparation for Reset Acknowledgement** Access: R/W Go Acknowledgement 1'b0 : Go=0 Ack <default> 1'b1 : Go=1 Ack Requirement is that when Go=0 request is sent, the agent has to indicate busy before sending the Go=0 acknowledgement. It can only go idle again once Go=1 is received.
	3:0	**Idle Messaging** Access: R/W Idle Messaging Bit[3] Secondary Pipe Clock Gating 1'b0 : Secondary pipe clock must be on <default> 1'b1 : Secondary pipe clock may be gated Bit[2] Primary Pipe Clock Gating 1'b0 : Primary pipe clock must be on <default> 1'b1 : Primary pipe clock may be gated

MSG_IDLE_BCS - IDLE Messaging Register for Blitter Engine		
		Bit[1] C6 Allowed 1'b0 : Do not allow GT to enter C6 <default> 1'b1 : GT may enter C6 Bit[0] Idle Indication 1'b0 : Pipe is busy <default> 1'b1 : Pipe is idle ** See "Valid Combinations for Idle Messaging" Table

IDLE Messaging Register for Media0 Engine

MSG_IDLE_VCS0 - IDLE Messaging Register for Media0 Engine

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	16
Address:	08004h

Message registers have bit-wise masking applied for writes. The register consists of 16 bits of data in [15:0], and 16 bits of corresponding masks in [31:16]. In order to set bit0, for example, the data would be 0x0001_0001. In order to clear bit0, for example, the data would be 0x0001_0000. Note that mask bit is the data bit offset + 16. Message registers are protected from non-GT writes via the Message Channel.

DWord	Bit	Description
0	15:6	**Reserved** Access: RO
	5	**Flush and Block Acknowledgement** Access: R/W Flush and Block Acknowledgement 1'b0 : Not flushed and blocked <default> 1'b1 : Unit has flushed and blocked its pipeline
	4	**Preparation for Reset Acknowledgement** Access: R/W Go Acknowledgement 1'b0 : Go=0 Ack <default> 1'b1 : Go=1 Ack Requirement is that when Go=0 request is sent, the agent has to indicate busy before sending the Go=0 acknowledgement. It can only go idle again once Go=1 is received.
	3:0	**Idle Messaging** Access: R/W Idle Messaging Bit[3] Secondary Pipe Clock Gating 1'b0 : Secondary pipe clock must be on <default> 1'b1 : Secondary pipe clock may be gated Bit[2] Primary Pipe Clock Gating 1'b0 : Primary pipe clock must be on <default> 1'b1 : Primary pipe clock may be gated Bit[1]

MSG_IDLE_VCS0 - IDLE Messaging Register for Media0 Engine

		C6 Allowed 1'b0 : Do not allow GT to enter C6 <default> 1'b1 : GT may enter C6 Bit[0] IDLE Indication - Media done 1'b0 : Pipe is busy <default> 1'b1 : Pipe is idle Refer to bits A024[10:9] for different Media turbo scenarios. ** See "Valid Combinations for Idle Messaging" Table

IDLE Messaging Register for Media1 Engine

MSG_IDLE_VCS1 - IDLE Messaging Register for Media1 Engine

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	16
Address:	08008h

Message registers have bit-wise masking applied for writes. The register consists of 16 bits of data in [15:0], and 16 bits of corresponding masks in [31:16]. In order to set bit0, for example, the data would be 0x0001_0001. In order to clear bit0, for example, the data would be 0x0001_0000. Note that mask bit is the data bit offset + 16. Message registers are protected from non-GT writes via the Message Channel.

DWord	Bit	Description
0	15:6	**Reserved** Access: RO
	5	**Flush and Block Acknowledgement** Access: R/W Flush and Block Acknowledgement 1'b0 : Not flushed and blocked <default> 1'b1 : Unit has flushed and blocked its pipeline
	4	**Preparation for Reset Acknowledgement** Access: R/W Go Acknowledgement 1'b0 : Go=0 Ack <default> 1'b1 : Go=1 Ack Requirement is that when Go=0 request is sent, the agent has to indicate busy before sending the Go=0 acknowledgement. It can only go idle again once Go=1 is received.
	3:0	**Idle Messaging** Access: R/W Idle Messaging Bit[3] Secondary Pipe Clock Gating 1'b0 : Secondary pipe clock must be on <default> 1'b1 : Secondary pipe clock may be gated Bit[2] Primary Pipe Clock Gating 1'b0 : Primary pipe clock must be on <default> 1'b1 : Primary pipe clock may be gated Bit[1]

MSG_IDLE_VCS1 - IDLE Messaging Register for Media1 Engine		
		C6 Allowed 1'b0 : Do not allow GT to enter C6 <default> 1'b1 : GT may enter C6 Bit[0] Idle Indication 1'b0 : Pipe is busy <default> 1'b1 : Pipe is idle ** See "Valid Combinations for Idle Messaging" Table

IDLE Messaging Register for Render Engine

MSG_IDLE_CS - IDLE Messaging Register for Render Engine

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	08000h

Message registers have bit-wise masking applied for writes. The register consists of 16 bits of data in [15:0], and 16 bits of corresponding masks in [31:16]. In order to set bit0, for example, the data would be 0x0001_0001. In order to clear bit0, for example, the data would be 0x0001_0000. Note that mask bit is the data bit offset + 16. Message registers are protected from non-GT writes via the Message Channel.
NOTE - GPGPU_ACTIVE and MEDIA_ACTIVE are context saved and restored; the other bits are cleared out before saving context

DWord	Bit	Description
0	31:16	**Context Save Mask** Access: R/W When context save is in progress, mask is forced to particular value to save off messages that need to be retained across an RC6 event. Currently for this register, the following fields are context saved and restored for an RC6 event: [7] GPGPU_ACTIVE [6] MEDIA_ACTIVE
	15:8	**Reserved** Access: RO
	7	**GPGPU Active Load Indication** Access: R/W Active Load Indication - bits[7:6] of this register 2'b00 : Render load is being executed <default> 2'b01 : Media load is being executed 2'b10 : GPGPU load is being executed 2'b11 : Undefined gpmunit self-clears this bit upon sampling.
	6	**Media Active Load Indication** Access: R/W Active Load Indication - bits[7:6] of this register 2'b00 : Render load is being executed <default> 2'b01 : Media load is being executed 2'b10 : GPGPU load is being executed

MSG_IDLE_CS - IDLE Messaging Register for Render Engine

		2'b11 : Undefined gpmunit self-clears this bit upon sampling.
	5	**Flush and Block Acknowledgement** Access: R/W Flush and Block Acknowledgement 1'b0 : Not flushed and blocked <default> 1'b1 : Unit has flushed and blocked its pipeline
	4	**Preparation for Reset Acknowledgement** Access: R/W Go Acknowledgement 1'b0 : Go=0 Ack <default> 1'b1 : Go=1 Ack Requirement is that when Go=0 request is sent, the agent has to indicate busy before sending the Go=0 acknowledgement. It can only go idle again once Go=1 is received. Also, Refer to the table in the description for bits A024[10:9]
	3:0	**Idle Messaging** Access: R/W Idle Messaging Bit[3] Secondary Pipe Clock Gating 1'b0 : Secondary pipe clock must be on <default> 1'b1 : Secondary pipe clock may be gated Bit[2] Primary Pipe Clock Gating 1'b0 : Primary pipe clock must be on <default> 1'b1 : Primary pipe clock may be gated Bit[1] C6 Allowed 1'b0 : Do not allow GT to enter C6 <default> 1'b1 : GT may enter C6 Bit[0] Idle Indication 1'b0 : Pipe is busy <default> 1'b1 : Pipe is idle ** See "Valid Combinations for Idle Messaging" Table Also, Refer to the table in the description for bits A024[10:9]

IDLE Messaging Register for VEBox

MSG_IDLE_VECS - IDLE Messaging Register for VEBox

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	16
Address:	08010h

Message registers have bit-wise masking applied for writes. The register consists of 16 bits of data in [15:0], and 16 bits of corresponding masks in [31:16]. In order to set bit0, for example, the data would be 0x0001_0001. In order to clear bit0, for example, the data would be 0x0001_0000. Note that mask bit is the data bit offset + 16. Message registers are protected from non-GT writes via the Message Channel.

DWord	Bit	Description
0	15:6	**Reserved** Access: RO
	5	**Flush and Block Acknowledgement** Access: R/W Flush and Block Acknowledgement 1'b0 : Not flushed and blocked <default> 1'b1 : Unit has flushed and blocked its pipeline
	4	**Preparation for Reset Acknowledgement** Access: R/W Go Acknowledgement 1'b0 : Go=0 Ack <default> 1'b1 : Go=1 Ack Requirement is that when Go=0 request is sent, the agent has to indicate busy before sending the Go=0 acknowledgement. It can only go idle again once Go=1 is received.
	3:0	**Idle Messaging** Access: R/W Idle Messaging Bit[3] Secondary Pipe Clock Gating 1'b0 : Secondary pipe clock must be on <default> 1'b1 : Secondary pipe clock may be gated Bit[2] Primary Pipe Clock Gating 1'b0 : Primary pipe clock must be on <default> 1'b1 : Primary pipe clock may be gated Bit[1]

MSG_IDLE_VECS - IDLE Messaging Register for VEBox		
		C6 Allowed 1'b0 : Do not allow GT to enter C6 <default> 1'b1 : GT may enter C6 Bit[0] Idle Indication 1'b0 : Pipe is busy <default> 1'b1 : Pipe is idle ** See "Valid Combinations for Idle Messaging" Table

IDLE Messaging Register for Wi-Di

MSG_IDLE_WIN - IDLE Messaging Register for Wi-Di

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	16
Address:	08014h

Message registers have bit-wise masking applied for writes. The register consists of 16 bits of data in [15:0], and 16 bits of corresponding masks in [31:16]. In order to set bit0, for example, the data would be 0x0001_0001. In order to clear bit0, for example, the data would be 0x0001_0000. Note that mask bit is the data bit offset + 16. Message registers are protected from non-GT writes via the Message Channel.

DWord	Bit	Description
0	15:5	**Reserved** Access: RO
	4	**Preparation for Reset Acknowledgement** Access: R/W Go Acknowledgement 1'b0 : Go=0 Ack <default> 1'b1 : Go=1 Ack Requirement is that when Go=0 request is sent, the agent has to indicate busy before sending the Go=0 acknowledgement. It can only go idle again once Go=1 is received.

Idle Switch Delay

IDLEDLY - Idle Switch Delay	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	0223Ch
Address:	1223Ch-1223Fh
Name:	Idle Switch Delay
ShortName:	IDLEDLY_VCSUNIT0
Address:	1A23Ch-1A23Fh
Name:	Idle Switch Delay
ShortName:	IDLEDLY_VECSUNIT
Address:	1C23Ch-1C23Fh
Name:	Idle Switch Delay
ShortName:	IDLEDLY_VCSUNIT1
Address:	2223Ch-2223Fh
Name:	Idle Switch Delay
ShortName:	IDLEDLY_BCSUNIT

The IDLEDLY register contains an Idle Delay field which specifies the minimum number of microseconds allowed for command streamer to wait before a context is switched out leading to IDLE state in Execlist mode, i.e following this context switch there is no active element available in HW to execute.
A default value of 0, means that by default, there is no restriction to wait on a context switch leading to IDLE. This register has no significance when Execlists are not enabled.

DWord	Bit	Description

ShortName:	INDIRECT_CTX_VCSUNIT1

Address:	221C4h-221C7h
Name:	Indirect Context Pointer
ShortName:	INDIRECT_CTX_BCSUNIT

This register is used to program the indirect address to be executed between CS and SVG engine context if enabled. This will only get executed due to regular context save/restore and not during power restore. This register is part of the execution list context and will be executed per context. Only supported if execution list is enabled. There is no preempting workloads within this context.

INDIRECT_CTX - Indirect Context Pointer

Workaround
Workaround: [Render CS Only][Execlist Mode of Scheduling]: SW must ensure arbitration is switched off while context restore is in progress for any given context. This is achieved by disabling arbitration by programming MI_ARB_ON_OFF to "Arbitration Disable" in RCS_INDIRECT_CTX buffer and by enabling back the arbitration by programming MI_ARB_ON_OFF to "Arbitration Enable" as the last command prior to MI_BATCH_END in the BB_PER_CTX_PTR buffer of every context submitted. Note that RCS_INDIRECT_CTX_OFFSET could be set to default value or any other legitimate value as per the programming notes of the register definition. Arbitration disable by programming MI_ARB_ON_OFF (Arbitration Disabled) in RCS_INDIRECT_CTX buffer. Arbitration enabled by programming MI_ARB_ON_OFF (Arbitration Enabled) as the last command prior to MI_BATCH_BUFFER_END in BB_PER_CTX_PTR buffer. Additional Note: This WA need not be applied when it is guaranteed for no preemption to occur during execution of GPGPU workload. Preemption of GPGPU workload can be avoided by Bracketing the GPGPU workload with MI_ARB_ON_OFF (Arbitration Disable) and MI_ARB_ON_OFF (Arbitration Enable) command. MI_ARB_ON_OFF is a privileged command and can only be programmed in ring buffer or in privileged batch buffer (batch buffer in GGTT memory). Pending execlist submitted must not trigger preemption of the ongoing GPGPU workload due to following reasons First context of the pending execlist submitted is not the same as the ongoing GPGPU context. Force restore bit set for the submitted pending execlist.

DWord	Bit	Description
0	31:6	**Indirect CS Context Address** Format: GraphicsAddress[31:6] Pointer to the Context in memory to be executed as a batch.
	5:0	**Size of Indirect CS Context** Format: U6 This is the size of the Indirect Context for CS. This size supports up to 63 cache lines worth of commands where a cache line is 64B. If programmed to zero then the indirect fetch of the CS context is disabled. Value: [0,63] Name:

Instruction Parser Mode Register

INSTPM - Instruction Parser Mode Register	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00004080 [CHV:B, CHV:C, CHV:K]
	0x00006080 [CHV:A]
Access:	R/W, RO
Size (in bits):	32
Trusted Type:	1
Address:	020C0h
Address:	120C0h-120C3h
Name:	Instruction Parser Mode Register
ShortName:	INSTPM_VCSUNIT0
Address:	1A0C0h-1A0C3h
Name:	Instruction Parser Mode Register
ShortName:	INSTPM_VECSUNIT
Address:	1C0C0h-1C0C3h
Name:	Instruction Parser Mode Register
ShortName:	INSTPM_VCSUNIT1
Address:	220C0h-220C3h
Name:	Instruction Parser Mode Register
ShortName:	INSTPM_BCSUNIT

The INSTPM register is used to control the operation of the Instruction Parser. Certain classes of instructions can be disabled (ignored) - often useful for detecting performance bottlenecks. Also, Synchronizing Flush operations can be initiated - useful for ensuring the completion (vs. only parsing) of rendering instructions.

Programming Notes

- If an instruction type is disabled, the parser will read those instructions but not process them.
- Error checking will be performed even if the instruction is ignored.
- All Reserved bits are implemented.
- This Register is saved and restored as part of Context.

Internal GAM State

INTSTATE - Internal GAM State			
Register Space:	MMIO: 0/2/0		
Project:	CHV, BSW		
Source:	PRM		
Default Value:	0x00000000		
Size (in bits):	32		
Address:	040C0h		
DWord		**Bit**	**Description**
0		31:0	**Reserved**

INTERRUPT LINE

INTRLINE - INTERRUPT LINE

Register Space:	PCI: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000100
Size (in bits):	16
Address:	0003Ch

3C - Interrupt. This register is programmed by SBIOS. It is not used by the graphics/display driver. This 8-bit register is used to communicate interrupt line routing information. It is read/write and must be implemented by the device. POST software will write the routing information into this register as it initializes and configures the system.
The value in this register tells which input of the system interrupt controller(s) the device's interrupt pin is connected to. The device itself does not use this value, rather it is used by device drivers and operating systems to determine priority and vector information.
3D - Interrupt. This register is programmed by SBIOS. It is not used by the graphics/display driver

DWord	Bit	Description
0	15:8	**INTERRUPT_PIN** Default Value: 01h Access: RO IPIN: Value indicates which interrupt pin this device uses. 01h: INTA
	7:0	**INTRLINE** Default Value: 00h Access: R/W ILIN: BIOS written value to communicate interrupt line routing information to the device driver. Used to communicate interrupt line routing information. POST software writes the routing information into this register as it initializes and configures the system. The value in this register indicates to which input of the system interrupt controller the device's interrupt pin is connected.

Interrupt Mask Register

IMR - Interrupt Mask Register

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0xFFFFFFFF
Access:	R/W, RO
Size (in bits):	32
Address:	020A8h
Address:	120A8h-120ABh
Name:	Interrupt Mask Register
ShortName:	IMR_VCSUNIT0
Address:	1A0A8h-1A0ABh
Name:	Interrupt Mask Register
ShortName:	IMR_VECSUNIT
Address:	1C0A8h-1C0ABh
Name:	Interrupt Mask Register
ShortName:	IMR_VCSUNIT1
Address:	220A8h-220ABh
Name:	Interrupt Mask Register
ShortName:	IMR_BCSUNIT

The IMR register is used by software to control which Interrupt Status Register bits are masked or unmasked. Unmasked bits will be reported in the IIR, possibly triggering a CPU interrupt, and will persist in the IIR until cleared by software. Masked bits will not be reported in the IIR and therefore cannot generate CPU interrupts.

DWord	Bit	Description
0	31:0	**Interrupt Mask Bits** Format: InterruptMask[32] Refer to the Interrupt Control Register section for bit definitions. This field contains a bit mask which selects which interrupt bits (from the ISR) are reported in the IIR. Reserved bits in the Interrupt Control Register are RO.

Value	Name	Description
FFFF FFFFh	**[Default]**	
0h	Not Masked	Will be reported in the IIR
1h	Masked	Will not be reported in the IIR

IOBAR

IOBAR - IOBAR

Register Space:	PCI: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000001
Size (in bits):	32
Address:	00020h

I/O Base Address. This is used only by SBIOS. This register is the base address for the MMIO_INDEX and MMIO_DATA registers.

This register provides the Base offset of the I/O registers within Device #2. Access to the 8Bs of IO space is allowed in PM state D0 when IO Enable (PCICMD bit 0) set. Access is disallowed :
* in PM states D1-D3 or
* if IO Enable is clear or
* if Device #2 is turned off or
* if Internal graphics is disabled thru the fuse or fuse override mechanisms.

Note that access to this IO BAR is independent of VGA functionality within Device #2.
If accesses to this IO bar is allowed then the GMCH claims all 8, 16 or 32 bit IO cycles from the CPU that falls within the 8B claimed.

DWord	Bit	Description
0	31:16	**RESERVED** Default Value: 0000h Access: RO Reserved
	15:6	**BASE_ADDRESS** Default Value: 0000h Access: R/W BA: Set by the OS, these bits correspond to address signals [15:6]. IOBAR is to be used for both GTLC register programming and GTT table programming. This is an indirect access method.
	5:1	**RESERVED** Default Value: 0h Access: RO
	0	**RESOURCE_TYPE_RTE** Default Value: 1b Access: RO Indicates a request for I/O space

L3 Bank Status

L3STAT - L3 Bank Status		
Register Space:	MMIO: 0/2/0	
Project:	CHV, BSW	
Source:	PRM	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	0B128h	
L3 Status register		
DWord	**Bit**	**Description**
0	31	**L3 Fill Access Status bit** Access: RO This register is Hardware Set and Clear. Set condition: set when the first command is seen on LTCC-LTCD interface. Reset condition: reset when the first Pipeline Flush command is seen on the LTCC-LTCD interface. Reset condition: This Flag will be reset only if we have atleast 1 modified line in the cache written by DC client.
	30:0	**Reserved** Project: CHV, BSW Access: RO

L3CD Error Status register 1

L3CDERRST - L3CD Error Status register 1

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000080
Size (in bits):	32
Address:	0B1F0h

DWord	Bit	Description
0	31:25	**Reserved** Access: RO
	24	**Double bit ECC error detected** Default Value: 0b Access: R/W One Clear Indicates if bank detected a double bit ECC error. When ltcd_lbcf_ecc_2bit_err_valid is set.
	23:14	**Parity row address error** Default Value: 0000000000b Access: R/W One Clear Data array address which has parity B1. Report the data array address which has the Error. ltcd_lbcf_parity_err_rownum[9:0].Once set by HW, it can be cleared only by MMIO Write of 1 to this register bit 13. Driver needs to write 1 to clear this bit.
	13	**Parity Error Valid** Access: R/W One Clear Parity Error valid. Report the Parity Error. ltcd_lbcf_parity_err_valid. Once set by HW, it can be cleared only by MMIO Write of 1 to this register bit 13. Driver needs to write 1 to clear this bit. when ltcd_lbcf_parity_err_valid is asserted, lbcf generates interrupt to ltiseqsl lbcf_ltiseqsl_parity_intr.
	12:11	**Parity error bank number** Access: R/W One Clear bank number which has parity error. Report the bank no. which has the Error. ltcd_lbcf_parity_err_banknum[1:0].Once set by HW, it can be cleared only by MMIO Write of 1 to this register bit 13. Driver needs to write 1 to clear this bit.

L3CDERRST - L3CD Error Status register 1

	10:8	**Parity Error sub-bank no** Access: R/W One Clear Parity Error in sub bank: ltcd0_lbcf_parity_err_subanknum[2:0].Once set by HW, it can be cleared only by MMIO Write of 1 to this register bit 13. Driver needs to write 1 to clear this bit.
	7	**Parity report enable** Default Value: 1b Access: R/W Parity report enable (LCPRTYRPTEN): lbcf_csr_lc_parity_report_en. This is the parity reporting enable, by default it is enabled. When enabled parity is reported by ltcd to sarb. When disabled by driver, ltcd should not send out any parity error to SARB. Driver needs to write 1 to clear this bit.
	6:0	**Reserved** Access: RO

L3 Control Register

L3CNTLREG - L3 Control Register

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000 CHV, BSW
Access:	R/W
Size (in bits):	32
Address:	07034h

Programming Notes	Project
The L3 allocation programming should assign all ways of the cache with no left over ways. Refer to L3 section for the recommended settings.	
Any L3 configuration change that reduces the data cache allocation when strong IA coherency is used requires the full flush of L3 prior to the programming update. An explicit or implicit flush of L3 (DC Flush) through the command streamer doesn't result in flushing/invalidating the IA Coherent lines from L3. However this can be achieved by setting the "**Pipe line flush Coherent lines**" control bit in the "L3SQCREG4" register.	
SLM comes up in an in-consistent state post reconfiguration and must be initialized by the driver for proper parity generation	CHV, BSW

DWord	Bit	Description
0	31:25	**All L3 Client Pool** Project: All Access: R/W Number of ways allocated for the all client pool. This is a combined pool for all clients. Value: 30h — Name: **[Default]** — Project: CHV, BSW **Programming Notes** When this field is non-zero, **DC Way Assignment** and **Read Only Client Pool** should be 0KB. Odd number values are not allowed. **Please refer to L3 Section with Allocation and Programming for recommended settings.**
	24:18	**DC Way Assignment** Project: All Access: R/W Number of ways allocated for DC. Note this allocation is only for DC data types. **Programming Notes** Note: This field must be 0KB if All L3 Client Pool is non-zero. Odd number values are not allowed. **Please refer to L3 HAS for valid programming values**

L3CNTLREG - L3 Control Register

17:11 **Read Only Client Pool**

Project:	All
Access:	R/W

Number of ways allocated for Read Only L3 clients. This is a combined pool for all Read Only clients.

Programming Notes
Note: This field must be 0KB if All L3 Client Pool is non-zero. Odd number values are not allowed. **Please refer to L3 HAS for valid programming values**

10 **Reserved**

Access:	R/W
Format:	PBC

9 **Error Detection Behavior Control**

Project:	CHV, BSW
Access:	R/W
Format:	Enable

The L3 error detection can be enabled to hang the GPU on a non-recoverable error due to SER type events. Such option will be used when corresponding context has data consistency requirements. Once error detection is enabled, s/w has to initialize URB or SLM to all 0's (based on usage model) prior to execution of the workload. Initialization is required to clean up the error detection logic and syndrome tracking.

Value	Name	Description	Project
0h	**[Default]**	RTL does not hang on parity errors or double bit error	CHV, BSW
1h		RTL enforces a hang on parity errors or double bit error	CHV, BSW

8 **GPGPU L3 Credit Mode Enable**

Project:	All
Access:	R/W
Format:	Enable

This bit is required to be enabled under GPGPU workloads to provide the MAX latency coverage from L3 cache. It will override the registers 0xB100[18:14] and 0xB100[23:19], to 0 and the maximum value respectively.

7:1 **URB Allocation**

Project:	All
Access:	R/W

Number of ways allocated for URB usage

Value	Name	Project
30h	**[Default]**	CHV, BSW

Programming Notes
Odd number values are not allowed. **Please refer to L3 HAS for valid programming values**

L3CNTLREG - L3 Control Register

	0	**SLM Mode Enable** Project: All Access: R/W Format: Enable When enabled, a 64KB (per bank) region of L3 is reserved for SLM.

L3 Control Register1

L3 Messaging Register

MSG_L3_LPFC - L3 Messaging Register

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	16
Address:	08038h

Message registers have bit-wise masking applied for writes. The register consists of 16 bits of data in [15:0], and 16 bits of corresponding masks in [31:16]. In order to set bit0, for example, the data would be 0x0001_0001. In order to clear bit0, for example, the data would be 0x0001_0000. Note that mask bit is the data bit offset + 16. Message registers are protected from non-GT writes via the Message Channel.

DWord	Bit	Description
0	15:2	**Reserved** Access: RO
	1	**Acknowledge that L3 Unblock Completed** Access: R/W Acknowledge that L3 Unblock Completed 1'b0 : L3 unblock not complete yet (default) 1'b1 : L3 unblock has completed gpmunit self-clears this bit upon sampling.
	0	**Acknowledge that L3 Flush and Block Completed** Access: R/W Acknowledge that L3 Flush and Block Completed 1'b0 : L3 flush and block not complete yet (default) 1'b1 : L3 flush and block has completed gpmunit self-clears this bit upon sampling.

L3 SLM Register

L3SLMREG - L3 SLM Register

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x40000000
Size (in bits):	32
Address:	0B110h

DWord	Bit	Description
0	31	**Disable Periodic SLM/SQ slot allocation** Default Value: 0b Access: R/W Disable Periodic SLM/SQ slot allocation: When cfg_lslm_livelock_fairarb_dis=1 lslm unit always has the higher priority and lslm_lsqc_block to lsqcunit is asserted as long as there are requests in SLM FIFO. lbcf_csr_lslm_livelock_fairarb_dis.
	30:26	**LSLM_SQ_PENDING_MAX** Default Value: 10000b Access: R/W If lslmunit has read data to be sent to lcbrunit this cfg register specifies the maximum number of clocks for which LSLMunit can block SQ request from being sent o lcbrunit. Default value = 8. Value cannot be zero. lbcf_csr_lslm_sqpend_max[4:0].
	25	**LSLM address disable** Default Value: 0b Access: R/W **Description** 0 - Enable b2b addr matching fix. lslmunit should not block the cycle in fifo if there is a match in the pipeline. 1 - Disable b2b addr matching fix. lslmunit should block the cycle in fifo if there is a match in the pipeline. lbcf_csr_lslm_same_addr_dis. Default = 0. Set this bit to 1'b1 to workaround Atomic b2b bug on SLM for CHV, BSW A-step only.
	24:0	**Reserved** Access: RO

L3 SQC register 4

L3SQCREG4 - L3 SQC register 4	
Register Space:	MMIO: 0/2/0

	7:6	**DCunit Priority Value** Default Value: 10b

L3SQCREG3 - L3 SQC registers 3

		Access: R/W DCunit Priority Value (SQDCPRIVAL): Identifies the priority value for all cycles that are initiated by DC. Priority is used in the L3 Super Queue (L3SQ). 00b = Priority 0. 01b = Priority 1. 10b = Priority 2 (default). 11b = Priority 3. lbcf_csr_dc_priority[1:0].
	5:4	**DAPR Priority Value** Default Value: 11b Access: R/W DAPR Priority Value (SQDAPRPRIVAL): Identifies the priority value for all cycles that are initiated by DAPR. Priority is used in the L3 Super Queue (L3SQ). 00b = Priority 0. 01b = Priority 1. 10b = Priority 2. 11b = Priority 3 (default). lbcf_csr_dapr_priority[1:0].
	3:2	**MTunit Priority Value** Default Value: 11b Access: R/W MTunit Priority Value (SQMTPRIVAL): Identifies the priority value for all cycles that are initiated by Sampler (MT). Priority is used in the L3 Super Queue (L3SQ). 00b = Priority 0. 01b = Priority 1. 10b = Priority 2. 11b = Priority 3 (default). lbcf_csr_mt_priority[1:0].
	1:0	**LSQCunit Priority Value** Default Value: 11b Access: R/W LSQCunit Priority Value (SQPRIVAL): Identifies the priority value for all cycles that are initiated by Super Queue (L3 Evictions). Priority is used in the L3 Super Queue (L3SQ). 00b = Priority 0. 01b = Priority 1. 10b = Priority 2. 11b = Priority 3 (default). lbcf_csr_lsqc_priority[1:0].

LBCF config save msg

LBCFCSR - LBCF config save msg		
Register Space:	MMIO: 0/2/0	
Project:	CHV, BSW	
Source:	PRM	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	0B2FCh	
This register is not context saved and is written by PM unit.		
DWord	**Bit**	**Description**
0	31:10	**Reserved** Access: RO
	9:0	**Context save bit** Access: R/W Hardware Clear Bit[9]: Power Context Save Request. 0: Power context save is not being requested (default). 1: Power context save is being requested. Unit needs to self-clear this bit upon sampling. Bits[8:0]: QWord Credits for Power Context Save Request. Minimum Credits = 1: Unit may send 1 QWord pair (enough for first LRI at least). Maximum Credits = 511: Unit may send 511 QWord pairs. A QWord pair is defined as a 32-bit register address and the corresponding 32-bits of register data. Note that the LRI header and END commands are 64-bits each (32-bit command followed by 32-bit NOOP) and consumes one QWord credit. Only valid with PWRCTX_SAVE_REQ (Bit9).

LBS config bits

LBSREG - LBS config bits

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x46000000 CHV, BSW
Size (in bits):	32
Address:	0B124h

Config Bits for LBS unit

DWord	Bit	Description
0	31:27	**Retry timer for lookup into LSQC** Default Value: 01000b Access: R/W Time between receiving Reject Response from LSQC and doing a snoop lookup request again onto LSQCunit. 00000b: 0 clocks. 00001b: 1 clocks. 00010b: 2 clocks. ... 01000b: 8 clocks (default value). ... 11111b: 32 clocks. lbcf_retry_timer[4:0].
	26	**Recycle parent faster in R/W perf mode** Default Value: 1b Access: R/W Arc into recycle as soon as parent becomes eligible to be recycled. 0: Disabled (recycle possible only when parent is recycled). 1: Enabled (default). lbcf_csr_lsqc_rwperf_quickrec.
	25	**Perf mode for Writes to same address** Default Value: 1b Project: CHV, BSW Access: R/W Performance improvement for writes to same address in L3: 0 - Performance mode is not enabled. 1 - Performance mode is enabled (default). lbcf_csr_lsqc_erlyrec.
	24:0	**Reserved** Access: RO

LEAKAGECOUNTER

LEAKAGECOUNTER - LEAKAGECOUNTER		
Register Space:	MMIO: 0/2/0	
Project:	CHV, BSW	
Source:	PRM	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	1300D4h	
Leakage counter readout		
DWord	**Bit**	**Description**
0	31:0	**Leakage_Counter** Default Value: 00000000h Access: RO This is a live read of the 32-bit leakage counter. Reading this register does not cause the counter to clear. Only the write-write protocol from Punit to Gunit will casue the leakage counter to clear.

LEAKAGECOUNTERCTL

LEAKAGECOUNTERCTL - LEAKAGECOUNTERCTL

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	1300D0h

Leakage counter control.

DWord	Bit	Description
0	31	**leakage_lock** Default Value: 0b Access: R/W Lock This is the lock bit for the leakage counter registers. 13_00D0-13_00DC.
	30:1	**Reserved** Default Value: 00000000h Access: RO Reserved
	0	**leakage_count_en** Default Value: 0b Access: R/W Lock Enable the leakage counters. When zero, the counters will be held to zero. As this transitions to 0-1, counting is enabled. Like the EMON Energy Counters, the leakage counter will perform a "sum of weights" for the 16 events(/subwells) described in 13_00D8 and 13_00DC.

LEAKAGEWEIGHT1

LEAKAGEWEIGHT1 - LEAKAGEWEIGHT1		
Register Space:	MMIO: 0/2/0	
Project:	CHV, BSW	
Source:	PRM	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	1300D8h	
Leakage weights for wells types 1 to 4.		

DWord	Bit	Description
0	31:24	**leakage_vdve** Default Value: 00h Access: R/W Lock Leakage weight for 'vdve' well type. One of these wells are expected on CHV, BSW.
	23:16	**Reserved** Default Value: 00h Access: R/W Lock
	15:8	**Reserved** Default Value: 00h Access: R/W Lock
	7:0	**leakage_aon** Default Value: 00h Access: R/W Lock Leakage weight for 'aon' well type. One of these wells are expected on CHV, BSW.

LEAKAGEWEIGHT2

LEAKAGEWEIGHT2 - LEAKAGEWEIGHT2

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	1300DCh

Leakage weights for wells types 5 to 8.

DWord	Bit	Description
0	31:24	**leakage_eupair** Default Value: 00h Access: R/W Lock Leakage weight for 'eupair' well type. Eight of these wells are expected on CHV, BSW.
	23:16	**leakage_ss** Default Value: 00h Access: R/W Lock Leakage weight for 'ss' well type. Two of these wells are expected on CHV, BSW.
	15:8	**leakage_l3** Default Value: 00h Access: R/W Lock Leakage weight for 'l3' well type. One of these wells are expected on CHV, BSW.
	7:0	**leakage_ffsc** Default Value: 00h Access: R/W Lock Leakage weight for 'ffsc' well type. One of these wells are expected on CHV, BSW.

LNCF config save msg

LNCFCSR - LNCF config save msg		
Register Space:	MMIO: 0/2/0	
Project:	CHV, BSW	
Source:	PRM	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	0B0FCh	
This register is not context saved and is written by pm unit.		
DWord	**Bit**	**Description**
0	31:10	**Reserved** Access: RO
	9:0	**Context save bit** Access: R/W Hardware Clear Bit[9].Power Context Save Request 0: Power context save is not being requested (default). 1: Power context save is being requested. Unit needs to self-clear this bit upon sampling. Bits[8:0].QWord Credits for Power Context Save Request. Minimum Credits = 1: Unit may send 1 QWord pair (enough for first LRI at least). Maximum Credits = 511: Unit may send 511 QWord pairs. A QWord pair is defined as a 32-bit register address and the corresponding 32-bits of register data. Note that the LRI header and END commands are 64-bits each (32-bit command followed by 32-bit NOOP) and consume one QWord credit. Only valid with PWRCTX_SAVE_REQ (Bit9).

Load Indirect Base Vertex

3DPRIM_BASE_VERTEX - Load Indirect Base Vertex	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	02440h-02443h
Valid Projects:	

DWord	Bit	Description
0	31:0	**Base Vertex** Format: S31 This register is used to store the Base Vertex of the 3D_PRIMITIVE command when Load Indirect Enable is set.

Load Indirect Instance Count

3DPRIM_INSTANCE_COUNT - Load Indirect Instance Count	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	02438h-0243Bh
Valid Projects:	

DWord	Bit	Description
0	31:0	**Instance Count** This register is used to store the Instance Count of the 3D_PRIMITIVE command when Load Indirect Enable is set.

Load Indirect Start Instance

3DPRIM_START_INSTANCE - Load Indirect Start Instance	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	0243Ch-0243Fh
Valid Projects:	

DWord	Bit	Description
0	31:0	**Start Vertex** Format: U32 This register is used to store the Start Instance of the 3D_PRIMITIVE command when Load Indirect Enable is set.

Load Indirect Start Vertex

3DPRIM_START_VERTEX - Load Indirect Start Vertex	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	02430h-02433h
Valid Projects:	

DWord	Bit	Description
0	31:0	**Start Vertex** Format: U32 This register is used to store the Start Vertex of the 3D_PRIMITIVE command when Load Indirect Enable is set.

Load Indirect Vertex Count

3DPRIM_VERTEX_COUNT - Load Indirect Vertex Count	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	02434h-02437h
Valid Projects:	

DWord	Bit	Description
0	31:0	**Vertex Count** Format: U32 This register is used to store the Vertex Count of the 3D_PRIMITIVE command when Load Indirect Enable is set.

LOW 2X FREQUENCY THRESHOLD

LOW2XFREQTHRESH - LOW 2X FREQUENCY THRESHOLD

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x000000A0
Size (in bits):	32
Address:	101128h

New for CHV, BSW.

BIOS/Driver programs the Low2x frequency threshold.

DWord	Bit	Description
0	31:16	**RESERVED** Default Value: 0000h Access: RO Reserved
	15:0	**L3FREQREG** Default Value: 00A0h Access: R/W This is control signal needed from clock unit that can be set at 1 when 2X clock frequency is less than or equal to 1GHz. It needs to be at 0 when 2X clock frequency is > 1GHz. Value when in HPLL mode: low2xthresh=0x00B4. This sets low2xfreq high whenever cu2x frequency is less than or equal to 800, 800, 1000, 800, and 800 for CZ400, CZ320, CZ333, CZ266, and CZ200 respectively. Value when in GPLL mode: low2xthresh=0x00A0. This sets low2xfreq high whenever cu2x frequency is less than or equal to 1000, 800, 834, 889, and 800 for CZ400, CZ320, CZ333, CZ266, and CZ200 respectively.

LPFC control register

LPFCCNTL - LPFC control register		
Register Space:	MMIO: 0/2/0	
Project:	CHV, BSW	
Source:	PRM	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	0B01Ch	
LPFC control register.		
DWord	**Bit**	**Description**
0	31	**LPFC enable signal** Access: R/W LPPC event collection enable signal. Incf_lpfc_cnt_en.
	30:0	**Reserved** Project: CHV, BSW Access: RO Reserved.

LTCD Error Injection Register

LBCFERR - LTCD Error Injection Register

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000 CHV, BSW

LTCD Error Inject control bits in LBCF

DWord	Bit	Description
0	31:25	**Reserved** Project: CHV, BSW Access: RO
	24	**LTISEQSL parity error interupt** Default Value: 0b Project: CHV, BSW Access: R/W Parity error interrupt to LTISEQ Slice.
	23	**Bank hang on parity disable** Default Value: 0b Project: CHV, BSW Access: R/W
	22	**Parity Error Injection Enable** Project: CHV, BSW Access: R/W 0: Disable parity error injection. 1: Enable parity error injection. lbcf_parity_err_inject_en. Do not Enable this when ECC Error injection is enabled.
	21	**Double Bit Error injection** Project: CHV, BSW Access: R/W 0: Default No error injected. 1: Double bit error is injected. lbcf_ecc_2bit_err_inject. Single bit Error Injection and double bit error injection are mutually exclusive.

LBCFERR - LTCD Error Injection Register

		Do not Enable this when Parity Error injection is enabled.
	20	**Single Bit Error injection** Project: CHV, BSW Access: R/W 0: Default No error injected. 1: Single bit error is injected. lbcf_ecc_1bit_err_inject. Single bit Error Injection and double bit error injection are mutually exclusive. Do not Enable this when Parity Error injection is enabled.
	19	**ECC Error Injection Enable** Project: CHV, BSW Access: R/W 0: Disable ECC error injection. 1: Enable ECC error injection. lbcf_ecc_err_inject_en. Do not Enable this when Parity Error injection is enabled.
	18:4	**Row address for error injection** Project: CHV, BSW Access: R/W Row address for which error is injected. For ECC error injection, the same row address is overloaded to inject ECC error for that particular row address. SLM configuration. For Address: Rowaddress [16:7] is applicable for SLM banks and Parity injection is enabled and Rowaddress[18:7] is applicable for ECC (for both NonSLM/SLM banks). Sub bank is applicable only for Parity injection. Only Subbank 0, 1, 2, 3 are supported and are only related to SLM Banks (4KB). Total 12 bits address. Bits 18:7: Row address. Bits 6:4: Sub-Bank number. lbcf_parity_err_inject_rowaddr[9:0].lbcf_parity_err_inject_subank[2:0].16:7 - For SLM parity only. lbcf_parity_err_inject_rowaddr[9:0].lbcf_ecc_err_inject_rowaddr[11:0].For ECC error injection, the same row address is overloaded to inject ECC error for that particular row address.
	3:2	**Bank ID for error injection** Project: CHV, BSW Access: R/W 00b: Inject in Bank 0. 01b: Inject in Bank 1. 10b: Inject in Bank 2. 11b: Inject in Bank 3 (error injection not supported for SLM bank3).

LBCFERR - LTCD Error Injection Register

		lbcf_err_inject_bankid[1:0].
	1:0	**Slice ID for Error injection** Project: CHV, BSW Access: R/W 00b: Inject error in Slice 0. 01b: Inject error in Slice 1. 10b: Inject error in Slice 2. lbcf_err_inject_sliceid.

MA

MA - MA

Address:	040A0h

This register is used to report error conditions. Error bits are writable.

DWord	Bit	Description
0	31:16	**Reserved** Format: MBZ
	15:9	**Reserved**
	8	**Unloaded PD Error** The Cache Line containing a PD entry being accessed was marked as invalid in the last PD load cycle.
	7	**Reserved**
	6	**Reserved**
	5	**Reserved**
	4	**Reserved**
	3	**Hardware Status Page Fault Error** HWSP's GTT translation generated a page fault (GTT entry not valid).
	2	**Invalid Page Directory entry error** PD entry's valid bit is 0.
	1	**Context Page Fault Error** A Context Page's GTT translation generated a page fault (GTT entry not valid).
	0	**TLB Page Fault Error** A TLB Page's GTT translation generated a page fault (GTT entry not valid).

MASTER_INT_CTL

MASTER_INT_CTL - MASTER_INT_CTL

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	44200h

This register has the master enable for graphics interrupts and gives an overview of what interrupts are pending.
An interrupt pending bit will read 1b while one or more interrupts of that category are set (IIR) and enabled (IER).
All Pending Interrupts are ORed together to generate the combined interrupt.
The combined interrupt is ANDed with the Master Interrupt enable to create the master enabled interrupt.
The master enabled interrupt goes to PCI device 2 interrupt processing.
The master interrupt enable must be set before any of these interrupts will propagate to PCI device 2 interrupt processing.

DWord	Bit	Description
0	31	**MASTER_INTERRUPT_ENABLE** Default Value: 0b Access: R/W THIS IS THE MASTER CONTROL FOR GRAPHICS INTERRUPT. this must be enabled for any of these interrupts to propagate to PCI dev2 interrupt processing. 0b - master interrupt disable, 1b - master interrupt enable
	30	**PCU_INTERRUPT_PENDING** Default Value: 0b Access: RO This field indicates if iterrups of this category is pending.
	29:8	**Reserved** Default Value: 00000b Access: RO Reserved
	7	**WDBOX_OACS_INTERRUPT_PENDING** Default Value: 0b Access: RO This field indicates if iterrups of this category is pending.
	6	**VEBOX_INTERRUPT_PENDING** Default Value: 0b

MASTER_INT_CTL - MASTER_INT_CTL

	Access:	RO
	This field indicates if iterrups of this category is pending.	
5	**Reserved**

Mirror of base of data stolen memory. Simply a read-only alias to the configuration registers.
Used by the MBC for boot context fetches.
This register contains the base address of Graphics Data Stolen DRAM memory. Note: This register is in device 0, 0xB0. Mirrored into device2, 0x5C.Graphics Stolen Memory is within DRAM space. The base of stolen memory will always be below 4G

DWord	Bit	Description
0	31:20	**BDSM** Default Value: 000h Access: RO BDSM: BASE_OF_Data_STOLEN_MEMORY. This register contains bits 31 to 20 of the base address of Data stolen DRAM memory. For certain GTLC generated accesses, this base register will be added to GTLC provided offset address, forming the full physical address for the PFI fabric. This is also used as a base for VGA paged accesses.
	19:1	**RESERVED** Default Value: 00000h Access: RO Reserved
	0	**BDSM_LOCK** Default Value: 0b Access: RO When set to 1b, this bit will lock all the bits in this register, including itself

MBGSM

MBGSM - MBGSM

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	108100h

Mirror of base of graphics stolen memory. Simply a read-only alias to the configuration registers.
Used by the MBC for boot context fetches.
Base of GTT table in Gfx Stolen Memory Note : This register is located in device 0, 0xB4. Mirrored into Device 2.
The GTT table is located within Graphics Stolen Memory in DRAM space.
The base of stolen memory will always be below 4G.

DWord	Bit	Description
0	31:20	**BGSM** Default Value: 000h Access: RO BGSM: Gfx Base of GTT Stolen Memory. This register contains bits 31 to 20 of the base address of GTT Table in stolen DRAM memory. BIOS determines base of GTT stolen memory by subtracting the GTT graphics stolen memory size (PCI offset 50 bits 9:8) from the Graphics Base of Data stolen(PCI offset 5C bits 31:20).
	19:1	**RESERVED** Default Value: 00000h Access: RO Reserved
	0	**BGSM_LOCK** Default Value: 0b Access: RO This bit will lock all writeable settings in this register including itself

MD

MD - MD

Register Space:	PCI: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	00098h

Message Data

DWord	Bit	Description
0	31:16	**RESERVED** Default Value: 0000h Access: RO Reserved
	15:0	**DATA** Default Value: 0000h Access: R/W MD: This 16-bit field is programmed by system software. This forms the lower word of data for the MSI write transaction.

MEDFW_ACK

MEDFW_ACK - MEDFW_ACK	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	1300BCh

This register contains the per thread force wake acknowledge bits for the Media power well.

DWord	Bit	Description
0	31:16	**RESERVED** Default Value: 0000h Access: RO Reserved.
	15:0	**FWAKEMEDIAACK** Default Value: 0000h Access: RO Force Wake Media request bits. Driver must poll on the corresponding bit to confirm that the well has woken. For example, if 13_00B8[0] is written to a 1 (along with 13_00B8[16]='1'), then bit0 of this register indicates when the force wake request has been completed.

Media 1 TLB Control Register

M1TCR - Media 1 TLB Control Register

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04264h

DWord	Bit	Description
0	31:1	**Reserved** Default Value: 00000000000000000000000000000000b Access: RO
	0	**Invalidate TLBs on the corresponding Engine** Default Value: 0b Access: R/W SW writes 1 to invalidate the TLBs for the associated engine and HW clears the bit when invalidation is complete. To ensure proper invalidation of the TLBs, SW has to ensure the corresponding engine's HW pipeline is flushed and cleared from all its memory accesses. Otherwise HW cannot guarantee the proper invalidation for TLBs. This bit is self clear.

Media 2 TLB Control Register

M2TCR - Media 2 TLB Control Register

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04268h

DWord	Bit	Description
0	31:1	**Reserved** Default Value: 00000000000000000000000000000000b Access: RO
	0	**Invalidate TLBs on the corresponding Engine** Default Value: 0b Access: R/W SW writes 1 to invalidate the TLBs for the associated engine and HW clears the bit when invalidation is complete. To ensure proper invalidation of the TLBs, SW has to ensure the corresponding engine's HW pipeline is flushed and cleared from all its memory accesses. Otherwise HW cannot guarantee the proper invalidation for TLBs. This bit is self clear.

Media forcewake request

MEDFW_REQ - Media forcewake request

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	1300B8h

This register contains per thread force wake request bits for the Render power Well. The upper 16 bits act as masks for the lower 16 bits. Bit 31 masks bit 15 and bit 16 masks bit 0.

1. Driver writes to GPM force wake request bit. (VV will have a Render(13_00B0(15:0)) and a Media (13_00B8(15:0)) bits.)
2. The GPM responds by writing (via PLINK) to 1300B4[15:0] or 1300BC[15:0] register.
3. Driver polls (1300B4[15:0] and/or 1300BC[15:0])status until 1... indicating that that well has completed wake sequence.

Since the registers are per thread, only the specific bit that was forced should be checked for status.

DWord	Bit	Description
0	31:16	**FWAKEMEDIAREQMSK** Default Value: 0000h Access: RO Mask bits for lower 16 bits to avoid a read modify/write. If '0', the corresponding bit in [15:0] is not changed. If '1', the corresponding bit in [15:0] is changed to the value in [15:0]
	15	**FWAKEMEDIAREQ15** Default Value: 0b Access: R/W Force Wake Media request 15.
	14	**FWAKEMEDIAREQ14** Default Value: 0b Access: R/W Force Wake Render request 14.
	13	**FWAKEMEDIAREQ13** Default Value: 0b Access: R/W

MEDFW_REQ - Media forcewake request

		Force Wake Render request 13.
	12	**FWAKEMEDIAREQ12** Default Value: 0b Access: R/W Force Wake Render request 12.
	11	**FWAKEMEDIAREQ11** Default Value: 0b Access: R/W Force Wake Render request 11.
	10	**FWAKEMEDIAREQ10** Default Value: 0b Access: R/W Force Wake Render request 10.
	9	**FWAKEMEDIAREQ9** Default Value: 0b Access: R/W Force Wake Render request 9.
	8	**FWAKEMEDIAREQ8** Default Value: 0b Access: R/W Force Wake Render request 8.
	7	**FWAKEMEDIAREQ7** Default Value: 0b Access: R/W Force Wake Render request 7.
	6	**FWAKEMEDIAREQ6** Default Value: 0b Access: R/W Force Wake Render request 6.
	5	**FWAKEMEDIAREQ5** Default Value: 0b

MEDFW_REQ - Media forcewake request

		Access: R/W Force Wake Render request 5.
	4	**FWAKEMEDIAREQ4** Default Value: 0b Access: R/W Force Wake Render request 4.
	3	**FWAKEMEDIAREQ3** Default Value: 0b Access: R/W Force Wake Render request 3.
	2	**FWAKEMEDIAREQ2** Default Value: 0b Access: R/W Force Wake Render request 2.
	1	**FWAKEMEDIAREQ1** Default Value: 0b Access: R/W Force Wake Render request 1.
	0	**FWAKEMEDIAREQ0** Default Value: 0b Access: R/W Force Wake Render request 0.

Media Power Meter Counter

MPMCNT - Media Power Meter Counter		
Register Space:	MMIO: 0/2/0	
Project:	CHV, BSW	
Source:	PRM

DWord	Bit	Description
0	31:0	**MEDIARC0TIME** Default Value: 00000000h Access: RO Media RC0 Residency Counter.

MEDIARC1COUNTER

MEDIARC1COUNTER - MEDIARC1COUNTER

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	138114h

This register contains the total RC1 residency (Media powered on and clock gated) time that Media was in since boot.
SOXi Context Save/Restore : No
The 40-bit HW counter will wrap around. The only clear condition is CZ reset.
When 0x13_8104[15] is set to zero, bits 31:0 of the 40-bit counter are reported. When 0x13_8104[15] is set to one, bits 39:8 of the 40-bit counter are reported.
The units are CZ clock cycles.
It is up to SW to periodically read this register and do a difference from the last time it was read. The primary usage for this register is for power characterization.
0x13_8104[3] controls if this register should count or if it should be gated: 0= clear, 1=count

DWord	Bit	Description
0	31:0	**MEDIARC1TIME** Default Value: 00000000h Access: RO Media RC1 Residency Counter.

MEDIARC6COUNTER

MEDIARC6COUNTER - MEDIARC6COUNTER	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	13810Ch

This register contains the total RC6 residency (Media power gated and clock gated) time that Media was in since boot. The counter will wrap around.
SOXi Context Save/Restore : No
The time is given in units of CZ clock cycles. The counter will reset on CZ reset going high.
This means that a warm reset will also reset this counter and it will also wrap around when it reaches max with no indication that an overflow occurred.
This register will freeze the count value (stop counting, but not reset) when pmu_gvd_renwakeack_nczfwoh=1.
This register will count whenever pmu_gvd_renwakeack_nczfwoh=0.
When 0x13_8104[15] is set to zero, bits 31:0 of the 40-bit counter are reported. When 0x13_8104[15] is set to one, bits 39:8 of the 40-bit counter are reported.
The units are CZ clock cycles.
It is up to SW to periodically read this register and do a difference from the last time it was read. The primary usage for this register is for power characterization.
0x13_8104[1] controls if this register should count or if it should be gated: 0= clear, 1=count

DWord	Bit	Description
0	31:0	**MEDIARC6TIME** Default Value: 00000000h Access: RO Media Residency Counter.

MEMBOUNDCOUNTER

MEMBOUNDCOUNTER - MEMBOUNDCOUNTER

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	138120h

SOXi Context Save/Restore : No
The 40-bit HW counter will wrap around. The only clear condition is CZ reset.
When 0x13_8104[15] is set to zero, bits 31:0 of the 40-bit counter are reported. When 0x13_8104[15] is set to one, bits 39:8 of the 40-bit counter are reported.
The units are CZ clock cycles.
It is up to SW to periodically read this register and do a difference from the last time it was read. The primary usage for this register is for power characterization.
0x13_8104[6] controls if this register should count or if it should be gated: 0= clear, 1=count

DWord	Bit	Description
0	31:0	**MEMBOUNDTIME** Default Value: 00000000h Access: RO Render RC0 Residency Counter.

Messaging Register for MGSRunit

MSG_MGSR - Messaging Register for MGSRunit

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Default Value:	0x00000000
Size (in bits):	32
Address:	00C04h

Message registers have bit-wise masking applied for writes. The register consists of 16 bits of data in [15:0], and 16 bits of corresponding masks in [31:16].
To set bit0, for example, the data would be 0x0001_0001.
To clear bit0, for example, the data would be 0x0001_0000.
Note that mask bit is the data bit offset + 16. Message registers are protected from non-GT writes via the Message Channel.

DWord	Bit	Description
0	31:16	**Reserved** Access: RO
	15:0	**MGSR Messages** Access: R/W Placeholder for MGSR Messsages. MGSRunit could self-clear these bits upon sampling.

MFC_AVC_CABAC_INSERTION_COUNT

AVC_CABAC_INSERTION_COUNT - MFC_AVC_CABAC_INSERTION_COUNT	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	128ACh
Valid Projects:	CHV, BSW

This register stores the count in bytes of **CABAC ZERO_WORD insertion. It is primarily provided for statistical data gathering.**

DWord	Bit	Description
0	31:0	**MFC AVC Cabac Insertion Count** Total number of bytes in the bitstream output before for the CABAC zero word insertion. This count is updated each time when the insertion count is incremented.

MFC_AVC Bitstream Decoding Front-End Parsing Logic Error Counter

MFC_VIN_AVD_ERROR_CNTR - MFC_AVC Bitstream Decoding Front-End Parsing Logic Error Counter

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Trusted Type:	1

Address:	12804h
Valid Projects:	CHV, BSW

DWord	Bit	Description
0 avd_error_flagsR[31:0]	31:0	**Reserved** Format: MBZ

MFC Image Status Control

MFC_IMAGE_STATUS_CONTROL - MFC Image Status Control

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	128B8h
Valid Projects:	CHV, BSW

This register stores the suggested data for next frame in multi-pass.

DWord	Bit	Description
0	31:24	**Cumulative slice delta QP**
	23:16	**QP Value** suggested slice QP delta value for frame level Rate control. This value can be +ve or -ve
	15	**QP-Polarity Change** Cumulative slice delta QP polarity change.
	14:13	**Num-Pass Polarity Change** Number of passes after cumulative slice delta QP polarity changes.
	12	**Reserved** Project: CHV, BSW Format: MBZ
	11:8	**Total Num-Pass**
	7:4	**Reserved** Format: MBZ
	3	**Missing Huffman Code** Project: CHV, BSW Jpeg HW encoder reports if Huffman table entry is missing.
	2	**Panic** Panic triggered to avoid too big packed file.
	1	**Frame Bit Count** Frame Bit count over-run/under-run flag
	0	**Max Conformance Flag** Max Macroblock conformance flag or Frame Bit count over-run/under-run

MFC Image Status Mask

MFC_IMAGE_STATUS_MASK - MFC Image Status Mask	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	128B4h
Valid Projects:	CHV, BSW

This register stores the image status(flags).

DWord	Bit	Description
0	31:0	**Control Mask** Control Mask for dynamic frame repeat.

MFC QP Status Count

MFC_QUP_CT - MFC QP Status Count

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	128BCh
Valid Projects:	CHV, BSW

This register stores the suggested QP COUNTS in multi-pass.

DWord	Bit	Description
0	31:24	**Cumulative QP Adjust** Format: U8 Cumulative QP adjustment after multiple passes. If there is no need to multi-pass, this value would be zero. (This is in sign magnitude form).
	23:0	**Cumulative QP** Format: U24 Cumulative QP for all MB of a Frame (Can be used for computing average QP).

MFD Error Status

MFD_ERROR_STATUS - MFD Error Status

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	12800h
Valid Projects:	CHV, BSW

This register stores the error status flags and count reports by the bit-stream decoder. This register is not part of hardware context save and restore. Driver should read the content prior to starting a new batch/frame.

DWord	Bit	Description
0	31:20	**Reserved** Format: MBZ This field is currently reserved
	19:16	**AVC Short Format Error Flags** Exists If: // AVC Short Format == Ture Bit-stream error detected by VLD short format bit-stream decoder**.** These flags are reset at the beginning of a frame and updated until starting of another frame. [19] – Slice Type SE Error Flag – Invalid Slice Type SE [18] – MMCO SE Error Flag – Invalid memory management control operation SE. MMCO Loop does not end (mmco control != 0) even after all MMCO SEs are decoded OR MMCO SEs are still being decoded and MMCO SE loop end (mmco control == 0) is hit [17] – Reordering IDC Error Flag – Syntax Element modification_of_pic_nums_idc >= 6 OR modification_of_pic_nums_idc != 3 (end of reordering loop) but reordering count has already hit maximum value [16] – Premature bitstream end is hit before finishing slice header decode
	15:0	**Bit-stream Error flags** Exists If: // AVC CAVLC, AVC CABAC, VC1 and MPEG2 == True Bitstream error detected by the VLD bit-steram decoder. These flags are reset at the beginning of a frame and updated until starting of another frame. AVC CAVLC: Please refer to AVC CAVLC table for each bit field AVC CABAC: Please refer to AVC CABAC table for each bit field VC1: Please refer to VC1 table for each bit field MPEG2: Please refer to MPEG2 table for each bit field

MFD Picture Parameter

MFD_PICTURE_PARAM - MFD Picture Parameter			
Register Space:	MMIO: 0/2/0

MFX_LAT_CT1 - MFX_Memory_Latency_Count1	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	12870h
Valid Projects:	CHV, BSW

This register stores the max and min memory latency counts reported on reference read requests. This register is not part of hardware context save and restore.

DWord	Bit	Description
0	31:24	**Max Request Count** This field indicates the maximum number of requests allowed by the memory sub-system channel.
	23:16	**Current Request Count** This field indicates the number of requests currently outstanding in the memory sub-system. This field should report with a value of zero at the end of frame; otherwise the motion compensation engine is most likely hung waiting for read data to be returned from sub-system.
	15:8	**MFX Reference picture read request - Max Latency Count in 8xMedia clock cycles** This field reports the maximum memory latency count on all reference reads requested by the motion compensation engine.
	7:0	**MFX Reference picture read request - Min Latency Count in 8xMedia clock cycles** This field reports the minimum memory latency count on all reference reads requested by the motion compensation engine.

MFX0 Context Element Descriptor (High Part)

Size (in bits):	32
Address:	04498h

DWord	Bit	Description
0	31:0	**MFX1 PDP2 Descriptor Register (Low Part)** Default Value: 00000000h Access: R/W

MFX1 PDP3 Descriptor Register (High Part)

MFX1_CTX_PDP3_H - MFX1 PDP3 Descriptor Register (High Part)

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	044A4h

DWord	Bit	Description
0	31:0	**MFX1 PDP3 Descriptor Register (High Part)** Default Value: 00000000h Access: R/W

MFX1 PDP3 Descriptor Register (Low Part)

MFX1_CTX_PDP3_L - MFX1 PDP3 Descriptor Register (Low Part)		
Register Space:	MMIO: 0/2/0	
Project:	CHV, BSW	
Source:	PRM	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	044A0h	

DWord	Bit	Description
0	31:0	**MFX1 PDP3 Descriptor Register (Low Part)** Default Value: 00000000h Access: R/W

MFX Frame BitStream SE/BIN Count

MFX_SE-BIN_CT - MFX Frame BitStream SE/BIN Count	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	1286Ch
Valid Projects:	CHV, BSW

This register stores the number of BINs (AVC CABAC) and SEs (CAVLD, VLD) decoded in a frame. This register is not part of hardware context save and restore.

DWord	Bit	Description
0	31:0	**MFX Frame Bit-stream SE/BIN Count** Total number of BINs/SEs decoded in current frame. This number is used with frame performance count to derive Bin/clk or SE/clk.

MFX Frame Macroblock Count

MFX_MB_COUNT - MFX Frame Macroblock Count

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	12868h
Valid Projects:	CHV, BSW

This register stores the number of Macro-blocks decoded/encoded in current frame. This register is not part of hardware context save and restore.

DWord	Bit	Description
0	31:20	**MBZ** Exists If: // JPEG == True Format: MBZ This field is currently reserved
	31:16	**Intra MB Count** Exists If: // AVC CAVLC, AVC CABAC, VC1 and MPEG2 == True Format: U16
	19:0	**JPEG Block Count** Exists If: // JPEG == True Format: U20 This 20-bit field indicates the number of 8x8 blocks within the JPEG frame. This field is clear at the start of decoding a new frame.
	15:0	**Number of MB Concealment** Exists If: // AVC CAVLC, AVC CABAC, VC1 and MPEG2 == True This 16-bit field indicates the number of MB is concealed by hardware. This field is clear at the start of decoding a new frame.

MFX Frame Motion Comp Miss Count

MFX_MISS_CT - MFX Frame Motion Comp Miss Count

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	12888h
Valid Projects:	CHV, BSW

This register stores the total number of cacheline hits occurred in the motion compensation cache per frame. This register is not part of hardware context save and restore.

DWord	Bit	Description
0	31:16	**Reserved** Format: MBZ
	15:0	**MFX Frame Motion Comp cache miss Count** Total number of CL misses occurred in the 12KB cache of the motion compensation engine per frame. This number is used along with **MFX Frame Motion Comp Read Count** to derive motion comp cache miss/hit ratio.

MFX Frame Motion Comp Read Count

MFX_READ_CT - MFX Frame Motion Comp Read Count	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	12484h

This register stores the total number of reference picture read requests made by the Motion Compensation engine per frame. This register is not part of hardware context save and restore.

DWord	Bit	Description
0	31:20	**Reserved** Format: MBZ
	19:0	**MFX Frame Motion Comp CL read request Count** Total number of reference picture read requests by the motion compensation engine per frame.

MFX Frame Row-Stored/BitStream Read Count

MFX_ROW-PER-BS_COUNT - MFX Frame Row-Stored/BitStream Read Count

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	12880h
Valid Projects:	CHV, BSW

This register stores the total number of row-stored/bit-stream read requests made by the pre-fetch engine per frame. This register is not part of hardware context save and restore.

DWord	Bit	Description
0	31:16	**Reserved** Format: MBZ
	15:0	**MFX row-stored/bit-stream read request Count** Total number of row-stored/bit-stream read requests sent by the memory pre-fetch engine per frame.

MFX LRA 0

MFX_LRA_0 - MFX LRA 0	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x7F403F00
Size (in bits):	32
Address:	04A50h

DWord	Bit	Description
0	31:24	**MFX LRA1 Max** Default Value: 01111111b Access: R/W Maximum value of programmable LRA1.
	23:16	**MFX LRA1 Min** Default Value: 01000000b Access: R/W Minimum value of programmable LRA1.
	15:8	**MFX LRA0 Max** Default Value: 00111111b Access: R/W Maximum value of programmable LRA0.
	7:0	**MFX LRA0 Min** Default Value: 00000000b Access: R/W Minimum value of programmable LRA0.

MFX LRA 1

MFX_LRA_1 - MFX LRA 1	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0xFFC0BF80
Size (in bits):	32
Address:	04A54h

DWord	Bit	Description
0	31:24	**MFX LRA3 Max** Default Value: 11111111b Access: R/W Maximum value of programmable LRA3.
	23:16	**MFX LRA3 Min** Default Value: 11000000b Access: R/W Minimum value of programmable LRA3.
	15:8	**MFX LRA2 Max** Default Value: 10111111b Access: R/W Maximum value of programmable LRA2.
	7:0	**MFX LRA2 Min** Default Value: 10000000b Access: R/W Minimum value of programmable LRA2.

MFX LRA 2

MFX_LRA_2 - MFX LRA 2	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x0000001B
Size (in bits):	32
Address:	04A58h

DWord	Bit	Description
0	31:8	**Reserved** Default Value: 000000h Access: RO
	7:6	**VCS LRA** Default Value: 00b Access: R/W Which LRA should VCS use.
	5:4	**VMX LRA** Default Value: 01b Access: R/W Which LRA should VMX use.
	3:2	**VMC LRA** Default Value: 10b Access: R/W Which LRA should VMC use.
	1:0	**VCR LRA** Default Value: 11b Access: R/W Which LRA should VCRSL1 use.

MFX LRA SL1 0

MFX_LRA_SL1_0 - MFX LRA SL1 0	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM

Size (in bits):	32
Address:	04A60h

DWord	Bit	Description
0	31:24	**MFX SL1 LRA1 Max** Default Value: 01111111b Access: R/W Maximum value of programmable LRA1.
	23:16	**MFX SL1 LRA1 Min** Default Value: 01000000b Access: R/W Minimum value of programmable LRA1.
	15:8	**MFX SL1 LRA0 Max** Default Value: 00111111b Access: R/W Maximum value of programmable LRA0.
	7:0	**MFX SL1 LRA0 Min** Default Value: 00000000b Access: R/W Minimum value of programmable LRA0.

MFX LRA SL1 1

MFX_LRA_SL1_1 - MFX LRA SL1 1

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0xFFC0BF80
Size (in bits):	32
Address:	04A64h

DWord	Bit	Description
0	31:24	**MFX SL1 LRA3 Max** Default Value: 11111111b Access: R/W Maximum value of programmable LRA3.
	23:16	**MFX SL1 LRA3 Min** Default Value: 11000000b Access: R/W Minimum value of programmable LRA3.
	15:8	**MFX SL1 LRA2 Max** Default Value: 10111111b Access: R/W Maximum value of programmable LRA2.
	7:0	**MFX SL1 LRA2 Min** Default Value: 10000000b Access: R/W Minimum value of programmable LRA2.

MFX LRA SL1 2

MFX_LRA_SL1_2 - MFX LRA SL1 2	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x0000001B
Size (in bits):	32
Address:	04A68h

DWord	Bit	Description
0	31:8	**Reserved** Default Value: 000000h Access: RO
	7:6	**VCSSL1 LRA** Default Value: 00b Access: R/W Which LRA should VCSSL1 use.
	5:4	**VMXSL1 LRA** Default Value: 01b Access: R/W Which LRA should VMXSL1 use.
	3:2	**VMCSL1 LRA** Default Value: 10b Access: R/W Which LRA should VMCSL1 use.
	1:0	**VCRSL1 LRA** Default Value: 11b Access: R/W Which LRA should VCRSL1 use.

MFX Memory Latency Count2

MFX_LAT_CT2 - MFX Memory Latency Count2

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	12874h
Valid Projects:	CHV, BSW

This register stores the accumulative memory latency count on reference picture read requests. This register is not part of hardware context save and restore.

DWord	Bit	Description
0	31:26	**Reserved** Format: MBZ
	25:0	**MFX Reference picture read request - Accumulative Memory Latency Count for the entire frame in 8xMedia clock cycles** The accumulative memory latency count of all reference reads requested by motion compensative engine per frame. This number is used with **MFX Frame Motion Comp Read Count** to derive average memory latency.

MFX Memory Latency Count3

MFX_LAT_CT3 - MFX Memory Latency Count3

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	12878h
Valid Projects:	CHV, BSW

This register stores the max and min memory latency counts reported on row-stored/bit-stream read requests. Max and current requests into memory sub-system engine. This register is not part of hardware context save and restore.

DWord	Bit	Description
0	31:24	**Max Request Count** This field indicates the maximum number of requests allowed by the memory sub-system channel.
	23:16	**Current Request Count** This field indicates the number of requests currently outstanding in the memory sub-system. This field should report with a value of zero at the end of frame; otherwise the pre-fetch engine most likely hung waiting for read data to be returned from sub-system.
	15:8	**MFX row-stored/bit-stream read request - Max Latency Count in 8xMedia clock cycles** This field reports the maximum memory latency count on all row-stored/bit-stream reads requested by the memory pre-fetch engine.
	7:0	**MFX row-stored/bit-stream read request - Min Latency Count in 8xMedia clock cycles** This field reports the minimum memory latency count on all row-stored/bit-stream reads requested by the memory pre-fetch engine.

MFX Memory Latency Count4

MFX_LAT_CT4 - MFX Memory Latency Count4	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	1287Ch
Valid Projects:	CHV, BSW

This register stores the accumulative memory latency count on row-stored/bit-stream read requests. This register is not part of hardware context save and restore.

DWord	Bit	Description
0	31:26	**Reserved** Format: MBZ
	25:0	**MFX row-stored/bit-stream read request - Accumulative Memory Latency Count for the entire frame in 8xMedia clock cycles** The accumulative memory latency count of all row-stored/bit-stream reads requested by pre-fetch engine per frame. This number is used with **Frame row-stored/bit-stream memory read count** to derive average memory latency.

MFX Pipeline Status Flags

MFX_STATUS_FLAGS - MFX Pipeline Status Flags

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	12838h
Valid Projects:	CHV, BSW

This register stores the various pipeline status flags. This register is not part of hardware context save and restore.

DWord	Bit	Description
0	31:17	**Reserved**
	16	**MFX Active** Frame decoding/encoding is in progress. Set on frame_start; clear on frame_end.
	15:10	**Reserved**
	9	**Streamout Enable**
	8	**Reserved**
	7	**Post Deblocking Mode Enable**
	6	**Pre Deblocking Mode Enable**
	5	**Decoder Mode Select** Value: 0 — Configure the MFD Engine for VLD Mode Value: 1 — Configure the MFD Engine for IT Mode
	4	**Codec Select** Value: 0 — Decode Value: 1 — Encode
	3:2	**Video Mode** Value: 00b — MPEG2 Value: 01b — VC1 Value: 10b — AVC Value: 11b — JPEG

MFX_STATUS_FLAGS - MFX Pipeline Status Flags

	1	**Decoder Short Format Mode**

Value	Name	Description
0		AVC/VC1 Short Format Mode is in use
1		AVC/VC1 Long Format Mode is in use

	0	**Stitch Mode**

Value	Name	Description
0b		Not in Stitch Mode
1b		In the Special Stitch Mode

MFX Slice Performance Count

MFX_SLICE_PERFORM_CT - MFX Slice Performance Count	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	12864h
Valid Projects:	CHV, BSW

This register stores the number of clock cycles spent decoding/encoding the current slice. This register is not part of hardware context save and restore.

DWord	Bit	Description
0	31:0	**MFX Frame Performance Count** Total number of clocks between slice start and slice end. This count is incremented on crm_clk

MGGC

MGGC - MGGC

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000028
Size (in bits):	32
Address:	108040h

Mirror of GMCH Graphics Control Register. Simply a read-only alias to the configuration registers.
Used by the MBC for boot context fetches.

DWord	Bit	Description
0	31:15	**RESERVED** Default Value: 00000h Access: RO Reserved
	14	**VAMEN** Default Value: 0b Access: RO Enables the use of the iGFX engines for Versatile Acceleration. 1 - iGFX engines are in Versatile Acceleration Mode. Device 2 Class Code is 048000h. 0 - iGFX engines are in iGFX Mode. Device 2 Class Code is 030000h.
	13:10	**RESERVED** Default Value: 0h Access: RO
	9:8	**GGMS** Default Value: 00b Access: RO GTT Graphics Memory Size (GGMS): This field is used to select the amount of Main Memory that is pre-allocated to support the Internal Graphics Translation Table. The BIOS ensures that memory is pre-allocated only when Internal graphics is enabled. GSM is assumed to be a contiguous physical DRAM space with DSM, and BIOS needs to allocate a contiguous memory chunk. Hardware will derive the base of GSM from DSM only using the GSM size programmed in the register. Hardware functionality in case of programming this value to Reserved is not guaranteed. 0h:No Preallocated Memory 1h: 2MB of Preallocated Memory 2h: 4MB of Preallocated Memory 3h: 8MB of Preallocated Memory

MGGC - MGGC

	7:3	**GMS** Default Value: 00101b Access: RO Graphics Mode Select(GMS): This field is used to select the amount of Main Memory that is pre-allocated to support the Internal Graphics device in VGA (non-linear) and Native (linear) modes. The BIOS ensures that memory is pre-allocated only when Internal graphics is enabled. Hardware does not clear or set any of these bits automatically based on IGD being disabled/enabled. BIOS Requirement: BIOS must not set this field to 0h if IVD (bit 1 of this register) is 0. 0h = 0MB 1h = 32MB 2h = 64MB 3h = 96MB 4h = 128MB 5h = 160MB 6h = 192MB 7h = 224MB 8h = 256MB 9h = 288MB Ah = 320MB Bh = 352MB Ch = 384MB Dh = 416MB Eh = 448MB Fh = 480MB 10h = 512MB 11h = 8MB 12h = 12MB 13h = 16MB 14h = 20MB 15h = 24MB 16h = 28MB 17h = 36MB 18h = 40MB 19h = 44MB 1Ah = 48MB 1Bh = 52MB 1Ch = 56MB 1Dh = 60MB 1Eh = Reserved 1Fh = Reserved ..... 20h:1024MB (Not supported for CHV, BSW)

MGGC - MGGC

		..... 30h:1536MB (Not supported for CHV, BSW) ..... 40h:2048MB (Not supported for CHV, BSW) ..... 80h:4096MB (Not supported for CHV, BSW) 81h - FF:Reserved Other = Reserved When GMS != '0 (and VD=0): Address[31:0] is compared with VGA memory range. (The VGA memory range is A_0000h to B_FFFFh.). If there is a match and MSE = 1 and MEMRD or MEMWR, the access will route as a Rmdwvgamemen_cr cycle on the RMbus. If the RMbus returns a hit the GVD will select the command. As well, when 0 the GVD will check if scldown3_address[15:0] is one of the VGA IO register range. (The VGA IO range is 03B0h - 03BBh and 03C0h - 03DFh.) If there is a match and IOSE = 1 and the SCL command is either an IORD or IOWR, the GVD will intiate a (VGA) register cycle on the RMbus. If the RMbus returns a hit the GVD will select the command When GMS == '0 : No address compare will occur against VGA memory range or the VGA IO register range. Also, CC[15:8] is changed to 8'h80 from 8'h00
	2	**RESERVED** Default Value: 0b Access: RO Reserved
	1	**VGA_DISABLE** Default Value: 0b Access: RO VGA Disable (VD): 0: Enable. Device 2 (IGD) claims VGA memory and IO cycles, the Sub-Class Code within Device 2 Class Code register is 00. 1: Disable. Device 2 (IGD) does not claim VGA cycles (Mem and IO), and the Sub- Class Code field within Device 2 function 0 Class Code register is 80. BIOS Requirement: BIOS must not set this bit to 0 if the GMS field pre-allocates no memory. This bit MUST be set to 1 if Device 2 is disabled either via a fuse or fuse override (CAPID0[38] = 1) or via a register (DEVEN[3] = 0).
	0	**GGCLCK** Default Value: 0b Access: RO When set to 1b, this will lock all the bits in this register, including itself

MGSR2GAM Message Register

MGSR2GAM_MSGREG - MGSR2GAM Message Register

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	040D8h

DWord	Bit	Description
0	31:16	**Mask Bits** Default Value: 0000h Access: RO Mask Bits act as Write Enables for the bits[15:0] of this register.
	15	**MGSR2GAM Message Register 15** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	14	**MGSR2GAM Message Register 14** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	13	**MGSR2GAM Message Register 13** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	12	**MGSR2GAM Message Register 12** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	11	**MGSR2GAM Message Register 11** Default Value: 0b Access: R/W For Future Use.

MGSR2GAM_MSGREG - MGSR2GAM Message Register

		This bit is self clear.
	10	**MGSR2GAM Message Register 10** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	9	**MGSR2GAM Message Register 9** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	8	**MGSR2GAM Message Register 8** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	7	**MGSR2GAM Message Register 7** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	6	**MGSR2GAM Message Register 6** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	5	**MGSR2GAM Message Register 5** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	4	**MGSR2GAM Message Register 4** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	3	**MGSR2GAM Message Register 3** Default Value: 0b Access: R/W For Future Use. This bit is self clear.

MGSR2GAM_MSGREG - MGSR2GAM Message Register

	2	**MGSR2GAM Message Register 2** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	1	**MGSR2GAM Message Register 1** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	0	**MGSR2GAM Message Register 0** Default Value: 0b Access: R/W Bit0 - Tail Update Ack Message. This bit is self clear.

Misc. Clocking / Reset Control Registers

MISCCPCTL - Misc. Clocking / Reset Control Registers

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000002
Size (in bits):	32
Address:	09424h

Miscellaneous Clocking / Reset Control Registers.

DWord	Bit	Description
0	31:8	**Bonus ECO bits** Access: R/W Bonus ECO bits
	7	**DOP clock gating enable for VEbox clks** Access: R/W Controls the Enabling of the DOP-level Vebox (cvclk) Clock Gating via PM event messages 1 - Clock gating is enabled 0 - Clock gating is disabled
	6	**DOP clock gating enable for Media clocks** Access: R/W Controls the Enabling of the DOP-level Media (cmclk) Clock Gating via PM event messages 1 - Clock gating is enabled 0 - Clock gating is disabled
	5	**Reserved** Access: RO Made Reserved field as we dont have Media 1 in CHV, BSW Controls the Enabling of the DOP-level Render (cmclk for 2nd media block) Clock Gating via PM event messages 1 - Clock gating is enabled 0 - Clock gating is disabled
	4	**Reserved**
	3	**DOP CLock gating Enable for Widi clocks** Access: R/W Controls the Enabling of the DOP-level Render (cwclk) Clock Gating via PM event messages 1 - Clock gating is enabled 0 - Clock gating is disabled

MISCCPCTL - Misc. Clocking / Reset Control Registers

	2	**DOP clock gating Enable for Fix clocks (cfclk)** Access: R/W Controls the Enabling of the DOP-level Render (cfclk/cf2xclk) Clock Gating via PM event messages 1 - Clock gating is enabled 0 - Clock gating is disabled
	1	**L1 Clock Ungate Enabling Control During Reset** Default Value: 1b Access: R/W Control to enable/disable L1 clock gating during soft resets and FLR reset processing 1 - disable L1 clock gating during soft resets and FLR 0 - enable L1 clock gating during soft resets and FLR (default op)
	0	**DOP Clock Gating Enable for Render Clocks** Access: R/W Controls the Enabling of the DOP-level Render (crclk/cr2xclk) Clock Gating via PM event messages 1 - Clock gating is enabled 0 - Clock gating is disabled

MISC. CTX control register

MISCCTXCTL - MISC. CTX control register		
Register Space:	MMIO: 0/2/0	
Project:	CHV, BSW	
Source:	PRM	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	0942Ch	
DWord	**Bit**	**Description**
0	31:1	**Reserved** Access: RO Reserved.
	0	**Context Restore ACk indication from Csunit** Access: R/W Set Context Restore ACk indication from Csunit 1'b1 : Csunit has completed restoring CPunits address space Once set, CPunit hardware clears this bit after sending the ctx save ack done message to CS 1'b0 : Csunit has NOT completed restoring CPunits address space

Misc. Reset Control Register

RSTCTL - Misc. Reset Control Register		
Register Space:	MMIO: 0/2/0	
Project:	CHV, BSW	
Source:	PRM	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	09420h	
Miscellaneous reset control registers.		

DWord	Bit	Description
0	31:4	**Reserved** Access: RO Reserved
	3:2	**Reset Staggering Period Control** Access: R/W Reset assertion staggering period between reset domains during FLR and soft-resets: 00: 24 cs clocks 01: 48 cs clocks 10: 72 cs clocks 11: 96 cs clocks
	1:0	**Reset Residency Control** Access: R/W Reset assertion residency period for FLR and soft-resets. 00: 24 cs clocks 01: 48 cs clocks 10: 96 cs clocks 11: 192 cs clocks

Miscellaneous Message Register for Power Managment Unit

MSG_MISC - Miscellaneous Message Register for Power Managment Unit

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	16
Address:	08048h

Message registers have bit-wise masking applied for writes. The register consists of 16 bits of data in [15:0], and 16 bits of corresponding masks in [31:16].
In order to set bit0, for example, the data would be 0x0001_0001.;In order to clear bit0, for example, the data would be 0x0001_0000.
Note that mask bit is the data bit offset + 16. Message registers are protected from non-GT writes via the Message Channel.

DWord	Bit	Description
0	15:3	**Reserved** Access: RO
	2	**Reserved**
	1	**Internal RFO Enable Ack (forwarded from MDRB to RPM to gpm)** Access: R/W From RPM on behalf of MGSR: Internal RFO Enable Acknowledgement b0 : RFO Disable Ack (default) b1 : RFO Enable Ack
	0	**GO Acknowledgement from OAunit** Access: R/W Go Acknowledgement b0 : Go=0 Ack <default> b1 : Go=1 Ack Normally the requirement is that when Go=0 request is sent, the agent has to indicate busy before sending the Go=0 acknowledgement. It can only go idle again once Go=1 is received. For OA, however, it does not have an idle indication to PM and thus do not have to do this.

MISR0

MISR0 - MISR0

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	182040h

Spare0 registers. Note: Changed for CHV, BSW.

DWord	Bit	Description
0	31:17	**Spare0** Default Value: 0000h Access: R/W Spare bits in case an ECO is needed.
	16	**Standby Threshold Periodic Enable** Default Value: 0000h Access: R/W Standby Threshold Periodic Enable
	15:0	**Standby Threshold** Default Value: 0000h Access: R/W

Description	Project
Standby Threshold For 33MHz cz freq (200MHz, 267MHz, 320MHz, 333MHz, 400MHz, 467MHz, 533MHz) 0 = 0 us 1 = 15.36 us 2 = 30.72 us 3 = 46.08 us FFFF ~= 1s For non-33MHz cz freq (350MHz, 356MHz, 360MHz, 373MHz), standby threshold will be in increments of (15.36us + (1-7)%)	CHV, BSW

MISR1

MISR1 - MISR1

Size (in bits):	32
Address:	182050h

Spare4 registers. Note: Changed for CHV, BSW.

DWord	Bit	Description
0	31:0	**Spare4** Default Value: 00000000h Access: R/W Spare bits in case an ECO is needed.

MMIO_INDEX

MMIO_INDEX - MMIO_INDEX

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	00000h

Contains address and target.
Punit cannot access IO space from message channel.
A 32 bit IO write to this port loads the offset of the MMIO register or offsetinto the GTT that needs to be accessed.
An IO Read returns the current value of this register. An 8/16 bit IO write to this register is completed but does not update this register.
This mechanism to access internal graphics MMIO registers must not be used to access VGA IO registers which are mapped through the MMIO space. VGA registers must be accessed directly through the dedicated VGA IO ports. This is used by SBIOS. It is not used by graphics driver.
This register is only accessible through the IOSF Primary bus. The base register is defined by IOBAR.

DWord	Bit	Description
0	31:2	**Register_offset** Default Value: 00000000h Access: R/W This field selects GTT entry or any one of the Dword registers within the MMIO register space of this device.
	1:0	**Target** Default Value: 00b Access: R/W 00 = MMIO Registers, 01 = GTT, 1X =Reserved

Mode Register for GAB

GAB_MODE - Mode Register for GAB

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	BlitterCS
Default Value:	0x00000000
Access:	r/w
Size (in bits):	32
Address:	220A0h-220A3h

The GAB_MODE register contains information that controls configurations in the GAB.

DWord	Bit	Description
0	31:16	**Mask** Access: WO Format: Mask
	15:6	**Reserved** Read/Write
	5:3	**BLB Arbitration Priority** Format: U3
	2:0	**BCS Arbitration Priority** Format: U3

Mode Register for GAC

GAC_MODE - Mode Register for GAC

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0x00000000 CHV, BSW
Access:	r/w
Size (in bits):	32

Address:	120A0h-120A3h
ShortName:	GAC_MODE
Valid Projects:	CHV, BSW

The GAC_MODE register contains information that controls configurations in the GAC.

DWord	Bit	Description
0	31:16	**Mask** Access: WO Format: Mask
	15:1	**Reserved** Access: r/w
	0	**Reserved** Project: CHV, BSW Access: r/w

Mode Register for GAFS

GAFS_MODE - Mode Register for GAFS

Register Space:	MMIO: 0/2/0

MSAC

MSAC - MSAC

Register Space:	PCI: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00010000
Size (in bits):	32
Address:	00060h

This register determines the size of the graphics memory aperture. Only the system BIOS will write this register based on pre-boot address allocation efforts. Graphics may read this register to determine the correct aperture size. System BIOS needs to save this value on boot so that it can reset it correctly during S3 resume. The size of the aperture must not be modified by software after its location is written into GMADR (offset 18h).

DWord	Bit	Description

MSI_CAPID_MC

MSI_CAPID_MC - MSI_CAPID_MC

Register Space:	PCI: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x0000B005
Size (in bits):	32
Address:	00090h

90-91h: Message Signaled Interrupts Capability ID
92-93h: Message Signaled Control Register

DWord	Bit	Description
0	31:24	**RESERVED** Default Value: 00h Access: RO Reserved
	23	**MODE_64B_ADDRCAP** Default Value: 0b Access: RO C64: 32-bit capable only
	22:20	**MULTIPLE_MESSAGE_ENABLE** Default Value: 000b Access: R/W MME: This field is RW for software compatibility, but only a single message is ever generated. System software programs this field to indicate the actual number of messages allocated to this device. This number will be equal to or less than the number actually requested. The encoding is the same as for the MMC field below.
	19:17	**MULTIPLE_MESSAGE_CAPABLE** Default Value: 000b Access: RO MMC: This device is only single message capable. System Software reads this field to determine the number of messages being requested by this device. Value: Number of requests 000: 1 001-111: Reserved

MSI_CAPID_MC - MSI_CAPID_MC

	16	**MSI_ENABLE** Default Value: 0b Access: R/W MSIE: If set, MSI is enabled and traditional interrupts are not used to generate interrupts. PCICMDSTS.BME must be set for an MSI to be generated. 0 : MSI interrupts are disabled. 1 : MSI interrupts are enabled. Permits sending an MSI interrupt.
	15:8	**POINTER_TO_NEXT_CAPABILITY** Default Value: B0h Access: R/W Once Points to the next item in the list(B0=VCID support). This register should be programmed by BIOS during boot-up. Once written, this register becomes Read_Only. This register can only be cleared by a Reset.
	7:0	**CAPABILITY_ID** Default Value: 05h Access: RO CAPID: Indicates an MSI capability

MTRR Capability Register 0

MTRR_CR_0 - MTRR Capability Register 0

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x0000050A
Size (in bits):	32
Address:	0F100h

Register to define MTRR - range register capabilities.

DWord	Bit	Description
0	31:11	**Reserved** Default Value: 00000000000000000000b Access: RO
	10	**Write Combining Support** Default Value: 1b Access: RO 0: Write Combining (WC) memory type is not supported. 1: Write Combining (WC) memory type is supported. GFX Implementation: More details on memory type section however WC support in GFX looks like streamlining non-cacheable accesses. This is the existing UC concept used in GFX architecture.
	9	**Reserved** Default Value: 0b Access: RO
	8	**Fixed Range MTRRs Support** Default Value: 1b Access: RO 0: No Fixed range MTRRs are supported. 1: Fixed Range MTRRs (IA32_MTRR_FIX64K_00000 through IA32_MTRR_FIX4K_0F8000) are supported.
	7:0	**Variable Range MTRR Count** Default Value: 0Ah Access: RO Indicates the number of variable ranges implemented.

MTRR Capability Register 1

MTRR_CR_1 - MTRR Capability Register 1		
Register Space:	MMIO: 0/2/0	
Project:	CHV, BSW	
Source:	PRM

ShortName:	PDP0_VCSUNIT1

Address:	22270h-22277h
Name:	Page Directory Pointer Descriptor - PDP0/PML4/PASID
ShortName:	PDP0_BCSUNIT

PDP0/PML4/PASID: This register can contain three values which depend on the element descriptor definition. **PASID[19:0]:** Populated in the first 20bits of the register and selected when Advanced Context flag is set in the element descriptor in execlist mode of submission. This is not valid in ring buffer mode of scheduling. **PML4[38:12]:** Pointer to base address of PML4 and selected when Legacy Context flag is set and 64b address support is selected. **PDP0[38:12]:** Pointer to one of the four page directory pointer (lowest) and defines the first 0-1GB of memory mapping. This is valid when Legacy Context Flag is set and 64bit virtual addressing is not supported. *Note: This is a guest physical address.*

Programming Notes	Project
Execlist Based Scheduling: SW should update PDP0/12/3 registers in context image with proper values before submitting the context to HW in execlist mode of scheduling. HW restores these registers as part of context restore to set the PPGTT access accordingly. PPGTT is always enabled in advanced context mode of execlist based scheduling and can be disabled only in legacy context mode. Privilege Access Bit in Element Descriptor controls the PPGTT enabling in legacy context mode.	

PDP0 - Page Directory Pointer Descriptor - PDP0/PML4/PASID

Ring Buffer Based Scheduling: A write via MMIO to PDP0_DESCRIPROR (lower Dword) triggers the Page Directory Restore in HW when PPGTT is enabled. SW should ensure PDP1/2/3 registers are programmed appropriately prior to programming PDP0. PDP0_DESCRIPTOR lower dword should be programmed at the end. Per-Process GTT Enable Bit in GFX_MODE register controls the PPGTT enabling and disabling. Programming Per-Process GTT Enable Bit in GFX_MODE register doesn't enable/disable the PPGTT translation of memory access immediately; the change comes in to affect only when the Page Directory registers are programmed. Programming Per-Process GTT Enable Bit in GFX_MODE register bit must be followed by programming Page Directory Registers in order to enable or disable the PPGTT translation of memory access. PDP* DESCRIPTOR registers must always be programmed through MI_LOAD_REGISTER_IMMEDIATE command in ring buffer with PDP0_DESCRIPRTOR lower dword written at the end. PDP0/12/3 registers are context save restored. PDP descriptors are power context save restored in VCS, BCS and VECS engines. PDP descriptors are context save restored per render context in RCS and must be programmed following MI_SET_CONTEXT command, in case of PDP descriptors programmed without context set (MI_SET_CONTEXT) will get lost on C6 entry/exit. PDP descriptor registers should be programmed after ensuring the pipe is completely flushed and TLB's invalidated.	CHV, BSW

DWord	Bit	Description
0	63	**PD Load Busy** Project: CHV, BSW Access: RO Format: Valid This read-only field gets set when PDP0 is written to indicating Page Directory Restore activity is in progress and will get reset once the activity is completed.

PCBR

PCBR - PCBR

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	182120h

This provides a base address for context save/restore of GT and Media power context to DRAM. Gunit adds the GAM provided offsets to this base register for power context reads and writes.
GTLC stores Power Context in DRAM.
The BIOS is expected to program this register and ensure proper allocation within Gfx stolen memory.

Removing bits 63:32 since this will always be below 4GB.

DWord	Bit	Description
0	31:12	**Power_Context_Address** Default Value: 0000000h Access: R/W Lock 4KB aligned address. Locked with bit 0.
	11:1	**Reserved** Default Value: 000h Access: RO Reserved
	0	**Power_Context_Register_Lock** Default Value: 0b Access: R/W Lock Writing a '1' to this register locks this bit - preventing further updates. The Power Context Address bits are also locked.

PCICMD_STS

PCICMD_STS - PCICMD_STS

Register Space:	PCI: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00100000
Size (in bits):	32
Address:	00004h

04h: PCI Command Register. 06h: PCI Status Register

DWord	Bit	Description
0	31:21	**RESERVED** Default Value: 000h Access: RO
	20	**CAPABILITY_LIST** Default Value: 1b Access: RO CAP: Indicates that the CAPPOINT register at 34h provides an offset into PCI Configuration Space containing a pointer to the location of the first item in the list
	19	**INTERRUPT_STATUS** Default Value: 0b Access: RO
	18:16	**RESERVED** Default Value: 000b Access: RO
	15:11	**RESERVED** Default Value: 00h
	10	**INTERRUPT_DISABLE** Default Value: 0b Access: R/W ID: 0 : Legacy interrupt message is enabled. ID: 1 : Disables legacy interrupt message generation on IOSF Sideband. Note : The interrupt status is not blocked from being reflected in PCISTS.IS. Note: MSI interrupt generation : (PCISTS.IS and PCICMD.BME and MSI_CAPID.MSIE) changes from 0 to 1. Note: Message bus interrupt assert is sent : (PCISTS.IS and ~PCICMD.ID and ~MSI_CAPID.MSIE) changes from 0 to 1. Note: Message bus interrupt de-assert is sent : (PCISTS.IS and ~PCICMD.ID and ~MSI_CAPID.MSIE) changes from 1 to 0.

PCICMD_STS - PCICMD_STS

	9:3	**RESERVED** Default Value: 00h Access: RO Reserved
	2	**BUS_MASTER_ENABLE** Default Value: 0b Access: R/W BME: (BME and MAE are observed. But context save/restore can occur.) 0 : Blocks the sending of MSI interrupts. 1 : Permits the sending of MSI interrupts
	1	**Reserved**
	0	**IO_SPACE_ENABLE** Default Value: 0b Access: R/W IOSE: 0 : I/O space is disabled. IORD and IOWr cycles will not be claimed. 1 : I/O space is enabled. VGA_IO and Gfx_IOBAR are checked. If an IORD/IOWR matches (VGA IO address range or GFX_IOBAR), the cycle will be claimed. Care should be taken in setting up GFX_IOBAR that more than 1 match is not made as this will result in unpredictable behavior. VGA_IO : Address[15:0] is checked to determine if it falls in the VGA IO range. (The VGA IO range is 03B0h - 03BBh and 03C0h - 03DFh.) Gfx_IOBAR : Address[15:3] is compared to GFX_IOBAR[15:3].

PCU INTERRUPT ENABLE REGISTER

PCU_INTERRUPT_IER - PCU INTERRUPT ENABLE REGISTER

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	444ECh-444EFh

This table indicates which events are mapped to each bit of the GT interrupt 1 register.
The IER enabled PCU interrupt IIR sticky bits are ORed together
to generate PCU interrupt pending bit in the master interrupt control register.

DWord	Bit	Description
0	31:26	**UNUSED0** Access: R/W
	25	**PCU_MAILBOX_EVT** Access: R/W PCU Pcode 2 driver mailbox event
	24	**PCU_THERMAL_EVT** Access: R/W PCU thermal event
	23:0	**UNUSED1** Access: R/W

PCU INTERRUPT IDENTITY REGISTER

PCU_INTERRUPT_IIR - PCU INTERRUPT IDENTITY REGISTER

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	444E8h-444EBh

This table indicates which events are mapped to each bit of the GT interrupt 1 register.
The IER enabled PCU interrupt IIR sticky bits are ORed together
to generate PCU interrupt pending bit in the master interrupt control register.

DWord	Bit	Description
0	31:26	**UNUSED0** Access: R/W One Clear
	25	**PCU_MAILBOX_EVT** Access: R/W One Clear PCU Pcode 2 driver mailbox event
	24	**PCU_THERMAL_EVT** Access: R/W One Clear PCU thermal event
	23:0	**UNUSED1** Access: R/W One Clear

PCU INTERRUPT MASK REGISTER

PCU_INTERRUPT_IMR - PCU INTERRUPT MASK REGISTER

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x03000000
Size (in bits):	32
Address:	444E4h-444E7h

This table indicates which events are mapped to each bit of the GT interrupt 1 register.
The IER enabled PCU interrupt IIR sticky bits are ORed together
to generate PCU interrupt pending bit in the master interrupt control register.

DWord	Bit	Description
0	31:26	**UNUSED0** Access: R/W
	25	**PCU_MAILBOX_EVT** Default Value: 1b Access: R/W PCU Pcode 2 driver mailbox event
	24	**PCU_THERMAL_EVT** Default Value: 1b Access: R/W PCU thermal event
	23:0	**UNUSED1** Access: R/W

PCU INTERRUPT STATUS REGISTER

PCU_INTERRUPT_ISR - PCU INTERRUPT STATUS REGISTER

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	444E0h-444E3h

This table indicates which events are mapped to each bit of the GT interrupt 1 register.
The IER enabled PCU interrupt IIR sticky bits are ORed together
to generate PCU interrupt pending bit in the master interrupt control register.

DWord	Bit	Description
0	31:26	**UNUSED0** Access: RO
	25	**PCU_MAILBOX_EVT** Access: RO PCU Pcode 2 driver mailbox event
	24	**PCU_THERMAL_EVT** Access: RO PCU thermal event
	23:0	**UNUSED1** Access: RO

Pending Head Pointer Register

UHPTR - Pending Head Pointer Register

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	02134h-02137h
Name:	Pending Head Pointer Register
ShortName:	UHPTR_RCSUNIT
Address:	12134h-12137h
Name:	Pending Head Pointer Register
ShortName:	UHPTR_VCSUNIT0
Address:	1A134h-1A137h
Name:	Pending Head Pointer Register
ShortName:	UHPTR_VECSUNIT
Address:	1C134h-1C137h
Name:	Pending Head Pointer Register
ShortName:	UHPTR_VCSUNIT1
Address:	22134h-22137h
Name:	Pending Head Pointer Register
ShortName:	UHPTR_BCSUNIT

Programming Notes	Source
Once SW uses UHPTR to preempt the existing workload, should explicitly program MI_SET_CONTEXT to save the preempted context status before submitting the new workload. In case SW doesn't want to save the state of the preempted context, it should at the minimum program RS_PREEMPT_STATUS to 0x0 so that the register status doesn't interfere with the new workloads.	RenderCS

DWord	Bit	Description
0	31:3	**Head Pointer Address** Format: GraphicsAddress[31:3] **Description** This register represents the GFX address offset where execution should continue in the ring buffer following execution of a Preemptable Command. Refer to the Preemption section for the list of preemptable commands supported in ring buffer mode of scheduling.

UHPTR - Pending Head Pointer Register

	2:1	**Reserved** Format: MBZ
	0	**Head Pointer Valid** **Description** This bit is set by the software to request a pre-emption. It is reset by hardware when a Preemptable command is parsed by the command streamer. The hardware uses the head pointer programmed in this register at the time the reset is generated. Refer to the Preemption section for the list of preemptable commands supported in ring buffer mode of scheduling. This bit is treated as set by command streamer only when arbitration is not disabled using MI_ARB_ON_OFF command. Preemption will not occur on MI_ARB_CHEK command when UHPTR is valid if the arbitration is disabled using MI_ARB_ON_OFF command.

Value	Name	Description
0	InValid	No valid updated head pointer register, resume execution at the current location in the ring buffer
1	Valid	Indicates that there is an updated head pointer programmed in this register

Plink G2H Spare

SPAREG2H - Plink G2H Spare		
Register Space:	MMIO: 0/2/0	
Project:	CHV, BSW	
Source:	PRM	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	0A194h-0A197h	
DWord	**Bit**	**Description**
0	31:9	**Reserved** Access: RO
	8:0	**Plink_G2H_Spare** Access: R/W These are spares for ECO use.

PM_PWR_CLK_STATE

PM_PWR_CLK_STATE - PM_PWR_CLK_STATE

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00008288
Size (in bits):	32
Address:	0A200h

PM Power Clock State Request

DWord	Bit	Description
0	31	**Enable** Access: R/W Power Clock State Enable: 0 : No specific power state set, no message/wait with PMunit 1 : CSunit sends the contents of this register to PMunit each time it is written, Send contents of this register to PMunit, wait for Ack. When CS writes to A200, requesting new set of resources: Actual EUs used = Async_EU if EUmin < Async_EU < EUmax Actual EUs used = EUmax if Async_EU > equal to EUmax Actual EUs used = EUmin if EUmin > equal to Async_EU Actual SSs used = Async_SS if SScountEn=0 Actual SSs used = SScount if SScountEn=1 After new resources are set by GPMunit, GPM replies to CS by writing 0001_0001 to 0x00_300c
	30:19	**RSVD** Access: RO Reserved (CSunit implements full 32b storage)
	18	**SCountEn** Access: R/W Programming Notes: Not supported in CHV, BSW. Must be zero (MBZ). — Project: CHV, BSW
	17:15	**SliceCount** Default Value: 001b Access: R/W Programming Notes: Not supported in CHV, BSW. Must be zero (MBZ). — Project: CHV, BSW

PM_PWR_CLK_STATE - PM_PWR_CLK_STATE

	14:13	**RSVD** Access: RO Reserved (CSunit implements full 32b storage)
	12	**Spare** Access: R/W Spare bit for CHV, BSW Programming Notes: Must be zero (MBZ). Project: CHV, BSW
	11	**SSCountEn** Access: R/W Enable Subslice Count Request 0 = Use async PMunit subslice count request 1 = Use SliceCount from this register
	10:8	**SScount** Default Value: 010b Access: R/W Number of subslices to power: 001 : 1 subslice 010 : 2 subslices (GT1-based CHV, BSW only)
	7:4	**EUmax** Default Value: 1000b Access: R/W Maximum number of EUs to power (per subslice if multiple subslices enabled). To specify an exact number of subslices, set EUmax equal to EUmin MinEU and MaxEU need to be even and that odd numbers are illegal
	3:0	**EUmin** Default Value: 1000b Access: R/W Minimum number of EUs to power (per subslice if multiple subslices enabled): 0010 : 2 EUs 0100 : 4 EUs 0110 : 6 EUs 1000 :8 EUs MinEU and MaxEU need to be even and that odd numbers are illegal When both subslices are enabled (ie 0x18_2168[11:10] = 2'b00)

Default Value:	0x00000002
Size (in bits):	32
Address:	0A72Ch

Subwell signals to be driven out to subslice1 wells: subwell 5.
This register is modified by HW based on sub-power domain configuration and SW should not be writing to this register.

DWord	Bit	Description
0	31:6	**Reserved** Default Value: 0000000h Access: RO Reserved
	5	**ss1_eu311_rst_b** Default Value: 0b Access: R/W Subwell control signal 'rst_b' for subwell 'ss1_eu311'
	4	**ss1_eu311_fwenb** Default Value: 0b Access: R/W Subwell control signal 'fwenb' for subwell 'ss1_eu311'
	3	**ss1_eu311_pwrok** Default Value: 0b Access: R/W Subwell control signal 'pwrok' for subwell 'ss1_eu311'
	2	**ss1_eu311_asyncrst_b** Default Value: 0b Access: R/W Subwell control signal 'asyncrst_b' for subwell 'ss1_eu311'

POWER_WELL_SS1_SIG2 - POWER_WELL_SS1_SIG2

	1	**ss1_eu311_pgenb** Default Value: 1b Access: R/W Subwell control signal 'pgenb' for subwell 'ss1_eu311' 0 = sub-well is powered on. 1 = sub-well is powered off.
	0	**ss1_eu311_clocken** Default Value: 0b Access: R/W Subwell control signal 'clocken' for subwell 'ss1_eu311'

Power Context Save

PWRCTXSAVE - Power Context Save

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04A04h

DWord	Bit	Description
0	31:16	**Mask Bits** Default Value: 0000h Access: RO
	15	**Extra Bits15** Default Value: 0b Access: R/W Extra Bits for future use.
	14	**Extra Bits14** Default Value: 0b Access: R/W Extra Bits for future use.
	13	**Extra Bits13** Default Value: 0b Access: R/W Extra Bits for future use.
	12	**Extra Bits12** Default Value: 0b Access: R/W Extra Bits for future use.
	11	**Extra Bits11** Default Value: 0b Access: R/W Extra Bits for future use.
	10	**Extra Bits10** Default Value: 0b Access: R/W Extra Bits for future use.

PWRCTXSAVE - Power Context Save

	9	**Power Context Save Request** Default Value: 0b Access: R/W Power Context Save. Bit[9].Power Context Save Request. 1'b0: Power context save is not being requested (default). 1'b1: Power context save is being requested. Unit needs to self-clear this bit upon sampling. This bit is self clear.
	8:0	**Power Context Save Quad Word Credits** Default Value: 000000000b Access: R/W Power Context Save. Bits[8:0].QWord Credits for Power Context Save Request. An initial length packet is required per power context save session, but that packet does not consume a credit. See protocol description for more details. Minimum Credits = 1: Unit may send 1 QWord pair. Maximum Credits = 511: Unit may send 511 QWord pairs. A QWord pair is defined as a 32-bit register address and the corresponding 32-bits of register data. Only valid with PWRCTX_SAVE_REQ (Bit9).

Power context Save Register for LPFC

LPCSR - Power context Save Register for LPFC		
Register Space:	MMIO: 0/2/0	
Project:	CHV, BSW	
Source:	PRM	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	0B408h	

DWord	Bit	Description
0	31:10	**Reserved** Access: RO Reserved.
	9:0	**Power context save register command** Access: R/W Hardware Clear Bit[9].Power Context Save Request. 1'b0: Power context save is not being requested (default). 1'b1: Power context save is being requested. Unit needs to self-clear this bit upon sampling. Bits[8:0].QWord Credits for Power Context Save Request. Minimum Credits = 1: Unit may send 1 QWord pair (enough for first LRI at least). Maximum Credits = 511: Unit may send 511 QWord pairs. A QWord pair is defined as a 32-bit register address and the corresponding 32-bits of register data. Note that the LRI header and END commands are 64-bits each (32-bit command followed by 32-bit NOOP) and consume one QWord credit. Only valid with PWRCTX_SAVE_REQ (Bit9).

Power Context Save request

PCTXSAVEREQ - Power Context Save request		
Register Space:	MMIO: 0/2/0	
Project:	CHV, BSW	
Source:	PRM	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	08110h	

DWord	Bit	Description
0	31:16	**Message Mask** Access: RO Message Mask bots for lower 16 bits
	15:10	**Reserved** Access: RO Reserved
	9	**Power context save req** Access: R/W Set Power Context Save Request 1'b0 : Power context save is not being requested (default) 1'b1 : Power context save is being requested CPUnit self-clears this bit upon sampling.
	8:0	**Power Context Save request credit count** Access: R/W QWord Credits for Power Context Save Request Minimum Credits = 1 : Unit may send 1 QWord pair (enough for first LRI at least) Maximum Credits = 511 : Unit may send 511 QWord pairs A QWord pair is defined as a 32-bit register address and the corresponding 32-bits of register data. Note that the LRI header and END commands are 64-bits each (32-bit command followed by 32-bit NOOP) and will consume one QWord credit. Only valid with PWRCTX_SAVE_REQ (Bit9).

POWERDOWN_STATE

POWERDOWN_STATE - POWERDOWN_STATE

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x66654321
Size (in bits):	32
Address:	0A710h

Subwell Power down state description.

DWord	Bit	Description
0	31:28	**pmcr_powerdown_state8** Default Value: 0110b Access: R/W The 8th state/signal that needs to be driven
	27:24	**pmcr_powerdown_state7** Default Value: 0110b Access: R/W The 7th state/signal that needs to be driven
	23:20	**pmcr_powerdown_state6** Default Value: 0110b Access: R/W The 6th state/signal that needs to be driven
	19:16	**pmcr_powerdown_state5** Default Value: 0101b Access: R/W The 5th state/signal that needs to be driven
	15:12	**pmcr_powerdown_state4** Default Value: 0100b Access: R/W The 4th state/signal that needs to be driven
	11:8	**pmcr_powerdown_state3** Default Value: 0011b Access: R/W

POWERDOWN_STATE - POWERDOWN_STATE

		The 3rd state/signal that needs to be driven
	7:4	**pmcr_powerdown_state2** Default Value: 0010b Access: R/W The 2nd state/signal that needs to be driven
	3:0	**pmcr_powerdown_state1** Default Value: 0001b Access: R/W This is the very first state and the signal that needs to be driven appropriately Encodings: 001 = Reset Sync Reset 010 = Reset Firewall 011 = Set Power EnB 100 = Reset Clock En 101 = Reset Async Reset 110 = Done 111 = Reserved. Open: Do we want to have an extra bit for future support

POWERDOWN_WAIT1

POWERDOWN_WAIT1 - POWERDOWN_WAIT1		
Register Space:	MMIO: 0/2/0	
Project:	CHV, BSW	
Source:	PRM	
Default Value:	0x01010101	
Size (in bits):	32	
Address:	0A714h	
Subwell power down state wait time 1.		
DWord	**Bit**	**Description**
0	31:24	**pmcr_powerdown_wait_state4_5** Default Value: 01h Access: R/W This is the programmed value as to how long there is a wait from the time signal 4 is driven before signal 5 can be driven
	23:16	**pmcr_powerdown_wait_state3_4** Default Value: 01h Access: R/W This is the programmed value as to how long there is a wait from the time signal 3 is driven before signal 4 can be driven
	15:8	**pmcr_powerdown_wait_state2_3** Default Value: 01h Access: R/W This is the programmed value as to how long there is a wait from the time signal 2 is driven before signal 3 can be driven
	7:0	**pmcr_powerdown_wait_state1_2** Default Value: 01h Access: R/W This is the programmed value as to how long there is a wait from the time signal 1 is driven before signal 2 can be driven. Note: The granularity of these are in 30ns intervals meaning the counters will increment/decrement every 30ns pulse

POWERDOWN_WAIT2

POWERDOWN_WAIT2 - POWERDOWN_WAIT2

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x01010101
Size (in bits):	32
Address:	0A718h

Subwell power down state wait time 2.

DWord	Bit	Description
0	31:24	**pmcr_powerdown_interval** Default Value: 01h Access: R/W Stagger between different power gate enables for power down.
	23:16	**pmcr_powerdown_wait_state7_8** Default Value: 01h Access: R/W This is the programmed value as to how long there is a wait from the time signal 7 is driven before signal 8 can be driven
	15:8	**pmcr_powerdown_wait_state6_7** Default Value: 01h Access: R/W This is the programmed value as to how long there is a wait from the time signal 6 is driven before signal 7 can be driven
	7:0	**pmcr_powerdown_wait_state5_6** Default Value: 01h Access: R/W This is the programmed value as to how long there is a wait from the time signal 5 is driven before signal 6 can be driven

Power Down/Up Control

PWRDWNUPCTL - Power Down/Up Control

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	0A294h-0A297h

DWord	Bit	Description
0	31:4	**Reserved** Access: RO
	3	**Block Signaling Policy** Access: R/W BlockAll signaling policy register. Applies to signaling sent to Wake FIFO (ie. IA GT FIFO and HW FIFO). 0 (default) : BlockALL signal only asserts for CPD. 1 : BlockALL signal can assert for CPD and for a timeperiod during RC6 entry. Note : This affects MMIO requests crossing from CZ clock domain to message channel in Gfx clock domain.
	2	**Serialize Power Requests** Access: R/W Determines whether simultaneous requests to REMOVE power are presented to the Punit at the same time or whether the handshake for one must complete before the handshake for the other may start. 0=simultaneous 1=serial
	1	**Powerdown Request Order** Access: R/W Determines which well is disabled first if both wells are requesting to enter standby simultaneously, if serialized. 0=render well power is removed first 1=media well power is removed first.
	0	**Wake Media First** Access: R/W When waking both wells, it determines which well wakes first. 0=wake render first 1=wake media first. (It is NOT possible to wake both simultaneously for di/dt reasons)

Power Enable stagger control

PWRENSTAGCNTRL - Power Enable stagger control

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000001
Size (in bits):	32
Address:	0A70Ch

Power Enable Stagger Control

DWord	Bit	Description
0	31:8	**Reserved** Access: RO
	7:0	**pgen_phase_interval** Default Value: 01h Access: R/W It is the separation between pgen0 and pgen1 on SSx. (units = 30ns) Default value 0x01. (Real silicon settings will be determined by circuit simulation, but expect it to be no higher than 0x21. Nominally, expect it to be 0x0A)

Power Meter Weight for gti_idle_cz

PMWGICZ - Power Meter Weight for gti_idle_cz

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	1300A4h

This register contains the power meter weight for the idleness in CZ clock domain.

DWord	Bit	Description
0	31:16	**RESERVED** Default Value: 0000h Access: RO Reserved
	15:0	**PMWGICZ** Default Value: 0000h Access: R/W This 16-bit value is used to indicate how often to accumulate power within the CZ clock domain. When this field is set to zero, CZ clock domain will not contribute to the overall energy count. Otherwise, the value in this register will dictate how often to add CZ power contribution.

Power Meter Weight for gti_idle_gs

PWRMTR_WT_GTI - Power Meter Weight for gti_idle_gs	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	0AABCh

DWord	Bit	Description
0	31:16	**Reserved** Access: RO
	15:0	**Power Meter Weight GTI** Access: R/W Power meter weight for gti_idle_gs.

Power Meter Weight for media/render

PWRMTR_WT_MEDREN - Power Meter Weight for media/render

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	0AAB8h

DWord	Bit	Description
0	31:16	**Power Meter Weight Render** Access: R/W Power meter weight for render_idle.
	15:0	**Power Meter Weight Media** Access: R/W Power meter event weight media_idle.

POWERUP_STATE

POWERUP_STATE - POWERUP_STATE

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x76543210
Size (in bits):	32
Address:	0A700h

Subwell Power up state description.

DWord	Bit	Description
0	31:28	**pmcr_powerup_state8** Default Value: 0111b Access: R/W The 8th state/signal that needs to be driven
	27:24	**pmcr_powerup_state7** Default Value: 0110b Access: R/W The 7th state/signal that needs to be driven
	23:20	**pmcr_powerup_state6** Default Value: 0101b Access: R/W The 6th state/signal that needs to be driven
	19:16	**pmcr_powerup_state5** Default Value: 0100b Access: R/W The 5th state/signal that needs to be driven
	15:12	**pmcr_powerup_state4** Default Value: 0011b Access: R/W The 4th state/signal that needs to be driven
	11:8	**pmcr_powerup_state3** Default Value: 0010b Access: R/W

POWERUP_STATE - POWERUP_STATE

		The 3rd state/signal that needs to be driven
	7:4	**pmcr_powerup_state2** Default Value: 0001b Access: R/W The 2nd state/signal that needs to be driven
	3:0	**pmcr_powerup_state1** Default Value: 0000b Access: R/W This is the very first state and the signal that needs to be driven appropriately Encodings: 0000 = First Set Clock En 0001 = Reset Power EnB 0010 = Reset Clock En 0011 = Set Firewall 0100 = Set Async Reset/ Set Pwrok 0101 = Final Set clock en 0110 = Set Sync Reset. 0111 = Done 1xxx = Reserved for future

POWERUP_WAIT1

POWERUP_WAIT1 - POWERUP_WAIT1

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x01010101
Size (in bits):	32
Address:	0A704h

Subwell power up state wait time 1

DWord	Bit	Description
0	31:24	**pmcr_powerup_wait_state4_5** Default Value: 01h Access: R/W This is the programmed value as to how long there is a wait from the time signal 4 is driven before signal 5 can be driven
	23:16	**pmcr_powerup_wait_state3_4** Default Value: 01h Access: R/W This is the programmed value as to how long there is a wait from the time signal 3 is driven before signal 4 can be driven
	15:8	**pmcr_powerup_wait_state2_3** Default Value: 01h Access: R/W This is the programmed value as to how long there is a wait from the time signal 2 is driven before signal 3 can be driven
	7:0	**pmcr_powerup_wait_state1_2** Default Value: 01h Access: R/W This is the programmed value as to how long there is a wait from the time signal 1 is driven before signal 2 can be driven. Note: The granularity of these are in 30ns intervals meaning the counters will increment or decrement every 30ns pulse unless we are asserting clocken in which case it is on a usync boundary

POWERUP_WAIT2

POWERUP_WAIT2 - POWERUP_WAIT2

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x01010101
Size (in bits):	32
Address:	0A708h

Subwell power up state wait time 2.

DWord	Bit	Description
0	31:24	**pmcr_powerup_interval** Default Value: 01h Access: R/W Stagger between different power gate enables on power up
	23:16	**pmcr_powerup_wait_state7_8** Default Value: 01h Access: R/W This is the programmed value as to how long there is a wait from the time signal 7 is driven before signal 8 can be driven
	15:8	**pmcr_powerup_wait_state6_7** Default Value: 01h Access: R/W This is the programmed value as to how long there is a wait from the time signal 6 is driven before signal 7 can be driven
	7:0	**pmcr_powerup_wait_state5_6** Default Value: 01h Access: R/W This is the programmed value as to how long there is a wait from the time signal 5 is driven before signal 6 can be driven

PPGTT Page Fault Data Registers

PP_PFD[0:31] - PPGTT Page Fault Data Registers

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Address:	04580h

The GTT Page Fault Log entries can be read from these registers.
4580h-4583h: Fault Entry 0
...
45FCh-45FFh: Fault Entry 31

DWord	Bit	Description
0	31:12	**Fault Entry Page Address** Format: GraphicsAddress[31:12] This RO field contains the faulting page address for this Fault Log entry. This field will contain a valid fault address only if the bit in the GTT Page Fault Indication Register corresponding with the address offset of this entry is set.
	11:0	**Reserved** Format: MBZ

Predicate Rendering Data Result

MI_PREDICATE_RESULT - Predicate Rendering Data Result	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS

ShortName:	MI_PREDICATE_RESULT_1_VECSUNIT
Address:	1C41Ch-1C41Fh
Name:	Predicate Rendering Data Result 1
ShortName:	MI_PREDICATE_RESULT_1_VCSUNIT1
Address:	2241Ch-2241Fh
Name:	Predicate Rendering Data Result 1
ShortName:	MI_PREDICATE_RESULT_1_BCSUNIT

DWord	Bit	Description
0	31:1	**Reserved** Format: MBZ
	0	**MI_PREDICATE_RESULT_1** This bit is used to predicate MI_BATCH_BUFFER_START commands in the RCS command stream. Usage Model: MI_MATH command will be used to do some ALU operations over GPR followed by a MI_LOAD_REGISTER_REGISTER to move the result from GPR to MI_PREDICATE_RESULT_1.

Predicate Rendering Data Result 2

MI_PREDICATE_RESULT_2 - Predicate Rendering Data Result 2

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32

Address:	023BCh-023BFh
Name:	Predicate Rendering Data Result 2
ShortName:	MI_PREDICATE_RESULT_2_RCSUNIT
Valid Projects:	CHV, BSW

Address:	123BCh-123BFh
Name:	Predicate Rendering Data Result 2
ShortName:	MI_PREDICATE_RESULT_2_VCSUNIT0
Valid Projects:	CHV, BSW

Address:	1A3BCh-1A3BFh
Name:	Predicate Rendering Data Result 2
ShortName:	MI_PREDICATE_RESULT_2_VECSUNIT
Valid Projects:	CHV, BSW

Address:	1C3BCh-1C3BFh
Name:	Predicate Rendering Data Result 2
ShortName:	MI_PREDICATE_RESULT_2_VCSUNIT1
Valid Projects:	CHV, BSW

Address:	223BCh-223BFh
Name:	Predicate Rendering Data Result 2
ShortName:	MI_PREDICATE_RESULT_2_BCSUNIT

DWord	Bit	Description
0	31:1	**Reserved** Format: MBZ
	0	**MI_PREDICATE_RESULT_2** This bit must be loaded with by SW based on GT mode of operation. This register must be loaded appropriately before using MI_SET_PREDICATE command. Value / Name / Description 0h / **[Default]** / Indicates GT2 mode and lower slice is disabled. 1h / / Indicates GT3 mode and lower slice is enabled.

Predicate Rendering Data Storage

MI_PREDICATE_DATA - Predicate Rendering Data Storage

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000, 0x00000000
Access:	R/W
Size (in bits):	64
Address:	02410h-02417h
Valid Projects:	

DWord	Bit	Description
0	63:32	**MI_PREDICATE_DATA_UDW** This register is used either as computed value based off the MI_PREDICATE_SRC0 and MI_PREDICATE_SRC1 or a temporary register. See Predicate Rendering section for more details.
	31:0	**MI_PREDICATE_DATA_LDW** This register is used either as computed value based off the MI_PREDICATE_SRC0 and MI_PREDICATE_SRC1 or a temporary register. See Predicate Rendering section for more details.

Predicate Rendering Temporary Register0

MI_PREDICATE_SRC0 - Predicate Rendering Temporary Register0

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000, 0x00000000
Access:	R/W
Size (in bits):	64
Address:	02400h-02407h
Valid Projects:	

DWord	Bit	Description
0	63:0	**MI_PREDICATE_SRC0** This register is a temporary register for Predicate Rendering. See Predicate Rendering section for more details.

Predicate Rendering Temporary Register1

MI_PREDICATE_SRC1 - Predicate Rendering Temporary Register1	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000, 0x00000000
Access:	R/W
Size (in bits):	64
Address:	02408h-0240Fh
Valid Projects:	CHV, BSW

DWord	Bit	Description
0	63:0	**MI_PREDICATE_SRC1** This register is a temporary register for Predicate Rendering. See Predicate Rendering section for more details.

Previous Idle/Busy/Avg Count for Freq Down Recommendation

RPPREVDN - Previous Idle/Busy/Avg Count for Freq Down Recommendation

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	0A064h-0A067h

DWord	Bit	Description
0	31:24	**Reserved** Access: RO Reserved

Primitives Generated By VF

IA_PRIMITIVES_COUNT - Primitives Generated By VF	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000, 0x00000000
Access:	R/W
Size (in bits):	64
Trusted Type:	1
Address:	02318h
Valid Projects:	

This register stores the count of primitives generated by VF. This register is part of the context save and restore.

DWord	Bit	Description
0	63:32	**IA Primitives Count Report UDW** Total number of primitives output by the Vertex Fetch (IA) stage. This count is updated for every primitive output by the VF stage, as long as Statistics Enable is set in VF_STATE (see the Vertex Fetch Chapter in the 3D Volume.)
	31:0	**IA Primitives Count Report LDW** Total number of primitives output by the Vertex Fetch (IA) stage. This count is updated for every primitive output by the VF stage, as long as Statistics Enable is set in VF_STATE (see the Vertex Fetch Chapter in the 3D Volume.)

Private PAT

PRIV_PAT - Private PAT

Register Space:	MMIO: 0/2/0

PS Depth Count

PS_DEPTH_COUNT - PS Depth Count	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000, 0x00000000
Access:	R/W
Size (in bits):	64
Trusted Type:	1
Address:	02350h

This register stores the value of the count of samples that have passed the depth test. This register is part of the context save and restore. Note that the value of this register can be obtained in a pipeline-synchronous fashion without a pipeline flush by using the 3DCONTROL command. See 3D Overview in the 3D volume.

DWord	Bit	Description
0..1	63:32	**Depth Count UDW** This register reflects the total number of samples that have passed the depth test (i.e., will be visible). All samples are counted when Statistics Enable is set in the Windower State. See the Windower chapter of the 3D volume for details. Samples that pass the depth test but fail the stencil test will not be counted.
	31:0	**Depth Count LDW** This register reflects the total number of samples that have passed the depth test (i.e., will be visible). All samples are counted when Statistics Enable is set in the Windower State. See the Windower chapter of the 3D volume for details. Samples that pass the depth test but fail the stencil test will not be counted.

PS Depth Count for Slice0

PS_DEPTH_COUNT_SLICE0 - PS Depth Count for Slice0	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000, 0x00000000
Access:	R/W
Size (in bits):	64
Trusted Type:	1
Address:	022D8h

This register stores the value of the count of pixels that have passed the depth test in Slice0. This register is part of the context save and restore. This register should not be programmed by SW.Note: In GT3 mode there are two slices Slice0 (Upper Slice) and Slice1 (Lower slice).

DWord	Bit	Description
0..1	63:32	**Depth Count UDW** This register reflects the total number of pixels that have passed the depth test in Slice0(i.e., will be visible). All pixels are counted when Statistics Enable is set in the Windower State. See the Windower chapter of the 3D volume for details. Pixels that pass the depth test but fail the stencil test will not be counted.
	31:0	**Depth Count LDW** This register reflects the total number of pixels that have passed the depth test in Slice0(i.e., will be visible). All pixels are counted when Statistics Enable is set in the Windower State. See the Windower chapter of the 3D volume for details. Pixels that pass the depth test but fail the stencil test will not be counted.

PS Depth Count for Slice1

PS_DEPTH_COUNT_SLICE1 - PS Depth Count for Slice1	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000, 0x00000000
Access:	R/W
Size (in bits):	64
Trusted Type:	1
Address:	022F8h

This register stores the value of the count of pixels that have passed the depth test in Slice1. This register is part of the context save and restore. This register should not be programmed by SW.Note: In GT3 mode there are two slices Slice0 (Upper Slice) and Slice1 (Lower slice).

DWord	Bit	Description
0..1	63:32	**Depth Count UDW** This register reflects the total number of pixels that have passed the depth test in Slice1(i.e., will be visible). All pixels are counted when Statistics Enable is set in the Windower State. See the Windower chapter of the 3D volume for details. Pixels that pass the depth test but fail the stencil test will not be counted.
	31:0	**Depth Count LDW** This register reflects the total number of pixels that have passed the depth test in Slice1(i.e., will be visible). All pixels are counted when Statistics Enable is set in the Windower State. See the Windower chapter of the 3D volume for details. Pixels that pass the depth test but fail the stencil test will not be counted.

PS Depth Count for Slice2

PS_DEPTH_COUNT_SLICE2 - PS Depth Count for Slice2	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000, 0x00000000
Access:	R/W
Size (in bits):	64
Trusted Type:	1
Address:	02450h

This register stores the value of the count of pixels that have passed the depth test in Slice2. This register is part of the render context save and restore. This register should not be programmed by SW.

DWord	Bit	Description
0..1	63:32	**Depth Count UDW** This register reflects the depth test in slice2 (i.e., will be visible). All pixels are counted when Statistics Enable is set in the Windower State. See the Windower chapter of the 3D volume for details. Pixels that pass the depth test but fail the stencil test will not be counted.
	31:0	**Depth Count LDW** This register reflects the depth test in slice2 (i.e., will be visible). All pixels are counted when Statistics Enable is set in the Windower State. See the Windower chapter of the 3D volume for details. Pixels that pass the depth test but fail the stencil test will not be counted.

PS Depth Count for Slice3

PS_DEPTH_COUNT_SLICE3 - PS Depth Count for Slice3	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000, 0x00000000
Access:	R/W
Size (in bits):	64
Trusted Type:	1
Address:	02460h

This register stores the value of the count of pixels that have passed the depth test in Slice3. This register is part of the render context save and restore. This register should not be programmed by SW.

DWord	Bit	Description
0..1	63:32	**Depth Count UDW** This register reflects the depth test in slice3 (i.e., will be visible). All pixels are counted when Statistics Enable is set in the Windower State. See the Windower chapter of the 3D volume for details. Pixels that pass the depth test but fail the stencil test will not be counted.
	31:0	**Depth Count LDW** This register reflects the depth test in slice3 (i.e., will be visible). All pixels are counted when Statistics Enable is set in the Windower State. See the Windower chapter of the 3D volume for details. Pixels that pass the depth test but fail the stencil test will not be counted.

PS Invocation Count

PS_INVOCATION_COUNT - PS Invocation Count	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000, 0x00000000
Access:	R/W
Size (in bits):	64
Trusted Type:	1
Address:	02348h

DWord	Bit	Description
0..1	63:32	**PS Invocation Count UDW** Reflects a count of the total number of pixels (including unlit "helper pixels" within a subspan that need to go through the PS shader to provide 2x2 gradients) that are dispatched to pixel shader invocations while Statistics Enable is set in the Windower. See the Windower chapter of the 3D volume for details. This count will generally be much greater than the actual count of PS threads since a single thread may process up to 32 pixels.
	31:0	**PS Invocation Count LDW** Reflects a count of the total number of pixels (including unlit "helper pixels" within a subspan that need to go through the PS shader to provide 2x2 gradients) that are dispatched to pixel shader invocations while Statistics Enable is set in the Windower. See the Windower chapter of the 3D volume for details. This count will generally be much greater than the actual count of PS threads since a single thread may process up to 32 pixels.

PS Invocation Count for Slice0

PS_INVOCATION_COUNT_SLICE0 - PS Invocation Count for Slice0

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000, 0x00000000
Access:	R/W
Size (in bits):	64
Trusted Type:	1
Address:	022C8h

This register stores the value of the count of pixels that get shaded in Slice0. This register is part of the context save and restore. This register should not be programmed by SW.Note: In GT3 mode there are two slices Slice0 (Upper Slice) and Slice1 (Lower slice).

Workaround
HW reports this count 4X the actual value and therefore SW must divide the count by 4 for correct reporting.

DWord	Bit	Description
0..1	63:32	**PS Invocation Count UDW** Reflects a count of the total number of pixels (including unlit "helper pixels" within a subspan that need to go through the PS shader to provide 2x2 gradients) that are dispatched to pixel shader invocations while Statistics Enable is set in the Windower in Slice0. See the Windower chapter of the 3D volume for details. This count will generally be much greater than the actual count of PS threads since a single thread may process up to 32 pixels.
	31:0	**PS Invocation Count LDW** Reflects a count of the total number of pixels (including unlit "helper pixels" within a subspan that need to go through the PS shader to provide 2x2 gradients) that are dispatched to pixel shader invocations while Statistics Enable is set in the Windower in Slice0. See the Windower chapter of the 3D volume for details. This count will generally be much greater than the actual count of PS threads since a single thread may process up to 32 pixels.

PS Invocation Count for Slice1

PS_INVOCATION_COUNT_SLICE1 - PS Invocation Count for Slice1

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000, 0x00000000
Access:	R/W
Size (in bits):	64
Trusted Type:	1
Address:	022F0h

This register stores the value of the count of pixels that get shaded in Slice0. This register is part of the context save and restore. This register should not be programmed by SW.Note: In GT3 mode there are two slices Slice0 (Upper Slice) and Slice1 (Lower slice).

Workaround

Workaround: HW reports this count 4X the actual value and therefore SW must divide the count by 4 for correct reporting.

DWord	Bit	Description

Default Value:	0x00000000	
Size (in bits):	32	
Address:	04100h	
DWord	**Bit**	**Description**
0	31:0	**PTE SW Fault Repair Low** Default Value: 00000000h Access: R/W Fixed PTE entry is written by SW here.

Punit to Gunit Message

P2GMESSAGE - Punit to Gunit Message

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	1300A8h

This register is used for messaging communication between Punit and Gunit.

DWord	Bit	Description
0	31:16	**P2GMSGMSK** Default Value: 0000h Access: RO Mask bits for lower 16 bits to avoid a read/modify write if '0' the corresponding bit in [15:0] is not changed if '1' the corresponding bit in [15:0] is changed to the value in [15:0]
	15	**Punit to Gunit Ack for (EU/SS) resource profile change** Default Value: 0b Access: WO New for CHV, BSW. Punit sends an ack to proceed with changing the EU/SS requested by CS. This is self clearing bit. Both this bit and bit 31 should be '1 and byte enables should be set for writing into this bit. Once written, ack will stay high for one czclk wide and self clears. Reads will always return '0. Other bits that are involved in the flow are A11C[28] and A11C[27].Sequencing. 1) CS sends (EU/SS) resource request to GPM. 2) GPM writes to offset 0xDA in Punit config space showing what the intended new configuration will be, when config bit allows. 3) Punit has opportunity to do whatever is needed, but can not wait for CPDack as it will result in a hang. 4) Based on a config unit setting, GPM will wait for an acknowledge from Punit. By default, GPM does not wait for ack due to large latency. 5) GPM continues to change the (EU/SS) resource profile. 6) GPM replies to CS with the new resource profile. 7) Execute the workload or arbitrate CPD.
	14:1	**P2G_MSG_RSVD** Default Value: 0000h Access: R/W P2GMSGReserved

P2GMESSAGE - Punit to Gunit Message

	0	**P2GMSG0** Default Value: 0b Access: R/W Context restore. this bit is used as part of the hardware context restore process. Step1: Punit writes '1(with mask bit 16 set) to initiate the HW context restore(for registers driver would normally restore) Step2: Gunit goes through context restore. Step3: Gunit writes a 1 to Punit register DB[0] indicating context restore has completed. This bit is cleared automatically when Gunit is powered down. Punit must do the same. The specific usage of this bit limits it to only be set once, for initial context restore request after an s0ix exit. Any subsequent write is undefined.

PWRCTXSAVE Message Register for Power Managment Unit

MSG_PWRCTXSAVE_GPM - PWRCTXSAVE Message Register for Power Managment Unit

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	16
Address:	08044h

Message registers have bit-wise masking applied for writes. The register consists of 16 bits of data in [15:0], and 16 bits of corresponding masks in [31:16]. In order to set bit0, for example, the data would be 0x0001_0001. In order to clear bit0, for example, the data would be 0x0001_0000. Note that mask bit is the data bit offset + 16. Message registers are protected from non-GT writes via the Message Channel.

DWord	Bit	Description
0	15:10	**Reserved** Access: RO
	9	**Power Context Save Request** Access: R/W Power Context Save Request 1'b0 : Power context save is not being requested <default> 1'b1 : Power context save is being requested Unit needs to self-clear this bit upon sampling.
	8:0	**QWord Credits for Power Context Save Request** Access: R/W QWord Credits for Power Context Save Request Minimum Credits = 1 : Unit may send 1 QWord pair (enough for first LRI at least) Maximum Credits = 511 : Unit may send 511 QWord pairs A QWord pair is defined as a 32-bit register address and the corresponding 32-bits of register data. Note that the LRI header and END commands are 64-bits each (32-bit command followed by 32-bit NOOP) and will consume one QWord credit. Only valid with PWRCTXSAVE_REQ (Bit9).

	15:8	**RCC LRA0 Max** Default Value: 00111111b Access: R/W Maximum value of programmable LRA0.
	7:0	**RCC LRA0 Min** Default Value: 00000000b Access: R/W Minimum value of programmable LRA0.

RCC LRA 1

RCC_LRA_1 - RCC LRA 1

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000001
Size (in bits):	32
Address:	04A44h

DWord	Bit	Description
0	31:2	**Reserved** Default Value: 00000000000000000000000000000000b Access: RO
	1	**MSC LRA** Default Value: 0b Access: R/W Which LRA should MSC use.
	0	**RCC LRA** Default Value: 1b Access: R/W Which LRA should RCC use.

RCC Virtual page Address Registers

RCCTLB_VA - RCC Virtual page Address Registers

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	04A00h-04A03h

These registers are directly mapped to the current Virtual Addresses in the RCCTLB (Render Cache for Color TLB).

DWord	Bit	Description
0	31:12	**Address** Project: All Format: GraphicsAddress[31:12] Page virtual address.
	11:0	**Reserved** Project: CHV, BSW Format: MBZ

RC Evaluation Interval

RCI - RC Evaluation Interval		
Register Space:	MMIO: 0/2/0	
Project:	CHV, BSW	
Source:	PRM	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	0A0A8h-0A0ABh	
DWord	**Bit**	**Description**
0	31:24	**Reserved** Access: RO
	23:0	**Render Standby Evaluation Interval** Access: R/W 0 = 0 usec 1 = 1.28 usec 2 = 2.56 usec 3 = 3.84 usec FF FFFF = 21.474 sec pmcr_rc_ei[23:0]

RC Idle Hysteresis

RCIHYST - RC Idle Hysteresis		
Register Space:	MMIO: 0/2/0	
Project:	CHV, BSW	
Source:	PRM	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	0A0ACh-0A0AFh	
DWord	**Bit**	**Description**
0	31:24	**Reserved** Access: RO
	23:0	**RC Idle Hysteresis Detection** Access: R/W Idle intervals must be longer than this value to be considered idle. 0 = 0 usec means disabled 1 = 1.28 usec 2 = 2.56 usec 3 = 3.84 usec FF FFFF = 21.474 sec This must not be set to more than 5ms to prevent the PCU from timing out on an S state entry

RCS_PREEMPTION_HINT

RCS_PREEMPTION_HINT - RCS_PREEMPTION_HINT

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	024BCh

Description

This register contains the Head pointer offset in to the Ring Buffer or the Dword aligned Graphics address in to the Batch Buffer corresponding to either MI_ARB_CHECK called Preemption Hint Address. When Preemption Hint Address is enabled, RCS will honor UHPTR only on parsing MI_ARB_CHK at Preemption Hint Address.

This register contains the Head pointer offset into the Ring Buffer or the Dword aligned Graphics address into the Batch Buffer corresponding to the below listed commands in execlist mode of operation

- MI_ARB_CHECK
- MI_WAIT_FOR_EVENT
- MI_SEMAPHORE_WAIT
- 3D_PRIMITIVE
- GPGPU_WALKER
- MEDIA_STATE_FLUSH
- PIPE_CONTROL (Only in GPGPU mode of pipeline selection)
- MI_ATOMIC (Post Sync Operation set in GPGPU mode of pipeline selection)
- MI_SEMAPHORE_SIGNAL (Post Sync Operation set in GPGPU mode of pipeline selection)

Programming Notes

Programming Restriction:
This register should NEVER be programmed in functional mode, this should be used only in validation mode to achieve deterministic behavior of UHPTR being sampled by a given MI_ARB_CHECK in command stream. Programmer has to ensure that RCS Preemption Hint register gets programmed before UHPTR is programmed and well before RCS crosses the corresponding execution point. Preemption hint for both RingBuffer and Batch Buffer can't be enabled simultaneously.

User must ensure the Preempted Hint Address programmed matches either Ring Head Offset or Batch Buffer Graphics Virtual Address and not both of them.
User must also ensure the Preempted Hint Address[19:0] programmed matches either Ring Head Offset[19:0] or Batch Buffer Graphics Virtual Address[19:0] and not both of them.

RCS_PREEMPTION_HINT - RCS_PREEMPTION_HINT

DWord	Bit	Description
0	31:2	**Preempted Hint Address** Project: CHV, BSW Format: U30 This field contains the Head offset in to the Ring Buffer when Preemption Hint is set to Ring Buffer and Dword aligned Graphics Address in to the batch buffer when Preemption Hint is set to Batch Buffer.
	1	**Batch Buffer Preemption Hint** Project: CHV, BSW Format: Enabled Value / Name / Description / Project: 0h / Disabled / Preemption hint is disabled in batch buffer. / CHV, BSW 1h / Enabled / Preemption hint is enabled in ring buffer and preemption hint address corresponds to the instruction in Batch Buffer. / CHV, BSW
	0	**Ring Preemption Hint** Project: CHV, BSW Format: Enable Value / Name / Description / Project: 0h / Disable / Preemption hint is disabled in ring buffer. / CHV, BSW 1h / Enabled / Preemption hint is enabled in ring buffer and preemption hint address corresponds to the instruction in Ring Buffer. / CHV, BSW

RCS_PREEMPTION_HINT_UDW

RCS_PREEMPTION_HINT_UDW - RCS_PREEMPTION_HINT_UDW

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	024C8h

This register contains the 4GB aligned base address of gfx 4GB virtual address space within the host's 64-bit virtual address space of the Batch Buffer corresponding to MI_ARB_CHECK command called Preemption Hint Address.

Programming Notes

Programming Restriction:
This register should NEVER be programmed in functional mode, this should be used only in validation mode to achieve deterministic behavior of UHPTR being sampled by a given MI_ARB_CHK in command stream.

DWord	Bit	Description
0	31:16	**Reserved** Format: MBZ
	15:0	**Preempted Hint Address Upper DWORD** Format: GraphicsAddress[47:32] This field contains the 4GB aligned base address of gfx 4GB virtual address space within the host's 64-bit virtual address space of the batch buffer when Preemption Hint is set to Batch Buffer. This field is not valid when Preemption Hint is set to Ring Buffer.

RCS Batch Buffer State Register

RCS_BB_STATE - RCS Batch Buffer State Register

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000 CHV, BSW
Access:	RO
Size (in bits):	32
Address:	02110h

This register contains the attributes of the current batch buffer initiated from the Ring Buffer.

This register should not be written by software. These fields should only get written by a context restore. Software should always set these fields via the MI_BATCH_BUFFER_START command when initiating a batch buffer. This register is saved and restored with context.

DWord	Bit	Description
0	31:9	**Reserved** Format: MBZ
	8	**Reserved** Format: MBZ
	7	**Resource Streamer Enable** Project: CHV, BSW Format: U1 When this bit is set, the Resource Streamer will execute the batch buffer. When this bit is clear the Resource Streamer will not execute the batch buffer.
	6	**Reserved**
	5	**Address Space Indicator** Project: CHV, BSW Note: This field reflects the effective address space indicator security level and may not be the same as the Address Space Indicator written using MI_BATCH_BUFFER_START. Value / Name / Description 0h / GGTT **[Default]** / This Batch buffer is located in GGTT memory and is privileged 1h / PPGTT / This Batch buffer is located in PPGTT memory and is non-privileged.
	4	**Reserved** Project: CHV, BSW Format: MBZ
	3:0	**Reserved** Format: MBZ

RCS Context Preemption Hint

RCS_CTXID_PREEMPTION_HINT - RCS Context Preemption Hint

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	024CCh
Address:	124CCh-124CFh
Name:	Context ID Preemption Hint
ShortName:	RCS_CTXID_PREEMPTION_HINT_VCSUNIT0
Address:	1A4CCh-1A4CFh
Name:	Context ID Preemption Hint
ShortName:	RCS_CTXID_PREEMPTION_HINT_VECSUNIT
Address:	1C4CCh-1C4CFh
Name:	Context ID Preemption Hint
ShortName:	RCS_CTXID_PREEMPTION_HINT_VCSUNIT1
Address:	224CCh-224CFh
Name:	Context ID Preemption Hint
ShortName:	RCS_CTXID_PREEMPTION_HINT_BCSUNIT

This register contains the Context ID of a context in execlist mode of operation. In execlist mode of operation RCS_PREEMPTION_HINT and RS_PREEMPTION_HINT registers are looked at by Render Command Streamer and Resource Streamer only on executing a context having Context ID that matches with the contents of this register. This register contents are valid and looked at only in execlist mode of operation

Programming Restriction:

This register should NEVER be programmed in functional mode, this must be used only in validation mode to achieve deterministic preemption behavior in execlist mode of operation.

DWord	Bit	Description
0	31:0	**Context ID Preemption Hint** Format: U32 If 0 this field has no effect. If nonzero it indicates the only context ID that can be preempted when execlists are enabled. A preemption attempt when the context ID of the currently executing ring context does not match this field will be ignored.

RC Wake Counter

RCWC - RC Wake Counter

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	0A0A4h-0A0A7h

DWord	Bit	Description
0	31:16	**Wake Counter Render** Access: RO Incremented for each wake event , wraps around wake_counter[15:0]
	15:0	**Wake Counter Media** Access: RO Incremented for each wake event , wraps around wake_counter[15:0]

RCZ Virtual Page Address Registers

RCZTLB_VA - RCZ Virtual Page Address Registers

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	04B00h-04B03h

These registers are directly mapped to the current Virtual Addresses in the RCZTLB (Render Cache for Z (Depth), Hi Z, and Stencil TLB).

DWord	Bit	Description
0	31:12	**Address** Format: GraphicsAddress[31:12] Page virtual address.
	11:0	**Reserved** Format: MBZ

Ready Bit Vector 0 for TLBPEND registers

TLBPEND_RDY0 - Ready Bit Vector 0 for TLBPEND registers	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Trusted Type:	1
Address:	04708h-0470Bh

This register contains the ready bits for entries 0-31 of TLBPEND structure (Cycles pending TLB translation).

DWord	Bit	Description
0	31:0	**Ready bits per entry**

Ready Bit Vector 1 for TLBPEND registers

TLBPEND_RDY1 - Ready Bit Vector 1 for TLBPEND registers	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Trusted Type:	1
Address:	0470Ch-0470Fh

This register contains the ready bits for entries 32-63 of TLBPEND structure (Cycles pending TLB translation).

DWord	Bit	Description
0	31:0	**Ready bits per entry**

Render C State Control 1

RCCTL1 - Render C State Control 1

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	0A090h-0A093h

DWord	Bit	Description

	23	**Reserved** Access: R/W
	22:0	**Reserved** Access: RO

Render forcewake acknowledge

RENFW_ACK - Render forcewake acknowledge

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	1300B4h

This register contains the per thread force wake acknowledge bits for the Render power well.

DWord	Bit	Description
0	31:16	**RESERVED** Default Value: 0000h Access: RO Reserved.
	15:0	**FWAKERENDERACK** Default Value: 0000h Access: RO Force Wake Render request bits. Driver must poll on the corresponding bit to confirm that the well has woken. For example, if 13_00B0[0] is written to a '1' (along with 13_00B0[16]='1'), then bit0 of this register indicates when the force wake request has been completed.

