Bit field values in hex use the 0x prefix. The BSpec currently uses the 0x prefix for hex in some parts and the h suffix for hex in other parts. For single bits, values appear as simply 0 or 1. For multi-bit binary values, the appropriate number of binary digits appears with a b suffix.

Instruction mnemonics are lowercase. Function names invoked using the *math* instruction are UPPERCASE. For example, SQRT.

Device names in the new syntax do not use the Dev prefix or square brackets and often appear in tagged tables with a blue background. For example:

Device names in the old syntax are in plain text in square brackets. For example, .

Tables describing bit field layouts or registers proceed from most significant to least significant bits. Figures showing bit fields or registers show most significant bits on the left and least significant bits on the right.

Any bit, field, or register described as Reserved should be regarded as undefined and unpredictable. Such bits should be treated as follows:

- When testing values, do not depend on the state of reserved bits. Mask out or otherwise ignore such bits.
- Sometimes software must initialize reserved bits. For example, a compiler must write complete instruction values when creating an instruction stream, including reserved bits. In such cases, write reserved bits as zeros unless otherwise indicated.
- Do not use reserved bits as extra storage for software-defined values; put nothing in such bits.
- When saving state and restoring state, save and restore any reserved bits as well.
- Do not assume that reserved bits are invariant between explicit writes. Software should function even if reserved bits change in undefined and unpredictable ways.

Any value, encoding, or combination of values or encodings described as Reserved must not be used. The EU's behavior is undefined in this case.

When a combination of instruction parameters or an EU state is described as producing undefined results or behavior, do not assume that undefined results or behavior are confined to specific instructions, operands, registers, or channels.

Fundamental Data Types

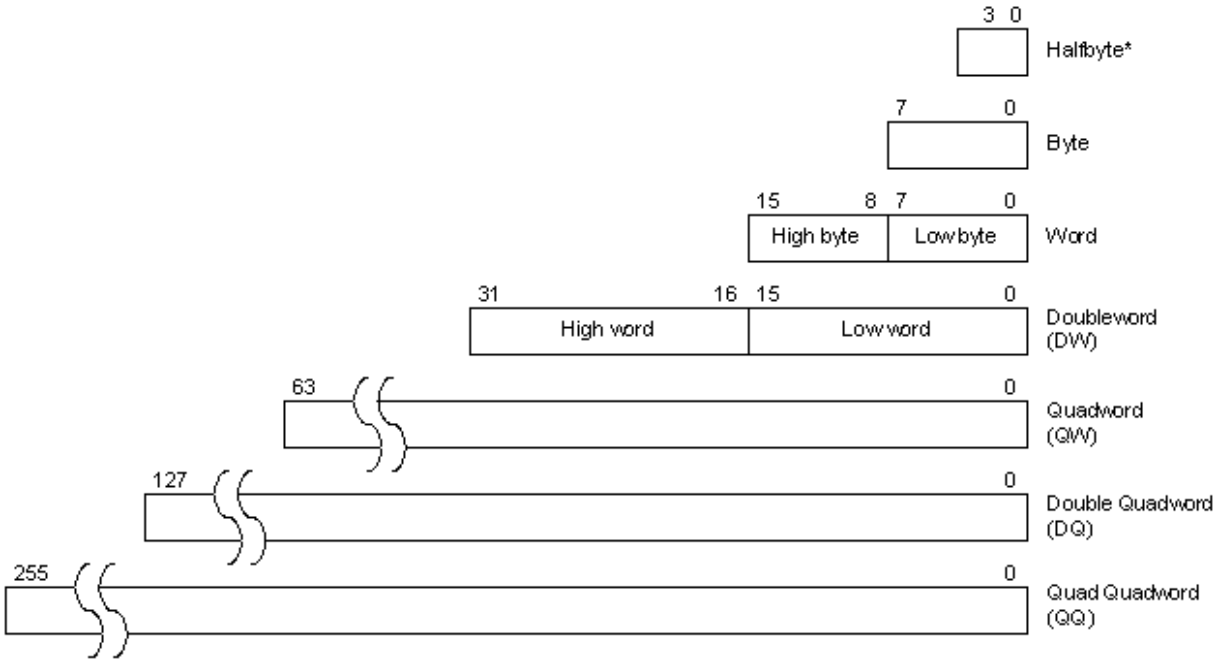
The fundamental data types in the GEN architecture are halfbyte, byte, word, doubleword (DW), quadword (QW), double quadword (DQ) and quad quadword (QQ). They are defined based on the number of bits of the data type, ranging from 4 bits to 256 bits. As shown in the figure below, a halfbyte contains 4 bits, a byte contains 8 bits, a word contains two bytes, a doubleword (DWord) contains two words, and so on. Halfbyte is a special data type that is not accessed directly as a standalone data element; it is only allowed as a subfield of the numeric data type of “packed signed halfbyte integer vector” described in the next section.

Fundamental Data Types



With the exception of halfbyte, the access of a data element to/from a GEN register or to/from memory must be aligned on the natural boundaries of the data type. The natural boundary for a word has an even-numbered address in units of bytes. The natural boundary for a doubleword has an address divisible by 4 bytes. Similarly, the natural boundary for a quadword, double quadword, and quad quadword has an address divisible by 8, 16, and 32 bytes, respectively. Double quadword, and quad quadword do not have corresponding numeric data types. Instead, they are used to describe a group (a vector) of numeric data elements of smaller size aligned to larger natural boundaries.

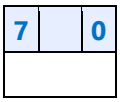
Numeric Data Types

The numeric data types defined in the GEN architecture include signed and unsigned integers and floating-point numbers (floats) of various sizes. These numeric data types are described below.

Integer Numeric Data Types

The Execution Unit supports the following integer data types. Signed integer types use two's complement representation for negative numbers.

UB: Unsigned Byte, 8-bit Unsigned Integer



B: Byte, 8-bit Signed Integer

7	6		0
S			

UW: Unsigned Word, 16-bit Unsigned Integer

15		0

W: Word, 16-bit Signed Integer

15	14		0
S			

UD: Unsigned Doubleword, 32-bit Unsigned Integer

31		0

D: Doubleword, 32-bit Signed Integer

31	30		0
S			

UQ: Unsigned Quadword, 64-bit Unsigned Integer BDW+

63		0

Q: Quadword, 64-bit Signed Integer BDW+

63	62		0
S			

UV: Packed Unsigned Half-Byte Integer Vector, 8 x 4-Bit Unsigned Integer

31	28	27	24	23	20	19	16	15	12	11	8	7	4	3	0

V: Packed Signed Half-Byte Integer Vector, 8 x 4-Bit Signed Integer

31	28	27	24	23	20	19	16	15	12	11	8	7	4	3	0
S		S		S		S		S		S		S		S	

The following table summarizes the EU integer data types.

Execution Unit Integer Data Types

Notation	Size in Bits	Name	Range
UB	8	Unsigned Byte Integer	[0, 255]
B	8	Signed Byte Integer	[-128, 127]
UW	16	Unsigned Word Integer	[0, 65535]
W	16	Signed Word Integer	[-32768, 32767]
UD	32	Unsigned Doubleword Integer	$[0, 2^{32} - 1]$
D	32	Signed Doubleword Integer	$[-2^{31}, 2^{31} - 1]$
UQ	64	Unsigned Quadword Integer	$[0, 2^{64} - 1]$
Q	64	Signed Quadword Integer	$[-2^{63}, 2^{63} - 1]$
UV	32	Packed Unsigned Half-Byte Integer Vector	[0, 15] in each of eight 4-bit immediate vector elements.
V	32	Packed Signed Half-Byte Integer Vector	[-8, 7] in each of eight 4-bit immediate vector elements.

Restriction: Only a raw move using the *mov* instruction supports a packed byte destination register region. For information about raw moves, refer to the **Description** in *mov – Move*.

Floating-Point Numeric Data Types

The Execution Unit supports the following floating-point data types.

Type or Description
The Float type uses the single precision format specified in IEEE Standard 754-1985 for Binary Floating-Point Arithmetic.
The Double Float type uses the double precision format specified in IEEE Standard 754-1985 for Binary Floating-Point Arithmetic.
In the ALT floating-point mode, representations for infinities, denorms, and NaNs within those formats are not used.

Type or Description
The EU does not support the double extended precision (80-bit) floating-point format found in the x86/x87/Intel 64 floating-point registers. All floating-point formats are signed using signed magnitude representation (a distinct sign bit, separate from the magnitude information).
The Half Float type uses the binary16 format specified in IEEE Standard 754-2008.
The F (Float) type supports both the ALT and IEEE floating-point modes, controlled by the Single Precision Floating-Point Mode bit in the Control Register.
Whether IEEE mode F calculations support denorms or flush denormalized values to zero is controlled by the Single Precision Denorm Mode bit in the Control Register.
The DF (Double Float) type only supports the IEEE floating-point mode. Whether DF calculations support denorms or flush denormalized values to zero is controlled by the Double Precision Denorm Mode bit in the Control Register.
The HF (Half Float) type only supports the IEEE floating-point mode.
Whether HF calculations support denorms or flush denormalized values to zero is controlled by the Half Precision Denorm Mode bit.

HF: Half Float, 16-bit Half-Precision Floating-Point Number BDW+

15	14		10	9		0
S	biased exp.			fraction		

F: Float, 32-bit Single-Precision Floating-Point Number

31	30		23	22		0
S	biased exponent			fraction		

DF: Double Float, 64-bit Double-Precision Floating-Point Number

63	62		52	51		0
S	biased exponent			fraction		

VF: Packed Restricted Float Vector, 4 x 8-Bit Restricted Precision Floating-Point Number

31	30		28	27		24	23	22		20	19		16	15	14		12	11		8	7	6		4	3		0
S	b. exp.			frac.			S	b. exp.			frac.			S	b. exp.			frac.			S	b. exp.			frac.		

The following table summarizes the EU floating-point data types.

Execution Unit Floating-Point Data Types

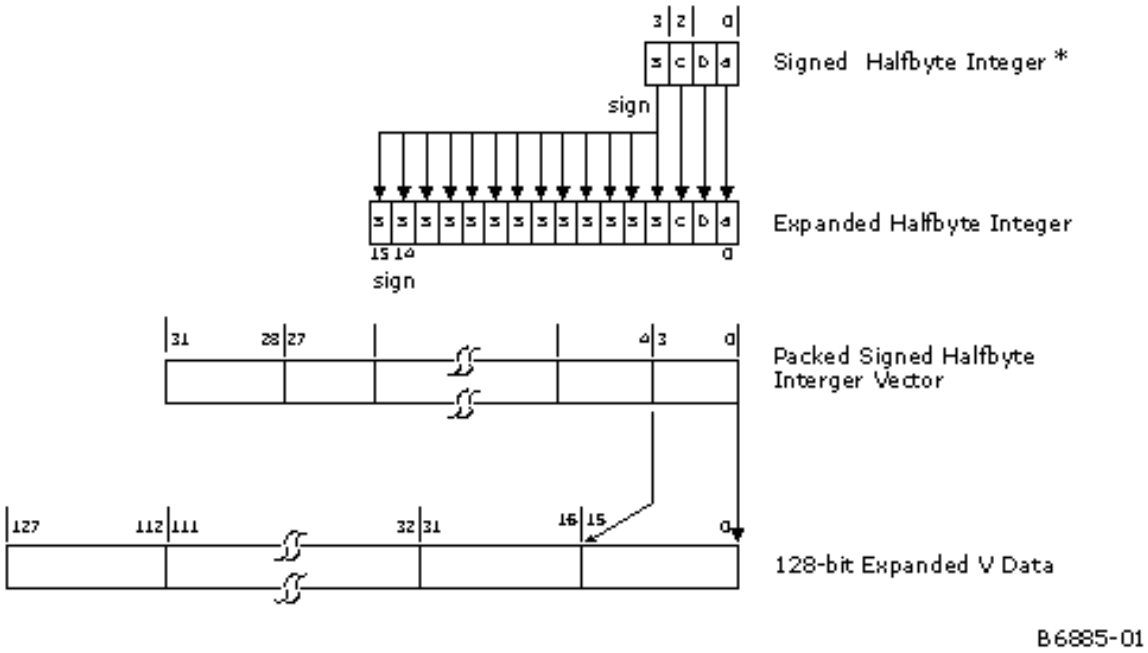
Notation	Size in Bits	Name	Range
HF	16	Half Float	Half precision, 1 sign bit, 5 bits for the biased exponent, and 10 bits for the significand: $[-(2-2^{-10})^{31}...-2^{-40}, 0.0, 2^{-40}... (2-2^{-10})^{31}]$
F	32	Float	Single precision, 1 sign bit, 8 bits for the biased exponent, and 23 bits for the significand: $[-(2-2^{-23})^{127}...-2^{-149}, 0.0, 2^{-149}... (2-2^{-23})^{127}]$
DF	64	Double Float	Double precision, 1 sign bit, 11 bits for the biased exponent, and 52 bits for the significand: $[-(2-2^{-52})^{1023}...-2^{-1074}, 0.0, 2^{-1074}... (2-2^{-52})^{1023}]$
VF	32	Packed Restricted Float Vector	Restricted precision. Each of four 8-bit immediate vector elements has 1 sign bit, 3 bits for the biased exponent (bias of 3), and 4 bits for the significand: [–31... –0.1328125, -0, 0, 0.1328125 ... 31]

Packed Signed Half-Byte Integer Vector

A packed signed halfbyte integer vector consists of 8 signed halfbyte integers contained in a doubleword. Each signed halfbyte integer element has a range from -8 to 7 with the sign on bit 3. This numeric data type is only used by an immediate source operand of doubleword in a GEN instruction. It cannot be used for the destination operand or a non-immediate source operand. GEN hardware converts the vector into an 8-element signed word vector by sign extension. This is illustrated in *Numeric Data Types*.

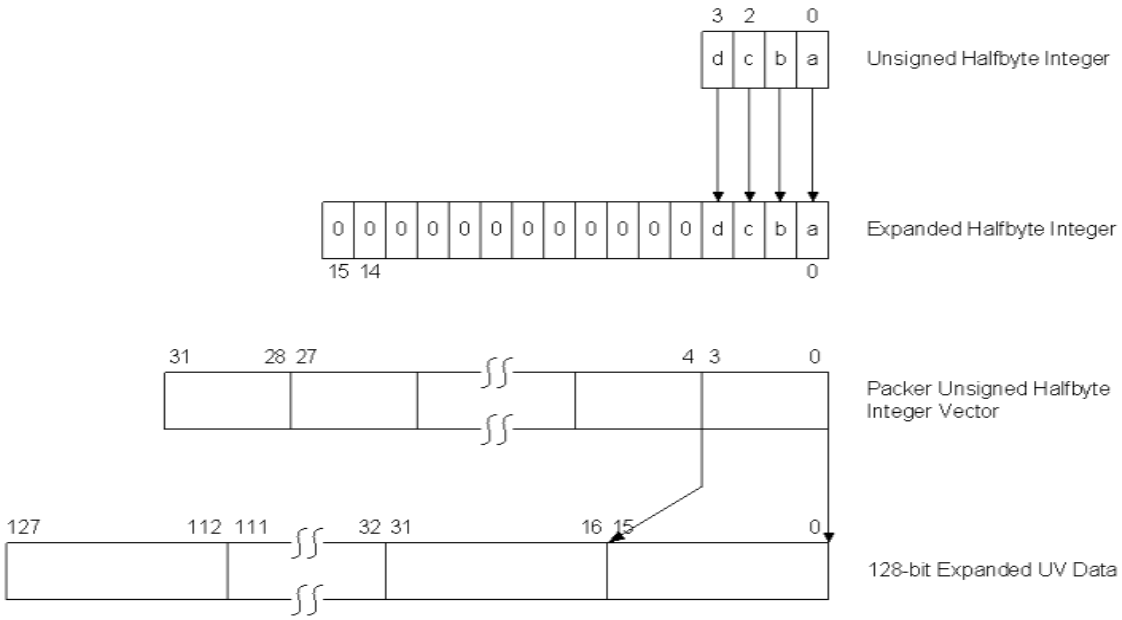
The short hand format notation for a packed signed half-byte vector is **V**.

Converting a Packed Half-Byte Vector to a 128-bit Signed Integer Vector



Packed UnSigned Half-Byte Integer Vector

A packed unsigned halfbyte integer vector consists of 8 unsigned halfbyte integers contained in a doubleword. Each unsigned halfbyte integer element has a range from 0 to 15. This numeric data type is only used by an immediate source operand of doubleword in a GEN instruction. It cannot be used for the destination operand or a non-immediate source operand. GEN hardware converts the vector into an 8-element signed word vector.

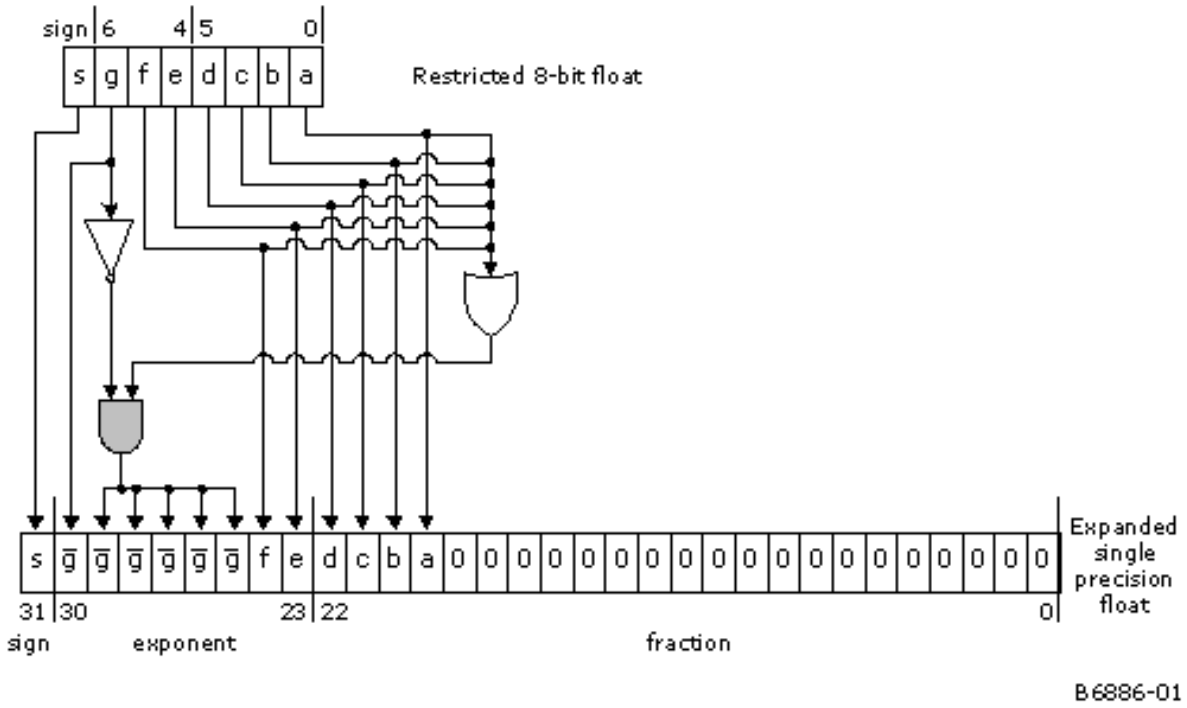


Packed Restricted Float Vector

A packed restricted float vector consists of 4 8-bit restricted floats contained in a doubleword. Each restricted float has the sign at bit 7, a 3-bit coded exponent in bits 4 to 6, a 4-bit fraction in bits 0 to 3, and an implied integer 1. The exponent is in excess-3 format – having a bias of 3. Restricted float provides zero, positive/negative normalized numbers with a small range (3-bit exponent) and small precision (4-bit fraction). This numeric data type is only used by an immediate source operand of doubleword in a GEN instruction. It cannot be used for the destination operand, or a non-immediate source operand.

The following figure shows how to convert an 8-bit restricted float into a single precision float. Converting a 3-bit exponent with a bias of 3 to an 8-bit exponent with a bias of 127 is by adding 4, or equivalently copying bit 2 to bit 7 and putting the inverted bit 2 to bits 6:2. A special logic is also needed to take care of positive/negative zeros.

Conversion from a Restricted 8-bit Float to a Single-Precision Float



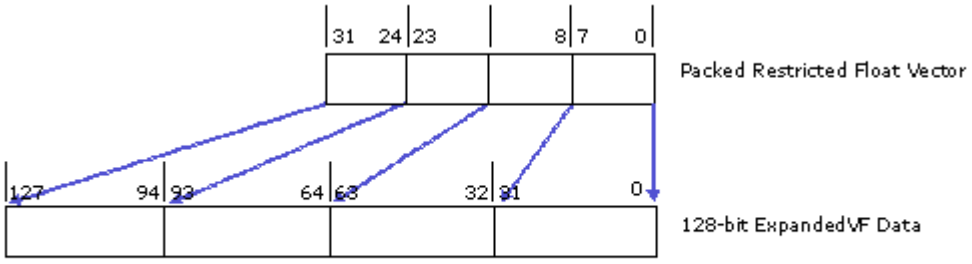
The following table shows all possible numbers of the restricted 8-bit float. Only normalized float numbers can be represented, including positive and negative zero, and positive and negative finite numbers. Normalized infinites, NaN, and denormalized float numbers cannot be represented by this type. It should be noted that this 8-bit floating point format does not follow IEEE-754 convention in describing numbers with small magnitudes. Specifically, when the exponent field is zero and the fraction field is not zero, an implied one is still present instead of taking a denormalized form (without an implied one). This results in a simple implementation but with a smaller dynamic range – the magnitude of the smallest non-zero number is 0.1328125.

Examples of Restricted 8-bit Float Numbers

Class	Hex #	Sign [7]	Exponent [6:4]	Fraction [3:0]	Extended 8-bit Exponent	Floating Number in Decimal
Positive Normalized Float	0x70-0x7F	0	111	0000 ... 1111	1000 0011	16 ... 31
	0x60-0x6F	0	110	0000 ... 1111	1000 0010	8 ... 15.5
	0x50-0x5F	0	101	0000 ... 1111	1000 0001	4 ... 7.75
	0x40-0x4F	0	100	0000 ... 1111	1000 0000	2 ... 3.875
	0x30-0x3F	0	011	0000 ... 1111	0111 1111	1 ... 1.9375
	0x20-0x2F	0	010	0000 ... 1111	0111 1110	0.5 ... 0.96875
	0x10-0x1F	0	001	0000 ... 1111	0111 1101	0.25 ... 0.484375
	0x01-0x0F	0	000	0001 ... 1111	0111 1100	0.1328125 ... 0.2421875
	0x00	0	000	0000	0000 0000	0 (+zero)
Negative Normalized Float	0xF0-0xFF	1	111	0000 ... 1111	1000 0011	-16 ... -31
	0xE0-0xEF	1	110	0000 ... 1111	1000 0010	-8 ... -15.5
	0xD0-0xDF	1	101	0000 ... 1111	1000 0001	-4 ... -7.75
	0xC0-0xCF	1	100	0000 ... 1111	1000 0000	-2 ... -3.875
	0xB0-0xBF	1	011	0000 ... 1111	0111 1111	-1 ... -1.9375
	0xA0-0xAF	1	010	0000 ... 1111	0111 1110	-0.5 ... -0.96875
	0x90-0x9F	1	001	0000 ... 1111	0111 1101	-0.25 ... -0.484375
	0x81-0x8F	1	000	0001 ... 1111	0111 1100	-0.1328125 ... -0.2421875
	0x80	1	000	0000	0000 0000	-0 (-zero)

The following figure shows the conversion of a packed exponent-only float to a 4-element vector of single precision floats.

The shorthand format notation for a packed signed half-byte vector is VF.



Floating Point Modes

GEN architecture supports two floating point operation modes, namely IEEE floating point mode (IEEE mode) and alternative floating point mode (ALT mode). Both modes follow mostly the requirements in IEEE-754 but with different deviations. The deviations will be described in details in later sections. The primary difference between these modes is on the handling of Infs, NaNs and denorms. The IEEE floating point mode may be used to support newer versions of 3D graphics API Shaders and the alternative floating point mode may be used to support early Shader versions. Taking DirectX 3D graphics API Shaders for example, shader models before version 3.0 may use the alternative floating point mode, while version 3.0 and following shader models may use the IEEE floating point mode.

These two modes are supported by all units that perform floating point computations, including GEN execution units, GEN shared functions like Extended Math, the Sampler and the Render Cache color calculator, and fixed functions like VF, Clipper, SF and WIZ. Host software sets floating point mode through the fixed function state descriptors for 3D pipeline and the interface descriptor for media pipeline. Therefore different modes may be associated with different threads running concurrently. Floating point mode control for EU and shared functions are based on the floating point mode field (bit 0) of *cr0* register.

IEEE Floating Point Mode

Partial Listing of Honored IEEE-754 Rules

Here is a summary of expected 32-bit floating point behaviors in GEN architecture. Refer to IEEE-754 for topics not mentioned.

- INF – INF = NaN
- 0 * (+/–)INF = NaN
- 1 / (+INF) = +0 and 1 / (–INF) = –0
    - (+/–)INF / (+/–)INF = NaN as A/B = A * (1/B)
- INV (+0) = RSQ (+0) = +INF, INV (–0) = RSQ (–0) = –INF, and SQRT (–0) = –0
- RSQ (–finite) = SQRT (–finite) = NaN
- LOG (+0) = LOG (–0) = –INF, LOG (–finite) = LOG (–INF) = NaN

- NaN (any OP) any-value = NaN with one exception for min/max mentioned below. Resulting NaN may have different bit pattern than the source NaN.
- Normal comparison with conditional modifier of EQ, GT, GE, LT, LE, when either or both operands is NaN, returns FALSE. Normal comparison of NE, when either or both operands is NaN, returns TRUE.
    - **Note:** Normal comparison is either a **cmp** instruction or an instruction with conditional modifier
- Special comparison **cmpn** with conditional modifier of EQ, GT, GE, LT, LE, when the second source operand is NaN, returns TRUE, regardless of the first source operand, and when the second source operand is not NaN, but first one is, returns FALSE. **Cmpn** of NE, when the second source operand is NaN, returns FALSE, regardless of the first source operand, and when the second source operand is not NaN, but first one is, returns TRUE.
    - This is used to support the proposed IEEE-754R rule on **min** or **max** operations. For which, if only one operand is NaN, min and max operations return the other operand as the result.
- Both normal and special comparisons of any non-NaN value against +/– INF return exact result according to the conditional modifier. This is because that infinities are exact representation in the sense that +INF = +INF and –INF = –INF.
    - NaN is unordered in the sense that NaN != NaN.
- IEEE-754 requires floating point operations to produce a result that is the nearest representable value to an infinitely precise result, known as "round to nearest even" (RTNE). 32-bit floating point operations must produce a result that is within 0.5 Unit-Last-Place (0.5 ULP) of the infinitely precise result. This applies to addition, subtraction, and multiplication.
- All arithmetic floating point instructions does Round To Nearest Even at the end of the computation, except the round instructions.

Complete Listing of Deviations or Additional Requirements vs IEEE-754

For a result that cannot be represented precisely by the floating point format, the EU uses rounding to nearest or even to produce a result that is within 0.5 Unit-Last-Place(0.5 ULP) of the infinitely precise result.

Description
The rounding mode is specified by the Rounding Mode field in the Control Register.
Source modifiers are not applied to NAN.
Handle denorms as follows: • When inputs are denorms in mixed mode (one of the source operand is half float and other is single precision float OR source is half float and destination is single precision float), on upconversion, they are non-denorms. So computes in 32b can handle this. • When outputs are denorms, the denorms are retained if there is a format conversion. • Mixed mode operations should always behave like sum of individual operations.

Other information regarding floating-point behaviors:

- NaN input to an operation always produces NaN on output, however the exact bit pattern of the NaN is not required to stay the same (unless the operation is a raw "mov" instruction which does not alter data at all.)
- x*1.0f must always result in x (except denorm flushed and possible bit pattern change for NaN).
- x +/- 0.0f must always result in x (except denorm flushed and possible bit pattern change for NaN). But -0 + 0 = +0.
- Fused operations (such as *mac*, *dp4*, *dp3*, etc.) may produce intermediate results out of 32-bit float range, but whose final results would be within 32-bit float range if intermediate results were kept at greater precision. In this case, implementations are permitted to produce either the correct result, or else ±inf. Thus, compatibility between a fused operation, such as *mac*, with the unfused equivalent, *mul* followed by *add* in this case, is not guaranteed.
- As the accumulator registers have more precision than 32-bit float, any instruction with accumulator as a source/destination operand may produce a different result than that using more general registers, as indicated in this table:

Description
Such an instruction may produce a different result than that using GRF registers.

- API Shader divide operations are implemented as x*(1.0f/y). With the two-step method, x*(1.0f/y), the multiply and the divide each independently operate at the 32-bit floating point precision level (accuracy to 1 ULP).
- See the Type Conversion section for rules on converting to and from float representations.

Min Max of Floating Point Numbers

A special comparison called Compare-NaN is introduced in the GEN architecture to handle the difference of above mentioned floating-point comparison and the rules on supporting MIN/MAX. To compute the MIN or MAX of two floating-point numbers, if one of the numbers is NaN and the other is not, MIN or MAX of the two numbers returns the one that is not NaN. When two numbers are NaN, MIN or MAX of the two numbers returns source1.

When both the sources are NaN inputs, the special case in the section 2.4.8 Floating point Min/Max Operations describe the results.
When one source is SNAN, DX, and IEEE treat the outputs differently. The special case section 2.4.8 Floating point Min/Max operations described the results.

Min and Max is supported by conditional select.

Note even though f0.0 is specified in the instruction, the flag register is not touched by this instruction.

The following tables detail the rules for this special compare-NaN operation for floating-point numbers. Notice that excepting "Not-Equal-To" comparison-NaN, last columns in all other tables have 'T'.

Results of "Less-Than" Comparison-NaN – CMPN.L

src0 src1	-inf	-Fin	-denorm	-0	+0	+denorm	+Fin	+inf	NaN
-inf	F	T	T	T	T	T	T	T	T
-Fin	F	T/F	T	T	T	T	T	T	T
-denorm	F	F	F	F	F	F	T	T	T
-0	F	F	F	F	T	F	T	T	T
+0	F	F	F	F	F	F	T	T	T
+denorm	F	F	F	F	F	F	T	T	T
+Fin	F	F	F	F	F	F	T/F	T	T
+inf	F	F	F	F	F	F	F	F	T
NaN	F	F	F	F	F	F	F	F	F

Results of "Greater-Than or Equal-To" Comparison-NaN – CMPN.GE

src0 src1	-inf	-Fin	-denorm	-0	+0	+denorm	+Fin	+inf	NaN
-inf	T	F	F	F	F	F	F	F	T

+inf	T	T	T	T	T	T	T	T	T
NaN	F	F	F	F	F	F	F	F	F

Alternative Floating Point Mode

The key characteristics of the alternative floating point mode is that NaN, Inf, and denorm are not expected for an application to pass into the graphics pipeline, and the graphics hardware must not generate NaN, Inf, or denorm as computation result. For example, a result that is larger than the maximum representable floating point number is expected to be flushed to the largest representable floating point number, i.e., +fmax. The fmax has an exponent of 0xFE and a mantissa of all one's, which is the same for IEEE floating point mode.

Note that this mode is applicable ONLY to Single Precision Float datatype.

Description
This also implies that ALT mode is not supported when Single precision datatype is involved in format conversion to double precision or half precision.

Description
ALT_MODE is supported for Single Precision float ONLY. Hence, ALT_MODE is NOT supported in mixed mode operation.

Here is the complete list of the differences of legacy graphics mode from the relaxed IEEE-754 floating point mode.

- Any +/- INF result must be flushed to +/- fmax, instead of being output as +/- INF.
- Extended mathematics functions of log(), rsq(), and sqrt() take the absolute value of the sources before computation to avoid generating INF and NaN results.

Alternative Floating Point Mode shows the support of these differences in various hardware units.

Supported Legacy Float Mode and Impacted Units

IEEE-754 Deviations	VF	Clipper	SF	WIZ	EU	EM	Sampler	RC
Any +/- INF result flushed to +/- fmax	Y	Y	Y	Y	Y	Y	Y	Y
Log, rsq, sqrt take abs() of sources	N/A	N/A	N/A	N/A	N/A	Y	N/A	N/A

Alternative Floating Point Mode shows some of the desired or recommended alternative floating point mode behaviors that do not have hardware design impact. The reasons of not needing special hardware support for these items are also provided. This is based on the compliance requirement that can be found in the DirectX 9 specification: "**Handling of NaNs, Infs, and denorms is undefined. Applications should not pass in such values into the graphics pipeline.**"

Dismissed Legacy Behaviors

Suggested IEEE-754 Deviations	Reason for Dismiss
Mov forces (+/-)INF to (+/-)fmax	(+/-)INF is never present as input
(+/-)INF – (+/-)INF = +/- fmax instead of NaN	(+/-)INF is never present as input
Denorm must be flushed to zero in all cases (including trivial mov and point sampling)	Denorm is never present as input
Anything*0=0 (including NaN*0=0 and INF*0=0)	NaN and INF are never present as input
Except propagated NaN, NaN is never generated	NaN is never present as input and GEN never generates NaN based on rules in the previous table
An input NaN gets propagated excepting (a)-(d)	NaN is never present as input
(a) Rcp (and rsq) of 0 yields fmax	N/A, as it is already covered by the general rule "Any +/- INF result flushed to +/- fmax"
(b) Sampler honors 0/0 = 0 as if (1/0)*0	There is no divide in Sampler
I Rcp (and rsq) of INF yields +/- 0	(+/-)INF is never present as input
(d) Sampler honors INF/INF = 0 as if (1/INF)=0 followed by Anything*0 = 0	There is no divide in Sampler

Floating-Point Support

The following sections describe BDW+ floating-point support relative to the IEEE Standard for Floating-Point Arithmetic, currently IEEE Standard 754-2008. These sections cover binary floating-point arithmetic, as the EU provides no support for decimal floating-point arithmetic.

Note: Hardware alone is usually not fully conformant to the IEEE standard. It requires software functions to supplement the hardware.

Compared to previous generations, BDW+ does the following:

- Adds the HF (Half Float) type and a corresponding HF execution data type and execution path.
- Adds flags to indicate IEEE floating-point exceptions and to enable or disable exception reporting to those flags.
- Adds the Single Precision Denorm Mode bit in Control Register 0. It can be enabled to allow calculations using the F (Float) type in IEEE floating-point mode to support denormals and gradual underflow.

Floating-Point Types and Values

The EU supports 16-bit (HF, Half Float), 32-bit (F, Float), and 64-bit (DF, Double Float) types in the IEEE Standard formats (respectively *binary16*, *binary32*, and *binary64* in IEEE 754-2008). See Floating-Point Numeric Data Types for the layout of the supported floating-point types.

Any bit pattern for a floating-point value corresponds to a value defined by the standard: ± finite (normalized nonzero finite number), ± 0 (signed zero), ± inf (signed infinity), ± denorm (denormalized, very small but nonzero number), or NaN (Not a Number). A NaN can be a signaling NaN (sNaN) or quiet NaN (qNaN).

These operating modes are available for the different floating-point types:

- Half Float uses the IEEE floating-point mode.

Description
Half Float support for denormals and gradual underflow is controlled by the Half Precision Denorm Mode bit.

- Float can use the ALT (Alternative Floating-Point Mode) or the IEEE floating-point mode. In IEEE mode, support for denormals and gradual underflow is controlled by the Single Precision Denorm Mode bit in the Control Register.
- Double Float uses the IEEE floating-point mode. Support for denormals and gradual underflow is controlled by the Double Precision Denorm Mode bit in the Control Register.

Flush to zero is not defined by IEEE Standard 754, but is implementation-specific and required by some APIs (including DirectX), thus the EU ISA for BDW supports either using or flushing Float or Double Float denorms based on the respective Denorm Mode bits.

Specifications in this volume sometimes reference ±fmax, the largest finite magnitude representable in a format, and ±fmin, the smallest normalized nonzero magnitude representable in a format. Calculating

those values uses the extreme exponent values for finite nonzero floating-point values, Emax and Emin below, along with the number of explicit fraction bits (not counting the implicit bit in the significand). The following table provides these values, with the fmax and fmin values generally approximate.

Floating-Point Type Parameters

Type	Exp. Bits	Exp. Bias	Emax	Emin	Explicit Fraction Bits	fmax	fmin
HF	5	15	15	-14	10	65504.0	about 6.1E-5
F	8	127	127	-126	23	about 3.4E38	about 1.18E-38
DF	11	1023	1023	-1022	52	about 1.79E308	about 2.23E-308

Where f is the number of explicit fraction bits, the general formula for fmax is $(2.0 - 2^{-f}) * 2^{Emax}$.

The general formula for fmin is 2^{Emin}.

Not a Number (NaN) Formats

A NaN has a biased exponent field with all bits set (as if encoding an exponent of Emax + 1), a nonzero fraction field (as a zero fraction field with that exponent indicates infinity), and either sign bit.

As specified in IEEE Standard 754-2008, the MSB of the fraction field, what would be the first bit following the binary point in a numeric value, determines a NaN's type:

0 - Signaling NaN (sNaN). The remaining fraction bits cannot all be zero.

1 - Quiet NaN (qNaN). The remaining fraction bits can have any value.

When an sNaN is an input, an operation normally signals the Invalid Operation exception and *quietizes* the NaN, producing the equivalent qNaN value, with MSB set to 1, at the output. Raw moves do not check for NaNs and do not signal exceptions or quietize NaN values.

When QNAN as one of the input to an operation this results in QNAN without raising the exception flag. This silently propagates and the output is the same QNAN as in the input.

Intel specifies the value *qNaN Indefinite* as a quiet NaN with all zeros in the remaining fraction bits, those other than the MSB. This value is useful because it is never produced by quietizing an sNaN, thus qNaN Indefinite may be used to initialize floating-point values that are not otherwise initialized by software, allowing the uninitialized case to be distinguished.

The EU applies numeric source modifiers (**-**, **(abs)**, or **-(abs)**) to NaN source values as well as to other values, possibly changing the sign bit of a NaN value when it is propagated. NaN sign bits are normally don't care values.

Per IEEE Standard 754-2008, a NaN's *payload* is contained in all fraction field bits other than the fraction MSB. Thus in the overall floating-point format, the sign bit, biased exponent, and fraction MSB are not part of the payload. NaN payload values are not affected by quietizing or by source modifiers. As noted above, an sNaN must have a nonzero payload and a qNaN can have any payload.

Floating-Point Rounding Modes

The EU supports the four rounding modes required in IEEE Standard 754 for binary floating-point arithmetic. If the unrounded result of infinite precision and range is exactly representable in the destination format, then that exact result is produced and no exception is signaled. For an unrounded result of infinite precision and range that is not exactly representable in the destination format (an *inexact* result), rounding chooses a numerically adjacent value in the destination format, while signaling the Inexact, Overflow, or Underflow exceptions when appropriate. The four rounding modes are:

RNE - Round to nearest or even. Choose the value in the destination precision nearest to the unrounded result. If the unrounded result is midway between two such values, choose the value with its least significant fraction bit as 0 (*even*).

RD - Round down, toward minus infinity.

RU - Round up, toward plus infinity.

RZ - Round toward zero.

The rounding mode is specified by the Rounding Mode field in the Control Register. It is initialized by Thread Dispatch. The normal default value is round to nearest or even. The Rounding Mode can be read to check the mode and written to change it. The Control Register and the Rounding Mode value are thread-specific; the Rounding Mode applies to all floating-point types, all execution channels, and all floating-point instructions executed by the thread after it is assigned.

Rounding an inexact result signals the Inexact Exception.

Rounding an inexact result preserves the sign of the result.

Infinities and NaNs are exact results and are not affected by the rounding mode.

Zeros are exact results, but the signs of zero results are affected by the rounding mode in certain cases:

X - X = +0 for RNE, RU, RZ

X - X = -0 for RD

(+0) + (-0) = (-0) + (+0) = +0 for RNE, RU, RZ

(+0) + (-0) = (-0) + (+0) = -0 for RD

Regardless of the rounding mode, (+0) + (+0) = +0 and (-0) + (-0) = -0.

The *directed rounding modes* are round down, round up, and round toward zero.

In IEEE mode, when a floating-point overflow occurs the result is determined by the sign of the result and the rounding mode:

+ and (RNE or RU): + inf

+ and (RD or RZ): + fmax

- and (RU or RZ): - fmax

- and (RNE or RD): - inf

Note that for floating-point overflow in IEEE mode, RNE always produces ± inf and RZ always produces ± fmax.

Floating-Point Operations and Precision

IEEE Standard 754-2008 requires the following floating-point operations to be precise within <= 0.5 *ulp* (unit in the last place) when using the round to nearest or even rounding mode:

ADD (*add* instruction)

DIV (*math* instruction with FDIV function code)

FMA (fused multiply add, *mad* instruction)

MUL (*mul* instruction)

SQRT (*math* instruction with SQRT function code)

SUB (*add* instruction using one **-** source modifier)

Conversions (float to float, float to int, and int to float)

Min/Max

Compare

Single Precision Floating-Point Rounding to Integral Values

The *rndd* (Round Down), *rnde* (Round to Nearest or Even), *rndu* (Round Up), and the *rndz* (Round to Zero) instructions round arbitary Float values to integral Float values. Each instruction specifies its rounding mode so these instructions are not affected by the Rounding Mode in the Control Register.

An integral source value produces the same value for the destination (ignoring any saturation). For magnitudes >= 8,388,608 (2^{23}) all Float values are integral.

The rounding instructions are sign preserving.

Signed zeros are propagated. In IEEE mode, signed infinities are propagated. In IEEE mode, sNaN inputs are quietized, the equivalent qNaN is produced, and the Invalid Operation exception is indicated. In IEEE mode, qNaN inputs are propagated.

No other exceptions are signaled for these instructions. For example if the source and result values differ, the Inexact exception is not signaled.

The Single Precision Denorm Mode in the Control Register affects the results of the *rndd* and *rndu* instructions for denorm source values.

Floating-Point to Integer Conversion

The *mov* and *sel* instructions can be used to convert floating-point values to integers. In the tables below, Imin is the smallest representable value in a signed integer type, Imax is the largest representable value

in an integer type, and f is a finite floating-point value after rounding to an integral value using the current rounding mode.

Converting unrepresentable floating-point values, including infinities, NaNs, and values that convert to integers outside of the destination type's range, signal Invalid Operation exceptions. When the destination integer type is unsigned, normalized nonzero negative inputs signal Invalid Operation exceptions and negative denorm inputs signal Inexact exceptions.

Data written in accumulator using implicit or explicit destination will not be IEEE compliant.

Floating-Point to Integer Conversion Results and Exceptions for Signed Integer Types

FP Value	Integer Result	FP Exception
qNaN	0	Invalid Operation
sNaN	0	Invalid Operation
+inf	Imax	Invalid Operation
f > Imax	Imax	Invalid Operation
Imin <= f <= Imax	f	Inexact if rounding changed f
f < Imin	Imin	Invalid Operation
-inf	Imin	Invalid Operation

Floating-Point to Integer Conversion Results and Exceptions for Unsigned Integer Types

FP Value	Integer Result	FP Exception
qNaN	0	Invalid Operation
sNaN	0	Invalid Operation
+inf	Imax	Invalid Operation
f > Imax	Imax	Invalid Operation
0 <= f <= Imax	f	Inexact if rounding changed f
f = -0	0	Inexact
-1 < f < -0	0	Inexact
-1 < f < -0	Real Indefinite	Invalid Operation
-fmax <= f <= -1	Real Indefinite	Invalid Operation
-inf	Real Indefinite	Invalid Operation

Note: Real Indefinite is encoded as Integer value 0.

Integer to Floating-Point Conversion

Integer to floating-point conversion follows these rules in IEEE mode:

- The result is never ± inf, never NaN, and never -0.

- If the integer source value is not exactly representable in the destination floating-point format, use the current rounding mode to choose an adjacent floating-point value and signal the Inexact Exception.
- If the integer source value is too large to represent in the destination floating-point format (only possible when converting to Half Float from D, UD, or UW) then signal the Overflow Exception. Based on the sign and the current rounding mode, the result is ± fmax or ± inf, as described in the Overflow Exception section.

Floating-Point Min/Max Operations

In the following Min/Max operations, sNaN inputs are preferred to non-NaN inputs and non-NaN inputs are preferred to qNaN inputs.

Min(x, qNaN) = Min(qNaN, x) = x with no exceptions signaled.

Min(x, sNaN) = Min(sNaN, x) = qNaN (quietized value corresponding to the input sNaN) and signal the Invalid Operation exception.

Note: DX deviates from this rule:

The DX behavior is inferred from the denorm bit.

Min(x, sNaN) = Min(sNaN, x) = x

Max(x, qNaN) = Max(qNaN, x) = x with no exceptions signaled.

Max(x, sNaN) = Max(sNaN, x) = qNaN (quietized value corresponding to the input sNaN) and signal the Invalid Operation exception.

Note: DX deviates from this rule:

The DX behavior is inferred from the denorm bit.

Max(x, sNaN) = Max(sNaN, x) = x

Special cases(when both sources are NaN inputs)

Min(qNaN, qNan) = qNaN (of the first source) and no exception raised

Min(qNaN, sNaN) = Min(sNaN, qNaN) = qNaN (quiet-ized sNaN and signal the Invalid Operation exception)

Min(sNaN, sNaN) = qNaN(of the first source and signal Invalid Operation Exception)

Max(qNaN, qNan) = qNaN (of the first source) and no exception raised

Max(qNaN, sNaN) = Max(sNaN, qNaN) = qNaN (quiet-ized sNaN and signal the Invalid Operation exception)

Max(sNaN, sNaN) = qNaN(of the first source and signal Invalid Operation Exception)

IEEE Floating-Point Exceptions

The EU detects the five floating-point exceptions defined by IEEE Standard 754:

Invalid Operation

Division by Zero

Overflow

Underflow

Inexact

Signaling Floating-Point Exceptions

When enabled in the Control Register, floating-point exceptions are detected and set *sticky* flag bits in the State Register. There is no mechanism for automatic transfer to a handler, so floating-point exceptions are not handled like other exceptions described in the Exceptions chapter.

Setting flags to indicating Floating-Point exceptions is the default exception handling approach specified by IEEE Standard 754. The flag bits are sticky because in normal operation the EU only sets these bits as exceptions occur, and does not clear these bits, so a set value sticks until cleared by software. The Control Register and State Register are cleared at reset and initialized at thread load. Both are read/write registers. These fields are used:

- **IEEE Exception Trap Enable** (Control Register cr0.0:ud bit 9). This bit enables trapping IEEE exception flags. This control bit may be updated by software. It is initially zero on thread load. If enabled, IEEE floating-point exceptions set sticky bits in the IEEE Exception field of sr0.1, in the State Register. **Note:** Software must set this flag at thread start to use the IEEE Exception flags.
- **IEEE Exception**. (State Register sr0.1:ud bits 7:0). The IEEE exception bits are sticky bits set by the opcodes when floating-point exceptions are triggered. These bits are defined per thread and all channels update one set of sticky bits. These bits are cleared on thread load and may be cleared by software. Exception updates to these bits may be disabled by clearing the IEEE Exception Trap Enable bit in the Control Register. The following table specifies the IEEE exception bits:

Bits	Definition
7:5	Reserved
4	Inexact Exception
3	Overflow Exception
2	Underflow Exception
1	Division by Zero Exception
0	Invalid Operation Exception

The IEEE exception flags are per thread, shared by all channels. (Maintaining separate per channel exception flags for 32 channels would require 160 bits per thread.)

Invalid Operation Exception

An Invalid Operation exception is signaled by any operation on a signaling NaN (sNaN) or by certain combinations of operations and operands with undefined results, always producing a quiet NaN (qNaN) result.

The following specific operations signal Invalid Operation, where *x* is a positive, finite, nonzero, and normalized number:

+inf - (+inf) or (-inf) - (-inf)

± 0 / ± 0

± inf / ± inf

± 0 × ± inf or ± inf × ± 0

Remainder(± *x*, ± 0)

Remainder(± inf, ± *x*)

Sqrt(-*x*)

Note that Sqrt(-0) is -0 per IEEE Standard 754 and does not cause any exception.

These instructions can signal specific Invalid Operation exceptions (and also on sNaN inputs except for Float inputs in ALT mode), producing a qNaN result:

add

dp2, *dp3*, *dp4*, and *dph* (the Dot Product instructions)

line

lrp

mac

mad

madm

math with the FDIV, SQRT, or RSQRTM function codes

mul

pln

These other instructions signal Invalid Operation exceptions on sNaN inputs (except for Float inputs in ALT mode), producing a qNaN result:

cmp, *cmpn*

frc

math with all other function codes for floating-point operations

mov except for raw moves

rndd, *rnde*, *rndu*, and *rndz* (the Round instructions)

sel

smov except for raw moves

Division by Zero Exception

The operation ± *x* / ± 0, where *x* is a positive, finite, nonzero, and normalized number, signals the Division by Zero Exception and produces a correctly signed ± inf result. Note that in accordance with the standard, ± 0 / ± 0 signals Invalid Operation, does not signal Division by Zero, and produces a qNaN result. This behavior can occur for the *math* instruction with the FDIV function code.

The operation $LOG_2(\pm 0)$ signals the Division by Zero Exception and produces -inf as the result. This behavior can occur for the *math* instruction with the LOG function code.

Overflow Exception

A floating-point *overflow* occurs when an operation with a finite result produces an internal result with magnitude > fmax, the maximum representable finite value in the destination format. The internal result is rounded to the destination precision with the current rounding mode but has an unbounded exponent. An overflow produces ± inf or ± fmax as the result, depending on the sign and the rounding mode.

The following algorithm describes floating-point overflow processing:

1. Compute the result with infinite precision and unbounded range.
2. Normalize the result using an unbounded exponent.
3. Round the result to the destination precision using an unbounded exponent and the current rounding mode.
4. If (abs(rounded unbounded result) > fmax(destination format)) {

   Set the Overflow Exception flag to 1.

   Output = ± inf or ± fmax depending on the sign and the rounding mode:

   + and (RNE or RU): + inf

   + and (RD or RZ): + fmax

   - and (RU or RZ): - fmax

   - and (RNE or RD): - inf

   }

   }

Note: The first three steps of the overflow and underflow algorithms are identical.

Underflow Exception

An *underflow* occurs when an operation produces a tiny but nonzero inexact result *x*, with abs(*x*) < fmin, where fmin = 2^{Emin}. See the Floating-Point Type Parameters table for the fmin and Emin values for different floating-point types.

IEEE Standard 754 allows underflow to be determined before or after rounding. The Execution Unit determines underflow after rounding, which is consistent with the behavior of the x87 and SSE instructions in the CPU.

When denorms are flushed to zero, no underflow exceptions are signaled. Flush to zero is not defined by IEEE Standard 754, but is implementation specific and required by some APIs (including DirectX), thus the EU ISA for BDW supports either using or flushing Float or Double Float denorms based on the respective Denorm Mode bits.

When denorms are enabled, if an operation's internal result rounded to the destination precision, but using an unbounded exponent range, has a magnitude that is less than fmin but nonzero AND the denorm result in the destination format is inexact, then signal the Underflow Exception.

The rounded result can be ± 0, ± fmin, or (when denorms are enabled) ± denorm.

IEEE Standard 754 requires the non-intuitive behavior that an exact denorm result does not set the Underflow Exception flag.

The following algorithm describes floating-point underflow processing:

1. Compute the result with infinite precision and unbounded range.
2. Normalize the result using an unbounded exponent.
3. Round the result to the destination precision using an unbounded exponent and the current rounding mode.
4. If (0 < abs(rounded unbounded result) < fmin(destination format) {

   if (flush denorms to zero) {

   Output = 0; // No underflow exception.

   }

   Else {

   Renormalize to the bounded exponent with the original infinite precision value...

   ...and round that value to the destination precision using the current rounding mode.

   If (the just computed value differs from the value computed in step (3) in exponent or mantissa) {

   Set the Underflow Exception flag to 1.

   } // Note: Underflow is not set if the tiny result is the same as when computed with an unbounded exponent.

   Output = rounded result using the destination precision and destination exponent range;

}

}

Else { // Not a tiny number.

Output = rounded number;

}

Inexact Exception

An Inexact Exception occurs when the internal unrounded result, with infinite precision and unbounded exponent range, differs from the generated result after format conversion, normalizing or denormalizing, and rounding. An Inexact Exception occurs irrespective of any saturation to exact zero or exact +1.0. The Inexact Exception is normal and may occur more often than not. For example, the calculation 1.0 / 3.0 is inexact in any binary floating-point format. These rules determine whether a result is inexact:

- Infinities and NaNs are never inexact.
- Flushing a denorm internal result to zero (always for Half Float and if the appropriate Denorm Mode is 0 for Float and Double Float) is always inexact.
- If any rounding occurs using the current Rounding Mode, so the rounded result differs from the internal unrounded result, the result is inexact. However explicit round to integral using any of the rounding instructions (*rndd*, *rnde*, *rndu*, and *rndz*) is never inexact.

Floating-Point Compare Operations

Four mutually exclusive relations are possible between two floating-point values, src0 and src1:

Less than. src0 < src1 and neither source is NaN.

Equal. src0 = src1 and neither source is NaN.

Greater than. src0 > src1 and neither source is NaN.

Unordered. Any source is NaN.

Any NaN compares unordered to any value, including itself.

Infinities of the same sign compare as equal.

Zeros compare as equal regardless of sign: -0 = +0.

Floating-Point Compare Relations

src1 / src0	-inf	-fin	-denorm	-0	+0	+denorm	+fin	+inf	NaN

Type Conversion

This topic is currently under development.

Float to Integer

Converting from float to integer is based on rounding toward zero(RTZ is for DX, IEEE expects all four rounding modes). If the floating point value is +0, -0, +Denorm, -Denorm, +NaN –r -NaN, the resulting integer value is always 0. If the floating point value is positive infinity (or negative infinity), the conversion result takes the largest (or the smallest) represent-able integer value. If the floating point value is larger (or smaller) than the largest (or the smallest) represent-able integer value, the conversion result takes the largest (or the smallest) represent-able integer value. The following table shows these special cases. The last two rows are just examples. They can be any number outside the represent-able range of the output integer type (UD, D, UW, W, UB and B).

Input Format	Output Format					
F	UD	D	UW	W	UB	B
+/- Zero	00000000	00000000	00000000	00000000	00000000	00000000
+/- Denorm	00000000	00000000	00000000	00000000	00000000	00000000
NAN	00000000	00000000	00000000	00000000	00000000	00000000
-NAN	00000000	00000000	00000000	00000000	00000000	00000000
INF	FFFFFFFF	7FFFFFFF	0000FFFF	00007FFF	000000FF	0000007F
-INF	00000000	80000000	00000000	00008000	00000000	00000080
$+2^{32}$ (*)	FFFFFFFF	7FFFFFFF	0000FFFF	00007FFF	000000FF	0000007F
$-2^{32}-1$ (*)	00000000	80000000	00000000	00008000	00000000	00000080

Integer to Integer with Same or Higher Precision

Converting an unsigned integer to a signed or an unsigned integer with higher precision is based on zero extension.

Converting an unsigned integer to a signed integer with the same precision is based on modular wrap-around. Without saturation, a larger than represent-able number becomes a negative number. With saturation, a larger than represent-able number is saturated to the largest positive represent-able number.

Converting a signed integer to a signed integer with higher precision is based on sign extension.

Converting a signed integer to an unsigned integer with higher precision is based on sign extension. Without saturation, a negative number becomes a large positive number with the sign bit wrapped-up. With saturation, a negative number is saturated to zero.

Integer to Integer with Lower Precision

Converting a signed or an unsigned integer to a signed or an unsigned integer with lower precision is based on bit truncation. Without saturation, only the lower bits are kept in the output regardless of the sign-ness of input and output. With saturation, a number that is outside the represent-able range is saturated to the closest represent-able value.

Integer to Float

Converting a signed or an unsigned integer to a single precision float number is to round to the closest representable float number. For any integer number with magnitude less than or equal to 24 bits, resulting float number is a precise representation of the input. However, if it is more than 24 bits, by default a “round to nearest even” is performed.

Double Precision Float to Single Precision Float

.

Double Precision Float	Single Precision Float
-inf	-inf
-finite	-finite/-denorm/-0
-denorm	-0
-0	-0
+0	+0
+denorm	+0
+finite	+finite/+denorm/+0
+inf	+inf
NaN	NaN

The upper Dword of every Qword will be written with undefined value when converting DF to F.

Single Precision Float to Double Precision Float

Converting a single precision floating-point number to a double precision floating-point number will produce a precise representation of the input.

Single Precision Float	Double Precision Float

Single Precision Float	Double Precision Float
-inf	-inf
-finite	-finite
-denorm	-finite
-0	-0
+0	+0
+denorm	+finite
+finite	+finite
+inf	+inf
NaN	NaN

Exceptions

The GEN Architecture defines a basic exception handling mechanism for several exception cases. This mechanism supports both normal operations such as extensions of the mask-stack depth, as well as detecting some illegal conditions.

Exception Types

Type	Trigger / Source	Sync/Async Recognition
Software Exception	Thread code	Synchronous
Breakpoint	• A bit in the instruction word • Breakpoint IP match • Breakpoint Opcode match	Synchronous
Illegal Opcode	Hardware	Synchronous
Halt	MMIO register write	Asynchronous
Context Save/Restore	Preemption Interrupt	Asynchronous

Threads may choose which exceptions to recognize and which to ignore. This mask information is specified on a per-kernel basis in fixed function state generated by the driver, and delivered to the EU as part of a new thread dispatch. Upon arrival at the EU, the exception-mask information is used to initialize the exception enable fields of that thread's cr0.1 register, which controls exception recognition. This register is instantiated on a per-thread basis, allowing independent control of exception type recognition across hardware threads. The exception enable bits in the cr0.1 register are read/write, and thus can be enabled/disabled via software at any time during thread execution.

The exception handling mechanism relies on the System Routine, a single subroutine that provides common exception handling for all threads on all EUs in the system. This System Routine is defined per-context and is identified via a System IP (SIP) register in context state. At the time of each context switch,

the appropriate SIP for that context is loaded into each EU, allowing each context to have custom implementation of exception handling routines if so desired.

The mechanism does not support handling recursive system routine access. This means when a thread cannot be asynchronously interrupted to an exception when executing a SIP.

Example:

An Exception is not supported when hardware is executing a SIP for context save and restore operations.

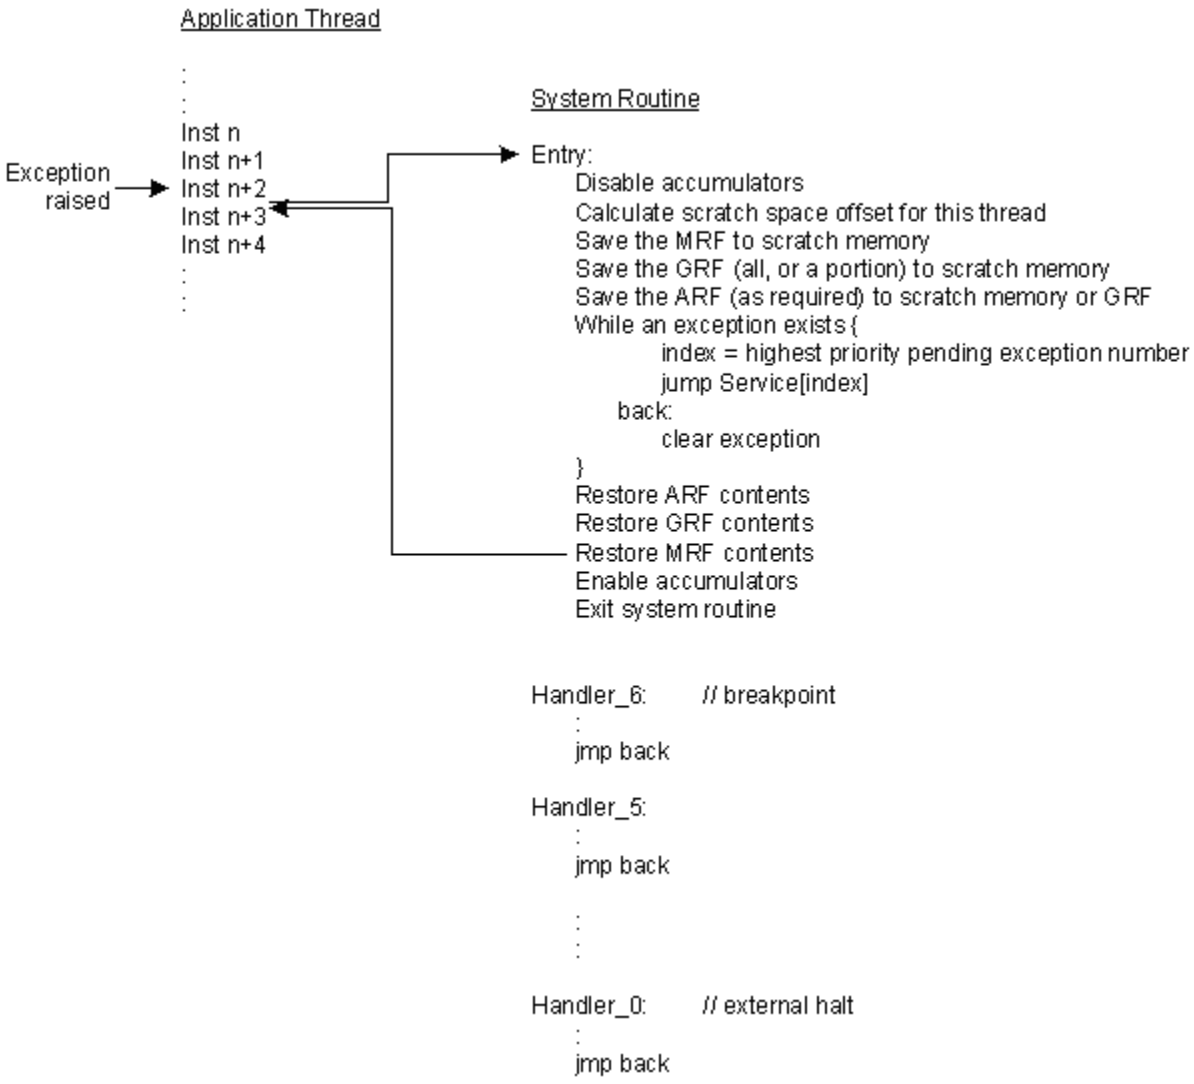
Exception-Related Architecture Registers

Exception-related registers are architecture registers cr0.0 through cr0.2. These registers are instantiated on a per-thread basis providing each hardware thread with unique control over exception recognition and handling. The registers provide the capability to mask exception types, determine the type of raised exception, store the return address, and control exiting from the System Routine back to the application thread.

Many of the bits in these registers are manipulated by both hardware and software. In all cases, the read/write operations by hardware and software occur at exclusive times in a thread's lifetime, thus there is no need for atomic read-modify-write operations when accessing these registers.

System Routine

The following diagram illustrates the basic flow of exception handling and the structure of the System Routine.



Invoking the System Routine

The System Routine is invoked in response to a raised exception. Once an exception is raised, no further instructions from the application thread are issued until the System Routine has executed and returned control back to the application thread.

After an exception is recognized by hardware, the EU saves the thread's IP into its AIP register (cr0.2), and then moves the System Routine offset, SIP, into the thread's IP register. At this point the next instruction issued for that thread is the first instruction of the System Routine.

The System Routine maintains the same execution priority, GRF register space, and thread state as the application thread from which it is invoked.

Due to assuming the same priority, there may be significant absolute time between an exception being raised and invoking the System Routine, as other higher priority threads within the EU continue to execute. From a thread's perspective, once an exception is recognized, the next instruction issued is from the System Routine.

At the time of System Routine invocation, there may still be outstanding registers in-flight from the application thread. Depending on the instruction sequence in the System Routine, an in-flight register may be referenced by the System Routine and cause a register-in-flight dependency. These dependencies are honored by the System Routine and may cause the System Routine to be suspended until the register retires.

Exception processing is not nested within the System Routine. If a future exception is detected while executing the System Routine, the exception is latched into cr0.1, but does not cause a nested re-invocation of the System Routine. The exception recognition hardware recognizes only one outstanding exception of each type; i.e., once a specific exception type is detected and latched in cr0.1, and until the exception is cleared, any further exception of that type is lost.

Accumulators are not natively preserved across the System Routine. To make sure the accumulators are in the identical state once control is returned to the application thread, the System Routine must either set the Accumulator Disable bit of cr0.0 before using any instruction that modifies an accumulator, or save and restore the accumulators (using GRF registers or system thread scratch memory) around the System Routine. Saving and restoring accumulators, including their extended precision bits, can be accomplished by a short series of moves and shifts of the accumulator register. Also note that the state of the Accumulator Disable bit itself must be preserved unless, by convention, the driver software limits its manipulation to only the System Routine.

Further, upon System Routine entry, the execution-related masks (Continue, Loop, If, and Active masks, contained in the Mask Register) will remain set as they were in the application thread. Thus only a subset of channels may be active for execution. To enable execution on all channels, the System Routine may choose to use the instruction option ‘NoMask’, or may choose to set the mask registers to the desired value so long as it saves/restores the original masks upon System Routine entry/exit.

Similarly there is no hardware mechanism to preserve flags, mask-stacks, or other architecture registers across the System Routine. The System Routine must ensure that these values are preserved (see the *Conditional Instructions Within the System Routine*section for related information).

Returning to the Application Thread

Prior to returning control to the application thread, the System Routine should clear the proper Exception Status and Control bit in cr0.1. Failure to do so forces the thread's execution to reenter the System Routine before any further instructions are executed from the application thread. (Note that single-stepping functionality is the one exception where the exception's Status and Control bit is not reset before exit.)

The System Routine may choose to loop within a single invocation of the System Routine until all pending exceptions are serviced, or may choose to service exceptions one at a time (a simpler solution, but less efficient).

The System Routine is exited, and control returned to the application thread, via a write to the Master Exception State and Control bit in cr0.0. Upon clearing this bit, the value of AIP (cr0.2) is restored to the thread's IP register and, with no further exceptions pending, execution resumes at that address. The System Routine must follow any write to the Master Exception State and Control bit with at least one SIMD-16 *nop* instruction to allow control to transition. Throughout the System Routine, the AIP register maintains its value at the time the exception was raised unless directly modified by the System Routine. (See the AIP register definition for specifics on the IP value saved to AIP).

System IP (SIP)

The System IP (SIP) is the 16 byte-aligned offset of the first instruction of the System Routine, relative to the General State Base Address. SIP is assigned by the STATE_SIP command to the command streamer which updates SIP in the EU.

The SIP is widened to 48 bits. However the EU still only uses the low 32 bits (bits 31:4 with bits 3:0 as zero).

When the System Routine is invoked, the application thread's current IP is first saved into the AIP field of cr0.2. The SIP address is then loaded into the thread's IP register and execution continues within the System Routine. Thus each invocation of the System Routine has a common entry point. Returning from the System Routine loads IP from AIP, continuing thread execution.

System Routine Register Space

The System Routine uses the same GRF space as the thread that invokes it.

As such all of the calling thread's registers and their contents are visible to the System Routine. Further, the System Routine must only use r0..r15 of the GRF, as a minimal thread may have requested and been allocated this few. If the System Routine requires more registers than this, the driver should establish a higher minimum allocation for all threads.

The System Routine may encounter any residual register dependencies of the calling thread until such time that they clear by the return of in-flight writebacks.

Only one 32-bit GRF location, r0.4, is reserved for System Routine use. This location is sufficient to allow the System Routine to calculate the appropriate offset of its private scratch memory in the larger system scratch memory space (as dictated by binding table entry 254). The offset is left as a driver convention, but is likely based on a combination of Thread and EU IDs (see the example system handler in the *System Scratch Memory Space*) section. Other than the reserved r0.4 register field, there is no explicit GRF register space dedicated to the System Routine, and any GRF needs must be accomplished via (a) convention between the System Routine and application code, or (b) the System Routine temporarily spilling the thread's GRF register contents to scratch memory and restoring those contents before System Routine exit.

No persistent storage is automatically allocated to the System Routine, although a driver implementation may set aside part of system scratch memory for the System Routine.

Any parameter passing to the System Routine (for use by software exceptions) is done via the GRF based on system thread/application thread convention.

System Scratch Memory Space

There is a single unified system scratch memory space per context shared by all EUs. It is anticipated that block is further partitioned into a unique scratch sub-space per thread via conventions implemented in the System Routine, with each hardware thread having a uniform block size at a calculated offset from the base address. The block address for a thread can be based on an offset derived from the thread's execution unit ID and thread ID made available through the TID and EUID field of architecture register sr0.0.

Per_Thread_Block_Size = System_Scratch_Block_Size / (EU_Count * Thread_Per_EU);

Offset = (sr0.0.EID * Threads_Per_EU + sr0.0.TID) * Per_Thread_Block_Size;

where in GEN:

Threads_Per_EU = 4

EU_Count = 8

System_Scratch_Block_Size is a driver choice.

Access to system scratch memory is performed through the Data Port via linear single register or block-based read/write messages. The driver may choose to use any binding table index for system scratch surface description. As a practical matter, the same index is expected to be used across all binding tables, as the index is typically hard coded in Data Port messages used within the System Routine coupled with the fact that a single System Routine is used for all threads. Read/write messages to the Data Port contain the address of the binding table (provided in r0 of all threads) and an offset, from which the Data Port calculates the final target address.

It is expected that the system scratch memory space is allocated by the driver at context-create time and remains persistent at a constant memory address throughout a context's lifetime.

Conditional Instructions Within the System Routine

It is expected that most, if not all, control flow within the System Routine is scalar in nature. If so, the System Routine should set SPF (Single Program Flow, cr0.0) to enable scalar branching. In this mode, conditional/loop instructions do not update the mask stacks and therefore do not have restrictions on their use nor require the save/restore of hardware mask stack registers.

If SIMD branching is desired within the System Routine, special considerations must be taken. Upon entry to the System Routine, the depth of the mask stacks is unknown at that point, and may be near full. If so, a subsequent conditional instruction and its associated mask ‘push’ may cause a stack overflow. This would generate an exception within the system routine, an unsupported occurrence. To prevent this, if the System Routine uses SIMD conditional instructions, it must save the mask stacks prior to the first

SIMD conditional instruction, and restore them after the last SIMD conditional instruction. As a general solution, it may be easiest to simply implement the save/restore as part of the entry/exit code sequence, using an available GRF register pair as a storage location. Once saved, the stacks should be reset to their empty condition, namely depth = 0 and top of stack = 0xFFFFFFFF.

Use of NoDDClr

The GEN instruction word defines an instruction option **NoDDClr** that overrides the native register dependency clearing mechanism of the typical instruction. When specified, NoDDClr does not clear, at register writeback time, the dependency placed on the destination register of the instruction. Use of this mechanism may provided increased performance when a kernel can guarantee no dependency issues between instructions, but may cause issues with exception handling in some circumstances as discussed here.

Typically NoDDClr is used in an instruction series to enable a sequence of writes to sub-fields of a GRF register without paying a dependency penalty on each instruction. In this case, NoDDClr and NoDDChk are used across an instruction sequence to allow the first instruction to set the destination dependency, interior instructions to write to the GRF register without dependency checks, and the last instruction to clear the dependency. (This sequence is referred to as a NoDDClr code block going forward). By only allowing the last instruction to clear the dependency, program execution is prevented from going beyond a certain point until all writes of that sequence are known to retire.

The problem arises if an exception is raised within a NoDDClr code block. In this case, there exists the potential for the System Routine to hang while attempting to save/restore a register used as a destination register by the NoDDCLr code block, as the outstanding dependency on that register will not clear until the final instruction of the NoDDCLr block is executed, sometime after the System Routine returns. Should the System Routine attempt to use that register, it hangs waiting on a dependency to be cleared by an instruction not yet issued.

Note: This is a known condition and will in some cases not allow the full GRF contents to be externally visible in System Routine scratch space during a break or halt exception.

To avoid this condition, guidelines are provided below for consideration. (Note that these are general guidelines, some of which can be alleviated through careful coding and register usage conventions and restrictions.)

Guideline
NoDDClr code blocks should only be used where absolutely necessary.
Instructions that may generate exceptions should not be placed within NoDDClr blocks. This includes most conditional branch instructions (if, do, while, ...).
If possible, use NoDDClr on registers high in the thread's register allocation (e.g. r120), thus even if a System Routine hang occurs, as much of the GRF is visible as possible. (Note that this would also require the System Routine to update the progress of the GRF dump, perhaps with each GRF block written, or to initialize the System Routine's scratch space to a known value, to be able to distinguish valid/locations from unwritten locations).

Also a driver implementation may consider a disable-NoDDclr option in which jitted code does not use the NoDDClr capability. In this case, there is no change to the code that is jitted other than removal of

the NoDDClr instruction option. The code executes as normal, but with a higher number of thread switches in what would have been a NoDDClr code block.

Exception Descriptions

This section describes conditions that can cause exceptions and transfer control to the System Routine.

Illegal Opcode

The GEN ISA defines a single *illegal* opcode. The byte value of the *illegal* opcode is 0x00 due to it being a likely byte value encountered by a wayward instruction pointer value. The *illegal* instruction signals an exception if exception handling is enabled and invokes the system interrupt routine. If exception handling is NOT enabled, the illegal opcode is executed resulting in undetermined behavior including a system hang. Hardware decodes all legal opcodes supported. Any byte value that is not in the legal opcode list is decoded as an illegal opcode to trigger exception.

Undefined Opcodes

All undefined opcodes in the 8-bit opcode space (which includes instruction bit 7, reserved for future opcode expansion) are detected by hardware. If an undefined opcode is detected, the opcode is overridden by hardware, forcing the opcode value within the pipeline to the defined *illegal* opcode. The offending instruction, should it eventually be issued down the execution unit's pipeline, generates an Illegal Opcode exception as described in the section *Illegal Opcode*. The memory location of the offending opcode keeps its original value. That location can be queried to determine the opcode value.

Software Exception

A mechanism is provided to allow an application thread to invoke an exception and is triggered using the Software Exception Set and Clear bit of cr0.1. Sub-function determination and parameter passing into and out of the exception handler is left to convention between the system-thread and application-thread. The thread's IP is incremented before saving AIP and entering the System Routine, causing execution to resume at the next application-thread instruction after returning from the System Routine.

Context Save and Restore

The System Routine is also used to save and restore the context of the Execution Unit. This feature is enabled in GPGPU workloads *only*.

When the execution engine receives a preemption or an interrupt, the application thread invokes the System Routine. The System Routine is invoked only when all in-flight registers have retired. The system routine is used to save all the state of the EU to memory. When the sequence is complete, the master exception control bit is cleared. This action stops all execution for the given thread and invalidates the thread. This means a new thread from a different context may be loaded. When the master exception control bit is cleared, software must ensure that all outstanding messages from the EU are dispatched out of the execution message pipeline. This is achieved by creating a dependency on the last send that is

saving EU state. A dummy instruction before clearing the master exception control bit ensures that this is achieved.

The System Routine is also invoked on a context restore request. In this case a dummy thread is loaded into the EU which starts with the System Routine. This routine now restores the state of the EU. The restore sequence used in such a case should be consistent with the save sequence to ensure that state is restored correctly. After completing the restore sequence, the System Routine must clear the master exception control bit in the Control Register. This enables hardware to switch to the application thread which continues execution.

Programming Note	
Context:	Context Save and Restore
When context save and restore is required to be supported for GPGPU work loads, Stack Overflow exception handling will not be supported. Software will either need to ensure stack is either completely disabled OR used in such a way, an exception will not trigger.	

Events That Do Not Generate Exceptions

The conditions described in this section are either not recognized or do not generate an exception.

Illegal Instruction Format

This condition includes malformed instructions in which the opcode is legal, but the source or destination operands or other instruction attributes do not comply with the instruction specification. There is no direct hardware support to detect these cases and the outcome of issuing a malformed instruction is undefined.

Note that GEN does not support self-modifying code, therefore the driver has an opportunity to detect such cases before the thread is placed in service.

Malformed Message

A message's contents, destination registers, lengths, and descriptors are not interpreted in any way by the execution unit. Errors in specifying message fields do not raise exceptions in the EU but may be detected and reported by the shared functions.

GRF Register Out of Bounds

Unique GRF storage is allocated to each thread which, at a minimum, satisfies the register requirements specified in the thread's declaration. References to GRF register numbers beyond that called for in the thread's declaration do not generate exceptions. Depending on the implementation, out-of-bounds register numbers may be remapped to r0..r15, although this functionality should not be relied upon by the thread. The hardware guarantees the isolation of each thread's register space, thus there is no possibility of direct register manipulation via an out-of-bounds register access.

Hung Thread

There is no hardware mechanism in the EU to detect a hung thread and such a thread may remain hung indefinitely. It is expected that one or more hung threads will eventually cause the driver to recognize a context timeout and take appropriate recovery action.

Instruction Fetch Out of Bounds

The EU implements a full 32-bit instruction address range (with the 4 LSBs don't care), making it possible for a thread to attempt to jump to any 16-byte aligned offset in the 32-bit instruction address range. (Instruction addresses are offsets from the General State Base Address.) The EU does not provide any type of address checking on instruction fetch requests sent to the memory/cache hierarchy, although error conditions for memory addresses are reported via the Page Table Error Register and other memory interface registers.

FPU Math Errors

The EU's floating point units (FPUs) have defined behaviors for traditional floating point errors and do not generate exceptions. There is no support for signaling FPU math errors as exceptions.

Adds the IEEE Exception Trap Enable bit, which enables trapping IEEE exception flags. If enabled, IEEE floating-point exceptions set sticky bits in the IEEE Exceptions field of sr0.1. Note that IEEE floating-point exceptions still do *not* transfer control to any handler.

Computational Overflow

Depending on source operand types and values, destination type, and the operation being performed, overflows may occur in the execution pipelines. Many instructions support the overflow (**.o**) conditional modifier that assigns flag bits based on whether or not an overflow occurs.

The EU never signals exceptions for overflows. Software must provide any overflow handling.

System Routine Example

The following code sequence illustrates some concepts of the System Routine. It is intended to be just a shell, without getting into the specifics of each exception handler.

This example contains SNB code for the message registers in the MRF. All message register and MRF references are specific to SNB. Other code in this example is useful for other processor generations.

The example frees enough MRF and GRF space to get the routine started, then jumps to the handler for the specific exception. Many other implementations are also valid, including single exception servicing (as opposed to looping) per invocation, and saving only the GRF or MRF space required by the exception being serviced.

```
#define ACC_DISABLE_MASK 0xFFFFFFFD
#define MASTER_EXCP_MASK 0x7FFFFFFF
#define SYSROUTINE_SCRATCH_BLKSIZE 16384 // for example
```

```
// Shared function IDs:
#define DPR 0x04000000
#define DPW 0x05000000

// Message lengths:

// Perform service routine.
// Jump to exit (or if looping on exceptions, go to next loop).
...
Service_15:
// Clear exception from cr0.1.
// Perform service routine.
// Jump to exit (or if looping on exceptions, go to next loop).

Exit:
// Restore f0.0.
// Restore other ARF registers (as required).
// Restore r12..r15.
// Restore r8..r11.
// Restore r4..r7.
// Restore r0..r3.
// Restore m8..m15.
// Restore m0..m7.
```

```
// Clear Master Exception State bit in cr0.0:
and (1) cr0.0 cr0.0 MASTER_EXCP_MASK
nop (16)
```

Below is a code sequence to programmatically clear the GRF scoreboard in case of a timeout waiting on a register that may never return.

At this point, all we know is we have a hung thread. We'd like to copy the GRF to scratch memory to make it visible, but there may be a register that is hung with an outstanding dependency. To get around any hung dependency, walk the GRF using NoDDChk, using an execution mask of f0 == 0 so we don't touch the register contents.

```
Clear_Dep:
mov f0 0x00
(f0) mov r0 0x00 {NoDDChk}
(f0) mov r1 0x00 {NoDDChk}
(f0) mov r2 0x00 {NoDDChk}
...
(f0) mov r127 0x00 {NoDDChk}
// GRF scoreboard now cleared.
```

Instruction Set Summary

Instruction Set Characteristics

SIMD Instructions and SIMD Width

GEN instructions are SIMD (single instruction multiple data) instructions. The number of data elements per instruction, or the execution size, depends on the data type. For example, the execution size for GEN instructions operating on 256-bit wide vectors can be up to 8 for 32-bit data types, and be up to 16 for 16-bit data. The maximum execution size for GEN instructions for 8-bit data types is also limited to 16.

An instruction compression mode is supported for 32-bit instructions (including mixed 32-bit and 16-bit data computation). A compressed GEN instruction works on twice as much SIMD data as that for a non-compressed GEN instruction. A compressed instruction is converted into two native instructions by the instruction dispatcher in the EU.

GEN instructions are executed on a narrower SIMD execution pipeline. Therefore, GEN native instructions take multiple execution cycles to complete.

Instruction Operands and Register Regions

Most GEN instructions may have up to three operands, two sources and one destination. Each operand is able to address a register region. Source operands support negate and absolute modifier and channel swizzle, and the destination operand supports channel mask.

Dual destination instructions are also supported (four-operand instructions in a general sense): One case is for the implied destination – flag register, where the conditional modifiers and the predicate modifiers

may apply. Another case is the message header creation (implied move or implied assembling of the header) in the *send* instruction.

Each execution channel contains an accumulator that is wider than the input data to support back-to-back accumulation operations with increased precision. The added precision (see accumulator register description in Execution Environment chapter) determines the maximum number of accumulations before possible overflow. The accumulator can be pre-loaded through the use of *mov*. It can also be pre-loaded by arithmetic instructions such as *add* or *mul*, since the result of these instructions can go to the accumulator. The accumulator registers are per thread and therefore safe for thread switching.

Register access can be direct or register-indirect. Register-indirect register access uses address registers plus an immediate offset term to compute the register addresses, and only applies to the first source operand (src0) and/or the destination operand.

There is one address register.

Description
There are 16 address sub-registers.

Each sub-register contains a 16-bit unsigned value. The leading two sub-registers form a special doubleword that can be used as the descriptor for the send instruction.

Source operand can also be immediate value (also referred to as inline constants). For instructions with two source operands, only the second operand src1 is allowed to be immediate. For instructions with only one source operand, the source operand src0 is used and it can be an immediate.

An immediate source operand can be a scalar value of specified type up to 32-bit wide, which is replicated to create a vector with length of Execution Size. An immediate operand can also be a special 32-bit vector with 8 elements each of 4-bit signed integer value, or a 32-bit vector with 4 elements each of 8-bit restricted float value.

Instruction Execution

It is implied that all instructions operate across all channels of data unless otherwise specified either via destination mask, predication, execution mask (caused by SIMD branch and loop instructions), or execution size.

Instruction execution size can be specified per instruction, from scalar (*ExecSize* = 1) up to the maximal execution size supported for the data type, with the restriction that execution size can only be in power of 2.

Instruction Formats

This section shows the machine formats of the GEN instruction set. The instructions in the GEN architecture have a fixed length of 128 bits in the native format. A compact format, discussed separately in this volume, can represent some instructions using 64 bits. Out of the 128 bits in the native format, there are 120 bits in use, and the remaining bits are reserved for future extensions. One instruction

consists of instruction fields that control various stages of execution. These fields are roughly grouped into the 4 DWords as follows:

- Instruction Operation Doubleword (DW0) contains the Opcode and other general instruction control fields.
- Instruction Destination Doubleword (DW1) specifies the destination operand (dst) and the register file and type of source operands.
- Instruction Source 0 Doubleword (DW2) contains the first source operand (src0).
- Instruction Source 1 Doubleword (DW3) contains the second source operand (src1) and is used to hold any 32-bit immediate source (Imm32 as src0 or src1).

Instructions with one source operand of type DF, Q, or UQ can use an Imm64 64-bit immediate source operand in DWord 2 and DWord3.

Most instructions have 1 or 2 source operands and use a common instruction format. Within that format, there are variations based on AddrMode and AccessMode. There is a separate instruction format for a small number of instructions with 3 source operands. Send, math, and branching instructions have format variations described separately.

The 3-source instructions have the following restrictions:

- Only GRF registers can be sources and only GRF registers can be the destination.
- Subregister numbers have DWord granularity if AccessMode is Align16.
- AccessMode is Align16, uses Align16-style swizzling, with extra replication control. There is no other regioning support.

The next two subsections describe the instruction formats for various processor generations using tables. The following diagrams provide another view of the same information. The first diagram is for native instructions with one or two source operands.

GEN Instruction Format – 1-src and 2-src

DW #	Instr Bits Alloc	High Bit	Low Bit	Instr Bits Used	AddrMode = Direct: AccessMode = Align16	AddrMode = Direct: AccessMode = Align1	AddrMode = Indirect: AccessMode = Align16	AddrMode = Indirect: AccessMode = Align1	SEND: MsgDesc Imm	SEND: MsgDesc Reg	MATH	Branch (2offsets)	Branch (1offset)	Imm Src[31:0]	Imm Src[63:0]

Instruction Fields

This section contains two large tables that together describe all instruction fields. The first table describes common instruction fields that are not specific to a source or destination operand. The second table describes fields used to describe source or destination operands, including fields that describe register regioning and immediate operand fields.

Notable changes for BDW+ instructions include adding three new data types (Q, UQ, HF), widening all type fields to four bits each to accomodate the new type encodings, providing a new source modifier interpretation for logical operations, widening the AddrSubRegNum fields to four bits to accomodate 16 (rather than 8) address subregisters, and supporting 64-bit immediate (Imm64) source values for instructions with single source operands.

In the assembler syntax, some fields appear in the positions used for destination or source operands but are not normal operands. Such fields appear in the Common Instruction Fields table, notably the JIP and UIP instruction offsets used in some flow control instructions.

Common Instruction Fields (Alphabetically by Short Name)

Field	Description
AccessMode	**Access Mode.** This field controls operand access for the instruction. It applies to all source and destination operands. When it is clear (**Align1**), the instruction uses byte-aligned addressing for source and destination operands. Source swizzle control and destination mask control are not supported. Elements must still be aligned on element-size boundaries. For example, a DWord operand must be aligned on a 4-byte boundary. When it is set (**Align16**), the instruction uses 16-byte-aligned addressing for source and destination operands. Source swizzle control and destination mask control are supported in this mode. A register region must start on 16-byte aligned address, but individual elements do not. For example, a packed array of 16 bytes can be an operand, where only the first byte, at offset 0, is at a 16-byte aligned address. 0 = **Align1** 1 = **Align16**
AccWrCtrl/ BranchCtrl	**Accumulator Write Control.** Enable or disable implicitly writing results to the accumulator as well as to the destination. 0 = Do not write results to the accumulator; write results only to the destination. 1 = **AccWrEn.** Write results to the accumulator as well as to the destination. This bit should not be set if the accumulator is the explicit destination operand. Some instructions do not allow this option, including *mov* and *send*. **Branch Control.** Used by the *goto* instruction to control branching. See the **goto** instruction description for more information about BranchCtrl.
CmptCtrl	**Compaction Control.** Indicates whether the instruction is compacted to the 64-bit compact instruction format. When this bit is set, the 64-bit compact instruction format is used. The EU decodes the compact format using lookup tables internal to the hardware, but documented for use by software tools. Only some instruction variations can be compacted, the variations supported by those lookup tables and the compact format. See EU Compact Instruction Format for more information. 0 = No Compaction. No compaction. 128-bit native instruction supporting all instruction options. 1 = **CmptCtrl**. Compaction is enabled. 64-bit compact instruction supporting only some instruction variations.

Field	Description
CondModifier	**Condition Modifier.** This field sets the flag register based on internal conditional signals output from the execution pipe such as sign, zero, overflow, NaNs, etc. If this field is 0000b, no flag registers are updated. Flag registers are not updated for instructions with embedded compares. This field applies to all instructions except send, sendc, and math. 0000b = Do not modify the flag register (normal) 0001b = Zero or Equal (**.z** or **.e**) 0010b = Not Zero or Not Equal (**.nz** or **.ne**) 0011b = Greater than (**.g**) 0100b = Greater than or equal (**.ge**) 0101b = Less than (**.l**) 0110b = Less than or equal (**.le**) 0111b = Reserved 1000b = Overflow (**.o**) 1001b = Unordered with Computed NaN (**.u**) 1010b-1111b = Reserved
DepCtrl	**Destination Dependency Control.** This field selectively disables destination dependency check and clear for this instruction. When it is set to 00b, normal destination dependency control is performed for the instruction; hardware checks for destination hazards to ensure data integrity. Specifically, a destination register dependency check is conducted before the instruction is made ready for execution. After the instruction is executed, the destination register scoreboard is cleared when the destination operands retire. When **NoDDClr** is set, the destination register scoreboard is *not* cleared when destination operands retire. When **NoDDChk** is set, hardware does not check for destination register dependencies before the instruction is made ready for execution. **NoDDClr** and **NoDDChk** are not mutually exclusive; both can be set. When this field is not 00b, hardware does not protect against destination hazards for the instruction. These settings are typically used to assemble data in a fine grained fashion (for example, a matrix-vector compute with dot-product instructions), where data integrity is guaranteed by software based on the intended usage of instruction sequences. 00b = Destination dependency checked and cleared (normal). 01b = **NoDDClr**. Destination dependency checked but not cleared. 10b = **NoDDChk**. Destination dependency not checked but cleared. 11b = **NoDDClr, NoDDChk**. Destination dependency not checked and not cleared. See the Destination Hazard and the Use of NoDDClr sections for more information.

Field	Description
EOT	**End of Thread.** For a *send* or *sendc* instruction, this bit controls thread termination. It is not used for other instructions. For a *send* or *sendc*instruction, if this field is set, the EU terminates the thread and also sets the EOT bit in the message sideband. 0 = The thread is not terminated. 1 = End of thread (EOT).
ExDesc	**Extended message descriptor.** A 32 bit immediate extended message descriptor for *send* and *sendc* instructions. This field is not used for other instructions.
ExecSize	**Execution Size.** Specifies the number of parallel execution channels and data elements for the instruction, a power of 2 from 1 to 32. The size cannot exceed the maximum number of channels allowed for the largest data type specified for a source or destination operand. *ExecSize* x largest data type size in bytes <= 64. 000b = 1 Channels (scalar operation). 001b = 2 Channels. Any data type. 010b = 4 Channels. Any data type. 011b = 8 Channels. Any data type. 100b = 16 Channels. 4-byte or smaller data types. Excludes DF, Q, and UQ types. 101b = 32 Channels. 2-byte or 1-byte data types. Excludes D, DF, F, Q, UD, and UQ types. 110b-111b = Reserved. An operand's *Width* must be <= *ExecSize*.
FC	**Function Control.** Specifies the extended math function carried out by the *math*instruction. Not used for any other instruction. This field is in the same position as the CondModifier instruction field, so the *math* instruction does not support conditional modifiers. See the *math* Extended Math Function instruction description for more information about this field.
FlagRegNum/ **FlagSubRegNum**	**Flag Register Number/Flag Sub-Register Number.** Selects the 32-bit flag register (f0 or f1) and the 16-bit flag subregister (.0 or .1). The specified flag subregister is the source for any predication and the destination for new flag values produced by any enabled conditional modifier. A flag subregister can be both a predication source and a conditional modifier destination in the same instruction. The number of flag bits used or updated depends on the execution size. 00b f0.0 01b f0.1 10b f1.0 11b f1.1
JIP	**Jump Instruction Pointer.** A Doubleword Signed Integer offset relative to the current IP (which references the current instruction) in units of bytes. Typically an immediate value in the instruction. For the *brc* (Branch Converging) instruction, both JIP and UIP can be contained in a register.

Field	Description
MaskCtrl	**Mask Control** (formerly WECtrl/Write Enable Control). This flag disables the normal write enables; it should normally be 0. 0 = Use the normal write enables in Dst.ChanEn (normal setting). 1 = NoMask. Write all channels except those disabled by predication or by other masks besides the write enables. MaskCtrl = NoMask also skips the check for PcIP[n] == ExIP before enabling a channel, as described in the Evaluate Write Enable section.
NibCtrl	**Nibble Control.** This field is used in some instructions along with QtrCtrl. See the description of QtrCtrl below. NibCtrl is only used for SIMD4 instructions with a 64bit datatype as source or destination. 0 = Use an odd 1/8th for DMask/VMask and ARF (first, third, fifth, or seventh depending on QtrCtrl). 1 = Use an even 1/8th for DMask/VMask and ARF (second, fourth, sixth, or eighth depending on QtrCtrl). Note that if eighths are given zero-based indices from 0 to 7, then NibCtrl = 0 indicates even indices and NibCtrl = 1 indicates odd indices.
NoSrcDepSet	**No Source Dependency Set.** In *send*, *sendc*, *sends* and *sendsc* instruction, this bit controls the setting of GRF source dependency. The source dependencies of both sources are considered together. When it is set to 0, normal write after read (WAR) dependency control is performed for the instruction; hardware checks for write after read hazard and ensure data integrity. Specifically source register dependency is set by the current instruction and a destination register dependency check is expected to be conducted before the next instruction is made ready for execution. When it is set to 1, hardware does not protect against write after read data hazard for the instruction. This setting is used in send instruction where the same source data is reused without modification by multiple send instruction. Software must send to the same shared function which must not be in fault and stream page fault mode and guarantee one of the following for all the source registers used in a send instruction to ensure data integrity. • The last send instruction before the instruction which modifies its source(s) does not use this setting. • The instruction which modifies the source(s) is either dependent on the destination register of the last send instruction with the source(s) or has instruction before it which does so. • The instruction which modifies the source(s) is either dependent on the source register of the last send instruction with the source(s) which does not use this setting or has instruction before it which does so. 0 = source dependency is set (normal). 1 = NoSrcDepSet. Source dependency is not set.