Render forcewake request

RENFW_REQ - Render forcewake request

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	1300B0h

This register contains per thread force wake request bits for the Render power Well. The upper 16 bits act as masks for the lower 16 bits. Bit 31 masks bit 15 and bit 16 masks bit 0.

1. Driver writes to GPM force wake request bit. (VV will have a Render(13_00B0(15:0)) and a Media (13_00B8(15:0)) bits.)
2. The GPM responds by writing (via PLINK) to 1300B4[15:0] or 1300BC[15:0] register.
3. Driver polls (1300B4[15:0] and/or 1300BC[15:0])status until 1... indicating that that well has completed wake sequence.

Since the registers are per thread, only the specific bit that was forced should be checked for status.

DWord	Bit	Description
0	31:16	**FWAKERENDERREQMSK** Default Value: 0000h Access: RO Mask bits for lower 16 bits to avoid a read modify/write. If '0', the corresponding bit in [15:0] is not changed. If '1', the corresponding bit in [15:0] is changed to the value in [15:0]
	15	**FWAKERENDERREQ15** Default Value: 0b Access: R/W Force Wake Render request 15.
	14	**FWAKERENDERREQ14** Default Value: 0b Access: R/W Force Wake Render request 14.
	13	**FWAKERENDERREQ13** Default Value: 0b Access: R/W Force Wake Render request 13.

RENFW_REQ - Render forcewake request

	12	**FWAKERENDERREQ12** Default Value: 0b Access: R/W Force Wake Render request 12.
	11	**FWAKERENDERREQ11** Default Value: 0b Access: R/W Force Wake Render request 11.
	10	**FWAKERENDERREQ10** Default Value: 0b Access: R/W Force Wake Render request 10.
	9	**FWAKERENDERREQ9** Default Value: 0b Access: R/W Force Wake Render request 9.
	8	**FWAKERENDERREQ8** Default Value: 0b Access: R/W Force Wake Render request 8.
	7	**FWAKERENDERREQ7** Default Value: 0b Access: R/W Force Wake Render request 7.
	6	**FWAKERENDERREQ6** Default Value: 0b Access: R/W Force Wake Render request 6.
	5	**FWAKERENDERREQ5** Default Value: 0b Access: R/W Force Wake Render request 5.

RENFW_REQ - Render forcewake request

	4	**FWAKERENDERREQ4** Default Value: 0b Access: R/W Force Wake Render request 4.
	3	**FWAKERENDERREQ3** Default Value: 0b Access: R/W Force Wake Render request 3.
	2	**FWAKERENDERREQ2** Default Value: 0b Access: R/W Force Wake Render request 2.
	1	**FWAKERENDERREQ1** Default Value: 0b Access: R/W Force Wake Render request 1.
	0	**FWAKERENDERREQ0** Default Value: 0b Access: R/W Force Wake Render request 0.

Render Geyserville Mode Control 1

RPMODECTL1 - Render Geyserville Mod

Render Mode Register for Software Interface

MI_MODE - Render Mode Register for Software Interface

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	0209Ch
Address:	1209Ch-1209Fh
Name:	Mode Register for Software Interface
ShortName:	MI_MODE_VCSUNIT0
Address:	1A09Ch-1A09Fh
Name:	Mode Register for Software Interface
ShortName:	MI_MODE_VECSUNIT
Address:	1C09Ch-1C09Fh
Name:	Mode Register for Software Interface
ShortName:	MI_MODE_VCSUNIT1
Address:	2209Ch-2209Fh
Name:	Mode Register for Software Interface
ShortName:	MI_MODE_BCSUNIT

The MI_MODE register contains information that controls software interface aspects of the Memory Interface function.

DWord	Bit	Description
0	31:16	**Masks** Format: Mask[15:0] A 1 in a bit in this field allows the modification of the corresponding bit in Bits 15:0
	15	**Suspend Flush** Format: U1

Value	Name	Description
0h	No Delay **[Default]**	HW will not delay flush, this bit will get cleared by MI_SUSPEND_FLUSH as well
1h	Delay Flush	Suspend flush is active

MI_MODE - Render Mode Register for Software Interface

Programming Notes
This should only be written to from the ring using MI_SUSPEND_FLUSH. It is considered undefined if written by software through MMIO

14 **Async Flip Performance mode**

Format:	U1

Value	Name	Description
0h	Performance mode enabled **[Default]**	The stall of the flip event is in the windower
1h	Performance mode disabled	The stall of the flip event is in the command stream

Programming Notes
This bit must be set to '1' on all projects disabling Async Flip Performance mode.
When Async Flip Performance mode is enabled stall is in the Windower allowing the commands following the MI_WAIT_FOR_EVENT to be parsed by command streamer, this breaks the usage model of controlling the display message generation in display engine using MI_LOAD_REGISTER_IMMEDIATE commands from ring buffer.

13 **Flush Performance mode**

Format:	U1

Value	Name	Description
0h	run fast restore **[Default]**	No NonPipelined SV flush.
1h	run slow legacy restore	With NonPipelined SV flush.

12 **Reserved**

Format:	MBZ

11 **Invalidate UHPTR enable**

Format:	Enable

If bit set H/W clears the valid bit of UHPTR (2134h, bit 0) when current active head pointer is equal to UHPTR.

10 **Atomic Read Return for MI_COPY_MEM_MEM**

Project:	CHV, BSW
Format:	U1

Value	Name	Description
0h	Disable **[Default]**	Hardware does a regular memory fence write to complete the write to the destination address before moving to the next instruction.
1h	Enable	Hardware does Atomic Move with Read Return to complete the write to the destination address before moving to the next instruction.

MI_MODE - Render Mode Register for Software Interface

9 **Rings Idle**

Format:	U1

Read Only Status bit

Value	Name	Description
0h	Not Idle **[Default]**	Parser not Idle or Ring Arbiter not Idle.
1h	Idle	Parser Idle and Ring Arbiter Idle.

Programming Notes
Writes to this bit are not allowed.

8 **Stop Rings**

Format:	U1

Value	Name	Description
0h	**[Default]**	Normal Operation.
1h		Parser is turned off and Ring arbitration is turned off.

Programming Notes
Software must set this bit to force the Rings and Command Parser to Idle. Software must read a 1 in the Ring Idle bit after setting this bit to ensure that the hardware is idle.
Software must clear this bit for Rings to resume normal operation.
Due to known HW issue when Stop Rings occur during execution of a batch buffer, memory access type of the batch buffer is reset and hence on resuming the memory access type can be inconsistent with the desired memory access type. SW must not set/reset Stop Rings to achieve stall and resume function in command streamer execution, however Stop Rings can be used by SW before resetting the engine.

7 **Reserved**

Format:	MBZ

6 **Vertex Shader Timer Dispatch Enable**

Project:	CHV, BSW
Format:	Enable

Value	Name	Description
0h	Disable **[Default]**	Disable the timer for dispatch of single vertices from the vertex shader. Vertex shader will try to collect 2 vertices before a dispatch
1h	Enable	Enable the timer for dispatch of single vertices. Dispatch a single vertex shader thread after the timer expires.

5 **Reserved**

Format:	MBZ

MI_MODE - Render Mode Register for Software Interface

4:1 **Predicate Enable**

Project:	CHV, BSW

This field gets set when "MI_SET_PREDICATE" command is parsed by render command streamer. Predicate Disable is the default mode of operation.

Value	Name	Description
0h	Predicate Disable	Predication is Disabled and RCS will process commands as usual.
1h	Predicate on Result2 clear	Following Commands will be NOOPED by RCS only if the MI_PREDICATE_RESULT_2 is clear.
2h	Predicate on Result2 set	Following Commands will be NOOPED by RCS only if the MI_PREDICATE_RESULT_2 is set.
3h	Predicate on Result clear	Following Commands will be NOOPED by RCS only if the MI_PREDICATE_RESULT is clear.
4h	Predicate on Result set	Following Commands will be NOOPED by RCS only if the MI_PREDICATE_RESULT is set.
5h	Predicate when two or more slices enabled	Following Commands will be NOOPED by RCS only when one slice is enabled, NOOPED when more than one slice is enabled.
6h	Predicate when one or three slices enabled	Following Commands will be Executed by RCS only when two slices are enabled, NOOPED when one or three slices are enabled.
7h	Predicate when one or two slices enabled	Following Commands will be Executed by RCS only when all the three slices are enabled, NOOPED when less than three slices are enabled.
8h-Eh	Reserved	
Fh	Predicate Always	Following Commands will be NOOPED by RCS unconditionally.

Programming Notes
SW must use MI_SET_PREDICATE instead of MMIO access.

0 **Mask IIR disable**

Format:	Disable

Mask IIR disable. Nominally the Interrupt controller masks interrupts in the IIR register if an interrupt acknowledge from the 3gio interface is pending. Setting this bit to a 1 allows interrupts to be visible to the interrupt controller while an interrupt acknowledge is pending.

Render Performance Status 1

RPSTAT1 - Render Performance Status 1	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	0A01Ch-0A01Fh

This register reflects real-time values and thus will not have a pre-determined default value out of reset.

DWord	Bit	Description
0	31:16	**Reserved** Access: RO
	15	**Last Requested Video Turbo Mode** Access: RO Last Requested Video Turbo Mode (CRTM): 0 = Most recent request was a normal request (from RPNSWREQ) 1 = Most recent request was a Video Turbo request (from RPVSWREQ)
	14:8	**Reserved** Access: RO
	7:0	**Reserved** Access: RO

Render Performance Status Register

RP_STATUS0 - Render Performance Status Register

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	0A01Ch

This register reflects real-time values and thus does not have a pre-determined default value out of reset.

DWord	Bit	Description
0	31:20	**Reserved** Access: RO
	19:18	**Current Actual Gear Ratio** Access: RO
	17:16	**Previous Actual Gear Ratio** Access: RO Previous Actual Gear Ratio (PAGR).
	15	**Last Requested Video Turbo Mode** Access: RO Last Requested Video Turbo Mode (CRTM): 0 = Most recent request was a normal request (from RPNSWREQ). 1 = Most recent request was a Video Turbo request (from RPVSWREQ).
	14	**Reserved** Access: RO
	13:7	**Current Actual GFX Freq** Access: RO This is the MLC ratio that the core is actually running.
	6:0	**Previous Actual GFX Freq** Access: RO This is the MLC ratio that the core was actually running before the current actual GFX frequency.

Render Power Clock State Register

R_PWR_CLK_STATE - Render Power Clock State Register

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000288 CHV, BSW
Access:	R/W
Size (in bits):	32
Address:	020C8h

This register contains the mode selection for configuring render engine to attain desired performance and power requirements for a given context. This register is render context save/restored. This register must be initialized correctly when the context is submitted for the first time. This register is context save/restored as part of Exec-List context image in both Exec-List and Ring-Buffer mode of scheduling. This register contents are valid only when "Enable" bit [31] of the register is set.

Programming Notes

This register must not be programmed directly through CPU MMIO cycle. Exec-List Scheduling Mode: Every context can have its own required render engine configuration by programming this register appropriately in the logical render context image in memory (LRCA) before submitting the context to the execlist submit port. This register must not be programmed using MI_LOAD_REGISTER_IMM command in ring buffer or in batch buffer, however programming "NON-SLM Indication" field through MI_LOAD_REGISTER_IMM is an exception defined below. If a need arises to change the render configuration for a context being executed in HW, Scheduler must preempt the context and update the desired render configuration in the logical render context image in memory and resubmit the context. Only "NON-SLM Indictaion" field in R_PWR_CLK_STATE register is allowed to be modified through MI_LOAD_REGISTER_IMM command in ring_buffer or privileged_batch_buffer. SW must modify only "NON-SLM Indication" field and must ensure to program other fields with the same value as in LRCA. SW must ensure to program PIPECONTROl flush command with CS Stall and HDC Flush prior to programming MI_LOAD_REGISTER_IMM command to modify "NON-SLM Indication" in R_PWR_CLK_STATE register. Example: //R_PWR_CLK_STATE register value in LRCA configured with two slices and NON-SLM indication reset: 0x80005_0000 //SW desires to set NON-SLM Indication filed in ring buffer MI_LOAD_REGISTER_IMM 0x20C8, 0x8005_0100 Ring Buffer Scheduling: This register must be programmed using MI_LOAD_REGISTER_IMM command in the ring buffer. When this register is being programmed to re-configure the number of slices, SW must context save the state before programming this register and restore the state after programming the register via dummy MI_SET_CONTEXT command, this will ensure the existing state is programmed to all the new slices that are powered up, in case of slice shutdown this is not required. EX: MI_SET_CONTEXT → CXTA MI_BATCH_BUFFER_START MI_BATCH_BUFFER_START MI_SET_CONTEXT → CXTB //Dummy Context to save existing render state to be restored latter. MI_LOAD_REGISTER_IMM : R_PWR_CLK_STATE (1 Slice to 3 Slices) // Slice configuration done. MI_SET_CONTEXT → CXTA // Context restore of valid state to all the slices powered up.

R_PWR_CLK_STATE - Render Power Clock State Register

DWord	Bit	Description
0	31	**Power Clock State Enable** Project: CHV, BSW Format: U1 Value / Name / Description: 0h – Power Clock State Disabled – No specific power state set, bits[30:0] are ignored. 1h – Power Clock State Enabled – Power Clock is set and bit[30:0] are valid and have the desired state.
	30:0	**Render Power Clock State** Project: CHV, BSW Format: Power Clock State Format CHV, BSW

Render Power Meter Counter

RPMCNT - Render Power Meter Counter	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	0A274h-0A277h

DWord	Bit	Description
0	31	**Render Power Meter Counter Overflow** Access: RO
	30:0	**Render PWRMTR Counter** Access: RO

Render Power Meter Counter No Clear

RPMCNTCLR - Render Power Meter Counter No Clear	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	0A28Ch-0A28Fh

Formerly cleared the count and the overflow bit, but now it is just a read-only value.

DWord	Bit	Description
0	31	**Render Power Meter Counter Overflow No Clear** Access: RO Formerly cleared the overflow bit, but now it is just a read-only value.
	30:0	**Render PWRMTR Counter No Clear** Access: RO Formerly cleared the count, but now is just a read-only value.

Render Promotion Timer - RC6

RC6TIMER - Render Promotion Timer - RC6

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	0A0B8h-0A0BBh

DWord	Bit	Description
0	31:24	**Reserved** Access: RO
	23:0	**RC6 Promote Time** Access: R/W Absolute time starting from post-hyst idle. 0 = 0 usec 1 = 1.28 usec 2 = 2.56 usec 3 = 3.84 usec FF FFFF = 21.474 sec pmcr_rc6_promotion_time[23:0]

RENDERRC0COUNTER

RENDERRC0COUNTER - RENDERRC0COUNTER	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	138118h

This register contains the total RC0 residency (Render powered on and clocks running) time that Render was in since boot.
SOXi Context Save/Restore : No
The 40-bit HW counter will wrap around. The only clear condition is CZ reset.
When 0x13_8104[15] is set to zero, bits 31:0 of the 40-bit counter are reported. When 0x13_8104[15] is set to one, bits 39:8 of the 40-bit counter are reported.
The units are CZ clock cycles.
It is up to SW to periodically read this register and do a difference from the last time it was read. The primary usage for this register is for power characterization.
0x13_8104[4] controls if this register should count or if it should be gated: 0= clear, 1=count

DWord	Bit	Description
0	31:0	**RENDERRC0TIME** Default Value: 00000000h Access: RO Render RC0 Residency Counter.

RENDERRC1COUNTER

RENDERRC1COUNTER - RENDERRC1COUNTER	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	138110h

This register contains the total RC1 residency (Render powered on and clock gated) time that Render was in since boot.
SOXi Context Save/Restore : No
The 40-bit HW counter will wrap around. The only clear condition is CZ reset.
When 0x13_8104[15] is set to zero, bits 31:0 of the 40-bit counter are reported. When 0x13_8104[15] is set to one, bits 39:8 of the 40-bit counter are reported.
The units are CZ clock cycles.
It is up to SW to periodically read this register and do a difference from the last time it was read. The primary usage for this register is for power characterization.
0x13_8104[2] controls if this register should count or if it should be gated: 0= clear, 1=count

DWord	Bit	Description
0	31:0	**RENDERRC1TIME** Default Value: 00000000h Access: RO Render RC1 Residency Counter.

RENDERRC6COUNTER

RENDERRC6COUNTER - RENDERRC6COUNTER

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	138108h

This register contains the total RC6 residency (Render power gated and clock gated) time that Render power well was in since boot. The counter will wrap around.
SOXi Context Save/Restore : No
The time is given in units of CZ clock cycles. The counter will reset on CZ reset going high.
This means that a warm reset will also reset this counter and it will also wrap around when it reaches max with no indication that an overflow occurred.
This register will freeze the count value (stop counting, but not reset) when pmu_gvd_renwakeack_nczfwoh=1.
This register will count whenever pmu_gvd_renwakeack_nczfwoh=0.
When 0x13_8104[15] is set to zero, bits 31:0 of the 40-bit counter are reported. When 0x13_8104[15] is set to one, bits 39:8 of the 40-bit counter are reported.
The units are CZ clock cycles.
It is up to SW to periodically read this register and do a difference from the last time it was read. The primary usage for this register is for power characterization.
0x13_8104[0] controls if this register should count or if it should be gated: 0= clear, 1=count.

DWord	Bit	Description
0	31:0	**RENDERRC6TIME** Default Value: 00000000h Access: RO Render Residency Counter.

Render TLB Control Register

RTCR - Render TLB Control Register

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04260h

DWord	Bit	Description
0	31:1	**Reserved** Default Value: 00000000000000000000000000000000b Access: RO
	0	**Invalidate TLBs on the corresponding Engine** Default Value: 0b Access: R/W SW writes 1 to invalidate the TLBs for the associated engine and HW clears the bit when invalidation is complete. To ensure proper invalidation of the TLBs, SW has to ensure the corresponding engine's HW pipeline is flushed and cleared from all its memory accesses. Otherwise HW cannot guarantee the proper invalidation for TLBs. This bit is self clear.

Render Watchdog Counter

PR_CTR - Render Watchdog Counter	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Address:	02190h
Address: Name: ShortName:	12190h-12193h Watchdog Counter PR_CTR_VCSUNIT0
Address: Name: ShortName:	1A190h-1A193h Watchdog Counter PR_CTR_VECSUNIT
Address: Name: ShortName:	1C190h-1C193h Watchdog Counter PR_CTR_VCSUNIT1
Address: Name: ShortName:	22190h-22193h Watchdog Counter PR_CTR_BCSUNIT

DWord	Bit	Description
0	31:0	**Counter Value** Format: U32 This register reflects the render watchdog counter value itself. It cannot be written to.

Render Watchdog Counter Threshold

PR_CTR_THRSH - Render Watchdog Counter Threshold

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00150000
Access:	R/W
Size (in bits):	32
Address:	0217Ch
Address:	1217Ch-1217Fh
Name:	Watchdog Counter Threshold
ShortName:	PR_CTR_THRSH_VCSUNIT0
Address:	1A17Ch-1A17Fh
Name:	Watchdog Counter Threshold
ShortName:	PR_CTR_THRSH_VECSUNIT
Address:	1C17Ch-1C17Fh
Name:	Watchdog Counter Threshold
ShortName:	PR_CTR_THRSH_VCSUNIT1
Address:	2217Ch-2217Fh
Name:	Watchdog Counter Threshold
ShortName:	PR_CTR_THRSH_BCSUNIT

DWord	Bit	Description
0	31:0	**Counter logic Threshold** Default Value: 00150000h Format: U32 This field specifies the threshold that the hardware checks against for the value of the render clock counter before generating an interrupt. The counter in hardware generates an interrupt when the threshold is reached, rolls over and starts counting again. The interrupt generated is the "Media Hang Notify" interrupt since this watchdog timer is intended primarily to remedy VLD hangs on the main pipeline.

Reported BitRateControl parameter Mask

MFX_VP8_CNTRL_MASK - Reported BitRateControl parameter Mask

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	12900h
Valid Projects:	CHV, BSW

This register stores the count of bytes of the bitstream output per frame

DWord	Bit	Description
0	31:6	**Reserved** Format: MBZ
	5	**Final Bitstream Buffer Overrun Mask** Format: U1 This is same bit reflected in MFX_VP8_ENC_CFG DW2 bit5. This denotes Final bitstream buffer overrun feature is enabled.
	4	**Intermediate Bitstream Buffer Overrun Mask** Format: U1 This is same bit reflected in MFX_VP8_ENC_CFG DW2 bit4. This denotes intermediate bitstream buffer overrun feature is enabled.
	3	**Intra MB Bit Count Conformance Mask** Format: U1 This is legacy support as AVC for Intra MB Bit Count conformance. This is same bit reflected in MFX_VP8_ENC_CFG DW2 bit3. This feature is not validated.
	2	**Inter MB Bit Count Conformance Mask** Format: U1 This is legacy support as AVC for Inter MB Bit Count conformance. This is same bit reflected in MFX_VP8_ENC_CFG DW2 bit2. This feature is not validated.

MFX_VP8_CNTRL_MASK - Reported BitRateControl parameter Mask

	1	**Frame Bit Rate Overflow Mask** Format: U1 This is same bit reflected in MFX_VP8_ENC_CFG DW2 bit0. It denotes if Frame Bit Rate Overflow is enabled for Bit Rate Control
	0	**Frame Bit Rate Underflow Mask** Format: U1 This is same bit reflected in MFX_VP8_ENC_CFG DW2 bit1. It denotes if Frame Bit Rate Underflow is enabled for Bit Rate Control

Reported BitRateControl parameter Status

MFX_VP8_CNTRL_STATUS - Reported BitRateControl parameter Status

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	12904h
Valid Projects:	CHV, BSW

This register stores the count of bytes of the bitstream output per frame

DWord	Bit	Description
0	31:8	**Reserved** Format: MBZ
	7	**QindexClampHigh Status** Format: U1 This denotes if Qindex is clamped by QindexClampHigh value programmed in MFX_VP8_PIC_STATE.DW7.
	6	**QindexClampLow Status** Format: U1 This denotes if Qindex is clamped by QindexClampLow value programmed in MFX_VP8_PIC_STATE.DW7.
	5	**Final Bitstream Buffer Overrun Status** Format: U1 This denotes if Final bitstream buffer overrun.
	4	**Intermediate Bitstream Buffer Overrun Status** Format: U1 This denotes if any of the Intermediate bitstream buffer overrun. (including FrameHeader, Partition1 to Partition8)
	3	**Intra MB Bit Count Conformance Status** Format: U1 This is legacy support as AVC for Intra MB Bit Count conformance. It denotes if Intra MB Bit Count meets conformance size. This feature is not validated.

MFX_VP8_CNTRL_STATUS - Reported BitRateControl parameter Status

	2	**Inter MB Bit Count Conformance Status** Format: U1 This is legacy support as AVC for Inter MB Bit Count conformance. It denotes if Inter MB Bit Count meets conformance size. This feature is not validated.
	1	**Frame Bit Rate Overflow Status** Format: U1 It denotes if Frame Bit Rate Overflow in current frame
	0	**Frame Bit Rate Underflow Status** Format: U1 It denotes if Frame Bit Rate Underflow in current frame

Reported Bitstream Output Bit Count for Syntax Elements Only Register

MFC_BITSTREAM_SE_BITCOUNT_FRAME - Reported Bitstream Output Bit Count for Syntax Elements Only Register

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	128A4h
Valid Projects:	CHV, BSW

This register stores the count of number of bits in the bitstream due to syntax elements only. This excludes header/ byte alignment /tail/EMU/CABAC-0word/padding bits but includes the stop-one-bit. This register is part of the context save and restore.

DWord	Bit	Description
0	31:0	**MFC Bitstream Syntax Element Only Bit Count** Total number of bits in the bitstream output due to syntax elements only. It includes the data bytes only. This count is updated for every time the internal bitstream counter is incremented and its reset at image start.

Reported Bitstream Output Byte Count per Frame Register

MFC_BITSTREAM_BYTECOUNT_FRAME - Reported Bitstream Output Byte Count per Frame Register	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	128A0h
Valid Projects:	CHV, BSW

This register stores the count of bytes of the bitstream output per frame

DWord	Bit	Description
0	31:0	**MFC Bitstream Byte Count per Frame** Total number of bytes in the bitstream output per frame from the encoder. This includes header/tail/byte alignment/data bytes/EMU (emulation) bytes/cabac-zero word insertion/padding insertion. This count is updated for every time the internal bitstream counter is incremented and its reset at image start.

Reported Bitstream Output CABAC Bin Count Register

MFC_AVC_CABAC_BIN_COUNT_FRAME - Reported Bitstream Output CABAC Bin Count Register	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	128A8h
Valid Projects:	CHV, BSW

This register stores the count of number of bins per frame.

DWord	Bit	Description
0	31:0	**MFC AVC Cabac Bin Count** Total number of BINs in the bitstream output per frame from the encoder. This count is updated for every time the bin counter is incremented and its reset at image start.

Reported Final Bitstream Byte Count

MFX_VP8_FRM_BYTE_CNT - Reported Final Bitstream Byte Count

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	12908h
Valid Projects:	CHV, BSW

This register stores the count of bytes of the bitstream output per frame

DWord	Bit	Description
0	31:0	**Final BitStream Byte Count** Format: U32 This register contains Final Bitstream byte count

Reported Frame Zero Padding Byte Count

MFX_VP8_FRM_ZERO_PAD - Reported Frame Zero Padding Byte Count

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	1290Ch
Valid Projects:	CHV, BSW

This register stores Frame Zero Padding Byte Count

DWord	Bit	Description
0	31:16	**Reserved** Format: MBZ
	15:0	**Frame Zero Padding Byte Count** Format: U16 This register contains Frame Zero Padding byte count This is legacy support. This feature is not validated.

Reported Timestamp Count

TIMESTAMP - Reported Timestamp Count	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000h, 00000000 CHV, BSW
Access:	RO. This register is not set by the context restore.
Size (in bits):	64
Address:	02358h
Address:	12358h-1235Fh
Name:	Reported Timestamp Count
ShortName:	TIMESTAMP_VCSUNIT0
Address:	1A358h-1A35Fh
Name:	Reported Timestamp Count
ShortName:	TIMESTAMP_VECSUNIT
Address:	1C358h-1C35Fh
Name:	Reported Timestamp Count
ShortName:	TIMESTAMP_VCSUNIT1
Address:	22358h-2235Fh
Name:	Reported Timestamp Count
ShortName:	TIMESTAMP_BCSUNIT

Description

This register provides an elapsed real-time value that can be used as a timestamp for GPU events over short periods of time. Note that the value of this register can be obtained in a 3D pipeline-synchronous fashion without a pipeline flush by using the PIPE_CONTROL command. See 3D Geometry Pipeline in the "3D and Media" volume. This register (effectively) counts at a constant frequency by adjusting the increment amount according to the actual reference clock frequency. SW therefore does not need to know the reference clock frequency. This register is not reset by a graphics reset. It will maintain its value unless a full chipset reset is performed.

Note: On Core platforms, the TIMESTAMP register is initialized with the value of the PCU ART and hence tracks bits 38:3 of the 100 MHz ART fairly closely. However, due to variability in the actual time it takes to download the ART value to GT, the value of the TIMESTAMP register will be lower than the value of the PCU ART by an amount dependent on the relative IA/CLR/GT frequencies at the time the timestamp was downloaded to GT (expected to range between 100 and 600 ns). When comparing the value sampled from this register by GT HW to values read from the PCU timer by other system agents, timing differences between GT HW reading the TIMESTAMP register and the involved non-GT agent(s) reading the PCU ART must also be comprehended.

TIMESTAMP - Reported Timestamp Count

DWord	Bit	Description
0	63:36	**Reserved** Project: CHV, BSW Format: MBZ
	35:0	**Timestamp Value** Project: CHV, BSW Format: U36 **Description** This register toggles based on time stamp granularity (base unit) defined in the “Time Stamp Bases” subsection in Power Management chapter.

Reset Flow Control Messages

RSTFCTLMSG - Reset Flow Control Messages

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	08108h

Soft-Reset and FLR Flow Control Message Registers

DWord	Bit	Description
0	31:16	**Message Mask** Access: RO Message Mask In order to write to bits 15:0, the corresponding message mask bits must be written. For example, for bit 14 to be set, bit 30 needs to be 1 : 40004000
	15:12	**Reserved**
	11	**MEDIA 1 Reset flow acknowledgement message** Access: R/W PM Acknowledgement Messages for Media 1 reset: '1' : PREP_RST_MEDIA1_ACK - Acknowledgement that graphics media1 (or 2nd vbox) is prepared for reset assertion. '0' : DONE_MEDIA1_RST_ACK - Acknowledgement that graphics media1 (or 2nd vbox) reset is de-asserted
	10	**WIDI Reset flow acknowledgement message** Access: R/W PM Acknowledgement Messages for WIDI reset: '1' : PREP_RST_WIDI_ACK - Acknowledgement that graphics widi is prepared for reset assertion. '0' : DONE_WIDI_RST_ACK - Acknowledgement that graphics widi reset is de-asserted
	9	**Reserved**
	8	**Vebox Reset flow Acknowledge Message** Access: R/W PM Acknowledgement Messages for Vebox reset: '1' : PREP_RST_VEBOX_ACK - Acknowledgement that graphics VE is prepared for reset assertion. '0' : DONE_VEBOX_RST_ACK - Acknowledgement that graphics VE reset is de-asserted

RSTFCTLMSG - Reset Flow Control Messages

	7	**Blitter Reset Flow Acknowledgement Messages** Access: R/W PM Acknowledgement Messages for Blitter reset: '1' : PREP_RST_BLIT_ACK - Acknowledgement that graphics blitter is prepared for reset assertion. '0' : DONE_BLIT_RST_ACK - Acknowledgement that graphics blitter reset is de-asserted
	6	**Media Reset Flow Acknowledgement Messages** Access: R/W PM Acknowledgement Messages for Media reset: '1' : PREP_RST_MEDIA_ACK - Acknowledgement that graphics media block is prepared for reset assertion. '0' : DONE_MEDIA_RST_ACK - Acknowledgement that the graphics media reset is de-asserted
	5	**Render Reset Flow Acknowledgement Messages** Access: R/W PM Acknowledgement Messages for Render reset: '1' : PREP_RST_RENDER_ACK - Acknowledgement that the graphics render block is prepared for reset assertion. '0' : DONE_RENDER_RST_ACK - Acknowledgement that the graphics render reset is de-asserted
	4	**GTI-Device Reset Flow Acknowledgement Messages** Access: R/W PM Acknowledgement Messages for GTI-Device reset: '1' : PREP_RST_GTIDEV_ACK - Acknowledgement that the GTI device is prepared for reset assertion. '0' : DONE_GTIDEV_RST_ACK - Acknowledgement that the GTI device reset is de-asserted
	3	**Reserved** Access: RO Reserved
	2	**FLR Done ack from Pmunit** Access: R/W Set FLR Done ack from Pmunit: 1: PM unit sets this bit to acknowledge the FLR done message has been forwarded to SA through GAM interface. 0: Default Value. If the bit was set by PM then Cpunit hardware clears it once FLR is completed.

RSTFCTLMSG - Reset Flow Control Messages

	1	**Global Resource Arbitration Acknowledgement Messages** Access: R/W Global Resource Arbitration Acknowledgement Message from PM: '1' : CP_ARB_REQ_ACK - Acknowledgement for CPunit's global resource arbitration request '0' : CP_ARB_RELEASE_ACK - Acknowledgement to CPunit's release of global resources
	0	**CP Busy / Idle Status Acknowledgement Messages** Access: R/W CP Busy / Idle Status Acknowledgement Message from PM: '0' : CP_NOT_BUSY_ACK - Acknowledgement that the CPunit is idle. '1' : CP_BUSY_ACK - Acknowledgement that the CPunit is busy.

RESET Messaging Register for Clocking Unit

MSG_RESET_GCP - RESET Messaging Register for Clocking Unit

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	16
Address:	08030h

Message registers have bit-wise masking applied for writes. The register consists of 16 bits of data in [15:0], and 16 bits of corresponding masks in [31:16]. In order to set bit0, for example, the data would be 0x0001_0001. In order to clear bit0, for example, the data would be 0x0001_0000. Note that mask bit is the data bit offset + 16. Message registers are protected from non-GT writes via the Message Channel.
Request to Prepare for Reset
1'b0 : Reset complete <default>
1'b1 : Prepare for reset

DWord	Bit	Description
0	15:8	**Reserved** Access: RO
	7	**Request to Prepare for FLR** Access: R/W [7] Prepare for devrst_b Domain Reset (FLR) Note: All resets except busrst_b will be asserted for an FLR

	5	**Request to Prepare for Wi-Di Reset** Access: R/W [5] Prepare for cwrst_b Domain Reset (winunit)
	4	**Reserved**
	3	**Request to Prepare for Blitter Reset** Access: R/W [3] Prepare for crblitrst_b Domain Reset (bcsunit)
	2	**Request to Prepare for VEBox Reset** Access: R/W [2] Prepare for cvrst_b Domain Reset (vecsunit)

MSG_RESET_GCP - RESET Messaging Register for Clocking Unit

	1	**Request to Prepare for Media0 Reset** Access: R/W [1] Prepare for cmrst_b Domain Reset (vcs0unit)
	0	**Request to Prepare for Render Reset** Access: R/W [0] Prepare for crrst_b Domain Reset (csunit)

Resource Streamer Context Offset

RS_CXT_OFFSET - Resource Streamer Context Offset

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00003B00
Access:	Read/32 bit Write Only
Size (in bits):	32
Address:	021B4h

DWord	Bit	Description
0	31:6	**RS Offset** Format: U26 This field indicates the offset (64bytes granular) in to the logical rendering context to which Resource Streamer context is save/restored when enabled. This field register must not be written directly (via MMIO) unless the Command Streamer is completely idle (i.e., the Ring Buffer is empty and the pipeline is idle) and RC6 is disabled. On way to program this register is via Load Register Immediate command in the ring buffer as part of initialization sequence. Value: ECh — **[Default]** — DefaultValueDesc
	5:0	**Reserved** Format: MBZ

Resource Streamer Preemption Status

RS_PREEMPT_STATUS - Resource Streamer Preemption Status

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	0215Ch

Preemption from First Level Batch Buffer: This register contains the offset in to the Batch Buffer on which Resource streamer got preempted. Note that it is offset from the Batch Start Address and not the graphics address corresponding to the preempted instruction on Batch Buffer. This register's contents will be looked at by Command Streamer on the next RS Start Trigger to provide the appropriate batch start address. Following preemption, context save happens on which this register is context saved, after context save the register gets auto reset by Command Streamer. This register gets context save/restored by Render Command Streamer as part of its render context. **Preemption from Second Level Batch Buffer:** This register contains the graphics address of the instruction in Second Level Batch Buffer on which Resource streamer got preempted. This register's contents will be looked at by Command Streamer on the next RS Start Trigger to provide the appropriate batch start address. Following preemption, context save happens on which this register is context saved, after context save the register gets auto reset by Command Streamer. This register gets context save/restored by Render Command Streamer as part of its render context.

Programming Notes

- This register is accessed by Render Command Streamer as part of render context save/restore; this register should be exercised by S/W only for resetting the register contents if required.
- Following preemption if there is no context save, SW should program this register with 0x0 so that it does not interfere with proceeding workloads.

DWord	Bit	Description
0	31:2	**Batch Buffer Offset** Format: Offset[31:2] This field specifies the DWord-aligned offset from the batch start address on which Resource Streamer got preempted.
	1	**RS_PREEMPT_STATUS** Format: MBZ This field when not set indicates RS got preempted on a natural sync point else it got preempted on a draw call.

RS_PREEMPT_STATUS - Resource Streamer Preemption Status

	0	**RS_PREEMPTED** Default Value: 0 Format: Enable If this bit is set indicates Resource Streamer got preempted. Other fields of this register are valid only when this bit is set.

Restored Timestamp LSDW

Revision Identification and Class code register. SOXi Context Save/Restore: Yes.

DWord	Bit	Description
0	31:24	**BASE_CLASS_CODE** Access: RO
	23:16	**SUB_CLASS_CODE** Access: RO When MGGC0[VAMEN] is 1, this value is 80h, indicating other multimedia device. When MGGC0[VAMEN] is 0 this value will be determined based on GGC register, GMS and IVD fields. When GGC[1] = 1 or GGC[7:3] = 5'b00000 this value is 80h, otherwise its 00h 00h: VGA compatible 80h: Non VGA (GMS = '00h' or IVD = '1b')
	15:8	**PROGRAMMING_INTERFACE** Default Value: 00h Access: RO
	7:0	**REVISION_ID** Default Value: 00000000b Access: R/W RID: The value in this field reflects the value of strapRID[7:0] (which is an input pin of GVD). For VV: The reset value will be the same as MID bits 23:16 (reference the MID register for MID register details). This register is read-able by any agent. Under SAI protection, the PMC and Punit (ie. 'Trusted_FW') can write this register and change the default value. No other agent has the ability to update this register. The PMC implementation will consider SRID and CRID before updating this register. Any PMC updates will be prior to Device 2 configuration. Note : The MID register will always reflect the stepping information. Even if PMC updates this register, the MID is available as a SRID reference.

RING_BUFFER_HEAD_PREEMPT_REG

RING_BUFFER_HEAD_PREEMPT_REG - RING_BUFFER_HEAD_PREEMPT_REG

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM

Address:	2214Ch-2214Fh
Name:	RING_BUFFER_HEAD_PREEMPT_REG
ShortName:	RING_BUFFER_HEAD_PREEMPT_REG_BCSUNIT

Description

This register contains the Head pointer offset in the ring when the last PREEMPTABLE command was executed and caused the head pointer to move due to the UHPTR register being valid. If the PREEMPTABLE command is executed as part of the batch buffer then the value of the register will be the offset in the ring of the command past the batch buffer start that contained the preemptable command.
This is a global register and context save/restored as part of power context image.

Preemptable Commands	Source
• MI_ARB_CHECK • 3D_PRIMITIVE • GPGPU_WALKER • MEDIA_STATE_FLUSH • PIPE_CONTROL (Only in GPGPU mode of pipeline selection)	RenderCS

RING_BUFFER_HEAD_PREEMPT_REG - RING_BUFFER_HEAD_PREEMPT_REG

- MI_ATOMIC (Post Sync Operation set in GPGPU mode of pipeline selection)
- MI_SEMAPHORE_SIGNAL (Post Sync Operation set in GPGPU mode of pipeline selection)

Programming Notes

Programming Restriction:
This register should NEVER be programmed by driver. This is for HW internal use only.

DWord	Bit	Description
0	31:21	**Last Wrap Count**
	20:2	**Preempted Head Offset** Format: U19 This field contains the Head pointer offset in the ring when the last MI_ARB_CHECK command was executed and caused the head pointer to move due to the UHPTR register being valid.
	1:0	**Ring/Batch Indicator** Format: Enabled

Value	Name	Description
0h	Ring	Preemptable command was executed in ring and caused head pointer to be updated.
1h	Batch	Preemptable command was executed in batch and caused head pointer to be updated.
2h	2nd level batch	Preemptable command was executed in second level batch and caused head pointer to be updated.

Ring Buffer Control

RING_BUFFER_CTL - Ring Buffer Control

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32

Address:	0203Ch-0203Fh
Name:	Ring Buffer Control
ShortName:	RING_BUFFER_CTL_RCSUNIT

Address:	1203Ch-1203Fh
Name:	Ring Buffer Control
ShortName:	RING_BUFFER_CTL_VCSUNIT0

Address:	1A03Ch-1A03Fh
Name:	Ring Buffer Control
ShortName:	RING_BUFFER_CTL_VECSUNIT

Address:	1C03Ch-1C03Fh
Name:	Ring Buffer Control
ShortName:	RING_BUFFER_CTL_VCSUNIT1

Address:	2203Ch-2203Fh
Name:	Ring Buffer Control
ShortName:	RING_BUFFER_CTL_BCSUNIT

Description	Source
These registers are used to define and operate the ring buffer mechanism which can be used to pass instructions to the command interface. The buffer itself is located in a physical memory region. The ring buffer is defined by a 4 Dword register set that includes starting address, length, head offset, tail offset, and control information. Refer to the Programming Interface chapter for a detailed description of the parameters specified in this ring buffer register set, restrictions on the placement of ring buffer memory, arbitration rules, and in how the ring buffer can be used to pass instructions.	RenderCS
Ring Buffer Head and Tail Offsets must be properly programmed before it is enabled. A Ring Buffer can be enabled when empty.	BlitterCS, VideoCS, VideoEnhancementCS

DWord	Bit	Description
0	31:21	**Reserved** Format: MBZ
	20:12	**Buffer Length**

RING_BUFFER_CTL - Ring Buffer Control

Format:	U9-1 in 4 KB pages - 1

This field is written by SW to specify the length of the ring buffer in 4 KB Pages.Range = [0 = 1 page = 4 KB, 1FFh = 512 pages = 2 MB]

Value	Name	Description
0		1 page = 4 KB
1FFh		512 pages = 2 MB

11 **RBWait**

Description	Source
Indicates that this ring has executed a WAIT_FOR_EVENT instruction and is currently waiting. Software can write a "1" to clear this bit, write of "0" has no effect. When the RB is waiting for an event and this bit is cleared, the wait will be terminated and the RB will be returned to arbitration.	
RenderCS: RBWait is not set on executing WAIIT_FOR_EVENT instruction waiting on Async Flip Pending.	RenderCS

10 **Semaphore Wait**

Description
Indicates that this ring has executed a MI_SEMAPHORE_WAIT instruction and is currently waiting for wait condition to satisfy.

9 **Reserved**

8 **Reserved**

Project:	CHV, BSW
Format:	MBZ

7:3 **Reserved**

Format:	MBZ

2:1 **Automatic Report Head Pointer**

Project:	CHV, BSW
Source:	PRM

Description
This field is written by software to control the automatic reporting (write) of this ring buffer's Head Pointer register (register DWord 1) to the corresponding location within the Hardware Status Page. Automatic reporting can either be disabled or enabled at 4KB, 64KB or 128KB boundaries within the ring buffer.
When Execlist Enable bit is set the head pointer will be reported to the head pointer location in the Per-Process Hardware Status Page. MI_AUTOREPORT_4KB option is not supported on A stepping.

RING_BUFFER_CTL - Ring Buffer Control

Value	Name	Description
0	MI_AUTOREPORT_OFF	Automatic reporting disabled
1	MI_AUTOREPORT_64KB	Report every 16 pages (64KB)
2	MI_AUTOREPORT_4KB	Report every page (4KB) This mode must not be enabled in Ring Buffer mode of scheduling to minimize the auto reports.
2	MI_AUTOREPORT_4KB	Report every page (4KB) This mode must not be enabled in Ring Buffer mode of scheduling to minimize the auto reports.
3	MI_AUTOREPORT_128KB	Report every 32 pages (128KB)

0 **Ring Buffer Enable**

Format:	Enable

This field is used to enable or disable this ring buffer. It can be enabled or disabled regardless of whether there are valid instructions pending. If disabled and the ring head equals ring tail, all state currently loaded in hardware is considered invalid.

Programming Notes	Source
Ring Buffer Mode of Scheduling: SW must follow the below programming notes during SW initialization phase or while enabling render engine's ring buffer for the first time, this would be coming out of boot, standby, hibernate or reset. SW must set the Force Wakeup bit to prevent GT from entering C6. • SW must dispatch workload (dummy context) to initialize render engine with default state such that any context switches that occur subsequently (Power Save) will save and restore coherent device state. Indirect pointers used in 3D states must point to valid graphics surface existing in memory. PP_DCLV followed by PP_DIR_BASE register should be programmed as part of initialization workload if PPGTT is enabled in GFX_MODE register. • SW must ensure all the register (MMIO) initialization/programming through CPU happens in this block or latter, this ensures the MMIO state is save/restored on subsequent context switches (Power Sequences). • Once the render engine is programmed with valid state and the configuration, Force Wakeup bit should be reset to enable C6 entry.	RenderCS
Render CS Only: Ring Buffer Mode of Scheduling: SW must follow the below programming notes before disabling ring buffer to ensure HW is not in middle of the IDLE flows. • SW must set the Force Wakeup bit to prevent GT from entering C6. • Disable IDLE messaging in CS (Write 0x2050[31:0] = 0x00010001) • Poll/Wait for register bits of 0x22AC[6:0] turn to 0x30 value. • Disable Ring Buffer • Enable IDLE messaging in CS (Write 0x2050[31:0] = 0x00010000) • Force Wakeup bit should be reset to enable C6 entry.	RenderCS

Ring Buffer Current Context ID Register

BCS_RCCID - Ring Buffer Current Context ID Register

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	BlitterCS
Default Value:	0x00000000, 0x00000000
Access:	R/W
Size (in bits):	64
Address:	22190h-22197h

This register contains the current ring context ID associated with the ring buffer.

Programming Notes

The current context registers must not be written directly (via MMIO). The RCCID register should only be updated indirectly from RNCID.

DWord	Bit	Description
0	63:0	**Unnamed** See Context Descriptor for BCS.

Ring Buffer Head

RING_BUFFER_HEAD - Ring Buffer Head	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	02034h-02037h
Name:	Ring Buffer Head
ShortName:	RING_BUFFER_HEAD_RCSUNIT
Address:	12034h-12037h
Name:	Ring Buffer Head
ShortName:	RING_BUFFER_HEAD_VCSUNIT0
Address:	1A034h-1A037h

ShortName:	RING_BUFFER_HEAD_VCSUNIT1
Address:	22034h-22037h
Name:	Ring Buffer Head
ShortName:	RING_BUFFER_HEAD_BCSUNIT

Description

This register is used to define and operate the ring buffer mechanism which can be used to pass instructions to the command interface. The buffer itself is located in a physical memory region. The ring buffer is defined by a 4 Dword register set that includes starting address, length, head offset, tail offset, and control information. Refer to the Programming Interface chapter for a detailed description of the parameters specified in this ring buffer register set, restrictions on the placement of ring buffer memory, arbitration rules, and in how the ring buffer can be used to pass instructions. **Ring Buffer Head Offsets must be properly programmed before ring is enabled. A Ring Buffer can be enabled when empty.**

DWord	Bit	Description
0	31:21	**Wrap Count** Format: U11 count of ring buffer wraps This field is incremented by 1 whenever the **Head Offset** wraps from the end of the buffer back to the start (i.e., whenever it wraps back to 0). Appending this field to the **Head Offset** field effectively creates a virtual 4GB Head "Pointer" which can be used as a tag associated with instructions placed in a ring buffer. The Wrap Count itself will wrap to 0 upon overflow.

RING_BUFFER_HEAD - Ring Buffer Head

	20:2	**Head Offset** Format: GraphicsAddress[20:2] DWord Offset This field indicates the offset of the *next* instruction DWord to be parsed. Software will initialize this field to select the first DWord to be parsed once the RB is enabled. (Writing the Head Offset while the RB is enabled is UNDEFINED). Subsequently, the device will increment this offset as it executes instructions - until it reaches the QWord specified by the **Tail Offset**. At this point the ring buffer is considered "empty". **Programming Notes** A RB can be enabled empty or containing some number of valid instructions.
	1	**Reserved** Format: MBZ
	0	**Reserved** Project: CHV, BSW Format: MBZ

Name:	Ring Buffer Tail
ShortName:	RING_BUFFER_TAIL_VCSUNIT1
Address:	22030h-22033h
Name:	Ring Buffer Tail
ShortName:	RING_BUFFER_TAIL_BCSUNIT

Description

These registers are used to define and operate the "ring buffer" mechanism which can be used to pass instructions to the command interface. The buffer itself is located in a linear memory region. The ring buffer is defined by a 4 Dword register set that includes starting address, length, head offset, tail offset, and control information. Refer to the Programming Interface chapter for a detailed description of the parameters specified in this ring buffer register set, restrictions on the placement of ring buffer memory, arbitration rules, and in how the ring buffer can be used to pass instructions. Ring Buffer Tail Offsets must be properly programmed before ring is enabled. A Ring Buffer can be enabled when empty.

DWord	Bit	Description
0	31:21	**Reserved** Format: MBZ

RING_BUFFER_TAIL - Ring Buffer Tail

	20:3	**Tail Offset** Format: GraphicsAddress[20:3] This field is written by software to specify where the valid instructions placed in the ring buffer end. The value written points to the QWord past the last valid QWord of instructions. In other words, it can be defined as the next QWord that software will write instructions into. Software must write subsequent instructions to QWords following the Tail Offset, possibly wrapping around to the top of the buffer (i.e., software can't skip around within the buffer). Note that all DWords prior to the location indicated by the **Tail Offset** must contain valid instruction data - which may require instruction padding by software. See **Head Offset** for more information. **Programming Notes** [Ring Buffer Mode Of scheduling only][Video CS, Video Enhancement CS, Blitter CS]: HW loses Page Directory (PPGTT) information on becoming IDLE. SW must always program the PD information through MI_LOAD_REGISTER_IMM command in the ring buffer prior to programming workload begins on every ring dispatch. This will ensure Page Directory information is not lost due to IDLE flows.
	2:0	**Reserved** Format: MBZ

Root Table Address Pointer Value First 31_0

RS_PREEMPT_STATUS_UDW

RS_PREEMPT_STATUS_UDW - RS_PREEMPT_STATUS_UDW

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	02174h

Preemption from First Level Batch Buffer: This register contains the offset in to the Batch Buffer on which Resource streamer got preempted. Note that it is offset from the Batch Start Address and not the graphics address corresponding to the preempted instruction on Batch Buffer. This register's contents will be looked at by Command Streamer on the next RS Start Trigger to provide the appropriate batch start address. Following preemption, context save happens on which this register is context saved, after context save the register gets auto reset by Command Streamer. This register gets context save/restored by Render Command Streamer as part of its render context. **Preemption from Second Level Batch Buffer:** This register contains the graphics address of the instruction in Second Level Batch Buffer on which Resource streamer got preempted. This register's contents will be looked at by Command Streamer on the next RS Start Trigger to provide the appropriate batch start address. Following preemption, context save happens on which this register is context saved, after context save the register gets auto reset by Command Streamer. This register gets context save/restored by Render Command Streamer as part of its render context.

Programming Notes

- This register is accessed by Render Command Streamer as part of render context save/restore; this register should be exercised by S/W only for resetting the register contents if required.
- Following preemption if there is no context save, SW should program this register with 0x0 so that it does not interfere with proceeding workloads.

DWord	Bit	Description
0	31:16	**Reserved** Format: MBZ
	15:0	**Batch Buffer Offset Upper DWORD** Format: GraphicsAddress[47:32] This field specifies the 4GB aligned base address of gfx 4GB virtual address space within the host's 64-bit virtual address space of the last preempted second level batch buffer in resource streamer.

RS Preemption Hint

RS_PRE_HINT - RS Preemption Hint

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	024C0h

This register contains the Dword aligned Graphics address in to the Batch Buffer corresponding to either 3D_PRIMITIVE or RCS-RS sync command called Preemption Hint Address. When Preemption Hint Address is enabled, RS will honor preemption request from RCS only on parsing 3D_PRIMITIVE/RCS-RS sync command at Preemption Hint Address.

Programming Notes

Programming Restriction:
This register should NEVER be programmed in functional mode, this should be used only in validation mode to achieve deterministic behavior of preempting Resource Streamer in command stream. Programmer has to ensure that RS Preemption Hint register gets programmed well before RS gets preempted by RCS. Note that this register should be programmed with caution as it can lead to indefinite stalls in RS.

a. RS will preempt on receiving preemption request from RCS only on reaching the instruction in the batch buffer corresponding to the address mentioned in RS_PREEMPT_HINT. RS could hit an RCS-RS sync command before reaching the address mentioned in the RS_PREEMPT_HINT, in this case RS should preempt on the sync command.

b. RS could hit the address mentioned in 3D_PREEMPT_HINT before receiving preempt request from RCS. In this case RS will stall at this command until it receives preemption request from RCS and then preempts.

DWord	Bit	Description
0	31:2	**Preemption Hint Address** Format: U30 This field contains the Dword aligned Graphics Address in to the batch buffer as Preemption Hint.
	1	**Reserved**
	0	**Preemption Hint** Format: Enabled 0h – Disabled – Preemption hint is disabled for Resource Streamer. 1h – Enabled – Preemption hint is enabled for Resource streamer.

RS Preemption Hint UDW

RS_PREEMPTION_HINT_UDW - RS Preemption Hint UDW

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	024C4h

This register contains the 4GB aligned base address of gfx 4GB virtual address space within the host's 64-bit virtual address space of the Batch Buffer corresponding to either 3D_PRIMITIVE or RCS-RS sync command called Preemption Hint Address. When Preemption Hint Address is enabled, RS will honor preemption request from RCS only on parsing 3D_PRIMITIVE/RCS-RS sync command at Preemption Hint Address.

Restriction

This register should NEVER be programmed in functional mode, this should be used only in validation mode to achieve deterministic behavior of preempting Resource Streamer in command stream. See RS_PRE_HINT definition for further restrictions.

DWord	Bit	Description
0	31:16	**Reserved** Format: MBZ
	15:0	**Preemption Hint Address Upper DWORD** Format: GraphicsAddress[47:32] This field contains the 4GB aligned base address of gfx 4GB virtual address space within the host's 64-bit virtual address space of the batch buffer as Preemption Hint.

Sampler control register

SAMPLER_CTL - Sampler control register

Address:	0B434h

DWord	Bit	Description
0	31	**Reserved**
	30:29	**Counter Enabling Selection** Default Value: 11b Access: R/W LPFC provides rudimentary compression by allowing software to select from several predefined levels of event reporting. Based on the value of this bitfield, only a certain number of the programmed events in the "Event Selection and Base Counters" registers (CNT0CL, CNT1CL, ..., CNT7CL) will be tracked and reported: Value / Selected Counters 00 - Counter 0 01 - Counters 0 & 1 10 - Counters 0, 1, 2, & 3 11 - Counters 0 - 7 Signal - lpconf_lpfc_cnt_enabled [1:0].
	28:24	**Reserved**
	23:0	**Save Timer Intervel** Default Value: 000000000001000000000000b Access: R/W Save Timer Interval (SVTMRINT). Save Timer Interval: This is the interval for sampling the performance counters and writing to memory. Each time it expires, the counters are sampled and packetized to be sent to DMA controller. The minimum granularity of sampling period if 256clocks. The value in this register is used as 256 x value to find the sampling window. For a 1Ghz core clock it provides up to 4ns of sampling period while matching the maximum capability of the event counters. 1h - 256clks. 2h - 512clks. ... 8h - 2048clks. Signal - lpconf_lpfc_savetimer_int [23:0].

SB_ADDRESS

SB_ADDRESS - SB_ADDRESS

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	182108h

The Sideband Address Register is used by the sideband transaction (triggered by Sideband Packet Register) for holding the address (of the internal register, within the destination unit).

IOSF SB access prevention: An IOSF SB write access targeting this register will complete with no affect.
An IOSF SB read access targeting this register will abort (with 1's being returned on IOSF SB).

DWord	Bit	Description
0	31:0	**SB_Addr** Default Value: 00000000h Access: R/W Address, written by IOSF primary, for triggered IOSF SB initiated access. 0x18_2100 (SB_Busy) bit 0 =1 then an IOSF primary write will NOT be captured. 0x18_2100 (SB_Busy) bit 0 = 0 then an IOSF primary write will be captured. Dword aligned addresses must be used.

SB_DATA

SB_DATA - SB_DATA

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	182104h

The Sideband Data Register is used by the sideband register access mechanism (triggered by Sideband Packet Register) for holding write-data in write-transactions or read-data for read-transactions as explained below.

IOSF SB access prevention :An IOSF SB write access targeting this register will complete with no affect.
An IOSF SB read access targeting this register will abort (with 1's being returned on IOSF SB).
Requirement : IOSF primary write to this register should not occur when a pending IOSF SB return is pending.

DWord	Bit	Description
0	31:0	**SB Data** Default Value: 00000000h Access: R/W Triggered IOSF SB write, this is the Data written in the IOSF SB initiated access. Triggered IOSF SB read, this is the Data read return from the IOSF SB initiated read access. 0x18_2100 (SB_Busy) bit 0 = 1 then an IOSF primary write will NOT be captured. 0x18_2100 (SB_Busy) bit 0 = 0 then an IOSF primary write will be captured.

SB_REQ_TRIGGER

SB_REQ_TRIGGER - SB_REQ_TRIGGER	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	182100h

When the Sideband Packet Register is written, the Gunit creates a transaction towards the destination agent on the IOSF sideband channel.
The fields sent with the write operation as transaction parameters:

- The Sideband Rid field (bits 31:24) is used as the transaction Rid.
- The Sideband Opcode field (bits 23:15) is used as the transaction opcode.
- The Sideband Port field (bits 15:8) is used as the transaction destination port.
- The source port is hard-coded to 6h (Gunit port).
- The Sideband Byte Enable Field (bits 7:4) is used as the transaction Byte Enable.

If the opcode results in a data write semantic transaction, the write-data will be taken from the Sideband Data Register. If the opcode results in a data read semantic transaction, the read-data will be placed in the Sideband Data Register and may later be read by software. When Sideband Busy is set, Sideband Packet Register, Sideband Data Register and Sideband Address Register fields cannot be written. If the opcode results in a data read semantic transaction, data will be ready at Sideband Data register only when the Sideband Busy is cleared. Fuse block access prevention:To prevent an attacker from using this mechanism to read the fuse block, writing the Fuse Block PortID to the Sideband Port will prevent the SB_busy bit from being set. This effectively 'aborts' the access. The triggered write is effectively dropped. The triggered read would supply whatever happened to be in the IOSF Sideband Doorbell Data register. IOSF SB access prevention :No usage models require IOSF SB accesses to the doorbell registers. No IOSF SB sources should be using IOSF SB accesses to the doorbell register to trigger a doorbell generated IOSF SB message. Software and firmware are PROHIBITED from using IOSF SB accesses to target and trigger accesses from this registers.

Usage of the doorbell mechanism :
From IOSF primary, to initiate a write on IOSF Sideband :
a. Write Data (0x18_2104)
b. Write Address (0x18_2108)
c. Write Packet and Trigger (0x18_2100)
d. Read poll 0x18_2100. When bit 0 = '0', then the write has completed on IOSF Sideband.
From IOSF primary, to initiate a read on IOSF Sideband :
a. Write Address (0x18_2108)
b. Write Packet and Trigger (0x18_2100)
c. Read poll 0x18_2100. When bit 0 = '0', then the read has completed on IOSF Sideband and data is available.
d. Read IOSF SB returned Data (0x18_2104)
If software attempts a read to a register and the result is a UR (Unsupported Request), the busy bit will be cleared with no update of the doorbell data register.

SB_REQ_TRIGGER - SB_REQ_TRIGGER

DWord	Bit	Description
0	31:24	**SB_DevFn** Default Value: 00h Access: R/W Device and Function number to be used for the IOSF SB access. Per the IOSF Specification, this 8-bit field ('fid' in the IOSF Spec) is a unique identifier of a target in a hierarchy of PCI buses (indicates Device Number [31:27] / Function Number [26:24] or Function Number [31:24]). The target is free to utilize this in an agent-specific manner.
	23:16	**SB_Opcode** Default Value: 00h Access: R/W Opcode to be used for the IOSF SB access.
	15:8	**SB_Port** Default Value: 00h Access: R/W Port to be used for the IOSF SB access.
	7:4	**SB_ByteEnables** Default Value: 0h Access: R/W Byte enables to be used for the iOSF SB access.
	3:1	**SB_BAR** Default Value: 000b Access: R/W BAR value
	0	**SB_Busy** Default Value: 0b Access: RO A write to this register will set this bit = '1' and triggers a IOSF SB request. When this bit is '1', the following registers are not IOSF primary write-able (0x18_2100, 0x18_2104, 0x18_2108)The completion of the IOSF SB access will clear this bit. 0 - 0x18_2100, 0x18_2104 and 0x18_2108 are writeable via IOSF Sideband. 1 - An IOSF SB access is in-progress. 0x18_2100, 0x18_2104 and 0x18_2108 are NOT writeable via IOSF Sideband.

Second Level Batch Buffer Head Pointer Preemption Register

SBB_PREEMPT_ADDR - Second Level Batch Buffer Head Pointer Preemption Register

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	0213Ch-0213Fh
Name:	Second Level Batch Buffer Head Pointer Preemption Register
ShortName:	SBB_PREEMPT_ADDR_RCSUNIT
Address:	1213Ch-1213Fh
Name:	Second Level Batch Buffer Head Pointer Preemption Register
ShortName:	SBB_PREEMPT_ADDR_VCSUNIT0
Address:	1A13Ch-1A13Fh
Name:	Second Level Batch Buffer Head Pointer Preemption Register
ShortName:	SBB_PREEMPT_ADDR_VECSUNIT
Address:	1C13Ch-1C13Fh
Name:	Second Level Batch Buffer Head Pointer Preemption Register
ShortName:	SBB_PREEMPT_ADDR_VCSUNIT1
Address:	2213Ch-2213Fh
Name:	Second Level Batch Buffer Head Pointer Preemption Register
ShortName:	SBB_PREEMPT_ADDR_BCSUNIT

Description

This register gets updated with the DWord-aligned graphics memory address of the PREEMPTABLE command in the second level batch buffer on which preemption has occurred.

This register value should be looked at only when the preemption has occurred in the second level batch buffer. This is indicated by "Ring/Batch Indicator" in "RING_BUFFER_HEAD_PREEMPT_REG". This register value retains its previous value and doesn't change when the preemption occurs on a preemptable command in ring buffer or in batch buffer.

Preemption is triggered by valid UHPTR in ring buffer mode of scheduling and by a pending execlist in Exec-List mode of scheduling. This is a global register and context save/restored as part of power context image.

SBB_PREEMPT_ADDR - Second Level Batch Buffer Head Pointer Preemption Register

Preemptable Commands	Source
MI_ARB_CHECK 3D_PRIMITIVE GPGPU_WALKER MEDIA_STATE_FLUSH PIPE_CONTROL (Only in GPGPU mode of pipeline selection) MI_ATOMIC (Post Sync Operation set in GPGPU mode of pipeline selection) MI_SEMAPHORE_SIGNAL (Post Sync Operation set in GPGPU mode of pipeline selection)	RenderCS

Programming Notes
Programming Restriction: This register should NEVER be programmed by driver, this is for HW internal use only.

DWord	Bit	Description
0	31:2	**Second Level Batch Buffer Head Pointer** Format: GraphicsAddress[31:2] This field specifies the DWord-aligned Graphics Memory Address of the PREEMPTABLE command in a batch buffer where the Preemption has occurred.
	1:0	**Reserved** Format: MBZ

Second Level Batch Buffer Head Pointer Register

SBB_ADDR - Second Level Batch Buffer Head Pointer Register

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	CommandStreamer
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Address:	02114h-02117h
Name:	Second Level Batch Buffer Head Pointer Register
ShortName:	SBB_ADDR_RCSUNIT
Address:	12114h-12117h
Name:	Second Level Batch Buffer Head Pointer Register
ShortName:	SBB_ADDR_VCSUNIT0
Address:	1A114h-1A117h
Name:	Second Level Batch Buffer Head Pointer Register
ShortName:	SBB_ADDR_VECSUNIT
Address:	1C114h-1C117h
Name:	Second Level Batch Buffer Head Pointer Register
ShortName:	SBB_ADDR_VCSUNIT1
Address:	22114h-22117h
Name:	Second Level Batch Buffer Head Pointer Register
ShortName:	SBB_ADDR_BCSUNIT

This register contains the current DWord Graphics Memory Address of the last-initiated batch buffer.

Programming Notes

This register should NEVER be programmed by driver, this is for HW internal use only. This register should not be written by software. These fields should only get written by a context restore. Software should always set these fields via the MI_BATCH_BUFFER_START command when initiating a batch buffer. This register is saved and restored with context.

DWord	Bit	Description
0	31:2	**Second Level Batch Buffer Head Pointer** Format: GraphicsAddress[31:2] This field specifies the DWord-aligned Graphics Memory Address where the last initiated Second Level Batch Buffer is currently fetching commands. This field is meaningful only when Valid field is set to "1".
	1	**Reserved** Format: MBZ

SBB_ADDR - Second Level Batch Buffer Head Pointer Register

	0	**Valid** Format: U1 **Value** / **Name** / **Description** / **Project** 0h / Invalid **[Default]** / Second Level Batch buffer Invalid / CHV, BSW 1h / Valid / Second Batch buffer Valid. / CHV, BSW

Second Level Batch Buffer State Register

SBB_STATE - Second Level Batch Buffer State Register

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000 CHV, BSW
Access:	R/W
Size (in bits):	32
Address:	02118h
Address:	12118h-1211Bh
Name:	Second Level Batch Buffer State Register
ShortName:	SBB_STATE_VCSUNIT0
Address:	1A118h-1A11Bh
Name:	Second Level Batch Buffer State Register
ShortName:	SBB_STATE_VECSUNIT
Address:	1C118h-1C11Bh
Name:	Second Level Batch Buffer State Register
ShortName:	SBB_STATE_VCSUNIT1
Address:	22118h-2211Bh
Name:	Second Level Batch Buffer State Register
ShortName:	SBB_STATE_BCSUNIT

This register contains the attributes of the second level batch buffer initiated from the batch Buffer.

This register should not be written by software. These fields should only get written by a context restore. Software should always set these fields via the MI_BATCH_BUFFER_START command when initiating a batch buffer. This register is saved and restored with context.

DWord	Bit	Description
0	31:9	**Reserved** Format: MBZ
	8	**Reserved** Project: CHV, BSW Format: MBZ
	7	**Resource Streamer Enable** Format: U1 When this bit is set, the Resource Streamer will execute the batch buffer. When this bit is clear the Resource Streamer will not execute the batch buffer.

SBB_STATE - Second Level Batch Buffer State Register

	6	**Reserved** Project: CHV, BSW Format: MBZ
	5	**Address Space Indicator** Project: CHV, BSW Note: This field reflects the effective address space indicator security level and may not be the same as the Address Space Indicator written using MI_BATCH_BUFFER_START.

Value	Name	Description
0h	GGTT **[Default]**	This second level batch buffer is located in GGTT memory and is privileged
1h	PPGTT	This second level batch buffer is located in PPGTT memory and is non-privileged.

	4	**Reserved** Project: CHV, BSW Format: MBZ
	3:0	**Reserved** Format: MBZ

Second Level Batch Buffer Upper Head Pointer Preemption Register

SBB_PREEMPT_ADDR_UDW

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32

Address:	02138h-0213Bh
Name:	Second Level Batch Buffer Upper Head Pointer Preemption Register
ShortName:	SBB_PREEMPT_ADDR_UDW_RCSUNIT

Address:	12138h-1213Bh
Name:	Second Level Batch Buffer Upper Head Pointer Preemption Register
ShortName:	SBB_PREEMPT_ADDR_UDW_VCSUNIT0

Address:	1A138h-1A13Bh
Name:	Second Level Batch Buffer Upper Head Pointer Preemption Register
ShortName:	SBB_PREEMPT_ADDR_UDW_VECSUNIT

Address:	1C138h-1C13Bh
Name:	Second Level Batch Buffer Upper Head Pointer Preemption Register
ShortName:	SBB_PREEMPT_ADDR_UDW_VCSUNIT1

Address:	22138h-2213Bh
Name:	Second Level Batch Buffer Upper Head Pointer Preemption Register
ShortName:	SBB_PREEMPT_ADDR_UDW_BCSUNIT

This register contains the 4GB aligned base address of gfx 4GB virtual address space within the host's 64-bit virtual address space of the last preempted second level batch buffer. This register follows the same rules as the SBB_PREEMPT_ADDR register.

Programming Notes

Programming Restriction: This register should NEVER be programmed by driver, this is for HW internal use only.

DWord	Bit	Description
0	31:16	**Reserved**
	15:0	**Second Level Batch Buffer Head Pointer Upper DWORD** Format: GraphicsAddress[47:32] This field specifies the 4GB aligned base address of gfx 4GB virtual address space of the last preempted second level batch buffer.

Second Level Batch Buffer Upper Head Pointer Register

SBB_ADDR_UDW - Second Level Batch Buffer Upper Head Pointer Register

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Access:	RO
Size (in bits):	32

Address:	0211Ch-0211Fh
Name:	Second Level Batch Buffer Upper Head Pointer Register
ShortName:	SBB_ADDR_UDW_RCSUNIT

Address:	1211Ch-1211Fh
Name:	Second Level Batch Buffer Upper Head Pointer Register
ShortName:	SBB_ADDR_UDW_VCSUNIT0

Address:	1A11Ch-1A11Fh
Name:	Second Level Batch Buffer Upper Head Pointer Register
ShortName:	SBB_ADDR_UDW_VECSUNIT

Address:	1C11Ch-1C11Fh
Name:	Second Level Batch Buffer Upper Head Pointer Register
ShortName:	SBB_ADDR_UDW_VCSUNIT1

Address:	2211Ch-2211Fh
Name:	Second Level Batch Buffer Upper Head Pointer Register
ShortName:	SBB_ADDR_UDW_BCSUNIT

This register contains the current Upper DWord of Graphics Memory Address of the last-initiated batch buffer.
Programming Restriction:
This register should NEVER be programmed by driver. This is for HW internal use only.

DWord	Bit	Description
0	31:16	**Reserved** Format: MBZ
	15:0	**Batch Buffer Head Pointer Upper DWORD** Format: GraphicsAddress[47:32] This field specifies the 4GB aligned base address of gfx 4GB virtual address space within the host's 64-bit virtual address space where the last initiated Batch Buffer is currently fetching commands. If no batch buffer is currently active, the Valid bit in BB_ADDR will be 0 and this field is meaningless.

Semaphore Polling Interval on Wait

SEMA_WAIT_POLL - Semaphore Polling Interval on Wait	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	0224Ch
Address:	1224Ch-1224Fh
Name:	Semaphore Polling Interval on Wait
ShortName:	SEMA_WAIT_POLL_VCSUNIT0
Address:	1A24Ch-1A24Fh
Name:	Semaphore Polling Interval on Wait
ShortName:	SEMA_WAIT_POLL_VECSUNIT
Address:	1C24Ch-1C24Fh
Name:	Semaphore Polling Interval on Wait
ShortName:	SEMA_WAIT_POLL_VCSUNIT1
Address:	2224Ch-2224Fh
Name:	Semaphore Polling Interval on Wait
ShortName:	SEMA_WAIT_POLL_BCSUNIT

The SEMA_WAIT_POLL register contains Poll Interval field which specifies the minimum number of microseconds allowed for command streamer to wait before re-fetching the data from the address mentioned in the MI_SEMAPHORE_WAIT command on WAIT Mode set to POLL until the condition is satisfied while the context is not switched out.
When a value of 0 is written the poll interval will be equal to the memory latency of the read completion.

DWord	Bit	Description
0	31:21	**Reserved** Format: MBZ
	20:0	**Poll Interval** Minimum number of micro-seconds allowed

SSID_SID

SSID_SID - SSID_SID

Register Space:	PCI: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	0002Ch

This register is used to uniquely identify the subsystem where the PCI device resides.

DWord	Bit	Description
0	31:16	**SUBID** Default Value: 0000h Access: R/W Once This value is used to identify the vendor of the subsystem.This register is programmed by BIOS during boot-up.Once written, this register becomes Read_Only. This register is cleared by a Reset.
	15:0	**SUBVID** Default Value: 0000h Access: R/W Once This value is used to identify the vendor of the subsystem.This register is programmed by BIOS during boot-up.Once written, this register becomes Read_Only. This register is cleared by a Reset.

Staggered EU/SAMPLER PAUSE on Frequency Change

GFXPAUSE - Staggered EU/SAMPLER PAUSE on Frequency Change

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	0A000h-0A003h

DWord	Bit	Description
0	31:19	**Reserved** Access: RO Reserved
	18	**Pause Lock** Access: R/W Lock 0 = Bits of EUPAUSE are R/W 1 = All bits of EUPAUSE are RO (including this lock bit)
	17	**EU Pause Enable** Access: R/W Lock 0 = Disabled; EUs will not be paused during frequency changes 1 = Enabled; EUs will be paused before graphics clocks are gated, and unpaused (staggered per EU) when the clocks are ungated
	16	**Sampler Stall Enable** Access: R/W Lock 0 = Disabled; Sampler will not be paused during frequency changes 1 = Enabled; Sampler will be paused before graphics clocks are gated, and unpaused when the clocks are ungated
	15:0	**Pause Count** Access: R/W Lock This is the minimum time the PMunit waits after asserting the EU or Sampler pause (if those are enabled) before allowing the core clocks to be gated. 0000 = Disabled 0001 - Count 1 CSclk ... FFFF = Count 65535 CSclks

Storage 1

STORAGE1 - Storage 1

Stream Output Num Primitives Written Counter

SO_NUM_PRIMS_WRITTEN[0:3] - Stream Output Num Primitives Written Counter

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000, 0x00000000
Access:	R/W
Size (in bits):	64
Address:	05200h-0521Fh

There is one 64-bit register for each of the 4 supported streams:5200h-5207h SO_NUM_PRIMS_WRITTEN0 (for Stream Out Stream #0)5208h-520Fh SO_NUM_PRIMS_WRITTEN1 (for Stream Out Stream #1)5210h-5217h SO_NUM_PRIMS_WRITTEN2 (for Stream Out Stream #2)5218h-521Fh SO_NUM_PRIMS_WRITTEN3 (for Stream Out Stream #3)These registers are used to count the number of primitives (aka objects: points, lines, triangles) which the SO stage has successfully written to a particular "stream's" Streamed Vertex Output buffers, subject to buffer overflow detection. (See the Stream Output section of the 3D pipeline volume).These registers are part of the context save and restore.

DWord	Bit	Description
0	63:0	**Num Prims Written Count** Format: U64 This count is incremented (by one) every time a GS thread outputs a DataPort Streamed Vertex Buffer Write message with the Increment Num Prims Written bit set in the message header (see the Geometry Shader and Data Port chapters in the 3D Volume.)

Stream Output Primitive Storage Needed Counters

SO_PRIM_STORAGE_NEEDED[0:3] - Stream Output Primitive Storage Needed Counters

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000, 0x00000000
Access:	RW. This register is set by the context restore.
Size (in bits):	64
Address:	05240h-0525Fh

There is one 64-bit register for each of the 4 supported streams:

5240h-5247h SO_PRIM_STORAGE_NEEDED0 (for Stream Out Stream #0)
5248h-524Fh SO_PRIM_STORAGE_NEEDED1 (for Stream Out Stream #1)
5250h-5257h SO_PRIM_STORAGE_NEEDED2 (for Stream Out Stream #2)
5258h-525Fh SO_PRIM_STORAGE_NEEDED3 (for Stream Out Stream #3)

These registers are used to count the number of primitives (aka objects: points, lines, triangles) which the SO stage has or would have written to a particular "stream's" Streamed Vertex Output buffers if all buffers had been large enough to accommodate the writes. (See the Stream Output section of the 3D pipeline volume).

These registers are part of the context save and restore.

DWord	Bit	Description
0	63:0	**Prim Storage Needed Count** Project: CHV, BSW Format: U64 This count is incremented (by one) by the SOL stage for each object (point, line, triangle) it writes or attempts to write to the corresponding stream's output buffers. The count is not affected by the actual number of buffers bound to the stream.

Stream Output Write Offsets

SO_WRITE_OFFSET[0:3] - Stream Output Write Offsets

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000
Access:	RW. This register is set by the context restore.
Size (in bits):	32
Address:	05280h-0528Fh

There is one R/W 32-bit register for each of the 4 supported stream output buffer slots:
5280h-5283h SO_WRITE_OFFSET0 (for Stream Out Buffer #0)
5284h-5287h SO_ WRITE_OFFSET1 (for Stream Out Buffer #1)
5288h-528Bh SO_ WRITE_OFFSET2 (for Stream Out Buffer #2)
528Ch-528Fh SO_ WRITE_OFFSET3 (for Stream Out Buffer #3)
These registers are used to set and track a DWord-granular Write Offset for each of the 4 Stream Output Buffer slots. Software can directly write them via MI_LOAD_REGxxx commands. The SOL stage will increment them as part of stream output processing. Software can cause them to be written to memory via MI_STORE_REGxxx commands. (See the Stream Output section of the 3D pipeline volume).
These registers are part of the context save and restore.

Programming Notes

- Software must ensure that no HW stream output operations can be in process or otherwise pending at the point that the MI_LOAD/STORE commands are processed. This will likely require a pipeline flush.
- The SOL stage will effectively advance the write offset by the buffer's Surface Pitch after each vertex is written (assuming no overflow is detected in any targetted SO buffer). Under "normal" conditions one would expect software to initialize the WriteOffset to some (possibly zero) multiple of Surface Pitch in order to align vertex writes to the buffer's Base Address, though it is not required to do so.

DWord	Bit	Description
0	31:2	**Write Offset** Project: CHV, BSW Format: U30 This field contains a DWord offset from the corresponding SO buffer's Base Address value. The SOL stage uses this value as a write offset when performing writes to the buffer. The SOL stage will increment this value as a part of performing stream output to the buffer. Note that the SOL stage uses the buffer's Surface Pitch to advance the Write Offset, without regard to the buffer's Base Address (see Programming Notes above).
	1:0	**Reserved** Format: MBZ

SWF1

SWF12

SWF12 - SWF12	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	4F02Ch

These (36 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation.
The use of these register is defined by software architecture.

DWord	Bit	Description
0	31:0	**SOFTWARE_FLAGS** Default Value: 00000000h Access: R/W These (36 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation. The use of these register is defined by software architecture.

SWF13

SWF13 - SWF13

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	4F030h

These (36 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation.
The use of these register is defined by software architecture.

DWord	Bit	Description
0	31:0	**SOFTWARE_FLAGS** Default Value: 00000000h Access: R/W These (36 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation. The use of these register is defined by software architecture.

SWF14

SWF14 - SWF14	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	4F034h

These (36 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation.
The use of these register is defined by software architecture.

DWord	Bit	Description
0	31:0	**SOFTWARE_FLAGS** Default Value: 00000000h Access: R/W These (36 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation. The use of these register is defined by software architecture.

SWF15

SWF15 - SWF15	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	4F038h

These (36 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation.
The use of these register is defined by software architecture.

DWord	Bit	Description
0	31:0	**SOFTWARE_FLAGS** Default Value: 00000000h Access: R/W These (36 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation. The use of these register is defined by software architecture.

SWF16

SWF16 - SWF16	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	4F03Ch

These (36 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation.
The use of these register is defined by software architecture.

DWord	Bit	Description
0	31:0	**SOFTWARE_FLAGS** Default Value: 00000000h Access: R/W These (36 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation. The use of these register is defined by software architecture.

SWF17

SWF17 - SWF17

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	4F040h

These (36 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation.
The use of these register is defined by software architecture.

DWord	Bit	Description
0	31:0	**SOFTWARE_FLAGS** Default Value: 00000000h Access: R/W These (36 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation. The use of these register is defined by software architecture.

SWF18

SWF18 - SWF18

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	4F058h

These (36 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation.
The use of these register is defined by software architecture.

DWord	Bit	Description
0	31:0	**SOFTWARE_FLAGS** Default Value: 00000000h Access: R/W These (36 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation. The use of these register is defined by software architecture.

SWF24

SWF24 - SWF24	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	4F05Ch

These (36 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation.
The use of these register is defined by software architecture.

DWord	Bit	Description
0	31:0	**SOFTWARE_FLAGS** Default Value: 00000000h Access: R/W These (36 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation. The use of these register is defined by software architecture.

SWF25

SWF25 - SWF25

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	4F060h

These (36 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation.
The use of these register is defined by software architecture.

DWord	Bit	Description
0	31:0	**SOFTWARE_FLAGS** Default Value: 00000000h Access: R/W These (36 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation. The use of these register is defined by software architecture.

SWF26

SWF26 - SWF26	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	4F064h

These (36 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation.
The use of these register is defined by software architecture.

DWord	Bit	Description
0	31:0	**SOFTWARE_FLAGS** Default Value: 00000000h Access: R/W These (36 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation. The use of these register is defined by software architecture.

SWF27

SWF27 - SWF27

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	4F068h

These (36 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation.
The use of these register is defined by software architecture.

DWord	Bit	Description
0	31:0	**SOFTWARE_FLAGS** Default Value: 00000000h Access: R/W These (36 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation. The use of these register is defined by software architecture.

SWF28

SWF28 - SWF28	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	4F06Ch

These (36 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation.
The use of these register is defined by software architecture.

DWord	Bit	Description
0	31:0	**SOFTWARE_FLAGS** Default Value: 00000000h Access: R/W These (36 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation. The use of these register is defined by software architecture.

SWF29

SWF29 - SWF29

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	4F070h

These (36 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation.
The use of these register is defined by software architecture.

DWord	Bit	Description
0	31:0	**SOFTWARE_FLAGS** Default Value: 00000000h Access: R/W These (36 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation. The use of these register is defined by software architecture.

SWF30

SWF30 - SWF30	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	4F074h

These (36 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation.
The use of these register is defined by software architecture.

DWord	Bit	Description
0	31:0	**SOFTWARE_FLAGS** Default Value: 00000000h Access: R/W These (36 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation. The use of these register is defined by software architecture.

SWF31

SWF31 - SWF31

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	4F078h

These (36 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation.
The use of these register is defined by software architecture.

DWord	Bit	Description
0	31:0	**SOFTWARE_FLAGS** Default Value: 00000000h Access: R/W These (36 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation. The use of these register is defined by software architecture.

SWF32

SWF32 - SWF32	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	4F07Ch

These (36 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation.
The use of these register is defined by software architecture.

DWord	Bit	Description
0	31:0	**SOFTWARE_FLAGS** Default Value: 00000000h Access: R/W These (36 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation. The use of these register is defined by software architecture.

SWF33

SWF33 - SWF33

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	4F080h

These (36 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation.
The use of these register is defined by software architecture.

DWord	Bit	Description
0	31:0	**SOFTWARE_FLAGS** Default Value: 00000000h Access: R/W These (36 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation. The use of these register is defined by software architecture.

SWF34

SWF34 - SWF34	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	4F084h

These (36 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation.
The use of these register is defined by software architecture.

DWord	Bit	Description
0	31:0	**SOFTWARE_FLAGS** Default Value: 00000000h Access: R/W These (36 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation. The use of these register is defined by software architecture.

SWF35

SWF35 - SWF35

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	4F088h

These (36 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation.
The use of these register is defined by software architecture.

DWord	Bit	Description
0	31:0	**SOFTWARE_FLAGS** Default Value: 00000000h Access: R/W These (36 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation. The use of these register is defined by software architecture.

SWF36

SWF36 - SWF36	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	4F08Ch

These (36 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation.
The use of these register is defined by software architecture.

DWord	Bit	Description
0	31:0	**SOFTWARE_FLAGS** Default Value: 00000000h Access: R/W These (36 DW) registers are used as scratch pad data storage space and have no direct effect on hardware operation. The use of these register is defined by software architecture.

SWSMISCI

SWSMISCI - SWSMISCI

Register Space:	PCI: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	000E0h

Software SMI or SCI.

The SCI mechanism for driver / BIOS communication. SMI is a system wide lock interrupt (halts all the cores) as opposed to SCI.

The SMI is slowly being phased out.
This register serves 2 purposes: 1) Support selection of SMI or SCI event source (SMISCISEL - bit15) 2) Event trigger (bit 0).
To generate a SW SCI event, software (System BIOS/Graphics driver) should program bit 15 (SMISCISEL) to 1. This is typically programmed once (assuming SMIs are never triggered). On a '0' to '1' subsequent transition in bit 0 of this register (caused by a software write operation), GMCH sends a single SCI message. The SCI will set the DMISCI bit in its TCO1_STS register and TCOSCI_STS bit in its GPE0 register upon receiving this message from DMI.
Once written as 1, software must write a '0' to this bit to clear it, and all other write transitions (1->0, 0->0, 1->1) or if bit 15 is '0' will not cause GMCH to send SCI message to DMI link.
To generate a SW SMI event, software should program bit 15:0 and trigger SMI.

DWord	Bit	Description
0	31:16	**RESERVED**
	15	**SMI_OR_SCI_EVENT_SELECT** Default Value: 0b Access: R/W MCS: SMI or SCI event select. 0 = SMI,1 = SCI
	14:1	**SOFTWARE_SCRATCH_BITS** Default Value: 0000h Access: R/W Used by driver to communicate information to SBIOS
	0	**SMI_OR_SCI_EVENT** Default Value: 0b Access: R/W MCE: MCS=1, setting this bit causes an SCI. MCS=0, setting this bit causes an SMI. A 1 to 0, 0 to 0 or 1 to 1 transition of this bit does not trigger any events. The graphics driver writes to this register as a means to interrupt the SBIOS.

Thread Dispatched Count Register

TDL_THR_DISP_COUNT - Thread Dispatched Count Register

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Address:	0E4BCh
Valid Projects:	CHV, BSW

This register provides the count of threads dispatched/valid in the subslice.

DWord	Bit	Description
0	31:6	**Reserved** Format: MBZ
	5:0	**Thread Count** Value: 0-56 — Name: Valid Range

Thread Faulted Count Register

TDL_THR_PF_COUNT - Thread Faulted Count Register

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Address:	0E5BCh
Valid Projects:	CHV, BSW

This register provides the count of threads faulted in each subslice.

DWord	Bit	Description
0	31	**Canonical fault indication bit to CS** The bit is set when a canonical fault on data fetch is reported by EU.
	30:6	**Reserved** Format: MBZ
	5:0	**Thread Count** Value: 0-56 — Name: Valid Range

Thread Fault Status Register 0

TDL_THR_PF_STATUS0 - Thread Fault Status Register 0	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Address:	0E6B8h

This register provides the status of each thread in the SubSlice. A bit set indicates the thread in the specific thread slot is faulted.

DWord	Bit	Description
0	31:24	**Row0, EU3, [Reserved, T6-T0]**
	23:16	**Row0, EU2, [Reserved, T6-T0]**
	15:8	**Row0, EU1, [Reserved, T6-T0]**
	7:0	**Row0, EU0, [Reserved, T6-T0]**

Thread Fault Status Register 1

TDL_THR_PF_STATUS1 - Thread Fault Status Register 1	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Address:	0E7B8h

This register provides the status of each thread in the SubSlice. A bit set indicates the thread in the specific thread slot is faulted.

DWord	Bit	Description
0	31:24	**Row1, EU3, [Reserved, T6-T0]**
	23:16	**Row1, EU2, [Reserved, T6-T0]**
	15:8	**Row1, EU1, [Reserved, T6-T0]**
	7:0	**Row1, EU0, [Reserved, T6-T0]**

Thread Load Status Register 0

TDL_THR_STATUS0 - Thread Load Status Register 0	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Address:	0E4B8h
This register provides the status of each thread in the SubSlice.	

DWord	Bit	Description
0	31:24	**Row0, EU3, [Reserved, T6-T0]**
	23:16	**Row0, EU2, [Reserved, T6-T0]**
	15:8	**Row0, EU1, [Reserved, T6-T0]**
	7:0	**Row0, EU0, [Reserved, T6-T0]**

Thread Load Status Register 1

TDL_THR_STATUS1 - Thread Load Status Register 1	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Address:	0E5B8h

This register provides the status of each thread in the SubSlice. A bit set indicates a valid thread is loaded in the thread slot.

DWord	Bit	Description
0	31:24	**Row1, EU3, [Reserved, T6-T0]**
	23:16	**Row1, EU2, [Reserved, T6-T0]**
	15:8	**Row1, EU1, [Reserved, T6-T0]**
	7:0	**Row1, EU0, [Reserved, T6-T0]**

Thread Mode Register

FF_MODE - Thread Mode Register

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00A00000 CHV, BSW
Access:	R/W
Size (in bits):	32
Address:	020A0h
Valid Projects:	

This register is used to program the FF shader Mode.

DWord	Bit	Description
0	31	**Reserved** Project: CHV, BSW Format: MBZ
	30	**TDS external Cache Disable** Project: CHV, BSW Value / Name / Description: 0b / Enable **[Default]** / The external TDS Cache is enabled if there is enough handles to enable the cache. 1b / Disable / The external TDS Cache is disabled even if there is enough handles to enable the cache. Only the internal TDS Cache will be used.
	29:26	**DS Hit Max Value** Format: U4 Description / Project: If the number of hits reaches the DS Hit Max Value and there is a pending miss to be dispatched, the DS will dispatch the pending miss vertex as a single dispatch. / Programming the value beyond the range will have undefined behavior if DS Reference Count Full Force miss enable is 0. When DS Reference Count Full Force miss enable is 1 then the value can be [1, Fh]. / CHV, BSW Value / Name / Project: 9 / **[Default]** / CHV, BSW [1,9] / / CHV, BSW

FF_MODE - Thread Mode Register

25:20 **VS Hit Max Value**

Format:	U6

Description
If the number of hits reaches the VS Hit Max Value and there is a pending miss to be dispatched, the VS will dispatch the pending miss vertex as a single dispatch.
Programming the value beyond the range will have undefined behavior if VS Reference Count Full Force miss enable is 0. When VS Reference Count Full Force miss enable is 1 then the value can be [1,3Fh].

Value	Name
10	**[Default]**
[1,26]	

19 **DS Reference Count Full Force Miss Enable**

Project:	CHV, BSW
Format:	Enable

Value	Name	Description
0b	**[Default]**	On a hit to the DS cache and the associated handle's reference count is full then stall until a derefernce.
1b		On a hit to the DS cache and the associated handle's reference count is full then force the cycle as a miss and allocate a new handle.

Programming Notes
To work around bugs, this must be set to 0.

18 **Reserved**

17:16 **Reserved**

15 **VS Reference Count Full Force Miss Enable**

Format:	U1

Value	Name	Description
[0,1]		
0b	**[Default]**	On a hit to the VS cache and the associated handle's reference count is full then stall until a derefernce.
1b		On a hit to the VS cache and the associated handle's reference count is full then force the cycle as a miss and allocate a new handle.

Programming Notes	Project
To work around bugs, this must be set to 0.	CHV, BSW

FF_MODE - Thread Mode Register

Thread Restart Control Register

TDL_THR_RESTART - Thread Restart Control Register	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Access:	WO
Size (in bits):	32
Address:	0E450h

This register provides control to restart page faulted and halted threads in each subslice.

DWord	Bit	Description
0	31:1	**Reserved** Format: MBZ
	0	**Restart All Faulted Threads** A write of 1 to this register restarts all threads that have halted due to page fault.

TILECTL

TILECTL - TILECTL	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	101000h

DWord	Bit	Description
0	31:3	**Reserved** Default Value: 00000000h Access: RO Reserved
	2	**Reserved** Default Value: 0b Access: RO Reserved.
	1	**TLBPF** Default Value: 0b Access: R/W Store multiple PTE enable 0: Only one Page Table Entry is stored in the Translation Lookaside Table Entry is stored in the Translation Lookaside Buffer cache for tiled cycles. 1: Multiple Page Table Entries are stored in the Translation Lookaside Buffer cache for tiled cycles. If tileX, then 4 entries are stored. If tileY, then 8 entries are stored.
	0	**SWZCTL** Default Value: 0b Access: R/W Not used for CHV, BSW. This register location is updated via GFX Driver prior to enabling DRAM accesses. The Driver needs to obtain the need for memory address swizzling via DRAM configuration registers and set the following bits. x0b - No Address Swizzling x1b - Address bit [6] needs to be swizzled for tiled surfaces

TiledResources Invalid Tile Detection Register

TRINVTILEDETCT - TiledResources Invalid Tile Detection Register

Register Space:	MMIO: 0/2/0
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04DECh
Name:	TiledResources Invalid Tile Detection Register
ShortName:	TRINVTILEDETCT

DWord	Bit	Description
0	31:0	**Invalid Tile Detection Value** Access: R/W **Value** / **Name** / **Description** 00000000h / **[Default]** / A 32bit value programmed to enable h/w to perform a match of TR-VA TT entries to detect Invalid Tiles. Hardware will flag each entry and space behind it as Invalid Tile for matched entries.

Tiled Resources Translation Table Control Registers

TRTTE - Tiled Resources Translation Table Control Registers

Register Space:	MMIO: 0/2/0
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04DF4h
Name:	Tiled Resources Translation Table Control Register
ShortName:	TRTTE

DWord	Bit	Description
0	31:2	**Reserved** Access: RO Value: 00000000000000000000000000000000b — **[Default]** — Reserved
	1	**TR-VA Translation Table Memory Location** Default Value: 0b Access: R/W This field specifies whether the translation tables for TR to VA are in virtual address space v/s physical (GPA) address space. 0: Tables are in Physical (GPA) space 1: Tables are in Virtual address space
	0	**TR - TT Enable** Default Value: 0b Access: R/W TR translation tables are disabled as default. This field needs to be enabled via s/w to get TR translation active.

TiledResources VA Detection Registers

TRVADR - TiledResources VA Detection Registers

Register Space:	MMIO: 0/2/0
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04DF0h
Name:	TiledResources VA Detection Registers
ShortName:	TRVADR

DWord	Bit	Description
0	31:8	**Reserved** Default Value: 000000h Access: RO
	7:4	**TR - VA Mask Value** Default Value: 0000b Access: R/W 4bit MASK value that is mapped to incoming address bits[47:44] MASK bits are used to identify which address bits need to be considered for compare. If particular mask bit is "1", mapping address bit needs to be compared to DATA value provided. If "0", corresponding address bit is masked which makes it don't care for compare. (This field defaults to "0000" to disable detection.). Note: The only usage model for GFX driver to set this field to "1111". Behaviour of h/w for any other setiing is not defined. Note: GFX driver shall use same TRVA MASK value for all contexts.
	3:0	**TR- VA Data Value** Access: R/W Value / Name / Description: 0000b **[Default]** 4bit Data value that is mapped to incoming address bits[47:44]. Data bits are used to compare address values that are not filtered by the TRVAMV for match Note: GFX driver shall use same TRVA Data value for all contexts

Tiled Resources VA Translation Table L3 ptr - DW0

TRVATTL3PTRDW0 - Tiled Resources VA Translation Table L3 ptr - DW0

Register Space:	MMIO: 0/2/0
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04DE0h
Name:	Tiled Resources VA Translation Table L3 ptr - DW0
ShortName:	TRVATTL3PTRDW0

DWord	Bit	Description
0	31:12	**TR - VA transln Table L3 Pointer (Lower Address)** Access: R/W Value / Name / Description: 00000h **[Default]** Lower address bits for tiled resource VA to virtual address translation L3 table
	11:0	**Reserved** Default Value: 000h Access: RO Reserved

Tiled Resources VA Translation Table L3 ptr - DW1

TRVATTL3PTRDW1 - Tiled Resources VA Translation Table L3 ptr - DW1

Register Space:	MMIO: 0/2/0
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04DE4h
Name:	Tiled Resources VA Translation Table L3 ptr - DW1
ShortName:	TRVATTL3PTRDW1

DWord	Bit	Description
0	31:16	**Reserved** Access: RO Value: 0000h — Name: **[Default]** — Description: Reserved
	15:0	**TR - VA transln Table L3 Pointer (Upper Address)** Default Value: 0000h Access: R/W Upper address bits for tiled resource VA to virtual address translation L3 table

TLB_RD_ADDRESS Register

TLB_RD_ADDR - TLB_RD_ADDRESS Register	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04B00h

DWord	Bit	Description
0	31:12	**Reserved** Default Value: 00000000000000000000b Access: RO
	11:0	**Reserved**

TLB_RD_DATA0 Register

TLB_RD_DATA0 - TLB_RD_DATA0 Register	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04B04h

DWord	Bit	Description
0	31:0	**TLB_READ_DATA0 Register** Default Value: 00000000h Access: RO address [43:12]

TLB_RD_DATA1 Register

TLB_RD_DATA1 - TLB_RD_DATA1 Register		
Register Space:	MMIO: 0/2/0	
Project:	CHV, BSW	
Source:	PRM	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	04B08h	
DWord	**Bit**	**Description**
0	31:0	**TLB_READ_DATA1 Register** Default Value: 00000000h Access: RO Bit[31:5] Reserved Bit[4] Cycle GTT SEL (1-GGTT Cycle, 0-PPGTT Cycle) Bit[3:0] address [47:44]

Transcode Attack Status Register

TRANS_STAT - Transcode Attack Status Register

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	09034h

Transcode Attack Status Register

DWord	Bit	Description
0	31:1	**RSVD** Access: RO RSVD
	0	**GKEYS_STATUS** Access: RO Transcode Attack Status bit

TRNULLDETCT

REG_TEMPLATE - TRNULLDETCT	
Register Space:	MMIO: 0/2/0
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04DE8h
Name:	TiledResources Null Tile Detection Register
ShortName:	TRNULLDETCT

DWord	Bit	Description
0	31:0	**Null Tile Detection Value** Access: R/W **Value** / **Name** / **Description** 00000000h / **[Default]** / A 32bit value programmed to enable h/w to perform a match of TR-VA TT entries to detect Null Tiles. Hardware will flag each entry and space behind it as Null Tile for matched entries.

Turbo Media Control

TMCTL - Turbo Media Control

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	0A190h-0A193h

DWord	Bit	Description
0	31:9	**Reserved** Access: RO
	8	**Bypass Media Idle Hysteresis Enable (aka Slice Shutdown)** Access: R/W 1 - Bypass idle hysteresis requirements for making an RC wish. 0 - Honor idle hysteresis <default>
	7:1	**Reserved** Access: RO
	0	**Bypass Render Idle Hysteresis Enable (aka Slice Shutdown)** Access: R/W 1 - Bypass idle hysteresis requirements for making an RC wish. 0 - Honor idle hysteresis <default>

Unblock Message Act to Busy Detection Timer

RCUBMABDTMR - Unblock Message Act to Busy Detection Timer

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	0A0B0h-0A0B3h

When locked exit policy is chosen, the GT core can be woken up in parallel with the IA cores waking up so an MMIO write to GT core might not be coming, or may be later in coming. If after the time programmed in this register is met and graphics is still idle, then RC1(e)/RC6x is allowed to be entered.
0 = 0 usec
1 = 1.28 usec
2 = 2.56 usec
3 = 3.84 usec
FF FFFF = 21.474 sec
pmcr_rc_sleep[23:0]

DWord	Bit	Description
0	31:24	**Reserved** Access: RO Reserved
	23:0	**Unblock Message Ack to Busy Detection Timer** Access: R/W When locked exit policy is chosen, the GT core can be woken up in parallel with the IA cores waking up so an MMIO write to GT core might not be coming, or may be later in coming. If after the time programmed in this register is met and graphics is still idle, then RC1(e)/RC6x is allowed to be entered. 0 = 0 usec 1 = 1.28 usec 2 = 2.56 usec 3 = 3.84 usec FF FFFF = 21.474 sec pmcr_rc_sleep[23:0]

Unit Level Clock Gating Control 1

UCGCTL1 - Unit Level Clock Gating Control 1

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x02800000
Size (in bits):	32
Address:	09400h

Unit Level Clock Gating Control Registers.Refer to the Programming notes mentioned near GT Interface Registers in PRM

DWord	Bit	Description
0	31	**Sarbunit Clock Gating Disable** Access: R/W SARB unit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	30	**Reserved** Access: R/W
	29	**Reserved** Access: R/W
	28	**ICunit Clock Gating Disable** Access: R/W ICunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	27	**HIZunit Clock Gating Disable** Access: R/W HIZunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	26	**GWunit Clock Gating Disable** Access: R/W GWunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)

UCGCTL1 - Unit Level Clock Gating Control 1

25	**GTIunit Clock Gating Disable** Default Value: 1b Access: R/W GTI Units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
24	**GSunit Clock Gating Disable** Access: R/W GSunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
23	**GPMunit Clock Gating Disable** Default Value: 1b Access: R/W GPMunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
22	**GAMunit Clock Gating Disable** Default Value: 0b Access: R/W GAMunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
21	**GACunit Clock Gating Disable** Default Value: 0b Access: R/W GACunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)

UCGCTL1 - Unit Level Clock Gating Control 1

20	**GABunit Clock Gating Disable** Default Value: 0b Access: R/W GABunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
19	**FTunit Clock Gating Disable** Access: R/W FTunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
18	**FLunit Clock Gating Disable** Access: R/W FLunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
17	**EU_FPUunit Clock Gating Disable** Access: R/W EU_FPUunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
16	**EU_TCunit Clock Gating Disable** Access: R/W EU_TCunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
15	**EU_EMunit Clock Gating Disable** Access: R/W EU_EMunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)

UCGCTL1 - Unit Level Clock Gating Control 1

14	**EU_GAunit Clock Gating Disable** Access: R/W EU_GAunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
13	**EUunit Clock Gating Disable** Access: R/W EUunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
12	**SVLunit Clock Gating Disable** Access: R/W SVLunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
11	**DTunit Clock Gating Disable** Access: R/W DTunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
10	**DMunit Clock Gating Disable** Access: R/W DMunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
9	**DGunit Clock Gating Disable** Access: R/W DGunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)

UCGCTL1 - Unit Level Clock Gating Control 1

	8	**DAPunit Clock Gating Disable** Access: R/W DAPunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	7	**CSunit Clock Gating Disable** Access: R/W CSunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	6	**CLunit Clock Gating Disable** Access: R/W CLunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	5	**BLBunit Clock Gating Disable** Access: R/W BLBunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	4	**BFunit Clock Gating Disable** Access: R/W BFunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	3	**BDunit Clock Gating Disable** Access: R/W BDunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)

UCGCTL1 - Unit Level Clock Gating Control 1

	2	**BCSunit Clock Gating Disable** Access: R/W BCSunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	1	**AVSunit Clock Gating Disable** Access: R/W AVSunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	0	**SPARE RAM Clock Gating Disable** Access: R/W SPARE RAM Clock Gating Disable Control: '0' : RAM Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : RAM Clock Gating Disabled. (i.e., clocks are toggling, always)

Unit Level Clock Gating Control 1

UCGCTL1 - Unit Level Clock Gating Control 1

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x02F00000

Unit Level Clock Gating Control Registers.

DWord	Bit	Description
0	31	**Sarbunit Clock Gating Disable** Access: R/W SARB unit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	30	**Reserved** Access: R/W
	29	**Reserved** Access: R/W
	28	**ICunit Clock Gating Disable** Access: R/W ICunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	27	**HIZunit Clock Gating Disable** Access: R/W HIZunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	26	**GWunit Clock Gating Disable** Access: R/W GWunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)

UCGCTL1 - Unit Level Clock Gating Control 1

25	**GTIunit Clock Gating Disable** Default Value: 1b Access: R/W GTI Units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
24	**GSunit Clock Gating Disable** Access: R/W GSunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
23	**GPMunit Clock Gating Disable** Default Value: 1b Access: R/W GPMunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
22	**GAMunit Clock Gating Disable** Default Value: 1b Access: R/W GAMunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
21	**GACunit Clock Gating Disable** Default Value: 1b Access: R/W GACunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
20	**GABunit Clock Gating Disable** Default Value: 1b

UCGCTL1 - Unit Level Clock Gating Control 1

		Access: R/W GABunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	19	**FTunit Clock Gating Disable** Access: R/W FTunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	18	**FLunit Clock Gating Disable** Access: R/W FLunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	17	**EU_FPUunit Clock Gating Disable** Access: R/W EU_FPUunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	16	**EU_TCunit Clock Gating Disable** Access: R/W EU_TCunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	15	**EU_EMunit Clock Gating Disable** Access: R/W EU_EMunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)

UCGCTL1 - Unit Level Clock Gating Control 1

	14	**EU_GAunit Clock Gating Disable** Access: R/W EU_GAunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	13	**EUunit Clock Gating Disable** Access: R/W EUunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	12	**SVLunit Clock Gating Disable** Access: R/W SVLunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	11	**DTunit Clock Gating Disable** Access: R/W DTunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	10	**DMunit Clock Gating Disable** Access: R/W DMunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	9	**DGunit Clock Gating Disable** Access: R/W DGunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)

UCGCTL1 - Unit Level Clock Gating Control 1

	8	**DAPunit Clock Gating Disable** Access: R/W DAPunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	7	**CSunit Clock Gating Disable** Access: R/W CSunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	6	**CLunit Clock Gating Disable** Access: R/W CLunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	5	**BLBunit Clock Gating Disable** Access: R/W BLBunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	4	**BFunit Clock Gating Disable** Access: R/W BFunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	3	**BDunit Clock Gating Disable** Access: R/W BDunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)

UCGCTL1 - Unit Level Clock Gating Control 1

	2	**BCSunit Clock Gating Disable** Access: R/W BCSunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	1	**AVSunit Clock Gating Disable** Access: R/W AVSunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	0	**SPARE RAM Clock Gating Disable** Access: R/W SPARE RAM Clock Gating Disable Control: '0' : RAM Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : RAM Clock Gating Disabled. (i.e., clocks are toggling, always)

Size (in bits):	32
Address:	09408h

Unit Level Clock Gating Control Registers.

DWord	Bit	Description
0	31	**Flunits 2nd Clock Gating Disable** Access: R/W Flunits 2nd Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	30	**SVRRunit Clock Gating Disable** Access: R/W SVRRunits' Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	29	**VCRunit Clock Gating Disable** Access: R/W VCRunits' Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	28	**EDTunit Clock Gating Disable** Access: R/W EDTunits' Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)

UCGCTL3 - Unit Level Clock Gating Control 3

	27	**VCIunit Clock Gating Disable** Access: R/W VCIunits' Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	26	**2x Assign fub XOR Clock Gating Disable** Default Value: 1b Access: R/W 2x Assign fub XOR Clock Gating Disable Control: '0' : 2x Assign fub XOR Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : 2x Assign fub XOR Clock Gating Disabled. (i.e., clocks are toggling, always)
	25	**HSunit Clock Gating Disable** Access: R/W HSunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	24	**SOLunit Clock Gating Disable** Access: R/W SOLunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	23	**QRCunit Clock Gating Disable** Access: R/W QRCunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	22	**MSPBISTunit Clock Gating Disable** Access: R/W MSPBISTunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)

UCGCTL3 - Unit Level Clock Gating Control 3

	21	**BSPunit Clock Gating Disable** Access: R/W BSPunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	20	**OACSunit Clock Gating Disable** Access: R/W OACSunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	19	**SBEunit Clock Gating Disable** Access: R/W SBEunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	18	**BCunit Clock Gating Disable** Access: R/W BCunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	17	**WMBE Clock Gating Disable** Access: R/W WMBEunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	16	**WMFEunit Clock Gating Disable** Access: R/W WMFEunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)

UCGCTL3 - Unit Level Clock Gating Control 3

	15	**VSCunit Clock Gating Disable** Access: R/W VSCunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	14	**Reserved** Access: R/W
	13	**USBunit Clock Gating Disable** Access: R/W USBunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	12	**STCunit Clock Gating Disable** Access: R/W STCunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	11	**VSunit Clock Gating Disable** Access: R/W VSunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	10	**VOPunit Clock Gating Disable** Access: R/W VOPunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)

UCGCTL3 - Unit Level Clock Gating Control 3

	9	**VMXunit Clock Gating Disable** Access: R/W VMXunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	8	**VMEunit Clock Gating Disable** Access: R/W VMEunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	7	**VMDunit Clock Gating Disable** Access: R/W VMDunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	6	**VMCunit Clock Gating Disable** Access: R/W VMCunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	5	**VLFunit Clock Gating Disable** Access: R/W VLFunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	4	**VITunit Clock Gating Disable** Access: R/W VITunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)

UCGCTL3 - Unit Level Clock Gating Control 3

	3	**VIPunit Clock Gating Disable** Access: R/W VIPunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	2	**VINunit Clock Gating Disable** Access: R/W VINunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	1	**VFTunit Clock Gating Disable** Access: R/W VFTunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	0	**VFEunit Clock Gating Disable** Access: R/W VFEunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)

DWord	Bit	Description
0	31	**VCOPunit clock gating disable bit** Access: R/W WVCOP units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always).
	30	**VMBunit clock gate disable bit** Access: R/W VMB units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	29	**VDMunit clock gate disable bit** Access: R/W VDM units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	28	**L3BANK unit cuclkgating disable bit** Access: R/W L3bank units cuclk Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	27	**L3BANK cu2x clock gate disable bit** Access: R/W L3BANK units cu2x Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks

UCGCTL5 - Unit Level Clock Gating Control 5

	26	**LNIunit clock gate disable bit** Access: R/W LNI units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	25	**LNEUNIT clock gate disable bit** Access: R/W LNE units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	24	**VVPunit clock gate disable bit** Access: R/W VVP units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	23	**WVFT unit clock gate disable bits** Access: R/W WVFT units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	22	**WBPS unit clock gate disable bit** Access: R/W WBPS units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	21	**WVMX unit clock gate disable bit** Access: R/W WVMX units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)

UCGCTL5 - Unit Level Clock Gating Control 5

	20	**WVIP unit clock gate disable bit** Access: R/W WVIP unit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	19	**WVIT unit clock gate disable bit** Access: R/W WVIT units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	18	**WVIS unit clock gate disable** Access: R/W WVIS units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	17	**RPM units clock gate disable** Access: R/W RPM units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	16	**Reserved**
	15	**VECS unit clock gate disable** Access: R/W VECS units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	14	**GAHSV unit clock gate disable** Access: R/W GAHSV units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)

UCGCTL5 - Unit Level Clock Gating Control 5

	13	**GAHSD unit clock gate disable** Access: R/W GAHSD units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	12	**GAV unit's clock gate disable** Access: R/W GAV units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	11	**RSunit's clock gate disable** Access: R/W RW units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	10	**VFW units clock gate disable** Access: R/W VFW units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	9	**VCW unit's clock gate disable** Access: R/W VCW units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	8	**VEO unit's clock gate disable** Access: R/W VEO units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)

UCGCTL5 - Unit Level Clock Gating Control 5

	7	**VDN unit's clock gate disable** Access: R/W VDN units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	6	**VTQunit's clock gate disable** Access: R/W VTQunits Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	5	**VPRunit's clock gate disable** Access: R/W VPR units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	4	**IMEunit's clock gate disable** Access: R/W IME units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	3	**CREunit clock gate disable** Access: R/W CRE units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	2	**GAPSL unit clock gate disable** Access: R/W GAPSL units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)

UCGCTL5 - Unit Level Clock Gating Control 5

	1	**GAPSU Clock gate disable** Access: R/W GAPSU units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	0	**SPMunit Clock gate disable** Access: R/W SPM units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)

Unit Level Clock Gating Disable bits

DWord	Bit	Description
0	30:28	**HDCunit clock gate disable** Access: R/W HDC units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	27	**Reserved**
	26	**GACVunit cuclk gate disable** Access: R/W GACV units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	25	**GACBunit clock gate disable** Access: R/W GACB units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	24	**GAPSunit clock gate disable** Access: R/W GAPS units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)

UCGCTL6 - Unit Level Clock Gating Control 6

	23	**GAMTunit clock gate disable** Access: R/W GAMT units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	22	**Reserved**
	21	**Reserved**
	20	**Reserved**
	19	**GACVunit clock gate disable** Access: R/W GACV units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	18	**BDMunit clock gate disable** Access: R/W BDM units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	17	**GATSunit clock gate disable** Access: R/W GATS units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	16	**Reserved**
	15	**STunit clock gate disable** Access: R/W ST units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)

UCGCTL6 - Unit Level Clock Gating Control 6

	14	**SDEunit clock gate disable** Access: R/W DE units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always) **Programming Notes** Due to SDEUNIT bug HSD#1802092, this bit should be programmed to a 1 for CHV, BSW
	13	**VIN(VID6) unit clock gate disable** Access: R/W VIN(VID6) units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	12	**VIN(VID5) unit clock gate disable** Access: R/W VIN(VID5) units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	11	**WVOPunit clock gate disable** Access: R/W WVOP units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	10	**WUSB unit clock gate disable** Access: R/W WUSB units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	9	**WSECunit clock gate disable** Access: R/W WSEC units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)

UCGCTL6 - Unit Level Clock Gating Control 6

	8	**WRSunit clcok gate disable** Access: R/W WRS units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	7	**WQRCunit clock gate disable** Access: R/W WQRC units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	6	**WMPC unit level clock gate disable** Access: R/W WMPC units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	5	**WINunit Clock gate disable** Access: R/W WIN units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	4	**WIME unit clock gate disable** Access: R/W WIME units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	3	**WHME unit clock gate disable** Access: R/W WHME units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)

UCGCTL6 - Unit Level Clock Gating Control 6

	2	**WAVMunit Clock Gate Disable** Access: R/W WAVM units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	1	**VSHMunit clock gate disable** Access: R/W VSHM units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	0	**VSLunit Clock gating disable** Access: R/W VSL units Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)

URB Context Offset

URB_CXT_OFFSET - URB Context Offset		
Register Space:	MMIO: 0/2/0	
Project:	CHV, BSW	
Source:	RenderCS	
Default Value:	0x00009AC0	
Access:	Read/32 bit Write Only	
Size (in bits):	32	
Address:	021B8h	
DWord	**Bit**	**Description**
0	31:6	**URB Offset** Default Value: 26Bh This field indicates the offset (64bytes granular) in to the logical rendering context to which URB contents are save/restored when enabled. This field register must not be written directly (via MMIO) unless the Command Streamer is completely idle (i.e., the Ring Buffer is empty and the pipeline is idle) and RC6 is disabled. One way to program this register is via Load Register Immediate command in the ring buffer as part of initialization sequence.
	5:0	**Reserved** Format: MBZ

Valid Bit Vector 0 for CVS

CVSTLB_VLD_0 - Valid Bit Vector 0 for CVS	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04C00h

This register contains the valid bits for entries 0-31 of CVSTLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 0 for CVS** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 0 for L3

L3TLB_VLD_0 - Valid Bit Vector 0 for L3	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04D00h

This register contains the valid bits for entries 0-31 of L3TLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 0 for L3** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 0 for MFX

MFXTLB_VLD_0 - Valid Bit Vector 0 for MFX	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04BA0h

This register contains the valid bits for entries 0-31 of MFXTLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 0 for MFX** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 0 for MFX SL1

MFXTLB_VLD_SL1_0 - Valid Bit Vector 0 for MFX SL1	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04BC0h

This register contains the valid bits for entries 0-31 of MFX SL1 TLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 0 for MFX SL1** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 0 for MTTLB

MTTLB_VLD0 - Valid Bit Vector 0 for MTTLB	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	04780h-04783h

This register contains the valid bits for entries 0-31 of MTTLB (Texture and constant cache TLB).

DWord	Bit	Description
0	31:0	**Valid bits per entry**

Valid Bit Vector 0 for MTVICTLB

VICTLB_VLD0 - Valid Bit Vector 0 for MTVICTLB	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	04788h-0478Bh

This register contains the valid bits for entries 0-31 of VICTLB (Vertex Fetch, Instruction Cache, and Command Streamer TLB).

DWord	Bit	Description
0	31:0	**Valid bits per entry**

Valid Bit Vector 0 for RCC

RCCTLB_VLD_0 - Valid Bit Vector 0 for RCC	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04DA0h

This register contains the valid bits for entries 0-31 of RCCTLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 0 for RCC** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 0 for RCCTLB

RCCTLB_VLD0 - Valid Bit Vector 0 for RCCTLB	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	04790h-04793h

This register contains the valid bits for entries 0-31 of RCCTLB (Render Cache for Color TLB).

DWord	Bit	Description
0	31:0	**Valid bits per entry**

Valid Bit Vector 0 for RCZTLB

RCZTLB_VLD0 - Valid Bit Vector 0 for RCZTLB	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	04798h-0479Bh
This register contains the valid bits for entries 0-31 of RCZTLB (Render Cache for Z (Depth), Hi Z, and Stencil TLB).	

DWord	Bit	Description
0	31:0	**Valid bits per entry**

Valid Bit Vector 0 for TLBPEND registers

TLBPEND_VLD0 - Valid Bit Vector 0 for TLBPEND registers	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Trusted Type:	1
Address:	04700h-04703h

This register contains the valid bits for entries 0-31 of TLBPEND structure (Cycles pending TLB translation).

DWord	Bit	Description
0	31:0	**Valid bits per entry**

Valid Bit Vector 0 for VEBX

VEBXTLB_VLD_0 - Valid Bit Vector 0 for VEBX	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04B20h

This register contains the valid bits for entries 0-31 of VEBXTLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 0 for VEBX** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 0 for WIDI

BWDTLB_VLD_0 - Valid Bit Vector 0 for WIDI	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04DC0h

This register contains the valid bits for entries 0-31 of BWDTLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 0 for WIDI** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 0 for Z

ZTLB_VLD_0 - Valid Bit Vector 0 for Z	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04B34h

This register contains the valid bits for entries 0-31 of ZTLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 0 for Z** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 1 for CVS

CVSTLB_VLD_1 - Valid Bit Vector 1 for CVS	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04C04h

This register contains the valid bits for entries 0-31 of CVSTLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 1 for CVS** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 1 for L3

L3TLB_VLD_1 - Valid Bit Vector 1 for L3	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04D04h

This register contains the valid bits for entries 0-31 of L3TLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 1 for L3** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 1 for MFX

MFXTLB_VLD_1 - Valid Bit Vector 1 for MFX	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04BA4h

This register contains the valid bits for entries 0-31 of MFXTLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 1 for MFX** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 1 for MFX SL1

MFXTLB_VLD_SL1_1 - Valid Bit Vector 1 for MFX SL1	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04BC4h

This register contains the valid bits for entries 0-31 of MFX SL1 TLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 1 for MFX SL1** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 1 for MTTLB

MTTLB_VLD1 - Valid Bit Vector 1 for MTTLB	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	04784h-04787h

This register contains the valid bits for entries 0-31 of MTTLB (Texture and constant cache TLBVertex Fetch, Instruction Cache, and Command Streamer TLB).

DWord	Bit	Description
0	31:0	**Valid bits per entry**

Valid Bit Vector 1 for MTVICTLB

MTVICTLB_VLD1 - Valid Bit Vector 1 for MTVICTLB	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	0478Ch-0478Fh

This register contains the valid bits for entries 0-31 of VICTLB (Vertex Fetch, Instruction Cache, and Command Streamer TLB).

DWord	Bit	Description
0	31:0	**Valid bits per entry**

Valid Bit Vector 1 for RCC

RCCTLB_VLD_1 - Valid Bit Vector 1 for RCC	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04DA4h

This register contains the valid bits for entries 0-31 of RCCTLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 1 for RCC** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 1 for RCCTLB

RCCTLB_VLD1 - Valid Bit Vector 1 for RCCTLB	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	04794h-04797h

This register is reserved for future RCC TLB extension.

DWord	Bit	Description
0	31:0	**Reserved** Format: MBZ

Valid Bit Vector 1 for RCZTLB

RCZTLB_VLD1 - Valid Bit Vector 1 for RCZTLB	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	0479Ch-0479Fh

This register contains the valid bits for entries 0-31 of RCZTLB (Render Cache for Z (Depth), Hi Z, and Stencil TLB).

DWord	Bit	Description
0	31:0	**Valid bits per entry**

Valid Bit Vector 1 for TLBPEND registers

TLBPEND_VLD1 - Valid Bit Vector 1 for TLBPEND registers	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Trusted Type:	1
Address:	04704h-04707h

This register contains the valid bits for entries 32-63 of TLBPEND structure (Cycles pending TLB translation).

DWord	Bit	Description
0	31:0	**Valid bits per entry**

Valid Bit Vector 1 for VEBX

VEBXTLB_VLD_1 - Valid Bit Vector 1 for VEBX	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04B24h

This register contains the valid bits for entries 0-31 of VEBXTLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 1 for VEBX** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 1 for WIDI

BWDTLB_VLD_1 - Valid Bit Vector 1 for WIDI	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04DC4h

This register contains the valid bits for entries 0-31 of BWDTLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 1 for WIDI** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 1 for Z

ZTLB_VLD_1 - Valid Bit Vector 1 for Z	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04B38h

This register contains the valid bits for entries 0-31 of ZTLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 1 for Z** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 2 for CVS

CVSTLB_VLD_2 - Valid Bit Vector 2 for CVS	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04C08h

This register contains the valid bits for entries 0-31 of CVSTLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 2 for CVS** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 2 for GAB

BWDTLB_VLD_3 - Valid Bit Vector 2 for GAB	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04DCCh

This register contains the valid bits for entries 0-31 of BWDTLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 3 for GAB** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 2 for L3

L3TLB_VLD_2 - Valid Bit Vector 2 for L3	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04D08h

This register contains the valid bits for entries 0-31 of L3TLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 2 for L3** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 2 for MFX

MFXTLB_VLD_2 - Valid Bit Vector 2 for MFX	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04BA8h

This register contains the valid bits for entries 0-31 of MFXTLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 2 for MFX** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 2 for MFX SL1

MFXTLB_VLD_SL1_2 - Valid Bit Vector 2 for MFX SL1	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04BC8h

This register contains the valid bits for entries 0-31 of MFX SL1 TLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 2 for MFX SL1** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 2 for RCC

RCCTLB_VLD_2 - Valid Bit Vector 2 for RCC	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04DA8h

This register contains the valid bits for entries 0-31 of RCCTLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 2 for RCC** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 2 for Z

ZTLB_VLD_2 - Valid Bit Vector 2 for Z	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04B3Ch

This register contains the valid bits for entries 0-31 of ZTLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 2 for Z** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 3 for CVS

CVSTLB_VLD_3 - Valid Bit Vector 3 for CVS	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04C0Ch

This register contains the valid bits for entries 0-31 of CVSTLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 3 for CVS** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 3 for L3

L3TLB_VLD_3 - Valid Bit Vector 3 for L3	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04D0Ch

This register contains the valid bits for entries 0-31 of L3TLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 3 for L3** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 3 for MFX

MFXTLB_VLD_3 - Valid Bit Vector 3 for MFX	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04BACh

This register contains the valid bits for entries 0-31 of MFXTLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 3 for MFX** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 3 for MFX SL1

MFXTLB_VLD_SL1_3 - Valid Bit Vector 3 for MFX SL1	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04BCCh

This register contains the valid bits for entries 0-31 of MFX SL1 TLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 3 for MFX SL1** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 3 for RCC

RCCTLB_VLD_3 - Valid Bit Vector 3 for RCC	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04DACh

This register contains the valid bits for entries 0-31 of RCCTLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 3 for RCC** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 3 for Z

ZTLB_VLD_3 - Valid Bit Vector 3 for Z	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04B40h

This register contains the valid bits for entries 0-31 of ZTLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 3 for Z** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 4 for L3

L3TLB_VLD_4 - Valid Bit Vector 4 for L3	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04D10h

This register contains the valid bits for entries 0-31 of L3TLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 4 for L3** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 4 for MFX

MFXTLB_VLD_4 - Valid Bit Vector 4 for MFX	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04BB0h

This register contains the valid bits for entries 0-31 of MFXTLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 4 for MFX** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 4 for MFX SL1

MFXTLB_VLD_SL1_4 - Valid Bit Vector 4 for MFX SL1	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04BD0h

This register contains the valid bits for entries 0-31 of MFX SL1 TLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 4 for MFX SL1** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 4 for RCC

RCCTLB_VLD_4 - Valid Bit Vector 4 for RCC	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04DB0h

This register contains the valid bits for entries 0-31 of RCCTLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 4 for RCC** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 4 for Z

ZTLB_VLD_4 - Valid Bit Vector 4 for Z	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04B44h

This register contains the valid bits for entries 0-31 of ZTLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 4 for Z** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 5 for L3

L3TLB_VLD_5 - Valid Bit Vector 5 for L3	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04D14h

This register contains the valid bits for entries 0-31 of L3TLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 5 for L3** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 5 for MFX

MFXTLB_VLD_5 - Valid Bit Vector 5 for MFX	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04BB4h

This register contains the valid bits for entries 0-31 of MFXTLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 5 for MFX** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 5 for MFX SL1

MFXTLB_VLD_SL1_5 - Valid Bit Vector 5 for MFX SL1	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04BD4h

This register contains the valid bits for entries 0-31 of MFX SL1 TLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 5 for MFX SL1** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 5 for RCC

RCCTLB_VLD_5 - Valid Bit Vector 5 for RCC	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04DB4h

This register contains the valid bits for entries 0-31 of RCCTLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 5 for RCC** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 5 for Z

ZTLB_VLD_5 - Valid Bit Vector 5 for Z	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04B48h

This register contains the valid bits for entries 0-31 of ZTLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 5 for Z** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 6 for L3

L3TLB_VLD_6 - Valid Bit Vector 6 for L3		
Register Space:	MMIO: 0/2/0	
Project:	CHV, BSW	
Source:	PRM	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	04D18h	
This register contains the valid bits for entries 0-31 of L3TLB.		
DWord	**Bit**	**Description**
0	31:0	**Valid Bit Vector 6 for L3** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 6 for MFX

MFXTLB_VLD_6 - Valid Bit Vector 6 for MFX	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04BB8h

This register contains the valid bits for entries 0-31 of MFXTLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 6 for MFX** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 6 for MFX SL1

MFXTLB_VLD_SL1_6 - Valid Bit Vector 6 for MFX SL1	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04BD8h

This register contains the valid bits for entries 0-31 of MFX SL1 TLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 6 for MFX SL1** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 6 for RCC

RCCTLB_VLD_6 - Valid Bit Vector 6 for RCC	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04DB8h

This register contains the valid bits for entries 0-31 of RCCTLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 6 for RCC** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 6 for Z

ZTLB_VLD_6 - Valid Bit Vector 6 for Z	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04B4Ch

This register contains the valid bits for entries 0-31 of ZTLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 6 for Z** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 7 for L3

L3TLB_VLD_7 - Valid Bit Vector 7 for L3		
Register Space:	MMIO: 0/2/0	
Project:	CHV, BSW	
Source:	PRM	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	04D1Ch	
This register contains the valid bits for entries 0-31 of L3TLB.		

DWord	Bit	Description
0	31:0	**Valid Bit Vector 7 for L3** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 7 for MFX

MFXTLB_VLD_7 - Valid Bit Vector 7 for MFX	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04BBCh

This register contains the valid bits for entries 0-31 of MFXTLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 7 for MFX** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 7 for MFX SL1

MFXTLB_VLD_SL1_7 - Valid Bit Vector 7 for MFX SL1	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04BDCh

This register contains the valid bits for entries 0-31 of MFX SL1 TLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 7 for MFX SL1** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 7 for RCC

RCCTLB_VLD_7 - Valid Bit Vector 7 for RCC	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04DBCh

This register contains the valid bits for entries 0-31 of RCCTLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 7 for RCC** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 7 for Z

ZTLB_VLD_7 - Valid Bit Vector 7 for Z	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04B50h

This register contains the valid bits for entries 0-31 of ZTLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 7 for Z** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 8 for L3

L3TLB_VLD_8 - Valid Bit Vector 8 for L3	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04D20h

This register contains the valid bits for entries 0-31 of L3TLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 8 for L3** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 8 for Z

ZTLB_VLD_8 - Valid Bit Vector 8 for Z	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04B54h

This register contains the valid bits for entries 0-31 of ZTLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 8 for Z** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 9 for L3

L3TLB_VLD_9 - Valid Bit Vector 9 for L3		
Register Space:	MMIO: 0/2/0	
Project:	CHV, BSW	
Source:	PRM	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	04D24h	
This register contains the valid bits for entries 0-31 of L3TLB.		
DWord	**Bit**	**Description**
0	31:0	**Valid Bit Vector 9 for L3** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 9 for Z

ZTLB_VLD_9 - Valid Bit Vector 9 for Z	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04B58h

This register contains the valid bits for entries 0-31 of ZTLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 9 for Z** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 10 for L3

L3TLB_VLD_10 - Valid Bit Vector 10 for L3	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04D28h

This register contains the valid bits for entries 0-31 of L3TLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 10 for L3** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 10 for Z

ZTLB_VLD_10 - Valid Bit Vector 10 for Z	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04B5Ch

This register contains the valid bits for entries 0-31 of ZTLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 10 for Z** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 11 for L3

L3TLB_VLD_11 - Valid Bit Vector 11 for L3	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04D2Ch

This register contains the valid bits for entries 0-31 of L3TLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 11 for L3** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 11 for Z

ZTLB_VLD_11 - Valid Bit Vector 11 for Z	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04B60h

This register contains the valid bits for entries 0-31 of ZTLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 11 for Z** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 12 for L3

L3TLB_VLD_12 - Valid Bit Vector 12 for L3	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04D30h

This register contains the valid bits for entries 0-31 of L3TLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 12 for L3** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 12 for Z

ZTLB_VLD_12 - Valid Bit Vector 12 for Z	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04B64h

This register contains the valid bits for entries 0-31 of ZTLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 12 for Z** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 13 for L3

L3TLB_VLD_13 - Valid Bit Vector 13 for L3	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04D34h

This register contains the valid bits for entries 0-31 of L3TLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 13 for L3** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 13 for Z

ZTLB_VLD_13 - Valid Bit Vector 13 for Z	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04B68h

This register contains the valid bits for entries 0-31 of ZTLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 13 for Z** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 14 for L3

L3TLB_VLD_14 - Valid Bit Vector 14 for L3	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04D38h

This register contains the valid bits for entries 0-31 of L3TLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 14 for L3** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 14 for Z

ZTLB_VLD_14 - Valid Bit Vector 14 for Z	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04B6Ch

This register contains the valid bits for entries 0-31 of ZTLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 14 for Z** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 15 for L3

L3TLB_VLD_15 - Valid Bit Vector 15 for L3	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04D3Ch

This register contains the valid bits for entries 0-31 of L3TLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 15 for L3** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 15 for Z

ZTLB_VLD_15 - Valid Bit Vector 15 for Z	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04B70h

This register contains the valid bits for entries 0-31 of ZTLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 15 for Z** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 16 for L3

L3TLB_VLD_16 - Valid Bit Vector 16 for L3	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04D40h

This register contains the valid bits for entries 0-31 of L3TLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 16 for L3** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 17 for L3

L3TLB_VLD_17 - Valid Bit Vector 17 for L3	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04D44h

This register contains the valid bits for entries 0-31 of L3TLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 17 for L3** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 18 for L3

L3TLB_VLD_18 - Valid Bit Vector 18 for L3	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04D48h

This register contains the valid bits for entries 0-31 of L3TLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 18 for L3** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 19 for L3

L3TLB_VLD_19 - Valid Bit Vector 19 for L3	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04D4Ch

This register contains the valid bits for entries 0-31 of L3TLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 19 for L3** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 20 for L3

L3TLB_VLD_20 - Valid Bit Vector 20 for L3	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04D50h

This register contains the valid bits for entries 0-31 of L3TLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 20 for L3** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 21 for L3

L3TLB_VLD_21 - Valid Bit Vector 21 for L3	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04D54h

This register contains the valid bits for entries 0-31 of L3TLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 21 for L3** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 22 for L3

L3TLB_VLD_22 - Valid Bit Vector 22 for L3	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04D58h

This register contains the valid bits for entries 0-31 of L3TLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 22 for L3** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector 23 for L3

L3TLB_VLD_23 - Valid Bit Vector 23 for L3	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04D5Ch

This register contains the valid bits for entries 0-31 of L3TLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector 23 for L3** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector for VLF

VLFTLB_VLD - Valid Bit Vector for VLF	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04B30h

This register contains the valid bits for entries 0-31 of VLFTLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector for VLF** Default Value: 00000000h Access: RO Valid Bits per Entry.

Valid Bit Vector for VLFSL1

VLFSL1TLB_VLD - Valid Bit Vector for VLFSL1	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04B2Ch

This register contains the valid bits for entries 0-31 of VLFSL1TLB.

DWord	Bit	Description
0	31:0	**Valid Bit Vector for VLFSL1** Default Value: 00000000h Access: RO Valid Bits per Entry.

VC

VC - VC

Register Space:	PCI: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	000B4h

Vendor Capabilities. Any SKU related fuses would be added here.

DWord	Bit	Description
0	31:1	**Reserved** Default Value: 0000000h Access: RO Reserved
	0	**Spare_bit** Default Value: 0b Access: RO Placeholder for SKU related fusing.

VCES Idle Switch Delay

VECS_IDLEDLY - VCES Idle Switch Delay

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoEnhancementCS
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	1A23Ch

The IDLEDLY register contains an Idle Delay field which specifies the minimum number of microseconds allowed for command streamer to wait before a context is switched out leading to IDLE state in execlists mode, i.e following this context switch there is no active element available in HW to execute.
A default value of 0, means that by default, there is no restriction to wait on a context switch leading to IDLE. This register has no significance when execlists are not enabled.

DWord	Bit	Description
0	31:21	**Reserved** Project: All Format: MBZ
	20:0	**IDLE Delay** Default Value: 0h Project: All Format: U21 Minimum number of micro-seconds allowed.

VCID

VCID - VCID

Register Space:	PCI: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x01070009
Size (in bits):	32
Address:	000B0h

Vendor Capability ID

DWord	Bit	Description
0	31:24	**VERSION** Default Value: 01h Access: RO VS: Identifies this as the first revision of the CAPID register definition.
	23:16	**LENGTH** Default Value: 07h Access: RO LEN: This field has the value 07h to indicate structure length (8 bytes)
	15:8	**NEXT_CAPABILITY_POINTER** Default Value: 00h Access: R/W Once 00 indicates capability list ends here. This register should be programmed by BIOS during boot-up. Once written, this register becomes Read_Only. This register can only be cleared by a Reset. Write-once allowing the capability list to be changed.
	7:0	**CAPABILITY_ID_CID** Default Value: 09h Access: RO Identifies this as a vendor dependent capability pointers.

VCS_PREEMPTION_HINT

VCS_PREEMPTION_HINT - VCS_PREEMPTION_HINT

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	124BCh
Valid Projects:	CHV, BSW

This register contains the Head pointer offset in to the Ring Buffer or the Dword aligned Graphics address in to the Batch Buffer corresponding to either MI_ARB_CHECK called Preemption Hint Address. When Preemption Hint Address is enabled, VCS will honor UHPTR only on parsing MI_ARB_CHK at Preemption Hint Address.

This register contains the Head pointer offset into the Ring Buffer or the Dword aligned Graphics address into the Batch Buffer corresponding to the below listed commands in execlist mode of operation

- MI_ARB_CHECK
- MI_WAIT_FOR_EVENT
- MI_SEMAPHORE_WAIT

Programming Notes

Programming Restriction: This register should NEVER be programmed in functional mode, this should be used only in validation mode to achieve deterministic behavior of UHPTR being sampled by a given MI_ARB_CHECK in command stream. Programmer has to ensure that VCS Preemption Hint register gets programmed before UHPTR is programmed and well before VCS crosses the corresponding execution point. Preemption hint for both RingBuffer and Batch Buffer can't be enabled simultaneously.

DWord	Bit	Description
0	31:2	**Preempted Hint Address** Format: U30 Format: GraphicsAddress[31:2] This field contains the Head offset in to the Ring Buffer when Preemption Hint is set to Ring Buffer and Dword aligned Graphics Address in to the batch buffer when Preemption Hint is set to Batch Buffer.
	1	**Batch Buffer Preemption Hint** Format: Enable Value / Name / Description 0h / Disabled / Preemption hint is disabled in batch buffer.

VCS_PREEMPTION_HINT - VCS_PREEMPTION_HINT

		1h	Enabled	Preemption hint is enabled in ring buffer and preemption hint address corresponds to the instruction in Batch Buffer.
	0	**Ring Preemption Hint**		

Format:	Enable

Value	Name	Description
0h	Disable	Preemption hint is disabled in ring buffer.
1h	Enabled	Preemption hint is enabled in ring buffer and preemption hint address corresponds to the instruction in Ring Buffer.

VCS_PREEMPTION_HINT_UDW

VCS_PREEMPTION_HINT_UDW - VCS_PREEMPTION_HINT_UDW

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	124C8h
Valid Projects:	CHV, BSW

This register contains the 4GB aligned base address of gfx 4GB virtual address space within the host's 64-bit virtual address space of the Batch Buffer corresponding to MI_ARB_CHECK command called Preemption Hint Address.

Programming Notes

Programming Restriction:This register should NEVER be programmed in functional mode, this should be used only in validation mode to achieve deterministic behavior of UHPTR being sampled by a given MI_ARB_CHK in command stream.

DWord	Bit	Description
0	31:16	**Reserved** Format: MBZ
	15:0	**Preempted Hint Address Upper DWORD** Format: GraphicsAddress[47:32] This field contains the 4GB aligned base address of gfx 4GB virtual address space within the host's 64-bit virtual address space of the batch buffer when Preemption Hint is set to Batch Buffer. This field is not valid when Preemption Hint is set to Ring Buffer.

VCS Context ID Preemption Hint

VCS_CTXID_PREEMPTION_HINT - VCS Context ID Preemption Hint

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	124CCh
Valid Projects:	CHV, BSW

This register contains the Context ID of a context in execlist mode of operation. In execlist mode of operation VCS_PREEMPTION_HINT registers are looked at by Video Command Streamer on executing a context having Context ID that matches with the contents of this register. This register contents are valid and looked at only in execlist mode of operation.

Programming Notes

This register should NEVER be programmed in functional mode, this must be used only in validation mode to achieve deterministic preemption behavior in execlist mode of operation.

DWord	Bit	Description
0	31:0	**Context ID Preemption Hint** Format: U32 If 0 this field has no effect. If nonzero it indicates the only context ID that can be preempted when execlists are enabled. A preemption attempt when the context ID of the currently executing ring context does not match this field will be ignored.

VCS Context Sizes

VCS_CXT_SIZE - VCS Context Sizes

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0x000A1105 CHV, BSW
Access:	Read/32 bit Write Only
Size (in bits):	32
Address:	121A8h
Valid Projects:	CHV, BSW

DWord	Bit	Description
0	31:21	**Reserved** Format: MBZ
	20:16	**VCS Context Size** Format: U5 Value: Ah, Name: **[Default]**, Project: CHV, BSW
	15:13	**Reserved** Format: MBZ
	12:8	**VCR Context Size** Format: U5 Value: 11h, Name: **[Default]**, Project: CHV, BSW
	7:5	**Reserved** Format: MBZ
	4:0	**Execlist Context Size** Format: U5 Value: 5h, Name: **[Default]**, Project: CHV, BSW

VCS Context Timestamp Count

VCS_CTX_TIMESTAMP - VCS Context Timestamp Count

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	123A8h
Valid Projects:	CHV, BSW

This register provides a mechanism to obtain cumulative run time of a GPU context on HW. This register gets context save/restored on a context switch. SW must reset this register on very first submission of a context to HW, then afterwards gets context save/restored maintaining the cumulative run time of the corresponding context. This register (effectively) counts at a constant frequency by adjusting the increment amount according to the actual reference clock frequency. SW therefore does not need to know the reference clock frequency. This register gets reset on an engine reset.

This register is context save restore on a context switch.

DWord	Bit	Description
0	31:0	**Timestamp Value** Format: U32 This register increments for every 80 ns of time.

VCS Counter for the bit stream decode engine

VCS_CNTR - VCS Counter for the bit stream decode engine	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0xFFFFFFFF
Access:	R/W
Size (in bits):	32
Address:	12178h-1217Bh
Valid Projects:	CHV, BSW

DWord	Bit	Description
0	31:0	**Count Value** Default Value: ffffffffh Writing a Zero value to this register starts the counting. Writing a Value of FFFF FFFF to this counter stops the counter.

VCS Error Identity Register

VCS_EIR - VCS Error Identity Register

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0x00000000
Access:	R/WC
Size (in bits):	32
Address:	120B0h
Valid Projects:	CHV, BSW

The EIR register contains the persistent values of Hardware-Detected Error Condition bits. Any bit set in this register will cause the Master Error bit in the ISR to be set. The EIR register is also used by software to clear detected errors (by writing a 1 to the appropriate bit(s) except for the unrecoverable bits described).

DWord	Bit	Description
0	31:16	**Reserved** Format: MBZ
	15:0	**Error Identity Bits** Format: Array of Error condition bits ee the table titled Hardware-Detected Error Bits This register contains the persistent values of ESR error status bits that are unmasked via the EMR register. The logical OR of all (defined) bits in this register is reported in the Master Error bit of the Interrupt Status Register. In order to clear an error condition, software must first clear the error by writing a 1 to the appropriate bit(s) in this field. If required, software should then proceed to clear the Master Error bit of the IIR.

Value	Name	Description
0h	**[Default]**	
1h	Error occurred	Error occurred

Programming Notes
Writing a 1 to a set bit will cause that error condition to be cleared. However, the Page Table Error bit (Bit 4) cannot be cleared except by reset (i.e., it is a fatal error).

VCS Error Mask Register

VCS_EMR - VCS Error Mask Register

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0xFFFFFFFF CHV, BSW
Access:	R/W
Size (in bits):	32
Address:	120B4h
Valid Projects:	CHV, BSW

The EMR register is used by software to control which Error Status Register bits are "masked" or "unmasked". "Unmasked" bits will be reported in the EIR, thus setting the Master Error ISR bit and possibly triggering a CPU interrupt, and will persist in the EIR until cleared by software. "Masked" bits will not be reported in the EIR and therefore cannot generate Master Error conditions or CPU interrupts.

Undefined or reserved bits in the Hardware Detected Error Bit Table will always return a read value of '1'

DWord	Bit	Description
0	31:16	**Reserved** Default Value: FFFFh Project: CHV, BSW Format: Must Be One
	15:0	**Error Mask Bits** Format: Array of error condition mask bits See the table titled Hardware-Detected Error Bits. This register contains a bit mask that selects which error condition bits (from the ESR) are reported in the EIR. **Value** / **Name** / **Description** 0000h / Not Masked / Will be reported in the EIR FFFFh / Masked **[Default]** / Will not be reported in the EIR

VCS Error Status Register

VCS_ESR - VCS Error Status Register

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Address:	120B8h
Valid Projects:	CHV, BSW

The ESR register contains the current values of all Hardware-Detected Error condition bits (these are all by definition persistent). The EMR register selects which of these error conditions are reported in the persistent EIR (i.e., set bits must be cleared by software) and thereby causing a Master Error interrupt condition to be reported in the ISR.

DWord	Bit	Description
0	31:16	**Reserved** Format: MBZ
	15:0	**Error Status Bits** Format: Array of error condition bits See the table titled Hardware-Detected Error Bits. This register contains the non-persistent values of all hardware-detected error condition bits.

Value	Name	Description
0h	**[Default]**	
1h	Error Condition Detected	Error Condition detected

VCS Execute Condition Code Register

VCS_EXCC - VCS Execute Condition Code Register

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0x00000000
Access:	R/W, RO
Size (in bits):	32
Trusted Type:	1
Address:	12028h
Valid Projects:	CHV, BSW

This register contains user defined and hardware generated conditions that are used by MI_WAIT_FOR_EVENT commands. An MI_WAIT_FOR_EVENT instruction excludes the executing ring from arbitration if the selected event evaluates to a 1, while instruction is discarded if the condition evaluates to a 0. Once excluded, a ring is enabled into arbitration when the selected condition evaluates to a 0.
This register also contains control for the invalidation of indirect state pointers on context restore.

DWord	Bit	Description
0	31:16	**Mask Bits** Format: Mask[15:0] These bits serve as a write enable for bits 15:0. If this register is written with any of these bits clear the corresponding bit in the field 15:0 will not be modified. Reading these bits always returns 0s.
	15:5	**Reserved** Format: MBZ
	4:0	**Reserved** Project: CHV, BSW Format: MBZ

VCS General Purpose Register

VCS_GPR - VCS General Purpose Register

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0x00000000, 0x00000000
Access:	R/W
Size (in bits):	64
Address:	12600h-1267Fh
Valid Projects:	CHV, BSW

This is a general purpose register bank of sixteen 64-bit registers, used as temporary storage by the MI_MATH command to do ALU operations.

Programming Notes

Any operation that initiates a read to register 0x1266C will return the value of 0x1260c register. This does not include context save or MI_MATH command operation.

DWord	Bit	Description
0	63:0	**Reserved** Format: MBZ

VCS Hardware Status Mask Register

VCS_HWSTAM - VCS Hardware Status Mask Register

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0xFFFFFFFF
Access:	R/W
Size (in bits):	32
Trusted Type:	1
Address:	12098h
Valid Projects:	CHV, BSW

Access: RO for Reserved Control bits

The HWSTAM register has the same format as the Interrupt Control Registers. The bits in this register are "mask" bits that prevent the corresponding bits in the Interrupt Status Register from generating a "Hardware Status Write" (PCI write cycle). Any unmasked interrupt bit (HWSTAM bit set to 0) will allow the Interrupt Status Register to be written to the ISR location (within the memory page specified by the Hardware Status Page Address Register) when that Interrupt Status Register bit changes state.

Programming Notes

- To write the interrupt to the HWSP, the corresponding IMR bit must also be clear (enabled).
- At most 1 bit can be unmasked at any given time.

DWord	Bit	Description
0	31:0	**Hardware Status Mask Register** Default Value: FFFFFFFFh Format: Array of Masks Refer to the table in the Interrupt Control Register section for bit definitions.