Field	Description
OpCode	**Operation Code.** Contains the instruction operation code. Each opcode used is given a unique mnemonic. For example, the opcode 0x01 has the mnemonic *mov* indicating a Move instruction. See the Opcode Encoding section for details of opcode encoding.
PredCtrl	**Predicate Control.** This field, together with PredInv, controls generating the predication mask (PMask) for the instruction. It allows per-channel conditional execution the instruction based on the content of the selected flag register. The encoding depends on the access mode. See the Predication section for more information about predication. In **Align16** access mode, there are eight encodings (including no predication). All encodings are based on group-of-4 predicate bits, including channel sequential, replication swizzles and horizontal any or all operations. The same configuration is repeated for each group-of-4 execution channels. In **Align1** access mode, there are twelve encodings (including no predication). The encodings apply to all execution channels with explicit channel grouping from a single channel up to a group of 16 channels. *Predicate Control in* **Align16** *access mode:* 0000b = No predication (normal). 0001b = Predication with sequential flag channel mapping. 0010b = Predication with replication swizzle **.x**. 0011b = Predication with replication swizzle **.y**. 0100b = Predication with replication swizzle **.z**. 0101b = Predication with replication swizzle **.w**. 0110b = Predication with **.any4h.** 0111b = Predication with **.all4h.** 1000b-1111b = Reserved. *Predicate Control in* **Align1** *access mode:* 0000b = No predication (normal). 0001b = Predication with sequential flag channel mapping. 0010b = Predication with **.anyv** (f0.0 OR f1.0 on the same channel). 0011b = Predication with **.allv** (f0.0 AND f1.0 on the same channel). 0100b = Predication with **.any2h** (any in group of 2 channels). 0101b = Predication with **.all2h** (all in group of 2 channels). 0110b = Predication with **.any4h** (any in group of 4 channels). 0111b = Predication with **.all4h** (all in group of 4 channels). 1000b = Predication with **.any8h** (any in group of 8 channels).

<table>
<tr><th>Field</th><th>Description</th></tr>
<tr><td></td><td>1001b = Predication with .all8h (all in group of 8 channels).
1010b = Predication with .any16h (any in group of 16 channels).
1011b = Predication with .all16h (all in group of 16 channels).
1100b = Predication with .any32h (any in group of 32 channels).
1101b = Predication with .all32h (all in group of 32 channels).
1110b-1111b = Reserved.</td></tr>
<tr><td>PredInv</td><td>Predicate Inverse. Together with PredCtrl, controls generation of the predication mask (PMask) for the instruction. When it is set and PredCtrl is not 0000b, predication uses the inverse of the predication bits produced by PredCtrl. In other words, the effect of PredInv happens after the effects of PredCtrl.
This field is ignored if PredCtrl is 0000b; there is no predication.
0 = +. Positive polarity of predication. Use the predication mask produced by PredCtrl.
1 = -. Negative polarity of predication. If PredCtrl is nonzero, invert the predication mask.
PMask is the final predication mask produced by the effects of both fields.</td></tr>
<tr><td>QtrCtrl</td><td>Quarter Control. This field provides explicit control for ARF selection.
This field combined with ExecSize determines which channels are used for the ARF registers.
Along with NibCtrl, 1/8 DMask/VMask and ARF can be selected.
<table>
<tr><th>QtrCtrl</th><th>NibCtrl</th><th>ExecSize</th><th>Syntax</th><th>Description</th></tr>

</table>

Field	Description
	<table><tr><td>11b</td><td>1</td><td>4</td><td>8N</td><td>Use eighth 1/8th for DMask/VMask and ARF.</td></tr></table> **2H** is only allowed for SIMD16 instruction in Single Program Flow mode (SPF = 1). NibCtrl is only allowed for SIMD4 instructions with a 64bit datatype as source or destination type.
Reg32	In a *send*, *sendc*, *sends* or *sendsc* instruction refers to the option of providing the message descriptor field DWords correspondingly as the first dwords of the Address Register rather than as an immediate operand.
Saturate	**Saturate.** Enables or disables destination saturation. When it is set, output values to the destination register are saturated. The saturation operation depends on the destination data type. Saturation is the operation that converts any value outside the saturation target range for the data type to the closest value in the target range. For a floating-point destination type, the saturation target range is [0.0, 1.0]. For a floating-point NaN, there is no "closest value"; any NaN saturates to 0.0. Note that enabling Saturate overrides all of the NaN propagation behaviors described for various numeric instructions. Any floating-point number greater than 1.0, including +INF, saturates to 1.0. Any negative floating-point number, including -INF, saturates to 0.0. Any floating-point number in the range 0.0 to 1.0 is not changed by saturation. For an integer destination type, the maximum range for that type is the saturation target range. For example, the saturation range for B (Signed Byte Integer) is [-128, 127]. When Saturate is clear, destination values are not saturated. For example, a wrapped result (modulo) is output to the destination for an overflowed integer value. See the Numeric Data Types section for information about data types and their ranges. 0 = No destination modification (normal). 1 = **sat**. Saturate the output.
SFID	**Shared Function ID.** Specifies a shared function that is the target of a *send*or *sendc* instruction. This field is not used for any other instructions. This field is in the same position as the CondModifier instruction field, so the *send* and *sendc*instructions do not support conditional modifiers.
ThreadCtrl	**Thread Control.** This field provides explicit control for thread switching. If this field is set to 00b, it is up to the Execution Unit to manage thread switching. This is the normal operating mode. In this mode, for example, if the current instruction cannot proceed due to operand dependencies, the EU switches to the next available thread to fill the compute pipe. For another example, if the current instruction is ready to run but another thread with higher priority also has an instruction ready, the EU switches to that thread. If this field is **Switch**, a forced thread switch occurs after the current instruction executes and before the next instruction. In addition, a long delay (longer than the execution pipe latency) for the current thread is introduced for the thread. Particularly, the instruction queue of the current thread is flushed after the current instruction is dispatched for execution. If this field is **Atomic**, the next instruction gets highest priority in the thread arbitration for the execution pipelines.

Field	Description
	Switch is designed primarily as a safety feature in case there are race conditions for certain instructions. 00b = Normal Thread Control. Execution may or may not be preempted by another thread following this instruction. 01b = **Atomic**. Prevent any thread switch immediately following this instruction. Always execute the next instruction (which may not be next sequentially if the current instruction branches). Atomic can be used with send, sends, sendc, sendsc ONLY. 10b = **Switch**. Force a switch to another thread after this instruction and before the next instruction. 11b = Reserved
UIP	**Update Instruction Pointer.** A Doubleword Signed Integer offset relative to the current IP (which references the current instruction) in units of bytes. Typically an immediate value in the instruction. For the *brc* (Branch Converging) instruction, both JIP and UIP can be contained in a register.

In the following table of operand fields, use just the last part of the field name. For example, to find the Src1.ChanSel field, look for ChanSel.

Source or Destination Operand Fields (Alphabetically by Short Name)

Field	Description
AddrImm	**Address Immediate.** A 10-bit signed integer offset in units of bytes, only used with the Indirect Addressing Mode. In that addressing mode, the Address Immediate value is added to an address subregister value to determine the operand's address in the GRF. Allowed for any GRF register operand, destination or source. ARF registers cannot be accessed with indirect addressing. The Address Immediate field cannot cover the 4K-byte range of the thread's GRF. Whatever address subregister value is used along with this offset provides a window into the GRF, limited by the offset range. In the Align16 Access Mode, the low four bits of AddrImm are zero and do not appear in the instruction format. Format = S9 Range = [-512, 511]
AddrMode	**Addressing Mode.** Whether the destination register and subregister are encoded in the instruction (Direct Addressing) or calculated using the contents of an address subregister and an offset (Indirect Addressing). This field applies to source and destination register operands, for instructions with 1 or 2 source operands. 0 = Direct Addressing ("Direct"). Direct register addressing. 1 = Indirect Addressing ("Register-Indirect" or "Indirect"). Register-indirect register addressing. Instructions with 3 source operands use Direct Addressing.

Field	Description
AddrSubRegNum	**Address Sub-Register Number.** The address register contains 16 Word-sized subregisters. This field is only used with the Indirect Addressing Mode and specifies the address subregister containing a value added to the Address Immediate value to determine the operand address. Format = U4 Range = [0, 15] Some variations of Indirect Addressing use multiple address subregisters, where AddrSubRegNum determines the first subregister used.
ChanEn	**Channel Enable.** Dst.ChanEn, used only for the destination operand and only in the Align16 Access Mode. Provides four channel enable bits applied modulo four to all *ExecSize* channels. For example, 0xF enables all channels, 0 disables all channels, 0xA enables odd-numbered channels, and so on. The assembler mnemonics are **x**, **y**, **z**, and **w** for channels 0, 1, 2, and 3 respectively. If MaskCtrl is 1 (mnemonic **NoMask**) then all channels are enabled regardless of the ChanEn value, equivalent to ChanEn of 0xF (**xyzw**). Predication and execution masking, in addition to ChanEn and MaskCtrl, determine what channels are actually written. For i in 0, 1, 2, 3: Bit i = 0 For channel j where j % 4 == i, disable writing that channel. Bit i = 1 For channel j where j % 4 == i, enable writing that channel.
ChanSel	**Channel Select.** This field controls the channel swizzle for a non-immediate source operand in the Align16 access mode. It is not used for immediate operands, destination operands, or in the Align1 access mode. The normally sequential channel assignment can be altered by explicitly identifying neighboring data elements for each channel. Out of the 8-bit field, 2 bits are assigned for each channel within the group of 4. ChanSel[1:0], [3:2], [5:4] and [7:6] are for channel 0 (**x**), 1 (**y**), 2 (**z**), and 3 (**w**) in the group, respectively. When operating on 64-bit operands, these channel selects must be used in pairs to select a contiguous 64-bit source. For example with an execution size of 8, r0.0<4>.zywz:f assigns the channels as follows: Chan0 = Data2, Chan1 = Data1, Chan2 = Data3, Chan3 = Data2; Chan4 = Data6, Chan5 = Data5, Chan6 = Data7, Chan7 = Data6. The 2-bit Channel Selection field for each channel within the group of 4 is defined as: 00b = **x**. Channel 0 is selected for the corresponding execution channel. 01b = **y**. Channel 1 is selected for the corresponding execution channel. 10b = **z**. Channel 2 is selected for the corresponding execution channel. 11b = **w**. Channel 3 is selected for the corresponding execution channel. Note: When using channel select for 64-bit operands, the valid selects are **.xy** and **.zw**. This is required to pick a pair of DWords.
Desc	**Message descriptor.** A 31 bit immediate message descriptor for *send*, *sendc*, *sends* and *sendsc* instructions.This field is not used for other instructions.
DstType	**Destination Type.** Dst.DstType specifies the numeric data type of the destination operand dst. The bits of the destination operand are interpreted as the identified numeric data type, rather than coerced into a type implied by the operator. For a *send* or *sendc* instruction, this field applies to CurrDst, the current destination operand. Three source instructions use a 3-bit encoding that allows fewer data types.

Field	Description
ExDesc	**Extended message descriptor.** A 32 bit immediate extended message descriptor for *send*, *sendc*, *sends* and *sendsc* instructions.This field is not used for other instructions.
HorzStride	**Horizontal Stride.** Is the distance in units of data element size between two adjacent data elements within a row (horizontal) in the register region for an operand. A horizontal stride of 0 is used for a row that is one-element wide, useful when an instruction repeats a column value or repeats a scalar value. For example, adding a single column to every column in a 2D array or adding a scalar to every element in a 2D array uses HorzStride of 0. A horizontal stride of 1 indicates that elements are adjacent within a row. References to HorzStride in this volume normally reference the value not the encoding, so there are references to HorzStride of 4, which is encoded as 11b. This field applies to both source and destination register operands. This field is used with both direct and indirect addressing. 00b = 0 Elements 01b = 1 Element 10b = 2 Elements 11b = 4 Elements See the Register Region Restrictions section for rules that constrain *HorzStride* in relation to other region parameters.
Imm[28:0]	A 29-bit immediate message descriptor for a *send* or *sendc* instruction. This field is not used for other instructions.
Imm32	A 32-bit immediate data field for an immediate source operand. Only one source operand can be immediate, the last source operand. Of course a destination operand is never immediate. For a two-source instruction, src1 can be immediate; for a one-source instruction src0 can be. The source type for an immediate operand cannot be B or UB (signed or unsigned byte). The source type can be one of the packed vector types that are only allowed as immediate operands: V, UV, or VF. For the W or UW (signed or unsigned word) source types, the 16-bit value must be replicated in both the low and high words of the 32-bit immediate value. The low order bits are directly used when fewer than 32-bits are needed for the source type. The 32-bit value is not coerced into the designated type. See the Numeric Data Types section for information about data types and their ranges. In *send*, *sendc*, *sends* or *sendsc* instruction, refers to the 31bit immediate message descriptor field and the 32bit immediate extended message descriptor field.
Imm64	A 64-bit immediate data field for an immediate source operand, only used for a one-source instruction with a 64-bit Source Type (DF, Q, or UQ).
RegFile	**Register File.** Select a source or destination register file or indicate an immediate source operand: 00b = ARF Architecture Register File. Only allowed for src0 or destination. 01b = GRF General Register File. Allowed for any source or destination. 10b = Reserved. 11b = Immediate operand. Only allowed for the last source operand. Not allowed for the

Field	Description
	destination operand or for any other source operand. Note that for flow control instructions requiring two offsets, regfile of source0 is required to be immediate since the 64b for immediates occupy the DW2 and DW3.
RegNum	**Register Number.** The register number for the operand. For a GRF register, is the part of a register address that aligns to a 256-bit (32-byte) boundary. For an ARF register, this field is encoded such that MSBs identify the architecture register type and LSBs provide the register number. An ARF register can only be dst or src0. Any src1 or src2 operands cannot be ARF registers. RegNum and SubRegNum together provide the byte-aligned address for the origin of a register region. RegNum provides bits 12:5 of that address. For one-source and two-source instructions, SubregNum provides bits 4:0. For three-source instructions, the address must be DWord-aligned; SubRegNum provides bits 4:2 of the address and bits 1:0 are zero. This field is present for the direct addressing mode and not present for indirect addressing. This field applies to both source and destination operands. Format = U8, if RegFile = GRF. 0x00 to 0x7F = Register number in the range [0, 127]. 0x80 to 0xFF = Reserved. Format = 8-bit encoding, if RegFile = ARF. This field encodes the architecture register type as well as providing the register number. See the ARF Registers Overview section and the sections for individual ARF registers for details.
RepCtrl	**Replicate Control.** This field is only present in three-source instructions, for each of the three source operands. It controls replication of the starting channel to all channels in the execution size. ChanSel does not apply when Replicate Control is set. This is applicable to 32b datatypes and 16b datatype. 64b datatypes cannot use the replicate control. 0 = No replication. 1 = Replicate across all channels.
SelReg32Desc	**Select Reg32 for message descriptor.** In *sends* or *sendsc* instruction, refers to the selection of Reg32 for the message descriptor field. 0 = Desc. 1 = Reg32. First Dword of Address Register is used for message descriptor.
SpecialAcc	**Special Accumulator.** Specify the accumulator numbers used by the IEEE macro instructions. The 8 special accumulators, acc2 to acc9 are encoded consecutively from 0000b to 0111b and noacc, indicating no special accumulator used is encoded as 1000b.
SrcMod	**Source Modifier.** Specify any numeric (normally) or logical (for logic instructions) modification to a source value before delivery to the execution pipe. The numeric value of each data element of a source operand can optionally have its absolute value taken, its sign inverted (arithmetic negation), or both (absolute value followed by arithmetic negation producing a guaranteed negative value). When used with logic instructions (*and*, *not*, *or*, *xor*), this field indicates whether the source bits are inverted (bitwise NOT) before delivery to the execution pipe, regardless of the source type. This field only applies to source operands. It does not apply to the destination. This field is not present for an immediate source operand.

Field	Description
	For no modification, there is no assembler notation or syntax. Encoding for all instructions other than logic instructions: 00b = No modification (normal). 01b = **(abs)**. Absolute value. 10b = **-**. Negation. 11b = **-(abs)**. Negation of the absolute value (forced negative value). Encoding for logic instructions: 00b = No modification (normal). 01b = No modification (normal). This encoding cannot be selected in the assembler syntax. 10b = **~** Indicates a bitwise NOT, inverting the source bits. 11b = No modification (normal). This encoding cannot be selected in the assembler syntax.
SrcType	**Source Type.** Specifies the numeric data type of a source operand. In a two-source instruction, each source operand has its own source type field. In a three-source instruction, one source type is used for all three source operands. The bits of a source operand are interpreted as the identified numeric data type, rather than coerced into a type implied by the operator. Depending on the RegFile field for the source, this field uses one of two encodings. For a non-immediate source (from a register file), use the Source Register Type Encoding, which is identical to the Destination Type encoding. For an immediate source, use the Source Immediate Type Encoding, which does not support signed or unsigned byte immediate values and does support the three packed vector types, V, UV, and VF. Note that three-source instructions do not support immediate operands, that only the second source (src1) of a two-source instruction can be immediate, and that 64-bit immediate values (DF, Q, or UQ) can only be used with one-source instructions. In a two-source instruction with a V (Packed Signed Half-Byte Integer Vector) or UV (Packed Unsigned Half-Byte Integer Vector) immediate operand, the other source operand must have a type compatible with packed word execution mode, one of B, UB, W, or UW. Note that DF (Double Float) and HF (Half Float) have different encodings in the Source Regster Type Encoding and the Source Immediate Type Encoding. The Source Register Type Encoding and Source Immediate Type Encoding lists apply to instructions with one or two source operands. Three source instructions can use operands with mixed-mode precision. When SrcType field is set to :f or :hf it defines precision for source 0 only, and fields Src1Type and Src2Type define precision for other source operands: 0b = **:f**. Single precision Float (32-bit). 1b = **:hf**. Half precision Float (16-bit).

Field	Description
SubRegNum	**Sub-Register Number.** The subregister number for the operand. For a GRF register, is the byte address within a 256-bit (32-byte) register. For an ARF register, determines the sub-register number according to the specified encoding for the given architecture register. RegNum and SubRegNum together provide the byte-aligned address for the origin of a GRF register region. RegNum provides bits 12:5 of that address. For one-source and two-source instructions, SubregNum provides bits 4:0. For three-source instructions, the address must be DWord-aligned; SubRegNum provides bits 4:2 of the address and bits 1:0 are zero. **Note:** The recommended instruction syntax uses subregister numbers within the GRF in units of actual data element size, corresponding to the data type used. For example for the F (Float) type, the assembler syntax uses subregister numbers 0 to 7, corresponding to subregister byte addresses of 0 to 28 in steps of 4, the element size. This field is present for the direct addressing mode and not present for indirect addressing. This field applies to both source and destination operands. Format = U5, if RegFile = GRF and the instruction has fewer than three source operands. 0x00 to 0x1F = Sub-Register number in the range of [0, 31]. Format = U3, if RegFile = GRF and the instruction has three source operands. 0x0 to 0x7 = Sub-Register number MSBs in the range of [0,7]. The two LSBs are zero. Format = U4, if RegFile = GRF and the instruction has three source operands. 0x0 to 0x15 = Sub-Register number MSBs in the range of [0,15]. Format = 5-bit encoding, if RegFile = ARF. See the ARF Registers Overview section and the sections for individual ARF registers for details.
VertStride	**Vertical Stride.** The vertical stride of a source operand's register region in units of data element size. Supported values are 0, powers of 2 from 1 to 32, and a special encoding used for indirect addressing in Align1 mode. Values greater than 32 are not supported due to the restriction that a source operand must reside within two adjacent 256-bit registers (64 bytes total). The special encoding 1111b (0xF) is only valid when the operand is in register-indirect addressing mode (AddrMode = 1). If this field is set to 0xF, one or more sub-registers of the address registers may be used to compute source addresses. Each address sub-register provides the origin for a row of data elements. The number of address sub-registers used is equal to instruction's ExecSize / source operand's Width. This field only applies to source operands. It does not apply to the destination. For Align16 access mode, only encodings of 0000b, 0010b, and 0011b are allowed. Other codes are reserved. Note 1: A Vertical Stride larger than 32 is not allowed due to the restriction that a source

Field	Description
	operand must reside within two adjacent 256-bit registers (64 bytes total). Note 2: In Align16 access mode, as encoding 1111b is reserved, only single-index indirect addressing is supported. Note 3: If indirect addressing is supported for src1, the encoding 1111b is reserved for src1 and only single-index indirect addressing is supported. Note 4: The encoding 0010b is used for 64-bit operands (types DF, Q, or UQ). 0000b = 0 Elements 0001b = 1 Element. Align1 mode only. 0010b = 2 Elements 0011b = 4 Elements 0100b = 8 Elements. Align1 mode only. 0101b = 16 Elements (applies to byte or word operands only). Align1 mode only. 0110b = 32 Elements (applies to byte operands only). Align1 mode only. 0111b-1110b = Reserved. 1111b = VxH or Vx1 mode (only valid for register-indirect addressing in Align1 mode).
Width	**Width.** The number of elements in the horizontal dimension of the region for a source operand. This field cannot exceed the ExecSize field of the instruction. This field only applies to source operands. It does not apply to the destination. 000b = 1 Element 001b = 2 Elements 010b = 4 Elements 011b = 8 Elements 100b = 16 Elements 101b-111b = Reserved Note that with ExecSize of 32, because the maximum Width is 16, there are at least two rows in a source region.

Native Instruction Layouts

This section describes the Execution Unit instruction formats.

DWord 0, bits 31:0 of the 128-bit instruction, has the same format regardless of the number of source operands.

The following three tables cover the most common instruction format, for instructions with 1 or 2 source operands; then the format for the few instructions with 3 source operands; and finally format variations used by a few specific instructions, including branching instructions.

Execution Unit Instruction Format for 1 or 2 Source Operands

Bits	Description	AddrMode and AccessMode Variations			
		AddrMode = Direct		AddrMode = Indirect	
		Align16	Align1	Align16	Align1
Any Imm32 32-bit or Imm64 64-bit immediate operand uses bits 127:96, replacing the following fields.					
127:122	Reserved				
121	Varies based on AddrMode	Reserved		Src1.AddrImm[9]	
120:117	Src1.VertStride				
116	Varies based on AccessMode	Reserved	Src1.Width	Reserved	Src1.Width
115:114		Src1.ChanSel[7:4]		Src1.ChanSel[7:4]	
113:112			Src1.HorzStride		Src1.HorzStride
111	Src1.AddrMode				
110:109	Src1.SrcMod				
108:105	Src1.SrcMod	Src1.RegNum		Src1.AddrSubRegNum	
104:101				Src1.AddrImm[8:4]	Src1.AddrImm[8:0]
100		Src1.SubRegNum[4]	Src1.SubRegNum[4:0]		
99:96		Src1.ChanSel[3:0]		Src1.ChanSel[3:0]	
Any Imm64 64-bit immediate operand uses bits 127:64, replacing the following fields.					
95	Varies based on AddrMode	Reserved		Src0.AddrImm[9]	
94:91	Src1.SrcType				
90:89	Src1.RegFile				
88:85	Src0.VertStride				
84	Varies based on AccessMode	Reserved	Src0.Width	Reserved	Src0.Width
83:82		Src0.ChanSel[7:4]		Src0.ChanSel[7:4]	
81:80			Src0.HorzStride		Src0.HorzStride
79	Src0.AddrMode				
78:77	Src0.SrcMod				
76:73	Varies based on AddrMode and AccessMode	Src0.RegNum		Src0.AddrSubRegNum	
72:69				Src0.AddrImm[8:4]	Src0.AddrImm[8:0]
68		Src0.SubRegNum[4]	Src0.SubRegNum[4:0]		
67:64		Src0.ChanSel[3:0]		Src0.ChanSel[3:0]	
63	Dst.AddrMode				

Bits	Description	AddrMode and AccessMode Variations			
		AddrMode = Direct		AddrMode = Indirect	
		Align16	Align1	Align16	Align1
62:61	Varies based on AccessMode	Reserved	Dst.HorzStride	Reserved	Dst.HorzStride
60:57	Varies based on AddrMode and AccessMode	Dst.RegNum		Dst.AddrSubRegNum	
56:53				Dst.AddrImm[8:4]	Dst.AddrImm[8:0]
52		Dst.SubRegNum[4]	Dst.SubRegNum[4:0]		
51:48		Dst.ChanEn[3:0]		Dst.ChanEn[3:0]	
47	Varies based on AddrMode	Reserved : MBZ		Dst.AddrImm[9]	
46:43	Src0.SrcType				
42:41	Src0.RegFile				
40:37	Dst.DstType				
36:35	Dst.RegFile				
34	MaskCtrl				
33:32	FlagRegNum / FlagSubRegNum				
31	Saturate				
29	CmptCtrl				
28	AccWrCtrl/BranchCtrl				
27:24	CondModifier				
23:21	ExecSize				
20	PredInv				
19:16	PredCtrl				
15:14	ThreadCtrl				
13:12	QtrCtrl				
11	NibCtrl				
10:9	DepCtrl				
8	AccessMode				
7	Reserved (for future Opcode expansion)				
6:0	Opcode				

The 3-source operand instructions are:

1. *bfe* - Bit Field Extract
2. *bfi2* - Bit Field Insert 2
3. *lrp* - Linear Interpolation
4. *mad* - Multiply Add
5. *madm* - Multiply Add for Macro

In the 3-source instruction format, the upper QWord contains three groups of 21 bits for the three source operands, where each group contains four fields in 20 bits and otherwise adjacent groups are separated by single reserved bits.

Specific instructions have different instruction formats as described below. These instructions include send / sendc, math, and branch instructions.

Execution Unit Instruction Format for Specific Instructions

The instruction fields Src0.VertStride, Src0.Width[1:0], Src0.ChanSel[7:4], Src0.HorzStride, Src0.ChanSel[3:0], Src0.AddrImm[3:0], Src1.SrcType and AccWrCtrl are not used for send/sendc/sends/sendsc instructions. Additionally for sends/sendsc instructions Src0.SrcMod, Dst.HorzStride, Dst.ChanEn, Dst.AddrImm[3:0] and Src0.SrcType are not used.

Src0.RegFile[1], Src1.RegFile[1] and Dst.RegFile[1] are implicitly set to 0, and Src0.RegFile[0] is implicitly set as 1 for sends/sendsc instructions. Also note, ExDesc[4] and ExDesc[16:9] are unused and not encoded below.

Bits	Regular 1 or 2 Source Operands Description	Empty white areas mean Same, use the regular description			
		send / sendc	sends / sendsc	math	Branch Instructions
127	Reserved	ExDesc[5] (EOT)			JIP[31:0]

EU Compact Instructions

On receiving an instruction with bit 29 (CmptCtrl) set, HW recognizes it as a 64-bit compact instruction. Hardware then uses the index fields inside the compact instruction to lookup values in the associated compaction tables, then uses the table outputs along with other fields in the compact instruction to reconstruct the 128-bit native-sized instruction.

Description
All flow control instructions use the new offset format, a signed 32-bit offset in units of bytes.

The native 128-bit instruction format provides access to all instruction options. Only some instruction options and combinations of instruction options can be represented in the compact instruction formats.

Which native instructions can be represented as compact instructions and the details of the compact instruction formats and the compaction tables used may change with each processor generation.

In the following instruction format tables the Mapping Bits and Mapping Description columns describe the mappings into native instruction fields.

Opcode Encoding

Byte 0 of the 128-bit instruction word contains the opcode. The opcode uses 7 bits. Bit location 7 in byte 0 is reserved for future opcode extension.

The opcodes are encoded and organized into five groups based on the type of operations: Special instructions, move/logic instructions (opcode=00xxxxxb), flow control instructions (opcode=010xxxxb), miscellaneous instructions (opcode=011xxxxb), parallel arithmetic instructions (opcode=100xxxxb), and vector arithmetic instructions (opcode=101xxxxb). Opcodes 110xxxb are reserved.

Note: Opcodes appear in the overall Instruction Set Summary Table as well. The following subsections still serve the purpose of describing various instruction groups.

Move and Logic Instructions

This instruction group has an opcode format of 00xxxxxb.

- The opcodes for move instructions (*mov*, *sel* and *movi*) share the common 5 MSBs in the form of 00000xxb.
- The opcodes for logic instructions (*not*, *and*, *or*, and *xor*) share the common 5 MSBs in the form of 00001xxb.
- The opcodes for shift instructions (*shr, shl,* ***asr***, **ror**, and **rol**) share the common 4 MSBs in the form of 0001xxxb.
- The opcodes for compare instructions (*cmp* and *cmpn*) share the common 6 MSBs in the form of 001000xb. Bit 0 indicates whether it is a normal compare, *cmp*, or a special compare-NaN, *cmpn*.

Move and Logic Instructions

Opcode		Instruction	Description	#src	#dst
dec	hex				
1	0x01	mov	Component-wise move	1	1
2	0x02	sel	Component-wise selective move based on predication	2	1
3	0x03	movi	Fast component-wise indexed move	1	1
4	0x04	not	Component-wise one's complement (bitwise not)	1	1
5	0x05	and	Component-wise logical AND (bitwise and)	2	1
6	0x06	or	Component-wise logical OR (bitwise or)	2	1
7	0x07	xor	Component-wise logical XOR (bitwise xor)	2	1
8	0x08	shr	Component-wise logical shift right	2	1
9	0x09	shl	Component-wise logical shift left	2	1
10	0x0A	smov	Scattered Move	1	1
11	0x0B	*Reserved*			
12	0x0C	asr	Component-wise arithmetic shift right	2	1
13	0x0D	*Reserved*			
16	0x10	cmp	Component-wise compare, store condition code in destination	2	1
17	0x11	cmpn	Component-wise compare-NaN, store condition code in destination	2	1
18	0x12	csel	Component-wise selective move based on result of compare	3	1
19	0x13	*Reserved*			
20	0x14	*Reserved*			
21	0x15	*Reserved*			
22	0x16	*Reserved*			
23	0x17	bfrev	Reverse bits	1	1
24	0x18	bfe	Bitfield extract	3	1
25	0x19	bfi1	Bitfield insert macro instruction 1, generate mask	2	1
26	0x1A	bfi2	Bitfield insert macro instruction 2, insert based on mask	3	1
27-31	0x1B-0x1F	*Reserved*			

Flow Control Instructions

This instruction group has an opcode format of 010xxxxb.

Flow Control Instructions

Opcode		Instruction	Description	#src	#dst
dec	hex				
32	0x20	jmpi	Jump indexed	1	0

Opcode		Instruction	Description	#src	#dst
dec	hex				
33	0x21	brd	Branch - Diverging	1	0
34	0x22	if	If	0/2	0
35	0x23	brc	Branch - Converging	1	-
36	0x24	else	Else	1	0
37	0x25	endif	End if	0	0
38	0x26	*Reserved*			
39	0x27	*Reserved*			
40	0x28	break	Break	1	0
41	0x29	cont	Continue	1	0
42	0x2A	halt	Halt	1	0
43	0x2B	calla	Subroutine call absolute	1	1
44	0x2C	call	Subroutine call	1	1
45	0x2D	return	Subroutine return	1	1
46	0x2E	goto	Goto	2	0
47	0x2F	join	Join	2	0

Miscellaneous Instructions

This instruction group has an opcode format of 011xxxxb.

Miscellaneous Instructions

Opcode		Instruction	Description	#src	#dst
dec	hex				
48	0x30	wait	Wait for (external) notification	1	0
49	0x31	send	Send	1	1
50	0x32	sendc	Conditional Send (based on TDR)	1	1
51	0x33	sends	Split Send	2	1
52	0x34	sendsc	Conditional Split Send (based on TDR)	2	1
53-55	0x35-0x37	*Reserved*			
56	0x38	math	Math functions for extended math pipeline	1/2	1/2
57-63	0x39-0x3F	*Reserved*			

Parallel Arithmetic Instructions

This instruction group has an opcode format of 100xxxxb.

Parallel Arithmetic Instructions

Opcode		Instruction	Description	#src	#dst
dec	hex				
64	0x40	add	Component-wise addition	2	1
65	0x41	mul	Component-wise multiply	2	1
66	0x42	avg	Component-wise average of the two source operands	2	1
67	0x43	frc	Component-wise floating point truncate-to-minus-infinity fraction	1	1
68	0x44	rndu	Component-wise floating point rounding up (ceiling)	1	1
69	0x45	rndd	Component-wise floating point rounding down (floor)	1	1
70	0x46	rnde	Component-wise floating point rounding toward nearest even	1	1
71	0x47	rndz	Component-wise floating point rounding toward zero	1	1
72	0x48	mac	Component-wise multiply accumulate	2	1
73	0x49	mach	multiply accumulate high	2	1
74	0x4A	lzd	leading zero detection	1	1
75	0x4B	fbh	Find first 1 for UD from msb side, or first 1/0 for D.	1	1
76	0x4C	fbl	First first 1 for UD from lsb side	1	1
77	0x4D	cbit	Count bits set	1	1
78	0x4E	addc	Integer add with carry	2	1 + acc.
79	0x4F	subb	integer subtract with borrow	2	1 + acc.

Vector Arithmetic Instructions

This instruction group has an opcode format of 101xxxxb.

Vector Arithmetic Instructions

Opcode		Instruction	Description	#src	#dst
dec	hex				
80	0x50	sad2	2-wide sum of absolute difference	2	1
81	0x51	sada2	2-wide sad accumulate	2	1
82-83	0x52-0x53	*Reserved*			
84	0x54	dp4	4-wide dot product for 4-vector	2	1
85	0x55	dph	4-wide homogenous dot product for 4-vector	2	1
86	0x56	dp3	3-wide dot product for 4-vector	2	1
87	0x57	dp2	2-wide dot product for 4-vector	2	1
88	0x58	*Reserved*			
89	0x59	line	Component-wise line equation computation (a multiply-add)	2	1
90	0x5A	pln	Component-wise floating point plane equation computation (a	2	1

Opcode		Instruction	Description	#src	#dst
dec	hex				
			multiply-multiply-add)		
91	0x5B	fma(mad)	Component-wise floating point mad computation (a multiple-add)	3	1
92	0x5C	lrp	Component-wise floating point lrp computation (blend)	3	1
93	0x5D	***fmam(madm)***	Component-wise floating point fused multiply and add for macro operations.	3	1
94-95	0x5E-0x5F	*Reserved*			

Special Instructions

There are two special instructions, namely, *nop* (opcode = 0x7E) and *illegal* (opcode = 0x00).

- *Nop* instruction may be used for instruction padding in memory between two normal instructions to force alignment or to introduce instruction execution delay. Currently, there is no need for between-instruction padding.
- *Illegal* instruction may be used for instruction padding in memory outside the normal instruction sequence such as before or after the kernel program as well as between subroutines.
- *Nop* and *illegal* instructions do not have source operands or destination operand. Therefore, they do not implicitly update the accumulator register. They cannot be compressed.

Special Instructions

Opcode		Instruction	Description	#src	#dst
dec	hex				
0	0x00	illegal	Illegal instruction	0	0
96-125	0x60-0x7D	*Reserved*			
126	0x7E	nop	No-op	0	0
127	0x7F	*Reserved*			

Native Instruction BNF

The Backus-Naur Form (BNF) grammar identifies the assembly language syntax, which is native to the hardware. It does not include intelligent defaults, assembler pragmas, etc.

Register Files and Register Numbers

Note: The recommended instruction syntax uses subregister numbers within the GRF in units of actual data element size, corresponding to the data type used. For example for the F (Float) type, the assembler syntax uses subregister numbers 0 to 7, corresponding to subregister byte addresses of 0 to 28 in steps of 4, the element size.

Instruction Set Summary Tables

The columns in the following tables specify instruction mnemonics, hex opcodes, full names, instruction groups, processor generation (where blank means available for SNB+), the number of source operands, whether the instruction supports predication, any support for source modifiers, an indication of supported data types, whether the instruction supports saturation, and any support for conditional modifiers.

See the separate Accumulator Restrictions table for information about how instructions are allowed to use accumulators.

With a dozen columns in these tables, some terse notation is used, like IVB+ for IVB+ in the Project column. If the Project column is blank, an instruction is supported for SNB+, all generations implemented or designed so far, from Sandy Bridge forward.

N and Y indicate No (no support for a feature) and Yes (full support for a feature) respectively.

A SrcMod (source modifier) value of Y indicates that a numeric source modifier is allowed, optionally specifying abolute value, negation, or a forced negative value. The value N indicates no source modifier support.

SrcMod Information
A SrcMod value of ** indicates a logical source modifier is allowed, optionally inverting all source bits (a NOT operation).

In the Src Types and Dst Type columns, Int means any integer type and * means such an extensive list of types that you must refer to the detailed instruction description.

Byte (B, UB) and QWord (Q, UQ) integer types cannot be mixed in the same instruction.

Accumulator Restrictions

This section describes restrictions on accumulator access: general restrictions, restrictions for specific instructions, and how those specific restrictions vary for processor generations. See Accumulator Registers

for a description of the accumulator registers.

Accumulator registers can be accessed as explicit source or destination operands, as an implicit source value when specified for a particular instruction (*sada2* for example), and as an implicit destination when the AccWrEn instruction option is used.

These general rules apply to accumulator access:

1. Flow control, *send*, *sendc*, and *wait* instructions cannot use accumulators.

2. Instructions that use the accumulator as an implicit source value cannot specify an explicit accumulator source operand.
3. Instructions that specify an implicit accumulator destination (with AccWrEn) cannot specify an explicit accumulator destination operand.
4. An instruction with both an explicit accumulator source operand and an explicit accumulator destination operand must specify the same accumulator register as the source and the destination.

Description
5. Instructions with three source operands cannot use explicit accumulator operands. AccWrEn may be allowed for implicitly updating the accumulator.

These descriptions are frequently used in this table:

- No restrictions.
- No accumulator access, implicit or explicit.
- Source operands cannot be accumulators.
- Source modifier is not allowed if source is an accumulator.
- Accumulator is an implicit source and thus cannot be an explicit source operand.
- Accumulator cannot be destination, implicit or explicit.
- AccWrEn is required. The accumulator is an implicit destination and thus cannot be an explicit destination operand.

These minor cases occur occasionally in the table:

- Integer source operands cannot be accumulators.
- No explicit accumulator access because this is a three-source instruction. AccWrEn is allowed for implicitly updating the accumulator.
- An accumulator can be a source or destination operand but not both.

A few instructions use more than one of the listed restrictions.

Accumulator Restrictions

Instructions	Accumulator Restrictions
add	No restrictions.
addc	AccWrEn is required. The accumulator is an implicit destination and thus cannot be an explicit destination operand.
and	Source modifier is not allowed if source is an accumulator.
asr *avg*	No restrictions.
bfe	No accumulator access, implicit or explicit.

Instructions	Accumulator Restrictions
bfi1 *bfi2* *bfrev* *cbit*	
cmp	No restrictions.
cmpn	No restrictions.
csel	No restrictions.
dp2 *dp3* *dp4* *dph*	Source operands cannot be accumulators.
fbh *fbl*	No accumulator access, implicit or explicit.
frc	No restrictions.
line	Source operands cannot be accumulators.
lrp	No explicit accumulator access because this is a three-source instruction. AccWrEn is allowed for implicitly updating the accumulator.
lzd	No restrictions.
mac	Accumulator is an implicit source and thus cannot be an explicit source operand.
mach	Accumulator is an implicit source and thus cannot be an explicit source operand. AccWrEn is required. The accumulator is an implicit destination and thus cannot be an explicit destination operand.
madm	No explicit accumulator access because this is a three-source instruction. AccWrEn is allowed for implicitly updating the accumulator.
math	No accumulator access, implicit or explicit.
mov	An accumulator can be a source or destination operand but not both.
movi	Source operands cannot be accumulators.
mul	Integer source operands cannot be accumulators.
not *or*	Source modifier is not allowed if source is an accumulator.
pln	Source operands cannot be accumulators.
rndd	No restrictions.

Instructions	Accumulator Restrictions
rnde *rndu* *rndz*	
sad2 *sada2*	Source operands cannot be accumulators.
sel	No restrictions.
shl	Accumulator cannot be destination, implicit or explicit.
shr	No restrictions.
smov	No restrictions.
subb	AccWrEn is required. The accumulator is an implicit destination and thus cannot be an explicit destination operand.
xor	Source modifier is not allowed if source is an accumulator.

Instruction Set Reference

This chapter describes the functions of 3D Media GPGPU Execution Units, listed in alphabetical order according to assembly language mnemonic.

EUISA Instructions List

Conventions

This section describes conventions used in instruction reference pages.

For each instruction that has source or destination types, a table lists the allowed type combinations and may also indicate the processor generations that support certain combinations. A notation like *W indicates that UW and W are both allowed. Multiple types listed together mean that any combination (Cartesian product) of the listed types is allowed.

If a source operand is floating-point, all source operands must have the same floating-point data type.

The Q and UQ types cannot be mixed with the B or UB types, neither as different source types nor as source type and destination type.

Accumulator restrictions are described in the Accumulator Restrictions section and also appear in instruction descriptions.

Pseudo Code Format

Instructions are explained in the following pseudo-code format that resembles the GEN assembly instruction format.

```
[(pred)] opcode (exec_size) dst src0 [src1]
```

Square brackets "[ ]" indicate that a field is optional. Saturation modifiers and instruction options are omitted for simplicity.

General Macros and Definitions

INST_MIN_SIZE is defined as a constant of 8 bytes.

```
#define INST_MIN_SIZE  8  // Instruction minimum size in bytes (for the compact instruction format)
```

The floor function converts a floating point value to an integral floating point value. For a given floating point value, from its closest two integral float values, floor returns the one that is closer to negative infinity. For example, floor(1.3f) = 1.0f and floor(-1.3f) = -2.0f.

```
float floor(float g)
{
    return maximum(any integral float f: f <= g)
}
```

The Condition function takes the conditional signals {SN, ZR, OF, IN, NC} of result, generates a Boolean value according to a conditional evaluation controlled by the conditional modifier cmod, and returns the Boolean.

```
Bool Condition(result, cmod)
```

The ConditionNaN function takes the conditional signals {SN, ZR, OF, IN, NC, NS} of result, generates a Boolean value according to a conditional evaluation controlled by the conditional modifier cmod, and returns the Boolean. The only difference between Condition and ConditionNaN is that ConditionNaN uses the NS (NaN of the second source) signal.

```
Bool ConditionNaN(result, cmod)
```

The Jump function jumps the instruction sequence from the current instruction location by InstCount 8-byte units, where each 16-byte native instruction is two units and each 8-byte compact instruction is one unit. If InstCount is positive and greater than zero, is an unconditional jump forward. If InstCount is negative, is an unconditional jump backward. If InstCount is zero, IP stays on the current instruction in an infinite loop.

```
void Jump(int InstCount)
{
    IP = IP + (InstCount * INST_MIN_SIZE)
}
```

Evaluate Write Enable

The WrEn should be evaluated as below.

Note: MaskCtrl = NoMask (1) skips the check for PcIP[n] == ExIP before enabling a channel.

```
if ( MaskCtrl == 1 ) {
  for ( n = 0; n < exec_size; n++ ) {
    WrEn[n] = 1;
  }
}
else {
  for ( n = 0; n < exec_size; n++ ) {
    if ( PcIP[n] == ExIP ) {
      WrEn[n] = 1;
    }
    else {
      WrEn[n] = 0;
    }
  }
}

if ( PredCtrl != 0000b ) {
  for ( n = 0; n < exec_size; n++ ) {
    WrEn[n] = WrEn[n] & PMask[n];
  }
}

for ( n = exec_size; n < 32; n++ ) {
  WrEn[n] = 0;
}
```

Round Instructions

rndd - Round Down

rndu - Round Up

rnde - Round to Nearest or Even

rndz - Round to Zero

rndd – Round Down

Description:

The *rndd* instruction takes component-wise floating point downward rounding (to the integral float number closer to negative infinity) of src0 and storing the rounded integral float results in dst. This is commonly referred to as the floor() function.

Each result follows the rules in the following tables based on the floating-point mode.

Floating-Point Round Down in IEEE mode

src0	–inf	–finite	–denorm	–0	+0	+denorm	+finite	+inf	NaN
dst	–inf	-finite	^	–0	+0	+0	**	+inf	NaN
Notes:									
^	Note: {-1, -0} depending on the Single Precision Denorm Mode.								
**	Result may be {+finite, +0}.								

Floating-Point Round Down in ALT mode

src0	–fmax	–finite	–denorm	–0	+0	+denorm	+finite	+fmax	***
dst	–fmax	-finite	–0	–0	+0	+0	**	+fmax	
Notes:									
**	Result may be {+finite, +0}.								
***	Result is undefined if src0 is {–inf, +inf, NaN}.								

rnde – Round to Nearest or Even

Description:

The *rnde* instruction takes component-wise floating point round-to-even operation of src0 with results in two pieces – a downward rounded integral float results stored in dst and the round-to-even increments stored in the rounding increment bits. The round-to-even increment must be added to the results in dst to create the final round-to-even values to emulate the round-to-even operation, commonly known as the round() function. The final results are the one of the two integral float values that is nearer to the input values. If the neither possibility is nearer, the even alternative is chosen.

Each result follows the rules in the following tables based on the floating-point mode.

Floating-Point Round to Nearest or Even in IEEE mode

src0	–inf	–finite	–denorm	–0	+0	+denorm	+finite	+inf	NaN
dst	–inf	*	–0	–0	+0	+0	**	+inf	NaN
Notes:									
*	Result may be {–finite, –0}.								
**	Result may be {+finite, +0}.								

Floating-Point Round to Nearest or Even in ALT mode

src0	–fmax	–finite	–denorm	–0	+0	+denorm	+finite	+fmax	***
dst	–fmax	*	–0	–0	+0	+0	**	+fmax	
Notes:									
*	Result may be {–finite, –0}.								
**	Result may be {+finite, +0}.								
***	Result is undefined if src0 is {–inf, +inf, NaN}.								

rndu – Round Up

Description:

The *rndu* instruction takes component-wise floating point upward rounding (to the integral float number closer to positive infinity) of src0, commonly known as the ceiling() function.

Each result follows the rules in the following tables based on the floating-point mode.

Floating-Point Round Up in IEEE mode

src0	–inf	–finite	–denorm	–0	+0	+denorm	+finite	+inf	NaN
dst	–inf	*	–0	–0	+0	^	+finite	+inf	NaN
Notes:									
*	Result may be {–finite, –0}.								
^	Note: {+1, +0} depending on the Single Precision Denorm Mode.								

Floating-Point Round Up in ALT mode

src0	–fmax	–finite	–denorm	–0	+0	+denorm	+finite	+fmax	***
dst	–fmax	*	–0	–0	+0	+0	+finite	+fmax	
Notes:									
*	Result may be {–finite, –0}.								
***	Result is undefined if src0 is {–inf, +inf, NaN}.								

rndz – Round to Zero

Description:

The *rndz* instruction takes component-wise floating point round-to-zero operation of src0 with results in two pieces – a downward rounded integral float results stored in dst and the round-to-zero increments stored in the rounding increment bits. The round-to-zero increment must be added to the results in dst to create the final round-to-zero values to emulate the round-to-zero operation, commonly known as the truncate() function. The final results are the one of the two closest integral float values to the input values that is nearer to zero.

Floating-Point Round to Zero in IEEE mode

src0	–inf	–finite	–denorm	–0	+0	+denorm	+finite	+inf	NaN
dst	–inf	*	–0	–0	+0	+0	**	+inf	NaN
Notes:									
*	Result may be {–finite, –0}.								
**	Result may be {+finite, +0}.								

Floating-Point Round to Zero in ALT mode

src0	–fmax	–finite	–denorm	–0	+0	+denorm	+finite	+fmax	***
dst	–fmax	*	–0	–0	+0	+0	**	+fmax	
Notes:									
*	Result may be {–finite, –0}.								
**	Result may be {+finite, +0}.								
***	Result is undefined if src0 is {–inf, +inf, NaN}.								

math – Extended Math Function

Function
math - Extended Math Function

Description:

The *math* instruction performs extended math function on the components in src0, or src0 and src1, and write the output to the channels of dst. The type of extended math function are based on the FC[3:0] encoding in the table below.

Function Control[3:0]	Function Description
0h	Reserved
1h	INV (reciprocal)
2h	LOG
3h	EXP
4h	SQRT
5h	RSQ
6h	SIN
7h	COS
8h	Reserved
9h	FDIV
Ah	POW
Ch	INT DIV – return quotient only
Dh	INT DIV – return remainder
Eh	INVM
Fh	RSQRTM

INV - Inverse

Precision:1 ULP

Src->	+inf	+0 / +Denorm	- 0 / -Denorm	-inf	NaN
Dest – IEEE mode	+0	+inf	-inf	-0	NaN
Dest – ALT mode		+fmax	-fmax		NaN
Src->	+inf	+0	- 0	-inf	NaN
Dest – IEEE mode	+0	+inf	-inf	-0	NaN

LOG – Logarithm

Precision:

DirectX 10 and below

If src0 is [0.5..2], **absolute error** must be no more than 2-21. If src0 is (0..0.5) or (2..+INF], **relative error** must be no more than 2-21

Note: In ALT mode log is computed as Log_2 (abs (src0))

Src->	+inf	+0 / +Denorm	-0 / -Denorm	-inf	-F	NaN
Dest – IEEE mode	**+inf**	**-inf**	**-inf**	**NaN**	**NaN**	**NaN**
Dest – ALT mode		**-fmax**	**-fmax**		**+F**	**NaN**
Src->	+inf	+0	- 0	-inf	-F	NaN
Dest – IEEE mode	**+inf**	**-inf**	**-inf**	**NaN**	**NaN**	**NaN**

EXP - Exponent

Precision:

DirectX 10 Relative error <= 3 ULP

GPGPU – Relative error <= 4 ULP

Src->	+inf	+0 / +Denorm	-0 / -Denorm	-inf	-F	NaN
Dest – IEEE mode	**+inf**	**1**	**1**	**0**	**+F**	**NaN**
Dest – ALT mode		**1**	**1**		**+F**	**NaN**
Src->	+inf	+0	- 0	-inf	-F	NaN
Dest – IEEE mode	**+inf**	**1**	**1**	**0**	**+F**	**NaN**

SQRT - Square Root

Precision:

DirectX 10 (and below) Relative error <= 1 ULP

GPGPU – Relative error <= 4 ULP

Notes:In ALT mode SQRT is computed as SQRT(abs (src0))

Src->	+inf	+0 / +Denorm	-0 / -Denorm	-inf	-F	NaN
Dest – IEEE mode	**+inf**	**0**	**-0**	**NaN**	**NaN**	**NaN**
Dest – ALT mode		**0**	**0**		**+F**	**NaN**
Src->	+inf	**+0**	**-0**	-inf	**-F**	**NaN**
Dest – IEEE mode	+inf	**0**	**-0**	NaN	**NaN**	**NaN**

RSQ - Reciprocal Square Root

Precision:

DirectX 10 and below Relative error <= 3 ULP

GPGPU – Relative error <= 4 ULP

Notes:In ALT mode RSQ is computed as RSQ(abs (src0))

Src->	+inf	+0 / +Denorm	-0 / -Denorm	-inf	-F	NaN
Dest – IEEE mode	**+0**	**+inf**	**-inf**	**NaN**	**NaN**	**NaN**
Dest – ALT mode		**+fmax**	**+fmax**		**+F**	**NaN**
Src->	+inf	+0	-0	-inf	-F	NaN
Dest – IEEE mode	**+0**	**+inf**	**-inf**	**NaN**	**NaN**	**NaN**

POW - Power Function

Precision:

DirectX 10+ do not have precision requirements for POW.

Half_pow precision for GPGPU; i.e., 8192 ULPs with following exception

POWR, POWN is not supported in hardware.

IEEE Mode:

Src0->								
Src1	abs(F > 1)	abs(F < 1)	abs(+F = = 1)	+inf	+0 / +Denorm	-Denorm / -0	-inf	NaN
+inf	+inf	0	NaN	+inf	0	0	+inf	NaN
+0 / Denorm	1	1	1	NaN	NaN	NaN	NaN	NaN
-0 / Denorm	1	1	1	NaN	NaN	NaN	NaN	NaN
-inf	0	+inf	NaN	0	+inf	+inf	0	NaN
-F	+F	+F	+F	0	+inf	+inf	0	NaN
NaN	NaN	NaN	NaN	NaN	NaN	NaN	NaN	NaN
+F	+F			+inf	0	0	NaN	NaN

IEEE Mode:

Src0->								
Src1	abs(F > 1)	abs(F < 1)	abs(+F = = 1)	+inf	+0	-0	-inf	NaN
+inf	+inf	0	NaN	+inf	0	0	+inf	NaN
+0	1	1	1	NaN	NaN	NaN	NaN	NaN
-0	1	1	1	NaN	NaN	NaN	NaN	NaN
-inf	0	+inf	NaN	0	+inf	+inf	0	NaN
-F	+F	+F	+F	0	+inf	+inf	0	NaN
NaN	NaN	NaN	NaN	NaN	NaN	NaN	NaN	NaN
+F	+F			+inf	0	0	NaN	NaN

ALT Mode:

Src0->							
Src1	+F	+inf	+0 / +Denorm	-0 / -Denorm	-inf	-F	NaN
+inf							
+0 / Denorm	1		1	1		1	NaN
-0 / Denorm	1		1	1		1	NaN
-inf							
-F	+F		+fmax	+fmax		+F	NaN
NaN			NaN	NaN		NaN	NaN
+F	+F		0	0		+F	NaN

SIN - SINE

Precision:

DirectX 10 and below Absolute error <= 0.0008 for the range of +/- 32767* pi

Outside of the above range the function will remain periodic, producing values between -1 and 1. However, the period of SIN is determined by the internal representation of Pi, meaning that as the magnitude of input increases the absolute error will, in general, also increase.

Src->	+inf	+0 / +Denorm	-0 / -Denorm	-inf	-F	NaN
Dest – IEEE mode	NaN	+0	-0	NaN	-1 to 1	NaN
Dest – ALT mode		+0	-0		-1 to 1	NaN
Src->	+inf	+0	-0	-inf	-F	NaN
Dest – IEEE mode	NaN	+0	-0	NaN	-1 to 1	NaN

COS - COSINE

Precision:

DirectX 10 and below Absolute error <= 0.0008 for the range of +/- 32767* pi

Outside of the above range the function will remain periodic, producing values between -1 and 1. However, the period of COS is determined by the internal representation of Pi, meaning that as the magnitude of input increases the absolute error will, in general, also increase.

Src->	+inf	+0 / +Denorm	-0 / -Denorm	-inf	-F	NaN
Dest – IEEE mode	NaN	+0	-0	NaN	-1 to 1	NaN
Dest – ALT mode		+1	+1		-1 to 1	NaN
Src->	+inf	+0	-0	-inf	-F	NaN
Dest – IEEE mode	NaN	+0	-0	NaN	-1 to 1	NaN

INT DIV - Integer Divide

Precision:32-bit integer

For signed inputs, INT DIV behavior is illustrated by the table below:

Inputs:	**Numerator**	**+**	**+**	**-**	**-**
	Denominator	**+**	**-**	**+**	**-**
Outputs:	**Quotient**	**+**	**-**	**-**	**+**
	Remainder	**+**	**+**	**-**	**-**

INVM/RSQRTM

These are special opcodes. These two special opcodes INVM and RSQRTM provide the initial approximation for a macro that finally produces an IEEE compliant FDIV and SQRT respectively. They perform the same operation as INV and RSQRT. However, the outputs of these opcodes have higher precision, i.e., 34 bits for single precision and 66 bits for double precision. 32 bits and 64 bits, for single and double precision respectively are stored in the GRF and the remaining bits are stored in the special accumulators acc2-acc9. These operations provide the initial approximation for inverse and sqrt operations. The final IEEE compliant values are derived through a series of special fma operations. The pseudo code for these macro operations is defined below.

Programming Notes: The GRF registers and accumulators used in the macros below are merely examples. There are no restrictions on using these in any specific order as long as the GRF register and the accumulator are paired correctly in writes and reads. Since early out handling requires flow control to channels that do not require compute through the macro, Single Program Flow must never be set for a macro operation.

Macro for Single Precision IEEE Compliant fdiv

[*Note: Constants are in quotes.*]

```
Set Rounding Mode in CR to RNE
GRF are initialized: r2 = 0, r6 = a, r4 = b, r5 = 1
The default data type for the macro is :f

math.eo.f0.0 (8) r8.acc2 r6.noacc r4.noacc 0xE
(-f0.0) if
madm (8) r9.acc3 r2.noacc r6.noacc r8.acc2    // Step(1), q0=a*y0
madm (8) r10.acc4 r5.noacc -r4.noacc r8.acc2  // Step(2), e0=(1-b*y0)
madm (8) r1.acc5 r8.acc2 r10.acc4 r8.acc2     // Step(3), y1=y0+e0*y0
madm (8) r11.acc6 r6.noacc -r4.noacc r9.acc3  // Step(4), r0=a-b*q0
madm (8) r9.acc7 r9.acc3 r11.acc6 r1.acc5     // Step(5), q1=q0+r0*y1
madm (8) r6.acc8 r6.noacc -r4.noacc r9.acc7   // Step(6), r1=a-b*q1

Change Rounding Mode in CR if required
Implicit Accumulator for destination is NULL

madm (8) r8.noacc r9.acc7 r6.acc8 r1.acc5      // Step(7), q=q1+r1*y1
endif
```

Macro for Double Precision IEEE Compliant fdiv

```
Set Rounding Mode in CR to RNE
GRF are initialized: r0 = 0, r6 = a, r7 = b, r1 = 1
The default data type for the macro is :df

math.eo.f0.0 (4) r8.acc2 r6.noacc r7.noacc 0xE
```

```
(-f0.0) if
madm (4) r9.acc3 r0.noacc r6.noacc r8.acc2    // Step(1), q0=a*y0
madm (4) r10.acc4 r1.noacc -r7.noacc r8.acc2  // Step(2), e0=(1-b*y0)
madm (4) r11.acc5 r6.noacc -r7.noacc r9.acc3  // Step(3), r0=a-b*q0
madm (4) r12.acc6 r8.acc2 r10.acc4 r8.acc2    // Step(4), y1=y0+e0*y0
madm (4) r13.acc7 r1.noacc -r7.noacc r12.acc6 // Step(5), e1=(1-b*y1)
madm (4) r8.acc8 r8.acc2 r10.acc4 r12.acc6    // Step(6), y2=y0+e0*y1
madm (4) r9.acc9 r9.acc3 r11.acc5 r12.acc6    // Step(7), q1=q0+r0*y1
madm (4) r12.acc2 r12.acc6 r8.acc8 r13.acc7   // Step(8), y3=y1+e1*y2
madm (4) r11.acc3 r6.noacc -r7.noacc r9.acc9  // Step(9), r1=a-b*q1

Change Rounding Mode in CR if required
Implicit Accumulator for destination is NULL

madm (4) r8.noacc r9.acc9 r11.acc3 r12.acc2   // Step(10), q=q1+r1*y3
endif
```

Macro for Single Precision IEEE Compliant sqrt

```
Set Rounding Mode in CR to RNE
GRF are initialized: r0 = 0, r8 = 1/2, r6 = a
The default datatype for the macro is :f

math.eo.f0.0 (8) r7.acc2 r6.noacc null 0xF
(-f0.0) if
madm (8) r9.acc3 r0.noacc r8.noacc r7.acc2    // Step(1), H0=1/2*y0
madm (8) r11.acc4 r0.noacc r6.noacc r7.acc2   // Step(2), S0=a*y0
madm (8) r10.acc5 r8.noacc -r11.acc4 r9.acc3  // Step(3), d0=1/2-S0*H0
madm (8) r9.acc6 r9.acc3 r10.acc5 r9.acc3     // Step(4), H1=H0+d0*H0
madm (8) r7.acc7 r11.acc4 r10.acc5 r11.acc4   // Step(5), S1=S0+d0*S0
madm (8) r10.acc8 r6.noacc -r7.acc7 r7.acc7   // Step(6), e0=a-S1*S1

Change Rounding Mode in CR if required
Implicit Accumulator for destination is NULL

madm (8) r7.noacc r7.acc7 r9.acc6 r10.acc8    // Step(7), S=S1+e0*H1
endif
```

Macro for Double Precision IEEE Compliant sqrt

```
Set Rounding Mode in CR to RNE
GRF are initialized: r0 = 0, r8 = 1/2, r6 = a, r1 = 1
The default datatype for the macro is :df

math.eo.f0.0 (4) r7.acc2 r6.noacc null 0xF
(-f0.0) if
madm (4) r9.acc3 r0.noacc r8.noacc r7.acc2    // Step(1), H0=1/2*y0
madm (4) r11.acc4 r0.noacc r6.noacc r7.acc2   // Step(2), S0=a*y0
```

```
madm (4) r10.acc5 r8.noacc -r11.acc4 r9.acc3  // Step(3), d=1/2-S0*H0
madm (4) r8.acc6 r1.noacc r8.noacc r1.noacc   // Step(0'') 3/2=1+1/2
madm (4) r8.acc7 r1.noacc r8.acc6 r10.acc5    // Step(4), e=1+3/2*d
madm (4) r7.acc8 r0.noacc r10.acc5 r11.acc4   // Step(5), T0=d*S0
madm (4) r10.acc9 r0.noacc r10.acc5 r9.acc3   // Step(6), G0=d*H0
madm (4) r7.acc8 r11.acc4 r8.acc7 r7.acc8     // Step(7), S1=S0+e*T0
madm (4) r8.acc7 r9.acc3 r8.acc7 r10.acc9     // Step(8), H1=H0+e*G0
madm (4) r9.acc3 r6.noacc -r7.acc8 r7.acc8    // Step(9), d1=a-S1*S1

Change Rounding Mode in CR if required
Implicit Accumulator for destination is NULL

madm (4) r7.noacc r7.acc8 r9.acc3 r8.acc7  // Step(10), S=S1+d1*H1
endif
```

Restrictions for the Use of Macros

3. Macro Operations need to be used as special subroutines. Interleaving other operations is not recommended.
4. Single precision operations must be SIMD8 and double precision operations must be SIMD4.
5. The macro sequences should be used with the Rounding Mode in CR set to RNE. The Rounding Mode may be changed only for the last *madm* of the macro depending on the requirement.

Workaround
When both srcs are NAN, FDIV produces denorminator NAN as output.

Send Message

send - Send Message

The following information describes the send message.

Send Message

Opcode	Instruction	Description
49 (0x31)	send <dest> <src> <ex_desc> <desc>	Send a message stored in GRF starting at <src> to a shared function identified by <ex_desc> along with control from <desc> with a GRF writeback location at <dest>.

Pred	Sat	Cond Mod	Src Mod	Src Types	Dst Type
Y					[FLT] [INT]

Format:

```
[(pred)] send (exec_size) <dest> <src> <ex_desc> <desc>
```

Syntax:

Syntax
[(pred)] send (exec_size) reg greg imm32 reg32a [(pred)] send (exec_size) reg greg imm32 imm32

Pseudocode:

```
Evaluate(WrEn);
<MsgChEnable> = WrEn;
<SourceReg> = <src>.RegNum;
MessageEnqueue(<MsgChEnable>, <ResponseReg>, <SourceReg>, <ex_dest>,
<desc>);
```

Description:

The *send* instruction performs data communication between a thread and external function units, including shared functions (Sampler, Data Port Read, Data Port Write, URB, and Message Gateway) and some fixed functions (e.g. Thread Spawner, who also have an unique Shared Function ID). The *send* instruction adds an entry to the EU's message request queue. The request message is stored in a block of contiguous GRF registers. The response message, if present, will be returned to a block of contiguous GRF registers. The return GRF writes may be in any order depending on the external function units. <src> is the lead GRF register for request. <dest> is the lead GRF register for response. The message descriptor field <desc> contains the Message Length (the number of consecutive GRF registers) and the Response Length (the number of consecutive GRF registers). It also contains the header present bit, and the function control signals. The extend mesage descriptor field <ex_desc> contains the target function ID. WrEn is forwarded to the target function in the message sideband.

The extended message descriptor field <ex_desc> also contains the extended function control field to be sent to the Target Shared Function over message sideband.

The *send* instruction is the only way to terminate a thread. When the EOT (End of Thread) bit of <ex_desc> is set, it indicates the end of thread to the EU, the Thread Dispatcher and, in most cases, the parent fixed function.

Message descriptor field <desc> can be a 32-bit immediate, *imm32*, or a 32-bit scalar register, <reg32a>. GEN restricts that the 32-bit scalar register <reg32a> must be the leading dword of the address register. It should be in the form of a0.0<0;1,0>:ud. When <desc> is a register operand, only the lower 29 bits of <reg32a> are used.

Syntax
<ex_desc> is a 32-bit immediate, imm32. The lower 4bits of the <ex_desc> specifies the SFID for the message. The bit5 of the extended message descriptor, the EOT field, always comes from bit 127 of the instruction word. A thread must terminate with a send instruction with EOT turned on. The higher 16bits, bit31:16 specify the 16bit extended function control field. Interpretation of the extended function control signals is subject to the target external function.

<src> is a 256-bit aligned GRF register. It serves as the leading GRF register of the request.

The source dependency control, {NoSrcDepSet} is used to control the setting of source dependency for the source.

<dest> serves for two purposes: to provide the leading GRF register location for the response message if present, and to provide parameters to form the channel enable sideband signals.

<dest> signals whether there is a response to the message request. It can be either a null register, a direct-addressed GRF register or a register-indirect GRF register. Otherwise, hardware behavior is undefined.

If <dest> is null, there is no response to the request. Meanwhile, the Response Length field in <desc> must be 0. Certain types of message requests, such as memory write (store) through the Data Port, do not want response data from the function unit. If so, the posted destination operand can be null.

If <dest> is a GRF register, the register number is forwarded to the shared function. In this case, the target function unit must send one or more response message phases back to the requesting thread. The number of response message phases must match the Response Length field in <desc>, which of course cannot be zero. For some cases, it could be an empty return message. An empty return message is defined as a single phase message with all channel enables turned off.

The subregister number, horizontal stride, destination mask and type fields of <dest> are always valid and are used in part to generate on the WrEn. This is true even if <dest> is a null register (this is an exception for null as for most cases these fields are ignored by hardware).

The 16-bit channel enables of the message sideband are formed based on the WrEn. Interpretation of the channel enable sideband signals is subject to the target external function. In general for a 'send' instruction with return messages, they are used as the destination dword write mask for the GRF registers starting at <dest>. For a message that has multiple return phases, the same set of channel enable signals applies to all the return phases.

Thread managed memory coherency: A special usage of using non-null <dest> is to support write-commit signaling for memory write service by the Data Port Write unit. If <post_dest> is not null for a memory write request, the Data Port along with the Data Cache or Render Cache will wait until all the posted writes for the request have reached the coherent domain before sending back to the requesting thread an empty message to <dest> register. A memory write reaching the coherent domain, also referred to as reaching the global observable state, means that subsequent read to the same memory location, no matter which thread issues the read, must return the data of the write.

NoDDClr and NoDDChk must not be used for send instruction.

r127 must not be used for return address when there is a src and dest overlap in send instruction.

Message Descriptor Definition

Description
Reserved : MBZ
Data Format. This field specifies the width of data read from sampler or written to render target. Format = U1 0 – Single Precision (32b) 1 – Half Precision (16b)

Reserved : MBZ
Message Length. This field specifies the number of 256-bit GRF registers starting from <src> to be sent out on the request message payload. Valid value ranges from 1 to 15. A value of 0 is considered erroneous. Format = U4 Range = [1,15]
Response Length. This field indicates the number of 256-bit registers expected in the message response. The valid value ranges from 0 to 16. A value 0 indicates that the request message does not expect any response. The largest response supported is 16 GRF registers. Format = U5 Range = [0,16]
Header Present. If set, indicates that the message includes a header. Depending on the target shared function, this field may be restricted to either enabled or disabled. Refer to the specific shared function section for details. Format = Enable
Function Control This field is intended to control the target function unit. Refer to the section on the specific target function unit for details on the contents of this field.

Extended Message Descriptor Definition

Bit	Description
31:16	Extended Function Control. This field is intended to control the target function unit. Refer to the section on the specific target function unit for details on the contents of this field.
15:6	reserved
5	**End Of Thread** This field, if set, indicates that this is the final message of the thread and the thread's resources can be reclaimed.
4	reserved
3:0	**Target Function ID** This field indicates the function unit for which the message is intended. ***Refer to "GPU Overview" document for the mapping of Shared Function IDs***

Restrictions:

Software must obey the following rules in signaling the end of thread using the *send* instruction:

- The posted destination operand must be null.
- No acknowledgement is allowed for the *send* instruction that signifies the end of thread. This is to avoid deadlock as the EU is expecting to free up the terminated thread's resource.
- A thread must terminate with a *send* instruction with message to a shared function on the output message bus; therefore, it cannot terminate with a *send* instruction with message to the following shared functions: Sampler unit, NULL function. For example, a thread may terminate with a URB write message or a render cache write message.
- A root thread originated from the media (generic) pipeline must terminate with a *send* instruction with message to the Thread Spawner unit. A child thread should also terminate with a send to TS. Please refer to the Media Chapter for more detailed description.
- The *send* instruction can not update accumulator registers.
- Saturate is not supported for *send* instruction.
- ThreadCtrl are not supported for *send* instruction.
- The *send* with EOT should use register space R112-R127 for <src>. This is to enable loading of a new thread into the same slot while the message with EOT for current thread is pending dispatch.
- SEND should not use 64-bit datatype for src or dest register.
- When context save and restore of a thread is required, the registers r0-r4 must not be used as *dest or src* registers. This is required to provide a grf register space to save sr1.0 by the system interrupt routine in the event of a mid thread pre-emption.

Extended Message Descriptor Definition

Bits	Description
5	**End Of Thread**This field, if set, indicates that this is the final message of the thread and the thread's resources can be reclaimed.
4	reserved
3:0	**Target Function ID** This field indicates the function unit for which the message is intended. Refer to volume GPU Overview for GPE Function IDs.

EU Programming Guide

Assembler Pragmas

Declarations

A register or a register region can be declared as a symbol using the following form

.declare <symbol> **Base**=RegFile RegBase {.SubRegBase} **ElementSize**=ElementSize {**SrcRegion**=DefaultSrcRegion} {**DstRegion**=DefaultDstRegion} {**Type**=DefaultType}

The register file, the base of the register origin and the element size (in unit of bytes) are the mandatory parameters for a declared register region. Optionally, the base of the sub-register address, the default source region, the default destination region and the default type can be provided in the declaration for the symbol.

For immediate register addressing mode, the declared symbol can be used in the following Cartesian form

<symbol>(RegOff, SubRegOff)<=RegNum = *RegBase*+ **RegOff***;* SubRegNum = *SubRegBase*+ **SubRegOff**

or in the following simplified row-aligned form

<symbol>(RegOff)<=RegNum = *RegBase*+ **RegOff;** SubRegNum = *SubRegBase*

For register-indirect-register-addressing mode, the declared symbol can be used to provide immediate address term in the following Cartesian form

<symbol>[IdxReg, RegOff, SubRegOff]<= RegNum (byte-aligned) = [**IdxReg]**+(*RegBase*+ **RegOff**)*32 + (*SubRegBase* + **SubRegOff**)**ElementSize*

or in the following simplified row-aligned form

<symbol>[IdxReg, RegOff]<= RegNum (byte-aligned) = [**IdxReg]**+(*RegBase*+ **RegOff**)*32

or in the form without the immediate address term

<symbol>[IdxReg]<= RegNum (byte-aligned) = [**IdxReg]**+ *RegBase*

Defaults and Defines

The default execution size is set according to the destination register type as the following

Destination Register Type	Default Execution Size
UB | B	(16)
UW | W	(16)
F | UD | D	(8)

The default execution size can be overwritten globally for all instructions using

.**default_execution_size***(Execution_Size)*

or be set according the **destination** register type using

.**default_execution_size**_*Type(Execution_Size)*

The default register type can be set for all register files using

.**default_register_type***Type*

or be set per register file using

.**default_register_type**_*RegFileType*

The default **source** register region for all symbols can be set using

.**default_source_register_region***<VirtStride; Width, HorzStride>*

or be set per register type using

.**default_source_register_region**_*type<VirtStride; Width, HorzStride>*

The default **destination** register region for all symbols can be set using

.**default_destination_register_region***< HorzStride>*

or be set per register type using

.**default_destination_register_region**_*type< HorzStride>*

Finally, the precompiler supports the string replacement statement of .define in the following form

.**define**<symbol>Expression

Programming Note	
Context:	Defaults and Defines
• **.declare** does not support nesting. In other words, each symbol in .declare must be self defined. This would allow the pre-processor to expand all symbols in one pass. • **.define** does support nesting. Only string substitution is supported (currently). • White space within square, angle and round brackets are allowed for easy source code alignment.	

Example Pragma Usages

Example: Declaration for 8x4=32-Byte Regions:

The following symbol Block can be used to address any 8x4 byte region within the Cartisian system of a 16x8 byte GRF register area starting from r0.

Declaration

```
// 32x4 Byte Array.declare BlockBase=r0 ElementSize=1 Region=<32;8,1>Type=b
```

Fully-Expressed Instr

```
mov(32)?:br0.16<32;8,1>:b// r0 xxxxxxxxxxxxxxxxoooooooooxxxxxxxx// r1
xxxxxxxxxxxxxxxxoooooooooxxxxxxxx// r2 xxxxxxxxxxxxxxxxoooooooooxxxxxxxx// r3
xxxxxxxxxxxxxxxxoooooooooxxxxxxxx
```

Short-handed Instr

Mov?:bBlock(0,16)// (0,16): RegNum=0, SubRegNum=16

Example: Declaration for 8x1 Float Regions:

The following symbol *Trans* can be used to address any 8x1 float region within the Cartisian system of a 8x4 float GRF register area starting from r5.

Declaration

```
// 8x4 float Array starting at r5.declare Trans Base=r5 ElementSize=4 Region=<0;8,1> Type=f
```

Fully-Expressed Instr

```
mov(8)?:fr6.0<0;8,1>:f// 2nd 16x1 Row of Trans. Matrix // r5 FFFFFFFF// r6 OOOOOOOO// r7
FFFFFFFF// r8 FFFFFFFF
```

Short-handed Instr

mov?:fTrans(1) // RegNum = 5+1 = 6

Example: Declaration for 8x1 Float Regions with 1x1 Indirect Addressing:

Trans region defined (same as in the previous example) is used in conjunction with the address register.

Declaration

```
//8x4 float data array and 16x1 word address array.declare TransBase=r5 ElementSize=4
Region=<0;8,1> Type=f
```

Fully-Expressed Instr

mov(8)?:fr[a0.0,224]<0;8,1>:f

Short-handed Instr

mov?:fTrans[a0.0,2] // [a0.0 + 5*32 + 2*32]

Example: Declaration with VxH Indirect Addressing:

The VxH register-indirect-register-addressing for Trans can be provided in the following short-hand form

Declaration

```
//8x4 float data array and word indices.declare TransBase=r5 ElementSize=4 Region=<0;8,1>
Type=f
```

Fully-Expressed Instr

mov(8)?:fr[a0.0,224]<1,0>:f

Short-handed Instr

mov?:fTrans[a0.0,2]<1,0> // [a0.0+224] [a0.1+224] ... [a0.7+224]

Example: Declaration with Vx1 Indirect Addressing:

```
As width (4) is smaller than the execution region size (8), multiple indexed registers are
used.
```

Declaration

```
//8x4 float data array and word address array.declare TransBase=r5 ElementSize=4
Region=<0;8,1> Type=f
```

Fully-Expressed Instr

mov(8)?:fr[a0.0,244]<4,1>:f

Short-handed Instr

```
mov?:fTrans[a0.0,2]<4,1>// [a0.0+224] [a0.1+224]
```

Assembly Programming Guideline

The following program skeleton illustrates the basic structure of a typical assembly program.

```
                          // single line comment

 /*          block comment
 */

 <preproc_directive>             // macros, include, etc.  Are global – handled by the pre-
processor
 <preproc_directive>             // applies to all code that follows in sequence

 // ------------ some kernel
 .kernel <kernel_name_string>    // [REQUIRED]

 // ------- Register requirements --------
 .reg_count_total    <uint>      // [REQUIRED] a more direct way to specify the parameters
required
 .reg_count_payload  <uint>      // [REQUIRED] rather than indirectly adding the
                          // the payload and temps together to get the total (as is the case
now)
                          // Note: no more "reg-count-temp"

 // -------------- Defaults ---------------
 <default…>               // these should be specified per-kernel and have only kernel-scope
 <default…>               // Same defaults as those already defined in the ISA doc, but just
 <default…>               // moved within the kernel to make each kernel completely self-
sufficient
                          // and not impacted defaults of earlier kernels

 // --------- Memory Requirements ---------
 // [optional] memory block info (just a placeholder for now...)

 <MBDa>                   // memory block descriptor a (TBD)
 <MBDb>                   // memory block descriptor b (TBD)
 <MBDc>                   // memory block descriptor c (TBD)
 <MBDd>                   // memory block descriptor d (TBD)

 // ---------------- Code  ----------------
 .code                           // [REQUIRED]
   <instruction>
   <instruction>
   <instruction>
 <LabelLine>                     // labels are code-block scope
   <instruction>
```

```
  <instruction>
.end_code                  // [REQUIRED]

.end_kernel                        // [REQUIRED]

// --------- next kernel -------------

// --------- next kernel -------------

// ...
```

Usage Examples

This topic is currently under development.

Vector Immediate

The immediate form of vector allows a constant vector to be in-lined in the instruction stream. An immediate vector is denoted by type v as *imm32:v*, where the 32-bit immediate field is partitioned into 8 4-bit subfields. Each 4-bit subfield contains a signed integer value. Therefore each 4-bit subfield has a range of [-8, +7]. This is depicted in the following figure.

31 28	27 24	23 20	19 16	15 12	11 8	7 4	3 0
V7	V6	V5	V4	V3	V2	V1	V0

Supporting DirectX 10 Pixel Shader Indexing

When a DirectX 10 Pixel Shader program is converted to run on GEN in channel-serial mode at 16 pixels in parallel, the per-pixel index must be translated into 16 indices with per channel offset. The creation of the per-channel offset can be achieved using the vector immediate.

Consider a generic DirectX 10 Pixel Shader instruction in the form of

opr4r[ind]r2

and assume that r0-r1 contain the 16 indices packed every other words, and r2-r3 contains source 1 and r4-r5 contain the destination. This instruction can be converted into the following GEN instructions. The corresponding operations are illustrated in *Supporting DirectX 10 Pixel Shader Indexing*.

mov (16) r11.0<1>:w 0x01234567:v// assigning a ramp vector, repeated once

mul (16)acc0:wr11.0<0;16,1>:w4:w// expand ramp range to 4 bytes per step

mac (16)r10.0<1>:wr0.0<16;8,2>:w32:w// r10 = index*32 + 0|4|...|28|0|4...|28

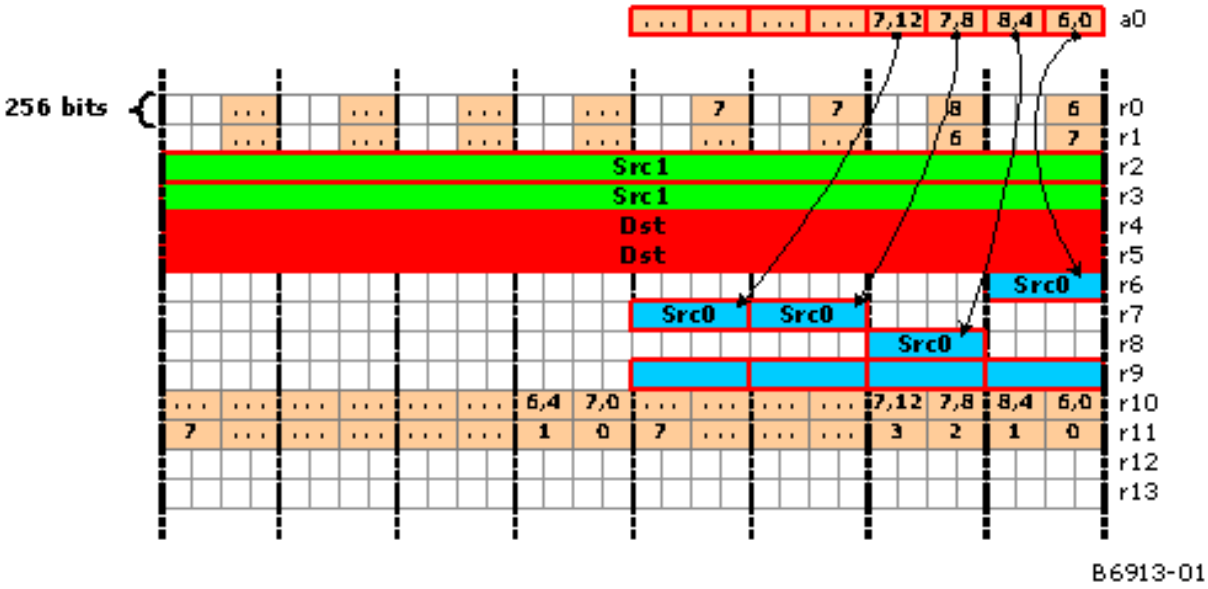
mov (8)a0.0<1>:wr10.0<0;8,1>:w

op (8)r4.0<1>:fr[a0.0]<1,0>:fr2.0<0;8,1>:w// Operate on the first half

mov (8)a0.0<1>:wr10.8<0;8,1>:w// Index values are off by a reg (32b)

op (8)r5.0<1>:fr[a0.0+32]<1,0>:fr3.0<0;8,1>:w// Operate on the second half.

Pixel Shader example using vector immediate.



Without vector immediate support, such translation has to either use a long sequence of scalar instructions which is very inefficient or use a constant load which requires additional constant to be managed in memory.

Supporting OpenGL Vertex Shader Instruction SWZ

When an OpenGL Vertex Shader program is converted to run on GEN in Vertex Pair, i.e. two 4-wide vectors in parallel, the special OpenGL Shader instruction SWZ (Swizzle) needs to be emulated. OpenGL SWZ instruction uses an extended swizzle control field that, in addition to the 4-wide full swizzle control, also includes constant 0 and 1 replacement as well as per channel sign reversal. The later two are not supported by the GEN native instruction. The vector immediate can significantly reduce the overhead of emulating such OpenGL instruction.

Consider an OpenGL Shader instruction in the form of

```
SWZ r1 r0.0-zx-1 // Expected results: r1.x = 0; r1.y = -r0.z; r1.z = r0.x; r1.w = -1
```

It can be emulated by the following three GEN instructions.

```
mul (8) r1.0<1>:f r0.xzxz 0x1F111F11:v // Constant vector of (1 -1 1 1 1 -1 1 1)
mov (1)f0.0 8b'10011001                // Set flag & masked out channels y and z
(f0.0)mov(8) r1.0<1>:f 0x000F000F:v    // Constant vector of (0 0 0 -1 0 0 0 -1)
```

In case that only 0, 1, -1 channel replacement is used and there is no signed swizzle, it may be emulated in two GEN instructions. This is illustrated by the following example:

OpenGL:

```
SWZ r1 r0.0zx-1 // Expected results: r1.x = 0; r1.y = r0.z; r1.z = r0.x; r1.w = -1
```

GEN:

```
mov (1)f0.0 8b'01100110                     // Set flag and masked out channels x and w
(f0.0)sel (8) r1.0<1>:f r0.yzxy 0x000F000F:v // Constant vector of (0 0 0 -1 0 0 0 -1)
```

Destination Mask for DP4 and Destination Dependency Control

The following example demonstrates the use of destination mask mode of floating point dot-product instruction as well as the use of destination dependency control to improve performance (i.e., avoiding unnecessary thread switch due to possible false dependencies).

Consider a generic DirectX 10 Vertex Shader macro of matrix-vector product that is implemented on GEN in the pair of 4-component vector mode. The DirectX 10 equivalent Shader instructions are as the following.

dp4 r5.x r0 r4

dp4 r5.y r1 r4

dp4 r5.z r2 r4

dp4 r5.w r3 r4

With destination dependency control, the GEN instructions are as the following. The first instruction in the sequence checks for the destination dependency, but does not clear the dependency bit. The subsequent two instructions would do neither of them. The last instruction avoids checking the destination dependency, but at completion, it clears the destination scoreboard. It ensures that the content of the destination register is coherent, if any of the following instructions uses the same register as source.

dp4 (8) r5.0<1>.x:f r0.0<4;4,1>:f r4.0<4;4,1>:f {NoDDClr}

dp4 (8) r5.0<1>.y:f r1.0<4;4,1>:f r4.0<4;4,1>:f {NoDDClr, NoDDCChk}

dp4 (8) r5.0<1>.z:f r2.0<4;4,1>:f r4.0<4;4,1>:f {NoDDClr, NoDDCChk}

dp4 (8) r5.0<1>.w:f r3.0<4;4,1>:f r4.0<4;4,1>:f {NoDDChk}

Just as a comparison, IF GEN DP4 implies reduction at the destination; additional shifted moves are required to achieve the same results. The corresponding codes are as the following. The lower performance due to the additional three move instruction as well as added back-to-back dependencies shows that why we choose to implement the destination channel replication for floating point DP4.

dp4 (8) r5.0<1>.y:f r1.0<4;4,1>:f r4.0<4;4,1>:f

mov (1) r5.1<1>:f r8.0<1;1,1>:f

dp4 (8) r5.0<1>.z:f r2.0<4;4,1>:f r4.0<4;4,1>:f

mov (1) r5.2<1>:f r8.0<1;1,1>:f

dp4 (8) r5.0<1>.w:f r3.0<4;4,1>:f r4.0<4;4,1>:f

mov (1) r5.3<1>:f r8.0<1;1,1>:f

dp4 (8) r5.0<1>.x:f r0.0<4;4,1>:f r4.0<4;4,1>:f

Null Register as the Destination

Null register can be used as the destination for most of the instructions. Here are some example usages.

- Null as destination for regular ALU instructions: As all ALU instructions can be configured to update the flag registers using the conditional modifiers, it is not necessary to have a destination register if the programmer only cares about the conditionals of the operation. In that case, a null in the destination operand field saves register space as well as one less dependency checking.
- Null as the destination for SEND/STOR instructions: for the send instruction that only send messages out to an external unit and does not require any return data or feedback, a null in the destination register field signifies the case.
    - One extension of such case is that even though the operation does not have any return values, a return phase with no payload but simply updating the scoreboard flag for a non-null register can provide a signaling mechanism between the thread and the target external unit. One application of this usage is to allow software to manage the coherency of shared memory resources such like the many caches in the system (particularly, valuable for read/write caches).

Use of LINE Instruction

LINE instruction is specifically designed to speed up floating point vector/matrix computation when a program operates in channel serial.

The following example demonstrates how to use LINE instruction to compute Line Equations for DirectX 10 Pixel Shader. In this example, 2 sets of (Cx#, Cy#, Don't Care, C0#) 4-tuple coefficient vectors are stored in registers R1.

R1: Cx0 Cy0 DC Co0 Cx1 Cy1 DC Co1

8 sets of coordinate 2-D vectors (X, Y) are stored in R2 and R3 in the channel serial mode as

R2: X0 X1 … X7

R3: Y0 Y1 … Y7

The objective is to compute the following two line equations for each set of 2D coordinate and store the results in R4 and R5 as

R4: (X0*Cx0 + Y0*Cy0+Co0) … (X7*Cx0 + Y7*Cy0+Co0)

R5: (X0*Cx1 + Y0*Cy1+Co1) … (X7*Cx1 + Y7*Cy1+Co1)

Example LINE Equations

```
//-------------
// Example compute LINE equation in channel serial scenario
//-------------
line (8) acc:f  r1<0;1,0>:f  r2<0;8,1>:f// does acc = X# * Cx0 + Co0
```

mac (8) r4<1>:f r1.1<0;1,0>:f r3<0;8,1>:f// does r4.# = Y# * Cy0 + acc.#

line (8) acc:f r1<0;1,0>:f r2<0;8,1>:f// does acc = X# * Cx0 + Co0

mac (8) r4<1>:f r1.1<0;1,0>:f r3<0;8,1>:f// does r4.# = Y# * Cy0 + acc.#

The next example is to compute homogeneous dot product for OpenGL pixel shader running in Channel Serial. In this example, an original OpenGL PS instruction is like

dph R2.x R0 R1

With register remapping, we can store the input coefficient vector R0 in original format in r0, but 8 sets of input coordinate vectors in channel serial format in r2, r3, r4 and r5, and the destination R2.x component in r6.

r0: Cx0 Cy0 Cz0 Co0 DC DC DC DC

r2: X0 X1 … X7

r3: Y0 Y1 … Y7

r4: Z0 Z1 … Z7

r5: W0 W1 … W7

The objective is to compute the following DPH equations and store the results in r6 as

R6: (X0*Cx0+Y0*Cy0+Z0*Cz0+Co0) … (X7*Cx0+Y7*Cy0+Z7*Cz0+Co0)

Example Homogeneous Dot Product in Channel Serial

//-------------

// Example compute homogeneous dot product in channel serial scenario

//-------------

line (8) acc:f r0<0;1,0>:f r2<0;8,1>:f// does acc = X# * Cx0 + Co0

mac (8) acc:f r0.1<0;1,0>:f r3<0;8,1>:f// does acc.# = Y# * Cy0 + acc.#

mac (8) r6<1>:f r0.2<0;1,0>:f r4<0;8,1>:f// does r6.# = Z# * Cz0 + acc.#

Mask for SEND Instruction

Execution mask (upto 16 bits) for the SEND instruction is transferred to the Shared Function. This provides optimized implementation of DirectX Shader instructions.

Channel Enables for Extended Math Unit

The following example demonstrates how to use the SEND instruction to get service from the Extended Math unit.

Let's consider COS instruction in DirectX 10 in the following form

[([!]p0.{select|any|all})] cos[_sat] dest[.mask], [-]src0[_abs][.swizzle]

For a SIMD4x2 VS implementation with the following register mappings

p0 =>f0.0

src0 =>r0

dest =>r1

The equivalent GEN instruction is as the following

[([!]f0.0.{select|any4h|all4h})] SEND (8) r1[.mask]:f m0 [-][(abs)]r0[.swizzle]:f MATHBOX|COS[|SAT]

If the source swizzle is replication, the message description field can be modified to MATHBOX|COS|SCALAR to take advantage of the fast mode (scalar mode) supported by the Extended Math. The implied move of the SEND instruction is equivalent to the following instruction:

MOV (8) m0[.mask]:f [-][(abs)]r0.0[.swizzle]:f {NoMask}

For a SIMD16 PS implementation, the register mappings are as the followings

p0 =>f0…f3 // in order of R, G, B, A

src0 =>r0,r1; r2,r3; r4,r5; r6,r7

dest =>r8,r9; r10,r11; r12,r13; r14,r15

There are several ways to translate the DirectX instruction, depending on the operand/instruction modifiers present in the DirectX instruction. If predicate is not present and the source swizzle is replication, say, src0.y, which is r2-r3, the translation could be as the following instructions

send (8) r8:f m0 -(abs)r2:f MATHBOX|COS

send (8) r9:f m1 -(abs)r3:f MATHBOX|COS {SecHalf}// use the second half of 8 flag bits

mov (16) r10:fr8:f // All destination color chan's are same

mov (16) r12:fr8:f // MOV is faster than most MathBox func's

mov (16) r14:fr8:f // These MOV's are compressed instructions

Notice that instead of issuing Extended Math messages with the same input data, destination color channel replication is performed by the MOV instructions. This is faster for the thread for most cases as many Extended Math functions consume multiple cycles. This also conserves message bus bandwidth as well as the usage of the shared resource – Extended Math. The destination mask in the DirectX 10 instruction indicates which of the r8 to r15 registers are updated. If the source swizzle is not replication, there will be 8 SEND instructions.

With predication on, if the predication modifier is p0.select, translation is to take the selected flag register f#. The other predication modifiers '.any' and '.all' are translated into '.any4v' and '.all4v', respectively. Notice that with predication on, it is not required to run all 4 pixels in a subspan in the same way, so no need to enforce .any4h/.any4v. The following example shows the instruction with predication (but without .select modifier).

(f0[.any4v|.all4v]) send (8) r8:f m0 -(abs)r2:f MATHBOX|COS

(f0[.any4v|.all4v]) send (8) r9:f m1 -(abs)r3:f MATHBOX|COS {SecHalf}

(f1[.any4v|.all4v]) mov (16) r10:fr8:f // All destination color chan's are same

(f2[.any4v|.all4v]) mov (16) r12:fr8:f // MOV is faster than most MathBox func's

(f3[.any4v|.all4v]) mov (16) r14:fr8:f // These MOV's are compressed instructions

The same instructions works also for predication with select component modifier. We simply replase f0 to f3 above by the selected flag register, say, f1. The modifier of any4h/all4v would also work.

Channel Enables for Scratch Memory

The following example demonstrates how to use the SEND instruction to get service from the Data Port for scratch memory access.

Let's consider general instruction in DirectX 10 that uses scratch memory as a source operand

[([!]p0.{select|any|all})] add dest[.mask], [-]src0[_abs][.swizzle], [-]src1[_abs][.swizzle]

For a SIMD4x2 VS implementation with the following register mappings

p0 =>f0

src0 =>r0

src1 =>s2 / r10

dest =>r1

In this example, the scratch memory offset is provided by an immediate and a GRF register r10 is used as the intermediate GRF location for spill/fill of scratch buffer accesses. This arithmetic instruction is converted into a Data Port read followed by an arithmetic instruction.

mov (8) r3:d r0:d {NoMask}// move scratch base address to be assembled with offset values

mov (1) r3.0:d 2*32 {NoMask}// s2 for vertex 0

mov (1) r3.1:d 2*32+16 {NoMask}// s2 for vertex 1

send (8) r10 m0 r3 DATAPORT|RC|READ_SIMD2

[([!]f0.{sel|any4h|all4h})] add (8) r1[.mask]:f [-][(abs)]r0[.swizzle]:f [-][(abs)]r10[.swizzle]:f

So if scratch register is the source, there is no need to use the channel enable side band. This is also true for channel-serial PS cases.