VCS IDLE Max Count

VCS_PWRCTX_MAXCNT - VCS IDLE Max Count

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0x00000040 CHV, BSW
Access:	R/W
Size (in bits):	32
Trusted Type:	1
Address:	12054h
Valid Projects:	CHV, BSW

This register contains the time in 0.64us to wait before telling power management hardware the render pipe is IDLE

DWord	Bit	Description
0	31:20	**Reserved** Format: MBZ
	19:0	**Reserved**

VCS Idle Switch Delay

VCS_IDLEDLY - VCS Idle Switch Delay

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	1223Ch
Valid Projects:	CHV, BSW

The IDLEDLY register contains an Idle Delay field which specifies the minimum number of microseconds allowed for command streamer to wait before a context is switched out leading to IDLE state in Execlist mode, i.e following this context switch there is no active element available in HW to execute.
A default value of 0, means that by default, there is no restriction to wait on a context switch leading to IDLE. This register has no significance when Execlists are not enabled.

DWord	Bit	Description
0	31:21	**Reserved** Project: All Format: MBZ
	20:0	**IDLE Delay** Project: All Format: U21 Minimum number of micro-seconds allowed.

VCS Instruction Parser Mode Register

VCS_INSTPM - VCS Instruction Parser Mode Register

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	120C0h-120C3h
Valid Projects:	CHV, BSW

The VCS_INSTPM register is used to control the operation of the VCS Instruction Parser. Certain classes of instructions can be disabled (ignored) - often useful for detecting performance bottlenecks. Also, "Synchronizing Flush" operations can be initiated - useful for ensuring the completion (vs. only parsing) of rendering instructions. DefaultValue=0000 0000h

Programming Notes

All reserved bits are implemented.

DWord	Bit	Description
0	31:16	**Masks** Format: Mask[15:0] These bits serve as write enables for bits 15:0. If this register is written with any of these bits clear the corresponding bit in the field 15:0 will not be modified. Reading these bits always returns 0s.
	15:11	**Reserved** Project: All Format: MBZ
	10	**Reserved**
	9	**Reserved** Project: CHV, BSW Format: MBZ
	8:7	**Reserved** Format: MBZ
	6:5	**Reserved** Project: CHV, BSW Format: MBZ
	4:0	**Reserved** Access: R/W

VCS_INSTPM - VCS Instruction Parser Mode Register			
		Format:	MBZ

VCS Interrupt Mask Register

VCS_IMR - VCS Interrupt Mask Register

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0xFFFFFFFF
Access:	R/W
Size (in bits):	32
Address:	120A8h
Valid Projects:	CHV, BSW

The IMR register is used by software to control which Interrupt Status Register bits are masked or unmasked. Unmasked bits will be reported in the IIR, possibly triggering a CPU interrupt, and will persist in the IIR until cleared by software. Masked bits will not be reported in the IIR and therefore cannot generate CPU interrupts.

DWord	Bit	Description
0	31:0	**Interrupt Mask Bits** Format: Array of interrupt mask bits Refer to the Interrupt Control Register section for bit definitions. This field contains a bit mask which selects which interrupt bits (from the ISR) are reported in the IIR.

Value	Name	Description
FFFF FFFFh	**[Default]**	
0h	Not Masked	Will be reported in the IIR
1h	Masked	Will not be reported in the IIR

VCS Mode Register for Software Interface

VCS_MI_MODE - VCS Mode Register for Software Interface

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0x00000200 CHV, BSW
Access:	R/W
Size (in bits):	32
Address:	1209Ch-1209Fh
Valid Projects:	CHV, BSW

The MI_MODE register contains information that controls software interface aspects of the command parser.

DWord	Bit	Description
0	31:16	**Masks** A 1 in a bit in this field allows the modification of the corresponding bit in Bits 15:0.
	15	**Suspend Flush** Mask: MMIO(0x209c)#31 Value / Name / Description: 0h / No Delay / HW will not delay flush, this bit will get cleared by MI_SUSPEND_FLUSH as well 1h / DelayFlush / Suspend flush is active
	14:12	**Reserved** Access: R/W
	11	**Invalidate UHPTR enable** If bit set H/W clears the valid bit of BCS_UHPTR (4134h, bit 0) when current active head pointer is equal to UHPTR.
	10	**Atomic Read Return for MI_COPY_MEM_MEM** Project: CHV, BSW Format: U1 Value / Name / Description: 0h / Disable **[Default]** / Hardware does a regular memory fence write to complete the write to the destination address before moving to the next instruction. 1h / Enable / Hardware does Atomic Move with Read Return to complete the write to the destination address before moving to the next instruction.

VCS_MI_MODE - VCS Mode Register for Software Interface

	9	**Ring Idle (Read Only Status bit)** Access: RO *Writes to this bit are not allowed.* 0 – Parser not idle 1 – Parser idle **[Default]**
	8	**Stop Ring** Software must set this bit to force the Ring and Command Parser to Idle. Software must read a "1" in Ring Idle bit after setting this bit to ensure that the hardware is idle. *Software must clear this bit for Ring to resume normal operation.* 0 – Normal Operation 1 – Parser is turned off
	7:0	**Reserved** Access: R/W

VCS Reported Timestamp Count

VCS_TIMESTAMP - VCS Reported Timestamp Count	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0x00000000, 0x00000000
Access:	RO. This register is not set by the context restore.
Size (in bits):	64
Address:	12358h
Valid Projects:	CHV, BSW

This register provides an elapsed real-time value that can be used as a timestamp. This register is not reset by a graphics reset. It will maintain its value unless a full chipset reset is performed. Note: This timestamp register reflects the value of the PCU TSC. The PCU TSC counts 10ns increments; this timestamp reflects bits 38:3 of the TSC (i.e. 80ns granularity, rolling over every 1.5 hours).

DWord	Bit	Description
0	63:36	**Reserved** Format: MBZ
	35:0	**Timestamp Value** Format: U36 This register toggles every 80 ns. The upper 28 bits are zero.

VCS Reset Control Register

VCS_RESET_CTRL - VCS Reset Control Register

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	120D0h
Valid Projects:	CHV, BSW

This register is to be used to control soft reset.

DWord	Bit	Description
0	31:16	**Mask Bits** Format: Mask[15:0] Must be set to modify corresponding bit in Bits 15:0. (All implemented bits)
	15:2	**Reserved** Format: MBZ
	1	**Ready for Reset** Format: U1 When set indicates video codec engine is ready for reset. This bit gets cleared on engine reset or when Soft Reset In progress is cleared.
	0	**Request Reset** Format: U1 When set indicates SW wishes to reset the video codec engine. On seeing this bit set Command Streamer will take appropriate action and set Ready For Reset status bit. This bit gets cleared on engine reset.

VCS Ring Buffer Next Context ID Register

VCS_RNCID - VCS Ring Buffer Next Context ID Register

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0x00000000, 0x00000000
Access:	R/W
Size (in bits):	64
Address:	12198h-1219Fh
Valid Projects:	CHV, BSW

This register contains the next ring context ID associated with the ring buffer.

Programming Notes

The current context (RCCID) register can be updated indirectly from this register on a context switch event. Note that this can only be triggered when arbitration is enabled or if the current context runs dry (head pointer becomes equal to tail pointer).

DWord	Bit	Description
0	63:0	**Context ID** See Context Descriptor for VCS.

VCS Semaphore Polling Interval on Wait

VCS_SEMA_WAIT_POLL - VCS Semaphore Polling Interval on Wait

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	1224Ch
Valid Projects:	CHV, BSW

The SEMA_WAIT_POLL register contains Poll Interval field which specifies the minimum number of microseconds allowed for command streamer to wait before re-fetching the data from the address mentioned in the MI_SEMAPHORE_WAIT command on WAIT Mode set to POLL until the condition is satisfied while the context is not switched out. When value of 0 is written the poll interval will be equal to the memory latency of the read completion.

DWord	Bit	Description
0	31:21	**Reserved** Format: MBZ
	20:0	**Poll Interval** Minimum number of micro-seconds allowed

VCS Threshold for the counter of bit stream decode engine

VCS_THRSH - VCS Threshold for the counter of bit stream decode engine

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoCS
Default Value:	0x00150000
Access:	R/W
Size (in bits):	32
Address:	1217Ch-1217Fh

DWord	Bit	Description
0	31:0	**Threshold Value** Default Value: 00150000h The value in this register reflects the number of clocks the bit stream decode engine is expected to run. If the value is exceeded the counter is reset and an interrupt may be enabled in the device.

VCW Clock Count

VCW_CLOCK_CNT - VCW Clock Count			
Register Space:	MMIO: 0/2/0		
Project:	CHV, BSW		
Source:	VideoEnhancementCS		
Default Value:	0x00000000		
Access:	RO		
Size (in bits):	32		
Trusted Type:	1		
Address:	08820h		
ShortName:	VCW0_CLOCK_CNT		
Address:	08920h		
ShortName:	VCW1_CLOCK_CNT		
DWord	**Bit**	**Description**	
0	31:24	**Reserved** Format:	MBZ
	23:0	**Max clock count** Default Value:	0h Maximum number of clocks taken by VCW to process a column

VCW Internal Latency

VCW_INTERNAL_LAT - VCW Internal Latency		
Register Space:	MMIO: 0/2/0	
Project:	CHV, BSW	
Source:	VideoEnhancementCS	
Default Value:	0x00000000	
Access:	RO	
Size (in bits):	32	
Trusted Type:	1	
Address:	08824h	
ShortName:	VCW0_INTERNAL_LAT	
Address:	08924h	
ShortName:	VCW1_INTERNAL_LAT	
DWord	**Bit**	**Description**
0	31:24	**Reserved** Format: MBZ
	23:0	**VCW internal data latency count** Default Value: 0h

VCW Min Max Latency

VCW_MINMAX_LAT - VCW Min Max Latency		
Register Space:	MMIO: 0/2/0	
Project:	CHV, BSW	
Source:	VideoEnhancementCS	
Default Value:	0x00000000	
Access:	RO	
Size (in bits):	32	
Trusted Type:	1	
Address:	08828h	
ShortName:	VCW0_MINMAX_LAT	
Address:	08928h	
ShortName:	VCW1_MINMAX_LAT	
DWord	**Bit**	**Description**
0	31:16	**Current request count** Default Value: 0h
	15:8	**Max latency** Default Value: 0h Maximum number of clocks taken for tag 200h
	7:0	**Min latency** Default Value: 0h Minimum number of clocks taken for tag 200h

VCW Total Latency

VCW_TOTAL_LAT - VCW Total Latency	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoEnhancementCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	0882Ch
ShortName:	VCW0_TOTAL_LAT
Address:	0892Ch
ShortName:	VCW1_TOTAL_LAT

DWord	Bit	Description
0	31:0	**Total latency** Default Value: 0h Accumumation of latency per frame for tag 200h

VCW XY position

VCW_XY_POS - VCW XY position

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoEnhancementCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1

	15:0	**Current X value** Default Value: 0h Current X position of VCW walker

VEBOX TLB Control Register

VTCR - VEBOX TLB Control Register

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04270h

DWord	Bit	Description
0	31:1	**Reserved** Default Value: 00000000000000000000000000000000b Access: RO
	0	**Invalidate TLBs on the corresponding Engine** Default Value: 0b Access: R/W SW writes 1 to invalidate the TLBs for the associated engine and HW clears the bit when invalidation is complete. To ensure proper invalidation of the TLBs, SW has to ensure the corresponding engine's HW pipeline is flushed and cleared from all its memory accesses. Otherwise HW cannot guarantee the proper invalidation for TLBs. This bit is self clear.

VEBX Context Element Descriptor (High Part)

VEBX_CTX_EDR_H - VEBX Context Element Descriptor (High Part)	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	044C4h

DWord	Bit	Description
0	31:0	**VEBX Context Element Descriptor (High Part)** Default Value: 00000000h Access: R/W

VEBX Context Element Descriptor (Low Part)

VEBX_CTX_EDR_L - VEBX Context Element Descriptor (Low Part)

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW

0	31:0	**VEBX PDP3 Descriptor Register (Low Part)** Default Value: 00000000h Access: R/W

VECS_PREEMPTION_HINT

VECS_PREEMPTION_HINT - VECS_PREEMPTION_HINT

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoEnhancementCS
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	1A4BCh

This register contains the Head pointer offset in to the Ring Buffer or the Dword aligned Graphics address in to the Batch Buffer corresponding to either MI_ARB_CHECK called Preemption Hint Address. When Preemption Hint Address is enabled, VECS will honor UHPTR only on parsing MI_ARB_CHK at Preemption Hint Address.

This register contains the Head pointer offset into the Ring Buffer or the Dword aligned Graphics address into the Batch Buffer corresponding to the below listed commands in execlist mode of operation

- MI_ARB_CHECK
- MI_WAIT_FOR_EVENT
- MI_SEMAPHORE_WAIT

Programming Notes

Programming Restriction:This register should NEVER be programmed in functional mode, this should be used only in validation mode to achieve deterministic behavior of UHPTR being sampled by a given MI_ARB_CHECK in command stream. Programmer has to ensure that VECS Preemption Hint register gets programmed before UHPTR is programmed and well before VECS crosses the corresponding execution point. Preemption hint for both RingBuffer and Batch Buffer can't be enabled simultaneously.

DWord	Bit	Description
0	31:2	**Preempted Hint Address** Format: U30 Format: GraphicsAddress[31:2] This field contains the Head offset in to the Ring Buffer when Preemption Hint is set to Ring Buffer and Dword aligned Graphics Address in to the batch buffer when Preemption Hint is set to Batch Buffer.
	1	**Batch Buffer Preemption Hint** Format: Enable 0h Disabled: Preemption hint is disabled in batch buffer. 1h Enabled: Preemption hint is enabled in ring buffer and preemption hint address corresponds to the instruction in Batch Buffer.

VECS_PREEMPTION_HINT - VECS_PREEMPTION_HINT

	0	**Ring Preemption Hint** Format: Enable **Value** / **Name** / **Description** 0h / Disable / Preemption hint is disabled in ring buffer. 1h / Enabled / Preemption hint is enabled in ring buffer and preemption hint address corresponds to the instruction in Ring Buffer.

VECS Context ID Preemption Hint

VECS_CTXID_PREEMPTION_HINT - VECS Context ID Preemption Hint

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoEnhancementCS
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	1A4CCh

This register contains the Context ID of a context in Execlist mode of operation. In execlist mode of operation VECS_PREEMPTION_HINT registers are looked at by Video Enhancement Command Streamer on executing a context having Context ID that matches with the contents of this register. This register contents are valid and looked at only in Execlist mode of operation.

Programming Notes

This register should NEVER be programmed in functional mode, this must be used only in validation mode to achieve deterministic preemption behavior in execlist mode of operation.

DWord	Bit	Description
0	31:0	**Context ID Preemption Hint** Format: U32 If 0 this field has no effect. If nonzero it indicates the only context ID that can be preempted when execlists are enabled. A preemption attempt when the context ID of the currently executing ring context does not match this field will be ignored.

VECS Context Timestamp Count

VECS_CTX_TIMESTAMP - VECS Context Timestamp Count

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoEnhancementCS
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	1A3A8h

This register provides a mechanism to obtain cumulative run time of a GPU context on HW. This register gets context save/restored on a context switch. SW must reset this register on very first submission of a context to HW, then afterwards gets context save/restored maintaining the cumulative run time of the corresponding context. Note that the value of this register can be obtained in a 3D pipeline-synchronous fashion without a pipeline flush by using the PIPE_CONTROL command. See 3D Geometry Pipeline in the "3D and Media" volume. This register (effectively) counts at a constant frequency by adjusting the increment amount according to the actual reference clock frequency. SW therefore does not need to know the reference clock frequency. This register gets reset on an engine reset.

This register is context save restore on a context switch.

DWord	Bit	Description
0	31:0	**Timestamp Value** Format: U32 This register increments for every 80 ns of time.

VECS Counter for the Video Enhancement Engine

VECS_CNTR - VECS Counter for the Video Enhancement Engine

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoEnhancementCS
Default Value:	0xFFFFFFFF
Access:	R/W
Size (in bits):	32
Address:	1A178h

DWord	Bit	Description
0	31:0	**Count Value** Default Value: ffffffffh Writing a Zero value to this register starts the counting. Writing a Value of FFFF FFFF to this counter stops the counter.

VECS Error Identity Register

VECS_EIR - VECS Error Identity Register

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoEnhancementCS
Default Value:	0x00000000
Access:	R/WC
Size (in bits):	32
Address:	1A0B0h

The EIR register contains the persistent values of Hardware-Detected Error Condition bits. Any bit set in this register will cause the Master Error bit in the ISR to be set. The EIR register is also used by software to clear detected errors (by writing a '1' to the appropriate bit(s) except for the unrecoverable bits described).

DWord	Bit	Description
0	31:16	**Reserved** Project: All Format: MBZ
	15:0	**Error Identity Bits** Project: All Format: Array of Error condition bits See Table 1 5. Hardware-Detected Error Bits This register contains the persistent values of ESR error status bits that are unmasked via the EMR register. (See **Error! Reference source not found**.). The logical OR of all (defined) bits in this register is reported in the Master Error bit of the Interrupt Status Register. In order to clear an error condition, software must first clear the error by writing a '1' to the appropriate bit(s) in this field. If required, software should then proceed to clear the Master Error bit of the IIR.

Value	Name	Description	Project
0h	**[Default]**		
1h	Error occurred	Error occurred	All

Programming Notes

Writing a '1' to a set bit will cause that error condition to be cleared. However, the Page Table Error bit (Bit 4) can not be cleared except by reset (i.e., it is a fatal error).

VECS Error Mask Register

VECS_EMR - VECS Error Mask Register

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoEnhancementCS
Default Value:	0xFFFFFFFF CHV, BSW
Access:	R/W
Size (in bits):	32
Address:	1A0B4h

The EMR register is used by software to control which Error Status Register bits are "masked" or "unmasked". "Unmasked" bits will be reported in the EIR, thus setting the Master Error ISR bit and possibly triggering a CPU interrupt, and will persist in the EIR until cleared by software. "Masked" bits will not be reported in the EIR and therefore cannot generate Master Error conditions or CPU interrupts.

Undefined or reserved bits in the Hardware Detected Error Bit Table will always return a read value of '1'

<table>
<tr><th>DWord</th><th>Bit</th><th>Description</th></tr>
<tr><td rowspan="2">0</td><td>31:16</td><td>Reserved
<table>
<tr><td>Default Value:</td><td>FFFFh</td></tr>
<tr><td>Project:</td><td>CHV, BSW</td></tr>
<tr><td>Format:</td><td>Must Be One</td></tr>
</table></td></tr>
<tr><td>15:0</td><td>Error Mask Bits
<table>
<tr><td>Project:</td><td>All</td></tr>
<tr><td>Format:</td><td>Array of error condition mask bits See Table 1 5. Hardware-Detected Error Bits</td></tr>
</table>
This register contains a bit mask that selects which error condition bits (from the ESR) are reported in the EIR.
<table>
<tr><th>Value</th><th>Name</th><th>Description</th></tr>
<tr><td>0000h</td><td>Not Masked</td><td>Will be reported in the EIR</td></tr>
<tr><td>FFFFh</td><td>Masked [Default]</td><td>Will not be reported in the EIR</td></tr>
</table></td></tr>
</table>

VECS Error Status Register

VECS_ESR - VECS Error Status Register

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoEnhancementCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Address:	1A0B8h

The ESR register contains the current values of all Hardware-Detected Error condition bits (these are all by definition "persistent"). The EMR register selects which of these error conditions are reported in the persistent EIR (i.e., set bits must be cleared by software) and thereby causing a Master Error interrupt condition to be reported in the ISR.

DWord	Bit	Description
0	31:16	**Reserved** Project: All Format: MBZ
	15:0	**Error Status Bits** Project: All Format: Array of error condition bits See Table 1 5. Hardware-Detected Error Bits This register contains the non-persistent values of all hardware-detected error condition bits.

Value	Name	Description	Project
0h	**[Default]**		
1h	Error Condition Detected	Error Condition detected	All

VECS General Purpose Register

VECS_GPR - VECS General Purpose Register

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoEnhancementCS
Default Value:	0x00000000, 0x00000000
Access:	R/W
Size (in bits):	64

Address: 1A600h-1A67Fh

This is a general purpose register bank of sixteen 64-bit registers, used as temporary storage by the MI_MATH command to do ALU operations.

Programming Notes	Project
Any operation that initiates a read to register 0x1A66C will return the value of 0x1A60c register. This does not include context save or MI_MATH command operation.	CHV, BSW

DWord	Bit	Description
0	63:0	**Reserved** Format: MBZ

VECS Hardware Status Mask Register

VECS_HWSTAM - VECS Hardware Status Mask Register

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoEnhancementCS
Default Value:	0xFFFFFFFF
Access:	R/W
Size (in bits):	32
Trusted Type:	1
Address:	1A098h

Access: RO for Reserved Control bits

The HWSTAM register has the same format as the Interrupt Control Registers. The bits in this register are "mask" bits that prevent the corresponding bits in the Interrupt Status Register from generating a "Hardware Status Write" (PCI write cycle). Any unmasked interrupt bit (HWSTAM bit set to 0) will allow the Interrupt Status Register to be written to the ISR location (within the memory page specified by the Hardware Status Page Address Register) when that Interrupt Status Register bit changes state.

Programming Notes

- To write the interrupt to the HWSP, the corresponding IMR bit must also be clear (enabled).
- At most 1 bit can be unmasked at any given time.

DWord	Bit	Description
0	31:0	**Hardware Status Mask Register** Default Value: FFFFFFFFh Project: All Format: Array of Masks refer to Table 4-4 in Interrupt Control Register section for bit definitions

VECS IDLE Max Count

VECS_PWRCTX_MAXCNT - VECS IDLE Max Count

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoEnhancementCS
Default Value:	0x00000040
Access:	R/W
Size (in bits):	32
Trusted Type:	1
Address:	1A054h

This register contains the time in 0.64us to wait before telling power management hardware the render pipe is IDLE

DWord	Bit	Description
0	31:20	**Reserved** Project: All Format: MBZ
	19:0	**Reserved**

VECS Instruction Parser Mode Register

VECS_INSTPM - VECS Instruction Parser Mode Register

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoEnhancementCS
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	1A0C0h-1A0C3h

The VECS_INSTPM register is used to control the operation of the VECS Instruction Parser. Certain classes of instructions can be disabled (ignored) - often useful for detecting performance bottlenecks. Also, "Synchronizing Flush" operations can be initiated - useful for ensuring the completion (vs. only parsing) of rendering instructions.

Programming Notes

All reserved bits are implemented

DWord	Bit	Description
0	31:16	**Masks** Format: Mask[15:0] These bits serve as write enables for bits 15:0. If this register is written with any of these bits clear the corresponding bit in the field 15:0 will not be modified. Reading these bits always returns 0s.
	15:11	**Reserved** Project: All Format: MBZ
	10	**Reserved**
	9	**Reserved** Project: CHV, BSW Format: MBZ
	8:7	**Reserved** Format: MBZ
	6:5	**Reserved** Project: CHV, BSW Format: MBZ
	4:0	**Reserved**

VECS Interrupt Mask Register

VECS_IMR - VECS Interrupt Mask Register

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoEnhancementCS
Default Value:	0xFFFFFFFF
Access:	R/W
Size (in bits):	32
Address:	1A0A8h

The IMR register is used by software to control which Interrupt Status Register bits are "masked" or "unmasked". "Unmasked" bits will be reported in the IIR, possibly triggering a CPU interrupt, and will persist in the IIR until cleared by software. "Masked" bits will not be reported in the IIR and therefore cannot generate CPU interrupts.

DWord	Bit	Description
0	31:0	**Interrupt Mask Bits** Project: All Format: Array of interrupt mask bits Refer to Table 4-4 in Interrupt Control Register section for bit definitions This field contains a bit mask which selects which interrupt bits (from the ISR) are reported in the IIR.

Value	Name	Description	Project
FFFF FFFFh	**[Default]**		
0h	Not Masked	Will be reported in the IIR	All
1h	Masked	Will not be reported in the IIR	All

VECS Mode Register for Software Interface

VECS_MI_MODE - VECS Mode Register for Software Interface

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoEnhancementCS
Default Value:	0x00000200 CHV, BSW
Access:	R/W
Size (in bits):	32
Address:	1A09Ch-1A09Fh

The MI_MODE register contains information that controls software interface aspects of the command parser

DWord	Bit	Description
0	31:16	**Masks** A "1" in a bit in this field allows the modification of the corresponding bit in Bits 15:0
	15	**Suspend Flush** Project: All Mask: MMIO(0x209c)#31 Value / Name / Description: 0h / No Delay / HW will not delay flush, this bit will get cleared by MI_SUSPEND_FLUSH as well 1h / Delay Flush / Suspend flush is active
	14:12	**Reserved** Format: MBZ
	11	**Invalidate UHPTR Enable** If bit set H/W clears the valid bit of BCS_UHPTR (4134h, bit 0) when current active head pointer is equal to UHPTR.
	10	**Atomic Read Return for MI_COPY_MEM_MEM** Project: CHV, BSW Format: U1 Value / Name / Description: 0h / Disable **[Default]** / Hardware does a regular memory fence write to complete the write to the destination address before moving to the next instruction. 1h / Enable / Hardware does Atomic Move with Read Return to complete the write to the destination address before moving to the next instruction.

VECS_MI_MODE - VECS Mode Register for Software Interface

	9	**Ring Idle (Read Only Status bit)** *Writes to this bit are not allowed.* **Value** / **Name** 0 – Parser not idle 1 – Parser idle **[Default]**
	8	**Stop Ring** 0 = Normal Operation. 1 = Parser is turned off. Software must set this bit to force the Ring and Command Parser to Idle. Software must read a "1" in Ring Idle bit after setting this bit to ensure that the hardware is idle. *Software must clear this bit for Ring to resume normal operation.*
	7:0	**Reserved** Format: MBZ

VECS PREEMPTION HINT UDW

VECS_PREEMPTION_HINT_UDW - VECS PREEMPTION HINT UDW

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoEnhancementCS
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	1A4C8h

This register contains the 4GB aligned base address of gfx 4GB virtual address space within the host's 64-bit virtual address space of the Batch Buffer corresponding to MI_ARB_CHECK command called Preemption Hint Address.

Programming Notes

Programming Restriction:This register should NEVER be programmed in functional mode, this should be used only in validation mode to achieve deterministic behavior of UHPTR being sampled by a given MI_ARB_CHK in command stream.

DWord	Bit	Description
0	31:16	**Reserved** Format: MBZ
	15:0	**Preempted Hint Address Upper DWORD** Format: GraphicsAddress[47:32] This field contains the 4GB aligned base address of gfx 4GB virtual address space within the host's 64-bit virtual address space of the batch buffer when Preemption Hint is set to Batch Buffer. This field is not valid when Preemption Hint is set to Ring Buffer.

VECS Reported Timestamp Count

VECS_TIMESTAMP - VECS Reported Timestamp Count

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoEnhancementCS
Default Value:	0x00000000, 0x00000000
Access:	RO. This register is not set by the context restore.
Size (in bits):	64
Address:	1A358h

This register provides an elapsed real-time value that can be used as a timestamp. This register is *not* reset by a graphics reset. It will maintain its value unless a full chipset reset is performed. Note: This timestamp register reflects the value of the PCU TSC. The PCU TSC counts 10ns increments; this timestamp reflects bits 38:3 of the TSC (i.e. 80ns granularity, rolling over every 1.5 hours).

DWord	Bit	Description
0	63:36	**Reserved** Project: All Format: MBZ
	35:0	**TimeStampValue** Project: All Format: U36 This register toggles every 80 ns. The upper 28 bits are zero.

VECS Reset Control Register

VECS_RESET_CTRL - VECS Reset Control Register	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoEnhancementCS
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	1A0D0h

This register is to be used to control soft reset.

DWord	Bit	Description
0	31:16	**Mask Bits** Format: Mask[15:0] Must be set to modify corresponding bit in Bits 15:0. (All implemented bits)
	15:2	**Reserved** Format: MBZ
	1	**Ready for Reset** Format: U1 When set indicates video enhancement engine is ready for reset. This bit gets cleared on engine reset or when Soft Reset In progress is cleared.
	0	**Request Reset** Format: U1 When set indicates SW wishes to reset the video enhancement engine. On seeing this bit set Command Streamer will take appropriate action and set Ready For Reset status bit. This bit gets cleared on engine reset.

VECS Semaphore Polling Interval on Wait

VECS_SEMA_WAIT_POLL - VECS Semaphore Polling Interval on Wait

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoEnhancementCS
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	1A24Ch

The SEMA_WAIT_POLL register contains Poll Interval field which specifies the minimum number of microseconds allowed for command streamer to wait before re-fetching the data from the address mentioned in the MI_SEMAPHORE_WAIT command on WAIT Mode set to POLL until the condition is satisfied while the context is not switched out. When value of 0 is written the poll interval will be equal to the memory latency of the read completion.

DWord	Bit	Description
0	31:21	**Reserved** Format: MBZ
	20:0	**Poll Interval** Minimum number of micro-seconds allowed

VECS Threshold for the Counter of Video Enhancement Engine

VECS_CTR_THRSH - VECS Threshold for the Counter of Video Enhancement Engine

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoEnhancementCS
Default Value:	0x00150000
Access:	R/W
Size (in bits):	32
Address:	1A17Ch

DWord	Bit	Description
0	31:0	**Threshold Value** Default Value: 00150000h The value in this register reflects the number of clocks the bit stream decode engine is expected to run. If the value is exceeded the counter is reset and an interrupt may be enabled in the device.

VEO Current Pipe 0 XY Register

VEO_CURRENT0_XY - VEO Current Pipe 0 XY Register	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoEnhancementCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32

VF will not allow pre-emption in the guardband region. 1h / Disable / When set to Disable**,** there will not be any preemption or GB consideration for autodraw (3DPRIMITIVE.End Offset Enable set to 1).
	7	**Guardband Disable** Format: U1 Value / Name / Description: 0h / Enable **[Default]** / VF will use the guardband to determine when a draw call can be pre-empted. VF will not allow pre-emption in the guardband region. 1h / Disable / VF will not use the guardband to determine when a draw call can be pre-empted. VF will allow pre-emption on any vertex in the draw call.

VFSKPD - VF Scratch Pad

	6	**Reserved**
	5	**TLB Prefectch Enable** Project: CHV, BSW Format: U1 Value 0h: Name: Disable **[Default]**; Description: The VF will generate prefetch of TLB when it is fetching sequential vertex data and four or fewer vertex buffers are valid. Value 1h: Name: Enable; Description: VF will disable prefetch of TLB entries.
	4	**Reserved**
	3	**Reserved**
	2	**Vertex Cache Implicit Disable Inhibit** Format: U1 Value 0h: Name: **[Default]**; Description: Allow VF to disable VS0 when Sequential index or Prim ID is a valid Element. Value 1h: Name: ; Description: VF never implicitly disables the vertex cache. Software must disable the VS0 Cache when required.
	1	**Disable Over Fetch Cache** Project: CHV, BSW Value 0h: Name: **[Default]**; Description: Cache will check for data in cache before making a request to memory Value 1h: Name: ; Description: Always re-fetch new data from memory. **Programming Notes** Note that the Disable Multiple Miss Read squash bit must be cleared for Disable Over Fetch Cache to be set.
	0	**Disable Multiple Miss Read squash** Project: CHV, BSW Format: Disable Value 0h: Name: **[Default]**; Description: Allow VF to squash reads that are to the same cacheline for vertex buffer requests. Value 1h: Name: ; Description: Disallow VF from squashing reads that are to the same cacheline for vertex buffer requests.

VFW Credit Count Register

VFW_CREDIT_CNT - VFW Credit Count Register		
Register Space:	MMIO: 0/2/0	
Project:	CHV, BSW	
Source:	VideoEnhancementCS	
Default Value:	0x00000002 CHV, BSW	
Access:	RO	
Size (in bits):	32	
Trusted Type:	1	
Address:	08810h	
Address:	08910h	

DWord	Bit	Description
0	31:8	**Reserved**
	7:0	**Credit Count** The number of outstanding credits between VFW and GAV. If zero VEBOX cannot proceed due to GAV not releasing credits.

Value	Name	Project
2h	**[Default]**	CHV, BSW

VIC Virtual page Address Registers

VICTLB_VA - VIC Virtual page Address Registers

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	RenderCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	04900h-04903h

These registers are directly mapped to the current Virtual Addresses in the VICTLB (Vertex Fetch, Instruction Cache, and Command Streamer TLB.)

DWord	Bit	Description
0	31:12	**Address** Format: GraphicsAddress[31:12] Page virtual address.
	11:0	**Reserved** Format: MBZ

VIDEOBUSYCOUNTER

VIDEOBUSYCOUNTER - VIDEOBUSYCOUNTER

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	138124h

SOXi Context Save/Restore : No
The 40-bit HW counter will wrap around. The only clear condition is CZ reset.
When 0x13_8104[15] is set to zero, bits 31:0 of the 40-bit counter are reported. When 0x13_8104[15] is set to one, its 39:8 of the 40-bit counter are reported.
The units are CZ clock cycles.
It is up to SW to periodically read this register and do a difference from the last time it was read. The primary usage for those registers for power characterization.
0x13_8104[7] controls if this register should count or if it should be gated: 0= clear, 1= count

DWord	Bit	Description
0	31:0	**VIDEOBUSYTIME** Default Value: 00000000h Access: RO Render RC0 Residency Counter.

Video Enhancement Mode Register

VEBOX_MODE - Video Enhancement Mode Register

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	VideoEnhancementCS
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Trusted Type:	1
Address:	1A29Ch

DWord	Bit	Description
0	31:16	**Mask Bits** Format: Mask[15:0] Must be set to modify corresponding bit in Bits 15:0. (All implemented bits)
	15	**Execlist Enable** Default Value: 0h Project: CHV, BSW Mask: MMIO#31 When set, software can utilize the execlist registers to load a context into hardware. When this bit is clear the execlist mechanism cannot be used. The ring must be loaded via MMIO access. **Programming Notes** This bit is not intended to be changed dynamically. Changing the value of this bit while rendering is in progress will have UNDEFINED results. This bit should be changed only after a full reset and before submitting any commands to the device
	14	**Interrupt Steering Bit** Project: CHV, BSW Format: U1 When set, Command Streamer sends interrupt messages to the SHIM of the ON CHIP Micro Controller through message channel. When reset, Command Streamer sends the interrupt messages to Display Engine as config writes on GAM interface.
	13:10	**Reserved** Project: All Format: MBZ
	9	**Per-Process GTT Enable** Project: All Format: Enable Per-Process GTT BS Mode Enable

VEBOX_MODE - Video Enhancement Mode Register

Value	Name	Description
0h	PPGTT Disable **[Default]**	When clear, the Global GTT will be used to translate memory access from designated commands and for commands that select the PPGTT as their translation space in Basic Scheduler Mode.
1h	PPGTT Enable	When set, the PPGTT will be used to translate memory access from designated commands and for commands that select the PPGTT as their translation space.

Programming Notes	Project
This bit is used for enabling PPGTT access in Ring Buffer mode of scheduling. Privilege field in context descriptor states the same in Execlist mode of scheduling. This field should be set before programming PDP0/1/2/3 registers in order to set the PPGTT translation of memory access.	CHV, BSW

8 **Reserved**

Project:	CHV, BSW

7 **64Bit Virtual Addressing Enable**

Project:	CHV, BSW
Format:	Enable

Per-Process GTT Enable

Value	Name	Description	Project
0h	64Bit Virtual Addressing Disable **[Default]**	When clear indicates GFX operating in 32bit Virtual Addressing for PPGTT based memory access.	All

Programming Notes
This bit is only valid when PPGTT is enabled in ring buffer mode of scheduling. Context Descriptor has a similar bit to control 64bit virtual addressing in execlist mode of scheduling. Irrespective of this field set or clear virtual addresses translated through GGTT are always 32Bit. This field should be programmed before enabling PPGTT access. When this field is not set or for GGTT virtual addresses, Graphics Address [47:32] field of any commands or register exercised by SW should be programmed to 0x0.
64 Bit Virtual Addressing is not supported on CHV, BSW and must not be set.

If a flip request is pending, the parser will wait until the flip operation has completed (i.e., the new front buffer address has now been loaded into the active front buffer registers). See Display Flip Pending Condition (in the Device Programming Interface chapter of MI Functions.
	13	**Display Plane B Syncronous Flip Pending Wait Enable** Format: Enable This field enables a wait for the duration of a Display Plane B Flip Pending condition. If a flip request is pending, the parser will wait until the flip operation has completed (i.e., the new front buffer address has now been loaded into the active front buffer registers). See Display Flip Pending Condition (in the Device Programming Interface chapter of MI Functions.
	12	**Display Sprite B Syncronous Flip Pending Wait Enable** Format: Enable

SYNC_FLIP_STATUS - Wait For Event and Display Flip Flags Register

		This field enables a wait for the duration of a Display Sprite B Flip Pending condition. If a flip request is pending, the parser will wait until the flip operation has completed (i.e., the new front buffer address has now been loaded into the active front buffer registers). See Display Flip Pending Condition in the Device Programming Interface chapter of MI Functions.
	11	**Reserved** Format: MBZ
	10	**Display Pipe B Scan Line Wait Enable** Format: Enable This field enables a wait while a Display Pipe B Scan Line condition exists. This condition is defined as the the start of the scan line specified in the Pipe B Display Scan Line Count Range Compare Register. See Scan Line Event in the Device Programming Interface chapter of MI Functions.
	9	**Display Pipe B Vertical Blank Wait Enable** Format: Enable This field enables a wait until the next Display Pipe B Vertical Blank event occurs. This event is defined as the start of the next Display Pipe B vertical blank period. Note that this can cause a wait for up to an entire refresh period. See Vertical Blank Event (See Programming Interface).

Wait For Event and Display Flip Flags Register 1

SYNC_FLIP_STATUS_1 - Wait For Event and Display Flip Flags Register 1

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32

Address:	022D4h
Name:	RCS Wait For Event and Display Flip Flags Register 1
ShortName:	RCS_SYNC_FLIP_STATUS_1

Address:	122D4h-122D7h
Name:	Wait For Event and Display Flip Flags Register 1
ShortName:	SYNC_FLIP_STATUS_1_VCSUNIT0

Address:	1A2D4h-1A2D7h
Name:	Wait For Event and Display Flip Flags Register 1
ShortName:	SYNC_FLIP_STATUS_1_VECSUNIT

Address:	1C2D4h-1C2D7h
Name:	Wait For Event and Display Flip Flags Register 1
ShortName:	SYNC_FLIP_STATUS_1_VCSUNIT1

Address:	222D4h
Name:	BCS Wait For Event and Display Flip Flags Register 1
ShortName:	BCS_SYNC_FLIP_STATUS_1
Valid Projects:	CHV, BSW

This register is the saved value of what wait for events are still valid. This register is part of context save and restore for RC6 feature.

DWord	Bit	Description
0	31:27	**Reserved**
	26	**Display Sprite C3 Synchronous Flip Pending Wait Enable** Project: CHV, BSW Format: Enable This field enables a wait for the duration of a Display Sprite C3 Flip Pending condition. If a flip request is pending, the parser will wait until the flip operation has completed (i.e., the new front buffer address has now been loaded into the active front buffer registers). See Display Flip Pending Condition in the Device Programming Interface chapter of MI Functions.

SYNC_FLIP_STATUS_1 - Wait For Event and Display Flip Flags Register 1

	25	**Display Sprite C3 Synchronous Flip Display Pending** Project: CHV, BSW Format: Enable This field enables a wait for the duration of a Display Sprite C3 Flip Pending condition. If a flip request is pending, the parser will wait until the flip operation has completed (i.e., the new front buffer address has now been loaded into the active front buffer registers). See Display Flip Pending Condition in the Device Programming Interface chapter of MI Functions.
	24	**Display Sprite B3 Synchronous Flip Pending Wait Enable** Project: CHV, BSW Format: Enable This field enables a wait for the duration of a Display Sprite B3 Flip Pending condition. If a flip request is pending, the parser will wait until the flip operation has completed (i.e., the new front buffer address has now been loaded into the active front buffer registers). See Display Flip Pending Condition in the Device Programming Interface chapter of MI Functions.
	23	**Display Sprite B3 Synchronous Flip Display Pending** Project: CHV, BSW Format: Enable This field enables a wait for the duration of a Display Sprite B3 Flip Pending condition. If a flip request is pending, the parser will wait until the flip operation has completed (i.e., the new front buffer address has now been loaded into the active front buffer registers). See Display Flip Pending Condition in the Device Programming Interface chapter of MI Functions.
	22	**Display Sprite A3 Synchronous Flip Pending Wait Enable** Project: CHV, BSW Format: Enable This field enables a wait for the duration of a Display Sprite A3 Flip Pending condition. If a flip request is pending, the parser will wait until the flip operation has completed (i.e., the new front buffer address has now been loaded into the active front buffer registers). See Display Flip Pending Condition in the Device Programming Interface chapter of MI Functions.
	21	**Display Sprite A3 Synchronous Flip Display Pending** Project: CHV, BSW Format: Enable This field enables a wait for the duration of a Display Sprite A3 Flip Pending condition. If a flip request is pending, the parser will wait until the flip operation has completed (i.e., the new front buffer address has now been loaded into the active front buffer registers). See Display Flip Pending Condition in the Device Programming Interface chapter of MI Functions.

SYNC_FLIP_STATUS_1 - Wait For Event and Display Flip Flags Register 1

	20	**Display Sprite C2 Synchronous Flip Pending Wait Enable** Project: CHV, BSW Format: Enable This field enables a wait for the duration of a Display Sprite C2 Flip Pending condition. If a flip request is pending, the parser will wait until the flip operation has completed (i.e., the new front buffer address has now been loaded into the active front buffer registers). See Display Flip Pending Condition in the Device Programming Interface chapter of MI Functions.
	19	**Display Sprite C2 Synchronous Flip Display Pending** Project: CHV, BSW Format: Enable This field enables a wait for the duration of a Display Sprite C2 Flip Pending condition. If a flip request is pending, the parser will wait until the flip operation has completed (i.e., the new front buffer address has now been loaded into the active front buffer registers). See Display Flip Pending Condition in the Device Programming Interface chapter of MI Functions.
	18	**Display Sprite B2 Synchronous Flip Pending Wait Enable** Project: CHV, BSW Format: Enable This field enables a wait for the duration of a Display Sprite B2 Flip Pending condition. If a flip request is pending, the parser will wait until the flip operation has completed (i.e., the new front buffer address has now been loaded into the active front buffer registers). See Display Flip Pending Condition in the Device Programming Interface chapter of MI Functions.
	17	**Display Sprite B2 Synchronous Flip Display Pending** Project: CHV, BSW Format: Enable This field enables a wait for the duration of a Display Sprite B2 Flip Pending condition. If a flip request is pending, the parser will wait until the flip operation has completed (i.e., the new front buffer address has now been loaded into the active front buffer registers). See Display Flip Pending Condition in the Device Programming Interface chapter of MI Functions.
	16	**Display Sprite A2 Synchronous Flip Pending Wait Enable** Project: CHV, BSW Format: Enable This field enables a wait for the duration of a Display Sprite A2 Flip Pending condition. If a flip request is pending, the parser will wait until the flip operation has completed (i.e., the new front buffer address has now been loaded into the active front buffer registers). See Display Flip Pending Condition in the Device Programming Interface chapter of MI Functions.

SYNC_FLIP_STATUS_1 - Wait For Event and Display Flip Flags Register 1

	15	**Display Sprite A2 Synchronous Flip Display Pending** Project: CHV, BSW Format: Enable This field enables a wait for the duration of a Display Sprite A2 Flip Pending condition. If a flip request is pending, the parser will wait until the flip operation has completed (i.e., the new front buffer address has now been loaded into the active front buffer registers). See Display Flip Pending Condition in the Device Programming Interface chapter of MI Functions.
	14	**Display Plane C Scan Line Event Pending** Project: CHV, BSW Format: Enable This field indicates scan line event operation is pending from Display Plane-C. This field gets set when MI_SCANLINE_INCL/EXCL command is parsed for Display Plane-C and gets reset on scan line event completion for Display Plane-C.
	13	**Display Plane B Scan Line Event Pending** Project: CHV, BSW Format: Enable This field indicates scan line event operation is pending from Display Plane-B. This field gets set when MI_SCANLINE_INCL/EXCL command is parsed for Display Plane-B and gets reset on scan line event completion for Display Plane-B.
	12	**Display Plane A Scan Line Event Pending** Project: CHV, BSW Format: Enable This field indicates scan line event operation is pending from Display Plane-A. This field gets set when MI_SCANLINE_INCL/EXCL command is parsed for Display Plane-A and gets reset on scan line event completion for Display Plane-A.
	11	**Reserved** Project: CHV, BSW Format: MBZ
	10	**Display Plane C Asyncronous Display Flip Pending** Format: Enable This field enables a wait for the duration of a Display Plane C Flip Pending condition. If a flip request is pending, the parser will wait until the flip operation has completed (i.e., the new front buffer address has now been loaded into the active front buffer registers). See Display Flip Pending Condition (in the Device Programming Interface chapter of MI Functions.

SYNC_FLIP_STATUS_1 - Wait For Event and Display Flip Flags Register 1

	9	**Display Plane C Syncronous Flip Display Pending** Format: Enable This field enables a wait for the duration of a Display Plane C Flip Pending condition. If a flip request is pending, the parser will wait until the flip operation has completed (i.e., the new front buffer address has now been loaded into the active front buffer registers). See Display Flip Pending Condition (in the Device Programming Interface chapter of MI Functions.
	8	**Display Sprite C Syncronous Flip Display Pending** Format: Enable This field enables a wait for the duration of a Display Sprite C Flip Pending condition. If a flip request is pending, the parser will wait until the flip operation has completed (i.e., the new front buffer address has now been loaded into the active front buffer registers). See Display Flip Pending Condition in the Device Programming Interface chapter of MI Functions.
	7	**Reserved** Source: BlitterCS Format: MBZ
	7	**Display Plane C Asyncronous Performance Flip Pending Wait Enable** Source: RenderCS Format: Enable This field enables a wait for the duration of a Display Plane C Flip Pending condition. If a flip request is pending, the parser will wait until the flip operation has completed (i.e., the new front buffer address has now been loaded into the active front buffer registers). See Display Flip Pending Condition (in the Device Programming Interface chapter of MI Functions.
	6	**Display Plane C Asyncronous Flip Pending Wait Enable** Format: Enable This field enables a wait for the duration of a Display Plane C "Flip Pending" condition. If a flip request is pending, the parser will wait until the flip operation has completed (i.e., the new front buffer address has now been loaded into the active front buffer registers). See Display Flip Pending Condition (in the Device Programming Interface chapter of MI Functions.
	5	**Display Plane C Syncronous Flip Pending Wait Enable** Format: Enable This field enables a wait for the duration of a Display Plane C Flip Pending condition. If a flip request is pending, the parser will wait until the flip operation has completed (i.e., the new front buffer address has now been loaded into the active front buffer registers). See Display Flip Pending Condition (in the Device Programming Interface chapter of MI Functions.

SYNC_FLIP_STATUS_1 - Wait For Event and Display Flip Flags Register 1

	4	**Display Sprite C Syncronous Flip Pending Wait Enable** Format: Enable This field enables a wait for the duration of a Display Sprite C Flip Pending condition. If a flip request is pending, the parser will wait until the flip operation has completed (i.e., the new front buffer address has now been loaded into the active front buffer registers). See Display Flip Pending Condition in the Device Programming Interface chapter of MI Functions.
	3	**Reserved** Format: MBZ
	2	**Display Pipe C Scan Line Wait Enable** Format: Enable This field enables a wait while a Display Pipe C Scan Line condition exists. This condition is defined as the the start of the scan line specified in the Pipe C Display Scan Line Count Range Compare Register. See Scan Line Event in the Device Programming Interface chapter of MI Functions.
	1	**Display Pipe C Vertical Blank Wait Enable** Format: Enable This field enables a wait until the next Display Pipe C Vertical Blank event occurs. This event is defined as the start of the next Display Pipe C vertical blank period. Note that this can cause a wait for up to an entire refresh period. See Vertical Blank Event (See Programming Interface).
	0	**Reserved** Project: CHV, BSW Format: MBZ

Walkers Fault Register

WF_REG - Walkers Fault Register		
Register Space:	MMIO: 0/2/0	
Project:	CHV, BSW	
Source:	PRM	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	04098h	

DWord	Bit	Description
0	31:1	**Walkers Fault Register** Default Value: 00000000000000000000000000000000b Access: R/W All bits are only valid with bit[0]=1.
	0	**Valid Bit** Default Value: 0b Access: R/W This bit indicates that the first fault for this engine has been recorded. It can only be cleared by SW, which also clears the other fields.

WD_WNIC_MSG_ADDR

WD_WNIC_MSG_ADDR - WD_WNIC_MSG_ADDR	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	6E530h

WNIC Message Address. This is a register within Gunit (CZ domain).
Address uses the address as shown.

DWord	Bit	Description
0	31:0	**Reserved**

WGBOX State Arbitration Priority Control

APC - WGBOX State Arbitration Priority Control

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32

DWord	Bit	Description
0	31:9	**Reserved** Format: MBZ

WIDI LRA 0

WIDI_LRA_0 - WIDI LRA 0

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x37201F00
Size (in bits):	32
Address:	04A90h

DWord	Bit	Description
0	31:30	**Reserved** Default Value: 00b
	29:24	**WIDI LRA1 Max** Default Value: 110111b Access: R/W Maximum value of programmable LRA1.
	23:22	**Reserved** Default Value: 00b Access: RO
	21:16	**WIDI LRA1 Min** Default Value: 100000b Access: R/W Minimum value of programmable LRA1.
	15:14	**Reserved** Default Value: 00b Access: RO
	13:8	**WIDI LRA0 Max** Default Value: 011111b Access: R/W Maximum value of programmable LRA0.
	7:6	**Reserved** Default Value: 00b Access: RO
	5:0	**WIDILRA0 Min** Default Value: 000000b Access: R/W Minimum value of programmable LRA0.

WIDI LRA 1

WIDI_LRA_1 - WIDI LRA 1	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x01000000
Size (in bits):	32
Address:	04A94h

DWord	Bit	Description
0	31:30	**Reserved** Default Value: 00b Access: RO
	29:28	**VMX** Default Value: 00b Access: R/W Which LRA should VMX use.
	27:26	**BSP** Default Value: 00b Access: R/W Which LRA should BSP use.
	25:24	**IME** Default Value: 01b Access: R/W Which LRA should IME/WRS use.
	23:14	**Reserved** Default Value: 0000000000b Access: RO
	13:8	**Reserved**
	7:6	**Reserved** Default Value: 00b Access: RO
	5:0	**Reserved**

WIDI TLB Control Register

WTCR - WIDI TLB Control Register

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04278h

DWord	Bit	Description
0	31:1	**Reserved** Default Value: 00000000000000000000000000000000b Access: RO
	0	**Invalidate TLBs on the corresponding Engine** Default Value: 0b Access: R/W SW writes 1 to invalidate the TLBs for the associated engine and HW clears the bit when invalidation is complete. To ensure proper invalidation of the TLBs, SW has to ensure the corresponding engine's HW pipeline is flushed and cleared from all its memory accesses. Otherwise HW cannot guarantee the proper invalidation for TLBs. This bit is self clear.

WRID_VALID_REG0

WRID_VALID_REG0 - WRID_VALID_REG0		
Register Space:	MMIO: 0/2/0	
Project:	CHV, BSW	
Source:	PRM	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	04070h	

DWord	Bit	Description
0	31:0	**WRID_VALID_REG0** Default Value: 00000000h Access: RO This register is for WRID Comparison usage. RO register with IA Access Type on DEV reset. wrdp_wrid_valid_vector[31:0] There are 96 write buffer. Each bit indicate the buffer is valid if set. Divide into 3 registers to accommodate all 96 deep

WRID_VALID_REG1

WRID_VALID_REG1 - WRID_VALID_REG1		
Register Space:	MMIO: 0/2/0	
Project:	CHV, BSW	
Source:	PRM	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	04074h	
DWord	**Bit**	**Description**
0	31:0	**WRID_VALID_REG1** Default Value: 00000000h Access: RO This register is for WRID Comparison usage. RO register with IA Access Type on DEV reset. wrdp_wrid_valid_vector[63:32] There are 96 write buffer. Each bit indicate the buffer is valid if set. Divide into 3 registers to accommodate all 96 deep.

WRID_VALID_REG2

WRID_VALID_REG2 - WRID_VALID_REG2		
Register Space:	MMIO: 0/2/0	
Project:	CHV, BSW	
Source:	PRM	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	04078h	
DWord	**Bit**	**Description**
0	31:0	**WRID_VALID_REG2** Default Value: 00000000h Access: RO This register is for WRID Comparison usage. RO register with IA Access Type on DEV reset. wrdp_wrid_valid_vector[95:64] There are 96 write buffer. Each bit indicate the buffer is valid if set. Divide into 3 registers to accommodate all 96 deep.

Write Watermark

WR_WATERMARK - Write Watermark

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x000FFEA4
Size (in bits):	32
Address:	04028h

DWord	Bit	Description
0	31:20	**Extra Bits** Default Value: 000000000000b Access: R/W
	19	**Watermark Timeout Enable** Default Value: 1b Access: R/W
	18:8	**Watermark Timeout** Default Value: 11111111110b Access: R/W Number of clocks that the write pipe queue is allowed to keep a ready write cycle, without reads or writes to the queue. Once this value is met, and if the feature is enabled, the watermark is considered reached, and all pending write requests are issued.
	7	**Watermark Enable** Default Value: 1b Access: R/W Enable Write Request Grouping
	6:0	**High Watermark** Default Value: 0100100b Access: R/W This is the number of write requests to be collected before initiating a write burst. Once a burst is initiated, it continues until all the available writes are requested.

ZTLB LRA 0

ZTLB_LRA_0 - ZTLB LRA 0	
Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x01007E00
Size (in bits):	32
Address:	04A30h

DWord	Bit	Description
0	31:29	**Reserved** Default Value: 000b Project: CHV, BSW Access: RO
	28:27	**STC LRA** Default Value: 00b Access: R/W Which LRA should STC use.
	26:18	**ZTLB LRA1 Min** Default Value: 001000000b Access: R/W Minimum value of programmable LRA1.
	17:9	**ZTLB LRA0 Max** Default Value: 000111111b Access: R/W Maximum value of programmable LRA0.
	8:0	**ZTLB LRA0 Min** Default Value: 000000000b Access: R/W Minimum value of programmable LRA0.

ZTLB LRA 1

ZTLB_LRA_1 - ZTLB LRA 1

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x33FD80BF CHV, BSW
Size (in bits):	32
Address:	04A34h

DWord	Bit	Description
0	31	**Reserved** Default Value: 0b Access: RO
	30:29	**HIZ LRA** Default Value: 01b Access: R/W Which LRA should HIZ use.
	28:27	**RCZ LRA** Default Value: 10b Access: R/W Which LRA should RCZ use.
	26:18	**ZTLB LRA2 Max** Access: R/W Maximum value of programmable LRA2. Value: 011111111b — Name: **[Default]** — Project: CHV, BSW
	17:9	**ZTLB LRA2 Min** Default Value: 011000000b Access: R/W Minimum value of programmable LRA2.
	8:0	**ZTLB LRA1 Max** Default Value: 010111111b Access: R/W Maximum value of programmable LRA1.

Intel® Open Source HD Graphics Programmers' Reference Manual (PRM)

Default Value: 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000

DWord	Bit	Description
0	31:16	**Constant Buffer 1 Read Length** Project: All Format: U16 read length This field specifies the length of the constant data to be loaded from memory in 256-bit units. **Programming Notes** (Project) • The sum of all four read length fields must be less than or equal to the size of 64 • Setting the value of the register to zero will disable buffer 1. • If disabled, the **Pointer to Constant Buffer 1** must be programmed to zero. if gather constant are enabled, this field must be non-zero if a there was a preceding corresponding 3DSTATE_GATHER_CONSTANT_*., otherwise this field must be zero. (CHV, BSW)
	15:0	**Constant Buffer 0 Read Length** Project: All Format: U16 read length This field specifies the length of the constant data to be loaded from memory in 256-bit units. **Programming Notes** • The sum of all four read length fields must be less than or equal to the size of 64 • Setting the value of the register to zero will disable buffer 0. • If disabled, the **Pointer to Constant Buffer 0** must be programmed to zero.
1	31:16	**Constant Buffer 3 Read Length** Project: All Format: U16 read length This field specifies the length of the constant data to be loaded from memory in 256-bit units. **Programming Notes** • The sum of all four read length fields must be less than or equal to the size of 64 • Setting the value of the register to zero will disable buffer 3.

3DSTATE_CONSTANT(Body)

		• If disabled, the **Pointer to Constant Buffer 3** must be programmed to zero.
	15:0	**Constant Buffer 2 Read Length** Project: All Format: U16 read length This field specifies the length of the constant data to be loaded from memory in 256-bit units. **Programming Notes** • The sum of all four read length fields must be less than or equal to the size of 64 • Setting the value of the register to zero will disable buffer 2. • If disabled, the **Pointer to Constant Buffer 2** must be programmed to zero.
2..3 **Project:** CHV, BSW	63:5	**Pointer To Constant Buffer 0** Project: CHV, BSW Format: GraphicsAddress[63:5]ConstantBuffer **Description** / **Project**: When CONSTANT_BUFFER Address Offset Disable in INSTPM register is set, the value of this field is the virtual address of the location of the push constant buffer. GraphicsAddress [63:48] are ignored by the HW and assumed to be in correct canonical form [63:48] == [47]. When CONSTANT_BUFFER Address Offset Disable in INSTPM register is cleared, the value of this field is the offset into the Dynamic State Base Address. Only [47:5] of the field are added to the base address to generate the virtual address to be fetched from memory. / CHV, BSW
	4:0	**Reserved** Project: CHV, BSW Format: MBZ
4..5 **Project:** CHV, BSW	63:5	**Pointer To Constant Buffer 1** Project: CHV, BSW Format: GraphicsAddress[63:5]ConstantBuffer This field points to the location of Constant Buffer 1. If gather constants are enabled This field is an offset of constant Buffer1 from the Gather Pool BASE ADDRESS. If gather constants is disabled, the value of this field is the virtual address of the location of the push constant buffer. GraphicsAddress [63:48] are ignored by the HW and assumed to be in correct canonical form [63:48] == [47]. **Programming Notes** Constant buffers must be allocated in linear (not tiled) graphics memory.
	4:0	**Reserved**

A32 Buffer Base Address Message Header Control

MHC_A32_BBA - A32 Buffer Base Address Message Header Control

Project:	CHV, BSW
Source:	PRM
Size (in bits):	32
Default Value:	0x00000000

DWord	Bit	Description
0	31:0	**Buffer Base Address Offset** Project: All Format: GeneralStateOffset[31:0] Specifies the base address offset page [31:10] for A32 stateless messages.

A64 Data Size Message Descriptor Control Field

MDC_A64_DS - A64 Data Size Message Descriptor Control Field

Project: CHV, BSW
Source: PRM
Size (in bits): 2
Default Value: 0x00000000

DWord	Bit	Description
0	1:0	**Data Size** Project: All Format: Enumeration Specifies the number of data elements to be read or written

Value	Name	Description	Project
00h	DE1	1 data element (B, DW, QW)	All
01h	DE2	2 data elements (B, DW, QW)	All
02h	DE4	4 data elements (B, DW, QW)	All
03h	DE8	8 data elements (B, DW, QW)	All

Restriction
The number of elements is constrained by SIMD Mode and Data Width. The max data payload limit is 256B: 2 elements SIMD16 QW, 4 elements SIMD16 DW, or 4 elements SIMD8 QW.

A64 Dual Oword Block Message Header

MH_A64_OWDB - A64 Dual Oword Block Message Header

Project:	CHV, BSW
Source:	DataPort 1
Size (in bits):	256
Default Value:	0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000

DWord	Bit	Description
0-1	63:0	**BlockOffset0** Project: All Format: U64 Specifies the U64 byte offset of Oword Block 0. **Programming Notes** If the BlockOffset is not in the 48-bit canonical address range, the access is Out-of-Bounds. **Restriction** The byte offset must be aligned to the message's data type. Dwords have [1:0] = 0, Qwords have [2:0] = 0, and Hwords have [4:0] = 0.
2-3	63:0	**BlockOffset1** Project: All Format: U64 Specifies the U64 byte offset of Oword Block 1. **Programming Notes** If the BlockOffset is not in the 48-bit canonical address range, the access is Out-of-Bounds. **Restriction** The byte offset must be aligned to the message's data type. Dwords have [1:0] = 0, Qwords have [2:0] = 0, and Hwords have [4:0] = 0.
4-7	127:0	**Reserved** Project: All Format: Ignore Ignored

A64 Hword Block Message Header

MH_A64_HWB - A64 Hword Block Message Header

Project: CHV, BSW

Source: DataPort 1

Size (in bits): 256

Default Value: 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000

DWord	Bit	Description
0-1	63:0	**BlockOffset** Format: U64 Specifies the U64 byte offset of Oword block. **Programming Notes** If the BlockOffset is not in the 48-bit canonical address range, the access is Out-of-Bounds. **Restriction** The byte offset must be aligned to the message's data type. Dwords have [1:0] = 0, Qwords have [2:0] = 0, and Hwords have [4:0] = 0.
2-4	95:0	**Reserved** Format: Ignore Ignored
5	31:0	**Hword Channel Mode** Project: CHV, BSW Format: MHC_A64_CMODE [CHV, BSW] Specifies the Hword Channel Mode
6-7	63:0	**Reserved** Format: Ignore Ignored

A64 Hword Data Blocks Message Descriptor Control Field

MDC_A64_DB_HW - A64 Hword Data Blocks Message Descriptor Control Field

Project: CHV, BSW
Source: PRM
Size (in bits): 3
Default Value: 0x00000001

DWord	Bit	Description
0	2:0	**Data Blocks** Project: All Format: Enumeration Specifies the number of Hwords to be read or written

Value	Name	Description	Project
01h	HW1 **[Default]**	1 Hword block	All
02h	HW2	2 Hword blocks	All
03h	HW4	4 Hword blocks	All
04h	HW8	8 Hword blocks	All
Others	Reserved	Ignored	All

A64 Oword Block Message Header

MH_A64_OWB - A64 Oword Block Message Header

Project: CHV, BSW

Source: DataPort 1

Size (in bits): 256

Default Value: 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000

DWord	Bit	Description
0-1	63:0	**BlockOffset** Project: All Format: U64 Specifies the U64 byte offset of Oword block. **Programming Notes** If the BlockOffset is not in the 48-bit canonical address range, the access is Out-of-Bounds. **Restriction** The byte offset must be aligned to the message's data type. Dwords have [1:0] = 0, Qwords have [2:0] = 0, and Hwords have [4:0] = 0.
2-7	191:0	**Reserved** Project: All Format: Ignore Ignored

A64 Oword Data Blocks Message Descriptor Control Field

MDC_A64_DB_OW - A64 Oword Data Blocks Message Descriptor Control Field

Project:	CHV, BSW
Source:	PRM
Size (in bits):	3
Default Value:	0x00000000

DWord	Bit	Description
0	2:0	**Data Blocks** Project: All Format: Enumeration Specifies the number of Oword blocks to be read or written

Value	Name	Description	Project
00h	OW1L	1 Oword, read into or written from the low 128 bits of the destination register	All
01h	OW1U	1 Oword, read into or written from the high 128 bits of the destination register	All
02h	OW2	2 Owords	All
03h	OW4	4 Owords	All
04h	OW8	8 Owords	All
Others	Reserved	Ignored	All

A64 Oword Dual Data Blocks Message Descriptor Control Field

MDC_A64_DB_OWD - A64 Oword Dual Data Blocks Message Descriptor Control Field

Project:	CHV, BSW
Source:	PRM
Size (in bits):	3
Default Value:	0x00000001

DWord	Bit	Description
0	2:0	**Data Blocks** Project: All Format: Enumeration Specifies the number of Oword blocks to be read or written

Value	Name	Description	Project
01h	OWD1 **[Default]**	1 Hword register, 2 Owords	All
03h	OWD4	4 Hword registers, 8 Owords	All
Others	Reserved	Ignored	All

AddrSubRegNum

AddrSubRegNum

Project:	CHV, BSW
Source:	Eulsa
Size (in bits):	4
Default Value:	0x00000000

Address Subregister Number This field provides the subregister number for the address register. The address register contains 8 sub-registers. The size of each subregister is one word. The address register contains the register address of the operand, when the operand is in register-indirect addressing mode. This field applies to the destination operand and the source operands. It is ignored (or not present in the instruction word) for an immediate source operand. This field is present if the operand is in register-indirect addressing mode; it is not present if the operand is directly addressed. An address subregister used for indirect addressing is often called an index register.

DWord	Bit	Description
0	3:0	**Address Subregister Number** Project: CHV, BSW Value: 0-15 — Name: Address Subregister Number

Any Binding Table Index Message Descriptor Control Field

MDC_BTS_SLM_A32 - Any Binding Table Index Message Descriptor Control Field

Project: CHV, BSW
Source: PRM
Size (in bits): 8
Default Value: 0x00000000

DWord	Bit	Description
0	7:0	**Binding Table Index** Project: All Format: Enumeration Specifies the surface for the message, which can be Surface State Model, SLM or Stateless.

Value	Name	Description	Project
00h-0EFh	BTS	Index of Binding Table State Surfaces	All
F0h-0FBh	Reserved	Reserved for future use	All
0FCh	Reserved	Reserved for future use	CHV, BSW
0FEh	SLM	Specifies an SLM access	All
0FFh	A32_A64	Specifies a A32 or A64 Stateless access that is locally coherent (coherent within a thread group)	All
0FDh	A32_A64_NC	Specifies a A32 or A64 Stateless access that is non-coherent (coherent within a thread).	All

Restriction
When using A32_A64_NC, SW must ensure that 2 threads do not both access the same cache line (64B)

Atomic Integer Binary Operation Message Descriptor Control Field

MDC_AOP2 - Atomic Integer Binary Operation Message Descriptor Control Field

Project: CHV, BSW
Source: PRM
Size (in bits): 4
Default Value: 0x00000001

DWord	Bit	Description
0	3:0	**Atomic Integer Operation Type** Project: All Format: Enumeration Specifies the atomic integer binary operation to be performed

Value	Name	Description	Project
01h	AOP_AND **[Default]**	new_dst = old_dst AND src0	All
02h	AOP_OR	new_dst = old_dst | src0	All
03h	AOP_XOR	new_dst = old_dst ^ src0	All
04h	AOP_MOV	new_dst = src0	All
07h	AOP_ADD	new_dst = old_dst + src0	All
08h	AOP_SUB	new_dst = old_dst - src0	All
09h	AOP_REVSUB	new_dst = src0 - old_dst	All
0Ah	AOP_IMAX	new_dst = imax(old_dst, src0)	All
0Bh	AOP_IMIN	new_dst = imin(old_dst, src0)	All
0Ch	AOP_UMAX	new_dst = umax(old_dst, src0)	All
0Dh	AOP_UMIN	new_dst = umin(old_dst, src0)	All
Others	Reserved	Ignored	All

Programming Notes
When Return Data Control is set, old_dst is returned.

Atomic Integer Trinary Operation Message Descriptor Control Field

MDC_AOP3 - Atomic Integer Trinary Operation Message Descriptor Control Field

Project: CHV, BSW
Source: PRM
Size (in bits): 4
Default Value: 0x0000000E

DWord	Bit	Description
0	3:0	**Atomic Integer Operation Type** Project: All Format: Enumeration Specifies the atomic integer trinary operation to be performed

Value	Name	Description	Project
00h	AOP_CMPWR_2W	new_dst = (src0_2W == old_dst_2W) ? src1_2W : old_dst_2W	All
0Eh	AOP_CMPWR **[Default]**	new_dst = (src0 == old_dst) ? src1 : old_dst	All
Others	Reserved	Ignored	All

Programming Notes
When Return Data Control is set, old_dst is returned.

Atomic Integer Unary Operation Message Descriptor Control Field

MDC_AOP1 - Atomic Integer Unary Operation Message Descriptor Control Field

Project: CHV, BSW
Source: PRM
Size (in bits): 4
Default Value: 0x00000005

DWord	Bit	Description
0	3:0	**Atomic Integer Operation Type** Project: All Format: Enumeration Specifies the atomic integer unary operation to be performed

Value	Name	Description	Project
05h	AOP_INC **[Default]**	new_dst = old_dst + 1	All
06h	AOP_DEC	new_dst = old_dst - 1	All
0Fh	AOP_PREDEC	new_dst = old_dst - 1	All
Others	Reserved	Ignored	All

Programming Notes
When Return Data Control is set, new_dst is returned by AOP_PREDEC and otherwise old_dst is returned.

AVC CABAC

AVC CABAC		
Project:	CHV, BSW	
Source:	VideoCS	
Size (in bits):	16	
Default Value:	0x00000000	

DWord	Bit	Description
0	15	**Reserved** Format: MBZ
	14	**Coefficient level out-of-bound Error** This flag indicates the coded coefficient level SEs in the bit-stream is out-of-bound.
	13	**Reserved** Format: MBZ
	12	**Reserved** Format: MBZ
	11	**Temporal Direction Motion Vector Out-of-Bound Error** This flag indicates motion vectors calculated from Temporal Direct Motion Vector is larger than the allowed range specified by the AVC spec.
	10	**Reserved** MBZ
	9	**Motion Vector Delta SE Out-of-Bound Error** This flag indicates inconsistent Motion Vector Delta SEs coded in the bit-stream.
	8	**Reference Index SE Out-of-Bound Error** This flag indicates inconsistent Reference Index SEs coded in the bit-stream.
	7	**MacroBlock QpDelta Error** This flag indicates out-of-bound MB QP delta SEs coded in the bit-stream.
	6	**Motion Vector Delta SE Error** This flag indicates out-of-bound motion vector delta SEs coded in the bit-stream.
	5	**Reference Index SE Error** This flag indicates out-of-bound Refidx SEs coded in the bit-stream.
	4	**Residual Error** This flag indicates out-of-bound absolute coefficient level SEs coded in the bit-stream.
	3	**Slice end Error** This flag indicates a pre-matured slice_end SE or inconsistent slice end on the last MB of a slice.
	2	**Chroma Intra prediction Mode Error** This flag indicates inconsistent Chroma Intra prediction mode SEs coded in the bit-stream.
	1	**Luma Intra prediction Mode Error** This flag indicates inconsistent luma Intra prediction mode SE coded in the bit-stream.

BCS Hardware-Detected Error Bit Definitions

BCS Hardware-Detected Error Bit Definitions

Project: CHV, BSW
Source: BlitterCS
Size (in bits): 16
Default Value: 0x00000000

DWord	Bit	Description
0	15:3	**Reserved** Format: MBZ
	2	**Command Privilege Violation Error** Project: CHV, BSW This bit is set if a command classified as privileged is parsed in a non-privileged batch buffer. The command will be converted to a NOOP and parsing will continue.
	1	**Reserved** Format: MBZ
	0	**Instruction Error** This bit is set when the Renderer Instruction Parser detects an error while parsing an instruction. Instruction errors include: • Client ID value (Bits 31:29 of the Header) is not supported (only MI, 2D and 3D are supported). • Defeatured MI Instruction Opcodes: Value: 1 — Name: — Description: Instruction Error detected **Programming Notes** This error indications cannot be cleared except by reset (i.e., it is a fatal error).

BINDING_TABLE_EDIT_ENTRY

BINDING_TABLE_EDIT_ENTRY		
Project:	CHV, BSW	
Source:	RenderCS	
Size (in bits):	32	
Default Value:	0x00000000	
DWord	**Bit**	**Description**
0	31:24	**Reserved** Format: MBZ
	23:16	**Binding Table Index** Format: U8 This field specifies the index of binding table entry that will be updated.
	15:0	**Surface State Pointer** Format: SurfaceStateOffset[21:6]RENDER_SURFACE_STATE [CHV, BSW] Surface State Pointer. This address points to a surface state block. This pointer is relative to the Surface State Base Address.

BINDING_TABLE_STATE

BINDING_TABLE_STATE

Project:	CHV, BSW
Source:	PRM
Size (in bits):	32
Default Value:	0x00000000

The binding table binds surfaces to logical resource indices used by shaders and other compute engine kernels. It is stored as an array of up to 256 elements, each of which contains one dword as defined here. The start of each element is spaced one dword apart. The first element of the binding table is aligned to a 32-byte boundary.

DWord	Bit	Description
0	31:6	**Surface State Pointer** Project: CHV, BSW Format: SurfaceStateOffset[31:6] This 64-byte aligned address points to a surface state block. This pointer is relative to the **Surface State Base Address**.
	5:0	**Reserved** Project: CHV, BSW Format: MBZ

Bit Definition for Interrupt Control Registers - Render

Bit Definition for Interrupt Control Registers - Render

Project:	CHV, BSW
Source:	RenderCS
Size (in bits):	32
Default Value:	0x00000000

DWord	Bit	Description
0	31:16	**Reserved** Project: CHV, BSW Format: MBZ Reserved for other command streamers - cannot be allocated by main command streamer.
	15:12	**Reserved** Project: CHV, BSW Format: MBZ
	11	**Wait on Semaphore** Project: CHV, BSW Exec-List Scheduling: Set when MI_SEMAPHORE_WAIT command is un-successful and when "Inhibit Synchronous Context Switch" is set. Scheduler can use this interrupt to preempt the context waiting on semaphore wait.
	10	**L3 Counter Save Interrupt** Project: CHV, BSW
	9	**Reserved** Project: CHV, BSW Format: MBZ
	8	**Context Switch Interrupt** Project: CHV, BSW Set when a context switch has just occurred. Execlist Enable bit needs to be set for this interrupt to occur.
	7	**Page Fault** Project: All Description: This interrupt is for handling Legacy Page Fault interface for all Command Streamers (BCS, RCS, VCS, VECS). When Fault Repair Mode is enabled, Interrupt mask register value is not looked at to generate interrupt due to page fault. Please refer to vol1c Project: CHV, BSW

Bit Definition for Interrupt Control Registers - Render

		"Page Fault Support" section for more details.
	6	**Timeout Counter Expired** Set when the render pipe timeout counter (0x02190) has reached the timeout threshold value (0x0217c).
	5	**L3 Parity Error (Slice0)** Project: CHV, BSW When this bit is set, L3 cache controller is indicating that it has encountered an parity error while checking the data.
	4	**PIPE_CONTROL Notify Interrupt** The Pipe Control packet (Fences) specified in 3D pipeline document may optionally generate an Interrupt. The Store QW associated with a fence is completed ahead of the interrupt.
	3	**Render Command Parser Master Error** When this status bit is set, it indicates that the hardware has detected an error. It is set by the device upon an error condition and cleared by a CPU write of a one to the appropriate bit contained in the Error ID register followed by a write of a one to this bit in the IIR. Further information on the source of the error comes from the "Error Status Register" which along with the "Error Mask Register" determine which error conditions will cause the error status bit to be set and the interrupt to occur. **Page Table Error:** Indicates a page table error. **Instruction Parser Error:** The Render Instruction Parser encounters an error while parsing an instruction.
	2	**Reserved** Project: CHV, BSW Format: MBZ
	1	**Reserved**
	0	**Render Command Parser User Interrupt** This status bit is set when an MI_USER_INTERRUPT instruction is executed on the Render Command Parser. Note that instruction execution is not halted and proceeds normally. A mechanism such as an MI_STORE_DATA instruction is required to associate a particular meaning to a user interrupt.

BLEND_STATE

BLEND_STATE

Project:	CHV, BSW
Source:	PRM
Size (in bits):	544
Default Value:	0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000

The blend state is stored as a structure containing a common DWORD that applies to all RTs and an array of up to 8 elements, each of which contains the two DWords for each. The start of each element is spaced 2 DWords apart. The blend state is aligned to a 64-byte boundary, which is pointed to by a field in 3DSTATE_BLEND_STATE_POINTERS. The 3-bit Render Target Index field in the Render Target Write data port message header is used to select which of the 8 elements from BLEND_STATE that is used on the current message.

DWord	Bit	Description
0	31	**Alpha To Coverage Enable** Format: Enable If set, Source0 Alpha is converted to a temporary 1/2/4-bit coverage mask and the mask bit corresponding to the sample# ANDed with the sample mask bit. If set, sample coverage is computed based on src0 alpha value. Value of 0 disables all samples and value of 1 enables all samples for that pixel. The same coverage needs to apply to all the RTs in MRT case. Further, any value of src0 alpha between 0 and 1 monotonically increases the number of enabled pixels.The field is applied to all the RTs in MRT case.
	30	**Independent Alpha Blend Enable** Format: Enable When enabled, the other fields in this instruction control the combination of the alpha components in the Color Buffer Blend stage. When disabled, the alpha components are combined in the same fashion as the color components.The field is applied to all the RTs in MRT case.
	29	**Alpha To One Enable** Format: Enable If set, Source0 Alpha is set to 1.0f after (possibly) being used to generate the AlphaToCoverage coverage mask.If Dual Source Blending is enabled, this bit must be disabled.The field is applied to all the RTs in MRT case.
	28	**Alpha To Coverage Dither Enable** Format: Enable If set, sample coverage is computed based on src0 alpha value and it modulates the sample coverage based on screen coordinates. Value of 0 disables all samples and value of 1 enables all

BLEND_STATE

		samples for that pixel. The same coverage needs to apply to all the RTs in MRT case. Further, any value of src0 alpha between 0 and 1 monotonically increases the number of enabled pixels. If AlphaToCoverage is disabled, AlphaToCoverage Dither does not have any impact.The field is applied to all the RTs in MRT case.
	27	**Alpha Test Enable** Format: Enable Enables the AlphaTest function of the Pixel Processing pipeline.The field is applied to all the RTs in MRT case. **Programming Notes** Alpha Test can only be enabled if Pixel Shader outputs a float alpha value. Alpha Test is applied independently on each render target by comparing that render target's alpha value against the alpha reference value. If the alpha test fails, the corresponding pixel write will be supressed only for that render target. The depth/stencil update will occur if alpha test passes for any render target.
	26:24	**Alpha Test Function** Format: 3D_Compare_Function This field specifies the comparison function used in the AlphaTest functionThe field is applied to all the RTs in MRT case.
	23	**Color Dither Enable** Format: Enable Enables dithering of colors (including any alpha component) before they are written to the Color Buffer. The field is applied to all the RTs in MRT case. **Programming Notes** For YUV render target formats, this field must be programmed to 0.
	22:21	**X Dither Offset** Format: U2 Specifies offset to apply to pixel X coordinate LSBs when accessing dither table.The field is applied to all the RTs in MRT case.
	20:19	**Y Dither Offset** Format: U2 Specifies offset to apply to pixel Y coordinate LSBs when accessing dither table.The field is applied to all the RTs in MRT case.
	18:0	**Reserved** Format: MBZ
1..16	63:0	**Entry** Format: BLEND_STATE_ENTRY [CHV, BSW]

BLEND_STATE_ENTRY

BLEND_STATE_ENTRY

Project: CHV, BSW
Source: PRM
Size (in bits): 64
Default Value: 0x00000000, 0x00000000

DWord	Bit	Description
0	63	**Logic Op Enable** Format: Enable Enables the LogicOp function of the Pixel Processing pipeline. **Programming Notes** Enabling LogicOp and Color Buffer Blending at the same time is UNDEFINED
	62:59	**Logic Op Function** Format: 3D_Logic_Op_Function This field specifies the function to be performed (when enabled) in the Logic Op stage of the Pixel Processing pipeline. Note that the encoding of this field is one less than the corresponding "R2_" ROP code defined in WINGDI.H, and is a rather contorted mapping of the OpenGL LogicOp encodings. However, this field was defined such that, when the 4 bits are replicated to 8 bits, they coincide with the ROP codes used in the Blter. Note: if the Logic Op Function does not depend on "D", the dest buffer is not read.
	58:37	**Reserved** Format: MBZ
	36	**Pre-Blend Source Only Clamp Enable** This field specifies whether the source(s) are clamped prior to blending, regardless of whether blending is enabled. If DISABLED, no clamping is performed prior to blending. If ENABLED, only source0 and source 1, if dual source is enabled, are clamped prior to the blend to the range specified by Color Clamp Range. Value / Name / Description 0 / Disabled / No clamping is performed prior to blending. 1 / Enabled / Only Source(s) are clamped prior to blend function. Other inputs to blend must not be clamped. **Programming Notes** See table in Pre-Blending Color Clamp subsection for programming restrictions as a function of RT format. This field is ignored (treated as DISABLED) for UINT and SINT RT surface formats. Blending is not supported for those RT surface formats. **When this bit is enabled Pre-Blend Color Clamp Enable RT[0] must be disabled.**
	35:34	**Color Clamp Range**

BLEND_STATE_ENTRY

Specifies the clamped range used in Pre-Blend and Post-Blend Color Clamp functions if one or both of those functions are enabled. Note that this range selection is shared between those functions. This field is ignored if both of the Color Clamp Enables are disabled

Value	Name	Description
0	COLORCLAMP_UNORM	Clamp Range [0,1]
1	COLORCLAMP_SNORM	Clamp Range [-1,1]
2	COLORCLAMP_RTFORMAT	Clamp to the range of the RT surface format (Note: The Alpha component is clamped to FLOAT16 for R11G11B10_FLOAT format).
3	Reserved	Reserved

33 **Pre-Blend Color Clamp Enable**

Format:	Enable

This field specifies whether the source, destination and constant color channels are clamped prior to blending, regardless of whether blending is enabled.If DISABLED, no clamping is performed prior to blending.If ENABLED, all inputs to the blend function are clamped prior to the blend to the range specified by Color Clamp Range.

Value	Name	Description
0	Disabled	No clamping is performed prior to blending.
1	Enabled	All inputs to the blend function are clamped prior to the blend to the range specified by Color Clamp Range.

Programming Notes
See table in Pre-Blending Color Clamp subsection for programming restrictions as a function of RT format. This field is ignored (treated as DISABLED) for UINT and SINT RT surface formats. Blending is not supported for those RT surface formats. The device will automatically clamp source color channels to the respective RT surface range.

32 **Post-Blend Color Clamp Enable**

Format:	Enable

If blending is enabled, this field specifies whether the blending output channels are first clamped to the range specified by Color Clamp Range. Regardless of whether this clamping is enabled, the blending output channels will be clamped to the RT surface format just prior to being written.

Programming Notes
See table in Pre-Blending Color Clamp subsection for programming restrictions as a function of RT format. This field is ignored (treated as DISABLED) for UINT and SINT RT surface formats. Blending is not supported for those RT surface formats. The device will automatically clamp source color channels to the respective RT surface range. **When this bit is enabled Pre-Blend Source Only Clamp Enable RT[0] must be disabled.**

31 **Color Buffer Blend Enable**

Format:	Enable

Enables the ColorBufferBlending (nee "alpha blending") function of the Pixel Processing Pipeline

BLEND_STATE_ENTRY

for this render target.

Programming Notes
Enabling LogicOp and ColorBufferBlending at the same time is UNDEFINED

30:26 Source Blend Factor

Format:	3D_Color_Buffer_Blend_Factor

Controls the "source factor" in the ColorBufferBlending function.Refer to Source Alpha Blend Factor for encodings.

25:21 Destination Blend Factor

Format:	3D_Color_Buffer_Blend_Factor

Controls the "destination factor" in the ColorBufferBlending function. Refer to Source Alpha Blend Factor for encodings.

20:18 Color Blend Function

Format:	3D_Color_Buffer_Blend_Function

This field specifies the function used to combine the color components in the ColorBufferBlending function of the Pixel Processing Pipeline. If Independent Alpha Blend Enable is disabled, this field will also control the blending of the alpha components in the ColorBufferBlending function.

17:13 Source Alpha Blend Factor

Format:	3D_Color_Buffer_Blend_Factor

Controls the "source factor" in alpha Color Buffer Blending stage.Note: For the source/destination alpha blend factors, the encodings indicating "COLOR" are the same as the encodings indicating "ALPHA", as the alpha component of the color is selected.

12:8 Destination Alpha Blend Factor

Format:	3D_Color_Buffer_Blend_Factor

Controls the "destination factor" in alpha Color Buffer Blending stage. Refer to Source Alpha Blend Factor for encodings.

7:5 Alpha Blend Function

Format:	3D_Color_Buffer_Blend_Function

This field specifies the function used to combine the alpha components in the Color Buffer blend stage of the Pixel Pipeline when the IndependentAlphaBlend state is enabled.

4 Reserved

Format:	MBZ

3 Write Disable Alpha

Format:	Disable

This field controls the writing of the alpha component into the Render Target.

BLEND_STATE_ENTRY

Value	Name	Description
0b	Enabled	Alpha component can be overwritten
1b	Disabled	Writes to the color buffer will not modify Alpha.

Programming Notes
For YUV surfaces, this field must be set to 0B (enabled).

2 **Write Disable Red**

Format:	Disable

This field controls the writing of the red component into the Render Target.

Value	Name	Description
0b	Enabled	Red component can be overwritten
1b	Disabled	Writes to the color buffer will not modify Red.

Programming Notes
For YUV surfaces, this field must be set to 0B (enabled).

1 **Write Disable Green**

Format:	Disable

This field controls the writing of the green component into the Render Target.

Value	Name	Description
0b	Enabled	Green component can be overwritten
1b	Disabled	Writes to the color buffer will not modify Green.

Programming Notes
For YUV surfaces, this field must be set to 0B (enabled).

0 **Write Disable Blue**

Format:	Disable

This field controls the writing of the Blue component into the Render Target.

Value	Name	Description
0b	Enabled	Blue component can be overwritten
1b	Disabled	Writes to the color buffer will not modify Blue.

Programming Notes
For YUV surfaces, this field must be set to 0B (enabled).

BR00 - BLT Opcode and Control

BR00 - BLT Opcode and Control

Project: CHV, BSW
Source: BlitterCS
Size (in bits): 32
Default Value: 0x00000000

DWord	Bit	Description
0	31	**BLT Engine Busy** This bit indicates whether the BLT Engine is busy (1) or idle (0). This bit is replicated in the SETUP BLT Opcode and Control register. Value: 0 — Name: Idle **[Default]** Value: 1 — Name: Busy
	30	**Setup Instruction Instruction** Default Value: 0 The current instruction performs clipping (1).
	29	**Setup Monochrome Pattern** This bit is decoded from the Setup instruction opcode to identify whether a color (0) or monochrome (1) pattern is used with the SCANLINE_BLT instruction. Value: 0 — Name: Color **[Default]** Value: 1 — Name: Monochrome
	28:22	**Instruction Target (Opcode)** Default Value: 0000000b This is the contents of the Instruction Target field from the last BLT instruction. This field is used by the BLT Engine state machine to identify the BLT instruction it is to perform. The opcode specifies whether the source and pattern operands are color or monochrome.
	21:20	**32bpp Byte Mask** This field is only used for 32bpp. Value: 00b — Name: **[Default]** Value: 1xb — Name: Write Alpha Channel Value: x1b — Name: Write RGB Channel
	19:17	**Monochrome Source Start** Default Value: 000b This field indicates the starting monochrome pixel bit position within a byte per scan line of the

BR00 - BLT Opcode and Control

source operand. The monochrome source is word aligned which means that at the end of the scan line all bits should be discarded until the next word boundary.

16 **Bit/Byte Packed**

Byte packed is for the NT driver.

Value	Name
0b	Bit **[Default]**
1b	Byte

15 **Src Tiling Enable**

Value	Name	Project
0b	Tiling Disabled (Linear) **[Default]**	
1b	Tiling enabled: Tile-X or Tile-Y	CHV, BSW

14:12 **Horizontal Pattern Seed**

Default Value:	0b

This field indicates the pattern pixel position which corresponds to X = 0.

11 **Dest Tiling Enable**

When set to '1', this means that Blitter is executing in Tiled mode. If '0' it means that Blitter is in Linear mode. Pre-Dev Blitter never executes in Tiled-Y mode, DevGT+ Blitter supports both Tile-X and Tile-Y modes. On reset, this bit will be '0'. This definition applies to only X, Y Blits.

Value	Name	Project
0b	Tiling Disabled (Linear blit) **[Default]**	
1b	Tiling enabled: Tile-X or Tile-Y	CHV, BSW

10:8 **Transparency Range Mode**

These bits control whether or not the byte(s) at the destination corresponding to a given pixel will be conditionally written, and what those conditions are. This feature can make it possible to perform various masking functions in order to selectively write or preserve graphics data already at the destination.

Value	Name	Description
xx0b	**[Default]**	No color transparency mode enabled. This causes normal operation with regard to writing data to the destination.
001b		[Source color transparency] The Transparency Color Low: (Pixel Greater or Equal) (source background register) and the Transparency Color High: (Pixel Less or Equal) (source foreground register) are compared to the source pixels. The range comparisons are done on each component (R, G, B) and then logically ANDed. If the source pixel components are not within the range defined by the Transparency Color registers, then the byte(s) at the destination corresponding to the current pixel are written with the result of the bit-wise operation.
011b		[Source and Alpha color transparency] The Transparency Color Low: (Pixel Greater or Equal) (source background register) and the Transparency Color

BR00 - BLT Opcode and Control

				High: (Pixel Less or Equal) (source foreground register) are compared to the source pixels. The range comparisons are done on each component (A, R, G, B) and then logically ANDed. If the source pixel components are not within the range defined by the Transparency Color registers, then the byte(s) at the destination corresponding to the current pixel are written with the result of the bit-wise operation."
		101b		[Destination and Alpha color transparency] The Transparency Color Low: (Pixel Greater or Equal) (source background register) and the Transparency Color High: (Pixel Less or Equal) (source foreground register) are compared to the destination pixels. The range comparisons are done on each component (A, R, G, B) and then logically ANDed. If the destination pixels are within the range, then the byte(s) at the destination corresponding to the current pixel are written with the result of the bit-wise operation.
		111b		[Destination color transparency] The Transparency Color Low: (Pixel Greater or Equal) (source background register) and the Transparency Color High: (Pixel Less or Equal) (source foreground register) are compared to the destination pixels. The range comparisons are done on each component (R, G, B) and then logically ANDed. If the destination pixels are within the range, then the byte(s) at the destination corresponding to the current pixel are written with the result of the bit-wise operation.
	7:5	**Pattern Vertical Seed**		
		Default Value:	000b	
		This field specifies the pattern scan line which corresponds to Y=0.		
	4	**Destination Read Modify Write**		
		Default Value:	0b	
		This bit is decoded from the last instruction's opcode field and Destination Transparency Mode to identify whether a Destination read is needed.		
	3	**Color Source**		
		Default Value:	0b	
		This bit is decoded from the last instructions opcode field to identify whether a color (1) source is used.		
	2	**Monochrome Source**		
		Default Value:	0b	
		This bit is decoded from the last instructions opcode field to identify whether a monochrome (1) source is used.		
	1	**Color Pattern**		
		Default Value:	0b	
		This bit is decoded from the last instructions opcode field to identify whether a color (1) pattern

1b	

DWord	Bit	Description
	29	**Monochrome Source Transparency Mode** This bit applies only when the source data is in monochrome. This bit determines whether or not the byte(s) at the destination corresponding to the pixel to which a given bit of the source data also corresponds will actually be written if that source data bit has the value of 0. This feature can make it possible to use the source as a transparency mask. The BLT Engine is configured to accepted either monochrome or color source data via the opcode field.

Value	Name	Description
0b	**[Default]**	This causes normal operation with regard to the use of the source data. Wherever a bit in the source data has the value of 0, the color specified in the background color register is used as the source operand in the bit-wise operation for the pixel corresponding to the source data bit, and the bytes at the destination corresponding to that pixel are written with the result.
1b		Wherever a bit in the source data has the value of 0, the byte(s) at the destination corresponding to the pixel to which the source data bit also corresponds are simply not written, and the data at those byte(s) at the

BR01 - Setup BLT Raster OP, Control, and Destination Offset

		destination are allowed to remain unchanged.

28 Monochrome Pattern Transparency Mode

This bit applies only when the pattern data is monochrome. This bit determines whether or not the byte(s) at the destination corresponding to the pixel to which a given bit of the pattern data also corresponds will actually be written if that pattern data bit has the value of 1. This feature can make it possible to use the pattern as a transparency mask. The BLT Engine is configured to accepted either monochrome or color pattern data via the opcode field.

Value	Name	Description
0b	**[Default]**	This causes normal operation with regard to the use of the pattern data. Wherever a bit in the pattern data has the value of 0, the color specified in the background color register is used as the pattern operand in the bit-wise operation for the pixel corresponding to the pattern data bit, and the bytes at the destination corresponding to that pixel are written with the result.
1b		Wherever a bit in the pattern data has the value of 0, the byte(s) at the destination corresponding to the pixel to which the pattern data bit also corresponds are simply not written, and the data at those byte(s) at the destination are allowed to remain unchanged.

27:26 32bpp Byte Mask

This bit applies only when the pattern data is monochrome. This bit determines whether or not the byte(s) at the destination corresponding to the pixel to which a given bit of the pattern data also corresponds will actually be written if that pattern data bit has the value of 1. This feature can make it possible to use the pattern as a transparency mask. The BLT Engine is configured to accepted either monochrome or color pattern data via the opcode field.

23:16 Raster Operation Select

These 8 bits are used to select which one of 256 possible raster operations is to be performed by the BLT Engine.

15:0 Destination Pitch (Offset)

For non-XY Blits, the signed 16bit field allows for specifying upto + 32Kbytes signed pitches in bytes (same as before). For X, Y Blits with tiled-X surfaces, the pitch for Destination will be 512Byte aligned and should be programmable upto + 128Kbytes. For X, Y Blits with tiled-Y surfaces, the pitch for Destination will be 128Byte aligned and should be programmable upto +

BR01 - Setup BLT Raster OP, Control, and Destination Offset		
		128Kbytes. In this case, this 16bit signed pitch field is used to specify upto + 32KDWords. For X, Y blits with nontiled surfaces (linear surfaces), this 16bit field can be programmed to byte specification of upto + 32Kbytes (same as before). These 16 bits store the signed memory address offset value by which the destination address originally specified in the Destination Address Register is incremented or decremented as each scan line's worth of destination data is written into the frame buffer by the BLT Engine, so that the destination address will point to the next memory address to which the next scan line's worth of destination data is to be written. If the intended destination of a BLT operation is within on-screen frame buffer memory, this offset is normally set so that each subsequent scan line's worth of destination data lines up vertically with the destination data in the scan line, above. However, if the intended destination of a BLT operation is within off-screen memory, this offset can be set so that each subsequent scan line's worth of destination data is stored at a location immediately after the location where the destination data for the last scan line ended, in order to create a single contiguous block of bytes of destination data at the destination.

BR05 - Setup Expansion Background Color

BR05 - Setup Expansion Background Color		
Project:	CHV, BSW	
Source:	BlitterCS	
Size (in bits):	32	
Default Value:	0x00000000	
DWord	**Bit**	**Description**
0	31:0	**Setup Expansion Background Color Bits** These bits provide the one, two, or four bytes worth of color data that select the background color to be used in the color expansion of monochrome pattern or source data for either the SCANLINE_BLT or TEXT_BLT instructions. BR05 is also used as the solid pattern for the PIXEL_BLT instruction. Whether one, two, or three bytes worth of color data is needed depends upon the color depth to which the BLT Engine has been set. For a color depth of 32bpp, 16bpp and 8bpp, bits [31:0], [15:0] and [7:0], respectively, are used.

BR07 - Setup Blit Color Pattern Address Lower Order Address bits

BR07 - Setup Blit Color Pattern Address Lower Order Address bits

Project:	CHV, BSW
Source:	BlitterCS
Size (in bits):	32
Default Value:	0x00000000

DWord	Bit	Description
0	31:6	**Setup Blit Color Pattern Address** Format: GraphicsAddress[31:6] Lower 32bits of the 48bit addressing. These 26 bits specify the starting address of the (8X8) pixel color **pattern from the SETUP_BLT instruction.** This register works identically to the Pattern Address register (BR15), but this version is **only used with the SCANLINE_BLT instruction execution** (the actual programming for this, is done in XY_SETUP_BLT command). The pattern data must be located in linear memory. The pattern data must be located on a pattern-size boundary. The pattern is always of 8x8 pixels, and therefore, its size is dependent upon its pixel depth. The pixel depth may be 8, 16, or 32 bits per pixel if the pattern is in color (the pixel depth of a color pattern must match the pixel depth to which the graphics system has been set). Monochrome patterns require 8 bytes and is supplied through the instruction. Color patterns of 8, 16, and 32 bits per pixel color depth must start on 64-byte, 128-byte and 256-byte boundaries, respectively. The Pattern Base Address programmed, must always be Cache Line (64byte) aligned.
	5:0	**Reserved** Format: MBZ

BR09 - Destination Address Lower Order Address Bits

BR09 - Destination Address Lower Order Address Bits		
Project:	CHV, BSW	
Source:	BlitterCS	
Size (in bits):	32	
Default Value:	0x00000000	
DWord	**Bit**	**Description**
0	31:0	**Destination Address Bits** Format: GraphicsAddress[31:0] When tiling is enabled for XY-blits, this base address should be limited to 4KB. when tiling is disabled for XY-blits, this base address should be CL (64byte) aligned. These lower 32bits of the 48bit address, which specify the starting pixel address of the destination data. This register is also the working destination address register for the lower 32bits of the address, and changes as the BLT Engine performs the accesses. Used as the scan line address (Destination Y Address and Destination Y1 Address) for BLT instructions: PIXEL_BLT, SCANLINE_BLT, and TEXT_BLT. In this case the address points to the first pixel in a scan line and is compared with the ClipRect Y1 and Y2 address registers to determine whether the scan line should be written or not. The Destination Y1 address is the top scan line to be written for text. Note that for non-XY blits (COLOR_BLT, SRC_COPY_BLT), this address points to the first byte to be written. Note: Some instructions affect only one scan line (requiring only one coordinate); other instructions affect multiple scan lines and need both coordinates.

BR11 - BLT Source Pitch (Offset)

BR11 - BLT Source Pitch (Offset)		
Project:	CHV, BSW	
Source:	BlitterCS	
Size (in bits):	32	
Default Value:	0x00000000	
DWord	**Bit**	**Description**
0	31:16	**Reserved**
	15:0	**Source Pitch (Offset)** For non-XY Blits with color source operand (SRC_COPY_BLT), the signed 16bit field allows for specifying upto + 32Kbytes signed pitch in bytes (same as before). For X, Y Blits with tiled-X surfaces, the pitch for Color Source will be 512Byte aligned and should be programmable upto + 128Kbytes. For X, Y Blits with tiled-Y surfaces, the pitch for Color Source will be 128Byte aligned and should be programmable upto + 128Kbytes. In this case, this 16bit signed pitch field is used to specify upto + 32KDWords. For X, Y blits with nontiled color source surfaces (linear surfaces), this 16bit field can be programmed to byte specification of upto + 32Kbytes (same as before). When the color source data is located within the frame buffer or AGP aperture, these signed 16 bits store the memory address offset (pitch) value by which the source address originally specified in the Source Address Register is incremented or decremented as each scan line's worth of source data is read from the frame buffer by the BLT Engine, so that the source address will point to the next memory address from which the next scan line's worth of source data is to be read. Note that if the intended source of a BLT operation is within on-screen frame buffer memory, this offset is normally set to accommodate the fact that each subsequent scan line's worth of source data lines up vertically with the source data in the scan line, above. However, if the intended source of a BLT operation is within off-screen memory, this offset can be set to accommodate a situation in which the source data exists as a single contiguous block of bytes where in each subsequent scan line's worth of source data is stored at a location immediately after the location where the source data for the last scan line ended.

BR12 - Source Address Lower order Address bits

BR12 - Source Address Lower order Address bits

Project:	CHV, BSW

Default Value: 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000

DWord	Bit	Description
0	31:0	**X Offset** Project: All Format: S31 X offset (in bytes) of the upper left corner of the block into the surface. **Programming Notes** Must be DWord aligned (Bits 1:0 MBZ) for the write form of the message.
1	31:0	**Y Offset** Project: All Format: S31 Y offset (in rows) of the upper left corner of the block into the surface.
2	31:0	**Media Block Message Control** Project: All Format: MHC_MBBM_CONTROL [CHV, BSW] Specifies the Byte Masked message subtype and its additional input parameters.
3	31:0	**Byte Mask** Project: All Format: U32 Specifies the Byte Mask for writes when Message Mode field is BYTE_MASK. **Programming Notes** The Byte mask applies horizontally to each row of output: bit 0 for byte 0, through bit 31 for byte 31.
4	31:0	**FFTID** Project: All Format: MHC_FFTID [CHV, BSW] Fixed Function Thread ID
5-7	95:0	**Reserved**

MH_MBBM - Byte Masked Media Block Message Header

		Project:	All
		Format:	Ignore
		Ignored	

Byte Masked Media Block Message Header Control

MHC_MBBM_CONTROL - Byte Masked Media Block Message Header Control

Project: CHV, BSW
Source: PRM
Size (in bits): 32
Default Value: 0x00000000

DWord	Bit	Description
0	31:30	**Message Mode** Project: All Format: Enumeration Specifies the Media Block Write Message subtype is Byte Masked. Value / Name / Description / Project: 02h / BYTE_MASK / The Block Height and Block Width fields are specified in this Dword. The Byte Mask qualifies which bytes are written. / All Others / Reserved / Reserved. / All
	29	**Reserved** Project: All Format: Ignore Ignored
	28:24	**Sub-Register Offset** Project: All Format: U5 This field is ignored (reserved) for Media Block Write message.
	23:22	**Reserved** Project: All Format: Ignore Ignored
	21:16	**Block Height** Project: All Format: U6 Height in rows of block being accessed. Range = [0,63] representing 1 to 64 rows Restriction: If Block Width (bytes), then Maximum Block Height (rows) is constrained by (# Dwords width) *

MHC_MBBM_CONTROL - Byte Masked Media Block Message Header Control

		(# rows) <= 64 Dwords.
	15:10	**Reserved** Project: All Format: Ignore Ignored
	9:8	**Register Pitch Control** Project: All Format: U2 This field is ignored (reserved) for a Media Block Write message.
	7:6	**Reserved** Project: All Format: Ignore Ignored
	5:0	**Block Width** Project: All Format: U6 Width in bytes of the block being accessed. Range = [0,31] representing 1 to 32 Bytes. **Programming Notes** Must be DWord aligned for Media Block Write message.

CC_VIEWPORT

CC_VIEWPORT

Project:	CHV, BSW
Source:	PRM
Size (in bits):	64
Default Value:	0x00000000, 0x00000000

The viewport state is stored as an array of up to 16 elements, each of which contains the DWords described here. The start of each element is spaced 2 DWords apart. The first element of the viewport state array is aligned to a 32-byte boundary. The Minimum Depth must be be greater than or equal to zero on D16_UNORM, D24_UNORM_X8_UINT, or D24_UNORM_S8_UINT depth formats. The Minimum Depth must be greater than or equal to -1.0 for D32_FLOAT_S8X24_UINT or D32_FLOAT formats. The Maximum Depth must be less than or equal to +1.0. The max must be greater than or equal to the min.

DWord	Bit	Description
0	31:0	**Minimum Depth** Project: All Format: IEEE_Float Indicates the minimum depth. The interpolated or computed depth is clamped to this value prior to the depth test. **Programming Notes** The Minimum depth value must be less-than-or-equal to the Maximum depth value. The Minimum depth value cannot be NAN (Not-A-Number). The Minimum depth value must not be less than -1.0.
1	31:0	**Maximum Depth** Project: All Format: IEEE_Float Indicates the maximum depth. The interpolated or computed depth is clamped to this value prior to the depth test. **Programming Notes** The Maximum depth value cannot be NAN (Not-A-Number). The Maximum depth value must be less-than-or-equal to +1.0.

Channel Mask Message Descriptor Control Field

MDC_CMASK - Channel Mask Message Descriptor Control Field

Project: CHV, BSW
Source: PRM
Size (in bits): 4
Default Value: 0x00000000

DWord	Bit	Description
0	3:0	**Mask**

Project:	All
Format:	Enumeration

For the read message, indicates that which channels are read from the surface and included in the writeback message. For the write message, indicates which channels are included in the message payload and written to the surface.

Value	Name	Description	Project
00h	RGBA **[Default]**	Red, Green, Blue, and Alpha are included	All
01h	GBA	Green, Blue, and Alpha are included	All
02h	RBA	Red, Blue, and Alpha are included	All
03h	BA	Blue and Alpha are included	All
04h	RGA	Red, Green, and Alpha are included	All
05h	GA	Green and Alpha are included	All
06h	RA	Red and Alpha are included	All
07h	A	Alpha is included	All
08h	RGB	Red, Green, and Blue are included	All
09h	GB	Green and Blue are included	All
0Ah	RB	Red and Blue are included	All
0Bh	B	Blue is included	All
0Ch	RG	Red and Green are included	All
0Dh	G	Green is included	All
0Eh	R	Red is included	All
0Fh	Reserved	Ignored	All

Channel Mode Message Descriptor Control Field

MDC_CMODE - Channel Mode Message Descriptor Control Field

Project: CHV, BSW
Source: PRM
Size (in bits): 1
Default Value: 0x00000000

DWord	Bit	Description
0	0	**Channel Mode** Project: All Format: Enumeration Two modes of channel-enable are provided: a SIMD8 or SIMD16 Dword channel serial view of a register, and a SIMD4x2 view of a register.

Value	Name	Description	Project
0	Oword	All 4 Dwords are read or written if one or more of these channels are enabled	All
1	Dword	Each Dword is read or written only if its corresponding channel is enabled.	All

COLOR_CALC_STATE

COLOR_CALC_STATE

Project:	CHV, BSW
Source:	PRM
Size (in bits):	192
Default Value:	0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000

This definition applies to [CHV, BSW] devices. It is pointed to by a field in 3DSTATE_CC_STATE_POINTERS, and stored at a 64-byte aligned boundary.

DWord	Bit	Description
0	31:24	**Stencil Reference Value** Project: CHV, BSW Format: U8.0 This field specifies the stencil reference value to compare against in the (front face) StencilTest function.
	23:16	**BackFace Stencil Reference Value** Project: CHV, BSW Format: U8.0 This field specifies the stencil reference value to compare against in the StencilTest function.
	15	**Round Disable Function Disable** Disables the round-disable function of the color calculator. Value 0 – Name: Cancelled – Description: Dithering is cancelled based on the data used by blend to avoid drift. Value 1 – Name: Not Cancelled – Description: Dithering is NOT cancelled.
	14:1	**Reserved** Format: MBZ
	0	**Alpha Test Format** This field selects the format for Alpha Reference Value and the format in which Alpha Test is performed. Value 0h – Name: ALPHATEST_UNORM8 – Description: UNorm8 Value 1h – Name: ALPHATEST_FLOAT32 – Description: Float32 **Programming Notes** Alpha-test format is independent of RT format. When PS outputs UNIT/SINT alpha-value, it will be treated as IEEE 32bit float number for the purpose of alpha-test.
1	31:0	**Alpha Reference Value As UNORM8**

COLOR_CALC_STATE

		Exists If: [Alpha Test Format] == 'ALPHATEST_UNORM8' Format: UNORM8 Upper 24 bits MBZ This field specifies the alpha reference value to compare against in the Alpha Test function.
	31:0	**Alpha Reference Value As FLOAT32** Exists If: [Alpha Test Format] == 'ALPHATEST_FLOAT32' Format: IEEE_Float This field specifies the alpha reference value to compare against in the Alpha Test function.
2	31:0	**Blend Constant Color Red** Format: IEEE_Float This field specifies the Red channel of the Constant Color used in Color Buffer Blending.
3	31:0	**Blend Constant Color Green** Format: IEEE_Float This field specifies the Green channel of the Constant Color used in Color Buffer Blending.
4	31:0	**Blend Constant Color Blue** Format: IEEE_Float This field specifies the Blue channel of the Constant Color used in Color Buffer Blending.
5	31:0	**Blend Constant Color Alpha** Format: IEEE_Float This field specifies the Alpha channel of the Constant Color used in Color Buffer Blending.

COLOR_PROCESSING_STATE - ACE State

COLOR_PROCESSING_STATE - ACE State

Project:	CHV, BSW
Source:	PRM
Size (in bits):	416
Default Value:	0x00000068, 0x4C382410, 0x9C887460, 0xEBD8C4B0, 0x604C3824, 0xB09C8874, 0x0000D8C4, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000

This state structure contains the ACE state used by the color processing function. It corresponds to DW29..DW41 of the Color Processing State.

DWord	Bit	Description
0	31:7	**Reserved** Format: MBZ
	6:2	**Skin Threshold** Format: U5 Used for Y analysis (min/max) for pixels which are higher than skin threshold. Value: 1-31 Value: 26 **[Default]**
	1	**Full Image Histogram** Default Value: 0 Format: Enable Used to ignore the area of interest for full image histogram.
	0	**ACE Enable** Format: Enable
1	31:24	**Y3** Default Value: 76 Format: U8 The value of the y_pixel for point 3 in PWL.
	23:16	**Y2** Default Value: 56 Format: U8 The value of the y_pixel for point 2 in PWL.
	15:8	**Y1**

COLOR_PROCESSING_STATE - ACE State

		Default Value: 36 Format: U8 The value of the y_pixel for point 1 in PWL.
	7:0	**Ymin** Default Value: 16 Format: U8 The value of the y_pixel for point 0 in PWL.
2	31:24	**Y7** Default Value: 156 Format: U8 The value of the y_pixel for point 7 in PWL.
	23:16	**Y6** Default Value: 136 Format: U8 The value of the y_pixel for point 6 in PWL.
	15:8	**Y5** Default Value: 116 Format: U8 The value of the y_pixel for point 5 in PWL.
	7:0	**Y4** Default Value: 96 Format: U8 The value of the y_pixel for point 4 in PWL.
3	31:24	**Ymax** Default Value: 235 Format: U8 The value of the y_pixel for point 11 in PWL.
	23:16	**Y10** Default Value: 216 Format: U8 The value of the y_pixel for point 10 in PWL.

COLOR_PROCESSING_STATE - ACE State

	15:8	**Y9** Default Value: 196 Format: U8 The value of the y_pixel for point 9 in PWL.
	7:0	**Y8** Default Value: 176 Format: U8 The value of the y_pixel for point 8 in PWL.
4	31:24	**B4** Default Value: 96 Format: U8 The value of the bias for point 4 in PWL.
	23:16	**B3** Default Value: 76 Format: U8 The value of the bias for point 3 in PWL.
	15:8	**B2** Default Value: 56 Format: U8 The value of the bias for point 2 in PWL.
	7:0	**B1** Default Value: 36 Format: U8 The value of the bias for point 1 in PWL.
5	31:24	**B8** Default Value: 176 Format: U8 The value of the bias for point 8 in PWL.
	23:16	**B7** Default Value: 156 Format: U8 The value of the bias for point 7 in PWL.

COLOR_PROCESSING_STATE - ACE State

	15:8	**B6** Default Value: 136 Format: U8 The value of the bias for point 6 in PWL.
	7:0	**B5** Default Value: 116 Format: U8 The value of the bias for point 5 in PWL.
6	31:16	**Reserved** Format: MBZ
	15:8	**B10** Default Value: 216 Format: U8 The value of the bias for point 10 in PWL.
	7:0	**B9** Default Value: 196 Format: U8 The value of the bias for point 9 in PWL.
7	31:27	**Reserved** Format: MBZ
	26:16	**S1** Format: U1.10 The value of the slope for point 1 in PWL. The default is 1024/1024.
	15:11	**Reserved** Format: MBZ
	10:0	**S0** Format: U1.10 The value of the slope for point 0 in PWL. The default is 1024/1024.
8	31:27	**Reserved** Format: MBZ
	26:16	**S3**

COLOR_PROCESSING_STATE - ACE State

		Format: U1.10 The value of the slope for point 3 in PWL. The default is 1024/1024.
	15:11	**Reserved** Format: MBZ
	10:0	**S2** Format: U1.10 The value of the slope for point 2 in PWL. The default is 1024/1024.
9	31:27	**Reserved** Format: MBZ
	26:16	**S5** Format: U1.10 The value of the slope for point 5 in PWL. The default is 1024/1024.
	15:11	**Reserved** Format: MBZ
	10:0	**S4** Format: U1.10 The value of the slope for point 4 in PWL. The default is 1024/1024.
10	31:27	**Reserved** Format: MBZ
	26:16	**S7** Format: U1.10 The value of the slope for point 7 in PWL. The default is 1024/1024.
	15:11	**Reserved** Format: MBZ
	10:0	**S6** Format: U1.10 The value of the slope for point 6 in PWL. The default is 1024/1024.
11	31:27	**Reserved** Format: MBZ
	26:16	**S9** Format: U1.10 The value of the slope for point 9 in PWL. The default is 1024/1024.

COLOR_PROCESSING_STATE - ACE State		
	15:11	**Reserved** Format: MBZ
	10:0	**S8** Format: U1.10 The value of the slope for point 8 in PWL. The default is 1024/1024.
12	31:11	**Reserved** Format: MBZ
	10:0	**S10** Format: U1.10 The value of the slope for point 10 in PWL. The default is 1024/1024.

COLOR_PROCESSING_STATE - CSC State

COLOR_PROCESSING_STATE - CSC State

Project: CHV, BSW

This state structure contains the STD/STE state used by the color processing function.

DWord	Bit	Description
0	31:24	**V_Mid** Default Value: 154 Format: U8 Rectangle middle-point V coordinate
	23:16	**U_Mid** Default Value: 110 Format: U8 Rectangle middle-point U coordinate
	15:10	**Hue Max** Default Value: 14 Format: U6 Rectangle half width
	9:4	**Sat Max** Default Value: 31 Format: U6 Rectangle half length.
	3	**Reserved** Format: MBZ
	2	**Output Control** Value 0: Output Pixels **[Default]** Value 1: Output STD Decisions

COLOR_PROCESSING_STATE - STD/STE State

	1	**STE Enable** Format: Enable
	0	**STD Enable** Format: Enable
1	31	**Reserved** Format: MBZ
	30:28	**Diamond Margin** Default Value: 4 Format: U3
	27:21	**Diamond du** Default Value: 0 Format: S6 2's complement Rhombus center shift in the sat-direction, relative to the rectangle center.
	20:18	**HS Margin** Default Value: 3 Format: U3
	17:10	**Cos(α)** Format: S0.7 2's Compliment The default is 79/128
	9:8	**Reserved** Format: MBZ
	7:0	**Sin(α)** Format: S0.7 2's Compliment The default is 101/128
2	31:21	**Reserved** Format: MBZ
	20:13	**Diamond Alpha** Format: U2.6 1 / tan(β) The default is 100/64
	12:7	**Diamond Th** Default Value: 35 Format: U6 Half length of the rhombus axis in the sat-direction.

COLOR_PROCESSING_STATE - STD/STE State

	6:0	**Diamond dv** Default Value: 0 Format: S6 2's complement
3	31:24	**Y_point_3** Default Value: 254 Format: U8 Third point of the Y piecewise linear membership function.
	23:16	**Y_point_2** Default Value: 47 Format: U8 Second point of the Y piecewise linear membership function.
	15:8	**Y_point_1** Default Value: 46 Format: U8 First point of the Y piecewise linear membership function.
	7	**VY_STD_Enable** Format: Enable Enables STD in the VY subspace.
	6:0	**Reserved** Format: MBZ
4	31:18	**Reserved** Format: MBZ
	17:13	**Y_Slope_2** Format: U2.3 Slope between points Y3 and Y4. The default is 31/8.
	12:8	**Y_Slope_1** Format: U2.3 Slope between points Y1 and Y2. The default is 31/8.
	7:0	**Y_point_4** Default Value: 255 Format: U8 Fourth point of the Y piecewise linear membership function

COLOR_PROCESSING_STATE - STD/STE State

5	31:16	**INV_skin_types_margin** Format: U0.16 1/(2* Skin_types_margin) Value: 20 — Name: **[Default]** — Description: Skin_Type_margin
	15:0	**Inverse Margin VYL** Format: U0.16 1 / Margin_VYL The default is 3300/65536
6	31:24	**P1L** Default Value: 216 Format: U8 Y Point 1 of the lower part of the detection PWLF.
	23:16	**P0L** Default Value: 46 Format: U8 Y Point 0 of the lower part of the detection PWLF.
	15:0	**Inverse Margin VYU** Format: U0.16 1 / Margin_VYU The default is 1600/65536.
7	31:24	**B1L** Default Value: 130 Format: U8 V Bias 1 of the lower part of the detection PWLF.
	23:16	**B0L** Default Value: 133 Format: U8 V Bias 0 of the lower part of the detection PWLF.
	15:8	**P3L** Default Value: 236 Format: U8 Y Point 3 of the lower part of the detection PWLF.
	7:0	**P2L**

COLOR_PROCESSING_STATE - STD/STE State

		Default Value: 236 Format: U8 Y point 2 of the lower part of the detection PWLF.
8	31:27	**Reserved** Format: MBZ
	26:16	**S0L** Format: S2.8 2's complement Slope 0 of the lower part of the detection PWLF. The default is -5/256.
	15:8	**B3L** Default Value: 130 Format: U8 V Bias 3 of the lower part of the detection PWLF.
	7:0	**B2L** Default Value: 130 Format: U8 V Bias 2 of the lower part of the detection PWLF.
9	31:22	**Reserved** Format: MBZ
	21:11	**S2L** Format: S2.8 2's complement Slope 2 of the lower part of the detection PWLF. The default is 0/256.
	10:0	**S1L** Format: S2.8 2's complement Slope 1 of the lower part of the detection PWLF. The default is 0/256.
10	31:27	**Reserved** Format: MBZ
	26:19	**P1U** Default Value: 66 Format: U8 Y Point 1 of the upper part of the detection PWLF.
	18:11	**P0U**

COLOR_PROCESSING_STATE - STD/STE State

		Default Value: 46 Format: U8 Y Point 0 of the upper part of the detection PWLF.
	10:0	**S3L** Format: S2.8 2's complement Slope 3 of the lower part of the detection PWLF. The default is 0/256.
11	31:24	**B1U** Default Value: 163 Format: U8 V Bias 1 of the upper part of the detection PWLF.
	23:16	**B0U** Default Value: 143 Format: U8 V Bias 0 of the upper part of the detection PWLF.
	15:8	**P3U** Default Value: 236 Format: U8 Y Point 3 of the upper part of the detection PWLF.
	7:0	**P2U** Default Value: 150 Format: U8 Y Point 2 of the upper part of the detection PWLF.
12	31:27	**Reserved** Format: MBZ
	26:16	**S0U** Format: S2.8 2's complement Slope 0 of the upper part of the detection PWLF. The default is 256/256.
	15:8	**B3U** Default Value: 140 Format: U8 V Bias 3 of the upper part of the detection PWLF.

COLOR_PROCESSING_STATE - STD/STE State

4	31:16	**Color Transit Slope 23** Default Value: 744 Format: U0.16 The calculation result of 1 / (BC3 - BC2) [1/62]
	15:0	**Color Transit Slope 12**

COLOR_PROCESSING_STATE - TCC State

		Default Value: 405 Format: U0.16 The calculation result of 1 / (BC2 - BC1) [1/57]
5	31:16	**Color Transit Slope 45** Default Value: 407 Format: U0.16 The calculation result of 1 / (BC5 - BC4) [1/57]
	15:0	**Color Transit Slope 34** Default Value: 1131 Format: U0.16 The calculation result of 1 / (BC4 - BC3) [1/61]
6	31:16	**Color Transit Slope 61** Default Value: 377 Format: U0.16 The calculation result of 1 / (BC1 - BC6) [1/62]
	15:0	**Color Transit Slope 56** Default Value: 372 Format: U0.16 The calculation result of 1 / (BC6 - BC5) [1/62]
7	31:22	**Color Bias 3** Default Value: 0 Format: U2.8 Color bias for BaseColor3.
	21:12	**Color Bias 2** Default Value: 150 Format: U2.8 Color bias for BaseColor2.
	11:2	**Color Bias 1** Default Value: 0 Format: U2.8 Color bias for BaseColor1.

COLOR_PROCESSING_STATE - TCC State

	1:0	**Reserved** Format: MBZ
8	31:22	**Color Bias 6** Default Value: 0 Format: U2.8 Color bias for BaseColor6.
	21:12	**Color Bias 5** Default Value: 0 Format: U2.8 Color bias for BaseColor5.
	11:2	**ColorBias4** Default Value: 0 Format: U2.8 Color bias for BaseColor4.
	1:0	**Reserved** Format: MBZ
9	31	**Reserved** Format: MBZ
	30:24	**UV Threshold** Default Value: 3 Format: U7 Low UV threshold.
	23:19	**Reserved** Format: MBZ
	18:16	**UV Threshold Bits** Default Value: 3 Format: U3 Low UV transition width bits.
	15:13	**Reserved** Format: MBZ
	12:8	**STE Threshold** Default Value: 0 Format: U5

COLOR_PROCESSING_STATE - TCC State

		Skin tone pixels enhancement threshold.
	7:3	**Reserved** Format: MBZ
	2:0	**STE Slope Bits** Default Value: 0 Format: U3 Skin tone pixels enhancement slope bits.
10	31:16	**Inverse UVMax Color** Default Value: 146 Format: U0.16 1 / UVMaxColor. Used for the SFs2 calculation.
	15:9	**Reserved** Format: MBZ
	8:0	**UVMax Color** Default Value: 448 Format: U9 The maximum absolute value of the legal UV pixels. Used for the SFs2 calculation.

Color Calculator State Pointer Message Header Control

MHC_RT_CCSP - Color Calculator State Pointer Message Header Control

Project: CHV, BSW
Source: PRM
Size (in bits): 32
Default Value: 0x00000000

DWord	Bit	Description
0	31:6	**Color Calculator State Pointer** Project: All Format: GeneralStateOffset[31:6] Specifies the 64-byte aligned point to the color calculator state. This pointer is relative to the General State Base Address.
	5:0	**Reserved** Project: All Format: Ignore Ignored

Color Code Message Header Control

MHC_RT_CC - Color Code Message Header Control		
Project:	CHV, BSW	
Source:	PRM	
Size (in bits):	32	
Default Value:	0x00000000	

DWord	Bit	Description
0	31:10	**Reserved** Project: All Format: Ignore Ignored
	9:8	**Color Code** Project: All Format: U2 This ID is assigned by the Windower unit and is used to track synchronizing events. Reserved for HW implementation use
	7:0	**FFTID** Project: All Format: U8 This ID is assigned by the fixed function unit and is a unique identifier for the thread. It is used to free up resources used by the thread upon thread completion.

Context Descriptor Format

Context Descriptor Format

Project:	CHV, BSW
Source:	PRM
Size (in bits):	64
Default Value:	0x00000020, 0x00000000

This is the format of context descriptors which make up submitted execlists.

DWord	Bit	Description

0	63:32	**Context ID**
		Context ID is a unique field assigned by GFX driver when a new context is created by which it is identified across all hierarchies of SW and HW.
		• Context ID is used for semaphore signaling by hardware and software.
		• Context ID matching is used by hardware to detect Lite Restore.
		• Context ID is used by hardware for page fault reporting and response with IOMMU.
		• Context switch reason and the associated Context ID are reported to Context Switch Status Buffer by hardware on a context switch.
		
		Context ID which is a 32 bit field is further divided in to three segments described below:
		• **Bits[63:55] (Bits 31:23 of Context ID)** is referred to as GroupID. GroupId+PASID combination of a context must be a unique identifier for contexts that are active in the system. The definition of active context is listed as:
		  • Any Context that is already submitted to h/w or already running in h/w.
		  • Any Context that hit page faults, was preempted (didn't run to context complete), and is waiting to be resubmitted pending IOMMU "last in group" response.
		  • Any Context that has experienced reset but not all faults are responded to.
		• **Bit[54] (Bit 22 of Context ID)** – MBZ for SW programming; this bit is used by hardware to distinguish between F&H vs F&S page requests and response messages to and from IOMMU. This bit is used by hardware on receiving page response to properly manage the page fault counters
		• **Bit[53] (Bit 21 of Context ID)** – MBZ from SW programming, is reserved for future hardware use.
		• **Bits[52:32] (Bits 20:0 of Context ID)** are for software use-only and must be unique field assigned by GFX driver when a new context is created.

	31:12	**Logical Ring Context Address (LRCA)** Format: GraphicsAddress[31:12] This field contains the 4 KB-aligned address of the Logical Ring Context associated with this execlist element. LRCA must be always programmed in GGTT memory.
	11:9	**Reserved**

Context Descriptor Format

	Format:	MBZ

8 Privilege Access

This field when set indicates PPGTT enabled in legacy context mode.
In advanced context mode this field is reserved and must be zero.

7:6 Fault Handling

Project:	CHV, BSW
Source:	RenderCS

Value	Name	Description	Project
0h	Fault and Hang	Fault model is not supported and fault occurrence is treated as catastrophic. GAM indicates Fault Error to Command streamer. Fault Error interrupt is reported to scheduler. Command Streamer will not initiate context switch on occurrence of Fault Error.	
1h	Reserved	Reserved	
2h	Reserved	Reserved	
3h	Reserved		

Programming Notes	Project
When execlist mode is set to "Legacy Context mode" Fault Handling mode must be set to "Fault and Hang." For proper programming for Page Fault modes, refer to memory interface section of the PRM for the corresponding generation.	CHV, BSW

7:6 Reserved

Project:	CHV, BSW
Source:	BlitterCS, VideoCS, VideoCS2, VideoEnhancementCS
Format:	MBZ

5 L3-LLC Coherency

Project:	CHV, BSW

The L3-LLC Coherency is controlled by HDC_Chicken0::ForceNonCoherent (bit 4). The L3-LLC Coherency bit must be set for the ForceNonCoherent control to work properly.

Value	Name
1h	Required **[Default]**
0h	Reserved

4:3 Addressing Mode & Legacy Context

Project:	CHV, BSW
Format:	U2

Legacy context set indicates GPU is operating in legacy context mode of operation and doesn't support any SVM features. Legacy context reset indicates GPU is operating in advanced context mode of operation and support SVM features. Based on the Context mode set Addressing mode is interpreted appropriately. The table below summarizes the combinations supported.

Context Descriptor Format

GFX engine always uses 32b virtual addressing mode when translated using GGTT irrespective of below options.

Value	Name	Description
00b	Advanced Context with no A/D support	GPU is enabled for advanced context mode and supports SVM features. GPU DOESN'T support Access and Dirty bit management in page tables. GPU supports 64b(48bit canonical) PPGTT graphics virtual addressing. PDP0_DESCRIPTOR contains the PASID (process address space identifier) and other PDP Descriptors are ignored.
01b	Legacy Context with no 64 bit VA support	GPU is enabled for legacy context mode of operation and DOESN'T support any SVM features. GPU supports 32b PPGTT graphics virtual addressing. PDP*_DESCRIPTOR contains the base address to 4GB of memory space supported.
10b	Advanced Context with A/D support	GPU is enabled for advanced context mode and supports SVM features. GPU DOES support Access and Dirty bit management in page tables. GPU supports 64b (48bit canonical) PPGTT graphics virtual addressing. PDP0_DESCRIPTOR contains the PASID (process address space identifier) and other PDP Descriptors are ignored.
11b	Legacy Context with 64 bit VA support	GPU is enabled for legacy context mode of operation and DOESN'T support any SVM features. GPU supports 64b (48bit canonical) PPGTT graphics virtual addressing and PDP0_DESCRIPTOR contains the base address to PML4 and other PDP Descriptors are ignored.

Programming Notes	Project
Advanced context and 64 bit Virtual addressing are not supported on CHV, BSW. Only legal value that must be programmed on CHV, BSW is "01b: Legacy Context with no 64 bit VA support".	CHV, BSW

2 **Force Restore**

Setting this bit will force a context restore operation when switching to this context even if the LRCA in the CCID register (normally the LRCA of the last context from the prior execlist) matches this one.

Note that it is legal (and likely desirable) for the **Render Context Restore Inhibit** bit (part of the CTXT_SR_CTL register) in the context image being restored to also be set. The "ring" context is being forced to be restored from a newly initialized context despite a possible LRCA match. However, the render context for such a newly initialized context will likely be uninitialized and so should not be restored.

Programming Notes	Project	Source
Force Restore bit must be always be set on all context submissions, when SW intends to use semaphore signaling (MI_SEMAPHORE_SIGNAL) between command streamers, this is to address known HW issue.	CHV, BSW	PRMPRM

1 **Force PD Restore**

Setting this bit will cause the on-chip page directory to be reloaded from the PD image in memory even on an LRCA match. No other operations of context restore will occur on an LRCA match, however. Software should set this bit if it has updated a context's page directory and

Context Descriptor Format		
		wants the context to begin using the new page directory without having to switch away from it (to another context) and back again. Setting this bit will have no effect if **Force Restore** is also set; a complete context restore (including the PD) will be performed.
	0	**Valid** Set if this register holds a valid context descriptor. SW should set this bit in the Element registers that it has set up to contain valid context descriptors. Any execlist elements that are not used in a submitted execlist must have this bit clear.

Context Status

Context Status

Project: CHV, BSW
Source: PRM
Size (in bits): 64
Default Value: 0x00000000, 0x00000000

DWord	Bit	Description
0	63:32	**Context ID** Format: U32
	31:25	**Reserved** Format: MBZ
	24:20	**Reserved** Project: Format: MBZ
	19:16	**Reserved** Project: CHV, BSW Format: MBZ
	19:16	**Display Plane** Project: CHV, BSW This indicates the display plane for which Wait on Scanline/V-Blank/Sync Flip has been executed leading to context switch. This field is only valid when one of the "Wait on Scanline" or "Wait on Vblnak" or "Wait on sync Flip" is set. Value / Name: 0h: Reserved (future Sprite A) 1h: Reserved (future Sprite B) 2h: Reserved (future Sprite C) 3h: Display Plane Sprite A2 4h: Display Plane Sprite B2 5h: Display Plane Sprite C2 6h: Display Plane Sprite A3 7h: Display Plane Sprite B3 8h: Display Plane Sprite C3 [9h, Fh]: Reserved
	15	**Lite Restore** Format: Enable This bit is only valid only when Preempted bit is set. When set, this bit indicates that a given

Context Status

		context got preempted with the same context resulting in Lite Restore in HW.
	14:12	**Display Plane** Project: CHV, BSW This indicates the display plane for which Wait on Scanline/V-Blank/Sync Flip has been executed leading to context switch. This field is only valid when one of the "Wait on Scanline" or "Wait on Vblnak" or "Wait on sync Flip" is set. (Future - could remove the Sprites and move to bits 19:16) 0h: Display Plane-A 1h: Display Plane-B 2h: Display Plane-C 3h: Display Plane Sprite A 4h: Display Plane Sprite B 5h: Display Plane Sprite C
	11	**Semaphore Wait Mode** 0h: Signal Mode 1h: Poll Mode
	10:9	**Reserved** Format: MBZ
	8	**Wait on Scanline**
	7	**Wait on Semaphore**
	6	**Wait on V-blank**
	5	**Wait on Sync Flip**
	4	**Context Complete** Element is completely processed (Head eqv to Tail) and resulted in a context switch.
	3	**ACTIVE to IDLE** Following this context switch there is no active element available in HW to execute
	2	**Element Switch** Context Switch happened from first element in the current execlist to the second element of the same execlist
	1	**Preempted** Submission of a new execlist has resulted in context switch. The switch is from element in current execlist to element in pending execlist
	0	**IDLE to ACTIVE** Execlist submitted when HW is IDLE. When this bit is set rest of the fields in CSQ are not valid.

Data Port 0 Message Types

MT_DP0 - Data Port 0 Message Types

Project:	CHV, BSW
Source:	DataPort 0
Size (in bits):	5
Default Value:	0x00000000

Lists all the Message Types in a Data Port 0 Message Descriptor [18:14]. The Legacy messages are encoded in Data Port 0 with Bit 18 set to zero. The Message Header is optional for many (but not all) of these operations. The Scratch Block messages are encoded in Data Port 0 with Bit 18 set to one. A Message Header is required.

DWord	Bit	Description
0	4	**Legacy DAP-DC Message** Format: Enumeration Legacy Message

Value	Name	Description
0h	No **[Default]**	Legacy DAP-DC Message
1h	Reserved	Scratch Block Message, descriptor uses different Message Type encoding

DWord	Bit	Description
	3:0	**Message Type** Format: Enumeration Specifies type of message

Value	Name	Description	Project
00h	MT0R_OWB **[Default]**	Oword Block Read message	
01h	MT0R_OWUB	Unaligned Oword Block Read message	
02h	MT0R_OWDB	Oword Dual Block Read message	
03h	MT0R_DWS	Dword Scattered Read message	
04h	MT0R_BS	Byte Scattered Read message	
07h	MT0_MEMFENCE	Memory Fence message	
08h	MT0W_OWB	Oword Block Write message	
0Ah	MT0W_OWDB	Oword Dual Block Write message	
0Bh	MT0W_DWS	Dword Scattered Write message	
0Ch	MT0W_BS	Byte Scattered Write message	
Others	Reserved	Ignored	

Data Port 1 Message Types

MT_DP1 - Data Port 1 Message Types

Project: CHV, BSW
Source: DataPort 1
Size (in bits): 5
Default Value: 0x00000000

Lists all the Message Types in a Data Port 1 Message Descriptor [18:14]. Most surface and atomic operations, both typed and untyped, are encoded on Data Port 1. The Message Header is optional for many (but not all) of these operations. Most A64 Stateless operations are also encoded on Data Port 1. The Message Header is forbidden for all A64 messages on Data Port 1.

DWord	Bit	Description
0	4:0	**Message Type** Format: Enumeration Specifies type of message

Value	Name	Description	Project
00h	MT1R_T **[Default]**	Transpose Read message	
01h	MT1R_US	Untyped Surface Read message

Data Size Message Descriptor Control Field

MDC_DS - Data Size Message Descriptor Control Field

Project: CHV, BSW
Source: PRM
Size (in bits): 2
Default Value: 0x00000000

DWord	Bit	Description
0	1:0	**Data Size** Project: All Format: Enumeration Specifies the number of Bytes to be read or written

Value	Name	Description	Project
00h	B	1 Byte	All
01h	W	2 Bytes	All
02h	DW	4 Bytes	All
03h	Reserved	Reserved	All

DstRegNum

DstRegNum

Project:	CHV, BSW
Source:	Eulsa
Size (in bits):	8
Default Value:	0x00000000

Description	Project
Register Number The register number for the operand. For a GRF register, is the part of a register address that aligns to a 256-bit (32-byte) boundary. For an ARF register, this field is encoded such that MSBs identify the architecture register type and LSBs provide the register number. An ARF register can only be dst or src0. Any src1 or src2 operands cannot be ARF registers. RegNum and SubRegNum together provide the byte-aligned address for the origin of a register region. RegNum provides bits 12:5 of that address. For one-source and two-source instructions, SubregNum provides bits 4:0. For three-source instructions, the address must be DWord-aligned; SubRegNum provides bits 4:2 of the address and bits 1:0 are zero. This field is present for the direct addressing mode and not present for indirect addressing. This field applies to both source and destination operands.	CHV, BSW

DWord	Bit	Description
0	7:0	**Destination Register Number** Value / Name / Description: 0-127 / If {Dst/Src0/Src1/Src2}.RegFile==GRF / 0-0ffh / If {Dst/Src0/Src1/Src2}.RegFile==ARF / This field is used to encode the architecture register as well as providing the register number. See GEN Execution Environment chapter for details.

DstSubRegNum

DstSubRegNum	
Project:	CHV, BSW
Source:	Eulsa
Size (in bits):	5
Default Value:	0x00000000

Description	Project
Subregister Number The subregister number for the operand. For a GRF register, is the byte address within a 256-bit (32-byte) register. For an ARF register, determines the sub-register number according to the specified encoding for the given architecture register. RegNum and SubRegNum together provide the byte-aligned address for the origin of a GRF register region. RegNum provides bits 12:5 of that address. For one-source and two-source instructions, SubregNum provides bits 4:0. For three-source instructions, the address must be DWord-aligned; SubRegNum provides bits 4:2 of the address and bits 1:0 are zero.	CHV, BSW

Programming Notes
Note: The recommended instruction syntax uses subregister numbers within the GRF in units of actual data element size, corresponding to the data type used. For example for the F (Float) type, the assembler syntax uses subregister numbers 0 to 7, corresponding to subregister byte addresses of 0 to 28 in steps of 4, the element size.

DWord	Bit	Description
0	4:0	**Destination Sub Register Number** Value / Name / Description: 0-31 / If {Dst/Src0/Src1/Src2}.RegFile==GRF / 0-0ffh / If {Dst/Src0/Src1/Src2}.RegFile==ARF / This field is used to encode the architecture register as well as providing the register number. See GEN Execution Environment chapter for details.

Dword Data Payload Register

MDCR_DW - Dword Data Payload Register

Project: CHV, BSW
Source: PRM
Size (in bits): 256
Default Value: 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000

DWord	Bit	Description
0.0	31:0	**Dword0** Project: All Format: U32 Specifies the slot 0 data in this payload register
0.1	31:0	**Dword1** Project: All Format: U32 Specifies the slot 1 data in this payload register

DX9_CONSTANTB_ENTRY

DX9_CONSTANTB_ENTRY		
Project:	CHV, BSW	
Source:	RenderCS	
Size (in bits):	32	
Default Value:	0x00000000	
This structure is the payload of the 3DSTATE_DX9_CONSTANTB_* commands. Each entry provides the values for the one boolean constant being updated.		
DWord	**Bit**	**Description**
0	31:0	**Component** Format: U32 The boolean value to be stored.

DX9_CONSTANTF_ENTRY

DX9_CONSTANTF_ENTRY		
Project:	CHV, BSW	
Source:	RenderCS	
Size (in bits):	128	
Default Value:	0x00000000, 0x00000000, 0x00000000, 0x00000000	
This structure is the payload of the 3DSTATE_DX9_CONSTANTF_* commands. Each entry provides the values for the four components of one float constant being updated.		
DWord	**Bit**	**Description**
0	127:96	**Component 3** Format: IEEE_Float The 4th component of the nth float to be stored.
	95:64	**Component 2** Format: IEEE_Float The 3rd component of the nth float to be stored.
	63:32	**Component 1** Format: IEEE_Float The 2nd component of the nth float to be stored.
	31:0	**Component 0** Format: IEEE_Float The 1st component of the nth float to be stored.

DX9_CONSTANTI_ENTRY

DX9_CONSTANTI_ENTRY		
Project:	CHV, BSW	
Source:	RenderCS	
Size (in bits):	128	
Default Value:	0x00000000, 0x00000000, 0x00000000, 0x00000000	
This structure is the payload of the 3DSTATE_DX9_CONSTANTI_* commands. Each entry provides the values for the four components of one integer constant being updated.		
DWord	**Bit**	**Description**
0	31:0	**Component 0** Format: U32 The 1st component of the nth float to be stored.
1	31:0	**Component 1** Format: U32 The 2nd component of the nth float to be stored.
2	31:0	**Component 2** Format: U32 The 3rd component of the nth float to be stored.
3	31:0	**Component 3** Format: U32 The 4th component of the nth float to be stored.

Encoder Statistics Format

Encoder Statistics Format

Project:	CHV, BSW
Source:	VideoEnhancementCS
Size (in bits):	128
Default Value:	0x00000000, 0x00000000, 0x00000000, 0x00000000

The per block data is intended for use by the video encoder and consists of 16 bytes of Denoise block data and FMD variances. Much of the data is encoded as an 8-bit mantissa with the leading 1 removed and a 4-bit shift. To recover the original 17-bit integer this code can be used: If (exp != 0) Number = ((0x100 | Mantissa) « exp) » 7; else Number = mantissa;

DWord	Bit	Description
0	31:24	**Tearing_Count 1 (FMD Variance[8])** Format: U8 Number of pixels that have (diff_cTcB > diff_cTcT + diff_cBcB) Value 0 — Name — Description: DI is Disabled
	23:16	**Tearing_Count 2** Format: U8 If the frame is Deinterlaced with Top First in the DN/DI state then this is (FMD Variance[9]) = Number of pixels that have (diff_cTpB > diff_cTcT + diff_pBpB) If the frame is bottom first then this is (FMD Variance[10]) = Number of pixels that have (diff_cBpT > diff_pTpT + diff_cBcB) Value 0 — Name — Description: DI is Disabled
	15:8	**Motion_Count (FMD Variance[7])** Format: U8 Number of pixels that are moving (different above a threshold) Value 0 — Name — Description: DI is Disabled
	7:0	**Reserved** Format: MBZ
1	31:28	**sSTAD** Format: U4 Shift for the Sum in time of absolute differences for 16x4. Value 0 — Name — Description: DN is Disabled — Project: CHV, BSW

Encoder Statistics Format

	27:24	**sSHCM** Format: U4 Shift for the Sum horizontaly of absolute differences. Value 0 — Name — Description: DN is Disabled
	23:20	**sSVCM** Format: U4 Shift for the Sum vertically of absolute differences.
	19:16	**sDiff_cTpT** Format: U4 Shift for the sum of differences in top fields of current and previous frame. Value 0 — Name — Description: DI is Disabled
	15:12	**sDiff_cBpB** Format: U4 Shift for the sum of differences in bottom field of current and previous frame. Value 0 — Name — Description: DI is Disabled
	11:8	**sDiff_cTcB** Format: U4 Shift for the sum of differences between top and bottom field in current frame. Value 0 — Name — Description: DI is Disabled
	7:4	**sDiff_cTpB** Format: U4 Shift for the sum of differences between current top and previous bottom. Value 0 — Name — Description: DI is Disabled
	3:0	**sDiff_cBpT** Format: U4 Shift for the sum of differences between current bottom and previous top. Value 0 — Name — Description: DI is Disabled
2	31:24	**mDiff_cBpB (FMD Variance[1])** Format: U8 Mantissa of sum of differences in bottom field of current and previous frame.

Encoder Statistics Format

		Value / **Name** / **Description**: 0 / / DI is Disabled
	23:16	**mDiff_cTcB (FMD Variance[2])** Format: U8 Mantissa of sum of differences between top and bottom field in current frame. **Value** / **Name** / **Description**: 0 / / DI is Disabled
	15:8	**mDiff_cTpB (FMD Variance[3])** Format: U8 Mantissa of sum of differences between current top and previous bottom. **Value** / **Name** / **Description**: 0 / / DI is Disabled
	7:0	**mDiff_cBpT (FMD Variance[4])** Format: U8 Mantissa of sum of differences between current bottom and previous top. **Value** / **Name** / **Description**: 0 / / DI is Disabled

34 MaskCtrl

Project:	CHV, BSW

(formerly WECtrl/Write Enable Control). This flag disables the normal write enables; it should normally be 0.

Value	Name	Description
0	Normal	Use the normal write enables in Dst.ChanEn (normal setting).
1	NoMask	Write all channels except those disabled by predication or by other masks besides the write enables.

Programming Notes
MaskCtrl = NoMask also skips the check for PcIP[n] == ExIP before enabling a channel, as described in the Evaluate Write Enable section.

33 Flag Register Number

EU_INSTRUCTION_BASIC_THREE_SRC		
		This field contains the flag register number for instructions with a non-zero Conditional Modifier.
	32	**Flag Subregister Number** This field contains the flag subregister number for instructions with a non-zero Conditional Modifier.

	46:44	**Src1.SrcType** Format: DataType This field specifies the numeric data type of the source operand src1. The bits of a source operand are interpreted as the identified numeric data type, rather than coerced into a type implied by the operator. Depending on RegFile field of the source operand, there are two different encoding for this field. If a source is a register operand, this field follows the Source Register Type Encoding. If a source is an immediate operand, this field follows the Source Immediate Type Encoding. **Programming Notes** Both source operands, src0 and src1, support immediate types, but only one immediate is allowed for a given instruction and it must be the last operand. Halfbyte integer vector (v) type can only be used in instructions in packed-word execution mode. Therefore, in a two-source instruction where src1 is of type :v, src0 must be of type :b, :ub, :w, or :uw.
	43:42	**Src1.RegFile** Format: RegFile [CHV, BSW]
	41:39	**Src0.SrcType** Format: DataType

EU_INSTRUCTION_BRANCH_CONDITIONAL

	38:37	**Src0.RegFile** Format: RegFile [CHV, BSW]
	36:34	**Destination Data Type** Format: DataType This field specifies the numeric data type of the destination operand dst. The bits of the destination operand are interpreted as the identified numeric data type, rather than coerced into a type implied by the operator. For a send instruction, this field applies to the CurrDst ? the current destination operand.
	33:32	**Destination Register File** Format: RegFile [CHV, BSW] **Value** / **Name** / **Description** 11b / Reserved / Note that it is obvious that immediate cannot be a destination operand.
	31:0	**Header** Format: EU_INSTRUCTION_HEADER [CHV, BSW]

EU_INSTRUCTION_COMPACT_TWO_SRC

EU_INSTRUCTION_COMPACT_TWO_SRC

Project:	CHV, BSW
Source:	Eulsa
Size (in bits):	64
Default Value:	0x00000000, 0x00000000

The following table describes the EU compact instruction format. The compact instruction format for 1 or 2-source instructions is essentially identical to the compact instruction format for earlier generations, but the compact fields expand to somewhat different fields in the native instruction format, as the native instruction format changed for CHV, BSW.

DWord	Bit	Description
0..1	63:56	**Src1.RegNum** Exists If: ([DataTypeIndex][Src1.RegFile]!='IMM') Format: SrcRegNum [CHV, BSW] Maps to 108:101 (Src1.RegNum)
	63:56	**Src1.RegNum** Exists If: ([DataTypeIndex][Src1.RegFile]=='IMM') Maps to 103:96 (Imm32[7:0])
	55:48	**Src0.RegNum** Format: SrcRegNum [CHV, BSW] Maps to 76:69 (Src0.RegNum)
	47:40	**Dst.RegNum** Format: DstRegNum [CHV, BSW] Maps to 60:53 (Dst.RegNum)
	39:35	**Src1Index** Exists If: ([DataTypeIndex][Src1.RegFile]!='IMM') Format: SrcIndex [CHV, BSW] If not an immediate operand, lookup one of 32 12-bit values that maps to bits 120:109. That value is used (from MSB to LSB) for the Src1.VertStride, various Src1 bit fields based on AccessMode (Src1.ChanSel[7:4], Src1.Width, Src1.HorzStride), Src1.AddrMode, and Src1.SrcMod bit fields Maps to 120:109
	39:35	**Src1Index** Exists If: ([DataTypeIndex][Src1.RegFile]=='IMM')

EU_INSTRUCTION_COMPACT_TWO_SRC

If an immediate operand, there is no lookup. Determines bits 127:104 (Imm32[31:8]) as follows: map bits 39:35 directly to bits 108:104. Sign extend to fill bits 127:109. Compact format bit 39 is thus copied to all of bits 127:108 for an immediate operand.

Maps to 127:104

34:30 **Src0Index**

Format:	SrcIndex [CHV, BSW]

Lookup one of 32 12-bit values. That value is used (from MSB to LSB) for the Src0.VertStride, various Src0 bit fields based on AccessMode (Src0.ChanSel[7:4], Src0.Width, Src0.HorzStride), Src0.AddrMode, and Src0.SrcMod bit fields. Note that this field spans a DWord boundary within the QWord compacted instruction.

Maps to 88:77

29 **Compaction Control**

Format:	CmptCtrl

28 **Reserved**

Format:	MBZ

27:24 **Reserved**

Exists If:	(Property[Conditional Modifier]=='false')
Format:	MBZ

27:24 **Conditional Modifier**

Exists If:	(Property[Conditional Modifier]=='true')
Format:	CondModifier [CHV, BSW]

23 **Accumulator Write Control**

Format:	AccWrCtrl

22:18 **SubRegIndex**

Lookup one of 32 15-bit values. That value is used (from MSB to LSB) for various fields for Src1, Src0, and Dst, including ChanEn/ChanSel, SubRegNum, and AddrImm[4] or AddrImm[4:0], depending on AddrMode and AccessMode.

Maps to 100:96, 68:64, 52:48

Value	Name	Description

EU_INSTRUCTION_CONTROLS_A

EU_INSTRUCTION_CONTROLS_A

Project: CHV, BSW
Source: EuIsa
Size (in bits): 16
Default Value: 0x00000000

DWord	Bit	Description
0	15:13	**ExecSize** Format: ExecSize [CHV, BSW] This field determines the number of channels operating in parallel for this instruction. The size cannot exceed the maximum number of channels allowed for the given data type.
	12	**Reserved** Exists If: (Property[Predication]=='false')
	12	**PredInv** Exists If: (Property[Predication]=='true') This field, together with PredCtrl, enables and controls the generation of the predication mask for the instruction. When it is set, the predication uses the inverse of the predication bits generated according to setting of Predicate Control. In other words, effect of PredInv happens after PredCtrl. This field is ignored by hardware if Predicate Control is set to 0000 there is no predication. PMask is the final predication mask produced by the effects of both fields.
	11:8	**Reserved** Exists If: (Property[Predication]=='false') Format: PredCtrl [CHV, BSW]
	11:8	**PredCtrl** Exists If: (Property[Predication]=='true') Format: PredCtrl [CHV, BSW] This field, together with PredInv, enables and controls the generation of the predication mask for the instruction. It allows per-channel conditional execution of the instruction based on the content of the selected flag register. Encoding depends on the access mode. In Align16 access mode, there are eight encodings (including no predication). All encodings are based on group-of-4 predicate bits, including channel sequential, replication swizzles and horizontal any|all operations. The same configuration is repeated for each group-of-4 execution channels.

Value	Name	Description
0	Positive **[Default]**	Positive polarity of predication. Use the predication mask produced by PredCtrl
1	Negative	Negative polarity of predication. If PredCtrl is nonzero, invert the predication mask.

EU_INSTRUCTION_CONTROLS_A

7:6 **Thread Control**

Format:	ThreadCtrl [CHV, BSW]

Thread Control. This field provides explicit control for thread switching. If this field is set to 00b, it is up to the GEN execution units to manage thread switching. This is the normal (and unnamed) mode. In this mode, for example, if the current instruction cannot proceed due to operand dependencies, the EU switches to the next available thread to fill the compute pipe. In another example, if the current instruction is ready to go, however, there is another thread with higher priority that also has an instruction ready, the EU switches to that thread. If this field is set to Switch, a forced thread switch occurs after the current instruction is executed and before the next instruction. In addition, a long delay (longer than the execution pipe latency) is introduced for the current thread. Particularly, the instruction queue of the current thread is flushed after the current instruction is dispatched for execution. Switch is designed primarily as a safety feature in case there are race conditions for certain instructions.

5:4 **QtrCtrl**

Format:	QtrCtrl [CHV, BSW]

Quarter Control. This field provides explicit control for ARF selection. This field combined with NibCtrl and ExecSize determines which channels are used for the ARF registers.

3 **NibCtrl**

Nibble Control. This field is used in some instructions along with QtrCtrl. See the description of QtrCtrl below. NibCtrl is only used for SIMD4 instructions with a DF (Double Float) source or destination.

Value	Name	Description
0	Odd	Use an odd 1/8th for DMask/VMask and ARF (first, third, fifth, or seventh depending on QtrCtrl).
1	Even	Use an even 1/8th for DMask/VMask and ARF (second, fourth, sixth, or eighth depending on QtrCtrl).

Programming Notes
Note that if eighths are given zero-based indices from 0 to 7, then NibCtrl = 0 indicates even indices and NibCtrl = 1 indicates odd indices.

2:1 **DepCtrl**

Format:	DepCtrl [CHV, BSW]

Destination Dependency Control. This field selectively disables destination dependency check and clear for this instruction. When it is set to 00, normal destination dependency control is performed for the instruction hardware checks for destination hazards to ensure data integrity. Specifically, destination register dependency check is conducted before the instruction is made ready for execution. After the instruction is executed, the destination register scoreboard will be cleared when the destination operands retire. When bit 10 is set (NoDDClr), the destination register scoreboard will NOT be cleared when the destination operands retire. When bit 11 is set (NoDDChk), hardware does not check for destination register dependency before the instruction is made ready for execution. NoDDClr and NoDDChk are not mutual exclusive. When this field is

EU_INSTRUCTION_CONTROLS_A

		not all-zero, hardware does not protect against destination hazards for the instruction. This is typically used to assemble data in a fine grained fashion (e.g. matrix-vector compute with dot-product instructions), where the data integrity is guaranteed by software based on the intended usage of instruction sequences.
	0	**AccessMode** Access Mode. This field determines the operand access for the instruction. It applies to all source and destination operands. When it is cleared (Align1), the instruction uses byte-aligned addressing for source and destination operands. Source swizzle control and destination mask control are not supported. When it is set (Align16), the instruction uses 16-byte-aligned addressing for all source and destination operands. Source swizzle control and destination mask control are supported in this mode.

Value	Name
0	Align1 **[Default]**
1	Align16

EU_INSTRUCTION_CONTROLS_B

EU_INSTRUCTION_CONTROLS_B

Project: CHV, BSW
Source: Eulsa
Size (in bits): 4
Default Value: 0x00000000

DWord	Bit	Description
0	3	**Reserved** Exists If: (Property[Saturation]=='false') Format: MBZ
	3	**Saturate** Exists If: (Property[Saturation]=='true') Enables or disables destination saturation. When it is set, output values to the destination register are saturated. The saturation operation depends on the destination data type. Saturation is the operation that converts any value outside the saturation target range for the data type to the closest value in the target range. For a floating-point destination type, the saturation target range is [0.0, 1.0]. For a floating-point NaN, there is no closest value; any NaN saturates to 0.0. Note that enabling Saturate overrides all of the NaN propagation behaviors described for various numeric instructions. Any floating-point number greater than 1.0, including +INF, saturates to 1.0. Any negative floating-point number, including -INF, saturates to 0.0. Any floating-point number in the range 0.0 to 1.0 is not changed by saturation. For an integer destination type, the maximum range for that type is the saturation target range. For example, the saturation range for B (Signed Byte Integer) is [-128, 127]. When Saturate is clear, destination values are not saturated. For example, a wrapped result (modulo) is output to the destination for an overflowed integer value. See the Numeric Data Typessection for information about data types and their ranges. Value / Name / Description: 0 — No destination modification **[Default]** 1 — sat — Saturate the output
	2	**Reserved**
	1	**CmptCtrl** Compaction Control Indicates whether the instruction is compacted to the 64-bit compact instruction format. When this bit is set, the 64-bit compact instruction format is used. The EU decodes the compact format using lookup tables internal to the hardware, but documented for use by software tools. Only some instruction variations can be compacted, the variations supported by those lookup tables and the compact format. See EU Compact Instruction Format [CHV, BSW] for more information. Value / Name / Description: 0 — NoCompaction — No compaction. 128-bit native instruction supporting all instruction options. 1 — Compacted — Compaction is enabled. 64-bit compact instruction supporting only some

EU_INSTRUCTION_CONTROLS_B

		instruction variations.
0	**AccWrCtrl** AccWrCtrl. This field allows per instruction accumulator write control.	

Value	Name	Description
0	Don't write to ACC **[Default]**	
1	Update ACC	Write result to the ACC, and destination

	30:27	**Src1.SrcType** Format: SrcType [CHV, BSW] This field specifies the numeric data type of the source operand src1. The bits of a source operand are interpreted as the identified numeric data type, rather than coerced into a type implied by the operator. Depending on RegFile field of the source operand, there are two different encoding for this field. If a source is a register operand, this field follows the Source Register Type Encoding. If a source is an immediate operand, this field follows the Source Immediate Type Encoding. Value / Name

EU_INSTRUCTION_SOURCES_REG_REG

		11b: Reserved
		Programming Notes Both source operands, src0 and src1, support immediate types, but only one immediate is allowed for a given instruction and it must be the last operand. Halfbyte integer vector (v) type can only be used in instructions in packed-word execution mode. Therefore, in a two-source instruction where src1 is of type :v, src0 must be of type :b, :ub, :w, or :uw.
	26:25	**Src1.RegFile** Format: RegFile [CHV, BSW]
	24:0	**Source 0** Exists If: (Structure[EU_INSTRUCTION_CONTROLS_A][AccessMode]=='Align16') AND (Structure[EU_INSTRUCTION_OPERAND_CONTROLS][Src0.RegFile]!='IMM') Format: EU_INSTRUCTION_OPERAND_SRC_REG_ALIGN16 [CHV, BSW]
	24:0	**Source 0** Exists If: (Structure[EU_INSTRUCTION_CONTROLS_A][AccessMode]=='Align1') AND (Structure[EU_INSTRUCTION_OPERAND_CONTROLS][Src0.RegFile]!='IMM') Format: EU_INSTRUCTION_OPERAND_SRC_REG_ALIGN1 [CHV, BSW]

GATHER_CONSTANT_ENTRY

GATHER_CONSTANT_ENTRY		
Project:	CHV, BSW	
Source:	RenderCS	
Size (in bits):	16	
Default Value:	0x00000000	
DWord	**Bit**	**Description**
0	15:8	**Constant Buffer Offset** Format: Offset[7:0]ConstantBuffer This field specifies the Offset in 128-bit units of the 128b entry fetched from the constant buffer for this entry (including when **On-Die Table Read Enable** is set).
	7:4	**Channel Mask** Mask: Mask[3:0] Format: ConstantBuffer Each bit of this field correspond to the 4 channels of each entry fetched from memory. When the bit is a 1, the corresponding 32-bit value is loaded in FF's push constant buffer. When the bit is a 0, the corresponding 32-bit value is not loaded. If this field is zero it means the entry is not used.
	3:0	**Binding Table Index Offset** Format: Constant Buffer Index offset [3:0]Surface State for ConstantBuffer This field specifies the Binding Table index offset from the **Constant Buffer Binding Table Block** starting point in the Binding Table. This value is added to the **Constant Buffer Binding Table Block** will result in the Binding Table Index pointing to the surface state containing the constant buffer to be referenced. If **?S Constant Buffer Dx9 Enable** is set then a value of '1' specifies that the fetch to the constant buffer should be offset by 4KB in order to address the upper 4K of the constant buffer. Any value greater than '1' is invalid when **VS Constant Buffer Dx9 Enable** is set.

Hardware-Detected Error Bit Definitions

Hardware-Detected Error Bit Definitions

Project: CHV, BSW
Source: RenderCS
Size (in bits): 32
Default Value: 0x00000000

DWord	Bit	Description
0	31:3	**Reserved** Format: MBZ
	2	**Command Privilege Violation Error** Project: CHV, BSW This bit is set if a command classified as privileged is parsed in a non-privileged batch buffer. The command will be converted to a NOOP and parsing will continue.
	1	**Reserved** Format: MBZ
	0	**Instruction Error** This bit is set when the Renderer Instruction Parser detects an error while parsing an instruction. Instruction errors include: • Client ID value (Bits 31:29 of the Header) is not supported (only MI, 2D and 3D are supported). • Defeatured MI Instruction Opcodes: Value: 1 — Name: — Description: Instruction Error detected **Programming Notes** This error indications cannot be cleared except by reset (i.e., it is a fatal error).

DWord	Bit	Description
0	31:0	**Interrupt Status Register Storage** Project: All The content of the ISR register is written to this location whenever an "unmasked" bit of the ISR (as determined by the HWSTAM register) changes state.

Hardware Status Page Layout

1..3	31:0	**Reserved** Project: All Must not be used.
4	31:0	**Ring Head Pointer Storage** Project: All The contents of the Ring Buffer Head Pointer register (register DWord 1) are written to this location either as result of an MI_REPORT_HEAD instruction or as the result of an "automatic report" (see RINGBUF registers).
5..15	31:0	**Reserved** Project: All Must not be used.
16..27	31:0	**Context Status DWords** Project: CHV, BSW
28..30 **Project:** CHV, BSW	31:0	**Reserved** Project: CHV, BSW Must not be used.
31 **Project:** CHV, BSW	31:0	**Last Written Status Offset** Project: CHV, BSW
32..39 **Project:** CHV, BSW	31:0	**Reserved** Project: CHV, BSW
40..46	31:0	**Reserved** Project: All
47	31:0	**Reserved** Project: CHV, BSW
48..1023	31:0	**General Purpose** Project: All These locations can be used for general purpose via the MI_STORE_DATA_INDEX or MI_STORE_DATA_IMM instructions.

Header Forbidden Message Descriptor Control Field

MDC_MHF - Header Forbidden Message Descriptor Control Field

Project:	CHV, BSW
Source:	PRM
Size (in bits):	1
Default Value:	0x00000000

DWord	Bit	Description
0	0	**Message Header Present** Project: All Format: Enumeration Indicates the message forbids a message header.

Value	Name	Description	Project
0h	No **[Default]**	Message header is not present	All
1h	Reserved	Not used	All

Header Present Message Descriptor Control Field

MDC_MHP - Header Present Message Descriptor Control Field

Project:	CHV, BSW
Source:	PRM
Size (in bits):	1
Default Value:	0x00000000

DWord	Bit	Description
0	0	**Message Header Present** Project: All Format: Enumeration Specifies if the message uses the optional message header.

Value	Name	Description	Project
0h	No	Message header is not present	All
1h	Yes	Message header is present	All

Header Required Message Descriptor Control Field

MDC_MHR - Header Required Message Descriptor Control Field

Project:	CHV, BSW
Source:	PRM
Size (in bits):	1
Default Value:	0x00000001

DWord	Bit	Description
0	0	**Message Header Present** Project: All Format: Enumeration Indicates the message requires a message header.

Value	Name	Description	Project
0h	Reserved	Not used	All
1h	Yes **[Default]**	Message header is present	All

HEVC_ARBITRATION_PRIORITY

HEVC_ARBITRATION_PRIORITY

Project: CHV, BSW
Source: PRM
Size (in bits): 2
Default Value: 0x00000000

This field controls the priority of arbitration used in the GAC/GAM pipeline for this surface.

DWord	Bit	Description
0	1:0	**Priority** Format: U2 Value / Name: 00b — Highest priority 01b — Second highest priority 10b — Third highest priority 11b — Lowest priority

HW Generated BINDING_TABLE_STATE

HW Generated BINDING_TABLE_STATE		
Project:	CHV, BSW	
Source:	PRM	
Size (in bits):	16	
Default Value:	0x00000000	
DWord	**Bit**	**Description**
0	15:0	**Surface State Pointer** Format: SurfaceStateOffset[21:6] [CHV, BSW]

Hword 1 Block Data Payload

MDP_HW1 - Hword 1 Block Data Payload		
Project:	CHV, BSW	
Source:	PRM	
Size (in bits):	256	
Default Value:	0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000	
DWord	**Bit**	**Description**
0.0-0.7	255:0	**Hword** Project: All Format: U256 Specifies the Hword data

Hword 2 Block Data Payload

MDP_HW2 - Hword 2 Block Data Payload

Project:	CHV, BSW
Source:	PRM
Size (in bits):	512
Default Value:	0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000

DWord	Bit	Description
0.0-0.7	255:0	**Hword0** Project: All Format: U256 Specifies the Hword data for element 0
1.0-1.7	255:0	**Hword1** Project: All Format: U256 Specifies the Hword data for element 1

Hword 4 Block Data Payload

MDP_HW4 - Hword 4 Block Data Payload		
Project:	CHV, BSW	
Source:	PRM	
Size (in bits):	1024	
Default Value:	0x00000000, 0x00000000	
DWord	**Bit**	**Description**
0.0-0.7	255:0	**Hword0** Project: All Format: U256 Specifies the Hword data for element 0
1.0-1.7	255:0	**Hword1** Project: All Format: U256 Specifies the Hword data for element 1
2.0-2.7	255:0	**Hword2** Project: All Format: U256 Specifies the Hword data for element 2
3.0-3.7	255:0	**Hword3** Project: All Format: U256 Specifies the Hword data for element 3

Hword 8 Block Data Payload

MDP_HW8 - Hword 8 Block Data Payload

Project:	CHV, BSW
Source:	PRM
Size (in bits):	2048
Default Value:	0x00000000, 0x00000000

DWord	Bit	Description
0.0-0.7	255:0	**Hword0** Project: All Format: U256 Specifies the Hword data for element 0
1.0-1.7	255:0	**Hword1** Project: All Format: U256 Specifies the Hword data for element 1
2.0-2.7	255:0	**Hword2** Project: All Format: U256 Specifies the Hword data for element 2
3.0-3.7	255:0	**Hword3** Project: All Format: U256 Specifies the Hword data for element 3
4.0-4.7	255:0	**Hword4** Project: All

MDP_HW8 - Hword 8 Block Data Payload		
		Format: U256 Specifies the Hword data for element 4
5.0-5.7	255:0	**Hword5** Project: All Format: U256 Specifies the Hword data for element 5
6.0-6.7	255:0	**Hword6** Project: All Format: U256 Specifies the Hword data for element 6
7.0-7.7	255:0	**Hword7** Project: All Format: U256 Specifies the Hword data for element 7

Hword Channel Mode Message Header Control

MHC_A64_CMODE - Hword Channel Mode Message Header Control

Project: CHV, BSW
Source: PRM
Size (in bits): 32
Default Value: 0x00000000

DWord	Bit	Description
0	31	**Reserved** Project: All Format: MDC_CMODE [CHV, BSW] Specifies whether the read or write operation occurs on all 4 Dwords if any of those channel enables are set, or else only on the dwords whose corresponding channel enable is set.
	30:0	**Reserved** Project: All Format: Ignore Ignored

Hword Register Blocks Message Descriptor Control Field

MDC_DB_HW - Hword Register Blocks Message Descriptor Control Field

Ignored Message Header

MH_IGNORE - Ignored Message Header	
Project:	CHV, BSW
Source:	DataPort 0
Size (in bits):	256
Default Value:	0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000

Some messages require a message header or have an optional message header, but do not use any information in the header.

DWord	Bit	Description
0-7	255:0	**Reserved** Project: All Format: Ignore Ignored

Inline Data Description for MFD_AVC_BSD_Object

Inline Data Description for MFD_AVC_BSD_Object

Project: CHV, BSW
Source: VideoCS
Size (in bits): 96
Default Value: 0x00000000, 0x00000000, 0x00000000

This structure includes all the required Slice Header parameters and error handling settings for AVC_BSD_OBJECT Command (DW3..DW5).

DWord	Bit	Description
0	31	**Concealment Method** This field specifies the method used for concealment when error is detected. If set, a copy from collocated macroblock location is performed from the concealment reference indicated by the ConCeal_Pic_Id field. If it is not set, a copy from the current picture is performed using Intra 16x16 Prediction method. Value / Name / Description: 0 — Intra 16x16 Prediction 1 — Inter P Copy
	30	**Init Current MB Number** When set, the current Slice_Start_MB_Num, Slice_MB_Start_Hor_Pos and Slice_MB_Start_Vert_Pos fields will be used to initialize the Current_MB_Number register. This effectively disables the concealment capability.
	29	**Intra PredMode (4x4/8x8 Luma) Error Control Bit** Project: CHV, BSW This field controls if AVC decoder will fix Intra Prediction Mode if the decoded value is incorrect according to MB position Value / Name / Description: 0 — AVC decoder will detect and fix IntraPredMode (4x4/8x8 Luma) Errors. 1 — AVC decoder will NOT detect IntraPredMode (4x4/8x8 Luma) Errors. The wrong IntraPredMode value will be retaind.
	28:27	**MB Error Concealment B Temporal Prediction mode** These two bits control how the reference L0/L1 are overridden in B temporal slice. Value / Name / Description: 00b — **[Default]** — Both Reference Indexes L0/L1 are forced to 0 during Concealment 01b — Only Reference Index L1 is forced to 0; Reference Index L0 is forced to -1 10b — Only Reference Index L0 is forced to 0; Reference Index L1 is forced to -1 11b — Reserved — Invalid
	26	**Reserved** Project: CHV, BSW

Inline Data Description for MFD_AVC_BSD_Object

	Format:	MBZ

25 MB Error Concealment B Temporal Motion Vectors Override Enable Flag

During MB Error Concealment on B slice with Temporal Direct Prediction, motion vectors are forced to 0 to improve image quality. This bit can be set to preserve the original weight prediction.

Value	Name	Description
0	**[Default]**	Predicted Motion Vectors are used during MB Concealment
1		Motion Vectors are Overridden to 0 during MB Concealment

24 MB Error Concealment B Temporal Weight Prediction Disable Flag

During MB Error Concealment on B slice with Temporal Direct Prediction, weight prediction is disabled to improve image quality. This bit can be set to preserve the original weight prediction.

Value	Name	Description
0	**[Default]**	Weight Prediction is Disabled during MB Concealment
1		Weight Prediction will not be overridden during MB Concealment

23:22 Reserved

Format:	MBZ

21:16 Concealment Picture ID

This field identifies the picture in the reference list to be used for concealment. This field is only valid if **Concealment Method** is Inter P Copy.

Bit Filed	Value	Defenition
21	0	Frame Picture
21	1	Field picture
20:16	All	Frame Store Index[4:0]

15 Reserved

Format:	MBZ

14 BSD Premature Complete Error Handling

BSD Premature Complete Error occurs in situation where the Slice decode is completed but there are still data in the bitstream.

Value	Name	Description
1		Set the interrupt to the driver (provide MMIO registers for MB address R/W)
0		Ignore the error and continue (masked the interrupt), assume the hardware automatically performs the error handling

13 Reserved

Format:	MBZ

12 MPR Error (MV out of range) Handling

Software must follow the action for each Value as follow:

Value	Name	Description

Inline Data Description for MFD_AVC_BSD_Object

	1		Set the interrupt to the driver (provide MMIO registers for MB address R/W)
	0		Ignore the error and continue (masked the interrupt), assume the hardware automatically performs the error handling

11 — Reserved

Format:	MBZ

10 — Entropy Error Handling

Software must follow the action for each Value as follow:

Value	Name	Description
1		Set the interrupt to the driver (provide MMIO registers for MB address R/W).
0		Ignore the error and continue (masked the interrupt), assume the hardware automatically perform the error handling.

9 — Reserved

Format:	MBZ

8 — MB Header Error Handling

Software must follow the action for each Value as follow:

Value	Name	Description
1		Set the interrupt to the driver (provide MMIO registers for MB address R/W).
0		Ignore the error and continue (masked the interrupt), assume the hardware automatically perform the error concealment.

7:6 — MB Error Concealment B Spatial Prediction mode

These two bits control how the reference L0/L1 are overridden in B spatial slice.

Value	Name	Description
00b	**[Default]**	Both Reference Indexes L0/L1 are forced to 0 during Concealment
01b		Only Reference Index L1 is forced to 0; Reference Index L0 is forced to -1
10b		Only Reference Index L0 is forced to 0; Reference Index L1 is forced to -1
11b	Reserved	Invalid

5 — Reserved

Project:	CHV, BSW
Format:	MBZ

4 — MB Error Concealment B Spatial Motion Vectors Override Disable Flag

During MB Error Concealment on B slice with Spatial Direct Prediction, motion vectors are forced to 0 to improve image quality. This bit can be set to use the predicted motion vectors instead. This bit does not affect normal decoded MB.

Value	Name	Description
0	**[Default]**	Motion Vectors are Overridden to 0 during MB Concealment
1		Predicted Motion Vectors are used during MB Concealment

3 — MB Error Concealment B Spatial Weight Prediction Disable Flag

During MB Error Concealment on B slice with Spatial Direct Prediction, weight prediction is

Inline Data Description for MFD_AVC_BSD_Object

disabled to improve image quality. This bit can be set to preserve the original weight prediction. This bit does not affect normal decoded MB.

Value	Name	Description
0	**[Default]**	Weight Prediction is Disabled during MB Concealment.
1		Weight Prediction will not be overridden during MB Concealment.

2 — Reserved

Project:	CHV, BSW
Format:	MBZ

1 — MB Error Concealment P Slice Motion Vectors Override Disable Flag

During MB Error Concealment on P slice, motion vectors are forced to 0 to improve image quality. This bit can be set to use the predicted motion vectors instead. This bit does not affect normal decoded MB.

Value	Name	Description
0	**[Default]**	Motion Vectors are Overridden to 0 during MB Concealment
1		Predicted Motion Vectors are used during MB Concealment

0 — MB Error Concealment P Slice Weight Prediction Disable Flag

During MB Error Concealment on P slice, weight prediction is disabled to improve image quality. This bit can be set to preserve the original weight prediction. This bit does not affect normal decoded MB.

Value	Name	Description
0	**[Default]**	Weight Prediction is Disabled during MB Concealment.
1		Weight Prediction will not be overridden during MB Concealment.

1

31:16 — First MB Byte Offset of Slice Data or Slice Header

Programming Notes	Project
MFX supports only DXVA2 Long and Short Format.	CHV, BSW

15:8 — Reserved

Format:	MBZ

7 — Fix Prev Mb Skipped

Enables an alternative method for decoding mb_skipped, to cope with an encoder that codes a skipped MB as a direct MB with no coefficient.

6:5 — Reserved

Format:	MBZ

Programming Notes
Please note that the field MUST be set to '0' at this time.

4 — Emulation Prevention Byte Present

Value	Name	Description
0		H/W needs to perform Emulation Byte Removal

Inline Data Description for MFD_AVC_BSD_Object

		1		H/W does not need to perform Emulation Byte Removal
	3	**LastSlice Flag** It is needed for both error concealment at the end of a picture (so, no more phantom). It is also needed to know to set the last MB in a picture correctly. **Value** / **Name** / **Description** 1 /	If the current Slice to be decoded is the very last slice of the current picture. 0 /	If the current Slice to be decoded is any slice other than the very last slice of the current picture
	2:0	**First Macroblock (MB)Bit Offset** Exists If: //AVC Long Format Only Format: U3 This field provides the bit offset of the first macroblock of the Slice in the first byte of the input compressed bitstream.
2 **Project:** CHV, BSW	31	**I Slice Concealment Mode** Project: CHV, BSW This field controls how AVC decoder handle MB concealment in I Slice **Value** / **Name** 0 / Intra Concealment 1 / Inter Concealment **Programming Notes** If this field is set to "1" (Inter Concealment), driver must provide a valid reference picture (programmed using "Concealment Reference Picture" field) for concealment reference picture. In this mode, weight prediction is disabled and motion vectors are forced to 0 as well.
	30	**Reserved** Project: CHV, BSW Format: MBZ
	29:24	**Concealment Reference Picture + Field Bit** Project: CHV, BSW Format: U6 This field provides the concealment reference picture for hardware to conceal in case driver wants to specify one concealment picture. This field matches with the DPB order sent to hardware. This field applies to all I/P/B slices **Bit Filed** / **Value** / **Defenition** 29 / MBZ / is reserved for future expansion 28:25 / All / Reference PIcture Number

Inline Data Description for MFD_AVC_BSD_Object

24	All	Field Bit(if the current picture is a field picture [Frame picture must be 0]

23 P Slice Concealment Mode

Project:	CHV, BSW

This field controls how AVC decoder handle MB concealment in P Slice

Value	Name
1	Intra Concealment
0	Inter Concealment

22:19 Reserved

Project:	CHV, BSW
Format:	MBZ

18:16 P Slice Inter Concealment Mode

Project:	CHV, BSW

This field controls how AVC decoder select reference picture for Concealment in P Slice.

Value	Name	Description
000b		Top of Reference List L0 (Use top entry of Reference List L0)
001b		Driver Specified Concealment Reference
010b		Predicted Reference (Use reference picture predicted using P-Skip Algorithm)
011b		Temporal Closest (Using POC to select the closest forward picture) [For L0: Closest POC smaller than current POC]
100b		First Long Term Picture in Reference List L0 (If no long term picture available, use Temporal Closest Picture)
101b-111b	Reserved	

15 B Slice Concealment Mode

Project:	CHV, BSW

This field controls how AVC decoder handle MB concealment in B Slice

Value	Name
1	Intra Concealment
0	Inter Concealment

14 Reserved

Project:	CHV, BSW
Format:	MBZ

13:12 B Slice Inter Direct Type Concealment Mode

Project:	CHV, BSW

AVC decoder can use Spatial or Temporal Direct for B Skip/Direct. This field determine can override the mode on how AVC decoder handles MB concealment in B slice.

Inline Data Description for MFD_AVC_BSD_Object

Value	Name	Description
00b		Use Default Direct Type (slice programmed direct type)
01b		Forced to Spatial Direct Only
10b		Forced to Temporal Direct Only
11b		Spatial Direct without Temporal Componenet (MovingBlock information)

11 **Reserved**

Project:	CHV, BSW
Format:	MBZ

10:8 **B Slice Spatial Inter Concealment Mode**

Project:	CHV, BSW

This field controls how AVC decoder select reference picture for Spatial Inter Concealment in B Slice.

Value	Name	Description
000b		Top of Reference List L0/L1 (Use top entry of Reference List L0/L1).
001b		Driver Specified Concealment Reference
011b		Temporal Closest (Using POC to select the closest forward picture) [For L0: Closest POC smaller than current POC] [For L1: Closest POC larger than current POC]
100b		" First Long Term Picture in Reference List L0/L1 (If no long term picture available, use Temporal Closest Picture)
101b-111b	Reserved	

7 **Reserved**

Project:	CHV, BSW
Format:	MBZ

6:4 **B Slice Temporal Inter Concealment Mode**

Project:	CHV, BSW

This field controls how AVC decoder select reference picture for Temporal Inter Concealment in B Slice

Value	Name	Description
000b		Top of Reference List L0/L1 (Use top entry of Reference List L0/L1)
001b		Driver Specified Concealment Reference
010b		Predicted Reference (Use reference picture predicted using B-Skip Algorithm)
011b		" Temporal Closest (Using POC to select the closest forward picture) [For L0: Closest POC smaller than current POC] [For L1: Closest POC larger than current POC]
100b		First Long Term Picture in Reference List L0/L1 (If no long term picture

1 Intra 8x8/4x4 Prediction Error Concealment Control Bit

Project:	CHV, BSW

This field controls if AVC goes into MB concealment mode (next MB) when an error is detected on Intra8x8/4x4 Prediction Mode (these 2 modes have fixed coding so it may not affect the bitstream.

Value	Name	Description
0		AVC decoder will NOT go into MB concealment when Intra8x8/4x4 Prediction mode is incorrect.
1		AVC decoder will go into MB concealment when Intra8x8/4x4 Prediction mode is incorrect.

0 Intra Prediction Error Control Bit (applied to Intra16x16/Intra8x8/Intra4x4 Luma and Chroma)

Project:	CHV, BSW

This field controls if AVC decoder will fix Intra Prediction Mode if the decoded value is incorrect according to MB position.

Value	Name	Description
0		AVC decoder will detect and fix Intra Prediction Mode Errors.
1		AVC decoder will retain the Intra Prediction value decoded from bitstream.

Inline Data Description - VP8 PAK OBJECT

Inline Data Description - VP8 PAK OBJECT

Project:	CHV, BSW
Source:	VideoCS
Size (in bits):	128
Default Value:	0x00000000, 0x00000000, 0x00000000, 0x00000000

This structure corresponds to Dw3..6 of MFX_VP8_PAK_OBJECT Command.

DWord	Bit	Description
0	31:23	**Reserved** Format: MBZ
	22:20	**MV Format(Motion Vector Size)** Exists If: //IntraMbFlag = 0 This field specifies the size and format of the output motion vectors. Value / Name / Description: 000b – Intra MB – No Motion vectors 100b – Inter Predict MB (Unpacked Motion Vector Mode) – Sixteen Motion Vectors Per MacroBlock Others – Reserved **Programming Notes** This field MBZ, when the **IntraMbFlag = 1**.
	19:18	**SegmentID** Format: U2 Segment number 0-3
	17	**Enable Coeff Clamp** Value / Name / Description: 1 – Magnitude of coefficients of the current MB is clamped based on the clamping matrix after quantization 0 – No Clamping
	16:14	**Reserved** Format: MBZ
	13	**Intra MB Flag** This field specifies whether the current macroblock is an Intra (I) Macroblock. For Key pictures (IsKyeFrameFlag DW2, bit[5] of MFX_VP8_PIC_STATE), this field must be set to 1. Value / Name: 0h – INTER (Inter MacroBlock)

Inline Data Description - VP8 PAK OBJECT

		1h: INTRA (Intra MacroBlock)

Programming Notes
For I-picture MB (Intra MB Flag =1), this field must be set to 1.

12:11 **RefPicSelect**

This field specifies which reference pic (among Last Frame, Golden Frame and Alt Frame) is selected for the current macroblock when Intra MB Flag = 0 .

Value	Name
00b	Last Frame
01b	Golden Frame
10b	Alt Frame

10:8 **MB Type 3-Bits - Inter/Intra MB**

MB Type 3 Bits [10:8] specifies InterMB MV mode configurations: 16x16 or 2 16x8 or 4 8x8 or 16 4x4 when Intra MB Flag = 0 and bit [8] = IntraMB mode configurations: 4x4 or 16x16 when Intra MB Flag = 1

Value	Name	Description
000b	16x16	**Inter MB** Only DW 6 bits 3:0 are used to indicate MVMode, MVMode can't be split
001b	2 16x8 (mv_Top Bottom)	**Inter MB [10:8]** Split MV is inferred. DW5 bits[3:0] are used for MVMode for first 16x8 partition, DW6 bits[3:0] are used for MVMode for second 16x8 partition.
010b	2 8 x16 (mv_left_right)	**Inter MB [10:8]** Split MV is inferred. DW5 bits[3:0] are used for MVMode for first 8x16 partition, DW5 bits[11:8] are used for MVMode for second 8x16 partition.
011b	4 8x8 (mv_quarters)	**Inter MB [10:8]** Split MV is inferred. DW5 bits[3:0] are used for MVMode for first 8x8 partition. DW5 bits[11:8] are used for MvMode for second 8x8 partition. DW6 bits[3:0] are used for MVMode for third 8x8 partition. DW6 bits[11:8] are used for MVMode for fourth 8x8 partition.
100b	16 4x4 (mv_16)	**Inter MB [10:8]** Split MV is inferred. There are 16 partitions. Each Sub-block uses 4 bits in DW6 and DW7.
0b	16x16	**Intra MB [8]** Only DW5, bits[3:0] are used for Y mode. For B_PRED, "16 4x4" should be used which implies B_PRED mode.
1b	16 4x4	**Intra MB [8]** All bits in DW5 and DW6 are used to represent B_PRED modes (Bmodes) in each sub-blocks.

	3:0	**B Mode for SubBlock8 (Y mode for the macroblock in non-B mode)** For Y-Mode and B-Mode Assignments refer to the assignment lists below this table.

INTERFACE_DESCRIPTOR_DATA

INTERFACE_DESCRIPTOR_DATA

Project: CHV, BSW

Source: RenderCS

Size (in bits): 256

Default Value: 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000

DWord	Bit	Description
0	31:6	**Kernel Start Pointer** Format: InstructionBaseOffset[31:6]Kernel Specifies the 64-byte aligned address offset of the first instruction in the kernel. This pointer is relative to the **Instruction Base Address.**
	5:0	**Reserved** Format: MBZ
1	31:16	**Reserved** Format: MBZ
	15:0	**Kernel Start Pointer High** Format: InstructionBaseOffset[47:32]Kernel This field specifies the high 16 bits of starting address of the Kernel Pointer.
2	31:20	**Reserved** Project: CHV, BSW Format: MBZ
	19	**Denorm Mode** This field specifies how Float denormalized numbers are handles in the dispatched thread. Value / Name / Description: 0h / Ftz / Float denorms will be flushed to zero when appearing as inputs, denorms will never come out of instructions. Double precision float and half precision float numbers are not flushed to zero. 1h / SetByKernel / Denorms will be handled in by kernel.
	18	**Single Program Flow** Specifies whether the kernel program has a single program flow (SIMDnxm with m = 1) or multiple program flows (SIMDnxm with m > 1). Value / Name: 0h / Multiple 1h / Single
	17	**Thread Priority**

INTERFACE_DESCRIPTOR_DATA

Specifies the priority of the thread for dispatch.

Value	Name
0h	Normal Priority
1h	High Priority

16 Floating Point Mode

Specifies the floating point mode used by the dispatched thread.

Value	Name
0h	IEEE-754
1h	Alternate

15:14 Reserved

Format:	MBZ

13 Illegal Opcode Exception Enable

Format:	Enable

This bit gets loaded into EU CR0.1[12] (note the bit # difference). See *Exceptions and ISA Execution Environment*.

12 Reserved

Format:	MBZ

11 Mask Stack Exception Enable

Format:	Enable

This bit gets loaded into EU CR0.1[11]. See *Exceptions and ISA Execution Environment*.

10:8 Reserved

Format:	MBZ

7 Software Exception Enable

Format:	Enable

This bit gets loaded into EU CR0.1[13] (note the bit # difference). See *Exceptions and ISA Execution Environment*.

6:0 Reserved

Format:	MBZ

3 31:5 Sampler State Pointer

Format:	DynamicStateOffset[31:5]SAMPLER_STATE

Specifies the 32-byte aligned address offset of the sampler state table. This pointer is relative to the **Dynamic State Base Address.***This field is ignored for child threads.*

4:2 Sampler Count

Format:	U3

INTERFACE_DESCRIPTOR_DATA

Specifies how many samplers (in multiples of 4) the kernel uses. Used only for prefetching the associated sampler state entries. *This field is ignored for child threads.If this field is not zero, sampler state is prefetched for the first instance of a root thread upon the startup of the media pipeline.*

Value	Name
[0,4]	
0h	No samplers used
1h	Between 1 and 4 samplers used
2h	Between 5 and 8 samplers used
3h	Between 9 and 12 samplers used
4h	Between 13 and 16 samplers used

1:0 Reserved

Format:	MBZ

4 — 31:16 Reserved

Format:	MBZ

15:5 Binding Table Pointer

Format:	SurfaceStateOffset[15:5]BINDING_TABLE_STATE*256

Specifies the 32-byte aligned address of the binding table. This pointer is relative to the **Surface State Base Address**. *This field is ignored for child threads.*

4:0 Binding Table Entry Count

Project:	CHV, BSW
Format:	U5

Specifies how many binding table entries the kernel uses. Used only for prefetching of the binding table entries and associated surface state. *This field is ignored for child threads.If this field is not zero, binding table and surface state are prefetched for the first instance of a root thread upon the startup of the media pipeline.*

Value	Name
[0,31]	

Programming Notes
The maximum number of prefetched binding table entries is limited to 31. For kernels using a large number of binding table entries, it may be wise to set this field to zero to avoid prefetching too many entries and thrashing the state cache.

5 — 31:16 Constant/Indirect URB Entry Read Length

Format:	U16

Specifies the amount of URB data read and passed in the thread payload for the Constant or Indirect URB entry, in 8-DW register increments. A value 0 means that no Constant or Indirect

INTERFACE_DESCRIPTOR_DATA

URB Entry will be loaded. The Constant URB Entry Read Offset field will then be ignored. In GPGPU mode this describes how much data is delivered in a single dispatch. Multiple dispatches in a thread group will deliver constant data offset by this value. The total amount of constant data is (Constant URB Read Length * Number of Threads in GPGPU Thread Group + Cross-Thread Constant Data Read Length).

If **Cross-Thread Constant Data Read Length** for Indirect is greater than 0, then this field must also be greater than 0. The allowed combinations are:

Constant/Indirect URB Entry Read Length **Entry Read Length**	Cross-Thread Constant **Data Read Length**	Notes
=0	=0	No Payload
>0	=0	Per-thread payload only
>0	>0	Both kinds of payload
=0	>0	Only for CURBE payloads

Value	Name
[0,63]	

15:0 Constant URB Entry Read Offset

Format:	U16

Specifies the offset (in 8-DW units) at which Constant URB data is to be read from the URB before being included in the thread payload.

Value	Name	Description
[0,1983]		Indicating [0,1983] 256-bit register increments. ROB has 64KB of storage; 2048 entries. However, lowest 64 entries are reserved for VFE/TS to store interface descriptor data. Hence, (URB Entry Read Offset + Read Length) shall not exceed 1984.

6 31:24 Reserved

Format:	MBZ

23:22 Rounding Mode

Format:	U2

Value	Name	Description
00b	RTNE **[Default]**	Round to Nearest Even
01b	RU	Round toward +Infinity
10b	RD	Round toward -Infinity
11b	RTZ	Round toward Zero

21 Barrier Enable

INTERFACE_DESCRIPTOR_DATA

		Format: Enable This field specifies whether the thread group requires a barrier. If not, it can be dispatched without allocating one.
	20:16	**Shared Local Memory Size** Project: CHV, BSW Format: U5 This field indicates how much shared local memory the thread group requires. The amount is specified in 4k blocks, but only powers of 2 are allowed: 0, 4k, 8k, 16k, 32k and 64k per half-slice.

Value	Name
0	Encodes 0k
1	Encodes 4k
2	Encodes 8k
4	Encodes 16k
8	Encodes 32k
16	Encodes 64k

Programming Notes	Project
If SLMSize > 0, then a barrier must also be allocated.	CHV, BSW

	15	**Reserved** Project: CHV, BSW Format: MBZ
	14:10	**Reserved** Format: MBZ
	9:0	**Number of Threads in GPGPU Thread Group** Project: CHV, BSW Format: U10 Specifies the number of threads that are in this thread group. The minimum value is 1, while the maximum value is the number of threads in a subslice for local barriers. See vol1b Configurations for the number of threads per subslice for different products. The maximum value for global barriers is limited by the number of threads in the system, or by 511, whichever is lower. This field should not be set to 0 even if the barrier is disabled, since an accurate value is needed for proper pre-emption.
7	31:8	**Reserved** Format: MBZ
	7:0	**Cross-Thread Constant Data Read Length** Format: U8 Specifies the amount of constant data in CURBE in 8-DW register increments which will be sent

INTERFACE_DESCRIPTOR_DATA

to every thread in the thread group in addition to the per thread ids specified by **Constant URB Entry Read Length**.

Value	Name
[0,127]	

Invalidate After Read Message Descriptor Control Field

MDC_IAR - Invalidate After Read Message Descriptor Control Field

Project:	CHV, BSW
Source:	PRM
Size (in bits):	1
Default Value:	0x00000000

DWord	Bit	Description
0	0	**Reserved** Project: All Format: MBZ Previously, this Enable field was intended to optimize scratch and spill/fill read messages, where the memory was only used by a single thread and did not need to be maintained after the thread completed. If enabled, it caused all lines in the L3 cache accessed by the message to be invalidated after the read occurred, regardless of whether the line contained modified data. It was intended as a performance hint indicating that the data would no longer be used to avoid writing back data to memory.

JPEG

JPEG		
Project:	CHV, BSW	
Source:	VideoCS	
Size (in bits):	16	
Default Value:	0x00000000	
DWord	**Bit**	**Description**
0	15:5	**Reserved** Format: MBZ
	4	**Inconsistent VLD SE Error** This flag indicates an inconsistent SE coded in the bit-stream. Bit-stream does not match any entries in the hauffman table.
	3	**Extra Block Error** This flag indicates extra block coded within an ECS data boundary.
	2	**Missing block Error** This flag indicates one or more blocks are missing within an ECS data boundary.
	1	**Extra ECS Error** This flag indicates extra ECS' coded in the bit-stream SCAN payload data.
	0	**Missing ECS Error** This flag indicates one or more ECS' are missing from the bit-stream SCAN payload data.

LOD Message Address Payload Control

MACD_LOD - LOD Message Address Payload Control

Project: CHV, BSW
Source: PRM
Size (in bits): 32
Default Value: 0x00000000

DWord	Bit	Description
0	31:4	**Reserved** Project: All Format: MBZ Ignored

Lower Oword Block Data Payload

MDP_OW1L - Lower Oword Block Data Payload		
Project:	CHV, BSW	
Source:	PRM	
Size (in bits):	256	
Default Value:	0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000	
DWord	**Bit**	**Description**
0.0-0.3	127:0	**Oword** Project: All Format: U128 Specifies the upper Oword data element
0.4-0.7	127:0	**Reserved** Project: All Format: Ignore Ignored

MEDIA_SURFACE_STATE

MEDIA_SURFACE_STATE

Project:	CHV, BSW
Source:	PRM
Exists If:	//([MessageType] == 'Deinterlace') OR ([MessageType] == 'Sample_8x8')
Size (in bits):	256
Default Value:	0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000

This is the SURFACE_STATE used by only deinterlace, sample_8x8, and VME messages.

DWord	Bit	Description
0	31:0	**Reserved** Project: CHV, BSW Format: MBZ
1	31:18	**Height** Format: U14-1 This field specifies the height of the surface in units of pixels. For PLANAR surface formats, this field indicates the height of the Y (luma) plane. Value: [0,16383] — Name: — Description: representing heights [1,16384] — Exists If: [Surface Type] != FM_STRBUF_* **Programming Notes** Height (field value + 1) must be a multiple of 2 for PLANAR_420 surfaces.If Vertical Line Stride is 1, this field indicates the height of the field, not the height of the frame.
	17:4	**Width** Format: U14-1 This field specifies the width of the surface in units of pixels. For PLANAR surface formats, this field indicates the width of the Y (luma) plane. Value: [0,16383] — Name: — Description: representing widths [1,16384] — Exists If: [Surface Type] != FM_STRBUF_* **Programming Notes** • The Width specified by this field multiplied by the pixel size in bytes must be less than or equal to the surface pitch (specified in bytes via the Surface Pitch field). • Width (field value + 1) must be a multiple of 2 for PLANAR_420, PLANAR_422, and all YCRCB_* and Y16_UNORM surfaces, and must be a multiple of 4 for PLANAR_411 and Y8_UNORM_VA surfaces. • For deinterlace messages, the Width (field value + 1) must be a multiple of 8.

MEDIA_SURFACE_STATE

- For Y8_UNORM_VA format width should be in multiple of 4, for Y16_UNORM_VA format width should be in multiple of 2, for Y1_UNORM format width should be in multiple of 32
- When Address Control = Mirror, the total width should be in multiple of 4bytes.

Width (field value + 1) must be a multiple of 2 for PLANAR_420_16

3:2 **Picture Structure**

Specifies the encoding of the current picture.

Value	Name
00b	Frame Picture
01b	Top Field Picture
10b	Bottom Field Picture
11b	Invalid, not allowed

1:0 **Cr(V)/Cb(U) Pixel Offset V Direction**

Default Value:	0
Format:	U0.2

Description	Project
Specifies the distance to the U/V values with respect to the even numbered Y channels in the V direction	CHV, BSW

Programming Notes	Project
This field is ignored for all formats except PLANAR_420_8	CHV, BSW

2 31:27 **Surface Format**

Project:	CHV, BSW

Specifies the format of the surface. All of the Y and G channels will use table 0 and all of the Cr/Cb/R/B channels will use table 1.

Note: Y8_UNORM_VA, Y16_UNORM and Y16_SNORM are used for all functions of sample_8x8 except AVS where rest of the formats are not used. These two formats are packed as 32bits in L1 though the individual pixels are either 8bpp or 16bpp respectively.

Value	Name	Description
4	PLANAR_420_8	
5	Y8_UNORM_VA	Sample_8x8 only except AVS
6	Y16_SNORM	Sample_8x8 only except AVS
7	Y16_UNORM_VA	Sample_8x8 only except AVS
8	R10G10B10A2_UNORM	Sample_8x8 only
9	R8G8B8A8_UNORM	Sample_8x8 AVS only

MEDIA_SURFACE_STATE

11	R8_UNORM (Cr/Cb)	Sample_8x8 AVS only
12	Y8_UNORM	Sample_8x8 AVS only
13	A8Y8U8V8_UNORM	Sample_8x8 AVS only
14	B8G8R8A8_UNORM	Sample_8x8 AVS only
15	R16G16B16A16	Sample_8x8 AVS only
16	Y1_UNORM	Sample_8x8 only for boolean surfaces (1bit/pixel)
Others	Reserved	

26 Interleave Chroma

Project:	CHV, BSW
Format:	Enable

Description
This field indicates that the chroma fields are interleaved in a single plane rather than stored as two separate planes. This field is only used for PLANAR surface formats.

25:22 Reserved

Project:	CHV, BSW
Format:	MBZ

21 Address Control

Project:	CHV, BSW

Value	Name	Description
0	CLAMP	Clamp
1	MIRROR	Mirror

20:3 Surface Pitch

Format:	U18-1 pitch in Bytes

This field specifies the surface pitch in (#Bytes - 1).

Value	Name	Description
[0,262143]		For other linear surfaces: representing [1B, 256KB]
[511, 262143]		For X-tiled surface: representing [512B, 256KB] = [1 tile, 512 tiles]
[127, 262143]		For Y-tiled surfaces: representing [128B, 256KB] = [1 tile, 2048 tiles]

Programming Notes
For tiled surfaces, the pitch must be a multiple of the tile widthIf Half Pitch for Chroma is set, this field must be a multiple of two tile widths for tiled surfaces, or a multiple of 2 bytes for linear surfaces.The Surface Pitches of current picture and reference picture should be declared as the identical type in VDI mode with identical Height, Width and Format.

2 Half Pitch for Chroma

Format:	Enable

MEDIA_SURFACE_STATE

This field indicates that the chroma plane(s) will use a pitch equal to half the value specified in the Surface Pitch field. This field is only used for PLANAR surface formats.

Programming Notes
Must be Zero as this field is not used.

1:0 **Tile Mode**

Format:	U2 Enumerated Type

This field specifies the type of memory tiling (Linear, WMajor, XMajor, or YMajor) employed to tile this surface. See Memory Interface Functions for details on memory tiling and restrictions.

Value	Name	Description	Project
0h	TILEMODE_LINEAR	Linear mode (no tiling)	All
1h	Reserved	Reserved	All
2h	TILEMODE_XMAJOR	X major tiling	All
3h	TILEMODE_YMAJOR	Y major tiling	All

Programming Notes

- Refer to *Memory Data Formats* for restrictions on TileMode direction for the various buffer types. (Of particular interest is the fact that YMAJOR tiling is not supported for display/overlay buffers).
- The corresponding cache(s) must be invalidated before a previously accessed surface is accessed again with an altered state of this field.
- Linear surfaces can be mapped to Main Memory (uncached) or System Memory (cacheable, snooped). Tiled (X/Y/W) surfaces can only be mapped to Main Memory.

3 31:30 **Reserved**

Project:	All
Format:	MBZ

29:16 **X Offset for U(Cb)**

Format:	U14 Pixel Offset

Description	Project
For non planar surfaces this field specifies the horizontal offset in pixels from the Surface Base Address to the start (origin) of the surface.	
For Planar surfaces this field specifies the horizontal offset in pixels from the Surface Base Address to the start (origin) of the U(Cb) plane or the interleaved UV plane if Interleave Chroma is enabled.	CHV, BSW

Programming Notes
For PLANAR_420 and PLANAR_422 surface formats, this field must indicate an even number of pixels.

15:14 **Reserved**

MEDIA_SURFACE_STATE

		Format: MBZ
	13:0	**Y Offset for U(Cb)** Format: U14 Row Offset **Description** / **Project** For non planar surfaces this field specifies the vertical offset in pixels from the Surface Base Address to the start (origin) of the surface. / For Planar surfaces this field specifies the vertical offset in rows from the Surface Base Address to the start (origin) of the U(Cb) plane or the interleaved UV plane if Interleave Chroma is enabled. / CHV, BSW
4	31:30	**Reserved** Project: All Format: MBZ
	29:16	**X Offset for V(Cr)** Exists If: //([Surface Format] is one of planar) AND ([Interleave Chroma] == '0') Format: U14 Pixel Offset **Description** / **Project** This field specifies the horizontal offset in pixels from the Surface Base Address to the start (origin) of the V(Cr) plane. / CHV, BSW **Programming Notes** For PLANAR_420 and PLANAR_422 surface formats, this field must indicate an even number of pixels.
	15	**Reserved** Format: MBZ
	14:0	**Y Offset for V(Cr)** Exists If: //([Surface Format] is one of planar) AND ([Interleave Chroma] == '0') Format: U15 Row Offset **Description** / **Project** This field specifies the veritical offset in rows from the Surface Base Address to the start (origin) of the V(Cr) plane. / CHV, BSW **Programming Notes** / **Project** This field must indicate a multiple of 4 (bit 0 & 1 = 00). / CHV, BSW
5	31	**Vertical Line Stride** Project: CHV, BSW

MEDIA_SURFACE_STATE

		Format: U1 in lines to skip between logically adjacent lines For Surfaces accessed via the sample_8x8 message:Specifies number of lines (0 or 1) to skip between logically adjacent lines - provides support of interleaved (field) surfaces as textures.For Other Surfaces:Vertical Line Stride must be zero. **Workaround** / **Project** All surfaces used by the sampler between sampler cache invalidates must have the same setting of this field in both RENDER_SURFACE_STATE and MEDIA_SURFACE_STATE. / CHV, BSW
	30	**Vertical Line Stride Offset** Project: CHV, BSW Format: U1 in lines of initial offset (when Vertical Line Stride == 1) For Surfaces accessed via the sample_8x8 message: Specifies the offset of the initial line from the beginning of the buffer. For Other Surfaces: Vertical Line Stride Offset must be zero. **Programming Notes** / **Project** This field must be set to 0 if Vertical Line Stride is 0. / CHV, BSW
	29:24	**Reserved** Format: MBZ
	23:20	**Reserved** Project: CHV, BSW Format: MBZ
	19:18	**Reserved** Project: CHV, BSW Format: MBZ
	17:7	**Reserved** Format: MBZ
	6:0	**Surface Memory Object Control State** Default Value: 0h DefaultVaueDesc Project: CHV, BSW Format: MEMORY_OBJECT_CONTROL_STATE This 7-bit field is used in various state commands and indirect state objects to define cacheability and other attributes related to memory objects.
6	31:0	**Surface Base Address** Project: CHV, BSW Format: GraphicsAddress[31:0] Specifies the low 32 bits of the byte-aligned base address of the surface. **Programming Notes** For SURFTYPE_BUFFER render targets, this field specifies the base address of first element of the

MEDIA_SURFACE_STATE

		surface. The surface is interpreted as a simple array of that single element type. The address must be naturally-aligned to the element size (e.g., a buffer containing R32G32B32A32_FLOAT elements must be 16-byte aligned).For SURFTYPE_BUFFER non-rendertarget surfaces, this field specifies the base address of the first element of the surface, computed in software by adding the surface base address to the byte offset of the element in the buffer.Mipmapped, cube and 3D sampling engine surfaces are stored in a 'monolithic' (fixed) format, and only require a single address for the base texture.Linear render target surface base addresses must be element-size aligned, for non-YUV surface formats, or a multiple of 2 element-sizes for YUV surface formats. Other linear surfaces have no alignment requirements (byte alignment is sufficient.)Linear depth buffer surface base addresses must be 64-byte aligned. Note that while render targets (color) can be SURFTYPE_BUFFER, depth buffers cannot.Tiled surface base addresses must be 4KB-aligned. Note that only the offsets from Surface Base Address are tiled, Surface Base Address itself is not transformed using the tiling algorithm.For tiled surfaces, the actual start of the surface can be offset from the Surface Base Address by the X Offset and Y Offset fields.Certain message types used to access surfaces have more stringent alignment requirements. Please refer to the specific message documentation for additional restrictions.
7	31:16	**Reserved** Format: MBZ
	15:0	**Surface Base Address High** Project: CHV, BSW Format: GraphicsAddress[47:32] Specifies the high 16 bits of the byte-aligned base address of the surface. Refer to Surface Base Address [31:0] for programming notes applying to this field.

MEMORY_OBJECT_CONTROL_STATE

MEMORY_OBJECT_CONTROL_STATE

Project: CHV, BSW
Source: PRM
Size (in bits): 7
Default Value: 0x00000000

DWord	Bit	Description
0	6:5	**Memory Type** Defines the memory type used in caching accesses to target caches. Value / Name: 00b – UC 01b – Reserved 10b – Reserved 11b – WB
	4:3	**Target Cache** Allows the control to target caching in the GFX pipeline for EU related surfaces. Value / Name: 00b – No Caching 01b – No Caching 1 10b – No Caching 2 11b – L3 Cache Allowed

Value / Name / Description / Project: 00h / Normal / The Block Height and Block Width fields are specified in this Dword. The Mask is ignofed by a media block read message. / All Others / Reserved / Reserved. / All
	29	**Reserved** Project: All Format: Ignore Ignored
	28:24	**Sub-Register Offset** Project: All Format: U5 Provides the sub-register offset in unit of bytes of a Merged Media Block Read message. This field is ignored (reserved) for a media block write message. Range = [0, 28]. Only a multiple of BasePitch, including 0, is valid. **Programming Notes** Sub-Register Offset and Register Pitch Control allow software to assembly multiple media block reads directly into a shared GRF register set. For example, if both are set to zero, the read data are written to GRF registers, aligning to the least significant bits of the first register, and the register pitch is equal to the next power-of-2 that is greater than or equal to the Block Width. If Register Pitch Control is non-zero, multiple media block read messages sharing the same Register Pitch Control but with different Sub-Register Offset can fill in the same set of GRF registers with media block data line interleaved. **Restriction** For the Sampler Cache Data, this field must be zero.

MHC_MBM_CONTROL - Merged Media Block Message Header Control

BasePitch is defined as the next the power-of-2 that is greater than or equal to the Block Width. Minimum BasePitch is 1 DWord.
Sub-Register Offset must be aligned to BasePitch (therefore will be a multiple of DWords as well). When Register Pitch Control = 0, Sub-Register Offset must align to BasePitch*Block Height. ensuring the output fits in a single GRF register. In general (and specifically when Sub-Register Offset is greater than 0), when the resulting data will cross a GRF register boundary, the data must be placed symmetrically between GRF registers.

23:22 Reserved

Project:	All
Format:	Ignore

Ignored

21:16 Block Height

Project:	All
Format:	U6

Height in rows of block being accessed. Range = [0,63] representing 1 to 64 rows

Restriction
If Block Width (bytes), then Maximum Block Height (rows) is constrained by (# Dwords width) * (# rows) <= 64 Dwords.

15:10 Reserved

Project:	All
Format:	Ignore

Ignored

9:8 Reserved

Project:	CHV, BSW*:A0
Format:	MBZ

Restriction : Must be zero.

7:6 Reserved

Project:	All
Format:	Ignore

Ignored

5:0 Block Width

Project:	All
Format:	U6

Width in bytes of the block being accessed. Range = [0,31] representing 1 to 32 Bytes.

MHC_MBM_CONTROL - Merged Media Block Message Header Control

Message Descriptor - Render Target Write

Message Descriptor - Render Target Write

Project:	CHV, BSW
Source:	PRM
Size (in bits):	32
Default Value:	0x00000000

DWord	Bit	Description
0	31	**Reserved** Format: MBZ
	30	**Data Format** Project: CHV, BSW Format: U1 Value / Name / Description: 0 – Single Precision – 32b 1 – Half Precision – 16b **Programming Notes** This field is applicable for Render Target Write Messages ONLY.
	29:14	**Reserved** Format: MBZ
	13	**Reserved** Project: CHV, BSW Format: MBZ
	12	**Last Render Target Select** This bit must be set on the last render target write message sent for each group of pixels. For single render target pixel shaders, this bit is set on all render target write messages. For multiple render target pixel shaders, this bit is set only on messages sent to the last render target. This bit must be zero for SIMD8 Image Write message. **Programming Notes** In general, when threads are not launched by 3D FF, this bit must be zero.
	11	**Slot Group Select** This field selects whether slots 15:0 or slots 31:16 are used for bypassed data. Bypassed data includes the antialias alpha, multisample coverage mask, and if the header is not present also includes the X/Y addresses and pixel enables. For 8- and 16-pixel dispatches, SLOTGRP_LO must be selected on every message. For 32-pixel dispatches, this field must be set correctly for each message based on which slots are currently being processed. Value / Name / Description

Message Descriptor - Render Target Write

0	SLOTGRP_LO	choose bypassed data for slots 15:0
1	SLOTGRP_HI	choose bypassed data for slots 31:16

Programming Notes
For SIMD8 Image Write message thsi field MBZ.

10:8 **Message Type**

This field specifies the type of render target message. For the SIMD8_DUALSRC_xx messages, the low bit indicates which slots to use for the pixel enables, X/Y addresses, and oMask.

Value	Name	Description
000b	SIMD16	SIMD16 single source message
001b	SIMD16_REPDATA	SIMD16 single source message with replicated data
010b	SIMD8_DUALSRC_LO	SIMD8 dual source message, use slots 7:0
011b	SIMD8_DUALSRC_HI	SIMD8 dual source message, use slots 15:8
100b	SIMD8_LO	SIMD8 single source message, use slots 7:0
111b	SIMD16_REPDATA	It's only supported when accessing *Tiled Memory*. Using this Message Type to access linear *(Untiled)* memory is UNDEFINED.

Programming Notes	Project
the above slots indicated are within the 16 slots selected by **Slot Group Select**. If SLOTGRP_HI is selected, the SIMD8 message types above reference slots 23:16 or 31:24 instead of 7:0 or 15:8, respectively.	
SIMD16_REPDATA message must not be used in SIMD8 pixel-shaders.	CHV, BSW

7:0 **Reserved**

Format:	MBZ

Message Descriptor - Sampling Engine

Message Descriptor - Sampling Engine

Project: CHV, BSW
Source: PRM
Size (in bits): 32
Default Value: 0x00000000

DWord	Bit	Description
0	31	**EOT** Project: All
	30	**Return Format** Project: CHV, BSW Format: U1 Value / Name / Description 0 / 32-bit / Return data is 32b 1 / 16-bit / Return data is 16b **Programming Notes** This field must be set to 32-bit for messages with SIMD Mode of SIMD4x2 or SIMD32/64. This field must be set to 32 for resinfo, LOD and sampleinfo messages.
	29	**Reserved** Project: CHV, BSW Format: MBZ
	28:25	**Message Length** Format: U4 This field specifies the number of 256-bit GRF registers starting from (src) to be sent out on the request message payload. Value / Name [1,15] **Programming Notes** A value of 0 is considered erroneous.
	24:20	**Response Length** Format: U5 This field indicates the number of 256-bit registers expected in the message response. Value / Name [0,16]

Message Descriptor - Sampling Engine

		Programming Notes A value 0 indicates that the request message does not expect any response. The largest response supported is 16 GRF registers.
	19	**Header Present** Format: Enable Specifies whether the message includes a header phase. If the header is not present (this field is zero), all of the fields normally contained in the header are assumed to be 0.
	18:17	**SIMD Mode[1:0]** Format: U2 Specifies the SIMD mode of the message being sent.
	16:12	**Message Type** Format: U5 Specifies the type of message being sent. For more details, please refer to **Message Format** section for the definition of these 5 bits..
	11:8	**Sampler Index** Format: U4 Specifies the index into the sampler state table. Ignored for ld, resinfo, sampleinfo, and cache_flush type messages. **Value**: [0,15] **Programming Notes** • For the deinterlace message, this field must be a multiple of 2 (even). • For the sample_8x8 message, this field must be a multiple of 4.
	7:0	**Binding Table Index** Format: U8 Specifies the index into the **binding table**. Ignored for cache_flush type messages. Values of 255 and 253 indicate stateless. 254 indicates SLM. 252 indicates bindless. **Value**: [0,255]

MFD_MPEG2_BSD_OBJECT Inline Data Description

MFD_MPEG2_BSD_OBJECT Inline Data Description

Project:	CHV, BSW
Source:	VideoCS
Size (in bits):	64
Default Value:	0x00000000, 0x00000000

DW0..1 corresponds to DW3..4 of the MFD_MPEG2_BSD_OBJECT.

DWord	Bit	Description
0	31:24	**Slice Horizontal Position** Format: U8 in Macroblocks This field indicates the horizontal position of the first macroblock in the slice.
	23:16	**Slice Vertical Position** Format: U8 in Macroblocks This field indicates the vertical position of the first macroblock in the slice.
	15:8	**Macroblock Count** Format: U8 in Macroblocks This field indicates the number of macroblocks in the slice, including skipped macroblocks.
	7	**Slice Concealment Override Bit** This bit forces hardware to handle the current slice in Conceal or Deocde Mode. If this bit is set to one, VIN will force the current slice to do concealment or to decode from bitstream regardless if the slice boundary has errors or not. Value / Name / Description: 1h — VIN will use driver-provided "Slice Concealment Type" regardless of valid slice boundary 0h — Driver must program "Slice Concealment Type" to '0'. VIN will set "Slice Concealment Type" depending if the slice boundary has error or not
	6	**Slice Concealment Type Bit** This bit can be forced by driver ("Slice Concealment Override Bit") or set by VINunit depending on slice boundary errors. Value / Name / Description: 1h — VMD will conceal all MBs of the slice regardless of bitstream. (If driver does not force the value of this bit, VIN will set this bit depending on slice boundary error. If the next slice position of the current slice is out-of-bound or the same or earlier than the current slice start position, VIN will set this bit for the next slice) 0h — VMD will decode MBs from the bitstream until the bitstream is run-out. Then VMD will conceal the remaining MBs.

MFD_MPEG2_BSD_OBJECT Inline Data Description

		Programming Notes VIN can turn this bit from 0 to 1 internally if "Slice Concealment Disable Bit" is "0" and VIN detects slice boundary errors.
	5	**Last Pic Slice** This bit is added to support error concealment at the end of a picture. Value / Name / Description: 1h — The current Slice is the last Slice of the entire picture 0h — The current Slice is not the last Slice of current picture
	4	**Reserved**
	3	**Is Last MB** Value / Name / Description: 1h — The current MB is the last MB in the current Slice 0h — The current MB is not the last MB in the current Slice
	2:0	**First Macroblock Bit Offset** Format: U3 This field provides the bit offset of the first macroblock in the first byte of the input bitstream.
1	31:29	**Reserved** Format: MBZ
	28:24	**Quantizer Scale Code** Format: U5 This field sets the quantizer scale code of the inverse quantizer. It remains in effect until changed by a decoded quantizer scale code in a macroblock. This field is decoded from the slice header by host software.
	23:17	**Reserved** Format: MBZ
	16:8	**Next Slice Vertical Position** Format: U9 in macroblocks This field indicates the vertical position (in macroblock units) of the first macroblock in the next slice. **Programming Notes** This field is primarily used for error concealment. In the case that current slice is the last slice, this field should set to the height of the picture (field picture will be in height of field) (since y-direction is zero-based numbering).
	7:0	**Next Slice Horizontal Position** Format: U8 in macroblocks This field indicates the horizontal position (in macroblock units) of the first macroblock in the

MFD_MPEG2_BSD_OBJECT Inline Data Description		
		next slice. **Programming Notes** This field is primarily used for error concealment. In the case that current slice is the last slice, this field should set 0.

Project:	CHV, BSW	
Source:	VideoCS	
Size (in bits):	16	
Default Value:	0x00000000	

DWord	Bit	Description
0	15:6	**Reserved** Format: MBZ
	5	**Missing EOB Error** This flag indicates missing EOB SEs coded in the bit-stream. Missing EOBs are concealed to match CBP of the error MB.
	4	**Inconsistent starting position Error - overlapping MBs** This flag indicates two slices overlapping one another by one or more MBs. Duplicate MBs decoded off the second slice shall be discarded.
	3	**Slice out-of-bound Error** This flag indicates a slice is running beyond the width of the picture. Out-of-bound MBs shall be discarded.
	2	**Premature frame end Error** This flag indicates missing slices/MBs coded in the bit-stream of a frame. One or more MBs are concealed to reach end of picture.
	1	**Inconsistent starting position Error - Missing MBs** This flag indicates one or more MBs are being concealed due to inconsistent MB starting and ending positions between slices.
	0	**MB Concealment Flag** . Each pulse from this flag indicates one MB is concealed by hardware.

Oword Data Blocks Message Descriptor Control Field

MDC_DB_OW - Oword Data Blocks Message Descriptor Control Field

Project: CHV, BSW
Source: PRM
Size (in bits): 3
Default Value: 0x00000000

DWord	Bit	Description
0	2:0	**Data Blocks** Project: All Format: Enumeration Specifies the number of Oword blocks to be read or written

Value	Name	Description	Project
00h	OW1L	1 Oword, read into or written from the low 128 bits of the destination register	All
01h	OW1U	1 Oword, read into or written from the high 128 bits of the destination register	All
02h	OW2	2 Owords	All
03h	OW4	4 Owords	All
04h	OW8	8 Owords	All
Others	Reserved	Ignored	All

Oword Data Payload Register

MDCR_OW - Oword Data Payload Register		
Project:	CHV, BSW	
Source:	PRM	
Size (in bits):	256	
Default Value:	0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000	
DWord	**Bit**	**Description**
0.0-0.3	127:0	**Oword0** Project: All Format: U128 Specifies the slot 0 data in this payload register
0.4-0.7	127:0	**Oword1** Project: All Format: U128 Specifies the slot 1 data in this payload register

Oword Dual Data Blocks Message Descriptor Control Field

MDC_DB_OWD - Oword Dual Data Blocks Message Descriptor Control Field

Project:	CHV, BSW
Source:	PRM
Size (in bits):	2
Default Value:	0x00000000

DWord	Bit	Description
0	1:0	**OW Dual Data Blocks** Project: All Format: Enumeration Specifies the number of Oword Blocks to be read or written

Value	Name	Description	Project
00h	OWD1	1 Hword register, 2 Owords	All
02h	OWD4	4 Hword registers, 8 Owords	All
Others	Reserved	Ignored	All

PALETTE_ENTRY

PALETTE_ENTRY		
Project:	CHV, BSW	
Source:	RenderCS	
Size (in bits):	32	
Default Value:	0x00000000	
DWord	**Bit**	**Description**
0	31:24	**Alpha** Format: U8 Alpha channel value for this entry in the texture color palette.
	23:16	**Red** Format: U8 Red channel value for this entry in the texture color palette.
	15:8	**Green** Format: U8 Green channel value for this entry in the texture color palette.
	7:0	**Blue** Format: U8 Blue channel value for this entry in the texture color palette.

Per Thread Scratch Space Message Header Control

MHC_PTSS - Per Thread Scratch Space Message Header Control

Project: CHV, BSW
Source: PRM
Size (in bits): 32
Default Value: 0x00000000

DWord	Bit	Description
0	31:4	**Reserved** Project: All Format: Ignore Ignored
	3:0	**Per Thread Scratch Space** Project: All Format: U4 Specifies the amount of scratch space allowed to be used by this thread for messages in which the Binding Table Index is Stateless model, otherwise this field is ignored.The data port will use this to bounds check scratch space messages. Value range = [0,11] represents [1KB, 2MB] in powers of two. **Programming Notes** Writes out of bounds will be ignored. Reads out of bounds will return 0.

Pixel Masked Media Block Message Header

MH_MBPM - Pixel Masked Media Block Message Header

Project: CHV, BSW

Source: DataPort 1

Size (in bits): 256

Default Value: 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000

DWord	Bit	Description
0	31:0	**X Offset** Project: All Format: S31 X offset (in bytes) of the upper left corner of the block into the surface. **Programming Notes** When Message Mode is set to PIXEL_MASK, this field must be a multiple of 32.
1	31:0	**Y Offset** Project: All Format: S31 Y offset (in rows) of the upper left corner of the block into the surface. **Programming Notes** When Message Mode is set to PIXEL_MASK, this field must be a multiple of 4.
2	31:0	**Media Block Message Control** Project: All Format: MHC_MBPM_CONTROL Specifies the message subtype is Pixel Masked.
3	31:0	**Pixel Mask** Project: All Format: U32 Specifies the Pixel Mask for writes when Message Mode field is PIXEL_MASK. **Programming Notes** The Pixel Mask applies to the 2x2 square tiles (UL, UR, LL, LR), which themselves tiled (UL, UR, LL, LR) and then repeated on the right for the remaining 16-bits to cover a 4 row 8 column area.
4	31:0	**FFTID** Project: All Format: MHC_FFTID [CHV, BSW] Fixed Function Thread ID

MH_MBPM - Pixel Masked Media Block Message Header		
5-7	95:0	**Reserved** Project: All Format: Ignore Ignored

Pixel Masked Media Block Message Header Control

MHC_MBPM_CONTROL - Pixel Masked Media Block Message Header Control

Project: CHV, BSW
Source: PRM
Size (in bits): 32
Default Value: 0x00000000

DWord	Bit	Description
0	31:30	**Message Mode** Project: All Format: Enumeration Specifies the Media Block Write Message subtype is Pixel Masked. Value / Name / Description / Project: 01h / PIXEL_MASK / Use the Pixel Mask in the Message Header. The Block Height and Block Width are ignored and behave as if they are set to 4 rows and 32 bytes, respectively. / All Others / Reserved / Reserved. / All
	29	**Reserved** Project: All Format: Ignore Ignored
	28:24	**Sub-Register Offset** Project: All Format: U5 This field is ignored (reserved) for a media block write message.

Pixel Sample Mask Message Header Control

MHC_PSM - Pixel Sample Mask Message Header Control

Project:	CHV, BSW
Source:	PRM
Size (in bits):	32
Default Value:	0x0000FFFF

DWord	Bit	Description
0	31:16	**Reserved** Format: Ignore Ignored
	15:0	**Pixel Sample Mask** Default Value: 0FFFFh Default Format: U16 SIMD16 and SIMD8 messages. All 16 bits are used for SIMD16. For untyped SIMD8 messages, the low 8 bits of field are used. If the header is not delivered, this field defaults to all ones. This field is ignored for SIMD4x2 messages.

Pixel Sample Mask Render Target Message Header Control

MHC_RT_PSM - Pixel Sample Mask Render Target Message Header Control

Project:	CHV, BSW
Source:	PRM
Size (in bits):	32
Default Value:	0x00000000

DWord	Bit	Description
0	31:16	**Dispatched Pixel/Sample Enables** Project: All Format: U16 One bit per pixel (or sample within pixel) indicating which pixels/samples were originally enabled when the thread was dispatched. The Dispatched Pixel/Sample Enables must be unmodified from the ones sent when the pixel shader thread was initiated. If the Dispatched Pixel/Sample Enables are modified, behavior is undefined. **Programming Notes** When operating in PER_SAMPLE mode these bits correspond to samples, not pixels. Each subspan slot (4 bits) corresponds to a specific sample location for the subspan. Note that in NUMSAMPLES_1 mode, a pixel and sample are synonomous. When operating in PER_PIXEL mode, this field is ignored, and instead the SampleEnableMask (obtained via bypass) are used to clear the Depth Scoreboard.
	15:0	**Pixel/Sample Enables** Project: All Format: U16 Specifies which pixels/samples are still lit based on kill instruction activity in the pixel shader. This mask is AND'd with the Dispatched Pixel/Sample Enables mask, and that is used to control actual accesses to the color buffer. Pixels/samples will be dropped on masked writes, and the GRF is not modified for masked reads. **Programming Notes** When operating in PER_SAMPLE mode these bits correspond to samples, not pixels, as the PS is run per-sample. Each subspan slot (4 bits) corresponds to a specific sample location for the subspan. When operating in PER_PIXEL mode, these bits still correspond to pixels, as the PS is run per-pixel. Each pixels mask bit is replicated according to Number of Multisamples and combined with other masks to control writes to the multisample locations.

Power Clock State Format

Power Clock State Format

Project:	CHV, BSW
Source:	RenderCS
Size (in bits):	31
Default Value:	0x00000288

Known Uses

- R_PWR_CLK_STATE - Render Power Clock State Register
- PM_PWR_CLK_STATE - PM Power Clock State Request (Intended, in GT/GTI space, not yet in use)
- PM_PWR_CLK_STATE (Intended, in GT/GTI space, not yet in use)

Exists If:	//[MessageType] != 'Sample_8x8'
Size (in bits):	480
Default Value:	0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000

This is the normal surface state used by all messages that use SURFACE_STATE except those that use MEDIA_SURFACE_STATE.

DWord	Bit	Description
0	31:29	**Surface Type** This field defines the type of the surface.

Value	Name	Description
0h	SURFTYPE_1D	Defines a 1-dimensional map or array of maps
1h	SURFTYPE_2D	Defines a 2-dimensional map or array of maps
2h	SURFTYPE_3D	Defines a 3-dimensional (volumetric) map
3h	SURFTYPE_CUBE	Defines a cube map or array of cube maps
4h	SURFTYPE_BUFFER	Defines an element in a buffer
5h	SURFTYPE_STRBUF	Defines a structured buffer surface
6h	Reserved	
7h	SURFTYPE_NULL	Defines a null surface

Programming Notes

A null surface is used in instances where an actual surface is not bound. When a write message is generated to a null surface, no actual surface is written to. When a read message (including any sampling engine message) is generated to a null surface, the result is all zeros. Note that a null surface type is allowed to be used with all messages, even if it is not specificially indicated as supported. All of the remaining fields in surface state are ignored for null surfaces, with the following exceptions:

- **Width, Height, Depth, LOD,** and **Render Target View Extent** fields must match the depth buffer's corresponding state for all render target surfaces, including null.

All sampling engine and data port messages support null surfaces with the above behavior, even if not mentioned as specifically supported, except for the following:

- Data Port Media Block Read/Write messages
- Data Port Transpose Read message
- The **Surface Type** of a surface used as a render target (accessed via the Data Port's

RENDER_SURFACE_STATE

Render Target Write message) must be the same as the **Surface Type** of all other render targets and of the depth buffer (defined in 3DSTATE_DEPTH_BUFFER), unless either the depth buffer or render targets are SURFTYPE_NULL.

For sampling using the 3D sampler, if the Surface Type is programmed to SURFTYPE_NULL, the Surface Format must be a supported surface format for the 3D sampler.

28 **Surface Array**

Format:	Enable

This field, if enabled, indicates that the surface is an array.

Programming Notes

If this field is *enabled*, the **Surface Type** must be SURFTYPE_1D, SURFTYPE_2D, or SURFTYPE_CUBE.
If this field is *disabled* and **Surface Type** is SURFTYPE_1D, SURFTYPE_2D, or SURFTYPE_CUBE, the **Depth** field must be set to zero.

27 **Reserved**

Project:	CHV, BSW
Format:	Enable

26:18 **Surface Format**

Format:	SURFACE_FORMAT [CHV, BSW]

This field specifies the format of the surface or element within this surface. This field is ignored for all data port messages other than the render target message and streamed vertex buffer write message. Some forms of the media block messages use the surface format.

17:16 **Surface Vertical Alignment**

Description	Project
For Sampling Engine and Render Target Surfaces: This field specifies the vertical alignment requirement in elements for the surface. Refer to the "Memory Data Formats" chapter for details on how this field changes the layout of the surface in memory. An *element* is defined as a pixel in uncompresed surface formats, and as a compression block in compressed surface formats. For MSFMT_DEPTH_STENCIL type multisampled surfaces, an element is a sample.	
This field applies to surface formats other than compressed formats.	CHV, BSW
For other surfaces: This field is ignored.	

Value	Name	Description
0h	Reserved	Reserved
1h	VALIGN 4	Vertical alignment factor j = 4
2h	VALIGN 8	Vertical alignment factor j = 8

RENDER_SURFACE_STATE

3h	VALIGN 16	Vertical alignment factor j = 16

Programming Notes
This field is intended to be set to VALIGN_4 if the surface was rendered as a depth buffer, for a multisampled (4x) render target, or for a multisampled (8x) render target, since these surfaces support only alignment of 4. Use of VALIGN_4 for other surfaces is supported, but increases memory usage.
This field is intended to be set to VALIGN_8 only if the surface was rendered as a stencil buffer, since stencil buffer surfaces support only alignment of 8. If set to VALIGN_8, Surface Format must be R8_UINT.
For uncompressed surfaces, the units of "j" are rows of pixels on the physical surface. For compressed texture formats, the units of "j" are in compression blocks, thus each increment in "j" is equal to h pixels, where h is the height of the compression block in pixels.

15:14 **Surface Horizontal Alignment**

Description	Project
For Sampling Engine and Render Target Surfaces: This field specifies the horizontal alignment requirement for the surface. This field is ignored when Tiled Resource Mode is not TRMODE_NONE (i.e. Tiled Resources are enabled). See the "Surface Layout and Tiling" section under Common Surface Formats for the table of alignment values for Tile Resrouces.	
This field applies to surface formats other than compressed formats.	CHV, BSW
For other surfaces: This field is ignored.	

Value	Name	Description
0h	Reserved	Reserved
1h	HALIGN 4	Horizontal alignment factor j = 4
2h	HALIGN 8	Horizontal alignment factor j = 8
3h	HALIGN 16	Horizontal alignment factor j = 16

Programming Notes
This field is intended to be set to HALIGN_8 only if the surface was rendered as a depth buffer with Z16 format or a stencil buffer. In this case it must be set to HALIGN_8 since these surfaces support only alignment of 8. For Z32 formats it must be set ot HALIGN_4. Use of HALIGN_8 for other surfaces is supported, but increases memory usage. For uncompressed surfaces, the units of "i" are pixels on the physical surface. For compressed texture formats, the units of "i" are in compression blocks, thus each increment in "i" is equal to w pixels, where w is the width of the compression block in pixels.
When Auxiliary Surface Mode is set to AUX_CCS_D or AUX_CCS_E, HALIGN 16 must be used.

13:12 **Tile Mode**

This field specifies the type of memory tiling (Linear, WMajor, XMajor, or YMajor) employed to

RENDER_SURFACE_STATE

tile this surface. See *Memory Interface Functions* for details on memory tiling and restrictions.

Value	Name	Description	Project
0h	LINEAR	Linear mode (no tiling)	
1h	WMAJOR	W major tiling	CHV, BSW
2h	XMAJOR	X major tiling	
3h	YMAJOR	Y major tiling	

Programming Notes

- Refer to *Memory Data Formats* for restrictions on *TileMode* direction for the various buffer types. (Of particular interest is the fact that YMAJOR tiling is not supported for display/overlay buffers).
- The corresponding cache(s) must be invalidated before a previously accessed surface is accessed again with an altered state of this field.
- Use of WMAJOR is valid only for sampling engine, Data Cache Data Port and render target surfaces and **Surface Format** must be R8_UINT. Vertical Line Stride must be zero. In addition to W tiling, this mode implies that the surface is stored as a stencil buffer. Refer to *Memory Data Formats* section for details on stencil buffer surface layout.
- Linear surfaces can be mapped to Main Memory (uncached) or System Memory (cacheable, snooped). Tiled (X/Y/W) surfaces can only be mapped to Main Memory.
- If **Surface Type** is SURFTYPE_BUFFER, this field must be TILEMODE_LINEAR
- If **Number of Multisamples** is not MULTISAMPLECOUNT_1, this field must be YMAJOR.

If **Surface Format** is ASTC*, this field must be TILEMODE_YMAJOR.

11 **Vertical Line Stride**

Format:	U1 In lines to skip between logically adjacent lines

For 2D Non-Array Surfaces accessed via the Sampling Engine or Data Cache Data Port: Specifies number of lines (0 or 1) to skip between logically adjacent lines - provides support of interleaved (field) surfaces as textures.

For Other Surfaces: Vertical Line Stride must be zero.

Programming Notes

This bit must not be set if the surface format is a compressed type (BCn*, FXT1, ETC*, EAC*, ASTC*).

This bit must not be set if the **Auxiliary Surface Mode** is not AUX_NONE.

If this bit is set on a sampling engine surface, the mip mode filter must be set to MIPFILTER_NONE and the min and mag mode filter cannot be set to MAPFILTER_FLEXIBLE.

Workaround	Project
All surfaces used by the sampler between sampler cache invalidates must have the same setting of this field in both RENDER_SURFACE_STATE and MEDIA_SURFACE_STATE.	CHV, BSW

RENDER_SURFACE_STATE

10 Vertical Line Stride Offset

Format:	U1 In lines of initial offset (when Vertical Line Stride == 1)

For 2D Non-Array Surfaces accessed via the Sampling Engine or Data Cache Data Port:
Specifies the offset of the initial line from the beginning of the buffer. Ignored when Vertical **Line Stride** is 0.
For Other Surfaces:
Vertical Line Stride Offset must be zero.

9 Sampler L2 Bypass Mode Disable

Format:	Disable

This field allows the Sampler L2 bypass mode to be disabled for the surface. If enabled, Sampler can still disable the L2 bypass as needed.

Programming Notes
This bit must be set for the following surface types: BC2_UNORM BC3_UNORM BC5_UNORM BC5_SNORM BC7_UNORM

8 Render Cache Read Write Mode
For Surfaces accessed via the Data Port to Render Cache:
This field specifies the way Render Cache treats a write request. If unset, Render Cache allocates a write-only cache line for a write miss. If set, Render Cache allocates a read-write cache line for a write miss.
For Surfaces accessed via the Sampling Engine or Data Port to Texture Cache or Data Cache:
This field is reserved : MBZ

Value	Name	Description
0h	Write-Only Cache	Allocating write-only cache for a write miss
1h	Read-Write Cache	Allocating read-write cache for a write miss

Programming Notes
This field is provided for performance optimization for Render Cache read/write accesses (from Gen4 EU's point of view).

7:6 Media Boundary Pixel Mode
For 2D Non-Array Surfaces accessed via the Data Port Media Block Read Message or Data Port Transpose Read message:
This field enables control of which rows are returned on vertical out-of-bounds reads using the Data Port Media Block Read Message or Data Port Transpose Read message. In the description below, frame mode refers to **Vertical Line Stride** = 0, field mode is **Vertical Line Stride** = 1 in which only the even or odd rows are addressable. The frame refers to the entire surface, while the field refers only to the even or odd rows within the surface.
For Other Surfaces:
Reserved : MBZ

Value	Name	Description
0h	NORMAL_MODE	The row returned on an out-of-bound access is the closest row

RENDER_SURFACE_STATE

		in the frame or field. Rows from the opposite field are never returned.
1h	Reserved	
2h	PROGRESSIVE_FRAME	The row returned on an out-of-bound access is the closest row in the frame, even if in field mode.
3h	INTERLACED_FRAME	In field mode, the row returned on an out-of-bound access is the closest row in the field. In frame mode, even out-of-bound rows return the nearest even row while odd out-of-bound rows return the nearest odd row.

5 **Cube Face Enable - Negative X**

Exists If:	[Surface Type] == 'SURFTYPE_CUBE'
Format:	Enable

For SURFTYPE_CUBE Surfaces accessed via the Sampling Engine: This field enable the individual face of a cube map. Enabling a face indicates that the face is present in the cube map, while disabling it indicates that that face is represented by the texture map's border color. Refer to Memory Data Formats for the correlation between faces and the cube map memory layout. Note that storage for disabled faces must be provided.

Programming Notes

When TEXCOORDMODE_CLAMP is used when accessing a cube map, this field must be programmed to 1b (face enabled).

4 **Cube Face Enable - Positive X**

Exists If:	[Surface Type] == 'SURFTYPE_CUBE'
Format:	Enable

For SURFTYPE_CUBE Surfaces accessed via the Sampling Engine: This field enable the individual face of a cube map. Enabling a face indicates that the face is present in the cube map, while disabling it indicates that that face is represented by the texture map's border color. Refer to Memory Data Formats for the correlation between faces and the cube map memory layout. Note that storage for disabled faces must be provided.

Programming Notes

When TEXCOORDMODE_CLAMP is used when accessing a cube map, this field must be programmed to 1b (face enabled).

3 **Cube Face Enable - Negative Y**

Exists If:	[Surface Type] == 'SURFTYPE_CUBE'
Format:	Enable

For SURFTYPE_CUBE Surfaces accessed via the Sampling Engine: This field enable the individual face of a cube map. Enabling a face indicates that the face is present in the cube map, while disabling it indicates that that face is represented by the texture map's border color. Refer to Memory Data Formats for the correlation between faces and the cube map memory layout. Note that storage for disabled faces must be provided.

Programming Notes

RENDER_SURFACE_STATE

		When TEXCOORDMODE_CLAMP is used when accessing a cube map, this field must be programmed to 1b (face enabled).
	2	**Cube Face Enable - Positive Y** Exists If: [Surface Type] == 'SURFTYPE_CUBE' Format: Enable **For SURFTYPE_CUBE Surfaces accessed via the Sampling Engine:** This field enable the individual face of a cube map. Enabling a face indicates that the face is present in the cube map, while disabling it indicates that that face is represented by the texture map's border color. Refer to Memory Data Formats for the correlation between faces and the cube map memory layout. Note that storage for disabled faces must be provided. **Programming Notes** When TEXCOORDMODE_CLAMP is used when accessing a cube map, this field must be programmed to 1b (face enabled).
	1	**Cube Face Enable - Negative Z** Exists If: [Surface Type] == 'SURFTYPE_CUBE' Format: Enable **For SURFTYPE_CUBE Surfaces accessed via the Sampling Engine:** This field enable the individual face of a cube map. Enabling a face indicates that the face is present in the cube map, while disabling it indicates that that face is represented by the texture map's border color. Refer to Memory Data Formats for the correlation between faces and the cube map memory layout. Note that storage for disabled faces must be provided. **Programming Notes** When TEXCOORDMODE_CLAMP is used when accessing a cube map, this field must be programmed to 1b (face enabled).
	5:0	**Reserved** Exists If: [Surface Type] != 'SURFTYPE_CUBE' Format: MBZ
	0	**Cube Face Enable - Positive Z** Exists If: [Surface Type] == 'SURFTYPE_CUBE' Format: Enable **For SURFTYPE_CUBE Surfaces accessed via the Sampling Engine:** This field enable the individual face of a cube map. Enabling a face indicates that the face is present in the cube map, while disabling it indicates that that face is represented by the texture map's border color. Refer to Memory Data Formats for the correlation between faces and the cube map memory layout. Note that storage for disabled faces must be provided. **Programming Notes** When TEXCOORDMODE_CLAMP is used when accessing a cube map, this field must be programmed to 1b (face enabled).
1	31	**Use Global Clear Value** Project: CHV, BSW

RENDER_SURFACE_STATE

Format:	Enable

Specifies that the global non 0/1 clear value should be used for clearing the render target.

Value	Name	Description
0h		Use 0/1 clear value programmed in surface state
1h		Use non-pipelined global non 0/1 clear values

Programming Notes	Project
If 3DSTATE_MULTISAMPLE::**Number of Multisamples** is not NUMSAMPLES_1, this field must be set to 0.	CHV, BSW

30:24 **Memory Object Control State**

Project:	All
Format:	MEMORY_OBJECT_CONTROL_STATE

Specifies the memory object control state for this surface and the associated Auxiliary surface (if any).

23:19 **Base Mip Level**

Project:	All
Format:	U4.1

Range: [0.0, 14.0]
Specifies which mip level is considered the "base" level when determining mag-vs-min filter and selecting the "base" mip level.

Programming Notes
This field also exists in SAMPLER_STATE. If both fields are zero, the Base Mip Level is zero. If one is nonzero, Base Mip Level is the nonzero field. It is illegal to have both Base Mip Level fields nonzero.

18 **Reserved**

Project:	
Format:	MBZ

17 **Reserved**

Format:	MBZ

16:15 **Reserved**

Format:	MBZ

14:0 **Surface QPitch**

Format:	QPitch[16:2]

RENDER_SURFACE_STATE

Description	Project
This field specifies the distance in rows between array slices. It is used only in the following cases: • **Surface Array** is enabled OR • **Number of Mulitsamples** is not NUMSAMPLES_1 and **Multisampled Surface Storage Format** set to MSFMT_MSS OR • **Surface Type** is SURFTYPE_CUBE	CHV, BSW

Value	Name	Description
[4h,1FFFCh]		in multiples of 4 (low 2 bits missing)

Programming Notes	Project
This field must be set to an integer multiple of the **Surface Vertical Alignment**. For compressed textures (BC*, FXT1, ETC*, EAC*, ASTC Surface Formats), this field is in units of rows in the uncompressed surface, and must be set to an integer multiple of the vertical alignment parameter "j" defined in the *Common Surface Formats* section.	CHV, BSW
Software must ensure that this field is set to a value sufficiently large such that the array slices in the surface do not overlap. Refer to the Memory Data Formats section for information on how surfaces are stored in memory.	

2 | 31:30 **Reserved**

Format:	MBZ

29:16 **Height**

Format:	U14-1

This field specifies the height of the surface, minus 1. If the surface is MIP-mapped, this field contains the height of the base MIP level. For buffers, this field specifies a portion of the buffer size.

Value	Name	Description	Project	Exists If
[0,0]		must be zero		[Surface Type] == 'SURFTYPE_1D'
[0,16383]		height of surface - 1 (y/v dimension)		[SurfaceType] == 'SURFTYPE_2D'
[0,2047]		height of surface - 1 (y/v dimension)	CHV, BSW	[SurfaceType] == 'SURFTYPE_3D'
[0,16383]		height of surface - 1 (y/v dimension)		[SurfaceType] == 'SURFTYPE_CUBE'
[0,16383]		contains bits [20:7] of the number of entries in the buffer - 1		([SurfaceType] == 'SURFTYPE_BUFFER') || ([SurfaceType] == 'SURFTYPE_STRBUF')

Programming Notes	Project
For typed buffer and structured buffer surfaces, the number of entries in the buffer	

RENDER_SURFACE_STATE

		ranges from 1 to 2^{27}. For raw buffer surfaces, the number of entries in the buffer is the number of bytes which can range from 1 to 2^{30}. After subtracting one from the number of entries, software must place the fields of the resulting 27-bit value into the **Height, Width**, and **Depth** fields as indicated, right-justified in each field. Unused upper bits must be set to zero.	
		If **Vertical Line Stride** is 1, this field indicates the height of the field, not the height of the frame	
		The **Height** of a render target must be the same as the **Height** of the other render targets and the depth buffer (defined in 3DSTATE_DEPTH_BUFFER), unless **Surface Type** is SURFTYPE_1D or SURFTYPE_2D with **Depth** = 0 (non-array) and **LOD** = 0 (non-mip mapped).	
		If this surface in memory is accessed with Vertical Line Stride set to both 0 and 1, this field must be an even value when Vertical Line Stride is 0.	
		If Media Pixel Boundary Mode is not set to NORMAL_MODE, this field must be an even value.	
		If Surface Format is PLANAR*, this field must be a multiple of 4	CHV, BSW
	15:14	**Reserved**	
		Format:	MBZ
	13:0	**Width**	
		Format:	U14-1

Description	Project
This field specifies the width of the surface, minus 1. If the surface is MIP-mapped, this field specifies the width of the base MIP level. The width is specified in units of pixels or texels. For buffers, this field specifies a portion of the buffer size.	
For surfaces accessed with the Media Block Read/Write message, this field is in units of DWords.	CHV, BSW
For surfaces accessed with the Transpose Read Message, this field is in units of DWords.	CHV, BSW

Value	Name	Description	Project	Exists If
[0,16383]		width of surface - 1 (x/u dimension)		[SurfaceType] == 'SURFTYPE_1D'
[0,16383]		width of surface - 1 (x/u dimension)		[SurfaceType] == 'SURFTYPE_2D'
[0,2047]		width of surface - 1 (x/u dimension)	CHV, BSW	[SurfaceType] == 'SURFTYPE_3D'
[0,16383]		width of surface - 1 (x/u dimension)		[SurfaceType] == 'SURFTYPE_CUBE'
[0,127]		contains bits [6:0] of the		([SurfaceType] == 'SURFTYPE_BUFFER')

RENDER_SURFACE_STATE

		number of entries in the buffer - 1		|| ([SurfaceType] == 'SURFTYPE_STRBUF')

Programming Notes	Project
• For surface types other than SURFTYPE_BUFFER or STRBUF The Width specified by this field must be less than or equal to the surface pitch (specified in bytes via the Surface Pitch field). • For cube maps, Width must be set equal to the Height. • For MONO8 textures, Width must be a multiple of 32 texels. • The **Width** of a render target must be the same as the **Width** of the other render target(s) and the depth buffer (defined in 3DSTATE_DEPTH_BUFFER), unless **Surface Type** is SURFTYPE_1D or SURFTYPE_2D with **Depth** = 0 (non-array) and **LOD** = 0 (non-mip mapped). • The **Width** of a render target with YUV surface format must be a multiple of 2. • For SURFTYPE_BUFFER: The low two bits of this field must be 11 if the Surface Format is RAW (the size of the buffer must be a multiple of 4 bytes).	
If **Surface Format** is PLANAR*, this field must be a multiple of 4	CHV, BSW

3 | 31:21 **Depth**

Format:	U11-1

This field specifies the total number of levels, minus 1, for a volume texture or the number of array elements, minus 1, allowed to be accessed starting at the **Minimum Array Element** for arrayed surfaces. If the volume texture is MIP-mapped, this field specifies the depth of the base MIP level. For buffers, this field specifies a portion of the buffer size.

Value	Name	Description	Project	Exists If
[0,2047]		number of array elements - 1		[SurfaceType] == 'SURFTYPE_1D'
[0,2047]		number of array elements - 1		[SurfaceType] == 'SURFTYPE_2D'
[0,2047]		depth of surface - 1 (z/r dimension)		[SurfaceType] == 'SURFTYPE_3D'
[0,340]		number of array elements - 1 [see programming notes for range]		[SurfaceType] == 'SURFTYPE_CUBE'
[0,1023]		contains bits [30:21] of the number of entries in the buffer - 1	CHV, BSW	([SurfaceType] == 'SURFTYPE_BUFFER') AND ([SurfaceFormat] == 'RAW')
[0,63]		contains bits [26:21] of the number of entries in the buffer - 1	CHV, BSW	([SurfaceType] == 'SURFTYPE_BUFFER') AND ([SurfaceFormat] != 'RAW')
[0,63]		contains bits [26:21] of the number of entries in the	CHV, BSW	[SurfaceType] == 'SURFTYPE_STRBUF'

RENDER_SURFACE_STATE

		buffer - 1

Programming Notes

The **Depth** of a render target must be the same as the **Depth** of the other render target(s) and of the depth buffer (defined in 3DSTATE_DEPTH_BUFFER).

For SURFTYPE_CUBE: For Sampling Engine Surfaces, the range of this field is [0,340], indicating the number of cube array elements (equal to the number of underlying 2D array elements divided by 6). For other surfaces, this field must be zero.

For SURFTYPE_BUFFER: The range of this field is [0,63] unless the Surface Format is RAW and Surface Ptich is 1 byte.

For SURFTYPE_1D, 2D, and CUBE: The range of this field is reduced by one for each increase from zero of **Minimum Array Element**. For example, if **Minimum Array Element** is set to 1024 on a 2D surface, the range of this field is reduced to [0,1023].

20 **Reserved**

Project:	CHV, BSW
Format:	MBZ

19 **Reserved**

Project:	
Format:	MBZ

18 **Reserved**

Project:	CHV, BSW
Format:	MBZ

17:0 **Surface Pitch**

Format:	U18-1 Pitch in #Bytes

Range

1. For surfaces of type SURFTYPE_BUFFER: [0,2047] -> [1B, 2048B]
2. For surfaces of type SURFTYPE_STRBUF: [0,2047] -> [1B, 2048B]
3. For other linear surfaces: [0, 262143] -> [1B, 256KB]
4. For X-tiled surface: [511, 262143] -> [512B, 256KB] = [1 tile, 512 tiles]
5. For Y-tiled surfaces: [127, 262143]->[128B, 256KB] = [1 tile, 2048 tiles]
6. For W-tiled surfaces: [127, 262143]->[128B, 256KB] = [1 tile, 2048 tiles]
7. For TileYF and TileYS surfaces, the range is dependent on the Cu parameter (refer to *Memory Data Formats* section for the definition of the Cu parameter depending on the case). The range in bytes is [2^{Cu}-1,262143] -> [(2^{Cu})B,256KB] = [1 tile, 256KB/(2^{Cu}) tiles]

This field specifies the surface pitch in (#Bytes - 1).
For surfaces of type SURFTYPE_BUFFER and SURFTYPE_STRBUF, this field indicates the size of the structure.

Programming Notes

RENDER_SURFACE_STATE

- For linear *render target* surfaces and surfaces accessed with the typed data port messages, the pitch must be a multiple of the element size for non-YUV surface formats. Pitch must be a multiple of 2 * element size for YUV surface formats.
- For untyped data port messages, which are only supported with **Surface Type** SURFTYPE_BUFFER, the pitch is ignored and assumed to be 1 byte.
- For linear surfaces with **Surface Type** of SURFTYPE_STRBUF, the pitch must be a multiple of 4 bytes.
- For linear surfaces with **Surface Type** of SURFTYPE_BUFFER and **Surface Format** RAW, the pitch must be 1 byte.
- For other linear surfaces, the pitch can be any multiple of bytes.
- For tiled surfaces, the pitch must be a multiple of the tile width.

If the surface is a stencil buffer (and thus has **Tile Mode** set to TILEMODE_WMAJOR), the pitch must be set to 2x the value computed based on width, as the stencil buffer is stored with two rows interleaved. For details on the separate stencil buffer storage format in memory, see GPU Overview (vol1a), Memory Data Formats, Surface Layout, 2D Surfaces, Stencil Buffer Layout (section 8.20.4.8).

4 — 31 — Reserved

Project:	CHV, BSW
Exists If:	[Surface Type] != 'SURFTYPE_STRBUF'
Format:	MBZ

30:29 — Render Target And Sample Unorm Rotation

Exists If:	[Surface Type] != 'SURFTYPE_STRBUF'

For Render Target Surfaces: This field specifies the rotation of this render target surface when being written to memory.

For Other Surfaces: This field is ignored.

Value	Name	Description
0h	0DEG	No rotation (0 degrees)
1h	90DEG	Rotate by 90 degrees
3h	270DEG	Rotate by 270 degrees

Programming Notes

Programming Notes for Render Target Surfaces only

- Rotation is not supported for render targets of any type other than simple, non-mip-mapped, non-array 2D surfaces. The surface must be using tiled with X major.
- **Width** and **Height** fields apply to the dimensions of the surface before rotation.
- For 90 and 270 degree rotated surfaces, the **Height** (rather than the **Width**) must be less than or equal to the **Surface Pitch** (specified in bytes).

RENDER_SURFACE_STATE

- For 90 and 270 degree rotated surfaces, the actual **Height** and **Width** of the surface in pixels (not the field value which is decremented) must both be even.

Rotation is supported only for surfaces with the following surface formats: B5G6R5_UNORM, B5G6R5_UNORM_SRGB, R8G8B8A8_UNORM, R8G8B8A8_UNORM_SRGB, B8G8R8[A|X]8_UNORM, B8G8R8[A|X]8_UNORM_SRGB, B10G10R10[A|X]2_UNORM, B10G10R10A2_UNORM_SRGB, R10G10B10A2_UNORM, R10G10B10A2_UNORM_SRGB, R16G16B16A16_FLOAT, R16G16B16X16_FLOAT

Range [0,2047] to indicate extent of [1,2048]
For Render Target and Typed Dataport 3D Surfaces:
This field indicates the extent of the accessible 'R' coordinates minus 1 on the LOD currently being rendered to.
For Render Target and Typed Dataport 1D and 2D Surfaces:
This field must be set to the same value as the Depth field.
For Other Surfaces:
This field is ignored.

6 **Multisampled Surface Storage Format**

Exists If:	[Surface Type] != 'SURFTYPE_STRBUF'

This field indicates the storage format of the multisampled surface.

Value	Name	Description	Project
0h	MSS	Multsampled surface was/is rendered as a render target	All
1h	DEPTH_STENCIL	Multisampled surface was rendered as a depth or stencil buffer	All

Programming Notes

- All multisampled render target surfaces must have this field set to MSFMT_MSS
- IF this field is MSFMT_DEPTH_STENCIL, the only sampling engine messages allowed are "ld2dms", "resinfo", and "sampleinfo".
- This field is ignored if **Number of Multisamples** is MULTISAMPLECOUNT_1

5:3 **Number of Multisamples**

Exists If:	[Surface Type] != 'SURFTYPE_STRBUF'

RENDER_SURFACE_STATE

This field indicates the number of multisamples on the surface.

Value	Name	Project
0h	MULTISAMPLECOUNT_1	All
1h	MULTISAMPLECOUNT_2	All
2h	MULTISAMPLECOUNT_4	All
3h	MULTISAMPLECOUNT_8	All
4h	Reserved	CHV, BSW
5h-7h	Reserved	

Programming Notes	Project
If this field is any value other than MULTISAMPLECOUNT_1, the **Surface Type** must be SURFTYPE_2D This field must be set to MULTISAMPLECOUNT_1 unless the surface is a Sampling Engine surface or Render Target surface.	
If this field is any value other than MULTISAMPLECOUNT_1, Surface Min LOD, Mip Count / LOD, and Resource Min LOD must be set to zero.	CHV, BSW

31:0 **Reserved**

Exists If:	[Surface Type] == 'SURFTYPE_STRBUF'
Format:	MBZ

2:0 **Multisample Position Palette Index**

Project:	CHV, BSW
Exists If:	[Surface Type] != 'SURFTYPE_STRBUF'

This field indicates the index into the sample position palette that the multisampled surface is using. This field is only used as a return value for the sampleinfo message, and is otherwise not used by hardware.

Value	Name
[0,7]	

5 31:25 **X Offset**

Format:	PixelOffset[8:2]

This field specifies the horizontal offset in pixels from the **Surface Base Address** to the start (origin) of the surface.
This field effectively loosens the alignment restrictions on the origin of tiled surfaces. Previously, tiled surface origin was (by definition) located at the base address, and thus needed to satisfy the 4KB base address alignment restriction. Now the origin can be specified at a finer (4-wide x 4-high pixel) resolution.

Value	Name	Description
[0,508]		In multiples of 4 (low 2 bits missing)

Programming Notes	Project
• For linear surfaces, this field must be zero.	

RENDER_SURFACE_STATE

- For surfaces accessed with the *Data Port Media Block Read/Write* message, the pixel size is assumed to be 32 bits in width.
- For surfaces accessed with the **Data Port Transpose Read message**, the pixel size is assumed to be 32 bits in width.
- For **Surface Format** with other than 8, 16, 32, 64, or 128 bits per pixel, this field must be zero.
- If **Render Target Rotation** is set to other than RTROTATE_0DEG, this field must be zero.
- If **Surface Type** not SURFTYPE_2D, this field must be zero.
- If **MIP Count** is not zero, this field must be zero.
- If **Number of Multisamples** is not MULTISAMPLECOUNT_1, this field must be zero.
- If **Surface Array** is enabled, this field must be zero.
- If **Auxiliary Surface Mode** is not AUX_NONE, this field must be zero.
- If **Surface Vertical Alignment** is VALIGN_8, this field must be a multiple of 8.
- For **Surface Format** with 8 bits per element, this field must be a multiple of 16.
- For **Surface Format** with 16 bits per element, this field must be a multiple of 8.

This field must be zero if Surface Format is PLANAR*.	CHV, BSW
If sampling an ASTC surface with block size of 5X5 or 5X4 and 0 < [(max(Suface_Width»1,1)%10] < 6, and accessing LOD=2 or higher, then this field must be programmed to 4 pixels.	CHV, BSW

24 **Reserved**

Format:	MBZ

23:21 **Y Offset**

Format:	RowOffset[4:2]

This field specifies the vertical offset in rows from the **Surface Base Address** to the start of the surface. (See additional description in the **X Offset** field.)

Value	Name	Description
[0,28]		In multiples of 4 (low two bits missing)

Programming Notes	Project
• For linear surfaces, this field must be zero. • For render targets in which the **Render Target Array Index** is not zero, this field must be zero. • For **Surface Format** with other than 8, 16, 32, 64, or 128 bits per pixel, this field must be zero. • If **Render Target Rotation** is set to other than RTROTATE_0DEG, this field must be zero.	

RENDER_SURFACE_STATE

- If **Surface Type** not SURFTYPE_2D, this field must be zero.
- If **MIP Count** is not zero, this field must be zero.
- If **Number of Multisamples** is not MULTISAMPLECOUNT_1, this field must be zero.
- If **Surface Array** is enabled, this field must be zero.
- If **Auxiliary Surface Mode** is not AUX_NONE, this field must be zero.

This field must be zero if **Surface Format** is PLANAR*.	CHV, BSW

20 **EWA Disable For Cube**

Project:	CHV, BSW
Format:	Disable

Specifies if EWA mode for LOD quality improvement needs to be disabled for cube maps.

Value	Name	Description
0h	Enable **[Default]**	EWA is enabled for cube maps
1h	Disable	EWA is disabled for cube maps

Programming Notes

This field indicates if EWA mode for LOD quality improvement needs to be disabled for cube maps. By default EWA would be on for cube maps hence this field must be 0. If there is any spec violation seen with EWA on cube maps then this field must be set to 1 to disable EWA for cubes.

19:18 **Reserved**

Project:	CHV, BSW
Format:	MBZ

17:16 **Reserved**

Project:	CHV, BSW
Format:	MBZ

15 **Reserved**

Format:	MBZ

14 **Coherency Type**

Specifies the type of coherency maintained for this surface.

Value	Name	Description	Project
0h	GPU coherent	Surface memory is kept coherent with GPU threads using GPU read/write ordering rules. Surface memory is backed by system memory but is not kept coherent with CPU (LLC).	All
1h	IA coherent	Surface memory is kept coherent with CPU (LLC).	All

RENDER_SURFACE_STATE

		Programming Notes This field may optionally be 1 (IA coherent) for messages sent to SFID_DP_DC0 or SFID_DP_DC1 or SFID_DP_DC2. This field is typically set to 0 (GPU coherent) if the context is operating in a non-SVM legacy mode (for example, Ring Buffer or a Execlist using 32-bit Virtual Address Legacy Context PPGTT32).
	13:12	**Reserved** Format: MBZ
	11:8	**Reserved** Project: CHV, BSW Format: MBZ
	7:4	**Surface Min LOD** Format: U4 In LOD Units **For Sampling Engine and Typed Surfaces:** This field indicates the most detailed LOD that can be accessed as part of this surface. This field is added to the delivered LOD (*sample_l, ld*, or *resinfo* message types) before it is used to address the surface. **For Other Surfaces:** This field is ignored. **Programming Notes** This field must be zero if the **Surface Format** is MONO8
	3:0	**MIP Count / LOD** Format: **Sampling Engine and Typed Surfaces:** U4 in (LOD units - 1) **Render Target Surfaces:** U4 in LOD units Range: **Sampling Engine and Typed Surfaces:** [0,14] representing [1,15] MIP levels **Render Target Surfaces:** [0,14] representing LOD **Other Surfaces:** [0] **For Sampling Engine and Typed Surfaces:** This field indicates the number of MIP levels allowed to be accessed starting at **Surface Min LOD**, which must be less than or equal to the number of MIP levels actually stored in memory for this surface. For sample* messages, the mip map access is clamped to be between the mipmap specified by the integer bits of the Min LOD and the ceiling of the value specified here. For ld* messages, out-of-bounds behavior results for LODs outside of the range specified in this field. **For Render Target Surfaces:** This field defines the MIP level that is currently being rendered into. This is the absolute MIP level on the surface and is not relative to the **Surface Min LOD** field, which is ignored for render target surfaces. **For Other Surfaces:** This field is reserved : MBZ **Programming Notes**

RENDER_SURFACE_STATE

		The **LOD** of a render target must be the same as the **LOD** of the other render target(s) and of the depth buffer (defined in 3DSTATE_DEPTH_BUFFER). For render targets with YUV surface formats, the **LOD** must be zero. For sampling engine surfaces with YCRCB* or PLANAR* surface format, **MIP Count** must be zero.
6	31	**Reserved** Exists If: ([Surface Format] != 'PLANAR') Format: MBZ
	31	**Separate UV Plane Enable** Exists If: ([Surface Format] == 'PLANAR') Format: Enable If enabled, this field indicates that the U and V are present as separate planes. If disabled, the UV data is interleaved on a single plane. **Programming Notes** — This field must be disabled (separate UV planes are not supported). — **Project**: CHV, BSW
	30	**Reserved** Project: Exists If: ([Surface Format] == 'PLANAR') Format: MBZ
	30:16	**Auxiliary Surface QPitch** Exists If: ([Surface Format] != 'PLANAR') Format: QPitch[16:2] This field specifies the distance in rows between array slices on the auxiliary surface. **Value**: [4h,1FFFCh] — **Name**: — **Description**: in multiples of 4 (low 2 bits missing) **Programming Notes** — This field must be set to an integer multiple of the **Surface Vertical Alignment** — **Project**: Software must ensure that this field is set to a value sufficiently large such that the array slices in the auxiliary surface do not overlap. Refer to the Memory Data Formats section for information on how surfaces are stored in memory. For non-multisampled render target's auxiliary surface, MCS, QPitch must be computed with Horizontal Alignment = 256 and Surface Vertical Alignment = 128. These alignments are only for MCS buffer and not for associated render target. — **Project**: CHV, BSW
	29:16	**X Offset for U or UV Plane** Exists If: ([Surface Format] == 'PLANAR') Format: U14 This field specifies the horizontal offset in pixels from the **Surface Base Address** to the start (origin) of the U plane or interleaved UV plane, depending on the setting of **Separate UV Plane**

RENDER_SURFACE_STATE

Enable.

Programming Notes
This field must be a multiple of 4 (bits 1:0 MBZ).
Auxiliary Surface Mode is forced to AUX_NONE.

15 **Reserved**

Project:	
Format:	MBZ

14 **Reserved**

Project:	All
Exists If:	([Surface Format] == 'PLANAR')
Format:	MBZ

14:12 **Reserved**

Exists If:	([Surface Format] != 'PLANAR')
Format:	MBZ

11:3 **Auxiliary Surface Pitch**

Project:	CHV, BSW
Exists If:	([Surface Format] != 'PLANAR')
Format:	U9-1 Pitch in #Tiles

This field specifies the Auxiliary surface pitch in (#Tiles - 1).

Value	Name	Description
[0, 511]		-> [1 tile, 512 tiles]

13:0 **Y Offset for U or UV Plane**

Exists If:	([Surface Format] == 'PLANAR')
Format:	U14

This field specifies the vertical offset in rows from the **Surface Base Address** to the start (origin) of the U plane or interleaved UV plane, depending on the setting of **Separate UV Plane Enable**.

Programming Notes
Auxiliary Surface Mode is forced to AUX_NONE.

Workaround
For formats PLANAR_420_* when this field is not a multiple of 4 the Out-of-Bounds Supression check must be disabled (HALF_SLICE_CHICKEN3[5] must be set to 1) to avoid false out of bound detection.

2:0 **Auxiliary Surface Mode**

Project:	CHV, BSW
Exists If:	([Surface Format] != 'PLANAR')
Format:	U3

RENDER_SURFACE_STATE

Specifies what type of surface the Auxiliary surface is. The Auxiliary surface has its own base address and pitch, but otherwise shares or overrides other fields set for the primary surface, detailed in the programming notes below.

Value	Name	Description	Project
0h	AUX_NONE	No Auxiliary surface is used	All
1h	AUX_MCS	The Auxiliary surfaces is an MCS (Multisample Control Surface)	CHV, BSW
2h	AUX_APPEND	The Auxiliary surface is an append buffer	All
3h	AUX_HIZ	The Auxiliary surface is a hierarchical depth buffer	All
4h	Reserved		
5h	Reserved		CHV, BSW
6h-7h	Reserved		

Programming Notes	Project
The CCS and hierarchical depth Auxiliary surface shares **Height, Width, Depth, Surface Type, Surface Array, Surface Min LOD, MIP Count / LOD, Surface Object Control State, Resource Min LOD**, and **Minimum Array Element** with the primary surface. The hierarchical depth Auxiliary surface uses **Surface Horizontal Alignment** of 16, **Surface Vertical Alignment** of 8, regardless of the primary surface's values for these fields. **X & Y Offset** are set to zero for the purpose of accessing the Auxiliary surface. If this field is set to AUX_HIZ, **Surface Format** must be be one of the following: R32_FLOAT, R24_UNORM_X8_TYPELESS, or R16_UNORM, and the format must match the format used when the surface was used as a depth buffer (with R channel corresponding to D channel).	
The CCS Auxiliary surface for non-multisampled render targets has Horizontal Alignment = 256 and Vertical alignment = 128.	CHV, BSW
If this field is set to AUX_HIZ, **Number of Multisamples** must be MULTISAMPLECOUNT_1, and Surface Type cannot be SURFTYPE_3D.	

7 | 31

Red Clear Color

Project:	CHV, BSW
Format:	Clear Color [CHV, BSW] Enumerated Type

For Sampling Engine Multisampled Surfaces and Render Targets:

Specifies the clear value for the red channel.

For Other Surfaces:

This field is ignored.

30

Green Clear Color

Project:	CHV, BSW
Format:	Clear Color [CHV, BSW] Enumerated Type

For Sampling Engine Multisampled Surfaces and Render Targets:

RENDER_SURFACE_STATE

Specifies the clear value for the green channel.
For Other Surfaces:
This field is ignored.

29 **Blue Clear Color**

Project:	CHV, BSW
Format:	Clear Color [CHV, BSW] Enumerated Type

For Sampling Engine Multisampled Surfaces and Render Targets:
Specifies the clear value for the blue channel.
For Other Surfaces:
This field is ignored.

28 **Alpha Clear Color**

Project:	CHV, BSW
Format:	Clear Color [CHV, BSW] Enumerated Type

For Sampling Engine Multisampled Surfaces and Render Targets:
Specifies the clear value for the alpha channel.
For Other Surfaces:
This field is ignored.

27:25 **Shader Channel Select Red**

Format:	Shader Channel Select [CHV, BSW] Enumerated Type

Specifies which surface channel is read or written in the Red shader channel.

Programming Notes	Project
The Shader channel selects also define which shader channels are written to which surface channel. If the Shader channel select is SCS_ZERO or SCS_ONE then it is not written to the surface. If the shader channel select is SCS_RED it is written to the surface red channel and so on. If more than one shader channel select is set to the same surface channel only the first shader channel in RGBA order will be written. Each shader channel select must be set to the same surface channel (R = SCS_RED, G = SCS_GREEN, B = SCS_BLUE, A = SCS_ALPHA) if the surface is accessed via the sampler's sample_unorm* or sample_8x8 messages.	
The Shader Channel Select fields do not affect the following sampling engine message types: resinfo, sampleinfo, LOD, and ld_mcs. These messages behave as if each Shader Channel Select is set to the same color surface channel.	
For the sampling engine *gather4** messages, the Gather4 Source Channel Select field in the message header defines which channel's Shader Channel Select is used to select the surface channel to be sampled. Other Shader Channel Select fields are ignored.	
For the sampling engine *sample*_c* and *gather4*_c* messages, the compare operation always occurs on the red channel from the surface regardless of the setting of the Shader Channel Select fields.	
For Render Target, Red, Green and Blue Shader Channel Selects MUST be such that	CHV,

RENDER_SURFACE_STATE

		only valid components can be swapped i.e. only change the order of components in the pixel. Any other values for these Shader Channel Select fields are not valid for Render Targets. This also means that there MUST not be multiple shader channels mapped to the same RT channel.	BSW
		When multiple Channel selects have the same value and shader channel is disabled, disable channel writes 0s to memory. This behavior does not match with Data Port message via HDC.	CHV, BSW
	24:22	**Shader Channel Select Green** Format: Shader Channel Select [CHV, BSW] Enumerated Type See **Shader Channel Select Red** for details.	
	21:19	**Shader Channel Select Blue** Format: Shader Channel Select [CHV, BSW] Enumerated Type See **Shader Channel Select Red** for details.	
	18:16	**Shader Channel Select Alpha** Format: Shader Channel Select [CHV, BSW] Enumerated Type See **Shader Channel Select Red** for details.	

Programming Notes	Project
Shader Channel Select Alpha must be set to SCS_ONE for the following formats when sampling (not reading via data port): BC6H_SF16 BC6H_UF16 R32G32B32_FLOAT R11G11B10_FLOAT L32X32_FLOAT PLANAR_420_8 ETC1_RGB8 ETC2_RGB8 EAC_R11 EAC_RG11 EAC_SIGNED_R11 EAC_SIGNED_RG11 ETC2_SRGB8 R8G8B8_UNORM_SRGB R8G8B8_UNORM R8G8B8_SNORM R8G8B8_UINT R8G8B8_SINT R16G16B16_FLOAT R16G16B16_UNORM R16G16B16_SNORM R16G16B16_UINT	CHV, BSW

RENDER_SURFACE_STATE

		R16G16B16_SINT |
		For Render Target, this field MUST be programmed to value = SCS_ALPHA. | CHV, BSW
	15:12	**Reserved** Format: | MBZ
	11:0	**Resource Min LOD** Format: | U4.8 in LOD units **For Sampling Engine Surfaces:** This field indicates the most detailed LOD that is present in the resource underlying the surface. Refer to the "LOD Computation Pseudocode" section for the use of this field. **For Other Surfaces:** This field is ignored. Value | Name [0,14] |
		Programming Notes This field must be zero if the **Surface Format** is MONO8 This field must be zero if the **ChromaKey Enable** is enabled in the associated sampler.
8..9	63:0	**Surface Base Address** Format: | GraphicsAddress[63:0]SurfaceBase Specifies the byte-aligned base address of the surface.

Programming Notes

- For SURFTYPE_BUFFER render targets, this field specifies the base address of first element of the surface. The surface is interpreted as a simple array of that single element type. The address must be naturally-aligned to the element size (e.g., a buffer containing R32G32B32A32_FLOAT elements must be 16-byte aligned).
- For SURFTYPE_BUFFER non-rendertarget surfaces, this field specifies the base address of the first element of the surface, computed in software by adding the surface base address to the byte offset of the element in the buffer. The base address must be aligned to element size.
- Linear depth buffer surface base addresses must be 64-byte aligned. Note that while render targets (color) can be SURFTYPE_BUFFER, depth buffers cannot.
- Mipmapped surfaces are stored in a "monolithic" (fixed) format, and only require a single address for the base MIP. All other MIPs are positioned relative to the base MIP.
- The Base Address for linear (non-tiled) render target surfaces and surfaces accessed with the typed surface read/write data port messages must be element-size aligned for Non-YUV surface formats, or a multiple of 2 element-sizes for YUV surface formats.

RENDER_SURFACE_STATE

- Other linear (non-tiled) surfaces have no alignment requirements (byte alignment is sufficient).
- For tiled surfaces, the actual start of the surface can be offset from the Surface Base Address by the X Offset and Y Offset fields. Tiles are inherently page-aligned (4K or 64K).
- Certain message types used to access surfaces have more stringent alignment requirements. Please refer to the specific data-port message documentation for additional restrictions.

10..11	63:62	**Reserved** Exists If: ([Surface Format] == 'PLANAR') Format: MBZ
	61:48	**X Offset for V Plane** Exists If: ([Surface Format] == 'PLANAR') Format: U14 This field specifies the horizontal offset in pixels from the **Surface Base Address** to the start (origin) of the V plane. **Programming Notes** This field must be a multiple of 4 (bits 1:0 MBZ). This field is ignored if **Separate UV Plane Enable** is disabled.
	47:46	**Reserved** Exists If: ([Surface Format] == 'PLANAR') Format: MBZ
	45:32	**Y Offset for V Plane** Exists If: ([Surface Format] == 'PLANAR') Format: U14 This field specifies the vertical offset in rows from the **Surface Base Address** to the start (origin) of the V plane. **Programming Notes** This field is ignored if **Separate UV Plane Enable** is disabled.
	31:21	**Auxiliary Table Index for Media Compressed Surface** Exists If: [Memory Compression Enable] ==1 This field is valid only if Media Memory Compression is on for the surface(Memory Compression Enable == 1). In that case, the Auxiliary Surface Base address is never expected to be used and hence can be overloaded. This represents the 11 bit index into the table in memory which maps the surface to the auxiliary base address.
	63:12	**Auxiliary Surface Base Address**

RENDER_SURFACE_STATE

		Exists If: ([Surface Format] != 'PLANAR') AND [Memory Compression Enable] == 0 Format: GraphicsAddress[63:12] Specifies the 4kbyte-aligned base address of the Auxiliary surface associated with the primary surface specified in other SURFACE_STATE fields.

Default Value: 0x00000000

DWord	Bit	Description
0	31	**Reserved** Project: All Format: Ignore Ignored
	30:27	**Viewport Index** Project: All Format: U4 For Render Target Write message, specifies the index of the viewport currently being used. Range = [0,15] Ignored by Render Target Read message.
	26:16	**Render Target Array Index** Project: All Format: U11 Specifies the array index to be used for the following surface types: SURFTYPE_1D: specifies the array index. Range = [0,511] SURFTYPE_2D: specifies the array index. Range = [0,511] SURFTYPE_3D: specifies the Z or R coordinate. Range = [0,2047] SURFTYPE_BUFFER: must be zero. SURFTYPE_CUBE: specifies the face identifier. Mapping (0,+x) (1,-x) (2,+y) (3,-y) (4,+z) (5,-z). **Programming Notes** The Render Target Array Index used by hardware for access to the Render Target is overridden with the Minimum Array Element defined in SURFACE_STATE if it is out of the range between Minimum Array Element and Depth. For cube surfaces, a depth value of 5 is used for this determination.
	15	**Front/Back Facing Polygon** Project: All Format: U1 Determines whether the polygon is front or back facing. Used by the render cache to determine which stencil test state to use. Value: 0h — Name: Front facing — Description: All — Project: All Value: 1h — Name: Back facing — Description: All — Project: All

MHC_RT_C0 - Render Target Message Header Control

14 **Stencil Present to Render Target**

Project:	All
Format:	Enable

For Render Target Write message, indicates that computed stencil is included in the message. Must be zero for Render Target Read message.

13 **Source Depth Present to Render Target**

Project:	All
Format:	Enable

For Render Target Write Message, indicates that source depth data is included in the message. Must be zero for Render Target Read message.

12 **oMask to Render Target**

Project:	All
Format:	Enable

For Render Target Write message, indicates that oMask data is present in the message and is to be used to mask off samples. Must be zero for Render Target Read message.

11 **Source0 Alpha Present to Render Target**

Project:	All
Format:	Enable

For Render Target Write message, indicates that Source0 Alpha (aka o0.a) data is included in RTWrite message. If present, these alpha values are used as inputs to AlphaTest and AlphaToCoverage functions. This is required to meet the API rules when writing to multiple render targets (MRTs). Must be zero for Render Target Read message.

Programming Notes

This bit should not be set when write to RT0, though sending and using redundant alpha will provide the correct results (at lower performance). This bit is not supported on Dual-Source Blend message types, as source0 alpha is already included in those messages. This bit is not supported on replicated data message types.

SAMPLER_BORDER_COLOR_STATE

SAMPLER_BORDER_COLOR_STATE

Project:	Pre-CHV, BSW
Source:	PRM
Size (in bits):	128
Default Value:	0x00000000, 0x00000000, 0x00000000, 0x00000000

Description	Project
The interpretation of the border color depends on the Texture Border Color Mode field in SAMPLER_STATE as follows: • DX9 mode: The border color is 8-bit UNORM format, regardless of the surface format chosen. For surface formats with one or more channels missing (i.e. R5G6R5_UNORM is missing the alpha channel), the value from the border color, if selected, will be used even for the missing channels. • DX10/OGL mode: the format of the border color depends on the format of the surface being sampled. If the map format is UINT, then the border color format is R32G32B32A32_UINT. If the map format is SINT, then the border color format is R32G32B32A32_SINT. Otherwise, the border color format is R32G32B32A32_FLOAT. For surface formats with one or more channels missing, the value from the border color is not used for the missing channels, resulting in these channels resulting in the overall default value (0 for colors and 1 for alpha) regardless of whether border color is chosen. The surface formats with "L" and "I" have special behavior with respect to the border color. The border color value used for the replicated channels (RGB for "L" formats and RGBA for "I" formats) comes from the red channel of border color. In these cases, the green and blue channels, and also alpha for "I", of the border color are ignored.The format of this state depends on the Texture Border Color Mode field.	CHV, BSW

Programming Notes

- DX9 mode is not supported for surfaces with more than 16 bits in any channel, other than 32-bit float formats which are supported.
- The conditions under which this color is used depend on the **Surface Type** - 1D/2D/3D surfaces use the border color when the coordinates extend beyond the surface extent; cube surfaces use the border color for "empty" (disabled) faces.
- The border color itself is accessed through the texture cache hierarchy rather than the state cache hierarchy. Thus, if the border color is changed in memory, the texture cache must be invalidated and the state cache does not need to be invalidated.
- MAPFILTER_MONO: The border color is ignored. Border color is fixed at a value of 0 by hardware.

SAMPLER_INDIRECT_STATE_BORDER_COLOR

SAMPLER_INDIRECT_STATE_BORDER_COLOR

Project:	CHV, BSW
Source:	PRM
Size (in bits):	128
Default Value:	0x00000000, 0x00000000, 0x00000000, 0x00000000

This structure is a one version of the SAMPLER_INDIRECT_STATE structure, suitable for many needs.
An instance of this structure is pointed to by the **Indirect State Pointer** field in SAMPLER_STATE.
The interpretation of the border color depends on the **Texture Border Color Mode** field in SAMPLER_STATE as follows:

- In **DX9** mode, the border color is 8-bit UNORM format, regardless of the surface format chosen. For surface formats with one or more channels missing (i.e. R5G6R5_UNORM is missing the alpha channel), the value from the border color, if selected, will be used *even for the missing channels*.
- In **DX10/OGL** mode, the format of the border color is R32G32B32A32_FLOAT, R32G32B32A32_SINT, or R32G32B32A32_UINT, depending on the surface format chosen. For surface formats with one or more channels missing, the value from the border color is not used for the missing channels, resulting in these channels resulting in the overall default value (0 for colors and 1 for alpha) regardless of whether border color is chosen. The surface formats with "L" and "I" have special behavior with respect to the border color. The border color value used for the replicated channels (RGB for "L" formats and RGBA for "I" formats) comes from the *red* channel of border color. In these cases, the green and blue channels, and also alpha for "I", of the border color are ignored.

Programming Notes

- DX9 mode is not supported for surfaces with more than 16 bits in any channel, other than 32-bit float formats which are supported.
- The conditions under which this color is used depend on the **Surface Type** - 1D/2D/3D surfaces use the border color when the coordinates extend beyond the surface extent; cube surfaces use the border color for "empty" (disabled) faces.
- The border color itself is accessed through the texture cache hierarchy rather than the state cache hierarchy. Thus, if the border color is changed in memory, the texture cache must be invalidated and the state cache does not need to be invalidated.
- MAPFILTER_MONO: The border color is ignored. Border color is fixed at a value of 0 by hardware.

29:28 Enable 8-tap filter

Adaptive Filtering (Mode = 11) ExistsIf:
R10G10B10A2_UNORM R8G8B8A8_UNORM (AYUV also) R8B8G8A8_UNORM B8G8R8A8_UNORM R16G16B16A16

Enable 8-tap Filtering on UV channel (Mode = 10) ExistsIf:
R10G10B10A2_UNORM R8G8B8A8_UNORM (AYUV also) R8B8_UNORM (CrCb) R8_UNORM R8B8G8A8_UNORM B8G8R8A8_UNORM R16G16B16A16 Y8_UNORM

Value	Name	Description
00b		4-tap filter is only done on all channels.
01b		Enable 8-tap Adaptive filter on G-channel. 4-tap filter on other channels.
10b		8-tap filter is done on all channels (UV-ch uses the Y-coefficients)
11b		Enable 8-tap Adaptive filter all channels (UV-ch uses the Y-coefficients).

Programming Notes
For 00 and 10, are applicable for RGB surfaces only or surface without Y-ch. In case it is a YUV surface it will default to adaptive mode automatically which is 01 and 11 respectively. Alpha channel is always bi-linear filter irrespective of the above modes.
Mode 01 and 00 are legacy support and are supported on all surface formats.
When Mode is 10 and Surface format is Y8_UNORM, Bypass X/Y Adaptive Filtering must be 1, and Default Sharp Level must be 255

SAMPLER_STATE

SAMPLER_STATE

Project:	CHV, BSW
Source:	PRM
Exists If:	//(MessageType != 'Deinterlace') && (MessageType != 'Sample_8x8')
Size (in bits):	128
Default Value:	0x00000000, 0x00000000, 0x00000000, 0x00000000

This is the normal sampler state used by all messages that use SAMPLER_STATE except sample_8x8 and deinterlace. The sampler state is stored as an array of up to 16 elements, each of which contains the dwords described here. The start of each element is spaced 4 dwords apart. The first element of the sampler state array is aligned to a 32-byte boundary.

DWord	Bit	Description
0	31	**Sampler Disable** Project: All Format: Disable This field allows the sampler to be disabled. If disabled, all output channels will return 0.
	30	**Reserved** Project: CHV, BSW
	29	**Texture Border Color Mode** For some surface formats, the 32 bit border color is decoded differently based on the border color mode. In addition, the default value of channels not included in the surface may be affected by this field. Refer to the "Sampler Output Channel Mapping" table for the values of these channels, and for surface formats that may only support one of these modes. Also refer to the definition of SAMPLER_BORDER_COLOR_STATE for more details on the behavior of the two modes defined by this field.

Value	Name	Description
0h	DX10/OGL	DX10/OGL mode for interpreting the border color
1h	DX9	DX9 and earlier mode for interpreting the border color

Programming Notes	Project
This field is required to be the same for every message over a period of time. A flush of the sampler cache must occur before a message with the opposite state of this field is delivered.	
This field must be set to DX9 mode when used with surfaces that have Surface Format P4A4_UNORM or A4P4_UNORM.	
This field must be set to DX10/OGL mode when used with surfaces that have Surface Format YCRCB_SWAPUV or YCRCB_SWAPY.	
This field must be set to DX10/OGL mode if **Surface Format** for the associated	CHV,

SAMPLER_STATE

	surface is UINT OR SINT.	BSW
	This field must be set to DX10/OGL mode if REDUCTION_MINIMUM or REDUCTION_MAXIMUM or message type is sample_min or sample_max.	

28:27 **LOD PreClamp Mode**

Project:	CHV, BSW

This field determines whether the computed LOD is clamped to [max,min] mip level before the mag-vs-min determination is performed.
PRECLAMP_OGL: LOD pre-clamped to **Min LOD** and **Max LOD**
OpenGL API currently clamps LOD to the **Min LOD** and **Max LOD** (from Sampler State) prior to performing min/mag determination, and therefore it is expected that an OpenGL driver would need to set this field to PRECLAMP_OGL.

Value	Name	Description
0h	NONE	LOD PreClamp disabled
1h	Reserved	
2h	OGL	LOD PreClamp enabled (OGL mode)

26:22 **Base Mip Level**

Project:	CHV, BSW
Format:	U4.1

Range: [0.0, 14.0]
Specifies which mip level is considered the "base" level when determining mag-vs-min filter and selecting the "base" mip level.

21:20 **Mip Mode Filter**

Project:	All
Format:	U2 Enumerated Type

This field determines if and how mip map levels are chosen and/or combined when texture filtering.

Value	Name	Description	Project
0h	NONE	Disable mip mapping - force use of the mipmap level corresponding to Min LOD.	All
1h	NEAREST	Nearest, Select the nearest mip map	All
2h	Reserved		All
3h	LINEAR	Linearly interpolate between nearest mip maps (combined with linear min/mag filters this is analogous to "Trilinear" filtering).	All

Programming Notes	Project
MIPFILTER_LINEAR is not supported for surface formats that do not support	

SAMPLER_STATE

"Sampling Engine Filtering" as indicated in the Surface Formats table unless using the sample_c message type or minimum/maximum operation.	
Mip Mode Filter must be set to MIPFILTER_NONE or MIPFILTER_NEAREST if Surface Format for the associated surface is UINT or SINT. However, all settings of this field are allowed with UINT/SINT if a minimum or maximum operation is being performed.	CHV, BSW

19:17 **Mag Mode Filter**

Project:	All
Format:	U3 Enumerated Type

This field determines how texels are sampled/filtered when a texture is being "magnified" (enlarged). For volume maps, this filter mode selection also applies to the 3rd (inter-layer) dimension.

Value	Name	Description	Project
0h	NEAREST	Sample the nearest texel	All
1h	LINEAR	Bilinearly filter the 4 nearest texels	All
2h	ANISOTROPIC	Perform an "anisotropic" filter on the chosen mip level	All
4h-5h	Reserved		All
6h	MONO	Perform a monochrome convolution filter	All
7h	Reserved		All

Programming Notes	Project
Only MAPFILTER_NEAREST and MAPFILTER_LINEAR are supported for surfaces of type SURFTYPE_3D.	
Only MAPFILTER_NEAREST is supported for surface formats that do not support "Sampling Engine Filtering" as indicated in the Surface Formats table unless using the sample_c message type or minimum/maximum operation.	
MAPFILTER_MONO: Only CLAMP_BORDER texture addressing mode is supported. . Both Mag Mode Filter and Min Mode Filter must be programmed to MAPFILTER_MONO. Mip Mode Filter must be MIPFILTER_NONE. Only valid on surfaces with Surface Format MONO8 and with Surface Type SURFTYPE_2D.	
MAPFILTER_ANISOTROPIC may cause artifacts at cube edges if enabled for cube maps with the TEXCOORDMODE_CUBE addressing mode.	
MAPFILTER_ANISOTROPIC will be overridden to MAPFILTER_LINEAR when using a sample_l or sample_l_c message type or when Force LOD to Zero is set in the message header.	
Both Mag Mode Filter and Min Mode Filter must be set to MAPFILTER_NEAREST if Surface Format for the associated surface is UINT or SINT. However, all settings of this field other than MAPFILTER_MONO are allowed with UINT/SINT if a minimum or maximum operation is being performed.	CHV, BSW
MAPFILTER_FLEXIBLE might have data corruption when sampled from surface with float32 format with exponent value exceeded 248	CHV, BSW

SAMPLER_STATE

MAPFILTER_FLEXIBLE operates on float16 or float32 surfaces could have erroneous signed for infinity output i.e. 0x7f800000 <-> 0xff800000	CHV, BSW
MAPFILTER_FLEXIBLE when float16 +/-inf apply to coefficient that are absolutely larger than 1.0 output result could be nan instead of +/-inf MAPFILTER_FLEXIBLE: A Null Tile reference will be reported back even if the associated texel has a coefficient of 0.0.	CHV, BSW

16:14 **Min Mode Filter**

Project:	All
Format:	U3 Enumerated Type

This field determines how texels are sampled/filtered when a texture is being "minified" (shrunk). For volume maps, this filter mode selection also applies to the 3rd (inter-layer) dimension.See Mag Mode Filter

Value	Name	Description	Project
0h	NEAREST	Sample the nearest texel	All
1h	LINEAR	Bilinearly filter the 4 nearest texels	All
2h	ANISOTROPIC	Perform an "anisotropic" filter on the chosen mip level	All
4h-5h	Reserved		All
6h	MONO	Perform a monochrome convolution filter	All
7h	Reserved		All

Programming Notes	Project
FLEXIBLE: A Null Tile reference will be reported back even if the associated texel has a coefficient of 0.0.	CHV, BSW

13:1 **Texture LOD Bias**

Project:	All
Format:	S4.8 2's complement

Range: [-16.0, 16.0)
This field specifies the signed bias value added to the calculated texture map LOD prior to min-vs-mag determination and mip-level clamping. Assuming mipmapping is enabled, a positive LOD bias will result in a somewhat blurrier image (using less-detailed mip levels) and possibly higher performance, while a negative bias will result in a somewhat crisper image (using more-detailed mip levels) and may lower performance.

Programming Notes
There is no requirement or need to offset the LOD Bias in order to produce a correct LOD for texture filtering (as was required for correct bilinear and anisotropic filtering in some legacy devices).

0 **Anisotropic Algorithm**

Project:	All

SAMPLER_STATE

		Format: U1 Enumerated Type Controls which algorithm is used for anisotropic filtering. Generally, the EWA approximation algorithm results in higher image quality than the legacy algorithm.

Value	Name	Description	Project
0h	LEGACY	Use the legacy algorithm for anisotropic filtering	All
1h	EWA Approximation	Use the new EWA approximation algorithm for anisotropic filtering	All

1	31:20	**Min LOD** Project: All Format: U4.8 in LOD units Range: [0.0, 14.0], where the upper limit is also bounded by the Max LOD. This field specifies the minimum value used to clamp the computed LOD after LOD bias is applied. Note that the minification-vs.-magnification status is determined after LOD bias and before this maximum (resolution) mip clamping is applied.The integer bits of this field are used to control the "maximum" (highest resolution) mipmap level that may be accessed (where LOD 0 is the highest resolution map). The fractional bits of this value effectively clamp the inter-level trilinear blend factor when trilinear filtering is in use.

Programming Notes

If Min LOD is greater than Max LOD, Min LOD takes precedence, i.e. the resulting LOD will always be Min LOD.

This field must be zero if the Min or Mag Mode Filter is set to MAPFILTER_MONO

	19:8	**Max LOD** Project: All Format: U4.8 in LOD units Range: [0.0, 14.0] This field specifies the maximum value used to clamp the computed LOD after LOD bias is applied. Note that the minification-vs.-magnification status is determined after LOD bias and before this minimum (resolution) mip clamping is applied.The integer bits of this field are used to control the "minimum" (lowest resolution) mipmap level that may be accessed.The fractional bits of this value effectively clamp the inter-level trilinear blend factor when trilinear filtering is in use.Force the mip map access to be between the mipmap specified by the integer bits of the Min LOD and the ceiling of the value specified here.
	7	**ChromaKey Enable** Project: CHV, BSW Format: Enable This field enables the chroma key function.

Programming Notes

SAMPLER_STATE

Supported only on a specific subset of surface formats. See section titled: "Surface Formats" in thsi volume for supported formats. This field must be disabled if min or mag filter is MAPFILTER_MONO or MAPFILTER_ANISOTROPIC. This field must be disabled if used with a surface of type SURFTYPE_3D.

6:5 **ChromaKey Index**

Project:	CHV, BSW
Format:	U2

Range: [0, 3]

This field specifies the index of the ChromaKey Table entry associated with this Sampler. This field is a "don't care" unless **ChromaKey Enable** is ENABLED.

4 **ChromaKey Mode**

Project:	CHV, BSW
Format:	U1 Enumerated Type

This field specifies the behavior of the device in the event of a ChromaKey match. This field is ignored if ChromaKey is disabled.

KEYFILTER_REPLACE_BLACK: In this mode, each texel that matches the chroma key is replaced with (0,0,0,0) (black with alpha=0) prior to filtering. This will tend to darken/fade edges of keyed regions. Note that the pixel pipeline must be programmed to use the resulting filtered texel value to gain the intended effect, e.g., handle the case of a totally keyed-out region (filtered texel alpha==0) through use of alpha test, etc.