Now, let's consider the case when a scratch register is the destination of an instruction.

p0 =>f0

src0 =>r0

src1 =>r1

dest =>s2 / r10

We have

add (8) m1:f [-][(abs)]r0[.swizzle]:f [-][(abs)]r1[.swizzle]:f

mov (8) r3:d r0:d {NoMask}// move scratch base address to be assembled with offset values

mov (1) r3.0:d 2*32 {NoMask}// s2 for vertex 0

mov (1) r3.1:d 2*32+16 {NoMask}// s2 for vertex 1

```
[([!]f0.{sel|any4h|all4h})] send (8) null[.mask] m0 r3 DATAPORT|RC|WRITE_SIMD2
```

Notice that with a null as the posted destination register, we are able to transfer the [.mask] over the message channel enables. In many cases for scratch memory assess, a write-with-commit is required, therefore, the posted destination register could be r10.

Now, let's consider the PS case when a scratch register is the destination of an instruction.

p0 =>f0-f4

src0 =>r0-r7

src1 =>r8-r15

dest =>s16-s23 / r16-r23

When predication is not on (or predication with swizzle control on), we have

add (16) m4:f [-][(abs)]r0/2/4/6_BasedOnSwizzle:f [-][(abs)] r8/10/12/14_BasedOnSwizzle:f

add (16) m6:f [-][(abs)]r0/2/4/6_BasedOnSwizzle:f [-][(abs)] r8/10/12/14_BasedOnSwizzle:f

add (16) m8:f [-][(abs)]r0/2/4/6_BasedOnSwizzle:f [-][(abs)] r8/10/12/14_BasedOnSwizzle:f

add (16) m10:f [-][(abs)]r0/2/4/6_BasedOnSwizzle:f [-][(abs)] r8/10/12/14_BasedOnSwizzle:f

mov (8) r3:d 0x76543210:v {NoMask}// ramp function

mul (16) acc0:d r3:d 16 {NoMask}// ramp function

add (8) acc0:d acc0:d 64 {NoMask,SecHalf}// ramp function

add (16) m2:d acc0:d 2*256 {NoMask}// ramp function

```
send (16) null m1 r3 DATAPORT|RC|WRITE_SIMD16
```

As there is no bit left from the unit specified descriptor field, the 4 bit mask must be put into the header field in m1, which requires at least two more instructions.

Alternatively, or for the case that predication without modifier is on, we can do a read-modify-write.

mov (8) r3:d 0x76543210:v {NoMask}// ramp function

mul (16) acc0:d r3:d 16 {NoMask}// ramp function

add (8) acc0:d acc0:d 64 {NoMask,SecHalf}// ramp function

add (16) m2:d acc0:d 2*256 {NoMask}// ramp function

```
send (16) r16 m1 r3 DATAPORT|RC|READ_SIMD16 // read from scratch
```

// some of the following four instructions may be omitted based on [.mask] field

[([!]f0.{sel|any4v|all4v})] add (16) r16:f [-][(abs)]r0/2/4/6_BasedOnSwizzle:f [-][(abs)] r8/10/12/14_BasedOnSwizzle:f

[([!]f0.{sel|any4v|all4v})] add (16) r18:f [-][(abs)]r0/2/4/6_BasedOnSwizzle:f [-][(abs)] r8/10/12/14_BasedOnSwizzle:f

[([!]f0.{sel|any4v|all4v})] add (16) r20:f [-][(abs)]r0/2/4/6_BasedOnSwizzle:f [-][(abs)] r8/10/12/14_BasedOnSwizzle:f

[([!]f0.{sel|any4v|all4v})] add (16) r22:f [-][(abs)]r0/2/4/6_BasedOnSwizzle:f [-][(abs)] r8/10/12/14_BasedOnSwizzle:f

mov (16) m4:f r16:f {NoMask}

mov (16) m6:f r18:f {NoMask}

mov (16) m8:f r20:f {NoMask}

mov (16) m10:f r22:f {NoMask}

```
send (16) null m1 null DATAPORT|RC|WRITE_SIMD16 {NoMask}// write back to scratch
```

Flow Control Instructions

Unconditional branches are performed through direct manipulation of the 32-bit IP architectural register. For example:

```
mov (1) IP <memory_address>// jump absoluteadd (1) IP IP <byte_count>// jump relative
```

Note that jump distances are specified in terms of bytes, as opposed to instruction counts in the case of *break*, *halt*, etc. To minimize confusion, an assembler-only instruction 'jmp <inst_count>', where <inst_count> is an immediate term, may be defined which takes an instruction count for a distance. The *jmp* pseudo-opcode can be mapped to an "add (1) ip ip <inst_count> * 16" instruction.

IP is aligned to an 8-byte boundary, thus the 3 LSBs are not maintained in the IP architectural register and should not be relied upon by software.

IP, when used as a source operand, reflects the memory address of the instruction in which it is used. The following are examples illustrating the use of IP:

```
add (1) IP4*16// jumps to HERE_1
add (1) IP0x35// jumps to HERE_1 (4 lsb's don't-care)  <instruction>
 <instruction>

HERE_1:<instruction>HERE_2:<instruction>
 <instruction>
 add (1) IP -2*16// jumps to HERE_2 ...
 add (1) IP 0// infinite loopadd (1) IP 0xF// infinite loop ...
```

Note for Assembler: The if/iff/else/while/break instructions identify relative addresses as the targets of an implicit jump associated with the instruction. These are optional in the assembly syntax as the jitter can determine the location of the matching instruction (e.g. matching endif instruction for a given if instruction).

Execution Masking

This topic is currently under development.

Branching

Example. If / Else / EndIf

```
//-------------
// Example if/else/endif scenario
// "if (r5==r4) ...else ... end-if"
//-------------
...
cmp.e.f0 (8) null r5 r4// does r5 == r4?
(f0) if (8)  HERE_1// "if" part - save then update IMASK;
//   or goto the 'else' if all false
...
...
HERE_1:// now do the 'else' part
else (8) HERE_2// "else" part - invert IMASK
//   or goto the 'endif' if all false
...
...
HERE_2:
endif// "end-if" part – restore IMASK
....// and continue...
```

If it is known that the code has no nested conditionals, a predicate can be used for a lower overhead, more efficient if/else/endif. (One must consider the probability of all channels taking the same branch, and the number of instructions under the if/else blocks as to which conditional method, predicate or mask, is most efficient).

Fast-If

Below is an example of a fast-if instruction. For the 'iff' instruction, only and iff-endif construct is allowed, as opposed to a if-else-endif. Note that the target address for branching if all enabled channels fail is one instruction beyond the endif, as the 'iff' does not push and update the IMask unless the branch is taken for at least one execution channel.

Example Fast If

```
//-------------
// Example – Fast If
//One instruction overhead conditional
//-------------
...
cmp.e.f0 (8) null r5 r4// any flag update
...
(f0)iff (8) HERE_1// "fast-if" – only pushes IMask;
//   if execution falls through,
//   else go to HERE_1
...
...
endif// "end-if" part – restores IMask
HERE_1:
...// and continue...
```

Cascade Branching

As there is no 'elseif' instruction, a C-like cascade branching such as if / elseif / else / endif, can be realized using the basic building blocks of if / else / endif as shown in the following example. Notice that two 'endif's' are required in order to pop the IStack correctly.

Example. If / Elseif / Else / EndIf

```
//-------------
// Example if/elseif/else/endif scenario
// "if (r5==r4) ...elseif (r6>r7) else ... end-if"
//-------------
...
cmp.e.f0 (8) null r5 r4// does r5 == r4?
(f0)if (8) HERE_1// "if" part - save then update IMask;
//   or go to the 'else' part if all false
...
...
```

```
HERE_1:// now do the ‘else’ part
else (8) HERE_2// “else if” part - invert IMask
//   or go to the ‘else’ part if all false
cmp.g.f0 (8) null r6 r7// is r6 > r7?
(f0)if (8) HERE_3// “if” part - save then update IMask;
//   or go to the ‘else’ part if all false
...
...
HERE_3:// now do the ‘else’ part
else (8) HERE_4// “else” part - invert IMask
//   or go to the ‘end-if’ part if all false
...
...
HERE_4:
endif// “end-if” part – restore IMask for elseif
HERE_2:
endif// “end-if” part – restore IMask for if
....
```

Compound Branches

Compound branches are supported through the ability logically combine flag registers for each intermediate result.

Example Compound Branch

```
//-------------
// Example: “if (r0 > r1) OR (r2 <= r3)”
//-------------
...
cmp.g.f0 (8) null r0:d r1:d// r0 > r1?
cmp.le.f1 (8) null r2:d r3:d// r2 <= r3?
or (1) f0:w f0:w f1:w// combine f0 and f1
(f0) if (8) HERE_1// Can now do normal if/else
```

...

...

HERE_1:endif

...

Example Compound Branch Using 'Any' or 'All'

```
//-------------
// Example: assuming we're doing a channel-serial vector in r0-r3
// We want to know if all components of the vector are > 0x80
//-------------
...
cmp.g.f0 (16)  null r0 0x80// r0 > 0x80?
cmp.g.f1 (16)  null r1 0x80// r1 > 0x80?
cmp.g.f2 (16)  null r2 0x80// r0 > 0x80?
cmp.g.f3 (16)  null r3 0x80// r1 > 0x80?
(f0.all4v) if (16) HERE_1
...
...// code executed only for those channels
...// where per-channel r0,r1,r2,r3 all > 0x80
...
HERE_1:endif
...// and continue...
```

Looping

Due to GEN's SIMD-16 architecture, it must support the case of up to 16 loops running in parallel. These must be handled as independent loops, each with its own loop-exit condition which could occur after a different number of loop iterations. To account for each channel's progress, a 16b loop-mask 'LMask' is defined with 1b associated to each execution channel. This mask keeps track of which channels remain active inside a loop block.

Basic Do-While Loop

Looping illustrates the most basic loop. Two operations must be accomplished before loop entry. (1) Prior to loop entry, there is some subset of enabled channels as dictated by the code sequence prior. In general, the active status of each channel is indicated in the virtual EMask any point in time. These active channels will become the channels over which the loop is run, and LMask must be initialized with the

EMask value. (2) Since a given loop may be nested within another loop, the previous LMask & CMask must be saved to the LStack for later restoration upon loop completion. The 'msave' instruction performs both the save and update in a single instruction, and thus all loop-blocks should be fronted with a "msave LStack LMask" and "msave LStack CMask" operation.

Note that the LMask and CMask share the same mask-stack. Thus, CMask must always be a 1's-subset of the LMask for proper stack operation. This is the case if CMask is updated to LMask each pass through the loop (see *Looping*) and through the 'break' instruction updating both masks.

Each pass through the loop, a loop terminating operation must be evaluated and stored in a flag register. This condition must be evaluated on a channel-by-channel basis as exemplified:

cmp.z.f0(8) null r2 d3// any operation that updates a flag

The result of this operation sets a bit per channel in the specified flag register, which is then used in the 'while' instruction. As loops are performed, channels may become disabled as their termination condition is met.

'While' termination is determined on a channel-by-channel basis by the logical AND of corresponding bit positions of AMask, CMask and the specified flag. If the result is '1' the channel remains enabled for the next pass of the loop; if '0' the channel is disabled until loop fall-through. The 'while' instruction causes the LMask to be updated with the latest result of enabled channels. If any channel remains enabled (LMask != ...000b), an additional pass through the loop is made. Once a channel is terminated for the loop operation, it remains terminated until the loop is complete for all channels.

Upon fall through, the 'while' instruction causes the previously saved LMask & CMask to be popped from the LStack, enabling execution on the same subset of channels enabled prior to loop entry (unless a channel had been otherwise terminate inside the loop via 'halt').

Example Basic Loop Construct

```
//-----------------------
//Example: Basic do-while loop structure
//-----------------------
...
do// save L/CMask & update
BEGIN_LOOP:
mov (1) CMask LMask{NoMask}// update CMask for this pass
...
...
<some flag update>
()while (8) BEGIN_LOOP// cond. branch
//   + restores LMask on fall-through
```

...

Do-While Loop with Break

A loop may also be terminated for any channel via the 'break' instruction. The 'break' instruction causes the corresponding bit positions of enabled channels to be cleared in the LMask. If the updated LMask = ...000b, a branch is made to the specified instruction location. An example is shown below in which the 'break' is at the same conditional-nesting level as the terminating 'while'. Its primary value may simply be to support a "do...break.. while (true)" –type structure for a more direct 1:1 translation from higher-level source code.

Example Loop Construct With Non-Nested 'Break'

```
//-------
//Example: While-true loop
//-------
#define BrkCode(i,d)(i « 16) + d
do// save L/CMask & update
BEGIN_LOOP:
mov (1) CMask LMask{NoMask} // update CMask for this pass
...
<some flag update>
()break (8) BrkCode(0,HERE_1)// Restores LMask when all
// channels complete loop.
...
...
while (8) BEGIN_LOOP// while true
HERE_1:
...
```

A break condition may occur from various levels of nested-ifs. This gives rise to the possibility that a the loop may terminate from within nested 'if's, and due to the jump inherent in the 'break' instruction, the associated 'endif's are not encountered to clean-up the IStack as nesting levels are exited.

Example Loop Construct With 'Break' From Within Nested If's

```
//-------
//Example: General Loop Structure w/ break inside if's
//-------
```

```
#define BrkCode(i,d)(i « 16) + d
do// save L/CMask & update
BEGIN_LOOP:
mov (1) CMask LMask{NoMask} // update CMask for this pass
...
if ...
if ...
if ...
...
()break (8) BrkCode(3,HERE_1)// we're 3 levels deep, so
...
endif
endif
endif
...
()break (8) BrkCode(0,HERE_1)
...
while (8) <flag_spec> BEGIN_LOOP// cond. branch
// + restores C/LMask on fall-through
HERE_1:
```

Do-While Loop with Continue

A continue instruction 'cont' is provided skip to the next iteration of the loop. Because not all channels participating in the loop may be enabled at the time this instruction is executed, some channels may require continuation of the loop. A special mask 'CMask' is defined which accounts for channels temporarily disabled for the current loop pass.

Since loops may nested, the CMask must be saved and restored around a loop similar to LMask. Since the CMask value within a properly constructed loop is always a subset of the LMask, it can share the LStack for storage, so long as it is pushed after LMask as shown in *Looping*. This save/restore operations are not required if the loop being entered does not have any occurrence of a continue instruction.

Example Do-While with Continue

```
//-------
//Example: General Loop Structure w/ basic break and cont.
```

```
//-------
#define ContCode(i,d)(i « 16) + d
do// save L/CMask & update
BEGIN_LOOP:
mov (1) CMask EMask// re-initialize CMask for this pass
...
...
() cont (8) ContCode(0,HERE_1)
...
HERE_1:
()while (8) BEGIN_LOOP// cond. branch
//   + restores C/LMask on fall-through
...
```

Indexed Jump

Example Indexed Jump

```
//-------------
// Code example shows the use of jmpi to perform a case statement
// of any number of options in 3 jumps
//-------------
.default_execution_size 8
...
jmpi r0<0,1,0>// jump relative, based on r0.a.x
// ----- Jump Table ------
jmp HERE_0// redirect for case 0
jmp HERE_1// redirect for case 1
jmp HERE_2// redirect for case 2
jmp HERE_3// redirect for case 3
...
HERE_0:// ... case 0 ...
```

...

jmp DONE

HERE_1:// ... case 1 ...

...

VDBOX Registers

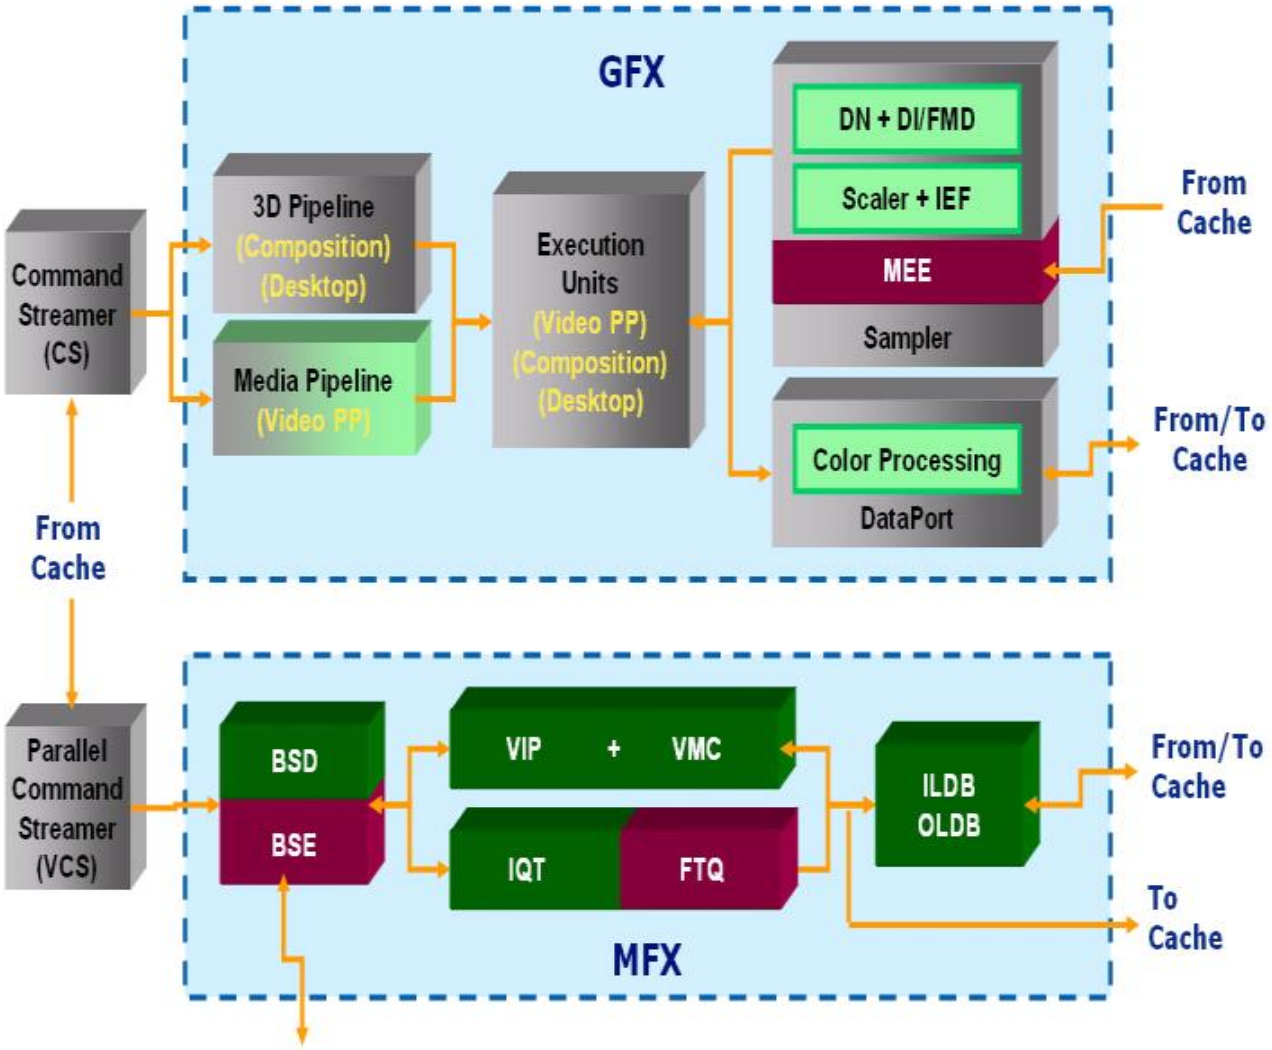
This section describes the VDBOX Command Memory Interface registers.

MFX Architecture

This section and the following sections of Media VDBOX contain the referential documentation on the Multi-Format Codecs, or MFX for those series of chips.

MFX Introduction

Multi-Format Codec (MFX) Engine is the hardware fixed function pipeline for decode and encoding. It includes multi-format decoding (MFD) and multi-format encoding (MFC).



MFC Overview

Multi-Format Codec (MFX) Engine is the hardware fixed function pipeline for decode and encoding. It includes multi-format decoding (MFD) and multi-format encoding (MFC).

Note: For Gen6, MFC only supports AVC (H.264).

Many decoding function blocks in MFD such as VIP, VMC, IQT, etc, are also used in encoding mode. Two blocks, FTQ and BSE, are encoding only.

The encoding process is partitioned across host software, the GPE engine, and the MFX engine. The generation of transport layer, sequence layer, picture layer, and slice header layer must be done in the host software. GP hardware is responsible for compressing from Slice Data Layer down to all macro-block and block layers. Specifically, GPE w/ VME acceleration is for motion vector estimation, motion estimation, and code decision.

MFC is operated concurrently with and independently from the GPE (3D/Media) pipeline with a separate command streamer. The two parallel engines have similar command protocol. They can be executed in parallel with different context. For encoding, motion search, MB mode decision, and rate control are performed using GPE pipeline resources.

MFC is implemented to achieve the following objectives:

- Compliant with next generation high definition optical video disc requirements, with sufficient performance headroom:
    - Support AVC 4:2:0 Main Profile and High Profile only (8-bit only), up to Level 4.1 resolution and up to 40 mbps bitstream. With sufficient duty cycles, higher bit rate contents can also be encoded. There is no support for Baseline, Extended, or High-10 Profiles.
- Performance requirements with MFX core frequency above 667MHz:
    - Real-time performance with 20% duty cycle or less.
    - Support concurrent decoding of two active HD bitstreams of different formats (for example, one AVC and one VC1 HD bitstream) and one active HD encoding.

As the result of this hardware partitioning, VPP and ENC are always running in GPE, and PAK is what runs exactly in MFC.

PAK – residue packing and entropy coding, including block transformation, quantization, data prediction, bitrate tuning and reference decoding. It delivers final packed bitstream and decoded key-frame reference:

- As the same as ENC, PAK is invoked on a Slice boundary; a single call of VPP can lead to multiple calls for PAK.
- Rate control is inside ENC and PAK only, not in VPP.
- PAK must always perform with reconstructed reference picture.

There is a general dependency of the three operation pipelines. Semaphores are inserted either according to frames or slices. The main CS will also be notified when the decoded reference is ready for the next frame set to be encoded. The detailed discussion will be found in a later section.

Host software is responsible for encoding the transport stream and all the sequence, picture, and slice layer/header in the bit-stream; the MFC system is responsible for compressing from Slice Data Layer down to all macro-block and block layers.

Sample Algorithmic Flow

Assuming all the hardware components are given, there are infinite usage possibilities left with intention for software to decide according to its own application needs depending upon the balanced requirement of coding speed, frame latency, power-consumption, and video quality, and depending upon the usage modes and user preferences (such as low-frame-rate-high-frame-quality vs. high-frame-rate-low-frame-quality).

The last part of this chapter, we illustrate a generic sample to show how a compression algorithm can be implemented to use our hardware.

Step 1. Application or driver initializes the encoder with desired configuration, including speed, quality, targeted bit-rate, input video info, and output format and restrictions.

Step 2. VPP – Application or driver feeds VPP one frame at a time in coded order with specified frame or field type, as well as transcoding information: motion vectors, coded complexity (i.e. bit size).

It will perform denoising and deblocking based on original and targeted bit-rate, and output additional

4 spatial variances and 2 temporal variances for each macroblock as well as the whole frame.

Step 3. ENC – Application or driver feeds ENC one coding slice buffer at a time including all VPP output. The frame level data is accessible to all slices.

a. Encoding setup unit (**ESE**) will set picture level quality parameters (including LUTs, and other costing functions) and set target bit-budget (TBB) and maximal bit-budget (MBB) to each macroblock based on rate-control (**RC**) scheme implemented. For B-frames, it will also make ME searching mode decision (either Fast, Slow or Uni-directional).
b. Loop over all macroblocks: calculate searching center (**MVP**) perform individual ME and IE (**MEE**). Multi-thread may be designed for HW according to a zigzag order for minimal dependency issue.
c. ENC make microblock level code decision (**CD**) outputs macroblock type, intra-mode, motion-vectors, distortions, as well as TBBs and MBBs.

Step 4. PAK – Application or driver feeds PAK one array of coded macroblocks covering a slice at a time, including all ENC output. Original frame buffer and reconstructed reference frame buffers are also available for PAK to access.

a. PAK may create bitstreams for all sequence, gop, picture, and slice level headers prior the first macroblock.
b. Loop over all macroblocks, accurate prediction block is constructed for either inter- or intra-predictions (**VMC** & **VIP**). If MB distortion is less than some predetermined threshold, for a B slice

this step can be skipped as well as the Steps (c)-(e) and jump directly to Step (f); for a key slice the prediction calculated here will be directly used as the reference thus it jumps to Step (e) after this step.

c. Differencing the predicted block from the original block derives the residue block. Forward transformation and quantization (**FTQ**) is performed. For B slice, it will jump to Step (f) right after. For other types of slice, Steps (d) and (e) can be performed in a thread in parallel with Step (f) and beyond.
d. This is for accurate construction of reference pictures. Inverse quantization and inverse transformation (**IQT**) are performed and added to the predictions to have the decoded blocks.
e. **ILDB** is applied accordingly to the reconstructed blocks.
f. Meanwhile macroblock codes: including its configuration info (types and modes), motion info (motion vectors and reference ids), and residual info (quantized coefficients), are collected for packing (**BSE**) in the following sub-steps:
    i. Code clean-up (in **MPR**). Check and verify Mbtype and Cbps, use Skip or Zero respectively if one can. In principal, when there are equivalent codes, use the simple one.
    ii. Drop dependency (in **MPR**). Calculate relative codes from the absolute codes by associate them with neighborhood information. All neighborhood correlations are solved in this step.
    iii. Unify symbols (in **SEC**). Translate relative codes into symbols, and table or context indices that are independent of the concept of syntax type.
    iv. Entropy coding (**VLE**) on symbols.
g. Parsing bitstream data in RBSP form (in **VLE**), and output to application or driver.
h. By the end of each picture, write out the accurate actual data size to designate buffer for ENC to access.

Synchronization Mechanism

Encoding of a video stream can be broken down to three major steps (as explained in the previous section):

1. VPP: video-stream pre-processing
2. ENC: encoding, *that is,* code decision of inter-MVs and intra-modes
3. PAK: bit-stream packing
    a. residual calculation, transformation, and quantization
    b. code bit-stream packing
    c. reference generation of keyframes

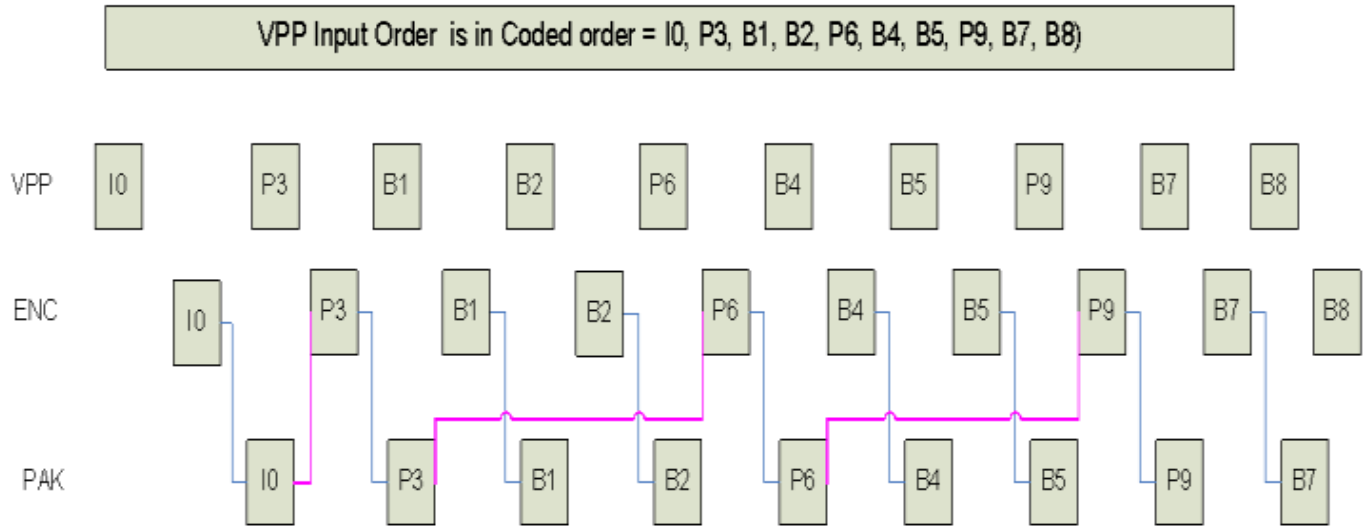
This section describes an architectural solution to map the first two steps in the GFX engine and the last step in the MFX engine. Since this mapping involves two OS-visible engines, managing them in parallel under one application is similar to the solution in earlier generations. Each engine has its own command streamers and has mechanisms to synchronize at required levels as described in the next sub-section.

Above three steps of encoding have dependencies in processing based on

i. Functional pipeline order, *i.e.* on a given frame, VPP needs to be performed first, then ENC, then PAK and finally MFD (*Multi-Format Decoding*) for key reference frame generation.
ii. I-frames are key frames for P and B, they have to be first in every pipe-stage.
iii. P-frames are key frames for B frames and therefore P frames are processed first before the dependent B frames
iv. GFX Engine is time slice to work on either VPP or ENC frame as we discussed in the previous chapter.
v. PAK + MFD are executed on the same frame in the MFX engine by macro-block level pipelining within a slice. It should be noted that for the sake of simplicity, an entire frame (potentially multiple slices) are processed in the corresponding engine and no smaller granularity of switching is allowed between the functional pipeline stages.

Three steps of the encoding can be interleaved on two engines in the following way on a frame by frame basis.

Command Stream Synchronization

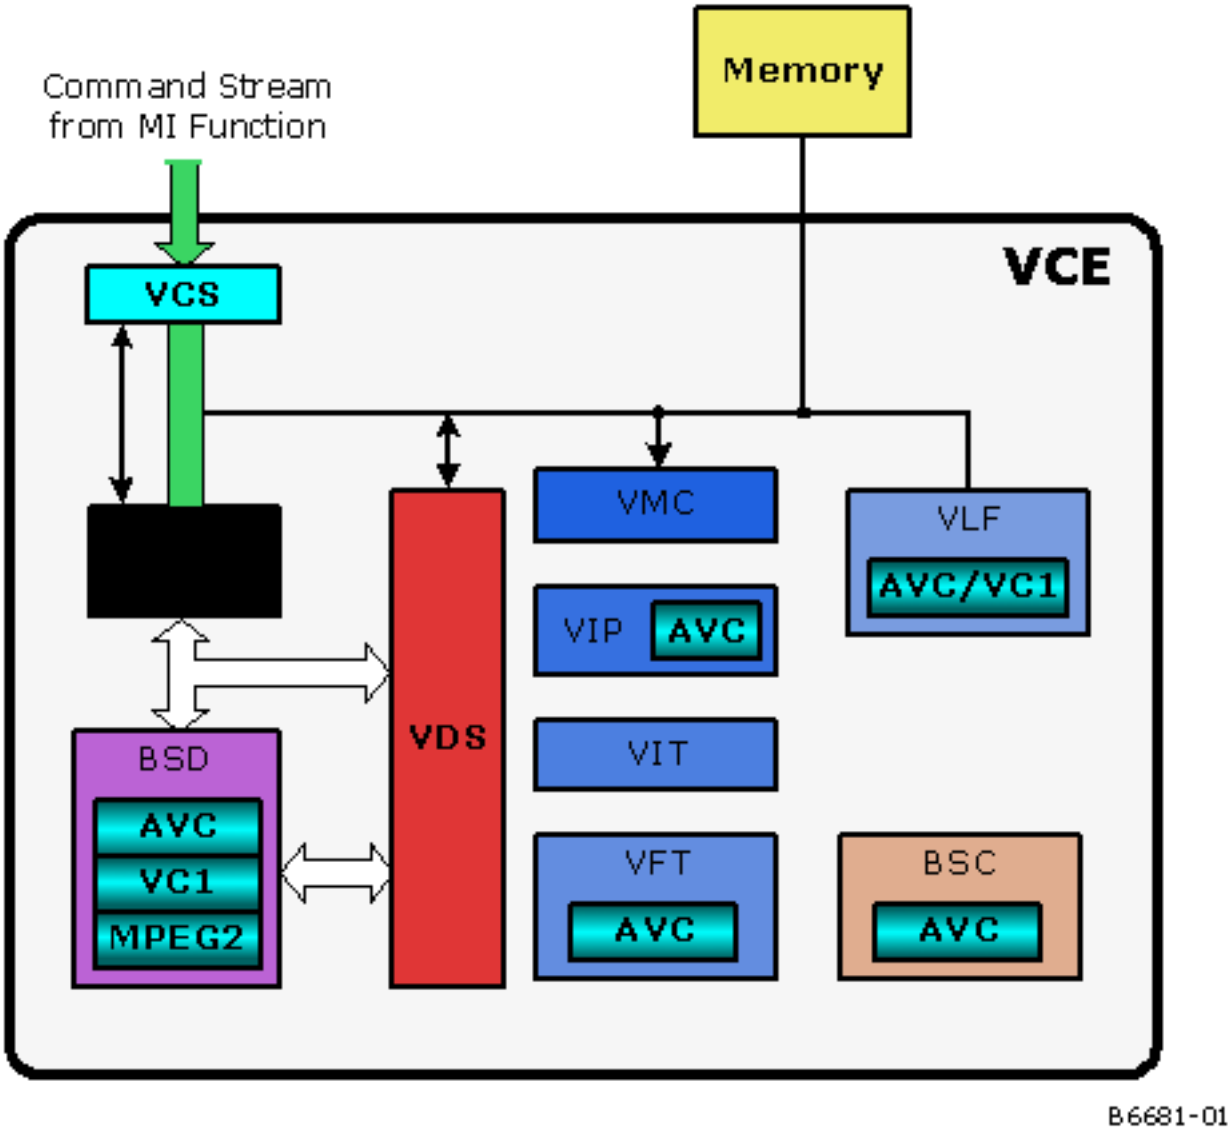


Restrictions

MFC implementation is subject to the following limitations.

- Context switching within MFC and with Graphics Engine occurs only at frame boundary to minimize the amount of information that needs to be tracked and maintained.

MFD Overview



When used for decoding, we also refer to the MFX Engine as the MFD Engine.

The Multi-Format Decoder (MFD) is a hardware fixed function pipeline for decoding the three video codec format and one image compression codec format: AVC (H.264), VC-1, MPEG2, and JPEG.

- Compliant with next generation high definition optical video disc requirements, with sufficient performance headroom:
  - Support AVC 4:2:0 Main and High (8-bit only) Profile only (no support for Baseline, Extended and High-10 Profiles), up to Level 5.1 (max 983,040 MB/s, max 36,864 MB/frame, and at most one dimension can reach 4K pixel) resolution and up to 40 mbps bitstream. With sufficient duty cycles, higher bit rate contents can also be decoded.
    - Allow a B-picture (frame or field) as a reference picture

- Support MVC 4:2:0 Stereoscopic Progressive Profile only, up to Level 5.1 (max 983,040 MB/s per view, max 36,864 MB/frame per view, and at most one dimension can reach 4K pixel) resolution and up to 40 mbps bitstream. With sufficient duty cycles, higher bit rate contents can also be decoded.
  - Does not support interlaced video specified in the Stereoscopic Profile
- Support VC1 4:2:0 Simple, Main and Advanced Profiles, up to Level 4 (max 491,520 MB/s and max 16,384 MB/frame; max only one dimension will be at 4K pixel) resolution and up to 40 mbps bitstream. With sufficient duty cycles, higher bit rate contents can also be decoded.
  - Allow a B-field as a reference picture only in interlaced field decoding, no other modes.
- Support MPEG2 HD Main Profile (4:2:0), up to High Level (1920x1152 pixels) and up to 80 mbps bitstream. With sufficient duty cycles, higher bit rate contents can also be decoded. No support for SNR and spatial-scalability.
  - Does not support B-picture as a reference picture.
- Support Baseline JPEG with five choma types (4:0:0, 4:1:1, 4:2:2, 4:2:0, and 4:4:4. No support for Extended DCT-based mode, Progressive mode, Loseless mode, nor Hierarchical mode.
  - H/W support 64Kx64K, but Surface State can support only up to 16kx16k

Features	Supported	Unsupported
Coding processes	Baseline sequential mode: • 8-bit pixel precision of source images • loadable 2 AC and 2 DC Huffman tables • 3 loadable quantization matrix for Y, U, V • Interleaved and non-interleaved Scans • Single and multiple Scans	Extended DCT-based mode, Lossless, Hierarchical modes: More than 8 bit pixel resolution, progressive mode, arithmetic coding, 4 AC and 4 DC Huffman tables (extended mode), predictive process (lossless), multiple frames (hierarchical)
Number of image channels	1 for grey image 3 for Y, Cb, Cr color image	4-th channel (usually alpha blending image)
Image resolution	Arbitrary image size up to 16K * 16K	Larger than 16K * 16K (64K * 64K is max. in the JPEG standard)

Features	Supported	Unsupported
Chroma subsampling ratio	Chroma 4:0:0 (grey image) Chroma 4:1:1 Chroma 4:2:0 Chroma horizontal 4:2:2 Chroma vertical 4:2:2 Chroma 4:4:4	Any other arbitrary ratio, e.g., 3:1 subsampled chroma
Additional feature (post-processing)	Image rotation: 90/180/270 degrees	

    - H/W does not impose restriction on picture frame aspect ratio, but is bounded by a max 256 MBs (4096 pixels) per dimension programmable at the H/W interface specifications.
        - For example, supporting HD video resolution 1920x1080/60i, 1920x1080/24p, 1280x720/60p
- Performance requirements with MFX core frequency above 1GHz
    - Real-time performance around 10% duty cycle
    - Support concurrently decoding of at least two active HD bitstreams of different formats (For example, one AVC and one VC1 HD bitstream)
- The parsing of transport layer and sequence layer is not performed in this hardware, and is required to be done in the host software.
- The MFD hardware pipeline is operated concurrently with and independently from the Graphics (3D/Media) pipeline with separate command streamer. The two parallel engines are designed with the similar command protocol. They can be executed in parallel with different context.
- Local storages and buffers along the hardware pipeline are kept at minimum. For example, there is no on-die row-store memory. They are resided on the system memory. MFD is designed to hide the memory access latency (in both the row stores and in the motion compensation units) in maximizing its decoding throughput.
- Support the following operating modes:
    - VLD mode - operation starts from entropy decoding of the compressed bit stream (parsing Slice Header and Slice Data Layer in AVC, Picture layer, Slice layer and MB Layer in VC-1, and MB-layer in MPEG2), all the way, to the reconstruction of display picture, including in-loop and out-loop deblocking, if any.
        - Streamout mode - a new feature of the VLD mode in assisting transcoding during decoding. Selected uncompressed data (e.g. per MB MV information) will be sent out to the EU and the ME engine (resided on the Sampler of the 3D Gx Pipeline) for encoding into a different format or for the purpose of transcaling and transrating. In addition, the uncompressed result may continue to be processed by the rest of pipeline as in VLD mode to generate the display picture for transcoding. That is, while

intermediate data are streaming out to the memory, the MFD Engine continues its decoding as ususal.

- For JPEG, only VLD mode is supported (No IT mode). Host software decodes Frame and Scan layers (down to Scan header in the JPEG bit stream syntax) and sends all the corresponding information and Scan payload to the MFD hardware pipeline.

  - IT mode - when host software has already performed all the bit stream parsing of the compressed data and packaging the uncompressed result into a specific format (as a sequence of per-MB record) stored in memory. The hardware pipeline will fetch one MB record at a time and perform the rest of the decoding process as in VLD mode
  - Host software (Application) is responsible for parsing and decoding all the transport and program layers, and all sequence layers. These parameters are passed to Driver and forwarded to H/W as needed through different STATE commands. Host software is also responsible for separating non-video data (audio, meta and user data) from sending to H/W.
    - MFD Engine is only responsible for macro-block and block layers decoding, plus certain level of header decoding. For AVC MFD starts decoding from Slice Header; for VC1, MFD starts decoding from Picture Header, and for MPEG2 decoding starts from MB Layer only.
    - For JPEG, MFD is responsible for ECS and block layers decoding.

- Support bitstream formats (compressed video data) for each codec
  - AVC - 2 formats
  - MVC - 2 formats
    - DXVA2 MVC Short Slice Format
    - DXVA2 AVC Long Slice Format Specification (exactly the same as AVC)
  - VC1 - 2 formats
    - Fully compliant to Picture Parameter and Slice Control Parameter interface definition
  - MPEG2
    - MB Layer only, according to DXVA 1 Specification
  - JPEG
    - ECS Layer
- The MFX codec is designed to be a stateless engine, that it does not retain any history of settings (states) for the encoding/decoding process of a picture. Hence, driver must issue the full set of MFX picture state command sequence prior to process each new picture. In addition, driver must issue the full set of Slice state command sequence prior to process a slice.
  - In particularly, RC6 always happens between frame boundaries. So at the beginning of every frame, all state information needs to be programmed. There is no state information as part of media context definition.
- To activate the AVC deblocker logic for incoming uncompressed 4:2:0-only video stream, one can pack the uncompressed video stream to compliant with the IPCM MB data format (including ILDB

control information) and feed them into the MFD engine in IT mode. Since the MFD Engine is in IPCM mode, transformation, inter and intra processing are all inactive.

Start Code Detection and removal are done in the CPU, but the Start Code Emulation Prevention Byte is detected and removed by the front end logic in the MFD. The bitstream format for each codec and for each mode is specified in this document.

Codec specific information are based on the following released documents from third parties:

- Draft of Version 4 of H.264/AVC (ITU-T Recommendation H.264 and ISO/IEC 14496-10 (MPEG-4 part 10) Advanced Video Coding); JVT-O205d1.doc; dated 2005-05-30
- Final Draft SMPTE Standard : VC1 Compressed Video Bitstream Format and Decoding Process, SMPTE 421M, dated 2006-1-6; PDF file.
- MPEG2 Recommendation ITU T H.262 (1995 E), ISO/IEC 13818-2: 1995 (E); doc file.
- Digital Compression and Coding of Continuous-tone Still Images, ITU-T Rec. T.81 and ISO/IEC 10918-1: Requirements and guidelines September 18 1992; itu-t81[1].pdf

MFD Memory Interface

The Memory Arbitrator follows the pre-defined arbitration policy (as indicated in the following listing P0 to P11, in which P0 is the highest priority) to select the next memory request to service, then it will perform the TLB translation (translation to physical address in memory), and make the actual request to memory.

The Memory Arbitration unit is also responsible for capturing the return data from memory (read request) and forward it to the appropriate unit along the MFD Engine.

- Read streams: (all 64B requests)
    - Commands for BSD : linear (including indirect data) (P0)
    - Indirect DMA (P1)
    - Row store for BSD: linear (P5)
    - Row store for MPR: linear (P6)
    - MC ref cache fetch : tiled (P2)
    - Intra row store: linear (P9)
    - ILDB row store: linear (P10)
- Write streams: (all 64B requests)
    - Row store write for BSD: linear and can avoid partial writes (P3)
    - Row store write for MPR: linear and can avoid partial writes (P4)
    - Intra row store write: linear and can avoid partial writes (P7)
    - ILDB row store write: linear and can avoid partial writes (P8)
    - Final dest writes: tiled and can potentially be partial, two ways to avoid these partials: 1) either write garbage and buffers are aligned or 2) read-modify writes for dribble end of line cases (P11)

MFD Codec-Specific Commands

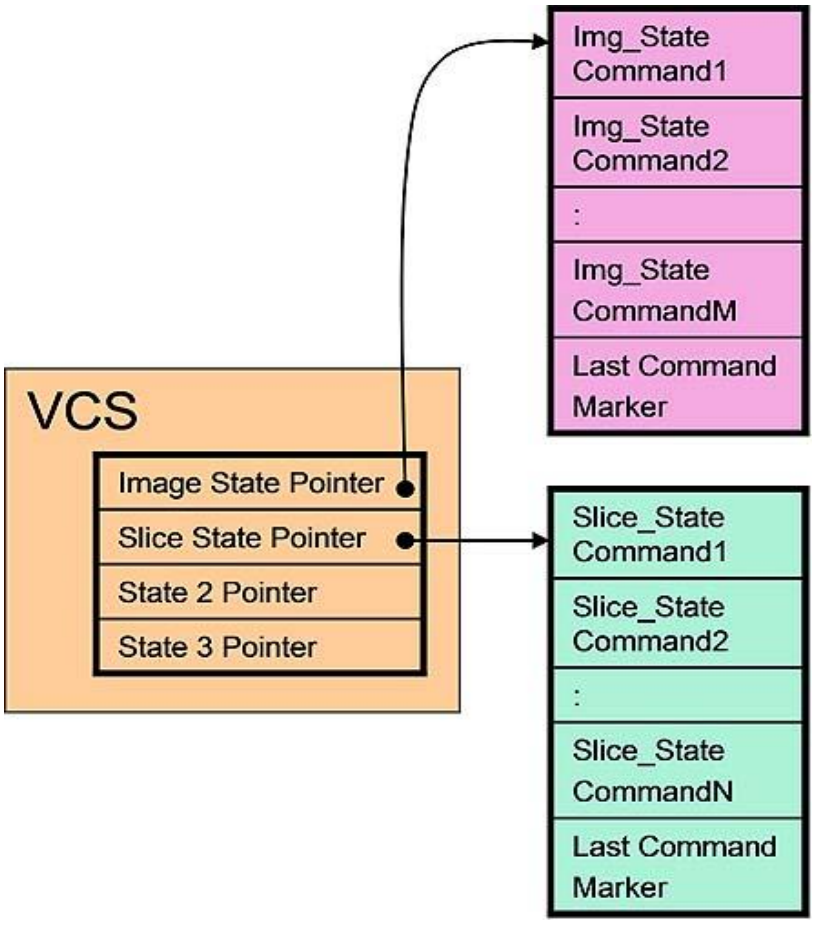
MFD hardware pipeline supports 3 different codec standards: AVC, VC1 and MPEG2. To make the interface flexible, each codec is designed with its own set of commands.

There are two categories of commands for each codec format: one set for VLD mode and one set for IT mode.

MFX State Model

The parallel video engine (PVE) supports two state delivery models: inline state model and indirect state model. For inline state model, the state commands (*_STATE) can be issued in batch buffers or ring buffers directly preceding object commands (*_OBJECT). In the indirect state model, the state commands are not placed in the batch buffers or ring buffers. Instead Indirect State Buffers provide state information (in the form of the above mentioned state commands) for the MFX pipeline. See MFX_STATE_POINTER for more details.

VCS (aka BCS) handles the difference of the two state delivery models. Therefore, the MFX pipeline always sees the state commands in both models. However, MFX hardware supports additional context save/restore of 'dynamic states'. Dynamic states are the internal signals that are persistent. This could be the CABAC context for macroblock encoding.



MFX State Model

The MFX codec is designed to be a stateless engine, that it does not retain any history of settings (states) for the encoding/decoding process of a picture. Hence, driver must issue the full set of MFX picture state command sequence prior to process each new picture. In addition, driver must issue the full set of Slice state command sequence prior to process a slice.

- In particular, RC6 always happens between frame boundaries. So at the beginning of every frame, all state information needs to be programmed. There is no state information as part of media context definition.

MFX Interruptability Model

MFX encoding and the encoding pipeline do not support interruption. All operations are frame based. Interrupts can only occur between frames; the driver will submit all the states at the beginning of each frame. Any state kept across frames is in MMIO registers that should be read between frames.

Software submits without any knowledge of where the parser head pointer is located. Also there is a non-deterministic amount of time for the new context to reach the command streamer. However, the state model for the MFX engine requires software to know exactly what state the pipeline is in at all times. This introduces cases where a preemption could occur during or after a state change without software ever knowing the state saved out to memory on the context switch.

Also, preemption is only allowed during the last macroblock in a row. Hardware cannot always perform a context switch when the new context is seen by the hardware. To avoid a switch during an invalid macroblock and to keep the state synchronized with software, there are two commands available that are used. MI_ARB_ON_OFF disables and enables preemption while MFX_WAIT ensures the context switch, if needed, preempts during macroblock execution. Below illustrates an example assuming VC1 VLD mode.

Command Ring/Batch	Notes
MI_ARB_ON_OFF = OFF	Disable preemption
S1	Inline or indirect state cmd 1
S2	Inline or indirect state cmd 2
S3	Inline or indirect state cmd 3
XXXX_OBJECT	Slice
MI_ARB_ON_OFF = ON	Enable preemption
MFX_WAIT	Allow preemption to occur while XXXX_OBJECT executes
MI_ARB_ON_OFF = OFF	Since arbitration is off again, state commands are allowed below
S4	Inline or indirect state cmd 4
S5	Inline or indirect state cmd 5
S6	Inline or indirect state cmd 6
XXXX_OBJECT	Slice
MI_ARB_ON_OFF = ON	Enable preemption
MFX_WAIT	Allow preemption to occur while XXXX_OBJECT executes

Command Ring/Batch	Notes
MI_ARB_ON_OFF = OFF	Since arbitration is off again, state commands are allowed below

Note that store DW commands may execute inside the preemption enabling window if needed.

Decoder Input Bitstream Formats

AVC Bitstream Formats – DXVA Short

Bitstream Buffer Address starts after the 3-byte start code, i.e. starts (and includes) at the NAL Header Byte. This byte must not be included in the Emulation Byte Detection Process.

AVC Bitstream Formats – DXVA Long

Bitstream Buffer Address starts after the 3-byte start code, i.e. starts (and includes) at the NAL Header Byte. This byte must not be included in the Emulation Byte Detection Process. Application will provide the Slice Header Skip Byte count (not including any possible Emulation Prevention Byte).

VC1 Bitstream Formats – Intel Long

Bitstream starts right at the MB layer, with any emulation byte crossing the header and MB layer being removed by application and the data length is adjusted.

MPEG2 Bitstream Formats – DXVA1

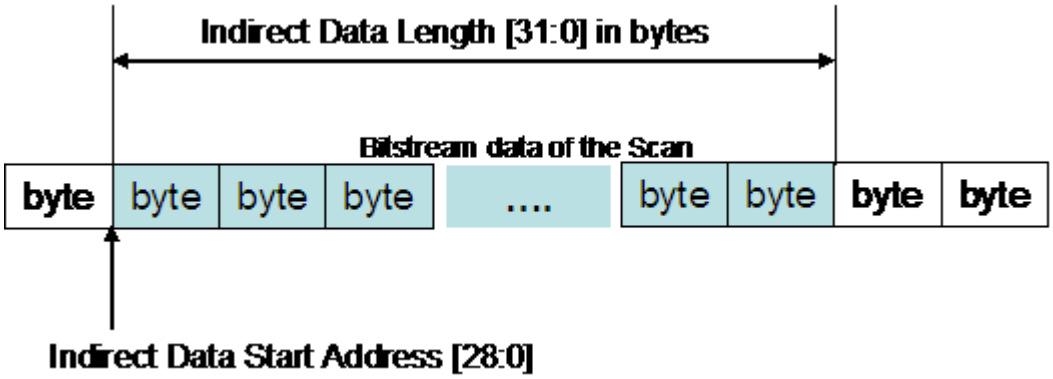
Bitstream buffer starts right at the very first MB data.

JPEG Bitstream Formats – Intel

Bitstream buffer starts right at the very first MCU data of each Scan.

The indirect data start address in MFD_JPEG_BSD_OBJECT specifies the starting Graphics Memory address of the bitstream data that follows the Scan header. It provides the byte address for the first MCU of the Scan. Different from MFD_MPEG2_BSD_OBJECT command, First MCU Bit Offset does not need to be specified because it is always set to zero.

Indirect data buffer for a Scan



The indirect data length in MFD_JPEG_BSD_OBJECT provides the length in bytes of the bitstream data for the Scan excluding Scan header. It includes the first byte of the first macroblock and the last byte of the last macroblock in the Scan. The Figure illustrates these parameters for a slice data.

Concurrent Multiple Video Stream Decoding Support

The natural place for switching across multiple streams is at the Slice boundary. Each Slice is a self-sustained unit of compressed video data and has no dependency with its neighbors (except for the Deblocking process). In addition, there is no interruptability within a Slice. However, when ILDB is invoked, the processing of some MBs will require neighbor MB information that crosses the Slice boundary. Hence, to limit the buffering requirement, in this version of hardware design, stream switching can only be performed at the picture boundary instead.

MFX Codec Commands Summary

DWord	Bit	Description
0	31:29	**Instruction Type =** GFXPIPE = 3h
	28:16	**3D Instruction Opcode =** PIPELINE_SELECT GFXPIPE[28:27 = 1h, 26:24 = 1h, 23:16 = 04h] (Single DW, Non-pipelined)
	15:1	**Reserved:** MBZ
	0	**Pipeline Select** 0: 3D pipeline is selected 1: Media pipeline is selected

Pipeline Type (28:27)	Opcode (26:24)	Sub Opcode (23:16)	Command	Definition Chapter
VC1 State				
2h	5h	0h	VC1_BSD_PIC_STATE	VC1 BSD
2h	5h	1h	Reserved	n/a
2h	5h	2h	Reserved	n/a
2h	5h	3h	VC1_BSD_BUF_BASE_STATE	VC1 BSD
2h	5h	4h	Reserved	n/a
2h	5h	5h-7h	Reserved	n/a
VC1 Object				
2h	5h	8h	VC1_BSD_OBJECT	VC1 BSD
2h	5h	9h-FFh	Reserved	n/a

Pipeline Type (28:27)	Opcode (26:24)	Sub Opcode (23:16)	Command	Definition Chapter
State				
2h	6h	2h-7h	Reserved	N/A
Object				
2h	6h	9h-FFh	Reserved	N/A

Note that it is possible for a command to appear in both IMAGE and SLICE state buffer, e.g. QM_STATE for JPEG can be issued at frame level or scan/slice level.

MFX Decoder Commands Sequence

The MFX codec is designed to be a stateless engine, that it does not retain any history of settings (states) for the encoding/decoding process of a picture. Hence, driver must issue the full set of MFX picture state command sequence prior to process each new picture. In addition, driver must issue the full set of Slice state command sequence prior to process a slice.

In particular, RC6 always happens between frame boundaries. So at the beginning of every frame, all state information needs to be programmed. There is no state information as part of media context definition

Examples for AVC

The following gives a sample command sequence programmed by a driver

a) For Intel or DXVA2 AVC Long Slice Bitstream Format

MFX_PIPE_MODE_SELECT

MFX_SURFACE_STATE

MFX_PIPE_BUF_ADDR_STATE

MFX_IND_OBJ_BASE_ADDR_STATE

MFX_BSP_BUF_BASE_ADDR_STATE

MFX_QM_STATE

VLD mode: MFX_AVC_PICID_STATE

MFX_AVC_IMG_STATE

MFX_AVC_DIRECTMODE_STATE

MFX_AVC_REF_IDX_STATE

MFX_AVC_WEIGHTOFFSET_STATE

MFX_AVC_SLICE_STATE

VLD mode: MFD_AVC_BSD_OBJECT

IT mode: MFD_IT_OBJECT

MI_FLUSH

b) For DXVA2 AVC Short Slice Bitstream Format (for VLD mode only)

MFX_PIPE_MODE_SELECT

MFX_SURFACE_STATE

MFX_PIPE_BUF_ADDR_STATE

MFX_IND_OBJ_BASE_ADDR_STATE

MFX_BSP_BUF_BASE_ADDR_STATE

MFD_AVC_DPB_STATE

VLD mode: MFX_AVC_PICID_STATE

MFX_AVC_IMG_STATE

MFX_QM_STATE

MFX_AVC_DIRECTMODE_STATE

VLD mode : MFD_AVC_SLICEADDR_OBJECT

VLD mode: MFD_AVC_BSD_OBJECT

VLD mode : MFD_AVC_BSD_SLICEADDR_OBJECT

VLD mode: MFD_AVC_BSD_OBJECT

... repeat these four commands N-1 times for a N-slice picture

VLD mode: MFD_AVC_BSD_OBJECT (for the last slice of the picture)

MI_FLUSH

Examples for VC1

The following gives a sample command sequence programmed by a driver

a) For Intel Proprietary Long Bitstream Format

MFX_VC1_DIRECTMODE_STATE

MFX_VC1_PRED_PIPE_STATE

MFX_VC1_LONG_PIC_STATE

VLD mode: MFD_VC1_BSD_OBJECT

IT mode: MFD_IT_OBJECT

MI_FLUSH

b) For DXVA2 VC1 Compliant Bitstream Format (for VLD mode only)

MFX_VC1_DIRECTMODE_STATE

MFX_VC1_PRED_PIPE_STATE

MFX_VC1_SHORT_PIC_STATE

VLD mode: MFD_VC1_BSD_OBJECT

MI_FLUSH

c) For DXVA2 VC1 Compliant Bitstream Format (for VLD mode only), and field pair picture

Batch buffer for top-field

states....

Slice_objs...

MI_flush

store register immediate (if VC1 short format with interlaced field pic)

MI_flush

Batch buffer for bottom field

load register immediate (if VC1 short format with interlaced field pic)

MI_flush

states....

Slice_objs...

MI_flush

Examples for JPEG

The following gives a sample command sequence programmed by a driver

Programmed once at the start of decoding

MFX_PIPE_MODE_SELECT

MFX_PIPE_SURFACE_STATE

MFX_IND_OBJ_BASE_ADDR_STATE

MFX_PIPE_BUF_ADDR_STATE

MFX_JPEG_PIC_STATE

Programmed at the start of Frame or Scan (These commands can be sent multiple times either before MFX_JPEG_PIC_STATE or before MFD_JPEG_BSD_OBJECT)

MFX_JPEG_HUFF_TABLE

MFX_QM_STATE

Programmed per Scan (These commands can be sent multiple times depending on each bit stream)

MFD_JPEG_ BSD_OBJECT

MI_FLUSH

MFX Pipe Common Commands

MFX Commands are organized into groups based on their scope of functioning. There are Pipeline Common state commands that are common to all codecs (encoder and decoder) and is applicable to the processing of one full frame/field. There are also individual codec Common state commands that are common to both encoder and decoder of that particular codec. These latter common state commands, some are applicable at the processing of one full frame/field, and some are applicable at the processing of an individual slice level.

MFX_STATE_POINTER

MFX_PIPE_MODE_SELECT

The Encoder Pipeline Modes of Operation (Per Frame):

1. PAK Mode: VCS-command driven, setup by driver. Like the IT mode of decoder, it is executed on a per-MB basis. Hence, each PAK Object command corresponds to coding of only one MB.
    a. Normal Mode (including transcoding): receive per-MB control and data (MV, mb_type, cbp, etc.). It generates the output compressed bitstream as well as the reconstructed reference pictures, one MB at a time, for later use.
    b. Encoder StreamOut Mode: to provide per-MB, per-Slice and per-Frame coding result and information (statistics) to the Host, Video Preprocessing Unit and ENC Unit to enhance their operations.

The Decoder Pipeline Modes of Operation (Per Frame):

1. VLD Mode: The output from the BSD (weight&offset/coeff/motion vectors record) can be sent in part (as specified) and to the remaining fixed function hardware pipeline to complete the decoding processing. The driver specifies through MFD commands of what to send out from the BSD unit and where to send the BSD output.
    a. For transcoding (including transrating and transcaling), part of the BSD output (a series of per-MB record) can be sent to memory for further processing to encode into a difference output format. This function is named as StreamOut. When StreamOut is active, not all MB information needs to be sent, only MVs and selective MB coding information.
2. IT Mode: In this mode, the BSD is not invoked. Instead host performs all the bitstream decoding and parsing; and the result are saved into memory in a specific per-MB record format. The MFD Engine VCS reads in these records one at time and finish the rest of the decoding (IT, MC, IntraPred and ILDB).

MB information is organized into two indirect data buffers, one for MVs and one for residue coefficients. As such, two indirect base address pointers are defined.

MFX_SURFACE_STATE

MFX_PIPE_BUF_ADDR_STATE

MFX_IND_OBJ_BASE_ADDR_STATE

MFX_BSP_BUF_BASE_ADDR_STATE

MFX_PAK_INSERT_OBJECT

MFX_STITCH_OBJECT

MFX_QM_STATE

Bits	31:24	23:16	15:8	7:0
Dword 1	QuantMatrix[0][3]	QuantMatrix[0][2]	QuantMatrix[0][1]	QuantMatrix[0][0]
Dword 2	QuantMatrix[0][7]	QuantMatrix[0][6]	QuantMatrix[0][5]	QuantMatrix[0][4]
Dword 3	QuantMatrix[1][3]	QuantMatrix[1][2]	QuantMatrix[1][1]	QuantMatrix[1][0]
...	...	...	...	...
Dword 16	QuantMatrix[7][7]	QuantMatrix[7][6]	QuantMatrix[7][5]	QuantMatrix[7][4]

MFX_FQM_STATE

This is a frame-level state. Reciprocal Scaling Lists are always sent from the driver regardless whether they are specified by an application or the default/flat lists are being used. This is done to save the ROM (to store the default matrices) inside the PAK Subsystem. Hence, the driver is responsible for determining the final set of scaling lists to be used for encoding the current slice, based on the AVC Spec (Fall-Back Rules A and B). For encoding, there is no need to send the qm_list_flags[i], i=0 to7 and qm_present_flag to the PAK, since Scaling Lists syntax elements are encoded above Slice Data Layer.

FQM Reciprocal Scaling Lists elements are 16-bit each, conceptually equal to 1/ScaleValue. QM matrix elements are 8-bit each, equal to ScaleValue. However, in AVC spec., the Reciprocal Scaling Lists elements are not exactly equal to one-over of the corresponding Scaling Lists elements. The numbers are adjusted to simplify hardware implementation.

For all the description below, a scaling list set contains 6 4x4 scaling lists (or forward scaling lists) and 2 8x8 scaling lists (or forward scaling lists).

In MFX PAK mode, PAK needs both forward Q scaling lists and IQ scaling lists. The IQ scaling lists are sent as in MFD in raster scan order as shown in MFX_AVC_QM_STATE. But the Forward Q scaling lists are sent in transport form, i.e. column-wise raster order (column-by-column) to simplify the H/W.

Precisely, if the reciprocal forward scaling matrix is F[4][4], then the 16 word of the matrix will be set as the following:

For JPEG encoder, 16-bit precision is used for each element 1/QM matrix. The 32 DWords are used for 64 QM elements with the following data structure:

	Bits 15:0	Bits 31:16
DWord1	1/QM[0][0]	1/QM[1][0]
DWord2	1/QM[2][0]	1/QM[3][0]
DWord3	1/QM[4][0]	1/QM[5][0]
DWord4	1/QM[6][0]	1/QM[7][0]
DWord5	1/QM[0][1]	1/QM[1][1]
DWord6	1/QM[2][1]	1/QM[3][1]
DWord7	1/QM[4][1]	1/QM[5][1]
DWord8	1/QM[6][1]	1/QM[7][1]
...		
DWord31	1/QM[4][7]	1/QM[5][7]

	Bits 15:0	Bits 31:16
DWord32	1/QM[6][7]	1/QM[7][7]

Bitplane Buffer

Bitplane coding is used in seven different cases in VC-1, although not all the seven syntax elements are present in the same picture header at the same time. The following list shows which syntax elements are coded as bitplanes in each picture header:

Progressive I and BI picture headers in AP: ACPRED, OVERFLAGS

Field interlace I and BI picture headers in AP: ACPRED, OVERFLAGS

Frame interlace I and BI picture headers in AP: FIELDTX, ACPRED, OVERFLAGS

Frame interlace P picture headers in AP: SKIPMB

Progressive P picture headers in SP and MP: MVTYPEMB, SKIPMB

Progressive P picture headers in AP: MVTYPEMB, SKIPMB

Field interlace B picture headers in AP: FORWARDMB

Frame interlace B picture headers in AP: DIRECTMB, SKIPMB

Progressive B picture headers in AP: DIRECTMB, SKIPMB

Progressive B picture headers in MP: DIRECTMB, SKIPMB

There are also seven different modes of coding the bitplane information. Except when the bitplane is coded in raw mode, the bitplane is decoded by the host and provided to the hardware in the bitplane buffer.

Since at most three bitplanes are encoded in any picture header, instead of using a complete byte for signaling the values of all the seven possible bitplanes for each MB, a more efficient approach is used with each byte divided in two nibbles and each nibble carries the data of up to four bitplanes for one MB.

PictureType	Bits 3, 7	Bit 2, 6	Bits 1, 5	Bits 0, 4
I or BI	0	OVERFLAGS	ACPRED	FIELDTX
P	0	MVTYPEMB	SKIPMB	0
B	0	FORWARDMB	SKIPMB	DIRECTMB

The bytes containing the above defined nibbles are stored in the bitplane buffer in raster scan order. The bitplane buffer is a linear buffer with a buffer pitch (as defined by Bitplane Buffer Pitch field in VC1_BSD_PIC_STATE command). When the number of macroblock in a row is odd, the last byte of the row containing the last macroblock in bits 0-3. The first macroblock of the next row starts at the next pitch offset from the first macroblock of the current row.

The bitplane buffer structure must be sent once per picture only if there is one or more syntax elements coded as bitplanes in the picture header.

Video Codecs

The following sections contain the various registers for video codec support. Specifically, the codec types supported are:

Supported Codec Types
Advanced Video Coding (AVC)/ H.264/MPEG-4 Part 10 (MVC)
MPEG-2 (H.222/H.262) — Used in Digital Video Broadcast and DVDs
VC1 — SMPTE 421M, known informally as VC-1
VP8 — Video compression format
JPEG and MJPEG — A video format in which video gram or interlaced field of a digital video sequence is compressed separately as a JPEG image
Other Codec Functions

Internal Media Rowstore table – An internal Media Rowstore Storage is added to reduce memory read/write to save power. If the internal Media Rowstore exists, driver should use the storage as the following table indicates.

AVC/VC1/MPEG2/JPEG/VP8 Decoder/Encoder:

[BSD is bitstream decoder rowstore; MPR is Motion Prediction rowstore; IP is Intra Prediction rowstore; VLF is loop filter rowstore]

Codec	Mode	Frame Width	BSD	MPR	IP	VLF	VDE	BSD Addr	MPR Addr	IP Addr	VLF ADDR	VDE ADDR

AVC (H.264)

AVC Common Commands

MFX Commands are organized into groups based on their scope of functioning. There are Pipeline Common state commands that are common to all codecs (encoder and decoder) and is applicable to the processing of one full frame/field. There are also individual codec Common state commands that are common to both encoder and decoder of that particular codec. These latter common state commands, some are applicable at the processing of one full frame/field, and some are applicable at the processing of an individual slice level.

MFX_AVC_IMG_STATE

A new command is added to support MPEG transport stream encapsulation of AVC bitstream in Encoder mode. This command should be used only when MPEG transport stream is needed.

MFX_AVC_DIRECTMODE_STATE

MFX_AVC_SLICE_STATE

MFX_AVC_REF_IDX_STATE

MFX_AVC_WEIGHTOFFSET_STATE

AVC Decoder Commands

These are decoder-only commands. They provide the pointer to the compressed input bitstream to be decoded.

MFD_AVC_DPB_STATE

NOTE modified from DXVA2 – The values in RefFrameList and UsedForReference_Flag are the primary means by which the H/W can determine whether the corresponding entries in RefFrameList, POCList, LTSTFrameNumList, and Non-ExistingFrame_Flag should be considered valid for use in the decoding process of the current picture or not. When RefFrameList[i] is marked to be invalid, the values of POCList[i][0], POCList[i][1], LTSTFrameNumList[i], UsedForReference_Flag[i], and Non-ExistingFrame_Flag[i] must all be equal to 0. When UsedForReference_Flag[i] = 0, the value of RefFrameList[i] must be marked invalid.

MFD_AVC_SLICEADDR

MFD_AVC_BSD_OBJECT

Inline Data Description for MFD_AVC_BSD_Object

MFD_AVC_PICID_STATE

NOTE 1: In AVC short format, PictureIDList has one-to-one corresponding to LongTermFrame_Flag list, Non-ExistingFrame_flag list, UsedForReference_Flag list, FrameNumList list in MFD_AVC_DPB_STATE.

NOTE 2: PictureIDList is only used to identify reference picture across frames. Hardware will convert the picture in the RefFrameList to PictureID before writing out DMV data and convert back to RefFrameList Index after reading out DMV data. The reference pictures and their orders in the RefFrameList can be changed across frames.

Session Decoder StreamOut Data Structure

When StreamOut is enabled, per MB intermediated decoded data (MVs, mb_type, MB qp, etc.) are sent to the memory in a fixed record format (and of fixed size). The per-MB records must be written in a strict raster order and with no gap (i.e. every MB regardless of its mb_type and slice type, must have an entry in the StreamOut buffer). Therefore, the consumer of the StreamOut data can offset into the StreamOut Buffer (**StreamOut Data Destination Base Address**) using individual MB addresses.

A StreamOut Data record format is detailed as follows:

DWord	Bit	Description
	23	**Reserved MBZ**
	22-20	**EdgeFilterFlag** (AVC) / **OverlapSmoothFilter** (VC1)
	19:17	**CodedPatternDC** (for AVC only, **111b** for others) The field indicates whether DC coefficients are sent. 1 bit each for Y, U and V.
	16	**Reserved MBZ**
	15	**Transform8x8Flag** When it is set to 0, the current MB uses 4x4 transform. When it is set to 1, the current MB uses 8x8 transform. The transform_szie_8x8_flag syntax element, if present in the output bitstream, is the same as this field. However, whether transform_szie_8x8_flag is present or not in the output bitstream depends on several conditions: This field is only allowed to be set to 1 for two conditions: It must be 1 if **IntraMbFlag** = INTRA and **IntraMbMode** = INTRA_8x8 It may be 1 if **IntraMbFlag** = INTER and there is no sub partition size less than 8x8 Otherwise, this field must be set to 0. 0: 4x4 integer transform 1: 8x8 integer transform
	14	**MbFieldFlag** This field specifies whether current macroblock is coded as a field or frame macroblock in MBAFF mode. This field is exactly the same as FIELD_PIC_FLAG syntax element in non-MBAFF mode. Same as the mb_field_decoding_flag syntax element in AVC spec. 0 = Frame macroblock 1 = Field macroblock

DWord	Bit	Description
	13	**IntraMbFlag** This field specifies whether the current macroblock is an Intra (I) macroblock. I_PCM is considered as Intra MB. For I-picture MB (IntraPicFlag =1), this field must be set to 1. This flag must be set in consistent with the interpretation of MbType (inter or intra modes). 0: INTER (inter macroblock) **1: INTRA (intra macroblock)**
	12:8	**MbType5Bits** This field is encoded to match with the best macroblock mode determined as described in the next section. It follows AVC encoding for inter and intra macroblocks.
	7	**MbPolarity** FieldMB Polarity - vctrl_vld_top_field AVC
	6	**Reserved MBZ**
	5:4	**IntraMbMode** This field is provided to carry information partially overlapped with MbType. This field is only valid if **IntraMbFlag** = INTRA, otherwise, it is ignored by hardware.
	3	**Reserved MBZ**
	2	**MbSkipFlag** Reserved MBZ (DXVA Encoder). HW (VDSunit) doesn't have skip MB info. It sets to 1 if any of the sub-blocks is inter, uses predicted MVs, and skips sending MVs explicitly in the code stream. Currently H/W can provide this flag and is defaulted to 0 always.
	1:0	**InterMbMode** This field is provided to carry redundant information as that in MbType. It also carries additional information such as skip. This field is only valid if **IntraMbFlag** =INTER, otherwise, it is ignored by hardware.
1	31:16	**MbYCnt (Vertical Origin).** This field specifies the vertical origin of current macroblock in the destination picture in units of macroblocks. Format = U8 in unit of macroblock.
	15:0	**MbXCnt (Horizontal Origin).** This field specifies the horizontal origin of current macroblock in the destination picture in units of macroblocks. Format = U8 in unit of macroblock.
2	31	**Conceal MB Flag.** This field specifies if the current MB is a conceal MB, use in AVC/VC1/MPEG2 mode.
	30	**Last MB of the Slice Flag.** This field indicate the current MB is a last MB of the slice. Use in AVC/VC1/MPEG2 mode.
	29:24	**Reserved**
	23:20	**CbpAcV**

DWord	Bit	Description
		0 in a bit – indicates the corresponding 8x8 block or 4x4 sub-block is not present (because all coefficient values are zero) 1 in a bit – indicates the corresponding 8x8 block or 4x4 sub-block is present (although it is still possible to have all its coefficients be zero – bad coding).
	19:16	**CbpAcU** 0 in a bit – indicates the corresponding 8x8 block or 4x4 sub-block is not present (because all coefficient values are zero) 1 in a bit – indicates the corresponding 8x8 block or 4x4 sub-block is present (although it is still possible to have all its coefficients be zero – bad coding).
	15:0	**CbpAcY** 0 in a bit – indicates the corresponding 8x8 block or 4x4 sub-block is not present (because all coefficient values are zero) 1 in a bit – indicates the corresponding 8x8 block or 4x4 sub-block is present (although it is still possible to have all its coefficients be zero – bad coding). Bit15=Y0Sub0, Bit0=Y3Sub3
3	31:28 AVC	**Skip8x8Pattern** (AVC) This field indicates whether each of the four 8x8 sub macroblocks is using the predicted MVs and will not be explicitly coded in the bitstream (the sub macroblock will be coded as direct mode). It contains four 1-bit subfields, corresponding to the 4 sub macroblocks in sequential order. The whole macroblock may be actually coded as B_Direct_16x16 or B_Skip, according to the macroblock type conversion rules described in a later sub section. This field is only valid for a B slice. It is ignored by hardware for a P slice. Hardware also ignores this field for an intra macroblock. 0 in a bit – Corresponding MVs are sent in the bitstream 1 in a bit – Corresponding MVs are not sent in the bitstream
	27:25	**Reserved**
	24:16	**NzCoefCountMB** – all coded coefficients input including AC/DC blocks in current MB. Range 0 to 384 (9 bits)
	15:8	**MbClock16** – MB compute clocks in 16-clock unit.
	7	**mbz** (AVC) **/ QScaleType** (MPEG2)
	6:0	**QpPrimeY** (AVC) **/ QScaleCode** (MPEG2) The luma quantization index. This is the per-MB QP value specified for the current MB.
4 to 6	31:0 Each	For intra macroblocks, definition of these fields are specified in 1 For inter macroblocks, definition of these fields are specified in 2
7	31:24	**Reserved**

DWord	Bit	Description
	23:20	**MvFieldSelect** (Ref polarity top or bottom bits) for VC1 and MPEG2 vcp_vds_mvdataR[162:159] VC1 vmd_vds_mt_vert_fld_selR[3:0] MPEG2
	19:12	**Reserved**
	11:10	**SubBlockCodeType V** (If 8x8, 8x4, 4x8, 4x4 type)
	9:8	**SubBlockCodeType U** (specifies 8x8, 8x4, 4x8, 4x4 type) VC1
	7:6	**SubBlockCodeType Y3** (specifies 8x8, 8x4, 4x8, 4x4 type) VC1
	5:4	**SubBlockCodeType Y2** (specifies 8x8, 8x4, 4x8, 4x4 type) VC1
	3:2	**SubBlockCodeType Y1** (specifies 8x8, 8x4, 4x8, 4x4 type) VC1
	1:0	**SubBlockCodeType Y0** (specifies 8x8, 8x4, 4x8, 4x4 type) VC1
Inter Cases:		
8	31:16	**MvFwd[0].y** – y-component of the forward motion vector of the 1st 8x8 or 1st 4x4 subblock
	15:0	**MvFwd[0].x** – x-component of the forward motion vector of the 1st 8x8 or 1st 4x4 subblock
9	31:0	**MvBck[0]** – the backward motion vector of the 1st 8x8 or 1st 4x4 subblock
10	31:0	**MvFwd[1]** – the forward motion vector of the 2nd 8x8 or 4th 4x4 subblock
11	31:0	**MvBck[1]** – the backward motion vector of the 2nd 8x8 or 4th 4x4 subblock
12	31:0	**MvFwd[2]** – the forward motion vector of the 3rd 8x8 or 8th 4x4 subblock
13	31:0	**MvBck[2]** – the backward motion vector of the 3rd 8x8 or 8th 4x4 subblock
14	31:0	**MvFwd[3]** – the forward motion vector of the 4th 8x8 or 12th 4x4 subblock
15	31:0	**MvBck[3]** – the backward motion vector of the 4th 8x8 or 12th 4x4 subblock
Intra Cases:		
8 to 15	31:0	**Reserved MBZ**

The inline data content of Dwords 4 to 6 is defined either for intra prediction or for inter prediction, but not both.

Inline data subfields for an Intra Macroblock

DWord	Bit	Description
4	31:16	**LumaIndraPredModes[1]** Specifies the Luma Intra Prediction mode for four 4x4 sub-block of a MB, 4-bit each.

DWord	Bit	Description
		AVC: See the bit assignment table later in this section. VC1: MBZ. MPEG2: MBZ.
	15:0	**LumaIndraPredModes[0]** Specifies the Luma Intra Prediction mode for four 4x4 sub-block, four 8x8 block or one intra16x16 of a MB. 4-bit per 4x4 sub-block (Transform8x8Flag=0, Mbtype=0 and intraMbFlag=1) or 8x8 block (Transform8x8Flag=1, Mbtype=0, MbFlag=1), since there are 9 intra modes. 4-bit for intra16x16 MB (Transform8x8Flag=0, Mbtype=1 to 24 and intraMbFlag=1), but only the LSBit[1:0] is valid, since there are only 4 intra modes. AVC: See the bit assignment table later in this section. VC1: MBZ. MPEG2: MBZ.
5 AVC INTRA	31:16	**LumaIndraPredModes[3]** Specifies the Luma Intra Prediction mode for four 4x4 sub-block of a MB, 4-bit each. AVC: See the bit assignment table later in this section. VC1: MBZ. MPEG2: MBZ.
	15:0	**LumaIndraPredModes[2]** Specifies the Luma Intra Prediction mode for four 4x4 sub-block of a MB, 4-bit each. AVC: See the bit assignment later in this section. VC1: MBZ. MPEG2: MBZ.
6	31:8	Reserved (Reserved for encoder turbo mode **IntraResidueDataSize**, when this is not 0, optional residue data are provided to the PAK; Reserved for decoder)
	7:0	**MbIntraStruct** The IntraPredAvailFlags[4:0] have already included the effect of the constrained_intra_pred_flag. See the diagram later for the definition of neighbors position around the current MB or MB pair (in MBAFF mode). 1 – IntraPredAvailFlagX, indicates the values of samples of neighbor X can be used in intra prediction for the current MB. 0 – IntraPredAvailFlagX, indicates the values of samples of neighbor X is not available for intra

DWord	Bit	Description
		prediction of the current MB. IntraPredAvailFlag-A and -E can only be different from each other when constrained_intra_pred_flag is equal to 1 and mb_field_decoding_flag is equal to 1 and the value of the mb_field_decoding_flag for the macroblock pair to the left of the current macroblock is equal to 0 (which can only occur when MbaffFrameFlag is equal to 1). IntraPredAvailFlag-F is used only if ○ it is in MBAFF mode, i.e. **MbaffFrameFlag** = 1, ○ the current macroblock is of frame type**,** i.e. **MbFieldFag** = 0, and ○ the current macroblock type is Intra8x8, that is, **IntraMbFlag** = INTRA, **IntraMbMode** = INTRA_8x8, and **Transform8x8Flag** = 1. In any other cases IntraPredAvailFlag-A shall be used instead.

Bits	IntraPredAvailFlags[4:0] Definition
7	**IntraPredAvailFlagF – F** (Left 8th row (-1,7) neighbor)
6	**IntraPredAvailFlagA – A** (Left neighbor top half)
5	**IntraPredAvailFlagE – E** (Left neighbor bottom half)
4	**IntraPredAvailFlagB – B** (Top neighbor)
3	**IntraPredAvailFlagC – C** (Top right neighbor)
2	**IntraPredAvailFlagD – D** (Top left corner neighbor)
1:0	**ChromaIntraPredMode –** 2 bits to specify 1 of 4 chroma intra prediction mode, see the table in later section.

Inline data subfields for an Inter Macroblock

DWord	Bit	Description
4	31:24	Reserved: MBZ (DXVA Decoder)
	23:16	Reserved: MBZ (DXVA Decoder)
	15:8	**SubMbPredModes**[bit 7:0] (Sub Macroblock Prediction Mode) This field describes the prediction mode of the sub macroblocks (four 8x8 blocks). It contains four subfields each with 2-bits, corresponding to the 4 fixed size 8x8 sub macroblocks in sequential order. This field is provided for MB with sub_mb_type equal to BP_8x8 only (B_8x8 and P_8x8 as defined in DXVA) This field is derived from MbType for a non-BP_8x8 inter macroblock, and carries redundant

DWord	Bit	Description
		information as MbType) Bits [1:0]: SubMbPredMode[0] – for 8x8 Block 0 Bits [3:2]: SubMbPredMode[1] – for 8x8 Block 1 Bits [5:4]: SubMbPredMode[2] – for 8x8 Block 2 Bits [7:6]: SubMbPredMode[3] – for 8x8 Block 3 Blocks of the MB is numbered as follows : 0 1 2 3 Each 2-bit value [1:0] is defined as : 00 – Pred_L0 01 – Pred_L1 10 – BiPred **For VC1:** Bits [1:0]: "00"= Y0 Forward only, "01"= Y0 Backward only, "10"= Y0 Bi direction Bits [3:2]: SubMbPredMode[1] – for 8x8 Block 1 Bits [5:4]: SubMbPredMode[2] – for 8x8 Block 2 Bits [7:6]: SubMbPredMode[3] – for 8x8 Block 3
	7:0	**SubMbShape**[bit 7:0] (Sub Macroblock Shape) This field describes the sub-block partitioning of each sub macroblocks (four 8x8 blocks). It contains four subfields each with 2-bits, corresponding to the 4 fixed size 8x8 sub macroblocks in sequential order. This field is provided for MB with sub_mb_type equal to BP_8x8 only (B_8x8 and P_8x8 as defined in DXVA) This field is forced to 0 for a non-BP_8x8 inter macroblock, and effectively carries redundant information as MbType). Bits [1:0]: SubMbShape[0] – for 8x8 Block 0 Bits [3:2]: SubMbShape[1] – for 8x8 Block 1 Bits [5:4]: SubMbShape[2] – for 8x8 Block 2 Bits [7:6]: SubMbShape[3] – for 8x8 Block 3 Blocks of the MB is numbered as follows : 0 1 2 3

DWord	Bit	Description
		Each 2-bit value [1:0] is defined as : 00 – SubMbPartWidth=8, SubMbPartHeight=8 01 – SubMbPartWidth=8, SubMbPartHeight=4 10 – SubMbPartWidth=4, SubMbPartHeight=8 11 – SubMbPartWidth=4, SubMbPartHeight=4 For VC-1, This field indicates the transformation types used for luma components, 2 bits for each 8x8.
5	31:24	**Frame Store ID L0[3]** Support up to 4 Frame store ID per L0 direction, one per MB partition, if exists. See details in later section. This field specifies the frame Store ID into the Reference Picture List0 Table. Bit 7: **Must Be One**: (This is reserved for control fields in future extension, when reference index are generated instead of frame store ID) 1: indicate it is in Frame store ID format. 0: indicate it is in Reference Index format. Bit 6:5: reserved MBZ Bit 4:0: Frame store index or Frame Store ID (Bit 4:1 is used to form the binding table index in intel implementation)
	23:16	**Frame Store ID L0[2]** Support up to 4 Frame store ID per L0 direction, one per MB partition, if exists. See details in later section. This field specifies the frame Store ID into the Reference Picture List0 Table. Bit 7: **Must Be One**: (This is reserved for control fields in future extension, when reference index are generated instead of frame store ID) 1: indicate it is in Frame store ID format. 0: indicate it is in Reference Index format. Bit 6:5: reserved MBZ Bit 4:0: Frame store index or Frame Store ID (Bit 4:1 is used to form the binding table index in intel implementation)
	15:8	**Frame Store ID L0[1]** Support up to 4 Frame store ID per L0 direction, one per MB partition, if exists. See details in later section. This field specifies the frame Store ID into the Reference Picture List0 Table. Bit 7: **Must Be One**: (This is reserved for control fields in future extension, when reference index are generated instead of frame store ID) 1: indicate it is in Frame store ID format.

DWord	Bit	Description
		0: indicate it is in Reference Index format. Bit 6:5: reserved MBZ Bit 4:0: Frame store index or Frame Store ID (Bit 4:1 is used to form the binding table index in intel implementation).
	7:0	**Frame Store ID L0[0]** Support up to 4 Frame store ID per L0 direction, one per MB partition, if exists. See details in later section. This field specifies the frame Store ID into the Reference Picture List0 Table. Bit 7: **Must Be One**: (This is reserved for control fields in future extension, when reference index are generated instead of frame store ID) 1: indicate it is in Frame store ID format. 0: indicate it is in Reference Index format. Bit 6:5: reserved MBZ Bit 4:0: Frame store index or Frame Store ID (Bit 4:1 is used to form the binding table index in intel implementation)
6	31:24	**Frame Store ID L1[3]** Support up to 4 Frame store ID per L0 direction, one per MB partition, if exists. See details in later section. This field specifies the frame Store ID into the Reference Picture List0 Table. Bit 7: **Must Be One**: (This is reserved for control fields in future extension, when reference index are generated instead of frame store ID) 1: indicate it is in Frame store ID format. 0: indicate it is in Reference Index format. Bit 6:5: reserved MBZ Bit 4:0: Frame store index or Frame Store ID (Bit 4:1 is used to form the binding table index in intel implementation)
	23:16	**Frame Store ID L1[2]** Support up to 4 Frame store ID per L0 direction, one per MB partition, if exists. See details in later section. This field specifies the frame Store ID into the Reference Picture List0 Table. Bit 7: **Must Be One**: (This is reserved for control fields in future extension, when reference index are generated instead of frame store ID) 1: indicate it is in Frame store ID format. 0: indicate it is in Reference Index format. Bit 6:5: reserved MBZ Bit 4:0: Frame store index or Frame Store ID (Bit 4:1 is used to form the binding table index in intel

DWord	Bit	Description
		implementation)
	15:8	**Frame Store ID L1[1]** Support up to 4 Frame store ID per L0 direction, one per MB partition, if exists. See details in later section. This field specifies the frame Store ID into the Reference Picture List0 Table. Bit 7: **Must Be One**: (This is reserved for control fields in future extension, when reference index are generated instead of frame store ID) 1: indicate it is in Frame store ID format. 0: indicate it is in Reference Index format. Bit 6:5: reserved MBZ Bit 4:0: Frame store index or Frame Store ID (Bit 4:1 is used to form the binding table index in intel implementation)
	7:0	**Frame Store ID L1[0]** Support up to 4 Frame store ID per L0 direction, one per MB partition, if exists. See details in later section. This field specifies the frame Store ID into the Reference Picture List0 Table. Bit 7: **Must Be One**: (This is reserved for control fields in future extension, when reference index are generated instead of frame store ID) 1: indicate it is in Frame store ID format. 0: indicate it is in Reference Index format. Bit 6:5: reserved MBZ Bit 4:0: Frame store index or Frame Store ID (Bit 4:1 is used to form the binding table index in intel implementation)

AVC Encoder PAK Commands

Each PAK Commands is composed of a command op-code DW and one or more command data DWs (inline data). The size of each command is specified as part of the op-code DW. Most of the commands have fixed size, except some are allowed to be of variable length.

There is an inherent order of executing MFC PAK commands that driver must follow.

MFC_AVC_PAK_OBJECT

PAK Object Inline Data Description

The Inline Data includes all the required MB encoding states, constitute part of the Slice Data syntax elements, MB Header syntax elements and their derivatives. It provides information for the following operations:

1. Forward and Inverse Transform
2. Forward and Inverse Quantization
3. Advanced Rate Control (QRC)
4. MB Parameter Construction (MPC)
5. CABAC/CAVLC encoding
6. Bit stream packing
7. Intra and inter-Prediction decoding loop
8. Internal error handling

These state/parameter values may subject to change on a per-MB basis, and must be provided in each MFC_AVC_PAK_OBJECT command. The values set for these variables are retained internally, until they are reset by hardware Asynchronous Reset or changed by the next MFC_AVC_PAK_OBJECT command.

The inline data has been designed to match the DXVA 2.0, with the exception of the starting byte (DW0:0-7) and the ending dword (DW7:0-31).

The Deblocker Filter Control flags (FilterInternalEdgesFlag, FilterTopMbEdgeFlag and FilterLeftMbEdgesFlag) are generated by H/W, which are depending on MbaffFrameFlag, CurrMbAddr, PicWidthInMbs and disable_deblocking_filter_idc states.

Current MB [x,y] address is not sent, it is assumed that the H/W will keep track of the MB count and current MB position internally.

DWord	Bit	Description
	30	**Reserved: MBZ**
	23	**Reserved: MBZ**
	19	**CbpDcY.** This field specifies if the Luma DC sub-block is coded. Setting it to 0 will force PAK to zero out the Luma sub-block. Otherwise, whether the sub-block is coded will be determined by the quantization process. 1 – the 4x4 DC-only Luma sub-block of the Intra16x16 coded MB is present; it is still possible that all DC coefficients are zero. 0 – no 4x4 DC-only Luma sub-block is present; either not in Intra16x16 MB mode or all DC coefficients are zero. **Programming Note** **Context:** PAK Object Inline Data Description - CbpDcY When Reference Mb: IPCM or inferred IPCM, current mb: base mode flag = 1: TcoeffLvlPredFlag = 1 ; all bits in CbpDcY, CbpDcU, CbpDcV, Cbp4x4Y[15:0], Cbp4x4V[15:0] and Cbp4x4U[15:0] must set to 1's.
	18	**CbpDcU.** This field specifies if the Chroma Cb DC sub-block is coded. Setting it to 0 will force PAK to zero out the Luma sub-block. Otherwise, whether the sub-block is coded will be determined by the quantization process. 1 – the 2x2 DC-only Chroma Cb sub-block of all coded MB (any type) is present; it is still possible that all DC coefficients are zero. 0 – no 2x2 DC-only Chroma Cb sub-block is present; all DC coefficients are zero. **Programming Note** **Context:** PAK Object Inline Data Description When Reference Mb: IPCM or inferred IPCM, current mb: base mode flag = 1: TcoeffLvlPredFlag = 1 ; all bits in CbpDcY, CbpDcU, CbpDcV, Cbp4x4Y[15:0], Cbp4x4V[15:0] and Cbp4x4U[15:0] must set to 1's.

<tr><td></td><td>17</td><td>CbpDcV. This field specifies if the Chroma Cb DC sub-block is coded. Setting it to 0 will force PAK to zero out the Luma sub-block. Otherwise, whether the sub-block is coded will be determined by the quantization process.

1 – the 2x2 DC-only Chroma Cr sub-block of all coded MB (any type) is present; it is still possible that all DC coefficients are zero.

0 – no 2x2 DC-only Chroma Cr sub-block is present; all DC coefficients are zero.

<table><tr><th colspan="2">Programming Note</th></tr><tr><td>Context:</td><td>PAK Object Inline Data Description</td></tr><tr><td colspan="2">When Reference Mb: IPCM or inferred IPCM, current mb: base mode flag = 1: TcoeffLvlPredFlag = 1 ; all bits in CbpDcY, CbpDcU, CbpDcV, Cbp4x4Y[15:0], Cbp4x4V[15:0] and Cbp4x4U[15:0] must set to 1’s.</td></tr></table></td></tr>
<tr><td></td><td>16</td><td>Reserved: MBZ
(reserved for future use as ExternalResidBufFlag for turbo mode)</td></tr>
<tr><td></td><td>15</td><td>Transform8x8Flag

This field indicates that 8x8 transform is used for the macroblock.

When it is set to 0, the current MB uses 4x4 transform. When it is set to 1, the current MB uses 8x8 transform. The transform_size_8x8_flag syntax element, if present in the output bitstream, is the same as this field. However, whether transform_szie_8x8_flag is present or not in the output bitstream depends on several other conditions.

This field is only allowed to be set to 1 for two conditions:

It must be 1 if IntraMbFlag = INTRA and IntraMbMode = INTRA_8x8

It may be 1 if IntraMbFlag = INTER and there is no sub partition size less than 8x8

Otherwise, this field must be set to 0.

<table><tr><th colspan="2">Programming Note</th></tr><tr><td>Context:</td><td>PAK Inline Object Data Description</td></tr><tr><td colspan="2">When AvcImgState EntropyCodingFlag is 1(CABAC), this field cannot be 1.</td></tr></table>
0: 4x4 integer transform

1: 8x8 integer transform</td></tr>
</table>

DWord	Bit	Description
	14	**FieldMbFlag** This field specifies the field polarity of the current macroblock, as the mb_field_decoding_flag syntax element in AVC spec. This field specifies whether current macroblock is coded as a field or frame macroblock in MBAFF mode. It is exactly the same as FIELD_PIC_FLAG syntax element in non-MBAFF mode. 0 = Frame macroblock 1 = Field macroblock
	13	**IntraMbFlag** This field specifies whether the current macroblock is an Intra (I) macroblock. I_PCM is considered as Intra MB. For I-picture MB (IntraPicFlag =1), this field must be set to 1. This flag must be set in consistent with the interpretation of MbType (inter or intra modes). 0: INTER (inter macroblock) 1: INTRA (intra macroblock)
	12:8	**MbType5Bits** This field is encoded to match with the best macroblock mode determined as described in the next section. It follows an unified encoding for inter and intra macroblocks according to AVC Spec.
	7	**FieldMbPolarityFlag** This field indicates the field polarity of the current macroblock. Within an MbAff frame picture, this field may be different per macroblock and is set to 1 only for the second macroblock in a MbAff pair if FieldMbFlag is set. Otherwise, it is set to 0. Within a field picture, this field is set to 1 if the current picture is the bottom field picture. Otherwise, it is set to 0. It is a constant for the whole field picture. This field is reserved and MBZ for a progressive frame picture. 0 = Current macroblock is a field macroblock from the **top** field 1 = Current macroblock is a field macroblock from the **bottom** field *Programming Note: Here bits [26:24] (MbAffFieldFlag and FiedlMbPolarityFlag) match with bits [10:8] of the Media Block Read message descriptor, simplifying the programming for message generation, as when MbAffFieldFlag is "1", kernels need to override the original "frame" surface state set for MBAFF frame picture.*
	6	MB Reserved: Inter MB converted to IPCM. This field is for HW purposes only. SW should not use it.