Value	Name	Description
0h	KEYFILTER_KILL_ON_ANY_MATCH	In this mode, if any contributing texel matches the chroma key, the corresponding pixel mask bit for that pixel is cleared. The result of this operation is observable only if the Killed Pixel Mask Return flag is set on the input message.
1h	KEYFILTER_REPLACE_BLACK	In this mode, each texel that matches the chroma key is replaced with (0,0,0,0) (black with alpha=0) prior to filtering. For YCrCb surface formats, the black value is A=0, R(Cr)=0x80, G(Y)=0x10, B(Cb)=0x80. This will tend to darken/fade edges of keyed regions. Note that the pixel pipeline must be programmed to use the resulting filtered texel value to gain the intended effect, e.g., handle the case of a totally keyed-out region (filtered texel alpha==0) through use of alpha test, etc.

3:1 **Shadow Function**

Project:	All

SAMPLER_STATE

		Format: U3 Enumerated Type This field is used for shadow mapping support via the sample_c message type, and specifies the specific comparison operation to be used. The comparison is between the texture sample red channel (except for alpha-only formats which use the alpha channel), and the "ref" value provided in the input message.

Value	Name
0h	PREFILTEROP ALWAYS
1h	PREFILTEROP NEVER
2h	PREFILTEROP LESS
3h	PREFILTEROP EQUAL
4h	PREFILTEROP LEQUAL
5h	PREFILTEROP GREATER
6h	PREFILTEROP NOTEQUAL
7h	PREFILTEROP GEQUAL

	0	**Cube Surface Control Mode** Project: All Format: U1 Enumerated Type When sampling from a SURFTYPE_CUBE surface, this field controls whether the TC* Address Control Mode fields are interpreted as programmed or overridden to TEXCOORDMODE_CUBE.

Value	Name	Project
0h	PROGRAMMED	All
1h	OVERRIDE	All

Programming Notes
This field must be set to CUBECTRLMODE_PROGRAMMED

2	31:30	**Reserved** Project: CHV, BSW

18 **U Address Mag Filter Rounding Enable**

Project:	All
Format:	Enable

Controls whether the texture address is rounded or truncated before being used to select texels to sample. Provides independent control of rounding on one texture address dimension (U/V/R) in either mag or min filter mode.

Programming Notes	Project
Hardware will **not** force rounding enable.	CHV, BSW

17 **U Address Min Filter Rounding Enable**

Project:	All
Format:	Enable

Controls whether the texture address is rounded or truncated before being used to select texels to sample. Provides independent control of rounding on one texture address dimension (U/V/R) in either mag or min filter mode.

Programming Notes	Project
Hardware will **not** force rounding enable.	CHV, BSW

16 **V Address Mag Filter Rounding Enable**

Project:	All
Format:	Enable

Controls whether the texture address is rounded or truncated before being used to select texels to sample. Provides independent control of rounding on one texture address dimension (U/V/R) in either mag or min filter mode.

Programming Notes	Project
Hardware will **not** force rounding enable.	CHV, BSW

15 **V Address Min Filter Rounding Enable**

Project:	All
Format:	Enable

Controls whether the texture address is rounded or truncated before being used to select texels to sample. Provides independent control of rounding on one texture address dimension (U/V/R) in either mag or min filter mode.

SAMPLER_STATE

		Programming Notes / **Project** Hardware will **not** force rounding enable. / CHV, BSW
	14	**R Address Mag Filter Rounding Enable** Project: All Format: Enable Controls whether the texture address is rounded or truncated before being used to select texels to sample. Provides independent control of rounding on one texture address dimension (U/V/R) in either mag or min filter mode. **Programming Notes** / **Project** Hardware will **not** force rounding enable. / CHV, BSW
	13	**R Address Min Filter Rounding Enable** Project: All Format: Enable Controls whether the texture address is rounded or truncated before being used to select texels to sample. Provides independent control of rounding on one texture address dimension (U/V/R) in either mag or min filter mode. **Programming Notes** / **Project** Hardware will **not** force rounding enable. / CHV, BSW
	12:11	**Trilinear Filter Quality** Project: All Format: U2 Enumerated Type Selects the quality level for the trilinear filter.

Value	Name	Description	Project
0	FULL	Full Quality. Both mip maps are sampled under all circumstances.	All
1	HIGH	High Quality. Same as full quality.	CHV, BSW
2	MED	Medium Quality. If the contribution of one mip map is less than 25%, only the other mip map contributes.	All
3	LOW	Low Quality. If the contribution of one mip map is less than 37.5%, only the other mip map contributes.	All

	10	**Non-normalized Coordinate Enable** Project: CHV, BSW Format: Enable This field, if enabled, specifies that the input coordinates (U/V/R) are in non-normalized space, where each integer increment is one texel on LOD 0. If disabled, coordinates are normalized, where the range 0 to 1 spans the entire surface. **Programming Notes** The following state must be set as indicated if this field is *enabled*:

SAMPLER_STATE

- TCX/Y/Z Address Control Mode must be TEXCOORDMODE_CLAMP, TEXCOORDMODE_HALF_BORDER, or TEXCOORDMODE_CLAMP_BORDER.
- Surface Type must be SURFTYPE_2D or SURFTYPE_3D.
- Mag Mode Filter must be MAPFILTER_NEAREST or MAPFILTER_LINEAR.
- Min Mode Filter must be MAPFILTER_NEAREST or MAPFILTER_LINEAR.
- Mip Mode Filter must be MIPFILTER_NONE.
- Min LOD must be 0.
- Max LOD must be 0.
- MIP Count must be 0.
- Surface Min LOD must be 0.
- Texture LOD Bias must be 0.

9 **Reserved**

Project:	CHV, BSW
Format:	MBZ

8:6 **TCX Address Control Mode**

Project:	All
Format:	Texture Coordinate Mode [CHV, BSW] Enumerated Type

Controls how the 1st (TCX, aka U) component of input texture coordinates are mapped to texture map addresses - specifically, how coordinates "outside" the texture are handled (wrap/clamp/mirror). The setting of this field is subject to being overridden by the Cube Surface Control Mode field when sampling from a SURFTYPE_CUBE surface.

Programming Notes	Project
When using cube map texture coordinates, each TC component must have the same Address Control Mode.	CHV, BSW
When TEXCOORDMODE_CUBE is not used accessing a cube map, the map's Cube Face Enable field must be programmed to 111111b (all faces enabled).	
MAPFILTER_MONO: Texture addressing modes must all be set to TEXCOORDMODE_CLAMP_BORDER. The **Border Color** is ignored in this mode, a constant value of 0 is used for border color. Software must pad the border texels within the map itself with 0.	
If **Surface Format** is PLANAR*, this field must be set to TEXCOORDMODE_CLAMP.	

5:3 **TCY Address Control Mode**

Project:	All
Format:	Texture Coordinate Mode [CHV, BSW] Enumerated Type

Controls how the 2nd (TCY, aka V) component of input texture coordinates are mapped to texture map addresses - specifically, how coordinates "outside" the texture are handled (wrap/clamp/mirror). See Address TCX Control Mode above for details

Programming Notes

SAMPLER_STATE

		If this field is set to TEXCOORDMODE_CLAMP_BORDER or TEXCOORDMODE_HALF_BORDER and a 1D surface is sampled, incorrect blending with the border color in the vertical direction may occur.
	2:0	**TCZ Address Control Mode** Project: All Format: Texture Coordinate Mode [CHV, BSW] Enumerated Type **Description** / **Project** Controls how the 3rd (TCZ) component of input texture coordinates are mapped to texture map addresses - specifically, how coordinates "outside" the texture are handled (wrap/clamp/mirror).See Address TCX Control Mode above for details If this field is set to TEXCOORDMODE_CLAMP_BORDER or TEXCOORDMODE_HALF_BORDER and a 3D surface is sampled, incorrect blending with the border color in the Q direction may occur. — CHV, BSW

SCISSOR_RECT

SCISSOR_RECT

Project: CHV, BSW
Source: RenderCS
Size (in bits): 64
Default Value: 0x00000000, 0x00000000

The viewport-specific state used by the SF unit (SCISSOR_RECT) is stored as an array of up to 16 elements, each of which contains the DWords described below. The start of each element is spaced 2 DWords apart. The location of first element of the array, as specified by Pointer to SCISSOR_RECT, is aligned to a 32-byte boundary.

DWord	Bit	Description
0	31:16	**Scissor Rectangle Y Min** Project: All Format: U16 Pixels from Drawing Rectangle origin (upper left corner) Specifies Y Min coordinate of (inclusive) Scissor Rectangle used for scissor test. Pixels with (Draw Rectangle-relative) Y coordinates less than Y Min will be clipped out if Scissor Rectangle is enabled. NOTE: If Y Min is set to a value greater than Y Max, all primitives will be discarded for this viewport. Value: [0,16383] — Name: — Project: CHV, BSW
	15:0	**Scissor Rectangle X Min** Project: All Format: U16 Pixels from Drawing Rectangle origin (upper left corner) Specifies X Min coordinate of (inclusive) Scissor Rectangle used for scissor test. 4	31:0	**Viewport Matrix Element m31** Format: IEEE_Float
5	31:0	**Viewport Matrix Element m32** Format: IEEE_Float
6	31:0	**Reserved** Format: MBZ
7	31:0	**Reserved** Format: MBZ
8	31:0	**X Min Clip Guardband** Format: IEEE_Float . This 32-bit float represents the XMin guardband boundary (normalized to Viewport.XMin == -1.0f). This corresponds to the left boundary of the NDC guardband. Workaround: Minimum allowed value for this field is -16384. — Project: CHV, BSW
9	31:0	**X Max Clip Guardband** Format: IEEE_Float This 32-bit float represents the XMax guardband boundary (normalized to Viewport..XMax == 1.0f). This corresponds to the right boundary of the NDC guardband. Workaround — Project

SF_CLIP_VIEWPORT

		Maximum allowed value for this field is 16383. — CHV, BSW
10	31:0	**Y Min Clip Guardband** Format: — IEEE_Float This 32-bit float represents the YMin guardband boundary (normalized to Viewport.YMin == -1.0f). This corresponds to the bottom boundary of the NDC guardband. **Workaround** / **Project** Minimum allowed value for this field is -16384. — CHV, BSW
11	31:0	**Y Max Clip Guardband** Format: — IEEE_Float This 32-bit float represents the YMax guardband boundary (normalized to Viewport.YMax == 1.0f). This corresponds to the top boundary of the NDC guardband. **Workaround** / **Project** Maximum allowed value for this field is 16383. — CHV, BSW
12 **Project:** CHV, BSW	31:0	**X Min ViewPort** Project: — CHV, BSW Format: — IEEE_Float This 32-bit float represents the Viewport.XMin. This is the X min of the viewport extents as programmed by API, and this value should be programmed in Screen Space coordinate and not as normalized coordinate.
13 **Project:** CHV, BSW	31:0	**X Max ViewPort** Project: — CHV, BSW Format: — IEEE_Float This 32-bit float represents the Viewport.XMax. This is the X max of the viewport extents as programmed by API, and this value should be programmed in Screen Space coordinate and not as normalized coordinate.
14 **Project:** CHV, BSW	31:0	**Y Min ViewPort** Project: — CHV, BSW Format: — IEEE_Float This 32-bit float represents the Viewport.YMin. This is the Y min of the viewport extents as programmed by API, and this value should be programmed in Screen Space coordinate and not as normalized coordinate.
15 **Project:** CHV, BSW	31:0	**Y Max ViewPort** Project: — CHV, BSW Format: — IEEE_Float

SF_CLIP_VIEWPORT		
		This 32-bit float represents the Viewport.Ymax. This is the Y max of the viewport extents as programmed by API, and this value should be programmed in Screen Space coordinate and not as normalized coordinate.

SF_OUTPUT_ATTRIBUTE_DETAIL

SF_OUTPUT_ATTRIBUTE_DETAIL

Source: RenderCS
Size (in bits): 16
Default Value: 0x00000000

DWord	Bit	Description
0	15	**Component Override W** Format: Enable If set, the W component of this output Attribute is overridden by the W component of the constant vector specified by ConstantSource.
	14	**Component Override Z** Format: Enable If set, the Z component of this output Attribute is overridden by the Z component of the constant vector specified by ConstantSource.
	13	**Component Override Y** Format: Enable If set, the Y component of output Attribute is overridden by the Y component of the constant vector specified by ConstantSource.
	12	**Component Override X** Format: Enable If set, the X component of output Attribute is overridden by the X component of the constant vector specified by ConstantSource.
	11	**Swizzle Control Mode** Project: CHV, BSW Format: U1 Enumerated Type When Attribute Swizzle Enable is ENABLED, this bit controls whether attributes 0-15 or 16-31 are subject to the following swizzle controls: • Component Override X/Y/Z/W • Constant Source • Swizzle Select • Source Attribute • WrapShortest Enables Note that the Number of SF Output Attributes field specifies how many attributes are output. Note: This field does not impact any functions which provide separate states for all 32 attributes (e.g., Point sprite, Constant interpolation).

SF_OUTPUT_ATTRIBUTE_DETAIL

Note: This field is only valid for the first indexed attribute (Attribute[0]). For all other indices, it is Reserved and MBZ.

10:9 Constant Source

Format:	U2 enumerated type

This state selects a constant vector which can be used to override individual components of this Attribute

Value	Name	Description
0h	CONST_0000	Constant.xyzw = 0.0,0.0,0.0,0.0
1h	CONST_0001_FLOAT	Constant.xyzw = 0.0,0.0,0.0,1.0
2h	CONST_1111_FLOAT	Constant.xyzw = 1.0,1.0,1.0,1.0
3h	PRIM_ID	Constant.xyzw = PrimID (replicated)

8 Reserved

Format:	MBZ

7:6 Swizzle Select

Format:	U2 enumerated type

This state, along with Source Attribute, specifies the source for this output Attribute.

Value	Name	Description
0h	INPUTATTR	This attribute is sourced from AttrInputReg[SourceAttribute]
1h	INPUTATTR_FACING	If the object is front-facing, this attribute is sourced from AttrInputReg[SourceAttribute]. If the object is back-facing, this attribute is sourced from AttrInputReg[SourceAttribute+1].
2h	INPUTATTR_W	This attribute is sourced from AttrInputReg[SourceAttribute]. The W component is copied to the X component.
3h	INPUTATTR_FACING_W	If the object is front-facing, this attribute is sourced from AttrInputReg[SourceAttribute]. If the object is back-facing, this attribute is sourced from AttrInputReg[SourceAttribute+1]. The W component is copied to the X component.

5 Reserved

Format:	MBZ

4:0 Source Attribute

Format:	U5

This field selects the source attribute for this Attribute. Source attribute 0 corresponds to the first 128 bits of data indicated by Vertex URB Entry Read Offset

03h	Reserved	Ignored	

Slot Group Select Render Cache Message Descriptor Control Field

MDC_RT_SGS - Slot Group Select Render Cache Message Descriptor Control Field

Project: CHV, BSW
Source: PRM
Size (in bits): 1
Default Value: 0x00000000

DWord	Bit	Description
0	0	**Slot Group Select** Project: All This field selects whether slots 15:0 or slots 31:16 are used for bypassed data. Bypassed data includes the antialias alpha, multisample coverage mask, and if the header is not present also includes the X/Y addresses and pixel enables. For 8- and 16-pixel dispatches, SLOTGRP_LO must be selected on every message. For 32-pixel dispatches, this field must be set correctly for each message based on which slots are currently being processed.

Value	Name	Description	Project
00h	SLOTGRP_LO	Choose bypassed data for slots 15:0	All
01h	SLOTGRP_HI	Choose bypassed data for slots 31:16	All

SO_DECL

SO_DECL

Project:	CHV, BSW
Source:	RenderCS
Size (in bits):	16
Default Value:	0x00000000

A list of SO_DECL structures are passed in the 3DSTATE_SO_DECL_LIST command. Each structure specifies either (a) the source and destination of an up-to-4-DWord appending write into an SO buffer, or (b) how many DWords to skip over in the destination SO buffer (i.e., a "hole" where the previous buffer contents are maintained).

DWord	Bit	Description
0	15:14	**Reserved** Project: All Format: MBZ
	13:12	**Output Buffer Slot** Project: All Format: U2 Buffer Index This field selects the destination output buffer slot.
	11	**Hole Flag** Project: All Format: Flag If set, the Component Mask field indirectly specifies a number of 32-bit locations to skip over (leave unmodified in memory) in the selected output buffer. The Register Index field is ignored. The only permitted Component Mask values are as follows: 0x0 No Dwords are skipped over (SO_DECL performs no operation) 0x1 (X) Skip 1 DWord 0x3 (XY) Skip 2 DWords 0x7 (XYZ) Skip 3 DWords 0xF (XYZW) Skip 4 DWords
	10	**Reserved** Project: All Format: MBZ
	9:4	**Register Index** Project: All Format: U6 128-bit granular offset into the source vertex read data

SO_DECL

If Hole Flag is clear, this field specifies the 128-bit offset into the source vertex data which supplies the source data to be written to the destination buffer, where the individual 32-component destination locations are selected by Component Mask. e.g., Register Index 0 corresponds with the first 128 bits of the data read from the vertex URB entry (as per corresponding Vertex Read Offset state)

There is only enough internal storage for the 128-bit vertex header and 32 128-bit vertex attributes.

Value	Name
[0,32]	
0h	**[Default]**

Programming Notes
It is the responsibility of software to map any API-visible source data specifications (e.g., vertex register number) into 128-bit granular URB read offsets.

3:0 **Component Mask**

Project:	All
Format:	MASK 4-bit Mask

This field is a 4-bit bitmask that selects which contiguous 32-bit component(s) are either written or skipped-over in the destination buffer. If this field is zero the SO_DECL operation is effectively a no-op. No data will be appended to the destination and the destination buffer's write pointer will not be advanced. If the **Hole Flag** is set, this field (if non-zero) indirectly specifies how much the destination buffer's write pointer should be advanced.See **Hole Flag** description above for restrictions on this field. If the **Hole Flag** is clear, this field (if non-zero) selects which source components are to be written to the destination buffer. The components must be contiguous, e.g. YZW is legal, but XZW is not. The selected source components are written to the destination buffer starting at the current write pointer, and then the write pointer is advanced past the written data. E.g., if YZW is specified, the three (YZW) components of the source register will be written to the destination buffer at the current write pointer, and the write pointer will be advanced by 3 DWords.

SrcRegNum

SrcRegNum

Project:	CHV, BSW
Source:	Eulsa
Size (in bits):	8
Default Value:	0x00000000

Description	Project
Register Number The register number for the operand. For a GRF register, is the part of a register address that aligns to a 256-bit (32-byte) boundary. For an ARF register, this field is encoded such that MSBs identify the architecture register type and LSBs provide the register number. An ARF register can only be dst or src0. Any src1 or src2 operands cannot be ARF registers. RegNum and SubRegNum together provide the byte-aligned address for the origin of a register region. RegNum provides bits 12:5 of that address. For one-source and two-source instructions, SubregNum provides bits 4:0. For three-source instructions, the address must be DWord-aligned; SubRegNum provides bits 4:2 of the address and bits 1:0 are zero. This field is present for the direct addressing mode and not present for indirect addressing. This field applies to both source and destination operands.	CHV, BSW

DWord	Bit	Description
0	7:0	**Source Register Number** Value / Name / Description 0-127 / If {Dst/Src0/Src1/Src2}.RegFile==GRF / 0-0ffh / If {Dst/Src0/Src1/Src2}.RegFile==ARF / This field is used to encode the architecture register as well as providing the register number. See GEN Execution Environment chapter for details.

SrcSubRegNum

SrcSubRegNum

Project:	CHV, BSW
Source:	Eulsa
Size (in bits):	5
Default Value:	0x00000000

Description	Project
Subregister Number The subregister number for the operand. For a GRF register, is the byte address within a 256-bit (32-byte) register. For an ARF register, determines the sub-register number according to the specified encoding for the given architecture register. RegNum and SubRegNum together provide the byte-aligned address for the origin of a GRF register region. RegNum provides bits 12:5 of that address. For one-source and two-source instructions, SubregNum provides bits 4:0. For three-source instructions, the address must be DWord-aligned; SubRegNum provides bits 4:2 of the address and bits 1:0 are zero.	CHV, BSW

Programming Notes
Note: The recommended instruction syntax uses subregister numbers within the GRF in units of actual data element size, corresponding to the data type used. For example for the F (Float) type, the assembler syntax uses subregister numbers 0 to 7, corresponding to subregister byte addresses of 0 to 28 in steps of 4, the element size.

DWord	Bit	Description
0	4:0	**Source Sub Register Number**

Value	Name	Description
0-31	If {Dst/Src0/Src1/Src2}.RegFile==GRF	
0-0ffh	If {Dst/Src0/Src1/Src2}.RegFile==ARF	This field is used to encode the architecture register as well as providing the register number. See GEN Execution Environment chapter for details.

Stateless Binding Table Index Message Descriptor Control Field

MDC_STATELESS - Stateless Binding Table Index Message Descriptor Control Field

Project: CHV, BSW
Source: PRM
Size (in bits): 8
Default Value: 0x000000FF

DWord	Bit	Description
0	7:0	**Binding Table Index** Project: All Format: Enumeration Specifies the message is Stateless

Value	Name	Description	Project
0FFh	A32_A64 **[Default]**	Specifies a A32 or A64 Stateless access that is locally coherent (coherent within a thread group)	All
0FDh	A32_A64_NC	Specifies a A32 or A64 Stateless access that is non-coherent (coherent within a thread).	All
Others	Reserved	Ignored	All

Restriction
When using A32_A64_NC, SW must ensure that 2 threads do not both access the same cache line (64B)

Stateless Block Message Header

MH_A32_GO - Stateless Block Message Header

Project: CHV, BSW
Source: DataPort 0
Size (in bits): 256
Default Value: 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000

DWord	Bit	Description
0-1	63:0	**Reserved** Project: All Format: Ignore Ignored
2	31:0	**Global Offset** Project: All Format: U32 Specifies the global element index into the buffer, in units of Owords, Dwords, or Bytes (depending on the message). **Programming Notes** If the address offset calculated with the Buffer Base Address and Global Offset is greater than the PTSS size or the GeneralStateBufferSize, then the access is Out-of-Bounds.
3	31:0	**Per Thread Scratch Space** Project: All Format: MHC_PTSS [CHV, BSW] Specifies amount of scratch space used by this thread, for Stateless bounds checking.
4	31:0	**Reserved** Project: All Format: Ignore Ignored
5	31:0	**Buffer Base Address** Project: All Format: MHC_A32_BBA [CHV, BSW] Specifies the surface address offset page [31:10] for A32 stateless messages.

Subspan Render Target Message Header Control

MHC_RT_SUBSPAN - Subspan Render Target Message Header Control

Project:	CHV, BSW
Source:	PRM
Size (in bits):	32
Default Value:	0x00000000

DWord	Bit	Description
0	31:16	**Y** Project: All Format: U16 Y coordinate for upper-left pixel of this subspan
	15:0	**X** Project: All Format: U16 X coordinate for upper-left pixel of this subspan

Surface Binding Table Index Message Descriptor Control Field

MDC_BTS - Surface Binding Table Index Message Descriptor Control Field

Project: CHV, BSW
Source: PRM
Size (in bits): 8
Default Value: 0x00000000

DWord	Bit	Description
0	7:0	**Binding Table Index** Project: All Format: Enumeration Specifies the Binding Table index for the message, which must be a Surface State Model.

Value	Name	Description	Project
00h-0EFh	BTS	Index of Binding Table State Surfaces	All
F0h-0FBh	Reserved	Reserved for future use	All
0FCh	Reserved	Reserved for future use	CHV, BSW
Others	Reserved	Ignored	All

Surface or Stateless Binding Table Index Message Descriptor Control Field

MDC_BTS_A32 - Surface or Stateless Binding Table Index Message Descriptor Control Field

Project: CHV, BSW
Source: PRM
Size (in bits): 8
Default Value: 0x00000000

DWord	Bit	Description
0	7:0	**Binding Table Index** Project: All Format: Enumeration Specifies the surface for the message, either Surface State Model or Stateless.

Value	Name	Description	Project
00h-0EFh	BTS	Index of Binding Table State Surfaces	All
F0h-0FBh	Reserved	Reserved for future use	All
0FCh	Reserved	Reserved for future use	CHV, BSW
0FFh	A32_A64	Specifies a A32 or A64 Stateless access that is locally coherent (coherent within a thread group)	All
0FDh	A32_A64_NC	Specifies a A32 or A64 Stateless access that is non-coherent (coherent within a thread).	All
Others	Reserved	Ignored	All

Restriction
When using A32_A64_NC, SW must ensure that 2 threads do not both access the same cache line (64B)

Surface Pixel Mask Message Header

MH1_BTS_PSM - Surface Pixel Mask Message Header

Project: CHV, BSW

Source: DataPort 1

Size (in bits): 256

Default Value: 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x0000FFFF

DWord	Bit	Description
0-6	223:0	**Reserved** Format: Ignore Ignored
7	31:0	**Pixel Sample Mask** Project: Format: MHC_PSM Specifies the 16-bit Pixel/Sample Mask used with SIMD16 and SIMD8 surfaces.

SW Generated BINDING_TABLE_STATE

SW Generated BINDING_TABLE_STATE

Project: CHV, BSW
Source: PRM
Size (in bits): 32
Default Value: 0x00000000

DWord	Bit	Description
0	31:5	**Surface State Pointer** Format: SurfaceStateOffset[31:5] This 32-byte aligned address points to a surface state block. This pointer is relative to the **Surface State Base Address** **Programming Notes** / **Project** Bit 5 of this pointer must be zero (i.e. **Surface State Pointer** must be 64-byte aligned). / CHV, BSW
	4:0	**Reserved** Format: MBZ

Thread Spawn Message Descriptor

Thread Spawn Message Descriptor

Project: All
Source: RenderCS
Size (in bits): 32
Default Value: 0x00000000

DWord	Bit	Description
0	31:20	**Reserved** Format: MBZ
	19	**Header Present** Format: MBZ **Programming Notes** This bit MBZ for all Thread Spawner messages.
	18:5	**Reserved** Format: MBZ
	4	**Resource Select** This field specifies the resource associated with the action taken by the Opcode. Value / Name / Description / Exists If: 0 / Spawn Child / Spawn a Child Thread / [Opcode] == 'Spawn Thread' 1 / Spawn Root / Spawn a Root Thread / [Opcode] == 'Spawn Thread' 0 / Dereference Resource / The URB Handle is Dereferenced / [Opcode] == 'Dereference Resource' 1 / Keep Resource / The URBHhandle is NOT Dereferenced / [Opcode] == 'Dereference Resource'
	3:2	**Reserved** Format: MBZ
	1	**Requester Type** This field indicates whether the requesting thread is a root thread or a child thread. If it is a root thread, when Opcode is 0, FF managed resources are dereferenced. If it is a child thread and Opcode is 0, no resource is dereferenced; no action is required by the TS. Value / Name: 0 / Root Thread 1 / Child Thread
	0	**Opcode** Indicates the operation performed by the message. A root thread must terminate with a message to TS (Opcode == 0 and EOT == 1). A child thread should also terminate with such a message. A thread cannot terminate with an Opcode of "spawn thread".

Thread Spawn Message Descriptor

Value	Name	Description
0	Dereference Resource	also used for end of thread
1	Spawn Thread	

TileW SIMD8 Data Control Dword

MDCD_TILEW - TileW SIMD8 Data Control Dword

Project:	CHV, BSW
Source:	PRM
Size (in bits):	32
Default Value:	0x00000000

DWord	Bit	Description
0	31:8	**Reserved** Project: All Format: Ignore Ignored
	7:0	**Red** Project: All Format: U8 Specifies the value of the red channel to be read or written.

0.7	31:0	**Red Slot7** Project: All Format: MDCD_TileW [CHV, BSW] Specifies the Slot 7 red channel data

Transpose Message Header

MH_T - Transpose Message Header

Project: CHV, BSW
Source: DataPort 1
Size (in bits): 256
Default Value: 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000

DWord	Bit	Description
0	31:0	**X Offset** Project: All Format: S31 X offset (in bytes) of the upper left corner of the block into the surface. **Programming Notes** This field must be a multiple of the Block Width in bytes. Must be DWORD aligned.
1	31:0	**Y Offset** Project: All Format: S31 Y offset (in rows) of the upper left corner of the block into the surface. **Programming Notes** This field must be a multiple of the Block Height.
2	31:0	**Block Dimensions** Project: All Format: MHC_BDIM [CHV, BSW] The height and width of the block to transpose.
3-7	159:0	**Reserved** Project: All Format: Ignore Ignored

Untyped Write Channel Mask Message Descriptor Control Field

MDC_UW_CMASK - Untyped Write Channel Mask Message Descriptor Control Field

Project: CHV, BSW
Source: PRM
Size (in bits): 4
Default Value: 0x00000000

DWord	Bit	Description
0	3:0	**Mask** Project: All Format: Enumeration For untyped surface write messages, indicates which channels are included in the message payload and written to the surface.

Value	Name	Description	Project
00h	RGBA **[Default]**	Red, Green, Blue, and Alpha are included	All
08h	RGB	Red, Green, and Blue are included	All
0Ch	RG	Red and Green are included	All
0Eh	R	Red is included	All
Others	Reserved	Ignored	All

Upper Oword Block Data Payload

MDP_OW1U - Upper Oword Block Data Payload		
Project:	CHV, BSW	
Source:	PRM	
Size (in bits):	256	
Default Value:	0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000	
DWord	**Bit**	**Description**
0.0-0.3	127:0	**Reserved** Project: All Format: Ignore Ignored
0.4-0.7	127:0	**Oword** Project: All Format: U128 Specifies the upper Oword data element

VC1

VC1		
Project:	CHV, BSW	
Source:	VideoCS	
Size (in bits):	16	
Default Value:	0x00000000	
DWord	**Bit**	**Description**
0	15:8	**Reserved** Format: MBZ
	7	**Syncmarker Error** This flag indicates missing sync marker SEs coded in the bit-stream.
	6	**Mbmode SE Error** This flag indicates inconsistent Macroblock SEs coded in the bit-stream.
	5	**Transformtype SE Error** This flag indicates inconsistent transform type SEs coded in the bit-stream.
	4	**Coefficient Error** This flag indicates inconsistent Coefficient SEs coded in the bit-stream.
	3	**Motion Vector SE Error** This flag indicates inconsistent Motion Vector SEs coded in the bit-stream.
	2	**Coded Block Pattern CY SE Error** This flag indicates inconsistent CBPCY SEs coded in the bit-stream.
	1	**Mquant Error** This flag indicates inconsistent MQUANT SEs coded in the bit-stream.
	0	**MB Concealment Flag** . Each pulse from this flag indicates one MB is concealed by hardware.

VCS Hardware-Detected Error Bit Definitions

VCS Hardware-Detected Error Bit Definitions

Project: CHV, BSW
Source: VideoCS
Size (in bits): 16
Default Value: 0x00000000

DWord	Bit	Description
0	15:3	**Reserved** Format: MBZ
	2	**Command Privilege Violation Error** Project: CHV, BSW This bit is set if a command classified as privileged is parsed in a non-privileged batch buffer. The command will be converted to a NOOP and parsing will continue.
	1	**Reserved** Format: MBZ
	0	**Instruction Error** This bit is set when the Renderer Instruction Parser detects an error while parsing an instruction. Instruction errors include: • Client ID value (Bits 31:29 of the Header) is not supported (only MI, 2D and 3D are supported). • Defeatured MI Instruction Opcodes: Value: 1 — Name: — Description: Instruction Error detected **Programming Notes** This error indications cannot be cleared except by reset (i.e., it is a fatal error).

VEBOX_CAPTURE_PIPE_STATE

VEBOX_CAPTURE_PIPE_STATE

Project:	CHV, BSW
Source:	VideoEnhancementCS
Size (in bits):	96
Default Value:	0x0F12644B, 0xA064AF0A, 0xE6FD4000

This command contains variables for controlling Demosaic and the White Balance Statistics.

DWord	Bit	Description
0	31:30	**Reserved** Project: CHV, BSW Format: MBZ
	29:24	**Good Pixel Threshold** Format: U6 The difference threshold between adjacent pixels for a pixel to be considered "good". Value: Fh — Name: **[Default]** — Project: CHV, BSW
	23	**Reserved** Format: MBZ
	22:20	**Shift Min Cost** Default Value: 1h Format: U3 The amount to shift the H2/V2 versions of min_cost.
	19:16	**Scale For Average Min Cost** Default Value: 2h Project: CHV, BSW Format: U4 The amount to scale the min_cost difference during the Avg interpolation decision
	15:8	**Average Color Threshold** Format: U8 The threshold between two colors in a pixel for the Avg interpolation to be considered. Value: 64h — Name: **[Default]** — Project: CHV, BSW
	7:0	**Average Min Cost Threshold** Default Value: 4Bh Project: CHV, BSW

VEBOX_CAPTURE_PIPE_STATE

		Format: U8 The threshold for the H and V Min_cost beyond which the Avg interpolation will be used.
1	31:28	**Scale For Min Cost** Default Value: Ah The amount to scale the min_cost difference during the confidence check.
	27:24	**Reserved** Project: CHV, BSW Format: MBZ
	23:16	**Bad Color Threshold 1** Default Value: 64h Format: U8 Color value threshold used during the bad pixel check.
	15:8	**Bad Color Threshold 2** Default Value: AFh Format: U8 Color value threshold used during the bad pixel check.
	7:4	**Reserved** Project: CHV, BSW Format: MBZ
	3:0	**Bad Color Threshold 3** Default Value: Ah Format: U4 Color value threshold used during the bad pixel check.
2	31:24	**Y Bright Value** Default Value: E6h The whitepoint threshold percentile in the Y histogram. Any pixel with Y value above this could be a whitepoint. This is the larger of the calculated Ybright value and the Ythreshold value, which is the minimum Y required to be considered a white point. **Programming Notes** / **Project** "0000" is appended to the LSBs before comparing with Y. / CHV, BSW
	23:16	**Y Outlier Value** Default Value: FDh The outlier threshold percentile in the Y histogram. Any pixel with Y value above this either clipped or an outlier in the image. These points will not be included in the white patch

VEBOX_CAPTURE_PIPE_STATE

calculation.

Programming Notes	Project
"0000" is appended to the LSBs before comparing with Y.	CHV, BSW

15:8 **UV Threshold Value**

The value denotes the maximum threshold of the ratio between U+V to Y can have to be considered a gray point.

Value	Name	Description
[255,0]		Encode a value from 255/256 to 0/256
64	**[Default]**	0.25 * 255 = 64

7:0 **Reserved**

Project:	CHV, BSW
Format:	MBZ

VEBOX_Ch_Dir_Filter_Coefficient

VEBOX_Ch_Dir_Filter_Coefficient

Project: All
Source: PRM
Size (in bits): 64
Default Value: 0x00000000, 0x00000000

DWord	Bit	Description
0..1	63:56	**Filter Coefficient[7]** Format: S1.6 2's Complement **Range:** [-2, +2)
	55:48	**Filter Coefficient[6]** Format: S1.6 2's Complement **Range:** [-2, +2)
	47:40	**Filter Coefficient[5]** Format: S1.6 2's Complement **Range:** [-2, +2)
	39:32	**Filter Coefficient[4]** Format: S1.6 2's Complement **Range:** [-2, +2)
	31:24	**Filter Coefficient[3]** Format: S1.6 2's Complement **Range:** [-2, +2)
	23:16	**Filter Coefficient[2]** Format: S1.6 2's Complement **Range:** [-2, +2)
	15:8	**Filter Coefficient[1]** Format: S1.6 2's Complement **Range:** [-2, +2)
	7:0	**Filter Coefficient[0]** Format: S1.6 2's Complement **Range:** [-2, +2)

VEBOX_DNDI_STATE

VEBOX_DNDI_STATE

Project: CHV, BSW

Source: VideoEnhancementCS

Size (in bits): 320

Default Value: 0x00000800, 0x00000000, 0x04950100, 0x407D0000, 0x00000000, 0x00000000, 0x00000000, 0x105064A5, 0x00000000, 0x00000000

This state table is used by the *Denoise and Deinterlacer Functions*. When DN is used in 12-bit mode with the Capture Pipe all the DN pixel thresholds **(temporal_diff_th, temp_diff_low, good_neighbor_th)** are compared with the 8 MSBs of the 12-bit pixels.

DWord	Bit	Description
0	31:24	**Denoise STAD Threshold** Format: U8 Threshold for denoise sum of temporal absolute differences.
	23:16	**Denoise Maximum History** Format: U8 Maximum allowed value for denoise history. Value: [128,240] — Name:
	15:12	**Reserved** Format: MBZ
	11:8	**Denoise History increase** Default Value: 8h Format: U4 Amount that denoise_history is increased MAX:15
	7:0	**Denoise ASD Threshold** Format: U8 Threshold for denoise absolute sum of differences. Value: [0,63] — Name:
1	31:30	**Reserved** Format: MBZ
	29:24	**Temporal Difference Threshold** Format: U6

VEBOX_DNDI_STATE

		Programming Notes **Temporal Difference Threshold minus Low Temporal Difference Threshold** must be larger than 0 and less than or equal to 16, except when both thresholds are set to 0.
	23:22	**Reserved** Format: MBZ
	21:16	**Low Temporal Difference Threshold** Format: U6 **Programming Notes** **Temporal Difference Threshold minus Low Temporal Difference Threshold** must be larger than 0 and less than or equal to 16, except when both thresholds are set to 0.
	15:13	**STMM C2** Format: U3 Bias for divisor in STMM equation. Value / Name / Description: [0,7] / / Representing values [1,8]
	12:8	**Denoise Moving Pixel Threshold** Format: U5 Threshold for number of moving pixels to declare a block to be moving. Value / Name: [0,16] /
	7:0	**Denoise Threshold for Sum of Complexity Measure** Format: U8
2	31:30	**Reserved** Format: MBZ
	29:24	**Good Neighbor Threshold** Format: U6 Difference from current pixel for neighboring pixels to be considered a good neighbor. MAX:63 Value / Name / Description: 4 / **[Default]** / Depending on GNE of previous frame
	23:20	**Content Adaptive Threshold Slope** Format: U4 Determines the slope of the Content Adaptive Threshold. +1 added internally to get CAT_slope. Value / Name / Description: 9 / **[Default]** / CAT_slope value = 10

VEBOX_DNDI_STATE

	19:16	**SAD Tight Threshold** Default Value: 5 Format: U4
	15:14	**Smooth MV Threshold** Format: U2
	13:12	**Reserved** Format: MBZ
	11:8	**Block Noise Estimate Edge Threshold** Default Value: 1 Format: U4 Threshold for detecting an edge in block noise estimate. MAX:15
	7:0	**Block Noise Estimate Noise Threshold** Format: U8 Threshold for noise maximum/minimum. Value: [0,31] — Name:
3	31	**STMM Blending Constant Select** Format: U1 Value 0: Use the blending constant for small values of STMM for stmm_md_th Value 1: Use the blending constant for large values of STMM for stmm_md_th
	30:24	**Blending constant across time for large values of STMM** Default Value: 64 Format: U7
	23:16	**Blending constant across time for small values of STMM** Default Value: 125 Format: U8
	15:14	**Reserved** Format: MBZ
	13:8	**Multiplier for VECM** Format: U6 Determines the strength of the vertical edge complexity measure.
	7:0	**Maximum STMM** Format: U8

VEBOX_DNDI_STATE

		Largest allowed STMM in blending equations
4	31:24	**Minimum STMM** Format: U8 Smallest allowed STMM in blending equations
	23:22	**STMM Shift Down** Format: U2 Amount to shift STMM down (quantize to fewer bits) Value / Name: 0 – Shift by 4 1 – Shift by 5 2 – Shift by 6 3 – Reserved
	21:20	**STMM Shift Up** Format: U2 Amount to shift STMM up (set range). Value / Name: 0 – Shift by 6 1 – Shift by 7 2 – Shift by 8 3 – Reserved
	19:16	**STMM Output Shift** Format: U4 Amount to shift output of STMM blend equation Value / Name: [0, 16] **Programming Notes** The value of this field must satisfy the following equation: stmm_max - stmm_min = 2 ^ stmm_output_shift
	15:8	**SDI Threshold** Format: U8 Threshold for angle detection in SDI algorithm.
	7:0	**SDI Delta** Format: U8 Delta value for angle detection in SDI algorithm.

VEBOX_DNDI_STATE

5	31:24	**SDI Fallback Mode 1 T1 Constant** Format: U8
	23:16	**SDI Fallback Mode 1 T2 Constant** Format: U8
	15:8	**SDI Fallback Mode 2 Constant (Angle2x1)** Format: U8
	7:0	**FMD Temporal Difference Threshold** Format: U8
6	31:24	**FMD #1 Vertical Difference Threshold** Format: U8
	23:16	**FMD #2 Vertical Difference Threshold** Format: U8
	15:14	**CAT Threshold** Default Value: 0 Format: U2
	13:8	**FMD Tear Threshold** Format: U6
	7	**MCDI Enable** Use Motion Compensated Deinterlace algorithm. **Programming Notes** This bit is Ignored if DI Enable is off.
	6	**Progressive DN** Format: Enable Indicates that the denoise algorithm should assume progressive input when filtering neighboring pixels. **DI Enable** must be disabled when this field is enabled **Value** / **Name** 0 – DN assumes interlaced video and filters alternate lines together 1 – DN assumes progressive video and filters neighboring lines together
	5:4	**Reserved** Format: MBZ
	3	**DN/DI Top First** Format: Enable Indicates the top field is first in sequence, otherwise bottom is first **Value** / **Name** 0 – Bottom field occurs first in sequence

VEBOX_DNDI_STATE

		1 — Top field occurs first in sequence
	2:0	**Reserved** Format: MBZ
7	31:29	**Reserved** Format: MBZ
	28:23	**Initial Denoise History** Default Value: 32 Format: U6 Initial value for Denoise history for both Luma and Chroma. (Dnmh_history_init * 4) <= (Dnmh_history_max)
	22:19	**Neighbor Pixel Threshold** Default Value: 10 Format: U4
	18	**Reserved** Format: MBZ
	17:16	**Progressive Cadence Reconstruction For 2nd Field Of Previous Frame** Format: U2

Value	Name	Description
0	Deinterlace	
1	Put together with previous field in sequence	1st field of previous frame
2	Put together with next field in sequence	1st field of current frame

	15:10	**MC Pixel Consistency Threshold** Default Value: 25 Format: U6
	9:8	**Progressive Cadence Reconstruction for 1st Field of Current Frame** Format: U2

Value	Name	Description
0	Deinterlace	
1	Put together with previous field in sequence	2nd field of previous frame
2	Put together with next field in sequence	2nd field of current frame

	7:4	**SAD THB** Default Value: 10 Format: U4

VEBOX_DNDI_STATE

	3:0	**SAD THA** Default Value: 5 Format: U4
8	31:24	**Reserved** Format: MBZ
	23:16	**Chroma Denoise STAD Threshold** Format: U8 Threshold for denoise sum of temporal absolute differences.
	15:13	**Reserved** Format: MBZ
	12	**Chroma Denoise Enable** Value 1: The U and V chroma channels will be denoise filtered. Value 0: The U and V channels will be passed to the next stage after DN unchanged.
	11:6	**Chroma Temporal Difference Threshold** Format: U6 **Programming Notes** 0<**[Chroma Temporal Difference Threshold - Chroma Low Temporal Difference Threshold]**«16 (Larger than 0 and less than or equal to 16)
	5:0	**Chroma Low Temporal Difference Threshold** Format: U6 **Programming Notes** 0<**[Chroma Temporal Difference Threshold - Chroma Low Temporal Difference Threshold]**«16 (Larger than 0 and less than or equal to 16)
9	31:12	**Reserved** Format: MBZ
	11:8	**Hot Pixel Count** Format: U4 Number of neighboring pixels different more than **HotPixThr** before a pixel is considered hot. Value: [0,8] **Programming Notes** 0 will cause all pixels to be considered hot and will perform a median filter on the entire image.

VEBOX_DNDI_STATE		
	7:0	**Hot Pixel Threshold** Format: U8 Threshold for a difference from the value of a neighboring pixel. Is shifted up to 12-bits before compare.

VEBOX TLB Control Register

VTCR - VEBOX TLB Control Register

Register Space:	MMIO: 0/2/0
Project:	CHV, BSW
Source:	PRM
Default Value:	0x00000000
Size (in bits):	32
Address:	04270h

DWord	Bit	Description
0	31:1	**Reserved** Default Value: 00000000000000000000000000000000b Access: RO
	0	**Invalidate TLBs on the corresponding Engine** Default Value: 0b Access: R/W SW writes 1 to invalidate the TLBs for the associated engine and HW clears the bit when invalidation is complete. To ensure proper invalidation of the TLBs, SW has to ensure the corresponding engine's HW pipeline is flushed and cleared from all its memory accesses. Otherwise HW cannot guarantee the proper invalidation for TLBs. This bit is self clear.

VECS Hardware-Detected Error Bit Definitions

VECS Hardware-Detected Error Bit Definitions

Project: CHV, BSW
Source: VideoEnhancementCS
Size (in bits): 16
Default Value: 0x00000000

DWord	Bit	Description
0	15:3	**Reserved** Format: MBZ
	2	**Command Privilege Violation Error** Project: CHV, BSW This bit is set if a command classified as privileged is parsed in a non-privileged batch buffer. The command will be converted to a NOOP and parsing will continue.
	1	**Reserved** Format: MBZ
	0	**Instruction Error** This bit is set when the Renderer Instruction Parser detects an error while parsing an instruction. Instruction errors include: • Client ID value (Bits 31:29 of the Header) is not supported (only MI, 2D and 3D are supported). • Defeatured MI Instruction Opcodes: Value: 1 — Name: — Description: Instruction Error detected **Programming Notes** This error indications cannot be cleared except by reset (i.e., it is a fatal error).

VERTEX_BUFFER_STATE

VERTEX_BUFFER_STATE

Project: CHV, BSW
Source: RenderCS
Size (in bits): 128
Default Value: 0x00000000, 0x00000000, 0x00000000, 0x00000000

This structure is used in 3DSTATE_VERTEX_BUFFERS to set the state associated with a VB. The VF function will use this state to determine how/where to extract vertex element data for all vertex elements associated with the VB.

DWord	Bit	Description
0	31:26	**Vertex Buffer Index** Project: All Format: U6 index This field contains an index value which selects the VB state being defined. Value: [0,32] — Name:
	25:23	**Reserved** Project: All Format: MBZ
	22:16	**Memory Object Control State** Project: All Format: MEMORY_OBJECT_CONTROL_STATE Specifies the memory object control state for this vertex buffer.
	15	**Reserved** Project: All Format: MBZ
	14	**Address Modify Enable** Project: All If set, the Buffer Starting Address field is used to update the state of this buffer. If clear, that field is ignored and the previously-programmed value is maintained.
	13	**Null Vertex Buffer** Project: All Format: Enable This field enabled causes any fetch for vertex data to return 0. Programming Notes — Project

VERTEX_BUFFER_STATE

		VERTEX_BUFFER_STATE.Null Vertex Buffer must be set when the VERTEX_BUFFER_STATE.Buffer Size is 0x0. — CHV, BSW
	12	**Reserved** Project: — All Format: — MBZ
	11:0	**Buffer Pitch** Format: — U12 Count of bytes This field specifies the pitch in bytes of the structures accessed within the VB. This information is required in order to access elements in the VB via a structure index. [0,2048] — Bytes — CHV, BSW **Programming Notes** • Different VERTEX_BUFFER_STATE structures can refer to the same memory region using different Buffer Pitch values. • See note on 64-bit float alignment in Buffer Starting Address.
1..2	63:0	**Buffer Starting Address** Format: — GraphicsAddress[63:0]Vertex_Buffer This field contains the byte-aligned Graphics Address LSBs of the first element of interest within the VB. Software must program this value with the combination (sum) of the base address of the memory resource and the byte offset from the base address to the starting structure within the buffer. If the Address ModifyEnable bit is clear, this field is ignored and the previous value of Buffer Starting Address for this buffer is maintained. **Programming Notes** • 64-bit floating point values must be 64-bit aligned in memory, or UNPREDICTABLE data will be fetched. When accessing an element containing 64-bit floating point values, the Buffer Starting Address and Source Element Offset values must add to a 64-bit aligned address, and BufferPitch must be a multiple of 64-bits. • VBs can only be allocated in linear (not tiled) graphics memory. • As computed index values are, by definition, interpreted as unsigned values, there is no issue with accesses to locations before (lower address value) the start of the buffer. However, these wrapped indices are subject to Max Index checking (see below).
3	31:0	**Buffer Size** Format: — U32 Count of bytes This field specifies the size of the buffer in bytes. Vertex element accesses which straddle or go past the end of the buffer will return 0's for all elements.Note that BufferSize=0 indicates that there is no valid data in the buffer. Value — Name

VERTEX_BUFFER_STATE			
		[0, FFFFFFFFh]	

VERTEX_ELEMENT_STATE

VERTEX_ELEMENT_STATE

Project:	All
Source:	RenderCS
Size (in bits):	64
Default Value:	0x00000000, 0x00000000

Description	Project
This structure is used in 3DSTATE_VERTEX_ELEMENTS to set the state associated with a vertex element. A vertex element is defined as an entity supplying from 1 to 4 DWord vertex components to be stored in the vertex URB entry. The number of supported vertex elements is:	
[CHV, BSW]: 34	CHV, BSW
The VF function will use this state, and possibly the state of the associated vertex buffer, to fetch/generate the source vertex element data, perform any required format conversions, padding with zeros, and store the resulting destination vertex element data into the vertex URB entry.	

Programming Notes	Project
• The (new) 3DSTATE_VF_SGVS command is used to specify optional insertion of VertexID and/or InstanceID into the input vertex data, logically following the processing of the VERTEX_ELEMENT_STATE structures. The VFCOMP_STORE_VID/IID encodings are no longer available in VERTEX_ELEMENT_STATE. • When SourceElementFormat is set to one of the *64*_PASSTHRU formats, 64-bit components are stored in the URB without any conversion. In this case, vertex elements must be written as 128 or 256 bits, with VFCOMP_STORE_0 being used to pad the output as required. E.g., if R64_PASSTHRU is used to copy a 64-bit Red component into the URB, Component 1 must be specified as VFCOMP_STORE_0 (with Components 2,3 set to VFCOMP_NOSTORE) in order to output a 128-bit vertex element, or Components 1-3 must be specified as VFCOMP_STORE_0 in order to output a 256-bit vertex element. Likewise, use of R64G64B64_PASSTHRU requires Component 3 to be specified as VFCOMP_STORE_0 in order to output a 256-bit vertex element. • When SourceElementFormat is set to one of the *64*_PASSTHRU formats then VFCOMP_STORE_SRC must be used for every valid component. • Any SourceElementFormat of *64*_PASSTHRU cannot be used with an element which has edge flag enabled.	CHV, BSW
The SourceElementFormat needs to be a single-component format with an element which has edge flag enabled.	

DWord	Bit	Description
0	31:26	**Vertex Buffer Index** Project: CHV, BSW

VERTEX_ELEMENT_STATE

Format:	U6

This field specifies which vertex buffer the element is sourced from.

Value	Name
[0,32]	Up to 33 VBs are supported

Programming Notes
It is possible for a vertex element to include only internally-generated data (VertexID, etc.), in which case the associated vertex buffer state is ignored.

25 **Valid**

Project:	CHV, BSW
Format:	Boolean

Value	Name	Description	Project
1h	TRUE	this vertex element is used in vertex assembly	All
0h	FALSE	this vertex element is not used.	All

24:16 **Source Element Format**

Project:	All
Format:	SURFACE_FORMAT [CHV, BSW]

Range: Valid formats are found in the 3D Primitive Processing FormatConversion portion of the vertex fetch chapter.
Format: The encoding of this field is identical the Surface Format field of the SURFACE_STATE structure, as described in the Sampler chapter.
This field specifies the format in which the memory-resident source data for this particular vertex element is stored in the memory buffer. This only applies to elements stored with VFCOMP_STORE_SRC component control. (All other component types have an explicit format).

15 **Edge Flag Enable**

Project:	CHV, BSW
Format:	Enable

Description	Project
When ENABLED, the source element is interpreted as an EdgeFlag for the vertex. If the source element is zero, the EdgeFlag will be set to FALSE. If the source element is non-zero, the EdgeFlag will be set to TRUE. The EdgeFlag bit will travel down the fixed function pipeline along with the vertex handle, etc. and not be stored in the vertex data like the other vertex elements. Refer to the fixed function descriptions for how this EdgeFlag affects rendering. Edge flags are supported for the following primitive topology types only, otherwise EdgeFlagEnable must not be ENABLED. • 3DPRIM_TRILIST*	

VERTEX_ELEMENT_STATE

- 3DPRIM_TRISTRIP*
- 3DPRIM_TRIFAN*
- 3DPRIM_POLYGON

If this bit is DISABLED for all valid VERTEX_ELEMENTs, the vertex will be assigned a default EdgeFlag of TRUE.

Edge flags are supported for all primitive topology types.	CHV, BSW

Programming Notes

- This bit must only be ENABLED on the last valid VERTEX_ELEMENT structure.
- When set, Component 0 Control must be set to VFCOMP_STORE_SRC, and Component 1-3 Control must be set to VFCOMP_NOSTORE.

14:12 **Reserved**

Project:	All
Format:	MBZ

11:0 **Source Element Offset**

Project:	All
Format:	U12 byte offset

Byte offset of the source vertex element data in the structures comprising the vertex buffer.

Value	Name
[0,2047]	

Programming Notes

See note on 64-bit float alignment in Buffer Starting Address.

Vertical Line Stride Override Message Descriptor Control Field

MDC_VLSO - Vertical Line Stride Override Message Descriptor Control Field

Project: CHV, BSW
Source: PRM
Size (in bits): 3
Default Value: 0x00000000

DWord	Bit	Description
0	2	**Vertical Line Stride Override** Project: All Format: Enable If set, override the Vertical Line Stride and Vertical Line Stride Offset fields in the surface state with the fields below.
	1	**Vertical Line Stride** Project: All Format: U1 Specifies number of lines (0 or 1) to skip between logically adjacent lines - provides support of interleaved (field) surfaces as textures.
	0	**Vertical Line Stride Offset** Project: All Format: U1 Specifies the offset of the initial line from the beginning of the buffer. Ignored when Override VerticalLine Stride is 0.

VFE_STATE_EX

VFE_STATE_EX

Project: CHV, BSW
Source: RenderCS
Size (in bits): 256
Default Value: 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000

DWord	Bit	Description
0	31:8	**Reserved**
	7:0	**Reserved** Format: MBZ
1	31:0	**VFE Control** This field is used by VFE depending on the mode of operation. See the following tables for details. If VFE Mode = AVC-IT or AVC-MC, this field is valid as defined in Table 1 13. If VFE Mode = VC1-IT, this field is valid as defined in Table 1 14. Otherwise, this field is reserved.
2	31:0	**Interface Descriptor Remap Table** This field contains the interface descriptor remap table entries for the first 8 kernel indices. Each table entry has 4 bits, providing a remapping range of [0, 15]. The input of this table is the Interface Descriptor Offset within the MEDIA_OBJECT or MEDIA_OBJECT_EX command. As the table is limited to map the first 16 values, any Interface Descriptor Offset greater than 15 is not remapped. Bits 31:28: Remap for index = 7 Bits 27:24: Remap for index = 6 Bits 23:20: Remap for index = 5 Bits 19:16: Remap for index = 4 Bits 15:12: Remap for index = 3 Bits 11:8: Remap for index = 2 Bits 7:4: Remap for index = 1 Bits 3:0: Remap for index = 0
3	31:0	**Interface Descriptor Remap Table (cont)** This field contains the interface descriptor remap table entries for the next 8 kernel indices (index = 8...15). Each table entry has 4 bits, providing a remapping range of [0, 15]. Bits 31:28: Remap for index = 15 Bits 27:24: Remap for index = 14 Bits 23:20: Remap for index = 13 Bits 19:16: Remap for index = 12 Bits 15:12: Remap for index = 11 Bits 11:8: Remap for index = 10 Bits 7:4: Remap for index = 9 Bits 3:0: Remap for index = 8
4	31	**Scoreboard Enable** Project: CHV, BSW This field enables and disables the hardware scoreboard in the Media Pipeline. If this field is cleared, hardware ignores the following scoreboard state fields. This should be enabled at all times in the state and the scoreboard enable field in the MEDIA_OBJECT command should be use instead. If this field is disabled, the scratch space pointer calculation will be incorrect and any attempt to use the scoreboard later will result in a hardware hang. Value 0: Scoreboard disabled

VFE_STATE_EX

		1 — Scoreboard enabled
	30	**Scoreboard Type** Project: CHV, BSW This field selects the type of scoreboard in use. This field must be zero (stalling scoreboard) Value 0 — Stalling Scoreboard Value 1 — Reserved (for Non-stalling scoreboard)
	29:8	**Reserved** Format: MBZ
	7:0	**Scoreboard Mask** Project: CHV, BSW Format: Boolean Each bit indicates the corresponding dependency scoreboard is enabled. The scoreboard is based on the relative (X, Y) distance from the current threads' (X, Y) position. Value [0,7] — Name: Bit n — Description: Score n is enabled
5	31:28	**Scoreboard 3 Delta Y** Project: CHV, BSW Format: S3 Relative vertical distance of the dependent instance assigned to scoreboard 3, in the form of 2's compliment.
	27:24	**Scoreboard 3 Delta X** Project: CHV, BSW Format: S3 Relative horizontal distance of the dependent instance assigned to scoreboard 3, in the form of 2's compliment.

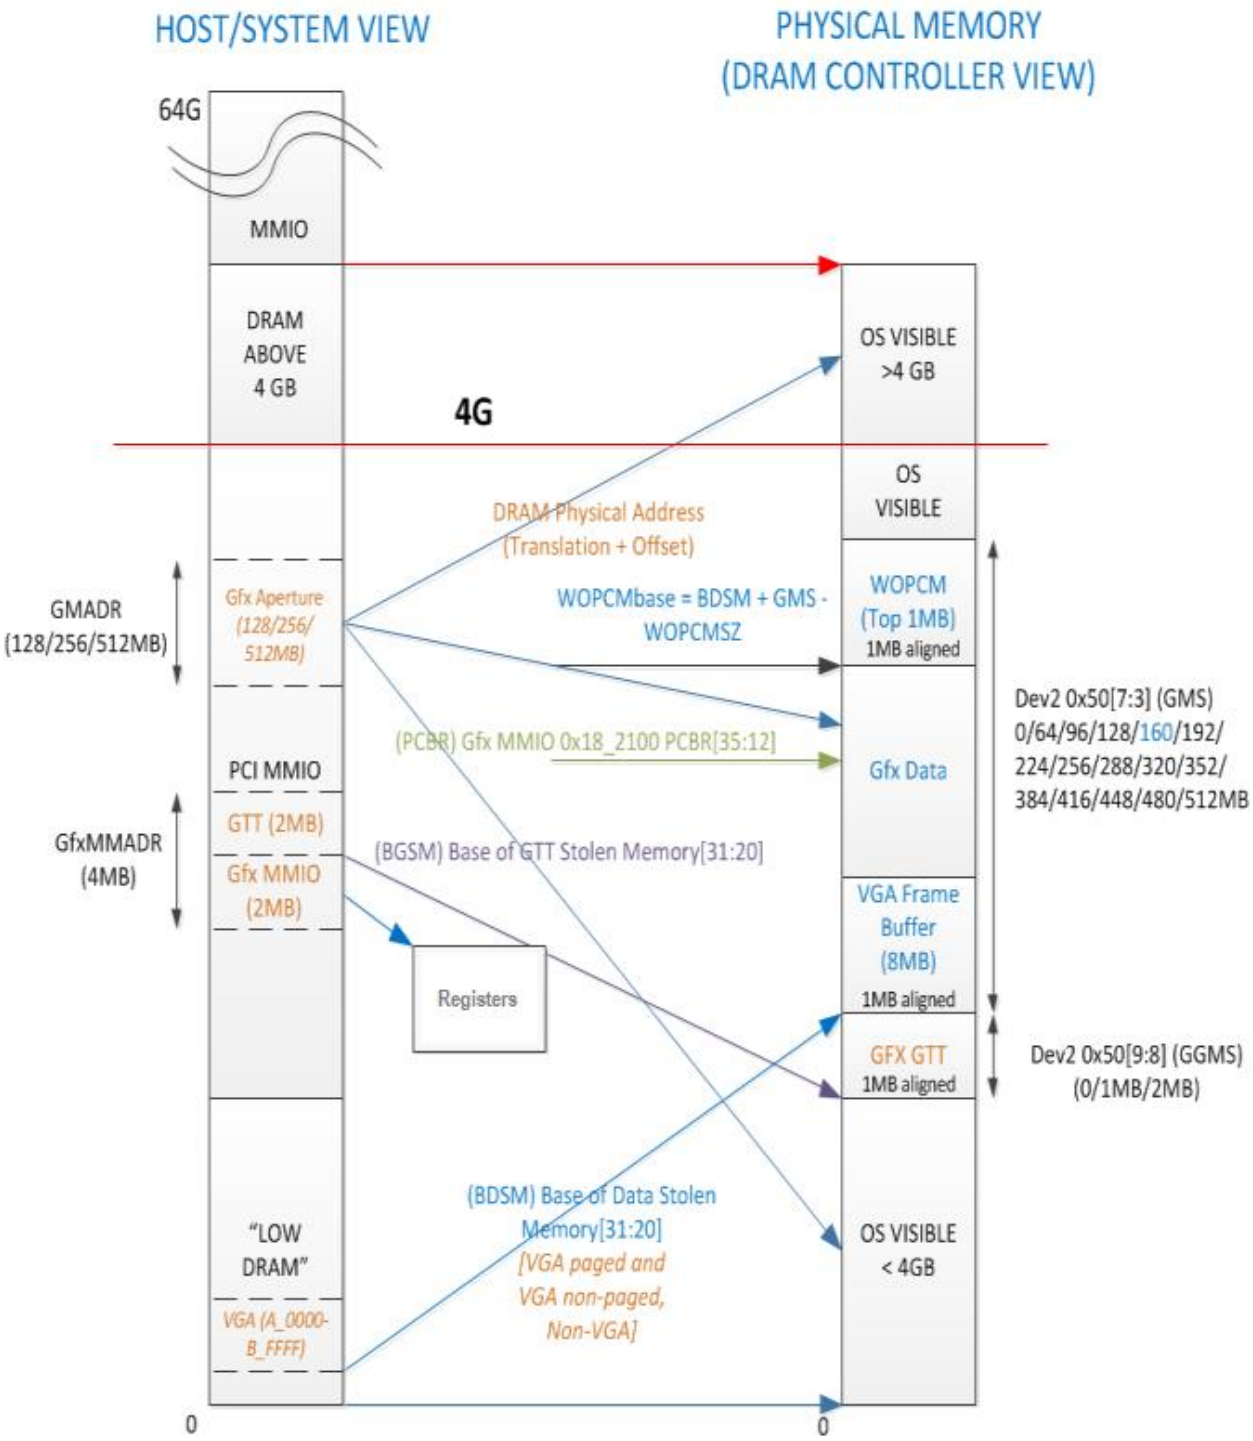
GenLC Registers

The figure below shows the different types of registers that reside within the GenLC block.

Memory Map

The diagram below shows the memory map for Gfx Device 2.



Relocatable Address Ranges

Bus 0, Device 2, Function 0:

1. **IOBAR** – IO access window for internal graphics. Though this window address/data register pair, using I/O semantics, the IGD and internal graphics instruction port registers can be accessed. Note, this allows accessing the same registers as GTTMMADR. The IOBAR can be used to issue writes to the GTTMMADR or the GTT table.
2. **GMADR** – Internal graphics translation window (128MB, 256MB, 512MB window).
3. **GTTMMADR** – This register requests a 4MB allocation for combined Graphics Translation Table Modification Range and Memory Mapped Range. GTTADR will be at GTTMMADR + 2MB while the MMIO base address will be the same as GTTMMADR.
4. **GGC.GMS** – Graphics Mode Select. Used to select the amount of main memory that is pre-allocated to support the internal graphics device in VGA (non-linear) and Native (linear) modes.
5. **GGC.GGMS** – GTT Graphics Memory Size. Used to select the amount of main memory that is pre-allocated to support the Internal Graphics Translation Table. (0-2MB options).

VGA memory and VGA IO addresses are also supported.

Legacy Video Area (A_0000h – B_FFFFh)

The legacy 128KB VGA memory range, frame buffer, (000A_0000h – 000B_FFFFh) can be mapped to Device #2. The VGA memory space is a 128KB space. The space's virtual address range, as seen on the IOSF bus, is A0000h-BFFFFh. The space's starting physical address is given by the Base of Data Stolen Memory register value (Dev 2 register BDSM[31:20]).

Table: Frame Buffer Accesses (VGA Memory Map Mode Register)

VRH_HT_GR06[3:2]	A0000h - AFFFFh	B0000h - B7FFFh	B8000h - BFFFFh
00	X	X	X
01	X		
10		X	
11			X

VGA Paged

The VGA frame buffer is 8MB (similar to client). The space's virtual address range, as seen on the IOSF bus, is A0000h-AFFFFh.

GTT Stolen Memory (GSM)

The base of the GTT table memory is contained in register BGSM. GSM is allocated to store the GFX translation table entries. This space is allocated to store accesses as page table entries get updated through virtual GTTMMADR range. Hardware is responsible to map PTEs into this physical space. Direct accesses to GSM are not allowed. The memory map programming and North Cluster IMR programming prevents direct GSM accesses. Only hardware translations and fetches can be directed to GSM.

ValleyView North Cluster has IMR registers that define stolen memory regions. The GSM will be mapped into an IMR region. The SAI attribute, driven on PFI, ensures the North Cluster does not invalidate GSM directed translations or fetches.

GTT Table Format Change

The GTT entry will be redefined to use bit 2 to indicate whether a page is snooped or not.

Only the Graphics-initiated accesses need this field; IOSF Host initiated cycles are already coherent, so the aperture translation path can ignore this GTT entry bit.

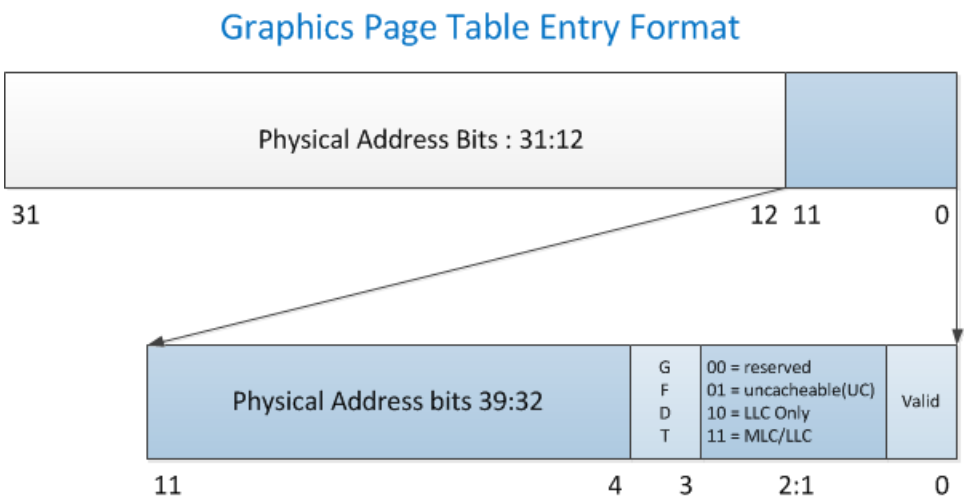


Table: GTT Table Entry Description

Bit	Description
31: 12	**Physical Page Address 31:12:** If the Valid bit is set, This field provides the page number of the physical memory page backing the corresponding Graphics Memory page.
11:4	Physical Start Address Extension: This field specified Bits 39:32 of the page table entry. This field must be zero for 32 bit addresses.
3	Graphics Data Type (GFDT) This field contains the GFDT bit for this surface when writes occur. GFDT can also be set by various state commands and indirect objects. The effective GFDT is the logical OR of the GTT entry with this field. This field is ignored for reads. Format = U1 0: No GFDT (default) 1: GFDT
2:1	Coherency Control (when GT is a non-caching agent – VLV LCIA) This field controls coherency with the CPU core caches 0x: data in this page is not coherent with the CPU caches 1x: data accesses in this page must be snooped in the CPU caches
0	**Valid PTE:** This field indicates whether the mapping of the corresponding Graphics Memory page is valid. 1: Valid 0: Invalid. An access (other than a CPU Read) through an invalid PTE will result in Page Table Error (Invalid PTE).

Graphics Stolen Memory

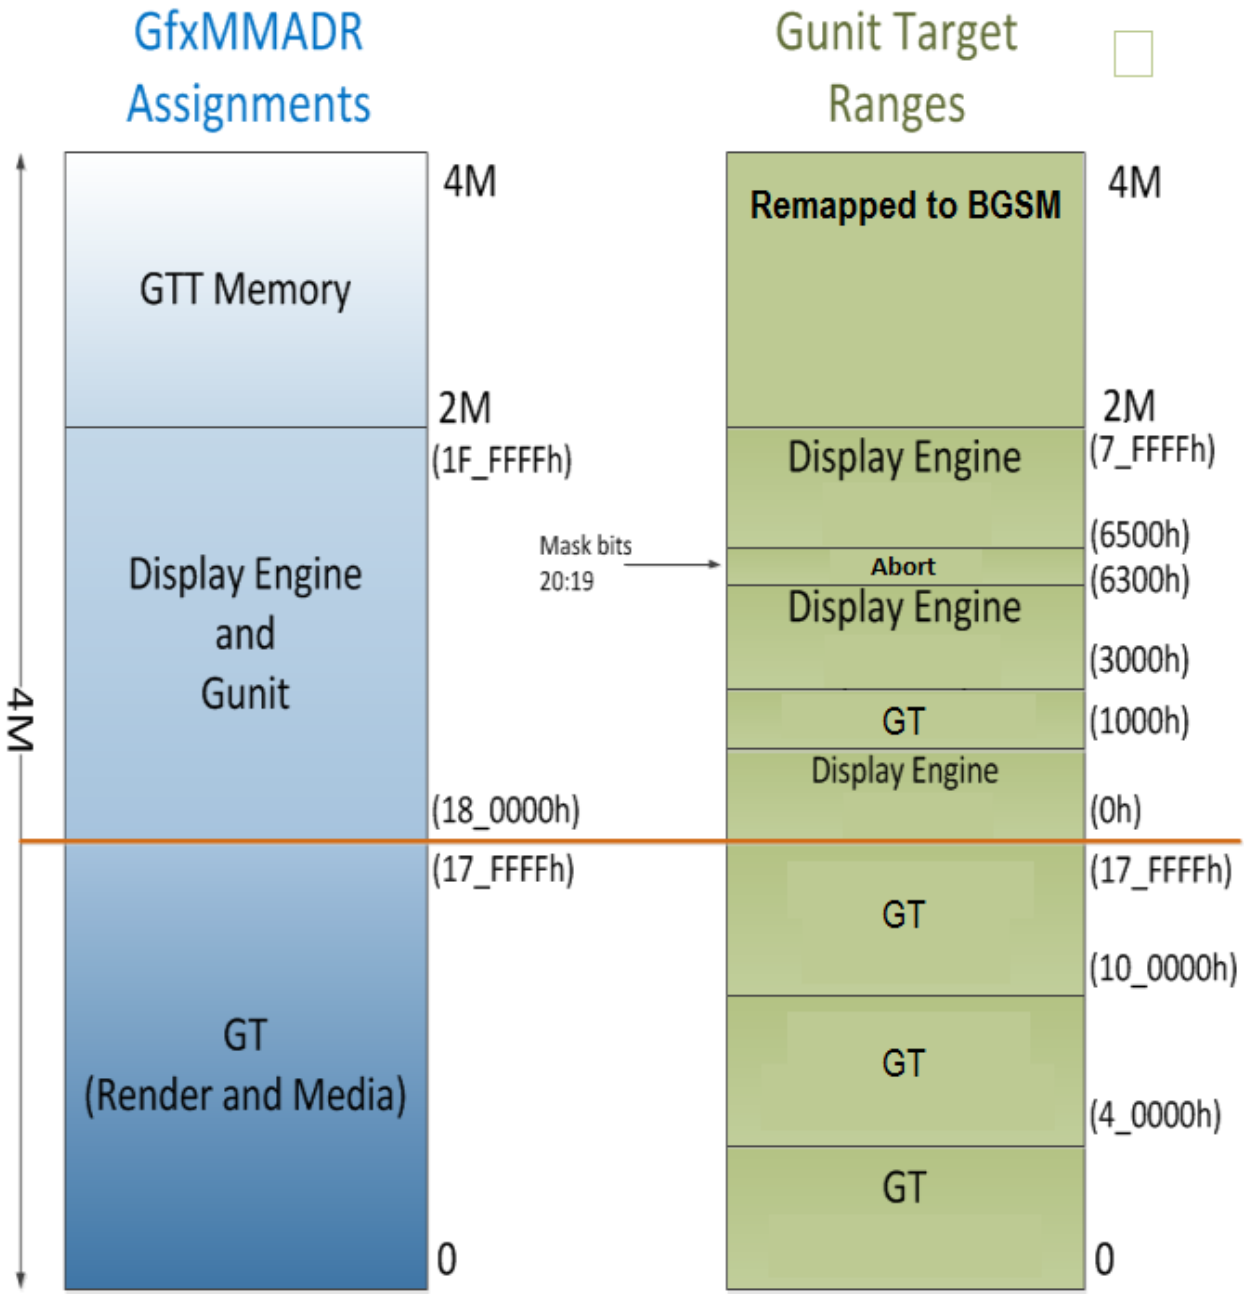
The Gen graphics engine relies on a sections of memory that are accessible to graphics but not to CPU software. This is called *stolen memory* or sometimes just *graphics memory*. This consists of 2 ranges, set up by BIOS:

1. GTT stolen memory: Programmable 1MB or 2MB space, used to store virtual->physical graphics translation tables. CPU software cannot access this directly; a section of the GTTMMADR BAR accessible to the Device 2 driver is mapped to this range.
    a. TLB fetch requests are mapped to this range
2. Data stolen memory: Programmable 32MB-512MB space, used for general graphics data (including frame buffers and other local structures). This range will be the target of some of the virtual address pages via the GTT.
    a. Lower 8MB – VGA frame buffer. VGA client can only access this region

For VLV, the Northbridge "IMR" mechanism will be used to reserve these 2 spaces for graphics hidden from the OS.

BAR1 – GTTMMADR (GTT and Regs)

This range will be marked as UC (Un-cacheable). This BAR is split in half. The bottom portion is registers while the top portion is the window to the GTT (Graphics Translation Table).



BAR2 – GMADR (Gfx Aperture Memory)

IOSF primary accesses targeting GMADR range are translated using the GTT translation table. The resulting physical addressed request is then sent to system memory. The GMADR range can be subdivided using the fence registers within Gfx MMIO space. TileY, TileX, and linear formats will be supported.

IOBAR Indirect MMIO or GTT access

The graphics interface (Device 2) contains an IOBAR register. If Device 2 is enabled, then IGD registers or the GTT table can be accessed using this IOBAR. The IOBAR is composed of an index register and a data register.

MMIO_Index: MMIO_INDEX is a 32 bit register. An IO write to this port loads the offset of the MMIO register or offset into the GTT that needs to be accessed. An IO Read returns the current value of this register. See IOBAR rules for detailed information.

MMIO_Data: MMIO_DATA is a 32 bit register. An IO write to this port is re-directed to the MMIO register pointed to by the MMIO-index register. An IO read to this port is re-directed to the MMIO register pointed to by the MMIO-index register.

The result of accesses through IOBAR can be:

a. Accesses directed to the GTT table. (i.e. route to DRAM)
b. Accesses to Graphics MMIO registers.

Note: GTT table space writes (GTTADR) are supported through this mapping mechanism.

This mechanism to access internal graphics MMIO registers must not be used to access VGA IO registers which are mapped through the MMIO space. VGA registers must be accessed directly through the dedicated VGA IO ports.

Register Range Assignments

- Gfx registers:
  - PCI Configuration registers (housed in Gfx)
  - Gfx "MIR" MMIO registers
    - Gfx related registers
    - Display "MIR" MMIO registers
      1. Housed in Gfx as a service to Display.
  - Gfx "GTLC" MMIO registers
    - SA,
    - GTLC interrupt registers
- GTLC MMIO registers
- Display MMIO registers

Register Clock Domains

This topic is still under development.

Domain Registers

PCI Configuration Registers

Table: PCI Configuration Register Summary

Name	Address	Functionality	Notes
DID	0x0000	PCI Device and Vendor ID Register	
PCICMD	0x0004	PCI Command and Status Register	
PCISTS	0x0006		
RIDCC	0x0008	Revision Identification and Class Codes	
HDR	0x000C	Header Type	
GTTMMADR	0x0010	BAR for Memory Mapped Registers and GTT Table	
GMADR	0x0018	BAR for Gfx Aperture	
IOBAR	0x0020	I/O BAR, BAR for the MMIO_INDEX and MMIO_DATA registers	Used only by SBIOS
SSID	0x002C	Subsystem Identifiers.	Only the BIOS can write this register, and only once after reset. After the first write, this register becomes read-only
CAPPOINT	0x0034	Capabilities Pointer	
INTR	0x003C	Interrupt	This register is programmed by SBIOS. It is not used by the graphics/display driver

Name	Address	Functionality	Notes
MGGC	0x0050	Graphics Control	Used to select the amount of memory pre-allocated to support the graphics device in VGA (non-linear) and Native (linear) modes
BDSM	0x005c	Base of Gfx Data Stolen Memory	Contains the VGA frame buffer and other Gfx data and command structures.
MSAC	0x0062	Multi-Size Aperture Control	
BGSM	0x0070	Base of GTT Stolen Memory	
MSI_CAPID	0x0090	Message Signaled Interrupts Capability ID and Control Register	
MA	0x0094	Message Address	Used for upstream IOSF Primary messages
MD	0x0098	Message Data	Data used for upstream IOSF Primary MSI messages
VCID	0x00B0	Vendor Capability ID	
VC	0x00B4	Vendor Capabilities	
FD	0x00C4	Functional Disable	Used by SBIOS, not by driver
PMCAP	0x00D0	Power Management Capabilities	
PMCS	0x00D4	Power Management Control/Status	Driver and SBIOS don't use this register
SWSMISCI	0x00E0	Software SMI or SCI	The graphics driver writes to this register as a means to interrupt the SBIOS
ASLE	0x00E4	System Display Event Register	SBIOS writes this register to generate an interrupt to the graphics/display driver
ASLS	0x00FC	ASL Storage	

Vendor ID and Device ID

PCI Address: 00h

Description: D2: PCI Device ID and Vendor ID Register

Field Name	Bit	Access	Reset Value	Description
DEVICE_IDENTIFICATION_NUMBER	31:16	RO	0F31	DID: Identifier assigned to the Device 2 Graphics PCI device.
VENDOR_IDENTIFICATION_NUMBER	15:0	RO	8086h	VID: PCI standard identification for Intel

PCICMD

PCI Address: 04h

Description: PCI Command Register

Field Name	Bit	Access	Reset Value	Description
Reserved	15:11	RO	00h	Reserved
INTERRUPT_DISABLE	10	RW	0b	**ID:** 0: Legacy interrupt message is enabled. 1: Disables legacy interrupt message generation on IOSF Sideband. **Note:** The interrupt status is not blocked from being reflected in PCISTS.IS. **Note:** MSI interrupt generation :(PCISTS.IS & PCICMD.BME & MSI_CAPID.MSIE) changes from 0 to 1. **Note:** Message bus interrupt assert is sent: (PCISTS.IS & ~PCICMD.ID & ~MSI_CAPID.MSIE) changes from 0 to 1. **Note:** Message bus interrupt de-assert is sent: (PCISTS.IS & ~PCICMD.ID & ~MSI_CAPID.MSIE) changes from 1 to 0
Reserved	9:3	RO	00h	Reserved
BUS_MASTER_ENABLE	2	RW	0b	**BME:**(BME & MAE are observed. But context save/restore can occur.) 0: Blocks the sending of MSI interrupts. 1: Permits the sending of MSI interrupts
Reserved	1	RW	0b	Reserved
IO_SPACE_ENABLE	0	RW	0b	**IOSE:** 0: I/O space is disabled. IORD and IOWr cycles will not be claimed. 1: I/O space is enabled. VGA_IO and Gfx_IOBAR are checked. If an IORD/IOWR matches (VGA IO address range or GFX_IOBAR), the cycle will be claimed. Care should be taken in setting up GFX_IOBAR that more than 1 match is not made as this will result in unpredictable behavior. VGA_IO: Address[15:0] is checked to determine if it falls in the VGA IO range. (The VGA IO range is 03B0h –03BBh and 03C0h – 03DFh.) Gfx_IOBAR: Address[15:3] is compared to GFX_IOBAR[15:3].

PCISTS

PCI Address: 06h

Description: PCI Status Register

Field Name	Bit	Access	Reset Value	Description
Reserved	15:5	RO	000h	Reserved
CAPABILITY_LIST	4	RO	1b	CAP: Indicates that the CAPPOINT register at 34h provides an offset into PCI Configuration Space containing a pointer to the location of the first item in the list
INTERRUPT_STATUS	3	RO	0b	IS: Reflects the state of the interrupt in the graphics device. 1: Determined by IIR and IER memory interface registers. Indicates a device 2 (Display/Media/Render) interrupt request. 0: No interrupt pending. Only when the Interrupt Disable bit in the command register is a 0 and this Interrupt Status bit is a 1, will the assert_IntX message be sent.

Revision ID (RID)

PCI Address: 08h

Description: Revision Identification

Field Name	Bit	Access	Reset Value	Description
REVISION_ID	7:0	RO	From metal straps	RID: The value in this field reflects the value of Revision ID. This register is read-able by any agent.

Class Codes (CC)

PCI Address: 09h

Description: Class Codes

Field Name	Bit	Access	Reset Value	Description
BASE_CLASS_CODE	23:16	RO	03h	**BCC:** This is an 8-bit value that indicates the base class code. When MGGC0[VAMEN] is 0 this code has the value 03h, indicating a Display Controller. When MGGC0[VAMEN] is 1 this code has the value 04h, indicating a Multimedia Device.
SUB_CLASS_CODE	15:8	RO	00h	When MGGC0[VAMEN] is 1, this value is 80h, indicating other multimedia device. When MGGC0[VAMEN] is 0 this value will be determined based on GGC register, GMS and IVD fields. When cfg_MGGC[17] = 1 or cfg_MGGC[22:20] = 3'b000 this value is 80h, otherwise its 00h 00h: VGA compatible 80h: Non VGA (GMS = "00h" or IVD = "1b")
PROGRAMMING_INTERFACE	7:0	RO	00h	**PI:** When MGGC0[VAMEN] is 0 this value is 00h, indicating a Display Controller. When MGGC0[VAMEN] is 1 this value is 00h, indicating a NOP.

HDR

PCI Address: 0Ch

Description: Header Type

Field Name	Bit	Access	Reset Value	Description
Reserved	31:24	RO	00h	Reserved
MULTI_FUNCTION_STATUS	23	RO	0b	MFUNC: Integrated graphics is a single function
HEADER_CODE	22:16	RO	00h	HDR: Indicates a type 0 configuration space header format
Reserved	15:0	RO	0000h	Reserved

GTTMMADR

PCI Address: 10-17h

Description: Gfx Memory Mapped Address Range. This is the base address for all memory mapped registers and GTT table.

This register requests allocation for the combined Graphics Translation Table Modification Range and Memory Mapped Range. The range requires 4 MB combined for MMIO and Global GTT aperture, with 512K of that used by MMIO and 2MB used by GTT. GTTADR will begin at (GTTMMADR + 2 MB) while the MMIO base address will be the same as GTTMMADR.

For the Global GTT, this range is defined as a memory BAR in graphics device config space. It is an alias into which software is required to write Page Table Entry values (PTEs). Software may read PTE values from the global Graphics Translation Table (GTT). PTEs cannot be written directly into the global GTT memory area.

The allocation is for 4MB and the base address is defined by bits [31:22].

Field Name	Bit	Access	Reset Value	Description
Reserved	63:36	RO	000000h	**Reserved for Memory Base Address (RSVD):** Must be set to 0 since addressing above 64GB is not supported.
Reserved	35:32	RO	0h	**Reserved – since 32 bit BAR.**
MBA	31:22	RW	0000h	**Memory Base Address (MBA):** 4MB combined for MMIO and Global GTT table aperture (2MB for MMIO and 2 MB for GTT).
Reserved	21:4	RO	00000h	**Reserved (RSVD):** Hardwired to 0's to indicate at least 4MB address range.
Reserved	3	RO	0b	**Prefetchable Memory (PREFMEM):** Hardwired to 0 to prevent prefetching.
MEMTYP	2:1	RO	00b	**Memory Type (MEMTYP):** 00: To indicate 32 bit base address 01: Reserved 10: To indicate 64 bit base address
Reserved	0	RO	0b	**Memory/IO Space (MIOS):** Hardwired to 0 to indicate memory space.

GMADR – Gfx Memory Address Range (ie. Gfx Aperture)

PCI Address: 18-1Fh

Description: Gfx Aperture location.

GMADR is a Prefetchable range in order to apply USWC attribute (from the processor point of view) to that range. The USWC attribute is used by the processor for write combining.

Accesses to this range will be translated to DRAM Physical memory addresses. Fence registers may be used to sub-divide this range and allow tiled surfaces (determined by fence registers).

The following sizes are supported: 128MB, 256MB, 512MB. (Determined by the MSAC register).

Field Name	Bit	Access	Reset Value	Description
Reserved	63:36	RO	00000000h	**Memory Base Address (MBA2):** Memory Base Address (MBA): Set by the OS, these bits correspond to address signals [63:36].
Reserved	35:32	RO	0h	**Reserved – 32 bit BAR supported**
MBA	31:29	RW	0000000b	**Memory Base Address (MBA):** Memory Base Address (MBA): Set by the OS, these bits correspond to address signals [31:29].
ADMSK512	28	RW-L	0b	**512MB Address Mask (512ADMSK):** This bit is either part of the Memory Base Address (R/W) or part of the Address Mask (RO), depending on the value of MSAC[2:1]. See MSAC (Dev2, Func 0, offset 62h) for details.
ADMSK256	27	RW-L	0b	**256 MB Address Mask (256ADMSK):** This bit is either part of the Memory Base Address (R/W) or part of the Address Mask (RO), depending on the value of MSAC[2:1]. See MSAC (Dev 2, Func 0, offset 62h) for details.
Reserved	26:4	RO	0000000h	**Address Mask (ADM):** Hardwired to 0s to indicate at least 128MB address range.
PREFMEM	3	RO	1b	**Prefetchable Memory (PREFMEM):** Hardwired to 1 to enable prefetching.

Reserved	0	RO	0b	**Memory/IO Space (MIOS):** Hardwired to 0 to indicate memory space.

IOBAR

PCI Address: 20-23h

Description: I/O Base Address. This is used only by SBIOS. This register is the base address for the MMIO_INDEX and MMIO_DATA registers

This register provides the Base offset of the I/O registers within Device #2. Access to the 8Bs of IO space is allowed in PM state D0 when IO Enable (PCICMD bit 0) set. Access is disallowed:

- in PM states D1-D3 or
- if IO Enable is clear or
- if Device #2 is turned off or
- if Internal graphics is disabled thru the fuse or fuse override mechanisms.

Note that access to this IO BAR is independent of VGA functionality within Device #2.

If accesses to this IO bar is allowed then the GMCH claims all 8, 16 or 32 bit IO cycles from the CPU that falls within the 8B claimed.

Field Name	Bit	Access	Reset Value	Description
Reserved	31:16	RO	0000h	Reserved
BASE_ADDRESS	15:3	RW	0000h	**BA:** Set by the OS, these bits correspond to address signals [15:3]. The IOBAR is to be used for both GTLC register programming and GTT table programming. This is an indirect access method.
Reserved	2:1	RO	0h	Reserved
RESOURCE_TYPE_RTE	0	RO	1b	Indicates a request for I/O space

Subsystem Vendor Identification (SSID)

PCI Address: 2C-2Dh

Description: This register is used to uniquely identify the subsystem where the PCI device resides.

Field Name	Bit	Access	Reset Value	Description
SUBVID	15:0	RW-O	0000h	This value is used to identify the vendor of the subsystem. This register should be programmed by BIOS during boot-up. Once written, this register becomes Read_Only. This register can only be cleared by a Reset.

Subsystem Identification (SID)

PCI Address: 2E-2Fh

Description: This register is used to uniquely identify the subsystem where the PCI device resides.

Field Name	Bit	Access	Reset Value	Description
SUBID	15:0	RW-O	0000h	This value is used to identify the vendor of the subsystem. This register should be programmed by BIOS during boot-up. Once written, this register becomes Read_Only. This register can only be cleared by a Reset.

CAPPOINT

PCI Address: 34-37h

Description: This register points to a linked list of capabilities implemented by this device.

The capability linked list is :

(Head-34, PMCAP-D0, MSI-90, VID-B0, ... End)

Field Name	Bit	Access	Reset Value	Description
Reserved	31:8	RO	000000h	Reserved
CAPABILITIES_POINTER	7:0	RW-O	D0h	The first item in the capabilities list is at address D0h (PMCS). This register should be programmed by BIOS during boot-up. Once written, this register becomes Read_Only. This register can only be cleared by a Reset.

Interrupt Line Register (INTRLINE)

PCI Address: 3Ch

Description: Interrupt. This register is programmed by SBIOS. It is not used by the graphics/display driver. This 8-bit register is used to communicate interrupt line routing information. It is read/write and must be implemented by the device. POST software will write the routing information into this register as it initializes and configures the system.

The value in this register tells which input of the system interrupt controller(s) the device's interrupt pin is connected to. The device itself does not use this value, rather it is used by device drivers and operating systems to determine priority and vector information.

Field Name	Bit	Access	Reset Value	Description
INTRLINE	7:0	RW	00h	ILIN: BIOS written value to communicate interrupt line routing information to the device driver Used to communicate interrupt line routing information. POST software writes the routing information into this register as it initializes and configures the system. The value in this register indicates to which input of the system interrupt controller the device's interrupt pin is connected.

INTR

PCI Address: 3Dh

Description: Interrupt. This register is programmed by SBIOS. It is not used by the graphics/display driver

Field Name	Bit	Access	*Reset Value*	Description
INTERRUPT_PIN	7:0	RO	01h	IPIN: Value indicates which interrupt pin this device uses. This field is hard coded to 1h since Valleyview Device 2 is a single function device. The PCI spec requires that it use INTA#. 01h: INTA#.

POWER_STATE_PS	1:0	RW	00b	This field indicates the current power state of the IGD and can be used to set the IGD into a new power state. If software attempts to write an unsupported state to this field, write operation must complete normally on the bus, but the data is discarded and no state change occurs. On a transition from D3 to D0 the graphics controller is optionally reset to initial values. Behavior of the graphics controller in supported states is detailed in the power management section of the Bspec. **Bits[1:0] Power state** 00: D0 Default 01: D1 Not Supported 10: D2 Not Supported 11: D3

SWSMISCI

PCI Address: E0-E1h

Description: Software SMI or SCI

The SCI mechanism for driver / BIOS communication. SMI is a system wide lock interrupt (halts the all the cores) as opposed to SCI. Vista and Win7 recommend to use the SCI. The SMI is slowly being phased out.

This register serves 2 purposes:

1. Support selection of SMI or SCI event source (SMISCISEL – bit15)
2. Event trigger (bit 0).

To generate a SW SCI event, software (System BIOS/Graphics driver) should program bit 15 (SMISCISEL) to 1. This is typically programmed once (assuming SMIs are never triggered). On a "0" to "1" subsequent transition in bit 0 of this register (caused by a software write operation), GMCH sends a single SCI message. The SCI will set the DMISCI bit in its TCO1_STS register and TCOSCI_STS bit in its GPE0 register upon receiving this message from DMI.

Once written as 1, software must write a "0" to this bit to clear it, and all other write transitions (1->0, 0->0, 1->1) or if bit 15 is "0" will not cause GMCH to send SCI message to DMI link.

To generate a SW SMI event, software should program bit 15 to 0 and trigger an SMI.

Field Name	Bit	Access	Reset Value	Description
Reserved	31:16	RO	0000h	Reserved
SMI_OR_SCI_EVENT_SELECT	15	RW	0b	MCS: SMI or SCI event select. 0 = SMI 1 = SCI
SOFTWARE_SCRATCH_BITS	14:1	RW	0000h	Used by driver to communicate information to SBIOS. No hardware functionality
SMI_OR_SCI_EVENT	0	RW	0b	**MCE:** MCS=1, setting this bit causes an SCI. MCS=0, setting this bit causes an SMI. A 1 to 0, 0 to 0 or 1 to 1 transition of this bit does not trigger any events. The graphics driver writes to this register as a means to interrupt the SBIOS

ASLE

PCI Address: E4-E7h

Description: System Display Event Register. SBIOS writes this register to generate an interrupt to the graphics/display driver

Field Name	Bit	Access	Reset Value	Description
ASLE_SCRATCH_TRIGGER_3	31:24	RW	00h	AST3: The writing of this by field (byte) – even if just writing back the original contents – will trigger a display controller interrupt (when the memory interface register bits IER[0] = 1 and IMR[0] = 0). If written as part of a 16-bit or 32-bit write, only one interrupt is generated in common
ASLE_SCRATCH_TRIGGER_2	23:16	RW	00h	AST2: The writing of this by field (byte) – even if just writing back the original contents – will trigger a display controller interrupt (when the memory interface register bits IER[0] = 1 and IMR[0] = 0). If written as part of a 16-bit or 32-bit write, only one interrupt is generated in common
ASLE_SCRATCH_TRIGGER_1	15:8	RW	00h	AST1: The writing of this by field (byte) – even if just writing back the original contents – will trigger a display controller interrupt (when the memory interface register bits IER[0] = 1 and IMR[0] = 0). If written as part of a 16-bit or 32-bit write, only one interrupt is generated in common
ASLE_SCRATCH_TRIGGER_0	7:0	RW	00h	AST0: The writing of this by field (byte) – even if just writing back the original contents – will trigger a display controller interrupt (when the memory interface register bits IER[0] = 1 and IMR[0] = 0). If written as part of a 16-bit or 32-bit write, only one interrupt is generated in common

ASLS

PCI Address: FCh

Description: ASL Storage. The Valleyview display driver does not need this register since memory Operational Region (OpRegion) is available. This register is kept for use as scratch space.

This software scratch register only needs to be read/write accessible. The exact bit register usage must be worked out in common between System BIOS and driver software, but storage for switching/indicating up to 6 devices is possible with this amount.

For each device, the ASL control method with require two bits for _DOD (BIOS detectable yes or no, VGA/NonVGA), one bit for _DGS (enable/disable requested), and two bits for _DCS (enabled now/disabled now, connected or not).

Field Name	Bit	Access	Reset Value	Description
SCRATCH	31:0	RW	00000000h	This register provides a means for the BIOS to communicate with the driver. This definition of this scratch register is worked out in common between System BIOS and driver software. Storage for up to 6 devices is possible. For each device, the ASL control method requires two bits for _DOD (BIOS detectable yes or no, VGA/NonVGA), one bit for _DGS (enable/disable requested), and two bits for DCS (enabled now/disabled now, connected or not).

Memory Interface Registers (MIR)

The graphics interface will claim GTTMMADR display offset range: 0x18_1000h to 0x18_2FFFh.

Table: Memory Interface Registers

Name	Address	Functionality	Notes
IIR_RW	0x18_2084	Alternate means to access the IIR register	Provides software RW access to the IIR register. Write/Restore to the IIR register using this address will not trigger an interrupt to the CPU.
SCPD0	0x18_209C	Scratch Pad 0 Register	
IER	0x18_20A0	Interrupt Enable Register	Contains an interrupt enable bit for each interrupt bit in the Interrupt Identity Register (IIR) register. A disabled interrupt will still appear in the Interrupt Identity Register to allow polling of interrupt sources. The bits in this register enable a CPU interrupt to be generated whenever the corresponding bit in the Interrupt Identity Register becomes set.

Name	Address	Functionality	Notes
IIR	0x18_20A4	Interrupt Identity Register	Contains the persistent values of the interrupt bits that are unmasked by the IMR and thus can generate a CPU interrupt (if enabled via the IER). When a CPU interrupt is generated, this should be the first register to be interrogated to determine the source of the interrupt. Bits set in this register will remain set until the interrupt condition is cleared by software. Writing a 1 into the appropriate bit position within this register clears interrupts.
IMR	0x18_20A8	Interrupt Mask	Used by software to control which ISR bits are masked or unmasked. Unmasked bits will be reported in the IIR, possibly triggering a CPU interrupt, and will persist in the IIR until cleared by software. Masked bits will not be reported in the IIR and therefore cannot generate CPU interrupts.
ISR	0x18_20AC	Interrupt Status	Contains the non-persistent value of all interrupt status bits. The IMR register selects which of these interrupt conditions are reported in the persistent IIR (i.e., set bits must be cleared by software). Bits in the IER are used to selectively enable IIR bits to cause CPU interrupts. The User Interrupt bit in this register is a short pulse therefore software should not expect to use this register to sample these conditions.
EIR	0x18_20B0	Error Identity	This register contains the persistent values of ESR error status bits that are unmasked via the EMR register. The logical OR of all (defined) bits in this register is reported in the Master Error bit of the Interrupt Status Register (ISR). In order to clear an error condition, software must first clear the error by writing a 1 to the appropriate bit(s) in this field. If required, software should then proceed to clear the Master Error bit of the IIR.
EMR	0x18_20B4	Error Mask	This register contains a bit mask that selects which error condition bits (from the ESR) are reported in the EIR.
ESR	0x18_20B8	Error Status	This register contains the non-persistent values of all hardware-detected error condition bits.
PCBR	0x18_2120	Power Context Base Register	

IIR_RW – Alternate IIR Access

MMIO Address Offset: 18_2084oh

Description: Alternate means to access the IIR register. This address provides software RW access to the IIR register. Write/Restore to the IIR register using this address will not trigger an interrupt to the CPU.

Field Name	Bit	Access	Reset Value	Description
VED_Power_Interrupt	31	RW	0b	See IIR register for definition of this bit.

SCPD0 – Scratch Pad 0 Register

MMIO Address Offset: 18_209Coh

Description: Scratch Pad 0 Register

Field Name	Bit	Access	Reset Value	Description
SCPD0	31:0	RW	00000000h	Software scratch pad

IER – Interrupt Enable Register

MMIO Address Offset: 18_20A0oh

Description: IER: Interrupt Enable Register. The IER register contains an interrupt enable bit for each interrupt bit in the Interrupt Identity Register (IIR) register. A disabled interrupt will still appear in the Interrupt Identity Register to allow polling of interrupt sources. The bits in this register enable a CPU interrupt to be generated whenever the corresponding bit in the Interrupt Identity Register becomes set.

Note: The MSI enable and PCICMD "Interrupt disable bit" are additional conditioning that occurs before an actual MSI or INTA message is generated.

Field Name	Bit	Access	Reset Value	Description
VED_Power_Interrupt	31	RW	0b	1 = Generate a CPU interrupt when associated IIR bit and this bit are both set indicating a VED power interrupt. 0 = Do not generate a CPU interrupt when associated IIR bit is set.

IIR – Interrupt Identity Register

MMIO Address Offset: 18_20A4oh

Description: The IIR register contains the persistent values of the interrupt bits that are unmasked by the IMR and thus can generate a CPU interrupt (if enabled via the IER). When a CPU interrupt is generated, this should be the first register to be interrogated to determine the source of the interrupt. Bits set in this register will remain set until the interrupt condition is cleared by software. Writing a 1 into the appropriate bit position within this register clears interrupts.

Programming Note: Prior to clearing a Display Pipe-sourced interrupt (e.g., Display Pipe A VBLANK) in the IIR, the corresponding interrupt (source) status in the PIPEASTAT register (e.g., Pipe A VBLANK Interrupt Status bit of PIPEASTAT) must first be cleared.

Note: Bits in this register can be written to '1' by software via a write to 0x18_2084.

A direct write of '1' to any set bit will clear the bit.

Field Name	Bit	Access	Reset Value	Description
VED_Power_Interrupt	31	RW1C	0b	1 = If associated ISR bit asserts and is not IMR masked. 0 = This interrupt condition has either not occurred, or was masked.

EIR – Error Identity Register

MMIO Address Offset: 18_20B0oh

Description: Error Identity. This register contains the persistent values of ESR error status bits that are unmasked via the EMR register. The logical OR of all (defined) bits in this register is reported in the Master Error bit of the Interrupt Status Register (ISR). In order to clear an error condition, software must first clear the error by writing a 1 to the appropriate bit(s) in this field. If required, software should then proceed to clear the Master Error bit of the IIR

Field Name	Bit	Access	Reset Value	Description
Reserved	31:7	RO	0000000h	Reserved
TLB_DataE	6	RW1C	0b	Set if TLB has a data valid error.
Gunit_TLB_PTE	5	RW1C	0b	Set if TLB has a PTE translation error.
PAGE_TABLE_ERROR	4	RW1C	0b	PTE: This bit is set when a Graphics Memory Mapping Error is detected and it's not EMR masked. The cause of the error is indicated (to some extent) in the PGTBL_ER register. This error condition cannot be cleared except by reset (i.e., it is a fatal error).
Reserved	3:1	RO	0h	Reserved
CLAIM_ERROR	0	RW1C	0b	If EMR[0]=1, this bit is set when an address within the address space is accessed, but no memory mapped register exists in this address. This error condition can be cleared by writing 1b to this bit.

EMR – Error Mask Register

MMIO Address Offset: 18_20B4oh

Description: Error Mask. This register contains a bit mask that selects which error condition bits (from the ESR) are reported in the EIR.

Field Name	Bit	Access	Reset Value	Description
Reserved	31:7	RO	0000000h	Reserved
TLB_DataE	6	RW	1b	1 = Masked. This error will neither be reported in the EIR, nor set the master error condition in the IIR. 0 = Unmasked. This interrupt will be reported in the EIR and will set the master error condition in the IIR.
TLB_PTE	5	RW	1b	1 = Masked. This error will neither be reported in the EIR, nor set the master error condition in the IIR. 0 = Unmasked. This interrupt will be reported in the EIR and will set the master error condition in the IIR.
PAGE_TABLE_ERROR	4	RW	1b	1 = Masked. This error will neither be reported in the EIR, nor set the master error condition in the IIR. 0 = Unmasked. This interrupt will be reported in the EIR and will set the master error condition in the IIR.
Reserved	3:1	RO	0h	Reserved
CLAIM_ERROR	0	RW	1b	1 = Masked. This error will neither be reported in the EIR, nor set the master error condition in the IIR. 0 = Unmasked. This interrupt will be reported in the EIR and will set the master error condition in the IIR.

ESR – Error Status Register

MMIO Address Offset: 18_20B8oh

Description: Error Status. This register contains the non-persistent values of all hardware-detected error condition bits.

Field Name	Bit	Access	Reset Value	Description

PAGE_TABLE_ERROR	4	RO	0b	1 = This error condition currently exists. 0 = This error condition currently does not exist.
Reserved	3:1	RO	0h	Reserved
CLAIM_ERROR	0	RO	0b	No RMbus claim occurred. Logging the error. 1 = This error condition currently exists. 0 = This error condition currently does not exist.

Power Context Base Register (PCBR)

MMIO Offset Address: 18_2120oh

Description: This provides an base address for context save/restore of GT and Media power context to DRAM.

The BIOS is expected to program this register and ensure proper allocation within Gfx stolen memory.

Field Name	Bit	Access	Reset Value	Description
Reserved	63:32	RO	000000h	Reserved
Power Context Address	31:12	RW-L	0000000h	4KB aligned address Locked with bit 0
Reserved	11:1	RO	000h	Reserved
Power Context Register Lock	0	RW-L	0b	Writing a '1' to this register locks this bit – preventing further updates. The Power Context Address bits are also locked.

GTLC: SA MMIO Registers

For Valleyview, the graphics interface will contain these registers.

This is range: 10_0000 to 17_FFFFh.

Table: GTLC SA MMIO registers

Name	Address	Functionality	Notes
Fence Registers	0x10_0000 to 0x10_007Fh	Fence Registers	Determine whether GMADR subregion is linear/TileX/TileY.
Gfx Flush Control	0x10_1008h	Invalidates TLB	Invalidates the TLB.
GTFIFOCTL	0x12_0008	GT FIFO Control	
GTLC Wake Control	0x13_0090	GTLC Wake Control	
GTLC Power Well Status	0x13_0094	GTLC Power Well Status	
Render Force Wake Req	0x13_00B0		
Render Force Wake Ack	0x13_00B4		
Media Force Wake Req	0x13_00B8		
Media Force Wake Ack	0x13_00BC		
Render RC6 (Standby) counter	0x13_8108		
Media RC6 (Standby) counter	0x13_810C		

Fence Registers

MMIO Address Offset: 10_0000h

Description: Fence Registers

Fence0 Register: 10_0000h

Fence1 Register: 10_0008h

....

Fence15 Register: 10_0078h

Field Name	Bit	Access	Reset Value	Description
FENCEUP	63:44	RW	00000000h	Bits 31:12 of the ending Graphics Address of the fence region. Fence regions must be aligned to a 4KB page. This address represents the last 4KB page of the fence region (Upper Bound is included in the fence region). Graphics Address is the offset within GMADR space.
Reserved	43	RO	0b	Reserved
Pitch	42:32	RW	000h	This field specifies the width (pitch) of the fence region in multiple of "tile widths". For Tile X this field must be programmed to a multiple of 512B ("003" is the minimum value) and for Tile Y this field must be programmed to a multiple of 128B ("000" is the minimum value). 000h = 128B 001h = 256B 002h = 384B 003h = 512B 004h = 640B 005h = 768B 006h = 896B 007h = 1024B ... 3FFh = 128KB

Field Name	Bit	Access	Reset Value	Description
				4FFh = 160KB 5FFh = 192KB 6FFh = 224KB 7FFh = 256KB
FENCELO	31:12	RW	000000h	Bits 31:12 of the starting Graphics Address of the fence region. Fence regions must be aligned to 4KB. This address represents the first 4KB page of the fence region (Lower Bound is included in the fence region). Graphics Address is the offset within GMADR.
Reserved	11:2	RO	000h	Reserved.
TILE	1	RW	0b	**This field specifies the spatial ordering of QW within tiles.** 0b - Consecutive SWords (32B) sequenced in the X direction 1b - Consecutive OWords (16B) sequenced in the Y direction
FENCEVAL	0	RW	0b	This field specifies whether or not this fence register defines a fence region. 0b - FENCE INVALID 1b - FENCE VALID

Gfx_FLSH_CNTL

MMIO Address Offset: 10_1008Description:

Description: Used to flush the TLB.

Field Name	Bit	Access	Reset Value	Description
Reserved	31:1	RO	00000000h	Reserved
GfxFlshCntl	0	WO	0b	A write to this bit flushes the GFX TLB in the graphics interface. The data associated with the write is discarded and a read returns all 0s.

GTFIFOCTL

MMIO Address Offset: 12_0008h

Description: GT FIFO Control. Number of free Wake FIFO entries.

Field Name	Bit	Access	Reset Value	Description
Reserved	31:7	RW	0b	Reserved (should not be changed)
GT_FIFO_FREE_ENTRIES	6:0	RO	40h	This value indicate the number of entries that are free within the GT FIFO. The free entries may be used for IA accesses and IO accesses to GT. The Wake FIFO depth is 64 entries. Zero entries free = "threshold has been hit" condition.

GTLC Wake Control

MMIO Address Offset: 13_0090h

Description: GT Wake Control. This register is used as a way to control the GTLC Render and Media Power wells.

Writing bit 0 during normal operation may result in a hang.

Field Name	Bit	Access	*Reset Value*	Description
Reserved	31:26	RO	00h	Reserved
RenderContextExists	25	RW	0b	• SW can only write a one to this bit. The usage is for support of s0ix, where the Driver would restore the value in this bit no later than the time a '1' is written to ALLOWWAKEREQ (bit 0 of this register) during s0ix exit. SW should not write '1' to this bit during a cold boot exit or warm reset exit. • CZ reset is the only thing that can clear this bit. • This bit is set by HW after the first Render context save after cold boot or warm reset. • SW can only write a one to this bit. If SW tries to write a zero, the previous value will be

Field Name	Bit	Access	*Reset Value*	Description
				maintained.
MediaContextExists	24	RW	0b	• SW can only write a one to this bit. The usage is for support of s0ix, where the Driver would restore the value in this bit no later than the time a '1' is written to ALLOWWAKEREQ (bit 0 of this register) during s0ix exit. SW should not write '1' to this bit during a cold boot exit or warm reset exit. • CZ reset is the only thing that can clear this bit. • This bit is set by HW after the first Media context save after cold boot or warm reset. • SW can only write a one to this bit. If SW tries to write a zero, the previous value will be maintained.
Reserved	23:17	RO	00h	Reserved
Reserved	16	RW	0b	Reserved
Reserved	15:9	RO	00h	Reserved
Reserved	8	RW	0b	Reserved
Reserved	7:1	RO	00h	Reserved
ALLOWWAKEREQ	0	RW	0	This bit is used as a way for the driver to make sure GTLC Render AND MEDIA engines do not wake while powered down. The usage is specifically with s0ix, where the driver wants to access the message channel common well (GSclk domain) and does not want the render/media wells to wake up. To remove ambiguity, this bit should be set to '1' and the ALLOWWAKEACK should be observed to the '1' before the FWAKEMEDIAREQ/FWAKERENDERREQ are set. Care must be taken to ONLY use this register prior to powering down the graphics interface for S0ix or after registers have been initialized.

GTLC Power Well Status

MMIO Address Offset: 13_0094h

Description: This register contains Ack and status information for power well requests.

Field Name	Bit	Access	Reset Value	Description
Reserved	31:8	RO	000000h	Reserved
Reserved	7	RO	0b	Reserved
Reserved	6	RO	0b	Reserved
Reserved	5	RO	0b	Reserved
Reserved	4	RO	0b	Reserved
Reserved	3:2	RO	00b	Reserved
ALLOWWAKEERR	1	RW1C	0b	HW set, SW cleared. When access to media or render is observed when ALLOWWAKE=0, the ALLOWWAKERR bit will be set. It will be up to SW or a power cycle to clear the ALLOWWAKEERR bit.
ALLOWWAKEACK	0	RO	0b	Indicates that the allow wake request has been completed.

Render Force wake req

MMIO Address Offset: 13_00B0h

Description: This register contains per thread force wake request bits for the Render power Well.. The upper 16 bits act as masks for the lower 16 bits. bit-31 masks bit-15 and bit 16 masks bit 0.

1. Driver writes to GPM force wake request bit. (VV will have a Render(13_00B0(15:0)) and a Media (13_00B8(15:0)) bits)
2. The GPM responds by writing (via PLINK) to 1300B4[15:0] or 1300BC[15:0] register.
3. Driver polls (1300B4[15:0] and/or 1300BC[15:0])status until 1 ... indicating that that well has completed wake sequence.

Since the registers are per thread, only the specific bit that was forced should be checked for status.

Field Name	Bit	Access	Reset Value	Description
FWAKERENDERREQMSK	31:16	RO	0000h	Mask bits for lower 16 bits to avoid a read modify/write. If '0', the corresponding bit in [15:0] is not changed. If '1', the corresponding bit in [15:0] is changed to the value in [15:0].
FWAKERENDERREQ	15:0	RW	0000h	Force Wake Render request bits.

Render Force wake ack

MMIO Address Offset: 13_00B4h

Description: This register contains the per thread force wake acknowledge bits for the Render power well.

Field Name	Bit	Access	Reset Value	Description
Reserved	31:16	RO	0000h	Reserved
FWAKERENDERACK	15:0	RW	0000h	Force Wake Render request bits. Driver must poll on the corresponding bit to confirm that the well has woken. For example, if 13_00B0[0] is written to a '1' (along with 13_00B0[16]='1'), then bit0 of this register indicates when the force wake request has been completed.

Media Force wake req

MMIO Address Offset: 13_00B8h

Description: This register contains per thread force wake request bits for the Media power Well. The upper 16 bits act as masks for the lower 16 bits. bit-31 masks bit-15 and bit 16 masks bit 0.

Field Name	Bit	Access	Reset Value	Description
FWAKEMEDIAREQMSK	31:16	RO	0000h	Mask bits for lower 16 bits to avoid a read modify/write. If '0', the corresponding bit in [15:0] is not changed. If '1', the corresponding bit in [15:0] is changed to the value in [15:0]
FWAKEMEDIAREQ	15:0	RW	0000h	Force Wake Media request bits

Media Force wake ack

MMIO Address Offset: 13_00BCh

Description: This register contains the per thread force wake acknowledge bits for the Media power well.

Field Name	Bit	Access	Reset Value	Description
Reserved	31:16	RO	0000h	Reserved
FWAKEMEDIAACK	15:0	RW	0000h	Force Wake Media request bits. Driver must poll on the corresponding bit to confirm that the well has woken. For example, if 13_00B0[0] is written to a '1' (along with 13_00B0[16]='1'), then bit0 of this register indicates when the force wake request has been completed.

Render RC6 (Standby) counter

MMIO Address Offset: 13_8108h

Description: This register contains the total RC6 residency (Render power gated and clock gated) time that Render power well was in since boot. The counter will wrap around. The time is given in units of 1.28 uSec.The 40-bit HW counter will wrap around. The only clear condition is reset. When 0x13_8104[15] is set to zero, bits 31:0 of the 40-bit counter are reported. When 0x13_8104[15] is set to one, bits 39:8 of the 40-bit counter are reported. The units are CZ clock cycles.

It is up to SW to periodically read this register and do a difference from the last time it was read. The primary usage for this register is for power characterization.

0x13_8104[0] controls if this register should count or if it should be gated: 0= clear, 1=count

Field Name	Bit	Access	Reset Value	Description
RENDERRC6TIME	31:0	RO	00000000h	Render Residency Counter

Media RC6 (Standby) counter

MMIO Address Offset: 13_810Ch

Description: This register contains the total RC6 residency (Media power gated and clock gated) time that Media was in since boot. The counter will wrap around. The time is given in units of cz clock cycles.

The 40-bit HW counter will wrap around. The only clear condition is CZ reset. When 0x13_8104[15] is set to zero, bits 31:0 of the 40-bit counter are reported. When 0x13_8104[15] is set to one, bits 39:8 of the 40-bit counter are reported. The units are CZ clock cycles.

It is up to SW to periodically read this register and do a difference from the last time it was read. The primary usage for this register is for power characterization.

0x13_8104[1] controls if this register should count or if it should be gated: 0= clear, 1=count

Field Name	Bit	Access	Reset Value	Description
MEDIARC6TIME	31:0	RO	00000000h	Media Residency Counter

GTLC: "Render/Media/PM" Interrupt Architecture

GTLC can send status messages for Render/Media and for Power Management. There are separate sets of IIR/IMR/IER/ISR registers for Render/Media and for Power Management.

The graphics interface will house these registers.

Table: GTLC "Display" MMIO registers

Name	Address	Functionality	Notes
GTLC MIR	0x4_400Ch		GTLC Master Interrupt Enable
GTLC ISR	0x4_4010h		
GTLC IMR	0x4_4014h		
GTLC IIR	0x4_4018h		
GTLC IER	0x4_401Ch		
PM ISR	0x4_4020h		
PM IMR	0x4_4024h		
PM IIR	0x4_4028h		
PM IER	0x4_402Ch		
SWF	0x4_F000h to 0x4_F08Fh		Software Flag registers. Used by software
GTSCRATCH	0x4_F100h to 0x4_F11Fh		GT Scratch pad registers. Used by software.

GTLC: Master Interrupt Register

MMIO Address Offset: 4400Ch

Description: GTLC Master Interrupt Control Register.

For VLV, the display engine has its own interrupt registers. As a result, only the GTLC Master interrupt bit remains. The graphics interface will house these registers.

<table>

GTLC: "Render/Media" Interrupts

Bit Definition for Interrupt Control Registers. All following interrupts are originated from GT in message format. DE needs to convert the message bits to events mapping one to one to following register.

Bit	Description
Blitter Interrupts (BCS bit31-bit22)	
31:30	*Reserved for Blitter Command Streamer*
29	**Blitter page directory faults:** This is a write of logic1 via interrupt message from GT via 0x50200 bit29
28	*Reserved for Blitter Command Streamer*
27	*Reserved for Blitter Command Streamer*
26	**Blitter MI_FLUSH_DW notify:** This is a write of logic1 via interrupt message from GT via 0x50200 bit26
25	**Blitter Command Streamererror interrupt:** This is a write of logic1 via interrupt message from GT via 0x50200 bit25
24	**Billter MMIO sync flush status:** This is a write of logic1 via interrupt message from GT via 0x50200 bit24
23	*Reserved for Blitter Command Streamer*
22	**Blitter Command Streamer MI_USER_INTERRUPT:** This is a write of logic1 via interrupt message from GT via 0x50200 bit22
Media Interrupts (VCS bit21-bit12)	
21	*Reserved for Video Command Streamer*
19	**Video page directory faults:** This is a write of logic1 via interrupt message from GT via 0x50200 bit19
18	**Video Command Streamer Watchdog counter exceeded:** This is a write of logic1 via interrupt message from GT via 0x50200 bit18
16	**Video MI_FLUSH_DW notify:** This is a write of logic1 via interrupt message from GT via 0x50200 bit16
15	**Video Command Streamer error interrupt:** This is a write of logic1 via interrupt message from GT via 0x50200 bit15
14	**Video MMIO sync flush status:** This is a write of logic1 via interrupt message from GT via 0x50200 bit14
12	**Video Command Streamer MI_USER_INTERRUPT:** This is a write of logic1 via interrupt message from GT via 0x50200 bit12
Render Interrupts (CS bit11-bit0)	
11:9	*Reserved for Main Command Streamer*
7	**Render page directory faults:** This is a write of logic1 via interrupt message from GT via 0x50200 bit7
6	**Render Command Streamer Watchdog counter exceeded:** This is a write of logic1 via interrupt message from GT via 0x50200 bit6
5	**L3 Parity Error Interrupt**
4	**Render PIPE_CONTROL notify:** This is a write of logic1 via interrupt message from GT via 0x50200 bit4
3	**Render Command Streamer error interrupt:** This is a write of logic1 via interrupt message from GT via 0x50200 bit3
2	**Render MMIO sync flush status:** This is a write of logic1 via interrupt message from GT via 0x50200 bit2
1	
0	**Render Command Streamer MI_USER_INTERRUPT:** This is a write of logic1 via interrupt message from GT via 0x50200 bit0

ISR – Interrupt Status Register

MMIO Address Offset: 4_4010h

Description: Interrupt Status

ISR	
Register Type:	MMIO
Project:	All
Default Value:	00000000h
Access Type:	Read Only
Size (in bits):	32

See the interrupt bit definition tables to find the source event for each interrupt bit.

Bit	Description
31:0	**Interrupt_Status_Bits** Project: All This field contains the non-persistent values of all interrupt status bits. The IMR register selects which of these interrupt conditions are reported in the persistent IIR.

Value	Name	Description	Project
0b	Condition Doesn't exist	Interrupt Condition currently does not exist	All
1b	Condition Exists	Interrupt Condition currently exists	All

Programming Notes

Some inputs to this register are short pulses; therefore software should not expect to use this register to sample these conditions.

IMR – Interrupt Mask Register

MMIO Address Offset: 4_4014h

Description: Interrupt Mask Register

IMR	
Register Type:	MMIO
Project:	All
Default Value:	FFFFFFFFh
Access Type:	R/W
Size (in bits):	32

For GT command streamer interrupts DO NOT use this register to mask interrupt events. Instead use the individual GT command streamer MASK bits.
For PM interrupts DO NOT use this register to mask interrupt events. Instead use the individual PM MASK bits in the corresponding PMunit register space.
See the interrupt bit definition tables to find the source event for each interrupt bit.

Bit	Description
31:0	**Interrupt_Mask_Bits** Project: All This field contains a bit mask which selects which interrupt bits from the ISR are reported in the IIR.

Value	Name	Description	Project
0b	Not Masked	Not Masked – will be reported in the IIR	All
1b	Masked	Masked – will not be reported in the IIR	All

IIR

MMIO Address Offset: 4_4018h

Description: Interrupt Identity Register

IIR	
Register Type:	MMIO
Project:	All
Default Value:	00000000h
Access Type:	R/W Clear
Size (in bits):	32

See the interrupt bit definition tables to find the source event for each interrupt bit.

Bit	Description
31:0	**Interrupt_Identity_Bits** Project: All This field holds the persistent values of the interrupt bits from the ISR which are unmasked by the IMR. If enabled by the IER, bits set in this register will generate a CPU interrupt. Bits set in this register will remain set (persist) until the interrupt condition is cleared by writing a '1' to the appropriate bits. For each bit, the IIR can store a second pending interrupt if two or more of the same interrupt conditions occur before the first condition is cleared. Upon clearing the interrupt, the IIR bit will momentarily go low, then return high to indicate there is another interrupt pending

Value	Name	Description	Project
0b	Condition Not Detected	Interrupt Condition Not Detected	All
1b	Condition Detected	Interrupt Condition Detected (may or may not have generated a CPU interrupt)	All

IER – Interrupt Enable Register

MMIO Address Offset: 4_401Ch

Description: Interrupt Enable Register

IER	
Register Type:	MMIO
Project:	All
Default Value:	00000000h
Access Type:	R/W
Size (in bits):	32

See the interrupt bit definition tables to find the source event for each interrupt bit.

Bit	Description
31:0	**Interrupt_Enable_Bits** Project: All The bits in this register enable a CPU interrupt to be generated whenever the corresponding bit in the IIR becomes set. A disabled interrupt will still appear in the IIR register to allow polling of interrupt sources. The DE_IER master interrupt control bit must be set to 1 for any interrupts to propagate to the system.

Value	Name	Description	Project
0b	Disable	Disable	All
1b	Enable	Enable	All

GTLC: "Power Management" Interrupts

The graphics interface routes the GTLC PM writes to the appropriate ISR/IIR registers. The bit assignments are below.

Power Management Interrupt Bit Definition	
Project:	All
Size (in bits):	32
Power Management interrupt bits come to the graphics interface via direct wires. The GT_IIR and PM_IIR are ORed together to generate the CPU interrupt. The Power Management Interrupt Control Registers all share the same bit definitions from this table.	

Bit	Description
31:7	**Reserved** Project: All; Format: MBZ
6	**Render Frequency Downward Timeout During RC6 interrupt:** This is a write of logic1 via interrupt message from GT via 0x50210 bit6
5	**RP UP threshold interrupt:** This is a write of logic1 via interrupt message from GT via 0x50210 bit5
4	**RP DOWN threshold interrupt:** This is a write of logic1 via interrupt message from GT via 0x50210 bit4
3	**Reserved** Project: All; Format: MBZ
2	**Render geyserville UP evaluation interval interrupt:** This is a write of logic1 via interrupt message from GT via 0x50210 bit2
1	**Render geyserville Down evaluation interval interrupt:** This is a write of logic1 via interrupt message from GT via 0x50210 bit1
0	*Reserved for GT PM unit*

ISR – Interrupt Status Register

MMIO Address Offset: 4_4020h

Description: Interrupt Status Register

ISR	
Register Type:	MMIO
Project:	All
Default Value:	00000000h
Access Type:	Read Only
Size (in bits):	32

See the interrupt bit definition tables to find the source event for each interrupt bit.

Bit	Description
31:0	**Interrupt_Status_Bits** Project: All This field contains the non-persistent values of all interrupt status bits. The IMR register selects which of these interrupt conditions are reported in the persistent IIR.

Value	Name	Description	Project
0b	Condition Doesn't exist	Interrupt Condition currently does not exist	All
1b	Condition Exists	Interrupt Condition currently exists	All

Programming Notes

Some inputs to this register are short pulses; therefore software should not expect to use this register to sample these conditions.

IMR – Interrupt Mask Register

MMIO Address Offset: 4_4024h

Description: Interrupt Mask Register

IMR	
Register Type:	MMIO
Project:	All
Default Value:	FFFFFFFFh
Access Type:	R/W
Size (in bits):	32

For GT command streamer interrupts DO NOT use this register to mask interrupt events. Instead use the individual GT command streamer MASK bits.
For PM interrupts DO NOT use this register to mask interrupt events. Instead use the individual PM MASK bits in the corresponding PMunit register space.
See the interrupt bit definition tables to find the source event for each interrupt bit.

Bit	Description
31:0	**Interrupt_Mask_Bits** Project: All This field contains a bit mask which selects which interrupt bits from the ISR are reported in the IIR.

Value	Name	Description	Project
0b	Not Masked	Not Masked – will be reported in the IIR	All
1b	Masked	Masked – will not be reported in the IIR	All

IIR – Interrupt Identity Register

MMIO Address Offset: 4_4028h

Description: Interrupt Identity Register

IIR	
Register Type:	MMIO
Project:	All
Default Value:	00000000h
Access Type:	R/W Clear
Size (in bits):	32

See the interrupt bit definition tables to find the source event for each interrupt bit.

Bit	Description
31:0	**Interrupt_Identity_Bits** Project: All This field holds the persistent values of the interrupt bits from the ISR which are unmasked by the IMR. If enabled by the IER, bits set in this register will generate a CPU interrupt. Bits set in this register will remain set (persist) until the interrupt condition is cleared by writing a '1' to the appropriate bits. For each bit, the IIR can store a second pending interrupt if two or more of the same interrupt conditions occur before the first condition is cleared. Upon clearing the interrupt, the IIR bit will momentarily go low, then return high to indicate there is another interrupt pending

Value	Name	Description	Project
0b	Condition Not Detected	Interrupt Condition Not Detected	All
1b	Condition Detected	Interrupt Condition Detected (may or may not have generated a CPU interrupt)	All

IER – Interrupt Enable Register

MMIO Address Offset: 4_402Ch

Description: Interrupt Enable Register

IER	
Register Type:	MMIO
Project:	All
Default Value:	00000000h
Access Type:	R/W
Size (in bits):	32

See the interrupt bit definition tables to find the source event for each interrupt bit.

Bit	Description
31:0	**Interrupt_Enable_Bits** Project: All The bits in this register enable a CPU interrupt to be generated whenever the corresponding bit in the IIR becomes set. A disabled interrupt will still appear in the IIR register to allow polling of interrupt sources. The DE_IER master interrupt control bit must be set to 1 for any interrupts to propagate to the system.

Value	Name	Description	Project
0b	Disable	Disable	All
1b	Enable	Enable	All

GTLC: Scratch Registers

The GTLC engine can target these registers with information. The driver is then able to read the registers.

SWF – Software Flags

MMIO Address Offset: 0x4_F000 – 0x4_F08C

Description: These (36 Dword) registers are used as scratch pad data storage space and have no direct effect on hardware operation. The use of these registers is defined by the software architecture.

SWF	
Register Type:	MMIO
Project:	All
Default Value:	00000000h
Access Type:	R/W
Size (in bits):	36x32

These registers are used as scratch pad data storage space and have no direct effect on hardware operation. The use of these registers is defined by the software architecture.

Dword	Bit	Description
0..35	31:0	**Software_Flags** Project: All

GTSCRATCH – GT Scratch registers

MMIO Address Offset: 0x4_F100 – 0x4_F11F

Description: These (8 Dword) registers are used as scratch pad data storage space and have no direct effect on hardware operation. The use of these registers is defined by the software architecture.

GTSCRATCH	
Register Type:	MMIO
Project:	All
Default Value:	00000000h
Access Type:	R/W
Size (in bits):	8x32

These registers are used as scratch pad data storage space and have no direct effect on hardware operation. The use of these registers is defined by the software architecture.

Dword	Bit	Description
0..7	31:0	**GT_Scratchpad** Project: All

Introduction

The integrated graphics component, specifically called the Graphics Processing Unit, or GPU, resides on the same chip die as the Central Processing Unit, or CPU, and communicates with the CPU via the on-chip bus, with internal memory and with output device(s). As Intel GPUs have evolved, they now occupy a significant percentage of space on the chip, and provide customers with high performance and low-power graphics processing, eliminating the need to purchase a separate video card for most users.

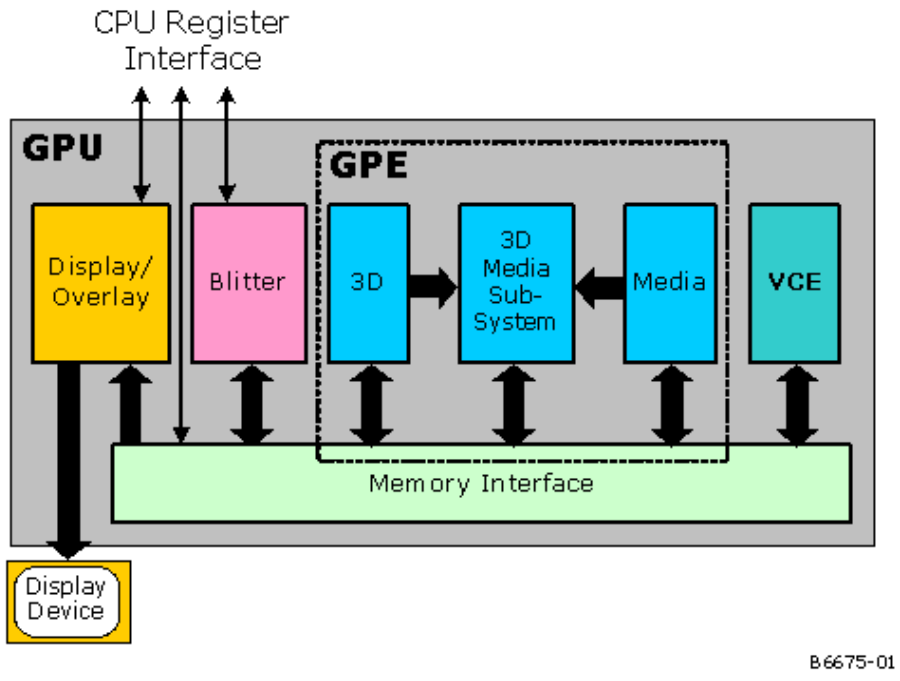
This Behavioral Specification, or BSpec for short, provides detailed narrative and referential information required by graphics device driver engineers and graphics API-level programmers to take advantage of the sophisticated architecture and programmability of the GPU.

Graphics Processing Unit (GPU)

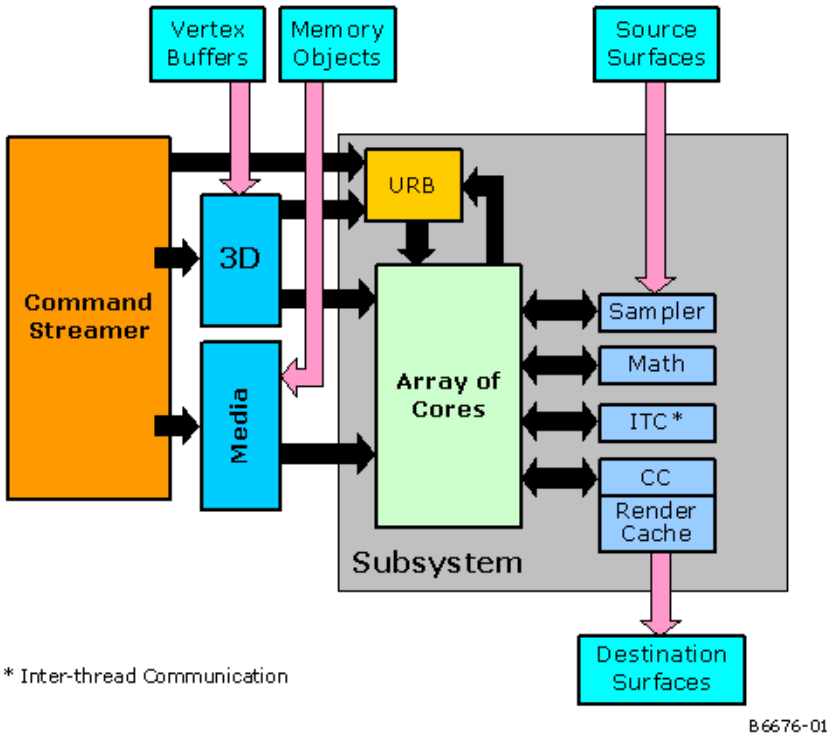
The Graphics Processing Unit is controlled by the CPU through a direct interface of memory-mapped IO registers, and indirectly by parsing commands that the CPU has placed in memory. The Display interface and Blitter (**bl**ock **i**mage **t**ransfer**er**) are controlled primarily by direct CPU register addresses, while the 3D and Media pipelines and the parallel Video Codec Engine (VCE) are controlled primarily through instruction lists in memory.

The subsystem contains an array of cores, or execution units, with a number of "shared functions", which receive and process messages at the request of programs running on the cores. The shared functions perform critical tasks, such as sampling textures and updating the render target (usually the frame buffer). The cores themselves are described by an instruction set architecture, or ISA.

Block Diagram of the GPU



GPU Overview



The subsystem consists of an array of *execution units* (*EUs*, sometimes referred to as an array of *cores*) along with a set of *shared functions* outside the EUs that the EUs leverage for I/O and for complex computations. Programmers access the subsystem via the 3D or Media pipelines.

EUs are general-purpose programmable cores that support a rich instruction set that has been optimized to support various 3D API shader languages as well as media functions (primarily video) processing.

Shared functions are hardware units which serve to provide specialized supplemental functionality for the EUs. A shared function is implemented where the demand for a given specialized function is insufficient to justify the costs on a per-EU basis. Instead a single instantiation of that specialized function is implemented as a stand-alone entity outside the EUs and shared among the EUs.

Invocation of the shared functionality is performed via a communication mechanism called a *message*. A message is a small self-contained packet of information created by a kernel and directed to a specific shared function. For SNB, the message is defined by a range of MRF registers that hold message operands, a destination shared function ID, a function-specific encoding of the desired operation, and a destination GRF register to which any writeback response is to be directed. Messages are dispatched to the shared function under software control via the send instruction. This instruction identifies the contents of the message and the GRF register locations to direct any response.

The message construction and delivery mechanisms are general in their definition and capable of supporting a wide variety of shared functions.

Command Stream (CS) Unit

The Command Stream (CS) unit manages the use of the 3D and Media pipelines; it performs switching between pipelines and forwarding command streams to the currently active pipeline. It manages allocation of the URB and helps support the Constant URB Entry (CURBE) function.

3D Pipeline

The 3D Pipeline provides specialized 3D primitive processing functions. These functions are provided by a pipeline of "fixed function" stages (units) and GEN threads spawned by these units. See *3D Pipeline Overview*.

Media Pipeline

The Media pipeline provides both specialized media-related processing functions and the ability to perform more general ("generic") functionality. These Media-specific functions are provided by a Video Front End (VFE) unit. A Thread Spawner (TS) unit is utilized to spawn GEN threads requested by the VFE unit, or as required when the pipeline is used for general processing. See *Media Pipeline Overview*.

Thread Dispatching

When the 3D and Media pipelines send requests for thread initiation to the Subsystem, the thread Dispatcher receives the requests. The dispatcher performs such tasks as arbitrating between concurrent requests, assigning requested threads to hardware threads on EUs, allocating register space in each EU among multiple threads, and initializing a thread's registers with data from the fixed functions and from the URB. This operation is largely transparent to software.

Execution Units (EUs)

The Execution Units (EUs) are the programmable shader units of the Gen Architecture. Each is a stand-alone programmable computational unit used for execution of 3D shaders and media/gpgpu kernels. Internally each is capable of multi-issue SIMD execution, and their hardware multi-threaded operation provides a very high-efficiency execution environment in the face of long data latencies typically associated with memory accesses. Each hardware thread within and EU has a dedicated large-capacity high-bandwidth register file (GRF) and associated independent thread-state . Execution is multi-issue per clock to pipelines capable of integer, single and double precision floating point operations, SIMD branch capability, logical operations, transcendental operations, and other miscellaneous operations. Communication to support units (shared functions) for operations such as texture sampling or scatter/gather load/stores is via 'messages' programmatically constructed and 'sent' to those functions, with dependency hardware causing the issuing thread to sleep until the requested data has been returned.

EU instance count varies by product generation, as well as by SKU within a given generation, and their capabilities have evolved over the many generation of the Gen Architecture.. Please see "Device Attributes" in the "Configuration" chapter for specific rates and capacities associated with Execution Units.

Shared Functions

Shared functions are hardware units that provide specialized supplemental functionality for the EUs. A shared function is implemented where the demand for a given specialized function is insufficient to justify the costs on a per-EU basis. Instead a single instantiation of that specialized function is implemented as a stand-alone entity outside the EUs and shared among the EUs.

Invocation of the shared functionality is performed via a communication mechanism called a message. A message is a small self-contained packet of information created by a kernel and directed to a specific shared function.

Programming Note	
Context:	Communication mechanism in shared functions
The message is defined by a range of Message Register File (MRF) registers that hold message operands, a destination shared function ID, a function-specific encoding of the desired operation, and a destination General Register File (GRF) register to which any writeback response is directed.	

Messages are dispatched to the shared function under software control via the *send* instruction. This instruction identifies the contents of the message and the GRF register locations to direct any response.

The message construction and delivery mechanisms are general in their definition and capable of supporting a wide variety of shared functions.

Fixed and Shared Function IDs

The following table lists the assignments (encodings) of the Shared Function and Fixed Function IDs used within the GPE. A Shared Function is a valid target of a message initiated via a *send* instruction. A Fixed Function is an identifiable unit of the 3D or Media pipeline. Note that the Thread Spawner is both a Shared Function and Fixed Function.

Function IDs

ID[3:0]	SFID	Shared Function	FFID	Fixed Function
0x0	SFID_NULL	Null	FFID_NULL	Null
0x1	Reserved	---	Reserved	---
0x2	SFID_SAMPLER	Sampler	Reserved	---
0x3	SFID_GATEWAY	Message Gateway	Reserved	---
0x4	SFID_DP_SAMPLER	Sampler Cache Data Port	FFID_HS	Hull Shader
0x5	SFID_DP_RC	Render Cache Data Port	FFID_DS	Domain Shader
0x6	SFID_URB	URB	Reserved	---
0x7	SFID_SPAWNER	Thread Spawner	FFID_SPAWNER	Thread Spawner
0x8	SFID_VME	Video Motion Estimation	Reserved	---
0x9	SFID_DP_CC	Constant Cache Data Port	FFID_VS	Vertex Shader
0xA	SFID_DP_DC0	Data Cache Data Port0	FFID_CS	Command Stream
0xB	SFID_PI	Pixel Interpolator	FFID_VF	Vertex Fetch
0xC	SFID_DP_DC1	Data Cache Data Port1	FFID_GS	Geometry Shader
0xD	SFID_CRE	Check & Refinement Engine	Reserved	---
0xE	Reserved	---	FFID_SF	Strip/Fan Unit
0xF	Reserved	---	FFID_WM	Windower/Masker Unit

Programming Note	
Context:	Shared Function ID
SFID_DP_DC1 is an extension of SFID_DP_DC0 to allow for for more messages types. They act as a single logical entity.	

Video Codec Engine

The parallel Video Codec Engine (VCE) is a fixed function video decoder and encoder engine. It is also referred to as the multi-format codec (MFX) engine, as a unified fixed function pipeline is implemented to support multiple video coding standards such as MPEG2, VC1, and AVC:

- VCS – VCE Command Streamer unit (also referred to as BCS)
- BSD – Bitstream Decoder unit
- VDS – Video Dispatcher unit
- VMC – Video Motion Compensation unit
- VIP – Video Intra Prediction unit
- VIT – Video Inverse Transform unit
- VLF – Video Loop Filter unit
- VFT – Video Forward Transform unit (encoder only)
- BSC – Bitstream Encoder unit (encoder only)

Register Address Maps

Graphics Register Address Map

This chapter provides address maps of the graphics controllers I/O and memory-mapped registers. Individual register bit field descriptions are provided in the following chapters. PCI configuration address maps and register bit descriptions are provided in the following chapter.

Memory and IO Space Registers

These are graphics MMIO ranges used for [CHV]. Note that this is only a subset of the complete definition of the MMIO address space.

Range Start (Hex)	Range End (Hex)	Unit Owning the Range
00002000	00002FFF	Render/Generic Media Engine
00004000	00004FFF	Render/Generic Media Graphics Memory Arbiter
00012000	000123FF	MFX Control Engine (Video Command Streamer)
00012400	00012FFF	Media Units (VIN Unit)
00014000	00014FFF	MFX Memory Arbiter
00022000	00022FFF	Blitter Engine
00024000	00024FFF	Blitter Memory Arbiter
00100000	00107FFF	Fence Registers
00140000	0017FFFF	MCHBAR (SA)

Programming Note	
Context:	Memory and IO space registers, graphics MMIO ranges
8800h-88FFh is a reserved range for GT. IA accesses to this region have no impact.	

Programming Note	
Context:	Memory and IO space registers, graphics MMIO ranges
TAP (backdoor) accesses to the reserved range of 8800h-88FFh result in hardware hangs. Do not use it.	

VGA and Extended VGA Register Map

For I/O locations, the value in the address column represents the register I/O address. For memory mapped locations, this address is an offset from the base address programmed in the MMADR register.

VGA and Extended VGA I/O and Memory Register Map

Address	Register Name (Read)	Register Name (Write)
2D Registers		
3B0h–3B3h	Reserved	Reserved
3B4h	VGA CRTC Index (CRX) (monochrome)	VGA CRTC Index (CRX) (monochrome)
3B5h	VGA CRTC Data (monochrome)	VGA CRTC Data (monochrome)
3B6h–3B9h	Reserved	Reserved
3Bah	VGA Status Register (ST01)	VGA Feature Control Register (FCR)
3BBh–3BFh	Reserved	Reserved
3C0h	VGA Attribute Controller Index (ARX)	VGA Attribute Controller Index (ARX)/ VGA Attribute Controller Data (alternating writes select ARX or write ARxx Data)
3C1h	VGA Attribute Controller Data (read ARxx data)	Reserved
3C2h	VGA Feature Read Register (ST00)	VGA Miscellaneous Output Register (MSR)
3C3h	Reserved	Reserved

Indirect VGA and Extended VGA Register Indices

The registers listed in this section are indirectly accessed by programming an index value into the appropriate SRX, GRX, ARX, or CRX register. The index and data register address locations are listed in the previous section. Additional details concerning the indirect access mechanism are provided in the *VGA and Extended VGA Register Description* Chapter (see SRxx, GRxx, ARxx or CRxx sections).

2D Sequence Registers (3C4h / 3C5h)

Index	Sym	Description
00h	SR00	Sequencer Reset
01h	SR01	Clocking Mode
02h	SR02	Plane / Map Mask
03h	SR03	Character Font
04h	SR04	Memory Mode
07h	SR07	Horizontal Character Counter Reset

2D Graphics Controller Registers (3CEh / 3CFh)

Index	Sym	Register Name
00h	GR00	Set / Reset
01h	GR01	Enable Set / Reset
02h	GR02	Color Compare
03h	GR03	Data Rotate
04h	GR04	Read Plane Select
05h	GR05	Graphics Mode
06h	GR06	Miscellaneous
07h	GR07	Color Don’t Care
08h	GR08	Bit Mask
10h	GR10	Address Mapping
11h	GR11	Page Selector
18h	GR18	Software Flags

2D Attribute Controller Registers (3C0h / 3C1h)

Index	Sym	Register Name
00h	AR00	Palette Register 0
01h	AR01	Palette Register 1
02h	AR02	Palette Register 2
03h	AR03	Palette Register 3
04h	AR04	Palette Register 4
05h	AR05	Palette Register 5
06h	AR06	Palette Register 6
07h	AR07	Palette Register 7
08h	AR08	Palette Register 8
09h	AR09	Palette Register 9
0Ah	AR0A	Palette Register A
0Bh	AR0B	Palette Register B
0Ch	AR0C	Palette Register C
0Dh	AR0D	Palette Register D
0Eh	AR0E	Palette Register E
0Fh	AR0F	Palette Register F
10h	AR10	Mode Control
11h	AR11	Overscan Color
12h	AR12	Memory Plane Enable
13h	AR13	Horizontal Pixel Panning
14h	AR14	Color Select

2D CRT Controller Registers (3B4h / 3D4h / 3B5h / 3D5h)

Index	Sym	Register Name
00h	CR00	Horizontal Total
01h	CR01	Horizontal Display Enable End
02h	CR02	Horizontal Blanking Start
03h	CR03	Horizontal Blanking End
04h	CR04	Horizontal Sync Start
05h	CR05	Horizontal Sync End
06h	CR06	Vertical Total
07h	CR07	Overflow
08h	CR08	Preset Row Scan
09h	CR09	Maximum Scan Line
0Ah	CR0A	Text Cursor Start
0Bh	CR0B	Text Cursor End
0Ch	CR0C	Start Address High
0Dh	CR0D	Start Address Low
0Eh	CR0E	Text Cursor Location High
0Fh	CR0F	Text Cursor Location Low
10h	CR10	Vertical Sync Start
11h	CR11	Vertical Sync End
12h	CR12	Vertical Display Enable End
13h	CR13	Offset
14h	CR14	Underline Location
15h	CR15	Vertical Blanking Start
16h	CR16	Vertical Blanking End
17h	CR17	CRT Mode
18h	CR18	Line Compare
22h	CR22	Memory Read Latch Data

Memory Object Overview

Any memory data accessed by the device is considered part of a *memory object* of some memory object type.

The following table lists the various memory objects types and an indication of their role in the system.

Memory Object Type	Role
Graphics Translation Table (GTT)	Contains PTEs used to translate "graphics addresses" into physical memory addresses.
Hardware Status Page	Cached page of sysmem used to provide fast driver synchronization.
Logical Context Buffer	Memory areas used to store (save/restore) images of hardware rendering contexts. Logical contexts are referenced via a pointer to the corresponding Logical Context Buffer.
Ring Buffers	Buffers used to transfer (DMA) instruction data to the device. Primary means of controlling rendering operations.
Batch Buffers	Buffers of instructions invoked indirectly from Ring Buffers.
State Descriptors	Contains state information in a prescribed layout format to be read by hardware. Many different state descriptor formats are supported.
Vertex Buffers	Buffers of 3D vertex data indirectly referenced through "indexed" 3D primitive instructions.
VGA Buffer (Must be mapped UC on PCI)	Graphics memory buffer used to drive the display output while in legacy VGA mode.
Display Surface	Memory buffer used to display images on display devices.
Overlay Surface	Memory buffer used to display overlaid images on display devices.
Overlay Register, Filter Coefficients	Memory area used to provide double-buffer for Overlay register and filter coefficient loading.
Cursor Surface	Hardware cursor pattern in memory.
2D Render Source	Surface used as primary input to 2D rendering operations.
2D Render R-M-W Destination	2D rendering output surface that is read in order to be combined in the rendering function. Destination surfaces that accessed via this Read-Modify-Write mode have somewhat different restrictions than Write-Only Destination surfaces.
2D Render Write-Only Destination	2D rendering output surface that is written but not read by the 2D rendering function. Destination surfaces that accessed via a Write-Only mode have somewhat different restrictions than Read-Modify-Write Destination surfaces.
2D Monochrome Source	1 bpp surfaces used as inputs to 2D rendering after being converted to foreground/background colors.
2D Color Pattern	8x8 pixel array used to supply the "pattern" input to 2D rendering functions.
DIB	"Device Independent Bitmap" surface containing "logical" pixel values that are converted (via LUTs) to physical colors.
3D Color Buffer	Surface receiving color output of 3D rendering operations. May also be accessed via R-M-W (aka blending). Also referred to as a Render Target.

Memory Object Type	Role
3D Depth Buffer	Surface used to hold per-pixel depth and stencil values used in 3D rendering operations. Accessed via RMW.
3D Texture Map	Color surface (or collection of surfaces) which provide texture data in 3D rendering operations.
"Non-3D" Texture	Surface read by Texture Samplers, though not in normal 3D rendering operations (for example, in video color conversion functions).
Motion Comp Surfaces	These are the Motion Comp reference pictures.
Motion Comp Correction Data Buffer	This is Motion Comp intra-coded or inter-coded correction data.

Hardware Status Page

The hardware status page is a naturally-aligned 4KB page residing in snooped system memory. This page exists primarily to allow the device to report status via PCI master writes – thereby allowing the driver to read/poll WB memory instead of UC reads of device registers or UC memory.

The address of this page is programmed via the HWS_PGA MI register. The definition of that register (in *Memory Interface Registers*) includes a description of the layout of the Hardware Status Page.

Memory Access Indirection

The GPE supports the indirection of certain graphics (GTT-mapped) memory accesses. This support comes in the form of two *base address* state variables used in certain memory address computations with the GPE.

The intent of this functionality is to support the dynamic relocation of certain driver-generated memory structures after command buffers have been generated but prior to the their submittal for execution. For example, as the driver builds the command stream it could append pipeline state descriptors, kernel binaries, etc. to a general state buffer. References to the individual items would be inserted in the command buffers as offsets from the base address of the state buffer. The state buffer could then be freely relocated prior to command buffer execution, with the driver only needing to specify the final base address of the state buffer. Two base addresses are provided to permit surface-related state (binding tables, surface state tables) to be maintained in a state buffer separate from the general state buffer.

While the use of these base addresses is unconditional, the indirection can be effectively disabled by setting the base addresses to zero. The following table lists the various GPE memory access paths and which base address (if any) is relevant.

Base Address Utilization

Base Address Used	Memory Accesses
General State Base Address	**DataPort Read/Write DataPort memory accesses resulting from 'stateless' DataPort Read/Write requests. See** *DataPort* **for a definition of the 'stateless' form of requests.**
Dynamic State Base Address	Sampler reads of SAMPLER_STATE data and associated SAMPLER_BORDER_COLOR_STATE.
	Viewport states used by CLIP, SF, and WM/CC
	COLOR_CALC_STATE, DEPTH_STENCIL_STATE, and BLEND_STATE
	Push Constants (depeding on state of **INSTPM<CONSTANT_BUFFER Address Offset Disable>**)
Instruction Base Address [CHV]	**Normal EU instruction stream** (non-system routine)
	System routine EU instruction stream (starting address = SIP)
Surface State Base Address	Sampler and DataPort reads of BINDING_TABLE_STATE, as referenced by BT pointers passed via 3DSTATE_BINDING_TABLE_POINTERS
	Sampler and DataPort reads of SURFACE_STATE data
Indirect Object Base Address	**MEDIA_OBJECT Indirect Data** accessed by the CS unit .
None	CS unit reads from **Ring Buffers**, **Batch Buffers**
	CS writes resulting from PIPE_CONTROL command
	All VF unit memory accesses (**Index Buffers**, **Vertex Buffers**)
	All Sampler **Surface Memory Data** accesses (texture fetch, etc.)
	All **DataPort memory accesses**except 'stateless' DataPort Read/Write requests (e.g., RT accesses.) See *DataPort* for a definition of the 'stateless' form of requests.
	Memory reads resulting from **STATE_PREFETCH** commands
	Any **physical memory access** by the device
	GTT-mapped accesses not included above (i.e., default)
	[CHV]: Push Constants (depeding on state of **INSTPM<CONSTANT_BUFFER Address Offset Disable>**)

The following notation is used in the BSpec to distinguish between addresses and offsets:

Notation	Definition
PhysicalAddress[n:m]	Corresponding bits of a physical graphics memory byte address (not mapped by a GTT)
GraphicsAddress[n:m]	Corresponding bits of an absolute, virtual graphics memory byte address (mapped by a GTT)
GeneralStateOffset[n:m]	Corresponding bits of a relative byte offset added to the General State Base Address value, the result of which is interpreted as a virtual graphics memory byte address (mapped by a GTT)
DynamicStateOffset[n:m]	Corresponding bits of a relative byte offset added to the Dynamic State Base Address value, the result of which is interpreted as a virtual graphics memory byte address (mapped by a GTT)
InstructionBaseOffset[n:m]	Corresponding bits of a relative byte offset added to the Instruction Base Address value, the result of which is interpreted as a virtual graphics memory byte address (mapped by a GTT)
SurfaceStateOffset[n:m]	Corresponding bits of a relative byte offset added to the Surface State Base Address value, the result of which is interpreted as a virtual graphics memory byte address (mapped by a GTT)

Instruction Ring Buffers

Instruction ring buffers are the memory areas used to pass instructions to the device. Refer to the Programming Interface chapter for a description of how these buffers are used to transport instructions.

The RINGBUF register sets (defined in Memory Interface Registers) are used to specify the ring buffer memory areas. The ring buffer must start on a 4KB boundary and be allocated in linear memory. The length of any one ring buffer is limited to 2MB.

Programming Note	
Context:	Instruction Ring Buffers in memory areas.
"Indirect" 3D primitive instructions (those that access vertex buffers) must reside in the same memory space as the vertex buffers.	

Instruction Batch Buffers

Instruction batch buffers are contiguous streams of instructions referenced via an MI_BATCH_BUFFER_START and related instructions (see Memory Interface Instructions, Programming Interface). They are used to transport instructions external to ring buffers.

Programming Note	
Context:	Instruction batch buffers in memory objects
Batch buffers should not be mapped to snooped SM (PCI) addresses. The device will treat these as MainMemory (MM) addresses and, therefore, not snoop the CPU cache.	

Programming Note	
Context:	Instruction batch buffers in memory objects
The batch buffer must be QWord aligned and a multiple of QWords in length. The ending address is the address of the last valid QWord in the buffer. The length of any single batch buffer is "virtually unlimited" (i.e., could theoretically be 4GB in length).	

Logical Contexts

This section is the lead section for the following subsections:

- BSD Logical Render Context Address (LRCA)
- Video Enhancement Logical Context Data
- Logical Contexts

BSD Logical Render Context Address (LRCA)

This section discusses the following topics for the BSD Logical Render Context Address (LRCA):

- Overall Context Layout
- Register State Context
- Ring Buffer [CHV]
- Ring Context [CHV]
- The Per-Process Hardware Status Page

Overall Context Layout

Context Layout

For [CHV], when Execlists are enabled, the Context Image for the media engine consists of two 4K pages:

- Per-Process HW Status Page (4K)
- Register State Context

When Execlists are disabled (ring buffer mode of scheduling) there is no concept of context for workloads submitted to the media engine, and hence there is no context image.

Register State context is explained in detail in the “Register State Context” Section.

Register/State Context

Note: **The Register/State Context is valid only when Execlists and PPGTT are enabled.**

DW Range	DW Count	State Field	Restore Inhibited	PPGTT and Execlists Enabled	PPGTT and Execlists Disabled	Power Context	Set Before Submitting Context?
00h	1	Context Control	R	S/R	X	S/R	Yes
01h	1	Ring Head Pointer Register	R	S/R	X	S/R	Yes
02h	1	Ring Tail Pointer Register	R	R	X	S/R	Yes
03h	1	Batch Buffer Current Head Register	NR	S/R	X	S/R	No
04h	1	Batch Buffer State Register	NR	S/R	X	S/R	No
05h	1	PPGTT Directory Cache Valid Register (Software always populates via host)	R	R	X	S/R	Yes
06h	1	Reserved	X	X	X	S/R	X
07h	1	PD Base Virtual Address Register	R	R	X	S/R	Yes
08h	1	MFX_STATE_POINTER 0	NR	S/R	X	S/R	Yes
09h	1	MFX_STATE_POINTER 1	NR	S/R	X	S/R	Yes
0Ah	1	MFX_STATE_POINTER 2	NR	S/R	X	S/R	Yes
0Bh	1	MFX_STATE_POINTER 3	NR	S/R	X	S/R	Yes
0Ch	1	VCS_CNTR — Media Watchdog Counter Control	NR	S/R	X	S/R	No
0Dh	1	VCS_THRSH — Media Watchdog Counter Threshold	NR	S/R	X	S/R	No
0Eh	1	Current Context ID Register	NR	S/R	X	S/R	No
0Fh	1	Reserved	X	X	X	S/R	X

Ring Buffer

Ring Buffer can exist anywhere in memory mapped via Global GTT. Ring buffer details are mentioned in the ring context area of LRCA (Ring Buffer - Start Address, Head Offset, Tail Pointer & Control Register) in the Execution List mode of scheduling.

Programming Note	
Context:	Ring buffers - ring context area of LRCA
Ring Buffer registers are directly programmed in the Ring Buffer mode of scheduling.	

Ring Context

Ring Context starts at 4K offset from LRCA. Ring context contains all the details that are needed to be initialized by SW for submitting a context to HW for execution (Ring Buffer Details, Page Directory Information, etc). Ring context is five cachelines in size.

Programming Note	
Context:	Submitting a context to HW for execution.
The last cacheline of the ring context is specific for a given Engine and hence SW needs to populate it accordingly.

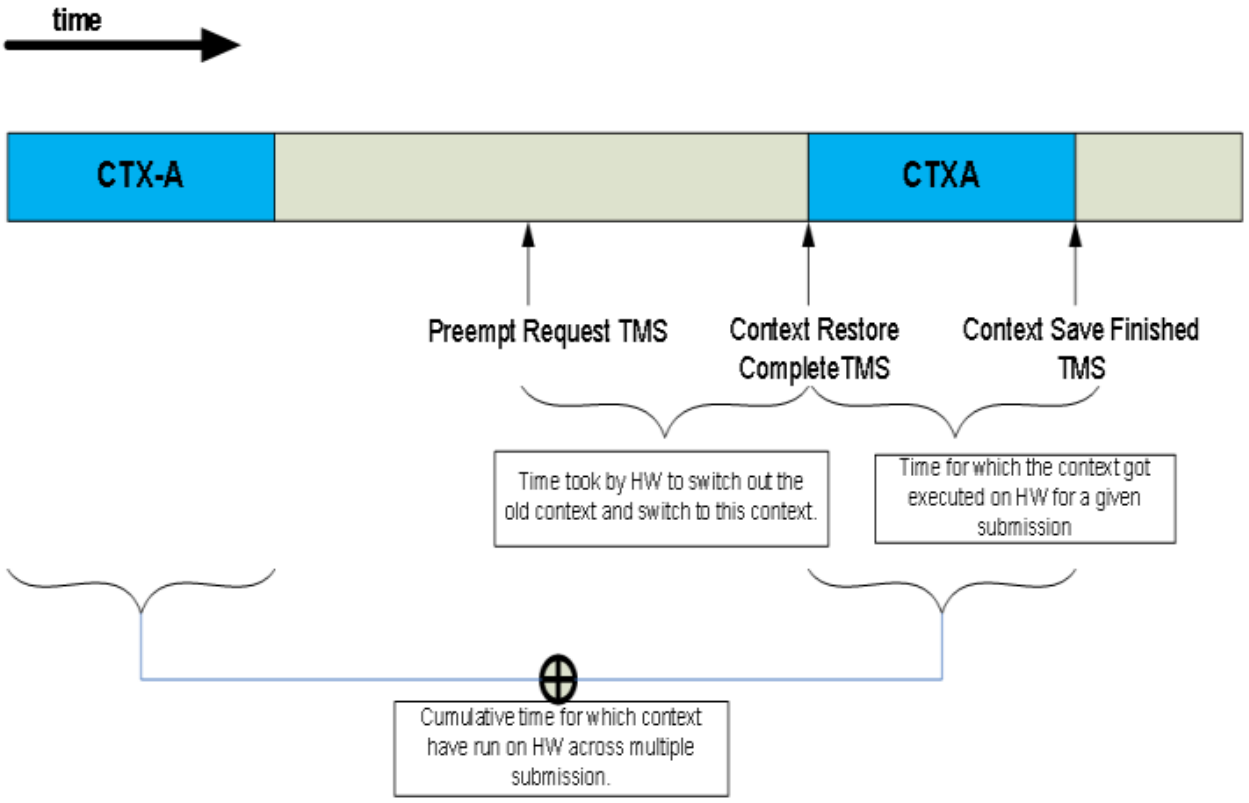
The Per-Process Hardware Status Page

The layout of the Per-Process Hardware Status Page is defined at **PPHWSP_LAYOUT**.

The DWord offset values in the table are in decimal.

Figure below explains the different timestamp values reported to PPHWSP on a context switch.



This page is designed to be read by SW to glean additional details about a context beyond what it can get from the context status.

Accesses to this page are automatically treated as cacheable and snooped. It is therefore illegal to locate this page in any region where snooping is illegal (such as in stolen memory).

Copy Engine Logical Context Data [CHV]

Overall Context Layout

Context Layout

For [CHV], when Execlists are enabled, the Context Image for the copy engine consists of two 4K pages:

Register State context is explained in detail in “Register State Context” Section.

Register/State Context

Ring Buffer

Ring Buffer can exist anywhere in memory mapped via Global GTT. Ring buffer details are mentioned in the ring context area of LRCA (Ring Buffer - Start Address, Head Offset, Tail Pointer & Control Register) in Execution List mode of scheduling. Ring Buffer registers are directly programmed in Ring Buffer mode of scheduling.

Ring Context

Ring Context starts at 4K offset from LRCA. Ring context contains all the details that are needed to be initialized by SW for submitting a context to HW for execution (Ring Buffer Details, Page Directory Information, etc). Ring context is five cachelines in size.

Programming Note	
Context:	Submitting a context to HW for execution
The last cacheline of the ring context is specific for a given Engine and hence SW needs to populate it accordingly.

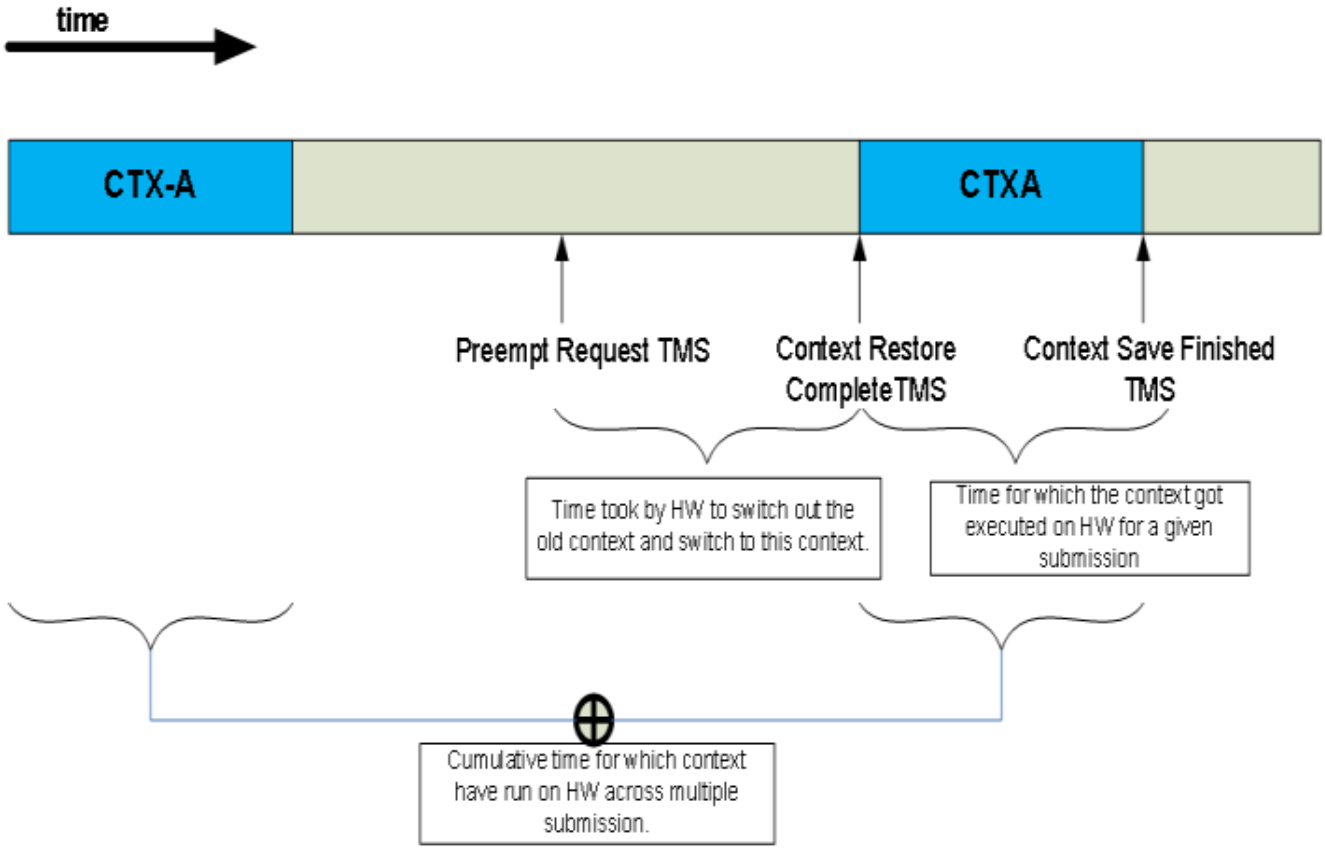
The Per-Process Hardware Status Page

The layout of the Per-Process Hardware Status Page is defined at **PPHWSP_LAYOUT**.

The DWord offset values in the table are in decimal.

Figure below explains the different timestamp values reported to PPHWSP on a context switch.



This page is designed to be read by SW to glean additional details about a context beyond what it can get from the context status.

Accesses to this page are automatically treated as cacheable and snooped. It is therefore illegal to locate this page in any region where snooping is illegal (such as in stolen memory).

Video Enhancement Logical Context Data

Overall Context Layout

Context Layout

For [CHV], when Execlists are enabled, the Context Image for the Video Enhancement engine consists of two 4K pages:

- Per-Process HW Status Page (4K)
- Register State Context

When Execlists are disabled (ring buffer mode of scheduling) there is no concept of context for workloads submitted to media engine and hence there is no context image.

Register State context is explained in detail in the “Register State Context” Section.

Ring Context

Ring Context starts at 4K offset from LRCA. Ring context contains all the details that are needed to be initialized by SW for submitting a context to HW for execution (Ring Buffer Details, Page Directory Information ..etc). Ring context is five cachelines in size.

Programming Note	
Context:	Submitting a context to HW for execution
The last cacheline of the ring context is specific for a given Engine and hence SW needs to populate it accordingly.

Memory Data Formats

This chapter describes the attributes associated with the memory-resident data objects operated on by the graphics pipeline. This includes object types, pixel formats, memory layouts, and rules/restrictions placed on the dimensions, physical memory location, pitch, alignment, etc. with respect to the specific operations performed on the objects.

Unsigned Normalized (UNORM)

An unsigned normalized value with *n* bits is interpreted as a value between 0.0 and 1.0. The minimum value (all 0's) is interpreted as 0.0, the maximum value (all 1's) is interpreted as 1.0. Values in between are equally spaced. For example, a 2-bit UNORM value would have the four values 0, 1/3, 2/3, and 1.

If the incoming value is interpreted as an n-bit integer, the interpreted value can be calculated by dividing the integer by 2^n-1.

Gamma Conversion (SRGB)

Gamma conversion is only supported on UNORM formats. If this flag is included in the surface format name, it indicates that a reverse gamma conversion is to be done after the source surface is read, and a forward gamma conversion is to be done before the destination surface is written.

Signed Normalized (SNORM)

Programming Note	
Context:	Signed normalized value in memory data formats.
A signed normalized value with *n* bits is interpreted as a value between -1 and +1.0. If the incoming value is interpreted as a 2's-complement n-bit integer, the interpreted value can be calculated by dividing the integer by 2^{n-1}-1. The most negative value of -2^{n-1} will result in a value slightly smaller than -1.0. This value is clamped to -1.0; thus, there are two representations of -1.0 in SNORM format.	

Unsigned Integer (UINT/USCALED)

The UINT and USCALED formats interpret the source as an unsigned integer value with *n* bits with a range of 0 to 2^n-1.

The UINT formats copy the source value to the destination (zero-extending if required), keeping the value as an integer.

The USCALED formats convert the integer into the corresponding floating point value (e.g., 0x03 --> 3.0f). For 32-bit sources, the value is rounded to nearest even.

Signed Integer (SINT/SSCALED)

A signed integer value with *n* bits is interpreted as a 2's complement integer with a range of -2^{n-1} to $+2^{n-1}$-1.

The SINT formats copy the source value to the destination (sign-extending if required), keeping the value as an integer.

The SSCALED formats convert the integer into the corresponding floating point value (e.g., 0xFFFD --> -3.0f). For 32-bit sources, the value is rounded to nearest even.

Floating Point (FLOAT)

Refer to IEEE Standard 754 for Binary Floating-Point Arithmetic. The IA-32 Intel (R) Architecture Software Developer's Manual also describes floating point data types .

64-bit Floating Point

Bit	Description
63	**Sign (s)**
62:52	**Exponent (e)** Biased Exponent
51:0	**Fraction (f)** Does not include "hidden one"

The value of this data type is derived as:

- if e == b'11..11' and f != 0, then v is NaN regardless of s
- if e == b'11..11' and f == 0, then v = $(-1)^s$*infinity (signed infinity)
- if 0 < e < b'11..11', then v = $(-1)^s*2^{(e-1023)}*(1.f)$
- if e == 0 and f != 0, then v = $(-1)^s*2^{(e-1022)}*(0.f)$ (denormalized numbers)
- if e == 0 and f == 0, then v = $(-1)^s$*0 (signed zero)

32-bit Floating Point

Bit	Description
31	**Sign (s)**
30:23	**Exponent (e)** Biased Exponent
22:0	**Fraction (f)** Does not include "hidden one"

The value of this data type is derived as:

- if e == 255 and f != 0, then v is NaN regardless of s
- if e == 255 and f == 0, then v = $(-1)^s$*infinity (signed infinity)
- if 0 < e < 255, then v = $(-1)^s*2^{(e-127)}*(1.f)$
- if e == 0 and f != 0, then v = $(-1)^s*2^{(e-126)}*(0.f)$ (denormalized numbers)
- if e == 0 and f == 0, then v = $(-1)^s*0$ (signed zero)

16-bit Floating Point

Bit	Description
15	**Sign (s)**
14:10	**Exponent (e)** Biased Exponent
9:0	**Fraction (f)** Does not include "hidden one"

The value of this data type is derived as:

- if e == 31 and f != 0, then v is NaN regardless of s
- if e == 31 and f == 0, then v = $(-1)^s$*infinity (signed infinity)
- if 0 < e < 31, then v = $(-1)^s*2^{(e-15)}*(1.f)$
- if e == 0 and f != 0, then v = $(-1)^s*2^{(e-14)}*(0.f)$ (denormalized numbers)
- if e == 0 and f == 0, then v = $(-1)^s*0$ (signed zero)

The following table represents relationship between 32 bit and 16 bit floating point ranges:

flt32 exponent	Unbiased exponent	Normalization	flt16 exponent	flt16 fraction
255				
254	127			
...				
127+16	16	Infinity	31	1.1111111111
127+15	15	Max exponent	30	1.xxxxxxxxxx
127	0		15	1.xxxxxxxxxx
113	-14	Min exponent	1	1.xxxxxxxxxx
112		Denormalized	0	0.1xxxxxxxxx
111		Denormalized	0	0.01xxxxxxxx
110		Denormalized	0	0.001xxxxxxx
109		Denormalized	0	0.0001xxxxxx
108		Denormalized	0	0.00001xxxxx
107		Denormalized	0	0.000001xxxx
106		Denormalized	0	0.0000001xxx
115		Denormalized	0	0.00000001xx
114		Denormalized	0	0.000000001x
113		Denormalized	0	0.0000000001
112		Denormalized	0	0.0
...				
0			0	0.0

Conversion from the 32-bit floating point format to the 16-bit format should be done with round to nearest even.

11-bit Floating Point

Bits	Description
10:6	**Exponent (e):** Biased exponent (the bias depends on e)
5:0	**Fraction (f):** Fraction bits to the right of the binary point

The value v of an 11-bit floating-point number is calculated from e and f as:

- if e == 31 and f != 0 then v = NaN
- if e == 31 and f == 0 then v = +infinity
- if 0 < e < 31, then v = $2^{(e-15)}$*(1.f)
- if e == 0 and f != 0, then v = $2^{(e-14)}$*(0.f) (denormalized numbers)
- if e == 0 and f == 0, then v = 0 (zero)

There is no sign bit and negative values are not represented.

The 11-bit floating-point format has one more bit of fractional precision than the 10-bit floating-point format.

The maximum representable finite value is 1.111111b * 2^{15} = FE00h = 65024.

10-bit Floating Point

Bits	Description
9:5	**Exponent (e):** Biased exponent (the bias depends on e)
4:0	**Fraction (f):** Fraction bits to the right of the binary point

The value v of a 10-bit floating-point number is calculated from e and f as:

- if e == 31 and f != 0 then v = NaN
- if e == 31 and f == 0 then v = +infinity
- if 0 < e < 31, then v = $2^{(e-15)}$*(1.f)
- if e == 0 and f != 0, then v = $2^{(e-14)}$*(0.f) (denormalized numbers)
- if e == 0 and f == 0, then v = 0 (zero)

There is no sign bit and negative values are not represented.

The maximum representable finite value is 1.11111b * 2^{15} = FC00h = 64512.

Shared Exponent

The R9G9B9E5_SHAREDEXP format contains three channels that share an exponent. The three fractions assume an impled “0” rather than an implied “1” as in the other floating point formats. This format does not support infinity and NaN values. There are no sign bits, only positive numbers and zero can be represented. The value of each channel is determined as follows, where “f” is the fraction of the corresponding channel, and “e” is the shared exponent.

$v = (0.f)*2^{(e-15)}$

Bit	Description
31:27	**Exponent (e)** Biased Exponent
26:18	**Blue Fraction**
17:9	**Green Fraction**
8:0	**Red Fraction**

Configurations Overview

The Intel "Gen" Graphics Architecture was first introduced to the market in 2004. Since that time, the architecture and its implementation have evolved to add many new features, increase performance, and improve power efficiency.

Configurations

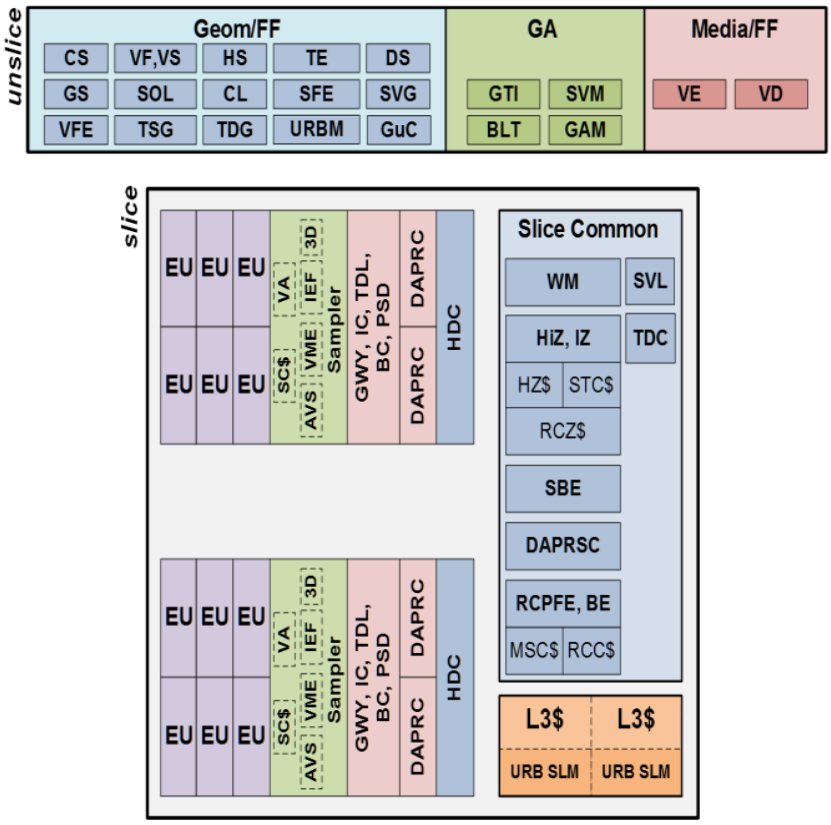
This chapter contains configurations details as described in the following sections:

- Top Level Block Diagrams
- Device Attributes
- Steppings & Device IDs

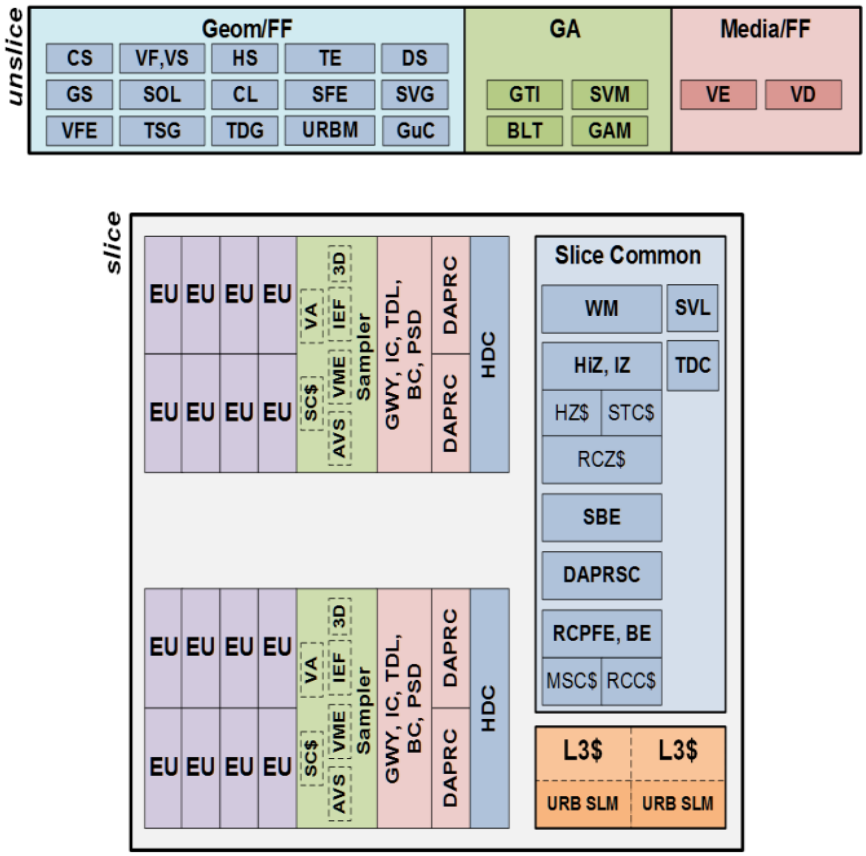
Top Level Block Diagrams

The diagram below shows basic feature blocks of the Cherryview (CHV) and Braswell (BSW) graphics architecture:

12 EU (2x6) Configuration:



16 EU (2x8) Configuration:



The above diagrams are based on the following functional partitions:

(a) Geometry Fixed Functions (Geom/FF)

(b) Media Fixed Functions (Media/FF)

(c) Global Assets and GT Interface (GA)

(d) One or more Subslices (two shown)

(e) A Slice Common block

(f) An L3 Cache (L3$) block

Note that the combination of (a), (b), and (c) is typically referred to as the “unslice”, while a combination of (d), (e), and (f) is referred to as a compute “slice”.

The functionality in each of these groupings is further broken down as follows:

- Unslice – Fixed function pipelines for 3D, GPGPU, and Media operations, and interface to the outside world.
  - The 3D Geometry / Fixed Function (Geom/FF) block consisting of:
    - 3D fixed function pipeline (CS, VFVS, HS, TE, DS, GS, SOL, SL, SFE, SVG)
    - Video Front-End unit (VFE)
    - Thread Spawner unit (TSG) and the global Thread Dispatcher unit (TDG)

        - Unified Return Buffer Manager (URBM)
    - Media fixed function assets:
        - Video Decode (VD) Box
        - Video Encode (VE) Box
        - Wireless Display (WD) BOX
    - The Global Assets (GA) block as the primary interface and memory stream gateway to the outside world, consisting of:
        - GT Interface (GTI)
        - State Variable Manager (SVM)
        - Blitter (BLT)
        - Graphics Arbiter (GAM)
- Subslice (three shown) – A compute unit with supporting fixed- or shared-function assets sufficient for the EU capability.
    - A bank of Execution Units (EUs) – eight per subslice shown
    - Sampler, supporting both media and 3D functions
    - Gateway (GWY)
    - Instruction cache (IC)
    - Local Thread Dispatcher (TDL)
    - Barycentric Calculator (BC)
    - Pixel Shader Dispatcher (PSD)
    - Data Cluster (HDC)
    - Dataport Render Cache (DAPRC) - two per subslice
- Slice Common – Scalable fixed function assets which support the compute horsepower provided two or more subslices.
    - 3D Fixed Function:
        - Windower/Mask unit (WM)
        - Plane-Z, Hi-Z (HZ) and Intermediate Z (IZ)
        - Setup Backend (SBE)
        - Pixel backend units
        - 3D stream caches for color, multi-sample surface, iz, and stencil (RCC$, MSC$, HZ$, RCZ$, STC$)
    - Media Fixed Function:
        - DAPRSC
        - RCPFE, BE
        - SVL
        - TDC
- L3 Cache – backing L3 cache for certain memory streams emanating from subslices.
    - L3 Data cache with support for data, URB, and shared local memory (SLM)

Device Attributes

Introduction

The hardware supports three engines:

- The Render command streamer interfaces to 3D/IE and display streams.
- The Media command streamer interfaces to the fixed function media.
- The Blitter command streamer interfaces to the blit commands.

Software interfaces of all three engines are very similar and should only differ on engine-specific functionality.

Memory Views Glossary

Term	Definition
CHV, BSW	CherryView CPU/GFX platform. 8th generation processor graphics (Gen8).
IOMMU	I/O Memory Mapping unit
SVM	Shared Virtual Memory, implies the same virtual memory view between the IA cores and processor graphics.
Page Walker (GAM)	GFX page walker which handles page level translations between GFX virtual memory to physical memory domain.

GPU Memory Interface

GPU memory interface functions are divided into 4 different major sections:

- Global Arbitration
- Memory Interface Functions
- Page Translations (GFX Page Walker)
- Ring Interface Functions (GTI)

GT Interface functions are covered at a different chapter/HAS and not part of this documentation. The following documentation is meant for GFX arbitration paths in accessing to memory/cache interfaces and page translations and page walker functions.

Global Arbitration

The global memory arbitration fabric is meant to be a hierarchal memory fabric where memory accesses from different stages of the pipeline are consolidated to a single interface towards GT's connection to CPU's ring interface.

The arbitration on the fabric is programmable via a simple per pipeline stage priority levels.

Programming Note	
Context:	Global Memory Arbitration
Arbitration allows 4 levels of arbitration where each pipeline level can be put into these 4 levels. Each consolidation stage simply follows the 4-level arbitration with grace periods to allow ahead of the pipeline to get a higher share of the memory bandwidth.	

The final arbitration takes places in GAM between parallel compute engines. Each engine (in some cases major pipeline stages are also separated, i.e. Z vs Color vs L3 vs Fixed Functions) gets a count in a grace period where its accesses are counted against a global pool. If a particular engine (or pipeline stage) exhausts its max allowed, it is dropped to a lower priority and goes to fixed pipeline based prioritization. Once all counts are expired, the grace period completes and resets.

The count values are programmable via MMIO (i.e. *_MAX_REQ_COUNT) registers with defaults favoring the pipeline order.

Graphics Memory Interface Functions

The major role of an integrated graphics device's Memory Interface (MI) function is to provide various client functions access to "graphics" memory used to store commands, surfaces, and other information used by the graphics device. This chapter describes the basic mechanisms and paths by which graphics memory is accessed.

Information not presented in this chapter includes:

- Microarchitectural and implementation-dependent features (e.g., internal buffering, caching, and arbitration policies).
- MI functions and paths specific to the operation of external (discrete) devices attached via external connections.
- MI functions essentially unrelated to the operation of the internal graphics devices, .e.g., traditional "chipset functions"
- GFX Page Walker and GT interface functions are covered in different chapters.

Graphics Memory Clients

The MI function provides memory access functionality to a number of external and internal graphics memory *clients*, as described in the table below.

Graphics Memory Clients

MI Client	Access Modes
Host Processor	Read/Write of Graphics Operands located in Main Memory. Graphics Memory is accessed using Device 2 Graphics Memory Range Addresses
External PEG Graphics Device	Write-Only of Graphics Operands located in Main Memory via the Graphics Aperture. (This client is not described in this chapter).
Peer PCI Device	Write-Only of Graphics Operands located in Main Memory. Graphics Memory is accessed using Device 2 Graphics Memory Range Addresses (i.e., mapped by GTT). Note that DMI access to Graphics registers is not supported.
Coherent Read/Write (internal)	Internally-generated snooped reads/writes.
Command Stream (internal)	DMA Read of graphics commands and related graphics data.
Vertex Stream (internal)	DMA Read of indexed vertex data from Vertex Buffers by the 3D Vertex Fetch (VF) Fixed Function.
Instruction/State Cache (internal)	Read of pipelined 3D rendering state used by the 3D/Media Functions and instructions executed by the EUs.
Render Cache (internal)	Read/Write of graphics data operated upon by the graphics rendering engines (Blt, 3D, MPEG, etc.) Read of render surface state.
Sampler Cache (internal)	Read of texture (and other sampled surface) data stored in graphics memory.
Display/Overlay Engines (internal)	Read of display, overlay, cursor and VGA data.
Media Engines	Read and write of media content and media processing.
uController	Read/Write (DMA) functions for u-controller and scheduler.

Graphics Memory Addressing Overview

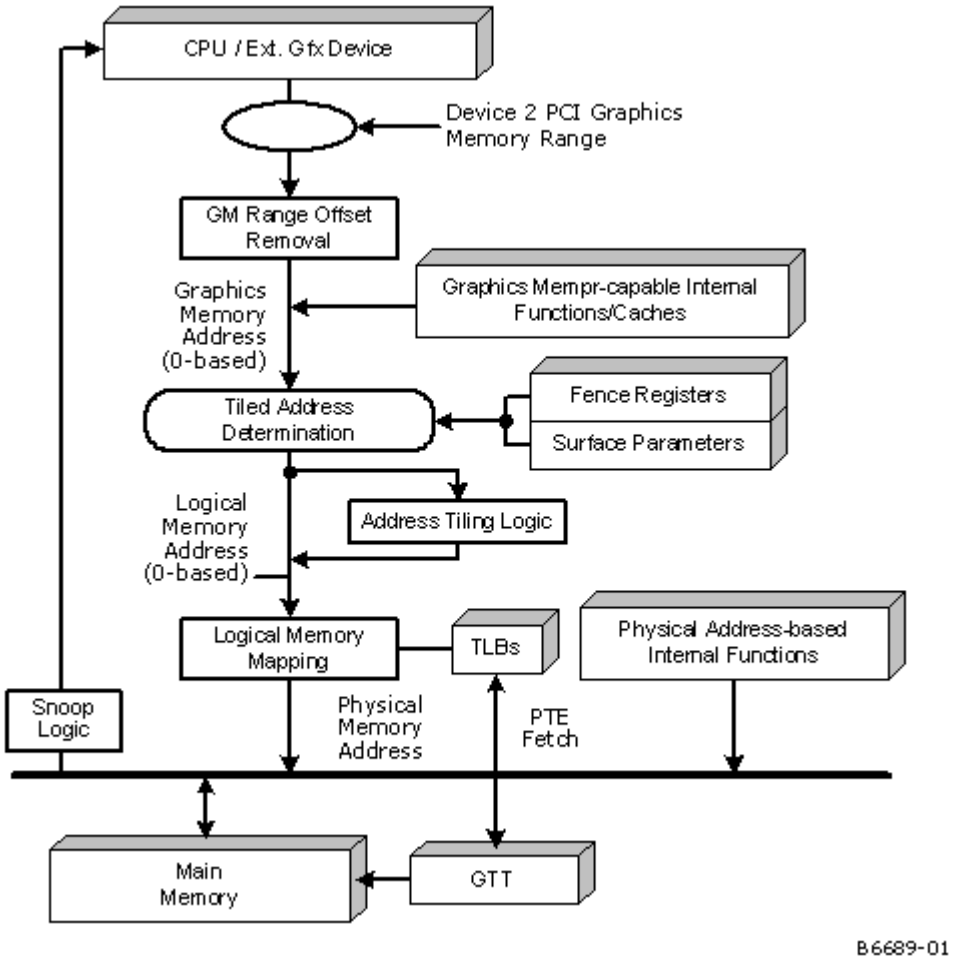
The Memory Interface function provides access to graphics memory (GM) clients. It accepts memory addresses of various types, performs a number of optional operations along *address paths*, and eventually performs reads and writes of graphics memory data using the resultant addresses. The remainder of this subsection will provide an overview of the graphics memory clients and address operations.

Graphics Address Path

Graphics Address Path shows the internal graphics memory address path, connection points, and optional operations performed on addresses. Externally-supplied addresses are normalized to zero-based *Graphics Memory* (*GM) addresses* (GM_Address). If the GM address is determined to be a tiled address (based on inclusion in a fenced region or via explicit surface parameters), *address tiling* is performed. At this point the address is considered a *Logical Memory address*, and is translated into a *Physical Memory address* via the GTT and associated TLBs. The physical memory location is then accessed.

CPU accesses to graphics memory are sent back on the ring to snoop. Hence pages that are mapped cacheable in the GTT will be coherent with the CPU cache if accessed through graphics memory aperture.

Graphics Memory Paths



The remainder of this chapter describes the basic features of the graphics memory address pipeline, namely Address Tiling, Logical Address Mapping, and Physical Memory types and allocation considerations.

Graphics Memory Address Spaces

The *Graphics Memory Address Spaces* table lists the five supported Graphics Memory Address Spaces. Note that the Graphics Memory Range Removal function is automatically performed to transform system addresses to internal, zero-based Graphics Addresses.

Due to a workaround, first 4KB of DSM has to be reserved for GFX hardware use during render engine execution.

Address Tiling Function Introduction

When dealing with memory operands (e.g., graphics surfaces) that are inherently rectangular in nature, certain functions within the graphics device support the storage/access of the operands using alternative (tiled) memory formats to increase performance. This section describes these memory storage formats, why and when they should be used, and the behavioral mechanisms within the device to support them.

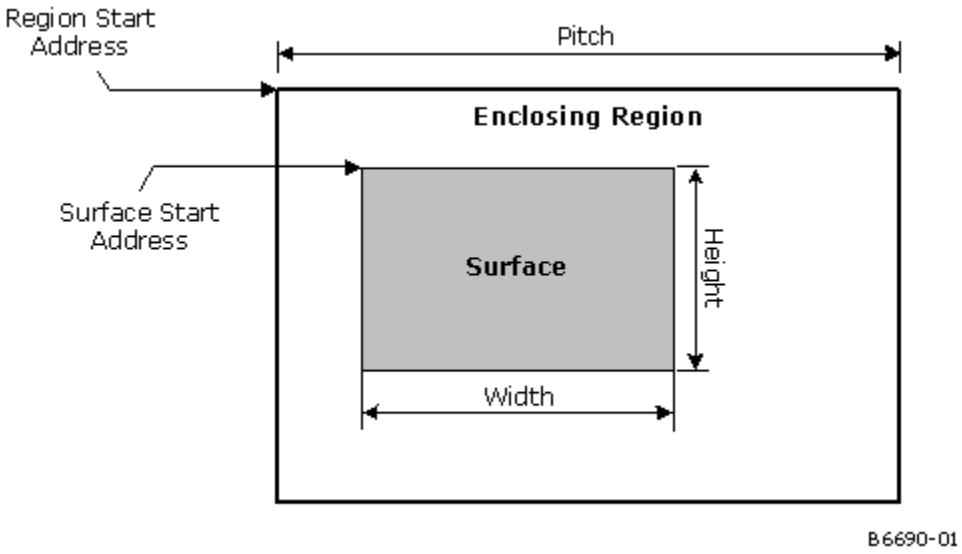
Legacy Tiling Modes:

- **TileY**: Used for most tiled surfaces when **TR_MODE**=TR_NONE.
- **TileX** : Used primarily for display surfaces.
- **TileW:** Used for Stencil surfaces.

Linear vs Tiled Storage

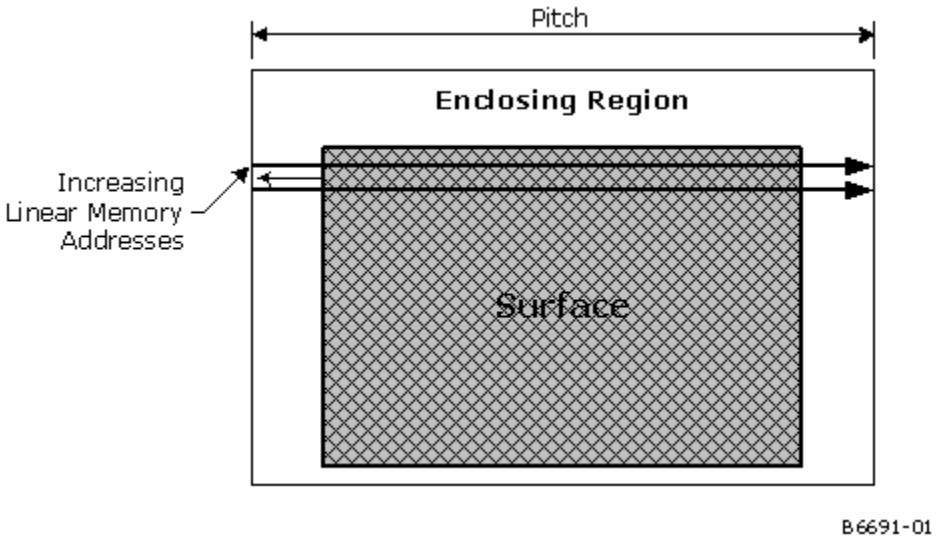
Regardless of the memory storage format, "rectangular" memory operands have a specific *width* and *height*, and are considered as residing within an enclosing rectangular region whose width is considered the *pitch* of the region and surfaces contained within. Surfaces stored within an enclosing region must have widths less than or equal to the region pitch (indeed the enclosing region may coincide exactly with the surface). *Rectangular Memory Operand Parameters* shows these parameters.

Rectangular Memory Operand Parameters



The simplest storage format is the *linear* format (see *Linear Surface Layout*), where each row of the operand is stored in sequentially increasing memory locations. If the surface width is less than the enclosing region's pitch, there will be additional memory storage between rows to accommodate the region's pitch. The pitch of the enclosing region determines the distance (in the memory address space) between vertically-adjacent operand elements (e.g., pixels, texels).

Linear Surface Layout

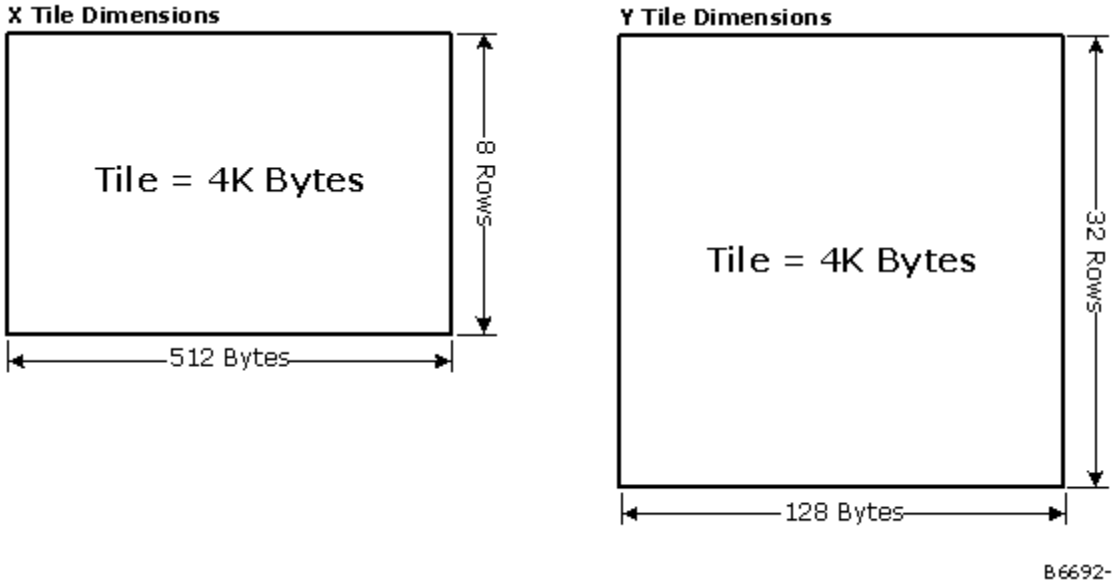


The linear format is best suited for 1-dimensional row-sequential access patterns (e.g., a display surface where each scanline is read sequentially). Here the fact that one object element may reside in a different memory page than its vertically-adjacent neighbors is not significant; all that matters is that horizontally-adjacent elements are stored contiguously. However, when a device function needs to access a 2D subregion within an operand (e.g., a read or write of a 4x4 pixel span by the 3D renderer, a read of a 2x2 texel block for bilinear filtering), having vertically-adjacent elements fall within different memory pages is to be avoided, as the page crossings required to complete the access typically incur increased memory latencies (and therefore lower performance).

One solution to this problem is to divide the enclosing region into an array of smaller rectangular regions, called memory *tiles*. Surface elements falling within a given tile will all be stored in the same physical memory page, thus eliminating page-crossing penalties for 2D subregion accesses within a tile and thereby increasing performance.

Tiles have a fixed 4KB size and are aligned to physical DRAM page boundaries. They are either 8 rows high by 512 bytes wide or 32 rows high by 128 bytes wide (see *Memory Tile Dimensions*). Note that the dimensions of tiles are irrespective of the data contained within – e.g., a tile can hold twice as many 16-bit pixels (256 pixels/row x 8 rows = 2K pixels) than 32-bit pixels (128 pixels/row x 8 rows = 1K pixels).

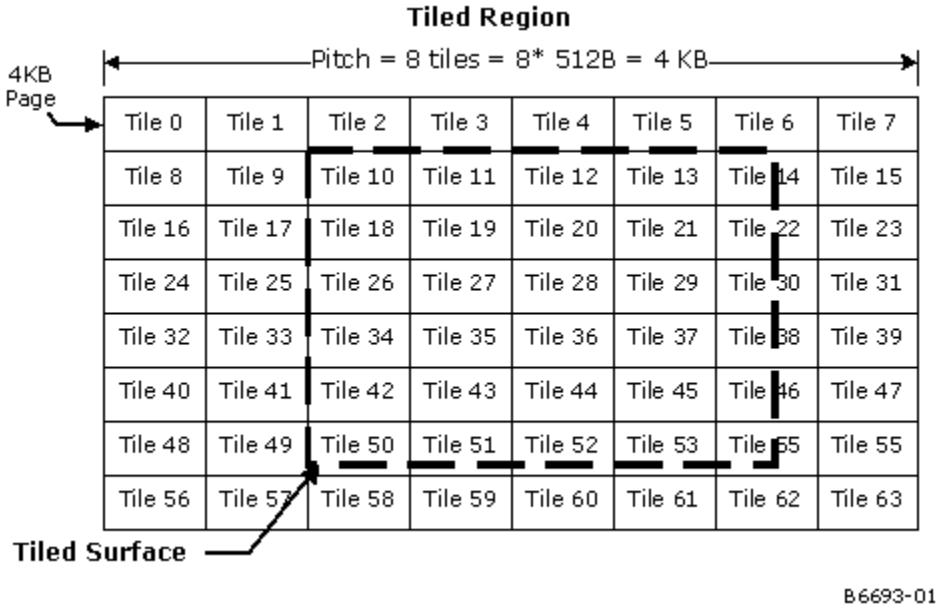
Memory Tile Dimensions



The pitch of a tiled enclosing region must be an integral number of tile widths. The 4KB tiles within a tiled region are stored sequentially in memory in row-major order.

The *Tiled Surface Layout* figure shows an example of a tiled surface located within a tiled region with a pitch of 8 tile widths (512 bytes * 8 = 4KB). Note that it is the *enclosing region* that is divided into tiles – the surface is not necessarily aligned or dimensioned to tile boundaries.

Tiled Surface Layout



Tile Formats

Multiple tile formats are supported by the Gen Core. The following sections define and describe these formats.

Tiling formats are controlled by programming the fields Tile_Mode and Tiled_Resource_Mode in the RENDER_SURFACE_STATE.

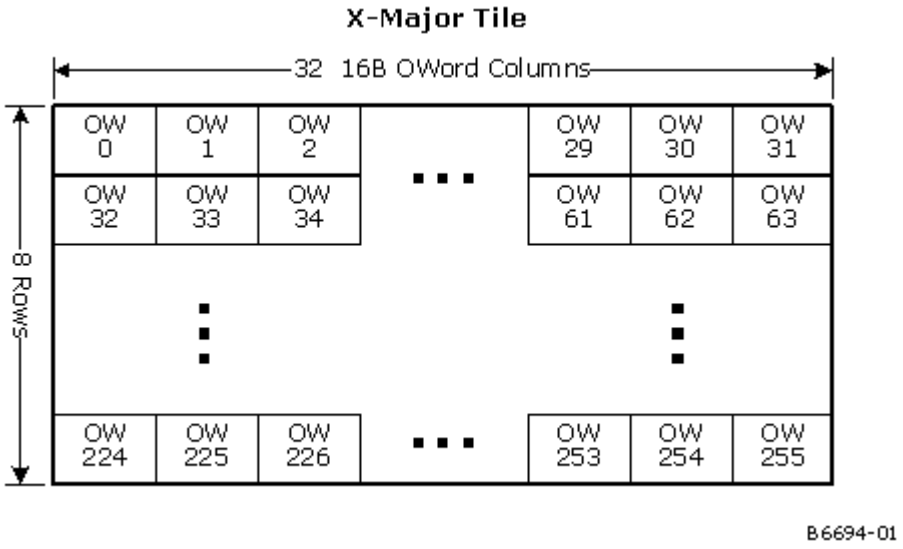
Tile-X Legacy Format

The legacy format Tile-X is a *X-Major* (row-major) storage of tile data units, as shown in the following figure. It is a 4KB tile which is subdivided into an 8-high by 32-wide array of 16-byte OWords . The selection of tile direction only impacts the internal organization of tile data, and does not affect how surfaces map onto tiles. Note that an X-major tiled region with a tile pitch of 1 tile is actually stored in a linear fashion.

Tile-X format is selected for a surface by programming the Tiled_Mode field in RENDER_SURFACE_STATE to XMAJOR.

For 3D sampling operation, a surface using Tile-X layout is generally lower performance the organization of texels in memory.

Tile X-Tile (X-Major) Layout



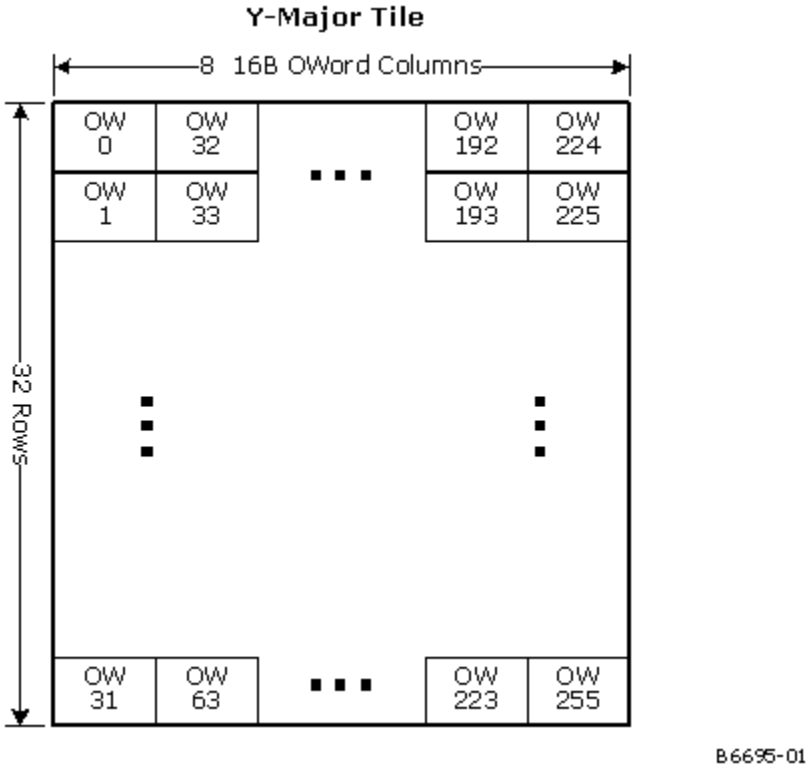
Tile-Y Legacy Format

The device supports Tile-Y legacy format which is *Y-Major* (column major) storage of tile data units, as shown in the following figure. A 4KB tile is subdivided 32-high by 8-wide array of OWords. The selection of tile direction only impacts the internal organization of tile data, and does not affect how surfaces map onto tiles.

Tile-Y surface format is selected by programming the Tile_Mode field in RENDER_SURFACE_STATE to YMAJOR.

Note that 3D sampling of a surface in Tile-Y format is usually has higher performance due to the layout of pixels.

Y-Major Tile Layout



Tiling Algorithm

The following pseudo-code describes the algorithm for translating a tiled memory surface in graphics memory to an address in logical space.

```
 Inputs:
     LinearAddress (offset into regular or LT aperture in terms of bytes)
     Pitch (in terms of tiles)
     WalkY (1 for Y and 0 for X)
     WalkW (1 for W and 0 for the rest)
 Static Parameters:
     TileH (Height of tile, 8 for X, 32 for Y, and 64 for W),
     TileW (Width of Tile in bytes, 512 for X, 128 for Y, and 64 for W)

 TileSize = TileH * TileW;
 RowSize = Pitch * TileSize;
 If ( Fenced ) {
     LinearAddress = LinearAddress - FenceBaseAddress;
     LinearAddrInTileW = LinearAddress div TileW;
     Xoffset_inTile = LinearAddress mod TileW;
     Y = LinearAddrInTileW div Pitch;
     X = LinearAddrInTileW mod Pitch + Xoffset_inTile;
 }

 // Internal graphics clients that access tiled memory already have the X, Y coordinates and
can start here.
 YOff_Within_Tile = Y mod TileH;
 XOff_Within_Tile = X mod TileW;
 TileNumber_InY = Y div TileH;
 TileNumber_InX = X div TileW;
 TiledOffsetY = RowSize * TileNumber_InY + TileSize * TileNumber_InX +
         TileH * 16 * (XOff_Within_Tile div 16) + YOff_Within_Tile * 16 + (XOff_Within_Tile
mod 16);
 TiledOffsetW = RowSize * TileNumber_InY + TileSize * TileNumber_InX +
         TileH * 8 * (XOff_Within_Tile div 8) +
         64 * (YOff_Within_Tile div 8) +
         32 * ((YOff_Within_Tile div 4) mod 2) +
         16 * ((XOff_Within_Tile div 4) mod 2) +
          8 * ((YOff_Within_Tile div 2) mod 2) +
          4 * ((XOff_Within_Tile div 2) mod 2) +
          2 * (YOff_Within_Tile mod 2) +
              (XOff_Within_Tile mod 2);
 TiledOffsetX = RowSize * TileNumber_InY + TileSize * TileNumber_InX + TileW *
YOff_Within_Tile + XOff_Within_Tile;
 TiledOffset = WalkW ? TiledOffsetW : (WalkY ? TiledOffsetY : TiledOffsetX);
 TiledAddress = Tiled ? (BaseAddress + TiledOffset) : (BaseAddress + Y*LinearPitch + X);
 TiledAddress = (Tiled &&
         (Address Swizzling for Tiled-Surfaces == 01)) ?
         (WalkW || WalkY) ?
         (TiledAddress div 128) * 128 +
         (((TiledAddress div 64) mod 2) ^
         ((TiledAddress div 512) mod 2)) +
         (TiledAddress mod 32)
         :
         (TiledAddress div 128) * 128 +
         (((TiledAddress div 64) mod 2) ^
         ((TiledAddress div 512) mod 2)
         ((TiledAddress Div 1024) mod2) +
         (TiledAddress mod 32)
         :
         TiledAddress;
```

Address Swizzling for Tiled-Surfaces is no longer used because the main memory controller has a more effective address swizzling algorithm.

For Address Swizzling for Tiled-Surfaces see ARB_MODE – Arbiter Mode Control register, ARB_CTL—Display Arbitration Control 1, and TILECTL - Tile Control register.

The Y-Major tile formats have the characteristic that a surface element in an even row is located in the same aligned 64-byte cacheline as the surface element immediately below it (in the odd row). This spatial locality can be exploited to increase performance when reading 2x2 texel squares for bilinear texture filtering, or reading and writing aligned 4x4 pixel spans from the 3D Render pipeline.

On the other hand, the X-Major tile format has the characteristic that horizontally-adjacent elements are stored in sequential memory addresses. This spatial locality is advantageous when the surface is scanned in row-major order for operations like display refresh. For this reason, the Display and Overlay memory streams only support linear or X-Major tiled surfaces. (Y-Major tiling is not supported by these functions.) This has the side effect that 2D- or 3D-rendered surfaces must be stored in linear or X-Major tiled formats if they are to be displayed. Non-displayed surfaces, e.g., “rendered textures”, can also be stored in Y-Major order.

Tiled Channel Select Decision

Before Gen8, there was a historical configuration control field to swizzle address bit[6] for in X/Y tiling modes. This was set in three different places: TILECTL[1:0], ARB_MODE[5:4], and DISP_ARB_CTL[14:13].

For Gen8 and subsequent generations, the swizzle fields are all reserved, and the CPU's memory controller performs all address swizzling modifications.

Tiling Support

The rearrangement of the surface elements in memory must be accounted for in device functions operating upon tiled surfaces. (Note that not all device functions that access memory support tiled formats). This requires either the modification of an element's linear memory address or an alternate formula to convert an element's X,Y coordinates into a tiled memory address.

However, before tiled-address generation can take place, some mechanism must be used to determine whether the surface elements accessed fall in a linear or tiled region of memory, and if tiled, what the tile region pitch is, and whether the tiled region uses X-Major or Y-Major format. There are two mechanisms by which this detection takes place: (a) an implicit method by detecting that the pre-tiled (linear) address falls within a "fenced" tiled region, or (b) by an explicit specification of tiling parameters for surface operands (i.e., parameters included in surface-defining instructions).

The following table identifies the tiling-detection mechanisms that are supported by the various memory streams.

Access Path	Tiling-Detection Mechanisms Supported
Processor access through the Graphics Memory Aperture	Fenced Regions
3D Render (Color/Depth Buffer access)	Explicit Surface Parameters
Sampled Surfaces	Explicit Surface Parameters
Blt operands	Explicit Surface Parameters
Display and Overlay Surfaces	Explicit Surface Parameters

Tiled (Fenced) Regions

The only mechanism to support the access of surfaces in tiled format by the host or external graphics client is to place them within “fenced” tiled regions within Graphics Memory. A fenced region is a block of Graphics Memory specified using one of the sixteen FENCE device registers. (See *Memory Interface Registers* for details). Surfaces contained within a fenced region are considered tiled from an external access point of view. Note that fences cannot be used to untile surfaces in the PGM_Address space since external devices cannot access PGM_Address space. Even if these surfaces (or any surfaces accessed by an internal graphics client) fall within a region covered by an enabled fence register, that enable will be effectively masked during the internal graphics client access. Only the explicit surface parameters described in the next section can be used to tile surfaces being accessed by the internal graphics clients.

Restriction: Each FENCE register (if its Fence Valid bit is set) defines a Graphics Memory region ranging from 4KB to the aperture size. The region is considered rectangular, with a pitch in tile widths from 1 tile width (128B or 512B) to 512 tile X widths (512 * 512B = 256KB) and 2048 tile Y widths (2048 * 128B = 256KB). Note that fenced regions must not overlap, or operation is UNDEFINED.

Context: Tiled (Fenced) Regions

Restriction: Also included in the FENCE register is a Tile Walk field that specifies which tile format applies to the fenced region.

Context: Tiled (Fenced) Regions

Tiled Surface Parameters

Internal device functions require explicit specification of surface tiling parameters via information passed in commands and state. This capability is provided to limit the reliance on the fixed number of fence regions.

The following table lists the surface tiling parameters that can be specified for 3D Render surfaces (Color Buffer, Depth Buffer, Textures, etc.) via SURFACE_STATE.

Surface Parameter	Description
Tiled Surface	If ENABLED, the surface is stored in a tiled format. If DISABLED, the surface is stored in a linear format.
Tile Walk	If Tiled Surface is ENABLED, this parameter specifies whether the tiled surface is stored in Y-Major or X-Major tile format.
Base Address	Additional restrictions apply to the base address of a Tiled Surface vs. that of a linear surface.
Pitch	Pitch of the surface. Note that, if the surface is tiled, this pitch must be a multiple of the tile width.

Tiled Surface Restrictions

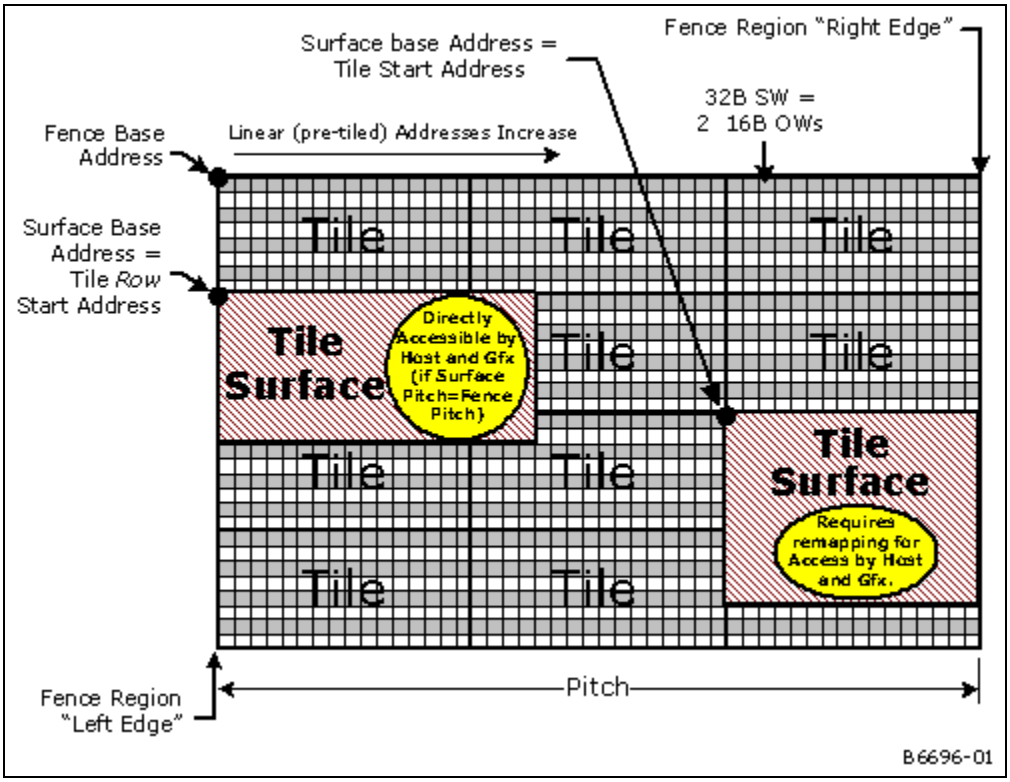
Additional restrictions apply to the Base Address and Pitch of a surface that is tiled. In addition, restrictions for tiling via SURFACE_STATE are subtly different from those for tiling via fence regions. The most restricted surfaces are those that will be accessed both by the host (via fence) and by internal device functions. An example of such a surface is a tiled texture that is initialized by the CPU and then sampled by the device.

The tiling algorithm for internal device functions is different from that of fence regions. Internal device functions always specify tiling in terms of a surface. The surface must have a base address, and this base address is not subject to the tiling algorithm. Only *offsets* from the base address (as calculated by X, Y addressing within the surface) are transformed through tiling. The base address of the surface must therefore be 4KB-aligned. This forces the 4KB tiles of the tiling algorithm to exactly align with 4KB device pages once the tiling algorithm has been applied to the offset. The width of a surface must be less than or equal to the surface pitch. There are additional considerations for surfaces that are also accessed by the host (via a fence region).

Fence regions have no base address per se. Host linear addresses that fall in a fence region are translated in their entirety by the tiling algorithm. It is as if the surface being tiled by the fence region has a base address in graphics memory equal to the fence base address, and all accesses of the surfaces are (possibly quite large) offsets from the fence base address. Fence regions have a virtual “left edge” aligned with the fence base address, and a “right edge” that results from adding the fence pitch to the “left edge”. Surfaces in the fence region must not straddle these boundaries.

Base addresses of surfaces that are to be accessed both by an internal graphics client and by the host have the tightest restrictions. In order for the surface to be accessed without GTT re-mapping, the surface base address (as set in SURFACE_STATE) must be a “Tile Row Start Address” (TRSA). The first address in each tile row of the fence region is a Tile Row Start Address. The first TRSA is the fence base address. Each TRSA can be generated by adding an integral multiple of the row size to the fence base address. The row size is simply the fence pitch in tiles multiplied by 4KB (the size of a tile.)

Tiled Surface Placement



The pitch in SURFACE_STATE must be set equal to the pitch of the fence that will be used by the host to access the surface if the same GTT mapping will be used for each access. If the pitches differ, a different GTT mapping must be used to eliminate the "extra" tiles (4KB memory pages) that exist in the excess rows at the right side of the larger pitch. Obviously no part of the surface that will be accessed can lie in pages that exist only in one mapping but not the other. The new GTT mapping can be done manually by SW between the time the host writes the surface and the device reads it, or it can be accomplished by arranging for the client to use a different GTT than the host (the PPGTT -- see *Logical Memory Mapping* below).

The width of the surface (as set in SURFACE_STATE) must be less than or equal to both the surface pitch and the fence pitch in any scenario where a surface will be accessed by both the host and an internal graphics client. Changing the GTT mapping will not help if this restriction is violated.

Surface Access	Base Address	Pitch	Width	Tile "Walk"
Host only	No restriction	Integral multiple of tile size <= 256KB	Must be <= Fence Pitch	No restriction
Client only	4KB-aligned	Integral multiple of tile size <= 256KB	Must be <= Surface Pitch	Restrictions imposed by the client (see Per Stream Tile Format Support)
Host and Client, No GTT Remapping	Must be TRSA	Fence Pitch = Surface Pitch = integral multiple of tile size <= 256KB	Width <= Pitch	Surface Walk must meet client restriction, Fence Walk = Surface Walk
Host and Client, GTT Remapping	4KB-aligned for client (will be tile-aligned for host)	Both must be Integral multiple of tile size <=128KB, but not necessarily the same	Width <= Min(Surface Pitch, Fence Pitch)	Surface Walk must meet client restriction, Fence Walk = Surface Walk

Per-Stream Tile Format Support

Main Memory

The integrated graphics device is capable of using 4KB pages of physical main (system) memory for graphics functions. Some of this main memory can be “stolen” from the top of system memory during initialization (e.g., for a VGA buffer). However, most graphics operands are dynamically allocated to satisfy application demands. To this end the graphics driver will frequently need to allocate locked-down (i.e., non-swappable) physical system memory pages – typically from a cacheable non-paged pool. The locked pages required to back large surfaces are typically non-contiguous. Therefore a means to support “logically-contiguous” surfaces backed by discontiguous physical pages is required. The Graphics Translation Table (GTT) that was described in previous sections provides the means.

Optimizing Main Memory Allocation

This section includes information for software developers on how to allocate SDRAM Main Memory (SM) for optimal performance in certain configurations. The general idea is that these memories are divided into some number of page types, and careful arrangement of page types both within and between surfaces (e.g., between color and depth surfaces) will result in fewer page crossings and therefore yield somewhat higher performance.

The algorithm for allocating physical SDRAM Main Memory pages to logical graphics surfaces is somewhat complicated by (1) permutations of memory device technologies (which determine page sizes and therefore the number of pages per device row), (2) memory device row population options, and (3) limitations on the allocation of physical memory (as imposed by the OS).

However, the theory to optimize allocation by limiting page crossing penalties is simple: (a) switching between open pages is optimal (again, the pages do not need to be sequential), (b) switching between memory device rows does not in itself incur a penalty, and (c) switching between pages within a particular bank of a row incurs a page miss and should therefore be avoided.

Application of the Theory (Page Coloring)

This section provides some scenarios of how Main Memory page allocation can be optimized.

3D Color and Depth Buffers

Here we want to minimize the impact of page crossings (a) between corresponding pages (1-4 tiles) in the Color and Depth buffers, and (b) when moving from a page to a neighboring page within a Color or Depth buffer. Therefore corresponding pages in the Color and Depth Buffers, and adjacent pages within a Color or Depth Buffer should be mapped to different page types (where a page's "type" or "color" refers to the row and bank it's in).

Media/Video

The Y surfaces can be allocated using 4 page types in a similar fashion to the Color Buffer diagram. The U and V surfaces would split the same 4 page types as used in the Y surface.

Physical Graphics Address Types

The Physical Memory Address Types table lists the various *physical* address types supported by the integrated graphics device. Physical Graphics Addresses are either generated by Logical Memory mappings or are directly specified by graphics device functions. *These physical addresses are not subject to tiling or GTT re-mappings*.

Physical Memory Address Types

Address Type	Description	Range
MM_Address	Main Memory Address. Offset into physical, *unsnooped* Main Memory.	[0,TopOfMemory-1]
SM_Address	System Memory Address. Accesses are snooped in processor cache, allowing shared graphics/ processor access to (locked) cacheable memory data.	[0,512GB]

Graphics Translation Tables

The Graphics Translation Tables GTT (Graphics Translation Table, sometimes known as the global GTT) and PPGTT (Per-Process Graphics Translation Table) are memory-resident page tables containing an array of DWord Page Translation Entries (PTEs) used in mapping logical Graphics Memory addresses to physical memory addresses, and sometimes snooped system memory “PCI” addresses.

The base address (MM offset) of the GTT and the PPGTT are programmed via the PGTBL_CTL and PGTBL_CTL2 MI registers, respectively. The translation table base addresses must be 4KB aligned. The GTT size can be either 128KB, 256KB, or 512KB (mapping to 128MB, 256MB, and 512MB aperture sizes respectively) and is physically contiguous. The global GTT should only be programmed via the range defined by GTTMMADR. The PPGTT is programmed directly in memory. The per-process GTT (PPGTT) size is controlled by the PGTBL_CTL2 register. The PPGTT can, in addition to the above sizes, also be 64KB in size (corresponding to a 64MB aperture). Refer to the GTT Range chapter for a bit definition of the PTE entries.

Virtual Memory

This section describes the different paging models, their behaviors, and the page table formats.

GFX Page Tables

GPU supports three page table mechanisms

- PPGTT – per process GTT (private GFX)
- GGTT- global GTT

All page tables have the same PTE format, the difference was how to reach the final physical page and which fields with PTE are used.

Page Table Modes

The GFX Aperture and Display accesses are always mapped thru Global GTT. This is done to keep the walk simple (i.e. 1-level), however GT accesses to memory can be mapped via Global GTT and/or ppGTT with various addressing modes.

The walk modes are listed as following:

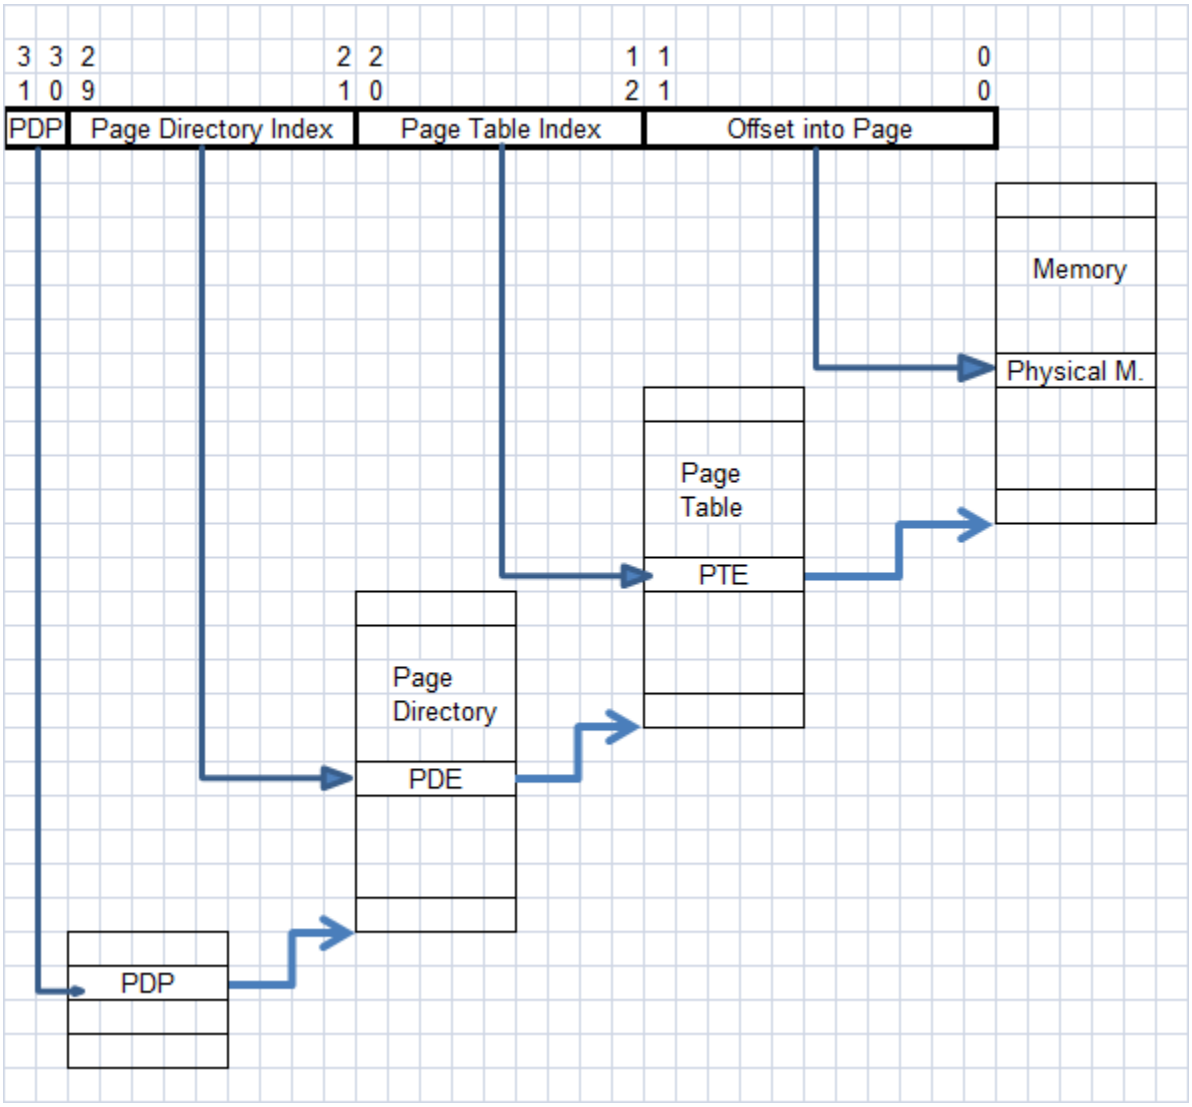
1. **Global GTT with 32b virtual addressing**: Global GTT usage is similar to pre-CHV, BSW behavior with extended capability to increase the VA to 4GB (from 2GB) and use a similar 64b PTE as ppGTT. The breakdown of the PTE for global GTT is given in later sections but fundamentally allows 1-level pagewalk where the 20b index is used to select the 64b PTE from stolen memory.
2. **Legacy 32b VA with ppGTT**: This is a mode where ppGTT page tables are managed via GFX s/w (driver) and context is tagged as Legacy 32b VA. Given each page walk is managed via 9b of the virtual address, 20b index is broken into 3 parts. However to optimize the walks and make it look like pre-CHV, BSW, s/w provides 4 pointers to page tables (called 4 PDP entries) – GPA. GFX h/w uses the four pointers and fetches the 4x4KB into h/w (for render and media) before the context execution starts. The optimization limits the dynamic (on demand) page walks to 1-level only.

Per Process GTT

Per process GTT mechanism has multiple hooks and mechanisms for s/w to prepare the page walks on hardware. The listed mechanisms here are selectable per-context and descriptors are delivered to hardware as part of context descriptor.

PPGTT for 32b Virtual Address

This page walk mechanism will be used for traditional 3D, Media type context. There is going to be a descriptor in the context header which will define the per process GTT walk that is required. For the standard context with 32bit virtual addressing, there is a possibility to take short cuts to reduce the overhead of the walk.



With 32-bit addressing the only entries that are needed for page directory pointers are 4x64bit locations (PDPE). For any standard context scheduling, it is required for s/w to provide 4 PDPEs as part of the context which would prevent h/w to do additional walks.

Hardware will do the remaining walks for PD and PTE similar to legacy behavior. In order to reduce the overhead of walks, hardware implements large caches for PDs.

Hardware does the remaining walks for PD and PTE similar to legacy behavior. To reduce the overhead of walks, hardware implements large caches for PDs:

- 4x4KB for 3D context
- 2x4x4KB for Media Context
- 4KB for VEBOX
- 4KB for Blitter

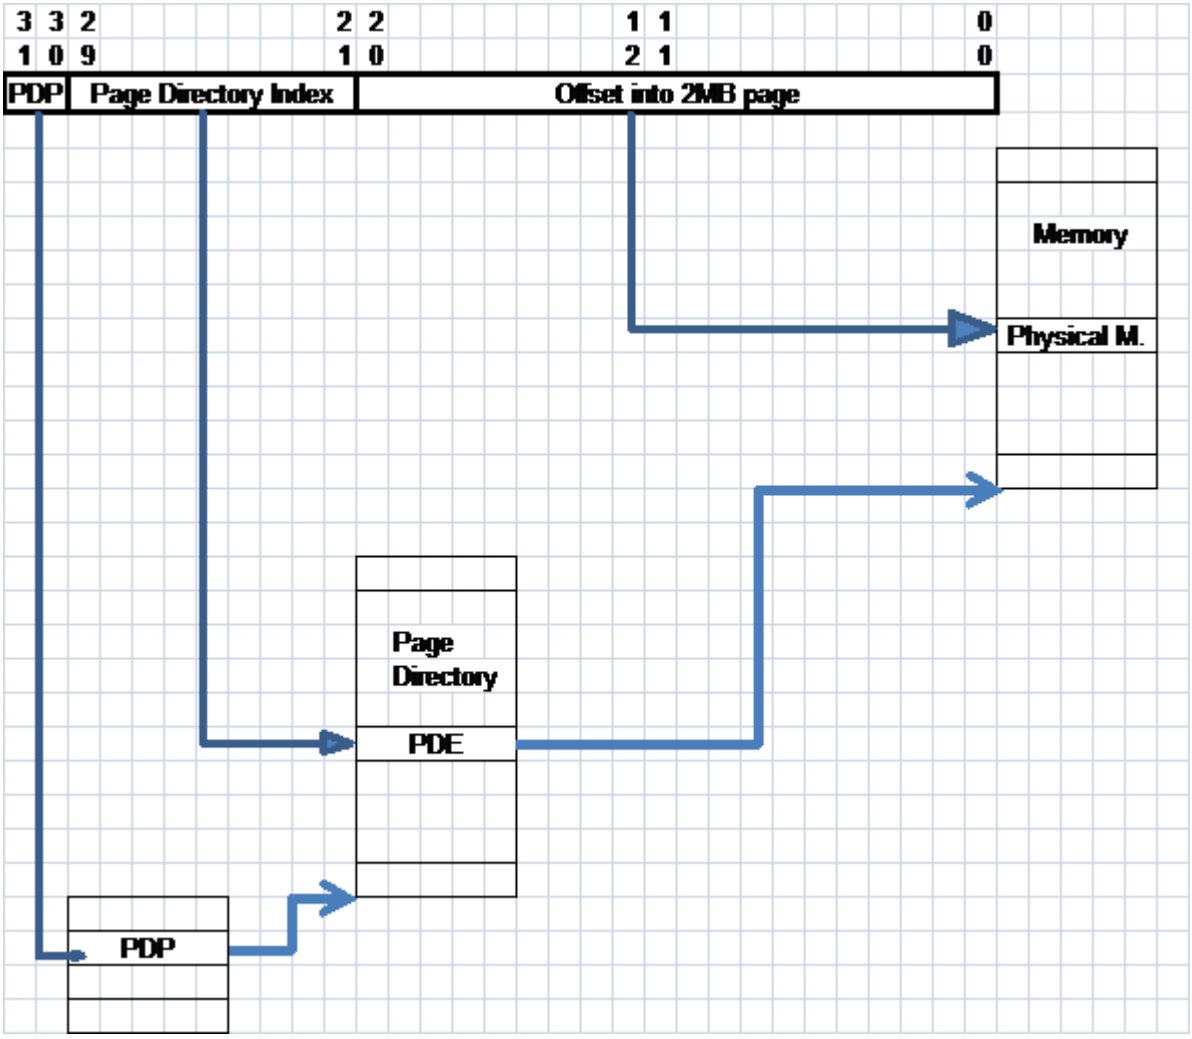
For Media and 3D context, the 16KB caches are preloaded for the entire page directory set up which limits the walk to 1-level before the final access. For remaining clients the PD cache is loaded on demand and can contain up to 512 entries.

Walk with 64KB Page

64KB Page size has a slightly different usage for how PTEs are selected for the corresponding 64KB page. In page table every 16th entry (PTE#0, PTE#16, PTE#32….PTE#496) should be used to index. This is calculated using address[21:16]& “0000”. Note that hardware should not make any assumptions for any other PTEs.

Walk with 2MB Page

There is an option in the page walk to work with bigger page sizes, one of those sizes is 2MB pages. If allocated the page directory entry will indicate the page size and walk can be shortened as follows:

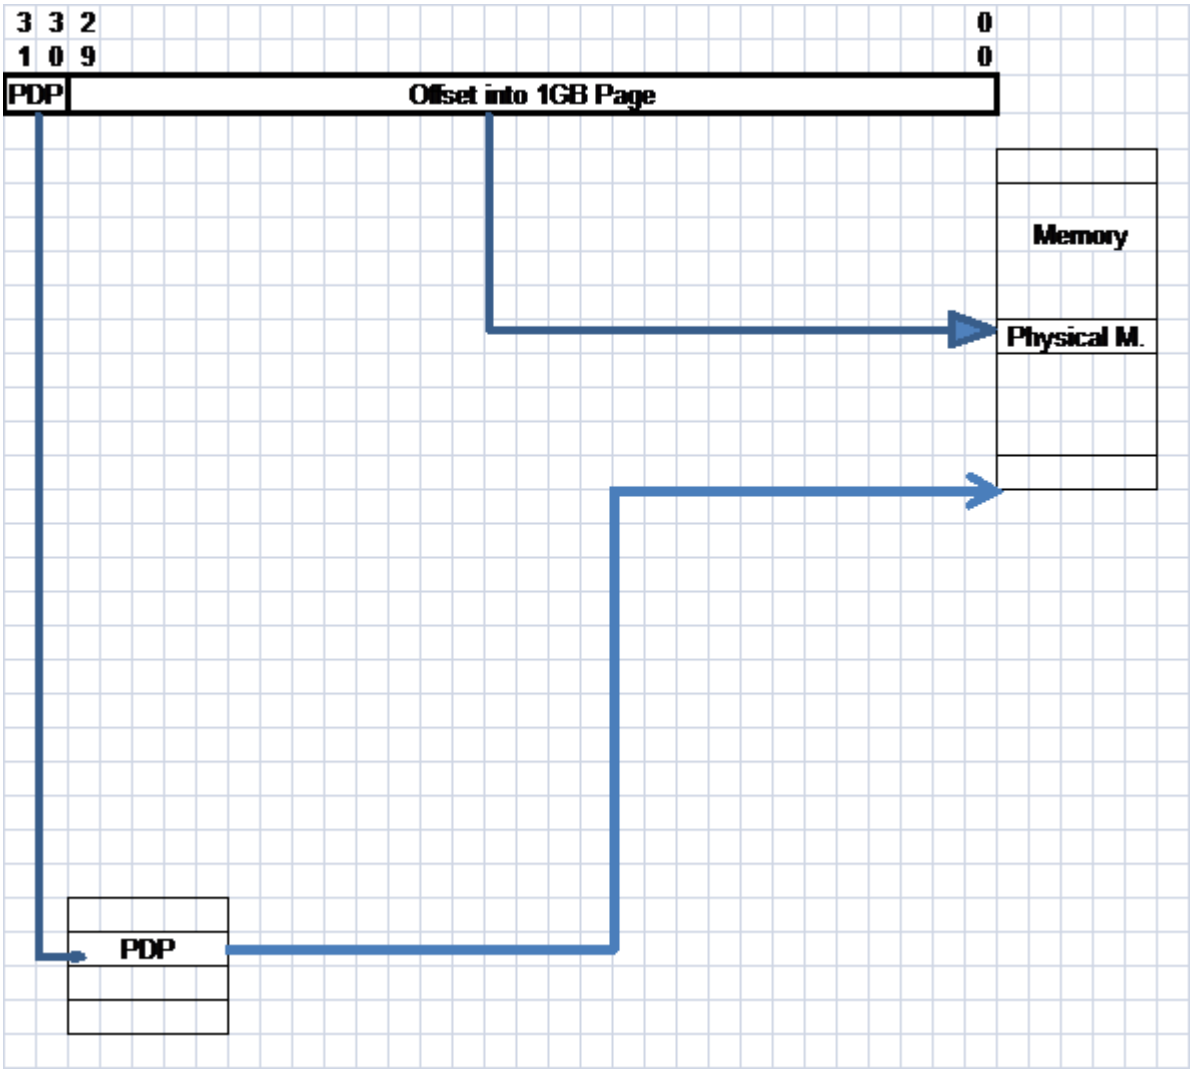


In this case there is no need to walk the page table after directory. And page directory has a pointer to 2MB range is physical memory.

Programming Note	
Context:	Walk with 2MB Page.
PPGTT32 is not going to support 2MB pages.	

Walk with 1GB Page

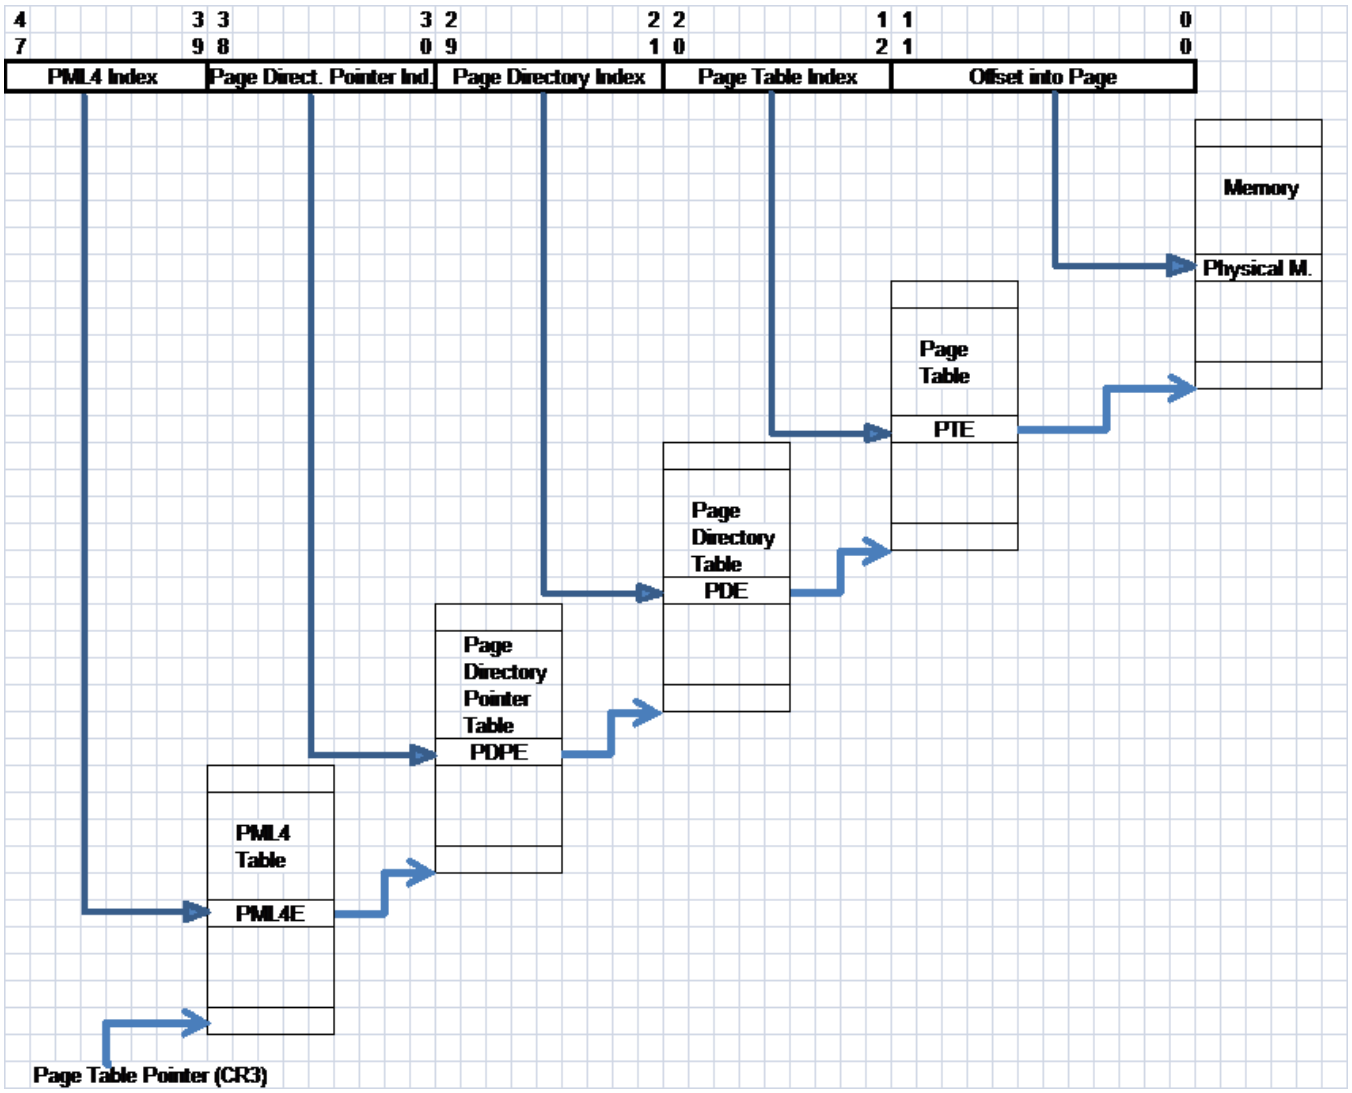
The same page walk is possible with 1GB page support as well.



Programming Note	
Context:	Walk with 1BG Page.
PPGTT32 is not going to support 1GB pages	

PPGTT for Standard Context (64b VA)

For advanced virtual addressing with legacy context, the full page walk mechanism needs to be exercised based on 48-bit canonical addressing.



64-bit (48b canonical) address requires 4-levels of page table format where the context carries a pointer to highest level page table (PML4 pointer or CR3). The rest of the walk is normal page walk thru various levels.

To repurpose the caches the following mechanism will be used:

- 3D: 4KB to store PML4, 4KB as PDP cache, 2x4PD cache.
- Media: 4KB to store PML4, 4KB as PDP cache, 2x4PD cache.
- VEBOX, Blitter: each with 4KB acting as PML4, PDP, PD cache.

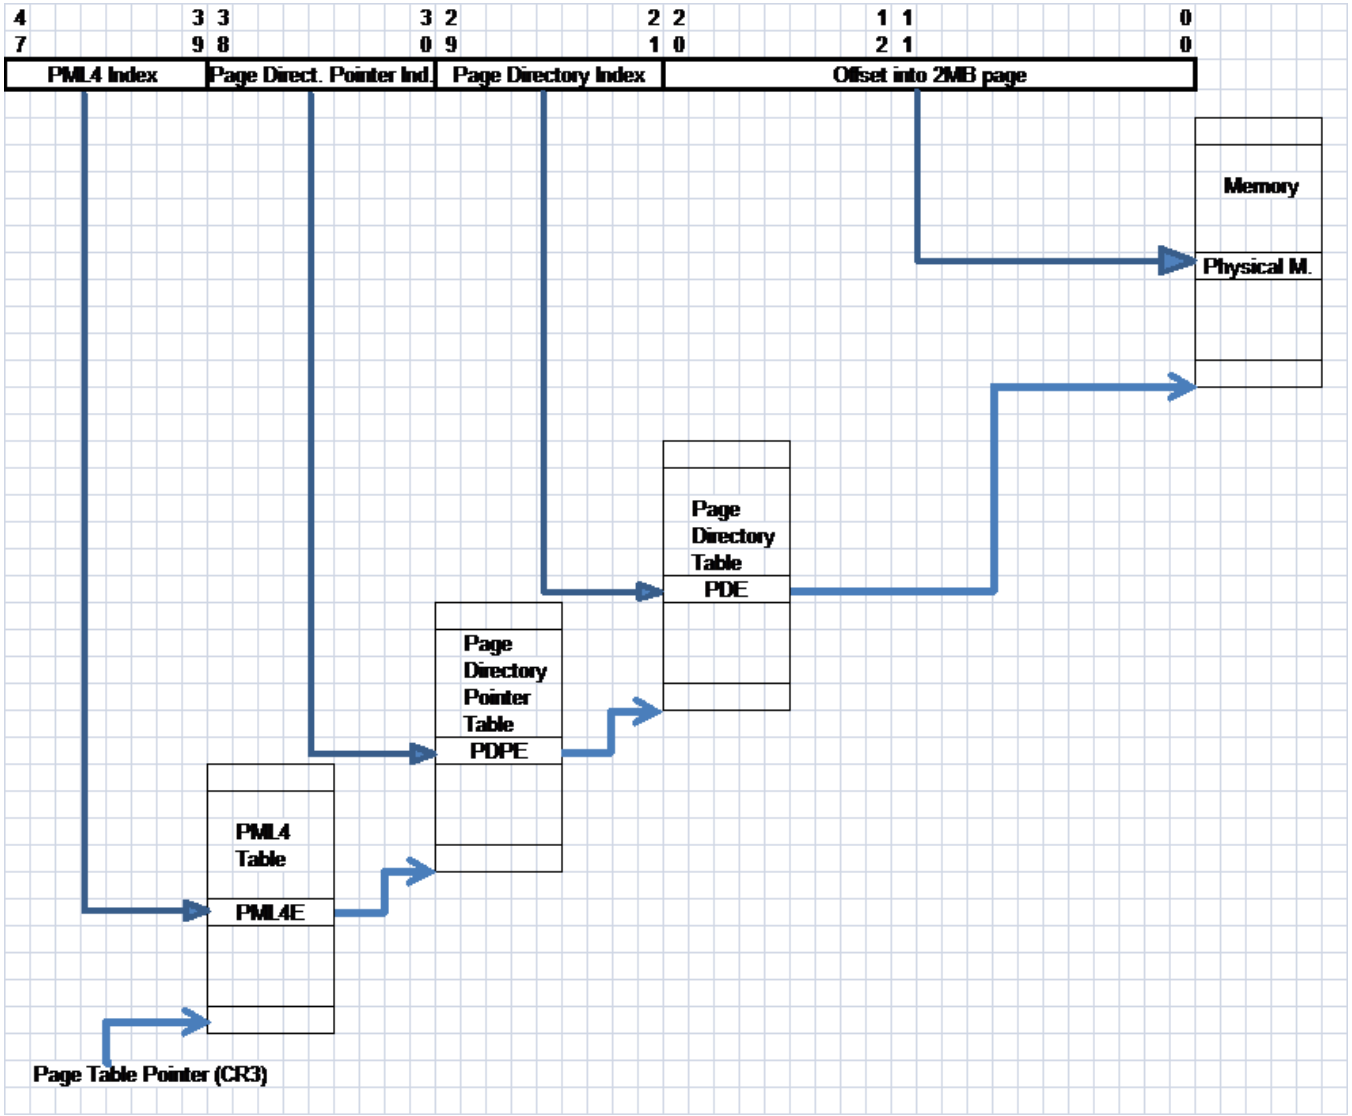
Programming Note	
Context:	PPGTT for Standard Context (64b VA)
Design can section the 512 entries within 4KB to separate areas for PML4, PDP, and PD.	

Walk with 64KB Page

64KB Page size has a slightly different usage for how PTEs are selected for the corresponding 64KB page. In page table every 16th entry (PTE#0, PTE#16, PTE#32….PTE#496) should be used to index. This is calculated using address[21:16]& "0000". Note that hardware should not make any assumptions for any other PTEs.

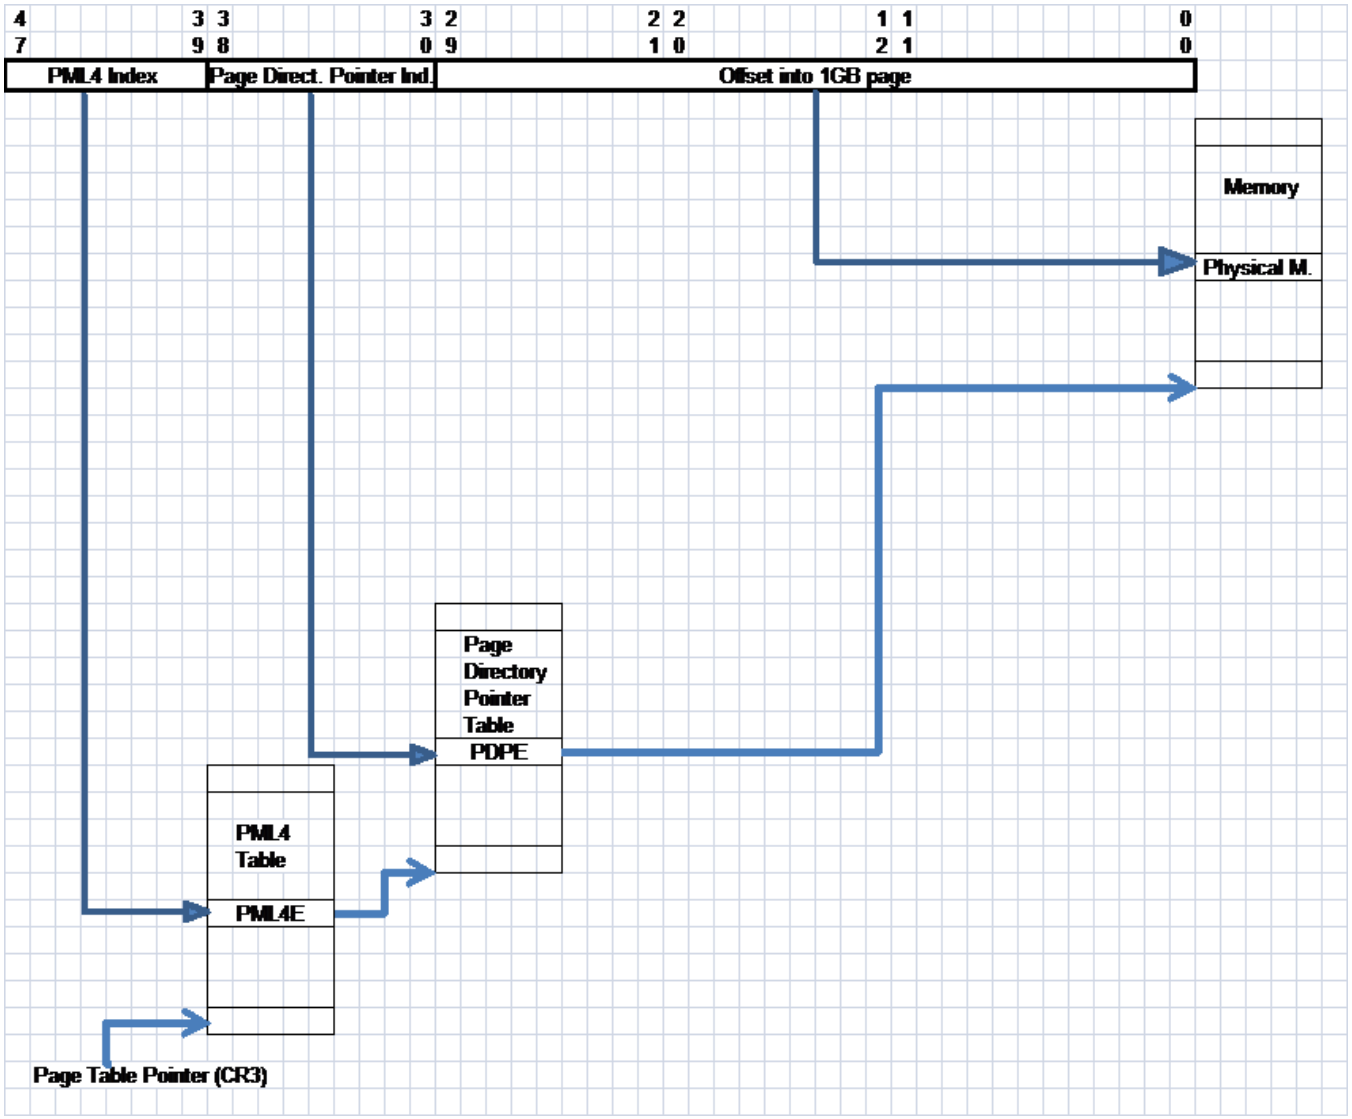
Walk with 2MB Page

Similar to the 32b VA walk, there is a support for larger pages where one of the sizes supported is 2MB.



Walk with 1GB Page

For the support for 1GB page size, the following mechanism is needed.



Programming Note	
Context:	Walk with 1 GB Page
PPGTT32 is not going to support 1GB pages.	

Global GTT

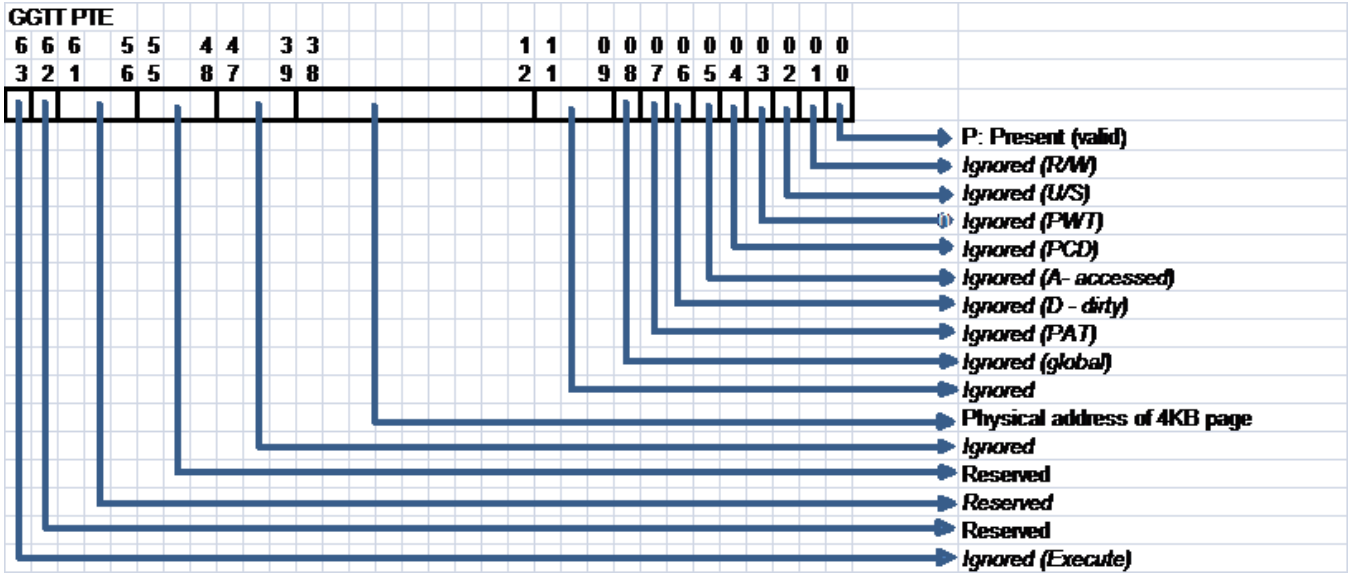
The Global GTT mechanism in CHV, BSW looks very similar to pre-CHV, BSW with the distinction of page table entry. Aperture and display will still use the global GTT even if GT core is mapped via per-process GTT.

The PTE format for CHV, BSW is updated to match per process GTT definitions and GSM is now expanded in size (2MB=>8MB) to cover for the entire 4GB (32b virtual addressing) space. Each entry corresponding to a 4KB page with 2^20 entries in GSM (each with 8B content)

For "*MI_update_GTT*", the page address provided 31:12 need to be shifted down to 22:3 for the correct QW position within the GGTT.

Page Table Entry

The following page table entry will be used for Global GTT:



- Present (Valid): The pointed PTE is valid
- *Ignored* - R/W (Read/Write): Are writes allowed to the region defined by this 4KB page. For GFX, in order 4KB memory to be usable it has to be both present and should also be write-able.
- *Ignored* - U/S (User/Supervisor access rights) : iGFX does not use these fields
- PWT/PCD/PAT bits are used as indexes into a PAT register which defines the cache attributes for the entire context.

PAT field is used to do the look up in private PAT for memory typing.

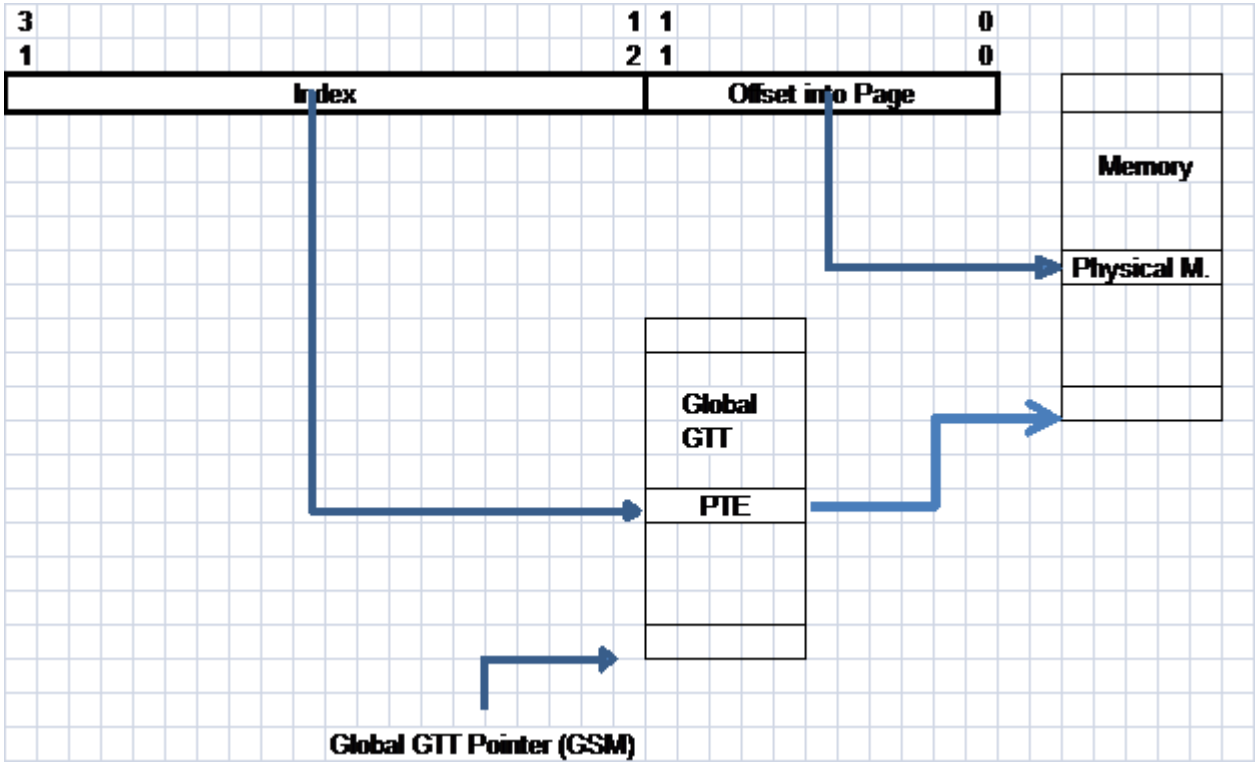
- *Ignored* - A (Accessed): It needs to be managed as the page table being accessed. Hardware needs to write this bit for the first access to the 4KB region defined with this PT entry.
- *Ignored* - D (Dirty): Hardware needs to set the dirty bit in page table if accessing this particular 4KB region in memory with the intention to modify it.
- *Ignored* - Global: this is not used by iGFX hardware, the field is used to identify global context where invalidation may not be required.
- Physical address of 4KB page

For the treatment of the page bit0 AND bit1 defines the validity of the page, the rest of the information is not relevant for Aperture and Display usage.

GGTT table entries are always read as uncacheable.

Page Walk

The global GTT page walk is identical to what it was before CHV, BSW. The only difference would be that each entry is 8B (instead of 4B) hence the entry selection needs to be updated once the corresponding Page Table miss read is returned.



GTT Cache

Processor graphics page walker implements a GTT cache which holds the remaining entries that are read as a cacheline but not used for the immediate page walk. This is only applicable in case of leaf walks and not including the 2MB/1GB page sizes. When s/w enables the use of 2MB/1GB page sizes, it will have to disable the GTT cache in CHV, BSW.

GFX Page Walker (GAM)

GPU supports various engines behind the same page walker. These streams/contexts are identified Client level IDs which are carried via the arbitration pipeline. Page walker using look-up tables does the correct selection for the page tables in case of concurrent context are running at the same time.

There are two different types of page table types:

Global graphics translation table (GGTT) is a single common translation table used for all processes. There can be many Per-process graphics translation table (PPGTT). This requires an additional lookup for translation. The actual location is not accessible directly via software since they're both located in graphics stolen memory (see graphics memory interface chapter for more detail).

Virtual Memory Structure	Memory Location
Global (GGTT)	GSM Only
Per-Process (PPGTT) – private	2 to4-level, Page Tables anywhere
Per-Process (IA32e) – shared	4 levels, Page Tables anywhere

IA32e compatible PPGTT is added to CHV, BSW to enable SVM (shared virtual memory) functions.

Context Definition for GFX Page Walker

Page Walker blocks need details about the context to decide on what type of page tables will be used, what would be the error handling cases would be and many other details to operate. The information will be passed to Page Walker (GAM) by the respective command streamer/DMA.

GAM supports the following engines:

- Render
- Media (VDBox) x2
- Blit
- VEBOX x2

The following fields will be sent to GAM:

- Context type (4 bits)
    - **Legacy vs Advanced Context**: Defines the context type and qualifies the rest of the fields. Same field may mean something else between the *Legacy* vs *Advanced* context. There is no restriction for what type of context can run in either combination.
        - *Requests without address-space-identifier (Legacy Context)*: These are the normal memory requests from endpoint devices. These requests typically specify the type of access (read/write/atomics), targeted DMA address/size, and identity of the device originating the request.
        - *Requests with address-space-identifier (Advanced Context)*: These are memory requests with additional information identifying the targeted process address space from endpoint devices supporting virtual memory capabilities. Beyond attributes in normal requests, these requests specify the targeted process address space identifier (PASID), and extended attributes such as Execute-Requested (ER) flag (to indicate reads that are instruction fetches), and Privileged-mode-Requested (PR) flag (to distinguish user versus supervisor access). For details, refer to the Process Address Space ID (PASID) Capability in the PCI-Express specifications.

Note CHV, BSW LP only supports Legacy PPGTT with 32b virtual addressing.

    - **A/D Support Enable**: Access and Dirty bits are used when OS managing the page tables and has been added to IA32e compatible page walk. Context will define whether A/D bits need to be managed via GPU. (only applicable in Advanced Context)
    - **Privileged Context Support**: Enables GPU to be able to run a privileged context which will translate into page table accesses regardless of user vs supervisor privileges. (only applicable in Advanced Context).
    - **32b vs 48b VA Support**: Enables 48b VA in page tables for the page walks. The rest of the h/w is seamless to 32b vs 48b VA address walks, however GAM will do the check and properly align the page walk to address bits.
        - *Note: Only applicable in Legacy Context, Advanced context is always 48b*.
        - Note: CHV, BSW LP only supports 32b VA
- **Function Number**: 3 bit field that defines the function number of the device. GFX device is always on BUS=0 and DEVICE=2. If we are not virtualized, our FUNCTION#=0 however if virtualized function number can be any 8 possible values (i.e. 0-7). The BUS/DEVICE/FUNCTION numbers are used to the initial walk for ROOT and CONTEXT tables.

- **PASID** – Process Address Space IDentifier: Use to identify the context that is submitted to h/w. We use the PASID in many places where during the page walk (i.e. PASID table look up) or while communicating with s/w on page faults. Each engine could be running an independent context with different PASID. The page walker should have a mechanism to be able to cache at least some number of PASID table entries (matching to the engine count) for faster walk.
- **Context ID** (Queue ID, Bell ID) – Context ID is used to further qualify the running context beyond the PASID. PASID is given per process, and same process may allocate multiple queues to communicate with h/w. The only way to further identify the process is to use an additional ID. For GFX h/w Context ID could be same as the bell number assigned to it. GAM h/w will use the context ID to populate the queue ID field while communicating page faults to s/w.
- **Page Table Pointers** – The field could be up to 256 bits (i.e. 4x64bits) to identify the page table pointers associated with the context. For legacy 32b context, the entire 256b is valid representing the 4 PDPTR table entries. For 48b legacy context only the lower 64b is relevant pointing to base of PML4. In case of advanced context, PASID is given in the context definition.

Context Definition Delivery

Context Definition is supposed to be delivered from the corresponding command streamer to GAM and GAM has independent storage for each engine present. Context Definition will be given by *CS to GAM via a new message:

Message: "Context Available"

GAM prepares for new context, cleans up internal state and does the proper fencing. Most of these steps should have been performed when context switch request was done for the previous context, but added here for completeness.

Message: "Context Receive Ready"

GAM is ready for the context. *CS writes all new context values into the descriptor registers. To push all context descriptors CS sends the following message to GAM also indicating new context descriptor is downloaded.

Message: "Context Launched"

GAM does the context requirements and sends the following message to CS to resume its command parser.

Message: Context Confirmed

GAM should send context confirmed message only after PD restore is done. CS waiting for context confirmed message will be treated as PD restore busy. Since all clients memory interface are blocked during PD restore it doesn't make any difference if the context confirmed message is send by GAM immediately or after PD restore.

Element Descriptor Register

General Description	Element Information: The register is populated by command streamer and consumed by GAM
Register Offset	See per engine list below

Bits	Access	Default	Field
63:32	RO	Xh	**Context ID:** Context identification number assigned to separate this context from others. Context IDs needs to be recycled in such a way that there could not be two active context with the same ID. This is a unique identification number by which a context is identified and referenced
31:12	RO	Xh	**LRCA:** Command Streamer Only
11:9	RO	Xh	**Function Number:** GFX device is considered to be on Bus0 with device number of 2. Function number is normally assigned as “0” however for gfx virtualization; there would be different function numbers which needs to be attached to context. Not used in CHV, BSW.
8	RO	Xh	**Privileged Context / GGTT vs PPGTT mode:** Differs in legacy vs advanced context modes: **In Legacy Context**: Defines the page tables to be used. This is how page walker come to know PPGTT vs GGTT selection for the entire context. “0”: Use Global GTT “1”: Use Per-Process GTT **In Advanced Context**: Defines the privilege level for the context “0”: user mode context “1”: supervisor mode context.
7:6	RO	Xh	**Fault Model:** “00”: Fault & Hang (chicken bit to survive). Same mode as gen7.5

Bits	Access	Default	Field
			"01": Fault & Halt/Wait. Same mode as gen7.5 "10": Fault & Stream & Switch "11": Fault & Continue: does not generate a page request to IOMMU.
5	RO	Xh	**Deeper IA coherency Support:** **In Advanced Context:** Defines the level of IA coherency "0": IA coherency is provided at LLC level for all streams of GPU (i.e. gen7.5 like mode) "1": IA coherency is provided at L3 level for EU data accesses of GPU
4	RO	Xh	**A&D Support / 32&64b Address Support:** Differs in legacy vs advanced context modes: **In Legacy Context**: Defines 32b vs 64b (48b canonical) addressing format "0": 32b addressing format "1": 64b (48b canonical) addressing format **In Advanced Context**: Defines A&D bit support "0": A&D bit management in page tables is NOT supported "1": A&D bit management in page tables is supported.
3	RO	Xh	**Context Type: Legacy vs Advanced** Defines the context type. "0": Advanced Context: Defines the rest of the advanced capabilities (i.e. OS page table support, fault models…). Note that advanced context is not bounded to GPGPU. "1": Legacy Context: Defines the context as legacy mode which is similar to prior generations of CHV, BSW. *Note that: Bits [8:4] differs in functions when legacy vs advanced context modes are selected.*
2	RO	Xh	**FR:** Command streamer specific
1	RO	Xh	**Scheduling Mode:** "1": Indicates execlist mode of scheduling. "0": Indicates Ring Buffer mode of scheduling.
0	RO	Xh	**Valid:** Indicates that element descriptor is valid. If GAM is programmed with an invalid descriptor, it will continue but flag an error.

PDP0/PML4/PASID Descriptor Register

General Description	PDP0/PML4/PASID: The register is populated by command streamer and consumed by GAM. It contains one of the 3 values which is determined by looking at the element descriptor.
Register Offset	See per engine list below

Bits	Access	Default	Field
63:0	RO	Xh	**PDP0/PML4/PASID:** This register can contain three values which depend on the element descriptor definition. **PASID[19:0]**: Populated in the first 20bits of the register and selected when Advanced Context flag is set. **PML4[38:12]:** Pointer to base address of PML4 and selected when Legacy Context flag is set and 64b address support is selected **PDP0[38:12]:** Pointer to one of the four page directory pointer (lowest) and defines the first 0-1GB of memory mapping *Note: This is a guest physical address* *(unused bits need to be populated as 0's)*

PDP1 Descriptor Register

General Description	PDP1: The register is populated by command streamer and consumed by GAM. It contains one of the pointers to PD.
Register Offset	See per engine list below

Bits	Access	Default	Field
63:12	RO	Xh	**PDP1:** Pointer to one of the four page directory pointer (lowest+1) and defines the first 1-2GB of memory mapping *Note: This is a guest physical address* *(unused bits need to be populated as 0's)*

PDP2 Descriptor Register

General Description	PDP2: The register is populated by command streamer and consumed by GAM. It contains one of the pointers to PD.
Register Offset	See per engine list below

Bits	Access	Default	Field
63:12	RO	Xh	**PDP2:** Pointer to one of the four page directory pointer (lowest+2) and defines the first 2-3GB of memory mapping *Note: This is a guest physical address* *(unused bits need to be populated as 0's)*

PDP3 Descriptor Register

General Description	PDP3: The register is populated by command streamer and consumed by GAM. It contains one of the pointers to PD.
Register Offset	See per engine list below

Bits	Access	Default	Field
63:12	RO	Xh	**PDP3:** Pointer to one of the four page directory pointer (lowest+3) and defines the first 3-4GB of memory mapping *Note: This is a guest physical address* *(unused bits need to be populated as 0's)*

List of Registers and Command Streamers

The following registers are message registers and not written directly by software.

Engine	Offset	Description
Render	x4400h	Element Descriptor Register
	x4408h	PDP0/PML4/PASID Descriptor Register
	x4410h	PDP1 Descriptor Register
	x4418h	PDP2 Descriptor Register
	x4420h	PDP3 Descriptor Register
Media0 (VDBOX0)	x4440h	Element Descriptor Register
	x4448h	PDP0/PML4/PASID Descriptor Register
	x4450h	PDP1 Descriptor Register
	x4458h	PDP2 Descriptor Register
	x4460h	PDP3 Descriptor Register
Media1 (VDBOX1)	x4480h	Element Descriptor Register
	x4488h	PDP0/PML4/PASID Descriptor Register
	x4490h	PDP1 Descriptor Register
	x4498h	PDP2 Descriptor Register
	x44A0h	PDP3 Descriptor Register
VEBOX	x44C0h	Element Descriptor Register
	x44C8h	PDP0/PML4/PASID Descriptor Register
	x44D0h	PDP1 Descriptor Register
	x44D8h	PDP2 Descriptor Register
	x44E0h	PDP3 Descriptor Register
Blitter	x4500h	Element Descriptor Register
	x4508h	PDP0/PML4/PASID Descriptor Register
	x4510h	PDP1 Descriptor Register
	x4518h	PDP2 Descriptor Register
	x4520h	PDP3 Descriptor Register

Updating Page Table Pointers (aka PD Load)

In case of legacy context, driver is allowed to add/remove pages as long as it is ensured that h/w is not using these entries. Pre-CHV, BSW flow allowed a mid-context PD load to update the PD entries and directed h/w to reload updated entries. CHV, BSW legacy context will require a similar mechanism.

Instead of a PD load, the new mechanism will let the driver update the page table pointers via sending a reload command. Mechanism will be overlapped to same sort messaging between CS and GAM to deliver the context header. CS will send the following message to GAM:

Message: Context Reload

GAM will respond immediately to CS with the following message

Message: Context Confirmed

Meanwhile GAM will block the related interfaces and updates the PDs or PML4.

Page Walker (GAM) Reset

GAM gets all the engine specific resets as well as device and bus resets to manage its internal logic domains. It is the expectation of SW when a particular GPU engine (i.e. Render, Media, ...) gets reset, all its related HW is cleared and comes out fresh for reprogramming. That is true for most of the logic with the exception of some shared HW blocks. The following blocks require additional steps (post-reset) from SW to further clean-up the HW:

- **Hardware TLBs:** The caching structures for the page walks are often considered shared resources. The expectation is for GFX driver to clear the TLBs via "TLB Invalidate" prior to reusing the engine post reset. This is the same process that was followed on previous GPU generations.
- **Page Requests:** At the time of the reset HW may have outstanding page requests to SW for page faulted accesses. These requests could be at any level hence it is required for SW to clear these paging requests pre/post-engine reset. Engine reset ensures no new page requests would be sent from HW. Page requests could be at the "page request queue" in memory where they could be mapped to a dummy page post engine reset completion. Or they could be at the MMIO registers which will block the completion of the reset; it is up to SW to service paging request interrupts without waiting for the completion of reset request.

Device reset (FLR) covers most of the page walker, however there are exceptions where IOMMU structures and all messaging towards rest of the system (system agent) should not be impacted by it. All external interactions and IOMMU related blocks are kept under bus (system) reset. GAM will keep the following blocks outside the device reset:

- IOMMU registers and content.
- All system agent messaging structures (including translation enable flows, root pointer structures, DMA fault reporting pieces.).

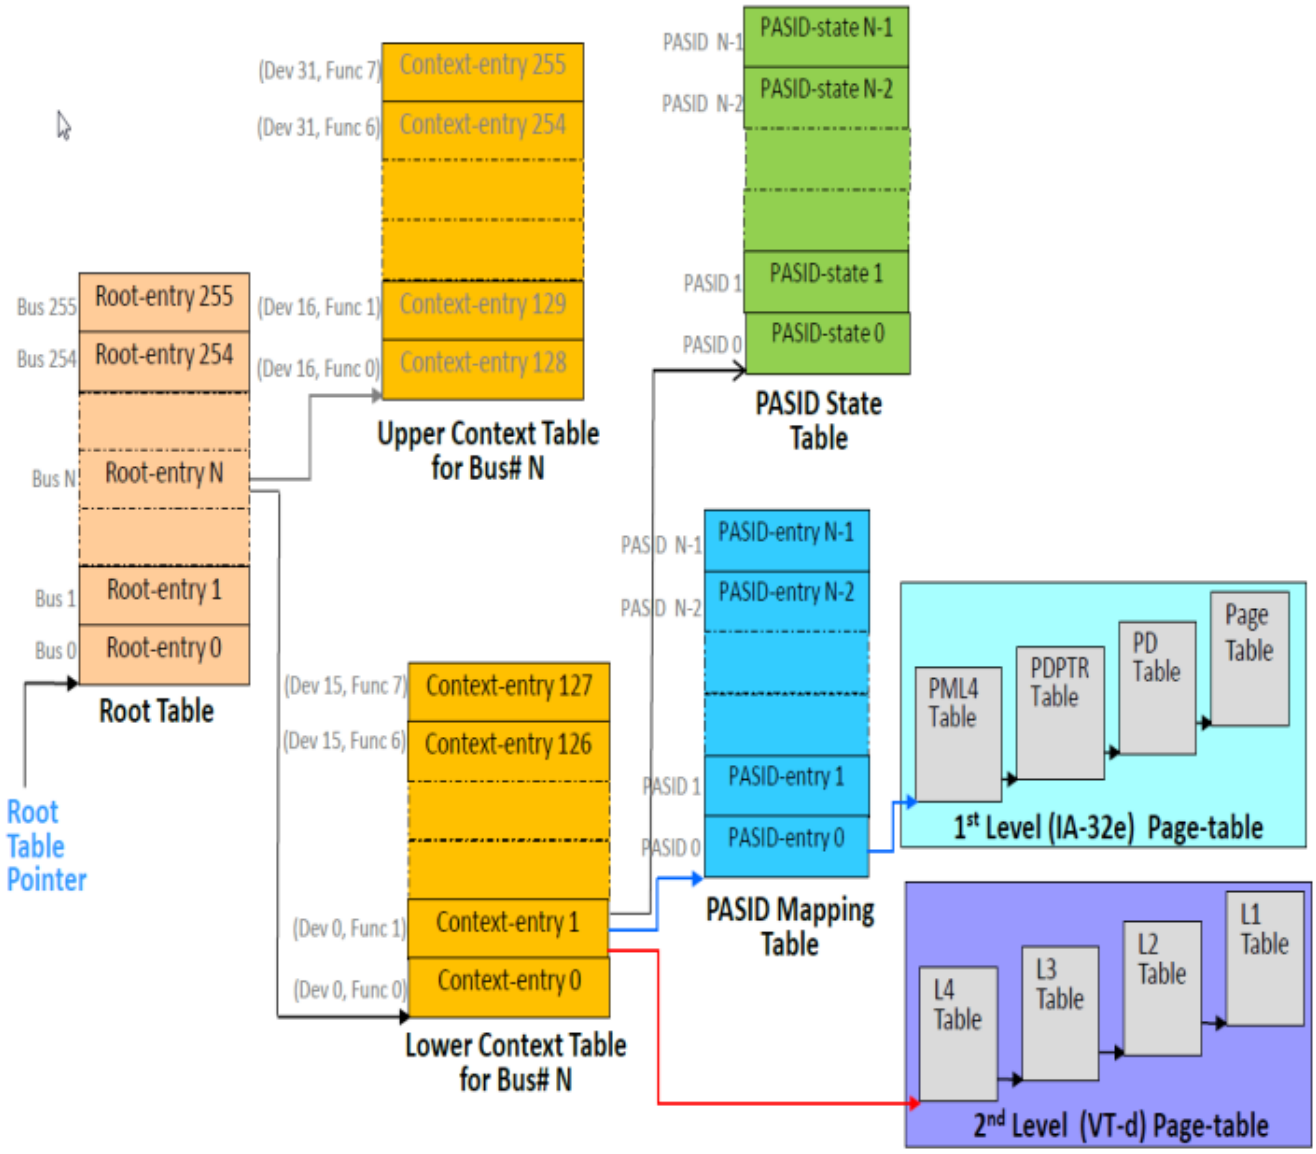
An engine being reset also means the particular context that engine is running, is complete or taken out. That will require GAM to decrement the PASID_State Counter if the engine was running a PASID based (advanced) context. For FLR (device reset), a similar requirement holds. In case of device reset, GAM would need to decrement all the PASID state counters that are active on the GPU before completing the sequence.

Legacy Context

Legacy context could use either Global GTT or Per Process GTT which is given to page walker as part of the context descriptor. Even under PPGTT, there could be accesses from Command Streamers that would require to use Global GTT which requires to treat the walk requirement per transaction.

For Legacy context indicator command streamer is going to pass the "context type" information along with other parameters that defines how certain behavior for paging needs to be.

Full Walk



In the full walk case (i.e. advanced context), the root of the 1st and 2nd level page tables share a common source. Both the root table and context table is walked with the assumption of GFX device is always on Bus#0 and it is always Device#2.

Function number however is part of the context and it can be non-Zero only for virtualized modes. GAM will receive the function number (for Context table look-up) as part of the context. Both Root entry and Context Entry should be fetched along with PASID Table entry prior to running the context accesses.

TLB Caching and Management

As compared to previous generation of TLB entry, IA32e page translation entry is quite different. At every stage of the page different bits need to be taken into account and proper treatment is required. Regardless of PPGTT vs GGTT usage, the paging entry has the same format. Linear address are translated using a hierarchy of in-memory paging structures located using the contents of CR3. IA-32e paging translates 48-bit linear addresses to 52-bit physical addresses. Although 52 bits corresponds to 4 PBytes, linear addresses are limited to 48 bits; at most 256 TBytes of linear-address space may be accessed at any given time. IA-32e paging may map linear addresses to 4-KByte pages, 2-MByte pages, or 1-GByte pages.

63	62–(M-1)	(M-1)–12	11–8	7	6	5	4	3	2	1	0	
Reserved[2]		Address of PML4 table		Ignored			PCD	PWT	Ign.			CR3
XD	Ignored	Rsvd.	Address of page-directory-pointer table		Ign.		Rsvd	Ign	A	PCD	PWT	U/S	R/W	1	PML4E: present
Ignored														0	PML4E: not present
XD	Ignored	Rsvd.	Address of 1GB page frame	Reserved		PAT	Ign.	G	1	D	A	PCD	PWT	U/S	R/W	1	PDPTE: 1GB page
XD	Ignored	Rsvd.	Address of page directory				Ign.		0	Ign	A	PCD	PWT	U/S	R/W	1	PDPTE: page directory
Ignored														0	PDTPE: not present
XD	Ignored	Rsvd.	Address of 2MB page frame	Reserved		PAT	Ign.	G	1	D	A	PCD	PWT	U/S	R/W	1	PDE: 2MB page
XD	Ignored	Rsvd.	Address of page table				Ign.		0	Ign	A	PCD	PWT	U/S	R/W	1	PDE: page table
Ignored														0	PDE: not present
XD	Ignored	Rsvd.	Address of 4KB page frame				Ign.	G	PAT	D	A	PCD	PWT	U/S	R/W	1	PTE: 4KB page
Ignored														0	PTE: not present

The following rules apply:

1. M is an abbreviation for MAXPHYSICAL ADDRESS.
2. Reserved fields must be "0".
3. Ignored field must be ignored. (There could be private information.)

All ignore options are part of the context entry and come from the IOMMU definition.

TLB Caches

For CHV, BSW the caching structures are separated as following with the architectural view, this is also applicable to s/w view of these caches when it comes to invalidations.

Context Cache - CC

This is the storage for context table entry which is achieved as part of root/context table walk.

Context cache can also be invalidated with directed invalidations, where HW needs to invalidate the content of the context cache along with all low level caches.

PASID Cache - PC

This is where the HW copy of the PASID table entry is kept and it is per context. This makes it unique for every HW engine that could be running an independent context (per GAM):

- Render/GPGPU
- MFX (VDBOX) – 1
- MFX (VDBOX) – 2
- Video Enhancement (VEBOX) – 1
- Video Enhancement (VEBOX) – 2
- Blitter

The cache content is updated if the corresponding engine is running an advanced context where its page table pointers are accessible via PASID table. In case of legacy context running engine, corresponding PASID Cache entry is not valid. Recommendation is to keep ONE physical storage per engine which is filled/invalidated during the context switch time.

PASID Cache can also be invalidated with the directed invalidations along with low level caches and needs to be re-filled prior to context resuming.

Intermediate Page Walk Caches (PML4, PDP, PD) – PWC

These are the stages where intermediate page walk entries are cached to speed-up/shorten the page walk when final TLB is missed. Each level can be cached separately or along with different levels, the cacheability structures will have programmability to move the boundary of different levels to accommodate more/less on each page walk level. However as a concept, for legacy 32b addressing mode, requirement is to cache 4PDPs along with 4x4KB PDs for certain engines, at least for render and media. The others will use cache concept.

TLB – Final Page Entry

The size of the TLBs has been increased over the previous generation and should be targeting the below table:

- L3 TLB: 768 TLB entries – This is where all HDC, I$, Constant, State, and Sampler streams are stored.
- MFX: 512 TLB entries – All Media streams (split 256/256 between two media engines).
- BLT: 32 entries.
- Z: 512 TLB entries – All depth accesses.
- C: 256 (256 TLB entries) – All color accesses.
- FF: 128 (128 TLB entries) – All FF accesses to memory.
- VLF: 32 (32 TLB entries) – Media surface.
- GAV: 192 (192 TLB entries) – Video enhancement. Increased compared to other Gen8 projects.
- WiDi: 64 (64 TLB entries) – Wireless Display.

All TLB entries are increased to 48b to contain larger address as well as the page attributes attached to it.

The max size of a single TLB is 256 entries, larger quantities have to be handled as set-associative storages. Set associativity is managed by low order page bits (i.e. address#12, address#13, ...).

TLB Entry Content

When a page walk entry is cached (or loaded prior to context start), certain bits need to be cached as well along with the physical address bits. The treatment on these bits would be considered when a HIT vs MISS decision needs to be made during a look up.

The purpose of caching is to accelerate the paging process by caching individual translations in **translation look-aside buffers** (**TLBs**). Each entry in a TLB is an individual translation. Each translation is referenced by a page number. It contains the following information from the paging-structure entries used to translate linear addresses with the page number:

- The physical address corresponding to the page number (the page frame).
- The access rights from the paging-structure entries used to translate linear addresses with the page number:
  - The logical-AND of the R/W flags.
  - The logical-AND of the U/S flags.
  - The logical-OR of the XD flags.
- Attributes from a paging-structure entry that identifies the final page frame for the page number (either a PTE or a paging-structure entry in which the PS flag is 1):
  - The dirty flag.
  - The memory type.

PRESENT: This is the same VALID bit description we had in previous page table designs. The lack of present bit (i.e. bit[0]=0) points that rest of the information in the page table entry is being invalid. For some fault models, even NOT PRESENT entries are cached to filter further page faults (*see fault models on caching page faulting entries*). If such entry is cached, there are couple ways that it can be removed from the page tables:

1. LRA selection where the entry becomes a victim for replacement
2. Global or Selective invalidation
3. Page fault response stating the faulting page is now fixed.

R/W Privilege: Certain pages can be allocated as read-only and write operations are not allowed. To make this check work, TLB has to keep the R/W bit. This bit has no affect on read operations; however for write operation privilege needs to be checked. If there is mis-match, the result of the TLB look-up should be a MISS. This does not mean a page fault immediately; the walk has to be re-done as for any TLB MISS result. There are cases OS may change page table privileges without invalidating pages in TLB (*note: all downgrades result in invalidation of the TLB, however upgrades can be done silently hence re-walk is required*). In case where the TLB Miss is due to privilege mis-match, the existing entry from TLB has to be invalidated and page walk will bring in the most up-to-date copy from memory.

The R/W privilege on final frame is generated as a logical-AND process of all upper page walks pointing to this location.

User vs Supervisor Privilege: The GPU typically operates in user mode when it comes to page tables. So the GTT walk can be treated as faulted when GPU encounters a page with supervisor privileges and the context is marked as user mode. The faulted entry can be cached back into TLB with "P" bit off indicating a faulted entry. However the page fault report should carry the correct reason why h/w detected the fault in the first place which was the user vs supervisor privilege. There is an option in context header to define the context as supervisor, than it legal to access supervisor pages.

- This is not stored in TLB

The U/S privilege on final frame is generated as a logical-AND process of all upper page walks pointing to this location.

Accessed Bit: This where a stage of the page walk cannot be used if the accessed bit is not set for that level in the page walk. This is true for both storage into TLB as well as to make progress on the page walk. In order to achieve the process of Accessed bit, every stage of the ppGTT read is done via a new semantics between the GAM and GTI such that GTI can atomically process A-bit w/o running into access violations. The details of the semantics are defined as part of the following sections. The "A" bit does not need to be stored as part of the TLB, just the fact that a valid page table entry is present in the TLB does mean that h/w took care off the "A" bit at the time the page was brought up to TLB. Note that TLB prefetching is disabled when A-bit management is enabled.

IA32e mode page tables cannot co-exist with TLB pre-fetching due to lack of A-bit management for all entries of the line.

- This is not stored in TLB

Dirty Bit: Similar to accessed bit, dirty bit needs to be managed. It is only applicable for "write" accesses. Given there are cases where a TLB entry was acquired as part of a read operation, the presence of D-bit should be maintained with the TLB. This gives us the capability to declare a TLB miss for a write access when the D-bit is not set even though TLB has a valid translation. In such case, The TLB entry needs to invalidated and the final stage of the walk needs to be re-done to ensure most up-to-date copy of GTT entry is brought into h/w. The operation of Dirty bit update is also atomic similar to A-bit management.

Execute (XD) Bit: XD bit is also present on every stage of the walk and applicable to executable code that GT would be fetching. In the first pass, instruction cache accesses are not allowed to proceed if the corresponding page does not have the execute credentials set properly. Similar treatment of the TLB entry as privilege bits is expected. A page entry that was already cached in TLB and later accessed for instruction space will have to check the XD bit which is also stored in TLB. If mis-match, the end result is a TLB miss and walk has to be re-done replacing the different stages of the walk.

The XD privilege on final frame is generated as a logical-OR process of all upper page walks pointing to this location.

Faulted Bit: There are usage models where the faulted entries are cached in TLB. This is to filter further faults to the same page as opportunistic way to prevent fault storms. When faulted bit is set the address is included in the TLB look up but final treatment is fault filtering. The rest of the bits are used to define what would be the reason for the fault. If the look-up conflicts with the original faulted reason, a re-walk is required. As a basic case, take a read access bringing up a PTE with W-flag cleared. A

subsequent write access has a conflict on privilege, and it will perform a re-walk. If the result of the re-walk is W-flag set, than TLB is upgraded and write makes progress. However if the result is still W-flag cleared, the write access will fault and TLB entry will be tagged as a faulted entry with only read-allowed. Subsequent write accesses will be filtered as fault but read accesses should cause a re-walk of the page and if successful, the TLB can be updated with PTE as valid with read-only attribute.