DWord	Bit	Description
	5:4	**IntraMbMode** This field is provided to carry information partially overlapped with MbType. This field is only valid if **IntraMbFlag** = INTRA, otherwise, it is ignored by hardware..
	3	Reserved: MBZ
	2	**SkipMbFlag** By setting it to 1, this field forces an inter macroblock to be encoded as a skipped macroblock. It is equivalent to mb_skip_flag in AVS spec, indicating that a macroblock is inferred as a P_Skip (or B_Skip) in a P Slice (or B Slice). Hardware honors input MVs for motion prediction and forces CBP to zero. By setting it to 0, an inter macroblock will be coded as a normal inter macroblock. The macroblock may still be coded as a skipped macroblock, according to the macroblock type conversion rules described in the later sub sections. This field can only be set to 1 for certain values of MbType. See details later. This field is only valid for an inter macroblock. For intra MB (bit 13 of this DW set to one), this bit must be set to zero. 0 = not a skipped macroblock 1 = is coded as a skipped macroblock
	1:0	**InterMbMode** This field is provided to carry redundant information as that encoded in MbType. This field is only valid if **IntraMbFlag** =0, otherwise, it is ignored by hardware.
4	15:8	MbYCnt (Vertical Origin). This field specifies the vertical origin of current macroblock in the destination picture in units of macroblocks. Format = U8 in unit of macroblock.
	7:0	MbXCnt (Horizontal Origin). This field specifies the horizontal origin of current macroblock in the destination picture in units of macroblocks. Format = U8 in unit of macroblock.
5	31:16	Cbp4x4V (Coded Block Pattern Cr) Only the lower 4 bits [3:0] are valid for 4:2:0. The 4x4 Cr sub-blocks are numbered as blk0 1 bit3 2 blk2 3 bit1 0 The cbpCr bit assignment is cbpCr bit [3 - X] for sub-block_num X. 0 in a bit - indicates the corresponding 4x4 sub-block is not present (because all coefficient values

DWord	Bit	Description
		are zero), or force to zero for PAK. 1 in a bit - indicates the corresponding 4x4 sub-block is present (although it is still possible to have all its coefficients be zero - bad coding). For monochrome, this field is ignored. For 4.2.2, [23:16] for U(Cb), and [31:24] ignored. For 4.4.4, the definition is the same as for luma component: 1bit per 4x4 block. **Programming Note** **Context:** PAK Object Inline Data Description When Reference Mb: IPCM or inferred IPCM, current mb: base mode flag = 1: TcoeffLvlPredFlag = 1 ; all bits in CbpDcY, CbpDcU, CbpDcV, Cbp4x4Y[15:0], Cbp4x4V[15:0] and Cbp4x4U[15:0] must set to 1's.
5	15:0	Cbp4x4U (Coded Block Pattern Cb) Only the lower 4 bits [3:0] are valid for 4:2:0. The 4x4 Cb sub-blocks are numbered as blk0 1 bit3 2 blk2 3 bit1 0 The cbpCb bit assignment is cbpCb bit [3 - X] for sub-block_num X. 0 in a bit - indicates the corresponding 4x4 sub-block is not present (because all coefficient values are zero), or force to zero for PAK. 1 in a bit - indicates the corresponding 4x4 sub-block is present (although it is still possible to have all its coefficients be zero - bad coding). For monochrome, this field is ignored. For 4.2.2, [7:0] for U(Cb), and [15:8] ignored. For 4.4.4, the definition is the same as for luma component: 1bit per 4x4 block. **Programming Note** **Context:** PAK Object Inline Data Description When Reference Mb: IPCM or inferred IPCM, current mb: base mode flag = 1: TcoeffLvlPredFlag = 1 ; all bits in CbpDcY, CbpDcU, CbpDcV, Cbp4x4Y[15:0], Cbp4x4V[15:0] and Cbp4x4U[15:0] must set to 1's.
6	31:28	**Skip8x8Pattern** This field indicates whether each of the four 8x8 sub macroblocks is using the predicted MVs and will not be explicitly coded in the bitstream (the sub macroblock will be coded as direct mode). It contains four 1-bit subfields, corresponding to the 4 sub macroblocks in sequential order. The whole macroblock may be actually coded as B_Direct_16x16 or B_Skip, according to the macroblock

DWord	Bit	Description
		type conversion rules described in a later sub section. This field is only valid for a B slice. It is ignored by hardware for a P slice. Hardware also ignores this field for an intra macroblock. 0 in a bit – Corresponding MVs are sent in the bitstream 1 in a bit – Corresponding MVs are not sent in the bitstream
	27	**EnableCoeffClamp** 1 = the magnitude of coefficients of the current MB will be clamped based on the clamping matrix after quantization 0 = no clamping
	26	**LastMbFlag** 1 – the current MB is the last MB in the current Slice 0 – the current MB is not the last MB in the current Slice - Reserved MBZ.
	25	**SkipMbConvDisable** This is a per-MB level control to enable and disable skip conversion. This field is ORed with SkipConvDisable field. This field is only valid for a P or B slice. It must be zero for other slice types. Rules are provided in Section *Macroblock Type Conversion Rules* 0 - Enable skip type conversion for the current macroblock 1 - Disable skip type conversion for the current macroblock
	24	Reserved MBZ.
	23:16	**Reserved. Ignored by HW, this field will be re-derived internally**. (was **QpPrimeV.** For 8-bit pixel data, QpCr is the same as QpPrimeCr, and it takes on a value in the range of 0 to 51, positive integer.)
	15:8	**Reserved. Ignored by HW, this field will be re-derived internally**. (Was **QpPrimeU.** For 8-bit pixel data, QpCb is the same as QpPrimeCb, and it takes on a value in the range of 0 to 51, positive integer.)
	7:0	**QpPrimeY** This is the per-MB QP value specified for the current MB. For 8-bit pixel data, QpY is the same as QpPrimeY, and it takes on a value in the range of 0 to 51, positive integer. **Programming Note** **Context:** PAK Object Inline Data Description This value may differ from the actual codes, when HW QRC is on

The inline data content of Dwords 4 to 6 is defined either for intra prediction or for inter prediction, but not both.

Inline data subfields for an Intra Macroblock

Dword	Bit	Description
7	31:16	**LumaIntraMode[1]** Specifies the Luma Intra Prediction mode for four 4x4 sub-block of a MB, 4-bit each. See the bit assignment table later in this section.
	15:0	**LumaIntraMode[0]** Specifies the Luma Intra Prediction mode for four 4x4 sub-block, four 8x8 block or one intra16x16 of a MB. 4-bit per 4x4 sub-block (Transform8x8Flag=0, Mbtype=0 and intraMbFlag=1) or 8x8 block (Transform8x8Flag=1, Mbtype=0, MbFlag=1), since there are 9 intra modes.

Dword	Bit	Description
		4-bit for intra16x16 MB (Transform8x8Flag=0, Mbtype=1 to 24 and intraMbFlag=1), but only the LSBit[1:0] is valid, since there are only 4 intra modes. See the bit assignment table later in this section.
8	31:16	**LumaIntraMode[3]** Specifies the Luma Intra Prediction mode for four 4x4 sub-block of a MB, 4-bit each. See the bit assignment table later in this section.
	15:0	**LumaIntraMode[2]** Specifies the Luma Intra Prediction mode for four 4x4 sub-block of a MB, 4-bit each. See the bit assignment later in this section.
9	31:8	Reserved: MBZ (Reserved for encocder turbo mode **IntraResidueDataSize**, when this is not 0, optional residue data are provided to the PAK; Reserved for decoder)
	7:0	**IntraStruct** This field contains 6 bits for IntraPredAvailFlags[5:0] and 2 bits for ChromaIntraPredMode. The IntraPredAvailFlags[4:0] (the lower 5 bits) have already included the effect of the constrained_intra_pred_flag. See the diagram later for the definition of neighbor position around the current MB or MB pair (in MBAFF mode). 1 – IntraPredAvailFlagY, indicates the values of samples of neighbor Y can be used in intra prediction for the current MB. 0 – IntraPredAvailFlagY, indicates the values of samples of neighbor Y is not available for intra prediction of the current MB. IntraPredAvailFlag-A and -E can only be different from each other when constrained_intra_pred_flag is equal to 1 and mb_field_decoding_flag is equal to 1 and the value of the mb_field_decoding_flag for the macroblock pair to the left of the current macroblock is equal to 0 (which can only occur when MbaffFrameFlag is equal to 1). IntraPredAvailFlag-F is used only if • It is in MBAFF mode, that is, **MbaffFrameFlag** = 1 • The current macroblock is of frame type, that is, **MbFieldFag** = 0 • The current macroblock type is Intra8x8, that is, **IntraMbFlag** = INTRA, **IntraMbMode** = INTRA_8x8, and **Transform8x8Flag** = 1 In any other cases IntraPredAvailFlag-A shall be used instead.

Bits	IntraPredAvailFlags Definition
7	**IntraPredAvailFlagF – F** (Left 8th row (-1,7) neighbor)

Dword	Bit	Description
		6 **IntraPredAvailFlagA – A** (Left neighbor top half) 5 **IntraPredAvailFlagE – E** (Left neighbor bottom half) 4 **IntraPredAvailFlagB – B** (Top neighbor) 3 **IntraPredAvailFlagC – C** (Top right neighbor) 2 **IntraPredAvailFlagD – D** (Top left corner neighbor) 1:0 **ChromaIntraPredMode –** 2 bits to specify 1 of 4 chroma intra prediction modes, see the table in later section.

Inline data subfields for an Inter Macroblock

DWord	Bit	Description
7	31:16	**Reserved: MBZ**
	15:8	**SubMbPredMode (Sub-Macroblock Prediction Mode):** If **InterMbMode** is INTER8x8, this field describes the prediction mode of the sub-partitions in the four 8x8 sub-macroblock. It contains four subfields each with 2-bits, corresponding to the four 8x8 sub-macroblocks in sequential order. This field is derived from sub_mb_type for a BP_8x8 macroblock. This field is derived from **MbType** for a non-BP_8x8 inter macroblock, and carries redundant information as **MbType**). If **InterMbMode** is INTER16x16, INTER16x8 or INTER8x16, this field carries the prediction modes of the sub macroblock (one 16x16, two 16x8 or two 8x16). The unused bits are set to zero. Bits [1:0]: SubMbPredMode[0] Bits [3:2]: SubMbPredMode[1] Bits [5:4]: SubMbPredMode[2] Bits [7:6]: SubMbPredMode[3]
	7:0	**SubMbShape** (Sub Macroblock Shape) This field describes the sub-block partitioning of each sub macroblocks (four 8x8 blocks). It contains four subfields each with 2-bits, corresponding to the 4 fixed size 8x8 sub macroblocks in sequential order. This field is provided for MB with sub_mb_type equal to BP_8x8 only (B_8x8 and P_8x8 as defined in DXVA). Otherwise, this field is ignored by hardware Bits [1:0]: SubMbShape[0] – for 8x8 Block 0

DWord	Bit	Description
		Bits [3:2]: SubMbShape[1] – for 8x8 Block 1 Bits [5:4]: SubMbShape[2] – for 8x8 Block 2 Bits [7:6]: SubMbShape[3] – for 8x8 Block 3 Blocks of the MB is numbered as follows : 01 23 Each 2-bit value [1:0] is defined as : 00 – SubMbPartWidth=8, SubMbPartHeight=8 01 – SubMbPartWidth=8, SubMbPartHeight=4 10 – SubMbPartWidth=4, SubMbPartHeight=8 11 – SubMbPartWidth=4, SubMbPartHeight=4
8	31:24	**RefPicSelect[0][3]** Support up to 4 reference pictures per L0 direction, one per MB partition, if exists. See details in later section. This field specifies the reference index into the Reference Picture List0 Table.
	23:16	**RefPicSelect[0][2]** Support up to 4 reference pictures per L0 direction, one per MB partition, if exists. See details in later section. This field specifies the reference index into the Reference Picture List0 Table.
	15:8	**RefPicSelect[0][1]** Support up to 4 reference pictures per L0 direction, one per MB partition, if exists. See details in later section. This field specifies the reference index into the Reference Picture List0 Table.
	7:0	**RefPicSelect[0][0]** Support up to 4 reference pictures per L0 direction, one per MB partition, if exists. See details in later section. This field specifies the reference index into the Reference Picture List0 Table.
9	31:24	**RefPicSelect[1] [3]** Support up to 4 reference pictures per L1 direction, one per MB partition, if exists. See details in later section. This field specifies the reference index into the Reference Picture List1 Table. For P- picture these bits must be set to zero.
	23:16	**RefPicSelect[1][2]** Support up to 4 reference pictures per L1 direction, one per MB partition, if exists. See details in later section. This field specifies the reference index into the Reference Picture List1 Table.

DWord	Bit	Description
		For P- picture these bits must be set to zero.
	15:8	**RefPicSelect[1][1]** Support up to 4 reference pictures per L1 direction, one per MB partition, if exists. See details in later section. This field specifies the reference index into the Reference Picture List1 Table. For P- picture these bits must be set to zero.
	7:0	**RefPicSelect[1][0]** Support up to 4 reference pictures per L1 direction, one per MB partition, if exists. See details in later section. This field specifies the reference index into the Reference Picture List1 Table. For P- picture these bits must be set to zero.

Luma Intra Prediction Modes

Luma Intra Prediction Modes (LumaIntraPredModes) is defined in *Luma Intra Prediction Modes* . It is further categorized as Intra16x16PredMode (*Luma Intra Prediction Modes*), Intra8x8PredMode (*Luma Intra Prediction Modes*) and Intra4x4PredMode (*Luma Intra Prediction Modes*), operating on 16x16, 8x8 and 4x4 block sizes, respectively. illustrates the intra prediction directions geometrically for the Intra4x4 prediction. When a macroblock is subdivided, the intra prediction is performed for the subdivision in a predetermined order. For example, *Luma Intra Prediction Modes* shows the block order for Intra4x4 prediction. And *Luma Intra Prediction Modes* shows the block order of Block8x8 in a 16x16 region or Block4x4 in an 8x8 region.

RefIdxL0/1[3]	x	x	x	blk3	Bit 31:24

MB Neighbor Availability in Intra-Prediction Modes (IntraPredAvailFlags)

Current MB is labelled as X. For non-MBAFF mode, 4 neighbors, A, B, C, D, are depicted in the following picture and are defined as the following.

- MB D: top left neighbor of current MB X

- MB C: top right neighbor of current MB X
- MB B: top neighbor of current MB X
- MB A: left neighbor of the current MB X

mbAddrD D (top-left)	**mbAddrB** B (top)	**mbAddrC** C (top-right)
mbAddrA A (left)	**CurrMbAddrX** X	N/A
N/A	N/A	N/A

For MBAFF mode, the current MB is labelled as X0 or X1, 4 neighbor pairs, A0/A1, B0/B1, C0/C1, D0/D1, are depicted in the following picture and are defined as the following.

- MB D0: first MB of top left neighbor MB pair of current MB pair X0/X1
- MB D1: second MB of top left neighbor MB pair of current MB pair X0/X1
- MB C0: first MB of top right neighbor MB pair of current MB pair X0/X1
- MB C1: second MB of top right neighbor MB pair of current MB pair X0/X1
- MB B0: first MB of top neighbor MB pair of current MB pari X0/X1
- MB B1: second MB of top neighbor MB pair of current MB pari X0/X1
- MB A0: first MB of left neighbor MB pair of the current MB pair X0/X1
- MB A1: second MB of left neighbor MB pair of the current MB pair X0/X1

mbAddrD D0	**mbAddrB** B0	**mbAddrC** C0
mbAddrD+1 D1	**mbAddrB+1** B1	**mbAddrC+1** C1
mbAddrA A0	**CurrMbAddrX** X0 or	N/A
mbAddrA+1 A1	**CurrMbAddrX** X1	N/A

For a given macroblock X (or X0/X1), the 6 neighbor availability signals, namely, A, B, C, D, E, F, are defined as the following.

- IntraPredAvailFlagF – F (Single neighbor pixel at the left 8th row (-1,7)
- IntraPredAvailFlagA – A (Left neighbor top half pixel group)
- IntraPredAvailFlagE – E (Left neighbor bottom half pixel group)
- IntraPredAvailFlagB – B (Top neighbor pixel group)
- IntraPredAvailFlagC – C (Top right neighbor pixel group)
- IntraPredAvailFlagD – D (Top left corner neighbor pixel)

The following table depicts the generation of IntraPredAvailFlags[5:0] signals in a condensed form. It should note that for most cases only one input neighbor signal is assigned for each condition. The exception is in the four places for deriving left neighbor A and E where the neighbor is only available if left neighbors (A0 and A1) are both available (A0&A1). Also note that F takes output value very similar to that for A except the two "AND" conditions, where F is assigned to A1 instead of (A0&A1).

Table: Definition of intra-prediction neighbor availability calculation in MBAFF mode

Output ⇒		**D**		**B**		**C**		**A**		**E**		**F**	
Current X \ Neighbor Y		**Y-Frame**	**Y-Field**	**Y-Frame**	**Y-Field**	**Y-Frame**	**Y-Field**	**Y-Frame**	**Y-Field**	**Y-Frame**	**Y-Field**	**Y-Frame**	**Y-Field**
X_0 (Top)	X-Frame	**D_1**	**D_1**	**B_1**	**B_1**	**C_1**	**C_1**	**A_0**	**A_0 & A_1**	**A_0**	**A_0 & A_1**	**A_0**	**A_1**
	X-Field	**D_1**	**D_0**	**B_1**	**B_0**	**C_1**	**C_0**	**A_0**	**A_0**	**A_1**	**A_0**	**A_0**	**A_0**
X_1 (Bottom)	X-Frame	**A_0**	**A_1**	**X_0**	**N/A**	**0**	**0**	**A_1**	**A_0 & A_1**	**A_1**	**A_0 & A_1**	**A_1**	**A_1**

Output ⇒		D		B		C		A		E		F	
Current X \ Neighbor Y		Y-Frame	Y-Field	Y-Frame	Y-Field	Y-Frame	Y-Field	Y-Frame	Y-Field	Y-Frame	Y-Field	Y-Frame	Y-Field
	X-Field	D_1	D_1	B_1	B_1	C_1	C_1	A_0	A_1	A_1	A_1	A_0	A_1

In *MB Neighbor Availability in Intra-Prediction Modes (IntraPredAvailFlags)* , *X-Frame* or *X-Field* indicates the frame/field mode of the current MB; and *Y-Frame* or *Y-Field* indicates the corresponding neighbor MB for the given neighbor location, being upper left (D) or left (A) for example. Therefore, "Y-" takes the selected neighbor MB name as in the output cell in the same column. For example, for output D, if X1 is a frame MB, Y = A, if X1 is a field MB, Y = D.

For non-MBAFF mode, as A0=A1, B0=B1, C0=C1 and D0=D1, the neighbor assignment is degenerated into the following simple table. Here, E is assigned to the same as A and F is forced to 0.

Table: Definition of intra-prediction neighbor availability calculation in non-MBAFF mode

Output ⇒	D	B	C	A	E	F
X	D0	B0	C0	A0	A0	0

To further explain the neighbor assignment rules in *MB Neighbor Availability in Intra-Prediction Modes (IntraPredAvailFlags)* , the following table provides description for each condition. Please note that this table is **informative** as it provides redundant information as in *MB Neighbor Availability in Intra-Prediction Modes (IntraPredAvailFlags)* .

Table: Detailed explanation of intra-prediction neighbor availability calculation in MBAFF mode

Current MB	Current MB Field	Neighbor MB Field	Neighbor MB Select (Y=?)	Neighbor Avail Result (OUTPUT)	Description
			D		
X0 (Top)	X-Frame	Y-Frame	D	D1	Top Frame MB uses [-1,-1] = D_31, thus D1 only, regardless D frame or field pair
	X-Frame	Y-Field	D	D1	
	X-Field	Y-Frame	D	D1	Top Field MB uses [-1,-2] = D_30, thus if D is frame pair, takes D1 (D1_14 pixel), and if D is field pair, takes D0 (D0_15 pixel)
	X-Field	Y-Field	D	D0	
X1 (Bottom)	X-Frame	Y-Frame	A	A0	Bottom Frame MB uses [-1,15] = A_15, thus A0 (A0_15 pixel) if A is a frame pair, or A1 (A1_7 pixel), if A is a field pair
	X-Frame	Y-Field	A	A1	
	X-Field	Y-Frame	D	D1	Bottom Field MB uses [-1,-1] = D_31, thus D1 only, regardless D frame or field pair
	X-Field	Y-Field	D	D1	
			B		
X0 (Top)	X-Frame	Y-Frame	B	B1	Top Frame MB uses [0...15,-1] = B_31, thus B1 only, regardless B frame or field pair
	X-Frame	Y-Field	B	B1	
	X-Field	Y-Frame	B	B1	Top Field MB uses [0...15,-2] = B_30, thus if B

Current MB	Current MB Field	Neighbor MB Field	Neighbor MB Select (Y=?)	Neighbor Avail Result (OUTPUT)	Description
			D		
	X-Field	Y-Field	B	B0	is frame pair, takes B1 (B1_14 row), and if B is field pair, takes B0 (B0_15 row)
X1 (Bottom)	X-Frame	Y-Frame	X	X0	Bottom Frame MB uses [0…15,15], thus X0 (X0_15 row)
	X-Frame	Y-Field	X	n/a	**Note:** X0 and X1 must have the same field type, this row is n/a.
	X-Field	Y-Frame	B	B1	Bottom Field MB uses [0…15,-1] = B_31, thus B1 only, regardless B frame or field pair
	X-Field	Y-Field	B	B1	
			C		
X0 (Top)	X-Frame	Y-Frame	C	C1	Top Frame MB uses [16…23,-1] = C_31, thus C1 only, regardless C frame or field pair
	X-Frame	Y-Field	C	C1	
	X-Field	Y-Frame	C	C1	Top Field MB uses [16…23,-2] = C_30, thus if C is frame pair, takes C1 (C1_14 row), and if C is field pair, takes C0 (C0_15 row)
	X-Field	Y-Field	C	C0	
X1 (Bottom)	X-Frame	Y-Frame	n/a	0	Bottom Frame MB doesn't have left-top neighbor by definition, thus forced to 0
	X-Frame	Y-Field	n/a	0	
	X-Field	Y-Frame	C	C1	Bottom Field MB uses [16…23,-1] = C_31, thus C1 only, regardless C frame or field pair
	X-Field	Y-Field	C	C1	
			A		
X0 (Top)	X-Frame	Y-Frame	A	A0	First Half of Top Frame MB uses [-1,0…7], thus A0 if A is a frame pair; but is only avail if both A0 and A1 are avail if A is a field pair due to the mix
	X-Frame	Y-Field	A	A0&A1	
	X-Field	Y-Frame	A	A0	First Half of Top Field MB uses [-1,0..2..4..14], thus take A0 (if A is frame pair, takes A0 even lines, and if A is field pair, takes A0 first half)
	X-Field	Y-Field	A	A0	
X1 (Bottom)	X-Frame	Y-Frame	A	A1	First Half of Bottom Frame MB uses [-1,16…23], thus A1 if A is a frame pair; but is only avail if both A0 and A1 are avail if A is a field pair due to the mix
	X-Frame	Y-Field	A	A0&A1	
	X-Field	Y-Frame	A	A0	First Half of Bottom Field MB uses [-1,1..3..15], thus take A0 (if A is frame pair, takes A0 odd lines, and if A is field pair, takes A1 first half)
	X-Field	Y-Field	A	A1	
			E		
X0 (Top)	X-Frame	Y-Frame	A	A0	Second Half of Top Frame MB uses [-1,8…15], thus A0 if A is a frame pair; but is only avail if
	X-Frame	Y-Field	A	A0&A1	

Current MB	Current MB Field	Neighbor MB Field	Neighbor MB Select (Y=?)	Neighbor Avail Result (OUTPUT)	Description
			D		
					both A0 and A1 are avail if A is a field pair due to the mix
	X-Field	Y-Frame	A	A1	Second Half of Top Field MB uses [-1,16..18..30], thus take A1 (if A is frame pair, takes A1 even lines, and if A is field pair, takes A0 second half)
	X-Field	Y-Field	A	A0	
X1 (Bottom)	X-Frame	Y-Frame	A	A1	Second Half of Bottom Frame MB uses [-1,24...31], thus A1 if A is a frame pair; but is only avail if both A0 and A1 are avail if A is a field pair due to the mix
	X-Frame	Y-Field	A	A0&A1	
	X-Field	Y-Frame	A	A1	Second Half of Bottom Field MB uses [-1,17..19..31], thus takes A1 (if A is frame pair, takes A1 odd lines, and if A is field pair, takes A1 second half)
	X-Field	Y-Field	A	A1	
			F		
X0 (Top)	X-Frame	Y-Frame	A	A0	Top Frame MB uses [-1,7] = A_7 (odd location), thus A0 if A is frame pair and A1 if field pair
	X-Frame	Y-Field	A	A1	
	X-Field	Y-Frame	A	A0	Top Field MB uses [-1,14] = A_14 (even location), thus A0 regardless A frame or field pair
	X-Field	Y-Field	A	A0	
X1 (Bottom)	X-Frame	Y-Frame	A	A1	Bottom Frame MB uses [-1,23] = A_23 (odd location), thus A1 regardless A frame or field pair
	X-Frame	Y-Field	A	A1	
	X-Field	Y-Frame	A	A0	Bottom Field MB uses [-1,15] = A_15 (odd location), thus A0 if A is frame pair and A1 if A is field pair
	X-Field	Y-Field	A	A1	

Macroblock Type for Intra Cases

MbType follows two different tables according to whether the macroblock is an inter or intra macroblock according to IntraMbFlag.

For an intra macroblock, MbType, as defined in *Macroblock Type for Intra Cases* , carries redundant information as IntraMbMode. The notation I_16x16_x_y_z used in the table, 'x' is Intra16x16LumaPredMode, 'y' is ChromaCbpInd, and 'z' is LumaCbpInd, as defined in *Macroblock Type for Intra Cases* .

MbType definition for Intra Macroblock

Macroblock Type	MbType
I_4x4	0
I_8x8	0
I_16x16_0_0_0	1
I_16x16_1_0_0	2
I_16x16_2_0_0	3
I_16x16_3_0_0	4
I_16x16_0_1_0	5
I_16x16_1_1_0	6
I_16x16_2_1_0	7
I_16x16_3_1_0	8
I_16x16_0_2_0	9
I_16x16_1_2_0	Ah
I_16x16_2_2_0	Bh
I_16x16_3_2_0	Ch
I_16x16_0_0_1	Dh
I_16x16_1_0_1	Eh
I_16x16_2_0_1	Fh
I_16x16_3_0_1	10h
I_16x16_0_1_1	11h
I_16x16_1_1_1	12h
I_16x16_2_1_1	13h
I_16x16_3_1_1	14h

Macroblock Type	MbType
I_16x16_0_2_1	15h
I_16x16_1_2_1	16h
I_16x16_2_2_1	17h
I_16x16_3_2_1	18h
I_PCM	19h (used by HW)

Note: MbType here is identical as specified in DXVA 2.0.

For Intra_16x16 modes, the 5 bits of value (MbType – 1) have the following meanings.

Sub field definition used by MbType for a macroblock with Intra16x16 prediction

Bits	Description
4	**LumaCbpInd** – Luma Coded Block Pattern Indicator 0 means none of the luma blocks are coded. 1 means that at least one luma block is coded. 0 = SUBMODE_I16_L_0 1 = SUBMODE_I16_L_NZ In VME output, this field is forced to be 1 before adding 1 in Intra_16x16 mode.
3:2	**ChromaCbpInd** – Chroma Coded Block Pattern Indicator 00 means none of chroma blocks are coded. 01 means that only the chroma DC block is coded, but all AC blocks are not coded. 10 means that at least one AC chroma block is coded. 00 = SUBMODE_I16_C_0 01 = SUBMODE_I16_C_DC 10 = SUBMODE_I16_C_NZ 11 = Reserved In VME output, this field is forced to be 10 before adding 1 in Intra_16x16 mode. *Programming Note: Adding 1 to MbType by VME hardware may have carry in to this field. But as '11' is reserved, the carry-in doesn't propagate into bit 4 or higher. This allows software to update MbType, if desired, using the redundant LumaIntraPredModes information.*
1:0	**Intra16x16PredMode** – Intra16x16 Prediction Mode These two bits carries redundant (identical) information as that in

Bits	Description
	LumaIntraPredModes[0][0]. 0 = SUBMODE_I16_VER 1 = SUBMODE_I16_HOR 2 = SUBMODE_I16_DC 3 = SUBMODE_I16_PLANE

IntraMbMode definition

IntraMbMode [1:0]	Description	Supported by VME?	Used by PAK?
0	**INTRA_16x16 (redundant with MbType)**	Yes	Ignored
1	**INTRA_8x8**	Yes	Yes
2	**INTRA_4x4**	Yes	Yes
3	**IPCM (redundant with MbType)**	No	Ignored

As an alternative representation, MbType is logically the same as the following, except the I_PCM and I_NxN (i.e. I_4x4 and I_8x8) cases:

- 24 types of 16x16 intra modes: **A**+**B**+**C**+**D**: (1h – 18h)

  MBTYPE_INTRA_16x16 1h A

  - 4 Intra16x16 modes:

    SUBMODE_I16_VER 0 B
    SUBMODE_I16_HOR 1 B
    SUBMODE_I16_DC 2 B
    SUBMODE_I16_PLN 3 B

  - 3 Chroma Cbp indices:

    SUBMODE_I16_C_0 0 C
    SUBMODE_I16_C_DC 4 C
    SUBMODE_I16_C_NZ 8 C

  - 2 Luma Cbp indices:

    SUBMODE_I16_L_0 0 D
    SUBMODE_I16_L_NZ Ch D

Macroblock Type for Inter Cases

Sub-Macroblock Prediction Mode, SubMbPredMode, indicates the prediction mode for the sub-partitions. Prediction mode specifies prediction direction being forward (from L0), backward (from L1) or bi-directional (from both L0 and L1). Its meaning depends on InterMbMode. *Macroblock Type for Inter Cases* provides the definition of the field.

- If InterMbMode is INTER16x16, only SubMbPredMode[0] is valid, it describes the prediction mode of the 16x16 macroblock. The other entries are set to zero by hardware.
    - For AVC, SubMbPredMode[0] contains redundant information as encoded in MbType parameter.
    - *Note: SubMbPredMode[1]-[3] are intentionally set to zero to allow a simple LUT to derive MbType as described later.*
- If InterMbMode is INTER16x8, and INTER8x16, only the first two entries SubMbPredMode[0] and SubMbPredMode[1] are valid, describing the sub-macroblock prediction mode.
    - For AVC, SubMbPredMode[0]/[1] contains redundant information as encoded in MbType parameter.
    - *Note: SubMbPredMode[2]-[3] are intentionally set to zero to allow a simple LUT to derive MbType as described later.*
- If InterMbMode is INTER8x8, each entry of SubMbPredMode describes the prediction mode of the sub-partition of an 8x8 sub-macroblock.
    - For AVC, SubMbPredMode can be derived from sub_mb_type field for BP_8x8 macroblocks as defined in AVC spec.
    - *Note on Direct Sub-macroblock Prediction Mode: Direct prediction is not conveyed through SubMbPredMode, instead, it is carried through Direct8x8Pattern.*

InterMbMode definition

MbSkipFlag	InterMbMode	Description
0	0	**INTER16x16**
0	1	**INTER16x8**
0	2	**INTER8x16**
0	3	**INTER8x8**
1	0	**PSKIP/BSKIP16x16***
1	3	**BSKIP**
1	1, 2	Reserved
Used by PAK	Ignored by PAK	

* BSKIP16x16 is an optional non-standard but equivalent optimization.

Definition of SubMbPredMode based on InterMbMode

SubMbPredMode	INTER16x16	INTER16x8	INTER8x16	INTER8x8
Bit	MbType = [1...3]	MbType = [16h]	MbType = [4...15h]	MbType = [16h]

5:4	MBZ	MBZ	MBZ	**Block8x8 2**
3:2	MBZ	**Block16x8 1**	**Block8x16 1**	**Block8x8 1**
1:0	**Block16x16**	**Block16x8 0**	**Block8x16 0**	**Block8x8 0**
	Ignored by PAK	**Ignored by PAK**	**Ignored by PAK**	**Used by PAK**

Definition of SubMbPredMode[i]

SubMbPredMode	Description	InterMbMode	VME Output	MvCountPred	Notes
0	Pred_L0	All	Yes	1	P or B Slice
1	Pred_L1	All	Yes	1	B Slice Only
2	BiPred	All	Yes	2	B Slice Only
3	Reserved	Reserved	Reserved	Reserved	Reserved

Sub-Macroblock Shape, SubMbShape[i], for i = 0...3, describes the shape of the sub partitions of the 8x8 sub-macroblock of a BP_8x8 macroblock. This field is only valid if InterMBMode is INTER8x8. They are defined in *Macroblock Type for Inter Cases* . The parameters can be derived from *sub_mb_type* field as defined in AVC spec.

Note: These fields must be correctly set even for **Direct** or **Skip** 8x8 cases, the individual B_Direct_8x8 block is flagged by the **Direct8x8Pattern** variable.

Definition of SubMbShape for an 8x8 region of a BP_8x8 macroblock (including BSKIP, BDIRECT)

	Description			
SubMbShape	NumSubMbPart	SubMbPartWidth	SubMbPartHeight	MvCountShape
0	1	8	8	1
1	2	8	4	2
2	2	4	8	2
3	4	4	4	4

For an inter macroblock, MbType, carries redundant information as InterMbMode and SubMbPredMode. *Macroblock Type for Inter Cases* provides the typical inter macroblock types and *Macroblock Type for Inter Cases* provides that with skip and direct modes. The definition of MbType for both P slice and B

slice is the same and is equivalent to that for mb_type of a B slice in the AVC spec. As direct mode is indicated using a separate field Direct8x8Pattern, 0 is reserved for MbType.

Here, MVCount is the number of motion vectors actually encoded in the bitstream. It is informative. For a BP_8x8 or equivalent Skip/Direct macroblock, MVCount is the sum of the following term for the four 8x8 sub macroblock (with i = 0...3):

MvCountShape[i] * MvCountPred[i] * MvCountDirect[i]

where MvCountShape[i] is block count for sub macroblock [i], MvCountPred[i] is the motion vector count for each block of sub macroblock[i], and MvCountDirect[i] is the multipler for direct mode for B Slice, indicating whether motion vectors are coded or not. It must be set to 1 for P slice. For B Slice, MvCountDirect[i] = !Direct8x8Pattern[i], which is 0 for a sub macroblock coded as direct mode and 1 otherwise.

In the tables, "DC" stands for "Don't Care" as PAK hardware ignores these fields.

MbType definition for Inter Macroblock (and MbSkipflag = 0)

Macroblock Type	MbType	MbSkipFlag	Direct8x8Pattern	SubMbShape	SubMbPredMode	MVCount
Reserved	0	-	-	-	-	-

Macroblock Type	Mb Type	Xfrm 8x8	MbSkip Flag	Direct8x8 Pattern	SubMb Shape	SubMb PredMode	MvCount	Notes
P_Skip_16x16	1	-	1	DC	DC	DC	0	Skipped macroblock. Motion compensation like P_L0_16x16
B_Skip_16x16_4MVPair	16h	vary	1	Fh	0	vary	0	Skipped macroblock. Motion compensation like B_8x8 with 8x8 subblocks, when **direct_8x8_inference_flag** is set to 1
B_Skip_16x16_16MVPair	16h	0	1	Fh	FFh	vary	0	Skipped macroblock. Motion compensation like B_8x8 with 4x4 subblocks, when **direct_8x8_inference_flag** is set to 0
B_Direct_16x16_4MVPair	16h	vary	0	Fh	0	vary	0	MbType coded as B_Direct_16x16. Motion compensation like B_8x8 with 8x8 subblocks, when **direct_8x8_inference_flag** is set to 1
B_Direct_16x16_16MVPair	16h	0	0	Fh	FFh	vary	0	MbType coded as B_Direct_16x16. Motion compensation like B_8x8 with 4x4 subblocks, when **direct_8x8_inference_flag** is set to 0

People might notice that B_DIRECT_16x16 and B_SKIP are mapped on BP_8x8 for AVC decoding interface in IT mode as the motion compensation operation for both modes are the same as BP_8x8. According to AVC Spec, motion vectors for B_DIRECT_16x16 and B_SKIP are derived from temporally co-located macroblock on an 8x8 sub macroblock basis if direct_8x8_inference_flag is set to 1 or on a 4x4 block basis if it is set to 0. For each sub macroblock or block, SubMbPredMode is derived, thus can any of the valid numbers. Motion vectors may also be different. In spatial direct mode, the motion vectors are subject to spatial neighbor macroblocks as well as co-located macroblock. The spatial prediction is based on the neighbor macroblocks, so the same spatial predicted motion vector applies to all sub macroblocks or blocks. However, under certain conditions, temporal predictor may replace (colZeroFlag) the spatial predictor for a given sub macroblock or block. Thus the motion vectors may differ.

In *Macroblock Type for Inter Cases* , the macroblock type names for major partitions nicely follow forms *BP_MbPredMode_MbShape* (like BP_L0_16x16) and *B_MbPredMode0_MbPredMode1_MbShape* (like B_L0_Bi_16x8). For minor partitions it is fixed as *BP_MbShape* as BP_8x8.

However, in *Macroblock Type for Inter Cases* the macroblock types for Skip and Direct modes does not follow the same rule. The third field in P_Skip_16x16 or B_Direct_16x16_x indicates that "Skip" or "Direct" applies to the entire 16x16 macroblock, even though MbShape is 8x8 as that in BP_8x8. In order to distinguish the SubMbShape being 8x8 or 4x4 for B_Skip and B_Direct, the fourth field is added. 4MVP**air** indicates upto 4 MV pairs are presented with SubMbShape equals to 0; and 16MVP**air** indicates up to 16 MV pairs are presented with SubMbShape equals to FFh.Also note that P_8x8ref0 is not specified in PAK input interface, it is up to hardware to detect and choose its packing format based on number of reference indices and reference index for the given macroblock.

Macroblock Type Conversion Rules

For improved coding efficiency the PAK hardware has the capability to convert macroblock types to use more efficiency coding modes such as DIRECT and SKIP. For an inter macroblock or a sub macroblock coded as DIRECT, no motion vector is needed in the bitstream for the macroblock or sub macroblock. If a macroblock is coded as SKIP, it only consumes one SKIP bit (no motion vector, no coefficients are coded). And infomaton about the macroblock is 'inferred' according to the rules stated in the AVC Spec.

As the input to PAK, the following signals can convey the information regarding DIRECT and SKIP:

- MbSkipFlag
- Direct8x8Pattern
- CodecBlockPattern (CbpY, CbpCb, CbpCr)

Such conversion can be enabled or disabled through the SLICE_STATE fields DirectConvDisable and SkipConvDisable as well as the in line command field MbSkipConvDisable.

A P slice doesn't support direct mode, it only supports P_Skip, which is equivalent to a 16_16_L0 prediction. Other prediction types cannot be converted to P_Skip. The following table describes the macroblock type conversion rules for a P slice. Here CBP = CbpY/CbpCb/CbpCr are the final computed results after quantization by the hardware. Note that hardware honors the input CbpY/CbpCb/CbpCr fields - if the value corresponding to a block is set to zero, the resulting CBP is also zero. The output

mb_skip_flag and mb_type are the symbols coded in the bitstream as defined in the AVC spec. *DC* stands for *Don't care*, *T* for *True*.

Note that the internal condition of MV==MVP is subject to the precise rules stated in the AVC Spec as quoted below. Note that there are exceptions for P_Skip from the normal motion vector prediction rules.

Derivation process for luma motion vectors for skipped macroblocks in P and SP slices

This process is invoked when mb_type is equal to P_Skip.

Outputs of this process are the motion vector mvL0 and the reference index refIdxL0.

The reference index refIdxL0 for a skipped macroblock is derived as follows.

refIdxL0 = 0. (8-168)

For the derivation of the motion vector mvL0 of a P_Skip macroblock type, the following applies.

- The process specified in subclause 8.4.1.3.2 is invoked with mbPartIdx set equal to 0, subMbPartIdx set equal to 0, currSubMbType set equal to "na", and listSuffixFlag set equal to 0 as input and the output is assigned to mbAddrA, mbAddrB, mvL0A, mvL0B, refIdxL0A, and refIdxL0B.

- The variable mvL0 is specified as follows.

- If any of the following conditions are true, both components of the motion vector mvL0 are set equal to 0.

- mbAddrA is not available

- mbAddrB is not available

- refIdxL0A is equal to 0 and both components of mvL0A are equal to 0

- refIdxL0B is equal to 0 and both components of mvL0B are equal to 0

- Otherwise, the derivation process for luma motion vector prediction as specified in subclause 8.4.1.3 is invoked with mbPartIdx = 0, subMbPartIdx = 0, refIdxL0, and currSubMbType = "na" as inputs and the output is assigned to mvL0.

NOTE - The output is directly assigned to mvL0, since the predictor is equal to the actual motion vector.

Macroblock type conversion rule for an inter macroblock in a P slice

Input		Internal			Output		Notes
Macroblock Type	SkipConvDisable || SkipConvDisable	CBP	MV == MVP	MbAffSkipAllowed	mb_skip_flag	mb_type	
P_Skip_16x16	DC	DC	DC	1	1	-	Forced to P_Skip; Hardware will force CBP to zero and also ignore SkipConvDisable control. Hardware doesn't check for

Input		Internal			Output		Notes
Macroblock Type	SkipConvDisable || SkipConvDisable	CBP	MV == MVP	MbAffSkipAllowed	mb_skip_flag	mb_type	
							MV==MVP error condition
P_Skip_16x16	DC	DC	DC	0	0	0	Reverse convert to P_L0_16x16; Hardware will force CBP to zero but reversely convert MbType as P_L0_16x16 once it determines that Skip is not allowed.
BP _16x16_L0	0	0	T	1	1	-	Converted to P_Skip. Even input doesn't provide skip hint, hardware can performance the optimization by detecting CBP and MV==MVP condition.
BP _16x16_L0	0	0	T	0	0	0	Reverse back to P_L0_16x16; Hardware will reverse back to P_L0_16x16 even Skip conditions are met once it determines that Skip is not allowed.
BP _16x16_L0	1	0	T	T	0	0	Still coded as P_L0_16x16 = 0.

A B slice supports both direct and skip modes. The following table describes the macroblock type conversion rules for a B slice. Hardware does not verify MV==MVP condition for a Skip/Direct macroblock in a B Slice as no DMV is performed by hardware.

Macroblock type conversion rule for an inter macroblock in a B slice

Input			Internal			Output		Notes
Macroblock Type	SkipConvDisable || SkipConvDisable	DirectConvDisable	CBP	MV == MVP	MbAffSkipAllowed	mb_skip_flag	mb_type	
B_Skip_8x8 B_Skip_4x4	DC	DC	DC	n/a	1	1	-	Forced to B_Skip; Hardware will force CBP to zero and also ignore SkipConvDisable control.
B_Skip_8x8 B_Skip_4x4	DC	DC	DC	n/a	0	0	0	REVERSE convert to B_Direct_16x16; Hardware will force CBP to zero and also reverse convert to B_Direct_16x16 when it discovers Skip is not allowed.
B_Direct_16x16_4MVPair/ 16MVPair	0	0	0	n/a	1	1	-	Converted to B_Skip. Hardware first converts to B_Direct_16x16 and then further to B_Skip if CBP = 0.
B_Direct_16x16_4MVPair/ 16MVPair	0	0	0	n/a	0	0	0	Converted to B_Direct_16x16. Hardware

Input			Internal			Output		Notes
Macroblock Type	SkipConvDisable || SkipConvDisable	DirectConvDisable	CBP	MV == MVP	MbAffSkipAllowed	mb_skip_flag	mb_type	
								first converts to B_Direct_16x16 and stop there as it discovers Skip is not allowed even CBP=0.
B_Direct_16x16_4MVPair/ 16MVPair	1	0	0	n/a	DC	0	0	Converted to B_Direct_16x16. Hardware converts to B_Direct_16x16 and stops there even though CBP = 0 as input disallows Skip conversion.
B_Direct_16x16_4MVPair/ 16MVPair	DC	0	NZ	n/a	DC	0	0	Converted to B_Direct_16x16. Hardware converts to B_Direct_16x16 and stops there because CBP != 0.
B_Direct_16x16_4MVPair/ 16MVPair	DC	1	DC	n/a	DC	0	16h	Stay as B_8x8. Hardware

Input			Internal			Output		Notes
Macroblock Type	SkipConvDisable || SkipConvDisable	DirectConvDisable	CBP	MV == MVP	MbAffSkipAllowed	mb_skip_flag	mb_type	
								stays at B_8x8 and codes each sub macroblocks even all are direct.

The internal signal MbAffSkipAllowed is added to deal with a restriction on the frame/field flag (MbFieldFlag) which is unique to MBAFF. MbAffSkipAllowed is always set to 1 in non-MBAFF modes. In MBAFF mode, a macroblock pair may be both skipped only if its MbFieldFlag is the same as its available neighbor macroblock pair A or B if A or B is available (in that order), or is not 0 if A/B are both not available. Otherwise, one of the macroblocks in the pair must be coded.

To reduce the burden on software, PAK hardware handles the above restriction correctly. For the first MB in a pair, MbAffSkipAllowed is always set to 1. Therefore, hardware allows converting the first MB to Skip if skip conversion is enabled. For the second MB in a pair, hardware sets MbAffSkipAllowed to 0 if the following is true:

- The current MB Pair has different MbFieldFlag than its available neighbor A or B if A or B is available, or is not 0 if A/B are both not available
- And the first MB is coded as a SKIP (could be forced or converted)

Otherwise, it sets MbAffSkipAllowed to 1. As MbAffSkipAllowed is to 0 for the above condition, hardware will disallow Skip mode for the second MB. If the input signal forces it to Skip, hardware performs reverse-convertion to code it as P_L0_16x16 or B_Direct_16x16 with CBP = 0 for a macroblock in a P or B Slice. This means that hardware is able to correct the programming mistake by software. If the macroblock is not forced to skip, hardware simply disallows Skip conversion.

Software still has an option to disallow Skip Conversion on a per-MB basis using the MbSkipConvDisable control field in the inline command.

Indirect Data Description

For each macroblock, an ENC-PAK data set consists of two types of data blocks: indirect **MV data block** and **inline MB information**.

The indirect MV data block may be in two modes: **unpackedmode** and **packed-size mode**.

Unpacked Motion Vector Data Block

In the **unpacked** mode, motion vectors are expanded (or duplicated) to either bidirectional 8x8 8MV major partition format, or bidirectional 4x4 32MV format. Thus either 32 bytes or 128 bytes is assigned to each MB.

Motion Vector block contains motion vectors in an intermediate format that is partially expanded according to the sub- macroblock size. During the expansion, a place that does not contain a motion vector is filled by replicating the relevant motion vector according to the following motion vector replication rules. If the relevant motion vector doesn't exist (for the given L0 or L1), it is zero filled.

Motion Vector Replication Rules:

- Rule #1
    - #1.1: For L0 MV, for any sub-macroblock or sub-partition where there is at least one motion vector
        - If L0 inter prediction exists, the corresponding L0 MV is used
        - Else it must be zero
    - #1.2: For L1 MV, for any sub-macroblock or sub-partition where there is at least one motion vector
        - If L1 inter prediction exists, the corresponding L1 MV is used
        - Else it must be zero
- For a macroblock with a 16x16, 16x8 or 8x16 sub-macroblock, MvSize = 8. The eight MV fields follow Rule #1.
    - The 16x16 is broken down into 4 8x8 sub-macroblocks. The 16x16 MVs (after rule #1) are replicated into all 8x8 blocks.
    - For an 8x16 partition, each 8x16 is broken down into 2 8x8 stacking vertically. The 8x16 MVs (after rule #1) are replicated into both 8x8 blocks.
    - For a 16x8 partition, each 16x8 is broken down into 2 8x8 stacking horizontally. The 16x8 MVs (after rule #1) are replicated into both 8x8 blocks.
- For macroblock with sub-macroblock of 8x8 without minor partition (SubMbShape[0…3] = 0), MvSize = 8, (e.g. mb_type equal to P_8x8, P_8x8ref0, or B_8x8)
    - There is no motion vector replication
- For macroblock with sub-macroblock of 8x8 with at least one minor partition (if any SubMbShape[i] != 0), MvSize = 32, (e.g. mb_type equal to P_8x8, P_8x8ref0, or B_8x8)
    - For an 8x8 sub-partition, the 8x8 MVs (after rule #1) is replicated into all the four 4x4 blocks.
    - For an 4x8 sub-partition within an 8x8 partition, each 4x8 is broken down into 2 4x4 stacking vertically. The 4x8 MVs (after rule #1) are replicated into both 4x4 blocks.

- For an 8x4 sub-partition within an 8x8 partition, each 8x4 is broken down into 2 4x4 stacking horizontally. The 8x4 MVs (after rule #1) are replicated into both 4x4 blocks.
- For a 4x4 sub-partition within an 8x8 partition, each 4x4 has its own MVs (after rule #1).

The motion vector(s) for a given sub-macroblock or a sub-partition are uniquely placed in the output message as shown by the non-duplicate fields in *Unpacked Motion Vector Data Block* and *Unpacked Motion Vector Data Block*.

MV_Yx_L0 and MV_Yx_L1 may be present individually or both. If one is not present, the corresponding field must be zero. Subsequently, the duplicated fields will be zero as well.

Packed-Size Motion Vector Data Block

In the packed case, no redundant motion vectors are sent. So the number of motion vectors sent, as specified by **MvQuantity** is the same as the motion vectors that will be packed (**MvPacked**).

The following tables are for information only. Fields like MvQuantity and MvPacked are not required interface fields.

MbSkipFlag	MbType	Description	Mv Quantity	MvSize	(Minimal MvSize)
1	1	P_Skip_16x16	0	8	1

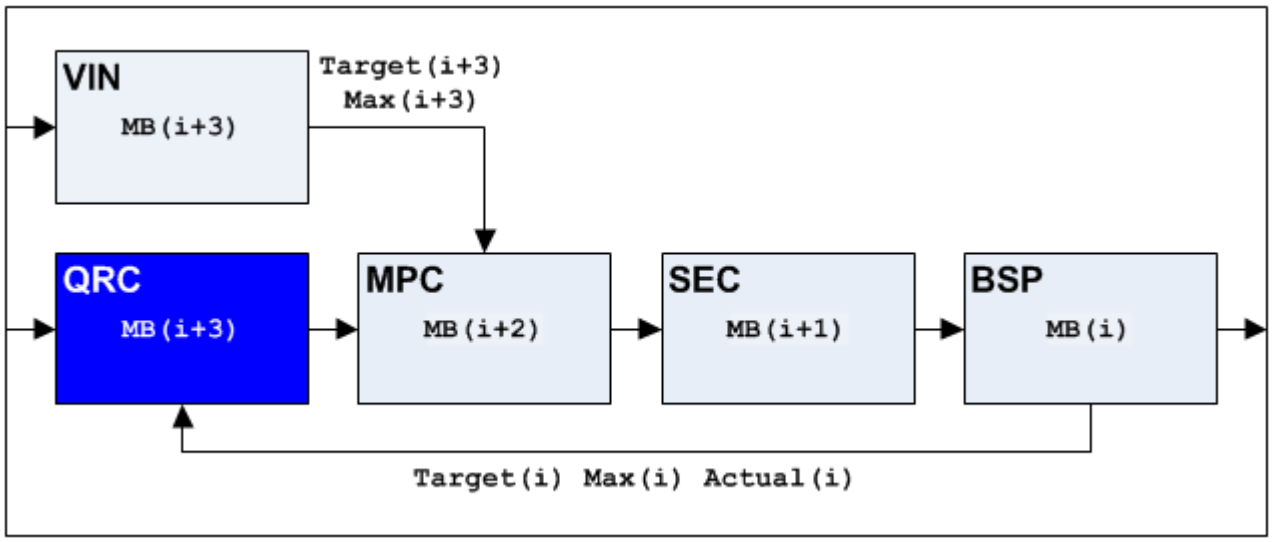
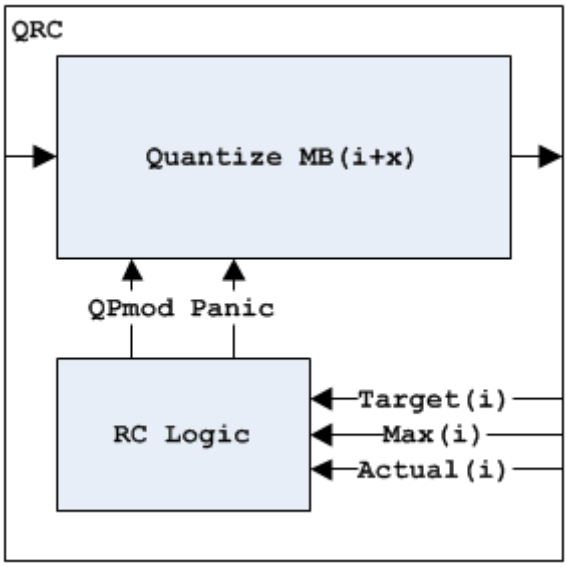
Macroblock Level Rate Control

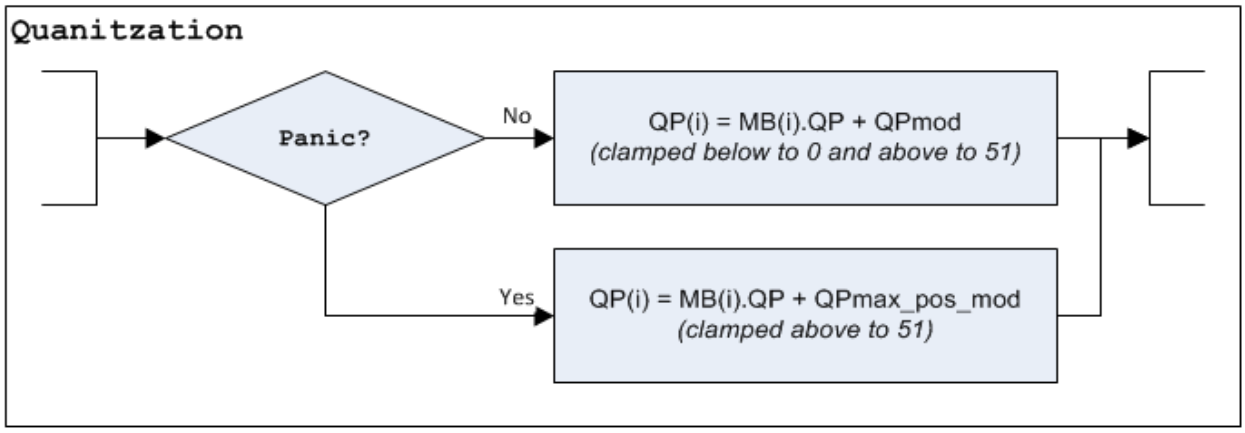
The QRC (Quantization Rate Control) unit receives data from BSP (Bit Serial Packer) and VIN (Video In) and generates adjustments to QP values across macroblocks.



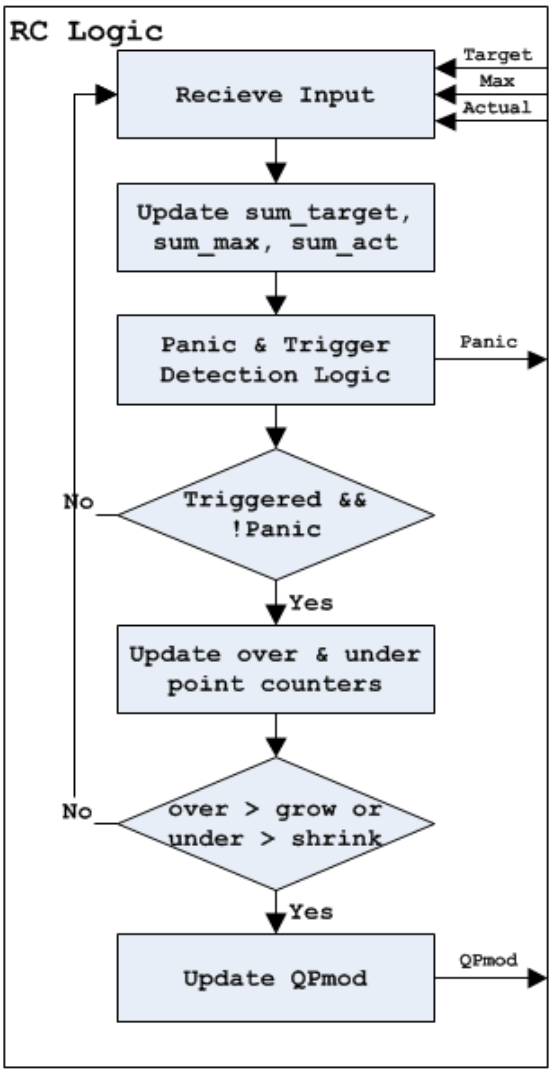
QRC can be logically partitioned into two units as shown below.



Macroblock level rate control is handled by the RC logic and the quantization logic.



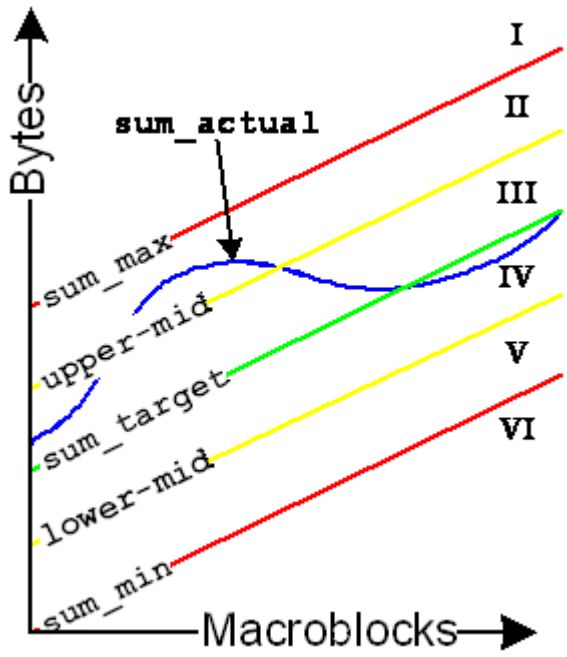
The signals QPmod and panic are generated by the RC logic based on data feedback from BSP. A flowchart of the RC logic is given below.



Theory of Operation Overview

BSP will generate a byte estimate for each macroblock packed. Additionally, the user will specify a target and max size per macroblock. The running sum of these signals (actual, target, max) creates “curves” which are used to identify when QP adjustments are necessary (see figure below). Three more curves are symmetrically generated by QRC (upper_midpt, lower_midpt, sum_min) from target and max. The values of target and max are specified by the user will dictate the shape of these curves.

The difference between sum_actual and sum_target (called ‘bytediff’) identifies the margin of error between the target and actual sizes. The difference between the current bytediff and the previously calculated bytediff represents the rate of change in this margin over time. The sign of this rate is used to identify if the correction is trending in the appropriate direction (towards bytediff = 0).



QPmod

Each macroblock will have a requested QP (which could vary across macroblocks or remain constant). QPmod is to be added to the QP requested. QPmod will be positive when the target was under-predicted and negative when the target is over-predicted.

QPmod is incremented or decremented when internal counters (called ‘over’ and ‘under’) reach tripping points (called ‘grow’ and ‘shrink’). For each MB processed and based on which region (1-6) sum_actual falls in, various amounts of points are added to either counters. If over exceeds grow, QPmod is incremented whereas if under exceeds shrink, QPmod is decremented.

To dampen the effect of repeated changes in the same direction, an increase in resistance for that direction and decrease in resistance for the complementary direction occurs (called ‘grow_resistance’ and

'shrink_resistance'). This resistance is added to grow or shrink, which then requires more points to trip the next correction in that direction.

The user can specify guard-bands that limit the amount QPmod can be modified. QPmod cannot exceed QPmax_pos_mod or become less than -QPmax_neg_mod_abs.

Triggering

The RC unit begins to modify QPmod occurs only when it is triggered.

Three levels of triggering exist: always, gentle, loose. Always means that RC will be active once sum_actual reaches regions 3 or 4. Gentle will trigger RC once sum_actual reaches regions 2 or 5. Loose waits to trigger RC when sum_actual reaches regions 1 or 6.

RC will deactivate (triggered = false) once sum_actual begins to track sum_target over a series of macroblocks. Specifically, the sign of the rate of change for bytediff is monitored over a window of macroblocks. When the sum of these signs over the window falls within a tolerance value (called 'stable'), triggered will reset to false.

Panic

When enabled, panic mode will occur whenever sum_actual reaches region 1 and will remain so until sum_actual reaches region 4. When panicking, all macroblocks will be quantized with QP = MB(n).QP + QPmax_pos_mod, clamped to 51.

User Controls

This unit achieves a large flexibility by allowing the user to define various key parameters. At the per-macroblock level, the values of target and max are specified and will create various shapes of curves that sum_actual will be compared against.

Per-slice, the user can specify the triggering sensitivity and the tolerance required to disable the trigger. Additionally, the user can enable panic detection.

The point values assigned to each of the 6 regions are exposed to the user which allow for asymmetrical control for over and under predictions amongst other things. Additionally, the user can specify the initial values of grow and shrink along with the resistance values applied when correction is invoked.

Lastly, the maximum and minimum values for QPmod are also exposed to the user.

AVC Encoder MBAFF Support

1. **Algorithm**

   Prediction of current macroblock motion vector is possible from neighboring macroblocks mbAddrA/mbAddrD/mbAddrB/mbAddrC/mbAddrA+1/mbAddrD+1/mbAddrB+1/mbAddrC+1. The selection of these macroblocks depends on coding type(field/frame) of current macroblock pair and the coding of neighboring macroblock pair.

   Selection of these macroblock pairs is described in detail in following sections.

1.1 Selection of Top LeftMB pair: The selection of Top Left MB pair depends on coding type of current and also top left macroblock pair.

1.2 Selection of LeftMB pair: The selection of Left MB pair depends on coding type of current and also left macroblock pair.

1.3 Selection of Top MB pair: The selection of Top MB pair depends on coding type of current and also top macroblock pair.

1.4 Selection of Top RightMB pair: The selection of Top Right MB pair depends on coding type of current and also top right macroblock pair.

1.5 Motion Vector and refIdx Scaling: Motion vectors and reference index of neighboring macroblocks (mbAddrA/mbAddrB/mbAddrC/mbAddrD) should be scaled before using them into prediction equations. Again the scaling depends on coding type of current and neighboring macroblock pair which is described as follows,

- If the current macroblock is a field macroblock and the macroblock mbAddrN is a frame macroblock ...

```
mvLXN[ 1 ] = mvLXN[ 1 ] / 2 (8-214)
refIdxLXN = refIdxLXN * 2   (8-215)
```

- Otherwise, if the current macroblock is a frame macroblock and the macroblock mbAddrN is a field macroblock ...

```
mvLXN[ 1 ] = mvLXN[ 1 ] * 2 (8-216)
refIdxLXN = refIdxLXN / 2   (8-217)
```

- Otherwise, the vertical motion vector component mvLXN[1] and the reference index refIdxLXN remain unchanged.

MPEG-2

MPEG2 Common Commands

MFX Commands are organized into groups based on their scope of functioning. There are Pipeline Common state commands that are common to all codecs (encoder and decoder) and is applicable to the processing of one full frame/field. There are also individual codec Common state commands that are common to both encoder and decoder of that particular codec. These latter common state commands, some are applicable at the processing of one full frame/field, and some are applicable at the processing of an individual slice level.

MFX_MPEG2_PIC_STATE

MPEG2 Decoder Commands

These are decoder-only commands. They provide the pointer to the compressed input bitstream to be decoded.

MFD_MPEG2_BSD_OBJECT

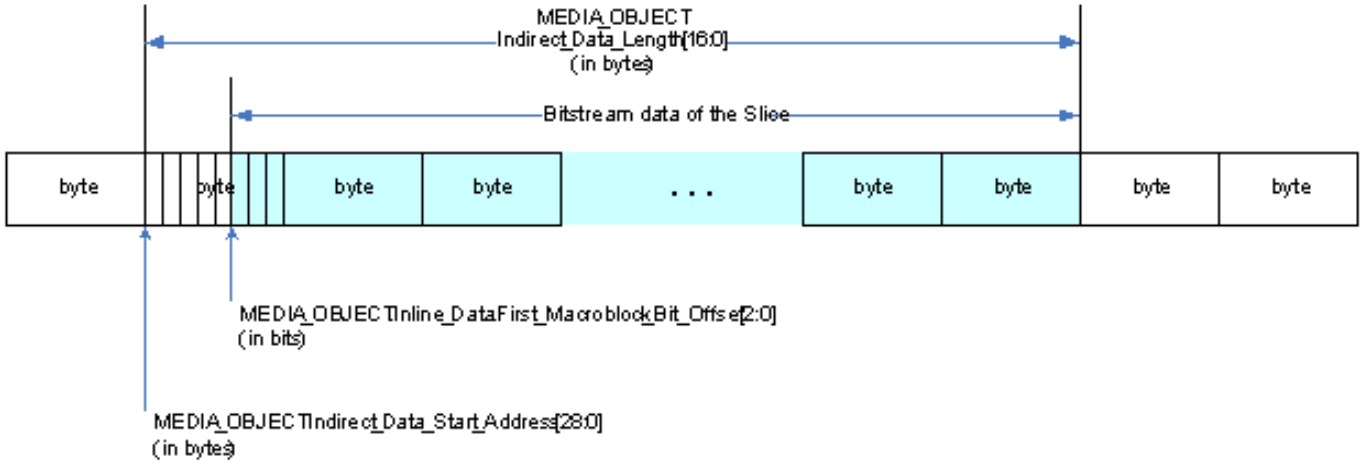
MFD_MPEG2_BSD_OBJECT Inline Data Description

Indirect Data Description

The indirect data start address in MFD_MPEG2_BSD_OBJECT specifies the starting Graphics Memory address of the bitstream data that follows the slice header. It provides the byte address for the first macroblock of the slice. Together with the First Macroblock Bit Offset field in the inline data, it provides the bit location of the macroblock within the compressed bitstream.

The indirect data length in MFD_MPEG2_BSD_OBJECT provides the length in bytes of the bitstream data for this slice. It includes the first byte of the first macroblock and the last **non-zero** byte of the last macroblock in the slice. Specifically, the zero-padding bytes (if present) and the next start-code are excluded. Hardware ignores the contents after the last non-zero byte. *Indirect Data Description* illustrates these parameters for a slice data.

Indirect data buffer for a slice



MPEG2 Encoder PAK Commands

The MFC_MPEG2_PAK_INSERT_OBJECT Command is identical to the MFC_AVC_PAK_INSERT_OBJECT command as described in this document.

The MFC_MPEG2_STITCH_OBJECT Command is identical as MFC_AVC_STITCH_OBJECT command as described in this document.

MFC_MPEG2_SLICEGROUP_STATE

MFC_MPEG2_PAK_OBJECT

PAK Object Inline Data Description – MPEG-2

The Inline Data includes all the required MB encoding states, constitute part of the Slice Data syntax elements, MB Header syntax elements and their derivatives. It provides information for the following operations:

1. Forward and Inverse Transform
2. Forward and Inverse Quantization
3. Advanced Rate Control (QRC)
4. MB Parameter Construction (MPC)
5. VLC encoding
6. Bit stream packing
7. Internal error handling

These state/parameter values may subject to change on a per-MB basis, and must be provided in each MFC_MPEG2_PAK_OBJECT command. The values set for these variables are retained internally, until they are reset by hardware Asynchronous Reset or changed by the next MFC_MPEG2_PAK_OBJECT command.

The inline data has been designed to match AVC MB structure for efficient transcoding.

Current MB [x,y] address is not sent, it is assumed that the H/W will keep track of the MB count and current MB position internally.

DWord	Bit	Description
1	31:27	Reserved: MBZ
	22-20	**MvFormat (Motion Vector Size)**. This field specifies the size and format of the input motion vectors. This field is reserved (MBZ) when the **IntraMbFlag** = 1. The valid encodings are: **011 = Unpacked: Two motion vector pairs** Others are reserved. *(The following encodings are intended for other formats:* *001 = 1MV: one 16x16 motion vector* *010 = 2MV: One 16x16 motion vector pair* *011 = 4MV: Four 8x8 motion vectors, or Two 16x8 motion vector pairs* *100 = 8MV: Four 8x8 motion vector pairs* *101 = 16MV: 16 4x4 motion vectors* *110 = 32MV: 16 4x4 motion vector pairs* *111 = Packed, number of MVs is given by **packedMvNum**.)*
	19	**CbpDcY.** This field specifies if the Luma DC coded. Must be 1 for MPEG-2.
	18	**CbpDcU.** This field specifies if the Chroma Cb DC coded. Must be 1 for MPEG-2**.**
	17	**CbpDcV.** This field specifies if the Chroma Cb DC coded. Must be 1 for MPEG-2**.**
	16	Reserved: MBZ
	15	**TransformFlag** Used to indicate transformation type for MPEG-2. 0 = Frame DCT transformation 1 = Field DCT transformation
	14	**FieldMbFlag** For MPEG-2, this flag is set to 1 if either the picture is in field type or the MB is INTER of field type, i.e. split into two 16x8 field blocks.

	13	**IntraMbFlag** This field specifies whether the current macroblock is an Intra (I) macroblock. For I-picture MB (IntraPicFlag =1), this field must be set to 1. This flag must be set in consistent with the interpretation of MbType (inter or intra modes). 0: INTER (inter macroblock) 1: INTRA (intra macroblock)
	12:8	**MbType** This field is encoded to match with the best macroblock mode determined as described in the next section. It follows an unified encoding for inter and intra macroblocks according to MFX Encoding reference as shown in Figure A.
	7:3	Reserved : MBZ
	2	**SkipMbFlag** By setting it to 1, this field forces an inter macroblock to be encoded as a skipped macroblock. It is equivalent to mb_skip_flag in AVS spec, Hardware honors input MVs for motion prediction and forces CBP to zero. By setting it to 0, an inter macroblock will be coded as a normal inter macroblock. The macroblock may still be coded as a skipped macroblock, according to the macroblock type conversion rules described in the later sub sections. This field can only be set to 1 for certain values of MbType. See details later. This field is only valid for an inter macroblock. Hardware ignores this field for an intra macroblock. 0 = not a skipped macroblock 1 = is coded as a skipped macroblock **Note:** When this flag is set to 1, the correct MVs are assumed for HW decoder to generate decoded reconstruction frame.
	1:0	**InterMbMode** This field is provided to carry redundant information as that encoded in MbType. This field is only valid if **IntraMbFlag** =0, otherwise, it is ignored by hardware.
2	31:16	**MbYCnt (Vertical Origin).** This field specifies the vertical origin of current macroblock in the destination picture in units of macroblocks. Format = U16 in unit of macroblock.

	15:0	**MbXCnt (Horizontal Origin).** This field specifies the horizontal origin of current macroblock in the destination picture in units of macroblocks. Format = U16 in unit of macroblock.
3	31:24	**MaxSizeInWord** PAK should not exceed this budget accumulatively, otherwise it will trickle the PANIC mode.
	23:16	**TargetSizeInWord** PAK should use this budget accumulatively to decide if it needs to limit the number of non-zero coefficients.
	15:13	**MBZ**
	12:0	**Cbp –** Coded Block Pattern. This field specifies whether blocks are present or not. Format = 6-bit mask (or 8-bit, & 12-bit, for 422 and 444). Bit 11: Y0Bit 10: Y1Bit 9: Y2Bit 8: Y3 Bit 7: Cb4Bit 6: Cr5Bits 0-5: MBZ
4	31	**LastMbInSlice –** the last MB in a slice.
	30	**FirstMbInSlice –** the first slice in a slice, it requires slice header insertion.
	29:28	**MBZ**
	27	**EnableCoeffClamp** 1 = the magnitude of coefficients of the current MB will be clamped based on the clamping matrix after quantization 0 = no clamping
	26	**LastMbInSG** 1 – the current MB is the last MB in the current slice group.
	25	**MbSkipConvDisable** This is a per-MB level control to enable and disable skip conversion. This field is ORed with SkipConvDisable field. This field is only valid for a P or B slice. It must be zero for other slice types. Rules are provided in *Macroblock Type Conversion Rules* 0 - Enable skip type conversion for the current macroblock 1 – Disable skip type conversion for the current macroblock

<table>
<tr><td></td><td>24</td><td>FirstMbInSG

</table>

7	31:0	**MV[0][1]** – the second forward MV if Mv[0][1] n/a: if Mv[1][1] available, it MUST be set to the same value as Mv[1][1]. else it MUST be set to the same value as Mv[0][0]
8	31:0	**MV[1][1]** – the second backward MV if Mv[1][1] n/a: it MUST be set to the same value as Mv[1][0]

The mapping between MPEG-2 spec and MfxMbCode can be achieved according to the following:

1) Renamed variables with identical meaning:

MPEG-2 Spec	MFX API	Value
macroblock_quant	**MbQuantPresent**	0 or 1
macroblock_intra	**IntraMbFlag**	0 or 1
dct_type	**Transform8x8Flag**	0 or 1
macroblock_pattern	**Cbp8x8**	remapped

2) Macroblock type remapping:

		B-spec Entry					MPEG-2 Spec				
Frame Type	Mb Type	Intra Mb Flag	Skip Mb Flag	Mb Type 5Bits	Field Mb Flag	Inter Mb Mode	macroblock_intra	motion_type_bit0	motion_type_bit1	motion_forward	motion_backward
IPB	Intra	1	0	1Ah	0/1	-	1	-	-	-	-
P **B** B	Skip	0	1	01h 02h 03h	0/1	0	0	-	-	1 0 1	0 1 1
P	0-MV*	0	0	01h	0/1	0	0	-	-	0	0

		B-spec Entry					MPEG-2 Spec				
Frame Type	Mb Type	Intra Mb Flag	Skip Mb Flag	Mb Type 5Bits	Field Mb Flag	Inter Mb Mode	macroblock_intra	motion_type_bit0	motion_type_bit1	motion_forward	motion_backward
P Frame	Frame type	0	0	01h	0	0	0	0	1	1	0
P Frame	Field type	0	0	04h	1	1	0	1	0	1	0
P Frame	dual prime	0	0	19h	0	0	0	1	1	1	0
P Field	One 16x16	0	0	01h	1	0	0	1	0	1	0
P Field	Two 16x8	0	0	04h	1	1	0	0	1	1	0
P Field	dual prime	0	0	19h	1	0	0	1	1	1	0
B Frame	Frame type	0	0	01h 02h 03h	0	0	0	0	1	1 0 1	0 1 1
B Frame	Field type	0	0	04h 06h 14h	1	1	0	1	0	1 0 1	0 1 1

		B-spec Entry					MPEG-2 Spec				
Frame Type	Mb Type	Intra Mb Flag	Skip Mb Flag	Mb Type 5Bits	Field Mb Flag	Inter Mb Mode	macroblock_intra	motion_type_bit0	motion_type_bit1	motion_forward	motion_backward
B Field	One 16x16	0	0	01h 02h 03h	1	0	0	1	0	1 0 1	0 1 1
B Field	Two 16x8	0	0	04h 06h 14h	1	1	0	0	1	1 0 1	0 1 1

- Notice that there is no special way to indicate 0 motion vector case for P frame. It is for PAK to handle internally by checking up the motion vector values.
- Notice also, the MbType5bits is adapted from AVC DXVA macroblock types. It may seems awkward from MPEG-2 perspective, but provides a common VME interface for us for simpler HW design and help the advanced transcoding solution.

    }
}
```

Video Codec VC-1

This section describes support for the open video compression standard VC-1, which is the common name for SMPTE 421M approved on April 3, 2006.

VC1 Common Commands

MFX Commands are organized into groups based on their scope of functioning. There are Pipeline Common state commands that are common to all codecs (encoder and decoder) and is applicable to the processing of one full frame/field. There are also individual codec Common state commands that are common to both encoder and decoder of that particular codec. These latter common state commands, some are applicable at the processing of one full frame/field, and some are applicable at the processing of an individual slice level.

MFX_VC1_PRED_PIPE_STATE

MFX_VC1_DIRECTMODE_STATE

VC1 Decoder Commands

These are decoder-only commands. They provide the pointer to the compressed input bitstream to be decoded.

MFD_VC1_LONG_PIC_STATE

AltPQuantConfig and **AltPQuantEdgeMask** are derived based on the following variables: *DQUANT*, *DQUANTFRM*, *DQPROFILE*, *DQSBEDGE*, *DQDBEDGE*, and *DQBILEVEL* defined in the VC1 standard, as shown in the following table.

Definition of AltPQuantConfig and AltPQuantEdgeMask

Inputs						Outputs		
DQUANT	DQUANT FRM	DQ PROFILE	DQDB EDGE	DQSB EDGE	DQBI LEVEL	AltPQuant Config	AltPQuant EdgeMask	Description
0	-	-	-	-	-	00b	0000b	No **AltPQuant**
1	0	-	-	-	-	00b	0000b	No **AltPQuant**
1	1	11b	-	-	0	10b	0000b	All MBs are different with *MQDIFF* and *ABSMQ*
1	1	11b	-	-	1	11b	0000b	All MBs may switch with 1-bit *MQDIFF*
2	-	-	-	-	-	01b	1111b	All edge MBs
1	1	00b	-	-	-	01b	1111b	All edge MBs
1	1	01b	00b	-	-	01b	0011b	Left and top MBs
1	1	01b	01b	-	-	01b	0110b	Top and right MBs
1	1	01b	10b	-	-	01b	1100b	Right and bottom MBs

Inputs						Outputs		
DQUANT	DQUANT FRM	DQ PROFILE	DQDB EDGE	DQSB EDGE	DQBI LEVEL	AltPQuant Config	AltPQuant EdgeMask	Description
1	1	01b	11b	-	-	01b	1001b	Bottom and left MBs
1	1	10b	-	00b	-	01b	0001b	Left MBs
1	1	10b	-	01b	-	01b	0010b	Top MBs
1	1	10b	-	10b	-	01b	0100b	Right MBs
1	1	10b	-	11b	-	01b	1000b	Bottom MBs

MFD_VC1_SHORT_PIC_STATE

Intel HW does not use the MVMODE and MVMODE2 provided at the revised DXVA2 VC1 VLD interface, instead, HW will decode them directly from the bitstream picture header.

MFD_VC1_BSD_OBJECT

For VC1, a slice/picture is always started with MB x positon equal to 0. Hence, no need to include in the Object Command.

Handling Emulation Bytes

In general, VC1 BSD unit is capable of handling emulation prevention bytes. However, there is a corner case that requires host software's intervention. Host software needs to overwrite the emulation byte if it overlaps the macroblock layer decode and there is not enough information for the hardware to detect the emulation byte.

The emulation bytes might have an overlap between the picture states and the first macroblock data. If the emulation bytes are 0x00 **0x000x03** 0x00 and the macroblock data starts in the middle of byte1 (**0x00**), then the host software needs to overwrite the **0x03** byte location with the previous byte (**0x00**) and change the byte offset accordingly. The hardware wouldn't know what the 1st byte was and will miss this **0x03** removal.

	31:16	Reserved			

Programming Note	
Context:	MFX_VP8_STATISTICS - Encoder Only

1. MBSkip_Prob_Total_Cnt and MBSkip_Prob_Cnt are collected to generate MBSkipProbability. After bit packing, Hardware returns both MBSkip_Prob_Total_Cnt and MBSkip_Prob_Cnt. Optimal packing could be performed in subsequent pass using MBSkipProbability of

   round (256 * (MBSkip_Prob_Total_Cnt- MBSkip_Prob_Cnt) / MBSkip_Prob_Total_Cnt))

2. Token Statistics counters collects token statistics of particular plane (4), coefficient band(8), neighbor context(3) and tree node position(11) as described in WebM Spec. Out of the space of 1056 counters, there are 270 of which has high significant in compression efficiency and are chosen for statistics collection.

VP8 Common Commands

Following are VP8 Common Commands:

MFX_VP8_PIC_STATE

For VP8 HW PAK, there are four VP8 versions supported and their programming is shown in Table1 below.

Version	MC Filter Select	Chroma Full Pixel MC Filter Mode	DBLK FilterType	DBLK FilterLevel for Segment0
0	0	0	0	Any FilterLevel
1	1	0	1	Any FilterLevel
2	1	0	0	0
3	1	1	1	0

Table1: VP8 Version

MC Filter Select: MFX_VP8_PIC_STATE.DW2.Bit0

Chroma Full Pixel MC Filter Mode: MFX_VP8_PIC_STATE.DW2.Bit1

DBKL Filter Type: MFX_VP8_PIC_STATE.DW2.Bit4

DBLK Filter Level for Segment0: MFX_VP8_PIC_STATE.DW3.Bit5:0

1. Note that when multiple segment is enabled, if Segment0 DBLK Filter is programmed to 0, Segment1,2,3 DBLK Filter should be set to 0 as well.
2. Note that MFX_VP8_Encoder_CFG.BW22.Bit22:20 (Bitstream Format Version). This field is used for generating Uncompressed header only. It is not used to control any Filter.

VP8 Decoder Commands

Following are VP* Decoder Commands:

MFD_VP8_BSD_OBJECT

VP8 Encoder Commands

MFX_VP8_Encoder_CFG

MFX_VP8_BSP_BUF_BASE_ADDR_STATE

MFX_VP8_PAK_OBJECT

VP8 PAK Object inline data:

12	SPLIT_ZERO
13	SPLIT_NEW

JPEG and MJPEG

JPEG Decoder Commands

Following are JPEG Decoder Commands:

MFD_JPEG_BSD_OBJECT

MFX_JPEG_PIC_STATE command is used for both encoding and decoding. Note the duplicate bits and the "Exists If" rows that specify what the bits represent for Encoder and Decoder.

MFX_JPEG_PIC_STATE

For JPEG decoding, the following program note is informative.

For **Rotation**, it is important to note that rotation of 90 or 270 degrees also requires exchanging **FrameWidthInBlksMinus1** with **FrameHeightInBlksMinus1** in the command. In addition, the rotation of 90 or 270 degrees also requires transportation of the quantization matrix will be transposed into the position (y, x).

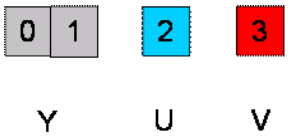
Chroma type is determined by the values of horizontal and vertical sampling factors of the components (*Hi* and Vi where *i* is a component id) in the Frame header as shown in the following table.

	H1	H2	H3	V1	V2	V3
0: YUV400	r	Not available	Not available	r	Not available	Not available
1: YUV420	2	1	1	2	1	1
2: YUV422H_2Y	2	1	1	1	1	1
3: YUV444	1	1	1	1	1	1
4: YUV411	4	1	1	1	1	1
5: YUV422V_2Y	1	1	1	2	1	1
6: YUV422H_4Y	2	1	1	2	2	2
7: YUV422V_4Y	2	2	2	2	1	1

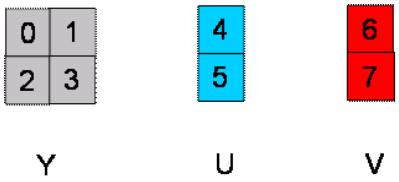
For YUV400, the value of *V1* can be 1, 2, or 3 and will be same as the value of *H1*, and the Minimum coded unit (MCU) is one 8x8 block. For the other chroma formats, if non-interleaved data, the MCU is one 8x8 block. For interleaved data, the MCU is the sequence of block units defined by the sampling factors of the components.

For example, the following figures show the MCU structures of interleaved data and the decoding order of blocks in the MCU:

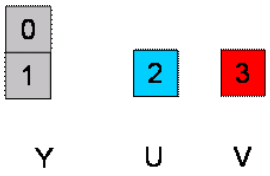
422H_2Y



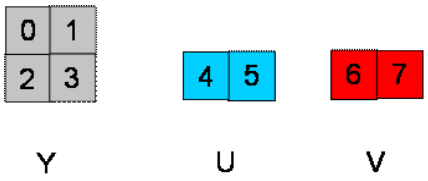
422H_4Y



422V_2Y

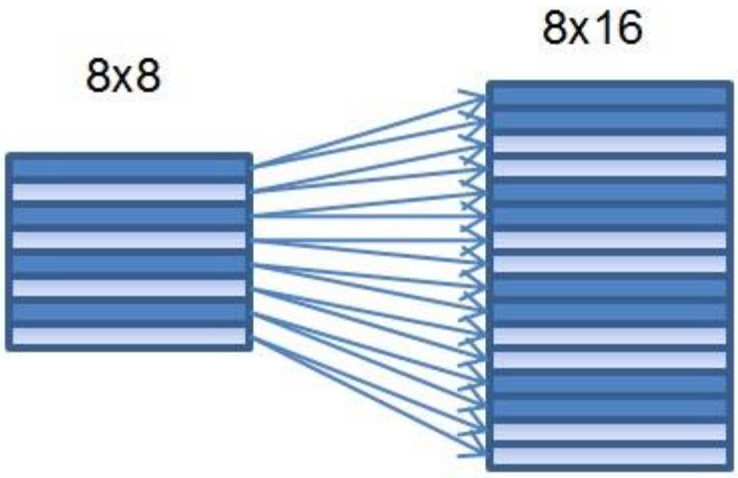


422V_4Y



If picture width *X* in the Frame header is not a multiple of 8, the decoding process needs to extend the number of columns to complete the right-most sample blocks. If the component is to be interleaved, the decoding process needs to extend the number of samples by one or more additional blocks so that the number of blocks is an integer multiple of *Hi*. In other words, "The number of blocks in width" in the table should be an integer multiple of (8x*H1*). Similarly, if picture height *Y* in the Frame header is not a multiple of 8, the decoding process needs to extend the number of lines to complete bottom-most block-row. If the component is to be interleaved, the decoding process also needs to extend the number of lines by one or more additional block-rows so that the number of block-row is an integer multiple of (8x*V1*). For example, if non-interleaved YUV411 with *X*=270, then "The number of blocks in width" shall be (270 + 7) / 8 = 34, where "/" is integer division. Therefore, **FrameWidthInBlksMinus1** is set to 33. However, for interleaved data, "The number of blocks in width" shall be ((270 + 31) / 32) x 4 = 36. Therefore, **FrameWidthInBlksMinus1** is set to 35.

VertUpSamplingEnb is used to convert an input chroma420 to an output chroma422 in the surface format of YUY2 or UYVY. To enable this flag, the input should be interleaved Scan, InputFormatYUV should be set to YUV420, and OutputFormatYUV should be set to YUY2 or UYVY. Vertical 2:1 up-sampling is only applied to chroma blocks where each line of 8x8 block pixels is replicated to make 8x16 U/V blocks. For example:



VertDownSamplingEnb is used to convert an input chroma422 to an output chroma420 in the surface format NV12. To enable this flag, the input should be interleaved Scan, InputFormatYUV should be set to YUV422H_2Y or YUV422H_4Y, and OutputFormatYUV should be set to NV12. Combined with AvgDownSampling flag, the following table and figures show the down-sampling methods.

VertDownSamplingEnb	AvgDownSampling	Down-Sampling Methods
0	0 or 1	No down-sampling.
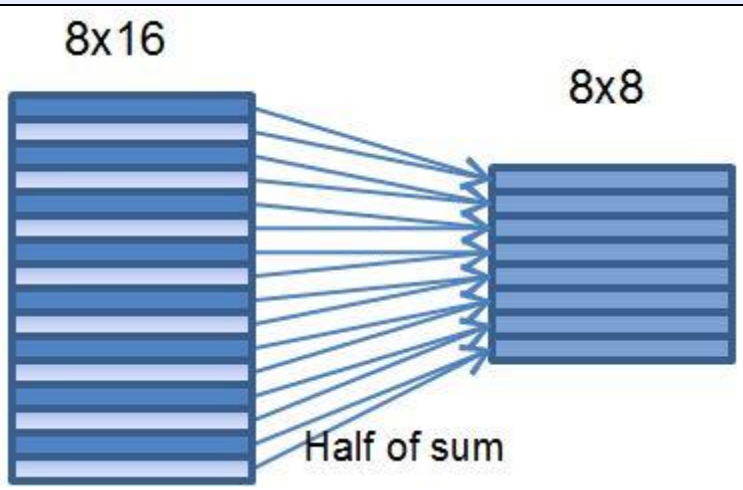
1	0	Drop every other line: 1	1	Average vertically neighboring two pixels:

VertDownSamplingEnb	AvgDownSampling	Down-Sampling Methods
		


The recent history forJPEG Decoder Commands are described in the following:

-
- InputFormat is the same as IVB, and should be programmed the same way as IVB.
- If the InputFormat is YUV400 or YUV444 or YUV411, then output cannot be NV12, YUY2 or UYVY, it has to be planar (like legacy IVB). But for 420 and 422 InputFormat, there's a choice of having Planar, NV12, YUY2 or UYVY OutputFormat and the surface state should be programmed accordingly.
- Refer "Output Format YUV" field for more details.

MFX_JPEG_HUFF_TABLE_STATE

JPEG Encoder Commands

JPEG Encoder Command Sequence:

MFX_PIPE_MODE_SELECT

MFX_SURFACE_STATE

MFX_PIPE_BUF_ADDR_STATE

MFX_JPEG_PIC_STATE

MFX_FQM_STATE (One each for Luma, CB and CR)

MFC_JPEG_ HUFF_TABLE_STATE (Huffman table 0 and 1 need two commands to be issued).

MFC_JPEG_SCAN_OBJECT

MFX_PAK_INSERT_OBJECT (Multiple commands can be given based on the need)

Following are JPEG Encoder Commands:

MFX_JPEG_PIC_STATE command is used for both encoding and decoding. Note the duplicate bits and the "Exists If" rows that specify what the bits represent for Encoder and Decoder.

Programming Note: For completion of partial MCUs in JPEG encoding, it is important to note the following:

If the image's dimensions are not an exact multiple of the MCU size, the encoded data should include padding to round up to the next complete MCU, which is called completion of partial MCU. If the number of lines is not aligned with MCU structure (not a multiple of MCU size, i.e. 8, 16, 32), the encoding process needs to extend the number of lines to complete the bottom-most MCU-row. Similarly, if the number of samples per line is not aligned with MCU structure, the encoding process needs to extend the number of columns to complete the right-most sample MCUs. JPEG standard recommends that any incomplete MCUs be completed by replication of the right-most column and the bottom line of each component Y, U, and V.

The following equations are used to set the command for encoding partial MCUs.

FrameWidthInBlksMinus1 = (((*X* + (H_1 *8 -1)) / (H_1 *8)) * H_1) – 1

FrameHeightInBlksMinus1 = (((*Y* + (V_1*8 -1)) / (V_1*8)) * V_1) – 1

```
For YUV400,
    PixelsInHoriLastMCU = X % 8
    PixelsInVertLastMCU = Y % 8

For YUV420,
    PixelsInHoriLastMCU = X % 16 if X % 2 = 0, ((X % 16) + 1) % 16 if X % 2 = 1
    PixelsInVertLastMCU = Y % 16 if Y % 2 = 0, ((Y % 16) + 1) % 16 if Y % 2 = 1

For YUV422H_2Y,
    PixelsInHoriLastMCU = X % 16 if X % 2 = 0, ((X % 16) + 1) % 16 if X % 2 = 1
    PixelsInVertLastMCU = Y % 8