TLB Accessed and Dirty Flags

For any paging-structure entry that is used during linear-address translation, bit 5 is the **accessed** flag. For paging-structure entries that map a page (as opposed to referencing another paging structure), bit 6 is the **dirty** flag. These flags are provided for use by memory-management software to manage the transfer of pages and paging structures into and out of physical memory.

Whenever the processor and/or GPU uses a paging-structure entry as part of linear-address translation, it sets the accessed flag in that entry (if it is not already set).

Whenever there is a write to a linear address, the processor and/or GPU sets the dirty flag (if it is not already set) in the paging-structure entry that identifies the final physical address for the linear address (either a PTE or a paging-structure entry in which the PS flag is 1).

Memory-management software may clear these flags when a page or a paging structure is initially loaded into physical memory. These flags are “sticky,” meaning that, once set, the processor and/or GPU does not clear them; only software can clear them.

A processor and/or GPU may cache information from the paging-structure entries in TLBs and paging-structure caches (see Section 4.10). This fact implies that, if software changes an accessed flag or a dirty flag from 1 to 0, the GPU might not set the corresponding bit in memory on a subsequent access using an affected linear address

Accessed bit is applicable to every stage of the page walk, however the dirty bit is only applicable to final stage of the walk.

The rule states that a particular access cannot be committed until the Accessed and/or Dirty bits are not visible to page management s/w. In order for GPU to follow the rule, GTT accesses (when A/D bits are supported) are going to be done via a special cycle definition between GAM and GTI.

Updating A/D Bits

New atomic operations are added to GAM to GPU interface (GTI) to handle paging entries. GAM has to set the correct atomic opcodes based on the access type and context entry controls as well as level of access.

Requires setting for opcodes are given in the table below. The steps of operations in the atomic ALUs are given later in the document.

The Following Atomics are only applicable in GTI and used for Page Walks

R/W => Bit[0]

Extended Access required => Bit[1]

Write Protect Enable => Bit[2]

Intermediate Entry => Bit[3]

Atomic Operation	Opcode	Description	New Destination Value	Applicable	Return Value (optional)
Atomic_Page_update_0000	1100_0000	Read Access Extended Access bit is disabled Write Protection is disabled Final PTE	Set bit[5] if not set		new_dst
Atomic_Page_update_0001	1100_0001	Write Access Extended Access bit is disabled Write Protection is disabled Final PTE	Set bit[5,6] if not set		new_dst
Atomic_Page_update_0000	1100_0010	Read Access Extended Access bit is enabled Write Protection is disabled Final PTE	Set bit[5,10] if not set		new_dst
Atomic_Page_update_0001	1100_0011	Write Access Extended Access bit is enabled Write Protection is disabled Final PTE	Set bit[5,6,10] if not set		new_dst

Atomic_Page_update_0100	1100_0100	Read Access Extended Access bit is disabled Write Protection is enabled Final PTE	Set bit[5] if not set		new_dst
Atomic_Page_update_0101	1100_0101	Write Access Extended Access bit is disabled Write Protection is enabled Final PTE	Set bit[5,6] if not set		new_dst
Atomic_Page_update_0100	1100_0110	Read Access Extended Access bit is enabled Write Protection is enabled Final PTE	Set bit[5,10] if not set		new_dst
Atomic_Page_update_0101	1100_0111	Write Access Extended Access bit is enabled Write Protection is enabled Final PTE	Set bit[5,6,10] if not set		new_dst
Atomic_Page_update_0000	1100_1000	Read Access Extended Access bit is disabled Write Protection is disabled Intermediate Paging Entry	Set bit[5] if not set		new_dst

Atomic_Page_update_0001	1100_1001	Write Access Extended Access bit is disabled Write Protection is disabled Intermediate Paging Entry	Set bit[5,6] if not set		new_dst
Atomic_Page_update_0000	1100_1010	Read Access Extended Access bit is enabled Write Protection is disabled Intermediate Paging Entry	Set bit[5,10] if not set		new_dst
Atomic_Page_update_0001	1100_1011	Write Access Extended Access bit is enabled Write Protection is disabled Intermediate Paging Entry	Set bit[5,6,10] if not set		new_dst
Atomic_Page_update_0100	1100_1100	Read Access Extended Access bit is disabled Write Protection is enabled Intermediate Paging Entry	Set bit[5] if not set		new_dst
Atomic_Page_update_0101	1100_1101	Write Access Extended Access bit is disabled Write Protection is enabled Intermediate Paging Entry	Set bit[5,6] if not set		new_dst

Atomic_Page_update_0100	1100_1110	Read Access Extended Access bit is enabled Write Protection is enabled Intermediate Paging Entry	Set bit[5,10] if not set		new_dst
Atomic_Page_update_0101	1100_1111	Write Access Extended Access bit is enabled Write Protection is enabled Intermediate Paging Entry	Set bit[5,6,10] if not set		new_dst

Atomic updates are only possible for cacheable memory types. There could be cases where the PTE could be in WT/WC/UC space where atomic update is not possible via WB space. Those are the cases where IA cores use bus lock to update the A/D bits in PTE.

GT core is not capable of supporting bus locks and has the following options. These options will be enabled/disabled via register space.

Option#1: Ignore the PAT/MTRR setting of the PTE and update the space as WB with atomic ops. This is the place GAM will decide to go forward with atomic updates assuming WB space works

Option#2: Once the memory type is determined and the end result of the page is WC/UC/WT space, we can not guarantee an atomic update. GAM will report an application error (catastrophic) to the scheduler and handle the case as error.

Bit	Access	Default Value	Description
1	R/W	0b	**A/D Bit Update on non-WB Space:** A/D bit updates are only possible via atomic operations which are required to be on WB space to work properly. On non-WB spaces, the A/D bit updates are done via bus locks which are not supported for GT. **"1":** Ignore the page level cacheability and do atomic updates for A/D bit management **"0":** Detect the page level cacheability as part of the atomic operation and throw a catastrophic error when non-WB space is seen for A/D bit updates.

PAT (IA32e)

If the PAT is supported, paging contributes to memory typing in conjunction with the PAT and the memory-type range registers (MTRRs) as specified.

The PAT is a 64-bit data structure defined in context entry when advanced context is chosen and for legacy context and internal 64b register is defined to keep the page table based cacheability. It is compromising eight (8) 8-bit entries (entry *i* comprises bits 8*i*+7:8*i* of the register).

For any access to a physical address, the table combines the memory type specified for that physical address by the MTRRs with a memory type selected from the PAT. Specifically, it comes from entry *i* of the PAT, where *i* is defined as follows:

- For an access to an entry in a paging structure whose address is in CR3 (e.g., the PML4 table with IA-32e paging):

i = 2*PCD+PWT, where the PCD and PWT values come from CR3.

- For an access to a paging-structure entry X whose address is in another paging structure entry Y, *i* = 2*PCD+PWT, where the PCD and PWT values come from Y.
- For an access to the physical address that is the translation of a linear address, *i* = 4*PAT+2*PCD+PWT, where the PAT, PCD, and PWT values come from the relevant PTE (if the translation uses a 4-KByte page), the relevant PDE (if the translation uses a 2-MByte page or a 4-MByte page), or the relevant PDPTE (if the translation uses a 1-GByte page).

PAT in Context Table Entry

PAT definition is embedded inside the context entry and already defined as part of the context entry definition (see related section). It allows 8 different settings which can be indexed using the following encodings listed as part of memory types. PAT in context entry is used for advanced context usage.

Memory Types and Applicability to GFX

The Memory Types defined for IA are listed below as:

Memory Type	Encoding in MTRR/PAT
Uncacheable (UC)	00h
Write Combining (WC)	01h
Write Through (WT)	04h
Write Protected (WP)	05h
WriteBack (WB)	06h
Uncached (UC-)	07h
Reserved*	02, 03, 08h-FFh

Note: * use of any reserved encodings will result in a FAULT and reported into fault registers.

- **Uncacheable (UC):** IA semantics for a UC cycle is slightly different than traditional UC concept that was adapted by GFX as part of integration into CPU. When UC type is selected from the MTRR table, GAM will enforce the request to be uncacheable in LLC/eLCC (turn-off the cacheability flags) and also force the fence semantics in GTI.

  Note: This behavior is not followed with a fence in case of GPUs.
- **Uncached (UC-)**: Same concept as UC from behavior perspective however the precedence can be overridden by WC unlike UC.
- **Write Combining (WC):** Write combining follows a streaming model in IA terms which is not cached in uncore. Semantically the existing GT use of UC concept overlaps with WC memory type defined by IA. GFX will treat the WC memory type as a streaming uncacheable memory type in GFX pipelines.
- **Write Through (WT):** Write through concept is already introduced as part of the gen7.5 design, the IA version of the WT overlaps with the same concept.
- **Write Protected (WP):** GFX has no concept of write protected; however this is simply a combination of two modes distributed over different access types:
  - **Reads**: Acts as WB.
  - **Writes**: Acts as WC.
- **Write Back (WB):** WB memory type is traditional memory type used where accesses are cached in uncore as per the directives provided. This is the main cacheable mode that will be used.

Basically, GPU will support all memory-types that CPU supports (as below), with the same meaning with respect to "**Cacheable**", "**Writeback Cacheable**", and "**Serialization**". Because the GPU has its own device-specific notion of what "*speculative processor ordering*" means, those are not specified/attached to memory-types.

Memory Type and Mnemonic	Cacheable	Writeback Cacheable	Allows Speculative Reads	Memory Ordering Model
Strong Uncacheable (UC)	No	No	No	Strong Ordering
Uncacheable (UC-)	No	No	No	Strong Ordering. Can only be selected through the PAT. Can be overridden by WC in MTRRs.
Write Combining (WC)	No	No	Yes	Weak Ordering. Available by programming MTRRs or by selecting it through the PAT.
Write Through (WT)	Yes	No	Yes	Speculative Processor Ordering.
Write Back (WB)	Yes	Yes	Yes	Speculative Processor Ordering.
Write Protected (WP)	Yes for reads; no for writes	No	Yes	Speculative Processor Ordering. Available by programming MTRRs.

The key similarities with CPU memory types are:

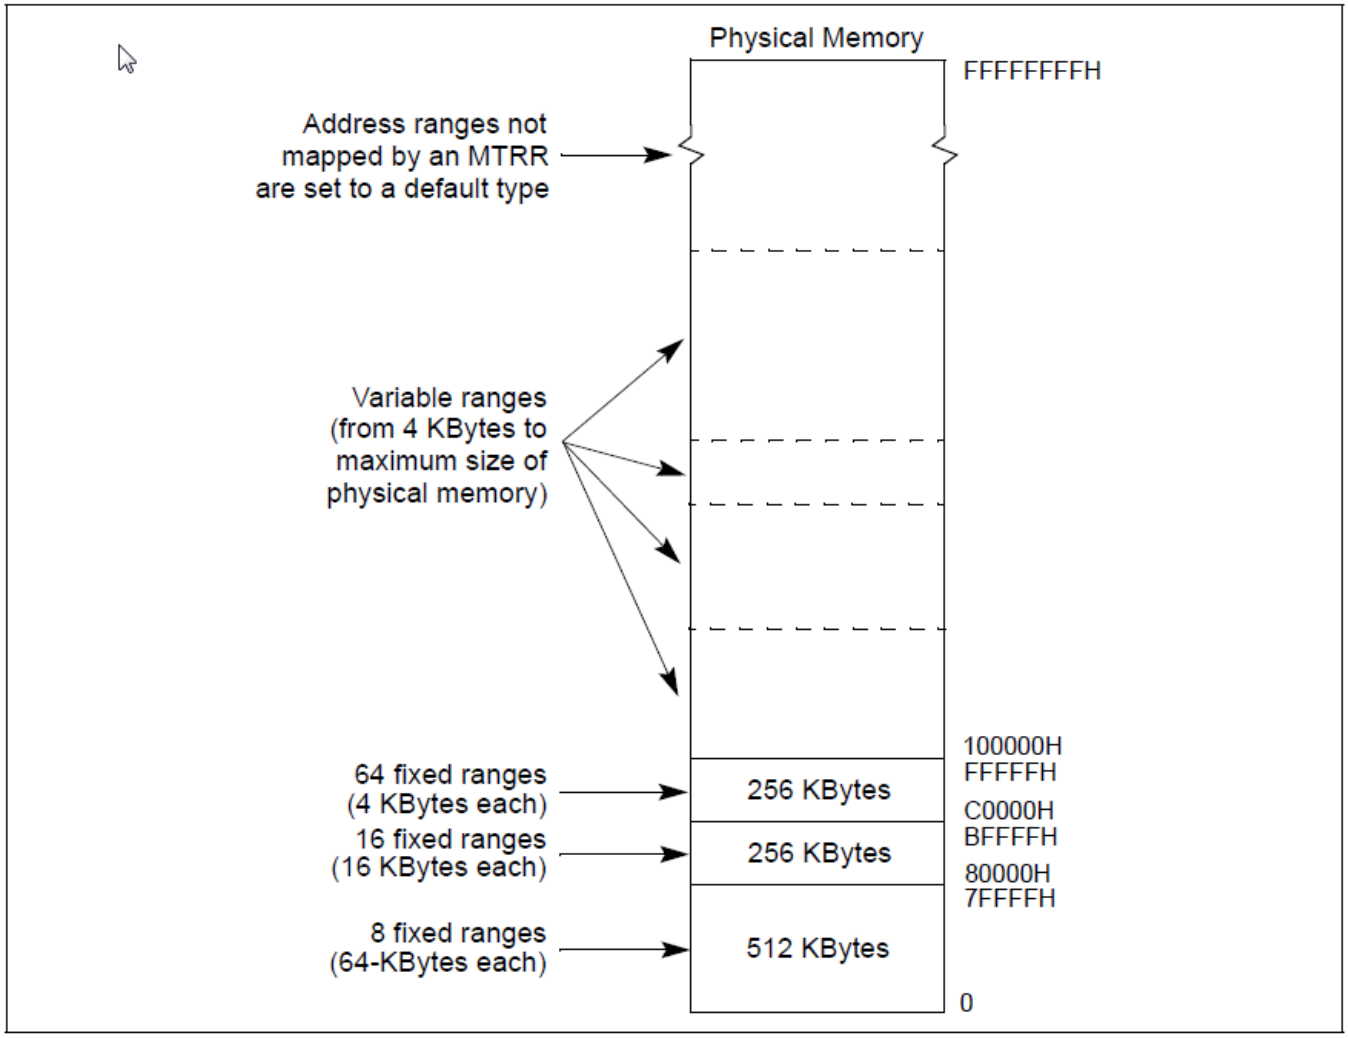
- GPU's cache (L3 cache) will be made coherent (works similar to MLC on CPUs).
- All GPU accesses (regardless of memory type) will snoop LLC.
- All GPU accesses will self-snoop.
- Outside of virtualization, GPU computes effective memory-type same as CPU (MTRR, PAT, PCD, PWT, etc.), and caches follow normal versus non-allocating mode per CD bit (similar to CPUs).
- UC, UC- and WC accesses do not allocate to caches. Will invalidate if line already exists in caches.
- UC- works same ways as CPU (i.e., unlike UC, UC- allows override by WC).
- WB accesses will allocate to cache without updating memory.
- WT behaves same as WB, except writes, updates memory along with allocate to cache.
- WP behaves same as WT, except writes always propagate to memory (invalidating any cache-line that hits).

The key difference with CPU memory types are:

- Speculative processor ordering not specified
- For GPU, only difference between UC/UC- and WC is that, UC has stronger ordering.

MTRR Ranges

Memory Type Range Registers are defined to cover the entire physical memory. The following table shows how each region is defined and how they map over the physical memory.



Memory Type Selection and Priority

Memory typing determination is split up to two categories:

- **Architectural Options**: This is the traditional memory typing defined via external specifications and controls the cacheability of various surfaces.
- **Design Specific Options**: To target product specific caches and cache optimizations

Design-Specific Memory Types

The following are the design specific memory types for CHV, BSW.

LRU Age: Both LLC and eDRAM uses LRU-like replacement algorithm with Age based determination

00: Age is 0

01: Age is 1

10: Age is 2

11: Age is 3

Target Cache: CHV, BSW has two large caches in Uncore where they could be separately targeted.

00: reserved

01: eLLC only

10: LLC only

11: eLLC/LLC

Both LRU and target cache selections can only be managed via non-architectural solutions.

Legacy Context: Selection is based on whether target cache field programmed in surface state is "00" or non-"00". If non-"00", than both the Age and Target cache parameters are picked from surface state and page table controls are ignored. If target cache parameter in surface state is "00" than, only page table controls are used via private PAT programming (see PAT calculation) and indexed into "PAT in MMIO Register Space".

Advanced Context: Decision is based on surface state only. Advanced context uses architectural definition of PAT via IA32e page tables which do not carry design specific information. The only mechanism to control cache LRU and targets is to program the surfaces state accordingly.

Memory Object Control State (Surface)

Bit	Description
6:5	**Memory Type: LLC/eLLC Cacheability Control (LeLLCCC)** This is the field used in GT interface block to determine what type of access need to be generated to uncore. For the cases where the LeLLCCC is set, cacheable transaction are generated to enable LLC usage for particular stream. 00: Use Cacheability Controls from page table / UC with Fence (if coherent cycle) 01/10: non-snooped 11: snooped **For CHV, BSW, GFX driver should use snooped type for only surfaces that are prepared by the driver in IA WB space. All other surfaces should be tagged as nonsnooped**
4:3	**Target Cache (TC)** This field allows the choice of LLC vs eLLC for caching

	00: eLLC Only – not snooped in GT 01: LLC Only 10: LLC/eLLC Allowed 11: L3, LLC, eLLC Allowed
2	**Reserved**
1:0	**Age for QUADLRU (AGE)** This field allows the selection of AGE parameter for a given surface in LLC or eLLC. . If a particular allocation is done at youngest age (“3”) it tends to stay longer in the cache as compared to older age allocations (“2”, “1”, or “0”). This option is given to driver to be able to decide which surfaces are more likely to generate HITs, hence need to be replaced least often in caches. 11: Good chance of generating hits. 10: Next good chance of generating hits 01: Decent chance of generating hits 00: Poor chance of generating hits

Architectural Memory Types

Memory typing is decided via several levels of checks and comparing different priority levels. The following table shows a visual mapping between these selections.

Context Type	2nd Level Translation	CD	EMTE	IGPT	Surface State	Private PAT	MTRR	IA32e PAT	EMT	Effective Memory Type
Legacy Context	X	X	X	X	UC	UC	X	X	X	UC
	X	X	X	X		WC	X	X	X	WC

Page Walker Access and Memory Types

Most of these notes are further explained in the document; however summarized as part of the page table behavior:

Page Walker Memory Types

1. Legacy Contexts
    a. GT access to root/extended-root table and context/extended-context table
    b. GTT access to private paging (PPGTT) entries
    c. GT access to GPA-to-HPA paging entries
    d. GT access to the translated page
2. Advanced context (without nesting)
    a. GT access to extended-root table and extended-context table
    b. GT access to PASID-entry & PASID-state entry
    c. GT access to IA-32e paging entries
    d. GT access to the translated page
3. Advanced context (with nesting)
    a. GT access to extended-root table and extended-context table
    b. GT access to PASID-entry & PASID-state entry
    c. GT access to IA-32e paging entries
    d. GT access to the translated page
    e. GT access to GPA-to-HPA paging entries to translate address of PASID-entry and PASID-state entry
    f. GT access to GPA-to-HPA paging entries to translate address of IA-32e paging entries
    g. GT access to GPA-to-HPA paging entries to translate address of page

For gen8, the following behavior is defined:

Error Cases

- A/D bit update attempt for paging entry in non-WB memory, cause page-walk to be aborted; Error reported to device in Translation Response, gets reported to driver as GPGPU context in error – catastrophic error case.
- Locked/Atomic operations to pages in non-WB memory aborted; gets reported to driver as GPGPU context in error (catastrophic error)
- CD=1 treated same as non-WB memory, for above lock behavior

Replacement

TLB replacements during runtime are based on LRA algorithm; in addition, invalidations and page responses will have to invalidate the TLB entries.

Invalidations of TLB

There are various ways to invalidate TLBs:

1. **Traditional invalidation from command streamer**: Could be part of any fence accesses including newly added atomics.
2. **SVM based invalidations**: Listed as part of the new SVM related invalidations, various stages of TLBs including intermediate stages can be invalidated selectively and/or as a whole.
3. **Context Switch**: A context switch has to invalidate caches to make sure we have no residual value of the TLBs across multiple PASIDs. GAM will treat the context reload message from CS as a form of TLB invalidation.
4. **A page response**: should invalidate faulted recordings. It should be done via address matching to kick the faulted entries within the matching PASID.

Invalidation response “Invalidation Wait Descriptor” should also be a fence for both READs and WRITEs that used the previous TLB entries. Gam can only respond to “invalidation wait descriptor” after getting a GTI EMPTY indication.

Optional Invalidations

The following cases are listed as page table updates which software may choose not to invalidate the TLBs.

- If a paging-structure is modified to change the Present (Valid) flag from 0 to 1, s/w may choose not to invalidate TLBs. This affects only the case where GPU keeps the faulted page in its TLB to filter out future faults. Regardless of s/w does invalidation or not, for the cases where h/w cares, there will be a page response from s/w which will be used to shootdown the faulted record from the TLB.

  GAM will only put faulted entries to its TLBs if there has been page request for it. This would mean only faultable surfaces can be stored in GAM TLBs as a faulted entry.

- If a paging-structure entry is modified to change the accessed flag from 0 to 1,no invalidation is necessary (assuming that an invalidation was performed the last time the accessed flag was changed from 1 to 0). This is because no TLB entry or paging-structure cache entry is created with information from a paging structure entry in which the accessed flag is 0.
- If a paging-structure entry is modified to change the R/W or U/S or XD flag from 0 to 1, failure to perform an invalidation may result in a "spurious" page-fault exception (e.g., in response to an attempted write access) but no other adverse behavior. Such an exception will occur at most once for each affected linear address

Faulting

Page Faults

CHV, BSW does not support page faulting

Memory Types and Cache Interface

This section has additional information on the types of memory which are accessible via the various GT mechanisms. It includes discussion on how the various paging models are used and accessed. See the Graphics Translation Tables for more detailed discussions on paging models.

This section also includes descriptions of how different surface types (MOCS) can be cached in the L3 and the different behaviors which can be enabled.

Memory Object Control State (MOCS)

The memory object control state defines the behavior of memory accesses beyond the graphics core, including encryption, graphics data types that allow selective flushing of data from outer caches, and controlling cacheability in the outer caches.

This control uses several mechanisms. Control state for all memory accesses can be defined page by page in the GTT entries. Memory objects that are defined by state per surface generally have additional memory object control state in the state structure that defines the other surface attributes. Memory objects without state defining them have memory object state control defined per class in the STATE_BASE_ADDRESS command, with class divisions the same as the base addresses. Finally, some memory objects only have the GTT entry mechanism for defining this control. The table below enumerates the memory objects and the location of the control state for each:

Memory Object	Location of Control State
surfaces defined by SURFACE_STATE: sampling engine surfaces, render targets, media surfaces, pull constant buffers, streamed vertex buffers	SURFACE_STATE
depth, stencil, and hierarchical depth buffers	corresponding state command that defined the buffer attributes
stateless buffers accessed by data port	STATE_BASE_ADDRESS
indirect state objects	STATE_BASE_ADDRESS
kernel instructions	STATE_BASE_ADDRESS
push constant buffers	3DSTATE_CONSTANT_(VS | GS | PS)
index buffers	3DSTATE_INDEX_BUFFER
vertex buffers	3DSTATE_VERTEX_BUFFERS
indirect media object	STATE_BASE_ADDRESS
generic state prefetch	GTT control only
ring/batch buffers	GTT control only
context save buffers	GTT control only
store DWord	GTT control only

MOCS Registers

These registers provide the detailed format of the MOCS table entries that need to be programmed to define each surface state.

MEMORY_OBJECT_CONTROL_STATE

MEMORY_OBJECT_CONTROL_STATE

Page Walker Access and Memory Types

Most of these notes are further explained in the document however summarized as part of the page table behavior:

Page Walker Memory Types

1. Legacy Contexts
    a. GT access to root/extended-root table and context/extended-context table
    b. GTT access to private paging (PPGTT) entries
    c. GT access to GPA-to-HPA paging entries
    d. GT access to the translated page
2. Advanced context (without nesting)
    a. GT access to extended-root table and extended-context table
    b. GT access to PASID-entry & PASID-state entry
    c. GT access to IA-32e paging entries
    d. GT access to the translated page
3. Advanced context (with nesting)
    a. GT access to extended-root table and extended-context table
    b. GT access to PASID-entry & PASID-state entry
    c. GT access to IA-32e paging entries
    d. GT access to the translated page
    e. GT access to GPA-to-HPA paging entries to translate address of PASID-entry and PASID-state entry
    f. GT access to GPA-to-HPA paging entries to translate address of IA-32e paging entries
    g. GT access to GPA-to-HPA paging entries to translate address of page

Gen8 Memory Typing for Paging

The following information is duplicated in the Page Walker Memory Types topic:

1. Legacy Contexts
    a. GT access to root/extended-root table and context/extended-context table
    b. GTT access to private paging (PPGTT) entries
    c. GT access to GPA-to-HPA paging entries
    d. GT access to the translated page
2. Advanced context (without nesting)
    a. GT access to extended-root table and extended-context table
    b. GT access to PASID-entry & PASID-state entry
    c. GT access to IA-32e paging entries
    d. GT access to the translated page
3. Advanced context (with nesting)
    a. GT access to extended-root table and extended-context table
    b. GT access to PASID-entry & PASID-state entry
    c. GT access to IA-32e paging entries
    d. GT access to the translated page
    e. GT access to GPA-to-HPA paging entries to translate address of PASID-entry and PASID-state entry
    f. GT access to GPA-to-HPA paging entries to translate address of IA-32e paging entries
    g. GT access to GPA-to-HPA paging entries to translate address of page

This information is new in this topic and references the cases and subcases enumerated above:

For case [1]:

- [1.a] is always covered as a non-cacheable access
- [1.b] & [1.c] is covered with MMIO register where PPGTT entries can be forced to be cached in LLC (default option is cached).
- [1.d] is defined via private PAT (MMIO based) and surface state.

For case [2]:

- [2.a] is always covered as a non-cacheable access
- [2.b] is always cached & PASID state table entry is always accessed “atomically”
- [2.c] is accessed as cached
- [2.d] use memory-type as evaluated through MTRR, CD, and PCD/PWT/PAT bits in leaf IA-32e paging entry

For case [3]:

- [3.a] is always covered as a non-cacheable access
- [3.b] is always cached & PASID state table entry is always accessed “atomically”
- [3.c] is accessed as cached
- [3.d] use memory-type as follows (this section is further described in detail in memory typing section)
    - If CD=1, memory-type is UC
    - If CD=0:
        - If EMTE=0 in extended-context-entry, it is handled same as [2.d]
        - If EMTE=1 in extended-context-entry:
            - If IGMT=1 in leaf GPA-to-HPA entry, memory type used is the EMT field in this GPA-to-HPA entry.
            - If IGMT=0 in leaf GPA-to-HPA entry, memory type from [2.d] is combined with EMT field in this GPA-to-HPA entry.
- [3.e] is always cached & PASID state table entry is always accessed “atomically”
- [3.f] &[3.g] is accessed as cached

Error Cases

- A/D bit update attempt for paging entry in non-WB memory, causes page-walk to be aborted; Error reported to device in Translation Response; For Gen, gets reported to driver as GPGPU context in error – catastrophic error case.
- Locked/Atomic operations to pages in non-WB memory aborted; For Gen, gets reported to driver as GPGPU context in error (catastrophic error).
- CD=1 treated same as non-WB memory, for above lock behavior.

Common Surface Formats

This section documents surfaces and how they are stored in memory, including 3D and video surfaces, including the details of compressed texture formats. Also covered are the surface layouts based on tiling mode and surface type.

Non-Video Surface Formats

This section describes the lowest-level organization of a surfaces containing discrete “pixel” oriented data (e.g., discrete pixel (RGB,YUV) colors, subsampled video data, 3D depth/stencil buffer pixel formats, bump map values etc. Many of these pixel formats are common to the various pixel-oriented memory object types.

Surface Format Naming

Unless indicated otherwise, all pixels are **stored** in “**little endian**” byte order. i.e., pixel bits 7:0 are stored in byte *n*, pixel bits 15:8 are stored in byte *n*+1, and so on. The format labels include color components in little endian order (e.g., R8G8B8A8 format is physically stored as R, G, B, A).

The name of most of the surface formats specifies its format. Channels are listed in little endian order (LSB channel on the left, MSB channel on the right), with the channel format specified following the channels with that format. For example, R5G5_SNORM_B6_UNORM contains, from LSB to MSB, 5 bits of red in SNORM format, 5 bits of green in SNORM format, and 6 bits of blue in UNORM format.

Intensity Formats

All surface formats containing “I” include an intensity value. When used as a source surface for the sampling engine, the intensity value is replicated to all four channels (R,G,B,A) before being filtered. Intensity surfaces are not supported as destinations.

Luminance Formats

All surface formats containing “L” include a luminance value. When used as a source surface for the sampling engine, the luminance value is replicated to the three color channels (R,G,B) before being filtered. The alpha channel is provided either from another field or receives a default value. Luminance surfaces are not supported as destinations.

R1_UNORM (same as R1_UINT) and MONO8

When used as a texel format, the R1_UNORM format contains 8 1-bit Intensity (I) values that are replicated to all color channels. Note that T0 of byte 0 of a R1_UNORM-formatted texture corresponds to Texel[0,0]. This is different from the format used for monochrome sources in the BLT engine.

7	6	5	4	3	2	1	0
T7	T6	T5	T4	T3	T2	T1	T0

Bit	Description
T0	**Texel 0** On texture reads, this (unsigned) 1-bit value is replicated to all color channels. Format: U1
...	**...**
T7	**Texel 7** On texture reads, this (unsigned) 1-bit value is replicated to all color channels. Format: U1

MONO8 format is identical to R1_UNORM but has different semantics for filtering. MONO8 is the only supported format for the MAPFILTER_MONO filter. See the *Sampling Engine* chapter.

Palette Formats

Palette formats are supported by the sampling engine. These formats include an index into the palette (Px) that selects the actual channel values from the palette, which is loaded via the 3DSTATE_SAMPLER_PALETTE_LOAD0 command.

P4A4_UNORM

This surface format contains a 4-bit Alpha value (in the high nibble) and a 4-bit Palette Index value (in the low nibble).

7			4	3			0
Alpha				Palette Index			

Bit	Description
7:4	**Alpha** Alpha value which will be replicated to both the high and low nibble of an 8-bit value, and then divided by 255 to yield a [0.0,1.0] Alpha value. Format: U4
3:0	**Palette Index** A 4-bit index which is used to lookup a 24-bit (RGB) value in the texture palette (loaded via 3DSTATE_SAMPLER_PALETTE_LOADx) Format: U4

A4P4_UNORM

This surface format contains a 4-bit Alpha value (in the low nibble) and a 4-bit Color Index value (in the high nibble).

7			4	3			0
Palette Index				Alpha			

Bit	Description
7:4	**Palette Index** A 4-bit color index which is used to lookup a 24-bit RGB value in the texture palette. Format: U4
3:0	**Alpha** Alpha value which will be replicated to both the high and low nibble of an 8-bit value, and then divided by 255 to yield a [0.0,1.0] alpha value.

Bit	Description
	Format: U4

P8A8_UNORM

This surface format contains an 8-bit Alpha value (in the high byte) and an 8-bit Palette Index value (in the low byte).

15			8	7			0
Alpha				Palette Index			

Bit	Description
15:8	**Alpha** Alpha value which will be divided by 255 to yield a [0.0,1.0] Alpha value. Format: U8
7:0	**Palette Index** An 8-bit index which is used to lookup a 24-bit (RGB) value in the texture palette (loaded via 3DSTATE_SAMPLER_PALETTE_LOADx) Format: U8

A8P8_UNORM

This surface format contains an 8-bit Alpha value (in the low byte) and an 8-bit Color Index value (in the high byte).

15			8	7			0
Palette Index				Alpha			

Bit	Description
15:8	**Palette Index** An 8-bit color index which is used to lookup a 24-bit RGB value in the texture palette. Format: U8
7:0	**Alpha** Alpha value which will be divided by 255 to yield a [0.0,1.0] alpha value. Format: U8

P8_UNORM

This surface format contains only an 8-bit Color Index value.

Bit	Description
7:0	**Palette Index** An 8-bit color index which is used to lookup a 32-bit ARGB value in the texture palette. Format: U8

P2_UNORM

This surface format contains only a 2-bit Color Index value.

Bit	Description
1:0	**Palette Index** A 2-bit color index which is used to lookup a 32-bit ARGB value in the texture palette. Format: U2

Compressed Surface Formats

This section contains information on the internal organization of compressed surface formats.

ETC1_RGB8

CHV, BSW: This format compresses UNORM RGB data using an 8-byte compression block representing a 4x4 block of texels. The texels are labeled as texel[row][column] where both row and column range from 0 to 3. Texel[0][0] is the upper left texel.

The 8-byte compression block is laid out as follows.

High 24 bits if "diff" is zero (individual mode):

Bits	Description
7:4	R0[3:0]
3:0	R1[3:0]
15:12	G0[3:0]
11:8	G1[3:0]
23:20	B0[3:0]
19:16	B1[3:0]

High 24 bits if "diff" is one (differential mode):

Bits	Description
7:3	R0[4:0]
2:0	dR1[2:0]
15:11	G0[4:0]
10:8	dG1[2:0]
23:19	B0[4:0]
18:16	dB1[2:0]

Low 40 bits:

Bits	Description
31:29	lum table index for sub-block 0
28:26	lum table index for sub-block 1
25	diff
24	flip
39	texel[3][3] index MSB
38	texel[2][3] index MSB
37	texel[1][3] index MSB
36	texel[0][3] index MSB
35	texel[3][2] index MSB

Bits	Description
34	texel[2][2] index MSB
33	texel[1][2] index MSB
32	texel[0][2] index MSB
47	texel[3][1] index MSB
46	texel[2][1] index MSB
45	texel[1][1] index MSB
44	texel[0][1] index MSB
43	texel[3][0] index MSB
42	texel[2][0] index MSB
41	texel[1][0] index MSB
40	texel[0][0] index MSB
55	texel[3][3] index LSB
54	texel[2][3] index LSB
53	texel[1][3] index LSB
52	texel[0][3] index LSB
51	texel[3][2] index LSB
50	texel[2][2] index LSB
49	texel[1][2] index LSB
48	texel[0][2] index LSB
63	texel[3][1] index LSB
62	texel[2][1] index LSB
61	texel[1][1] index LSB
60	texel[0][1] index LSB
59	texel[3][0] index LSB
58	texel[2][0] index LSB
57	texel[1][0] index LSB
56	texel[0][0] index LSB

The 4x4 is divided into two 8-pixel sub-blocks, either two 2x4 sub-blocks or two 4x2 sub-blocks controlled by the “flip” bit. If flip=0, sub-block 0 is the 2x4 on the left and sub-block 1 is the 2x4 on the right. If flip=1, sub-block 0 is the 4x2 on the top and sub-block 1 is the 4x2 on the bottom.

The “diff” bit controls whether the red/green/blue values (R0/G0/B0/R1/G1/B1) are stored as one 444 value per sub-block (“individual” mode with diff = 0), or a single 555 value for the first sub-block (R0/G0/B0) and a 333 delta value (dR1/dG1/dB1) for the second sub-block (“differential” mode with diff = 1). The delta values are 3-bit two’s-complement values that hold values in the range [-4,3]. These values are added to the 5-bit values for sub-block 0 to obtain the 5-bit values for sub-block 1 (if the value is outside of the range [0,31], the result of the decompression is undefined). From the 4- or 5-bit

per channel values, an 8-bit value for each channel is extended by replication and provides the 888 base color for each sub-block.

For each sub-block one of 8 different luminance columns is selected based on the 3-bit lum table index. Then each texel selects one of the 4 rows of the selected column with a 2-bit per-texel index. The chosen value in the table is added to the 8-bit base color for the sub-block (obtained in the previous step) to obtain the texel's color. Values in the table are given in decimal, representing an 8-bit UNORM as an 8-bit signed integer.

Luminance Table

	0	1	2	3	4	5	6	7
0	2	5	9	13	18	24	33	47
1	8	17	29	42	60	80	106	183
2	-2	-5	-9	-13	-18	-24	-33	-47
3	-8	-17	-29	-42	-60	-80	-106	-183

ETC2_RGB8 and ETC2_SRGB8

The ETC2_RGB8 format builds on top of ETC1_RGB8, using a set of invalid bit sequences to enable three new modes. The two modes of ETC1_RGB8 are also supported with ETC2_RGB8, and will not be documented in this section as they are covered in the ETC1_RGB8 section.

The detection of the three new modes is based on RGB and diff bits in locations as defined for ETC1 differential mode. The mode is determined as follows (x indicates don't care):

diff	Rt	Gt	Bt	mode
0	x	x	x	individual
1	0	x	x	T
1	1	0	x	H
1	1	1	0	planar
1	1	1	1	differential

The inputs in the above table are defined as follows:

```
Rt = (R0 + dR1) in [0,31]
Gt = (G0 + dG1) in [0,31]
Bt = (G0 + dB1) in [0,31]
```

8-byte compression block for mode determination

Bits	Description
7:3	R0[4:0]
2:0	dR1[2:0]
15:11	G0[4:0]
10:8	dG1[2:0]
23:19	B0[4:0]
18:16	dB1[2:0]
31:26	ignored
25	diff
24	ignored
63:32	ignored

The fields in the table above are used *only* for mode determination. Some of the bits in this table are overloaded with other values within each mode. The algorithm is defined such that there is no ambiguity in modes when this is done.

T mode

The "T" mode has the following bit definition:

8-byte compression block for "T" mode

Bits	Description
7:5	ignored
4:3	R0[3:2]
2	ignored
1:0	R0[1:0]
15:12	G0[3:0]
11:8	B0[3:0]
23:20	R1[3:0]
19:16	G1[3:0]

40	texel[0][0] index MSB
55	texel[0][0] index LSB
54	texel[2][3] index LSB
53	texel[1][3] index LSB

Bits	Description
52	texel[0][3] index LSB
51	texel[3][2] index LSB
50	texel[2][2] index LSB
49	texel[1][2] index LSB
48	texel[0][2] index LSB
63	texel[3][1] index LSB
62	texel[2][1] index LSB
61	texel[1][1] index LSB
60	texel[0][1] index LSB
59	texel[3][0] index LSB
58	texel[2][0] index LSB
57	texel[1][0] index LSB
56	texel[0][0] index LSB

The “T” mode has two base colors stored as 4 bits per channel, R0/G0/B0 and R1/G1/B1, as in the individual mode, however the bit positions for these are different. For each channel, the 4 bits are extended to 8 bits by bit replication.

A 3-bit distance index “di” is also defined in the compression block. This value is used to look up the distance in the following table:

distance index “di”	distance “d”
0	3
1	6
2	11
3	16
4	23
5	32
6	41
7	64

Four colors are possible on each texel. These colors are defined as the following:

```
P0 = (R0, G0, B0)
P1 = (R1, G1, B1) + (d, d, d)
P2 = (R1, G1, B1)
P3 = (R1, G1, B1) – (d, d, d)
```

All resulting channels are clamped to the range [0,255]. One of the four colors is then assigned to each texel in the block based on the 2-bit texel index.

H mode

The “H” mode has the following bit definition:

8-byte compression block for “H” mode

Bits	Description
7	ignored
6:3	R0[3:0]
2:0	G0[3:1]
15:13	ignored

58	texel[2][0] index LSB
57	texel[1][0] index LSB
56	texel[0][0] index LSB

The “H” mode has two base colors stored as 4 bits per channel, R0/G0/B0 and R1/G1/B1, as in the individual and T modes, however the bit positions for these are different. For each channel, the 4 bits are extended to 8 bits by bit replication.

A 3-bit distance index “di” is defined by 2 MSBs in the compression block and the LSB computed by the following equation, where R/G/B values are the 8-bit values from the first step:

```
di[0] = ((R0 « 16) | (G0 « 8) | B0) >= ((R1 « 16) | (G1 « 8) | B1)
```

The distance “d” is then looked up in the same table used for T mode. The four colors for H mode are computed as follows:

```
P0 = (R0, G0, B0) + (d, d, d)
P1 = (R0, G0, B0) - (d, d, d)
P2 = (R1, G1, B1) + (d, d, d)
P3 = (R1, G1, B1) - (d, d, d)
```

All resulting channels are clamped to the range [0,255]. One of the four colors is then assigned to each texel in the block based on the 2-bit texel index as in T mode.

Planar mode

The “planar” mode has the following bit definition:

8-byte compression block for “planar” mode

Bits	Description
7	ignored
6:1	R0[5:0]
0	G0[6]
15	ignored
14:9	G0[5:0]
8	B[5]
23:21	ignored
20:19	B[4:3]
18	ignored
17:16	B0[2:1]
31	B0[0]
30:26	RH[5:1]
25	diff = 1
24	RH[0]
39:33	GH[6:0]
32	BH[5]
47:43	BH[4:0]
42:40	RV[5:3]
55:53	RV[2:0]
52:48	GV[6:2]
63:62	GV[1:0]
61:56	BV[5:0]

The “planar” mode has three base colors stored as RGB 676, with red & blue having 6 bits and green having 7 bits. These three base colors are each extended to RGB 888 with bit replication.

The color of each texel is then computed using the following equations, with x and y representing the texel position within the compression block:

```
texel[y][x].R = x(RH-R0)/4 + y(RV-R0)/4 + R0
texel[y][x].G = x(GH-G0)/4 + y(GV-G0)/4 + G0
texel[y][x].B = x(BH-B0)/4 + y(BV-B0)/4 + B0
```

All resulting channels are clamped to the range [0,255].

The ETC2_SRGB8 format is decompressed as if it is ETC2_RGB8, then a conversion from the resulting RGB values to SRGB space is performed.

EAC_R11 and EAC_SIGNED_R11

These formats compress UNORM/SNORM single-channel data using an 8-byte compression block representing a 4x4 block of texels. The texels are labeled as texel[row][column] where both row and column range from 0 to 3. Texel[0][0] is the upper left texel.

The 8-byte compression block is laid out as follows.

EAC_R11 compression block layout

Bits	Description
7:0	R0[7:0]
15:12	m[3:0]
11:8	ti[3:0]
23:21	texel[0][0] index
20:18	texel[1][0] index
17:16,31	texel[2][0] index
30:28	texel[3][0] index
27:25	texel[0][1] index
24,39:38	texel[1][1] index
37:35	texel[2][1] index
34:32	texel[3][1] index
47:45	texel[0][2] index
44:42	texel[1][2] index
41:40,55	texel[2][2] index
54:52	texel[3][2] index
51:49	texel[0][3] index
48,63:62	texel[1][3] index
61:59	texel[2][3] index
58:56	texel[3][3] index

The “ti” (table index) value from the compression block is used to select one of the columns in the table below.

Intensity modifier (im) table

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
0	-3	-3	-2	-2	-3	-3	-4	-3	-2	-2	-2	-2	-3	-1	-4	-3
1	-6	-7	-5	-4	-6	-7	-7	-5	-6	-5	-4	-5	-4	-2	-6	-5
2	-9	-10	-8	-6	-8	-9	-8	-8	-8	-8	-8	-7	-7	-3	-8	-7
3	-15	-13	-13	-13	-12	-11	-11	-11	-10	-10	-10	-10	-10	-10	-9	-9
4	2	2	1	1	2	2	3	2	1	1	1	1	2	0	3	2
5	5	6	4	3	5	6	6	4	5	4	3	4	3	1	5	4
6	8	9	7	5	7	8	7	7	7	7	7	6	6	2	7	6
7	14	12	12	12	11	10	10	10	9	9	9	9	9	9	8	8

The eight possible color values R_i are then computed from the 8 values in the column labeled im_i, where i ranges from 0 to 7:

For EAC_R11:

```
if (m == 0) Ri = R0*8 + 4 + imi else Ri = R0*8 + 4 + (imi * m * 8)
```

Each value is clamped to the range [0,2047].

For EAC_SIGNED_R11:

```
if (m == 0) Ri = R0*8 + imi else Ri = R0*8 + (imi * m * 8)
```

Each value is clamped to the range [-1023,1023].

Note that in the signed case, the R0 value is a signed, 2’s complement value in the range [-127, 127]. Before being used in the above equations, an R0 value of -128 must be clamped to -127.

Finally, each texel red value is selected from the 8 possible values R_i using the 3-bit index for that texel. The green, blue, and alpha values are set to their default values.

The final value represents an 11-bit UNORM or SNORM as an unsigned/signed integer.

ETC2_RGB8_PTA and ETC2_SRGB8_PTA

The ETC2_RGB8_PTA format is similar to ETC2_RGB8 but eliminates the “individual” mode in favor of allowing a punch-through alpha. The “diff” bit from ETC2_RGB8 is renamed to “opaque” in this format, and the mode selection behaves as if the “diff” bit is always 1, making the “individual” mode inaccessible for these formats.

An alpha value of either 0 or 255 (representing 0.0 or 1.0) is possible with this format. If alpha is determined to be zero, the three other channels are also forced to zero, regardless of what value the normal decompression algorithm would have produced.

Differential Mode

In differential mode, if the opaque bit is set, the luminance table for ETC2_RGB8 is used. If the opaque bit is not set, the following luminance table is used (note that rows 0 and 2 have been zeroed out, otherwise the table is the same):

Luminance Table for opaque bit not set

	0	1	2	3	4	5	6	7
0	0	0	0	0	0	0	0	0
1	8	17	29	42	60	80	106	183
2	0	0	0	0	0	0	0	0
3	-8	-17	-29	-42	-60	-80	-106	-183

For each texel, if the opaque bit is zero and the corresponding texel index is equal to 2, the alpha value is set to zero (and therefore RGB for that texel will also end up at zero). Otherwise alpha is set to 255 and RGB is the result of the normal decompression calculations.

T and H Modes

In both of these modes, if the opaque bit is zero and the texel index is equal to 2, the alpha value is set to zero (and therefore RGB will also end up at zero). Otherwise alpha is set to 255.

Planar Mode

In planar mode, the opaque bit is ignored and alpha is set to 255.

The ETC2_SRGB8_PTA format is decompressed as if it is ETC2_RGB8_PTA, then a conversion from the resulting RGB values to SRGB space is performed, with alpha remaining unchanged.

ETC2_EAC_RGBA8 and ETC2_EAC_SRGB8_A8

The ETC2_EAC_RGBA8 format is a combination of ETC2_RGB8 and EAC_R8. A 16-byte compression block represents each 4x4. The low-order 8 bytes are used to compute alpha (instead of red) using the EAC_R8 algorithm. The high-order 8 bytes are used to compute RGB using the ETC2_RGB8 algorithm. The EAC_R8 format differs from EAC_R11 as described below.

The ETC2_EAC_SRGB8_A8 format is decompressed as if it is ETC2_EAC_RGBA8, then a conversion from the resulting RGB values to SRGB space is performed, with alpha remaining unchanged.

EAC_R8 Format:

The EAC_R8 format used within these surface formats is identical to EAC_R11 described in an earlier section, except the procedure for computing the eight possible color values Ri is performed as follows:

Ri = R0 + (imi * m)

Each value is clamped to the range [0,255].

EAC_RG11 and EAC_SIGNED_RG11

These formats compress UNORM/SNORM double-channel data using a 16-byte compression block representing a 4x4 block of texels. The texels are labeled as texel[row][column] where both row and column range from 0 to 3. Texel[0][0] is the upper left texel.

The 16-byte compression block is laid out as follows.

EAC_RG11 compression block layout

Bits	Description
63:56	G0[7:0]
55:52	Gm[3:0]
51:48	Gti[3:0]
47:45	texel[0][0] G index
44:42	texel[1][0] G index
41:39	texel[2][0] G index
38:36	texel[3][0] G index
35:33	texel[0][1] G index
32:30	texel[1][1] G index
29:27	texel[2][1] G index
26:24	texel[3][1] G index
23:21	texel[0][2] G index
20:18	texel[1][2] G index
17:15	texel[2][2] G index
14:12	texel[3][2] G index
11:9	texel[0][3] G index
8:6	texel[1][3] G index
5:3	texel[2][3] G index
66:64	texel[3][3] G index
63:56	R0[7:0]
55:52	Rm[3:0]
51:48	Rti[3:0]
47:45	texel[0][0] R index
44:42	texel[1][0] R index
41:39	texel[2][0] R index
38:36	texel[3][0] R index
35:33	texel[0][1] R index
32:30	texel[1][1] R index
29:27	texel[2][1] R index

Bits	Description
26:24	texel[3][1] R index
23:21	texel[0][2] R index
20:18	texel[1][2] R index
17:15	texel[2][2] R index
14:12	texel[3][2] R index
11:9	texel[0][3] R index
8:6	texel[1][3] R index
5:3	texel[2][3] R index
2:0	texel[3][3] R index

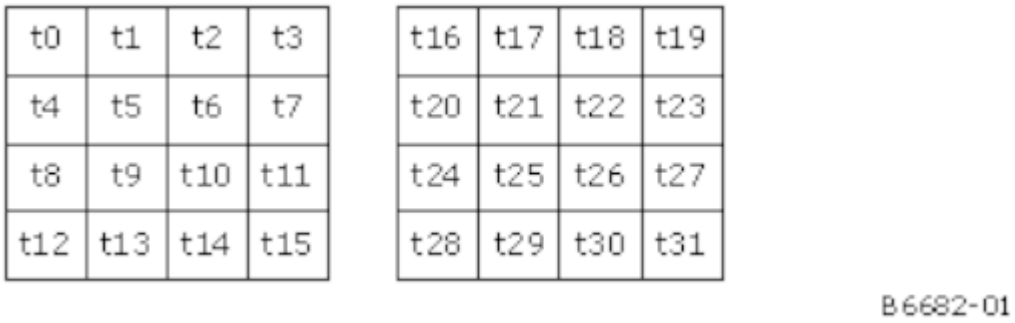
These compression formats are identical to the EAC_R11 and EAC_SIGNED_R11 formats, except that they supply two channels of output data, both red and green, from two independent 8-byte portions of the compression block. The low half of the compression block contains the red information, and the high half contains the green information. Blue and alpha channels are set to their default values.

Refer to the EAC_R11 and EAC_SIGNED_R11 specification for details on how the red and green channels are generated using the data in the compression block.

FXT Texture Formats

There are four different FXT1 compressed texture formats. Each of the formats compress two 4x4 texel blocks into 128 bits. In each compression format, the 32 texels in the two 4x4 blocks are arranged according to the following diagram:

FXT1 Encoded Blocks



Overview of FXT1 Formats

During the compression phase, the encoder selects one of the four formats for each block based on which encoding scheme results in best overall visual quality. The following table lists the four different modes and their encodings:

FXT1 Format Summary

Bit 127	Bit 126	Bit 125	Block Compression Mode	Summary Description
0	0	X	**CC_HI**	2 R5G5B5 colors supplied. Single LUT with 7 interpolated color values and transparent black
0	1	0	**CC_CHROMA**	4 R5G5B5 colors used directly as 4-entry LUT.
0	1	1	**CC_ALPHA**	3 A5R5G5B5 colors supplied. LERP bit selects between 1 LUT with 3 discrete colors + transparent black and 2 LUTs using interpolated values of Color 0,1 (t0-15) and Color 1,2 (t16-31).
1	x	x	**CC_MIXED**	4 R5G5B5 colors supplied, where Color0,1 LUT is used for t0-t15, and Color2,3 LUT used for t16-31. Alpha bit selects between LUTs with 4 interpolated colors or 3 interpolated colors + transparent black.

FXT1 CC_HI Format

In the CC_HI encoding format, two base 15-bit R5G5B5 colors (Color 0, Color 1) are included in the encoded block. These base colors are then expanded (using high-order bit replication) to 24-bit RGB colors, and used to define an 8-entry lookup table of interpolated color values (the 8th entry is transparent black). The encoded block contains a 3-bit index value per texel that is used to lookup a color from the table.

CC_HI Block Encoding

The following table describes the encoding of the 128-bit (DQWord) CC_HI block format:

FXT CC_HI Block Encoding

Bit	Description
127:126	Mode = '00'b (CC_HI)
125:121	Color 1 Red
120:116	Color 1 Green
115:111	Color 1 Blue
110:106	Color 0 Red
105:101	Color 0 Green
100:96	Color 0 Blue
95:93	Texel 31 Select
...	...
50:48	Texel 16 Select
47:45	Texel 15 Select
...	...
2:0	Texel 0 Select

CC_HI Block Decoding

The two base colors, Color 0 and Color 1 are converted from R5G5B5 to R8G8B8 by replicating the 3 MSBs into the 3 LSBs, as shown in the following table:

FXT CC_HI Decoded Colors

Expanded Color Bit	Expanded Channel Bit	Encoded Block Source Bit
Color 1 [23:19]	Color 1 Red [7:3]	[125:121]
Color 1 [18:16]	Color 1 Red [2:0]	[125:123]
Color 1 [15:11]	Color 1 Green [7:3]	[120:116]
Color 1 [10:08]	Color 1 Green [2:0]	[120:118]
Color 1 [07:03]	Color 1 Blue [7:3]	[115:111]
Color 1 [02:00]	Color 1 Blue [2:0]	[115:113]
Color 0 [23:19]	Color 0 Red [7:3]	[110:106]
Color 0 [18:16]	Color 0 Red [2:0]	[110:108]
Color 0 [15:11]	Color 0 Green [7:3]	[105:101]
Color 0 [10:08]	Color 0 Green [2:0]	[105:103]
Color 0 [07:03]	Color 0 Blue [7:3]	[100:96]
Color 0 [02:00]	Color 0 Blue [2:0]	[100:98]

These two 24-bit colors (Color 0, Color 1) are then used to create a table of seven interpolated colors (with Alpha = 0FFh), along with an eight entry equal to RGBA = 0,0,0,0, as shown in the following table:

FXT CC_HI Interpolated Color Table

Interpolated Color	Color RGB	Alpha
0	Color0.RGB	0FFh
1	(5 * Color0.RGB + 1 * Color1.RGB + 3) / 6	0FFh
2	(4 * Color0.RGB + 2 * Color1.RGB + 3) / 6	0FFh
3	(3 * Color0.RGB + 3 * Color1.RGB + 3) / 6	0FFh
4	(2 * Color0.RGB + 4 * Color1.RGB + 3) / 6	0FFh
5	(1 * Color0.RGB + 5 * Color1.RGB + 3) / 6	0FFh
6	Color1.RGB	0FFh
7	RGB = 0,0,0	0

This table is then used as an 8-entry Lookup Table, where each 3-bit Texel n Select field of the encoded CC_HI block is used to index into a 32-bit A8R8G8B8 color from the table completing the decode of the CC_HI block.

FXT1 CC_CHROMA Format

In the CC_CHROMA encoding format, four 15-bit R5B5G5 colors are included in the encoded block. These colors are then expanded (using high-order bit replication) to form a 4-entry table of 24-bit RGB colors. The encoded block contains a 2-bit index value per texel that is used to lookup a 24-bit RGB color from the table. The Alpha component defaults to fully opaque (0FFh).

CC_CHROMA Block Encoding

The following table describes the encoding of the 128-bit (DQWord) CC_CHROMA block format:

FXT CC_CHROMA Block Encoding

Bit	Description
127:125	Mode = '010'b (CC_CHROMA)
124	Unused
123:119	Color 3 Red
118:114	Color 3 Green
113:109	Color 3 Blue
108:104	Color 2 Red
103:99	Color 2 Green
98:94	Color 2 Blue
93:89	Color 1 Red

CC_CHROMA Block Decoding

The four colors (Color 0-3) are converted from R5G5B5 to R8G8B8 by replicating the 3 MSBs into the 3 LSBs, as shown in the following tables:

FXT CC_CHROMA Decoded Colors

Expanded Color Bit	Expanded Channel Bit	Encoded Block Source Bit
Color 3 [23:17]	Color 3 Red [7:3]	[123:119]
Color 3 [18:16]	Color 3 Red [2:0]	[123:121]
Color 3 [15:11]	Color 3 Green [7:3]	[118:114]
Color 3 [10:08]	Color 3 Green [2:0]	[118:116]
Color 3 [07:03]	Color 3 Blue [7:3]	[113:109]
Color 3 [02:00]	Color 3 Blue [2:0]	[113:111]
Color 2 [23:17]	Color 2 Red [7:3]	[108:104]
Color 2 [18:16]	Color 2 Red [2:0]	[108:106]
Color 2 [15:11]	Color 2 Green [7:3]	[103:99]
Color 2 [10:08]	Color 2 Green [2:0]	[103:101]
Color 2 [07:03]	Color 2 Blue [7:3]	[98:94]
Color 2 [02:00]	Color 2 Blue [2:0]	[98:96]
Color 1 [23:17]	Color 1 Red [7:3]	[93:89]
Color 1 [18:16]	Color 1 Red [2:0]	[93:91]
Color 1 [15:11]	Color 1 Green [7:3]	[88:84]
Color 1 [10:08]	Color 1 Green [2:0]	[88:86]
Color 1 [07:03]	Color 1 Blue [7:3]	[83:79]
Color 1 [02:00]	Color 1 Blue [2:0]	[83:81]
Color 0 [23:17]	Color 0 Red [7:3]	[78:74]
Color 0 [18:16]	Color 0 Red [2:0]	[78:76]
Color 0 [15:11]	Color 0 Green [7:3]	[73:69]
Color 0 [10:08]	Color 0 Green [2:0]	[73:71]
Color 0 [07:03]	Color 0 Blue [7:3]	[68:64]
Color 0 [02:00]	Color 0 Blue [2:0]	[68:66]

This table is then used as a 4-entry Lookup Table, where each 2-bit Texel n Select field of the encoded CC_CHROMA block is used to index into a 32-bit A8R8G8B8 color from the table (Alpha defaults to 0FFh) completing the decode of the CC_CHROMA block.

FXT CC_CHROMA Interpolated Color Table

Texel Select	Color ARGB
0	Color0.ARGB
1	Color1.ARGB
2	Color2.ARGB
3	Color3.ARGB

FXT1 CC_MIXED Format

In the CC_MIXED encoding format, four 15-bit R5G5B5 colors are included in the encoded block: Color 0 and Color 1 are used for Texels 0-15, and Color 2 and Color 3 are used for Texels 16-31.

Each pair of colors are then expanded (using high-order bit replication) to form 4-entry tables of 24-bit RGB colors. The encoded block contains a 2-bit index value per texel that is used to lookup a 24-bit RGB color from the table. The Alpha component defaults to fully opaque (0FFh).

CC_MIXED Block Encoding

The following table describes the encoding of the 128-bit (DQWord) CC_MIXED block format:

FXT CC_MIXED Block Encoding

Bit	Description
127	Mode = ‘1’b (CC_MIXED)
126	Color 3 Green [0]
125	Color 1 Green [0]
124	Alpha [0]
123:119	Color 3 Red
118:114	Color 3 Green
113:109	Color 3 Blue
108:104	Color 2 Red
103:99	Color 2 Green
98:94	Color 2 Blue
93:89	Color 1 Red
88:84	Color 1 Green
83:79	Color 1 Blue
78:74	Color 0 Red
73:69	Color 0 Green
68:64	Color 0 Blue
63:62	Texel 31 Select
...	...
33:32	Texel 16 Select
31:30	Texel 15 Select
...	...
1:0	Texel 0 Select

CC_MIXED Block Decoding

The decode of the CC_MIXED block is modified by Bit 124 (Alpha [0]) of the encoded block.

Alpha[0] = 0 Decoding

When Alpha[0] = 0 the four colors are encoded as 16-bit R5G6B5 values, with the Green LSB defined as per the following table:

FXT CC_MIXED (Alpha[0]=0) Decoded Colors

Encoded Color Bit	Definition
Color 3 Green [0]	Encoded Bit [126]
Color 2 Green [0]	Encoded Bit [33] XOR Encoded Bit [126]
Color 1 Green [0]	Encoded Bit [125]
Color 0 Green [0]	Encoded Bit [1] XOR Encoded Bit [125]

The four colors (Color 0-3) are then converted from R5G5B6 to R8G8B8 by replicating the 3 MSBs into the 3 LSBs, as shown in the following table:

FXT CC_MIXED Decoded Colors (Alpha[0] = 0)

Expanded Color Bit	Expanded Channel Bit	Encoded Block Source Bit
Color 3 [23:17]	Color 3 Red [7:3]	[123:119]
Color 3 [18:16]	Color 3 Red [2:0]	[123:121]
Color 3 [15:11]	Color 3 Green [7:3]	[118:114]
Color 3 [10]	Color 3 Green [2]	[126]
Color 3 [09:08]	Color 3 Green [1:0]	[118:117]
Color 3 [07:03]	Color 3 Blue [7:3]	[113:109]
Color 3 [02:00]	Color 3 Blue [2:0]	[113:111]
Color 2 [23:17]	Color 2 Red [7:3]	[108:104]
Color 2 [18:16]	Color 2 Red [2:0]	[108:106]
Color 2 [15:11]	Color 2 Green [7:3]	[103:99]
Color 2 [10]	Color 2 Green [2]	[33] XOR [126]]
Color 2 [09:08]	Color 2 Green [1:0]	[103:100]
Color 2 [07:03]	Color 2 Blue [7:3]	[98:94]
Color 2 [02:00]	Color 2 Blue [2:0]	[98:96]
Color 1 [23:17]	Color 1 Red [7:3]	[93:89]
Color 1 [18:16]	Color 1 Red [2:0]	[93:91]
Color 1 [15:11]	Color 1 Green [7:3]	[88:84]
Color 1 [10]	Color 1 Green [2]	[125]
Color 1 [09:08]	Color 1 Green [1:0]	[88:86]
Color 1 [07:03]	Color 1 Blue [7:3]	[83:79]
Color 1 [02:00]	Color 1 Blue [2:0]	[83:81]
Color 0 [23:17]	Color 0 Red [7:3]	[78:74]

Expanded Color Bit	Expanded Channel Bit	Encoded Block Source Bit
Color 0 [18:16]	Color 0 Red [2:0]	[78:76]
Color 0 [15:11]	Color 0 Green [7:3]	[73:69]
Color 0 [10]	Color 0 Green [2]	[1] XOR [125]
Color 0 [09:08]	Color 0 Green [1:0]	[73:71]
Color 0 [07:03]	Color 0 Blue [7:3]	[68:64]
Color 0 [02:00]	Color 0 Blue [2:0]	[68:66]

The two sets of 24-bit colors (Color 0,1 and Color 2,3) are then used to create two tables of four interpolated colors (with Alpha = 0FFh). The Color0,1 table is used as a lookup table for texel 0-15 indices, and the Color2,3 table used for texels 16-31 indices, as shown in the following figures:

FXT CC_MIXED Interpolated Color Table (Alpha[0]=0, Texels 0-15)

Texel 0-15 Select	Color RGB	Alpha
0	Color0.RGB	0FFh
1	(2*Color0.RGB + Color1.RGB + 1) /3	0FFh
2	(Color0.RGB + 2*Color1.RGB + 1) /3	0FFh
3	Color1.RGB	0FFh

FXT CC_MIXED Interpolated Color Table (Alpha[0]=0, Texels 16-31)

Texel 16-31 Select	Color RGB	Alpha
0	Color2.RGB	0FFh
1	(2/3) * Color2.RGB + (1/3) * Color3.RGB	0FFh
2	(1/3) * Color2.RGB + (2/3) * Color3.RGB	0FFh
3	Color3.RGB	0FFh

Alpha[0] = 1 Decoding

When Alpha[0] = 1, Color0 and Color2 are encoded as 15-bit R5G5B5 values. Color1 and Color3 are encoded as RGB565 colors, with the Green LSB obtained as shown in the following table:

FXT CC_MIXED (Alpha[0]=0) Decoded Colors

Encoded Color Bit	Definition
Color 3 Green [0]	Encoded Bit [126]
Color 1 Green [0]	Encoded Bit [125]

All four colors are then expanded to 24-bit R8G8B8 colors by bit replication, as show in the following diagram.

FXT CC_MIXED Decoded Colors (Alpha[0] = 1)

Expanded Color Bit	Expanded Channel Bit	Encoded Block Source Bit
Color 3 [23:17]	Color 3 Red [7:3]	[123:119]
Color 3 [18:16]	Color 3 Red [2:0]	[123:121]
Color 3 [15:11]	Color 3 Green [7:3]	[118:114]
Color 3 [10]	Color 3 Green [2]	[126]
Color 3 [09:08]	Color 3 Green [1:0]	[118:117]
Color 3 [07:03]	Color 3 Blue [7:3]	[113:109]
Color 3 [02:00]	Color 3 Blue [2:0]	[113:111]
Color 2 [23:19]	Color 2 Red [7:3]	[108:104]
Color 2 [18:16]	Color 2 Red [2:0]	[108:106]
Color 2 [15:11]	Color 2 Green [7:3]	[103:99]
Color 2 [10:08]	Color 2 Green [2:0]	[103:101]
Color 2 [07:03]	Color 2 Blue [7:3]	[98:94]
Color 2 [02:00]	Color 2 Blue [2:0]	[98:96]
Color 1 [23:17]	Color 1 Red [7:3]	[93:89]
Color 1 [18:16]	Color 1 Red [2:0]	[93:91]
Color 1 [15:11]	Color 1 Green [7:3]	[88:84]
Color 1 [10]	Color 1 Green [2]	[125]
Color 1 [09:08]	Color 1 Green [1:0]	[88:87]
Color 1 [07:03]	Color 1 Blue [7:3]	[83:79]
Color 1 [02:00]	Color 1 Blue [2:0]	[83:81]
Color 0 [23:19]	Color 0 Red [7:3]	[78:74]
Color 0 [18:16]	Color 0 Red [2:0]	[78:76]
Color 0 [15:11]	Color 0 Green [7:3]	[73:69]
Color 0 [10:08]	Color 0 Green [2:0]	[73:71]
Color 0 [07:03]	Color 0 Blue [7:3]	[68:64]
Color 0 [02:00]	Color 0 Blue [2:0]	[68:66]

The two sets of 24-bit colors (Color 0,1 and Color 2,3) are then used to create two tables of four colors. The Color0,1 table is used as a lookup table for texel 0-15 indices, and the Color2,3 table used for texels 16-31 indices. The color at index 1 is the linear interpolation of the base colors, while the color at index 3 is defined as Black (0,0,0) with Alpha = 0, as shown in the following figures:

FXT CC_MIXED Interpolated Color Table (Alpha[0]=1, Texels 0-15)

Texel 0-15 Select	Color RGB	Alpha
0	Color0.RGB	0FFh
1	(Color0.RGB + Color1.RGB) /2	0FFh
2	Color1.RGB	0FFh
3	Black (0,0,0)	0

FXT CC_MIXED Interpolated Color Table (Alpha[0]=1, Texels 16-31)

Texel 16-31 Select	Color RGB	Alpha
0	Color2.RGB	0FFh
1	(Color2.RGB + Color3.RGB) /2	0FFh
2	Color3.RGB	0FFh
3	Black (0,0,0)	0

These tables are then used as a 4-entry Lookup Table, where each 2-bit Texel n Select field of the encoded CC_MIXED block is used to index into the appropriate 32-bit A8R8G8B8 color from the table, completing the decode of the CC_CMIXED block.

FXT1 CC_ALPHA Format

In the CC_ALPHA encoding format, three A5R5G5B5 colors are provided in the encoded block. A control bit (LERP) is used to define the lookup table (or tables) used to dereference the 2-bit Texel Selects.

CC_ALPHA Block Encoding

The following table describes the encoding of the 128-bit (DQWord) CC_ALPHA block format:

FXT CC_ALPHA Block Encoding

Bit	Description
127:125	Mode = '011'b (CC_ALPHA)
124	LERP
123:119	Color 2 Alpha
118:114	Color 1 Alpha
113:109	Color 0 Alpha
108:104	Color 2 Red
103:99	Color 2 Green
98:94	Color 2 Blue
93:89	Color 1 Red
88:84	Color 1 Green
83:79	Color 1 Blue
78:74	Color 0 Red
73:69	Color 0 Green
68:64	Color 0 Blue
63:62	Texel 31 Select
...	...
33:32	Texel 16 Select
31:30	Texel 15 Select
...	...
1:0	Texel 0 Select

CC_ALPHA Block Decoding

Each of the three colors (Color 0-2) are converted from A5R5G5B5 to A8R8G8B8 by replicating the 3 MSBs into the 3 LSBs, as shown in the following tables:

FXT CC_ALPHA Decoded Colors

Expanded Color Bit	Expanded Channel Bit	Encoded Block Source Bit
Color 2 [31:27]	Color 2 Alpha [7:3]	[123:119]
Color 2 [26:24]	Color 2 Alpha [2:0]	[123:121]
Color 2 [23:17]	Color 2 Red [7:3]	[108:104]
Color 2 [18:16]	Color 2 Red [2:0]	[108:106]
Color 2 [15:11]	Color 2 Green [7:3]	[103:99]
Color 2 [10:08]	Color 2 Green [2:0]	[103:101]
Color 2 [07:03]	Color 2 Blue [7:3]	[98:94]

Expanded Color Bit	Expanded Channel Bit	Encoded Block Source Bit
Color 2 [02:00]	Color 2 Blue [2:0]	[98:96]
Color 1 [31:27]	Color 1 Alpha [7:3]	[118:114]
Color 1 [26:24]	Color 1 Alpha [2:0]	[118:116]
Color 1 [23:17]	Color 1 Red [7:3]	[93:89]
Color 1 [18:16]	Color 1 Red [2:0]	[93:91]
Color 1 [15:11]	Color 1 Green [7:3]	[88:84]
Color 1 [10:08]	Color 1 Green [2:0]	[88:86]
Color 1 [07:03]	Color 1 Blue [7:3]	[83:79]
Color 1 [02:00]	Color 1 Blue [2:0]	[83:81]
Color 0 [31:27]	Color 0 Alpha [7:3]	[113:109]
Color 0 [26:24]	Color 0 Alpha [2:0]	[113:111]
Color 0 [23:17]	Color 0 Red [7:3]	[78:74]
Color 0 [18:16]	Color 0 Red [2:0]	[78:76]
Color 0 [15:11]	Color 0 Green [7:3]	[73:69]
Color 0 [10:08]	Color 0 Green [2:0]	[73:71]
Color 0 [07:03]	Color 0 Blue [7:3]	[68:64]
Color 0 [02:00]	Color 0 Blue [2:0]	[68:66]

LERP = 0 Decoding

When LERP = 0, a single 4-entry lookup table is formed using the three expanded colors, with the 4th entry defined as transparent black (ARGB=0,0,0,0). Each 2-bit Texel n Select field of the encoded CC_ALPHA block is used to index into a 32-bit A8R8G8B8 color from the table completing the decode of the CC_ALPHA block.

FXT CC_ALPHA Interpolated Color Table (LERP=0)

Texel Select	Color	Alpha
0	Color0.RGB	Color0.Alpha
1	Color1.RGB	Color1.Alpha
2	Color2.RGB	Color2.Alpha
3	Black (RGB=0,0,0)	0

LERP = 1 Decoding

When LERP = 1, the three expanded colors are used to create two tables of four interpolated colors. The Color0,1 table is used as a lookup table for texel 0-15 indices, and the Color1,2 table used for texels 16-31 indices, as shown in the following figures:

FXT CC_ALPHA Interpolated Color Table (LERP=1, Texels 0-15)

Texel 0-15 Select	Color ARGB
0	Color0.ARGB
1	(2*Color0.ARGB + Color1.ARGB + 1) /3
2	(Color0.ARGB + 2*Color1.ARGB + 1) /3
3	Color1.ARGB

FXT CC_ALPHA Interpolated Color Table (LERP=1, Texels 16-31)

Texel 16-31 Select	Color ARGB
0	Color2.ARGB
1	(2*Color2.ARGB + Color1.ARGB + 1) /3
2	(Color2.ARGB + 2*Color1.ARGB + 1) /3
3	Color1.ARGB

DXT/BC1-3 Texture Formats

Note that non-power-of-2 dimensioned maps may require the surface to be padded out to the next multiple of four texels – here the pad texels are not referenced by the device.

An 8-byte (QWord) block encoding can be used if the source texture contains no transparency (is opaque) or if the transparency can be specified by a one-bit alpha. A 16-byte (DQWord) block encoding can be used to support source textures that require more than one-bit alpha: here the 1st QWord is used to encode the texel alpha values, and the 2nd QWord is used to encode the texel color values.

These three types of format are discussed in the following sections:

- Opaque and One-bit Alpha Textures (DXT1)
- Opaque Textures (DXT1_RGB)
- Textures with Alpha Channels (DXT2-5)

DXT2 and DXT3 are equivalent compression formats from the perspective of the hardware. The only difference between the two is the use of pre-multiplied alpha encoding, which does not affect hardware.

Likewise, DXT4 and DXT5 are the same compression formats with the only difference being the use of pre-multiplied alpha encoding.

Note that the surface formats DXT1-5 are referred to in the DirectX Specification as BC1-3. The mapping between formats is shown below:

- DXT1 ⇒ BC1
- DXT2/DXT3 ⇒ BC2
- DXT4/DXT5 ⇒ BC3

Programming Note	
Context:	DXT Texture Formats
• Any single texture must specify that its data is stored as 64 or 128 bits per group of 16 texels. If 64-bit blocks—that is, format DXT1—are used for the texture, it is possible to mix the opaque and one-bit alpha formats on a per-block basis within the same texture. In other words, the comparison of the unsigned integer magnitude of color_0 and color_1 is performed uniquely for each block of 16 texels. • When 128-bit blocks are used, then the alpha channel must be specified in either explicit (format DXT2 or DXT3) or interpolated mode (format DXT4 or DXT5) for the entire texture. Note that as with color, once interpolated mode is selected then either 8 interpolated alphas or 6 interpolated alphas mode can be used on a block-by-block basis. Again the magnitude comparison of alpha_0 and alpha_1 is done uniquely on a block-by-block basis.	

Opaque and One-bit Alpha Textures (DXT1/BC1)

Texture format DXT1 is for textures that are opaque or have a single transparent color. For each opaque or one-bit alpha block, two 16-bit R5G6B5 values and a 4x4 bitmap with 2-bits-per-pixel are stored. This totals 64 bits (1 QWord) for 16 texels, or 4-bits-per-texel.

In the block bitmap, there are two bits per texel to select between the four colors, two of which are stored in the encoded data. The other two colors are derived from these stored colors by linear interpolation.

The one-bit alpha format is distinguished from the opaque format by comparing the two 16-bit color values stored in the block. They are treated as unsigned integers. If the first color is greater than the second, it implies that only opaque texels are defined. This means four colors will be used to represent the texels. In four-color encoding, there are two derived colors and all four colors are equally distributed in RGB color space. This format is analogous to R5G6B5 format. Otherwise, for one-bit alpha transparency, three colors are used and the fourth is reserved to represent transparent texels. Note that the color blocks in DXT2-5 formats strictly use four colors, as the alpha values are obtained from the alpha block .

In three-color encoding, there is one derived color and the fourth two-bit code is reserved to indicate a transparent texel (alpha information). This format is analogous to A1R5G5B5, where the final bit is used for encoding the alpha mask.

The following piece of pseudo-code illustrates the algorithm for deciding whether three- or four-color encoding is selected:

```
 if (color_0 > color_1)
 {
   // Four-color block: derive the other two colors.
   // 00 = color_0, 01 = color_1, 10 = color_2, 11 = color_3
   // These two bit codes correspond to the 2-bit fields
   // stored in the 64-bit block.  color_2 = (2 * color_0 + color_1) / 3;
    color_3 = (color 0 + 2 * color_1) / 3;
 }
 else
 {
   // Three-color block: derive the other color.  // 00 = color_0, 01 = color_1, 10 =
color_2,
   // 11 = transparent.  // These two bit codes correspond to the 2-bit fields
   // stored in the 64-bit block.  color_2 = (color_0 + color_1) / 2;
    color_3 = transparent;
 }
```

The following tables show the memory layout for the 8-byte block. It is assumed that the first index corresponds to the y-coordinate and the second corresponds to the x-coordinate. For example, Texel[1][2] refers to the texture map pixel at (x,y) = (2,1).

Here is the memory layout for the 8-byte (64-bit) block:

Word Address	16-bit Word
0	Color_0
1	Color_1
2	Bitmap Word_0
3	Bitmap Word_1

Color_0 and Color_1 (colors at the two extremes) are laid out as follows:

Bits	Color
15:11	Red color component
10:5	Green color component
4:0	Blue color component

Bits	Texel
1:0 (LSB)	Texel[0][0]
3:2	Texel[0][1]
5:4	Texel[0][2]
7:6	Texel[0][3]
9:8	Texel[1][0]
11:10	Texel[1][1]
13:12	Texel[1][2]
15:14	Texel[1][3]

Bitmap Word_1 is laid out as follows:

Bits	Texel
1:0 (LSB)	Texel[2][0]
3:2	Texel[2][1]
5:4	Texel[2][2]
7:6	Texel[2][3]
9:8	Texel[3][0]
11:10	Texel[3][1]
13:12	Texel[3][2]
15:14 (MSB)	Texel[3][3]

Example of Opaque Color Encoding

As an example of opaque encoding, we will assume that the colors red and black are at the extremes. We will call red color_0 and black color_1. There will be four interpolated colors that form the uniformly distributed gradient between them. To determine the values for the 4x4 bitmap, the following calculations are used:

```
00 ? color_0
01 ? color_1
10 ? 2/3 color_0 + 1/3 color_1
11 ? 1/3 color_0 + 2/3 color_1
```

Example of One-bit Alpha Encoding

This format is selected when the unsigned 16-bit integer, color_0, is less than the unsigned 16-bit integer, color_1. An example of where this format could be used is leaves on a tree to be shown against a blue sky. Some texels could be marked as transparent while three shades of green are still available for the leaves. Two of these colors fix the extremes, and the third color is an interpolated color.

The bitmap encoding for the colors and the transparency is determined using the following calculations:

```
00 ? color_0
01 ? color_1
10 ? 1/2 color_0 + 1/2 color_1
11 ? Transparent
```

Opaque Textures (DXT1_RGB)

Texture format DXT1_RGB is identical to DXT1, with the exception that the One-bit Alpha encoding is removed. Color 0 and Color 1 are not compared, and the resulting texel color is derived strictly from the Opaque Color Encoding. The alpha channel defaults to 1.0.

Programming Note	
Context:	Opaque Textures (DXT1_RGB)
The behavior of this format is not compliant with the OGL spec.	

Compressed Textures with Alpha Channels (DXT2-5 / BC2-3)

There are two ways to encode texture maps that exhibit more complex transparency. In each case, a block that describes the transparency precedes the 64-bit block already described for DXT1. The transparency is either represented as a 4x4 bitmap with four bits per pixel (explicit encoding), or with fewer bits and linear interpolation analogous to what is used for color encoding.

The transparency block and the color block are laid out as follows:

Word Address	64-bit Block
3:0	Transparency block
7:4	Previously described 64-bit block

Explicit Texture Encoding

For explicit texture encoding (DXT2 and DXT3 formats), the alpha components of the texels that describe transparency are encoded in a 4x4 bitmap with 4 bits per texel. These 4 bits can be achieved through a variety of means such as dithering or by simply using the 4 most significant bits of the alpha data. However they are produced, they are used just as they are, without any form of interpolation.

Note: DirectDraw's compression method uses the 4 most significant bits.

The following tables illustrate how the alpha information is laid out in memory, for each 16-bit word.

This is the layout for Word 0:

Bits	Alpha
3:0 (LSB)	[0][0]
7:4	[0][1]
11:8	[0][2]
15:12 (MSB)	[0][3]

This is the layout for Word 1:

Bits	Alpha
3:0 (LSB)	[1][0]
7:4	[1][1]
11:8	[1][2]
15:12 (MSB)	[1][3]

This is the layout for Word 2:

Bits	Alpha
3:0 (LSB)	[2][0]
7:4	[2][1]
11:8	[2][2]
15:12 (MSB)	[2][3]

This is the layout for Word 3:

Bits	Alpha
3:0 (LSB)	[3][0]
7:4	[3][1]
11:8	[3][2]
15:12 (MSB)	[3][3]

Three-Bit Linear Alpha Interpolation

The encoding of transparency for the DXT4 and DXT5 formats is based on a concept similar to the linear encoding used for color. Two 8-bit alpha values and a 4x4 bitmap with three bits per pixel are stored in the first eight bytes of the block. The representative alpha values are used to interpolate intermediate alpha values. Additional information is available in the way the two alpha values are stored. If alpha_0 is greater than alpha_1, then six intermediate alpha values are created by the interpolation. Otherwise, four intermediate alpha values are interpolated between the specified alpha extremes. The two additional implicit alpha values are 0 (fully transparent) and 255 (fully opaque).

The following pseudo-code illustrates this algorithm:

```
// 8-alpha or 6-alpha block?
if (alpha_0 > alpha_1) {
   // 8-alpha block: derive the other 6 alphas.
   // 000 = alpha_0, 001 = alpha_1, others are interpolated
  alpha_2 = (6 * alpha_0 + alpha_1) / 7;      // Bit code 010
  alpha_3 = (5 * alpha_0 + 2 * alpha_1) / 7; // Bit code 011
  alpha_4 = (4 * alpha_0 + 3 * alpha_1) / 7; // Bit code 100
  alpha_5 = (3 * alpha_0 + 4 * alpha_1) / 7; // Bit code 101
  alpha_6 = (2 * alpha_0 + 5 * alpha_1) / 7; // Bit code 110
  alpha_7 = (alpha_0 + 6 * alpha_1) / 7;      // Bit code 111
 }
else {
   // 6-alpha block: derive the other alphas.
   // 000 = alpha_0, 001 = alpha_1, others are interpolated
  alpha_2 = (4 * alpha_0 + alpha_1) / 5;      // Bit code 010
  alpha_3 = (3 * alpha_0 + 2 * alpha_1) / 5; // Bit code 011
  alpha_4 = (2 * alpha_0 + 3 * alpha_1) / 5; // Bit code 100
  alpha_5 = (alpha_0 + 4 * alpha_1) / 5;      // Bit code 101
  alpha_6 = 0;                                // Bit code 110
  alpha_7 = 255;                              // Bit code 111
}
```

The memory layout of the alpha block is as follows:

Byte	Alpha
0	Alpha_0
1	Alpha_1
2	[0][2] (2 LSBs), [0][1], [0][0]
3	[1][1] (1 LSB), [1][0], [0][3], [0][2] (1 MSB)
4	[1][3], [1][2], [1][1] (2 MSBs)
5	[2][2] (2 LSBs), [2][1], [2][0]
6	[3][1] (1 LSB), [3][0], [2][3], [2][2] (1 MSB)
7	[3][3], [3][2], [3][1] (2 MSBs)

BC4

These formats (BC4_UNORM and BC4_SNORM) compresses single-component UNORM or SNORM data. An 8-byte compression block represents a 4x4 block of texels. The texels are labeled as texel[row][column] where both row and column range from 0 to 3. Texel[0][0] is the upper left texel.

The 8-byte compression block is laid out as follows:

Bit	Description
7:0	red_0
15:8	red_1
18:16	texel[0][0] bit code
21:19	texel[0][1] bit code
24:22	texel[0][2] bit code
27:25	texel[0][3] bit code
30:28	texel[1][0] bit code
33:31	texel[1][1] bit code
36:34	texel[1][2] bit code
39:37	texel[1][3] bit code
42:40	texel[2][0] bit code
45:43	texel[2][1] bit code
48:46	texel[2][2] bit code
51:49	texel[2][3] bit code
54:52	texel[3][0] bit code
57:55	texel[3][1] bit code
60:58	texel[3][2] bit code
63:61	texel[3][3] bit code

There are two interpolation modes, chosen based on which reference color is larger. The first mode has the two reference colors plus six equal-spaced interpolated colors between the reference colors, chosen based on the three-bit code for that texel. The second mode has the two reference colors plus four interpolated colors, chosen by six of the three-bit codes. The remaining two codes select min and max values for the colors. The values of red_0 through red_7 are computed as follows:

```
red_0 = red_0;                          // bit code 000
red_1 = red_1;                          // bit code 001
if (red_0 > red_1) {
    red_2 = (6 * red_0 + 1 * red_1) / 7; // bit code 010
    red_3 = (5 * red_0 + 2 * red_1) / 7; // bit code 011
    red_4 = (4 * red_0 + 3 * red_1) / 7; // bit code 100
    red_5 = (3 * red_0 + 4 * red_1) / 7; // bit code 101
    red_6 = (2 * red_0 + 5 * red_1) / 7; // bit code 110
    red_7 = (1 * red_0 + 6 * red_1) / 7; // bit code 111
}
else {
    red_2 = (4 * red_0 + 1 * red_1) / 5; // bit code 010
    red_3 = (3 * red_0 + 2 * red_1) / 5; // bit code 011
    red_4 = (2 * red_0 + 3 * red_1) / 5; // bit code 100
    red_5 = (1 * red_0 + 4 * red_1) / 5; // bit code 101
    red_6 = UNORM ? 0.0 : -1.0;          // bit code 110 (0 for UNORM, -1 for SNORM)
    red_7 = 1.0;                         // bit code 111
}
```

BC5

These formats (BC5_UNORM and BC5_SNORM) compresses dual-component UNORM or SNORM data. A 16-byte compression block represents a 4x4 block of texels. The texels are labeled as texel[row][column] where both row and column range from 0 to 3. Texel[0][0] is the upper left texel.

The 16-byte compression block is laid out as follows:

Bit	Description
7:0	red_0
15:8	red_1
18:16	texel[0][0] red bit code
21:19	texel[0][1] red bit code
24:22	texel[0][2] red bit code
27:25	texel[0][3] red bit code
30:28	texel[1][0] red bit code
33:31	texel[1][1] red bit code
36:34	texel[1][2] red bit code
39:37	texel[1][3] red bit code
42:40	texel[2][0] red bit code
45:43	texel[2][1] red bit code
48:46	texel[2][2] red bit code
51:49	texel[2][3] red bit code

Bit	Description
54:52	texel[3][0] red bit code
57:55	texel[3][1] red bit code
60:58	texel[3][2] red bit code
63:61	texel[3][3] red bit code
71:64	green_0
79:72	green_1
82:80	texel[0][0] green bit code
85:83	texel[0][1] green bit code
88:86	texel[0][2] green bit code
91:89	texel[0][3] green bit code
94:92	texel[1][0] green bit code
97:95	texel[1][1] green bit code
100:98	texel[1][2] green bit code
103:101	texel[1][3] green bit code
106:104	texel[2][0] green bit code
109:107	texel[2][1] green bit code
112:110	texel[2][2] green bit code
115:113	texel[2][3] green bit code
118:116	texel[3][0] green bit code
121:119	texel[3][1] green bit code
124:122	texel[3][2] green bit code
127:125	texel[3][3] green bit code

There are two interpolation modes, chosen based on which reference color is larger. The first mode has the two reference colors plus six equal-spaced interpolated colors between the reference colors, chosen based on the three-bit code for that texel. The second mode has the two reference colors plus four interpolated colors, chosen by six of the three-bit codes. The remaining two codes select min and max values for the colors. The values of red_0 through red_7 are computed as follows:

```
red_0 = red_0;                          // bit code 000
red_1 = red_1;                          // bit code 001
if (red_0 > red_1) {
    red_2 = (6 * red_0 + 1 * red_1) / 7; // bit code 010
    red_3 = (5 * red_0 + 2 * red_1) / 7; // bit code 011
    red_4 = (4 * red_0 + 3 * red_1) / 7; // bit code 100
    red_5 = (3 * red_0 + 4 * red_1) / 7; // bit code 101
    red_6 = (2 * red_0 + 5 * red_1) / 7; // bit code 110
    red_7 = (1 * red_0 + 6 * red_1) / 7; // bit code 111
}
else {
    red_2 = (4 * red_0 + 1 * red_1) / 5; // bit code 010
    red_3 = (3 * red_0 + 2 * red_1) / 5; // bit code 011
    red_4 = (2 * red_0 + 3 * red_1) / 5; // bit code 100
    red_5 = (1 * red_0 + 4 * red_1) / 5; // bit code 101
    red_6 = UNORM ? 0.0 : -1.0;          // bit code 110 (0 for UNORM, -1 for SNORM)
    red_7 = 1.0;                         // bit code 111
}
```

The same calculations are done for green, using the corresponding reference colors and bit codes.

BC6H

For CHV, BSW, these formats (BC6H_UF16 and BC6H_SF16) compresses 3-channel images with high dynamic range (> 8 bits per channel). BC6H supports floating point denorms but there is no support for INF and NaN, other than with BC6H_SF16 –INF is supported. The alpha channel is not included, thus alpha is returned at its default value.

The BC6H block is 16 bytes and represents a 4x4 block of texels. The texels are labeled as texel[row][column] where both row and column range from 0 to 3. Texel[0][0] is the upper left texel. BC6H has 14 different modes, the mode that the block is in is contained in the least significant bits (either 2 or 5 bits).

The basic scheme consists of interpolating colors along either one or two lines, with per-texel indices indicating which color along the line is chosen for each texel. If a two-line mode is selected, one of 32 partition sets is indicated which selects which of the two lines each texel is assigned to.

Field Definition

There are 14 possible modes for a BC6H block, the format of each is indicated in the 14 tables below. The mode is selected by the unique mode bits specified in each table. The first 10 modes use two lines (“TWO”), and the last 4 use one line (“ONE”). The difference between the various two-line and one-line modes is with the precision of the first endpoint and the number of bits used to store delta values for the remaining endpoints. Two modes (9 and 10) specify each endpoint as an original value rather than using the deltas (these are indicated as having no delta values).

The endpoints values and deltas are indicated in the tables using a two-letter name. The first letter is “r”, “g”, or “b” indicating the color channel. The second letter is “w”, “x”, “y”, or “z” indicating which of the four endpoints. The first line has endpoints “w” and “x”, with “w” being the endpoint that is fully specified (i.e. not as a delta). The second line has endpoints “y” and “z”. Modes using ONE mode do not have endpoints “y” and “z” as they have only one line.

In addition to the mode and endpoint data, TWO blocks contain a 5-bit “partition” which selects one of the partition sets, and a 46-bit set of indices. ONE blocks contain a 63-bit set of indices. These are described in more detail below.

Mode 0: (TWO) Red, Green, Blue: 10-bit endpoint, 5-bit deltas

Bit	Description
1:0	mode = 00
2	gy[4]
3	by[4]
4	bz[4]
14:5	rw[9:0]
24:15	gw[9:0]
34:25	bw[9:0]
39:35	rx[4:0]
40	gz[4]
44:41	gy[3:0]

123:120	texel[3][2] index

Bit	Description
127:124	texel[3][3] index

Endpoint Computation

The endpoints can be defined in many different ways, as shown above. This section describes how the endpoints are computed from the bits in the compression block. The method used depends on whether the BC6H format is signed (BC6H_SF16) or unsigned (BC6H_UF16).

First, each channel (RGB) of each endpoint is extended to 16 bits. Each is handled identically and independently, however in some modes different channels have different incoming precision which must be accounted for. The following rules are employed:

- If the format is BC6H_SF16 or the endpoint is a delta value, the value is sign-extended to 16 bits
- For all other cases, the value is zero-extended to 16 bits

If there are no endpoints that are delta values, endpoint computation is complete. For endpoints that are delta values, the next step involves computing the absolute endpoint. The “w” endpoint is always absolute and acts as a base value for the other three endpoints. Each channel is handled identically and independently.

```
x = w + x
y = w + y
z = w + z
```

The above is performed using 16-bit integer arithmetic. Overflows beyond 16 bits are ignored (any resulting high bits are dropped).

Palette Color Computation

The next step involves computing the color palette values that provide the available values for each texel's color. The color palette for each line consists of the two endpoint colors plus 6 (TWO mode) or 14 (ONE mode) interpolated colors. Again each channel is processed independently.

First the endpoints are unquantized, with each channel of each endpoint being processed independently. The number of bits in the original base *w* value represents the precision of the endpoints. The input endpoint is called *e*, and the resulting endpoints are represented as 17-bit signed integers and called e' below.

For the BC6H_UF16 format:

- if the precision is already 16 bits, e' = e
- if e = 0, e' = 0
- if e is the maximum representible in the precision, e' = 0xFFFF
- otherwise, e' = ((e « 16) + 0x8000) » precision

For the BC6H_SF16 format, the value is treated as sign magnitude. The sign is not changed, e' and e refer only to the magnitude portion:

- if the precision is already 16 bits, e' = e
- if e = 0, e' = 0
- if e is the maximum representible in the precision, e' = 0x7FFF
- otherwise, e' = ((e « 15) + 0x4000) » (precision - 1)

Next, the palette values are generated using predefined weights, using the tables below:

```
palette[i] = (w' * (64 - weight[i]) + x' * weight[i] + 32) » 6
```

TWO mode weights:

palette index	0	1	2	3	4	5	6	7
weight	0	9	18	27	37	46	55	64

ONE mode weights:

palette index	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
weight	0	4	9	13	17	21	26	30	34	38	43	47	51	55	60	64

The two end palette indices are equal to the two endpoints given that the weights are 0 and 64. In the above equation w' and x' represent the endpoints e' computed in the previous step corresponding to w and x, respectively. For the second line in TWO mode, w and x are replaced with y and z.

The final step in computing the palette colors is to rescale the final results. For BC6H_UF16 format, the values are multiplied by 31/64. For BC6H_SF16, the values are multiplied by 31/32, treating them as sign magnitude. These final 16-bit results are ultimately treated as 16-bit floats.

Texel Selection

The final step is to select the appropriate palette index for each texel. This index then selects the 16-bit per channel palette value, which is re-interpreted as a 16-bit floating point result for input into the filter. This procedure differs depending on whether the mode is TWO or ONE.

ONE Mode

In ONE mode, there is only one set of palette colors, but the “indices” field is 63 bits. This field consists of a 4-bit palette index for each of the 16 texels, with the exception of the texel at [0][0] which has only 3 bits, the missing high bit being set to zero.

TWO Mode

32 partitions are defined for TWO, which are defined below. Each of the 32 cases shows the 4x4 block of texels, and is indexed by adding its hexadecimal row number (00-1C) to its column number (0-3). Each texel in the 4x4 block indicates whether that texel is part of line 0 (endpoints *w* and *x*) or line 1

(endpoints *y* and *z*). Each case has one texel each of "[0]" and "[1]", the index that this is at is termed the "fix-up index". These texels have one less bit in the index.

	0				1				2				3

18	[0]	0	[1]	1	[0]	0	0	0	[0]	1	[1]	0	[0]	0	[1]	1
	0	0	0	1	1	0	0	0	0	1	1	0	0	1	1	0
	0	0	0	1	[1]	0	0	0	0	1	1	0	0	1	1	0
	0	0	0	0	1	1	0	0	0	1	1	0	1	1	0	0
1C	[0]	0	0	1	[0]	0	0	0	[0]	1	[1]	1	[0]	0	[1]	1
	0	1	1	1	1	1	1	1	0	0	0	1	1	0	0	1
	[1]	1	1	0	[1]	1	1	1	1	0	0	0	1	0	0	1
	1	0	0	0	0	0	0	0	1	1	1	0	1	1	0	0

The 46-bit "indices" field consists of a 3-bit palette index for each of the 16 texels, with the exception of the bracketed texels that have only two bits each. The high bit of these texels is set to zero.

BC7

These formats (BC7_UNORM and BC7_UNORM_SRGB) compresses 3-channel and 4-channel fixed point images.

The BC7 block is 16 bytes and represents a 4x4 block of texels. The texels are labeled as texel[row][column] where both row and column range from 0 to 3. Texel[0][0] is the upper left texel. BC7 has 8 different modes, the mode that the block is in is contained in the least significant bits (1-8 bits depending on mode).

The basic scheme consists of interpolating colors and alpha in some modes along either one, two, or three lines, with per-texel indices indicating which color/alpha along the line is chosen for each texel. If a two- or three-line mode is selected, one of 64 partition sets is indicated which selects which of the two lines each texel is assigned to, although some modes are limited to the first 16 partition sets. In the color-only modes, alpha is always returned at its default value of 1.0.

Some modes contain the following fields:

- **P-bits.** These represent shared LSB for all components of the endpoint, which increases the endpoint precision by one bit. In some cases both endpoints of a line share a P-bit.
- **Rotation bits.** For blocks with separate color and alpha, this 2-bit field allows selection of which of the four components has its own indexes (scalar) vs. the other three components (vector).
- **Index selector.** This 1-bit field selects whether the scalar or vector components uses the 3-bit index vs. the 2-bit index.

Field Definition

There are 8 possible modes for a BC7 block, the format of each is indicated in the 8 tables below. The mode is selected by the unique mode bits specified in each table. Each mode has particular characteristics described at the top of the table.

Mode 0: Color only, 3 lines (THREE), 4-bit endpoints with one P-bit per endpoint, 3-bit indices, 16 partitions

Bit	Description
0	mode = 0

94	P0
95	P1
96	P2
97	P3
127:98	indices

Undefined mode values (bits 7:0 = 00000000) return zero in the RGB channels.

The indices fields are variable in length and due to the different locations of the fix-up indices depending on partition set there are a very large number of possible configurations. Each mode above indicates how many bits each index has, and the fix-up indices (one in ONE mode, two in TWO mode, and three in THREE mode) each have one less bit than indicated. However, the indices are always packed into the index fields according to the table below, with the specific bit assignments of each texel following the rules just given.

Bit	Description
LSBs	texel[0][0] index
	texel[0][1] index
	texel[0][2] index
	texel[0][3] index
	texel[1][0] index
	texel[1][1] index
	texel[1][2] index
	texel[1][3] index
	texel[2][0] index
	texel[2][1] index
	texel[2][2] index
	texel[2][3] index
	texel[3][0] index
	texel[3][1] index
	texel[3][2] index
MSBs	texel[3][3] index

Endpoint Computation

The endpoints can be defined with different precision depending on mode, as shown above. This section describes how the endpoints are computed from the bits in the compression block. Each component of each endpoint follows the same steps.

If a P-bit is defined for the endpoint, it is first added as an additional LSB at the bottom of the endpoint value. The endpoint is then bit-replicated to create an 8-bit fixed point endpoint value with a range from 0x00 to 0xFF.

Palette Color Computation

The next step involves computing the color palette values that provide the available values for each texel's color. The color palette for each line consists of the two endpoint colors plus 2, 6, or 14 interpolated colors, depending on the number of bits in the indices. Again each channel is processed independently.

The equation to compute each palette color with index i, given two endpoints is as follows, using the tables below to determine the weight for each palette index:

```
palette[i] = (E0 * (64 - weight[i]) + E1 * weight[i] + 32) » 6
```

2-bit index weights:

palette index	0	1	2	3
weight	0	21	43	64

3-bit index weights:

palette index	0	1	2	3	4	5	6	7
weight	0	9	18	27	37	46	55	64

4-bit index weights:

palette index	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
weight	0	4	9	13	17	21	26	30	34	38	43	47	51	55	60	64

The two end palette indices are equal to the two endpoints given that the weights are 0 and 64. In the above equation E0 and E1 represent the even-numbered and odd-numbered endpoints computed in the previous step for the component and line currently being computed.

Texel Selection

The final step is to select the appropriate palette index for each texel. This index then selects the 8-bit per channel palette value, which is interpreted as an 8-bit UNORM value for input into the filter (In BC7_UNORM_SRGB to UNORM values first go through inverse gamma conversion). This procedure differs depending on whether the mode is ONE, TWO, or THREE.

ONE Mode

In ONE mode, there is only one set of palette colors, thus there is only a single “partition set” defined, with all texels selecting line 0 and texel [0][0] being the “fix-up index” with one less bit in the index.

TWO Mode

64 partitions are defined for TWO, which are defined below. Each of the 64 cases shows the 4x4 block of texels, and is indexed by adding its hexadecimal row number (00-3C) to its column number (0-3). Each texel in the 4x4 block indicates whether that texel is part of line 0 (endpoints *0* and *1*) or line 1 (endpoints *2* and *3*). Each case has one texel each of "[0]" and "[1]", the index that this is at is termed the "fix-up index". These texels have one less bit in the index.

	0				1				2				3

THREE Mode

64 partitions are defined for THREE, which are defined below. Each of the 64 cases shows the 4x4 block of texels, and is indexed by adding its hexadecimal row number (00-3C) to its column number (0-3). Each texel in the 4x4 block indicates whether that texel is part of line 0 (endpoints *0* and *1*), line 1 (endpoints *2* and *3*), or line 2 (endpoints *4* and *5*). Each case has one texel each of "[0]", "[1]", and "[2]", the index that this is at is termed the "fix-up index". These texels have one less bit in the index.

Adaptive Scalable Texture Compression (ASTC)

This section describes the data structure of the Adaptive Scalable Texture Compression (ASTC) format, as well as the decoding flow of ASTC. Also described are the header format and mipmap layout in the compressed texture file of *.astc. This is based on the reference encoder and decoder from the Khronos committee, with an extension to support multiple miplevel texture.

ASTC is a new compressed texture format with following characteristics:

1. ASTC compression format is currently only used for static texture, due to the large amount of computation and high latency required to find the optimal configuration in compression. It cannot be used to compress dynamic textures such as a shadow map.
2. ASTC is a lossy compression technique that cannot be used to compress dynamic textures which do not tolerate quality degradation.
3. ASTC has a huge range of compression ratio and block size, but these choices are fixed for each texture for all blocks at all mipmap levels.
4. ASTC has options to support compression from 1 to 4 channels for texture data.
5. ASTC can support both high and low dynamic textures.
6. ASTC can support both 2D and 3D textures.

Project	Supported Formats
CHV, BSW	2D LDR profile.

ASTC Fundamentals

This section describes some background details and new surface formats for ASTC.

Background

ASTC is a more advanced texture compression technique than the existing BC and ETC, and can reduce footprint & BW of static texture further in Graphics application by providing a texture compression solution at higher compression ratios. To best find the balance point of visual quality and compression, it provides a wide range of bit rate selection from 8bpp to 0.89 bpp in 2D, and 4.6bpp to 0.6 bpp in 3D at various block size of footprints. It also has flexibility to specify 1-4 components, selection of dual plane mode among the specified color components.

It extends the existing linear model on color distribution of each block in multiple partitions (up to 4), with flexible compact supporting on index/weight for color interpolation. ASTC also has a support of high dynamic range (HDR) image and 3D textures. The mixture of HDR and LDR data is within each block level allows a great flexibility to represent high dynamics variation at fine granularity. The support of 3D texture explores the data coherency in all 3 dimensions, without the need to mimic 3D map with 2D slices. On top of everything, void-extent regions are introduced for both 2D and 3D maps as further optimization on large constant region.

Due to the computational complexity and processing delay of the encoding process, ASTC compression encoding is always offline, and can only be used for static texture. It does not support auto mipmap generation and cannot be considered as a format for render target.

The ASTC provides a wide spectrum of bit per pixel for both 2D and 3D texture for both LDR and HDR images, hence a wide range of compression to any 2D and 3D texture.

LDR Compression Ratios:

2D Block Footprint	Bit Rate (bpp)	Compression ratio (LDR 32bpp)
4x4	8.00	4.0
5x4	6.40	5.0
5x5	5.12	6.3
6x5	4.27	7.5
6x6	3.56	9.0
8x5	3.20	10.0
8x6	2.67	12.0
10x5	2.56	12.5
10x6	2.13	15.0
8x8	2.00	16.0
10x8	1.60	20.0
10x10	1.28	25.0
12x10	1.07	29.9
12x12	0.89	36.0

HDR Compression Ratios:

Compared against fixed compression ratios of 4x or 8x on BC* formats, ASTC provides compression ratios from 4x to 36x for 2D LDR, 8x to 72x in 2D HDR maps, 7x to 54x on 3D LDR (32bpp) maps, and 14x to 108x in 3D HDR (64bpp). This can reduce bandwidth and footprint of a static 2D HDR or 3D textures to a small fractional of the existing BC formats, and greatly improve the performance on the graphic applications using these textures intensively.

Another benefit of ASTC is that, with the large range of selection of footprints and bpp, it can provide a good trade-off between quality degradation of the compressed texture and performance, due to the bandwidth and footprints reduction. This could not be achieved by any previously existing texture compression technologies.

Although ASTC has a huge benefit of bandwidth reduction, the expected performance gain in real 3D application from this technique depends on how much texture bandwidth bottleneck is relative to the throughput of computing in EU, Sampler, and other fixed function components.

New Surface Formats for ASTC Texture

The ASTC data format natively supports 14 2D block size, 10 3D block size, and each decoded format should support either UN8 (with sRGB con version) or Float16 at each color component. Following is the full list of all different surface formats as the full combination of different block shapes and UN8 or Float16 options.

Value	[26] LDR/Full [25] 2D/3D [24] U8srgb /FLT16	Width 2D [23:21] 3D [23:22]	Height 2D [20:18] 3D [21:20]	Depth 2D: n/a 3D: [19:18]	Binary form	Name	(BPE)

ASTC File Format and Memory Layout

Content for this topic is currently under development.

ASTC Header Data Structure and Amendment

The 1st block of an ASTC compression texture is a header file. Its byte layout in the original header structure in *.astc file is:

```
struct astc_header
{
    uint8_t magic[4];
    uint8_t blockdim_x;
    uint8_t blockdim_y;
    uint8_t blockdim_z;
    uint8_t xsize[3]; // x-size = xsize[0] + xsize[1] + xsize[2]
    uint8_t ysize[3]; // x-size, y-size and z-size are given in texels;
    uint8_t zsize[3]; // block count is inferred
};
```

Since there are limited ranges for block dimensions in x, y and z directions as described in following, we could store additional information in the unused upper bits of these byte fields

Block Dimension	2D	3D
blockdim_x	4, 5, 6, 8, 10, 12	3, 4, 5, 6
blockdim_y	4, 5, 6, 8, 10, 12	3, 4, 5, 6
blockdim_z	1	3, 4, 5, 6

Since blockdim_z is in the range of [1,6], only lower 3 bits of blockdim_z is used. We proposed the **Intel astc extension format** with *numLODs* stored in the upper 5 bits of the byte field used for blockdim_z. This new byte field can be defined as:

numLODs_blockdim_z = (numLODs-1) « 3 | (blockdim_z & 0x7) ;

New header:

```
struct astc_header
{
    uint8_t magic[4];
    uint8_t blockdim_x;
    uint8_t blockdim_y;
uint8_t numLODs_blockdim_z;
uint8_t xsize[3]; // width = xsize[0] + (xsize[1]«8) + (xsize[2]«16)
uint8_t ysize[3]; // height= ysize[0] + (ysize[1]«8) + (ysize[2]«16)
uint8_t zsize[3]; // depth = zsize[0] + (zsize[1]«8) + (zsize[2]«16)
// x_size, y_size and z_size are given in texels;

// block count is inferred
};
```

The driver or the software responsible for managing the memory resource will get numLODs and blockdim_z in:

numLODs = ((numLODs_blockdim_z » 3) & 0x1F) + 1;

blockdim_z = numLODs_blockdim_z & 0x7;

Data Layout in ASTC Compression File

A number of parameters are useful to determine where given pixels are located on the 2D & 3D surface. First, the width and height for each LOD level "L" is computed as:

$$W_L = \left((width \gg L) > 0\right)? width \gg L : 1)$$

$$H_L = \left((height \gg L) > 0\right)? height \gg L : 1)$$

$$D_L = \left((depth \gg L) > 0\right)? depth \gg L : 1)$$

The numbers of blocks in width, height and depth slab in each LOD are:

Nw(L) = Ceil(WL /Bw);

Nh (L) = Ceil(HL /Bh);

Ns (L) = Ceil(DL /Bd)

Where Bw, Bh and Bd is the block width, height and depth respectively.

Since ASTC has a native tile format specified by the encoding block size, the total number of blocks in each LOD level of the mipmap is described by nBL = Nw(L) * Nh (L) * Ns (L), The total number of blocks in the entire texture map is a summation of nBL's from all mipmap levels and all slabs, which are all pre-compressed via ASTC encoder. All the blocks in each LOD are in raster sequenced in width, height and then depth slab order.

Total ASTC Data Block Layout in All Mipmap Levels

The entire layout of the compression texture file looks like:

Address	Data Description
Addr0 (Base Address)	Header structure
Addr0+16	1st Data Block in LOD_0
Addr0+32	2nd Data Block in LOD_0
…	…
Addr1 = Addr0+16*nB0	Last Data Block in LOD_0
Addr1 +16	1st Data Block in LOD_1
Addr1+32	2nd Data Block in LOD_1
…	…
Addr2 = Addr1+16*nB1	Last Data Block in LOD_1
Addr2+16	1st Data Block in LOD_2
Addr2+32	2nd Data Block in LOD_2
…	…
Addr3 = Addr2+16*nB2	Last Data Block in LOD_2
…	…

Data Layout in Memory for All Mipmap Levels

The following equations for give the base address (U_offset, V_offset) in Cartesian coordinates for the starting point of each mip map at LOD L and depth slab q:

LOD=0:

U_offset (0, q) = 0;

*V_offset (0, q) = q * h0;*

LOD=1:

*U_offset (1, q) = (q%2)*w1;*

*V_offset (1, q) = D0*h0 + (q»1)*h1;*

LOD=2:

*U_offset (2, q) = (q%4)*w2;*

*V_offset (2, q) = D0*h0 + ceil(D1/2) * h1 + (q»2)*h2;*

LOD=3:

*U_offset (3, q) = (q%8)*w3;*

*V_offset (3, q) = D0*h0 + ceil(D1/2) * h1 + ceil(D2/2) * h2 + (q»3)*h3;*

••••••

Since ASTC has a native tile format specified by the encoding block size, the total number of blocks in each LOD level of the mipmap is described by nBL = Nw(L) * Nh (L) * Ns (L). The memory layout for TileY format are considered with 512bit (16Bx4) in 1 cacheline granularity, the total number of blocks is: 4*((Ceil(HL /Bh)+3)/4 * Ceil(WL /Bw) * Ceil(DL /Bd):

Here is the full list describing the total number of rows and columns of data in each mipmap for texture in ASTC format:

Table for block dimension in 2D

Block Size	ASTC Block Height (in line)	ASTC Block Width (in Byte)
4	((Ceil(HL /4) +3)/4) *4	Ceil(WL /4) * 16
5	((Ceil(HL /5) +3)/4) *4	Ceil(WL /5) * 16
6	((Ceil(HL /6) +3)/4) *4	Ceil(WL /6) * 16
8	((Ceil(HL /8) +3)/4) *4	Ceil(WL /8) * 16
10	((Ceil(HL /10) +3)/4) *4	Ceil(WL /10) * 16
12	((Ceil(HL /12) +3)/4) *4	Ceil(WL /12) * 16

Table for block dimension in 3D

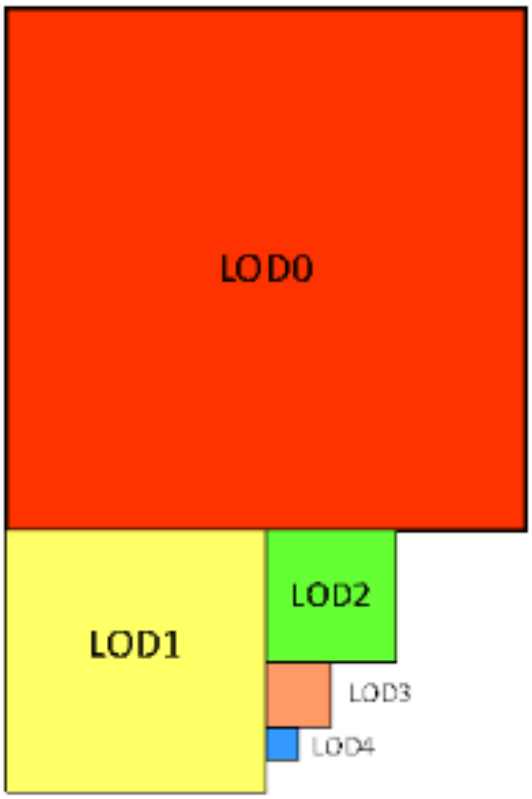
Block Size	ASTC Block Height (in line)	ASTC Block Width (in Byte)	ASTC Block Depth/slab (in slice)
3	((Ceil(HL /3) +3)/4) *4	Ceil(WL /3) * 16	Ceil(DL /3)
4	((Ceil(HL /4) +3)/4) *4	Ceil(WL /4) * 16	Ceil(DL /4)
5	((Ceil(HL /5) +3)/4) *4	Ceil(WL /5) * 16	Ceil(DL /5)
6	((Ceil(HL /6) +3)/4) *4	Ceil(WL /6) * 16	Ceil(DL /6)

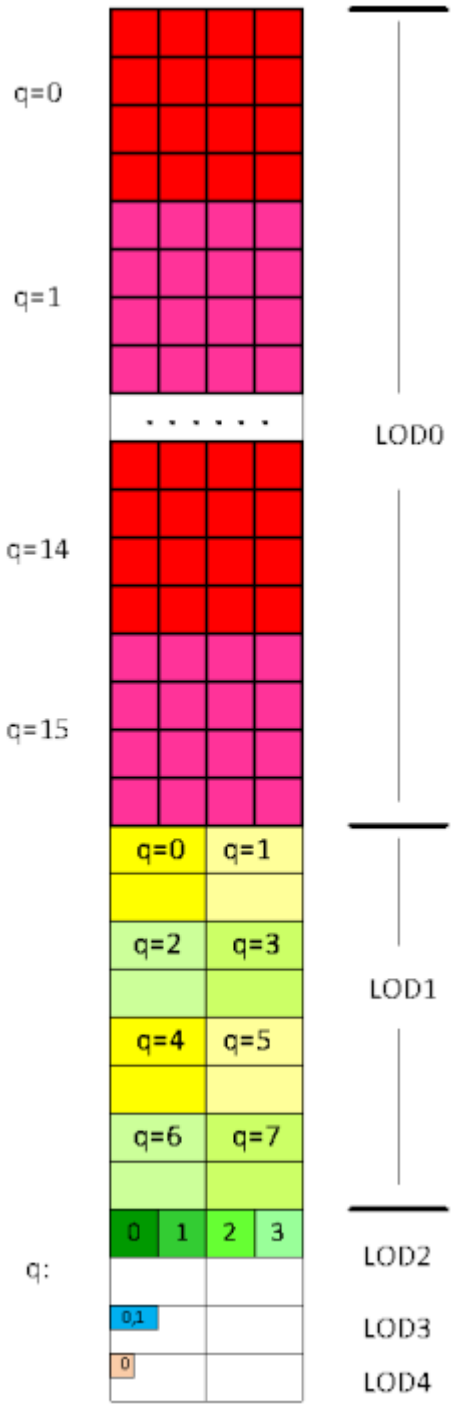
For example, an image of 64x64 with 5x5 block coding in LOD0 will have:

Block Height: (13+3)/4*4=16 (lines)

Block Width: 13 *16 = 208 (Bytes)

The following diagram illustrate the memory layout for 2D and 3D map respectively.





ASTC Data Structure

Content for this topic is currently under development.

Layout and Description of Block Data

The block data structure is described in the following table in the categories of the block being partition enabled (2-4 partitions) or disabled (only 1 partition), as well as 1 plane or dual-plane mode. Where CEM refers to Color Endpoint Mode, and CCS stands for Color Channel Selection:

Layout of Partitioning Disabled (1 partition) and Enabled (multi-partition) blocks

Partition Disable	127:19			18:17	16:13	12:11	10:0
(1 Plane)	Index Data		Color Endpoint Data		CEM	00	Index Mode
(2 Planes)	Index Data		Color Endpoint Data	CCS	CEM	00	Index Mode
Multi-partitions	127:29			28:23	22:13	12:11	10:0
(1 Plane)	Index Data	Rest of CEM	Color Endpoint Data	CEM (Initial 6 bits)	Partition Index	Part	Index Mode
(2 Planes)	Index Data	CCS	Rest of CEM	Color Endpoint Data	CEM (Initial 6 bits)	Partition Index	Part	Index Mode

The 11 bit “Index mode” field specifies how the Texel Index Data is encoded. The bit encoding of this field is listed in next two tables, one for the 2D and one for the 3D.

The “Part” field specifies the number of partitions minus one. If dual plane mode is enabled, the number of partitions must be 3 or fewer. In case 4 partitions in such situation are specified, the error value is returned for all texels in the block. The size and layout of the extra configuration data depends on the number of partition, and the number of planes in the image.

Partitioning

For any non-void extend region, each block is subdivided into 1, 2, 3 or 4 partitions, with a separate color endpoint pair for each partition. The number of partitions is specified by the partition count-1 in bits [12:11] of block data. If 2 or more partitions are selected, partitioning is enabled, the 10 bit partition index is then used to select one from 1024 partitioning patterns, where the total set of patterns supported in ASTC depends on the partition count and block size. The partitioning patterns are produced generatively, which supports a very large set of partitioning patterns for different block sizes with a modest number of hardware gates implementation.

Index Mode

The “Index mode” field specifies how the Texel Index Data is encoded. The bit encoding of this field is listed in next two tables, one for the 2D and one for the 3D.

The Index Mode field specifies the width (N), height (M) and depth (Q) of the grid of indices, what range of values they use, and whether dual index planes are present. The index ranges are encoded using a 3 bit value R, which is interpreted together with a precision bit H, as follows:

Mode R(r2 r1 r0)	Low-precision (H=0)					High-precision (H=1)			
	Index Range	Trits	Quints	Bits		Index Range	Trits	Quints	Bits
0 0 0	Invalid					Invalid			
0 0 1	Invalid					Invalid			
0 1 0	[0,1]			1		[0,9]		1	1
0 1 1	[0,2]	1				[0,11]	1		2
1 0 0	[0,3]			2		[0,15]			4
1 0 1	[0,4]		1			[0,19]		1	2
1 1 0	[0,5]	1		1		[0,23]	1		3
1 1 1	[0,7]			3		[0,31]			5

Each index value is encoded using the specified number of Trits, Quints and Bits. The details of this encoding can be found in Section - *Integer Sequence Encoding*. Due to the encoding of the R field, bits r2 and r1 cannot both be zero

The number of indices provided for a block is not tied to the block size in any way, instead, the indices form an N*M*Q ordered grid. N, M and Q are specified on a per-block basis rather then being a global texture property. For 2D blocks, N and M can be set to any value from 2 to 12 while Q is fixed at 1; for 3D blocks, N, M and Q can be set to any value from 2 to 5. The range used for each index can be set separately for each block. The Index Bit Mode field species the values of N, M, Q and the range; it also specifies whether Dual Index Planes are present or not as well.

The D bit in following tables is set to indicate dual-plane mode. In this mode, the maximum allowed number of partitions is 3. The size of the grid in each dimension must be less than or equal to the corresponding dimension of the block footprint. If the grid size is greater than the footprint dimension in any axis, then this is an illegal block encoding and all texels will decode to the error color.

For 2D blocks, the index mode field is laid out as follows:

The bit encoding of the index mode field for 2D Blocks

Bits									Width	Height	Notes
10	9	8	7	6	5	4	3:2	1:0	N	M	
D	H	B		A		r0	0 0	r2 r1	B+4	A+2	
D	H	B		A		r0	0 1	r2 r1	B+8	A+2	
D	H	B		A		r0	1 0	r2 r1	A+2	B+8	
D	H	0	B	A		r0	1 1	r2 r1	A+2	B+6	
D	H	1	B	A		r0	1 1	r2 r1	B+2	A+2	
D	H	0	0	A		r0	r2 r1	0 0	12	A+2	
D	H	0	1	A		r0	r2 r1	0 0	A+2	12	
D	H	1	1	0	0	r0	r2 r1	0 0	6	10	
D	H	1	1	0	1	r0	r2 r1	0 0	10	6	
B		1	0	A		r0	r2 r1	0 0	A+6	B+6	D=0, H=0
x	x	1	1	1	1	1	1 1	0 0	-	-	Void-Extent
x	x	1	1	1	x	x	x x	0 0	-	-	Reserve
x	x	x	x	x	x	x	0 0	0 0	-	-	Reserve

Note that, due to the encoding of the R field (r0, r1, r2), bits r2 and r1 cannot both be zero, which disambiguates the first five rows from the rest of the table. The penultimate row of the table is reserved only if bits [5:2] are not all 1, in which case it encodes a void-extent block (as shown in the previous row)

For 3D blocks, the index mode field is laid out as follows:

3D Index Mode Layout

Bits											Notes			
10	9	8	7	6	5	4	3	2	1	0	N	M	Q	(D, H)
D	H	B		A		r0	C		r2	r1	A+2	B+2	C+2	
B		0	0	A		r0	r2	r1	0	0	6	B+2	A+2	(0, 0)
B		0	1	A		r0	r2	r1	0	0	A+2	6	B+2	(0, 0)
B		1	0	A		r0	r2	r1	0	0	A+2	B+2	6	(0, 0)
D	H	1	1	0	0	r0	r2	r1	0	0	6	2	2	
D	H	1	1	0	1	r0	r2	r1	0	0	2	6	2	
D	H	1	1	1	0	r0	r2	r1	0	0	2	2	6	
x	x	1	1	1	1	1	1	1	0	0	-	-	-	Void-Extent
x	x	1	1	1	1	x	x	x	0	0	-	-	-	Reserve
x	x	x	x	x	x	x	0	0	0	0	-	-	-	Reserve

The D bit is set to indicate dual-plane mode:

1: dual index planes are used

0: single index plane is used

In this mode, the maximum allowed number of partitions is 3. The size of the grid in each dimension must be less than or equal to the corresponding dimension of the block footprint. If the grid size is greater than the footprint dimension in any axis, then this is an illegal block encoding and all texels will decode to the error color. The penultimate row of the table is reserved only if bits [4:2] are not all 1, in which case it encodes a void-extent block (as shown in the previous row).

H: Index Range Bit:

1: the High-Precision group is selected.

0: The Low-Precision group is selected.

Here is the detail description:

- The encoding of xx111111100 is for the void-extent block.
- The pattern xxxxxxx0000 (the bottom 4 bits being 0000b) is reserved for future extension, and should result a NaN-vector when such a pattern is decoded.
- Any encodings not listed in the table are considered invalid and result in undened behavior if encountered by decoders.

Given the limitation of the fix length of 128 bits per block, there are restrictions that will not allow every possible encoding:

- The total number of indexes (N*M*Q for single index plane, 2*N*M*Q for dual index planes) must not exceed 64.
- The length of the Index Integer Sequence must not exceed 96 bits.
- The length of the Index Integer Sequence must be at least 24 bits.
- The above restriction, combined with the other field widths of the format, implicitly restricts the Color Integer Sequence to a maximum of 75 bits.
- Blocks that violate these restrictions are not legally produced by the encoder, result a vector of NaNs if encountered by decoders.

Here is how the indices in each block are encoded and stored:

- They are encoded using the Integer Sequence Encoding method described in Appendix.
- The resulting bit-sequence is then bit-reversed, and stored from the top of the block downwards. The ordering of the indices in the Integer Sequence is a simple scan line-like ordering.

The indices are used in two steps to interpolate between two endpoint colors for each texel.

- First, they are scaled from whatever interval they were to the range [0,64];
- The resulting value is then used as a weight to interpolate between the two endpoints.

Index Planes

Depending on the Index Bits mode selected, an ASTC compressed block may offer 1 or 2 index planes. In the case of 2 index planes, two indices rather than just one are supplied for each texel that receives indices. Of these two indices, the first one is used for a weighted sum of three of the color components; the second is used for a weighted sum of the fourth color component. If only 1 index plane is present, it applies to all four color components.

If two index planes are used, then a 2-bit bit field is needed to indicate which of the color components the second index plane applies to. These two bits are stored just below the index bits, except in the case where leftover color endpoint type bits are present; in that case, these two bits are stored just below the leftover color endpoint type bits. This two-bit bit-field has the following layout:

Channel	Red	Green	Blue	Alpha
Value	0	1	2	3

If index infill is present while two index planes are being used, then index infill is performed on each index plane separately. If two index planes are used, the indexes are stored interleaved: the first index belongs to the first index plane, the second index belongs to the second index plane, the third index belongs to the first index plane, and so on.

Index Infill Procedure

In ASTC, each block has an N*M*Q ordered grid of indices. N, M and Q may or may not match the dimensions of the actual block (e.g. it is possible to encode a 5x3 grid for an 8x8 block); if they don't match, then the grid is scaled so that its corner indexes align with the corner texels of the block, a bilinear index infill procedure is defined to interpolate an index for each texel. This procedure picks 1 to 4 indexes, and assigns each of them a weight; these weights are always a multiple of 1/16. The exact details of this interpolation procedure are specified below.

Color Endpoint Mode

In single-partition mode, the Color Endpoint Mode (CEM) field stores one of 16 possible values. Each of these specifies how many raw data values are encoded, and how to convert these raw values into two RGBA color endpoints. They can be summarized as follows:

List of Color Endpoint Modes

CEM	Description	Class	# of integers to represent each pair of color end points
0	LDR Luminance or Alpha, direct	0	2
1	LDR Luminance, base+offset	0	2
2	HDR Luminance, large range	0	2
3	HDR Luminance, small range	0	2
4	LDR Luminance+Alpha, direct	1	4
5	LDR Luminance+Alpha, base+offset	1	4
6	LDR RGB, base+scale	1	4
7	HDR RGB, base+scale	1	4
8	LDR RGB, direct	2	6
9	LDR RGB, base+offset	2	6
10	LDR RGB, base+scale plus two A	2	6
11	HDR RGB, direct	2	6
12	LDR RGBA, direct	3	8: D=0; 6: D=1
13	LDR RGBA, base+offset	3	8: D=0; 6: D=1
14	HDR RGB, direct + LDR Alpha	3	8: D=0; 6: D=1
15	HDR RGB, direct + HDR Alpha	3	8: D=0; 6: D=1

Project	Description
CHV, BSW	LDR modes are supported in ASTC LDR profile, which is enabled since CHV, BSW.

In 2-4 partition modes, the encoding of Color Endpoint Modes are listed in following tables, where the endpoint mode representation may take from 6 to 14 bits, of which the first 6 bits are stored just after the partition indices, and the remaining bits are stored just below the index bits at variable position in the remaining space.

Partition / Class Types		High bits				[1:0]
Same Class	**6b [5:0]**	[5:2] Color Endpoint Mode				0 0
Different Classes	**2-Partions 8b [7:0]**	[7:6] Mode in P1	[5:4] Mode in P0	[3:3] Class Select for P1	[2:2] Class Select for P0	0 1 (Class 0 & 1)
	3-Partions 11b [10:0]			[10:9] Mode in P2	[8:7] Mode in P1	1 0 (Class 1 & 2)
		[6:5] Mode in P0	[4:4] Class Select for P2	[3:3] Class Select for P1	[2:2] Class Select for P0	
	4-Partions 14b [13:0]	[13:12] Mode in P2	[11:10] Mode in P1	[9:8] Mode in P2	[7:6] Mode in P1	1 1 (Class 2 & 3)
		[5:5] Class Select for P3	[4:4] Class Select for P2	[3:3] Class Select for P1	[2:2] Class Select for P0	

More specifically, if the CEM selector value in bits [24:23] is not 00, then data layout is as follows:

List of Color Endpoint Class Types encoding under multi-partitions

Partitions							...	28	27	26	25	24	23
2	...	Index	M1				...	M0		C1	C0	CEM	
3	...	Index	M2	M1	M0		...	M0	C2	C1	C0	CEM	
4	...	Index	M3	M2	M1	M0	...	C3	C2	C1	C0	CEM	

In this view, each partition *i* has two fields. C*i* is the class selector bit, choosing between the two possible CEM classes (0 indicates the lower of the two classes), and M*i* is a two-bit field specifying the low bits of the color endpoint mode within that class. The additional bits appear at a variable bit position, immediately below the texel index data. The ranges used for the data values are not explicitly specified. Instead, they are derived from the number of available bits remaining after the configuration data and index data have been specified. Details of the decoding procedure for Color Endpoints can be found later.

Color Endpoint Data Size Determination

The size of the data used to represent color endpoints is not explicitly specified. Instead, it is determined from the index mode and number of partitions as follows:

```
config_bits = 17;
if (num_partitions>1)
if (single_CEM)
config_bits = 29;
else
config_bits = 24 + 3*num_partitions;

num_indices = M * N * Q; // size of index grid

if (dual_plane)
config_bits += 2;
num_indices *= 2;

index_bits = floor(num_indices*8*trits_in_index_range/5) +
floor(num_indices*7*quints_in_index_range/3) +
num_indices*bits_in_index_range;

remaining_bits = 128 - config_bits - index_bits;
num_CEM_pairs = base_CEM_class+1 + count_bits(extra_CEM_bits);
```

The CEM value range is then looked up from a table indexed by remaining bits and num_CEM_pairs. This table is initialized such that the range is as large as possible, consistent with the constraint that the number of bits required to encode num_CEM_pairs pairs of values is not more than the number of remaining bits. An equivalent iterative algorithm would be:

```
num_CEM_values = num_CEM_pairs*2;
for(range = each possible CEM range in descending order of size)
{
   CEM_bits = floor(num_CEM_values*8*trits_in_CEM_range/5) +
      floor(num_CEM_values*7*quints_in_CEM_range/3) +
      num_CEM_values*bits_in_CEM_range;
if (CEM_bits <= remaining_bits)
   break;
}
return range;
```

In cases where this procedure results in unallocated bits, these bits are not read by the decoding process and can have any value.

Void-Extent Blocks

As noted in the index mode, a specifically type of encoding is the void-extended type (2D), an efficient way to encode a constant color for large blocks of regions in texture. The data structure of a void extent is listed in following 2 tables as 2D and 3D blocks respectively.

Layout of 2D Void-Extend Block, being supported in LDR since CHV, BSW.

127:112	111:96	95:80	79:64	63:51	50:38	37:25	24:12	11:10	9	8:0
A	B	G	R	T_high	T_low	S_high	S_low	Res:11	H	111111100

Bit 9 H is the Dynamic Range flag, which indicates the format in which colors are stored. A 0 value indicates LDR, in which case the color components are stored as UNORM16 values. A 1 indicates HDR, in which case the color components are stored as FP16 values. If a void-extent block with HDR values is decoded in LDR mode, then the result will be the error color, opaque magenta, for all texels within the block. The low and height coordinate values are treated as unsigned integers and then normalized into the range 0..1 (by dividing by 2^{13}-1 for 2D or 2^{9}-1, for 3D respectively). The high values for each dimension must be greater than the corresponding low values, unless they are all all-1s. If all the coordinates are all-1s, then the void extent is ignored, and the block is simply a constant color block.The existence of single-color blocks with void extents must not produce results different from those obtained if these single-color blocks are defined without void-extents. Any situation in which the results would differ is invalid. Results from invalid void extents are undefined. If a void-extent appears in a MIPmap level other than the most detailed one, then the extent will apply to all of the more detailed levels too. This allows decoders to avoid sampling more detailed MIPmaps. If the more detailed MIPmap level is *not* a constant color in this region, then the block may be marked as constant color, but without a void extent, as detailed above. If a void-extent extends to the edge of a texture, then filtered texture colors may not be the same color as that specified in the block, due to texture border colors,

wrapping, or cube face wrapping. Care must be taken when updating or extracting partial image data that void-extents in the image do not become invalid.

Decoding Process

Overview Decoding Flow

The goal for this feature is to reconstruct a cacheline (512b) of a target texture data at 4x4 region in UNORM8 A8R8G8B8 or 4x2 in FLT16 A16R16G16B16 with certain performance target, given the input texture coordinate (s,t,r). The scope of the u-architecture includes

- The additional surface format of the post decoding block, and the footprint (equivalent bpp). These are both global to each texture surface, and can be passed to the Sampler in the surface state via sampler messages.
- With post-scaled texture coordinate (u, v, p), the additional address calculation in FT to find the particular block location relative to the native block size specified in the surface state, as well as the relative texel position within that block. Assuming the block size for the block is Bu, Bv, Bp, the dimensions of a 2D surface as measured in block size tsize is:

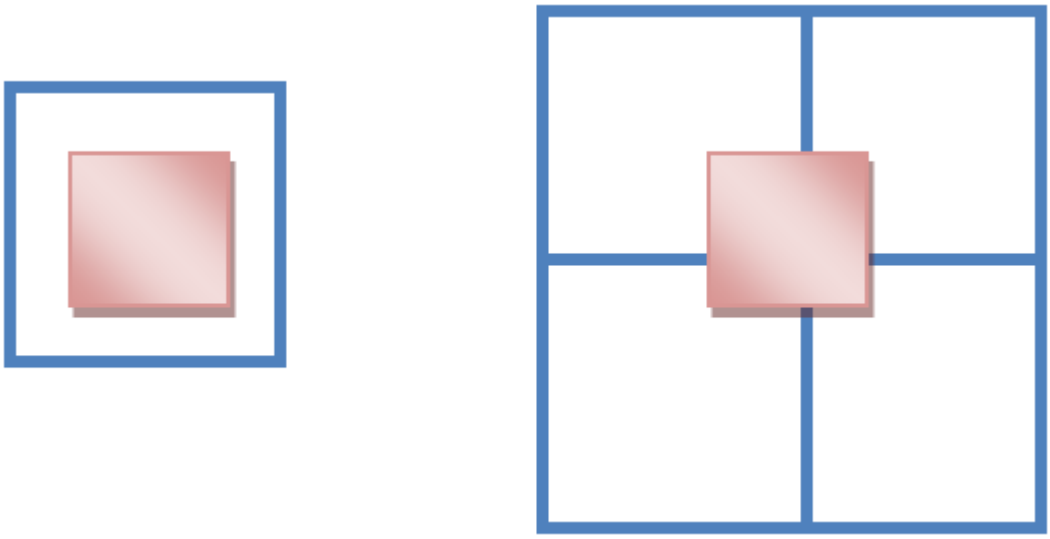
```
bw = MAX ( 2, (w+ tsize -1)/ tsize )
bh  = MAX (2, (h+ tsize -1)/ tsize)
```

Here the division is an integer division. The relationship between non-negative image coordinates [row,col] =[u, v] and block coordinates is

```
bu  = u / tsize  ;  buu = u % tsize;
bv  = v / tsize  ;  bvv =  v % tsize;
bp  = p / tsize  ;  bpp = p % tsize;
```

- With the selected sets of block size from 4x4 to 12x12 in 2D and 3x3x3 to 6x6x6 in 3D maps,1~4 blocks of source texture needs to be fetched, depending on whether the destination tile size (4x2 in FLT16 or 4x4 in UNORM8888) is inclusive or come across a few source blocks, as shown in Fig.

Destination tile is inclusive within one tile or across up to 4 tiles in source texture region



- Decode 1 to 4 128-bit ASTC compressed blocks fetched from DRAM in Sampler from ASTC compression format to either UNORM8 (LDR) or FLT16(HDR), reconstruct the texels needed in the texture filtering stage. The total decoding processing include:

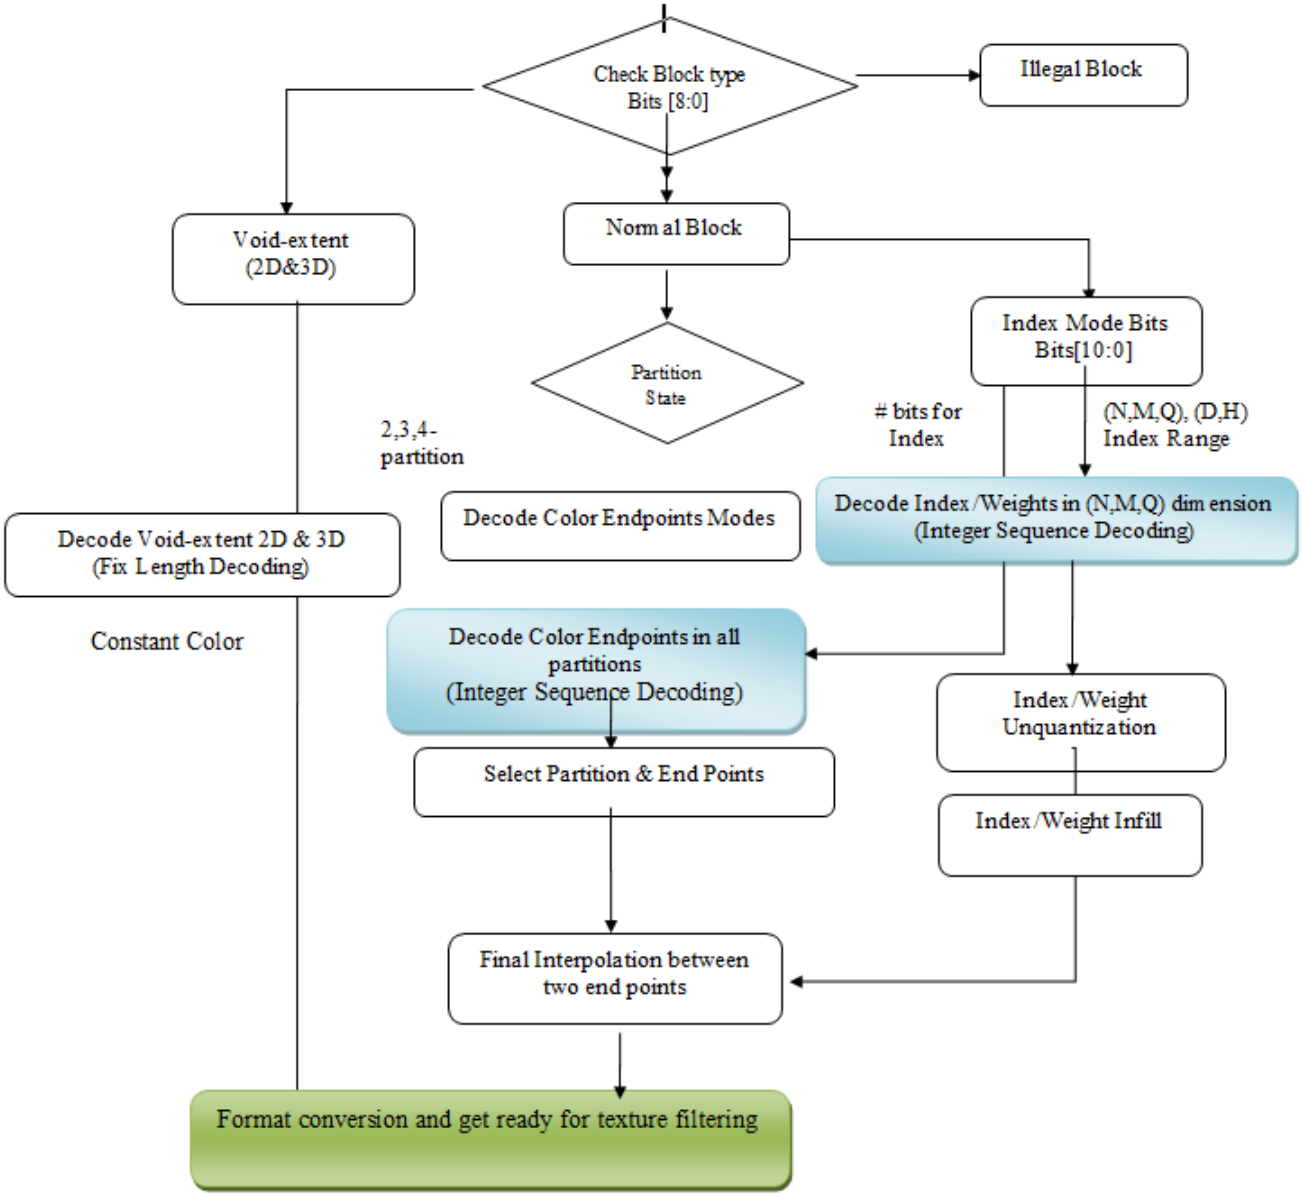
Front End Decoding Processing:

1. Detect if an ASTC block is a void-extent type, illegal type, or a normal non-void-extent type.
2. Decode the partition state – number of partitions in the current block.
3. Decode the index mode for the block include the partition seed and (N,M,Q) dimension of the compact sampling domain.
4. Decode the color endpoints modes in each partition.
5. Calculate the bit position and total # of bits used for Index.
6. Calculate the bit position and total # of bits and # of integers used in the Color endpoints in all partitions within the block.
7. With Integer Sequence Decoding, get all the indices in the compact domain defined by NxMxQ grid.
8. With Integer Sequence Decoding, get all the color end points from 16 modes in FLT16 for all partitions.

Back End Decoding Processing:

1. Reconstruct the indices at the selected sampling locations with infill scaling.
2. Find the partition from the partition seed at each sampling location.
3. Reconstruct the texture color value with the index and the pair of color end points at each sampling location.
4. If Block type is void extent, get the constant color from the high 64 bits and assign to the sampling location.
5. Convert the data to UNORM8 if LDR data is needed for the subsequent FL filtering process. Under void-extent block type

Following is the flow diagram of the decoding process:



Integer Sequence Encoding

Both the index data and the endpoint color data are variable width, and are specified using a sequence of integer values. The range of each value in a sequence (e.g. a color index) is constrained. Since it is often the case that the most efficient range for these values is not a power of two, each value sequence is encoded using a technique known as "integer sequence encoding". This allows efficient, hardware-friendly packing and unpacking of values with non-power-of-two ranges. In a sequence, each value has an identical range. The range is specified in one of the following forms:

Value range	MSB encoding	LSB encoding	Value	Block	Packed block size
0 .. 2^n-1	-	*n* bit value *m* (*n* <= 8)	*m*	1	*n*
0 .. (3 * 2^n)-1	Base-3 "trit" value *t*	*n* bit value *m* (*n* <= 6)	*t* * 2^n + *m*	5	8 + 5*n
0 .. (5 * 2^n)-1	Base-5 "quint" value *q*	*n* bit value *m* (*n* <= 5)	*q* * 2^n + *m*	3	7 + 3*n

Since 3^5 is 243, it is possible to pack five trits into 8 bits (which has 256 possible values), so a trit can effectively be encoded as 1.6 bits. Similarly, since 5^3 is 125, it is possible to pack three quints into 7 bits (which has 128 possible values), so a quint can be encoded as 2.33 bits.

The encoding scheme packs the trits or quints, and then interleaves the *n* additional bits in positions that satisfy the requirements of an arbitrary length stream. This makes it possible to correctly specify lists of values whose length is not an integer multiple of 3 or 5 values. It also makes it possible to easily select a value at random within the stream. If there are insufficient bits in the stream to fill the final block, then unused (higher order) bits are assumed to be 0 when decoding.

To decode the bits for value number *i* in a sequence of bits *b*, both indexed from 0, perform the following:

If the range is encoded as *n* bits per value, then the value is bits *b*[*i***n*+*n*-1:*i***n*] – a simple multiplexing operation.

If the range is encoded using a trit, then each block contains 5 values (v0 to v4), each of which contains a trit (t0 to t4) and a corresponding LSB value (m0 to m4). The first bit of the packed block is bit floor(*i*/5)*(8+5**n*). The bits in the block are packed as follows (in this example, *n* is 4):

Trit-based Packing

27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
T7			m4		T6		T5		m3		T4		m2		T3	T2		m1				T1	T0	m0			

The five trits t0 to t4 are obtained by bit manipulations of the 8 bits T[7:0] as follows:

```
if T[4:2] = 111
   C = { T[7:5], T[1:0] }; t4 = t3 = 2
else
   C = T[4:0]
   if T[6:5] = 11
      t4 = 2; t3 = T[7]
   else
      t4 = T[7]; t3 = T[6:5]
```

```
if C[1:0] = 11
   t2 = 2; t1 = C[4]; t0 = { C[3], C[2]&~C[3] }
else if C[3:2] = 11
   t2 = 2; t1 = 2; t0 = C[1:0]
else
   t2 = C[4]; t1 = C[3:2]; t0 = { C[1], C[0]&~C[1] }
```

Endpoint Unquantization

Each color endpoint is specified as a sequence of integers in a given range. These values are packed using integer sequence encoding, as a stream of bits stored from just above the configuration data, and growing upwards. Once unpacked, the values must be unquantized from their storage range, returning them to a standard range of 0..255. For bit-only representations, this is simple bit replication from the most significant bit of the value. For trit or quint-based representations, this involves a set of bit manipulations and adjustments to avoid the expense of full-width multipliers. This procedure ensures correct scaling, but scrambles the order of the decoded values relative to the encoded values. This must be compensated for using a table in the encoder.

The initial inputs to the procedure are denoted A, B, C and D and are decoded using the range as follows:

Range	Trits	Quints	Bits	Bit value	A (9 bits)	B (9 bits)	C (9 bits)	D (3 bits)
0..5	1		1	a	aaaaaaaaa	000000000	204	Trit value
0..9		1	1	a	aaaaaaaaa	000000000	113	Quint value
0..11	1		2	ba	aaaaaaaaa	b000b0bb0	93	Trit value
0..19		1	2	ba	aaaaaaaaa	b0000bb00	54	Quint value
0..23	1		3	cba	aaaaaaaaa	cb000cbcb	44	Trit value
0..39		1	3	cba	aaaaaaaaa	cb0000cbc	26	Quint value
0..47	1		4	dcba	aaaaaaaaa	dcb000dcb	22	Trit value
0..79		1	4	dcba	aaaaaaaaa	dcb0000dc	13	Quint value
0..95	1		5	edcba	aaaaaaaaa	edcb000ed	11	Trit value
0..159		1	5	edcba	aaaaaaaaa	edcb0000e	6	Quint value
0..191	1		6	fedcba	aaaaaaaaa	fedcb000f	5	Trit value

These are then processed as follows:

T= D * C + B;

T = T ^ A;

T = (A & 0x80) | (T » 2);

The multiply in the first line is nearly trivial as it only needs to multiply by 0, 1, 2, 3 or 4.

LDR Endpoint Decoding

The decoding method used depends on the Color Endpoint Mode (CEM) field, which specifies how many values are used to represent the endpoint. The CEM field also specifies how to take the *n* unquantized color endpoint values v0 to vn-1 and convert them into two RGBA color endpoints e0 and e1. The HDR Modes are more complex and do not fit neatly into the table. They are documented in following section. The LDR methods can be summarized as follows.

Color Endpoint Modes

CEM	Range	Description	# of end points	Endpoints Reconstruction
0	LDR	Luminance, direct	2	e0=(v0,v0,v0,0xFF); e1=(v1,v1,v1,0xFF);

1	LDR	Luminance
		base+offset
			2	L0 = (v0»2)|(v1&0xC0); L1=L0+(v1&0x3F);
				if (L1>0xFF) { L1=0xFF; }
				e0=(L0,L0,L0,0xFF); e1=(L1,L1,L1,0xFF);

2	HDR	Luminance, large range	2	See next Section
3	HDR	Luminance, small range	2	See next Section
4	LDR	Luminance+Alpha Direct	4	e0=(v0,v0,v0,v2); e1=(v1,v1,v1,v3);

5	LDR	Luminance+Alpha, base+offset	4	bit_transfer_signed(v1,v0);
				bit_transfer_signed(v3,v2);
				e0=(v0,v0,v0,v2); e1=(v0+v1,v0+v1,v0+v1,v2+v3);
				clamp_unorm8(e0); clamp_unorm8(e1);

6	LDR	RGB base+scale	4	e0=(v0*v3»8,v1*v3»8,v2*v3»8, 0xFF); e1=(v0,v1,v2,0xFF);

				if(v1+v3+v5>=0) { e0=(v0,v2,v4,v6);
				e1=(v0+v1,v2+v3,v4+v5,v6+v7); }
				else { e0=blue_contract(v0+v1,v2+v3,v4+v5,v6+v7);
				e1=blue_contract(v0,v2,v4,v6); }
				clamp_unorm8(e0); clamp_unorm8(e1);

14	HDR	RGB + LDR Alpha	8	See next Section
15	HDR	RGB + HDR Alpha	8	See next Section

Mode 14 is special in that the alpha values are interpolated linearly, but the color components are interpolated logarithmically. This is the only endpoint format with mixed-mode operation, and will return the error value if encountered in LDR mode. The bit_transfer_signed procedure transfers a bit from one signed byte value (a) to another (b). The result is an 8-bit signed integer value and a 6-bit integer value sign extended to 8 bits. Note that, as is often the case, this is easier to express in hardware than in C:

```
bit_transfer_signed(uint16_t& a, uint16_t& b)
{
b »= 1;
b |= a & 0x80;
a »= 1;
a &= 0x3F;
if( (a&0x20)!=0 ) a-=0x40;
}
```

For the purposes of this pseudocode, the signed bytes are passed in as unsigned 16-bit integers because the semantics of a right shift on a signed value in C are undefined.

The blue_contract procedure is used to give additional precision to RGB colors near grey:

```
color blue_contract( int r, int g, int b, int a )
{
color c;
c.r = (r+b) » 1;
c.g = (g+b) » 1;
c.b = b;
c.a = a;
return c;
}
```

The clamp_unorm8 procedure is used to clamp a color into the UNORM8 range:

```
void clamp_unorm8(color c)
{
if(c.r < 0) {c.r=0;} else if(c.r > 255) {c.r=255;}
if(c.g < 0) {c.g=0;} else if(c.g > 255) {c.g=255;}
if(c.b < 0) {c.b=0;} else if(c.b > 255) {c.b=255;}
```

if(c.a < 0) {c.a=0;} else if(c.a > 255) {c.a=255;}

}

HDR Endpoint Decoding

The 6 HDR CEM modes on color endpoints reconstruction and surface formats are only used in full-profile ASTC texture in float 16 bit.

- HDR Endpoint Mode 2: HDR Luminance, large range
- HDR Endpoint Mode 3: HDR Luminance, small range
- HDR Endpoint Mode 7: HDR RGB, base + scale
- HDR Endpoint Mode 11: HDR RGB, direct
- HDR Endpoint Mode 14: HDR RGB, direct + LDR Alpha
- HDR Endpoint Mode 15: HDR RGB, direct + HDR Alpha

HDR Endpoint Mode 2 (HDR Luminance, Large Range)

Mode 2 represents luminance-only data with a large range. It encodes using two values (v0, v1). The complete decoding procedure is as follows:

```
If (v1 >= v0)
{
   y0 = (v0 « 4);
   y1 = (v1 « 4);
}
else {
   y0 = (v1 « 4) + 8;
   y1 = (v0 « 4) - 8;
}
// Construct RGBA result (0x780 is 1.0f)

e0 = (y0, y0, y0, 0x780);
e1 = (y1, y1, y1, 0x780);
```

HDR Endpoint Mode 3 (HDR Luminance, Small Range)

Mode 3 represents luminance-only data with a small range. It packs the bits for a base luminance value, together with an offset, into two values (v0, v1):

Value	Bit[7]	Bit[6]	Bit[5]	Bit[4]	Bit[3]	Bit[2]	Bit[1]	Bit[0]
V0	M	L[6:0]						
V1	X[3:0]				D[3:0]			

The bit field marked as X allocates different bits to L or d depending on the value of the mode bit M. The complete decoding procedure is as follows:

```
// Check mode bit and extract.
    If ((v0&0x80) !=0)
{
y0 = ((v1 & 0xE0) « 4) | ((v0 & 0x7F) « 2);
d = (v1 & 0x1F) « 2;
}
else {
y0 = ((v1 & 0xF0) « 4) | ((v0 & 0x7F) « 1);
d = (v1 & 0x0F) « 1;
}
// Add delta and clamp
y1 = y0 + d;
if(y1 > 0xFFF) { y1 = 0xFFF; }
// Construct RGBA result (0x780 is 1.0f)
e0 = (y0, y0, y0, 0x780);
e1 = (y1, y1, y1, 0x780);
```

HDR Endpoint Mode 7 (HDR RGB, Base+Scale)

Mode 7 packs the bits for a base RGB value, a scale factor, and some mode bits into the four values (v0, v1, v2, v3).

HDR Mode 7 Value Layout

Value	Bit[7]	Bit[6]	Bit[5]	Bit[4]	Bit[3]	Bit[2]	Bit[1]	Bit[0]
V0	M[3]	M[2]	R[5:0]					
V1	M[1]	X0	X1	G[4:0]				
V2	M[0]	X2	X3	B[4:0]				
V3	X4	X5	X6	S[4:0]				

The mode bits M[0:3] are a packed representation of an endpoint bit mode, together with the major component index. For modes 0 to 4, the component (red, green, or blue) with the largest magnitude is identified, and the values are swizzled to ensure that it is decoded from the red channel. The endpoint bit mode is used to determine the number of bits assigned to each component of the endpoint, and the destination of each of the extra bits X0 to X6, as follows:

Endpoint Bit Mode

	Number of bits					Description of Extra Bits						
Mode	R	G	B	Scale		X0	X1	X2	X3	X4	X5	X6
0	11	5	5	7		R[9]	R[8]	R[7]	R[10]	R[6]	S[6]	S[5]
1	11	6	6	5		R[8]	G[5]	R[7]	B[5]	R[6]	R[10]	R[9]
2	10	5	5	8		R[9]	R[8]	R[7]	R[6]	S[7]	S[6]	S[5]
3	9	6	6	7		R[8]	G[5]	R[7]	B[5]	R[6]	S[6]	S[5]
4	8	7	7	6		G[6]	G[5]	B[6]	B[5]	R[6]	R[7]	S[5]
5	7	7	7	7		G[6]	G[5]	B[6]	B[5]	R[6]	S[6]	S[5]

The complete decoding procedure is as follows:

```
// Extract mode bits and unpack to major component and mode.
int modeval = ((v0 & 0xC0) » 6) | ((v1 & 0x80) » 5) | ((v2 & 0x80) » 4);
int majcomp;
int mode;
if( (modeval & 0xC ) != 0xC ) { majcomp = modeval » 2; mode = modeval & 3; }
else if( modeval != 0xF ) { majcomp = modeval & 3; mode = 4; }
else { majcomp = 0; mode = 5; }
// Extract low-order bits of r, g, b, and s.
int red = v0 & 0x3f;
```

```
int green = v1 & 0x1f;
int blue = v2 & 0x1f;
int scale = v3 & 0x1f;
// Extract high-order bits, which may be assigned depending on mode
int x0 = (v1 » 6) & 1; int x1 = (v1 » 5) & 1;
int x2 = (v2 » 6) & 1; int x3 = (v2 » 5) & 1;
int x4 = (v3 » 7) & 1; int x5 = (v3 » 6) & 1; int x6 = (v3 » 5) & 1;
// Now move the high-order xs into the right place.
int ohm = 1 « mode;
if( ohm & 0x30 ) green |= x0 « 6;
if( ohm & 0x3A ) green |= x1 « 5;
if( ohm & 0x30 ) blue |= x2 « 6;
if( ohm & 0x3A ) blue |= x3 « 5;
if( ohm & 0x3D ) scale |= x6 « 5;
if( ohm & 0x2D ) scale |= x5 « 6;
if( ohm & 0x04 ) scale |= x4 « 7;
if( ohm & 0x3B ) red |= x4 « 6;
if( ohm & 0x04 ) red |= x3 « 6;
if( ohm & 0x10 ) red |= x5 « 7;
if( ohm & 0x0F ) red |= x2 « 7;
if( ohm & 0x05 ) red |= x1 « 8;
if( ohm & 0x0A ) red |= x0 « 8;
if( ohm & 0x05 ) red |= x0 « 9;
if( ohm & 0x02 ) red |= x6 « 9;
if( ohm & 0x01 ) red |= x3 « 10;
if( ohm & 0x02 ) red |= x5 « 10;
// Shift the bits to the top of the 12-bit result.
static const int shamts[6] = { 1,1,2,3,4,5 };
int shamt = shamts[mode];
red «= shamt; green «= shamt; blue «= shamt; scale «= shamt;
// Minor components are stored as differences
```

if(mode != 5) { green = red - green; blue = red - blue; }

// Swizzle major component into place

if(majcomp == 1) swap(red, green);

if(majcomp == 2) swap(red, blue);

// Clamp output values, set alpha to 1.0

e1.r = clamp(red, 0, 0xFFF);

e1.g = clamp(green, 0, 0xFFF);

e1.b = clamp(blue, 0, 0xFFF);

e1.alpha = 0x780;

e0.r = clamp(red - scale, 0, 0xFFF);

e0.g = clamp(green - scale, 0, 0xFFF);

e0.b = clamp(blue - scale, 0, 0xFFF);

e0.alpha = 0x780;

HDR Endpoint Mode 11 (HDR RGB, Direct)

Mode 11 specifies two RGB values, which it calculates from a number of bitfields (a, b0, b1, c, d0 and d1) which are packed together with some mode bits into the six values (v0, v1, v2, v3, v4, v5):

HDR Mode 11 Value Layout

Value	Bit[7]	Bit[6]	Bit[5]	Bit[4]	Bit[3]	Bit[2]	Bit[1]	Bit[0]
V0	a[7:0]							
V1	m[0]	a[8]	c[5:0]					
V2	m[1]	X0	b0[5:0]					
V3	m[2]	X1	b1[5:0]					
V4	mj[0]	X2	X4	d0[4:0]				
V5	mj[1]	X3	X5	d1[4:0]				

If the major component bits mj[1:0] = b11, then the RGB values are specified directly as

HDR Mode 11 Value Layout

Value	Bit[7]	Bit[6]	Bit[5]	Bit[4]	Bit[3]	Bit[2]	Bit[1]	Bit[0]
V0	R0[11:4]							
V1	R1[11:4]							
V2	G0 [11:4]							
V3	G1[11:4]							
V4	1	B0[11:5]						
V5	1	B1[11:5]						

The mode bits m[2:0] specify the bit allocation for the different values, and the destinations of the extra bits X0 to X5:

Endpoint Bit Mode

Mode	Number of bits				Description of Extra Bits					
	a	b	c	d	X0	X1	X2	X3	X4	X5
0	9	7	6	7	b0[6]	b1[6]	d0[6]	d1[6]	d0[5]	d1[5]
1	9	8	6	6	b0[6]	b1[6]	b0[7]	b1[7]	d0[5]	d1[5]
2	10	6	7	7	a[9]	c[6]	d0[6]	d1[6]	d0[5]	d1[5]
3	10	7	7	6	b0[6]	b1[6]	a[9]	c[6]	d0[5]	d1[5]
4	11	8	6	5	b0[6]	b1[6]	b0[7]	b1[7]	a[9]	a[10]
5	11	6	7	6	a[9]	a[10]	c[7]	c[6]	d0[5]	d1[5]
6	12	7	7	5	b0[6]	b1[6]	a[11]	c[6]	a[9]	a[10]
7	12	6	7	6	a[9]	a[10]	a[11]	c[6]	d0[5]	d1[5]

The complete decoding procedure is as follows:

```
// Find major component
int majcomp = ((v4 & 0x80) » 7) | ((v5 & 0x80) » 6);
// Deal with simple case first
if( majcomp == 3 )
{
e0 = (v0 « 4, v2 « 4, (v4 & 0x7f) « 5, 0x780);
e1 = (v1 « 4, v3 « 4, (v5 & 0x7f) « 5, 0x780);
return;
}
// Decode mode, parameters.
```

```
int mode = ((v1 & 0x80) » 7) | ((v2 & 0x80) » 6) | ((v3 & 0x80) » 5);
int va = v0 | ((v1 & 0x40) « 2);
int vb0 = v2 & 0x3f;
int vb1 = v3 & 0x3f;
int vc = v1 & 0x3f;
int vd0 = v4 & 0x7f;
int vd1 = v5 & 0x7f;
// Assign top bits of vd0, vd1.
static const int dbitstab[8] = {7,6,7,6,5,6,5,6};
vd0 = signextend( vd0, dbitstab[mode] );
vd1 = signextend( vd1, dbitstab[mode] );
// Extract and place extra bits
int x0 = (v2 » 6) & 1;
int x1 = (v3 » 6) & 1;
int x2 = (v4 » 6) & 1;
int x3 = (v5 » 6) & 1;
int x4 = (v4 » 5) & 1;
int x5 = (v5 » 5) & 1;
int ohm = 1 « mode;
if( ohm & 0xA4 ) va |= x0 « 9;
if( ohm & 0x08 ) va |= x2 « 9;
if( ohm & 0x50 ) va |= x4 « 9;
if( ohm & 0x50 ) va |= x5 « 10;
if( ohm & 0xA0 ) va |= x1 « 10;
if( ohm & 0xC0 ) va |= x2 « 11;
if( ohm & 0x04 ) vc |= x1 « 6;
if( ohm & 0xE8 ) vc |= x3 « 6;
if( ohm & 0x20 ) vc |= x2 « 7;
if( ohm & 0x5B ) vb0 |= x0 « 6;
if( ohm & 0x5B ) vb1 |= x1 « 6;
if( ohm & 0x12 ) vb0 |= x2 « 7;
```

```
if( ohm & 0x12 ) vb1 |= x3 « 7;
// Now shift up so that major component is at top of 12-bit value
int shamt = (modeval » 1) ^ 3;
va «= shamt; vb0 «= shamt; vb1 «= shamt;
vc «= shamt; vd0 «= shamt; vd1 «= shamt;
e1.r = clamp( va, 0, 0xFFF );
e1.g = clamp( va - vb0, 0, 0xFFF );
e1.b = clamp( va - vb1, 0, 0xFFF );
e1.alpha = 0x780;
e0.r = clamp( va - vc, 0, 0xFFF );
e0.g = clamp( va - vb0 - vc - vd0, 0, 0xFFF );
e0.b = clamp( va - vb1 - vc - vd1, 0, 0xFFF );
e0.alpha = 0x780;
if( majcomp == 1 )
{
swap( e0.r, e0.g ); swap( e1.r, e1.g );
}
else if( majcomp == 2 )
{
swap( e0.r, e0.b ); swap( e1.r, e1.b );
}
```

HDR Endpoint Mode 14 (HDR RGB, Direct + LDR Alpha)

Mode 14 specifies two RGBA values, using the eight values (v0, v1, v2, v3, v4, v5, v6, v7). First, the RGB values are decoded from (v0..v5) using the method from Mode 11. Then the alpha values are filled in from v6 and v7:

```
// Decode RGB as for mode 11
(e0,e1) = decode_mode_11(v0,v1,v2,v3,v4,v5)
// Now fill in the alphas
e0.alpha = v6;
e1.alpha = v7;
```

HDR Endpoint Mode 15 (HDR RGB, Direct + HDR Alpha)

Mode 15 specifies two RGBA values, using the eight values (v0, v1, v2, v3, v4, v5, v6, v7). First, the RGB values are decoded from (v0..v5) using the method from Mode 11. The alpha values are stored in values v6 and v7 as a mode and two values which are interpreted according to the mode:

HDR Mode 15 Alpha Value Layout

Value	Bit[7]	Bit[6]	Bit[5]	Bit[4]	Bit[3]	Bit[2]	Bit[1]	Bit[0]
V6	M0	A[6:0]						
V7	M1	B[6:0]						

The alpha values are decoded from v6 and v7 as follows:

```
// Decode RGB as for mode 11
(e0,e1) = decode_mode_11(v0,v1,v2,v3,v4,v5)
// Extract mode bits
mode = ((v6 » 7) & 1) | ((v7 » 6) & 2);
v6 &= 0x7F;
v7 &= 0x7F;
if(mode==3)
{
// Directly specify alphas
e0.alpha = v6 « 5;
e1.alpha = v7 « 5;
}
else
{
// Transfer bits from v7 to v6 and sign extend v7.
v6 |= (v7 « (mode+1))) & 0x780;
v7 &= (0x3F » mode);
v7 ^= 0x20 » mode;
v7 -= 0x20 » mode;
v6 «= (4-mode);
v7 «= (4-mode);
// Add delta and clamp
```

```
v7 += v6;
v7 = clamp(v7, 0, 0xFFF);
e0.alpha = v6;
e1.alpha = v7;
}
```

Restrictions on Number of Partitions Per Block

Following table gives total number of partitions for each CEM mode given the restriction of total up to 16 integer values being decoded from the Integer Sequence Coding sequence.

Groups	Max Number of Partition	CEM Modes
(v0,v1)	4	0,1,2,3
(v0,v1,v2,v3)	4	4,5,6,7
(v0,v1,v2,v3,v4,v5)	3	8,9,10,11
(v0,v1,v2,v3,v4,v5,v6,v7)	2	12,13,14,15

Index Decoding

The index information is stored as a stream of bits, growing downwards from the most significant bit in the block. Bit *n* in the stream is thus bit 127-*n* in the block.

For each location in the index grid, a value (in the specified range) is packed into the stream. These are ordered in a raster pattern starting from location (0,0,0), with the X dimension increasing fastest, and the Z dimension increasing slowest. If dual-plane mode is selected, both indices are emitted together for each location, plane 0 first, then plane 1.

Index Unquantization

Each index plane is specified as a sequence of integers in a given range. These values are packed using integer sequence encoding.

Once unpacked, the values must be unquantized from their storage range, returning them to a standard range of 0..64. The procedure for doing so is similar to the color endpoint unquantization.

First, we unquantize the actual stored index values to the range 0..63.

For bit-only representations, this is simple bit replication from the most significant bit of the value.

For trit or quint-based representations, this involves a set of bit manipulations and adjustments to avoid the expense of full-width multipliers.

For representations with no additional bits, the results are as follows:

Index Unquantization Values

Range	0	1	2	3	4
0..2	0	32	63	-	-
0..4	0	16	32	47	63

For other values, we calculate the initial inputs to a bit manipulation procedure. These are denoted A, B, C and D and are decoded using the range as follows:

Index Unquantization Parameters

Range	Trits	Quints	Bits	Bit value	A (7 bits)	B (7 bits)	C (7 bits)	D (3 bits)
0..5	1		1	a	aaaaaaa	0000000	50	Trit
0..9		1	1	a	aaaaaaa	0000000	28	Quint
0..11	1		2	ba	aaaaaaa	b000b0b	23	Trit
0..19		1	2	ba	aaaaaaa	b0000b0	13	Quint
0..23	1		3	cba	aaaaaaa	cb000cb	11	Trit

These are then processed as follows:

T = D * C + B;

T = T ^ A;

T = (A & 0x20) | (T » 2);

The multiply in the first line is nearly trivial as it only needs to multiply by 0, 1, 2, 3 or 4. As a final step, for all types of value, the range is expanded from 0..63 up to 0..64 as follows:

if (T > 32) { T += 1; }

This allows the implementation to use 64 as a divisor during interpolation, which is much easier than using 63.

Infill Process

After unquantization, the indexes are subject to index selection and infill. The infill method is used to calculate the index for a texel position, based on the indices in the stored index grid array (which may be a different size). The procedure below must be followed exactly, to ensure bit exact results. The block size is specified as three dimensions along the s, t and r axes (Bs, Bt, Br). Texel coordinates within the block (s,t,r) can have values from 0 to one less than the block dimension in that axis.

For each block dimension, we compute scale factors (Ds, Dt, Dr)

Ds = floor((1024 + floor(Bs/2)) / (Bs-1));

Dt = floor((1024 + floor(Bt/2)) / (Bt-1));

Dr = floor((1024 + floor(Br/2)) / (Br-1));

Since the block dimensions are constrained, these are easily looked up in a table. These scale factors are then used to scale the (s,t,r) coordinates to a homogeneous coordinate (cs, ct, cr):

cs = Ds * s;

ct = Dt * t;

cr = Dr * r;

This homogeneous coordinate (cs, ct, cr) is then scaled again to give a coordinate (gs, gt, gr) in the index-grid space . The index-grid is of size (N, M, Q), as specified in the index mode field:

gs = (cs*(N-1)+32) » 6;

gt = (ct*(M-1)+32) » 6;

gr = (cr*(Q-1)+32) » 6;

The resulting coordinates may be in the range 0..176. These are interpreted as 4:4 unsigned fixed point numbers in the range 0.0 .. 11.0. If we label the integral parts of these (js, jt, jr) and the fractional parts (fs, ft, fr), then:

js = gs » 4; fs = gs & 0x0F;

jt = gt » 4; ft = gt & 0x0F;

jr = gr » 4; fr = gr & 0x0F;

These values are then used to interpolate between the stored indices. This process differs for 2D and 3D.

For 2D, bilinear interpolation is used:

v0 = js + jt*N;

p00 = decode_index(v0);

p01 = decode_index(v0 + 1);

p10 = decode_index(v0 + N);

p11 = decode_index(v0 + N + 1);

The function decode_index(n) decodes the nth index in the stored index stream. The values p00 to p11 are the indices at the corner of the square in which the texel position resides. These are then weighted using the fractional position to produce the effective index i as follows:

w11 = (fs*ft+8) » 4;

w10 = ft – w11;

w01 = fs – w11;

w00 = 16 – fs – ft + w11;

i = (p00*w00 + p01*w01 + p10*w10 + p11*w11 + 8) » 4;

For 3D, simplex interpolation is used as it is cheaper than a naïve trilinear interpolation. First, we pick some parameters for the interpolation based on comparisons of the fractional parts of the texel position:

fs>ft	ft>fr	fs>fr	s1	s2	w0	w1	w2	w3
True	True	True	1	N	16-fs	fs-ft	ft-fr	fr
False	True	True	N	1	16-ft	ft-fs	fs-fr	fr
True	False	True	1	N*M	16-fs	fs-fr	fr-ft	ft
True	False	False	N*M	1	16-fr	fr-fs	fs-ft	ft
False	True	False	N	N*M	16-ft	ft-fr	fr-fs	fs
False	False	False	N*M	N	16-fr	fr-ft	ft-fs	fs

The effective index *i* is then calculated as:

v0 = js + jt*N + jr*N*M;

p0 = decode_index(v0);

p1 = decode_index(v0 + s1);

p2 = decode_index(v0 + s1 + s2);

p3 = decode_index(v0 + N*M + N + 1);

i = (p0*w0 + p1*w1 + p2*w2 + p3*w3 + 8) » 4;

Index Application

Once the effective index *i* for the texel has been calculated, the color endpoints are interpolated and expanded. For LDR endpoint modes, each color component C is calculated from the corresponding 8-bit endpoint components C0 and C1 as follows:

If sRGB conversion is not enabled, C0 and C1 are first expanded to 16 bits by bit replication:

C0 = (C0 « 8) | C0; C1 = (C1 « 8) | C1;

If sRGB conversion is enabled, C0 and C1 are expanded to 16 bits differently, as follows:

C0 = (C0 « 8) | 0x80; C1 = (C1 « 8) | 0x80;

C0 and C1 are then interpolated to produce a UNORM16 result C:

C = floor((C0*(64-i) + C1*i + 32)/64)

If sRGB conversion is enabled, the top 8 bits of the interpolation result are passed to the external sRGB conversion block. Otherwise, if C = 65535, then the final result is 1.0 (0x3C00) otherwise C is divided by 216 and the infinite-precision result of the division is converted to FP16 with round-to-zero semantics. For HDR endpoint modes, color values are represented in a 12-bit logarithmic representation, and interpolation occurs in a piecewise-approximate logarithmic manner as follows:

In LDR mode, the error result is returned.

In HDR mode, the color components from each endpoint, C0 and C1, are initially shifted left 4 bits to become 16-bit integer values and these are interpolated in the same way as LDR. The 16-bit value C is then decomposed into the top five bits, E, and the bottom 11 bits M, which are then processed and recombined with E to form the final value Cf:

C = floor((C0*(64-i) + C1*i + 32)/64)

E = (C&0xF800) » 11; M = C&0x7FF;

if (M < 512) { Mt = 3*M; }

else if (M >= 1536) { Mt = 5*M – 2048; }

else { Mt = 4*M – 512; }

Cf = (E«10) + (Mt»3)

This final value Cf is interpreted as an IEEE FP16 value. If the result is +Inf or NaN, it is converted to the bit pattern 0x7BFF, which is the largest representable finite value.

Dual-Plane Decoding

If dual-plane mode is disabled, all of the endpoint components are interpolated using the same index value. If dual-plane mode is enabled, two indices are stored with each texel. One component is then selected to use the second index for interpolation, instead of the first index. The first index is then used for all other components.

The component to treat specially is indicated using the 2-bit Color Component Selector (CCS) field as follows:

Dual Plane Color Component Selector Values

Value	Index 0	Index 1
0	GBA	R
1	RBA	G
2	RGA	B
3	RGB	A

The CCS bits are stored at a variable position directly below the index bits and any additional CEM bits.

Partition Pattern Generation

When multiple partitions are active, each texel position is assigned a partition index. This partition index is calculated using a seed (the partition pattern index), the texel's x,y,z position within the block, and the number of partitions. An additional argument, small_block, is set to 1 if the number of texels in the block is less than 31, otherwise it is set to 0. The full partition selection algorithm is as follows:

```
int select_partition(int seed, int x, int y, int z
int partitioncount, int small_block)
{
if( small_block ){ x «= 1; y «= 1; z «= 1; }
seed += (partitioncount-1) * 1024;
uint32_t rnum = hash52(seed);
uint8_t seed1 = rnum & 0xF;
uint8_t seed2 = (rnum » 4) & 0xF;
uint8_t seed3 = (rnum » 8) & 0xF;
uint8_t seed4 = (rnum » 12) & 0xF;
uint8_t seed5 = (rnum » 16) & 0xF;
uint8_t seed6 = (rnum » 20) & 0xF;
uint8_t seed7 = (rnum » 24) & 0xF;
uint8_t seed8 = (rnum » 28) & 0xF;
uint8_t seed9 = (rnum » 18) & 0xF;
uint8_t seed10 = (rnum » 22) & 0xF;
uint8_t seed11 = (rnum » 26) & 0xF;
uint8_t seed12 = ((rnum » 30) | (rnum « 2)) & 0xF;
```

```
seed1 *= seed1; seed2 *= seed2; seed3 *= seed3; seed4 *= seed4;
seed5 *= seed5; seed6 *= seed6; seed7 *= seed7; seed8 *= seed8;
seed9 *= seed9; seed10 *= seed10; seed11 *= seed11; seed12 *= seed12;
int sh1, sh2, sh3;
if( seed & 1 )
{ sh1 = (seed & 2 ? 4 : 5); sh2 = (partitioncount == 3 ? 6 : 5); }
else
{ sh1 = (partitioncount == 3 ? 6 : 5); sh2 = (seed & 2 ? 4 : 5); }
sh3 = (seed & 0x10) ? sh1 : sh2:
seed1 »= sh1; seed2 »= sh2; seed3 »= sh1; seed4 »= sh2;
seed5 »= sh1; seed6 »= sh2; seed7 »= sh1; seed8 »= sh2;
seed9 »= sh3; seed10 »= sh3; seed11 »= sh3; seed12 »= sh3;
int a = seed1*x + seed2*y + seed11*z + (rnum » 14);
int b = seed3*x + seed4*y + seed12*z + (rnum » 10);
int c = seed5*x + seed6*y + seed9 *z + (rnum » 6);
int d = seed7*x + seed8*y + seed10*z + (rnum » 2);
a &= 0x3F; b &= 0x3F; c &= 0x3F; d &= 0x3F;
if( partitioncount < 4 ) d = 0;
if( partitioncount < 3 ) c = 0;
if( a >= b && a >= c && a >= d ) return 0;
else if( b >= c && b >= d ) return 1;
else if( c >= d ) return 2;
else return 3;
}
```

As has been observed before, the bit selections are much easier to express in hardware than in C.

The seed is expanded using a hash function hash52, which is defined as follows:

```
uint32_t hash52( uint32_t p )
{
p ^= p » 15; p -= p « 17; p += p « 7; p += p « 4; p ^= p » 5;
p += p « 16; p ^= p » 7; p ^= p » 3; p ^= p « 6; p ^= p » 17;
return p;
```

}

This assumes that all operations act on 32-bit values

Data Size Determination

The size of the data used to represent color endpoints is not explicitly specified. Instead, it is determined from the index mode and number of partitions as follows:

config_bits = 17;

if(num_partitions>1)

if(single_CEM)

config_bits = 29;

else

config_bits = 24 + 3*num_partitions;

num_indices = M * N * Q; // size of index grid

if(dual_plane)

config_bits += 2;

num_indices *= 2;

index_bits = ceil(num_indices*8*trits_in_index_range/5) +

ceil(num_indices*7*quints_in_index_range/3) +

num_indices*bits_in_index_range;

remaining_bits = 128 – config_bits – index_bits;

num_CEM_pairs = base_CEM_class+1 + count_bits(extra_CEM_bits);

The CEM value range is then looked up from a table indexed by remaining bits and num_CEM_pairs. This table is initialized such that the range is as large as possible, consistent with the constraint that the number of bits required to encode num_CEM_pairs pairs of values is not more than the number of remaining bits.

An equivalent iterative algorithm would be:

num_CEM_values = num_CEM_pairs*2;

for(range = each possible CEM range in descending order of size)

{

CEM_bits = ceil(num_CEM_values*8*trits_in_CEM_range/5) +

ceil(num_CEM_values*7*quints_in_CEM_range/3) +

num_CEM_values*bits_in_CEM_range;

if(CEM_bits <= remaining_bits)

break;

}

return range;

In cases where this procedure results in unallocated bits, these bits are not read by the decoding process and can have any value.

3D Void-Extent Blocks

The layout of a 3D Void-Extent block is as follows:

127:112	111:96	95:80	79:64	63:55	54:46	45:37	36:28	27:19	18:10	9:9	8:0
A	B	G	R	P_high	P_low	T_high	T_low	S_high	S_low	D	111111100

Bit 9 is the Dynamic Range flag, which indicates the format in which colors are stored. Value 0 indicates LDR, in which case the color components are stored as UNORM16 values, while value 1 indicates HDR, in which case the color components are stored as FP16 values.

The reason for the storage of UNORM16 values in the LDR case is due to the possibility that the value will need to be passed on to sRGB conversion. By storing the color value in the format which comes out of the interpolator, before the conversion to FP16, we avoid having to have separate versions for sRGB and linear modes.

If a void-extent block with HDR values is decoded in LDR mode, then the result will be the error color, opaque magenta, for all texels within the block.

The minimum and maximum coordinate values are treated as unsigned integers and then normalized into the range 0..1 (by dividing by 2^{13}-1 or 2^{9}-1, for 2D and 3D respectively). The maximum values for each dimension must be greater than the corresponding minimum values, unless they are all all-1s. If all the coordinates are all-1s, then the void extent is ignored, and the block is simply a constant-color block.

Illegal Encodings

In ASTC, there is a variety of ways to encode an illegal block. Decoders are required to recognize all illegal blocks and emit the standard Error Block color value upon encountering an illegal block. The standard Error Block color value is opaque magenta (R, G, B, A) = (0xFF, 0x00, 0xFF, 0xFF) in the LDR operation mode, and a vector of NaNs (**R, G, B, A**)=(NaN, NaN, NaN, NaN) in the HDR operation mode. It is recommended that the NaN be encoded as the bit-pattern 0xFFFF.

Here is a comprehensive list of situations that represent illegal block encodings:

- The index bit mode specified is one of the modes explicitly listed as Reserved.
- An index bit mode has been specified that would require more than 64 indexes total.
- An index bit mode has been specified that would require more than 96 bits for the Index Integer Sequence Encoding.

- An index bit mode has been specified that would require fewer than 24 bits for the Index Integer Sequence Encoding.
- The size of the index grid exceeds the size of the block footprint in any dimension.
- Color endpoint modes have been specified such that the Color Integer Sequence Encoding would require more than 18 integers.
- The number of bits available for color endpoint encoding after all the other fields have been counted is less than *ceil(13C/5)* where C is the number of color endpoint integers (this would restrict color integers to a range smaller than 0..5, which is not supported).
- Dual Index Mode is enabled for a block with 4 partitions.
- Void-Extent blocks where the low coordinate for some texture axis is greater than or equal to the high coordinate.
- Under 3D mode, the depth (Q) is not 1

In LDR mode, a block which has both HDR and LDR endpoint modes assigned to different partitions is not an error block. Only those texels which belong to the HDR partition will result in the error color. Texels belonging to a LDR partition will be decoded as normal.

Profile Support

In order to ease verification and accelerate adoption, an LDR-only subset of the full ASTC specification has been made available.

Implementations of this LDR Profile must satisfy the following requirements:

- All textures with valid encodings for LDR Profile must decode identically using either a LDR Profile or Full Profile decoder.
- All features included only in the Full Profile must be treated as reserved in the LDR Profile, and return the error color on decoding.
- Any sequence of API calls valid for the LDR Profile must also be valid for the Full Profile and return identical results when given a texture encoded for the LDR Profile.

The feature subset for the LDR profile is:

- 2D textures only.
- Only those block sizes listed in Table 5 are supported.
- LDR operation mode only.
- Only LDR endpoint formats must be supported namely formats 0, 1, 4, 5, 6, 8, 9, 10, 12, 13.
- Decoding from a HDR endpoint results in the error color.
- Interpolation returns UNORM8 results when used in conjunction with sRGB.
- LDR void extent blocks must be supported, but void extents may not be checked.

Video Pixel/Texel Formats

This section describes the “video” pixel/texel formats with respect to memory layout. See the Overlay chapter for a description of how the Y, U, V components are sampled.

Packed Memory Organization

Color components are all 8 bits in size for YUV formats. For YUV 4:2:2 formats each DWord will contain two pixels and only the byte order affects the memory organization.

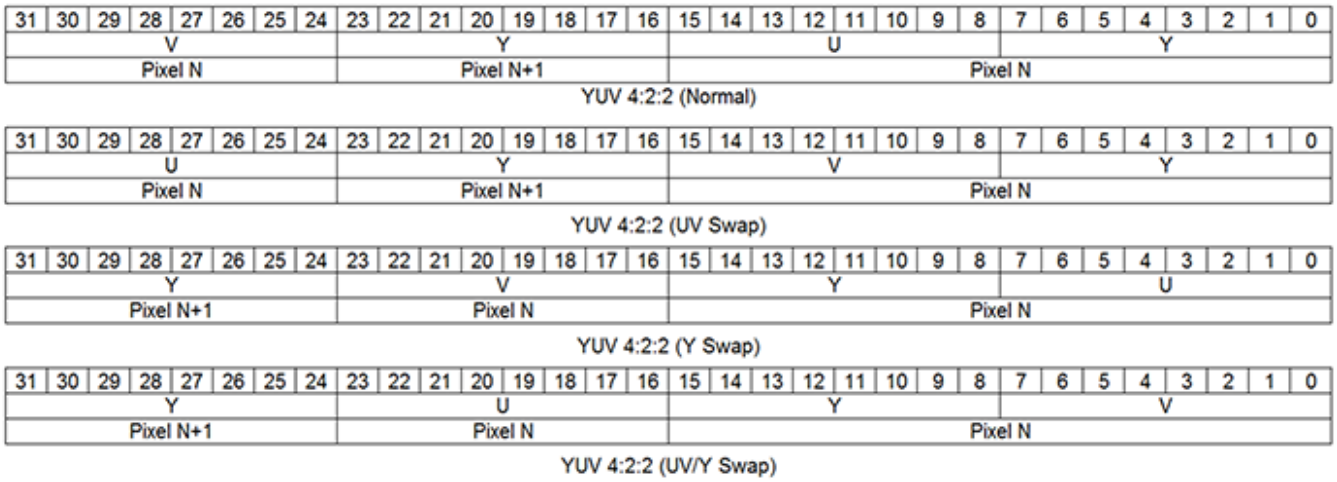
The following four YUV 4:2:2 surface formats are supported, listed with alternate names:

- YCRCB_NORMAL (YUYV/YUY2)
- YCRCB_SWAPUVY (VYUY) (R8G8_B8G8_UNORM)
- YCRCB_SWAPUV(YVYU) (G8R8_G8B8_UNORM)
- YCRCB_SWAPY (UYVY)

The channels are mapped as follows:

Cr (V)	Red
Y	Green
Cb (U)	Blue

Memory layout of packed YUV 4:2:2 formats



Planar Memory Organization

Planar formats use what could be thought of as separate buffers for the three color components. Because there is a separate stride for the Y and U/V data buffers, several memory footprints can be supported.

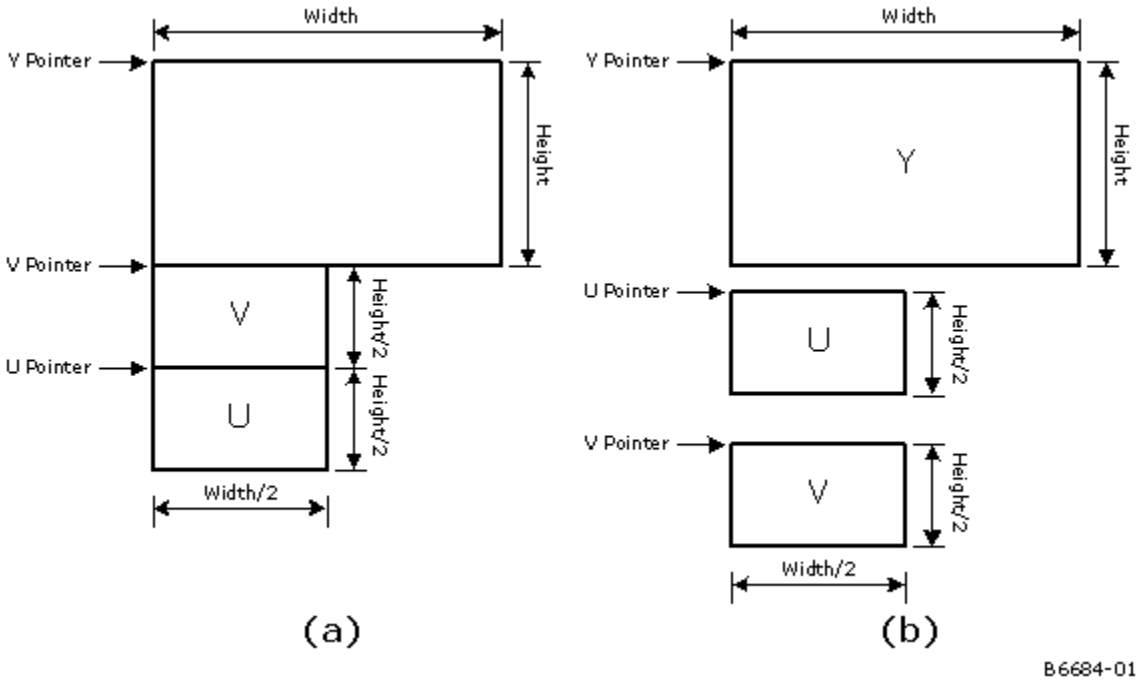
Note: There is no direct support for use of planar video surfaces as textures. The sampling engine can be used to operate on each of the 8bpp buffers separately (via a single-channel 8-bit format such as I8_UNORM). The U and V buffers can be written concurrently by using multiple render targets from the pixel shader. The Y buffer must be

written in a separate pass due to its different size.

The following figure shows two types of memory organization for the YUV 4:2:0 planar video data:

1. The memory organization of the common YV12 data, where all three planes are contiguous and the strides of U and V components are half of that of the Y component.
2. An alternative memory structure that the addresses of the three planes are independent but satisfy certain alignment restrictions.

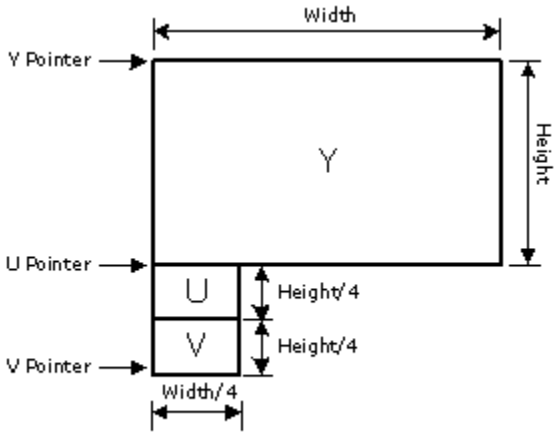
YUV 4:2:0 Format Memory Organization



The following figure shows memory organization of the planar YUV 4:1:0 format where the planes are contiguous.

Note: The chroma planes (U and V), when separate (case b above) are treated as half-pitch with respect to the Y plane. In general, YV12 is supported only in linear format because separate planes cannot be supported correctly with a tiled format.

YUV 4:1:0 Format Memory Organization



B6685-01

The table below shows how position within a Planar YUV surface chroma plane is calculated for various cases ot U and V pitch and position. It also shows restrictions on the alignment of the planes in memory when Y Height is a multiple of 4 or when Interleaved Chroma (e.g. NV21) is used.

Case	Interleave Chroma	Pitch	Vertical U/V Offset	Restrictions
YUV with Half Pitch Chroma	No	Half	When U is below Y Y_Uoffset = Y_Height * 2 Y_Voffset = Y_Height * 2 + V_Height When V is below Y Y_Uoffset = Y_Height * 2 + V_Height Y_Voffset = Y_Height * 2	(Y Height)%4 = 0 (U Height)%2 = 0 (V Height)%2 = 0 Vertical for Y surface must be 0
YUV with Full Pitch Chroma	Yes	Full	When U is below Y Y_Uoffset = Y_Height Y_Voffset = Y_Height + V_Height When V is below Y Y_Uoffset = Y_Height + V_Height Y_Voffset = Y_Height	(Y Height)%2 = 0 (U Height)%2 = 0 (V Height)%2 = 0
YUV for Media Sampling	Yes	Always Full	Same as 3D full pitch	Same as 3D full pitch

Raw Format

A format called "RAW" is available that is only supported with the untyped surface read/write, block, scattered, and atomic operation data port messages. It means that the surface has no inherent format. Surfaces of type RAW are addressed with byte-based offsets. The RAW surface format can be applied only to surface types of BUFFER and STRBUF.

Surface Memory Organizations

See *Memory Interface Functions* chapter for a discussion of tiled vs. linear surface formats.

Display, Overlay, Cursor Surfaces

These surfaces are memory image buffers (planes) used to refresh a display device in non-VGA mode. See the Display chapter for specifics on how these surfaces are defined/used.

2D Render Surfaces

These surfaces are used as general source and/or destination operands in 2D BLT operations.

Note that there is no coherency between 2D render surfaces and the texture cache. Software must explicitly invalidate the texture cache before using a texture that has been modified via the BLT engine.

See the 2D Instruction and 2D Rendering chapters for specifics on how these surfaces are used, restrictions on their size, placement, etc.

2D Monochrome Source

These 1 BPP (bit per pixel) surfaces are used as source operands to certain 2D BLT operations, where the BLT engine expands the 1 BPP source to the required color depth.

The texture cache stores any monochrome sources. There is no mechanism to maintain coherency between 2D render surfaces and texture-cached monochrome sources. Software must explicitly invalidate the texture cache before using a memory-based monochrome source that has been modified via the BLT engine. (Here the assumption is that SW enforces memory-based monochrome source surfaces as read-only surfaces.)

See the 2D Instruction and 2D Rendering chapters for specifics on how these surfaces are used, restrictions on their size, placement, coherency rules, etc.

2D Color Pattern

Color pattern surfaces are used as special pattern operands in 2D BLT operations.

The device uses the texture cache to store color patterns. There is no mechanism to maintain coherency between 2D render surfaces and (texture)-cached color patterns. Software is required to explicitly invalidate the texture cache before using a memory-based color pattern that has been modified via the BLT engine. (Here the assumption is that SW enforces memory-based color pattern surfaces as read-only surfaces.)

See the *2D Instruction* and *2D Rendering* chapters for specifics on how these surfaces are used, restrictions on their size, placement, etc.

3D Color Buffer (Destination) Surfaces

3D Color Buffer surfaces hold per-pixel color values for use in the 3D Pipeline. The 3D Pipeline always requires a Color Buffer to be defined.

See the Non-Video Pixel/Texel Formats section in this chapter for details on the Color Buffer pixel formats. See the 3D Instruction and 3D Rendering chapters for Color Buffer usage details.

The Color Buffer is defined as the BUFFERID_COLOR_BACK memory buffer via the 3DSTATE_BUFFER_INFO instruction. That buffer can be mapped to LM or SM (snooped or unsnooped), and can be linear or tiled. When both the Depth and Color Buffers are tiled, the respective Tile Walk directions must match.

When a linear Color Buffer and a linear Depth Buffer are used together:

- The buffers may have different pitches, though both pitches must be a multiple of 32 bytes.
- The buffers must be co-aligned with a 32-byte region.

3D Depth Buffer Surfaces

Depth Buffer surfaces hold per-pixel depth values and per-pixel stencil values for use in the 3D Pipeline. The 3D Pipeline does not require a Depth Buffer in general, though a Depth Buffer is required to perform non-trivial Depth Test and Stencil Test operations.

The Depth Buffer is specified via the 3DSTATE_DEPTH_BUFFER command. See the description of that instruction in *Windower* for restrictions.

See *Depth Buffer Formats* below for a summary of the possible depth buffer formats. See the Depth Buffer Formats section in this chapter for details on the pixel formats. See the *Windower* and *DataPort* chapters for details on the usage of the Depth Buffer.

Depth Buffer Formats

DepthBufferFormat / DepthComponent	BPP (Bits Per Pixel)	Description
D32_FLOAT_S8X24_UINT	64	32-bit floating point Z depth value in first DWord, 8-bit stencil in lower byte of second DWord
D32_FLOAT	32	32-bit floating point Z depth value
D24_UNORM_S8_UINT	32	24-bit fixed point Z depth value in lower 3 bytes, 8-bit stencil value in upper byte
D16_UNORM	16	16-bit fixed point Z depth value

3D Separate Stencil Buffer Surfaces

Separate Stencil Buffer surfaces hold per-pixel stencil values for use in the 3D Pipeline. Note that the 3D Pipeline does not require a Stencil Buffer to be allocated, though a Stencil Buffer is required to perform non-trivial Stencil Test operations.

UNRESOLVED CROSS REFERENCE, Depth Buffer Formats summarizes Stencil Buffer formats. Refer to the Stencil Buffer Formats section in this chapter for details on the pixel formats. Refer to the *Windower* chapters for Stencil Buffer usage details.

The Stencil buffer is specified via the 3DSTATE_STENCIL_BUFFER command. See that instruction description in *Windower* for restrictions.

Depth Buffer Formats

DepthBufferFormat / DepthComponent	BPP (bits per pixel)	Description
R8_ UNIT	8	8-bit stencil value in a byte

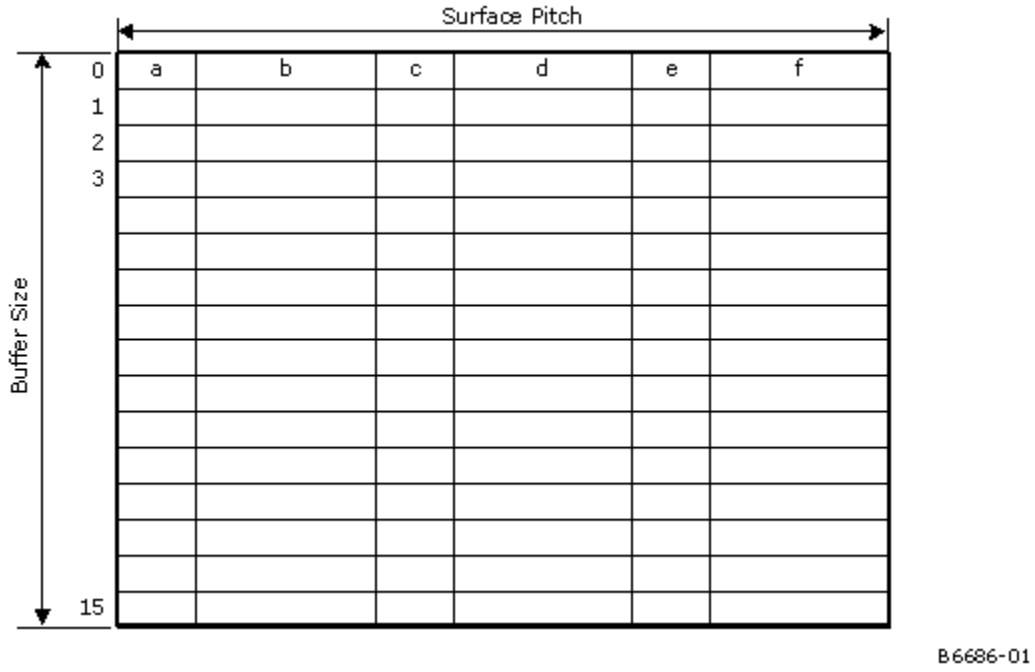
Surface Layout

In addition to restrictions on maximum height, width, and depth, surfaces are also restricted to a maximum size in bytes. This maximum is 2 GB for all products and all surface types.

Buffers

A buffer is an array of structures. Each structure contains up to 2048 bytes of elements. Each element is a single surface format using one of the supported surface formats depending on how the surface is being accessed. The surface pitch state for the surface specifies the size of each structure in bytes.

The buffer is stored in memory contiguously with each element in the structure packed together, and the first element in the next structure immediately following the last element of the previous structure. Buffers are supported only in linear memory.



Structured Buffers

A structured buffer is a surface type that is accessed by a 2-dimensional coordinate. It can be thought of as an array of structures, where each structure is a predefined number of DWords in size. The first coordinate (U) defines the array index, and the second coordinate (V) is a byte offset into the structure which must be a multiple of 4 (DWord-aligned). A structured buffer must be defined with **Surface Format** RAW.

The structured buffer has only one dimension programmed in SURFACE_STATE which indicates the array size. The byte offset dimension (V) is assumed to be bounded only by the **Surface Pitch**.

1D Surfaces

One-dimensional surfaces are identical to 2D surfaces with height of one. Arrays of 1D surfaces are also supported. Please refer to the 2D Surfaces section for details on how these surfaces are stored.

2D Surfaces

Surfaces that comprise texture mip-maps are stored in a fixed "monolithic" format and referenced by a single base address. The base map and associated mipmaps are located within a single rectangular area of memory identified by the base address of the upper left corner and a pitch. The base address references the upper left corner of the base map. The pitch must be specified at least as large as the widest mip-map. In some cases it must be wider; see the section on Minimum Pitch below.

These surfaces may be overlapped in memory and must adhere to the following memory organization rules:

- For non-compressed texture formats, each mipmap must start on an even row within the monolithic rectangular area. For 1-texel-high mipmaps, this may require a row of padding below the previous mipmap. This restriction does not apply to any compressed texture formats; each subsequent (lower-res) compressed mipmap is positioned directly below the previous mipmap.
- Vertical alignment restrictions vary with memory tiling type: 1 DWord for linear, 16-byte (DQWord) for tiled. (Note that tiled mipmaps are *not* required to start at the left edge of a tile row.)

Computing MIP Level Sizes

Map width and height specify the size of the largest MIP level (LOD 0). Less detailed LOD level (i+1) sizes are determined by dividing the width and height of the current (i) LOD level by 2 and truncating to an integer (floor). This is equivalent to shifting the width/height by 1 bit to the right and discarding the bit shifted off. The map height and width are clamped on the low side at 1.

In equations, the width and height of an LOD "*L*" can be expressed as:

W_L = *((width » L) > 0? width » L:1)*

H_L = *((height » L) > 0? height » L:1)*

If the surface is multisampled and it is a depth or stencil surface or **Multisampled Surface StorageFormat** in SURFACE_STATE is MSFMT_DEPTH_STENCIL, W_L and H_L must be adjusted as follows before proceeding:

Number of Multisamples	W_L =	H_L =
2	ceiling(W_L / 2) * 4	H_L [no adjustment]
4	ceiling(W_L / 2) * 4	ceiling(H_L / 2) * 4
8	ceiling(W_L / 2) * 8	ceiling(H_L / 2) * 4d
16	ceiling(W_L / 2) * 8	ceiling(H_L / 2) * 8

Base Address for LOD Calculation

It is conceptually easier to think of the space that the map uses in Cartesian space (x, y), where x and y are in units of texels, with the upper left corner of the base map at (0, 0). The final step is to convert from Cartesian coordinates to linear addresses as documented at the bottom of this section.

It is useful to think of the concept of "stepping" when considering where the next MIP level will be stored. We either step down or step right when moving to the next higher LOD.

- for MIPLAYOUT_RIGHT maps:
    - step right when moving from LOD 0 to LOD 1
    - step down for all of the other MIPs
- for MIPLAYOUT_BELOW maps:
    - step down when moving from LOD 0 to LOD 1
    - step right when moving from LOD 1 to LOD 2
    - step down for all of the other MIPs

To account for the cache line alignment required, we define *i* and *j* as the width and height, respectively, of an *alignment unit*. This alignment unit is defined below. We then define lower-case w_L and h_L as the padded width and height of LOD "*L*" as follows:

$$w_L = i * ceil\left(\frac{W_L}{i}\right)$$

$$h_L = j * ceil\left(\frac{H_L}{j}\right)$$

For separate stencil buffer, the width must be mutiplied by 2 and height divided by 2 as follows:

$$w_l = 2 * i * ceil\left(\frac{W_L}{i}\right)$$

$$h_L = 1/2 * j * ceil\left(\frac{H_L}{j}\right)$$

Equations to compute the upper left corner of each MIP level are then as follows:

for *MIPLAYOUT_RIGHT* maps: $LOD_0 = (0,0)$ $LOD_1 = (w_0,0)$ $LOD_2 = (w_0,h_1)$ $LOD_3 = (w_0,h_1 + h_2)$ $LOD_4 = (w_0,h_1 + h_2 + h_3)$ ...	for *MIPLAYOUT_BELOW* maps: $LOD_0 = (0,0)$ $LOD_1 = (0,h_0)$ $LOD_2 = (w_1,h_0)$ $LOD_3 = (w_1,h_0 + h_2)$ $LOD_4 = (w_1,h_0 + h_2 + h_3)$ ...	
Minimum Pitch for MIPLAYOUT_RIGHT and Other Maps

For MIPLAYOUT_RIGHT maps, the minimum pitch must be calculated before choosing a fence to place the map within. This is approximately equal to 1.5x the pitch required by the base map, with possible adjustments made for cache line alignment. For MIPLAYOUT_BELOW and MIPLAYOUT_LEGACY maps, the minimum pitch required is equal to that required by the base (LOD 0) map.

A safe but simple calculation of minimum pitch is equal to 2x the pitch required by the base map for MIPLAYOUT_RIGHT maps. This ensures that enough pitch is available, and since it is restricted to MIPLAYOUT_RIGHT maps, not much memory is wasted. It is up to the driver (hardware independent) whether to use this simple determination of pitch or a more complex one.

Cartesian to Linear Address Conversion

A set of variables are defined in addition to the i and j defined above.

- b = bytes per texel of the native map format (0.5 for DXT1, FXT1, and 4-bit surface format, 2.0 for YUV 4:2:2, others aligned to surface format)
- t = texel rows / memory row (4 for DXT1-5 and FXT1, 1 for all other formats)
- p = pitch in bytes (equal to pitch in dwords * 4)
- B = base address in bytes (address of texel 0,0 of the base map)
- x, y = cartestian coordinates from the above calculations in units of texels (assumed that x is always a multiple of i and y is a multiple of j)
- A = linear address in bytes

$$A = B + \frac{yp}{t} + xbt$$

This calculation gives the linear address in bytes for a given MIP level (taking into account L1 cache line alignment requirements).

Compressed Mipmap Layout

Mipmaps of textures using compressed (DXTn, FXT) texel formats are also stored in a monolithic format. The compressed mipmaps are stored in a similar fashion to uncompressed mipmaps, with each block of source (uncompressed) texels represented by a 1 or 2 QWord compressed block. The compressed blocks occupy the same logical positions as the texels they represent, where each row of compressed blocks represent a 4-high row of uncompressed texels. The format of the blocks is preserved, i.e., there is no “intermediate” format as required on some other devices.

The following exceptions apply to the layout of compressed (vs. uncompressed) mipmaps:

- Mipmaps are not required to start on even rows, therefore each successive mip level is located on the texel row immediately below the last row of the previous mip level. Pad rows are neither required nor allowed.
- The dimensions of the mip maps are first determined by applying the sizing algorithm presented in Non-Power-of-Two Mipmaps above. Then, if necessary, they are padded out to compression block boundaries.

Surface Arrays

Arrays of 1D and 2D surfaces can be treated as a single surface. This section covers the layout of these composite surfaces.

For All Surfaces

Both 1D and 2D surfaces can be specified as an array. An array surface is indicated by enabling the **Surface Array** field in SURFACE_STATE. 2D multisampled surfaces with Multisampled **Surface Storage Format** set to MSFMT_MSS also are stored like an array in memory.

A value QPitch is defined which indicates the worst-case height for one slice in the texture array. This QPitch is multiplied by the array index to and added to the vertical component of the address to determine the vertical component of the address for that slice. Within the slice, the map is stored identically to a 2D surface.

Since cube surfaces are stored identically to 2D arrays, QPitch is used to determine the spacing between faces of the cube.

For CMS/UMS multisampled surfaces, QPitch is used to determine the spacing between sample slices. For IMS multisampled surfaces, QPitch must account for the additional slice size due to sample storage.

For surfaces defined with SURFACE_STATE, The QPitch field in this state defines the value of QPitch. Software must ensure that QPitch is sufficiently large to avoid overlap between array slices in the memory layout. If an auxiliary surface is defined, a separate QPitch must be set for that surface.

For *depth* and stencil surfaces, QPitch is set in the corresponding state command.

Multisampled Surfaces

Multisampled render targets and sampling engine surfaces are supported. There are three types of multisampled surface layouts designated as follows:

- **IMS** Interleaved Multisampled Surface
- **CMS** Compressed Mulitsampled Surface
- **UMS** Uncompressed Multisampled Surface

These surface layouts are described in the following sections.

Compressed Multisampled Surfaces

Multisampled render targets can be compressed. If **MCS Enable** is enabled in SURFACE_STATE, hardware handles the compression using a software-invisible algorithm. However, performance optimizations in the multisample resolve kernel using the sampling engine are possible if the internal format of these surfaces is understood by software. This section documents the formats of the Multisample Control Surface (MCS) and Multisample Surface (MSS).

The MCS surface consists of one element per pixel, with the element size being an 8-bit unsigned integer value for 4x multisampled surfaces and a 32-bit unsigned integer value for 8x multisampled surfaces. Each field within the element indicates which sample slice (SS) the sample resides on.

For CHV, BSW, the 2x MCS is 8 bits per pixel. The 8 bits are encoded as follows:

2x MCS [CHV, BSW]

7:2	1	0
reserved	sample 1 SS	sample 0 SS

Each 1-bit field indicates which sample slice (SS) the sample's color value is stored. An MCS value of 0x00 indicates that both samples are stored in sample slice 0 (thus have the same color). This is the fully compressed case. An MCS value of 0x03 indicates that all samples in the pixel are in the clear state and none of the sample slices are valid. The pixel's color must be replaced with the surface's clear value.

For CHV, BSW, the 4x MCS is 8 bits per pixel. The 8 bits are encoded as follows:

4x MCS [CHV, BSW]

7:6	5:4	3:2	1:0
sample 3 SS	sample 2 SS	sample 1 SS	sample 0 SS

Each 2-bit field indicates which sample slice (SS) the sample's color value is stored. An MCS value of 0x00 indicates that all four samples are stored in sample slice 0 (thus all have the same color). This is the fully compressed case. An MCS value of 0xff indicates that all samples in the pixel are in the clear state, and none of the sample slices are valid. The pixel's color must be replaced with the surface's clear value.

For CHV, BSW, extending the mechanism used for the 4x MCS to 8x requires 3 bits per sample times 8 samples, or 24 bits per pixel. The 24-bit MCS value per pixel is placed in a 32-bit footprint, with the upper 8 bits unused as shown below.

8x MCS [CHV, BSW]

31:24	23:21	20:18	17:15	14:12	11:9	8:6	5:3	2:0
reserved	sample 7 SS	sample 6 SS	sample 5 SS	sample 4 SS	sample 3 SS	sample 2 SS	sample 1 SS	sample 0 SS

Other than this, the 8x algorithm is the same as the 4x algorithm. The MCS value indicating clear state is 0x00ffffff.

Physical MSS Surface

The physical MSS surface is stored identically to a 2D array surface, with the height and width matching the *pixel* dimensions of the logical multisampled surface. The number of array slices in the physical surface is 2, 4, 8, or 16 times that of the logical surface (depending on the number of multisamples). Sample slices belonging to the same logical surface array slice are stored in adjacent physical slices. The sampling engine *ld2dss* message gives direct access to a specific sample slice.

Uncompressed Multisampled Surfaces

UMS surfaces similar to CMS, except that the MCS is disabled, and there is no MCS surface. UMS contains only an MSS surface, where each sample is stored on its sample slice (SS) of the same index.

Cube Surfaces

The 3D Pipeline supports *cubic environment maps*, conceptually arranged as a cube surrounding the origin of a 3D coordinate system aligned to the cube faces. These maps can be used to supply texel (color/alpha) data of the environment in any direction from the enclosed origin, where the direction is supplied as a 3D "vector" texture coordinate. These cube maps can also be mipmapped.

Each texture map level is represented as a group of six, square *cube face* texture surfaces. The faces are identified by their relationship to the 3D texture coordinate system. The subsections below describe the cube maps as described at the API as well as the memory layout dictated by the hardware.

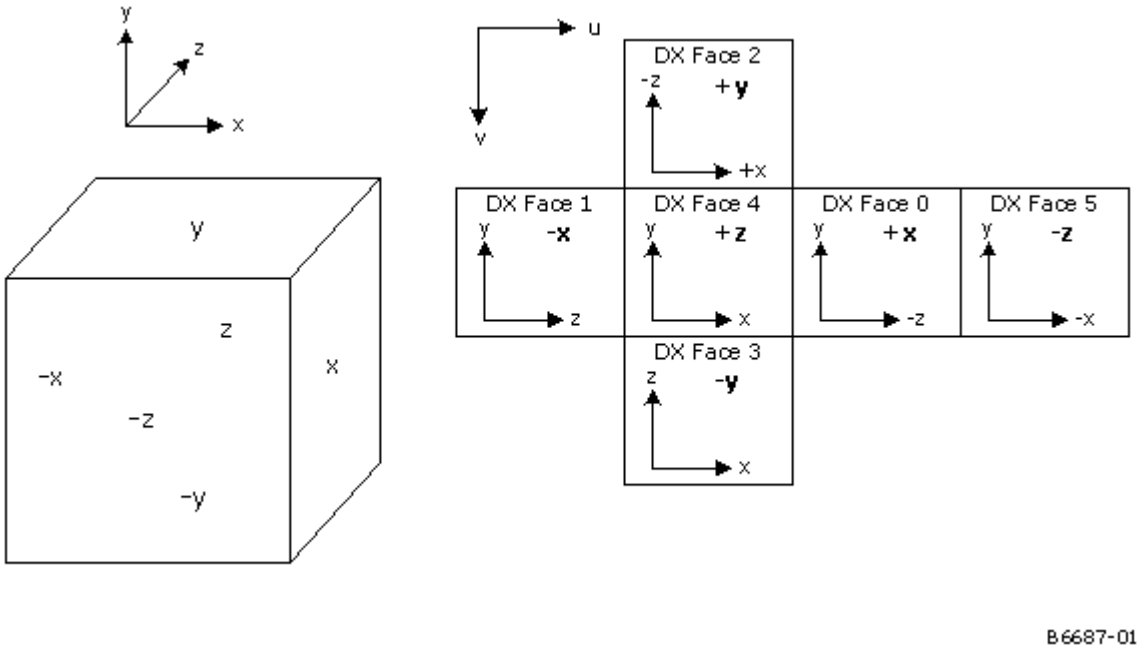
DirectX API Definition

The diagram below describes the cube map faces as they are defined at the DirectX API. It shows the axes on the faces as they would be seen from the inside (at the origin).

The origin of the U,V texel grid is at the top left corner of each face.

This will be looking directly at face 4, the +z -face. Y is up by default.

DirectX Cube Map Definition



Hardware Cube Map Layout

The cube face textures are stored in the same way as 2D array surfaces are stored (see section *2D Surfaces*for details). For cube surfaces, the depth (array instances) is equal to 6. The array index "q" corresponds to the face according to the following table:

"q" coordinate	face
0	+x
1	-x
2	+y
3	-y
4	+z
5	-z

Restrictions

- The cube map memory layout is the same whether or not the cube map is mip-mapped, and whether or not all six faces are "enabled", though the memory backing disabled faces or non-supplied levels can be used by software for other purposes.
- The cube map faces all share the same **Surface Format**

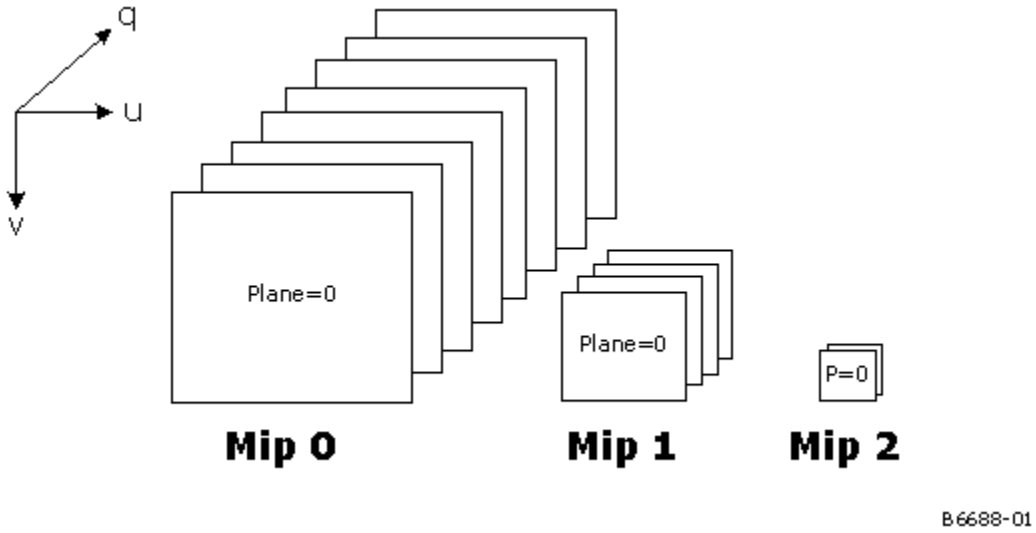
Cube Arrays

Cube arrays are stored identically to 2D surface arrays. A group of 6 consecutive array elements makes up a single cube map. A cube array with N array elements is stored identically to a 2D array with 6N array elements.

3D Surfaces

Multiple texture map surfaces (and their respective mipmap chains) can be arranged into a structure known as a Texture3D (volume) texture. A volume texture map consists of many *planes* of 2D texture maps. See *Sampler* for a description of how volume textures are used.

Volume Texture Map



The number of planes defined at each successive mip level is halved. Volumetric texture maps are stored as follows. All of the LOD=0 q-planes are stacked vertically, then below that, the LOD=1 q-planes are stacked two-wide, then the LOD=2 q-planes are stacked four-wide below that, and so on.

The width, height, and depth of LOD "L" are as follows:

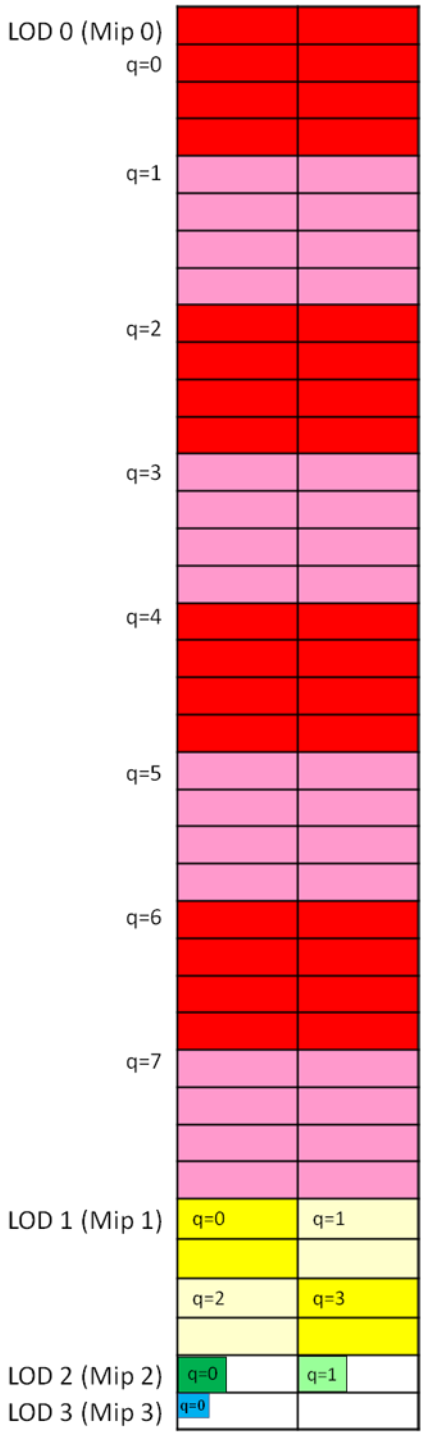
$W_L = ((width » L) > 0 ? width » L:1)$

$H_L = ((height » L) > 0 ? height » L:1)$

This is the same as for a regular texture. For volume textures we add:

$D_L = ((depth » L) > 0 ? depth » L:1)$

Cache-line aligned width and height are as follows, with i and j being a function of the map format as shown in Alignment Unit Size.



LOD 0 (Mip 0)
q=0
q=1
q=2
q=3
q=4
q=5
q=6
q=7
LOD 1 (Mip 1)
q=0
q=1
q=2
q=3
LOD 2 (Mip 2)
q=0
q=1
LOD 3 (Mip 3)
q=0

$$w_L = i * ceil\left(\frac{W_L}{i}\right)$$

$$h_L = j * ceil\left(\frac{H_L}{j}\right)$$

It is not necessary to cache-line align in the "depth" dimension (i.e. lowercase "*d*").

The following equations for $LOD_{L,q}$ give the base address Cartesian coordinates for the map at LOD L and depth q.

$$LOD_{0,q} = (0, q * h_0)$$

$$LOD_{1,q} = ((q\%2) * w_1, D_0 * h_0 + (q >> 1) * h_1)$$

$$LOD_{2,q} = ((q\%4) * w_2, D_0 * h_0 + ceil\left(\frac{D_1}{2}\right) * h_1 + (q >> 2) * h_2)$$

$$LOD_{3,q} = ((q\%8) * w_3, D_0 * h_0 + ceil\left(\frac{D_1}{2}\right) * h_1 + ceil\left(\frac{D_2}{4}\right) * h_2 + (q >> 3) * h_3)$$

These values are then used as "base addresses" and the 2D MIP Map equations are used to compute the location within each LOD/q map.

Minimum Pitch

The minimum pitch required to store the 3D map may in some cases be greater than the minimum pitch required by the LOD=0 map. This is due to cache line alignment requirements that may impact some of the MIP levels requiring additional spacing in the horizontal direction.

Surface Padding Requirements

This section covers the requirements for padding around surfaces stored in memory, as there are cases where the device will overfetch beyond the bounds of the surface due to implementation of caches and other hardware structures.

Alignment Unit Size

This section documents the alignment parameters *i* and *j* that are used depending on the surface.

Alignment Parameters, CHV, BSW

Surface Defined By	Surface Format	Alignment Unit Width "*i*"	Alignment Unit Height "*j*"
3DSTATE_DEPTH_BUFFER	D16_UNORM	8	4
	not D16_UNORM	4	4
3DSTATE_STENCIL_BUFFER	N/A	8	8
SURFACE_STATE	BC*, ETC*, EAC*	4	4
	FXT1	8	4
	ASTC	Value of ASTC_2DBlockWidth (4, 5, 6, 8, 10, or 12)	Value of ASTC_2DBlockHeight (4, 5, 6, 8, 10, or 12)
	all others	set by **Surface Horizontal Alignment**	set by **Surface Vertical Alignment**

Sampling Engine Surfaces

The sampling engine accesses texels outside of the surface if they are contained in the same cache line as texels that are within the surface. These texels will not participate in any calculation performed by the sampling engine and will not affect the result of any sampling engine operation, however if these texels lie outside of defined pages in the GTT, a GTT error will result when the cache line is accessed. In order to avoid these GTT errors, "padding" at the bottom and right side of a sampling engine surface is sometimes necessary.

It is possible that a cache line will straddle a page boundary if the base address or pitch is not aligned. All pages included in the cache lines that are part of the surface must map to valid GTT entries to avoid errors. To determine the necessary padding on the bottom and right side of the surface, refer to the table in Alignment Unit Size section for the i and j parameters for the surface format in use. The surface must then be extended to the next multiple of the alignment unit size in each dimension, and all texels contained in this extended surface must have valid GTT entries.

For example, suppose the surface size is 15 texels by 10 texels and the alignment parameters are i=4 and j=2. In this case, the extended surface would be 16 by 10. Note that these calculations are done in texels, and must be converted to bytes based on the surface format being used to determine whether additional pages need to be defined.

Buffer Padding Requirements

For compressed textures (BC*, FXT1, ETC*, EAC*, and ASTC* surface formats), padding at the bottom of the surface is to an even compressed row. This is equivalent to a multiple of 2*q*, where *q* is the compression block height in texels. Thus, for padding purposes, these surfaces behave as if $j = 2q$ only for surface padding purposes. The value of *j* is still equal to *q* for mip level alignment and QPitch calculation. For cube surfaces, an additional two rows of padding are required at the bottom of the surface. This must be ensured regardless of whether the surface is stored tiled or linear. This is due to the potential rotation of cache line orientation from memory to cache.

For packed YUV, 96 bpt, 48 bpt, and 24 bpt surface formats, additional padding is required. These surfaces require an extra row plus 16 bytes of padding at the bottom in addition to the general padding requirements.

For linear surfaces, additional padding of 64 bytes is required at the bottom of the surface. This is in addition to the padding required above.

Programming Note	
Context:	Sampling Engine Surfaces.
For SURFTYPE_BUFFER, SURFTYPE_1D, and SURFTYPE_2D non-array, non-MSAA, non-mip-mapped surfaces in linear memory, the only padding requirement is to the next aligned 64-byte boundary beyond the end of the surface. The rest of the padding requirements documented above do not apply to these surfaces.	

Programming Note	
Context:	Sampling Engine Surfaces.
For SURFTYPE_2D and SURFTYPE_3D with linear mode and height % 4 != 0, the surface must be padded with 4-(height % 4)***Surface Pitch** # of bytes.	

Programming Note	
Context:	Sampling Engine Surfaces
For SURFTYPE_1D with linear mode, the surface must be padded to 4 times the Surface Pitch # of bytes	

Render Target and Media Surfaces

The data port accesses data (pixels) outside of the surface if they are contained in the same cache request as pixels that are within the surface. These pixels will not be returned by the requesting message, however if these pixels lie outside of defined pages in the GTT, a GTT error will result when the cache request is processed. In order to avoid these GTT errors, “padding” at the bottom of the surface is sometimes necessary.

Graphics Command Formats

This section describes the general format of the graphics device commands.

Graphics commands are defined with various formats. The first DWord of all commands is called the *header* DWord. The header contains the only field common to all commands, the *client* field that determines the device unit that processes the command data. The Command Parser examines the client field of each command to condition the further processing of the command and route the command data accordingly.

Graphics commands vary in length, though are always multiples of DWords. The length of a command is either:

- Implied by the client/opcode
- Fixed by the client/opcode yet included in a header field (so the Command Parser explicitly knows how much data to copy/process)
- Variable, with a field in the header indicating the total length of the command

Note that command *sequences* require QWord alignment and padding to QWord length to be placed in Ring and Batch Buffers.

The following subsections provide a brief overview of the graphics commands by client type provides a diagram of the formats of the header DWords for all commands. Following that is a list of command mnemonics by client type.

Memory Interface Commands

Memory Interface (MI) commands are basically those commands which do not require processing by the 2D or 3D Rendering/Mapping engines. The functions performed by these commands include:

- Control of the command stream (e.g., Batch Buffer commands, breakpoints, ARB On/Off, etc.)
- Hardware synchronization (e.g., flush, wait-for-event)
- Software synchronization (e.g., Store DWORD, report head)
- Graphics buffer definition (e.g., Display buffer, Overlay buffer)
- Miscellaneous functions

All of the following commands are defined in *Memory Interface Commands*.

Memory Interface Commands for RCP

Opcode (28:23)	Command	Pipes
1 DWord		
00h	MI_NOOP	All
01h	MI_SET_PREDICATE	Render

2D Commands

The 2D commands include various flavors of BLT operations, along with commands to set up BLT engine state without actually performing a BLT. Most commands are of fixed length, though there are a few commands that include a variable amount of "inline" data at the end of the command.

All the following commands are defined in *Blitter Instructions*.

78h-7Fh	Reserved

3D Commands

The 3D commands are used to program the graphics pipelines for 3D operations.

Refer to the *3D* chapter for a description of the 3D state and primitive commands and the *Media* chapter for a description of the media-related state and object commands.

For all commands listed in **3D Command Map**, the Pipeline Type (bits 28:27) is 3h, indicating the 3D Pipeline.

Scheduling

Content for this topic is currently under development.

Execlists

Execlists are the method by which new contexts are submitted for execution. Note that this mechanism cannot be used when the **Execlist Enable** bit in the corresponding engines MODE register is not set, i.e GFX_MODE register for Render Engine, BLT_MODE register for Blitter Engine, VCS_MODE register for Video Engine, or VECS_MODE register for Video Enhancement Engine. If this bit is not set in the engine's MODE register, writing to the registers in this section is UNDEFINED.

Broadwell implements two execlists. Each execlist can have up to two context descriptors in it, each describing a context to run. SW assembles an execlist by writing each of the context descriptor elements to the Execlist Submit Port register. Writing the final DWord triggers the submission. It is the responsibility of SW to keep track of when an empty execlist entry is available to receive a new execlist submitted via the Submit Port. Submitting a new execlist when there is already a pending execlist (in addition to the current execlist) is UNDEFINED. In general, the interrupt indicating that the pending execlist has become the current execlist should always be observed before a new pending execlist is submitted. This includes the case where the ring is idle and the very first execlist is submitted; it should not be assumed that this execlist becomes the current list instantaneously.

The submission of a new execlist (known as a preemption request) is interpreted as a request to switch execlists as soon as possible. This is the only trigger for a execlist switch. Within an execlist, a switch from one element (context) to the next can be triggered for several reasons, all of which are synchronous to what the running context itself is doing. Once a context is switched out, the relevant context state and context descriptor doesn't exist in HW, only way the context can be brought back in to HW is by SW resubmitting the context through Execlist Submit Port.

SW must ensure the contexts submitted to both the context descriptors in the execlist are different; i.e SW must not submit the same context descriptor to both the elements of the execlist.

The following are Execlist Registers:

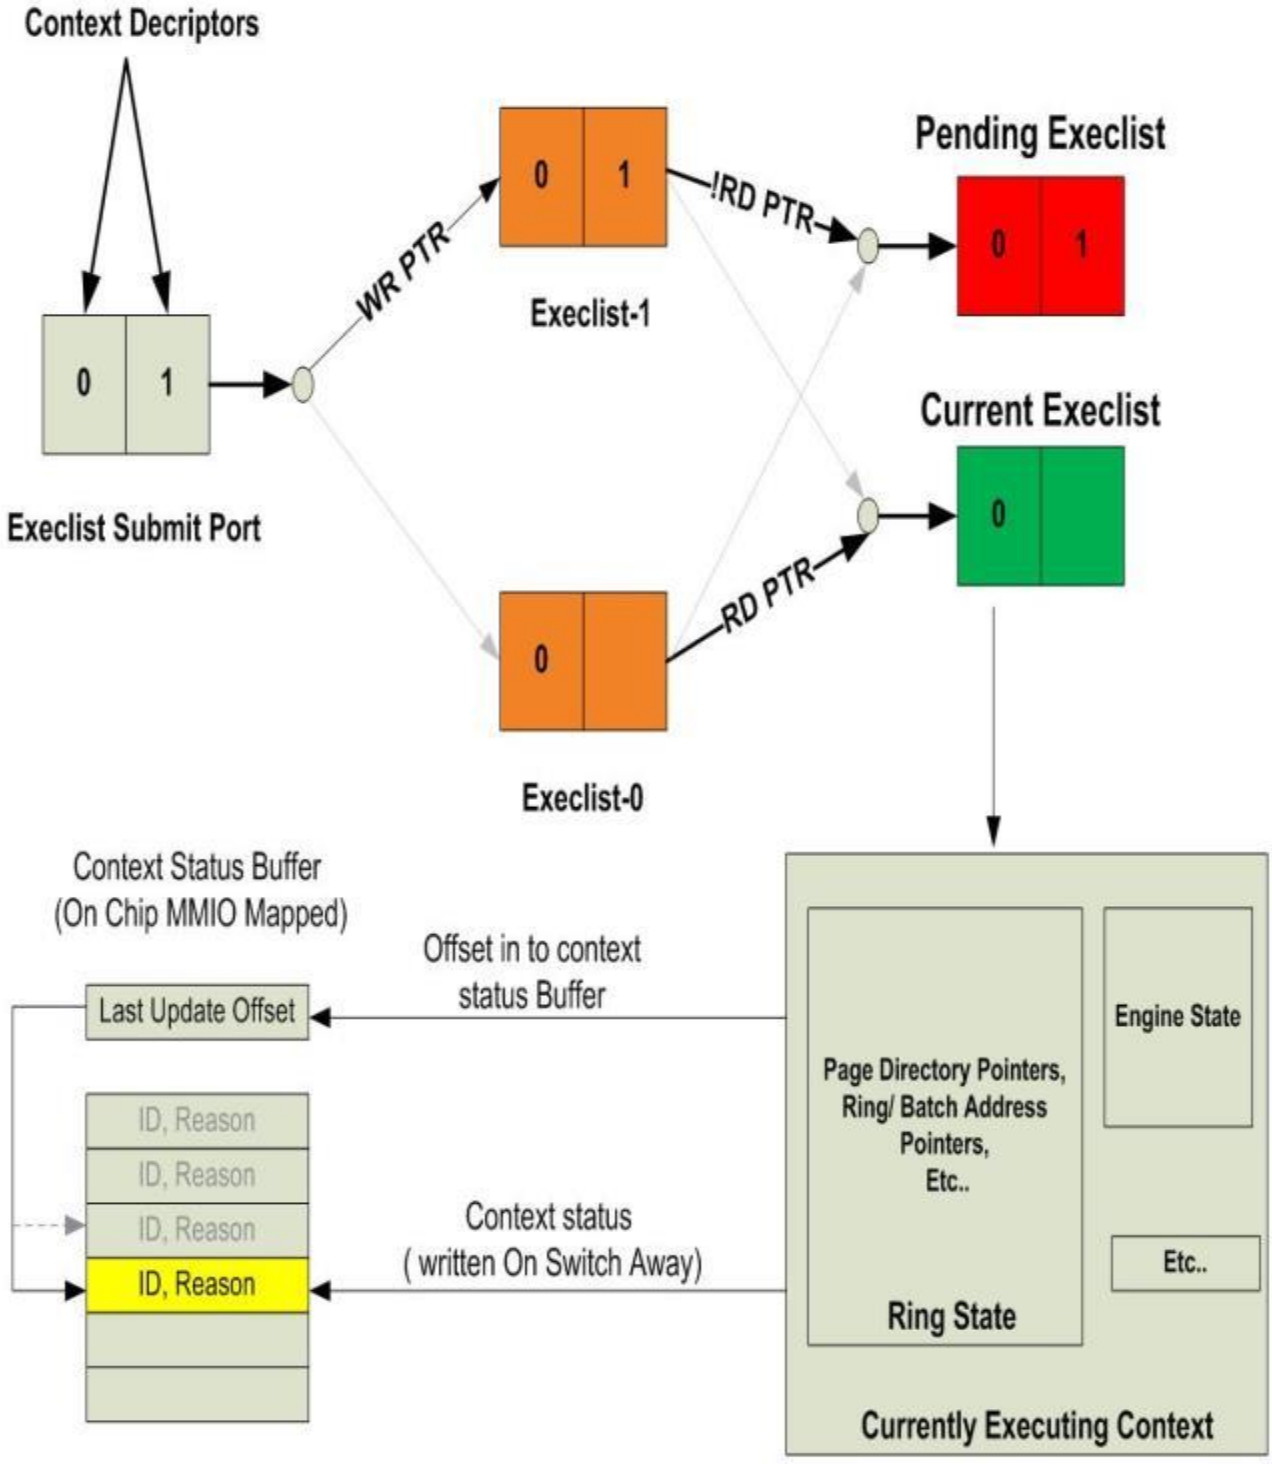
Execlist Submit Port Register

Execlist 0 Contents Register

Execlist 1 Contents

EXECLIST_STATUS - Execlist Status Register

Execlist Structure [CHV]



Before submitting a context for the first time, the context image must be properly initialized. Proper initialization includes the ring context registers (ring location, head/tail pointers, etc.) and the page directory.

Render CS Only: Render state need not be initialized; the **Render Context Restore Inhibit** bit in the Context/Save image in memory should be set to prevent restoring garbage render context. See the Logical Ring Context Format section for details.

Context Descriptor Format Structure

Context Descriptor Format

Context Descriptor Format

Before submitting a context for the first time, the context image must be properly initialized. Proper initialization includes the ring context registers (ring location, head/tail pointers, etc.) and the page directory.

Render CS Only: Render state need not be initialized; the **Render Context Restore Inhibit** bit in the Context/Save image in memory should be set to prevent restoring garbage render context. See the Logical Ring Context Format section for details.

Programming Note on Context ID field in the Context Descriptor

This section describes the current usage by SW.

General Layout:

63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48	47	46	45	44	43	42	41	40	39	38	37	36	35	34	33	32
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	09	08	07	06	05	04	03	02	01	00
Eng. ID				**SW Counter**					**HW Use**		**SW Context ID**																					

Eng. ID = Engine ID (a software defined enum to identify RCS, BCS etc..)

SW Counter = Submission Counter. (SW generates an unique counter value on every submission to ensure GroupID + PASID is unique to avoid ambiguity in fault reporting & handling)

Bit 20 = Is Proxy submission. If Set to true, SW Context ID[19:0] = LRCA [31:20], else it is an index into the Context Pool.

Logical Ring Context Format

When execlists are enabled, the Context Image for the each engine (Render, Video, Blitter, Video Enhancement) consists of Per-Process HW Status Page, Ring Context and Engine Context:

- Per-Process HW Status Page (4K)
- Ring Context (Ring Buffer Control Registers, Page Directory Pointers ..etc)
- Engine Context (PipelineState, Non-pipelineState, Statistics)

When execlists are disabled, the context image doesn't consist the Per-Process HW status page.

The detailed format of the Blitter/Video/VideoEnahancement logical ring context is documented in the "GPU Overview" volume, "Memory Data Formats" chapter.

The detailed format of the Render logical Ring and Engine Context including their size is mentioned in section "Graphics BSpec: 3D-Media-GPGPU Engine > Render Command Memory Interface > Render Engine Logical Context Data > Register/State Context" for each product.

Context Status

A context switch interrupt will be sent anytime a context switch or execlist change occurs (including the execlist change without context switch scenario described in the ELSP -- Execlist Submit Port Register section). A status QW for the context that was just switched away from will be written to the Context Status Buffer in the Global Hardware Status Page. A copy of the Context Status Buffer is also maintained ON CHIP inside the command streamer, which is MMIO mapped and can be read/written using MMIO access.

Context Status Buffer in Global Hardware Status Page is exercised when IA based scheduling is done. The status contains the context ID and the reason for the context switch. Note that since there will have been no running contexts when the very first (after reset) execlist is submitted or when HW is idle, the Context ID in the first Context Status Qword will be UNDEFINED, this is indicated by setting IDLE to ACTIVE bit in the context status.

Format of Context Status QWord

Bits	Description
63:32	**Context ID**
31:29	Reserved
28	Reserved
28	**POSH Context Complete** States the state of the POSH pipeline on a context switch by render pipe. When set indicates POSH pipe has completely processed (Head eqv to Tail) the submitted workload.
27:24	Reserved
23:20	Reserved
19:16	Reserved
19:16	**Display Plane.** This indicates the display plane for which Wait on Scanline/V-Blank/Sync Flip has been executed leading to context switch. This field when set to “0000b” indicates display plane on which Wait on Scanline/V-Blank/Sync Flip has been executed is indicated on bits [14:12]. This field is only valid when one of the “Wait on Scanline” or “Wait on Vblnak” or “Wait on sync Flip” is set. 0000b: Reserved (future Sprite A) (Look at field 14:12) 0001b: Reserved (future Sprite B) 0010b: Reserved (future Sprite C) 0011b: Display Plane Sprite A2 0100b: Display Plane Sprite B2 0101b: Display Plane Sprite C2 0110b: Display Plane Sprite A3 0111b: Display Plane Sprite B3 1000b: Display Plane Sprite C3 1001b to 1111b: Reserved

Bits	Description
15	**Lite Restore.** This bit is only valid only when Preempted bit is set. When set, this bit indicates a given context got preempted with the same context resulting in Lite Restore in HW.
14:12	**Display Plane.** This indicates the display plane for which Wait on Scnaline/V-Blank/Sync Flip has been executed leading to context switch. This field is only valid when one of the “Wait on Scanline” or “Wait on Vblnak” or “Wait on sync Flip” is set. 000b: Display Plane-A 001b: Display Plane-B 010b: Display Plane-C 011b: Display Plane Sprite-A 100b: Display Plane Sprite-B 101b: Display Plane Sprite-C
14:12	**Display Plane.** This indicates the display plane for which Wait on Scnaline/V-Blank/Sync Flip has been executed leading to context switch. This field is only valid when one of the “Wait on Scanline” or “Wait on Vblnak” or “Wait on sync Flip” is set. This field must be looked at only when Display Plane on bits [19:16] is “0000b” and when one of the “Wait on Scanline” or “Wait on Vblank” or “Wait on sync Flip” is set. 000b: Display Plane-A 001b: Display Plane-B 010b: Display Plane-C 011b: Display Plane Sprite-A 100b: Display Plane Sprite-B 101b: Display Plane Sprite-C
11	**Semaphore Wait Mode** 0: Signal Mode 1: Poll Mode This field is valid and must be looked at only when the "Wait on Semaphore" field is set.
10	Reserved
9	Reserved
8	**Wait on Scanline** has resulted in context switch. This may be cleared during context exit if the condition is met. If none of the bits specifying why we exit and ring is not complete, then scheduler should reschedule the context when possible.
8	**Wait on Scanline** has resulted in context switch.

Bits	Description
7	**Wait on Semaphore** has resulted in context switch. This may be cleared during context exit if the condition is met. If none of the bits specifying why we exit and ring is not complete, then scheduler should reschedule the context when possible.
7	**Wait on Semaphore** has resulted in context switch.
6	**Wait on V-Blank** has resulted in context switch. This may be cleared during context exit if the condition is met. If none of the bits specifying why we exit and ring is not complete, then scheduler should reschedule the context when possible.
6	**Wait on V-Blank** has resulted in context switch.
5	**Wait on Sync Flip** has resulted in context switch. This may be cleared during context exit if the condition is met. If none of the bits specifying why we exit and ring is not complete, then scheduler should reschedule the context when possible.
5	**Wait on Sync Flip** has resulted in context switch.
4	**Context Complete** Element is completely processed (Head eqv to Tail) and resulted in a context switch.
3	**ACTIVE to IDLE** following this context switch there is no active element available in HW to execute.
2	**Element Switch.** Context Switch happened from first element in the current execlist to the second element of the same execlist.
1	**Preempted.** Submission of a new execlist has resulted in context switch. The switch is from element in current execlist to element in pending execlist.
0	**IDLE to ACTIVE.** Execlist Submitted when HW is IDLE. When this bit is set rest of the fields in CSQ are not valid.

Context Status should be inferred as described in the tables below. In the two tables below only one of the context switch types will be set and it's quite possible multiple context switch reasons are set. A "Y" in a cell indicates the possibility of the context switch type for the corresponding context switch reason.

Inference of Context Status

Ctx Switch Type Ctx Switch Reason	IDLE to Active	Preempted/ Execlist Switch	**Element Switch	ACTIVE to IDLE
Context Complete	X	Y	Y	Y
Wait on Sync Flip	X	Y	Y	Y
Wait on V-Blank	X	Y	Y	Y
Wait on ScanLine	X	Y	Y	Y
Wait on Semaphore	X	Y	Y	Y
High Priority Context	Y	Y	X	Y

** This field is not valid when High Priority Context field is set and HW must force it to '0'.

When SW services a context switch interrupt, it should read the Context Status Buffer beginning where it left off reading the last time it serviced a context switch interrupt. It should read up to the **Context Status Buffer Write Pointer,** which is recorded in the Context Status Buffer Pointer register. At the end of the context switch interrupt processing SW will update the **Context Status Buffer Read Pointer** with the write buffer pointer value. The status QWs can be examined to determine which contexts were switched out between context interrupt service intervals, and why.

Number of Context Status Entries

Project	Number of Status Entries
CHV	6 (QW) Entries

Status QWords are written to the Context Status Buffer at incrementing locations. The Context Status Buffer has a limited size (see Table Number of Context Status Entries) and simply wraps around to the beginning when the end is reached. Normally the number of status updates that can occur without SW intervening to submit a new execlist (and presumably reading any new status) is the number of execlists times the maximum number of context elements per execlist. Also note that there is no predictable relationship between a context's position in an execlist and the position of its corresponding status QWord in the Context Status Buffer.

The Context Status Buffer fits into a single cacheline so that the whole buffer is read from memory at once if the driver performs a cacheable read.

Format of the Context Status Buffer

QW	Description
7	**Last Written Status Offset.** The lower byte of this QWord is written on every context switch with the (pre-increment) value of the b>Context Status Buffer Write Pointer. The lower 3 bits increment for every status QWord write; bits[7:3] are reserved and must be '0'. The lowest 3 bits indicate which of the Context Status QWords was just written. The rest of the bits [63:8] are reserved.
6	Reserved: MBZ
5:0	**Context Status QWords.** A circular buffer of context status QWs. As each context is switched away from, its status is written here at ascending QWs as indicated by the **Last Written Status Offset**. Once QW 5 has been written, the pointer wraps around so that the next status will be written at QW0. Format = ContextStatusDW

The following are Context Status Registers:

CTXT_ST_PTR - Context Status Buffer Pointer Register

CTXT_ST_BUF - Context Status Buffer Contents

RINGBUF — Ring Buffer Registers

See the "Device Programming Environment" chapter for detailed information on these registers.

RING_BUFFER_TAIL - Ring Buffer Tail

RING_BUFFER_HEAD - Ring Buffer Head

RING_BUFFER_START - Ring Buffer Start

RING_BUFFER_CTL - Ring Buffer Control

UHPTR - Pending Head Pointer Register

Virtual Memory Control

Per-Process GTT (PPGTT) is setup for an engine (Render, Blitter, Video and Video Enhancement) by programming corresponding Page Directory Pointer (PDP) registers listed below. Refer "Graphics Translation Tables" in "Memory Overview" for more details on Per-Process page table entries and related translations.

Render Engine Command Streamer (RCS)

The RCS (Render Command Streamer) unit primarily serves as the software programming interface between the O/S driver and the Render Engine. It is responsible for fetching, decoding, and dispatching of data packets (3D/Media Commands with the header DWord removed) to the front end interface module of Render Engine.

Logic Functions Included
• MMIO register programming interface. • DMA action for fetching of ring data from memory. • Management of the Head pointer for the Ring Buffer. • Decode of ring data and sending it to the appropriate destination: 3D (Vertex Fetch Unit) & GPGPU. • Handling of user interrupts. • Flushing the 3D and GPGPU Engine. • Handle NOP.
• DMA action for fetching of execlists from memory. • Handling of ring context switch interrupt.

The register programming bus is a DWord interface bus that is driven by the configuration master. The RCS unit only claims memory mapped I/O cycles that are targeted to its range of 0x2000 to 0x27FF. The Gx and MFX Engines use semaphore to synchronize their operations.

RCS operates completely independent of the MFx CS.

The simple sequence of events is as follows: a ring (say PRB0) is programmed by a memory-mapped register write cycle. The DMA inside RCS is kicked off. The DMA fetches commands from memory based on the starting address and head pointer. The DMA requests cache lines from memory (one cacheline CL at a time). There is guaranteed space in the DMA FIFO (8 CL deep) for data coming back from memory. The DMA control logic has copies of the head pointer and the tail pointer. The DMA increments the head pointer after making requests for ring commands. Once the DMA copy of the head pointer becomes equal to the tail pointer, the DMA stops requesting.

The parser starts executing once the DMA FIFO has valid commands. All the commands have a header DWord packet. Based on the encoding in the header packet, the command may be targeted towards Vertex Fetch Unit or GPPGU engine or the command parser. After execution of every command, the actual head pointer is updated. The ring is considered empty when the head pointer becomes equal to the tail pointer.

Batch Buffer Privilege Register

FORCE_TO_NONPRIV - FORCE_TO_NONPRIV

Mode Registers

The following are the Mode Registers:

INSTPM - Instruction Parser Mode Register

EXCC - Execute Condition Code Register

NOPID - NOP Identification Register

CSPREEMPT - CSPREEMPT

RCS_CTXID_PREEMPTION_HINT - RCS Context Preemption Hint

RCS_PREEMPTION_HINT - RCS_PREEMPTION_HINT

RCS_PREEMPTION_HINT_UDW - RCS_PREEMPTION_HINT_UDW

RS_PRE_HINT - RS Preemption Hint

RS_PREEMPTION_HINT_UDW - RS Preemption Hint UDW

IDLEDLY - Idle Switch Delay

SEMA_WAIT_POLL - Semaphore Polling Interval on Wait

CS_RESET_CTRL - CS Reset Control Register

HWS_PGA - Hardware Status Page Address Register

Hardware Status Page Layout

Logical Context Support

The following are the Logical Context Support Registers:

BB_ADDR - Batch Buffer Head Pointer Register

BB_ADDR_UDW - Batch Buffer Upper Head Pointer Register

RCS_BB_STATE - RCS Batch Buffer State Register

CTXT_SR_CTL - Context Save/Restore Control Register

CCID - Current Context Register

CXT_SIZE - Context Sizes

RS_CXT_OFFSET - Resource Streamer Context Offset

URB_CXT_OFFSET - URB Context Offset

CXT_EL_OFFSET - Exec-List Context Offset

SYNC_FLIP_STATUS - Wait For Event and Display Flip Flags Register

SYNC_FLIP_STATUS_1 - Wait For Event and Display Flip Flags Register 1

WAIT_FOR_RC6_EXIT - Control Register for Power Management

SBB_ADDR - Second Level Batch Buffer Head Pointer Register

SBB_ADDR_UDW - Second Level Batch Buffer Upper Head Pointer Register

SBB_STATE - Second Level Batch Buffer State Register

PS_INVOCATION_COUNT_SLICE0 - PS Invocation Count for Slice0

PS_INVOCATION_COUNT_SLICE1 - PS Invocation Count for Slice1

PS_INVOCATION_COUNT_SLICE2 - PS Invocation Count for Slice2

PS_DEPTH_COUNT_SLICE0 - PS Depth Count for Slice0

PS_DEPTH_COUNT_SLICE1 - PS Depth Count for Slice1

PS_DEPTH_COUNT_SLICE2 - PS Depth Count for Slice2

DISPLAY_MESSAGE_FORWARD_STATUS - Display Message Forward Status Register

R_PWR_CLK_STATE - Render Power Clock State Register

Context Save Registers

The following are the Context Save Registers:

BB_PREEMPT_ADDR - Batch Buffer Head Pointer Preemption Register

BB_PREEMPT_ADDR_UDW - Batch Buffer Upper Head Pointer Preemption Register

RING_BUFFER_HEAD_PREEMPT_REG - RING_BUFFER_HEAD_PREEMPT_REG

BB_START_ADDR - Batch Buffer Start Head Pointer Register

BB_START_ADDR_UDW - Batch Buffer Start Head Pointer Register for Upper DWord

BB_ADDR_DIFF - Batch Address Difference Register

BB_OFFSET - Batch Offset Register

SBB_PREEMPT_ADDR - Second Level Batch Buffer Head Pointer Preemption Register

SBB_PREEMPT_ADDR_UDW - Second Level Batch Buffer Upper Head Pointer Preemption Register

BB_PER_CTX_PTR - Batch Buffer Per Context Pointer

TDL_CONTEXT_SAVE - Context Save Request to TDL

MI Commands for Render Engine

This chapter describes the formats of the "Memory Interface" commands, including brief descriptions of their use. The functions performed by these commands are discussed fully in the *Memory Interface Functions* Device Programming Environment chapter.

This chapter describes MI Commands for the original graphics processing engine. The term "for Rendering Engine" in the title has been added to differentiate this chapter from a similar one describing the MI commands for the Media Decode Engine.

The commands detailed in this chapter are used across product families. However, slight changes may be present in some commands (i.e., for features added or removed), or some commands may be removed entirely. Refer to the *Preface* chapter for product specific summary.

MI_NOOP

MI_ARB_CHECK

MI_ARB_ON_OFF

MI_BATCH_BUFFER_START

MI_CONDITIONAL_BATCH_BUFFER_END

MI_DISPLAY_FLIP

MI_DISPLAY_FLIP

MI_LOAD_SCAN_LINES_EXCL

MI_LOAD_SCAN_LINES_INCL

MI_CLFLUSH

MI_MATH

MI_REPORT_HEAD

MI_STORE_DATA_IMM

MI_STORE_DATA_INDEX

MI_ATOMIC

MI_COPY_MEM_MEM

MI_LOAD_REGISTER_IMM

MI_LOAD_REGISTER_REG

MI_LOAD_REGISTER_MEM

MI_STORE_REGISTER_MEM

MI_SUSPEND_FLUSH

MI_UPDATE_GTT

MI_USER_INTERRUPT

MI_WAIT_FOR_EVENT

MI_SEMAPHORE_SIGNAL

MI_SEMAPHORE_WAIT

User Mode Privileged Commands

A subset of the commands are privileged. These commands may be issued only from a privileged batch buffer or directly from a ring buffer. Batch buffers in GGTT memory space are privileged and batch buffers in PPGTT memory space are non-privileged. On parsing privileged command from a non-privileged batch buffer, a Command Privilege Violation Error is flagged and the command is dropped. Command Privilege Violation Error is logged in Error identity register of command streamer which gets propagated as "Command Parser Master Error" interrupt to SW. Privilege access violation checks in HW can be disabled by setting "Privilege Check Disable" bit in GFX_MODE register. When privilege access checks are disabled HW will execute the Privilege command as expected.

User Mode Privileged Commands

User Mode Privileged Command	Function in Non-Privileged Batch Buffers
MI_UPDATE_GTT	Command is converted to NOOP.
MI_STORE_DATA_IMM	Command is converted to NOOP if **Use Global GTT** is enabled.
MI_STORE_DATA_INDEX	Command is converted to NOOP.
MI_STORE_REGISTER_MEM	Register read is always performed. Memory update is dropped if **Use Global GTT** is enabled.
MI_BATCH_BUFFER_START	Command when executed from a batch buffer can set its "Privileged" level to its parent batch buffer or lower. Chained or Second level batch buffer can be "Privileged" only if the parent or the initial batch buffer is "Privileged". This is HW enforced.
MI_LOAD_REGISTER_IMM	Command is converted to NOOP if the register accessed is privileged.
MI_LOAD_REGISTER_MEM	Command is converted to NOOP if **Use Global GTT** is enabled. Command is converted to NOOP, if the register accessed is privileged.
MI_LOAD_REGISTER_REG	Register write to a **Privileged Register** will be discarded.
MI_REPORT_PERF_COUNT	Command is converted to NOOP if **Use Global GTT** is enabled If a privilege access violation occurs, the Report ID field in the report generated by the next legitimate MI_REPORT_PERF_COUNT may be corrupted.
PIPE_CONTROL	Still send flush down, Post-Sync Operation is NOOP if **Use Global GTT** or Use "Store Data Index" is enabled. Post-Sync Operation LRI to **Privileged Register** is discarded.

User Mode Privileged Command	Function in Non-Privileged Batch Buffers
	Programming Note **Context:** User Mode Privileged Commands Command Privilege Violation error will not be set in a predictable fashion on a Privilege Access Violation from a PIPE_CONTROL command.
MI_SET_CONTEXT	Command is converted to NOOP.
MI_ATOMIC	Command is converted to NOOP if **Use Global GTT** is enabled.
MI_COPY_MEM_MEM	Command is converted to NOOP if **Use Global GTT** is used for source or destination address.
MI_SEMAPHORE_WAIT	Command is converted to NOOP if **Use Global GTT** is enabled.
MI_ARB_ON_OFF	Command is converted to NOOP.
MI_DISPLAY_FLIP	Command is converted to NOOP.
MI_CONDITIONAL_BATCH_BUFFER_END	Command is converted to NOOP if **Use Global GTT** is enabled.

Parsing one of the commands in the table above from a non-privileged batch buffer will flag an error and convert the command to a NOOP.

The table below lists the non-privileged registers that can be written to from a non-privileged batch buffer executed from Render Command Streamer.

User Mode Non-Privileged Registers

MMIO Name	MMIO Offset	SIZE in DWords
NOPID	0x2094	1
MI_PREDICATE_RESULT_2	0x23BC	1

PERF_CNT_2_DW0	0x91c0	1
PERF_CNT_2_DW1	0x91c4	1

Watchdog Timer Registers

These registers together implement a watchdog timer. Writing ones to the control register enables the counter, and writing zeros disables the counter. The second register is programmed with a threshold value which, when reached, signals an interrupt that then resets the counter to 0. Program the threshold value before enabling the counter or extremely frequent interrupts may result.

Note: The counter itself is not observable. It increments with the main render clock.

Programming Notes: When watch dog timer is enabled, HW does not trigger any kind of idle sequences. SW must enable and disable watch dog timer for any given workload within the same command buffer dispatch. SW must disable watch dog timer around semaphore waits and wait for events commands so that HW can trigger appropriate idle sequence for power savings.

PR_CTR - Render Watchdog Counter

PR_CTR_THRSH - Render Watchdog Counter Threshold

Command Stream Front End

Interrupt Control Registers

The Interrupt Control Registers described in this section all share the same bit definition. The bit definition is as follows:

Bit Definition for Interrupt Control Registers - Render

Bit Definition for Interrupt Control Registers - Blitter

Bit Definition for Interrupt Control Registers Media#1 (VDBOX1)

Bit Definition for Interrupt Control Registers Media#2 (VDBOX2)

Bit Definition for Interrupt Control Registers- Video Enhancement(VDBOX)

The following table specifies the settings of interrupt bits stored upon a "Hardware Status Write" due to ISR changes:

Bit	Interrupt Bit	ISR Bit Reporting Via Hardware Status Write (When Unmasked Via HWSTAM)
9	Reserved	
8	**Context Switch Interrupt.** Set when a context switch has just occurred.	Not supported to be unmasked.
7	**Page Fault.** This bit is set whenever there is a pending PPGTT (page or directory) fault. This interrupt is for handling Legacy Page Fault interface for all Command Streamers (BCS, RCS, VCS, VECS). When Fault Repair Mode is enabled, Interrupt mask register value is not looked at to generate interrupt due to page fault. Please refer to vol1c "Page Fault Support" section for more details.	Set when event occurs, cleared when event cleared. Not supported to be unmasked.
6	**Media Decode Pipeline Counter Exceeded Notify Interrupt.** The counter threshold for the execution of the media pipeline is exceeded. Driver needs to attempt hang recovery.	Not supported to be unmasked. Only for Media Pipe.
5	**L3 Parity interrupt**	Only for Render Pipe
4	**Flush Notify Enable**	0
3	**Master Error**	Set when error occurs, cleared when error cleared.
2	Reserved	
0	**User Interrupt**	0

RCS_HWSTAM - Render Hardware Status Mask Register

RCS_IMR - Render Interrupt Mask Register

VCS_HWSTAM - VCS Hardware Status Mask Register

VCS_IMR - VCS Interrupt Mask Register

BCS_HWSTAM - BCS Hardware Status Mask Register

BCS_IMR - BCS Interrupt Mask Register

VECS_HWSTAM - VECS Hardware Status Mask Register

VECS_IMR - VECS Interrupt Mask Register

Hardware-Detected Error Bit Definitions (for EIR EMR ESR)

This section defines the Hardware-Detected Error bit definitions and ordering that is common to the EIR, EMR, and ESR registers. The EMR selects which error conditions (bits) in the ESR are reported in the EIR. Any bit set in the EIR will cause the Master Error bit in the ISR to be set. EIR bits will remain set until the appropriate bit(s) in the EIR is cleared by writing the appropriate EIR bits with 1 (except for the unrecoverable bits described below).

The following structures describe the Hardware-Detected Error bits:

RCS Hardware-Detected Error Bit Definitions Structure

BCS Hardware-Detected Error Bit Definitions Structure

VCS Hardware-Detected Error Bit Definitions Structure

VECS Hardware-Detected Error Bit Definitions Structure

The following are the EIR, EMR, and ESR registers:

RCS_EIR - Error Identity Register

RCS_EMR - Error Mask Register

RCS_ESR - Error Status Register

BCS_EIR - BCS Error Identity Register

BCS_EMR - BCS Error Mask Register

BCS_ESR - BCS Error Status Register

VCS_EIR - VCS Error Identity Register

VCS_EMR - VCS Error Mask Register

VCS_ESR - VCS Error Status Register

VECS_EIR - VECS Error Identity Register

VECS_EMR - VECS Error Mask Register

VECS_ESR - VECS Error Status Register

Blitter Engine Command Streamer (BCS)

The BCS (Blitter Command Streamer) unit primarily serves as the software programming interface between the O/S driver and the Blitter Engine. It is responsible for fetching, decoding, and dispatching of data packets (Blitter Commands) to the front end interface module of Blitter Engine.

Logic Functions Included
• MMIO register programming interface. • DMA action for fetching of ring data from memory. • Management of the Head pointer for the Ring Buffer. • Decode of ring data and sending it to the blit engine. • Handling of user interrupts. • Flushing the Blitter Engine. • Handle NOP.
• DMA action for fetching of execlists from memory. • Handling of ring context switch interrupt.

The register programming bus is a DWord interface bus that is driven by the configuration master. The BCS unit only claims memory mapped I/O cycles that are targeted to its range of 0x22000 to 0x224FF. The Blitter, Render and Media Engines use semaphore to synchronize their operations.

BCS operates completely independent of the othe render and media command streams.

The simple sequence of events is as follows: a ring (say PRB0) is programmed by a memory-mapped register write cycle. The DMA inside BCS is kicked off. The DMA fetches commands from memory based on the starting address and head pointer. The DMA requests cache lines from memory (one cacheline CL at a time). There is guaranteed space in the DMA FIFO (8 CL deep) for data coming back from memory. The DMA control logic has copies of the head pointer and the tail pointer. The DMA increments the head pointer after making requests for ring commands. Once the DMA copy of the head pointer becomes equal to the tail pointer, the DMA stops requesting.

The parser starts executing once the DMA FIFO has valid commands. All the commands have a header DWord packet. Based on the encoding in the header packet, the command may be targeted towards Blit Engine or the command parser. After execution of every command, the actual head pointer is updated. The ring is considered empty when the head pointer becomes equal to the tail pointer.

Watchdog Timer Registers

These are the Watchdog Timer registers:

BCS_CNTR - BCS Counter for the Blitter Engine

BCS_CTR_THRSH - BCS Watchdog Counter Threshold

Hardware-Detected Error Bit Definitions (for EIR EMR ESR)

This section defines the Hardware-Detected Error bit definitions and ordering that are common to the EIR, EMR, and ESR registers. The EMR selects which error conditions (bits) in the ESR are reported in the EIR. Any bit set in the EIR causes the Master Error bit in the ISR to be set. EIR bits remain set until the appropriate bits in the EIR are cleared by writing the appropriate EIR bits with 1 (except for the unrecoverable bits described below).

The following structure describes the Hardware-Detected Error bits:

BCS Hardware-Detected Error Bit Definitions Structure

The following are the EIR, EMR, and ESR registers:

BCS_EIR - BCS Error Identity Register

BCS_EMR - BCS Error Mask Register

BCS_ESR - BCS Error Status Register

Logical Context Support

The following are the Logical Context Support Registers:

BB_ADDR - Batch Buffer Head Pointer Register

BB_ADDR_UDW - Batch Buffer Upper Head Pointer Register

SBB_ADDR - Second Level Batch Buffer Head Pointer Register

SBB_ADDR_UDW - Second Level Batch Buffer Upper Head Pointer Register

CTXT_SR_CTL - Context Save/Restore Control Register

BCS_SYNC_FLIP_STATUS - BCS Wait for event and Display flip flags Register

SYNC_FLIP_STATUS - Wait For Event and Display Flip Flags Register

SYNC_FLIP_STATUS_1 - Wait For Event and Display Flip Flags Register 1

DISPLAY_MESSAGE_FORWARD_STATUS - Display Message Forward Status Register

BB_ADDR_DIFF - Batch Address Difference Register

BB_OFFSET - Batch Offset Register

RING_BUFFER_HEAD_PREEMPT_REG - RING_BUFFER_HEAD_PREEMPT_REG

BB_PREEMPT_ADDR - Batch Buffer Head Pointer Preemption Register

BB_PREEMPT_ADDR_UDW - Batch Buffer Upper Head Pointer Preemption Register

SBB_PREEMPT_ADDR - Second Level Batch Buffer Head Pointer Preemption Register

SBB_PREEMPT_ADDR_UDW - Second Level Batch Buffer Upper Head Pointer Preemption Register

MI_PREDICATE_RESULT_1 - Predicate Rendering Data Result 1

MI_PREDICATE_RESULT_2 - Predicate Rendering Data Result 2

INDIRECT_CTX - Indirect Context Pointer

INDIRECT_CTX_OFFSET - Indirect Context Offset Pointer

BB_PER_CTX_PTR - Batch Buffer Per Context Pointer

Mode Registers

The following are Mode Registers:

BCS_CXT_SIZE - BCS Context Sizes

BCS_MI_MODE - BCS Mode Register for Software Interface

BLT_MODE - Blitter Mode Register

BCS_INSTPM - BCS Instruction Parser Mode Register

Programming Note	
Context:	Mode Registers in Blitter Engine Command Streamer

- The BCS_INSTPM register is used to control the operation of the BCS Instruction Parser. Certain classes of instructions can be disabled (ignored) – often useful for detecting performance bottlenecks. Also, "Synchronizing Flush" operations can be initiated – useful for ensuring the completion (vs. only parsing) of rendering instructions.
- All Reserved bits are implemented.

BCS_EXCC - BCS Execute Condition Code Register

BCS_IDLEDLY - BCS Idle Switch Delay

BCS_SEMA_WAIT_POLL - BCS Semaphore Polling Interval on Wait

BCS_RESET_CTRL - BCS Reset Control Register

BCS_PREEMPTION_HINT - BCS_PREEMPTION_HINT

BCS_PREEMPTION_HINT_UDW - BCS_PREEMPTION_HINT_UDW

BCS_CTXID_PREEMPTION_HINT - BCS Context ID Preemption Hint

HWS_PGA - Hardware Status Page Address Register

Hardware Status Page Layout

MI Commands for Blitter Engine

This chapter describes the formats of the "Memory Interface" commands, including brief descriptions of their use. The functions performed by these commands are discussed fully in the *Memory Interface Functions* Device Programming Environment chapter.

This chapter describes MI Commands for the blitter graphics processing engine. The term "for Blitter Engine" in the title has been added to differentiate this chapter from a similar one describing the MI commands for the Media Decode Engine and the Rendering Engine.

The commands detailed in this chapter are used across products. However, slight changes may be present in some commands (i.e., for features added or removed), or some commands may be removed entirely. Refer to the *Preface* chapter for product specific summary.

MI_NOOP

MI_ARB_CHECK

MI_ARB_ON_OFF

MI_BATCH_BUFFER_START

A subset of the commands are privileged. These commands may be issued only from a privileged batch buffer or directly from a ring. Batch buffers in GGTT memory space are privileged and batch buffers in PPGTT memory space are non-privileged. On parsing privileged command from a non-privileged batch buffer, a Command Privilege Violation Error is flagged and the command is dropped. Command Privilege Violation Error is logged in Error identity register of command streamer which gets propagated as "Command Parser Master Error" interrupt to SW. Privilege access violation checks in HW can be disabled by setting "Privilege Check Disable" bit in BLT_MODE register. When privilege access checks are disabled HW executes privileged commands as expected.

User Mode Privileged Commands

User Mode Privileged Command	Function in Non-Privileged Batch Buffers
MI_UPDATE_GTT	Command is converted to NOOP.
MI_STORE_DATA_IMM	Command is converted to NOOP if **Use Global GTT** is enabled.
MI_STORE_DATA_INDEX	Command is converted to NOOP.
MI_STORE_REGISTER_MEM	Command is converted to NOOP if **Use Global GTT** is enabled.
MI_BATCH_BUFFER_START	Command when executed from a batch buffer can set its "Privileged" level to its parent batch buffer or lower. Chained or Second level batch buffer can be "Privileged" only if the parent or the initial batch buffer is "Privileged". This is HW enforced.
MI_LOAD_REGISTER_IMM	Command is converted to NOOP if the register accessed is privileged.
MI_LOAD_REGISTER_MEM	Command is converted to NOOP if **Use Global GTT** is enabled. Register write to a **Privileged Register** is discarded.
MI_LOAD_REGISTER_REG	Register write to a **Privileged Register** is discarded.

MI_ATOMIC	Command is converted to NOOP if **Use Global GTT** is enabled.
MI_COPY_MEM_MEM	Command is converted to NOOP if **Use Global GTT** is used for source or destination address.
MI_SEMAPHORE_WAIT	Command is converted to NOOP if **Use Global GTT** is enabled.
MI_SEMAPHORE_SIGNAL	Command is converted to NOOP.
MI_ARB_ON_OFF	Command is converted to NOOP.
MI_DISPLAY_FLIP	Command is converted to NOOP.
MI_FLUSH_DW	Command is converted to NOOP if **Use Global GTT** or Use "Store Data Index" is enabled.
MI_CONDITIONAL_BATCH_BUFFER_END	Command is converted to NOOP if **Use Global GTT** is enabled.

Parsing one of the commands in the table above from a non-privileged batch buffer flags an error and converts the command to a NOOP.

The following table lists the non-privileged registers that can be written to from a non-secure batch buffer executed from Render Command Streamer.

User Mode Non-Privileged Registers

MMIO Name	MMIO Offset	Size in DWords
BCS_GPR	22600h	32
BCS_SWCTRL	22200h	32

MI_BATCH_BUFFER_END

MI_LOAD_REGISTER_MEM

MI_STORE_REGISTER_MEM

MI_SUSPEND_FLUSH

MI_UPDATE_GTT

MI_USER_INTERRUPT

MI_WAIT_FOR_EVENT

MI_SEMAPHORE_SIGNAL

MI_SEMAPHORE_WAIT

User Mode Privileged Commands

A subset of the commands are privileged. These commands may be issued only from a privileged batch buffer or directly from a ring buffer. Batch buffers in GGTT memory space are privileged and batch buffers in PPGTT memory space are non-privileged. On parsing a privileged command from a non-privileged batch buffer, a Command Privilege Violation Error is flagged and the command is dropped. Command Privilege Violation Error is logged in Error identity register of command streamer which gets propagated as "Command Parser Master Error" interrupt to SW. Privilege access violation checks in HW can be disabled by setting "Privilege Check Disable" bit in BLT_MODE register. When privilege access checks are disabled HW executes privileged commands as expected.

User Mode Privileged Commands

User Mode Privileged Command	Function in Non-Privileged Batch Buffers
MI_UPDATE_GTT	Command is converted to NOOP.
MI_STORE_DATA_IMM	Command is converted to NOOP if **Use Global GTT** is enabled.
MI_STORE_DATA_INDEX	Command is converted to NOOP.
MI_STORE_REGISTER_MEM	Command is converted to NOOP if **Use Global GTT** is enabled.
MI_BATCH_BUFFER_START	Command when executed from a batch buffer can set its "Privileged" level to its parent batch buffer or lower. Chained or Second level batch buffer can be "Privileged" only if the parent or the initial batch buffer is "Privileged". This is HW enforced.
MI_LOAD_REGISTER_IMM	Command is converted to NOOP if the register accessed is privileged.
MI_LOAD_REGISTER_MEM	Command is converted to NOOP if **Use Global GTT** is enabled. Register write to a **Privileged Register** is discarded.
MI_LOAD_REGISTER_REG	Register write to a **Privileged Register** is discarded.
MI_ATOMIC	Command is converted to NOOP if **Use Global GTT** is enabled.
MI_COPY_MEM_MEM	Command is converted to NOOP if **Use Global GTT** is used for source or destination address.
MI_SEMAPHORE_WAIT	Command is converted to NOOP if **Use Global GTT** is enabled.
MI_SEMAPHORE_SIGNAL	Command is converted to NOOP.
MI_ARB_ON_OFF	Command is converted to NOOP.
MI_DISPLAY_FLIP	Command is converted to NOOP.
MI_FLUSH_DW	Still send flush down, Post-Sync Operation is converted to NOOP if **Use Global GTT** or Use "Store Data Index" is enabled.
MI_CONDITIONAL_BATCH_BUFFER_END	Command is converted to NOOP if **Use Global GTT** is enabled.

Parsing one of the commands in the table above from a non-privileged batch buffer will flag an error and convert the command to a NOOP.

The following table lists the non-privileged registers that can be written to from a non-privileged batch buffer executed from Blitter Command Streamer.

User Mode Non-Privileged Registers

MMIO Name	MMIO Offset	Size in DWords
BCS_GPR	22600h	32
BCS_SWCTRL	22200h	32

Video Command Streamer (VCS)

The VCS (Video Command Streamer) unit primarily serves as the software programming interface between the O/S driver and the MFD Engine. It is responsible for fetching, decoding, and dispatching of data packets (Media Commands with the header DWord removed) to the front end interface module of MFX Engine.

Its logic functions include:

- MMIO register programming interface

  DMA action for fetching of execlists and ring data from memory
- Management of the Head pointer for the Ring Buffer
- Decode of ring data and sending it to the appropriate destination: AVC, VC1, or MPEG2 engine
- Handling of user interrupts

  Handling of ring context switch interrupt
- Flushing the MFX Engine
- Handle NOP

The register programming (RM) bus is a DWord interface bus that is driven by the Gx Command Streamer. The VCS unit only claims memory mapped I/O cycles that are targeted to its range of 0x4000 to 0x4FFFF. The Gx and MFX Engines use semaphore to synchronize their operations.

VCS operates completely independent of the Gx CS.

The simple sequence of events is as follows: a ring (say PRB0) is programmed by a memory-mapped register write cycle. The DMA inside VCS is kicked off. The DMA fetches commands from memory based on the starting address and head pointer. The DMA requests cache lines from memory (one cacheline CL at a time). There is guaranteed space in the DMA FIFO (16 CL deep) for data coming back from memory. The DMA control logic has copies of the head pointer and the tail pointer. The DMA increments the head pointer after making requests for ring commands. Once the DMA copy of the head pointer becomes equal to the tail pointer, the DMA stops requesting.

The parser starts executing once the DMA FIFO has valid commands. All the commands have a header DWord packet. Based on the encoding in the header packet, the command may be targeted towards AVC/VC1/MPEG2 engine or the command parser. After execution of every command, the actual head pointer is updated. The ring is considered empty when the head pointer becomes equal to the tail pointer.

Watchdog Timer Registers

The following registers are defined as Watchdog Timer registers:

VCS_CNTR - VCS Counter for the bit stream decode engine

VCS_THRSH - VCS Threshold for the counter of bit stream decode engine

VCS Hardware - Detected Error Bit Definitions (for EIR EMR ESR)

This section defines the Hardware-Detected Error bit definitions and ordering that are common to the EIR, EMR, and ESR registers. The EMR selects which error conditions (bits) in the ESR are reported in the EIR. Any bit set in the EIR causes the Master Error bit in the ISR to be set. EIR bits remain set until the appropriate bits in the EIR are cleared by writing the appropriate EIR bits with 1 (except for the unrecoverable bits described below).

The following links describe the Hardware-Detected Error bits.

VCS Hardware-Detected Error Bit Definitions

VCS_EIR - VCS Error Identity Register

VCS_EMR - VCS Error Mask Register

VCS_ESR - VCS Error Status Register

Logical Context Support

This section contains the registers for Logical Context Support.

BB_STATE - Batch Buffer State Register

CTXT_SR_CTL - Context Save/Restore Control Register

BB_ADDR_DIFF - Batch Address Difference Register

BB_ADDR - Batch Buffer Head Pointer Register

SBB_ADDR - Second Level Batch Buffer Head Pointer Register

SBB_ADDR_UDW - Second Level Batch Buffer Upper Head Pointer Register

BB_OFFSET - Batch Offset Register

RING_BUFFER_HEAD_PREEMPT_REG - RING_BUFFER_HEAD_PREEMPT_REG

BB_PREEMPT_ADDR - Batch Buffer Head Pointer Preemption Register

BB_PREEMPT_ADDR_UDW - Batch Buffer Upper Head Pointer Preemption Register

SBB_PREEMPT_ADDR - Second Level Batch Buffer Head Pointer Preemption Register

SBB_PREEMPT_ADDR_UDW - Second Level Batch Buffer Upper Head Pointer Preemption Register

MI_PREDICATE_RESULT_1 - Predicate Rendering Data Result 1

MI_PREDICATE_RESULT_2 - Predicate Rendering Data Result 2

DISPLAY_MESSAGE_FORWARD_STATUS - Display Message Forward Status Register

FORCE_TO_NONPRIV - FORCE_TO_NONPRIV

INDIRECT_CTX - Indirect Context Pointer

INDIRECT_CTX_OFFSET - Indirect Context Offset Pointer

BB_PER_CTX_PTR - Batch Buffer Per Context Pointer

Mode Registers

The following are Mode Registers:

VCS_CXT_SIZE - VCS Context Sizes]

VCS_MI_MODE - VCS Mode Register for Software Interface

MFX_MODE - Video Mode Register

VCS_INSTPM - VCS Instruction Parser Mode Register

VCS_IDLEDLY - VCS Idle Switch Delay

VCS_RESET_CTRL - VCS Reset Control Register

VCS_CTXID_PREEMPTION_HINT - VCS Context ID Preemption Hint

VCS_PREEMPTION_HINT - VCS_PREEMPTION_HINT

VCS_PREEMPTION_HINT_UDW

VCS_SEMA_WAIT_POLL - VCS Semaphore Polling Interval on Wait

HWS_PGA - Hardware Status Page Address Register

Hardware Status Page Layout

Registers in Media Engine

This topic describes the memory-mapped registers associated with the Memory Interface, including brief descriptions of their use. The functions performed by some of these registers are discussed in more detail in the Memory Interface Functions, Memory Interface Instructions, and Programming Environment chapters.

The registers detailed in this chapter are used across multiple projects and are extentions to previous projects. However, slight changes may be present in some registers (i.e., for features added or removed), or some registers may be removed entirely. These changes are clearly marked within this chapter.

GFX Pending TLB Cycles Information Registers

The following registers contain information about cycles that did not complete their TLB translation.

Information is organized as 64 entries, where each entry has a valid and ready bit, collapsed into separate registers.

VCS_TIMESTAMP - VCS Reported Timestamp Count

VCS_CTX_TIMESTAMP - VCS Context Timestamp Count

Memory Interface Commands for Video Codec Engine

This chapter describes the formats of the "Memory Interface" commands, including brief descriptions of their use. The functions performed by these commands are discussed fully in the *Memory Interface Functions* Device Programming Environment chapter.

This chapter describes MI Commands for the Video Codec Engine.

The commands detailed in this chapter are used across product families. However, slight changes may be present in some commands (i.e., for features added or removed), or some commands may be removed entirely. Refer to the *Preface* chapter for details.

User Mode Privileged Commands

A subset of the commands are privileged. These commands may be issued only from a privileged batch buffer or directly from a ring. Batch buffers in GGTT memory space are privileged and batch buffers in PPGTT memory space are non-privileged. On parsing privileged command from a non-privileged batch buffer, a Command Privilege Violation Error is flagged and the command is dropped. Command Privilege Violation Error is logged in Error identity register of command streamer which gets propagated as "Command Parser Master Error" interrupt to SW. Privilege access violation checks in HW can be disabled by setting "Privilege Check Disable" bit in MFX_MODE register. When privilege access checks are disabled HW will execute the Privilege command as expected.

User Mode Privileged Commands

User Mode Privileged Command	Function in Non-Privileged Batch Buffers
MI_UPDATE_GTT	Command is converted to NOOP.
MI_STORE_DATA_IMM	Command is converted to NOOP if **Use Global GTT** is enabled.
MI_STORE_DATA_INDEX	Command is converted to NOOP.
MI_STORE_REGISTER_MEM	Command is converted to NOOP if **Use Global GTT** is enabled.
MI_BATCH_BUFFER_START	Command when executed from a batch buffer can set its "Privileged" level to its parent batch buffer or lower. Chained or Second level batch buffer can be "Privileged" only if the parent or the initial batch buffer is "Privileged". This is HW enforced.
MI_LOAD_REGISTER_IMM	Command is converted to NOOP if the register accessed is privileged.
MI_LOAD_REGISTER_MEM	Command is converted to NOOP if **Use Global GTT** is enabled Register write to a **Privileged Register** will be discarded.
MI_LOAD_REGISTER_REG	Register write to a **Privileged Register** will be discarded.
MI_ATOMIC	Command is converted to NOOP if **Use Global GTT** is enabled.
MI_COPY_MEM_MEM	Command is converted to NOOP if **Use Global GTT** is used for source or destination address.
MI_SEMAPHORE_SIGNAL	Command is converted to NOOP.
MI_SEMAPHORE_WAIT	Command is converted to NOOP if **Use Global GTT** is enabled.
MI_ARB_ON_OFF	Command is converted to NOOP.
MI_FLUSH_DW	Still send flush down, Post-Sync Operation is converted to NOOP if **Use Global GTT** or Use "Store Data Index" is enabled.
MI_CONDITIONAL_BATCH_BUFFER_END	Command is converted to NOOP if **Use Global GTT** is enabled.
MI_SEMAPHORE_SIGNAL	Command is converted to NOOP.

Parsing one of the commands in the table above from a non-privileged batch buffer flags an error and converts the command to a NOOP.

The following table lists the non-privileged registers that can be written to from a non-secure batch buffer

executed from Video Command Streamer.

User Mode Non-Privileged Registers

MMIO Name	MMIO Offset	Size in DWords
VCS_GPR	12600h	32
VCS_GPR (2nd VCS)	1C600h	32
MFC_VDBOX1	12800h	64
MFC_VDBOX2	1C800h	64

Video Enhancement Engine Command Interface

The following topics describe the Video Enhancement Engine Command Interface.

VECS_RINGBUF — Ring Buffer Registers

The following are Ring Buffer Registers:

RING_BUFFER_TAIL - Ring Buffer Tail

RING_BUFFER_HEAD - Ring Buffer Head

RING_BUFFER_START - Ring Buffer Start

RING_BUFFER_CTL - Ring Buffer Control

UHPTR - Pending Head Pointer Register

Watchdog Timer Registers

The following are Watchdog Timer Registers:

VECS_CNTR - VECS Counter for the Video Enhancement Engine

VECS_CTR_THRSH - VECS Threshold for the Counter of Video Enhancement Engine

Logical Context Support

The following are Logical Context Support Registers:

BB_ADDR - Batch Buffer Head Pointer Register

BB_ADDR_UDW - Batch Buffer Upper Head Pointer Register

SBB_ADDR - Second Level Batch Buffer Head Pointer Register

SBB_ADDR_UDW - Second Level Batch Buffer Upper Head Pointer Register

BB_STATE - Batch Buffer State Register

CTXT_SR_CTL - Context Save/Restore Control Register

VECS_TIMESTAMP - VECS Reported Timestamp CountCHV

VECS_CTX_TIMESTAMP - VECS Context Timestamp Count

BB_ADDR_DIFF - Batch Address Difference Register

BB_OFFSET - Batch Offset Register

RING_BUFFER_HEAD_PREEMPT_REG - RING_BUFFER_HEAD_PREEMPT_REG

BB_PREEMPT_ADDR - Batch Buffer Head Pointer Preemption Register

BB_PREEMPT_ADDR_UDW - Batch Buffer Upper Head Pointer Preemption Register

SBB_PREEMPT_ADDR - Second Level Batch Buffer Head Pointer Preemption Register

SBB_PREEMPT_ADDR_UDW - Second Level Batch Buffer Upper Head Pointer Preemption Register

MI_PREDICATE_RESULT_1 - Predicate Rendering Data Result 1

MI_PREDICATE_RESULT_2 - Predicate Rendering Data Result 2

DISPLAY_MESSAGE_FORWARD_STATUS - Display Message Forward Status Register

FORCE_TO_NONPRIV - FORCE_TO_NONPRIV

INDIRECT_CTX - Indirect Context Pointer

INDIRECT_CTX_OFFSET - Indirect Context Offset Pointer

BB_PER_CTX_PTR - Batch Buffer Per Context Pointer

Mode Registers

The following are Mode Registers:

VECS_MI_MODE — VECS Mode Register for Software Interface

VEBOX_MODE - Video Mode Register

VECS_INSTPM—VECS Instruction Parser Mode Register

HWS_PGA - Hardware Status Page Address Register

Hardware Status Page Layout

VECS_RESET_CTRL - VECS Reset Control Register

VECS_PREEMPTION_HINT

VECS_PREEMPTION_HINT_UDW

VECS_CTXID_PREEMPTION_HINT - VECS Context ID Preemption Hint

VECS_SEMA_WAIT_POLL - VECS Semaphore Polling Interval on Wait

MI Commands for Video Enhancement Engine

This chapter describes the formats of the "Memory Interface" commands, including brief descriptions of their use. The functions performed by these commands are discussed fully in the *Memory Interface Functions* Device Programming Environment chapter.

This chapter describes MI Commands for the Video Codec Engine.

The commands detailed in this chapter are used across product families. However, slight changes may be present in some commands (i.e., for features added or removed), or some commands may be removed entirely. Refer to the *Preface* chapter for details.

User Mode Privileged Commands

A subset of the commands are privileged. These commands may be issued only from a privileged batch buffer or directly from a ring. Batch buffers in GGTT memory space are privileged and batch buffers in PPGTT memory space are non-privileged. On parsing a privileged command from a non-privileged batch buffer, a Command Privilege Violation Error is flagged and the command is dropped. A Command Privilege Violation Error is logged in the Error identity register of the command streamer which gets propagated as "Command Parser Master Error" interrupt to SW. Privilege access violation checks in HW can be disabled by setting "Privilege Check Disable" bit in VEBOX_MODE register. When privilege access checks are disabled HW executes privileged commands as expected.

User Mode Privileged Commands

User Mode Privileged Command	Function in Non-Privileged Batch Buffers
MI_UPDATE_GTT	Command is converted to NOOP.
MI_STORE_DATA_IMM	Command is converted to NOOP if **Use Global GTT** is enabled.
MI_STORE_DATA_INDEX	Command is converted to NOOP.
MI_STORE_REGISTER_MEM	Command is converted to NOOP if **Use Global GTT** is enabled.
MI_BATCH_BUFFER_START	Command when executed from a batch buffer can set its "Privileged" level to its parent batch buffer or lower. Chained or Second level batch buffer can be "Privileged" only if the parent or the initial batch buffer is "Privileged". This is HW enforced.
MI_LOAD_REGISTER_IMM	Command is converted to NOOP if the register accessed is privileged.
MI_LOAD_REGISTER_MEM	Command is converted to NOOP if **Use Global GTT** is enabled. Register write to a **Privileged Register** will be discarded.
MI_LOAD_REGISTER_REG	Register write to a **Privileged Register** will be discarded.
MI_ATOMIC	Command is converted to NOOP if **Use Global GTT** is enabled.
MI_COPY_MEM_MEM	Command is converted to NOOP if **Use Global GTT** is used for source or destination address.
MI_SEMAPHORE_SIGNAL	Command is converted to NOOP.
MI_SEMAPHORE_WAIT	Command is converted to NOOP if **Use Global GTT** is enabled.
MI_ARB_ON_OFF	Command is converted to NOOP.
MI_FLUSH_DW	Still send flush down, Post-Sync Operation is converted to NOOP if **Use Global GTT** or Use "Store Data Index" is enabled.
MI_CONDITIONAL_BATCH_BUFFER_END	Command is converted to NOOP if **Use Global GTT** is enabled.

Parsing one of the commands in the table above from a non-privileged batch buffer will flag an error and convert the command to a NOOP.

The table below lists the non-privileged registers that can be written to from a non-secure batch buffer executed from the Render Command Streamer.

User Mode Non-Privileged Registers

MMIO Name	MMIO Offset	Size in DWords
VECS_GPR	1A600h	32

Preemption

Preemption is a means by which HW is instructed to stop executing an ongoing workload and switch to the new workload submitted. Preemption flows are different based on the mode of scheduling.

Ring Buffer Scheduling

In Ring Buffer mode of scheduling SW triggers preemption by programming UHPTR (Updated Head Pointer Register) register with a valid head pointer. UHPTR contains head pointer and head pointer valid bit; the head pointer is valid only when the head pointer valid bit is set.

HW triggers preemption on a preemptable command on detecting Head Pointer Valid bit asserted in the UHPTR register. Following preemption HW updates its current head pointer with the Head Pointer from the UHPTR and starts execution; i.e all the commands from current head pointer to the updated head pointer are skipped by HW. HW samples the head pointer and the batch buffer address on preemption and updates them to the RING_BUFFER_HEAD_PREEMPT_REG and BB_PREEMPT_ADDR respectively. RING_BUFFER_HEAD_PREEMPT_REG and BB_PREEMPT_ADDR provide the graphics memory address of the preemptable command on which last preemption has occurred. HW resets the head pointer valid bit in UHPTR upon completion of preemption.

Programming Notes:

Preemption is not supported for Media Workloads. Hence preemption can be achieved only on Command Buffer boundaries. Media Command Buffers must be bracketed with MI_ARB_OFF and MI_ARB_ON commands to avoid preemption of media command buffers.

Example:

```
Ring Buffer
.
.
.
MI_ARB_ON_OFF     // OFF
MI_BATCH_START    // Media Workload
MI_ARB_ON_OFF     // ON
MI_ARB_CHK        // Preemptable command outside media command buffer.
.
.
End Ring Buffer
```

The following tables list the Preemptable Commands in the Ring Buffer mode of scheduling:

Engine (below)	Preemptable Commands				
	MI_ARB_CHECK	3DPRIMITIVE	GPGPU_WALKER	PIPE_CONTROL ***	MEDIA STATE FLUSH
Render	AP	Object Level (if enabled *)	Mid-Thread (if enabled **)	PIPESEL-GPGPU MODE	PIPESEL-GPGPU MODE
Blitter	AP	N/A	N/A	N/A	N/A
Media	AP	N/A	N/A	N/A	N/A
VideoEnhancement	AP	N/A	N/A	N/A	N/A

AP: Allow preemption on UHPTR valid and arbitration enabled. Arbitration can be enabled/disabled using MI_ARB_ON_OFF command.

ExecList Scheduling

In ExecList mode of scheduling SW triggers preemption by submitting a new pending execlist to ELSP (ExecList Submit Port). HW triggers preemption on a preemptable command on detecting the availability of the new pending execlist, following preemption context switch happens to the newly submitted execlist. As part of the context switch preempted context state is saved to the preempted context LRCA, context state contains the details such that on resubmission of the preempted context HW can resume execution from the point where it was preempted.

Example:

```
Ring Buffer

MI_ARB_ON_OFF   // OFF
MI_BATCH_START  // Media Workload
MI_ARB_ON_OFF   // ON
MI_ARB_CHK      // Preemptable command outside media command buffer.
```

The following tables list the Preemptable Commands in ExecList mode of scheduling:

Engine (below)	Preemptable Commands							
	MI_ARB_CHECK	Element Boundary	Semaphore Wait	Wait for Event	3DPRIMITIVE	GPGPU_WALKER	PIPE_CONTROL ***	MEDIA STATE FLUSH
Render	AP	AP	Unsuccessful & AP	Unsuccessful & AP	Object Level (if enabled *)	Mid-Thread (if enabled **)	PIPESEL-GPGPU MODE	PIPESEL-GPGPU MODE
Blitter	AP	AP	Unsuccessful & AP	Unsuccessful & AP	N/A	N/A	N/A	N/A
Media	AP	AP	Unsuccessful & AP	N/A	N/A	N/A	N/A	N/A
Video Enhancement	AP	AP	Unsuccessful & AP	N/A	N/A	N/A	N/A	N/A

Preemption is not supported for Media Workloads. Hence preemption can be achieved only on Command Buffer boundaries. Media Command Buffers must be bracketed with MI_ARB_OFF and MI_ARB_ON command to avoid preemption of media command buffers.

Table Notes:

AP - Allow Preemption if arbitration is enabled.

* 0x229c bit 11 determines whether the level of preemption is command or object level.

** 0x20E4 bits 2:1 determine the level of preemption for GPGPU workloads.

*** MI_ATOMIC and MI_SEMAPHORE_SIGNAL commands with Post Sync Op bit set are treated as PIPE_CONTROL command with Post Sync Operation as Atomics or Semaphore Signal.

**** Any Header with the value [31:29] = "011", [28:27] = "00" OR "11" and [26:24] = "001". Refer to Graphics Command Formats.

Command Streamer (CS) ALU Programming

The command streamer implements a rudimentary Arithmetic Logic Unit (ALU) which supports basic arithmetic (Addition and Subtraction) and logical operations (AND, OR, XOR) on two 64-bit operands.

The ALU has two 64-bit registers at the input, SRCA and SRCB, to which source operands are loaded. The ALU result is written to a 64-bit accumulator. The Zero Flag and Carry Flag are assigned based on the accumulator output.

See the ALU Programming section in the Render Engine Command Streamer, for a description of the ALU programming model. That model is the same for all command streamers that support ALU programming, but each command streamer uses different address offsets for the registers used. The following subsections describe the ALU registers in the Blitter command streamer.