    X: the number of samples per line in Y-image

    Y: the number of lines in Y-image

    H1: horizontal sampling factor of Y-image in the Frame header

    V1:  vertical sampling factor of Y-image in the Frame header
```

Note that PixelsInHoriLastMCU=0 does not mean the num of pixels in the right-most MCUs = 0, but does mean that the right-most MCUs are fully filled with pixels, i.e., not a partial MCU.

For example, for input image dimension 17x26 pixels and an interleaved Scan, the following equations and the table show how to set the command for each OutputMcuStructure.

	YUV400	YUV420	YUV422H_2Y
MCU size of Y	8x8	16x16	16x8
MCU size of U and V	8x8	8x8	8x8
H_1 and V_1	1, 1	2, 2	2, 1

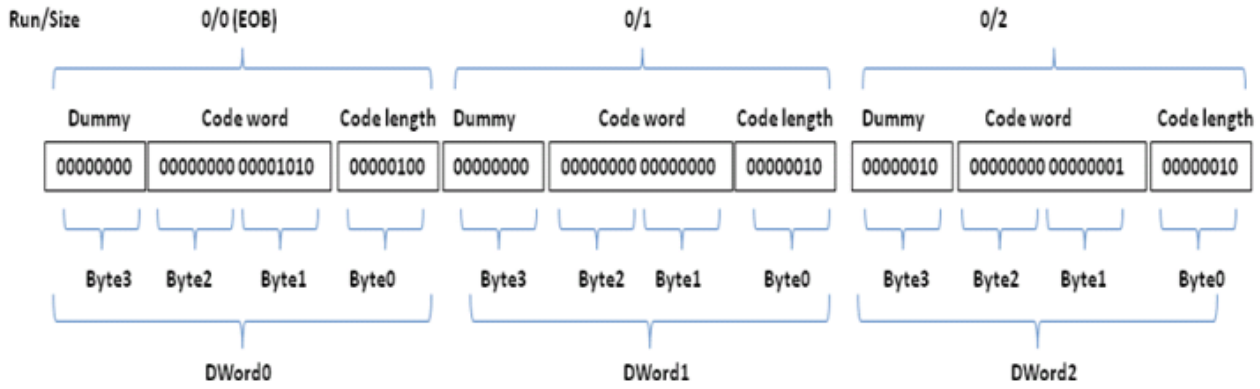
	YUV400	YUV420	YUV422H_2Y
FrameWidthInBlksMinus1	2	3	3
FrameHeightInBlksMinus1	3	3	3
PixelsInHoriLastMCU	1	2	2
PixelsInVertLastMCU	2	10	2

MFC_JPEG_SCAN_OBJECT
MFC_JPEG_ HUFF_TABLE_STATE

The JPEG standard Table K.5 shows the real table of code length and code word as follows:

Run/Size	Code length	Code word
0/0 (EOB)	4	1010
0/1	2	00
0/2	2	01
0/3	3	100
0/4	4	1011
0/5	5	11010
0/6	7	1111000
0/7	8	11111000
0/8	10	1111110110
0/9	16	1111111110000010
0/A	16	1111111110000011

It is not necessary to send Run/size in the command as driver will send the increasing order of run/size. Each symbol aligns to a DWord with the following byte structure. Each DWord (a group of 4 bytes) contains Byte0 for Code length, Byte1 and Byte2 for Code word, and Byte3 for dummy.



Driver will program to always send 12 pairs of Code length and Code Word in DC coefficient table and 162 pairs in AC coefficient table. When a Huffman table contains valid full entries of Run/Size, all the Code word and Code length will not be zero. If a Huffman table is customized or optimized, the table can contain smaller set of Code length and Code Word, i.e., the number of entries of the real Huffman table will be less than 12 for DC, or less than 162 for AC. For the customized Huffman table, driver will set the missing entry (Run/Size) to Code length = 0 and Code word = 0.

MFX_PAK_INSERT_OBJECT

More Decoder and Encoder

MFD IT Mode Decode Commands

This is the decoder-only command to support the IT-mode specified in DXVA interface.

Only MPEG2-IT mode is supported.

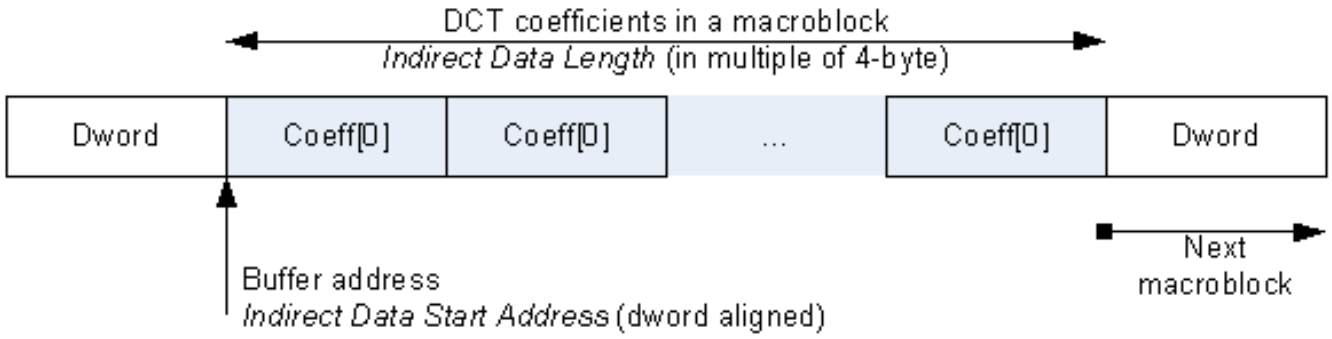
MFD_IT_OBJECT

Common Indirect IT-COEFF Data Structure

Transform-domain residual data block in MPEG2-IT mode follows the same data structure.

The indirect IT-COEFF data start address in MFD_IT_OBJECT command specifies the doubleword aligned address of the first non-zero DCT coefficient of the first block of the macroblock. Only the non-zero coefficients are present in the data buffer and they are packed in the 8x8 block sequence of Y0, Y1, Y2, Y3, Cb4 and Cr5, as shown in *Common Indirect IT-COEFF Data Structure*. When an 8x8 block is further subdivided into 4x4 subblocks, the coefficients, if present, are organized in the subblock order. The smallest subblock division is referred to as a **transform block**. The indirect IT-COEFF data length in the command includes all the non-zero coefficients for the macroblock. It must be doubleword aligned.

Structure of the IDCT Compressed Data Buffer



Each non-zero coefficient in the indirect data buffer is contained in a doubleword-size data structure consisting of the coefficient index, end of block (EOB) flag and the fixed-point coefficient value in 2's compliment form. As shown in *Common Indirect IT-COEFF Data Structure*, *index* is the row major 'raster' index of the coefficient **within a transform block** (*please note that it is not converted to 8x8 block basis*). A coefficient is a 16-bit value in 2's complement.

Structure of a transform-domain residue unit

DWord	Bit	Description
0	31:16	**Transform-Domain Residual (coefficient) Value.** This field contains the value of the non-zero transform-domain residual data in 2's compliment.
	15:7	Reserved: MBZ
	6:1	**Index.** This field specifies the raster-scan address (raw address) of the coefficient within the transform block. For a coefficient at Cartesian location (row, column) = (y, x) in a transform block of width W, Index is equal to (y * W + x). For example, coefficient at location (row, column) = (0, 0) in a 4x4 transform block has an index of 0; that at (2, 3) has an index of 2*4 + 3 = 11. The valid range of this field depends on the size of the transform block. Format = U6 Range = [0, 63]
	0	**EOB (End of Block).** This field indicates whether the transform-domain residue is the last one of the current transform block.

Allowed transform block dimensions per coding standard

Transform Block Dimension	MPEG2
8x8	Yes
8x4	No
4x8	No
4x4	No

Inline Data Description in MPEG2-IT Mode

The content in this command is similar to that in the MEDIA_OBJECT command in IS mode described in the Media Chapter.

Each MFD_IT_OBJECT command corresponds to the processing of one macroblock. Macroblock parameters are passed in as inline data and the non-zero DCT coefficient data for the macroblock is passed in as indirect data.

Inline Data Description in MPEG2-IT Mode depicts the inline data format. Inline data starts at dword 7 of MFD_IT_OBJECT command. There are 7 dwords total.

Inline data in MPEG2-IT Mode

DWord	Bit	Description
+0	31:28	**Motion Vertical Field Select.** A bit-wise representation of a long [2][2] array as defined in §6.3.17.2 of the *ISO/IEC 13818-2* (see also §7.6.4).

	15:0	**Motion Vectors – Field 1, Forward, Horizontal Component**
+5	31:16	**Motion Vectors – Field 1, Backward, Vertical Component**
	15:0	**Motion Vectors – Field 1, Backward, Horizontal Component**

Indirect Data Format in MPEG2-IT Mode

MPEG2-IT mode only contains IT-COEFF indirect data which is described in Section *Common Indirect IT-COEFF Data Structure*.

MFX Deblocking Commands

Following are MFX Deblocking Commands:

MFX_DBK_OBJECT

Encoder StreamOut Mode Data Structure Definition

When StreamOut is enabled, per MB (and/or per Slice, per Picture) intermediated coding data (for example, bit allocated for each MB, and so on) are sent to the memory in a fixed record format (and of fixed size) from the PAK. The per-MB records must be written in a strict raster order and with no gap (that is, every MB regardless of its mb_type and slice type, must have an entry in the StreamOut buffer). Therefore, the consumer of the StreamOut data can offset into the StreamOut Buffer (**StreamOut Data Destination Base Address**) using individual MB addresses.

Adding per macroblock stream out for PAK is for the following purposes:

- Immediate multi-pass PAK (without host or EU intervention)
  - 3200-bit conformance
  - Re-quantization
- Providing information for host for offline processing
- Providing information for updated QP's

The description for the fixed format PAK streamout record:

Streamout Pointer: Use the existing streamout pointer and enabler

Per Macroblock Information (a fixed size structure)

DWord	Bit	Description
0	31:24	**MbQpY** - Actual QPY used by the macroblock.
	23:16	**MbClock16** – MB compute clocks in 16-clock unit.
	15:8	Reserved: MBZ
	7:4	Reserved: MBZ (future conformance flags)
	3	Reserved
	2	**MbRcFlag:** MB level Rate control flag(pass through) The same value as **RateControlCounterEnable** of MFX_AVC_SLICE_STATE Command
	1	**MbInterConfFlag:** MB level InterMB conformance flag to trigger mutli-pass 1- if total Bit Count of an inter macroblock is more than Inter Conformance Max size limit in the MFX_AVC_IMG_STATE Command
	0	**MbIntraConfFlag:** MB level IntraMB conformance flag to trigger mutli-pass 1- if total Bit Count of an intra macroblock is more than Intra Conformance Max size limit in the MFX_AVC_IMG_STATE Command
1	31:29	Reserved
	28:16	**MbBits:** Total Bit Count for the macroblock
	15:12	Reserved
	12:0	**MbHdrBits:** Header Bit count (bit count due to Pre-coefficient data) for the macroblock
2	31:27	Reserved
	26:0	**Cbp:** Coded Block Pattern of sub-blocks

DWord	Bit	Description
3	31:30	Reserved
	29	**IntraMBFlag**
	28:24	**MBType5Bits**
	23:17	Reserved
	16	**ClampFlag:** Coefficient clamping flag for RC (Status) 1 - Indicates if clamping of any coefficient is done on the macroblock for Rate Control
	15:0	Reserved (future QRC stat output)

PAK Frame Statistics StreamOut

The following frame statistics are written to memory at the conclusion of a frame. If Multipass occurs, these values are overwritten by the end of any subsequent passes of the current frame (hence it contains only the final pass statistics).

The streamout is done to the MB streamout surface, starting at the next CL boundary. If MB streamout is disabled, Frame level streamout starts with 0 offset.

MFX_PAK_FRAME_STATISTICS		
Source:	**VideoCS**	
Length Bias:	**2**	
DWord	**Bit**	**Description**
0	31:16	Reserved : MBZ
	15:0	SumSliceHeader – Report the total size (in bits) of all slice headers inserted into the bitstream for this frame.
1	31:0	SumMBHeader – Report the total size (in bits) of all MB headers (non coeff bits) inserted into the bitstream for this frame.
2	31:0	SumNZC – Report the total number of nonzero coefficients after quantization.
3	31:0	Reserved: MBZ
4	31:16	IntraMB16x16 – Count of # of MB's that were of type Intra 16x16
	15:0	IntraMB8x8 – Count of # of MB's that were of type Intra 8x8
5	31:16	IntraMB4x4 – Count of # of MB's that were of type Intra 4x4
	15:0	InterMB16x16 – Count of # of MB's that were of type Inter 16x16
6	31:16	InterMB16x8 – Count of # of MB's that were of type Inter 16x8
	15:0	InterMB8x16 – Count of # of MB's that were of type Inter 8x16
7	31:16	InterMB8x8 – Count of # of MB's that were of type Inter 8x8
	15:0	InterSkip16x16 – Count of # of MB's that were of type Inter 16x16 skip

8:49	31:0	RhoDomainStats – Each DW contains 1 of the 42 registers containing the raw Rho Domain coefficient metrics. DW 8 is QP 10 and DW 49 is QP51.
50	31:0	Reserved: MBZ

PAK Multi-Pass

Multi-Pass PAK Usages:

- Intra MB 3200-bit conformance
- Inter MB Re-quantization
- Frame level Re-quantization

How to Enable Multi-Pass PAK?

- Using the existing conditional batch buffer execution capability to skip/execute the second pass
    - How to dynamically change the condition?
        - Defined one error condition register with a mask. Do HW status page update at the end of the first pass. 0 means all OK, non-zero means there is an error condition, requiring second pass. Mask is used by the host to control what kind of multi-pass is intended.
        - For example, one error bit is 3200-bit conformance violation. Another error bit is the total bit count exceeds (too much or too little) the target range (need to define the target range in the state).
        - **The logic perfectly fits in the conditional batch buffer control logic that VCS has today in GT. There is no additional logic need to be added in VCS to support media functionality.** (**Batch Buffer Skip:** This field only takes effect if Compare Semaphore is set and the value at **Semaphore Address is NOT greater than the Semaphore Data Dword)**.
- Adding a picture level state command to enable and control the behavior of the second pass PAK
    - How to control the re-PAK? Added 3 conformance flags (error registers) in the per-MB streamout. Then the error control is based on the error register and the mask defined in picture level states. There are 8 register flags defined out of which only the 3200-bit case has usage model defined for today. The rest are left for future usage.

Issues and Limitations:

- There is no programmable engine in MFX for flexible control: Therefore, whatever we have defined must consider flexibility

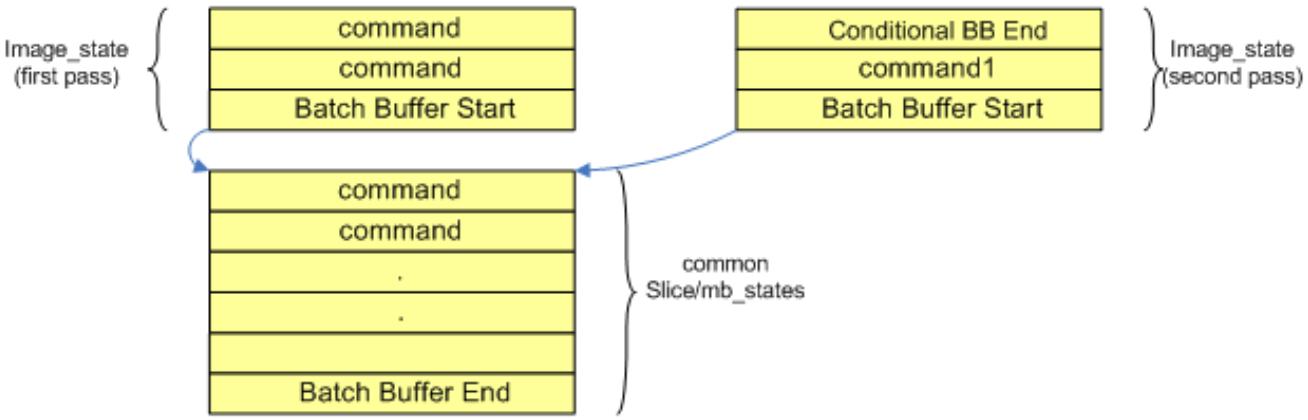
Following 2 MI packets are used inside VCS without any change to support Multipass-PAK behaviour.

- MI_Conditional_Batch_Buffer_End
- Memory Interface Registers

Driver Usage

Driver places Image states in one batch buffer and all slice level and macroblock level states into another batch buffer and link 2 batch buffers. Also replicate Image states with multipass changes in another batch buffer link them to slice/macroblock batch buffer. In this way, only Image states are replicated but not the slice/macroblock states. The image states includes all buffers defined at image(indirectMV, original pixel buffer, etc). Following changes are needed in the Multipass Image State,

- **Reset- Stream-Out Enable(disable stream out in the second pass)**
- **Set- MacroblockStatEnable (enable reading of macroblock status buffer)**
- **Reset- 3200-bit conformance (do not report 3200-bit conformance)**



Define Conditional Batch Buffer End for CS/VCSVINunit

Programming Reference

Monochrome Picture Processing

Monochrome picture is specified using the Surface State with Surface Format of 12. Therefore, MFX hardware, in either decode or encode mode, does not generate any read or write traffic for U/V components. The motivation for this bandwidth optimization is that monochrome video coding might be used for wireless display.

For Encoder:

1. No read in UV original components
2. Processing UV component - no
3. Reconstructed UV component reference picture - no
4. Filter UV component - no

For Decoder:

1. VLD mode: There is no color component coming out of the decoding pipeline in Monochrome mode and so no processing and not writing output.

2. IT mode: There is no color component in the coefficient buffer, and so no processing and not writing output.

Context Switch

There is no pre-emption for the BCS pipeline; hence every command buffer is required to contain all the states setup (preamble). Specifically, CPU can not interrupt the BCS-BSD pipe, to stop the operation in the middle of decoding a bitstream data.

Switch of contexts can only be performed at picture boundary.

No state needs to be saved.

PMSI Support

Pipeline Flush

Implicit flush for AVC and VC1 is performed at the end of Slice : for MPEG2 is done when a new image/picture command is issued. Because MPEG2 a slice can be one MB, no point to flush. MPEG2 will snoop the next command if it is an img_state command.

Explicit flush MI (1 bit to do media pipeline vs Gx pipeline) flush and cache flush (switch reference frame) – MI flush has bit to do cache flush. MI flush is for driver synchronization.

MMIO Interface

A set of registers are defined and accessible through MMIO interface to serve multiple purposes:

- Use for system configuration
- For accessing Performance counters

The following is the table for all the MMIO addresses for MFX.

Decoder Registers

Following are Decoder Registers:

MFD_ERROR_STATUS - MFD Error Status

AVC CAVLC

AVC CABAC

VC1

MPEG2

JPEG

MFD_PICTURE_PARAM - MFD Picture Parameter

MFX_STATUS_FLAGS - MFX Pipeline Status Flags

MFX_FRAME_PERFORMANCE_CT - MFX Frame Performance Count

MFX_SLICE_PERFORM_CT - MFX Slice Performance Count

MFX_MB_COUNT - MFX Frame Macroblock Count

MFX_SE-BIN_CT - MFX Frame BitStream SE/BIN Count

MFX_LAT_CT1 - MFX_Memory_Latency_Count1

MFX_LAT_CT2 - MFX Memory Latency Count2

MFX_LAT_CT3 - MFX Memory Latency Count3

MFX_LAT_CT4 - MFX Memory Latency Count4

MFX_SE-BIN_CT - MFX Frame BitStream SE/BIN Count

MFX_READ_CT - MFX Frame Motion Comp Read Count

MFX_MISS_CT - MFX Frame Motion Comp Miss Count

Encoder Registers

Following are the Encoder Registers:

Register
MFC_VIN_AVD_ERROR_CNTR - MFC_AVC Bitstream Decoding Front-End Parsing Logic Error Counter .
MFC_BITSTREAM_BYTECOUNT_FRAME - Reported Bitstream Output Byte Count per Frame Register
MFC_BITSTREAM_SE_BITCOUNT_FRAME - Reported Bitstream Output Bit Count for Syntax Elements Only Register
MFC_AVC_CABAC_BIN_COUNT_FRAME - Reported Bitstream Output CABAC Bin Count Register
AVC_CABAC_INSERTION_COUNT - MFC_AVC_CABAC_INSERTION_COUNT
MFC_AVC_MINSIZE_PADDING_COUNT - Bitstream Output Minimal Size Padding Count Report Register
MFC_IMAGE_STATUS_MASK - MFC Image Status Mask
MFC_IMAGE_STATUS_CONTROL - MFC Image Status Control
MFC_QUP_CT - MFC QP Status Count
MFC_BITSTREAM_BYTECOUNT_SLICE - Bitstream Output Byte Count Per Slice Report Register
MFC_BITSTREAM_SE_BITCOUNT_SLICE - Bitstream Output Bit Count for the last Syntax Element Report Register
MFX_PAK_ERROR Register
MFX_PAK_WARNING Register
MFX_VP8_CNTRL_MASK - Reported BitRateControl parameter Mask
MFX_VP8_CNTRL_STATUS - Reported BitRateControl parameter Status
MFX_VP8_FRM_BYTE_CNT - Reported Final Bitstream Byte Count
MFX_VP8_FRM_ZERO_PAD - Reported Frame Zero Padding Byte Count
MFX_VP8_BRC_DQindex - Reported BitRateControl DeltaQindex
MFX_VP8_BRC_DLoopFilter - Reported BitRateControl DeltaLoopFilter
MFX_VP8_BRC_CumulativeDQindex01 - Reported BitRateControl CumulativeDeltaQindex and Qindex 01
MFX_VP8_BRC_CumulativeDQindex23 - Reported BitRateControl CumulativeDeltaQindex and Qindex 23
MFX_VP8_BRC_CumulativeDLoopFilter01 - Reported BitRateControl CumulativeDeltaLoopFilter and LoopFilter 01
MFX_VP8_BRC_CumulativeDLoopFilter23 - Reported BitRateControl CumulativeDeltaLoopFilter and LoopFilter 23
MFX_VP8_BRC_Convergence_Status - Reported BitRateControl Convergence Status

MMIO Interface

A set of registers are defined and accessible through MMIO interface to serve multiple purposes:

- Use as Status register for Bit Rate Control
- Use for Context Switch in Multipass

Register Name	Description	Register Type	Address Offset	Dec/Enc
MFX_VP8_CNTRL_MASK	BitRateControl parameter Mask register	RO	12900	Enc
MFX_VP8_CNTRL_STATUS	BitRateControl parameter Status register	RO	12904	Enc
MFX_VP8_FRM_BYTE_CNT	Final Bitstream Byte count	RO	12908	Enc
MFX_VP8_FRM_ZERO_PAD	Final Bitstream Zero Padding Byte count	RO	1290B	Enc
MFX_VP8_BRC_DQindex	BitRateControl Delta Qindex	RO	12910	Enc
MFX_VP8_BRC_DLoopFilter	BitRateControl Delta LoopFilter	RO	12914	Enc
MFX_VP8_BRC_CumulativeDQindex01	BitRateControl Cumulative Delta Qindex for Seg0/1	RW	12918	Enc
MFX_VP8_BRC_CumulativeDQindex23	BitRateControl Cumulative Delta Qindex for Seg2/3	RW	1291C	Enc
MFX_VP8_BRC_CumulativeDLoopFilter01	BitRateControl Cumulative Delta LoopFilter for Seg0/1	RW	12920	Enc
MFX_VP8_BRC_CumulativeDLoopFilter23	BitRateControl Cumulative Delta LoopFilter for Seg2/3	RW	12924	Enc
MFX_VP8_BRC_Convergence_Status	BitRateControl Convergence Status	RW	12928	Enc
MFX_VP8_DEBUG_CPBAC0_Bottom	CPBAC0 engine Bottom State	RO	1292C	Enc
MFX_VP8_DEBUG_CPBAC0_RangeCount	CPBAC0 engine Range/Count State	RO	12930	Enc
MFX_VP8_DEBUG_CPBAC0_Misc	CPBAC0 engine Misc. States	RO	12934	Enc
MFX_VP8_DEBUG_CPBAC1_Bottom	CPBAC1 engine Bottom State	RO	12938	Enc
MFX_VP8_DEBUG_CPBAC1_RangeCount	CPBAC1 engine Range/Count State	RO	1293C	Enc
MFX_VP8_DEBUG_CPBAC1_Misc	CPBAC1 engine Misc. States	RO	12940	Enc

The following registers are the same as above except they have a different Address Offset. They are used if the second VDbox (VP8 Encoder) exists.

Register Name	Description	Register Type	Address Offset	Dec/Enc
MFX_VP8_CNTRL_MASK	BitRateControl parameter Mask register	RO	1C900	Enc
MFX_VP8_CNTRL_STATUS	BitRateControl parameter Status register	RO	1C904	Enc
MFX_VP8_FRM_BYTE_CNT	Final Bitstream Byte count	RO	1C908	Enc
MFX_VP8_FRM_ZERO_PAD	Final Bitstream Zero Padding Byte count	RO	1C90B	Enc
MFX_VP8_BRC_DQindex	BitRateControl Delta Qindex	RO	1C910	Enc
MFX_VP8_BRC_DLoopFilter	BitRateControl Delta LoopFilter	RO	1C914	Enc
MFX_VP8_BRC_CumulativeDQindex01	BitRateControl Cumulative Delta Qindex for Seg0/1	RW	1C918	Enc
MFX_VP8_BRC_CumulativeDQindex23	BitRateControl Cumulative Delta Qindex for Seg2/3	RW	1C91C	Enc
MFX_VP8_BRC_CumulativeDLoopFilter01	BitRateControl Cumulative Delta LoopFilter for Seg0/1	RW	1C920	Enc
MFX_VP8_BRC_CumulativeDLoopFilter23	BitRateControl Cumulative Delta LoopFilter for Seg2/3	RW	1C924	Enc
MFX_VP8_BRC_Convergence_Status	BitRateControl Convergence Status	RW	1C928	Enc

Media VEBOX Introduction

The VEBOX is an independent pipe with a variety of image enhancement functions.

The following sections are contained in Media VEBOX:

Feature
Denoise
Deinterlacer
VEBOX Output Statistics
VEBOX State

Denoise

This section discusses the Denoise feature in the chipset.

- **Denoise Filter** - detects noise in the input image and filters the image with either a temporal filter or a spatial filter. The temporal filter is applied when low motion is detected.
- **Chroma Denoise Filter** - detects noise in the U and V planes separately and applies a temporal filter.
- **Block Noise Estimate (BNE)** - as part of the Global Noise Estimate (GNE) algorithm, BNE estimates the noise over each block of pixels in the input picture.
- **Global Noise Estimate (GNE)** - GNE is calculated at the end of the frame by combining all the BNEs. The final GNE value is used to control the denoise filter for the next input frame. Noise estimates are kept between frames and blended together.

Motion Detection and Noise History Update

This logic detects motion of the current block for the denoise filter. The detected motion is then combined with motion detected in the co-located block of the past frame, and stored in the denoise history table.

Block Noise Estimate (Part of Global Noise Estimate)

The BNE estimates the amount of noise in each rectangular region of the input picture. The BNE estimate is computed separately for each color component in the input picture. The estimates from BNE are summed together to generate the Global Noise Estimate (GNE) for the entire input picture.

Temporal Filter

Temporal denoise is applied to each pixel based on the noise strength measured from the input pictures. Each pair of co-located pixels in the current and previous input pictures is blended together to generated the output pixel.

Context Adaptive Spatial Filter

For each pixel in the local neighborhood, its luma value is compared to the center pixel to be filtered.

Each pixel in the neighborhood for which the difference is less than good_neighbor_th is marked as a "good neighbor". The filtered output pixel is then equal to average of “good neighbor” pixels.

Chroma Noise Detection

The operation of chroma noise detection module is similar to the luma noise detection module. The U & V channels are processed individually to generate a noise estimate for each of the 2 channels.

Chroma Noise Reduction Filter

A simple and effective temporal-domain chroma noise reduction filter is applied. The Noise History is updated based on the motion detection result as before. The Noise History value is used to control the temporal denoise filter.

Denoise Blend

The denoise blend combines the temporal and spatial denoise outputs.

Deinterlacer

The deinterlacer (DI) takes the top and bottom fields of each input frame and converts them into two output frames. This block also gathers statistics from a film mode detector at the end of the frame. If the film mode detector determines that the input is progressive, then the input fields are put together directly to construct the progressive output frame.

Features:

- **Deinterlacer** - DI starts by estimating how much motion is present across the input fields. Low motion scenes are reconstructed by temporal deinterlacer, while high motion scenes are reconstructed by spatial deinterlacer.
- **Film Mode Detection** - This detector determines if the input fields are created by sampling film content and converting it to interlaced video. If so, the deinterlacer is turned off in favor of reconstructing the progressive output frame directly from adjacent input fields in the Progressive Cadence Reconstruction mode. Various sum-of-absolute differences are computed per block.
- **Chroma Upsampling** - If the input is 4:2:0, then chroma data is doubled vertically to 4:2:2. Chroma data is then processed by chroma deinterlacer or progressive cadence reconstruction.

VEBOX Output Statistics

Overall Surface Format

Statistics are gathered on both per-block (16x4) basis and per-frame basis. There are 16 bytes of encoder statistics data per 16x4 block, plus a variety of per frame data which are stored in a linear surface. The 16 bytes of encoder statistics per block are output if either DN or DI are enabled and are organized into a surface with a pitch equal to the output surface width rounded to the next higher 64 boundary (so that each line starts and ends on a cache line boundary). The height of the surface is ¼ of the height of the output surface. If both DN and DI are disabled then the encoder stats are not output and the per frame information is output at the base address. The encoder statistics can be disabled with a state variable to lower the output bandwidth. The offsets for the other statistics do not change.

The per frame information is written twice per frame to allow for a 2 slice solution - in a single slice the second set of data will be all 0. The final per frame information is found by adding each individual Dword, clamping the data to prevent it from overflowing the Dword.

The Deinterlacer outputs two frames for each input frame. When IECP is applied to the Deinterlacer output, separate GCC and STD per frame statistics are created for each output frame. In this case, 4 copies of the per frame information are written - two copies for the two slice solution times two output frames. For the case of DN and no DI, only the first set of per frame statistics will be written.

Statistics Surface when DI Enabled and DN either On or Off

16 Bytes for X=0, Y=0	16 Bytes for X=16, Y=0	16 Bytes for X=32, Y=0	....	16 Bytes for X=Width-16, Y=0	
16 Bytes for X=0, Y=4					
16 Bytes for X=0, Y=8					
.....					
16 Bytes for X=0, Y=Height-4					
17 DWs Reserved		2DW of STD (Previous Slice 0)	2DW of GCC (Previous Slice 0)	11 DWs of Reserved	
11 DWs FMD (Slice 0)	6 DWs of GNE (Slice 0)	2DW of STD (Current Slice 0)	2DW of GCC (Current Slice 0)	2DWs of Auto focus (Current Slice 0)	9 DWs of Reserved
17 DWs Reserved		2DW of STD (Previous Slice 1)	2DW of GCC (Previous Slice 1)	11 DWs of Reserved	
11 DWs FMD (Slice 1)	6 DWs of GNE (Slice 1)	2DW of STD (Current Slice 1)	2DW of GCC (Current Slice 1)	2DWs of Auto focus (Current Slice 1)	9 DWs of Reserved

Statistics Surface when DN Enabled and DI Disabled

16 Bytes for X=0, Y=0	16 Bytes for X=16, Y=0	16 Bytes for X=32, Y=0	....	16 Bytes for X=Width-16, Y=0	
16 Bytes for X=0, Y=4					
16 Bytes for X=0, Y=8					
.....					
16 Bytes for X=0, Y=Height-4					
11 DWs White Balance Stats (Slice 0)	6 DWs of GNE (Slice 0)	2DW of STD (Slice 0)	2DW of GCC (Slice 0)	2DWs of Auto focus (Slice 0)	9 DWs of Reserved
11 DWs White Balance Stats (Slice 1)	6 DWs of GNE (Slice 1)	2DW of STD (Slice 1)	2DW of GCC (Slice 1)	2DWs of Auto focus (Slice 1)	9 DWs of Reserved

Statistics Surface when both DN and DI Disabled

11 DWs White Balance Stats (Slice 0)	6 DWs of GNE (Slice 0)	2DW of STD (Slice 0)	2DW of GCC (Slice 0)	2DWs of Auto focus (Slice 0)	9 DWs of Reserved
11 DWs White Balance Stats (Slice 1)	6 DWs of GNE (Slice 1)	2DW of STD (Slice 1)	2DW of GCC (Slice 1)	2DWs of Auto focus (Slice 1)	9 DWs of Reserved

When DN and DI are both disabled, only the per frame statistics are written to the output at the base address.

Statistics Offsets

The statistics have different offsets from the base address depending on what is enabled.

The encoder statistics size is based on the frame size:

```
Encoder_size = width * (height+3)/4
```

where

width is the width of the output surface rounded to the next higher 64 boundary and

height is the output surface height in pixels.

Offset	DI on	DI off + DN on	DI off + DN off
Per_Command_Previous_Slice0	Encoder_size	N/A	N/A
Per_Command_Current_Slice0	Encoder_size + 0x80	Encoder_size + 0x00	0x00
Per_Command_Previous_Slice1	Encoder_size + 0x100	N/A	N/A
Per_Command_Current_Slice1	Encoder_size + 0x180	Encoder_size + 0x80	0x80

LACE and ACE

The ACE Histograms are in a separate surface with the LACE Histograms and RGB Histograms.

For simplicity the offsets are the same in all modes - if a surface is disabled then it simply is not written, but the following surfaces offsets are not changed.

The starting offsets from the beginning of LACE/ACE/RGB Histogram Output are:

Offset	DI on	RGB on	DI on + RGB on
Red Histogram_Slice0	N/A	0x0000	0x0000
Green_Histogram_Slice0	N/A	0x0400	0x0400
Blue_Histogram_Slice0	N/A	0x0800	0x0800
Red Histogram_Slice1	N/A	0x0C00	0x0C00
Green_Histogram_Slice1	N/A	0x1000	0x1000
Blue_Histogram_Slice1	N/A	0x1400	0x1400
ACE_Histo_Previous_Slice0	0x1800	N/A	0x1800
ACE _Histo_Current_Slice0	0x1C00	0x1C00	0x1C00

Offset	DI on	RGB on	DI on + RGB on
ACE_Histo_Previous_Slice1	0x2000	N/A	0x2000
ACE_Histo_Current_Slice1	0x2400	0x2400	0x2400
LACE Histogram Current	0x1800	0x1800	0x1800
LACE Histogram Previous	0x1800+LACE_hist_size	N/A	0x1800+LACE_hist_size

Per Command Statistics

The Per Command Statistics are placed after the encoder statistics if either DN or DI is enabled. If the frame is split into multiple calls to the VEBOX, each call outputs only the statistics gathered during that call and software provides different base address per call and sums the resulting output to compute the per-frame data.

The final address of each statistic is:

> **Statistics Output Address** + **Per_Command_Offset** (pick the one for the slice desired and the current/previous frame for Deinterlacer) + **PerStatOffset**

FMD Variances and GNE Statistics

These are the 11 FMD variances (Variance 0 ~ 10) and Global Noise Estimate Statistics (Sums and Counts) collected in each VEBOX call.

Note that pixel values in blocks that are close to the edge of the frame (within a 16x4 block that intersects or touches the frame edge) are not used in the variance computation.

FMD variances are 0 when the Deinterlacer is disabled.

GNE estimates are 0 when the Denoise is disabled.

Counter Id	PerStatOffset	Associated Counter
0	0x00	FMD Variance 0
1	0x04	FMD Variance 1
2	0x08	FMD Variance 2
3	0x0C	FMD Variance 3
4	0x10	FMD Variance 4
5	0x14	FMD Variance 5
6	0x18	FMD Variance 6
7	0x1C	FMD Variance 7
8	0x20	FMD Variance 8
9	0x24	FMD Variance 9
10	0x28	FMD Variance 10
11	0x2C	GNE Sum Luma (Sum of BNEs for all passing blocks)
12	0x30	GNE Sum Chroma U

Counter Id	PerStatOffset	Associated Counter
13	0x34	GNE Sum Chroma V
14	0x38	GNE Count Luma (Count of number of block in GNE sum)
15	0x3C	GNE Count Chroma U
16	0x40	GNE Count Chroma V

Skin-Tone Data

The register Ymax stores the largest luma value. It is reset at the start of a command to zero.

The register Ymin stores the smallest luma value. It is reset at the start of a command to:

Reset Value
0xFFFF (65535 in 16 bits)

When comparing the luma values to Ymax or Ymin,

Feature
16-bit values are used: For 16bpc luma pixels: the entire 16 bits are used. For 8bpc luma pixels: 8 zeros are appended to the LSB.

There is also a 29-bit counter of all the skin pixels (Number of Skin Pixles).

Register values are 0 if the STD/STE function is disabled.

The registers are stored with the offsets as shown below.

PerStatOffset	Associated Register
0x044	Ymax (bits 31:16), Ymin (bits 15:0)
0x048	Number of Skin Pixels (bits [28:0], other bits zero)

Gamut Compression: Out of Range Pixels

The statistics gathered for Gamut Compression are:

1. Count of out-of-range pixels (29 bits) and
2. Sum of the distances from out-of-range pixels to the closest range boundaries (32 bits).

If the sum is greater than the maximum 32-bit value, then it is clamped to the maximum 0xFFFFFFFF.

Both values are reset to zero at the start of each command.

Both values are zero if the GCC function is disabled.

PerStatOffset	Associated Register
0x04C	Sum of distances of out-of-range pixels (clamped to 0xFFFFFFFF)
0x050	Number of out-of-range pixels (bits [28:0], other bits are zero)

Histograms

The histograms are in separate surfaces called the ACE/LACE and RGB Histogram.

Ace Histogram

The Ace Histogram counts the number of pixels at different luma values.

It has 256 bins, each of which is 24 bits.

Any count that exceeds 24 bits is clamped to the maximum value.

The data is stored on DWord boundaries with the upper 8 bits equal to zero.

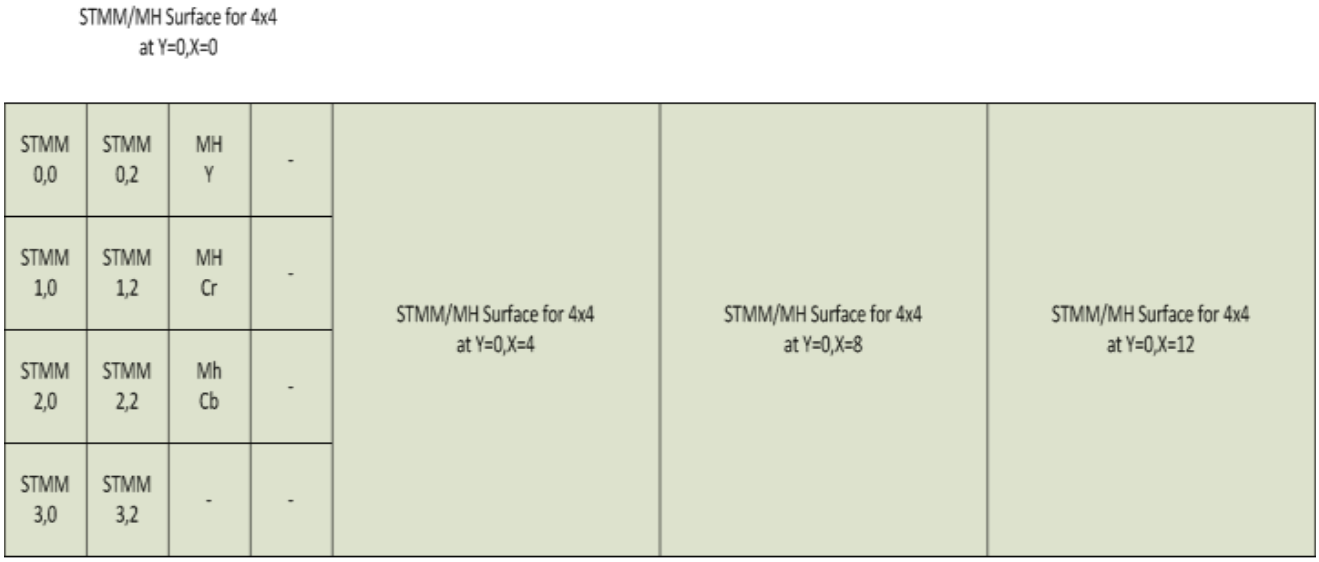
The Ace Histogram in non-capture mode is created by summing two independent 24-bit histograms, each of which is clamped to 24 bits. This means that the sum can reach 25 bits when both independent histograms are clamped or near clamped.

Y[9:2]	PerStatOffset	Associated Counter
0	0x000	ACE histogram, bin 0
1	0x004	ACE histogram, bin 1
2	0x008	ACE histogram, bin 2
...	...	...
255	0x3fc	ACE histogram, bin 255

STMM / Denoise

The STMM/Denoise history is a custom surface used for both input and output. The previous frame information is read in for the DN (Denoise History) and DI (STMM) algorithms; while the current frame information is written out for the next frame.

STMM / Denoise Motion History Cache Line



Byte	Data
0	STMM for 2 luma values at luma Y=0, X=0 to 1
1	STMM for 2 luma values at luma Y=0, X=2 to 3
2	Luma Denoise History for 4x4 at 0,0
3	Not Used
4-5	STMM for luma from X=4 to 7
6	Luma Denoise History for 4x4 at 0,4
7	Not Used
8-15	Repeat for 4x4s at 0,8 and 0,12
16	STMM for 2 luma values at luma Y=1,X=0 to 1
17	STMM for 2 luma values at luma Y=1, X=2 to 3
18	U Chroma Denoise History
19	Not Used
20-31	Repeat for 3 4x4s at 1,4, 1,8 and 1,12
32	STMM for 2 luma values at luma Y=2,X=0 to 1
33	STMM for 2 luma values at luma Y=2, X=2 to 3
34	V Chroma Denoise History
35	Not Used

Byte	Data
36-47	Repeat for 3 4x4s at 2,4, 2,8 and 2,12
48	STMM for 2 luma values at luma Y=3,X=0 to 1
49	STMM for 2 luma values at luma Y=3, X=2 to 3
50-51	Not Used
36-47	Repeat for 3 4x4s at 3,4, 3,8 and 3,12

VEBOX State and Primitive Commands

Every engine can have internal state that can be common and reused across the data entities it processes instead of reloading for every data entity.

There are two kinds of state information:

1. Surface state or state of the input and output data containers.
2. Engine state or the architectural state of the processing unit.

For example in the case of DN/DI, architectural state information such as denoise filter strength can be the same across frames. This section gives the details of both the surface state and engine state.

Each frame should have these commands, in this order:

1. VEBOX_State
2. VEBOX_Surface_state for input & output
3. VEB_DI_IECP

Alternatively VEBOX_Tiling_Convert can be used instead of VEB_DI_IECP.

VEBOX State

This chapter discusses various commands that control the internal functions of the VEBOX. The following commands are covered:

Feature
DN/DI State Table Contents
VEBOX_IECP_STATE
VEBOX_FORWARD_GAMMA_CORRECTION_STATE

Command
VEBOX_STATE
VEBOX_Ch_Dir_Filter_Coefficient

DN-DI State Table Contents

This section contains tables that describe the state commands that are used by the Denoise and Deinterlacer functions.

Command
VEBOX_DNDI_STATE

VEBOX_IECP_STATE

For all piecewise linear functions in the following table, the control points must be monotonically increasing (increasing continuously) from the lowest control point to the highest. Functions which have bias values associated with each control point have the additional restriction that any control points which have the same value must also have the same bias value. The piecewise linear functions include:

- For Skin Tone Detection:
    - Y_point_4 to Y_point_0
    - P3L to P0L
    - P3U to P0U
    - SATP3 to SATP1
    - HUEP3 to HUEP1
    - SATP3_DARK to SATP1_DARK
    - HUEP3_DARK to HUEP1_DARK
- For ACE:
    - Ymax, Y10 to Y1 and Ymin
    - There is no state variable to set the bias for Ymin and Ymax. The biases for these two points are equal to the control point values: B0 = Ymin and B11 = Ymax. That means that if control points adjacent to Ymin and Ymax have the same value as Ymin/Ymax then the biases must also be equal to the Ymin/Ymax control points based on the restriction mentioned above.
- Forward Gamma correction
- Gamut Expansion:
    - Gamma Correction

Inverse Gamma Correction

Command
VEBOX_IECP_STATE
VEBOX_STD_STE_STATE
VEBOX_ACE_LACE_STATE

Command
VEBOX_TCC_STATE
VEBOX_PROCAMP_STATE
VEBOX_CSC_STATE
VEBOX_ALPHA_AOI_STATE
VEBOX_FRONT_END_CSC_STATE

Command
VEBOX_VERTEX_TABLE
VEBOX_CAPTURE_PIPE_STATE
VEBOX_FORWARD_GAMMA_CORRECTION_STATE
VEBOX_RGB_TO_GAMMA_CORRECTION

VEBOX Surface State

Command
VEBOX_SURFACE_STATE

Surface Format Restrictions

The surface formats and tiling allowed are restricted, depending on which function is consuming or producing the surface.

Surface Formats - Feature Notes

Feature
Surfaces are 4 kb aligned, chroma X offset is cache line aligned (16 byte).
If Y8/Y16 is used as the input format, it must also be used for the output format (chroma is not created by VEBOX).
If IECP and either DN or DI are enabled at the same time, it is possible to select any input that is legal for DN/DI and any output which is legal for IECP. The only exception is that if DN or DI are enabled, the IECP is not able to output P216 and P016.
16-bit data from IECP or DN is rounded when converting to 8-bit output formats.
High Speed Bypass has the same format limitations as IECP Input/Output, but the surface formats for the input and output must be the same.
Capture Input is only linear Bayer Surface Format.
Input formats for Demosaic, White Balance, Vignette and Black Level Correction must be linear Bayer.
For capture pipe, we **can** support the combination of DN and P216 and P016. For capture pipe with a P016 output the U/V output is not an average of the 4 component pixels, but the U/V for pixel 4 (the lower right pixel of the 4).

VEB DI IECP Commands

The VEB_DI_IECP command causes the VEBOX to start processing the frames specified by VEB_SURFACE_STATE using the parameters specified by VEB_DI_STATE and VEB_IECP_STATE.

Command
VEB_DI_IECP Command
VEB_DI_IECP Command
VEB_TilingConvert Command

The Surface Control bits for each surface:

Command
VEB_DI_IECP
VEB_DI_IECP Command Surface Control Bits
VEBOX_TILING_CONVERT

High Efficiency Video Coding (HEVC) Introduction

The HEVC Codec Pipeline (HCP) is a fixed function hardware video codec responsible for decoding and encoding HEVC (High Efficiency Video Coding) video streams.

Scope

The primary scope of the HCP BSpec document is to provide a description of the HCP commands processed by the Video Command Streamer (VCS). The secondary scope is to provide a description of the status registers on the Message Channel Interface to support encoding and decoding of the HEVC video format.

The BSpec sections include:

- Summary of Features
- Architecture Overview
- Commands
- Register Definitions
- Acronyms and Applicable Standards

Summary of Features

The following sections define the HEVC Decoder and Encoder general features and the features specific to HEVC decoding and encoding, respectively.

HCP Hardware Pipeline Features

- Supports both decoder and encoder functions, setup on a per picture basis:
  - Hardware acceleration provides Ctb/CU level decode and encode.
  - No context switch is supported within a frame process.
- Supports Video Command Streamer (VCS):
  - Shared with MFX HW pipeline, and at any one time, only one pipeline (MFX or HCP) and one operation (decoding or encoding) can be active.
- Supports Message Channel Interface:

Feature
Supports Tile-YS and Tile-YF.
Supports Tile-Y Legacy.

- Supports NV12 video buffer plane:
  - Supports 4:2:0, 8-bit per pixel component (Y, Cb and Cr) video.
- Supports 8Kx8K frame size.

HEVC Decoder Features

- Supports full-featured HEVC Main Profile standard, up to Level 6.2.
- Supports the long format HW decoding interface:
  - All headers (SPS, PPS, Slice Header) are parsed and decoded outside the HCP HW pipeline. They are then fed to the HW through a set of HCP state commands.
- Supports inner-loop decode with hardware entry points for Encoder.
- Error detection/resiliency down to the Ctb/CU level.

HEVC Encoder Features

- Supports ENC-PAK architecture
- Supports multiple pass BRC rate control operation flow
- Supports the HEVC Main Profile standard, with certain restrictions on the feature set and coding parameters, listed in the following table:

HEVC Encoder Features and Restrictions

Note that there is a difference between what PAK supported and what ENC supported. A feature/function that is supported in the PAK, does not necessary being supported by ENC and MediaSDK and the like.

Coding Tool	Gen9 Support	Gen9 Restriction	Comments
LCU Size	Yes (spec)		Support all 3 sizes: 16x16, 32x32, 64x64.
CU Size	Yes (spec)		Support 8x8, 16x16, 32x32, 64x64. Max 64 CU per LCU; min. CU size intel supported is 8x8 for all LCU size.
PU Partition	Yes (spec)		Support all inter symmetric (square) and asymmetric (non-square) PU partitioning, according to HEVC spec. PU Size for inter : Smallest allowed is 4x8 and 8x4, and they cannot be bidirectional. Inter 4x4 PU is not allowed in Main Profile.
TU QuadTree		Partial (intel) max depth is set to 3	Max depth is 3 (64x64 CU with 4x4 TU). Decoder supports this depth, but probably no need to search this for encode. Better to just split CU. HM common conditions set the max to 2 for both inter and intra. Intel Encoder only supports 2 levels of quad-tree. That is, max_transform_hierarchy_depth_inter/intra <= 2. Max num of TUs per CU is 16.
AMP	Yes (spec)		Asymmetric Motion Partition (rectangular PU partitioning - 2NxnU, 2NxnD, nLx2N or nRx2N). Available only for 64x64 to 16x16 CU.
AMVP	Yes (spec)		Adaptive/Advanced Motion Vector Prediction : spatial and PU-based temporal co-located MV candidates with scaling. Logic available from decoder. HW PAK is supporting temporal MV candidates.

Coding Tool	Gen9 Support	Gen9 Restriction	Comments
Merge	Yes (spec)		Merge Skip and Regular Merge. Max. 5 MV Merge candidates (4 spatial + 1 temporal co-located) with scaling. Logic available from decoder. [merge_flag, merge_index, skip_flag]
Parallel Motion Merge		No (intel)	Tool for parallel decode of MVs. Since this isn't constrained by Main Profile, the decoder has to meet performance targets in the worst case anyway.
MC Interpolation Filter	Yes (spec)		¼-pel Luma MV precision, 1/8-pel Chroma MV precision. 8-tap Luma filtering for both ½-pel and ¼-pel locations (1-pass). 4-tap Chroma filtering. Use separable (first horizontal then vertical 1-D filtering) filter coefficients. Not all filter kernels are symmetrical and can map into simple arithmetic. It is a DCT-IF based filter. All operations are within 16-bit data.
Weighted Prediction	Yes (spec)		Free for PAK since decoder already has it. Cross fade and fade-in/out detection required by VME. VME must supply weights, implicit weighted prediction is not supported in HEVC. Only explicit weight is supported. They are both unidirectional and bidirectional.
Combined Reference Frame List		No (intel)	Combine List0 and List1 into a single list to remove uni-prediction signaling overhead.
Intra modes	Yes (spec)		33 directions and DC/Planar modes, with adaptive pre-filtering on reference pixels and boundary smoothing. Intel ENC-VME Mode search reduction for large CUs (64x64 and 32x32) for performance speed up with minimal loss.
IPCM (intra)		No (intel)	Can be disabled completely by SPS, or only allowed at certain CU sizes. No bit maximum on CUs in any profile/level (yet), so as of today there's no mandate to support this for encode. Gen9 PAK does not support IPCM, so ENC cannot generate IPCM mode.
Constrained Intra		No (intel)	Allow only intra neighboring blocks for current block intra-prediction. Enabling this is a coding loss and does not result in a performance improvement in HW designs.
2D DCT Transform	Yes (spec)		Square shape only; 32x32, 16x16, 8x8 and 4x4.
Transform Skip Evaluation		No (intel) ENC will estimate the use of transform skip	Significant coding gains for screen content (PowerPoint etc.). This tool is disabled in the common conditions but isn't explicitly disallowed by Main Profile. FQ is not bypass.
Sign bit hiding		No (intel)	Coding gain by removing one bypass bin per TU. Requires some smarts in the PAK.
Trellis		No (intel)	Trellis Quantization
SAO		No (intel)	Difficult to implement in single pass, performance impact in 2-pass or with previous frame search. Needs investigation. Decoder will support it.

Coding Tool	Gen9 Support	Gen9 Restriction	Comments
Loop Filter across tiles/slices boundary		No (intel)	Can be disabled for tiles and or slices in SPS, so that filter across all tiles and slices boundaries. Main profile doesn't constrain.
Scaling List	Yes (spec)		This uses the default (or custom) qp adjustment on a per-frequency basis within a TU. Good coding improvement over flat scaling.
dQP		Partial (intel) Yes for LCU; No for CU	Being able to change QP per LCU or even up to once per 8x8 CU can lead to significant coding gains. Not sure how easy it is for VME to decide qp values though.
Chroma QP offset		No (intel)	No ROI.
Dependent slices		No (intel)	It is now part of Main Profile, but Intel will not support it. SW can perform the slice repackaging without re-encoding.
Tiles		No (intel)	Although in Main Profile, it results in coding loss and doesn't improve performance on HW. SW parallel processing (multithreaded) tool
Wavefront (aka WPP)		No (intel)	Latest Main Profile spec has included Wavefront. We got a feedback that this feature is highly desirable to support high performance multithreading HEVC decoder.
Lossless coding		No (intel)	Note: this is not the same as IPCM. Also details of this are in flux.
Interlaced Video		No (intel)	Only progressive video encoding is supported.
LM mode	No (spec)		Chroma-from-luma intra prediction (Linear Mode) is not allowed in Main Profile (yet).
NSQT	No (spec)		Non square transform is not allowed in the Main Profile
ALF	No (spec)		Expensive and not in Main Profile currently. If decoder is going to support it, may consider for encoder as well.
Entropy slices	No (spec)		Not allowed in Main Profile, it is a SW parallel processing (multithreaded) tool.
Slice granularity != 0	No (spec)		Not allowed by Main Profile, and highly likely to be removed from the standard completely.

Architecture Overview

This section discusses HEVC features as follows:

Name
VP9 Decoder

VP9 Decoder

The HCP Decoder, following diagram, is a hardware based pipeline that accelerates the stream decode for an external Host Processor. The Host Processor is defined as a system processor external to the HCP that is responsible for high level parsing of the elementary stream and workload creation.

HCP Command Summary

The HCP is configured for encoding or decoding through a set of batch commands defined in the following sections. The software driver builds a frame level workload using these commands and stores these workloads in graphics memory where they are fetched by the Video Command Streamer (VCS) and presented to the HCP for processing. The commands are processed by the Workload Parser within the HCP and the hardware is configured by the Workload Parser prior to each frame level encode or decode. A workload is defined as a set of commands necessary to encode or decode one frame.

The software driver is required to read the HCP disable fuse to determine if the HCP is enabled. If it is disabled, then the software driver must not enable HCP batch commands to be sent to the HCP or a hang event may occur. Only when the HCP is enabled through the fuse, should the batch commands be sent to the HCP.

Workload Command Model

DWord0 of each command is defined in HCP DWord0 Command Definition. The HCP is selected with the **Media Instruction Opcode "7h**" for all HCP Commands.

HCP DWord0 Command Definition

DWord	Bits	Description
0	31:29	**Command Type** = PARALLEL_VIDEO_PIPE = 3h
	28:27	**Pipeline Type** = 2h
	26:23	**Media Instruction Opcode = Codec/Engine Name** = HCP = 7h
	22:16	**Media Instruction Command** = *<see Workload Command Model >*
	15:12	**Reserved: MBZ**

DWord	Bits	Description
	11:0	**Dword Length** (Excludes Dwords 0, 1) = <*command length*>

Each HCP command has assigned a media instruction command as defined in HCP Media Instruction Commands (Opcode=7h).

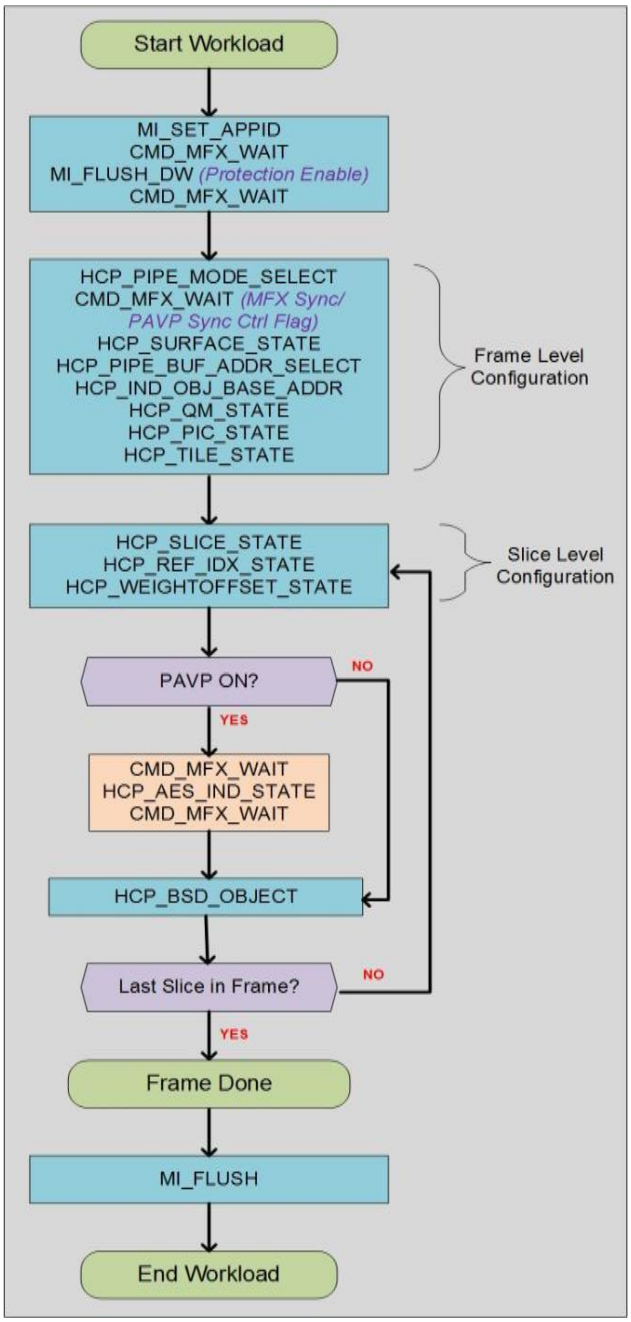
HCP Media Instruction Commands (Opcode=7h)

Media Instruction Command	Command DWord0 [22:16]	Gen9 Mode	Scope
HCP_PIPE_MODE_SELECT	0h	Enc/Dec	Picture
HCP_SURFACE_STATE	1h	Enc/Dec	Picture
HCP_PIPE_BUF_ADDR_STATE	2h	Enc/Dec	Picture
HCP_IND_OBJ_BASE_ADDR_STATE	3h	Enc/Dec	Picture
HCP_QM_STATE	4h	Enc/Dec	Picture
HCP_FQM_STATE (encoder only)	5h	Enc	Picture
Reserved	8h-Fh		
HCP_PIC_STATE	10h	Enc/Dec	Picture
HCP_TILE_STATE	11h	Dec	Picture
HCP_REF_IDX_STATE	12h	Enc/Dec	Slice
HCP_WEIGHTOFFSET	13h	Enc/Dec	Slice
HCP_SLICE_STATE	14h	Enc/Dec	Slice
Reserved	15h-1Fh		
HCP_BSD_OBJECT_STATE (decoder only)	20h	Dec	Slice
HCP_PAK_OBJECT (encoder only)	21h	Enc	LCU
HCP_INSERT_PAK_OBJECT (encoder only)	22h	Enc	Bitstream

HCP Decoder Command Sequence

The long format workload for the HCP is based upon a single frame decode. There are no states saved between frame decodes in the HCP. Once the bit stream DMA is configured with the HCP_BSD_OBJECT command, and the bit stream is presented to the HCP, the frame decode will begin.

HCP Long Format Decode Workload Flowchart



HCP Encoder Command Sequence

For a single frame encoding process (w/o multiple slices per frame), the command sequence is listed below. There are no states saved between frame encoded in the HCP. There should be no other commands or context switch within a group of PAK OBJECT Commands, representing a complete slice. HCP and MFX share the same VCS, but there is no common encoding and decoding command that can be executed in both pipes mi_flush and MMIO commands.

------ Per Frame Level Commands

HCP_PIPE_MODE_SELECT

HCP_SURFACE_STATE

HCP_PIPE_BUF_ADDR_STATE

HCP_IND_OBJ_BASE_ADDR_STATE

HCP_FQM_STATE – issue n number of times

HCP_QM_STATE – issue n number of times

HCP_PIC_STATE

------- Per Slice Level Commands (2 cases)

------- A Frame with only 1 Slice:

HCP_REF_IDX_STATE – set to provide L0 list for a P or B-Slice

HCP_REF_IDX_STATE – set to provide L1 list for a B-Slice

HCP_WEIGHTOFFSET_STATE Command – set to provide for L0 of a P or B-Slice

HCP_WEIGHTOFFSET_STATE Command - set to provide for L1 of a B-Slice

HCP_SLICE_STATE

HCP_PAK_INSERT_OBJECT – if header present at 1st slice start

------- A group of LCUs Per Slice

HCP_PAK_OBJECT

…

HCP_PAK_INSERT_OBJECT – if tail present at frame end

MI_FLUSH – when the frame is done

------ A Frame with Multiple Slices:

HCP_REF_IDX_STATE – set to provide L0 list for a P or B-Slice

HCP_REF_IDX_STATE – set to provide L1 list for a B-Slice

HCP_WEIGHTOFFSET_STATE Command – set to provide for L0 of a P or B-Slice

HCP_WEIGHTOFFSET_STATE Command - set to provide for L1 of a B-Slice

HCP_SLICE_STATE

HCP_PAK_INSERT_OBJECT – if header present at 1st slice start of a frame

HCP_PAK_OBJECT - a group of LCUs for a slice or a frame

…

HCP_PAK_INSERT_OBJECT – if tail present at slice or frame end

HCP_REF_IDX_STATE – set to provide L0 list for a P or B-Slice

HCP_REF_IDX_STATE – set to provide L1 list for a B-Slice

HCP_WEIGHTOFFSET_STATE Command – set to provide for L0 of a P or B-Slice

HCP_WEIGHTOFFSET_STATE Command - set to provide for L1 of a B-Slice

HCP_SLICE_STATE

HCP_PAK_INSERT_OBJECT – if header present at slice start

HCP_PAK_OBJECT - a group of LCUs for a slice or a frame

…

HCP_PAK_INSERT_OBJECT – if tail present at last slice end (frame end)

MI_FLUSH – when the frame is done

MFX_STITCH_OBJECT – a generic bitstream stitching command from MFX pipe

MI_FLUSH

MI_FLUSH is not allowed between Slices. HEVC CABAC has simplified its operation from AVC. There is no longer a BSP_BUF_BASE_ADDR_STATE Command, as only a small local internal buffer is needed for BSP/BSE row store. THE HCP PAK_INSERT_OBJECT has been designed to support both inline and indirectly payload. Nevertheless, the MFX_STITCH_OBJECT command can still be used to stitch HEVC bitstreams together, and is run in the MFX pipe. No HEVC specific STITCH command is implemented. The SURFACE_STATE command for HEVC is redesigned and much simplified from that of MFX pipe.

Memory Address Attributes

This section defines the memory address attributes for the third DWord of the HCP command buffer address.

NOTE: The first DWord defines the lower address range and the second Dword defines the upper address range in the HCP command buffer address.

MemoryAddressAttributes

HCP Pipe Common Commands

The HCP Pipe Common Commands specify the HEVC Decoder pipeline level configuration.

Commands
HCP_PIPE_MODE_SELECT (VideoCS)
HCP_SURFACE_STATE (VideoCS)
HCP_PIPE_BUF_ADDR_STATE (VideoCS)

Buffer Name	Minimum Size in CLs	Notes
Deblocking Filter Line Buffer	((picture_width_in_pixels + 31) & (-32)) » 3	Eq. ensures multiple of 4
Deblocking Filter Tile Line Buffer	((picture_width_in_pixels + 31) & (-32)) » 3	Eq. ensures multiple of 4
Deblocking Filter Tile Column Buffer	((picture_height_in_pixels + 6*pic_height_in_ctb + 31) & (-32)) » 3	Eq. ensures multiple of 4
Metadata Line Buffer (all intra slices)	(picture_width_in_pixels + pic_width_in_lcu*8 + 1023) » 9	Eq. ensures multiple of 2
Metadata Tile Line Buffer (all intra slices)	(picture_width_in_pixels + pic_width_in_lcu *16 + 1023) » 9	Eq. ensures multiple of 2
Metadata Tile Column Buffer (all intra slices)	(picture_height_in_pixels + picture_height_in_pixels *8 + 1023) » 9	Eq. ensures multiple of 2
Metadata Line Buffer (some inter slices)	(((picture_width_in_pixels+15)»4)*188 + pic_width_in_lcu*9 + 1023) » 9	Eq. ensures multiple of 2
Metadata Tile Line Buffer (some inter slices)	(((picture_width_in_pixels +15)»4)*172 + pic_width_in_lcu *9 + 1023) » 9	Eq. ensures multiple of 2
Metadata Tile Column Buffer (some inter slices)	(((picture_height_in_pixels +15)»4)*176 + picture_height_in_lcu *89 + 1023) » 9	Eq. ensures multiple of 2
SAO Line Buffer	(((picture_width_in_pixels » 1) + pic_width_in_ctb * 3)+15) & (-16)) » 3	Eq. ensures multiple of 2
SAO Tile Line Buffer	(((picture_width_in_pixels » 1) + picture_width_in_ctb * 6)+15) & (-16)) » 3	Eq. ensures multiple of 2
SAO Tile Column Buffer	(((picture_height_in_pixels » 1) + pic_height_in_ctb * 6)+15) & (-16)) » 3	Eq. ensures multiple of 2

Buffer Name	Minimum Size in CLs	Notes
Current and Collocated Motion Vector Temporal Buffer (lcu=16x16)	(((picture_width_in_pixels+63)»6)*((picture_height_in_pixels+15)»4)	Eq. ensures multiple of 2

Internal Media Rowstore Table

If the internal Media Rowstore exists, driver should use the storage as the following table indicates.

HEVC Pipeline	Frame Width	DAT	DF	SAO	DAT Addr	DF Addr	SAO Addr
HEVC	<= 2048	Y	Y	Y	0	64	320
	2048 < x <= 4096	Y	Y	N	0	128	N/A
	4096 < x <=8196	Y	N	N	0	N/A	N/A

VP9 Common Commands

Commands
HCP_PIPE_MODE_SELECT
HCP_SURFACE_STATE
HCP_PIPE_BUF_ADDR_STATE
HCP_IND_OBJ_BASE_ADDR_STATE
HCP_VP9_SEGMENT_STATE
HCP_VP9_PIC_STATE

HCP Common Commands

HCP_PIC_STATE (VideoCS)

HCP_TILE_STATE (VideoCS)

HCP_REF_IDX_STATE (VideoCS)

HCP_WEIGHTOFFSET_STATE (VideoCS)

HCP_SLICE_STATE (VideoCS)

HEVC_VP9_RDOQ_STATE

VP9 Commands

HCP_BSD_OBJECT (triggers HW start)

HCP_VP9_PAK_OBJECT

Tile Size and CU Stream-out Records

CU statistics record (individual PUs per record down to 8x8 only) (Note: For Advanced BRC but not supported in HW yet)

Fields	Bits	
Skip	3:0	Indicates Skip flag Group 4 4x4s -> 4 bits
InterMode	11:4	InterMode: 0 NEARESTMV, 1 NEARMV, 2 ZEROMV, 3NEWMV Group 4 4x4s total 8 bits
Reserved	15:12	
NZ coeff count	28:16	Number of non-zero coeffs; sum of YUV, 13bits
Reserved	31:29	
NumBitsforCoeffs	47:32	Number of Bits for coefficients per block, 16bits
NumBitsforBlock	63:48	Number of Bits in block

Stream-in Probability Table

In Encoder mode, two sets of this table will be streamed out: one for the current frame probability update and one for future frame.

Stream-in formats for creating compressed header

The following memory surfaces are input to PAK for Compressed Header coding

i. Prob Diff Surface

In Probability Diff Surface, there are 1805 8-bit Probability Diffs. Each of them corresponding to a Probability Diff in Compressed Header syntax. Although, for a given compressed header, not all the Probability Diff would be coded (depends on update flag), Probability Diff Surface is fully populated with 1805 entries (1805*8 / 512 = 29 cachelines). The 1805 8-bit Probability Diffs are expected to follow Compressed Header syntax order and fully packed.

ii. Compressed Header Syntax Surface

Each of the Compressed header Coding element (described in (2)) is represented by a 4-bit field. These 4-bit fields follows Compressed Header Syntax. Each of the field has a valid, Bin_probDiff_select, Prob_select, Bin as described in the table below.

	Description
Valid	Set to 1 if this is a valid Bin OR ProbabilityDiff field to code; Set to 0 to skip coding this field
Bin_ProbDiff_select	Set to 1 if Current field is a Bin (corresponding Prob, Bin are indicated by next 2 bits); Set to 0 if Current field is Probability Diff (probability diff to be coded is located in probability surface - ReMap)
Prob_Select	If current field is Bin, set to 1 if prob is 252; set to 0 if prob is 128
Bin	if current field is Bin, this is Bin value to be encoded

Compressed Header Syntax Surface is a fixed length surface. For syntax that should not be coded, valid bit should be set to 0. Total length of Compressed Header syntax Surface has 4033 Coding elements (16132 bits in 32 cachelines):

1805 Prob Diff and Prob Update flag

4 is_coeff_updated flag (per 4x4, 8x8, 16x16, 32x32)

5 control fields (MIN (tx_mode, ALLOW_32x32), tx_mode == TX_MODE_SELECT, use_compound_pred, use_hybrid_pred)

Probability Statistics Counters Table

In VP9 encoding, statistic collection is required to utilize the Forward Adaptation feature, which can substantially improve decoding performance because no intermediate computations based on encountered tokens is necessary. After encoding a frame, the VP9 encoder writes a Statistics Counter in the memory surface (HCP_IND_OBJ_BASE_ADDR_STATE: HCP VP9 PAK Probability Counter Streamout). The counter written in the memory surface is the same order as the VP9 Compressed header format.

The Statistics Counters collect frame statistics per symbol. In the VP9 Encoder, the PAK engine is responsible for statistics counter collection. The Kernel performs probability updates based on statistics counter values.

Each counter has has an associated context according to the VP9 Specification/Model.

Probability Statistics Counters Table

Note: The following table is arranged such that each row corresponds to sixteen 32-bit counters. In other words, each row corresponds to 512 bits (1 Cacheline). The VP9 Encoder PAK engine will have a total of 193 cacheline writers in the memory surface (HCP_IND_OBJ_BASW_ADDR_STATE: HCP VP9 PAK Probability Counter Streamout) at the end of each frame.

For brevity, data in the table is abbreviated. A Context Legend table has been provided after the Probability Statistics Counters table that explains the data in more detail.

SB, CU/PU and TU Sizes – Encoder Only

CU/PU/TU Partitioning Configurations

SB size	CU size	min/max TU range
64x64	64x64	32x32..4x4
	32x32	32x32..4x4
	16x16	16x16..4x4
	8x8	8x8..4x4

PU Options for a Given CU

Current CU size	Possible CU sizes	Allowed CU/PU partition types.
64x64	64x64	2Nx2N, 2NxN, Nx2N
	32x32	2Nx2N, 2NxN, Nx2N
	16x16	2Nx2N, 2NxN, Nx2N
	8x8	2Nx2N, 2NxN, Nx2N, NxN

Definition of the VP9 CU Record Structure - Encoder Only

The following table defines the CU record structure as indirect data to the PAK Object Command. Entries are DW based (4 bytes) and cache aligned. This memory surface is pointed to by the HCP Indirect CU Object Base Address in the HCP_IND_OBJ_BASE_ADDR_STATE Command.

VP9 CU Record Structure Definition (UnPacked CU)

DW	Bit	Field	Bits	Definition	Comments

Allowed SB Size Encoder Only

The following table details the SB size allowed and the number of records per SB for the encoder.

Allowed SB Size – Encoder Only

SB Size Allowed	Number of Records per SB
64x64	64

Note: HW will support partial SBs within a frame bourndary to a minimun CU8x8 granularity

HCP Commands

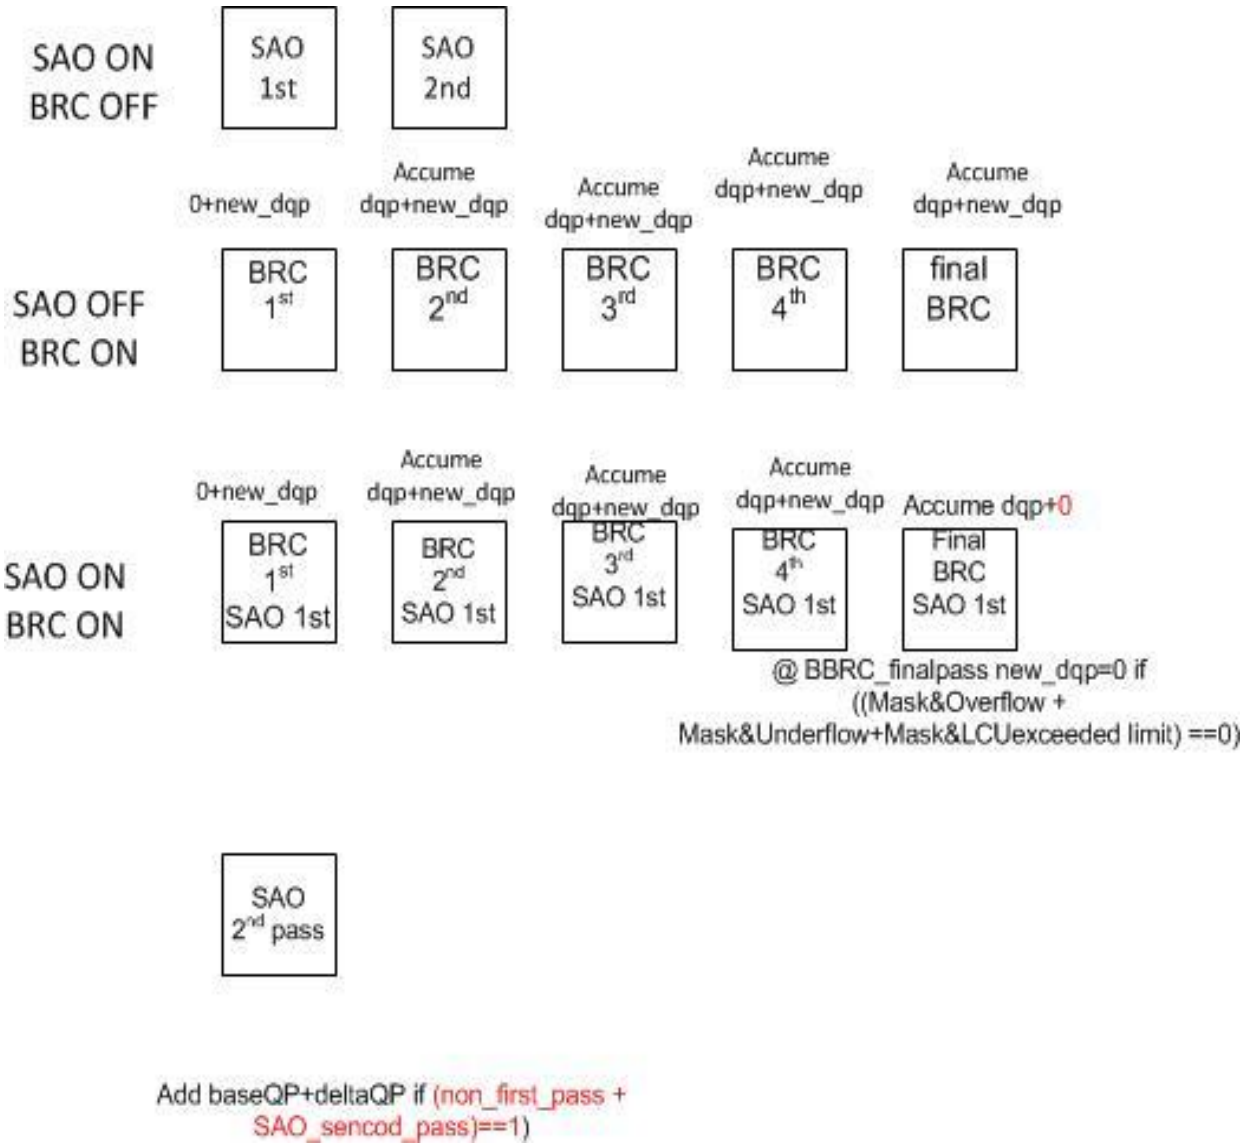
The HCP Commands specify the HEVC BSD object and PAK object level configuration.

HCP_BSD_OBJECT (VideoCS)

HCP_PAK_OBJECT_VideoCS

HCP_PAK_INSERT_OBJECT_VideoCS

Multipass flow during BRC and SAO



CU and Slice level stat streamOut

Along with final bitstream, HLC writes out two statistics related streamout cachelines to the memory. Streamout0 cacheline is composed of 4 quarter cachelines, each containing information on CU skip flag, coding block flag for the TUs in a CU, residual/coefficient bit count for a CU, total bit count for CU, LCU exceed limit flag. A typical streamout0 cacheline, therefore, has information on statistics for 4 CUs and lcu exceed limit flag.

Streamout1 cacheline is composed of quarter cachelines., each quarter cacheline consisting of bit count of current slice.

Pak pipeline streamout enable bit, set by HCP_PIPE_MODE_SELECT command, enables or disables the streamout.

Streamout 0: Per CU Quarter Cacheline Format

Level	Field	Width	Cacheline	Comment
CU	CU Skip Flag	1	qcacheline[0]	Packed in Quarter Cacheline in CU format
LCU	LCU exceed limit	1	qcacheline[1]	Packed in Quarter Cacheline in CU format (valid in last CU of LCU)
	Reserved	14	qcacheline[15:2	Reserved
CU	TU CBF Y/U/V	48	qcacheline[63:16]	Packed in Quarter Cacheline in CU format
CU	CU Coefficient Bit Count (Only residual)	18	qcacheline[81:64]	Packed in Quarter Cacheline in CU format
CU	CU Bit Count (all CU Syntax)	18	qcacheline[113:96]	Packed in Quarter Cacheline in CU format
	Reserved	14	qcacheline[127:114]	Reserved

Streamout 1: Per Slice Quarter Cacheline

Level	Field	Width	Cacheline	Comment
Slice	Slice Bit Count (slice header + data + tail)	32	cacheline[31:0]	
	Reserved	32	cacheline[63:32]	
	SlicePositionX[15:0]	16	cacheline[79:64]	
	SlicePositionY[15:0]	16	cacheline[95:80]	
	Reserved	32	cacheline[127:96]	

Definition of the CU Record Structure for Ext Interface – Encoder Only

The following table defines the CU record structure as indirect data to the PAK Object Command. Entries are DW based (4 bytes) and cache aligned. This memory surface is pointed to by the HCP Indirect CU Object Base Address in the HCP_IND_OBJ_BASE_ADDR_STATE Command.

CU Record Structure Definition

DWord	Bitfield	Field	Bits	Definition	Comments
0	1:0	cu_size	2	0: 8x8	
				1: 16x16	
				2: 32x32	
				3: 64x64	
	2	cu_pred_mode	1	0: Intra	For I slices, pred_mode is always 0.
				1: Inter	
	3	cu_transquant_bypass_flag	1		Note: HW ignores this bit for RhoDomain calculation so the statics will be slightly inaccurate. This bit should not be set to 1 if transform_skip=1
	6:4	cu_part_mode	3	0: 2Nx2N	
				1: 2NxN (inter only)	
				2: Nx2N (inter only)	
				3: NxN (intra only)	only if CU size is 8x8
				4: 2NxhN (inter only)	
				5: hNx2N (inter only)	
	7	IPCM_enable	1	1: Enable IPCM 0: Disable IPCM	MBZ Reserved If IPCM is enabled, then entire CU is IPCM predicted. Both PU and TU sizes should be same as CU size. Cu_pred_mode is ignored when IPCM is enbled. Note: Supports 8bit pixel depth only
	10:8	intra_chroma_mode	3	0: DM	(use Luma mode, from block 0 if NxN)
				1: Reserved	(supposedly to be defined for LM mode)

DWord	Bitfield	Field	Bits	Definition	Comments
				2: Planar	
				3: Vertical	
				4: Horizontal	
				5: DC	
	11	zero_out_coefficient	1	0: Do not force coefficients to zero 1: Force coefficients to zero	If this bit it set to 1, HW will force coefficients to zero.
	15:12	Reserved	5		
	22:16	cu_qp	7	in 7-bit	Valid range: 0 to 51 for 8bit mode -12 to 51 for 10bit mode *diff_cu_qp_delta_depth = 0 (No QP change allowed at CU Level.* Only allow QP change across LCU, no change across CU for PAK only.
	23	cu_qp_sign	1	0:positive 1:negative	Indicates sign bit for QP. Must be zero for 8bit mode
	31:24	interpred_idc[3:0][1:0]	8	2 bits each 0: L0 1: L1 2: Bi 3: reserved	in Z-order interpred_idc[0][1:0] - block 0 = [25:24] interpred_idc[15][1:0] - block 15 = [31:30]
1	5:0	intra_mode[0][5:0]	6	final explicit luma mode. Valid values are 0..34.	1 per cu partition, and only active partitions have valid intra mode value
	7:6	Reserved	2		
	13:8	intra_mode[1][5:0]	6	final explicit luma mode. Valid values are 0..34.	
	15:14	Reserved	2

10	3:0 7:4 11:8 15:12	reserved[0] intra_chroma_mode1[2:0] reserved[0] intra_chroma_mode2[2:0] reserved[0] intra_chroma_mode3[2:0] reserved[3:0]		3-bits each	
10	3:0 7:4 11:8 15:12	ref_idx_l0[0][3:0] ref_idx_l0[1][3:0] ref_idx_l0[2][3:0] ref_idx_l0[3][3:0]	16	4-bit each	in Z-order (1st index starts at LSB and goes up)
	19:16 23:20 27:24 31:28	ref_idx_l1[0][3:0] ref_idx_l1[1][3:0] ref_idx_l1[2][3:0] ref_idx_l1[3][3:0]	16	4-bit each	Combined list is not supported in Z-order (1st index starts at LSB and goes up)
11		tu_size[15:0]	32	0: 4x4	in Z-order (1st index starts at LSB and goes up)
				1: 8x8	
				2: 16x16	
				3: 32x32	
12	15:0	tu_xform_Yskip[15:0]	16	0: TU transform skip flag for luma	In Z-order (1st index starts at LSB and goes up). Populated for each TU even if transform skip

DWord	Bitfield	Field	Bits	Definition	Comments
				component is not set (normal transform) 1: TU transform skip flag for luma component is set	is not supported for that particular TU size. This bit should not be set to 1 if transquant_bypass=1
	27:16	Reserved	12		
	31:28	tu_countm1[3:0]	4	number of TU count per CU minus 1	Intel restriction max 16 TU per CU (however spec allows up to 256 TUs). If there is no TU inside a CU, it is indicated by cbf and skip flag.
13	15:0	tu_xform_Uskip[15:0]	16	0: TU transform skip flag for chroma cb component is not set (normal transform) 1: TU transform skip flag for chroma cb component is set	Indexed by tu_xform_Yskip index. Populated for each TU even if transform skip is not supported for that particular TU size. For the case where a 4x4 chroma TU is associated with a group of four 4x4 luma TUs the chroma cb transform skip is coded in the same position as the last 4x4 luma TU (the prior 3 indexed positions are skipped/ignored). For example an 8x8 CU with four 4x4 luma TUs would code the chroma cb TU transform skip flag as tu_xform_Uskip[3]. Restriction: For 422, 2 TUs for each Chroma correspond to 1 Luma TU share the same transformskip flag. This bit should not be set to 1 if transquant_bypass=1
	31:16	tu_xform_Vskip[15:0]	16	0: TU transform skip flag for chroma cr component is not set (normal transform) 1: TU transform skip flag for chroma cr component is set	Indexing identical tu_xform_Uskip. Populated for each TU even if transform skip is not supported for that particular TU size. This bit should not be set to 1 if transquant_bypass=1

Intel restriction max 16 TU per CU, max 256 TUs in a CU.

Max 64 CUs, and each CU record max is 1 cacheline 64 bytes in size (1 cacheline 64 bytes)

LCU, CU, TU, and PU Sizes – Encoder Only

LCU/CU Partitioning Configurations

LCU size	min CU size	CU Depth	Hierarchical Depth=CU Depth+1
64x64	64x64	0	1
	32x32	1	2
	16x16	2	3
	8x8	3	4
32x32	32x32	0	1
	16x16	1	2
	8x8	2	3
16x16	16x16	0	1
	8x8	1	2
8x8	8x8	X	Not allowed in spec

PU Options for a Given CU

Current CU size (leaf node)	min CU sizes (Pic State)	Allowed PU partition types.
64x64 (2Nx2N) Must be a LCU	64x64	Skip : 2Nx2N Intra : 2Nx2N, NxN Inter : 2Nx2N, 2NxN, Nx2N, NxN
	32x32	Skip : 2Nx2N Intra : 2Nx2N (no NxN defined in the spec.) Inter :

		2Nx2N, 2NxN, Nx2N, 2NxnU, 2NxnD, nLx2N, nRx2N
	16x16	Skip : 2Nx2N Intra : 2Nx2N (no NxN defined in the spec.) Inter : 2Nx2N, 2NxN, Nx2N, 2NxnU, 2NxnD, nLx2N, nRx2N
	8x8	Skip : 2Nx2N Intra : 2Nx2N (no NxN defined in the spec.) Inter : 2Nx2N, 2NxN, Nx2N, 2NxnU, 2NxnD, nLx2N, nRx2N
32x32 (2Nx2N) Can or is not a LCU	32x32	Skip : 2Nx2N Intra : 2Nx2N,

		NxN Inter : 2Nx2N, 2NxN, Nx2N, NxN
	16x16	Skip : 2Nx2N Intra : 2Nx2N Inter : 2Nx2N, 2NxN, Nx2N, 2NxnU, 2NxnD, nLx2N, nRx2N
	8x8	Skip : 2Nx2N Intra : 2Nx2N Inter : 2Nx2N, 2NxN, Nx2N, 2NxnU, 2NxnD, nLx2N, nRx2N
16x16 (2Nx2N) Can or is not a LCU	16x16	Skip : 2Nx2N Intra : 2Nx2N, NxN Inter : 2Nx2N, 2NxN, Nx2N, NxN
	8x8	Skip :

		2Nx2N Intra : 2Nx2N Inter : 2Nx2N, 2NxN, Nx2N, 2NxnU, 2NxnD, nLx2N, nRx2N
8x8 (2Nx2N) Cannot be a LCU	8x8	Skip : 2Nx2N Intra : 2Nx2N and NxN Inter : 2Nx2N, 2NxN, Nx2N (both NxN and AMP are not allowed for 8x8 inter CU)

Note: In an 8x8 Inter CU NxN isn't allowed if the SPS parameter disable_inter_4x4 is 1. In Main profile currently this flag is always 1.

U.D, L and R (Up, Down, Left and Right)

n = ¼ or – .

TU Partitioning for a Given CU

CU size	TU size	TU Depth	Max Depth=TU Depth+1	PAK supported TU sizes and corresponding number of TUs in CU
64x64	64x64	0	1	no 64x64 transform, so automatically breakdown into 4 32x32 TUs.
	32x32	1	2	number of TUs in CU = 4
	16x16	2	3	number of TUs in CU = 16
	8x8	3	4	this configuration is currently not supported.

	4x4	4	5	this configuration is currently not supported.
32x32	32x32	0	1	number of TUs in CU = 1
	16x16	1	2	number of TUs in CU = 4
	8x8	2	3	number of TUs in CU = 16
	4x4	3	4	this configuration is currently not supported.
16x16	16x16	0	1	number of TUs in CU = 1
	8x8	1	2	number of TUs in CU = 4
	4x4	2	3	number of TUs in CU = 16
8x8	8x8	0	1	number of TUs in CU = 1
	4x4	1	2	number of TUs in CU = 4

The actual level of partitioning is governed by

- MaxTUSize and MinTUSize in Pic State.
- max_transform_hierarchy_depth_inter <= 2 (intel restriction) DW4 bit 3:2 Pic State
- max_transform_hierarchy_depth_intra <= 2 (intel restriction) DW4 bit 1:0 Pic State

Allowed LCU Size – Encoder Only

The following table details the LCU size allowed and the number of records per LCU for the encoder.

LCU Size Allowed	Fixed Number of Records per LCU
64x64	64
32x32	16
16x16	4

Note: 0.5 CL per CU record in VME mode and 1 CL per CU record in extENC mode.

HEVC Error Concealment

The HCP implements an error concealment policy, which is always enabled and cannot be disabled. The objective is that the HCP will always complete a frame/field workload by either decoding the bit stream normally until it finishes the workload or by concealing blocks until the slice or workload is completed. It should never be allowed to hang.

Error concealment, implemented by the HCP hardware, is configured for each slice in the HCP_BSD_OBJECT command. The following information in the HCP_BSD_OBJECT command is utilized for error concealment.

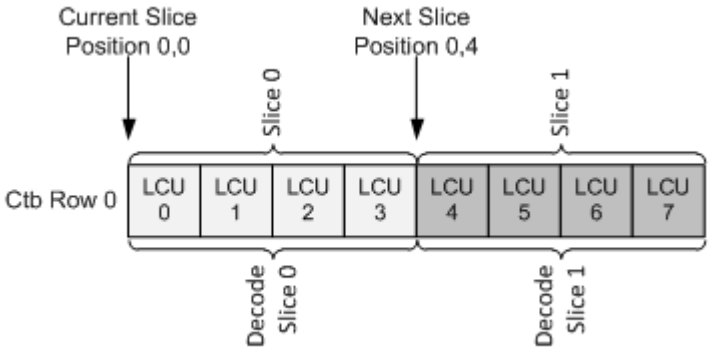
- **SliceStartCtbY, SliceStartCtbX:** The current slice position specified in Ctb coordinates.
- **NextSliceStartCtbY, NextSliceStartCtbX:** The next slice position specified in Ctb coordinates. If the current slice is the last slice in the picture, the next slice values are set to (0,0).
- **LastSliceofPic:** Indicates that the current slice is the last slice in the picture.
- **slice_type:** Indicates the picture type: I, P or B.

The host software will remove all extra slices in the picture. The HCP will not be given a workload that includes extra slices beyond the picture. The last slice in the picture will always be marked by the host software.

The host software will remove any overlapping slices in the picture. The HCP will not be given a workload that includes overlapping slices in the picture.

A HCP_BSD_OBJECT command will include the current slice position and the next slice position. For non-errored streams, it is guaranteed that the slice bit stream will be decoded by the HCP starting from the current slice position through to the Ctb (inclusive) adjacent to the Ctb indicated by the next slice position. *HEVC Error Concealment* illustrates the example of a non-errored stream decode starting with XXX.

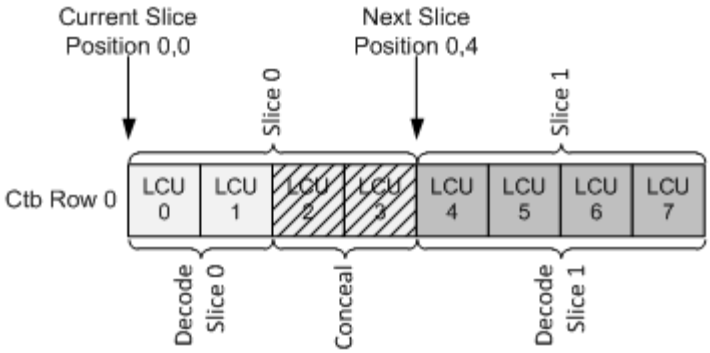
HEVC Slice Decode for Non-errored Stream Cases



For error stream cases where the next slice position does not align itself with the last successfully decoded Ctb in the current slice, the HCP will conceal Ctbs from the last decoded Ctb in the current slice through to the last Ctb prior to the Ctb indicated by the next slice position. If the error occurs such that the current decoded Ctb cannot be decoded, the HCP will ensure that the current Ctb is written out by

any means before writing out concealed Ctbs for the remaining Ctbs in the current slice. In the case of the last slice in a picture, the HCP will conceal Ctbs from the last decoded Ctb in the current slice through to the last Ctb position in the picture indicated by the resolution of the picture in the HCP_PICT_STATE command. *HEVC Error Concealment* illustrates the case described.

HEVC Slice Decode for Missing Blocks in a Slice



Since the host software removes overlapping slices, the next slice position will never be equal to or less than the current slice position.

A concealed Ctb for an I-slice is constructed by the HCP specifying the Intra_Planar prediction mode for the Ctb.

A concealed Ctb for a P-slice is constructed by the HCP specifying the skip_flag.

A concealed Ctb for a B-slice is constructed by the HCP specifying the skip_flag.

VP9 Register Definitions

This section describes the VP9 Register Definitions as follows:

- Register Attributes Description
- VP9 Register Map
- VP9 Encoder Register Descriptions

Register Attributes Description

Host Register Attributes gives the defined register tags and their description.

Host Register Attributes

Tag	Name	Description
R/W	Read/Write	Bit is read and writeable.
R/SW	Read/Special Write	Bit is readable. Write is only allowed once after a reset.
RO	Read Only	Bit is only readable, but writes have no effects.
WO	Write Only	Bit is only writeable, reads return zeroes.
RV	Reserved	Bit is reserved and not visible. Reads will return 0, and writes have no effect.
NA	Not Accessible	This bit is not accessible.

VP9 Register Map

These are MMIO register definitions for decoder/encoder:

VP9 Encoder Register Descriptions

HCP_IMAGE_STATUS_MASK - HCP Image Status Mask

HCP_IMAGE_STATUS_CONTROL - HCP Image Status Control

HCP_UNIT_DONE - HCP Unit Done

HEVC Register Definitions

The Message Channel Interface is a read-only bus used to access the HCP status registers. All registers are 32 bits where reserved bits return a value of zero and subtractive-decode is used to return 0x0000 for all register holes. The Unit ID is 28h. For HCP, the address range is 0x0001E900h to 0001E9FFh.

Register Attributes Description

Host Register Attributes gives the defined register tags and their description.

Host Register Attributes

Tag	Name	Description
R/W	Read/Write	Bit is read and writeable.
R/SW	Read/Special Write	Bit is readable. Write is only allowed once after a reset.
RO	Read Only	Bit is only readable, but writes have no effects.
WO	Write Only	Bit is only writeable, reads return zeros.
RV	Reserved	Bit is reserved and not visible. Reads will return 0, and writes have no effect.
NA	Not Accessible	This bit is not accessible.

HCP Decoder Register Map

This documents all HEVC Decoder MMIO Registers.

HCP Decoder Register Descriptions

The HCP implements the following MMIO registers. A description of the register including its address and DWord descriptions are provided.

HCP CABAC Status

HCP Picture Checksum cIdx0

HCP Picture Checksum cIdx1

HCP Picture Checksum cIdx2

HCP Encoder Register Map

These are MMIO register definitions for encoder.

HCP Encoder Register Descriptions

HCP_FRAME_PERFORMANCE_CT - HCP Frame Performance Count

HCP_LAT_CT1 - HCP Memory Latency Count1

HCP_LAT_CT2 - HCP Memory Latency Count2

HCP_LAT_CT3 - HCP Memory Latency Count3

HCP_LAT_CT4 - HCP Memory Latency Count4

HCP_LAT_CT5 - HCP Memory Latency Count5

HCP_LAT_CT6 - HCP Memory Latency Count6

HCP_BIN_CT - HCP Frame BitStream BIN Count

HCP_READ_CT - HCP Frame Motion Comp Read Count

HCP_MISS_CT - HCP Frame Motion Comp Miss Count

HCP_BITSTREAMSE_BITCOUNT_FRAME - Reported Bitstream Output Bit Count for Syntax Elements Only

HCP_CABAC_BIN_COUNT_FRAME - Reported Bitstream Output CABAC Bin Count Register

HCP_CABAC_INSERTION_COUNT - Reported Bitstream Output CABAC Insertion Count

HCP_MINSIZE_PADDING_COUNT - Bitstream Output Minimal Size Padding Count Report Register

HCP_IMAGE_STATUS_CONTROL - HCP Image Status Control

HCP_QP_STATUS_COUNT - HCP Qp Status Count

HCP_UNIT_DONE - HCP Unit Done

HCP_IMAGE_STATUS_MASK - HCP Image Status Mask

HUC Status Register Descriptions

Following are HUC Status Register Descriptions:

UKERNEL_HDR_INFO - uKernel Header Info

Acronyms and Applicable Standards

Acronyms and Abbreviations

The table below defines acronyms and abbreviations used in this document.

Acronyms

Acronym	Meaning
AAC	Advanced Audio Coding — part of the MPEG specification, AAC is the latest development in audio compression. It provides higher-quality audio reproduction than MPEG-1 Layer 3 (MP3), while requiring nearly 50% less data. It is defined in ISO/IEC 13818-7.
ADSL	Asymmetrical Digital Subscriber Line — an asymmetrical DSL technology that takes advantage of the one-way nature of most multimedia communication, and provides much faster data rates for downstream (to the subscriber) then the upstream.
API	Application Programming Interface — a set of routines used by an application program to request and carry out low-level services performed by the operating system.
ARGB	Alpha Red Green Blue — color channel components.
ARIB	Association of Radio Industries and Business — designated by the Ministry of Public Management, Home Affairs, Posts and Telecommunications (MPHPT) in Japan. ARIB members include broadcasters, radio equipment manufacturers, telecommunication operators, and related organizations.
ASP	Advanced Simple Profile – MPEG4-2
ATSC	ATSC Advanced Television Systems Committee – an organization in US that establishes and promotes technical standards for advanced television systems, such as digital television (DTV).

Acronym	Meaning
BDU	Bit-stream Data Unit
BIST	Built In Self Test
BPP	Bits Per Pixel
BSD	Byte Stream Decoder
CA, CAM	Conditional Access, Conditional Access Module – the removable descrambling module implemented in digital cable or satellite television system. The data flows through the module, which can have any proprietary scrambling algorithm implemented, yet maintaining system interface compatibility. The CAMs are usually provided by the operators in the TV network.
CPU	Central Processing Unit
DAA	Direct Access Arrangement
DAC	Digital-to-Analog Converter
DDA	Digital Difference Analyzer
DDS	Direct Digital Synthesizer
DPB	Decoded Picture Buffer. This buffer holds the decoded pictures for reference and for output along with the currently decoding picture. This differs from the DPB in the standard, which only holds the decoded pictures for reference.
DVB	Digital Video Broadcasting — a set of open worldwide standards that define digital broadcasting using existing satellite, cable, and terrestrial infrastructures. It uses MPEG-2 specification as a universal foundation and expands it with DVB data structures and processes DVB-compliant digital broadcasting and equipment is widely available to consumers and is indicated with the DVB logo.
DVB-S	Satellite television DVB standards, based on QPSK and 8-DPSK modulation.
DVB-T	Terrestrial television DVB standards, based on 2k and 8k OFDM modulation.
DVD	Digital Versatile Disc
DVD-R	Recordable DVD. Since different disk formats are currently in use, including DVD-R,DVD+R, they are collectively mentioned as DVD-R in this document
DVI	Digital Visual Interface standard (EIA/CEA-861A). The standard defines a method for sending digital video signals over DVI and OpenLDI interface specifications. The standard is fully backward compatible with earlier DVI standards. New features include carrying auxiliary video information, such as aspect ratio and native video format information.
DVO	Digital Video Output - the parallel, low voltage signaling interface defined for Intel® video chipsets
DSL xDSL	Digital Subscriber Line – transmission of data over copper telephone lines capable of bringing high-bandwidth to subscribers. Many flavors of DSL are currently in use, which are collectively called xDSL throughout the document.
DSP	Digital Signal Processor
DST	Destination
DWord	A 32-bit word
ES	Elementary Streams — the raw output of an encoder, containing only what is necessary for a decoder to approximate the original picture or audio.
FIFO	First in First Out

Acronym	Meaning
FIR	Finite Impulse Response
FPU	Floating Point Unit
FW	Firmware running on the decoder controller, as used in Volume 4 of the *Olo River Plus Silicon EAS*
IDR	Instantaneous Decoding Refresh
IEEE 1394 1394	IEEE 1394 or iLink* or FireWire* An IEEE electronics industry standard for connecting multimedia and computing Up to 63 devices can be attached to your PC via a single plug-and-socket connection.
IEEE 802.11 802.11	The Institute for Electronics and Electrical Engineers (IEEE) wireless network specification. 802.11g and 802.11a networks can transmit payload at the rates in excess 34Mbits/s and allow for the wireless transmission at distances from several dozen to several hundred feet indoors.
IF	Intermediate Frequency — the fixed, relatively low-frequency carrier to which current programs are ported by the tuner.
GMCH	Graphics and Memory Control Hub — a chip that connects the IA processor to memory and other components in PC.
HDD	Hard Disk Drive — magnetic mass storage device used in media centers for audiovisual program recording.
HDMI	High Definition Multimedia Interface (HDMI). This interface is used between any audio/video source, such as a set-top box, DVD player, or A/V receiver, and an audio or video monitor, such as a DTV. HDMI supports standard, enhanced or high-definition video, plus multi-channel digital audio on a single cable. The format transmits all ATSC HDTV standards and supports eight-channel digital audio (at up to a 192kHz sampling rate), with bandwidth to spare for future enhancements.
HDTV	High-Definition Television — HDTV specifically refers to the highest-resolution formats of the 18 total DTV formats, true HDTV is generally considered to be 1,080-line interlaced (1080i) or 720-line progressive (720p).
HSR	Hidden Surface Removal
HW	Hardware
I/F	Interface
IEEE	IEEE 32-bit Floating Point number format representation
ISP	Image Synthesis Processor — A collective term to describe all components of the hidden surface removal operation within the PowerVR architecture.
LOD	Level Of Detail — used in texturing calculations.
LSB	Least Significant Bit
LUT	Look-up table
MBAFF	Block Adaptive Field Frame mode
MFD	Multi-Format Decoder
MMU	Memory Management Unit
MMMC	Multi-port, Multi-channel Memory Controller
MSA	Intel Micro Signal Architecture — microprocessor architecture combining the features of microcontroller and digital signal processor. MSA is used here as a synonym of the processor core

Acronym	Meaning
	used in Olo River Plus
MSB	Most Significant Bit
MPEG	Motion Picture Experts Group – Organization that develops standards for digital video and digital audio compression.
MPR	Inter Prediction Module
NAL	Network Abstraction Layer
NAL unit	Syntax structure in a H.264 stream
NTSC	National Television System Committee, North American 525-line analog broadcast TV standard.
NIM	Network Interface Module – the integrated tuner and digital demodulator in the (satellite) TV systems. The DVB NIMs output MPEG transport stream.
NOP	No operation
OEM	Original Equipment Manufacturer
OGL/OpenGL	Open GL application programming interface
PAL	Phase Alternation Line - TV standard used in Europe. PAL uses 625 lines per frame, a 25 frames per second update rate and YUV color encoding. The number of visible pixels for PAL video is 768 x 576.
PCI	Peripheral Component Interconnect bus, a bi-directional bus defined in PCI 2.x specification
PES	Packetized Elementary Streams — packetized streams are the ES streams arranged in data packets with PES header starting every packet. The syntax of the ES and PES is defined in MPEG. See definition for ES.
PIP	Picture In Picture display mode
POD	Point of Deployment conditional access module — the removable conditional access module defined in the OpenCable* specification in US.
PPS	Picture Parameter set
PTS	Presentation time stamp
PVR	Personal Video Recorder, also PDR or personal digital recorder — an interactive TV-recording device that records programs in digital format and allows users to search for/record shows based on type (for instance all basketball games or all episodes of a particular program). Users can also pause, rewind, stop, or fast-forward live programs with only a small time lag.
PWL	Piece-wise Linear
PXD	Pixel Decoder Module
RF	Radio Frequency – usually, modulated carriers which can be directly received by the tuners of TVs or radio receivers
RISC	Reduced Instruction Set Computer
RHW	Reciprocal Homogenous W — W is a 3-D coordinate representation like X Y Z
RSB	Row Store Buffer
RTL	Register Transfer Language/Level
SEI	Supplementary Enhancement Information

Acronym	Meaning
SIF	Semaphore Interface Module
SIMD	Single Instruction Multiple Data
SMPTE	Society of Motion Picture and Television Engineers
SOC	System on chip
SP	Simple Profile – MPEG4-2
SPS	Sequence Parameter set
SRC	Source
SDTV	Standard-Definition Television — a digital television system that is similar to current analog TV standards in picture resolution and aspect ratio. Typical SDTV resolution is 480i or 480p.
STB	Set Top Box — a device that effectively turns a television set into an interactive Internet device and/or allows the television to receive and decode digital television (DTV) broadcasts.
TA	Tile Accelerator
TS	MPEG-2 Transport Stream — a sequence of 188-byte packets carrying the multi-program audiovisual data
TSP	Texture Shading Processor — a collective term to describe all components of the texture, shading and pixel blending operations within the PowerVR architecture.
VCL	Video Coded Layer
VCXO	Voltage Controlled Crystal Oscillator
VGP/ VGP Lite	Vertex Geometry Processor
VLC	Variable length coded. This refers to the collection of coding techniques that are used in VC1, and include CABAC, CAVLC and Exp-Golomb.
VOL	Video Object Layer
VOP	Video Object Plane
WAN	Wide Area Network
WSS	Wide Screen Signaling
XDS	Extended Data Services — data services sending data in line 21/283 of the analog NTSC TV signal
XSI	Intel® XScale® System Interconnect
X, Y, Z, W	3-D coordinate representations
YUV	YUV texture format, primarily for video formats

Intel® Open Source HD Graphics and Intel Iris™ Plus Graphics

Programmer's Reference Manual

For the 2016 - 2017 Intel Core™ Processors, Celeron™ Processors, and Pentium™ Processors based on the "Kaby Lake" Platform

Blitter (BLT) Engine Command Streamer

A separate pipeline for Blitter operations is used in future generations. This pipeline has its own command streamer and operates completely independently of the other command streamers. This command streamer supports a separate set of registers starting at offset 20000h.

Software Control Bit Definitions

Registers in the range 22XX are not protected from the load register immediate instruction if the command is executed in the non-secure batch buffer.

BCS_SWCTRL - BCS SW Control

Registers for Blitter Engine Command Streamer

These are the Registers for the Blitter Engine Command Streamer.

GAB_MODE - Mode Register for GAB

BLT Engine

Introduction

2D Rendering can be divided into 2 categories: classical BLTs, described here, and 3D BLTs. 3D BLTs are operations which can take advantage of the 3D drawing engine's functionality and access patterns.

Functions such as Alpha BLTs, arithmetic (bilinear) stretch BLTs, rotations, transposing pixel maps, color space conversion, and DIBs are all considered 3D BLTs and are covered in the 3D rendering section. DIBs can be thought of as an indexed texture which uses the texture palette for performing the data translation. All drawing engines have swappable context. The same hardware can be used by multiple driver threads where the current state of the hardware is saved to memory and the appropriate state is loaded from memory on thread switches.

All operands for both 3D and classical BLTs can be in graphics aperture or cacheable system memory. Some operands can be immediates which are sent through the command stream. Immediate operands are: patterns, monochrome sources, DIB palettes, and DIB source operands. All non-monochrome operands which are not tiled have a stride granularity of a double-word (4 bytes).

The classical BLT commands support both linear addressing and X, Y coordinates with and without clipping. All X1 and Y1 destination and clipping coordinates are inclusive, while X2 and Y2 are exclusive. Currently, only destination coordinates can be negative. The source and clipping coordinates must be positive. If clipping is disabled, but a negative destination coordinate is specified, the negative coordinate is clipped to 0. Linear address BLT commands must supply a non-zero height and width. If either height or width = 0, then no accesses occur.

Classical BLT Engine Functional Description

The graphics controller provides a hardware-based BLT engine to off load the work of moving blocks of graphics data from the host CPU. Although the BLT engine is often used simply to copy a block of graphics data from the source to the destination, it also has the ability to perform more complex functions. The BLT engine is capable of receiving three different blocks of graphics data as input as shown in the figure below. The source data may exist in the frame buffer or the Graphics aperture. The pattern data always represents an 8x8 block of pixels that can be located in the frame buffer, Graphics aperture, or passed through a command packet. The pattern data must be located in linear memory. The data already residing at the destination may also be used as an input. The destination data can also be located in the frame buffer or graphics aperture.

Block Diagram and Data Paths of the BLT Engine

The BLT engine may use any combination of these three different blocks of graphics data as operands, in both bit-wise logical operations to generate the actual data to be written to the destination, and in per-pixel write-masking to control the writing of data to the destination. It is intended that the BLT engine will perform these bit-wise and per-pixel operations on color graphics data that is at the same color depth that the rest of the graphics system has been set. However, if either the source or pattern data is monochrome, the BLT engine has the ability to put either block of graphics data through a process called "color expansion" that converts monochrome graphics data to color. Since the destination is often a location in the on-screen portion of the frame buffer, it is assumed that any data already at the destination will be of the appropriate color depth.

Basic BLT Functional Considerations

Color Depth Configuration and Color Expansion

The graphics system and BLT engine can be configured for color depths of 8, 16, and 32 bits per pixel.

The configuration of the BLT engine for a given color depth dictates the number of bytes of graphics data that the BLT engine will read and write for each pixel while performing a BLT operation. It is assumed that any graphics data already residing at the destination which is used as an input is already at the color depth to which the BLT engine is configured. Similarly, it is assumed that any source or pattern data used as an input has this same color depth, unless one or both is monochrome. If either the source or pattern data is monochrome, the BLT engine performs a process called "color expansion" to convert such monochrome data to color at the color depth to which the BLT engine has been set.

During "color expansion" the individual bits of monochrome source or pattern data that correspond to individual pixels are converted into 1, 2, or 4 bytes (which ever is appropriate for the color depth to which the BLT engine has been set). If a given bit of monochrome source or pattern data carries a value of 1, then the byte(s) of color data resulting from the conversion process are set to carry the value of a specified foreground color. If a given bit of monochrome source or pattern data carries a value of 0, the resulting byte(s) are set to the value of a specified background color or not written if transparency is selected.

The BLT engine is set to a default configuration color depth of 8, 16, or 32 bits per pixel through BLT command packets. Whether the source and pattern data are color or monochrome must be specified using command packets. Foreground and background colors for the color expansion of both monochrome source and pattern data are also specified through the command packets. The source foreground and background colors used in the color expansion of monochrome source data are specified independently of those used for the color expansion of monochrome pattern data.

Graphics Data Size Limitations

The BLT engine is capable of transferring very large quantities of graphics data. Any graphics data read from and written to the destination is permitted to represent a number of pixels that occupies up to 65,536 scan lines and up to 32,768 bytes per scan line at the destination. The maximum number of pixels that may be represented per scan line's worth of graphics data depends on the color depth.

Any source data used as an input must represent the same number of pixels as is represented by any data read from or written to the destination, and it must be organized so as to occupy the same number of scan lines and pixels per scan line.

The actual number of scan lines and bytes per scan line required to accommodate data read from or written to the destination are set in the destination width & height registers or using X and Y coordinates within the command packets. These two values are essential in the programming of the BLT engine, because the engine uses these two values to determine when a given BLT operation has been completed.

Bit-Wise Operations

The BLT engine can perform any one of 256 possible bit-wise operations using various combinations of the three previously described blocks of graphics data that the BLT engine can receive as input.

The choice of bit-wise operation selects which of the three inputs will be used, as well as the particular logical operation to be performed on corresponding bits from each of the selected inputs. The BLT engine automatically foregoes reading any form of graphics data that has not been specified as an input by the choice of bit-wise operation. An 8-bit code written to the raster operation field of the command packets chooses the bit-wise operation. The following table lists the available bit-wise operations and their corresponding 8-bit codes.

Per-Pixel Write-Masking Operations

The BLT engine is able to perform per-pixel write-masking with various data sources used as pixel masks to constrain which pixels at the destination are to be written to by the BLT engine. As shown in the figure below, either monochrome source or monochrome pattern data may be used as pixel masks. Color pattern data cannot be used. Another available pixel mask is derived by comparing a particular color range per color channel to either the color already specified for a given pixel at the destination or source.

Block Diagram and Data Paths of the BLT Engine

The command packets can specify the monochrome source or the monochrome pattern data as a pixel mask. When this feature is used, the bits that carry a value of 0 cause the bytes of the corresponding pixel at the destination to not be written to by the BLT engine, thereby preserving whatever data was originally carried within those bytes. This feature can be used in writing characters to the display, while also preserving the pre-existing backgrounds behind those characters. When both operands are in the transparent mode, the logical AND of the 2 operands are used for the write enables per pixel.

The 3-bit field, destination transparency mode, within the command packets can select per-pixel write-masking with a mask based on the results of color comparisons. The monochrome source background and foreground are range compared with either the bytes for the pixels at the destination or the source operand. This operation is described in the BLT command packet and register descriptions.

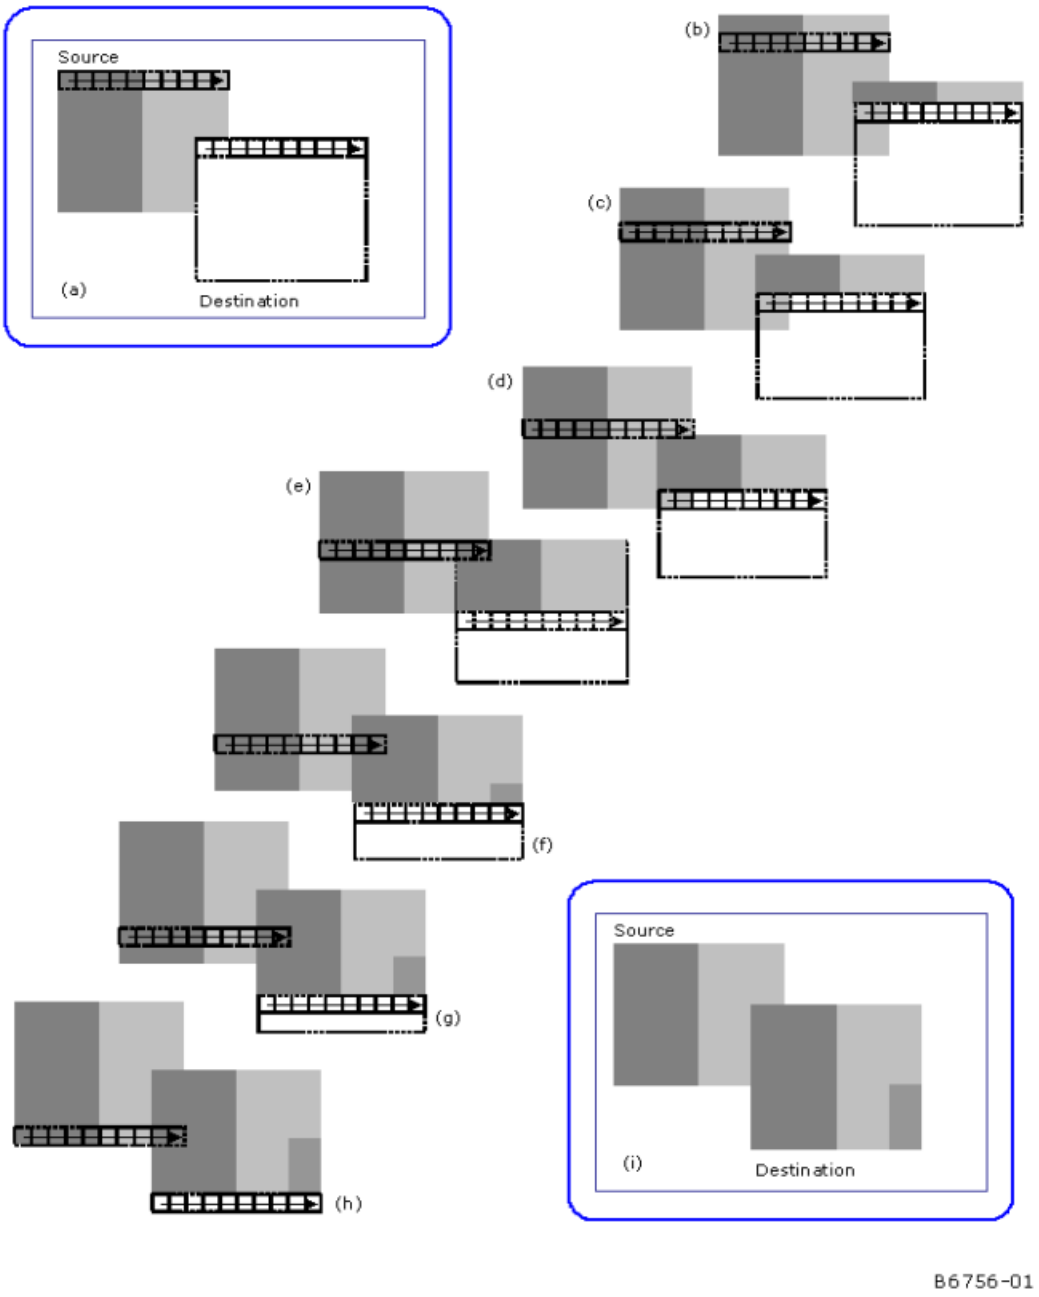
When the Source and Destination Locations Overlap

It is possible to have BLT operations in which the locations of the source and destination data overlap. This frequently occurs in BLT operations where a user is shifting the position of a graphical item on the display by only a few pixels. In these situations, the BLT engine must be programmed so that destination data is not written into destination locations that overlap with source locations before the source data at those locations has been read. Otherwise, the source data will become corrupted. The XY commands determine whether there is an overlap and perform the accesses in the proper direction to avoid data corruption.

The following figure shows how the source data can be corrupted when a rectangular block is copied from a source location to an overlapping destination location. The BLT engine typically reads from the source location and writes to the destination location starting with the left-most pixel in the top-most line of both, as shown in step (a). As shown in step (b), corruption of the source data has already started with the copying of the top-most line in step (a) — part of the source that originally contained lighter-colored pixels has now been overwritten with darker-colored pixels. More source data corruption occurs as steps (b) through (d) are performed. At step (e), another line of the source data is read, but the two

right-most pixels of this line are in the region where the source and destination locations overlap, and where the source has already been overwritten as a result of the copying of the top-most line in step (a). Starting in step (f), darker-colored pixels can be seen in the destination where lighter-colored pixels should be. This errant effect occurs repeatedly throughout the remaining steps in this BLT operation. As more lines are copied from the source location to the destination location, it becomes clear that the end result is not what was originally intended.

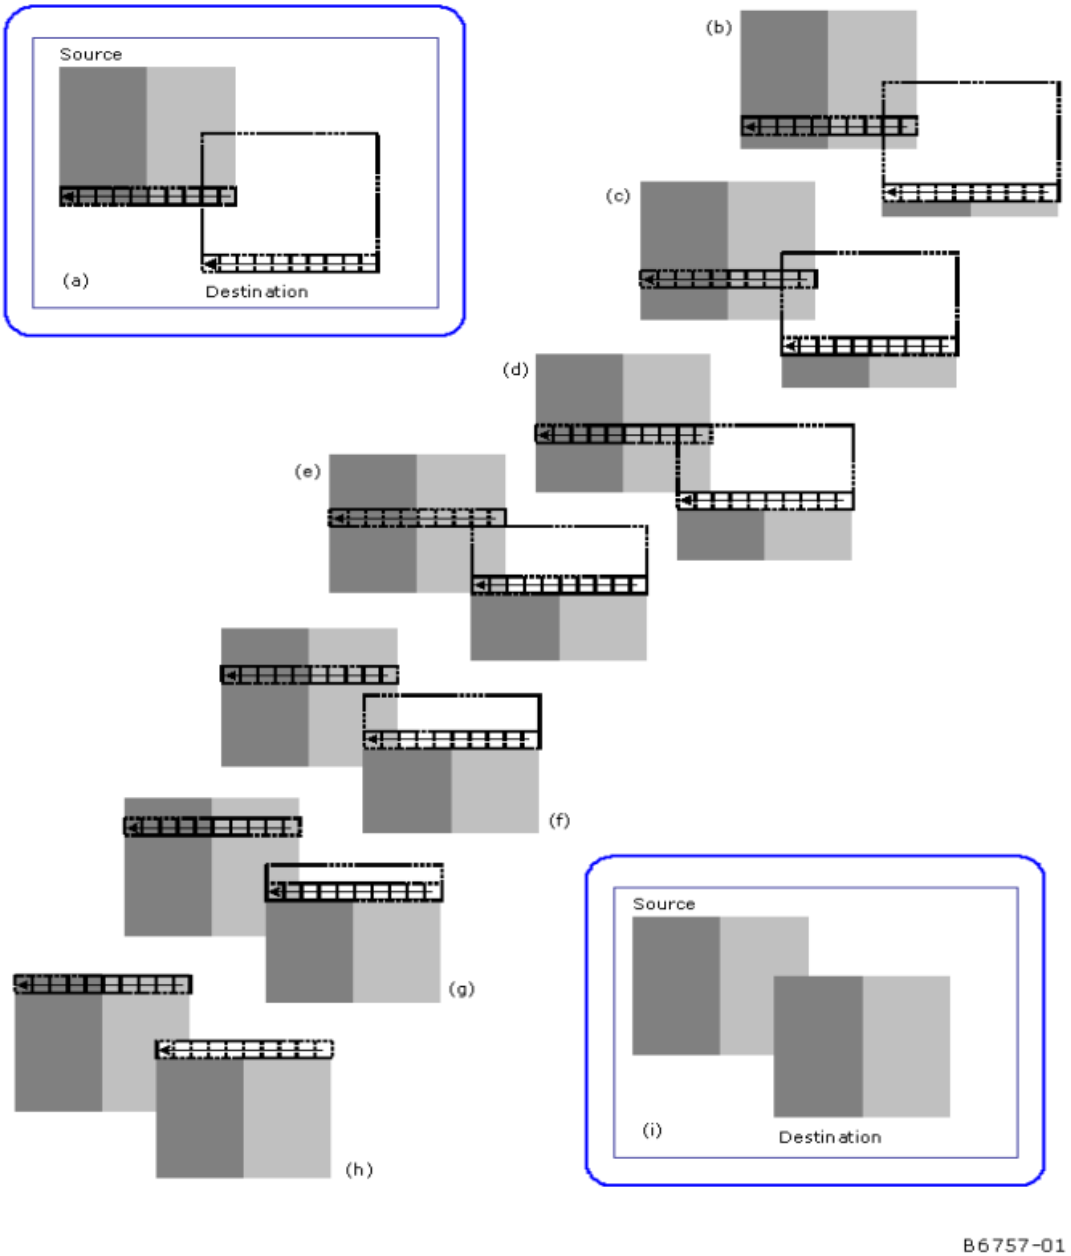
Source Corruption in BLT with Overlapping Source and Destination Locations



The BLT engine can alter the order in which source data is read and destination data is written when necessary to avoid source data corruption problems when the source and destination locations overlap. The command packets provide the ability to change the point at which the BLT engine begins reading and writing data from the upper left-hand corner (the usual starting point) to one of the other three corners. The BLT engine may be set to read data from the source and write it to the destination starting at any of the four corners of the panel.

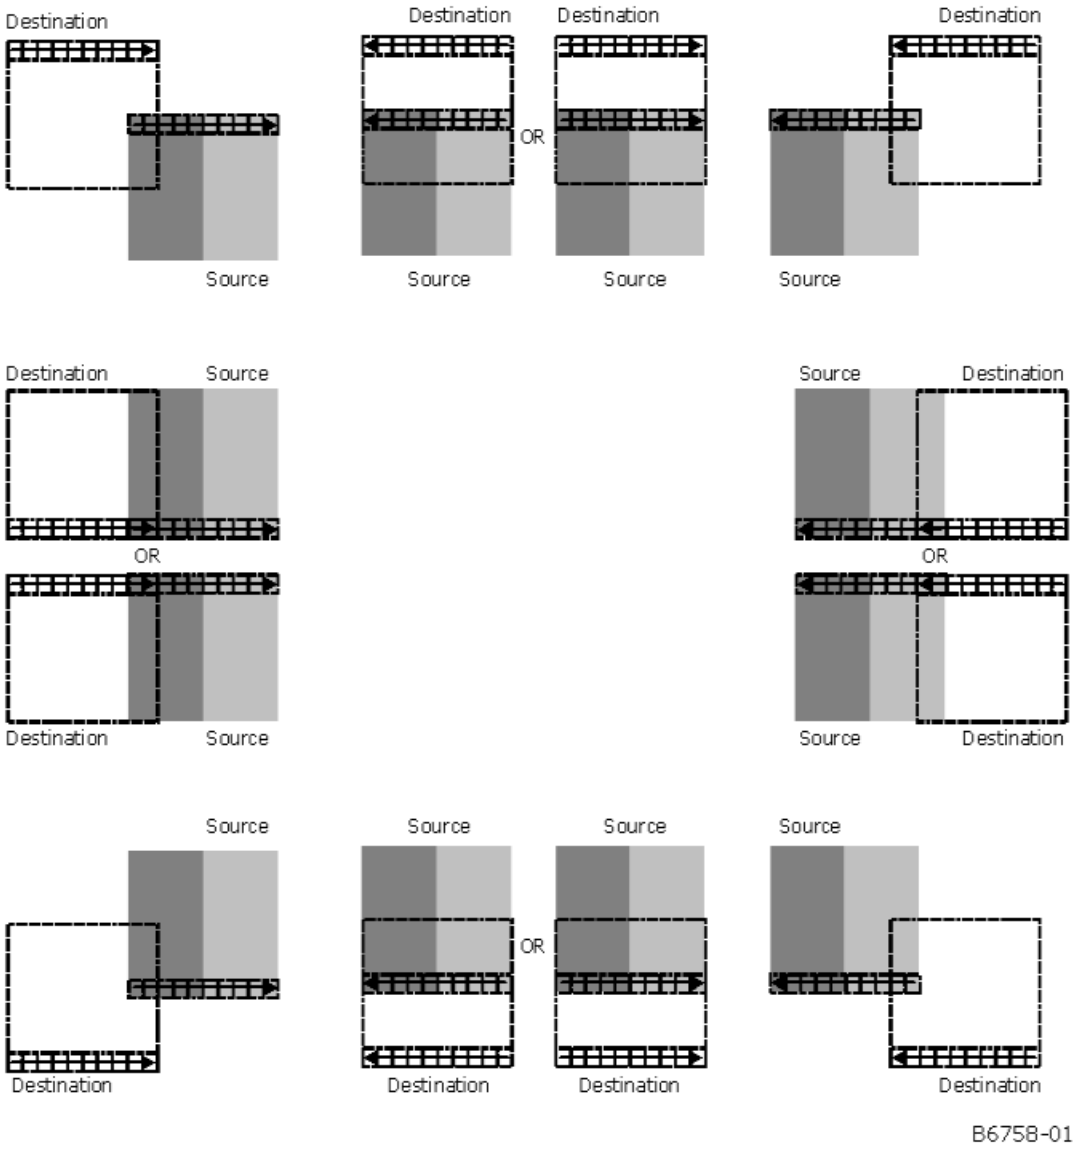
The XY command packets perform the necessary comparisons and start at the proper corner of each operand which avoids data corruption.

Correctly Performed BLT with Overlapping Source and Destination Locations



The following figure illustrates how this feature of the BLT engine can be used to perform the same BLT operation as was illustrated in the figure above, while avoiding the corruption of source data. As shown in the figure below, the BLT engine reads the source data and writes the data to the destination starting with the right-most pixel of the bottom-most line. By doing this, no pixel existing where the source and destination locations overlap will ever be written to before it is read from by the BLT engine. By the time the BLT operation has reached step (e) where two pixels existing where the source and destination locations overlap are about to be over written, the source data for those two pixels has already been read.

Suggested Starting Points for Possible Source and Destination Overlap Situations



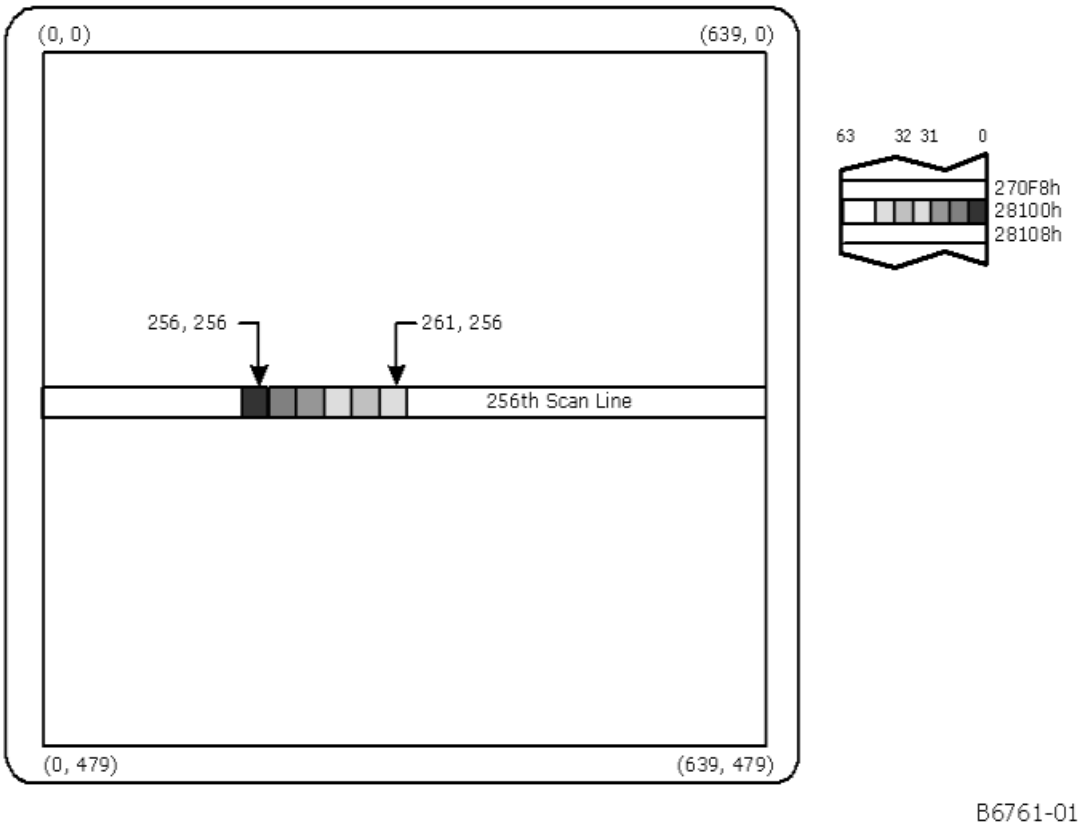
The figure above shows the recommended lines and pixels to be used as starting points in each of 8 possible ways in which the source and destination locations may overlap. In general, the starting point should be within the area in which the source and destination overlap.

Basic Graphics Data Considerations

Contiguous vs. Discontinuous Graphics Data

Graphics data stored in memory, particularly in the frame buffer of a graphics system, has organizational characteristics that often distinguish it from other varieties of data. The main distinctive feature is the tendency for graphics data to be organized in a discontinuous block of graphics data made up of multiple sub-blocks of bytes, instead of a single contiguous block of bytes.

Representation of On-Screen Single 6-Pixel Line in the Frame Buffer

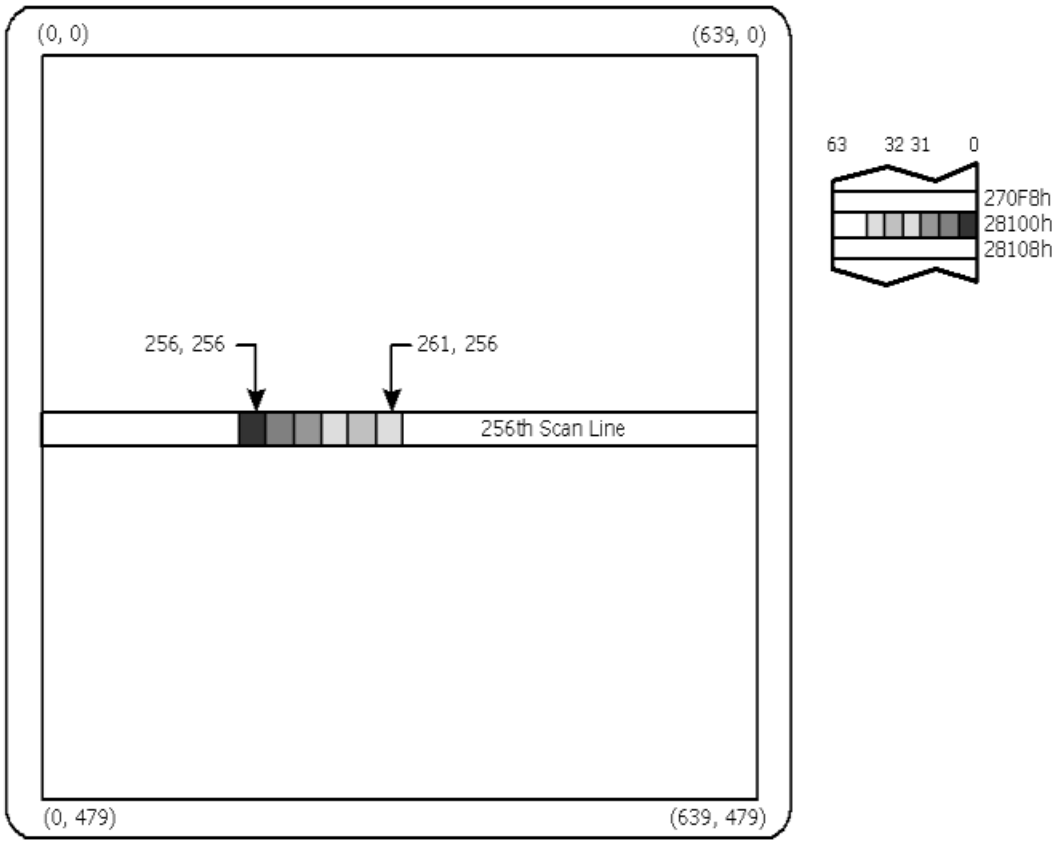


The figure above shows an example of contiguous graphics data — a horizontal line made up of six adjacent pixels within a single scan line on a display with a resolution of 640x480. Presuming that the graphics system driving this display has been set to 8 bits per pixel and that the frame buffer's starting address of 0h corresponds to the upper left-most pixel of this display, then the six pixels that make this horizontal line starting at coordinates (256, 256) occupies the six bytes starting at frame buffer address 28100h, and ending at address 28105h.

In this case, there is only one scan line's worth of graphics data in this single horizontal line, so the block of graphics data for all six of these pixels exists as a single, contiguous block comprised of only these six bytes. The starting address and the number of bytes are the only pieces of information that a BLT engine would require to read this block of data.

The simplicity of the above example of a single horizontal line contrasts sharply to the example of discontinuous graphics data depicted in the figure below. The simple six-pixel line of the figure above is now accompanied by three more six-pixel lines placed on subsequent scan lines, resulting in the 6x4 block of pixels shown.

Representation of On-Screen 6x4 Array of Pixels in the Frame Buffer



Since there are other pixels on each of the scan lines on which this 6x4 block exists that are not part of this 6x4 block, what appears to be a single 6x4 block of pixels on the display must be represented by a discontinuous block of graphics data made up of 4 separate sub-blocks of six bytes apiece in the frame buffer at addresses 28100h, 28380h, 28600h, and 28880h. This situation makes the task of reading what appears to be a simple 6x4 block of pixels more complex. However, there are two characteristics of this 6x4 block of pixels that help simplify the task of specifying the locations of all 24 bytes of this discontinuous block of graphics data: all four of the sub-blocks are of the same length, and the four sub-blocks are separated from each other at equal intervals.

The BLT engine is designed to make use of these characteristics of graphics data to simplify the programming required to handle discontinuous blocks of graphics data. For such a situation, the BLT engine requires only four pieces of information: the starting address of the first sub-block, the length of a sub-block, the offset (in bytes), pitch, of the starting address of each subsequent sub-block, and the quantity of sub-blocks.

Source Data

The source data may exist in the frame buffer or elsewhere in the graphics aperture where the BLT engine may read it directly, or it may be provided to the BLT engine by the host CPU through the command packets. The block of source graphics data may be either contiguous or discontinuous, and may be either in color (with a color depth that matches that to which the BLT engine has been set) or monochrome.

The source select bit in the command packets specifies whether the source data exists in the frame buffer or is provided through the command packets. Monochrome source data is always specified as being supplied through an immediate command packet.

If the color source data resides within the frame buffer or elsewhere in the graphics aperture, then the Source Address Register, specified in the command packets is used to specify the address of the source.

In cases where the host CPU provides the source data, it does so by writing the source data to ring buffer directly after the BLT command that requires the data or uses an IMMEDIATE_INDIRECT_BLT command packet which has a size and pointer to the operand in Graphics aperture.

The block of bytes sent by the host CPU through the command packets must be quadword-aligned and the source data contained within the block of bytes must also be aligned.

To accommodate discontinuous source data, the source and destination pitch registers can be used to specify the offset in bytes from the beginning of one scan line's worth source data to the next. Otherwise, if the source data is contiguous, then an offset equal to the length of a scan line's worth of source data should be specified.

Monochrome Source Data

The opcode of the command packet specifies whether the source data is color or monochrome. Since monochrome graphics data only uses one bit per pixel, each byte of monochrome source data typically carries data for 8 pixels which hinders the use of byte-oriented parameters when specifying the location and size of valid source data. Some additional parameters must be specified to ensure the proper reading and use of monochrome source data by the BLT engine. The BLT engine also provides additional options for the manipulation of monochrome source data versus color source data.

The various bit-wise logical operations and per-pixel write-masking operations were designed to work with color data. In order to use monochrome data, the BLT engine converts it into color through a process called color expansion, which takes place as a BLT operation is performed. In color expansion the single bits of monochrome source data are converted into one, two, or four bytes (depending on the color depth) of color data that are set to carry value corresponding to either the foreground or background color that have been specified for use in this conversion process. If a given bit of monochrome source data carries a value of 1, then the byte(s) of color data resulting from the conversion process will be set to carry the value of the foreground color. If a given bit of monochrome source data carries a value of 0, then the resulting byte(s) will be set to the value of the background color. The foreground and background colors used in the color expansion of monochrome source data

can be set in the source expansion foreground color register and the source expansion background color register.

The BLT Engine requires that the bit alignment of each scan line's worth of monochrome source data be specified. Each scan line's worth of monochrome source data is word aligned but can actually start on any bit boundary of the first byte. Monochrome text is special cased and it is bit or byte packed, where in bit packed there are no invalid pixels (bits) between scan lines. There is a 3 bit field which indicates the starting pixel position within the first byte for each scan line, Mono Source Start.

Note that the Monosource surface start Base Address, should always be Cache Line (64byte) aligned.

The BLT engine also provides various clipping options for use with specific BLT commands (BLT_TEXT) with a monochrome source. Clipping is supported through: Clip rectangle Y addresses or coordinates and X coordinates along with scan line starting and ending addresses (with Y addresses) along with X starting and ending coordinates.

The maximum immediate source size is 128 bytes.

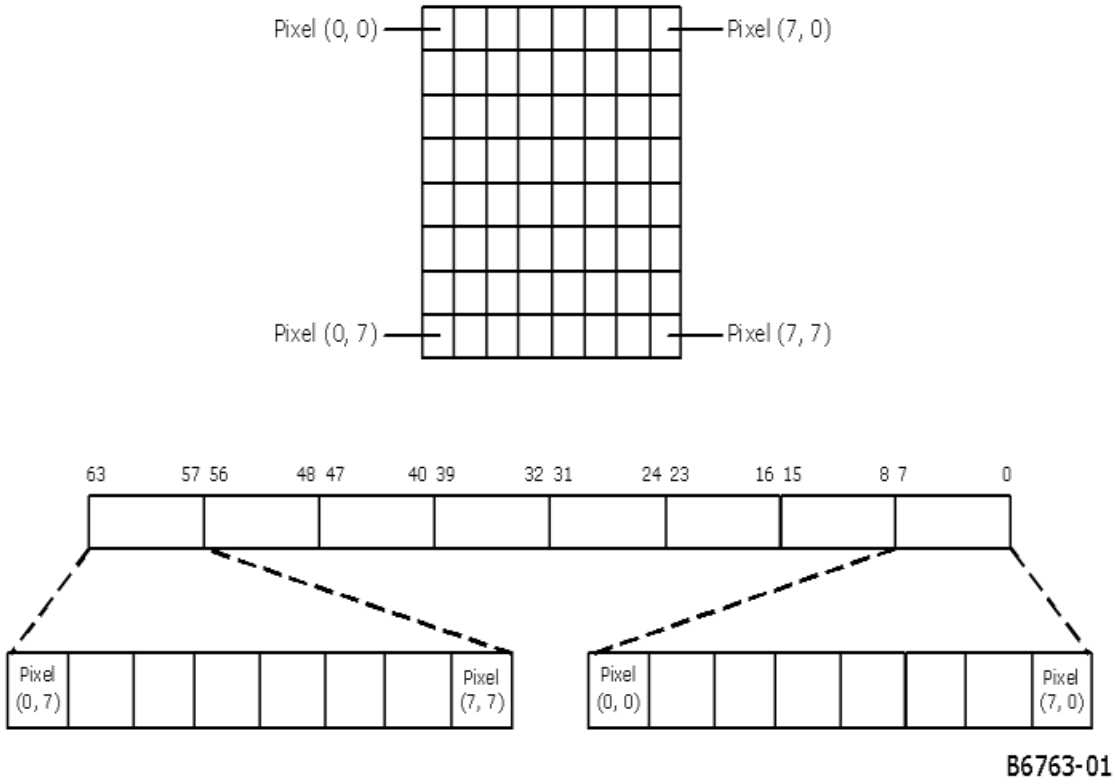
Pattern Data

The color pattern data must exist within the frame buffer or Graphics aperture where the BLT engine may read it directly or it can be sent through the command stream. The pattern data must be located in linear memory. Note also that the Color Pattern surface start Base Address, should always be Cache Line (64byte) aligned.

Monochrome pattern data is supplied by the command packet when it is to be used. As shown in figure below, the block of pattern graphics data always represents a block of 8x8 pixels. The bits or bytes of a block of pattern data may be organized in the frame buffer memory in only one of three ways, depending upon its color depth which may be 8, 16, or 32 bits per pixel (whichever matches the color depth to which the BLT engine has been set), or monochrome.

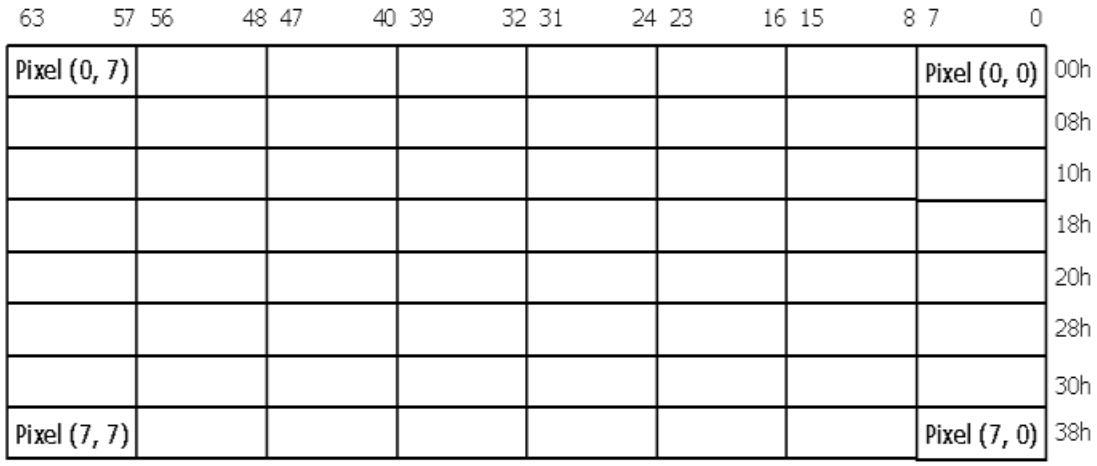
The maximum color pattern size is 256 bytes.

Pattern Data -- Always an 8x8 Array of Pixels



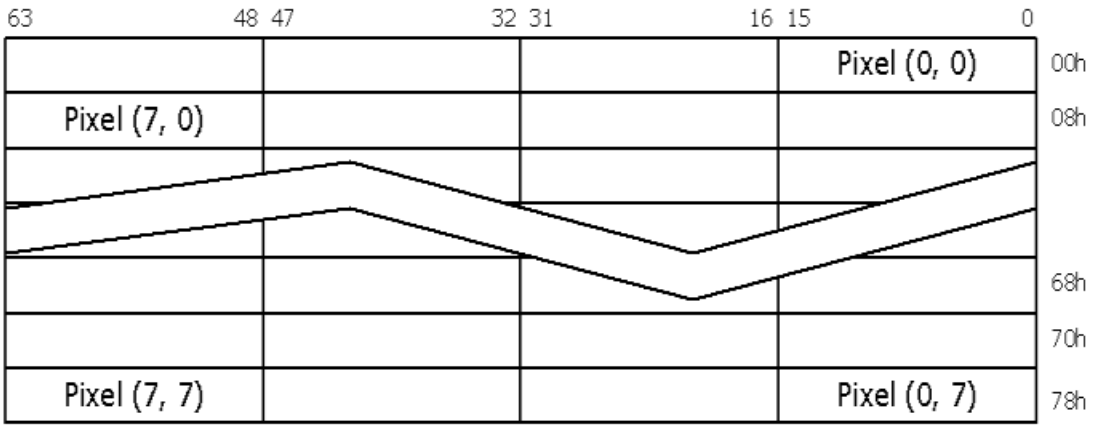
The Pattern Address Register is used to specify the address of the color pattern data at which the block of pattern data begins. The three least significant bits of the address written to this register are ignored, because the address must be in terms of quadwords. This is because the pattern must always be located on an address boundary equal to its size. Monochrome patterns take up 8 bytes, or a single quadword of space, and are loaded through the command packet that uses it. Similarly, color patterns with color depths of 8, 16, and 32 bits per pixel must start on 64-byte, 128-byte and 256-byte boundaries, respectively. The next 3 figures show how monochrome, 8bpp, 16bpp, and 32bpp pattern data , respectively, is organized in memory.

8bpp Pattern Data -- Occupies 64 Bytes (8 quadwords)



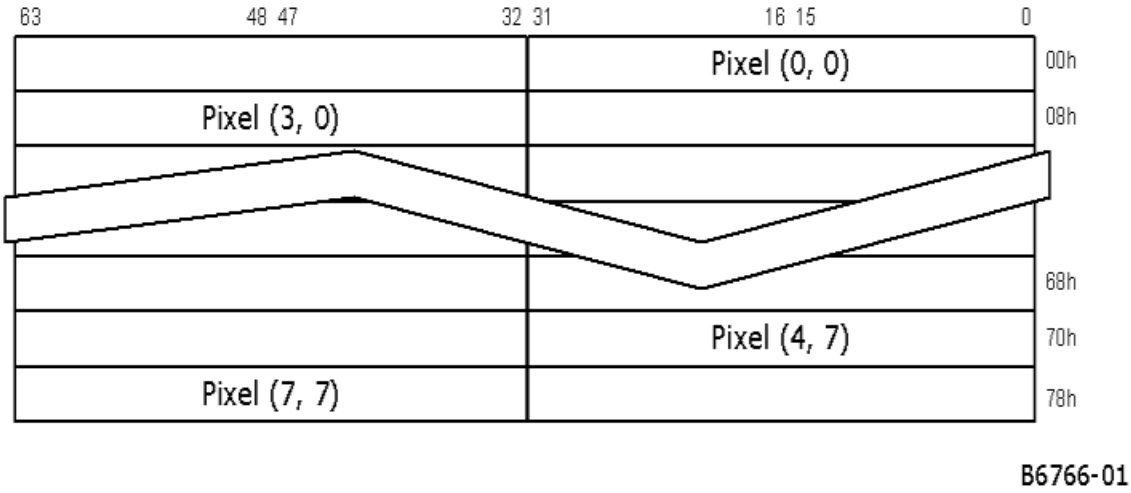
B6764-01

16bpp Pattern Data -- Occupies 128 Bytes (16 quadwords)



B6765-01

32bpp Pattern Data -- Occupies 256 Bytes (32 quadwords)



The opcode of the command packet specifies whether the pattern data is color or monochrome. The various bit-wise logical operations and per-pixel write-masking operations were designed to work with color data. In order to use monochrome pattern data, the BLT engine is designed to convert it into color through a process called “color expansion” which takes place as a BLT operation is performed. In color expansion, the single bits of monochrome pattern data are converted into one, two, or four bytes (depending on the color depth) of color data that are set to carry values corresponding to either the foreground or background color that have been specified for use in this process. The foreground color is used for pixels corresponding to a bit of monochrome pattern data that carry the value of 1, while the background color is used where the corresponding bit of monochrome pattern data carries the value of 0. The foreground and background colors used in the color expansion of monochrome pattern data can be set in the Pattern Expansion Foreground Color Register and Pattern Expansion Background Color Register.

Destination Data

There are actually two different types of “destination data”: the graphics data already residing at the location that is designated as the destination, and the data that is to be written into that very same location as a result of a BLT operation.

The location designated as the destination must be within the frame buffer or Graphics aperture where the BLT engine can read from it and write to it directly. The blocks of destination data to be read from and written to the destination may be either contiguous or discontinuous. All data written to the destination will have the color depth to which the BLT engine has been set. It is presumed that any data already existing at the destination which will be read by the BLT engine will also be of this same color depth — the BLT engine neither reads nor writes monochrome destination data.

The Destination Address Register is used to specify the address of the destination.

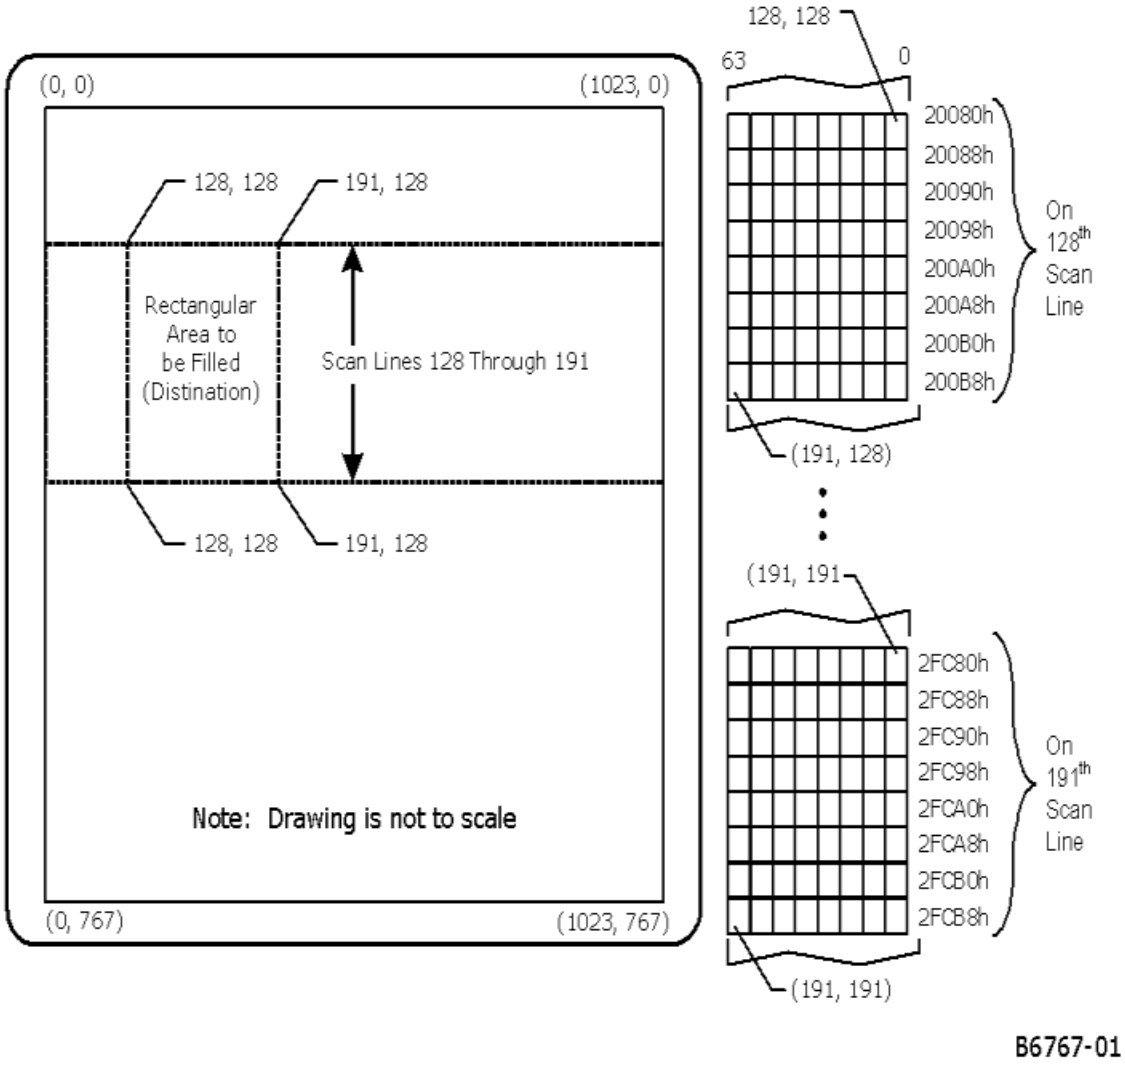
To accommodate discontinuous destination data, the Source and Destination Pitch Registers can be used to specify the offset in bytes from the beginning of one scan line's worth of destination data to the next. Otherwise, if the destination data is contiguous, then an offset equal to the length of a scan line's worth of destination data should be specified.

BLT Programming Examples

Pattern Fill — A Very Simple BLT

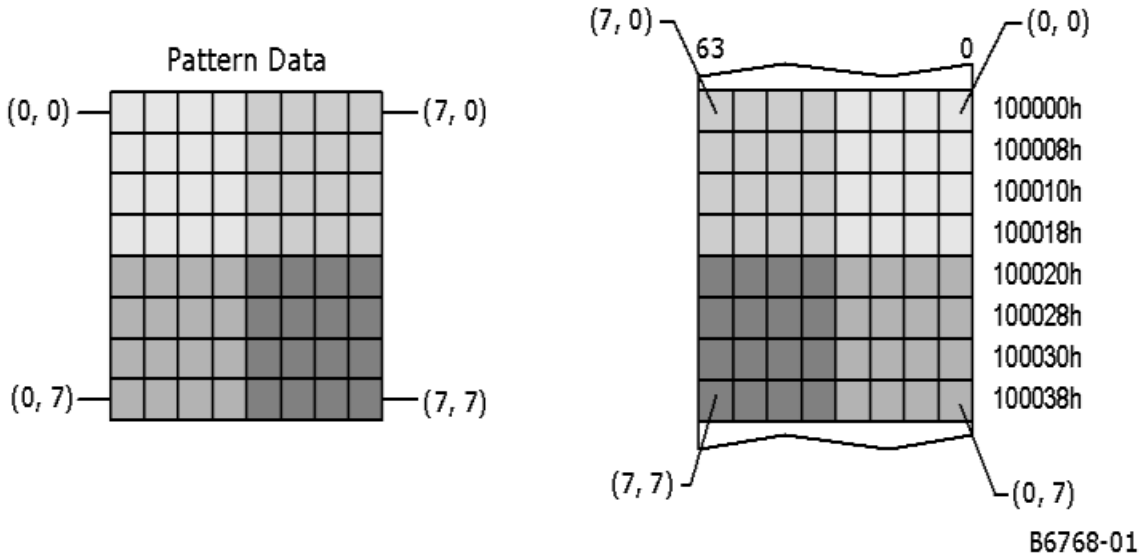
In this example, a rectangular area on the screen is to be filled with a color pattern stored as pattern data in off-screen memory. The screen has a resolution of 1024x768 and the graphics system has been set to a color depth of 8 bits per pixel.

On-Screen Destination for Example Pattern Fill BLT



As shown in the figure above, the rectangular area to be filled has its upper left-hand corner at coordinates (128, 128) and its lower right-hand corner at coordinates (191, 191). These coordinates define a rectangle covering 64 scan lines, each scan line's worth of which is 64 pixels in length — in other words, an array of 64x64 pixels. Presuming that the pixel at coordinates (0, 0) corresponds to the byte at address 00h in the frame buffer memory, the pixel at (128, 128) corresponds to the byte at address 20080h.

Pattern Data for Example Pattern Fill BLT



As shown in figure above, the pattern data occupies 64 bytes starting at address 100000h. As always, the pattern data represents an 8x8 array of pixels.

The BLT command packet is used to select the features to be used in this BLT operation, and must be programmed carefully. The vertical alignment field should be set to 0 to select the top-most horizontal row of the pattern as the starting row used in drawing the pattern starting with the top-most scan line covered by the destination. The pattern data is in color with a color depth of 8 bits per pixel, so the dynamic color enable should be asserted with the dynamic color depth field should be set to 0. Since this BLT operation does not use per-pixel write-masking (destination transparency mode), this field should be set to 0. Finally, the raster operation field should be programmed with the 8-bit value of F0h to select the bit-wise logical operation in which a simple copy of the pattern data to the destination takes place. Selecting this bit-wise operation in which no source data is used as an input causes the BLT engine to automatically forego either reading source data from the frame buffer.

The Destination Pitch Register must be programmed with number of bytes in the interval from the start of one scan line's worth of destination data to the next. Since the color depth is 8 bits per pixel and the horizontal resolution of the display is 1024, the value to be programmed into these bits is 400h, which is equal to the decimal value of 1024.

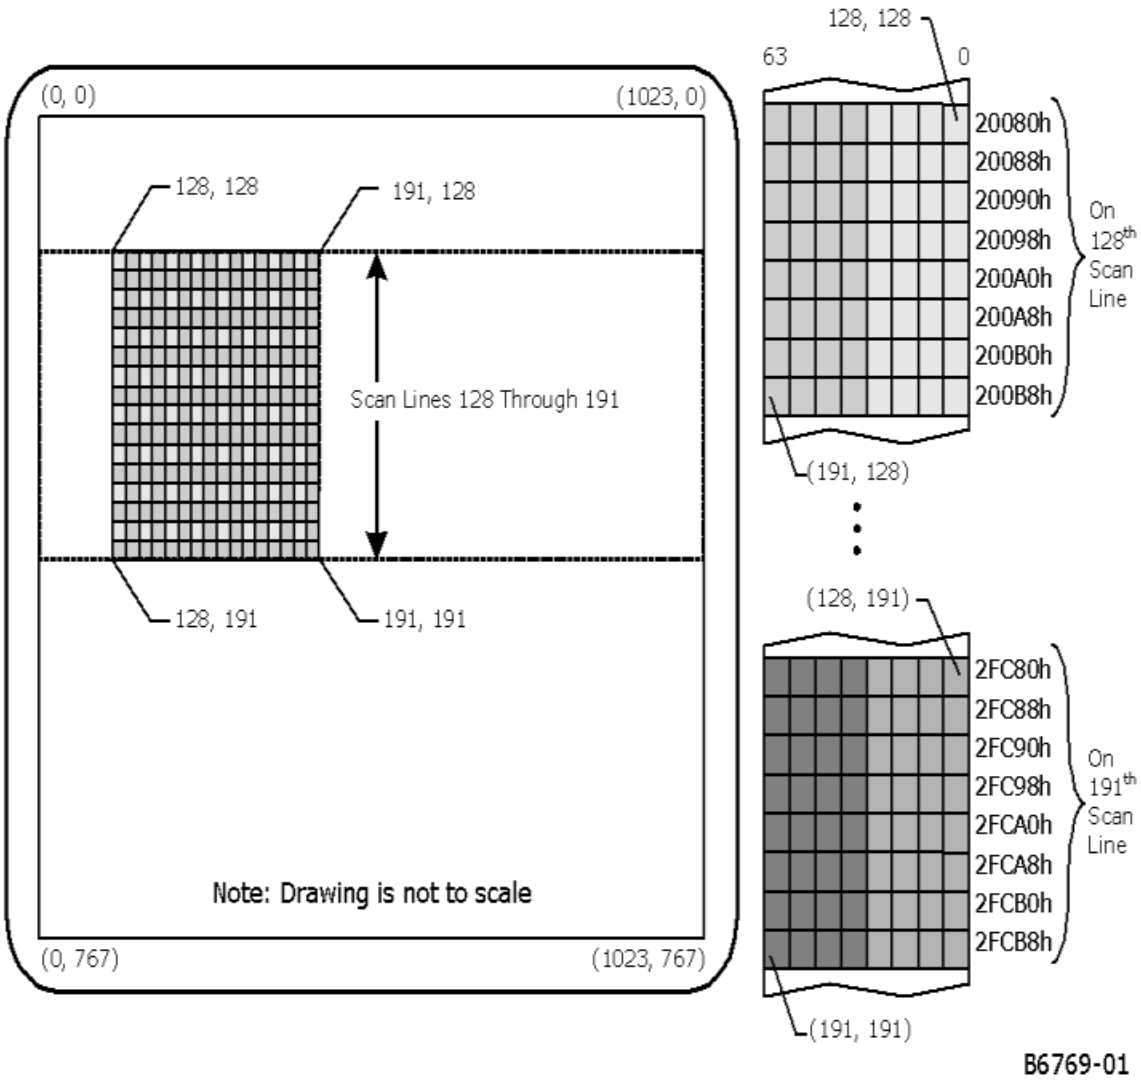
Bits [31:3] of the Pattern Address Register must be programmed with the address of the pattern data.

Similarly, bits [31:0] of the Destination Address Register must be programmed with the byte address at the destination that will be written to first. In this case, the address is 20080h, which corresponds to the byte representing the pixel at coordinates (128, 128).

This BLT operation does not use the values in the Source Address Register or the Source Expansion Background or Foreground Color Registers.

The Destination Width and Height Registers (or the Destination X and Y Coordinates) must be programmed with values that describe to the BLT engine the 64x64 pixel size of the destination location. The height should be set to carry the value of 40h, indicating that the destination location covers 64 scan lines. The width should be set to carry the value of 40h, indicating that each scan line's worth of destination data occupies 64 bytes. All of this information is written to the ring buffer using the PAT_BLT (or XY_PAT_BLT) command packet.

Results of Example Pattern Fill BLT

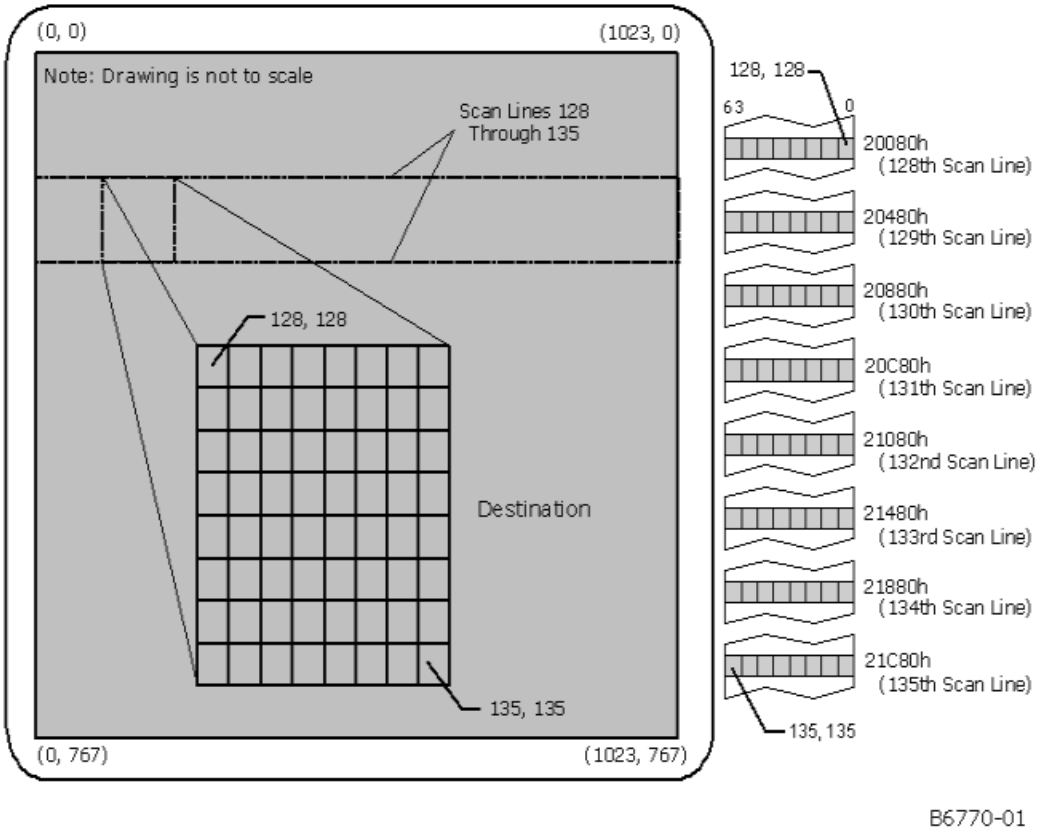


The figure above shows the end result of performing this BLT operation. The 8x8 pattern has been repeatedly copied ("tiled") into the entire 64x64 area at the destination.

Drawing Characters Using a Font Stored in System Memory

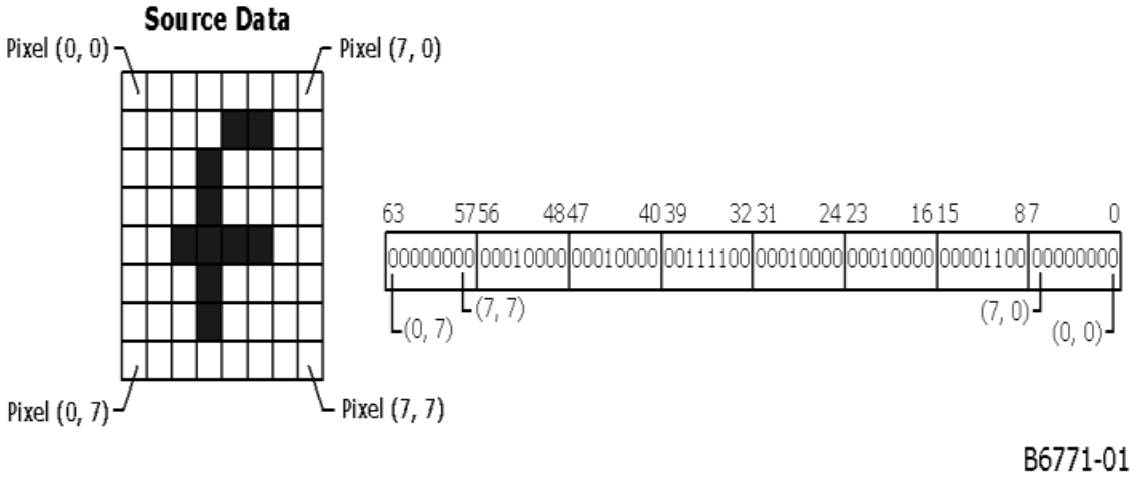
In this example BLT operation, a lowercase letter "f" is to be drawn in black on a display with a gray background. The resolution of the display is 1024x768, and the graphics system has been set to a color depth of 8 bits per pixel.

On-Screen Destination for Example Character Drawing BLT



The figure above shows the display on which this letter "f" is to be drawn. As shown in this figure, the entire display has been filled with a gray color. The letter "f" is to be drawn into an 8x8 region on the display with the upper left-hand corner at the coordinates (128, 128).

Source Data in System Memory for Example Character Drawing BLT



The figure above shows both the 8x8 pattern making up the letter "f" and how it is represented somewhere in the host's system memory — the actual address in system memory is not important. The letter "f" is represented in system memory by a block of monochrome graphics data that occupies 8 bytes. Each byte carries the 8 bits needed to represent the 8 pixels in each scan line's worth of this graphics data. This type of pattern is often used to store character fonts in system memory.

During this BLT operation, the host CPU will read this representation of the letter "f" from system memory, and write it to the BLT engine by performing memory writes to the ring buffer as an immediate monochrome BLT operand following the BLT_TEXT command. The BLT engine will receive this data through the command stream and use it as the source data for this BLT operation. The BLT engine will be set to the same color depth as the graphics system — 8 bits per pixel, in this case. Since the source data in this BLT operation is monochrome, color expansion must be used to convert it to an 8 bpp color depth. To ensure that the gray background behind this letter "f" is preserved, per-pixel write masking will be performed, using the monochrome source data as the pixel mask.

The BLT Setup and Text_immediate command packets are used to select the features to be used in this BLT operation. Only the fields required by these two command packets must be programmed carefully. The BLT engine ignores all other registers and fields. The source select field in the Text_immediate command must be set to 1, to indicate that the source data is provided by the host CPU through the command packet. Finally, the raster operation field should be programmed with the 8-bit value CCh to select the bit-wise logical operation that simply copies the source data to the destination. Selecting this bit-wise operation in which no pattern data is used as an input, causes the BLT engine to automatically forego reading pattern data from the frame buffer.

The Setup Pattern/Source Expansion Foreground Color Register to specify the color with which the letter "f" will be drawn. There is no Source address. All scan lines of the glyph are bit packed and the clipping is controlled by the ClipRect registers from the SETUP_BLT command and the Destination Y1, Y2, X1, and X2 registers in the TEXT_BLT command. Only the pixels that are within (inclusive comparisons) the clip rectangle are written to the destination surface.

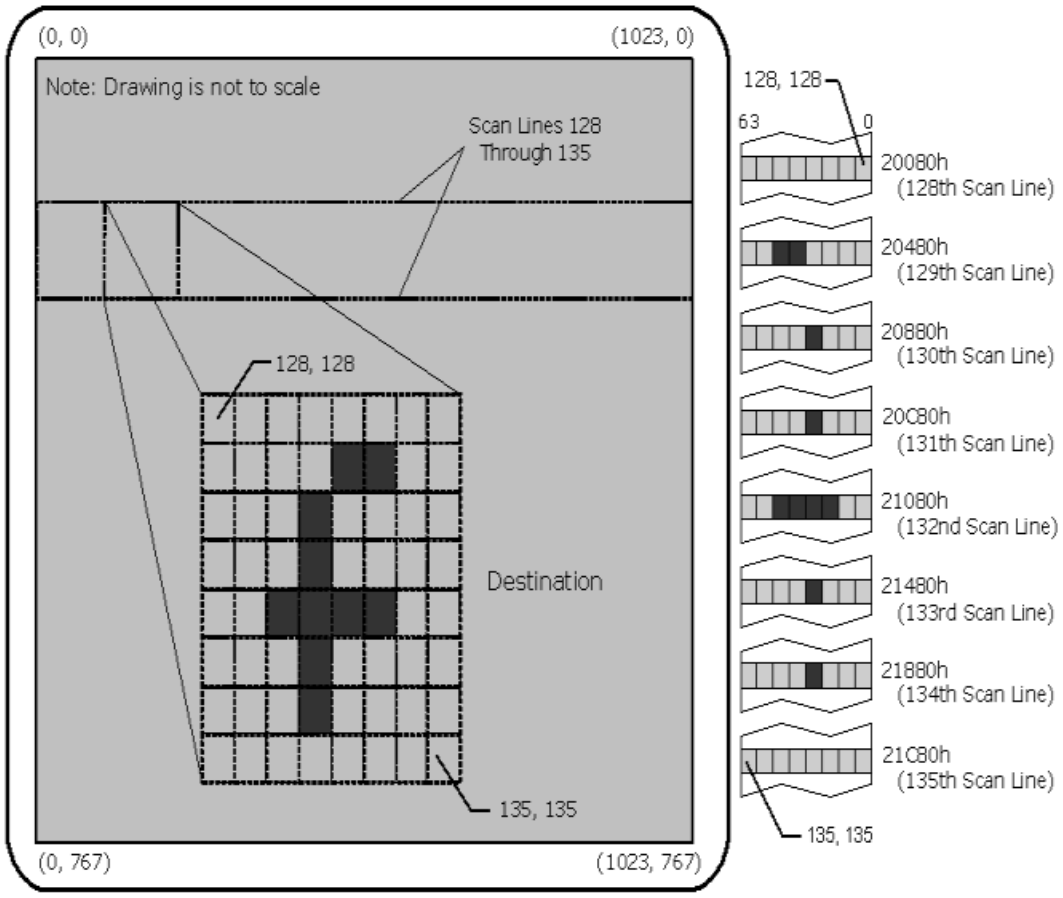
The Destination Pitch Register must be programmed with a value equal to the number of bytes in the interval between the first bytes of each adjacent scan line's worth of destination data. Since the color depth is 8 bits per pixel and the horizontal resolution of the display is 1024 pixels, the value to be programmed into these bits is 400h, which is equal to the decimal value of 1024. Since the source data used in this BLT operation is monochrome, the BLT engine will not use a byte-oriented pitch value for the source data.

Since the source data is monochrome, color expansion is required to convert it to color with a color depth of 8 bits per pixel. Since the Setup Pattern/Source Expansion Foreground Color Register is selected to specify the foreground color of black to be used in drawing the letter "f", this register must be programmed with the value for that color. With the graphics system set for a color depth of 8 bits per pixel, the actual colors are specified in the RAMDAC palette, and the 8 bits stored in the frame buffer for each pixel actually specify the index used to select a color from that palette. This example assumes that the color specified at index 00h in the palette is black, and therefore bits [7:0] of this register should be set to 00h to select black as the foreground color. The BLT engine ignores bits [31:8] of this register because the selected color depth is 8 bits per pixel. Even though the color expansion being performed on the source data normally requires that both the foreground and background colors be specified, the value used to specify the background color is not important in this example. Per-pixel write-masking is being performed with the monochrome source data as the pixel mask, which means that none of the pixels in the source data that will be converted to the background color will ever be written to the destination. Since these pixels will never be seen, the value programmed into the Pattern/Source Expansion Background Color Register to specify a background color is not important.

The Destination Width and Height Registers are not used. The Y1, Y2, X1, and X2 are used to describe to the BLT engine the 8x8 pixel size of the destination location. The Destination Y1 and Y2 address (or coordinate) registers must be programmed with the starting and ending scan line address (or Y coordinates) of the destination data. This address is specified as an offset from the start of the frame buffer of the scan line at the destination that will be written to first. The destination X1 and X2 registers must be programmed with the starting and ending pixel offsets from the beginning of the scan line.

This BLT operation does not use the values in the Pattern Address Register, the Source Expansion Background Color Register, or the Source Expansion Foreground Color Register.

Results of Example Character Drawing BLT



B6772-01

The preceding shows the end result of performing this BLT operation. Only the pixels that form part of the actual letter "f" have been drawn into the 8x8 destination location on the display, leaving the other pixels within the destination with their original gray color.

BLT Instruction Overview

This chapter defines the instructions used to control the 2D (BLT) rendering function.

The instructions detailed in this chapter are used across devices. However, slight changes may be present in some instructions (i.e., for features added or removed), or some instructions may be removed entirely. Refer to the *Device Dependencies* chapter for summary information regarding device-specific behaviors/interfaces/features.

The XY instructions offload the drivers by providing X and Y coordinates and taking care of the access directions for overlapping BLTs without fields specified by the driver.

Color pixel sizes supported are 8, 16, and 32 bits per pixel (bpp). All pixels are naturally aligned.

BLT Engine State

Most of the BLT instructions are state-free, which means that all states required to execute the command is within the instruction. If clipping is not used, then there is no shared state for many of the BLT instructions. This allows the BLT Engine to be shared by many drivers with minimal synchronization between the drivers.

Instructions which share state are:

All instructions that are X,Y commands and use the Clipping Rectangle by asserting the Clip Enable field

All XY_Setup Commands (XY_SETUP_BLT and XY_SETUP_MONO_PATTERN_SL_BLT, XY_SETUP_CLIP_BLT) load the shared state for the following commands:

XY_PIXEL_BLT	(Negative Stride (=Pitch) Not Allowed)
XY_SCANLINES_BLT	
XY_TEXT_BLT	(Negative Stride (=Pitch) Not Allowed)
XY_TEXT_IMMEDIATE_BLT	(Negative Stride (=Pitch) Not Allowed)

State registers that are saved & restored in the Logical Context:

BR1+	Setup Control (Solid Pattern Select, Clipping Enable, Mono Source Transparency Mode, Mono Pattern Transparency Mode, Color Depth[1:0], Raster Operation[7:0], & Destination Pitch[15:0]) + 32bpp Channel Mask[1:0], Mono / Color Pattern
BR05	Setup Background Color
BR06	Setup Foreground Color
BR07	Setup Pattern Base Address
BR09	Setup Destination Base Address
BR20	DW0 for a Monochrome Pattern
BR21	DW1 for a Monochrome Pattern
BR24	ClipRectY1’X1

BR25 ClipRectY2’X2

Cacheable Memory Support

The BLT Engine can be used to transfer data between cacheable (“system”) memory and uncached (“main”, or “UC”) graphics memory using the BLT instructions. The GTT must be properly programmed to map memory pages as cacheable or UC. Only linear-mapped (not tiled) surfaces can be mapped as cacheable.

Transfers between cacheable sources and cacheable destinations are not supported. Patterns and monochrome sources can not be located in cacheable memory.

Cacheable write operands do not snoop the processor’s cache nor update memory until evicted from the render cache. Cacheable read or write operands are not snooped (nor invalidated) from either internal cache by external (processor, hublink,…) accesses.

Device Cache Coherency: Render & Texture Caches

Software must initiate cache flushes to enforce coherency between the render and texture caches, i.e., both the render and texture caches must be flushed before a BLT destination surface can be reused as a texture source. Color sources and destinations use the render cache, while patterns and monochrome sources use the texture cache.

BLT Engine Instructions

The Instruction Target field is used as an opcode by the BLT Engine state machine to qualify the control bits that are relevant for executing the instruction. The descriptions for each DWord and bit field are contained in the *BLT Engine Instruction Field Definition* section. Each DWord field is described as a register, but none of these registers can be written or read through a memory mapped location; they are internal state only.

BLT Programming Restrictions

Overlapping Source/Destination BLTs:

For all products *negative pitch* programming is allowed only when the source and destination surfaces are of the same type: linear source to linear destination copy, or tiled source to tiled destination copy. This is a must requirement. In such cases:

- Both the pitches must be programmed to be a negative value, if the source and destination surfaces are overlapping.
- Either of the pitches can be programmed to a negative value if required to do mirroring, but only if the complete source and destination surfaces are not overlapping anywhere on the surfaces.

Description
For the XY_FAST_COPY_BLT instruction, this restriction applies: When two sequential fast copy blits have different source surfaces, but their destinations refer to the same destination surface and therefore destinations overlap, a Flush must be inserted between the two blits.
The **pitch** length for **Linear Surfaces** is OWord-aligned (16-byte multiple), as the BSpec says. (For Tiled surfaces, the pitch length is always Cacheline aligned (64-byte multiple), as Tile surface pitches must be a multiple of Tile widths, which are always cacheline aligned).

Legacy Blits:

The following condition must be avoided when programming the BLT engine: Linear surfaces with a cache line in scan line Y for the source stream overlapping with a cache line in scan line Y-1 for the dest stream (=> non-aligned surface pitches). The cache coherency rules combined with the Blitter data consumption rules result in UNDEFINED operation.

All reserved fields must be programmed to 0s.

When using monosource or text data (bit/byte/word aligned): Do not program pixel widths greater than 32,745 pixels.

The other way to do this is driver should always program a dummy 3D.

NON-PIPELINE state following the BLT commands:

Description
For Monosource and Color Pattern surfaces, and also linear colour source and destination surfaces, the start **Base Address** programmed should always be Cache Line (64 byte) aligned.

Workaround	
Context:	BLT Engine
An XY_FULL_MONOSOURCE_IMMEDIATE_PATTERN command should always be followed by MI_FLUSH_DW.	

Programming Note	
Context:	Fast Copy Blitter
XY_FAST_COPY command with source Linear and destination Tiled Y and height%4 == 3 is not supported. Use the XY_SOURCE_COPY command for such workloads.	

Programming Note	
Context:	Fast Copy Blitter + Frame Buffer Compression
Fast Copy workloads targetting the Front Buffer with FBC enabled is not supported.	

BLT Engine Instruction Field Definitions

This section describes the BLT Engine instruction fields. These descriptions are in the format of register descriptions. These registers are internal and are not readable. Some of these registers are state that is saved and restored for supporting separate software threads.

VGA and Extended VGA Registers

This section describes the registers and the functional operation notations for the observable registers in the VGA section. This functionality is provided as a means for support of legacy applications and operating systems. It is important to note that these registers in general have the desired effects only when running VGA display modes.

The main exceptions to this are the palette interface which allows real mode DOS applications and full screen VGA applications under an OS control running in high resolution (non-VGA) modes to access the palette through the VGA register mechanisms and the use of the ST01 status bits that determine when the VGA enters display enable and sync periods. Other exceptions include the register bits that control the memory accesses through the A000:0000 and B000:0000 memory segments which are used during operating system emulation of VGA for "DOS box" applications. Some of the functions of the VGA are enabled or defeated through the programming of the VGA control register bits that are located in the MMIO register space.

Given the legacy nature of this function, it has been adapted to the changing environment that it must operate within. The three most notable changes are the addition of high resolution display mode support, new operating system support, and the use of fixed resolution display devices (such as LCD panels). Additional control bits in the PCI Config space will affect the ability to access the registers and memory aperture associated with VGA.

Mode of Operation	VGA Disable	VGA Display	VGA Registers	Palette (VGA)	VGA Memory	VGA Banking
VGA DOS	No	Yes	Yes	Yes	Yes	No
HiRes DOS	Yes	No	Yes	Yes	No	Yes
Fullscreen DOS	Yes/No	No/Yes	Yes	Yes	Yes	Yes
DOS Emulation	Yes	No	Yes	Yes	Yes	Yes

VGA Display Mode	Dot Clock Select	Dot Clock Range	132 Column Text Support	9-Dot Disable Support	Main Use
Native	VGA Clock Select	25/28 MHz	No	No	Analog CRT (VGA connector)
Centered	Fixed at display Requirements	Product Specific	No	Yes	Digital Display
Upper Left Corner	Fixed at display Requirements	Product Specific	No	Yes	Internal Panel

Native, Centered, and Upper Left Corner support varies from product to product.

Even in the native VGA display operational modes, not all combinations of bit settings result in functional operating modes. VGA display modes have the restriction that they can be used only when all other display planes are disabled.

These registers are accessed via I/O space. The I/O space resides in the PCI compatibility hole and uses only the addresses that were part of the original VGA I/O space (which includes EGA and MDA emulation). Accesses to the VGA I/O addresses are steered to the proper bus and rely on proper setup of bridge registers. Extended VGA registers such as GR10 and GR11 use additional indexes for the already defined I/O addresses. VGA register accesses are allowed as 8 or 16 bit naturally aligned transactions only. Word transactions must have the least significant bit of the address set to zero. DWORD I/O operations should not be performed on these registers.

Some products may support access to these registers through MMIO. The access method varies and is documented elsewhere.

General Control and Status Registers

The setup, enable, and general registers are all directly accessible by the CPU. A sub indexing scheme is not used to read from and write to these registers.

Name	Function	Read		Write	
		I/O	Memory Offset	I/O	Memory Offset
ST00	VGA Input Status Register 0	3C2h	3C2h	--	--
ST01	VGA Input Status Register 1	3BAh/3DAh[1]	3BAh/3DAh[1]	--	--
FCR	VGA Feature Control Register	3CAh	3CAh	3BAh/3DAh[1]	3BAh/3DAh[1]
MSR	VGA Miscellaneous Output Register	3CCh	3CCh	3C2h	3C2h

[1] The address selection for ST01 reads and FCR writes is dependent on CGA or MDA emulation mode as selected via the MSR register.

Various bits in these registers provide control over the real-time status of the horizontal sync signal, the horizontal retrace interval, the vertical sync signal, and the vertical retrace interval. The horizontal retrace interval is the period during the drawing of each scan line containing active video data, when the active video data is not being displayed. This period includes the horizontal front and back porches, and the horizontal sync pulse. The horizontal retrace interval is always longer than the horizontal sync pulse. The vertical retrace interval is the period during which the scan lines not containing active video data are drawn. This includes the vertical front porch, back porch, and the vertical sync pulse. The vertical retrace interval is normally longer than the vertical sync pulse.

ST00 - Input Status 0

I/O (and Memory Offset) Address: 3C2h

Default: 00h

Attributes: Read Only

Bit	Descriptions
7	**CRT Interrupt Pending.** This bit is here for EGA compatibility and **will always return zero**. The generation of interrupts was originally enabled, through bits [4,5] of the Vertical Retrace End Register (CR11). This ability to generate interrupts at the start of the vertical retrace interval is a feature that is typically unused by DOS software and therefore is only supported through other means for use under a operating system support. 0 = CRT (vertical retrace interval) interrupt is not pending. 1 = CRT (vertical retrace interval) interrupt is pending
6:5	**Reserved.** Read as 0s.
4	**RGB Comparator / Sense.** This bit is here for compatibility and **will always return one**. Monitor detection must be done be done through the programming of registers in the MMIO space. 0 = Below threshold 1 = Above threshold
3:0	**Reserved.** Read as 0s.

ST01 - Input Status 1

I/O (and Memory Offset) Address: 3BAh/3DAh

Default: 00h

Attributes: Read Only

The address selection is dependent on CGA or MDA emulation mode as selected via the MSR register.

Bit	Descriptions
7	**Reserved (as per VGA specification).** Read as 0s.
6	**Reserved.** Read as 0.
5:4	**Video Feedback 1, 0.** These bits are connected to 2 of the 8 color bits sent to the palette. Bits 4 and 5 of the Color Plane Enable Register (AR12) selects which two of the 8 possible color bits become connected to these 2 bits of this register. These bits exist for EGA compatibility.
3	**Vertical Retrace/Video.** 0 = VSYNC inactive (Indicates that a vertical retrace interval is not taking place). 1 = VSYNC active (Indicates that a vertical retrace interval is taking place). VGA pixel generation is not locked to the display output but is loosely coupled. A VSYNC indication may not occur during the actual VSYNC going to the display but during the VSYNC that is generated as part of the VGA pixel generation. The exact relationship will vary with the VGA display operational mode. This status bit will remain active when the VGA is disabled and the device is running in high resolution modes (non-VGA) to allow for applications that (now incorrectly) use these status registers bits. In this case, the status will come from the pipe that the VGA is assigned to. Bits 4 and 5 of the Vertical Retrace End Register (CR11) previously could program this bit to generate an interrupt at the start of the vertical retrace interval. This ability to generate interrupts at the start of the vertical retrace interval is a feature that is largely unused by legacy software. Interrupts are not supported through the VGA register bits.
2:1	**Reserved.** Read as 0s.

Bit	Descriptions
0	**Display Enable Output.** Display Enable is a status bit (bit 0) in VGA Input Status Register 1 that indicates when either a horizontal retrace interval or a vertical retrace interval is taking place. This bit was used with the EGA graphics system (and the ones that preceded it, including MDA and CGA). In those cases, it was important to check the status of this bit to ensure that one or the other retrace intervals was taking place before reading from or writing to the frame buffer. In these earlier systems, reading from or writing to the frame buffer at times outside the retrace intervals meant that the CRT controller would be denied access to the frame buffer. Those behaviors resulted in either "snow" or a flickering display. This bit provides compatibility with software designed for those early graphics controllers. This bit is currently used in DOS applications that access the palette to prevent the sparkle associated with read and write accesses to the palette RAM with the same address on the same clock cycle. **This status bit remains active when the VGA display is disabled and the device is running in high resolution modes (non-VGA) to allow for applications that (now considered incorrect) use these status registers bits. In this case, the status will come from the pipe that the VGA is assigned to. When in panel fitting VGA or centered VGA operation, the meaning of these bits will not be consistent with native VGA timings.** 0 = Active display data is being sent to the display. Neither a horizontal retrace interval or a vertical retrace interval is currently taking place. 1 = Either a horizontal retrace interval (horizontal blanking) or a vertical retrace interval (vertical blanking) is currently taking place.

FCR - Feature Control

I/O (and Memory Offset) Address: 3BAh/3DAh - Write; 3CAh - Read

Default: 00h

Attributes: See Address above

The I/O address used for writes is dependent on CGA or MDA emulation mode as selected via the MSR register. In the original EGA, bits 0 and 1 were used as part of the feature connector interface. Feature connector is not supported in these devices and those bits will always read as zero.

Bit	Descriptions
7:4	**Reserved.** Read as 0.
3	**VSYNC Control.** This bit is provided for compatibility only and has no other function. Reads and writes to this bit have no effect other than to change the value of this bit. The previous definition of this bit selected the output on the VSYNC pin. 0 = Was used to set VSYNC output on the VSYNC pin (default). 1 = Was used to set the logical 'OR' of VSYNC and Display Enable output on the VSYNC pin. This capability was not typically very useful.
2:0	**Reserved.** Read as 0.

MSR - Miscellaneous Output

I/O (and Memory Offset) Address: 3C2h - Write; 3CCh - Read

Default: 00h

Attributes: See Address above

Bit	Descriptions
7	**CRT VSYNC Polarity.** This is a legacy function that is used in native VGA modes. For most cases, sync polarity will be controlled by the port control bits. The VGA settings can be optionally selected for compatibility with the original VGA when used in the VGA native mode. Sync polarity was used in VGA to signal the monitor how many lines of active display are being generated. 0 = Positive Polarity (default). 1 = Negative Polarity.
6	**CRT HSYNC Polarity.** This is a legacy function that is used in native VGA modes. For most cases, sync polarity will be controlled by the port control bits. The VGA settings can be optionally selected for compatibility with the original VGA when used in the VGA native mode. 0 = Positive Polarity (default). 1 = Negative Polarity
5	**Page Select.** In Odd/Even Memory Map Mode 1 (GR6), this bit selects the upper or lower 64 KB page in display memory for CPU access: 0 = Upper page (default) 1 = Lower page. Selects between two 64KB pages of frame buffer memory during standard VGA odd/even modes (modes 0h through 5h). Bit 1 of register GR06 can also program this bit in other modes. This bit is would normally set to 1 by the software.
4	**Reserved.** Read as 0.
3:2	**Clock Select.** These bits can select the dot clock source for the CRT interface. The bits should be used to select the dot clock in standard native VGA modes only. When in the centering or upper left corner modes, these bits should be set to have no effect on the clock rate. The actual frequencies that these bits select, if they have any affect at all, is programmable through the DPLL MMIO registers. 00 = CLK0, 25.175 MHz (for standard VGA modes with 640 pixel (8-dot) horizontal resolution) (default) 01 = CLK1, 28.322 MHz. (for standard VGA modes with 720 pixel (9-dot) horizontal resolution) 10 = Was used to select an external clock (now unused) 11 = Reserved

Bit	Descriptions
1	**A0000-BFFFFh Memory Access Enable.** VGA Compatibility bit enables access to video memory (frame buffer) at A0000-BFFFFh. When disabled, accesses to VGA memory are blocked in this region. This bit is independent of and does not block CPU access to the video linear frame buffer at other addresses. 0 = Prevent CPU access to memory/registers/ROM through the A0000-BFFFF VGA memory aperture (default). 1 = Allow CPU access to memory/registers/ROM through the A0000-BFFFF VGA memory aperture. This memory must be mapped as UC by the CPU.
0	**I/O Address Select.** This bit selects 3Bxh or 3Dxh as the I/O address for the CRT Controller registers, the Feature Control Register (FCR), and Input Status Register 1 (ST01). Presently ignored (whole range is claimed), but will "ignore" 3Bx for color configuration or 3Dx for monochrome. It is typical in AGP chipsets to shadow this bit and properly steer I/O cycles to the proper bus for operation where a MDA exists on another bus such as ISA. 0 = Select 3Bxh I/O address (MDA emulation) (default). 1 = Select 3Dxh I/O address (CGA emulation).

In standard VGA modes using the analog VGA connector, bits 7 and 6 indicate which of the three standard VGA vertical resolutions the standard VGA display should use. Extended modes, including those with a vertical resolution of 480 scan lines, may use a setting of 0 for both of these bits. Different connector standards and timing standards specify the proper use of sync polarity. This setting was "reserved" in the VGA standard.

Analog CRT Display Sync Polarities

V	H	Display	Horizontal Frequency	Vertical Frequency
P	P	200 Line	15.7 KHz	60 Hz
N	P	350 Line	21.8 KHz	60 Hz
P	N	400 Line	31.5 KHz	70 Hz
N	N	480 Line	31.5 KHz	60 Hz

Sequencer Registers

The sequencer registers are accessed via either I/O space or Memory space. To access registers the VGA Sequencer Index register (SRX) at I/O address 3C4h (or memory address 3C4h) is written with the index of the desired register. Then the desired register is accessed through the data port for the sequencer registers at I/O address 3C5 (or memory address 3C5).

SRX - Sequencer Index

I/O (and Memory Offset) Address: 3C4h

Default: 00h

Attributes: Read/Write

Bit	Description
7:3	**Reserved.** Read as 0s.
2:0	**Sequencer Index.** This field contains a 3-bit Sequencer Index value used to access sequencer data registers at indices 0 through 7.

SR00 - Sequencer Reset

I/O (and Memory Offset) Address: 3C5h(Index=00h)

Default: 00h

Attributes: Read/Write

Bit	Descriptions
7:2	**Reserved.** Read as 0.
1	**Reserved.** Reserved for VGA compatibility (was reset).
0	**Reserved.** Reserved for VGA compatibility. (was reset)

SR01 - Clocking Mode

I/O (and Memory Offset) Address: 3C5h (Index=01h)

Default: 00h

Attributes: Read/Write

Bit	Descriptions
7:6	**Reserved.** Read as 0s.
5	**Screen Off.** 0 = Normal Operation (default). 1 = Disables video output (blanks the screen) and turns off display data fetches. Synchronization pulses to the display, however, are maintained. Setting this bit to 1 had been used as a way to more rapidly update and improve CPU access performance to the frame buffer during VGA modes. In non-VGA modes (VGA Disable=1), this bit has no effect. Before the VGA is disabled through the MMIO VGA control register, this bit should be set to stop the memory accesses from the display. The following sequence must be used when disabling the VGA plane. 1. Write SR01 to set bit 5 = 1 to disable video output. 2. Wait for 100us. 3. Disable the VGA plane via Bit 31 of the MMIO VGA control register (location found in the MMIO display register programming specification).
4	**Shift 4.** 0 = Load video shift registers every 1 or 2 character clocks (depending on bit 2 of this register) (default). 1 = Load shift registers every 4th character clock.
3	**Dot Clock Divide.** Setting this bit to 1 stretches doubles all horizontal timing periods that are specified in the VGA horizontal CRTC registers. This bit is used in standard VGA 40-column text modes to stretch timings to create horizontal resolutions of either 320 or 360 pixels (as opposed to 640 or 720 pixels, normally used in standard VGA 80-column text modes). The effect of this is that there will actually be twice the number of pixels sent to the display per line. 0 = Pixel clock is left unaltered (used for 640 (720) pixel modes); (default). 1 = Pixel clock divided by 2 (used for 320 (360) pixel modes).
2	**Shift Load.** Bit 4 of this register must be 0 for this bit to be effective. 0 = Load video data shift registers every character clock (default). 1 = Load video data shift registers every other character clock.
1	**Reserved.** Read as 0.

Bit	Descriptions
0	**8/9 Dot Clocks.** This bit determines whether a character clock is 8 or 9 dot clocks long if clock doubling is disabled and 16 or 18 clocks if it is. This also changes the interpretation of the pixel panning values (see chart). An additional control bit determines if this bit is to be ignored and 8-dot characters are to be used always. The 9-dot disable would be used when doubling the horizontal pixels on a 1280 wide display or non-doubling on a 640 wide display. Panning however will occur according to the expected outcome. 0 = 9 dot clocks (9 horizontal pixels) per character in text modes with a horizontal resolution of 720 pixels. 1 = 8 dot clocks (8 horizontal pixels) per character in text or graphics modes with a horizontal resolution of 640 pixels.

SR02 - Plane/Map Mask

I/O (and Memory Offset) Address: 3C5h (Index=02h)

Default: 00h

Attributes: Read/Write

Bit	Descriptions
7:4	**Reserved.** Read as 0s.
3:0	**Memory Planes [3:0] Processor Write Access Enable.** In both the Odd/Even Mode and the Chain 4 Mode, these bits still control access to the corresponding color plane. 0 = Disable. 1 = Enable. This register is referred to in the VGA standard as the Map Mask Register.

SR03 - Character Font

I/O (and Memory Offset) Address: 3C5h (index=03h)

Default: 00h

Attributes: Read/Write

In text modes, bit 3 of the video data's attribute byte normally controls the foreground intensity. This bit may be redefined to control switching between character sets. This latter function is enabled whenever there is a difference in the values of the Character Font Select A and the Character Font Select B bits. If the two values are the same, the character select function is disabled and attribute bit 3 controls the foreground intensity.

Bit 1 of the Memory Mode Register (SR04) must be set to 1 for the character font select function of this register to be active. Otherwise, only character maps 0 and 4 are available.

<table>
<tr><th>Bit</th><th>Descriptions</th></tr>

SR04 - Memory Mode Register

I/O (and Memory Offset) Address: 3C5h (index=04h)

Default: 00h

Attributes: Read/Write

Bit	Description
7:4	**Reserved.** Read as 0.
3	**Chain 4 Mode.** The selections made by this bit affect both CPU Read and write accesses to the frame buffer. 0 = The manner in which the frame buffer memory is mapped is determined by the setting of bit 2 of this register (default). 1 = The frame buffer memory is mapped in such a way that the function of address bits 0 and 1 are altered so that they select planes 0 through 3. This setting is used in mode x13 to allow all four planes to be accessed via sequential addresses.
2	**Odd/Even Mode.** Bit 3 of this register must be set to 0 for this bit to be effective. The selections made by this bit affect only non-paged CPU accesses to the frame buffer through the VGA aperture. 0 = The frame buffer memory is mapped in such a way that the function of address bit 0 such that even addresses select planes 0 and 2 and odd addresses select planes 1 and 3 (default). 1 = Addresses sequentially access data within a bit map, and the choice of which map is accessed is made according to the value of the Plane Mask Register (SR02).
1	**Extended Memory Enable.** This bit must be set to 1 to enable the selection and use of character maps in plane 2 via the Character Map Select Register (SR03). 0 = Disable CPU accesses to more than the first 64KB of VGA standard memory (default). 1 = Enable CPU accesses to the rest of the 256KB total VGA memory beyond the first 64KB.
0	**Reserved.** Read as 0.

SR07 - Horizontal Character Counter Reset

I/O (and Memory Offset) Address: 3C5h (index=07h)

Default: 00h

Attributes: Read/Write

For standard VGAs, writing this register (with any data) causes the horizontal character counter to be held in reset (the character counter output will remain 0). It remained in reset until a write occurred to any other sequencer register location with SRX set to an index of 0 through 6. In this implementation that sequence has no such special effect.

The vertical line counter is clocked by a signal derived from the horizontal display enable (which does not occur if the horizontal counter is held in reset). Therefore, if a write occurs to this register during the vertical retrace interval, both the horizontal and vertical counters will be set to 0. A write to any other sequencer register location (with SRX set to an index of 0 through 6) may then be used to start both counters with reasonable synchronization to an external event via software control. Although this was a standard VGA register, it was not documented.

Bit	Description
7:0	**Horizontal Character Counter.**

Graphics Controller Registers

The graphics controller registers are accessed via either I/O space or Memory space. Accesses to the registers of the VGA Graphics Controller are done through the use of address 3CEh (or memory address 3CEh) written with the index of the desired register. Then the desired register is accessed through the data port for the graphics controller registers at I/O address 3CFh (or memory address 3CFh). Indexes 10 and 11 should only be accessed through the I/O space only.

GRX - GRX Graphics Controller Index Register

I/O (and Memory Offset) Address: 3CEh

Default: 000UUUUUb (U=Undefined)

Attributes: Read/Write

Bit	Description
7:5	**Reserved.** Read as 0.
4:0	**Graphics Controller Register Index.** This field selects any one of the graphics controller registers (GR00-GR18) to be accessed via the data port at I/O (or memory offset) location 3CFh.

GR00 - Set/Reset Register

I/O (and Memory Offset) Address: 3CFh (index=00h)

Default: 0Uh (U=Undefined)

Attributes: Read/Write

Bit	Description
7:4	**Reserved.** Read as 0.
3:0	**Set/Reset Plane [3:0].** When the Write Mode bits (bits 0 and 1) of the Graphics Mode Register (GR05) are set to select Write Mode 0, all 8 bits of each byte of each memory plane are set to either 1 or 0 as specified in the corresponding bit in this register, if the corresponding bit in the Enable Set/Reset Register (GR01) is set to 1. When the Write Mode bits (bits 0 and 1) of the Graphics Mode Register (GR05) are set to select Write Mode 3, all CPU data written to the frame buffer is rotated, then logically ANDed with the contents of the Bit Mask Register (GR08), and then treated as the addressed data's bit mask, while value of these four bits of this register are treated as the color value.

GR01 - Enable Set/Reset Register

I/O (and Memory Offset) Address: 3CFh (Index=01h)

Default: 0Uh (U=Undefined)

Attributes: Read/Write

Bit	Description
7:4	**Reserved.** Read as 0.
3:0	**Enable Set/Reset Plane [3:0].** This register works in conjunction with the Set/Reset Register (GR00). The Write Mode bits (bits 0 and 1) must be set for Write Mode 0 for this register to have any effect. 0 = The corresponding memory plane can be read from or written to by the CPU without any special bitwise operations taking place. 1 = The corresponding memory plane is set to 0 or 1 as specified in the Set/Reset Register (GR00).

GR02 - Color Compare Register

I/O (and Memory Offset) Address: 3CFh (Index=02h)

Default: 0Uh (U=Undefined)

Attributes: Read/Write

Bit	Description
7:4	**Reserved.** Read as 0.
3:0	**Color Compare Plane [3:0].** When the Read Mode bit (bit 3) of the Graphics Mode Register (GR05) is set to select Read Mode 1, all 8 bits of each byte of each of the 4 memory planes of the frame buffer corresponding to the address from which a CPU read access is being performed are compared to the corresponding bits in this register (if the corresponding bit in the Color Don't Care Register (GR07) is set to 1). The value that the CPU receives from the read access is an 8-bit value that shows the result of this comparison, wherein value of 1 in a given bit position indicates that all of the corresponding bits in the bytes across all of the memory planes that were included in the comparison had the same value as their memory plane's respective bits in this register.

GR03 - Data Rotate Register

I/O (and Memory Offset) Address: 3CFh (Index=03h)

Default: 0Uh (U=Undefined)

Attributes: Read/Write

Bit	Description
7:5	**Reserved.** Read as 0.
4:3	**Function Select.** These bits specify the logical function (if any) to be performed on data that is meant to be written to the frame buffer (using the contents of the memory read latch) just before it is actually stored in the frame buffer at the intended address location. 00 = Data being written to the frame buffer remains unchanged, and is simply stored in the frame buffer. 01 = Data being written to the frame buffer is logically ANDed with the data in the memory read latch before it is actually stored in the frame buffer. 10 = Data being written to the frame buffer is logically ORed with the data in the memory read latch before it is actually stored in the frame buffer. 11 = Data being written to the frame buffer is logically XORed with the data in the memory read latch before it is actually stored in the frame buffer.
2:0	**Rotate Count.** These bits specify the number of bits to the right to rotate any data that is meant to be written to the frame buffer just before it is actually stored in the frame buffer at the intended address location.

GR04 - Read Plane Select Register

I/O (and Memory Offset) Address: 3CFh (Index=04h)

Default: 0Uh (U=Undefined)

Attributes: Read/Write

Bit	Description
7:2	**Reserved.** Read as 0.
1:0	**Read Plane Select.** These two bits select the memory plane from which the CPU reads data in Read Mode 0. In Odd/Even Mode, bit 0 of this register is ignored. In Chain 4 Mode, both bits 1 and 0 of this register are ignored. The four memory planes are selected as follows: 00 = Plane 0

Bit	Description
	01 = Plane 1 10 = Plane 2 11 = Plane 3 These two bits also select which of the four memory read latches may be read via the Memory read Latch Data Register (CR22). The choice of memory read latch corresponds to the choice of plane specified in the table above. The Memory Read Latch Data register and this additional function served by 2 bits are features of the VGA standard that were never documented.

GR05 - Graphics Mode Register

I/O (and Memory Offset) Address: 3CFh (Index=05h)

Default: 0UUU U0UUb (U=Undefined)

Attributes: Read/Write

Bit	Description
7	**Reserved.** Read as 0.
6:5	**Shift Register Control.** In standard VGA modes, pixel data is transferred from the 4 graphics memory planes to the palette via a set of 4 serial output bits. These 2 bits of this register control the format in which data in the 4 memory planes is serialized for these transfers to the palette. **Bits [6:5]=00** One bit of data at a time from parallel bytes in each of the 4 memory planes is transferred to the palette via the 4 serial output bits, with 1 of each of the serial output bits corresponding to a memory plane. This provides a 4-bit value on each transfer for 1 pixel, making possible a choice of 1 of 16 colors per pixel. Serial Out / 1st Xfer / 2nd Xfer / 3rd Xfer / 4th Xfer / 5th Xfer / 6th Xfer / 7th Xfer / 8th Xfer Bit 3 / plane3 bit7 / plane3 bit6 / plane3 bit5 / plane3 bit4 / plane3 bit3 / plane3 bit2 / plane3 bit1 / plane3 bit0 Bit 2 / plane2 bit7 / plane2 bit6 / plane2 bit5 / plane2 bit4 / plane2 bit3 / plane2 bit2 / plane2 bit1 / plane2 bit0 Bit 1 / plane1 bit7 / plane1 bit6 / plane1 bit5 / plane1 bit4 / plane1 bit3 / plane1 bit2 / plane1 bit1 / plane1 bit0 Bit 0 / plane0 bit7 / plane0 bit6 / plane0 bit5 / plane0 bit4 / plane0 bit3 / plane0 bit2 / plane0 bit1 / plane0 bit0

Bit	Description
	Bits [6:5]=01 Two bits of data at a time from parallel bytes in each of the 4 memory planes are transferred to the palette in a pattern that alternates per byte between memory planes 0 and 2, and memory planes 1 and 3. First the even-numbered and odd-numbered bits of a byte in memory plane 0 are transferred via serial output bits 0 and 1, respectively, while the even-numbered and odd-numbered bits of a byte in memory plane 2 are transferred via serial output bits 2 and 3. Next, the even-numbered and odd-numbered bits of a byte in memory plane 1 are transferred via serial output bits 0 and 1, respectively, while the even-numbered and odd-numbered bits of memory plane 3 are transferred via serial out bits 1 and 3. This provides a pair of 2-bit values (one 2-bit value for each of 2 pixels) on each transfer, making possible a choice of 1 of 4 colors per pixel. Serial Out 1st Xfer 2nd Xfer 3rd Xfer 4th Xfer 5th Xfer 6th Xfer 7th Xfer 8th Xfer Bit 3 plane2 bit7 plane2 bit5 plane2 bit3 plane2 bit1 plane3 bi7t plane3 bit5 plane3 bit3 plane3 bit1 Bit 2 plane2 bit6 plane2 bit4 plane2 bit2 plane2 bit0 plane3 bit6 plane3 bit4 plane3 bit2 plane3 bit0 Bit 1 plane0 bit7 plane0 bit5 plane0 bit3 plane0 bit1 plane1 bit7 plane1 bit5 plane1 bit3 plane1 bit1 Bit 0 plane0 bit6 plane0 bit4 plane0 bit2 plane0 bit0 plane1 bit6 plane1 bit4 plane1 bit2 plane1 bit0 This alternating pattern is meant to accommodate the use of the Odd/Even mode of organizing the 4 memory planes, which is used by standard VGA modes 2h and 3h. **Bits [6:5]=1x** Four bits of data at a time from parallel bytes in each of the 4 memory planes are transferred to the palette in a pattern that iterates per byte through memory planes 0 through 3. First the 4 most significant bits of a byte in memory plane 0 are transferred via the 4 serial output bits, followed by the 4 least significant bits of the same byte. Next, the same transfers occur from the parallel byte in memory planes 1, 2 and lastly, 3. Each transfer provides either the upper or lower half of an 8 bit value for the color for each pixel, making possible a choice of 1 of 256 colors per pixel. This is the setting used in mode x13. Serial Out 1st Xfer 2nd Xfer 3rd Xfer 4th Xfer 5th Xfer 6th Xfer 7th Xfer 8th Xfer Bit 3 plane0 plane0 plane1 plane1 plane2 plane2 plane3 plane3

Bit	Description
	<table><tr><td></td><td>bit7</td><td>bit3</td><td>bit7</td><td>bit3</td><td>bit7</td><td>bit3</td><td>bit7</td><td>b3it</td></tr><tr><td>Bit 2</td><td>plane0 bit6</td><td>plane0 bit2</td><td>plane1 bit6</td><td>plane1 bit2</td><td>plane2 bit6</td><td>plane2 bit2</td><td>plane3 bit6</td><td>plane3 bit2</td></tr><tr><td>Bit 1</td><td>plane0 bit5</td><td>plane0 bit1</td><td>plane1 bit5</td><td>plane1 bit1</td><td>plane2 bit5</td><td>plane2 bit1</td><td>plane3 bit5</td><td>plane3 bit1</td></tr><tr><td>Bit 0</td><td>plane0 bit4</td><td>plane0 bit0</td><td>plane1 bit4</td><td>plane1 bit0</td><td>plane2 bit4</td><td>plane2 bit0</td><td>plane3 bit4</td><td>plane3 bit0</td></tr></table> This pattern is meant to accommodate mode 13h, a standard VGA 256-color graphics mode.
4	**Odd/Even Mode.** 0 = Addresses sequentially access data within a bit map, and the choice of which map is accessed is made according to the value of the Plane Mask Register (SR02). 1 = The frame buffer is mapped in such a way that the function of address bit 0 is such that even addresses select memory planes 0 and 2 and odd addresses select memory planes 1 and 3. This works in a way that is the inverse of (and is normally set to be the opposite of) bit 2 of the Memory Mode Register (SR02).
3	**Read Mode.** 0 = During a CPU read from the frame buffer, the value returned to the CPU is the memory plane selected by bits 1 and 0 of the Read Plane Select Regist 1 = During a CPU read from the frame buffer, all 8 bits of the byte in each of the 4 memory planes corresponding to the address from which a CPU read access is being performed are compared to the corresponding bits in this register (if the corresponding bit in the Color Don't Care Register (GR07) is set to 1). The value that the CPU receives from the read access is an 8-bit value that shows the result of this comparison. A value of 1 in a given bit position indicates that all of the corresponding bits in the bytes across all 4 of the memory planes that were included in the comparison had the same value as their memory plane's respective bits in this register.
2	**Reserved.** Read as 0.

Bit	Description
1:0	**Write Mode.** 00 = Write Mode 0 - During a CPU write to the frame buffer, the addressed byte in each of the 4 memory planes is written with the CPU write data after it has been rotated by the number of counts specified in the Data Rotate Register (GR03). If, however, the bit(s) in the Enable Set/Reset Register (GR01) corresponding to one or more of the memory planes is set to 1, then those memory planes will be written to with the data stored in the corresponding bits in the Set/Reset Register (GR00). 01 = Write Mode 1 - During a CPU write to the frame buffer, the addressed byte in each of the 4 memory planes is written to with the data stored in the memory read latches. (The memory read latches stores an unaltered copy of the data last read from any location in the frame buffer.) 10 = Write Mode 2 - During a CPU write to the frame buffer, the least significant 4 data bits of the CPU write data is treated as the color value for the pixels in the addressed byte in all 4 memory planes. The 8 bits of the Bit Mask Register (GR08) are used to selectively enable or disable the ability to write to the corresponding bit in each of the 4 memory planes that correspond to a given pixel. A setting of 0 in a bit in the Bit Mask Register at a given bit position causes the bits in the corresponding bit positions in the addressed byte in all 4 memory planes to be written with value of their counterparts in the memory read latches. A setting of 1 in a Bit Mask Register at a given bit position causes the bits in the corresponding bit positions in the addressed byte in all 4 memory planes to be written with the 4 bits taken from the CPU write data to thereby cause the pixel corresponding to these bits to be set to the color value. 11 = Write Mode 3 - During a CPU write to the frame buffer, the CPU write data is logically ANDed with the contents of the Bit Mask Register (GR08). The result of this ANDing is treated as the bit mask used in writing the contents of the Set/Reset Register (GR00) are written to addressed byte in all 4 memory planes.

GR06 - Miscellaneous Register

I/O (and Memory Offset) Address: 3CFh (Index=06h)

Default: 0Uh (U=Undefined)

Attributes: Read/Write

Bit	Description
7:4	**Reserved.** Read as 0s.
3:2	**Memory Map Mode.** These 2 bits control the mapping of the VGA address range for frame buffer into the CPU address space as follows: 00 = A0000h - BFFFFh 01 = A0000h - AFFFFh 10 = B0000h - B7FFFh 11 = B8000h - BFFFFh This function is used in standard VGA modes, extended VGA modes (132 column text), and in non-VGA modes (hi-res). 132 column text modes are no longer supported. VGA aperture memory accesses are also controlled by the PCI configuration Memory Enable bit and MSR<1>. For accesses using GR10 and GR11 to paged VGA RAM or to device MMIO registers, set these bits to 01 to select the (A0000-AFFFF) range. The CPU must map this memory as uncacheable (UC).
1	**Chain Odd/Even.** This bit provides the ability to alter the interpretation of address bit A0, so that it may be used in selecting between the odd-numbered memory planes (planes 1 and 3) and the even-numbered memory planes (planes 0 and 2). 0 = A0 functions normally. 1 = A0 is switched with a high order address bit, in terms of how it is used in address decoding. The result is that A0 is used to determine which memory plane is being accessed (A0=0 for planes 0 and 2 and A0=1 for planes 1 and 3).

Bit	Description
0	**Graphics/Text Mode.** This is one of two bits that are used to determine if the VGA is operating in text or graphics modes. The other bit is in AR10[0], these two bits need to be programmed in a consistent manner to achieve the proper results. 0 = Text mode. 1 = Graphics mode.

GR07 - Color Don't Care Register

I/O (and Memory Offset) Address: 3CFh (Index=07h)

Default: 0Uh (U=Undefined)

Attributes: Read/Write

Bit	Description
7:4	**Reserved.** Read as 0.
3:0	**Ignore Color Plane [3:0].** These bits have effect only when bit 3 of the Graphics Mode Register (GR05) is set to 1 to select read mode 1. 0 = The corresponding bit in the Color Compare Register (GR02) will not be included in color comparisons. 1 = The corresponding bit in the Color Compare Register (GR02) is used in color comparisons.

GR08 - Bit Mask Register

I/O (and Memory Offset) Address: 3CFh (Index=08h)

Default: Undefined

Attributes: Read/Write

Bit	Description
7:0	**Bit Mask.** 0 = The corresponding bit in each of the 4 memory planes is written to with the corresponding bit in the memory read latches. 1 = Manipulation of the corresponding bit in each of the 4 memory planes via other mechanisms is enabled. This bit mask applies to any writes to the addressed byte of any or all of the 4 memory planes, simultaneously. This bit mask is applicable to any data written into the frame buffer by the CPU, including data that is also subject to rotation, logical functions (AND, OR, XOR), and Set/Reset. To perform a proper read-modify-write cycle into frame buffer, each byte must first be read from the frame buffer by the CPU (and this will cause it to be stored in the memory read latches), this Bit Mask Register must be set, and the new data then written into the frame buffer by the CPU.

GR10 - Address Mapping

I/O (avoid MMIO access) Address: 3CFh (Index=10h)

Default: 00h

Attributes: R/W

This register should only be accessed using I/O operations and never be accessed through the A/B segment addressing map, I/O space register map, or direct MMIO operations.

Bit	Description
7:4	**Page Select Extension - Unused** These bits form the upper bits of a 12-bit page selection value. When combined with the GR11 <7:0> bits they define the offset into stolen memory to the 64KB page that is accessible via the VGA Memory paging mechanism. These bits are ignored.
3	**Reserved**

Bit	Description
2:1	**Paging Map Target.** When paging is enabled, these bits determine the target for data cycle accesses through the VGA memory aperture. VGA graphics memory starts from the base of graphics data stolen memory defined in the PCI configuration BDSM register. VGA display uses the first four 64KB pages of VGA graphics memory. 00 = VGA Graphics Memory 01 = Reserved 10 = Reserved 11 = Reserved
0	**Page Mapping Enable.** This mode allows the mapping of the VGA memory address space. Once this is enabled, no VGA memory address swizzle will be performed, addresses are directly mapped to memory. A single paging register is used to map the 64KB [A0000:AFFFF] window. An internal address is generated using GR11 as the address lines extension to the lower address lines of the access A[15:2]. When mapping is enabled, the B0000:BFFFF area must be disabled using GR06<3:2>=01. The use of addresses in the A0000-BFFFF range require that both the graphics device PCI configuration memory enable and MSR<1> be enabled. 0 = Disable (default) 1 = Enable

GR11 - Page Selector

I/O (avoid MMIO access) Address: 3CFh (Index=11h)

Default: 00h

Attributes: R/W

Bit	Description
7	**Reserved**
6:0	**Page Select.** When concatenated with the GR10<7:4> bits, selects a 64KB window within target area when Page Mapping is enabled (GR10[0]=1). This requires that the graphics device PCI configuration space memory enable, the GR06<3:2> bits to be 01 (select A0000-AFFFF only), and the MSR<1:1> bit to be set. This register provides the Address[22:16] bits for the access. VGA paging of frame buffer memory is for non-VGA packed modes only and should not be enabled when using basic VGA modes. This register should only be accessed using I/O operations.

GR18 - Software Flags

I/O (and Memory Offset) Address: 3CFh (Index=18h)

Default: 00

Attributes: R/W

Bit	Description
7:0	**Software Flags.** Used as scratch pad space in video BIOS. These bits are separate from the bits which appear in the memory mapped IO space. They are used specifically by the SMI BIOS which does not have access to memory mapped IO at the time they are required. These register bits have no effect on H/W operation.

Attribute Controller Registers

Unlike the other sets of indexed registers, the attribute controller registers are not accessed through a scheme employing entirely separate index and data ports. I/O address 3C0h (or memory address 3C0h) is used both as the read and write for the index register, and as the write address for the data port. I/O address 3C1h (or memory address 3C1h) is the read address for the data port.

To write to the attribute controller registers, the index of the desired register must be written to I/O address 3C0h (or memory address 3C0h), and then the data is written to the very same I/O (memory) address. A flip-flop alternates with each write to I/O address 3C0h (or memory address 3C0h) to change its function from writing the index to writing the actual data, and back again. This flip-flop may be deliberately set so that I/O address 3C0h (or memory address 3C0h) is set to write to the index (which provides a way to set it to a known state) by performing a read operation from Input Status Register 1 (ST01) at I/O address 3BAh (or memory address 3BAh) or 3DAh (or memory address 3DAh), depending on whether the graphics system has been set to emulate an MDA or a CGA as per MSR[0].

To read from the attribute controller registers, the index of the desired register must be written to I/O address 3C0h (or memory address 3C0h), and then the data is read from I/O address 3C1h (or memory address 3C1h). A read operation from I/O address 3C1h (or memory address 3C1h) does not reset the flip-flop to writing to the index. Only a write to 3C0h (or memory address 3C0h) or a read from 3BAh or 3DAh (or memory address 3BAh or 3DAh), as described above, will toggle the flip-flop back to writing to the index.

ARX - Attribute Controller Index Register

I/O (and Memory Offset) Address: 3C0h

Default: 00UU UUUUb (U=Undefined)

Attributes: Read/Write

Bit	Description
7:6	**Reserved.** Read as 0s.
5	**Video Enable.** In the VGA standard, this is called the "Palette Address Source" bit. Clearing this bit will cause the VGA display data to become all 00 index values. For the default palette, this will cause a black screen. The video timing signals continue. Another control bit will turn video off and stop the data fetches. 0 = Disable. Attribute controller color registers (AR[00:0F]) can be accessed by the CPU. 1 = Enable. Attribute controller color registers (AR[00:0F]) are inaccessible by the CPU.
4:0	**Attribute Controller Register Index.** These five bits are used to select any one of the attribute controller registers (AR[00:14]), to be accessed.

AR[00:0F] - Palette Registers [0:F]

I/O (and Memory Offset) Address: Read at 3C1h and Write at 3C0h; (index=00h-0Fh)

Default: 00UU UUUUb (U=Undefined)

Attributes: Read/Write

Bit	Description
7:6	**Reserved.** Read as 0.
5:0	**Palette Bits P[5:0].** In each of these 16 registers, these are the lower 6 of 8 bits that are used to map either text attributes or pixel color input values (for modes that use 16 colors) to the 256 possible colors available to be selected in the palette. Bits 3 and 2 of the Color Select Register (AR14) supply bits P7 and P6 for the values contained in all 16 of these registers. Bits 1 and 0 of the Color Select Register (AR14) can also replace bits P5 and P4 for the values contained in all 16 of these registers, if bit 7 of the Mode Control Register (AR10) is set to 1.

AR10 - Mode Control Register

I/O (and Memory Offset) Address:	Read at 3C1h and Write at 3C0h; (index=10h)
Default:	UUh (U=Undefined)
Attributes:	Read/Write

Bit	Description
7	**Palette Bits P5, P4 Select.** **0** = P5 and P4 for each of the 16 selected colors (for modes that use 16 colors) are individually provided by bits 5 and 4 of their corresponding Palette Registers (AR[00:0F]). **1** = P5 and P4 for all 16 of the selected colors (for modes that use 16 colors) are provided by bits 1 and 0 of Color Select Register (AR14).
6	**Pixel Width/Clock Select.** **0** = Six bits of video data (translated from 4 bits via the palette) are output every dot clock. **1** = Two sets of 4 bits of data are assembled to generate 8 bits of video data which is output every other dot clock, and the Palette Registers (AR[00:0F]) are bypassed. This bit is set to 0 for all of the standard VGA modes, except mode 13h.
5	**Pixel Panning Compatibility.** **0** = Scroll both the upper and lower screen regions horizontally as specified in the Pixel Panning Register (AR13). **1** = Scroll only the upper screen region horizontally as specified in the Pixel Panning Register (AR13). This bit has application only when split-screen mode is being used, where the display area is divided into distinct upper and lower regions which function somewhat like separate displays.
4	**Reserved.** Read as 0.
3	**Enable Blinking/Select Background Intensity.** **0** = Disables blinking in graphics modes, and for text modes, sets bit 7 of the character attribute bytes to control background intensity, instead of blinking. **1** = Enables blinking in graphics modes and for text modes, sets bit 7 of the character attribute bytes to control blinking, instead of background intensity. The blinking rate is derived by dividing the VSYNC signal. The Blink Rate Control field of the VGA control register defines the blinking rate.

Bit	Description
2	**Enable Line Graphics Character Code.** **0** = Every 9th pixel of a horizontal line (i.e., the last pixel of each horizontal line of each 9-pixel wide character box) is assigned the same attributes as the background of the character of which the given pixel is a part. **1** = Every 9th pixel of a horizontal line (i.e., the last pixel of each horizontal line of each 9-pixel wide character box) is assigned the same attributes as the 8th pixel if the character of which the given pixel is a part. This setting is intended to accommodate the line-drawing characters of the PC's extended ASCII character set -- characters with an extended ASCII code in the range of B0h to DFh. In some literature describing the VGA standard, the range of extended ASCII codes that are said to include the line-drawing characters is mistakenly specified as C0h to DFh, rather than the correct range of B0h to DFh.
1	**Select Display Type.** **0** = Attribute bytes in text modes are interpreted as they would be for a color display. **1** = Attribute bytes in text modes are interpreted as they would be for a monochrome display.
0	**Graphics/Alphanumeric Mode.** This bit (along with GR06[0]) select either graphics mode or text mode. These two bits must be programmed in a consistent manner to achieve the desired results. **0** = Alphanumeric (text) mode. **1** = Graphics mode.

AR11 - Overscan Color Register

I/O (and Memory Offset) Address: Read at 3C1h and Write at 3C0h; (index=11h)

Default: UUh (U=Undefined)

Attributes: Read/Write

Bit	Description
7:0	**Overscan.** These 8 bits select the overscan (border) color index value. The actual border color will be determined by the contents of the palette at the selected index. The border color is displayed between the end of active and the beginning of blank or the end of blank and the beginning of active on CRT type devices driven from the DAC output port. For native VGA modes on digital display ports there is the option of including the border in the active region or not depending on a control bit in the port control register. For centered VGA modes, the VGA control register determines if the border is included in the centered region or not. For monochrome displays, this value should be set to 00h.

AR12 - Memory Plane Enable Register

I/O (and Memory Offset) Address: Read at 3C1h and Write at 3C0h; (index=12h)

Default: 00UU UUUUb (U=Undefined)

Attributes: Read/Write

Bit	Description
7:6	**Reserved.** Read as 0.
5:4	**Video Status Mux.** These 2 bits are used to select 2 of the 8 possible palette bits (P7-P0) to be made available to be read via bits 5 and 4 of the Input Status Register 1 (ST01). The table below shows the possible choices. Bit [5:4] / ST01 Bit 5 / ST01 Bit 4 00 / P2 (default) / P0 (default) 01 / P5 / P4 10 / P3 / P1 11 / P7 / P6 These bits are typically unused by current software; they are provided for EGA compatibility.
3:0	**Enable Plane [3:0].** These 4 bits individually enable the use of each of the 4 memory planes in providing 1 of the 4 bits used in video output to select 1 of 16 possible colors from the palette to be displayed. 0 = Disable the use of the corresponding memory plane in video output to select colors, forcing the bit that the corresponding memory plane would have provided to a value of 0. 1 = Enable the use of the corresponding memory plane in video output to select colors. AR12 is referred to in the VGA standard as the Color Plane Enable Register.

AR13 - Horizontal Pixel Panning Register

I/O (and Memory Offset) Address: Read at 3C1h and Write at 3C0h; (index=13h)

Default: 0Uh (U=Undefined)

Attributes: Read/Write

Bit	Description
7:4	**Reserved.**
3:0	**Horizontal Pixel Shift 3-0.** This field holds a 4-bit value that selects the number of pixels by which the image is shifted horizontally to the left. This function is available in both text and graphics modes and allows for pixel panning. In text modes with a 9-pixel wide character box, the image can be shifted up to 9 pixels to the left. In text modes with an 8-pixel wide character box, and in graphics modes other than those with 256 colors, the image can be shifted up to 8 pixels to the left. A pseudo 9-bit mode is when the 9-dot character is selected but overridden by the VGA control bit. In standard VGA mode 13h (where bit 6 of the Mode Control Register, AR10, is set to 1 to support 256 colors), bit 0 of this register must remain set to 0, and the image may be shifted up to only 4 pixels to the left. In this mode, the number of pixels by which the image is shifted can be further controlled using bits 6 and 5 of the Preset Row Scan Register (CR08).

Number of Pixels Shifted				
Bits [3:0]	**9-dot**	**Pseudo 9-dot**	**8-dot**	**256-Color**
0	1	1	0	0
1	2	2	1	Undefined
2	3	3	2	1
3	4	4	3	Undefined
4	5	5	4	2
5	6	6	5	Undefined
6	7	7	6	3
7	8	7	7	Undefined
8	0	0	Undefined	Undefined

AR14 - Color Select Register

I/O (and Memory Offset) Address: Read at 3C1h and Write at 3C0h; (index=14h)

Default: 0Uh (U=Undefined)

Attributes: Read/Write

Bit	Description
7:4	**Reserved.**
3:2	**Palette Bits P[7:6].** These are the 2 upper-most of the 8 bits that are used to map either text attributes or pixel color input values (for modes that use 16 colors) to the 256 possible colors contained in the palette. These 2 bits are common to all 16 sets of bits P5 through P0 that are individually supplied by Palette Registers 0-F (AR[00:0F]).
1:0	**Alternate Palette Bits P[5:4].** These 2 bits can be used as an alternate version of palette bits P5 and P4. Unlike the P5 and P4 bits that are individually supplied by Palette Registers 0-F (AR[00:0F]), these 2 alternate palette bits are common to all 16 of Palette Registers. Bit 7 of the Mode Control Register (AR10) is used to select between the use of either the P5 and P4 bits that are individually supplied by the 16 Palette Registers or these 2 alternate palette bits.

VGA Color Palette Registers

In devices that have multiple display pipes, there is one palette for each display pipe. These palettes are the same for VGA modes and non-VGA modes. Accesses through VGA register methods can optionally read or write from either one.

For each palette, the color data stored in these 256 color data positions can be accessed only through a complex sub-addressing scheme, using a data register and two index registers. The Palette Data Register at I/O address 3C9h (or memory address offset 3C1h) is the data port. The Palette Read Index Register at I/O address 3C7h (or memory address offset 3C7h) and the Palette Write Index Register at I/O address 3C8h (or memory address offset 3C8h) are the two index registers. The Palette Read Index Register is the index register that is used to choose the color data position that is to be read from via the data port, while the Palette Write Index Register is the index register that is used to choose the color data position that is to be written to through the same data port. This arrangement allows the same data port to be used for reading from and writing to two different color data positions. Reading and writing the color data at a color data position involves three successive reads or writes since the color data stored at each color data position consists of three bytes.

To read a palette color data position, the index of the desired color data position must first be written to the Palette Read Index Register. Then all three bytes of data in a given color data position may be read at the Palette Data Register. The first byte read from the Palette Data Register retrieves the 8-bit value specifying the intensity of the red color component. The second and third bytes read are the corresponding 8-bit values for the green and blue color components respectively. After completing the third read operation, the Palette Read Index Register is automatically incremented so that the data of the next color data position becomes accessible for being read. This allows the contents of all of the 256 color data positions of the palette to be read in sequence. This is done by specifying only the index of the 0th color data position in the Palette Read Index Register, and then simply performing 768 successive reads from the Palette Data Register.

Writing a color data position, entails a very similar procedure. The index of the desired color data position must first be written to the Palette Write Index Register. Then all three bytes of data to specify a given color may be written to the Palette Data Register. The first byte written to the Palette Data Register specifies the intensity of the red color component, the second byte specifies the intensity for the green color component, and the third byte specifies the same for the blue color component. One important detail is that all three of these bytes must be written before the hardware will actually update these three values in the given color data position. When all three bytes have been written, the Palette Write Index Register is automatically incremented so that the data of the next color data position becomes accessible for being written. This allows the contents of all of the 256 color data positions of the palette to be written in sequence. This is done by specifying only the index of the 0th color data position in the Palette Write Index Register, and then simply performing 768 successive writes to the Palette Data Register.

DACMASK - Pixel Data Mask Register

I/O (and Memory Offset) Address: 3C6h

Default: Undefined

Attributes: Read/Write

Bit	Description
7:0	**Pixel Data Mask.** In indexed-color mode, the 8 bits of this register are logically ANDed with the 8 bits of pixel data received from the frame buffer for each pixel. The result of this ANDing process becomes the actual index used to select color data positions within the palette. This has the effect of limiting the choice of color data positions that may be specified by the incoming 8-bit data. 0 = Corresponding bit in the resulting 8-bit index being forced to 0. 1 = Allows the corresponding bit in the resulting index to reflect the actual value of the corresponding bit in the incoming 8-bit pixel data.

DACSTATE - DAC State Register

I/O (and Memory Offset) Address: 3C7h

Default: 00h

Attributes: Read Only

Bit	Description
7:2	**Reserved.** Read as 0.
1:0	**DACState.** This field indicates which of the two index registers was most recently written. **Bits [1:0]** Index Register Indicated 00 = Palette Write Index Register at I/O Address 3C7h (default) 01 = Reserved 10 = Reserved 11 = Palette Read Index Register at I/O Address 3C8h

DACRX - Palette Read Index Register

I/O (and Memory Offset) Address: 3C7h

Default: 00h

Attributes: Write Only

Bit	Description
7:0	**Palette Read Index.** The 8-bit index value programmed into this register chooses which of 256 standard color data positions within the palette are to be made accessible for being read from via the Palette Data Register (DACDATA). The index value held in this register is automatically incremented when all three bytes of the color data position selected by the current index have been read. A write to this register will abort a uncompleted palette write sequence. This register allows access to the palette even when running non-VGA display modes.

DACWX - Palette Write Index Register

I/O (and Memory Offset) Address: 3C8h

Default: 00h

Attributes: Write Only

Bit	Description
7:0	**Palette Write Index.** The 8-bit index value programmed into this register chooses which of 256 standard color data positions within the palette are to be made accessible for being written via the Palette Data Register (DACDATA). The index value held in this register is automatically incremented when all three bytes of the color data position selected by the current index have been written. This register allows access to the palette even when running non-VGA display modes.

DACDATA - Palette Data Register

I/O (and Memory Offset) Address: 3C9h

Default: Undefined

Attributes: Read/Write

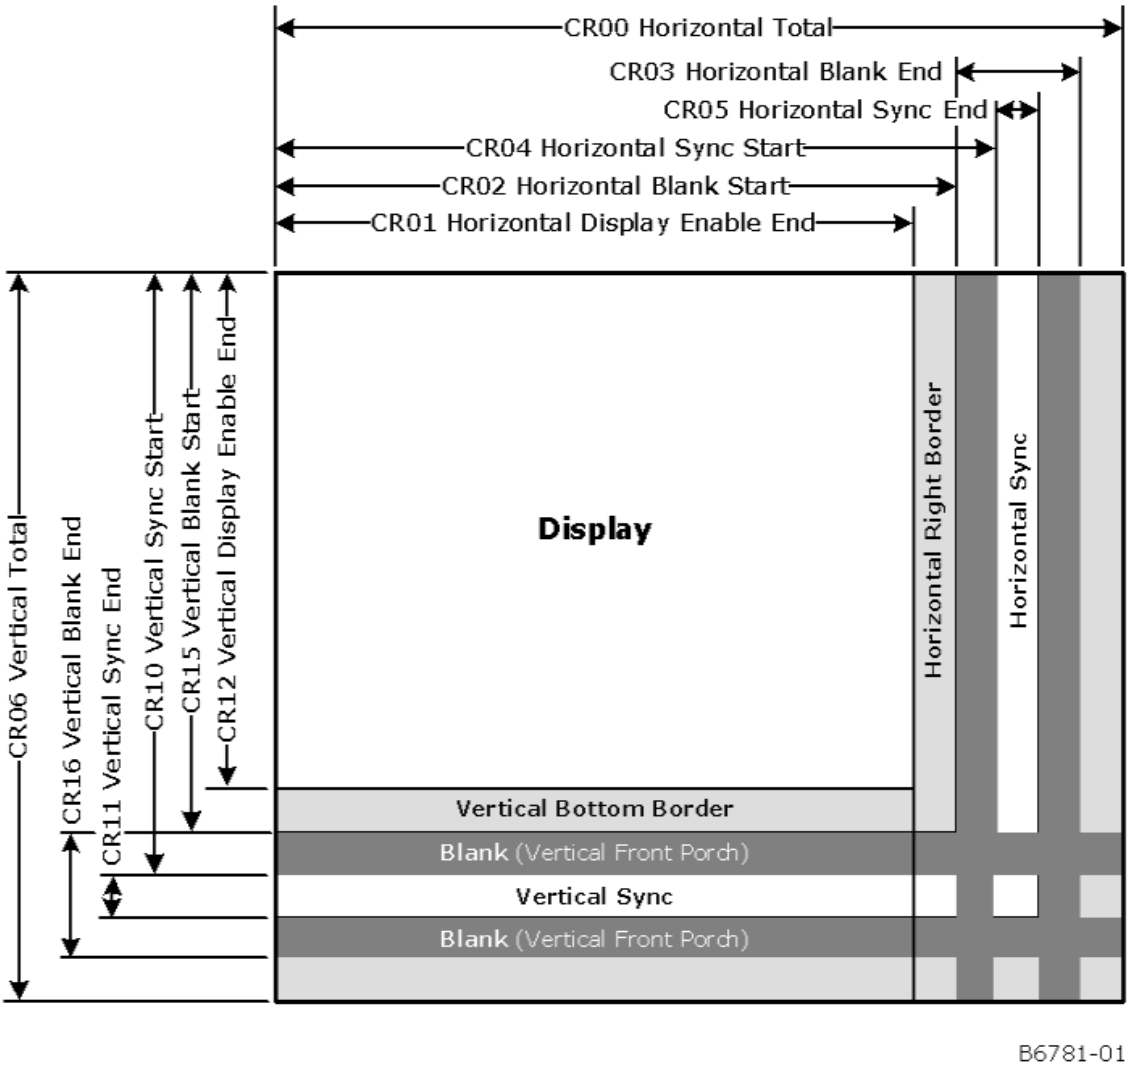
Bit	Description
7:0	**Palette Data.** This byte-wide data port provides read or write access to the three bytes of data of each color data position selected using the Palette Read Index Register (DACRX) or the Palette Write Index Register (DACWX). The three bytes in each color data position are read or written in three successive read or write operations. The first byte read or written specifies the intensity of the red component of the color specified in the selected color data position. The second byte is for the green component, and the third byte is for the blue component. When writing data to a color data position, all three bytes must be written before the hardware will actually update the three bytes of the selected color data position. When reading or writing to a color data position, ensure that neither the Palette Read Index Register (DACRX) or the Palette Write Index Register (DACWX) are written to before all three bytes are read or written. A write to either of these two registers causes the circuitry that automatically cycles through providing access to the bytes for red, green and blue components to be reset such that the byte for the red component is the one that will be accessed by the next read or write operation via this register. This register allows access to the palette even when running non-VGA display modes. Writes to the palette can cause sparkle if not done during inactive video periods. This sparkle is caused by an attempt to write and read the same address on the same cycle. Anti-sparkle circuits will substitute the previous pixel value for the read output.

CRT Controller Register

For native VGA modes, the CRTC registers determine the display timing that is to be used. In centered VGA modes, these registers determine the size of the VGA image that is to be centered in the larger timing generator defined rectangle.

The CRT controller registers are accessed by writing the index of the desired register into the CRT Controller Index Register at I/O address 3B4h or 3D4h, depending on whether the graphics system is configured for MDA or CGA emulation. The desired register is then accessed through the data port for the CRT controller registers located at I/O address 3B5h or 3D5h, again depending upon the choice of MDA or CGA emulation as per MSR[0]. For memory mapped accesses, the Index register is at 3B4h (MDA mode) or 3D3h (CGA mode) and the data port is accessed at 3B5h (MDA mode) or 3D5h (CGA mode).

The following figure shows display fields and dimensions and the particular CRxx register that provides the control.



Group 0 Protection: In the original VGA, CR[0:7] could be made write-protected by CR11[7]. In BIOS code, this write protection is set following each mode change. Other protection groups have no current use, and would not be used going forward by the BIOS or by drivers. They are the result of an industry fad some years ago to attempt to write protect other groups of registers; however, all such schemes were chip specific. Only the write protection (Group 0 Protection) is supported.

CRX - CRT Controller Index Register

I/O (and Memory Offset) Address: 3B4h/3D4h

Default: 0Uh (U=Undefined)

Attributes: Read/Write

Bit	Description
7	**Reserved.** Read as 0.
6:0	**CRT Controller Index.** These 7 bits are used to select any one of the CRT controller registers to be accessed via the data port at I/O location 3B5h or 3D5h, depending upon whether the graphics system is configured for MDA or CGA emulation. The data port memory address offsets are 3B5h/3D5h.

CR00 - Horizontal Total Register

I/O (and Memory Offset) Address: 3B5h/3D5h (index=00h)

Default: 00h

Attributes: Read/Write (Group 0 Protection)

Bit	Description
7:0	**Horizontal Total.** This register is used to specify the total length of each scan line. This encompasses both the part of the scan line that is within the active display area and the part that is outside of it. Programming this register to a zero has the effect of stopping the fetching of display data. This field should be programmed with a value equal to the total number of character clocks within the entire length of a scan line, minus 5.

CR01 - Horizontal Display Enable End Register

I/O (and Memory Offset) Address: 3B5h/3D5h (index=01h)

Default: Undefined

Attributes: Read/Write (Group 0 Protection)

Bit	Description
7:0	**Horizontal Display Enable End.** This register is used to specify the end of the part of the scan line that is within the active display area relative to its beginning. In other words, this is the horizontal width of the active display area. This field should be programmed with a value equal to the number of character clocks that occur within the horizontal active display area, minus 1. Horizontal display enable will go active at the beginning of each line during vertical active area, it will go inactive based on the programming of this register or the programming of the horizontal total (CR00) register. When this register value is programmed to a number that is larger than the total number of characters on a line, display enable will be active for all but the last character of the horizontal display line.

CR02 - Horizontal Blanking Start Register

I/O (and Memory Offset) Address: 3B5h/3D5h (index=02h)

Default: Undefined

Attributes: Read/Write (Group 0 Protection)

Bit	Description
7:0	**Horizontal Blanking Start.** This register is used to specify the beginning of the horizontal blanking period relative to the beginning of the active display area of a scan line. Horizontal blanking should always be set to start no sooner than after the end of horizontal active. This field should be programmed with a value equal to the number of character clocks that occur on a scan line from the beginning of the active display area to the beginning of the horizontal blanking.

CR03 - Horizontal Blanking End Register

I/O (and Memory Offset) Address: 3B5h/3D5h (index=03h)

Default: 1UUU UUUUb (U=Undefined)

Attributes: Read/Write (Group 0 Protection)

Bit	Description
7	**Reserved.** Values written to this bit are ignored, and to maintain consistency with the VGA standard, a value of 1 is returned when this bit is read. At one time, this bit was used to enable access to certain light pen registers. At that time, setting this bit to 0 provided this access, but setting this bit to 1 was necessary for normal operation.
6:5	**Display Enable Skew Control.** Defines the degree to which the start and end of the active display area are delayed along the length of a scan line to compensate for internal pipeline delays. These 2 bits describe the delay in terms of a number character clocks. **Bit [6:5]** Amount of Delay 00 = no delay 01 = delayed by 1 character clock 10 = delayed by 2 character clocks 11 = delayed by 3 character clocks
4:0	**Horizontal Blanking End Bits [4:0].** This field provides the 5 least significant bits of a 6-bit value that specifies the end of the blanking period relative to its beginning on a single scan line. Bit 7 of the Horizontal Sync End Register (CR05) supplies the most significant bit. This 6-bit value should be programmed to be equal to the least significant 6 bits of the result of adding the length of the blanking period in terms of character clocks to the value specified in the Horizontal Blanking Start Register (CR02). End of blanking should occur before horizontal total.

CR04 - Horizontal Sync Start Register

I/O (and Memory Offset) Address: 3B5h/3D5h (index=04h)

Default: Undefined

Attributes: Read/Write (Group 0 Protection)

Bit	Description
7:0	**Horizontal Sync Start** This register is used to specify the position of the beginning of the horizontal sync pulse relative to the start of the active display area on a scan line. This field should be set equal to the number of character clocks that occur from beginning of the active display area to the beginning of the horizontal sync pulse on a single scan line. Horizontal sync should always occur at least 2 clocks after the start of horizontal blank and 2 clocks before the end of horizontal blank. The actual start of sync will also be affected by both the horizontal sync skew register field and whether it is a text or graphics mode.

CR05 - Horizontal Sync End Register

I/O (and Memory Offset) Address: 3B5h/3D5h (index=05h)

Default: 00h

Attributes: Read/Write (Group 0 Protection)

Bit	Description
7	**Horizontal Blanking End Bit 5.** This bit provides the most significant bit of a 6-bit value that specifies the end of the horizontal blanking period relative to its beginning. Bits [4:0] of Horizontal Blanking End Register (CR03) supplies the 5 least significant bits. See CR03[4:0] for further details. This 6-bit value should be set to the least significant 6 bits of the result of adding the length of the blanking period in terms of character clocks to the value specified in the Horizontal Blanking Start Register (CR02).
6:5	**Horizontal Sync Delay.** This field defines the degree to which the start and end of the horizontal sync pulse are delayed to compensate for internal pipeline delays. This capability is supplied to implement VGA compatibility. These field describes the delay in terms of a number character clocks. **Bit [6:5] — Amount of Delay** 00 — no delay 01 — delayed by 1 character clock 10 — delayed by 2 character clocks 11 — delayed by 3 character clocks
4:0	**Horizontal Sync End.** This field provides the 5 least significant bits of a 5-bit value that specifies the end of the horizontal sync pulse relative to its beginning. A value equal to the 5 least significant bits of the horizontal character counter value at which time the horizontal retrace signal becomes inactive (logical 0). Thus, this 5-bit value specifies the width of the horizontal sync pulse. To obtain a retrace signal of W, the following algorithm is used: Value of Horizontal Sync start Register (CR04) + width of horizontal retrace signal in character clock units = 5 bit result to be programmed in this field

CR06 - Vertical Total Register

I/O (and Memory Offset) Address: 3B5h/3D5h (index=06h)

Default: 00h

Attributes: Read/Write (Group 0 Protection)

Bit	Description
7:0	**Vertical Total Bits [7:0].** This field provides the 8 least significant bits of either a 10-bit or 12-bit value that specifies the total number of scan lines. This includes the scan lines both inside and outside of the active display area. In standard VGA modes, the vertical total is specified with a 10-bit value. The 8 least significant bits of this value are supplied by these 8 bits of this register, and the 2 most significant bits are supplied by bits 5 and 0 of the Overflow Register (CR07).

CR07 - Overflow Register (Vertical)

I/O (and Memory Offset) Address: 3B5h/3D5h (index=07h)

Default: UU0U UUU0b (U=Undefined)

Attributes: Read/Write (Group 0 Protection on bits [7:5, 3:0])

Bit	Description
7	**Vertical Sync Start Bit 9.** The vertical sync start is a 10-bit that specifies the beginning of the vertical sync pulse relative to the beginning of the active display area. The 8 least significant bits of this value are supplied by bits [7:0] of the Vertical Sync Start Register (CR10), and the most and second-most significant bits are supplied by this bit and bit 2, respectively, of this register. This 10-bit value should be programmed to be equal to the number of scan lines from the beginning of the active display area to the start of the vertical sync pulse. Since the active display area always starts on the 0th scan line, this number should be equal to the number of the scan line on which the vertical sync pulse begins.
6	**Vertical Display Enable End Bit 9.** The vertical display enable end is a 10-bit that specifies the number of the last scan line within the active display area. In standard VGA modes, the vertical display enable end is specified with a 10-bit value. The 8 least significant bits of this value are supplied by bits [7:0] of the Vertical Display Enable End Register (CR12), and the most and second-most significant bits are supplied by this bit and bit 1, respectively, of this register. This 10-bit value should be programmed to be equal to the number of the last scan line within in the active display area. Since the active display area always starts on the 0th scan line, this number should be equal to the total number of scan lines within the active display area, minus 1.
5	**Vertical Total Bit 9.** The vertical total is a 10-bit value that specifies the total number of scan lines. This includes the scan lines both inside and outside of the active display area. The 8 least significant bits of this value are supplied by bits [7:0] of the Vertical Total Register (CR06), and the most and second-most significant bits are supplied by this bit and bit 0, respectively, of this register. This 10-bit value should be programmed equal to the total number of scan lines, minus 2.

Bit	Description
4	**Line Compare Bit 8.** This bit provides the second most significant bit of a 10-bit value that specifies the scan line at which the memory address counter restarts at the value of 0. Bit 6 of the Maximum Scan Line Register (CR09) supplies the most significant bit, and bits 7-0 of the Line Compare Register (CR18) supply the 8 least significant bits. Normally, this 10-bit value is set to specify a scan line after the last scan line of the active display area. When this 10-bit value is set to specify a scan line within the active display area, it causes that scan line and all subsequent scan lines in the active display area to display video data starting at the very first byte of the frame buffer. The result is what appears to be a screen split into a top and bottom part, with the image in the top part being repeated in the bottom part. When used in cooperation with the Start Address High Register (CR0C) and the Start Address Low Register (CR0D), it is possible to create a split display, as described earlier, but with the top and bottom parts displaying different data. The top part will display what data exists in the frame buffer starting at the address specified in the two aforementioned start address registers, while the bottom part will display what data exists in the frame buffer starting at the first byte of the frame buffer.
3	**Vertical Blanking Start Bit 8.** The vertical blanking start is a 10-bit that specifies the beginning of the vertical blanking period relative to the beginning of the active display area. The 8 least significant bits of this value are supplied by bits [7:0] of the Vertical Blanking Start Register (CR15), and the most and second-most significant bits are supplied by bit 5 of the Maximum Scan Line Register (CR09) and this bit of this register, respectively. This 10-bit value should be programmed to be equal to the number of scan lines from the beginning of the active display area to the beginning of the blanking period. Since the active display area always starts on the 0th scan line, this number should be equal to the number of the scan line on which the vertical blanking period begins.
2	**Vertical Sync Start Bit 8.** The vertical sync start is a 10-bit value that specifies the beginning of the vertical sync pulse relative to the beginning of the active display area. The 8 least significant bits of this value are supplied by bits [7:0] of the Vertical Sync Start Register (CR10), and the most and second-most significant bits are supplied by bit 7 and this bit, respectively, of this register. This 10-bit value should be programmed to be equal to the number of scan lines from the beginning of the active display area to the start of the vertical sync pulse. Since the active display area always starts on the 0th scan line, this number should be equal to the number of the scan line on which the vertical sync pulse begins.

Bit	Description
1	**Vertical Display Enable End Bit 8.** The vertical display enable end is a 10-bit value that specifies the number of the last scan line within the active display area. The 8 least significant bits of this value are supplied by bits [7:0] of the Vertical Display Enable End Register (CR12), and the two most significant bits are supplied by bit 6 and this bit, respectively, of this register. This 10-bit or value should be programmed to be equal to the number of the last scan line within in the active display area. Since the active display area always starts on the 0th scan line, this number should be equal to the total number of scan lines within the active display area, minus 1.
0	**Vertical Total Bit 8.** The vertical total is a 10-bit value that specifies the total number of scan lines. This includes the scan lines both inside and outside of the active display area. The 8 least significant bits of this value are supplied by bits [7:0] of the Vertical Total Register (CR06), and the most and second-most significant bits are supplied by bit 5 and this bit, respectively, of this register. This 10-bit value should be programmed to be equal to the total number of scan lines, minus 2.

CR08 - Preset Row Scan Register

I/O (and Memory Offset) Address: 3B5h/3D5h (index=08h)

Default: 0UUU UUUUb (U=Undefined)

Attributes: Read/Write

Bit	Description
7	**Reserved.** Read as 0s.
6:5	**Byte Panning.** This field holds a 2-bit value that selects number of bytes (up to 3) by which the image is shifted horizontally to the left on the screen. This function is available in both text and graphics modes. In text modes with a 9-pixel wide character box, the image can be shifted up to 27 pixels to the left, in increments of 9 pixels. In text modes with an 8-pixel wide character box, and in all standard VGA graphics modes, the image can be shifted up to 24 pixels to the left, in increments of 8 pixels. When the Nine dot disable bit of the VGA control register is set, the pixel shift will be equivalent to the 8-dot mode. The image can be shifted still further, in increments of individual pixels, through the use of bits [3:0] of the Horizontal Pixel Panning Register (AR13).
4:0	**Starting Row Scan Count.** This field specifies which horizontal line of pixels within the character boxes of the characters used on the top-most row of text on the display will be used as the top-most scan line. The horizontal lines of pixels of a character box are numbered from top to bottom, with the top-most line of pixels being number 0. If a horizontal line of the these character boxes other than the top-most line is specified, then the horizontal lines of the character box above the specified line of the character box will not be displayed as part of the top-most row of text characters on the display. Normally, the value specified by these 5 bits should be 0, so that all of the horizontal lines of pixels within these character boxes will be displayed in the top-most row of text, ensuring that the characters in the top-most row of text do not look as though they have been cut off at the top.

Number of Pixels Shifted

Bit [6:5]	9-Pixel Text	8-Pixel Text & Graphics
00	0	0
01	9	8
10	18	16
11	27	24

CR09 - Maximum Scan Line Register

I/O (and Memory Offset) Address: 3B5h/3D5h (index=09h)

Default: 00h

Attributes: Read/Write

Bit	Description
7	**Double Scanning Enable.** 0 = Disable. When disabled, the clock to the row scan counter is equal to the horizontal scan rate. This is the normal setting for many of the standard VGA modes. 1 = Enable. When enabled, the clock to the row scan counter is divided by 2. This is normally used to allow CGA-compatible modes that have only 200 scan lines of active video data to be displayed as 400 scan lines (each scan line is displayed twice).
6	**Line Compare Bit 9.** This bit provides the most significant bit of a 10-bit value that specifies the scan line at which the memory address counter restarts at the value of 0. Bit 4 of the Overflow Register (CR07) supplies the second most significant bit, and bits 7-0 of the Line Compare Register (CR18) supply the 8 least significant bits. Normally, this 10-bit value is set to specify a scan line after the last scan line of the active display area. When this 10-bit value is set to specify a scan line within the active display area, it causes that scan line and all subsequent scan lines in the active display area to display video data starting at the very first byte of the frame buffer. The result is what appears to be a screen split into a top and bottom part, with the image in the top part being repeated in the bottom part. When used in cooperation with the Start Address High Register (CR0C) and the Start Address Low Register (CR0D), it is possible to create a split display, as described earlier, but with the top and bottom parts displaying different data. The top part will display whatever data exists in the frame buffer starting at the address specified in the two aforementioned start address registers, while the bottom part will display whatever data exists in the frame buffer starting at the first byte of the frame buffer.
5	**Vertical Blanking Start Bit 9.** The vertical blanking start is a 10-bit value that specifies the beginning of the vertical blanking period relative to the beginning of the active display area. The 8 least significant bits of this value are supplied by bits [7:0] of the Vertical Blanking Start Register (CR15), and the most and second-most significant bits are supplied by this bit and bit 3 of the Overflow Register (CR07), respectively. This 10-bit value should be programmed to be equal to the number of scan line from the beginning of the active display area to the beginning of the blanking period. Since the active display area always starts on the 0th scan line, this number should be equal to the number of the scan line on which the vertical blanking period begins.

Bit	Description
4:0	**Starting Row Scan Count.** This field provides all 5 bits of a 5-bit value that specifies the number of scan lines in a horizontal row of text. This value should be programmed to be equal to the number of scan lines in a horizontal row of text, minus 1.

CR0A - Text Cursor Start Register

I/O (and Memory Offset) Address: 3B5h/3D5h (index=0Ah)

Default: 00UU UUUUb (U=Undefined)

Attributes: Read/Write

Bit	Description
7:6	**Reserved.** Read as 0.
5	**Text Cursor Off.** This text cursor exists only in text modes, so this register is entirely ignored in graphics modes. 0 = Enables the text cursor. 1 = Disables the text cursor.
4:0	**Text Cursor Start.** This field specifies which horizontal line of pixels in a character box is to be used to display the first horizontal line of the cursor in text mode. The horizontal lines of pixels in a character box are numbered from top to bottom, with the top-most line being number 0. The value specified by these 5 bits should be the number of the first horizontal line of pixels on which the cursor is to be shown.

CR0B - Text Cursor End Register

I/O (and Memory Offset) Address: 3B5h/3D5h (index=0Bh)

Default: 0UUU UUUUb (U=Undefined)

Attributes: Read/Write

Bit	Description
7	**Reserved.** Read as 0.
6:5	**Text Cursor Skew.** This field specifies the degree to which the start and end of each horizontal line of pixels making up the cursor is delayed to compensate for internal pipeline delays. These 2 bits describe the delay in terms of a number character clocks. **Bit [6:5]** Amount of Delay 00 = No delay 01 = Delayed by 1 character clock 10 = Delayed by 2 character clocks 11 = Delayed by 3 character clocks
4:0	**Text Cursor End.** This field specifies which horizontal line of pixels in a character box is to be used to display the last horizontal line of the cursor in text mode. The horizontal lines of pixels in a character box are numbered from top to bottom, with the top-most line being number 0. The value specified by these 5 bits should be the number of the last horizontal line of pixels on which the cursor is to be shown.

CR0C - Start Address High Register

I/O (and Memory Offset) Address: 3B5h/3D5h (index=0Ch)

Default: Undefined

Attributes: Read/Write

Bit	Description
7:0	**Start Address Bits [15:8].**This register provides either bits 15 through 8 of a 16-bit value that specifies the memory address offset from the beginning of the frame buffer at which the data to be shown in the active display area begins. (default is 0) In standard VGA modes, the start address is specified with a 16-bit value. The eight bits of this register provide the eight most significant bits of this value, while the eight bits of the Start Address Low Register (CR0D) provide the eight least significant bits.

CR0D - Start Address Low Register

I/O (and Memory Offset) Address: 3B5h/3D5h (index=0Dh)

Default: Undefined

Attributes: Read/Write

Bit	Description
7:0	**Start Address Bits [7:0]** This register provides either bits 7 through 0 of a 16 bit value that specifies the memory address offset from the beginning of the frame buffer at which the data to be shown in the active display area begins. (default is 0) In standard VGA modes the start address is specified with a 16-bit value. The eight bits of the Start Address High Register (CR0C) provide the eight most significant bits of this value, while the eight bits of this register provide the eight least significant bits.

CR0E - Text Cursor Location High Register

I/O (and Memory Offset) Address: 3B5h/3D5h (index=0Eh)

Default: Undefined

Attributes: Read/Write

Bit	Description
7:0	**Text Cursor Location Bits [15:8].** This field provides the 8 most significant bits of a 16-bit value that specifies the address offset from the beginning of the frame buffer at which the text cursor is located. Bit 7:0 of the Text Cursor Location Low Register (CR0F) provide the 8 least significant bits.

CR0F - Text Cursor Location Low Register

I/O (and Memory Offset) Address: 3B5h/3D5h (index=0Fh)

Default: Undefined

Attributes: Read/Write

Bit	Description
7:0	**Text Cursor Location Bits [7:0].** This field provides the 8 least significant bits of a 16-bit value that specifies the address offset from the beginning of the frame buffer at which the text cursor is located. Bits 7:0 of the Text Cursor Location High Register (CR0E) provide the 8 most significant bits.

CR10 - Vertical Sync Start Register

I/O (and Memory Offset) Address: 3B5h/3D5h (index=10h)

Default: Undefined

Attributes: Read/Write

Bit	Description
7:0	**Vertical Sync Start Bits [7:0].** This register provides the 8 least significant bits of a 10-bit that specifies the beginning of the vertical sync pulse relative to the beginning of the active display area of a screen. In standard VGA modes, this value is described in 10 bits with bits [7,2] of the Overflow Register (CR07) supplying the 2 most significant bits. This 10-bit value should equal the vertical sync start in terms of the number of scan lines from the beginning of the active display area to the beginning of the vertical sync pulse. Since the active display area always starts on the 0th scan line, this number should be equal to the number of the scan line on which the vertical sync pulse begins.

CR11 - Vertical Sync End Register

I/O (and Memory Offset) Address: 3B5h/3D5h (index=11h)

Default: 0U00 UUUUb (U=Undefined)

Attributes: Read/Write

Bit	Description
7	**Protect Registers [0:7].** The ability to write to Bit 4 of the Overflow Register (CR07) is not affected by this bit (i.e., bit 4 of the Overflow Register is always writeable). 0 = Enable writes to registers CR[00:07]. (default) 1 = Disable writes to registers CR[00:07].
6	**Reserved.** In the VGA standard, this bit was used to switch between 3 and 5 frame buffer refresh cycles during the time required to draw each horizontal line.
5	**Vertical Interrupt Enable.** This bit is reserved for compatibility only. While this bit may be written or read, it's value will have no effect. VGA does not provide an interrupt signal which would be connected to an input of the system's interrupt controller. Bit 7 of Input Status Register 0 (ST00) originally indicated the status of the vertical retrace interrupt. 0 = Enable the generation of an interrupt at the beginning of each vertical retrace period. 1 = Disable the generation of an interrupt at the beginning of each vertical retrace period.
4	**Vertical Interrupt Clear.** This is reserved for compatibility only. VGA does not provide an interrupt signal which would be connected to an input of the system's interrupt controller. 0 = Setting this bit to 0 clears a pending vertical retrace interrupt. This bit must be set back to 1 to enable the generation of another vertical retrace interrupt.
3:0	**Vertical Sync End.** This 4-bit field provides a 4-bit value that specifies the end of the vertical sync pulse relative to its beginning. This 4-bit value should be set to the least significant 4 bits of the result of adding the length of the vertical sync pulse in terms of the number of scan lines that occur within the length of the vertical sync pulse to the value that specifies the beginning of the vertical sync pulse (see the description of the Vertical Sync Start Register for more details).

CR12 - Vertical Display Enable End Register

I/O (and Memory Offset) Address: 3B5h/3D5h (index=12h)

Default: Undefined

Attributes: Read/Write

Bit	Description
7:0	**Vertical Display Enable End Bits [7:0].** This register provides the 8 least significant bits of a 10-bit value that specifies the number of the last scan line within the active display area. In standard VGA modes, this value is described in 10 bits with bits [6,1] of the Overflow Register (CR07) supplying the two most significant bits. This 10-bit value should be programmed to be equal to the number of the last scan line within in the active display area. Since the active display area always starts on the 0th scan line, this number should be equal to the total number of scan lines within the active display area,minus 1.

CR13 - Offset Register

I/O (and Memory Offset) Address: 3B5h/3D5h (index=13h)

Default: Undefined

Attributes: Read/Write

Bit	Description
7:0	**Offset Bits [7:0].** This register provides either all 8 bits of an 8-bit value that specifies the number of words or DWords of frame buffer memory occupied by each horizontal row of characters. Whether this value is interpreted as the number of words or DWords is determined by the settings of the bits in the Clocking Mode Register (SR01). In standard VGA modes, the offset is described with an 8-bit value, all the bits of which are provided by this register. This 8-bit value should be programmed to be equal to either the number of words or DWords (depending on the setting of the bits in the Clocking Mode Register, SR01) of frame buffer memory that is occupied by each horizontal row of characters.

CR14 - Underline Location Register

I/O (and Memory Offset) Address: 3B5h/3D5h (index=14h)

Default: 0UUU UUUUb (U=Undefined)

Attributes: Read/Write

Bit	Description
7	**Reserved.** Read as 0.
6	**DWord Mode.** 0 = Frame buffer addresses are interpreted by the frame buffer address decoder as being either byte addresses or word addresses, depending on the setting of bit 6 of the CRT Mode Control Register (CR17). 1 = Frame buffer addresses are interpreted by the frame buffer address decoder as being DWord addresses, regardless of the setting of bit 6 of the CRT Mode Control Register (CR17). This bit is used in conjunction with bits 6 and 5 of the CRT Mode Control Register (CR17) to select how frame buffer addresses from the CPU are interpreted by the frame buffer address decoder as shown below: **CR14[6] / CR17[6] / Addressing Mode** 0 / 0 / Word Mode 0 / 1 / Byte Mode 1 / 0 / DWord Mode 1 / 1 / DWord Mode
5	**Count By 4.** 0 = The memory address counter is incremented either every character clock or every other character clock, depending upon the setting of bit 3 of the CRT Mode Control Register. 1 = The memory address counter is incremented either every 4 character clocks or every 2 character clocks, depending upon the setting of bit 3 of the CRT Mode Control Register. . This is used in mode x13 to allow for using all four planes. This bit is used in conjunction with bit 3 of the CRT Mode Control Register (CR17) to select the number of character clocks are required to cause the memory address counter to be incremented as shown, below: **CR14[5] / CR17[3] / Addressing Incrementing Interval** 0 / 0 / every character clock 0 / 1 / every 2 character clocks 1 / 0 / every 4 character clocks 1 / 1 / every 2 character clocks

Bit	Description
4:0	**Underline Location.** This field specifies which horizontal line of pixels in a character box is to be used to display a character underline in text mode. The horizontal lines of pixels in a character box are numbered from top to bottom, with the top-most line being number 0. The value specified by these 5 bits should be the number of the horizontal line on which the character underline mark is to be shown.

CR15 - Vertical Blanking Start Register

I/O (and Memory Offset) Address: 3B5h/3D5h (index=15h)

Default: Undefined

Attributes: Read/Write

Bit	Description
7:0	**Vertical Blanking Start Bits [7:0].** This register provides the 8 least significant bits of a 10-bit value that specifies the beginning of the vertical blanking period relative to the beginning of the active display area of the screen. In standard VGA modes, the vertical blanking start is specified with a 10-bit value. The most and second-most significant bits of this value are supplied by bit 5 of the Maximum Scan Line Register (CR09) and bit 3 of the Overflow Register (CR07), respectively. This 10-bit value should be programmed to be equal the number of scan lines from the beginning of the active display area to the beginning of the vertical blanking period. Since the active display area always starts on the 0th scan line, this number should be equal to the number of the scan line on which vertical blanking begins.

CR16 - Vertical Blanking End Register

I/O (and Memory Offset) Address: 3B5h/3D5h (index=16h)

Default: Undefined

Attributes: Read/Write

This register provides a 8-bit value that specifies the end of the vertical blanking period relative to its beginning.

Bit	Description
7:0	**Vertical Blanking End Bits [7:0].** This 8-bit value should be set equal to the least significant 8 bits of the result of adding the length of the vertical blanking period in terms of the number of scan lines that occur within the length of the vertical blanking period to the value that specifies the beginning of the vertical blanking period (see the description of the Vertical Blanking Start Register for details).

CR17 - CRT Mode Control

I/O (and Memory Offset) Address: 3B5h/3D5h (index=17h)

Default: 0UU0 UUUUb (U=Undefined)

Attributes: Read/Write

Bit	Description
7	**CRT Controller Reset.** This bit has no effect except in native VGA modes (non-centered). 0 = Forces horizontal and vertical sync signals to be inactive. No other registers or outputs are affected. 1 = Permits normal operation.
6	**Word Mode or Byte Mode.** 0 = The memory address counter's output bits are shifted by 1 bit position before being passed on to the frame buffer address decoder such that they are made into word-aligned addresses when bit 6 of the Underline Location Register (CR17) is set to 0. 1 = The memory address counter's output bits remain unshifted before being passed on to the frame buffer address decoder such that they remain byte-aligned addresses when bit 6 of the Underline Location Register (CR17) is set to 0. This bit is used in conjunction with bits 6 and 5 of the CRT Mode Control Register (CR17) to control how frame buffer addresses from the memory address counter are interpreted by the frame buffer address decoder as shown below: CR14[6] CR17[6] **Address Mode** 0 0 Word Mode - Addresses from the memory address counter are shifted once to become word-aligned 0 1 Byte Mode - Addresses from the memory address counter are not shifted 1 0 DWord Mode - Addresses from the memory address counter are shifted twice to become DWord-aligned 1 1 DWord Mode - Addresses from the memory address counter are shifted twice to become DWord-aligned
5	**Address Wrap.** This bit is only effective when word mode is made active by setting bit 6 in both the Underline Location Register and this register to 0. 0 = Wrap frame buffer address at 16 KB. This is used in CGA-compatible modes. 1 = No wrapping of frame buffer addresses.

Bit	Description
4	**Reserved.** Read as 0.
3	**Count By 2.** This bit is used in conjunction with bit 5 of the Underline Location Register (CR14) to select the number of character clocks are required to cause the memory address counter to be incremented. 0 = The memory address counter is incremented either every character clock or every 4 character clocks, depending upon the setting of bit 5 of the Underline Location Register. 1 = The memory address counter is incremented either every other clock. CR14[5] CR17[3] Address Incrementing interval 0 0 every character clock 0 1 every 2 character clocks 1 0 every 4 character clocks 1 1 every 2 character clocks
2	**Horizontal Retrace Select.** This bit provides a way of effectively doubling the vertical resolution by allowing the vertical timing counter to be clocked by the horizontal retrace clock divided by 2 (usually, it would be undivided). 0 = The vertical timing counter is clocked by the horizontal retrace clock. 1 = The vertical timing counter is clocked by the horizontal retrace clock divided by 2.
1	**Select Row Scan Counter.** 0 = A substitution takes place, where bit 14 of the 16-bit memory address generated of the memory address counter (after the stage at which these 16 bits may have already been shifted to accommodate word or DWord addressing) is replaced with bit 1 of the row scan counter at a stage just before this address is presented to the frame buffer address decoder. 1 = No substitution takes place. See following tables.
0	**Compatibility Mode Support.** 0 = A substitution takes place, where bit 13 of the 16-bit memory address generated of the memory address counter (after the stage at which these 16 bits may have already been shifted to accommodate word or DWord addressing) is replaced with bit 0 of the row scan counter at a stage just before this address is presented to the frame buffer address decoder. 1 = No substitution takes place. See following tables.

The following tables show the possible ways in which the address bits from the memory address counter can be shifted and/or reorganized before being presented to the frame buffer address decoder. First, the

address bits generated by the memory address counter are reorganized, if need be, to accommodate byte, word or DWord modes. The resulting reorganized outputs (MAOut15-MAOut0) from the memory address counter may also be further manipulated with the substitution of bits from the row scan counter (RSOut1 and RSOut0) before finally being presented to the input bits of the frame buffer address decoder (FBIn15-FBIn0).

CR18 - Line Compare Register

I/O (and Memory Offset) Address: 3B5h/3D5h (index=18h)

Default: Undefined

Attributes: Read/Write

Bit	Description
7:0	**Line Compare Bits [7:0].** This register provides the 8 least significant bits of a 10-bit value that specifies the scan line at which the memory address counter restarts at the value of 0. Bit 6 of the Maximum Scan Line Register (CR09) supplies the most significant bit, and bit 4 of the Overflow Register (CR07) supplies the second most significant bit. Normally, this 10-bit value is set to specify a scan line after the last scan line of the active display area. When this 10-bit value is set to specify a scan line within the active display area, it causes that scan line and all subsequent scan lines in the active display area to display video data starting at the very first byte of the frame buffer. The result is what appears to be a screen split into a top and bottom part, with the image in the top part being repeated in the bottom part. (This register is only used in split screening modes, and this is not a problem because split screening is not actually used for extended modes. As a result, there is no benefit to extending the existing overflow bits for higher resolutions.) When used in cooperation with the Start Address High Register (CR0C) and the Start Address Low Register (CR0D), it is possible to create a split display, as described earlier, but with the top and bottom parts displaying different data. The top part will display whatever data exists in the frame buffer starting at the address specified in the two aforementioned start address registers, while the bottom part will display whatever data exists in the frame buffer starting at the first byte of the frame buffer.

CR22 - Memory Read Latch Data Register

I/O (and Memory Offset) Address: 3B5h/3D5h (index=22h)

Default: 00h

Attributes: Read Only

Bit	Description
7:0	**Memory Read Latch Data.** This field provides the value currently stored in 1 of the four memory read latches. Bits 1 and 0 of the Read Map Select Register (GR04) select which of the four memory read latches may be read via this register.

CR24 - Toggle State of Attribute Controller Register

I/O (and Memory Offset) Address: 3B5h/3D5h (index=24h)

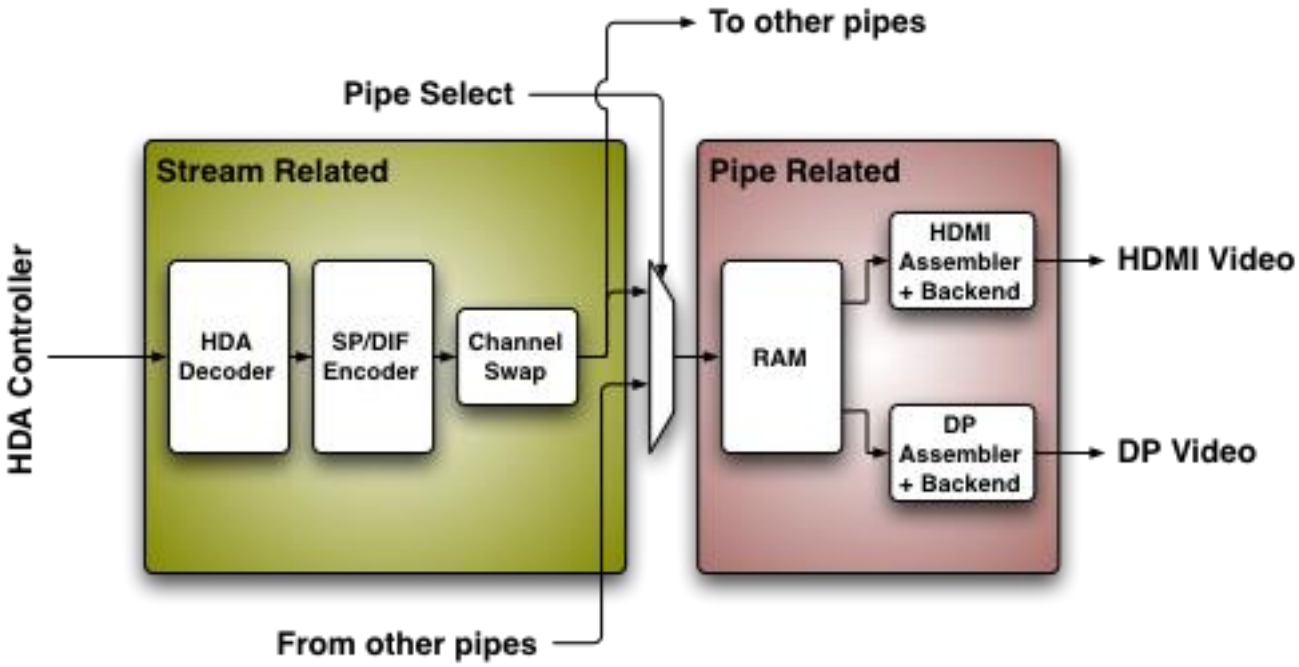
Default: 00h

Attributes: Read Only

Bit	Description
7	**Toggle Status.** Indicates where the last write to attribute register was to: 0 = index port 1 = data port
6:0	**Reserved.** Read as 0.

Display Audio Codec Verbs

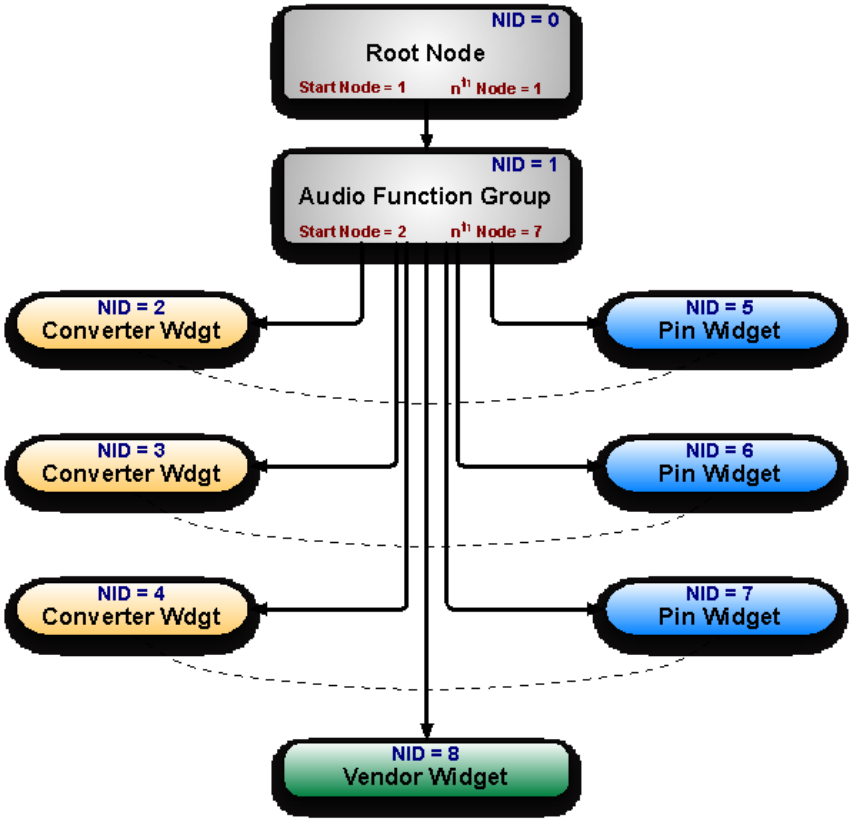
Block Diagram



Codec Node Hierarchy

The diagram below shows the hierarchy of the internal codec. The codec is presented as a single codec with multiple endpoints. By operating as a single codec, only one driver needs to be loaded on the system.

Inside the codec are three "converter widgets" and three "pin widgets", responsible for taking data from HD Audio DMA engines and placing into an HDMI/DP stream. Each pin widget has a 1-1 connection to a converter widget (as indicated by the dotted lines in the diagram).



Programming

Programming of the codec is performed by "verbs" as described in the HD Audio specification. These verbs travel over the internal HD Audio link at a rate of 1 verb per frame. A verb can either come from the CORB, with responses using the RIRB, or using an immediate command and response mechanism (ICR). Device 2 contains its own copy of an ICR mechanism as a back-door into the audio codec.

04h	PARAM_SNC	Subordinate Node Count

Parameter 00h: VID - Vendor ID

Bit	Reset	Description
31:16	8086h	**Vendor ID (VID):** Indicates the 16-bit Vendor ID values used to identify the codec to the PnP subsystem.
15:00	2809h	**Device ID (DID):** Indicates the 16-bit Device ID values used to identify the codec to the PnP subsystem. It is 280Bh for KBL

Parameter 02h: RID - Revision ID

Bit	Reset	Description
31:24	*0*	*Reserved*
23:20	1h	**Major Revision (MJR):** Indicates the major revision number (left of the decimal) of the High Definition Audio Specification to which the codec is fully compliant.
19:16	0h	**Minor Revision (MNR):** Indicates the minor revision number (right of the decimal) or "dot number" of the High Definition Audio Specification to which the codec is fully compliant.
15:08	00h	**Revision ID (RID):** Indicates the vendor's revision number for this given Device ID.
07:00	00h	**Stepping ID (SID):** Indicates optional vendor stepping number within the revision.

Parameter 04h: PARAM_SNC - Subordinate Node Count

Bit	Reset	Description
31:24	*0*	*Reserved*
23:16	0h	**Starting Node Number (SNN):** Indicates the first sub-node's ID is 01h.
15:08	00h	Reserved
07:00	01h	**Total Number of Nodes (TNN):** Indicates one sub-node

F37h GET CCF - Get Current Clock Frequency

Bits	Default	Description
31:6	0	*Reserved*
05	0	**Current Clock 192 MHz (C192)**: Indicates the current clock is 192 MHz. Reserved for Display Codec
04	1	**Current Clock 96 MHz (C96)**: Indicates the current clock is 96 MHz.
03	0	**Current Clock 48 MHz (C48)**: Indicates the current clock is 48 MHz.
02	0	**Current Clock 24 MHz (C24)**: Indicates the current clock is 24 MHz. Reserved for Display Codec
01	0	**Current Clock 12 MHz (C12)**: Indicates the current clock is 12 MHz. Reserved for Display Codec
00	0	**Current Clock 6 MHz (C6)**: Indicates the current clock is 6 MHz. Reserved for Display Codec

Node ID 01h Audio Function Group Verbs

Set Verb	Get Verb	Symbol	Name
-	F00h	GET PARAM	Get Parameters
705h	F05h	SET_PS / GET_PS	Set Power State
-	F20h	GET_SSID	Get Subsystem ID
720h	F20h	SET_SSID0	Set/Get Subsystem ID
721h	F21h	SET_SSID1	Set/Get Subsystem ID
722h	F22h	SET_SSID2	Set//Get Subsystem ID
723h	F23h	SET_SSID3	Set/Get Subsystem ID
724h	F24h	SET CCF	Set/Get Current Clock Frequency

F00h Get Parameters

Parameter	Symbol	Register Name
04h	PARAM_SNC	Subordinate Node Count
05h	PARAM_FGT	Function Group Type
08h	PARAM_FGC	Function Group Capabilities
0Fh	PARAM SPS	Supported Power States

Parameter 04h: PARAM_SNC - Subordinate Node Count

Bit	Reset	Description
31:24	*0*	*Reserved*
23:16	02h	**Start Node Number (SNN):** Indicates the start node number of widget or functional nodes in the Functional Group.
15:08	*0*	*Reserved*
07:00	07h	**Total Number of Nodes (TNN):** Indicates 7 widgets in the Functional Group. (HDMI/DP converters (3) + HDMI/DP pins (3) + Vendor Defined Widget (1)).

Parameter 05h: PARAM_FGT - Function Group Type

Bit	Reset	Description
31:09	*0*	*Reserved*
08	0	**Unsolicited Capable (UC):** Not capable of generating an unsolicited response.
07:00	01h	**Node Type (NT):** Indicates Audio Function Group.

Parameter 08h: PARAM_FGC - Function Group Capability

Bit	Reset	Description
31:04	*0*	*Reserved*
03:00	00h	**Output Delay (OD)**Output Delay.

Parameter 0Fh: PARAM_SPS - Supported Power States

Bit	Reset	Description
31	1	**Extended Power State Supported (EPSS):** Indicates support for low power states
30	1	**Clock Stop (CS):** Indicates support for D3 when clock is stopped.
29:04	*0*	*Reserved*
03	1	**D3 Supported (D3S):** Indicates support for D3.
02	0	**D2 Supported (D2S):** Indicates no support for D2.
01	0	**D1 Supported (D1S):** Indicates no support for D1.
00	1	**D0 Supported (D0S):** Indicates support for D0.

Parameter 16h: PARAM_A2CAP - Azalia 2 Capabilities

Bits	Reset	Description
31:17	*0*	*Reserved*
16	0	**Independent Codec Clock (ICC):** When set, this indicates that the codec generates its own clock, which may drift from the link clock. When cleared, the codec's clock is locked to the link clock.
15:06	*0*	*Reserved*
05	*0*	*Reserved for 192 MHz support.*
04	1	**96MHz Supported (S96):** Indicates 96 MHz clock is supported.
03	1	**48MHz Supported (S48):** Indicates 48 MHz clock is supported.This bit must always be set.
02	0	**24MHz Supported (S24):** Indicates 24 MHz clock is supported. Reserved for Display Codec
01	0	**12MHz Supported (S12):** Indicates 12 MHz clock is supported. Reserved for Display Codec
00	0	**6MHz Supported (S6)**Indicates 6 MHz clock is supported. Reserved for Display Codec

705h SET_PS - Set Power State

Bits	Description
07:02	Reserved
01:00	**Requested Power State (RPS):** Only D0 (00) and D3 (11) may be requested

F05h GET_PS - Get Power State

Bits	Reset	Description
31:11	0	Reserved
10	0	**Settings Reset (SR):** Haswell does not change the default values.
09	1	**Clock Stop OK (CSOK):** Clock stopping in D3 is OK
08	0	**Error (ERR):** No error will ever be reported.
07:06	0	Reserved
05:04	11	**Actual Power State (APS):** Indicates the current power state of the node.
03:02	0	Reserved
01:00	11	**Requested Power State (CPS):** Reflects value written with SET_PS verb.

F20h GET SSID - Get Subsystem ID0

Bits	Reset	Description
31:00	80860101h	**Subsystem ID (SSID):** Reports the sub-system ID set via SET_SSIDx verbs.

720h SET SSID0 - Set Subsystem ID0

Bits	Description
07:00	Subsystem ID Bits [7:0]

721h SET SSID1 - Set Subsystem ID1

Bits	Description
07:00	Subsystem ID Bits [15:8]

722h SET SSID2 - Set Subsystem ID2

Bits	Description
07:00	Subsystem ID Bits [23:16]

723h SET SSID3 - Set Subsystem ID3

Bits	Description
07:00	Subsystem ID Bits [31:24]

724h SET CCF - Set Current Clock Frequency

Bits	Description
07:06	Reserved
05	**Set Clock 192 MHz (S192)**: Set clock to 192 MHz.
04	**Set Clock 96 MHz (S96)**: Set clock to 96 MHz
03	**Set Clock 48 MHz (S48)**: Set clock to 48 MHz
02	**Set Clock 24 MHz (S24)**: Set clock to 24 MHz
01	**Set Clock 12 MHz (S12)**: Set clock to 12 MHz
00	**Set Clock 6 MHz (S6)**: Set clock to 6 MHz

F24h GET CCF - Get Current Clock Frequency

Bits	Bits	Description
31:06	0	*Reserved*
05	0	**Current Clock 192 MHz (C192)**: Indicates the current clock is 192 MHz.
04	0	**Current Clock 96 MHz (C96)**: Indicates the current clock is 96 MHz.
03	0	**Current Clock 48 MHz (C48)**: Indicates the current clock is 48 MHz.
02	0	**Current Clock 24 MHz (C24)**: Indicates the current clock is 24 MHz.
01	0	**Current Clock 12 MHz (C12)**: Indicates the current clock is 12 MHz.
00	0	**Current Clock 6 MHz (C6)**: Indicates the current clock is 6 MHz.

7FFh SET Function Group Reset

Bits	Reset	Description
07:00	00h	The Function Reset command causes the functional unit, and all widgets associated with the functional unit, to return to their power-on reset values. Note that some controls such as the Configuration Default controls should not be reset with this command. It is also possible that certain other controls, such as Caller-ID, should not be reset. This command does not affect the Link interface logic, which must be reset with the link RST# signal. Therefore, a codec must not initiate a Status Change request on the link.

Node ID 02h 03h 04h Audio Output Convertor Widget Verbs

Verb	Symbol	Verb Name
2h	SET_SDF	Set Stream Descriptor Format
Ah	GET_SDF	Get Stream Descriptor Format
F00h	GET_PARAM	Get Parameters
705h	SET_PS	Set Power State
F05h	GET_PS	Get Power State
706h	SET_CSID	Set Channel and Stream ID
F06h	GET_CSID	Get Channel and Stream ID
F0Dh	SET_DC1	Get Digital Converter
70Dh	SET_DC1	Set Digital Converter 1

Verb	Symbol	Verb Name
70Eh	SET_DC2	Set Digital Converter 2
73Eh	SET_DC3	Set Digital Converter 3
73Fh	SET_DC4	Set Digital Converter 4
72Dh	SET_CCC	Set Converter Channel Count
F2Dh	GET_CCC	Get Converter Channel Count

2hAh SETGET_SDF - SetGET Stream Descriptor Format

Bits	Reset	Description
31:15	0	Reserved
14	0	**Sample Base Rate (SBR):**
13:11	000	**Sample Base Rate Multiplier (SBRM):**
10:08	000	**Sample Base Rate Divisor (SBRD):**
07	0	Reserved
06:04	011	**Bits / Sample (BPS):** • 001b: Data is packed in memory in 16 bit containers on 16 bit boundaries • 010b: Data is packed in memory in 20 bit containers on 32 bit boundaries • 011b: Data is packed in memory in 24 bit containers on 24 bit boundaries • 100b: Data is packed in memory in 32 bit containers on 32 bit boundaries All other bit combinations reserved
03:00	1h	**# Channels in Stream (NCS):** 2 channels in each frame

F00h Get Parameters

Parameter	Symbol	Register Name
09h	PARAM_AWC	Audio Widget Capabilities
0Ah	PARAM_PSB	Parameter Sizes and Bit Rates
0Bh	PARAM_SF	Stream Formats
0Fh	PARAM_SPS	Power Supported States

Parameter 09h: AWC - Audio Widget Capabilities

Bits	Reset	Description
31:24	0	Reserved
23:20	0h	**Widget Type (TYPE):** Indicates this is an audio output widget
19:16		Sample Delay in Widget (DELAY):
15:13	011	**Channel Count Extension (CCE):** These three bits, combined with STRO, indicate that there are 8 channels supported.
11	0	**L-R Swap (LRS):** Indicates no left/right channel swap.
10	1	**Power Control (PC):** Indicates power state control
09	1	**Digital (DIG):** Indicates support for digital streams.
08	0	**Connection List (CL):** Indicates no connection list
07	0	**Unsolicited Capable (UC):** Indicates support for unsolicited responses.
06	0	**Processing Widget (PW):** Indicates no support for processing
05	0	**Stripe (STRP):** Indicates striping not supported.
04	1	**Format Override (FO):** Indicates support for formatting
03	1	**Amp Parameter Override (APO):** Indicates no amplifier support.
02	0	**Out Amp Present (OAP):** Indicates no output amplifier present.
01	0	**In Amp Present (IAP):** Indicates no input amplifier present.
00	1	**Stereo (STRO):** Indicates a stereo widget

Parameter 0Ah: PSB - PCM Sizes and Bit Rates

Bits	Reset	Description
31:21	0	*Reserved*
20	1	**32-bit Support (B32):** Indicates 32-bit samples supported
19	1	**24-bit Support (B24):** Indicates 24-bit samples supported
18	0	**20-bit Support (B20):** Indicates 20-bit samples supported
17	1	**16-bit Support (B16):** Indicates 16-bit samples supported
16	0	**8-bit Support (B8):** Indicates 8-bit samples not supported
15:12	0	*Reserved*
11	0	**384 kHz Support (R12):** Indicates 384 kHz not supported
10	1	**192 kHz Support (R11):** Indicates 192 kHz supported
09	1	**176.4 kHz Support (R10):** Indicates 176.4 kHz supported
08	1	**96 kHz Support (R9):** Indicates 96 kHz supported
07	1	**88.2 kHz Support (R8):** Indicates 88.2 kHz supported
06	1	**48 kHz Support (R7):** Indicates 48 kHz supported
05	1	**44.1 kHz Support (R6):** Indicates 44.1 kHz supported
04	1	**32 kHz Support (R5):** Indicates 32 kHz supported
03	0	**22.05 kHz Support (R4):** Indicates 22.05 kHz not supported
02	0	**16 kHz Support (R3):** Indicates 16 kHz not supported
01	0	**11.025 kHz Support (R2):** Indicates 11.025 kHz not supported
00	0	**8 kHz Support (R1):** Indicates 8 kHz not supported

Parameter 0Bh: SF - Stream Formats

Bits	Reset	Description
31:03	0	*Reserved*
02	1	**AC3 Support (AC3):** Indicates AC3 stream format is supported
01	0	**Float32 Support (F32):** Indicates float32 stream format not supported
00	1	**PCM Support (PCM):** Indicates PCM format is supported.

Parameter 0Fh: PARAM_SPS - Supported Power States

Bit	Reset	Description
31	1	**Extended Power State Supported (EPSS):** Indicates support for low power states
30:04	0	*Reserved*
03	1	**D3 Supported (D3S):** Indicates support for D3.
02	0	**D2 Supported (D2S):** Indicates no support for D2.
01	0	**D1 Supported (D1S):** Indicates no support for D1.
00	1	**D0 Supported (D0S):** Indicates support for D0.

705h SET_PS - Set Power State

Bits	Description
07:02	Reserved
01:00	**Requested Power State (RPS):** Only D0 (00) and D3 (11) may be requested

F05h GET_PS - Get Power State

Bits	Reset	Description
31:11	0	Reserved
10	0	**Settings Reset (SR):** ???
09	0	**Clock Stop OK (CSOK):** Clock stopping in D3 is not OK

Bits	Reset	Description
08	0	**Error (ERR):** No error will ever be reported.
07:06	0	Reserved
05:04	11	**Actual Power State (APS):** Indicates the current power state of the node.
03:02	0	Reserved
01:00	11	**Requested Power State (CPS):** Reflects value written with SET_PS verb.

706hF06h GETSET_CSID - GetSet Channel and Stream ID

Bits	Reset	Description
07:04	0h	**Stream ID (SID):** Link stream used by the converter for data output.
03:00	0h	**Lowest Channel Number (LCN):** Lowest channel used by the converter.

Digital Converter Verbs

F0Dh: GET_DC - Get Digital Converter

Bits	Reset	Description
31:24	0	Reserved
23	1	**Keep Alive (KA):** See SET_DC3.KA
22:20	0	Reserved
19:16	0h	**IEC Coding Type (ICT):** See SET_DC3.ICT
15	0	Reserved
14:08	00h	**Category Code (CC):** See SET_DC1.CC
07	0	**Level (LVL):** See SET_DC1.LVL
06	0	**Professional (PRO):** See SET_DC1.PRO
05	0	**Audio is not PCM (AUDIO):** See SET_DC1.AUDIO
04	0	**Copyright (COPY):** See SET_DC1.COPY
03	0	**Pre-emphasis (PRE):** See SET_DC1.PRE

Bits	Reset	Description
02	0	**Validity Configuration (VCFG):** See SET_DC1.VCFG
01	0	**Validity (V):** See SET_DC1.V
00	1	**Digital Enable (DIGEN):** See SET_DC1.DIGEN

70Dh: SET_DC1 - Set Digital Converter 1

Bits	Description
07	**Level (LVL):** S/PDIF IEC Generation Level.
06	**Professional (PRO):** When set, indicates professional use of channel.
05	**Audio is not PCM (AUDIO):** When set, data is non-PCM format.
04	**Copyright (COPY):** When set, copyright asserted.
03	**Pre-emphasis (PRE):** When set, enables filter pre-emphasis.
02	**Validity Configuration (VCFG):** Determines S/PDIF transmitter behavior when data is not being transmitted.
01	**Validity (V):** Affects the validity flag transmitted in each sub-frame, and enables S/PDIF transmitter to maintain connection during error or mute conditions.
00	**Digital Enable (DIGEN):** When set, enables digital content

70Eh: Digital Converter 2

Bits	Description
07	Reserved
06:00	**Category Code (CC):** S/PDIF IEC Category Code.

73Eh: Digital Converter 3

Bits	Description
07	Keep Alive
06:04	Reserved
03:00	IEC Coding Type

73Fh: Digital Converter 4

Bits	Description
07:00	Reserved

72DhF2Dh GETSET_CCC - GetSet Converter Channel Count

Bits	Reset	Description
07:04	0	Reserved
03:00	0000	Converter Channel Count 1 (0th order)

Node ID 05h 06h 07h Pin Widget Verbs

Set Verb	Get Verb	Symbol	Verb Name

73Ch	F3Ch	SET_DPID / GET_DPID	Set/Get DisplayPort Stream ID

3h SET_AM - Set Amplifier Mute

Bits	Bits	Description
15	0	**Set Output Amp (SOA):**.
14	0	**Set Input Amp (SIA):**.
13	0	**Set Left Amp (SLA):**.
12	0	**Set Right Amp (SRA):**.
11:08	0h	**Index (IDX):**
07	1	**Mute (MUTE):** When set, amp muted.
06:00	0	*Reserved*

B8h GET_AM - Get Amplifier Mute

Bits	Bits	Description
31:08	0	*Reserved*
07	1	**Mute (MUTE):** When set, amp muted.
06:00	0	*Reserved*

F00h Get Parameters

Parameter	Symbol	Register Name
09h	PARAM_AWC	Audio Widget Capabilities
0Ch	PARAM_PC	Pin Capabilities
0Eh	PARAM_CLL	Connection List Length
12h	PARAM OAC	Output Amplifier Capabilities
15h	PARAM_DLL	Device List Length
0Fh	PARAM_SPS	Supported Power States

Parameter 09h: AWC - Audio Widget Capabilities

Bits	Reset	Description
31:24	0	Reserved
23:20	4h	**Widget Type (TYPE):** Indicates this is a pin complex widget
19:16	0	**Sample Delay in Widget (DELAY):** No delay through the pin widget.
15:13	011	**Channel Count Extension (CCE):** This field, combined with STRO, indicate 8 channels supported.
11	0	**L-R Swap (LRS):** Indicates no left/right channel swap.
10	1	**Power Control (PC):** Indicates power state control
09	1	**Digital (DIG):** Indicates support for digital streams.
08	1	**Connection List (CL):** Indicates a connection list
07	1	**Unsolicited Capable (UC):** Indicates support for unsolicited responses.
06	0	**Processing Widget (PW):** Indicates no support for processing
05	0	**Stripe (STRP):** Indicates striping not supported.
04	0	**Format Override (FO):** Indicates no support for formatting
03	1	**Amp Parameter Override (APO):** Indicates no amplifier override support.
02	1	**Out Amp Present (OAP):** Indicates no output amplifier present.
01	0	**In Amp Present (IAP):** Indicates no input amplifier present.
00	1	**Stereo (STRO):** Indicates a stereo widget

Parameter 0Ch: PC - Pin Capabilities

Bits	Reset	Description
31:28	0	*Reserved*
27	1	**High Bit Rate (HBR):** Indicates support for high bit-rate audio

Bits	Reset	Description
26	0	*Reserved*
25	1	**Multi Stream Capable (MSC):** Indicates support for DisplayPort Multistream. Will be zero in vanilla mode.
24	1	**DisplayPort (DP):** Indicates support for DisplayPort
23:08	0	*Reserved*
07	1	**HDMI (HDMI):** Indicates support for HDMI
06:05	0	*Reserved*
04	1	**Output Capable (OC):** Pin is output capable
03	0	*Reserved*
02	1	**Presence Detect Capable (PDC):** Indicates capability for presence detection
01:00	0	*Reserved*

Parameter 0Eh: CLL - Connection List Length

Bits	Reset	Description
31:08	0	*Reserved*
07	0	**Long Form (LF):** Indicates connection list is short form
06:00	03h	**Length (LEN):** Indicates there is one item in the connection list.

Parameter 12h: OAC - Output Amplifier Capabilities

Bits	Reset	Description
31	1	**Mute Capable (MC):** Muting is capable on this pin
30:00	0	Reserved

Parameter 15h: DLL - Device List Length

Bits	Reset	Description
31:06	0	*Reserved*
05:00	00h	**Length (LEN):** Indicates no devices

Parameter 0Fh: PARAM_SPS - Supported Power States

Bit	Reset	Description
31	1	**Extended Power State Supported (EPSS):** Indicates support for low power states
30:04	0	*Reserved*
03	1	**D3 Supported (D3S):** Indicates support for D3.
02	0	**D2 Supported (D2S):** Indicates no support for D2.
01	0	**D1 Supported (D1S):** Indicates no support for D1.
00	1	**D0 Supported (D0S):** Indicates support for D0.

701hF01h SETGET_CSC - SetGet Connection Select Control

Bits	Reset	Description
07:00	00h	**Connection Select Control (CSC):**

F02h GET_CLE - Get Connection List Entry

Bits	Reset	Description
31:08	0	Reserved
07:00	Varies	**Connection List Entry (CLE):** 02h for NodeID 05h, 03h for NodeID 06h, and 04h for NodeID 07h.

705h SET_PS - Set Power State

Bits	Description
07:02	Reserved
01:00	**Requested Power State (RPS):** Only D0 (00) and D3 (11) may be requested

F05h GET_PS - Get Power State

Bits	Reset	Description
31:11	0	Reserved
10	0	**Settings Reset (SR):** Haswell does not change the default values.
09	0	**Clock Stop OK (CSOK):** Clock stopping in D3 is not OK
08	0	**Error (ERR):** No error will ever be reported.
07:06	0	Reserved
05:04	11	**Actual Power State (APS):** Indicates the current power state of the node.
03:02	0	Reserved
01:00	11	**Requested Power State (CPS):** Reflects value written with SET_PS verb.

707hF07h SETGET_PWC - SetGet Pin Widget Control

Bits	Reset	Description
07	0	Reserved
06	1	**Out Enable (OE):** When set, the audio is enabled
05:02	0	Reserved
01:00	00	**Encoded Packet Type (EPT):**

708hF08h SETGET_UE - SetGet Unsolicited Enable

Bits	Description
07	**Unsolicited Enable (UE):** When set, unsolicited responses are allowed
06	Reserved
05:00	**Tag (TAG):**

F09h GET_PS - Get Pin Sense

Bits	Reset	Description
31	0	**Presence Detect (PD):** When set presence is detected on this pin.
30	0	**ELD Value (ELDV):**
29	0	**Inactive (INA):**
28:00	28:00	Reserved

71Ch SET_CD0 - Set Configuration Default Byte 0

Bits	Description
07:04	Default Association (DA):
03:00	Sequence (SEQ):

71Dh SET_CD1 - Set Configuration Default Byte 1

Bits	Description
07:04	Color (COL):
03:00	Miscellaneous (MISC):

71Eh SET_CD2 - Set Configuration Default Byte 2

Bits	Description
07:04	Default Device (DD):
03:00	Connection Type (CT):

71Fh SET_CD3 - Set Configuration Default Byte 3

Bits	Description
07:06	**Port Connectivity (PC):** External connectivity of the pin complex. • 00 = Connected to jack • 01 = No physical connection • 10 = Fixed function device (integrated speaker, mic, etc.) • 11 = Both a jack and internal connection
05:00	**Location (LOC):**

Bits	Description

	Bits 3:0										
Bits 5:4	0h: N/A	1h: Rear	2h: Front	3h: Left	4h: Right	5h: Top	6h: Bottom	7h: Special	8h: Special	9h: Special	Ah-Fh Reserved
00: External	Y	Y	Y	Y	Y	Y	Y	Y	Y		
01: Internal	Y							Y	Y	Y	
10: Separate Chassis	Y	Y	Y	Y	Y	Y	Y				
11: Other	Y						Y	Y	Y		

F1Ch GET_CD - Get Configuration Default

Bits	Description
31:30	**Port Connectivity (PC):** See SET_CD3.PC
29:24	**Location (L):** See SET_CD3.L
23:20	**Default Device (DD):** See Set_CD2.DD
19:16	**Connection Type (CT):** See Set_CD2.CT
15:12	**Color (COL):** See SET_CD1.COL
11:08	**Miscellaneous (MISC):** See SET_CD1.MISC
07:04	**Default Association (DA):** See SET_CD0.DA
03:00	**Sequence (SEQ):** See SET_CD0.SEQ

F2Eh HDMIDP Info Size

Bits	Reset	Description
31:08	0	Reset
07:00	Varies	**Size (SZ):** Indexes 0 - 3 return 1Eh, index 1000 returns 53h, others reserved.

F2Fh Get ELD Data

Parameter	Symbol	Register Name
07:0h	PARAM_INDX	ELD DATA Index

Parameter nn: ELD Data

Bits	Reset	Description
31:00	0	ELD Data

730hF30h SETGET_HII - SetGet HDMI Info Index

Bits	Reset	Description
07:05	000	**Infoframe Packet Index (IPI):** Value / Name / Value / Name 000 / Audio / 011 / GP3 001 / GP / 100 / GP4 010 / GP2 / Others / Reserved
04:00	00h	**Byte Offset Index Pointer (BOI):**

731hF31h SETGET_HID - SetGet HDMI Info Data

Bits	Reset	Description
07:00	00h	**Data (DATA):** Data at current index pointed to from SET_HII verb.

732hF32h SETGET_HITC - SetGet HDMI Info Transmit Control

Bits	Reset	Description
07:06	00	**InfoFrame Control Current Indexed Frame (IFCCIF):** • 00 = Disable Transmit • 01 = Reserved • 10 = Transmit Once • 11 = Best Effort
05:00	0	*Reserved*

733h SET_PC - Set Protection Control

Bits	Description
07:03	**Unsolicited Response Sub Tag (URST):** Subtag to use for unsolicited responsed.
02	Reserved

734hF34h SETGET_CCM - GetSet Converter Channel Map

Bits	Reset	Description
07:04	0h	Converter Channel (CC):
03:00	0h	Slot (SN):

735h SET_DS - Set Device Select

Bits	Reset	Description
07:06	0	*Reserved*
05:00	00h	**Device (D):** 000001, 000010 (based upon number of devices present)

F35h: GET_DS - Get Device Select

Bits	Description
31:12	**Reserved:** Set to 0
11:06	**SinK Device ID:** Sink Device ID in the multi stream topology of the DP hierarchy. Device attached to Pipe A will have ID of "00000", PipeB will have "00001" and Pipe C will have "00010".
05:00	**Device (D):**Device Entry index currently set

F36h GET_DDLE - Get Display Device List Entry

Bits	Bits	Description
31:12	0	*Reserved*
11	0	**Reserved?**
10	0	**IA of Entry 2**
09	0	**ELDV of Entry 2**

Bits	Bits	Description
08	0	**PD of Entry 2**
07	0	**Reserved?**
06	0	**IA of Entry 1**
05	0	**ELDV of Entry 1**
04	0	**PD of Entry 1**
03	0	**Reserved?**
02	0	**IA of Entry 0**
01	0	**ELDV of Entry 0**
00	0	**PD of Entry 0**

73ChF3Ch SETGET_DPID - SetGet DisplayPort Stream ID

Bits	Reset	Description
07:03	00h	**Tag (TAG):** Represents the SSID that will go in the lower 5 bits of the SSID
02:00	000	**Index (IDX):** Pointer to program multiple SSID

Node ID 08h Intel Vendor Widget Verbs

Set Verb	Get Verb	Symbol	Verb Name
-	F00h	GET_PARAM	Get Parameters
-	F80h	GET_HDPS	Get HDMI/DP Status
781h	F81h	SET_HVV / GET_HVV	Set/Get iDisp Codec Vendor Verb
782h	-	SET_GTCT	Set GTC Trigger
-	F83h	GET_CWC	Get Captured Wall Clock
	F84h	GET_CGTC	Get Captured GTC Value
	F85h	GET_GOF	Get GTC Offset Value
785h	-	SET_GOF0	Set GTC Offset Value Byte 0
786h	-	SET_GOF1	Set GTC Offset Value Byte 1
787h	-	SET_GOF2	Set GTC Offset Value Byte 2
788h	-	SET_GOF3	Set GTC Offset Value Byte 3

Set Verb	Get Verb	Symbol	Verb Name
789h	F89h	SET_GDI / GET_GDI	Set/Get GTC Offset Device Index

F00h Get Parameters

Parameter	Symbol	Register Name
09h	PARAM_AWC	Audio Widget Capabilities

Parameter 09h: AWC - Audio Widget Capabilities

Bits	Reset	Description
31:24	0	Reserved
23:20	Fh	**Widget Type (TYPE):** Indicates this is a vendor defined widget
19:00	0	Reserved

71Eh SET_GET_GFXMAILBOX - Set Get GFX MAILBOX Byte 2

71Eh: SET GFX MAILBOXM

Bits	Default	Description
07:00	00	Contents to be defined by GFX driver and audio driver

F1Eh: GET GFX MAILBOX

Bits	Default	Description
31:24	00h	Other values of 71F, verbs
23:16	00h	Contents to be defined by GFX driver and audio driver
15:00	0000h	Other values of 71D, 71C verb

728h SET CLOCK OFF - Set Clock Off Command

Bits	Description
07:00	Data is Irrelevant

708hF08h SETGET_UE - SetGet Unsolicited Enable

Bits	Description
07	**Unsolicited Enable (UE):** When set, unsolicited responses from GFX MAIL BOX register writes are allowed.
06	Reserved
05:00	**Tag (TAG):** Tag for GFX Mail box register unsol responses.

781hF81h GETSET_VV - GetSet iDisp Codec Vendor Verb

Bits	Bits	Description
07:06	0	**Port Select:** This filed is programmed to select the port to be exposed to the inbox driver in the vanilla mode. Will not reset on double function group reset. 00 -> Port B 01 -> Port C 10 -> Port D 11 -> Reserved
05:04	0	**Reserved**
03	0	**Enable WFA:** When Set, WFA mode is enabled**.** Will not reset on double function group reset.
02	0	**Reserved**
01	0	**Enable DP1.2 Features (EDP12):** When set, DP1.2 features are enabled.Will not reset on double function group reset.
00	0	**Enable 3rd Pin and Converter Widget (E3P):** When set, the second and third pin and converter widget is enabled and can respond to HD Audio Verbs. When cleared, the second and third pin and converter widget is disabled and cannot respond to HD Audio verbs.Will not reset on double function group reset.

782h SET_GTCT - Set GTC Trigger

Bits	Bits	Description
07:00	0	**Any data:** The value of this field is irrelevant. The access of the SET causes a capture to occur.

F83h GET_CGTC - Get Captured GTC Value

Bits	Bits	Description
07	0	**GTC Value:** 32-bit GTC value captured on the SET_GTCT verb

F84h GET_CWC - Get Captured Wall Clock Value

Bits	Bits	Description
31:00	0	**Wall Clock Value:** 32-bit wall clock value captured on the SET_GTCT verb

F85h GET GOF - Get GTC Offset Value

Bits	Reset	Description
31:00	0h	**Value (VAL):** Reports the GTC Offset Value.

785h SET GOF0 - Set GTC Offset Value Byte 0

Bits	Description
07:00	GTC Offset Value Bits [7:0]

786h SET GOF1 - Set GTC Offset Value Byte 1

Bits	Description
07:00	GTC Offset Value Bits [15:8]

787h SET GOF2 - Set GTC Offset Value Byte 2

Bits	Description
07:00	GTC Offset Value Bits [23:16]

788h SET GOF3 - GTC Offset Value Byte 3

Bits	Description
07:00	GTC Offset Value Bits [31:24]

789hF89h SETGET_GDI - SetGet GTC Device Index

Bits	Reset	Description
07:06	0	*Reserved*
05:00	00h	**Device (D):** 000001, 000010 (based upon number of devices present) This is the pipe based. 000000 i s pipeA and so on and so forth.

3h SET_AM - Set Amplifier Mute

Bits	Bits	Description
15	0	**Set Output Amp (SOA):**.
14	0	**Set Input Amp (SIA):**.

Bits	Bits	Description
13	0	**Set Left Amp (SLA):**.
12	0	**Set Right Amp (SRA):**.
11:08	0h	**Index (IDX):**
07	1	**Mute (MUTE):** When set, amp muted.
06:00	0	*Reserved*

B8h GET_AM - Get Amplifier Mute

Bits	Bits	Description
31:08	0	*Reserved*
07	1	**Mute (MUTE):** When set, amp muted.
06:00	0	*Reserved*

F00h Get Parameters

Parameter	Symbol	Register Name
09h	PARAM_AWC	Audio Widget Capabilities
0Ch	PARAM_PC	Pin Capabilities
0Eh	PARAM_CLL	Connection List Length
12h	PARAM OAC	Output Amplifier Capabilities
0Fh	PARAM_PS	Suppoted Power States

Parameter 09h: AWC - Audio Widget Capabilities

Bits	Reset	Description
31:24	0	Reserved
23:20	4h	**Widget Type (TYPE):** Indicates this is a pin complex widget
19:16	0	**Sample Delay in Widget (DELAY):** No delay through the pin widget.
15:13	011	**Channel Count Extension (CCE):** This field, combined with STRO, indicate 8 channels supported.

Bits	Reset	Description
11	0	**L-R Swap (LRS):** Indicates no left/right channel swap.
10	1	**Power Control (PC):** Indicates power state control
09	1	**Digital (DIG):** Indicates support for digital streams.
08	1	**Connection List (CL):** Indicates a connection list
07	1	**Unsolicited Capable (UC):** Indicates support for unsolicited responses.
06	0	**Processing Widget (PW):** Indicates no support for processing
05	0	**Stripe (STRP):** Indicates striping not supported.
04	0	**Format Override (FO):** Indicates no support for formatting
03	1	**Amp Parameter Override (APO):** Indicates no amplifier override support.
02	1	**Out Amp Present (OAP):** Indicates no output amplifier present.
01	0	**In Amp Present (IAP):** Indicates no input amplifier present.
00	1	**Stereo (STRO):** Indicates a stereo widget

Parameter 0Ch: PC - Pin Capabilities

Bits	Reset	Description
31:28	0	*Reserved*
27	1	**High Bit Rate (HBR):** Indicates support for high bit-rate audio
26	0	*Reserved*
25	0	*MST capable (DP1.2)*
24	1	**DisplayPort (DP):** Indicates support for DisplayPort
23:08	0	*Reserved*
07	1	**HDMI (HDMI):** Indicates support for HDMI

Bits	Reset	Description
06:05	0	*Reserved*
04	1	**Output Capable (OC):** Pin is output capable
03	0	*Reserved*
02	1	**Presence Detect Capable (PDC):** Indicates capability for presence detection
01:00	0	*Reserved*

Parameter 0Eh: CLL - Connection List Length

Bits	Reset	Description
31:08	0	*Reserved*
07	0	**Long Form (LF):** Indicates connection list is short form
06:00	03h	**Length (LEN):** Indicates there is one item in the connection list.

Parameter 12h: OAC - Output Amplifier Capabilities

Bits	Reset	Description
31	1	**Mute Capable (MC):** Muting is capable on this pin
30:00	0	Reserved

Parameter 0Fh: PARAM_SPS - Supported Power States

Bit	Reset	Description
31	1	**Extended Power State Supported (EPSS):** Indicates support for low power states
30:04	0	*Reserved*
03	1	**D3 Supported (D3S):** Indicates support for D3.
02	0	**D2 Supported (D2S):** Indicates no support for D2.
01	0	**D1 Supported (D1S):** Indicates no support for D1.

Bit	Reset	Description
00	1	**D0 Supported (D0S):** Indicates support for D0.

701hF01h SETGET_CSC - SetGet Connection Select Control

Bits	Reset	Description
07:00	00h	**Connection Select Control (CSC)**

F02h GET_CLE - Get Connection List Entry

Bits	Reset	Description
31:24	0	Reserved
23:16	100	**Connection List Entry (CLE):** Hardwired to Converter ID 4
15:08	011	**Connection List Entry (CLE)**: Hardwired to Converter ID 3
07:00	010	**Connection List Entry (CLE)**: Hardwired to Converter ID 2

705h SET_PS - Set Power State

Bits	Description
07:02	Reserved
01:00	**Requested Power State (RPS):** Only D0 (00) and D3 (11) may be requested

F05h GET_PS - Get Power State

Bits	Reset	Description
31:11	0	Reserved
10	0	**Settings Reset (SR):** Haswell does not change the default values.
09	0	**Clock Stop OK (CSOK):** Clock stopping in D3 is not OK
08	0	**Error (ERR):** No error will ever be reported.
07:06	0	Reserved
05:04	11	**Actual Power State (APS):** Indicates the current power state of the node.

Bits	Reset	Description
03:02	0	Reserved
01:00	11	**Requested Power State (CPS):** Reflects value written with SET_PS verb.

707hF07h SETGET_PWC - SetGet Pin Widget Control

Bits	Reset	Description
07	0	Reserved
06	1	**Out Enable (OE):** When set, the audio is enabled
05:02	0	Reserved
01:00	00	**Encoded Packet Type (EPT)**

708hF08h SETGET_UE - SetGet Unsolicited Enable

Bits	Description
07	**Unsolicited Enable (UE):** When set, unsolicited responses are allowed
06	Reserved
05:00	**Tag (TAG)**

F09h GET_PS - Get Pin Sense

Bits	Reset	Description
31	0	**Presence Detect (PD):** When set presence is detected on this pin.
30	0	**ELD Value (ELDV)**
29	0	**Inactive (INA)**
28:00	28:00	Reserved

71Ch SET_CD0 - Set Configuration Default Byte 0

Bits	Description
07:04	**Default Association (DA)**
03:00	**Sequence (SEQ)**

71Dh SET_CD1 - Set Configuration Default Byte 1

Bits	Description
07:04	**Color (COL)**
03:00	**Miscellaneous (MISC)**

71Eh SET_CD2 - Set Configuration Default Byte 2

Bits	Description
07:04	**Default Device (DD)**
03:00	**Connection Type (CT)**

71Fh SET_CD3 - Set Configuration Default Byte 3

<table>
<tr><th>Bits</th><th>Description</th></tr>
<tr><td>07:06</td><td>Port Connectivity (PC): External connectivity of the pin complex.
00 = Connected to jack
01 = No physical connection
10 = Fixed function device (integrated speaker, mic, etc.)
11 = Both a jack and internal connection</td></tr>
<tr><td>05:00</td><td>Location (LOC):

<tr><td></td><td></td></tr>
</table>

F1Ch GET_CD - Get Configuration Default

Bits	Description
31:30	**Port Connectivity (PC):** See SET_CD3.PC
29:24	**Location (L):** See SET_CD3.L
23:20	**Default Device (DD):** See Set_CD2.DD
19:16	**Connection Type (CT):** See Set_CD2.CT
15:12	**Color (COL):** See SET_CD1.COL
11:08	**Miscellaneous (MISC):** See SET_CD1.MISC
07:04	**Default Association (DA):** See SET_CD0.DA
03:00	**Sequence (SEQ):** See SET_CD0.SEQ

F2Fh Get ELD Data

Parameter	Symbol	Register Name
07:0h	PARAM_INDX	ELD DATA Index

Parameter nn: ELD Data

Bits	Reset	Description
31:00	0	ELD Data

733h SET_PC - Set Protection Control

Bits	Description
07:03	**Unsolicited Response Sub Tag (URST):** Subtag to use for unsolicited responsed.
02	Reserved

734hF34h SETGET_CCM - GetSet Converter Channel Map

Bits	Reset	Description
07:04	0h	**Converter Channel (CC)**
03:00	0h	**Slot (SN)**

740hF40h SETGET PTS Offset Byte0

Bits	Reset	Description
07:00	00h	**PTS B0(PTSB0):** Bits 7:0 of the 32 bit 2's complement offset value. Should be added to the PTS value before sending to the circular buffer in the PES packet. Get verb will give the 32 bits value

741hF41h SETGET PTS Offset Byte1

Bits	Reset	Description
07:00	00h	**PTS B1(PTSB1):** Bits 15:8 of the 32 bit 2's complement offset value. Should be added to the PTS value before sending to the circular buffer in the PES packet. Get verb will give the 32 bits value

742hF42h SETGET PTS Offset Byte2

Bits	Reset	Description
07:00	00h	**PTS B2(PTSB2):** Bits 23:16 of the 32 bit 2's complement offset value. Should be added to the PTS value before sending to the circular buffer in the PES packet. Get verb will give the 32 bits value

743hF43h SETGET PTS Offset Byte3

Bits	Reset	Description
07:00	00h	**PTS B3(PTSB3):** Bits 31:24 of the 32 bit 2's complement offset value. Should be added to the PTS value before sending to the circular buffer in the PES packet. Get verb will give the 32 bits value

North Display Engine Registers

This chapter contains the register descriptions for the display portion of a family of graphics devices.

These registers vary by devices within the family of devices, so special attention needs to be paid to which devices use which registers and register fields.

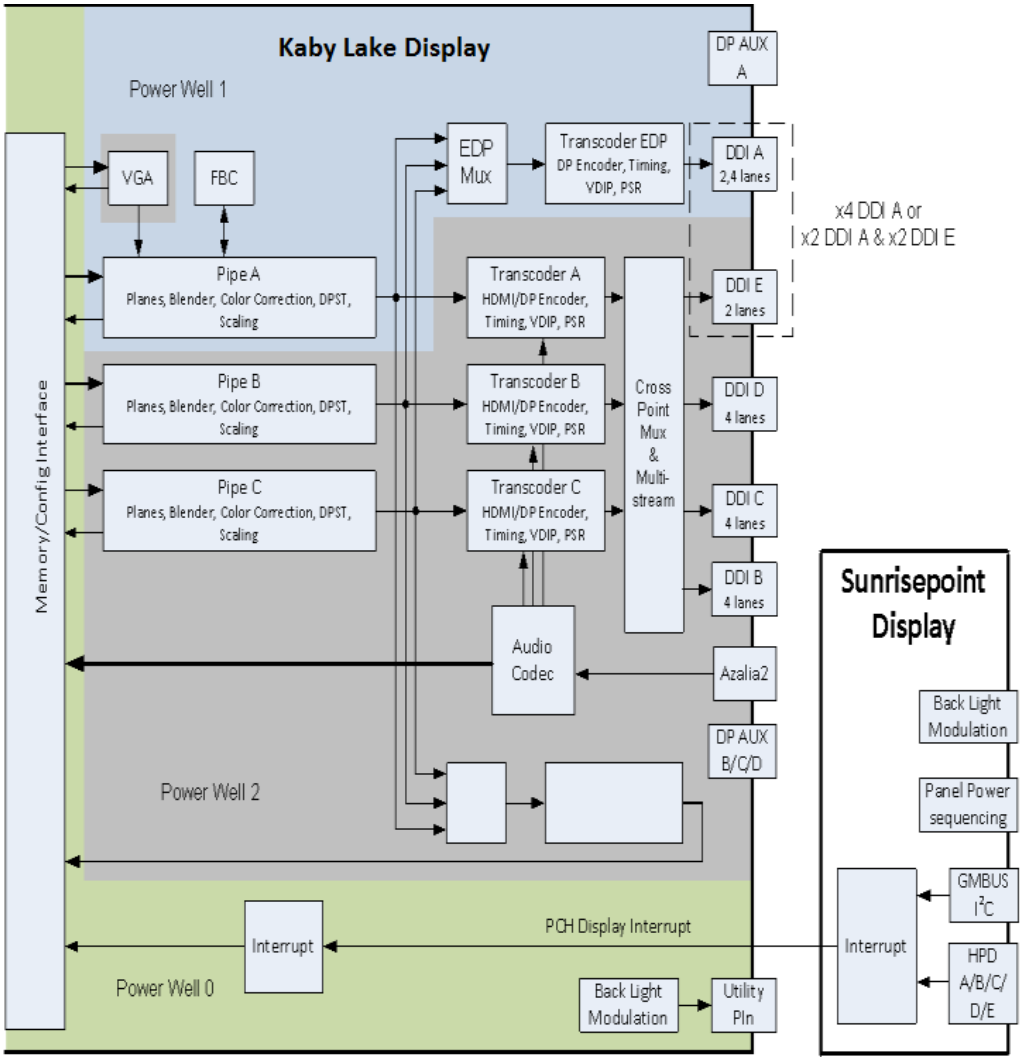
Different devices within the family may add, modify, or delete registers or register fields relative to another device in the same family based on the supported functions of that device.

This chapter contains the register descriptions for the display portion of a family of graphics devices.

These registers vary by devices within the family of devices, so special attention needs to be paid to which devices use which registers and register fields.

Different devices within the family may add, modify, or delete registers or register fields relative to another device in the same family based on the supported functions of that device.

Display Connections

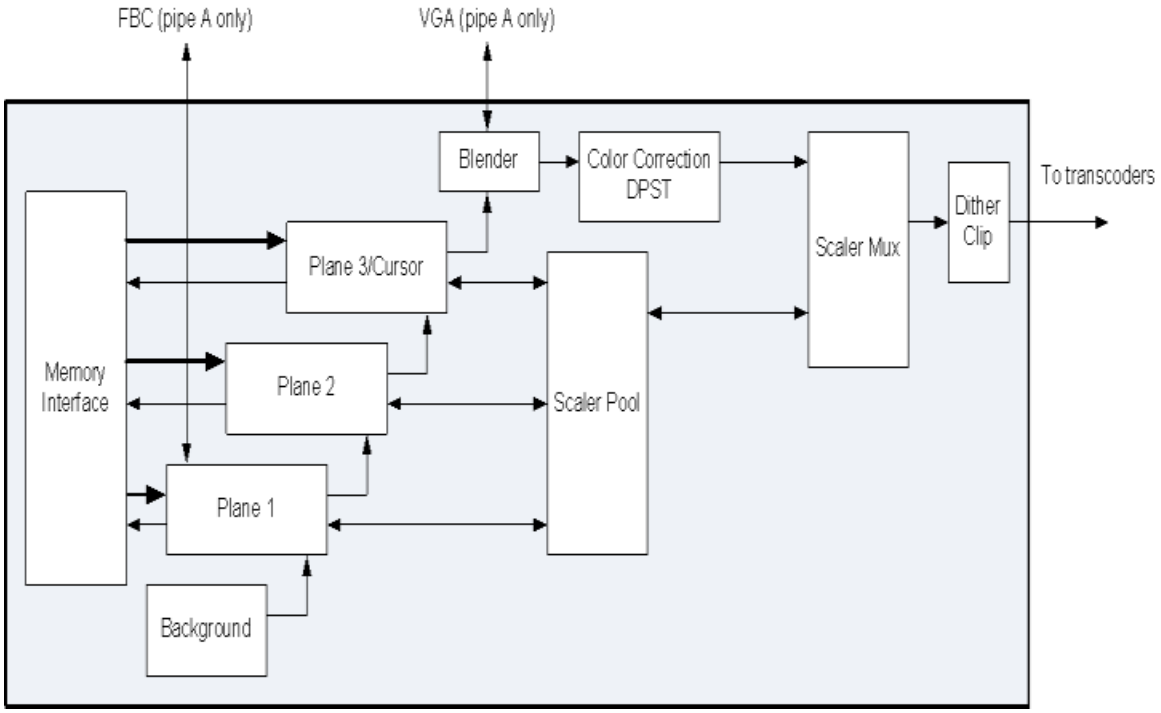


The front end of the display contains the pipes. There are three instances which are referred to as Pipe A, Pipe B, and Pipe C.

The pipes connect to the transcoders. There are five instances which are referred to as Transcoder A, Transcoder B, Transcoder C, Transcoder EDP, and Transcoder WD0.

The transcoders connect to the DDIs. There are five instances which are referred to as DDI A, DDI B, DDI C, DDI D, and DDI E.

Display Pipes



The display pipes contain the planes, blending, color correction, DPST, scaling, dithering, and clipping.

Each display pipe has three planes and a cursor. Each plane can be used as a sprite, primary, or overlay.

The background color that is seen under the bottom most plane is programmable.

The plane blending follows a fixed Z-order. Plane 1 is the bottom most plane and higher numbered planes stack on top of it.

The cursor and top most plane are mutually exclusive and cannot be both enabled at the same time.

Pipe A and Pipe B each have two pipe scalers. Pipe C has one pipe scaler.

Each pipe scaler can be assigned to scale an individual plane or scale the blended output.

Display Transcoders

The display transcoders contain the timing generators, port encoders, Audio/Video mixers, Video Data Island Packet mixers, and Panel Self Refresh controllers.

Transcoder EDP does not support HDMI, DVI, or Audio.

Transcoder WD0 only supports display capture and write back to memory.

Audio

The Azalia interface provides data to the audio codec.

The audio codec connects to the Audio/Video mixers in the transcoders.

DDIs

The DDIs contain the DisplayPort transport control and other port logic to interface to the DDI physical pins.

DDI A, DDI B, DDI C, and DDI D support lane reversal where the internal lane to package lane mapping is swapped.

DDI E does not support lane reversal.

DDI A and DDI E do not support DisplayPort multistream.

DDI A and DDI E share 2 lanes. DDI A is capable of supporting up to 4 lanes when DDI E is not connected, but only 2 lanes when DDI E is connected. DDI E is capable of supporting up to 2 lanes when connected. Dynamic switching between the two configurations is not supported.

DisplayPort A and E Lane Mapping:

Package Pin	Non-Reversed when DDI A is x4 capable	Reversed when DDI A is x4 capable	Non-Reversed when DDI A is x2 capable	Reversed when DDI A is x2 capable
DDIA/DDIE 3	Port A Main Link Lane 3	Port A Main Link Lane 0	Port E Main Link Lane 1	Port E Main Link Lane 1
DDIA/DDIE 2	Port A Main Link Lane 2	Port A Main Link Lane 1	Port E Main Link Lane 0	Port E Main Link Lane 0
DDIA/DDIE 1	Port A Main Link Lane 1	Port A Main Link Lane 2	Port A Main Link Lane 1	Port A Main Link Lane 0
DDIA/DDIE 0	Port A Main Link Lane 0	Port A Main Link Lane 3	Port A Main Link Lane 0	Port A Main Link Lane 1

DisplayPort B, C, and D Lane Mapping:

Package Pin	Non-Reversed	Reversed
DDI 3	Main Link Lane 3	Main Link Lane 0
DDI 2	Main Link Lane 2	Main Link Lane 1
DDI 1	Main Link Lane 1	Main Link Lane 2
DDI 0	Main Link Lane 0	Main Link Lane 3

HDMI/DVI TMDS Lane Mapping:

Package Pin	Non-Reversed	Reversed
DDI 3	TMDS Clock	TMDS Data2
DDI 2	TMDS Data0	TMDS Data1
DDI 1	TMDS Data1	TMDS Data0
DDI 0	TMDS Data2	TMDS Clock

DDI Equivalent Names:

DDI Name	Equivalent Names
DDI A	Port 0, DDI-A, DDIA, Port A, DDI0, eDP
DDI B	Port 1, DDI-B, DDIB, Port B, DDI1
DDI C	Port 2, DDI-C, DDIC, Port C, DDI2
DDI D	Port 3, DDI-D, DDID, Port D, DDI3
DDI E	Port 4, DDI-E, DDIE, Port E, DDI4

Pipe to Transcoder to DDI Mappings

Twin modes are not supported.

Any pipe can drive any single DDI.

With DisplayPort multistream it is possible to have multiple pipes driving a single DDI. DDI B, DDI C, and DDI D support multistream. DDI A and DDI E do not support multistream.

Pipe A can connect to either Transcoder A, Transcoder EDP, or Transcoder WD0, but not more than one simultaneously.

Pipe B can connect to either Transcoder B, Transcoder EDP, or Transcoder WD0, but not more than one simultaneously.

Pipe C can connect to either Transcoder C, Transcoder EDP, or Transcoder WD0, but not more than one simultaneously.

Transcoder A is tied to Pipe A.

Transcoder B is tied to Pipe B.

Transcoder C is tied to Pipe C.

Transcoder EDP can connect to Pipe A, Pipe B, or Pipe C, but only one at a time.

Transcoder WD0 can connect to Pipe A, Pipe B, or Pipe C, but only one at a time.

Transcoder A can connect to DDI B, DDI C, DDI D, or DDI E, but only one at a time.

Transcoder B can connect to DDI B, DDI C, DDI D, or DDI E, but only one at a time.

Transcoder C can connect to DDI B, DDI C, DDI D, or DDI E, but only one at a time.

Transcoder EDP can connect only to DDI A.

Transcoder WD0 does not connect to any DDI. Transcoder WD0 output only goes to memory write back.

DDI A can connect only to Transcoder EDP. DDI A does not support DisplayPort multistream.

DDI B can connect to Transcoder A, Transcoder B, or Transcoder C, individually or simultaneously if DisplayPort multistream is used.

DDI C can connect to Transcoder A, Transcoder B, or Transcoder C, individually or simultaneously if DisplayPort multistream is used.

DDI D can connect to Transcoder A, Transcoder B, or Transcoder C, individually or simultaneously if DisplayPort multistream is used.

DDI E can connect to Transcoder A, Transcoder B, or Transcoder C, individually.

Terminology

Term	Description
DP	DisplayPort
SST, DP SST	DisplayPort Single Stream Transport
MST, DP MST	DisplayPort Multi Stream Transport

Register Access Field	Description	Implementation
R/W (Read/Write)	The value written into this register will control hardware and is the same value that will be read.	Write data is stored. Read is from the stored data. Stored value is used to control hardware.
Reserved	Unused register bit. Don't assume a value for these bits. Writes have no effect.	Write data is ignored. Read is zero.
MBZ (Must Be Zero)	Always write a zero to this register.	May be implemented as Reserved or as R/W.
PBC (Preserve Bit Contents)	Software must write the original value back to this bit. This allows new features to be added using these bits.	May be implemented as Reserved or as R/W.
Read Only	The read value is determined by hardware. Writes to this bit have no effect.	Write data is ignored. Read is from a status signal or some other internal source.
Write Only	The value written into this register will control hardware. Reads return zero.	Write data is stored. Read is zero. Stored value is used to control hardware.
R/W Clear (Read/Write Clear)	Sticky status bit. Hardware will set the bit, software can clear it with a write of 1b.	Internal hardware events set a sticky bit. Read is from the sticky bit. A write of 1b clears the sticky bit.
R/W Set (Read/Write Set)	Sticky status bit. Software can set the bit with a write of 1b. Hardware will clear the bit.	A write of 1b sets a sticky bit. Internal hardware events clear a sticky bit. Read is from the sticky bit.

Register Access Field	Description	Implementation
Double Buffered	Write when desired and the written value will take effect at the time of the update point specified in the 'Double Buffer Update Point' parameter. Reads will return the written value, which is not necessarily the value being currently used to control hardware. Some have a specific arming sequence where a write to another register, specified in the 'Double Buffer Armed By' parameter, is required before the update can take place. Once the armed by register is written to, the written values of all registers controlled by that arming will take effect at the time of the double buffer update point. This is used to ensure atomic updates of several registers. Note: Once armed, by write to the armed by register, the registers controlled by this arming should not be changed until the double buffer update point is reached. If changed, this will disarm the sequence and will require another write to the armed by register to get it to the armed status again.	Two stages of registers used. Write data is stored into first stage. Read is from the first stage stored data. First stage stored value is transferred to second stage storage at the double buffer update point. Second stage stored value is used to control hardware. Arm/disarm logic may be used for some registers to control the double buffer update point.
Write/Read Status	The value written into this register will control hardware. The read value is determined by hardware.	Write data is stored. Stored value is used to control hardware. Read is from a status signal or some other internal source.

Mode Set

A mode set sequence is the programming sequence that must be followed when enabling or disabling output to a display. There are several different mode set sequences documented in the following sections. The sequence to use depends on which type of port is being enabled or disabled.

Sequences to Initialize Display

These sequences are used to initialize the display engine before any display engine functions can be enabled.

Most display engine functions will not operate while display is not initialized. Only basic PCI, I/O, and MMIO register read/write operations are supported when display is not initialized.

Initialize Sequence

1. Enable PCH Reset Handshake
    a. Set NDE_RSTWRN_OPT RST PCH Handshake En to 1b.
2. Enable Power Well 1 (PG1) and Misc IO Power
    a. Poll for FUSE_STATUS Fuse PG0 Distribution Status = 1b.
        - Timeout and fail after 5 us.
    b. Set PWR_WELL_CTL Power Well 1 Request and Misc IO Power Request to 1b.
    c. Poll for PWR_WELL_CTL Power Well 1 State and Misc IO Power State = 1b.
        - Timeout and fail after 10 us.
    d. Poll for FUSE_STATUS Fuse PG1 Distribution Status = 1b.
        - Timeout and fail after 5 us.
3. Enable CDCLK PLL
    a. Set CDCLK_CTL CD Frequency Select to the minimum.
    b. Configure DPLL0 link rate to the rate required for the eDP panel, or 810 MHz (DP 1.62 GHz) if there is no eDP panel.
    c. Set LCPLL1_CTL PLL enable to 1b.
    d. Poll for LCPLL1_CTL PLL lock = 1b.
        - Timeout and fail after 5 ms.
4. Follow Sequences for Changing CD Clock Frequency
5. Enable DBUF
    a. Set DBUF_CTL DBUF Power Request to 1b.
    b. Poll for DBUF_CTL DBUF Power State = 1b.
        - Timeout and fail after 10 us.

Un-initialize Sequence

1. Disable all display engine functions using the full mode set disable sequence on all pipes, transcoders, ports, planes, and power well 2 (PG2).
2. Disable DBUF
    a. Clear DBUF_CTL DBUF Power Request to 0b.
    b. Poll for DBUF_CTL DBUF Power State = 0b.
        - Timeout and fail after 10 us.
3. Disable CDCLK PLL
    a. Clear LCPLL1_CTL PLL enable to 0b.
    b. Poll for LCPLL1_CTL PLL lock = 0b.
        - Timeout and fail after 1 ms.
4. Disable Power Well 1 (PG1) and Misc IO Power
    a. Clear PWR_WELL_CTL Power Well 1 Request and Misc IO Power Request to 0b.
    b. Wait for 10us. Do not poll for the power well to disable. Other clients may be keeping it enabled.

Sequences for DisplayPort

This topic describes how to enable and disable DisplayPort.

Enable Sequence

Display must already be initialized

DDIA Lane Capability Control must be configured prior to enabling any ports or port clocks

1. **Enable Power Wells**

If not PipeA+DDIA - Enable Power Well 2 a. Enable PWR_WELL_CTL Power Well 2 Request b. Wait for PWR_WELL_CTL Power Well 2 State = Enabled, timeout after 20 us c. Wait for FUSE_STATUS FUSE PG2 Distribution Status = Done, timeout after 1 us

2. **If panel power sequencing is required - Enable Panel Power**
    a. Enable panel power sequencing
    b. Wait for panel power sequencing to reach the enabled state
3. **Enable Port PLL**
    a. If PLL is not already enabled, follow port clock programming sequence from Clocks section
    b. If PLL to port mapping is flexible, configure PLL to port mapping to direct the PLL output to the DDI

4. **If IO power is controlled through PWR_WELL_CTL - Enable IO Power**
    a. Enable PWR_WELL_CTL DDI IO Power Request for the DDI that will be used
    b. Wait for PWR_WELL_CTL DDI IO Power Request = Enabled, timeout after 20 us
5. **Enable and Train DisplayPort**
    a. Configure and enable DP_TP_CTL with link training pattern 1 selected
    b. Configure voltage swing and related IO settings. Refer to DDI Buffer section.
    c. Configure and enable DDI_BUF_CTL
    d. Gen9: Wait >518 us for buffers to enable before starting training or allow for longer time in TP1 before software timeout.
    e. Follow DisplayPort specification training sequence (see notes for failure handling)
    f. If DisplayPort multi-stream - Set DP_TP_CTL link training to Idle Pattern, wait for 5 idle patterns (DP_TP_STATUS Min_Idles_Sent) (timeout after 800 us)
    g. Set DP_TP_CTL link training to Normal.
6. **Enable Planes, Pipe, and Transcoder (repeat to add multiple pipes on a single port for multi-streaming)**
    a. If DisplayPort multi-stream - use AUX to program receiver VC Payload ID table to add stream
    b. Configure Transcoder Clock Select to direct the Port clock to the Transcoder
    c. Configure and enable planes (VGA or hires). This can be done later if desired.
    d. If VGA - Clear VGA I/O register SR01 bit 5
    e. Enable panel fitter if needed (must be enabled for VGA)
    f. Configure transcoder timings, M/N/TU/VC payload size, and other pipe and transcoder settings
    g. Configure and enable TRANS_DDI_FUNC_CTL
    h. If DisplayPort multistream - Enable pipe VC payload allocation in TRANS_DDI_FUNC_CTL
    i. If DisplayPort multistream - Wait for ACT sent status in DP_TP_STATUS and receiver DPCD (timeout after >410us)
    j. Configure and enable TRANS_CONF
    k. If panel power sequencing is required - Enable panel backlight

SRD and/or Audio can be enabled after everything is complete. Follow the audio enable sequence in the audio registers section.

Notes

Changing voltage swing during link training:

- Change the swing setting following the DDI Buffer section. The port does not need to be disabled.

Changing port width (lane count) or frequency during link training:

1. Follow Disable Sequence for DisplayPort to Disable Port

2. If PLL frequency needs to change, Follow Disable Sequence for DisplayPort to Disable PLL, then follow Enable Sequence for DisplayPort to Enable PLL, using the new frequency settings
3. Follow Enable Sequence for DisplayPort to Enable and Train DisplayPort, using the new port width settings

If the mode set fails, follow the disable sequence to disable everything that had been enabled up to the failing point.

Enabling DisplayPort Sync Mode

See TRANS_DDI_FUNC_CTL Port Sync Mode Enable for restrictions.

1. Follow the enable sequence for the DisplayPort slave, but skip the step that sets DP_TP_CTL link training to Normal (stay in Idle Pattern).
    - Set TRANS_DDI_FUNC_CTL Port Sync Mode Master Select and Port Sync Mode Enable when configuring and enabling TRANS_DDI_FUNC_CTL.
2. Wait 200 uS.
3. Follow the enable sequence for the DisplayPort master, but skip the step that sets DP_TP_CTL link training to Normal (stay in Idle Pattern).
4. Set DisplayPort slave DP_TP_CTL link training to Normal.
5. Set DisplayPort master DP_TP_CTL link training to Normal.

Software may need to use DOUBLE_BUFFER_CTL to ensure updates to plane and pipe registers will take place in the same frame.

For example: If pipe A and pipe B are synchronized together and software needs the surface addresses for two planes to update at the same time, software should use DOUBLE_BUFFER_CTL when writing the surface address registers for both planes, otherwise there is a possibility that the updates could be split across a vertical blank such that one plane would update on the current vertical blank and the other plane would update on the next vertical blank.

Disable Sequence

SRD and Audio must be disabled first. Follow the audio disable sequence in the audio registers section.

1. **If panel power sequencing is required - Disable panel backlight**
2. **Disable Planes, Pipe, and Transcoder (repeat to remove multiple pipes from a single port for multi-streaming)**
    a. If VGA
        i. Set VGA I/O register SR01 bit 5 for screen off
        ii. Wait for 100 us
    b. Disable planes (VGA or hires)
    c. Disable TRANS_CONF

d. Wait for off status in TRANS_CONF, timeout after two frame times
e. If DisplayPort multistream - use AUX to program receiver VC Payload ID table to delete stream
f. If done with this VC payload
    i. Disable VC payload allocation in TRANS_DDI_FUNC_CTL
    ii. Wait for ACT sent status in DP_TP_STATUS and receiver DPCD
g. Disable TRANS_DDI_FUNC_CTL with DDI_Select set to None
h. Disable panel fitter
i. Configure Transcoder Clock Select to direct no clock to the transcoder

3. **Disable Port (all pipes and VC payloads on this port must already be disabled)**
    a. Disable DDI_BUF_CTL
    b. Disable DP_TP_CTL (do not set port to idle when disabling)
    c. Gen9: Wait 8 us or poll on DDI_BUF_CTL Idle Status for buffers to return to idle
4. **If panel power sequencing is required - Disable Panel Power**
    a. Disable panel power sequencing
5. **If IO power is controlled through PWR_WELL_CTL - Disable IO Power**
    a. Disable PWR_WELL_CTL DDI IO Power Request for the DDI that was used
6. **Disable Port PLL**
    a. If PLL to port mapping is flexible, configure PLL to port mapping to direct no clock to the DDI
    b. If this PLL is no longer needed, follow PLL disable sequence from Clocks section
7. **Disable Power Wells**
    a. If no required resource is in the power well - Disable PWR_WELL_CTL Power Well 2 Request

Disabling DisplayPort Sync Mode

1. Follow the disable sequence for the DisplayPort slave.
2. Follow the disable sequence for the DisplayPort master.

Sequences for HDMI and DVI

This topic describes how to enable and disable HDMI and DVI.

Enable Sequence

Display must already be initialized

1. **Enable Power Wells**
    a. Enable PWR_WELL_CTL Power Well 2 Request
    b. Wait for PWR_WELL_CTL Power Well 2 State = Enabled, timeout after 20 us
    c. Wait for FUSE_STATUS FUSE PG2 Distribution Status = Done, timeout after 1 us
2. **Enable Port PLL**
    a. If PLL is not already enabled, follow port clock programming sequence from Clocks section
    b. If PLL to port mapping is flexible, configure PLL to port mapping to direct the PLL output to the DDI
3. **If IO power is controlled through PWR_WELL_CTL - Enable IO Power**
    a. Enable PWR_WELL_CTL DDI IO Power Request for the DDI that will be used
    b. Wait for PWR_WELL_CTL DDI IO Power Request = Enabled, timeout after 20 us
4. **Enable Planes, Pipe, and Transcoder**
    a. Configure Transcoder Clock Select to direct the Port clock to the Transcoder
    b. Configure and enable planes (VGA or hires). This can be done later if desired.
    c. If VGA - Clear VGA I/O register SR01 bit 5
    d. Enable panel fitter if needed (must be enabled for VGA)
    e. Configure transcoder timings and other pipe and transcoder settings
    f. Configure and enable TRANS_DDI_FUNC_CTL
    g. Configure and enable TRANS_CONF
5. **Enable Port**
    a. Configure voltage swing and related IO settings. Refer to the DDI Buffer section.
    b. Configure and enable DDI_BUF_CTL

Audio can be enabled after everything is complete. Follow the audio enable sequence in the audio registers section.

Notes

If the mode set fails, follow the disable sequence to disable everything that had been enabled up to the failing point.

Disable Sequence

Audio must be disabled first. Follow the audio disable sequence in the audio registers section.

1. **Disable Planes, Pipe, and Transcoder**
    a. If VGA
        i. Set VGA I/O register SR01 bit 5 for screen off
        ii. Wait for 100 us
    b. Disable planes (VGA or hires)
    c. Disable TRANS_CONF
    d. Wait for off status in TRANS_CONF, timeout after two frame times
    e. Disable TRANS_DDI_FUNC_CTL with DDI_Select set to None
    f. Disable panel fitter
    g. Configure Transcoder Clock Select to direct no clock to the transcoder
2. **Disable Port**
    a. Disable DDI_BUF_CTL
3. **If IO power is controlled through PWR_WELL_CTL - Disable IO Power**
    a. Disable PWR_WELL_CTL DDI IO Power Request for the DDI that was used used
4. **Disable Port PLL**
    a. If PLL to port mapping is flexible, configure PLL to port mapping to direct no clock to the DDI
    b. If this PLL is no longer needed, disable it
5. **Disable Power Wells**

a. If no required resource is in the power well - Disable PWR_WELL_CTL Power Well 2 Request

Sequences for Display C5 and C6

Display C5 (DC5) is a power saving state where hardware dynamically disables power well 1 and the CDCLK PLL and saves the associated registers.

DC5 can be entered when software allows it, power well 2 is disabled, and hardware detects that all pipes are disabled or pipe A is enabled with PSR active.

Display C6 (DC6) is a deeper power saving state where hardware dynamically disables power well 0 and saves the associated registers.

DC6 can be entered when software allows it, the conditions for DC5 are met, and the PCU allows DC6.

DC6 cannot be used if the backlight is being driven from the display utility pin.

Core CPUs support DC5 and DC6.

The context save and restore program is reset on cold boot, warm reset, PCI function level reset, and hibernate/suspend.

Sequence to Allow DC5 or DC6

1. Load the correct stepping specific Display Context Save and Restore (CSR) program from the binary package.
    a. Read the package header and extract the correct individual firmware. Binary package format details can be found in sections below.
    b. Skip the header section at the start of the program binary.
    c. Copy the payload into **Display CSR Program Storage** .
    d. Perform the MMIO writes specified in the header section.
2. Configure display engine to have power well 2 disabled, following the appropriate mode set disable sequences for any ports using power well 2. This can be done earlier if desired.
3. Set display register 0x45520 bit 1 to 1b. It does not need to be cleared at any time.
4. Set DC_STATE_EN Dynamic DC State Enable = "Enable up to DC5" for DC5 or "Enable up to DC6" for DC6.

Programming Note	
Context:	Display C5 and C6
Do not switch between "Enable up to DC5" and "Enable up to DC6" without moving to "Disable" and reloading the CSR program in between. Disable DC5/DC6 during mode set and re-enable after the mode set programming is completed. MMIO accesses have more latency when DC5/DC6 is enabled. For optimal performance, disable DC5/DC6 when programming a set of registers and re-enable them after the programming is completed.	

Sequence to Disallow DC5 and DC6

1. Set DC_STATE_EN Dynamic DC State Enable = "Disable".

DMC Firmware Package

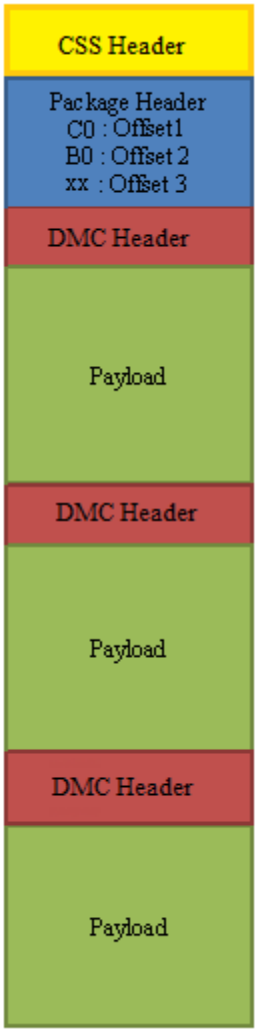
Display Micro-Controller firmware package includes all the firmwares that are required for different steppings of the product. The stepping dependent firmwares are all packaged and released as a single binary package. The package contains the CSS header, followed by the package header and the actual DMC firmwares.

Packaged firmware uses the following naming convention - <project>_dmc_ver<major>_<minor>.bin. The major version will get incremented whenever there is a change in the header layout and would require an update to the driver firmware loading module.

Major version 1

CSS Header	1.0
Package Header	1
DMC Header	1

Package Layout



CSS Header

```
typedef struct _CssHeader {
      uint32_t     moduleType;                    // 0x09 for DMC
      uint32_t     headerLen;                     // CSS header length in dwords
      uint32_t     headerVer;                     // 0x10000
      uint32_t     moduleID;                      // Not used
      uint32_t     moduleVendor;                  // Not used
      uint32_t     date;                          // YYYYMMDD(YYYY « 16 + MM « 8
+ DD)
      uint32_t     size;                          // Total dmc fw binary size in
dwords - (CSS_Headerlen + PackageHeaderLen + dmc FWsLen)/4
      uint32_t     keySize;                       // Not used
      uint32_t     modulusSize;                   // Not used
      uint32_t     exponentSize;                  // Not used
      uint32_t     reserved1[12];                 // Not used
      uint32_t     version;                       // Major Minor
      uint32_t     reserved2[8];                  // Not used
      uint32_t     uKernelHeaderInfo;             // Not used
} CssHeader;
```

Package Header

Package header contains the firmware/stepping mapping table and the corresponding firmware offsets to the individual binaries, within the package. Mapping table will list the exceptions first, followed by the default entries. An Offset value of "0xFFFFFFFF" in the mapping table indicates that there is no firmware available/supported for that stepping. The offsets to the individual binary are DWord aligned. The first individual binary starts at an offset value of "0x00000000" after the CSS Header and the Package Header.

Stepping/Version mapping example

Stepping	FW Version
A1	1.1
B*	1.6
**	2.3

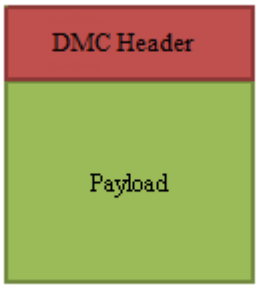
```
typedef struct _PackageHeader {
      uint8_t      headerLen;                     // DMC package header length
in dwords
      uint8_t      headerVer;                     // 0x01
```

```
      uint8_t      reserved[10];                    // Reserved
      uint32_t     numEntries;                      // Number of valid entries in
the FWInfo array below
      struct _FWInfo_ {
            uint16_t     reserved1;                 // Reserved
            char         stepping;                  // Stepping (A, B, C, ..., *).
* is a wildcard
            char         substepping;               // Sub-stepping (0, 1, ...,
*). * is a wildcard
            uint32_t     offset;                    // FW offset within the
package
            uint32_t     reserved2;                 // Reserved
      } FWInfo[20];
} PackageHeader;
```

DMC firmware binary

Each individual DMC firmware binary has a header followed by a payload whose size is specified in the header section. Along with the version, length, firmware size etc. the header section also specifies a list of MMIO addresses and data. These MMIO write cycles, in the 0x80000 - 0x8FFFF address range, should be executed as part of the initial CSR program setup.

DMC firmware Layout



```
for i = 1 to <mmioCount>
      Perform MMIO write to address <mmioaddr[i]> with data <mmiodata[i]>
typedef struct _DMCHeader {
     uint32_t    reserved;              // 0x40403E3E
     uint8_t     headerLen;             // DMC binary header length in bytes
     uint8_t     headerVer;             // 0x01
     uint16_t    dmccVer;               // Reserved
     uint32_t    project;               // Major, Minor
```

```
    uint32_t    fwSize;                 // Firmware program size (excluding header)
    in dwords
    uint32_t    fwVersion;              // Major Minor version
    uint32_t    mmioCount;              // Number of valid MMIO cycles present in
    the MMIO address and data arrays below.
    uint32_t    mmioaddr[8];            // MMIO address
    uint32_t    mmiodata[8];            // MMIO data
    unint8_t    dfile[32];              // Reserved
    uint32_t    reserved1[2];           // Reserved
} DMCHeader;
```

Display Resolution Support

A display resolution is only supported if it meets all the restrictions below for Maximum Pipe Pixel Rate, Maximum Port Link Rate, Maximum Memory Read Bandwidth, and Maximum Watermark.

Maximum Pipe Pixel Rate

The display resolution must fit within the maximum pixel rate output from the pipe. Make sure that the display pipe is able to feed pixels at a rate required to support the desired resolution.

For each enabled plane on the pipe {

If plane scaling enabled {

Horizontal down scale amount = Maximum[1, plane horizontal size / scaler horizontal window size]

Vertical down scale amount = Maximum[1, plane vertical size / scaler vertical window size]

Plane down scale amount = Horizontal down scale amount * Vertical down scale amount

Plane Ratio = 1 / Plane down scale amount

}

Else {

Plane Ratio = 1

}

If plane source pixel format is 64 bits per pixel {

Plane Ratio = Plane Ratio * 8/9

}

}

Pipe Ratio = Minimum Plane Ratio of all enabled planes on the pipe

If pipe scaling is enabled {

Horizontal down scale amount = Maximum[1, pipe horizontal source size / scaler horizontal window size]

Vertical down scale amount = Maximum[1, pipe vertical source size / scaler vertical window size]

Note: The progressive fetch - interlace display mode is equivalent to a 2.0 vertical down scale

Pipe down scale amount = Horizontal down scale amount * Vertical down scale amount

Pipe Ratio = Pipe Ratio / Pipe down scale amount

}

Pipe maximum pixel rate = CDCLK frequency * Pipe Ratio // See the display clocks section for the supported CDCLK frequencies.

Maximum Port Link Rate

The display resolution must fit within the maximum link rate for each port type.

Port Type	Maximum Link Bit Rate
eDP/DP	HBR2 5.4 GHz
HDMI	3 GHz
DVI	1.65 GHz
MIPI DSI	1.066 GHz

Maximum Memory Read Bandwidth

The display resolution must not exceed the available system memory bandwidth, considering factors like thermal throttling and bandwidth available for other memory clients.

For each pipe {

For each plane enabled on the pipe { // cursor can be ignored

Plane bandwidth MB/s = pixel rate MHz * source pixel format in bytes * plane down scale amount * pipe down scale amount

Total display bandwidth MB/s = Total display bandwidth + Plane bandwidth

}

}

Raw system memory bandwidth = (# of memory channels * memory frequency * 8 bytes)

If Total display bandwidth > system memory bandwidth available for display {Bandwidth is exceeded}

Programming Note	
Context:	Display Resolution Support
Do not use more than 60% of raw system memory bandwidth for display.	

Maximum Watermark

The display resolution must not exceed the level 0 maximum watermark value. See the volume on Watermark Programming.

Display Resolution Capabilities

These are examples of common resolutions that meet all the resolution restrictions for up to 3 simultaneous displays, 4 primary or sprite planes with 32bpp pixel format, and 1 cursor, with no panel fitter down scaling.

Attribute	CD 675 MHz	CD 540 MHz	CD 450 MHz	CD 337.5 MHz
eDP/DP x4 single stream	3840x2560 60Hz 24Bpp[4] 4096x2304 60Hz 24Bpp[4]	3840x2160 60Hz 30Bpp[4]	3200x2000 60Hz 30Bpp[3]	2880x1620 60Hz 30Bpp[2] 4096x2160 30Hz 30Bpp[2]
HDMI	Same as entry to the right	Same as entry to the right	Same as entry to the right	4Kx2K 24-30Hz 24Bpp[2]
DVI	Same as entry to the right	Same as entry to the right	Same as entry to the right	1920x1200 60Hz 24Bpp[1]

Each entry is showing the highest common resolutions at that CD clock frequency step. Lower resolutions are also supported. Higher, less common, resolutions can also work, but need to be calculated individually.

eDP, DP, DVI, and MIPI DSI are calculated using CVT 1.2 RB1 blanking and pixel rate.

HDMI is calculated using HDMI specification blanking and pixel rate.

Bpp is referring to the port output bits per pixel.

[1]Requires at least single channel DDR3 1333 for 3 simultaneous displays

[2]Requires at least single channel DDR3 1600 for 3 simultaneous displays

[3]Requires at least dual channel DDR3 1333 for 3 simultaneous displays

[4]Requires at least dual channel DDR3 1600 for 3 simultaneous displays

Examples

Example pipe pixel rate:

Plane 1 enabled at 32bpp, plane 2 enabled at 16bpp, pipe scaling enabled and down scale amount 1.12, and CDCLK 450 MHz:

Plane 1 ratio = 1

Plane 2 ratio = 1

Pipe ratio = Minimum[1, 1] = 1

Pipe ratio = 1/1.12 = 0.89

Pipe maximum pixel rate = 450 MHz * 0.89 = 400.5 MHz

Example pipe pixel rate:

Plane 1 enabled at 64bpp and plane down scale amount 1.25, plane 2 enabled at 32bpp, no panel fitting enabled, and CDCLK 540 MHz:

Plane 1 ratio = 1/1.25 * 8/9 = 0.71

Plane 2 ratio = 1

Pipe ratio = Minimum[1, 0.71] = 0.71

Pipe maximum pixel rate = 540 MHz * 0.71 = 383.4 MHz

Example memory bandwidth:

System memory bandwidth available for display = 4000 MB/s

Pipe A - Plane 1 enabled at 32bpp, plane 2 enabled at 16bpp, scaling disabled, pixel rate 148.5 MHz

Pipe B - Plane 1 enabled at 32bpp, scaling disabled, pixel rate 148.5 MHz

Pipe C - Plane 1 enabled at 32bpp, scaling disabled, pixel rate 148.5 MHz

Pipe A - Plane 1 bandwidth = 148.5 * 4 bytes = 594 MB/s

Pipe A - Plane 2 bandwidth = 148.5 * 2 bytes = 297 MB/s

Pipe B - Plane 1 bandwidth = 148.5 * 4 bytes = 594 MB/s

Pipe C - Plane 1 bandwidth = 148.5 * 4 bytes = 594 MB/s

Total display bandwidth = 594 + 297 + 594 + 594 = 2079 MB/s

System memory bandwidth available for display not exceeded

Example memory bandwidth:

System memory bandwidth available for display = 4000 MB/s

Pipe A - Plane 1 enabled at 32bpp, plane 2 plane enabled at 32bpp, pipe scaling enabled and down scale amount 1.12, pixel rate 414.5 MHz

Pipe B - Plane 1 enabled at 32bpp, scaling disabled, pixel rate 414.5 MHz

Pipe C - Plane 1 enabled at 32bpp, scaling disabled, pixel rate 414.5 MHz

Pipe A - Plane 1 bandwidth = 414.5 * 4 bytes * 1.12 = 1863 MB/s

Pipe A - Plane 2 bandwidth = 414.5 * 4 bytes * 1.12 = 1863 MB/s

Pipe B - Plane 1 bandwidth = 414.5 * 4 bytes = 1658 MB/s

Pipe C - Plane 1 bandwidth = 414.5 * 4 bytes = 1658 MB/s

Total display bandwidth = 1863 + 1863 + 1658 + 1658 = 7042 MB/s

System memory bandwidth available for display **exceeded**

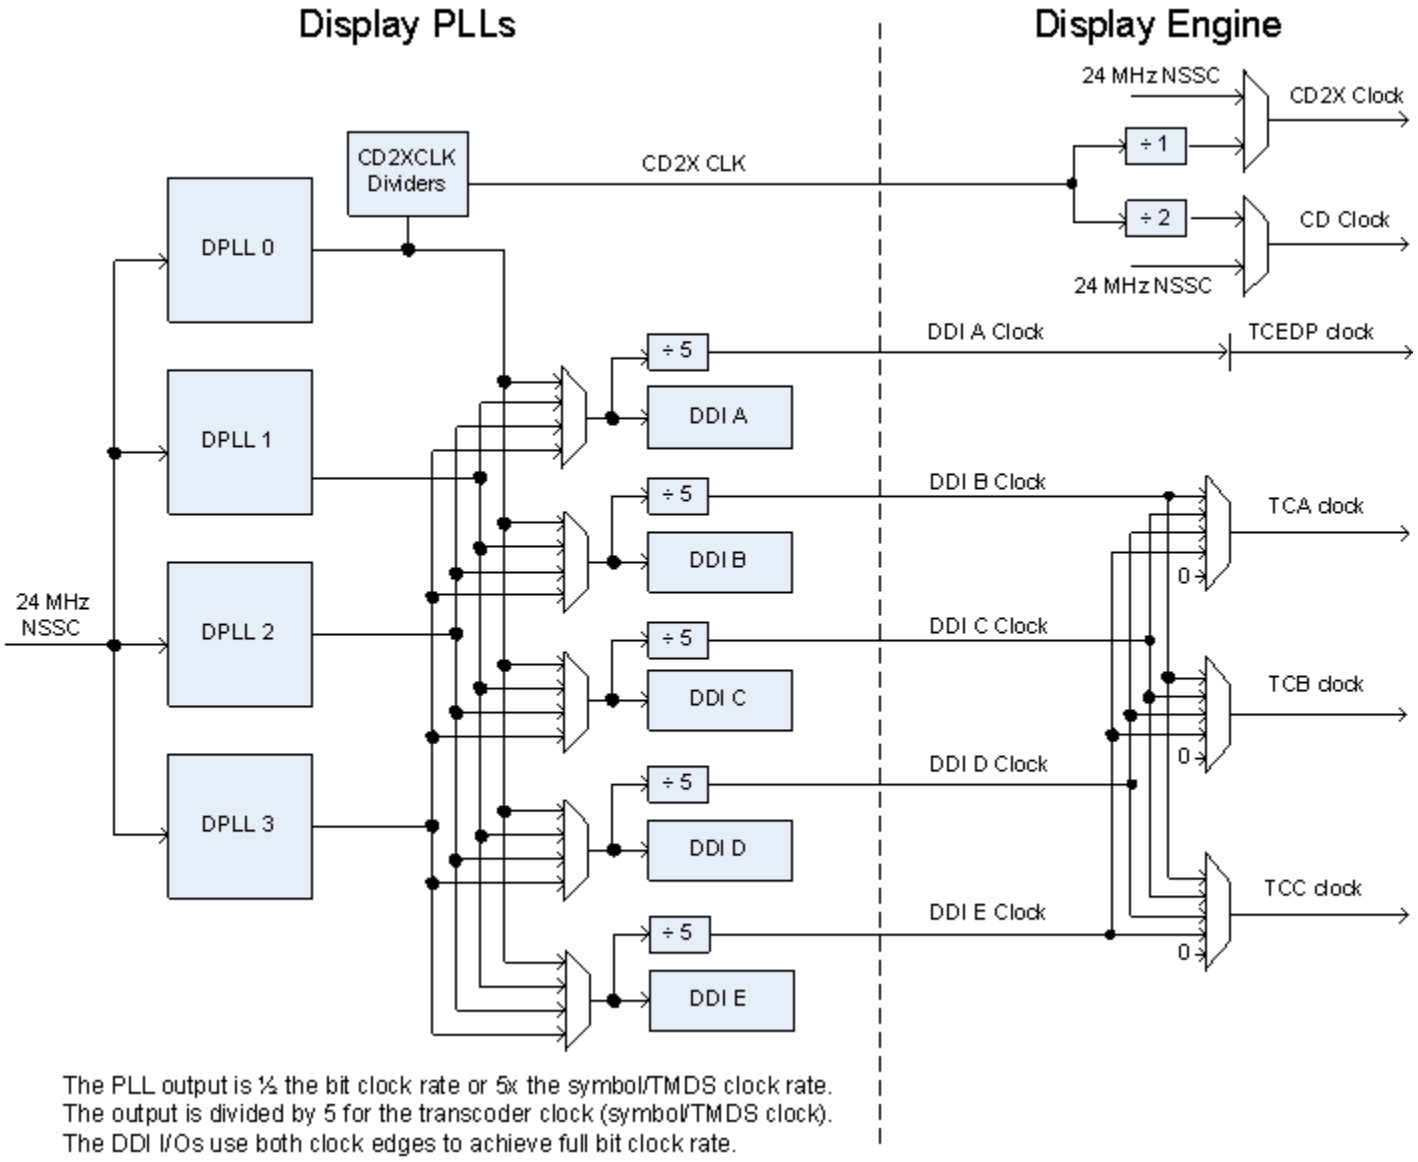
Overview of Supported Display Clock Paths



The display engine clocking structure has multiple PLLs and clocks. The flow is from reference to PLL to DDI (port) clock to transcoder clock.

Display Engine Clock Reference

There is one display engine clock reference.

	Non-SSC (NSSC) Reference
Usage	Non-spread spectrum reference for DPLL and alternate source for CD and CD2X clocks
Frequency	24 MHz
Default After Reset	Enabled
Programming	Not programmable by display software.

Display Engine PLLs

There are four display engine PLLs (DPLLs).

The PLL output frequencies are 5x the symbol/TMDS rate, which is 1/2 the bit rate.

The PLL output is divided by 5 to become the symbol/TMDS clock frequency used in the display engine.

Both edges of the PLL output are used in the DDI I/Os to double the frequency to bit clock rate.

A single PLL output may be used by multiple DDI ports simultaneously if those DDI ports all require the same frequency and spread characteristics.

	DPLL0 (LCPLL 1)	DPLL1 (LCPLL 2), DPLL2 (WRPLL 1), DPLL3 (WRPLL 2)
Usage	Sources for DDI clocks and CD clock	Source for DDI clocks
Input	Non-SSC reference	Non-SSC reference
Frequency	Programmable selection in the range 0.1 to 2.7 GHz (0.2 to 5.4 GHz bit rate). CD clock usage does not allow spread spectrum to be used.	Programmable selection in the range 0.1 to 2.7 GHz (0.2 to 5.4 GHz bit rate). Spread spectrum can be added if needed.
Default After Reset	Disabled	Disabled
Programming	DPLL enable and frequency must be programmed by software when enabling and disabling a display. Frequency programming is done through the DPLL_CTRL1 register. Enable is programmed through the LCPLL1_CTL register. See the section on Port Clock Programming.	DPLL enable, SSC enable, and frequency must be programmed by software when enabling and disabling a display. Frequency and SSC programming is done through the DPLL_CTRL1 and DPLL*_CFGCR* registers. Enables are programmed through the LCPLL2_CTL and WRPLL_CTL registers. See the section on Port Clock Programming.

Recommended PLL Selection

Avoid changing frequencies on DPLL 0 since that requires DPLL 0 to be disabled, which impacts CDCLK and requires display features to be disabled.

Use DPLL 2 as a last choice because that PLL can be taken by HDPORT in some cases. See register HDPORT_STATE.

- For eDP Non-SSC, use DPLL 0 with frequency set to match the eDP panel requirement.
- For eDP SSC or external displays, use DPLLs 1, 3, 2 in that order, depending on the availability.
- If DPLL 0 is not used for eDP, run DPLL 0 in DisplayPort mode with link rate 810 MHz (DP 1.62 GHz). This will select VCO 8100 for generating CDCLK.

DDI Clocks

There is one DDI clock tied to each DDI port.

A single DDI clock output may be used by multiple transcoders simultaneously for DisplayPort Multi-streaming.

	DDI clocks A, B, C, D, and E
Usage	DDI ports I/O bit clock and symbol/TMDS clock, source for transcoder clocks
Input	Programmable selection between the DPLLs
Frequency	DPLL frequency
Default After Reset	Disabled
Programming	Mapping of DPLL to DDI must be programmed by software when enabling and disabling a display. Programming is done through the DPLL_CTRL2 registers. See the section on Port Clock Programming.

Transcoder Clocks

There is one Transcoder clock tied to each display transcoder, except Transcoder WD which uses only CD clock.

	Transcoder clock EDP	Transcoder clocks A, B, C
Usage	Transcoder EDP symbol clock	Transcoders A, B, and C symbol/TMDS clocks
Input	Always uses DDI A clock	Programmable selection between DDI clocks B, C, D, and E.
Frequency	PLL output frequency divided by 5	PLL output frequency divided by 5
Default After Reset	Connected to DDI A Clock	Disabled

Programming	Not programmable.	Mapping of DDI to Transcoder must be programmed by software when enabling and disabling a display. Programming is done through the TRANS_CLK_SEL registers.

CD Clock

CD clock refers to the Core Display clock which includes the Core Display 1X Clock (CD clock, CDclk, cdclk, CDCLK) and the Core Display 2X Clock (CD2X clock, cd2xclk, CD2XCLK).

	CD clock
Usage	Clocking for most display engine functions
Input	DPLL0 CD2X output (with several frequency options) and Non-SSC reference.
Frequency	Non-SSC reference - 24 MHz CD, 24 MHz CD2X DPLL0 with VCO 8100: • 450 MHz CD, 900 MHz CD2X • 540 MHz CD, 1080 MHz CD2X • 337.5 MHz CD, 675 MHz CD2X • 675 MHz CD, 1350 MHz CD2X DPLL0 with VCO 8640: • 432 MHz CD, 864 MHz CD2X • 540 MHz CD, 1080 MHz CD2X • 308.57 MHz CD, 617.14 MHz CD2X • 617.14 MHz CD, 1234.28 MHz CD2X
Default After Reset	Enabled with the Non-SSC reference - 24 MHz CD, 24 MHz CD2X
Programming	CD clock cannot be disabled. CD clock frequency must be programmed by software when enabling and disabling a display. Programming is done through the CDCLK_CTL register.

Port Clock Programming

DisplayPort Programming

DisplayPort PLL Enable Sequence

1. Configure DPLL_CTRL1 to enable programming, set SSC enable/disable (no SSC for DPLL0), select DP mode, and set link rate.
2. Read back DPLL_CTRL1 to ensure writes completed before the next step.
3. Enable DPLL through LCPLL1_CTL (DPLL0), LCPLL2_CTL (DPLL1), WRPLL_CTL1 (DPLL2), or WRPL_CTL2 (DPLL3).
4. Wait for PLL lock status in DPLL_STATUS.
5. For each DDI that will use this DPLL. Configure DPLL_CTRL2 to turn on the clock for the DDI and map the DPLL to the DDI.

DisplayPort PLL Disable Sequence

1. For each DDI that was using this DPLL. Configure DPLL_CTRL2 to turn off the clock for the DDI.
2. Disable DPLL through LCPLL1_CTL (DPLL0), LCPLL2_CTL (DPLL1), WRPLL_CTL1 (DPLL2), or WRPL_CTL2 (DPLL3).

Example of DisplayPort on DDIA using HBR 2.7 GHz link rate with SSC

DPLL0 does not support SSC, so this case must use one of the other DPLLs. This example assumes DPLL1 is available.

1. Configure DPLL1 in the DPLL_CTRL1 register
   - DPLL1 Override = 1b (Enable)
   - DPLL1 Link Rate = 001b (1350 MHz - DP 2.7 GHz)
   - DPLL1 SSC = 1b (Enable)
   - DPLL1 HDMI Mode = 0b (DP mode)
2. Read back DPLL_CTRL1 to ensure writes completed
3. Enable DPLL1 in the LCPLL2_CTL register
   - PLL Enable = 1b (Enabled)
4. Wait for PLL lock status in DPLL_STATUS
5. Configure DPLL1 mapping to DDIA in the DPLL_CTRL2 register
   - DDIA Select Override = 1b (Enable)
   - DDIA Clock Select = 01b (DPLL1)
   - DDIA Clock Off = 0b (On)

HDMI and DVI Programming

HDMI and DVI PLL Enable Sequence

1. Configure DPLL_CTRL1 to enable programming, disable SSC, and use HDMI mode.
2. Configure DPLL_CFGCR1 to enable programming and set DCO frequency.
3. Configure DPLL_CFGCR2 to set the dividers and DCO central frequency.
4. Read back DPLL_CTRL1, DPLL_CFGCR1, and DPLL_CFGCR2 ensure writes completed before the next step.
5. Enable DPLL through LCPLL2_CTL (DPLL1), WRPLL_CTL1 (DPLL2), or WRPL_CTL2 (DPLL3).
6. Wait for PLL lock status in DPLL_STATUS.
7. For each DDI that will use this DPLL. Configure DPLL_CTRL2 to turn on the clock for the DDI and map the DPLL to the DDI.

HDMI and DVI PLL Disable Sequence

1. For each DDI that was using this DPLL. Configure DPLL_CTRL2 to turn off the clock for the DDI.
2. Disable DPLL through LCPLL2_CTL (DPLL1), WRPLL_CTL1 (DPLL2), or WRPL_CTL2 (DPLL3).

Formula for HDMI and DVI DPLL Programming

Reference frequency = 24 MHz.

Symbol clock frequency MHz = DCO Frequency / (P0 * P1 * P2) / 5.

AFE clock = Symbol clock frequency MHz * 5 = DCO Frequency / (P0 * P1 * P2).

P2 can be 1, 2, 3, or 5.

If P2 != 2, then P1 must be 1. Else P1 can be 1 to 255.

If P1 == 1, then P0 can be 1, 2, 3, or 7. Else P0 can be 2, 3, or 7.

An even value for the divider (P0 * P1 * P2) is preferred.

DCO central frequency must be 8400, 9000, or 9600 MHz.

DCO frequency must be within +1% or -6% of DCO central frequency. It is preferred to get as close to the DCO central frequency as possible, but using an even divider value takes precedence.

Note: If the desired symbol clock frequency cannot be achieved with the valid values of P0, P1, P2, and DCO frequencies, use a different screen resolution with a different symbol clock frequency.

Algorithm to Find HDMI and DVI DPLL Programming

1. Find AFE clock
2. For each legal divider (P*Q*K), find the DCO. Try even dividers first. Only use odd dividers if a good even is not found.

3. Try the DCO with each central frequency.
4. Select the divider and central frequency that gives the DCO with minimum deviation from DCO central frequency and fits within the +1% and -6% requirement.
5. Find the P, Q, K values to create that divider.

Pseudo-code for HDMI and DVI DPLL Programming

```
 Minimum Positive Deviation = 1%
 Minimum Negative Deviation = 6%
 Chosen Central Frequency = NONE
 AFE Clock = 5 * Symbol Clock MHz
 Even Candidate Dividers[] = { 4, 6, 8, 10, 12, 14, 16, 18, 20, 24, 28, 30, 32, 36, 40, 42,

   Return Success // Valid result found
Return Fail  // No valid result found
```

Example of DVI on DDIB using 113.309 MHz symbol clock

This example assumes DPLL3 is available.

Frequency programming algorithm finds DCO central frequency = 9000 MHz, P0=2, P1=4, P2=2, DCO Frequency = 9064.72

1. Configure DPLL3 in the DPLL_CTRL1 register
    - DPLL3 Override = 1b (Enable)
    - DPLL3 SSC = 0b (Disable)
    - DPLL3 HDMI Mode = 1b (HDMI mode)
2. Configure DPLL3 in the DPLL3_CFGCR1 register

    DCO Integer = INT(9064.72/24) = 377

    DCO Fraction = INT(((9064.72/24) - DCO Integer) * 2^15) = 22,828

    - Frequency Enable = 1b (Enable)
    - DCO Fraction = 592Ch (22828)
    - DCO Integer = 179h (377)
3. Configure DPLL3 in the DPLL3_CFGCR2 register
    - Qdiv Ratio = P1 = 04h (4)
    - Qdiv Mode = 1b (Enable)
    - Kdiv = P2 = 01b (2)
    - Pdiv = P0 = 001b (2)
    - Central Frequency = 01b (9000 MHz)
4. Read back DPLL_CTL1, DPLL3_CFGCR1, and DPLL3_CFGCR2 to ensure writes completed
5. Enable DPLL3 in the WRPLL_CTL2 register
    - PLL Enable = 1b (Enabled)
6. Wait for PLL lock in DPLL_STATUS
7. Configure DPLL3 mapping to DDIB in the DPLL_CTRL2 register
    - DDIB Select Override = 1b (Enable)
    - DDIB Clock Select = 11b (DPLL3)
    - DDIB Clock Off = 0b (On)

Example of HDMI on DDIC using 296.703 MHz symbol clock

This example assumes DPLL2 is available.

Frequency programming algorithm finds DCO central frequency = 9000 MHz, P0=1, P1=3, P2=2, DCO Frequency = 8901.09

1. Configure DPLL2 in the DPLL_CTRL1 register
    - DPLL2 Override = 1b (Enable)
    - DPLL2 SSC = 0b (Disable)
    - DPLL2 HDMI Mode = 1b (HDMI mode)

2. Configure DPLL2 in the DPLL2_CFGCR1 register

   DCO Integer = INT(8901.09/24) = 370

   DCO Fraction = INT(((8901.09/24) - DCO Integer) * 2^15) = 28,794

   - Frequency Enable = 1b (Enable)
   - DCO Fraction = 707Ah (28794)
   - DCO Integer = 172h (370)
3. Configure DPLL2 in the DPLL2_CFGCR2 register
   - Qdiv Mode = 0b (Disable) // P1=1
   - Kdiv = P2 = 01b (2)
   - Pdiv = P0 = 010b (3)
   - Central Frequency = 01b (9000 MHz)
4. Read back DPLL_CTL1, DPLL2_CFGCR1, and DPLL2_CFGCR2 to ensure writes completed
5. Enable DPLL2 in the WRPLL_CTL1 register
   - PLL Enable = 1b (Enabled)
6. Wait for PLL lock status in DPLL_STATUS
7. Configure DPLL2 mapping to DDIC in the DPLL_CTRL2 register
   - DDIC Select Override = 1b (Enable)
   - DDIC Clock Select = 10b (DPLL2)
   - DDIC Clock Off = 0b (On)

Sequences for Changing CD Clock Frequency

The CD clock frequency can be programmed to select between several frequencies.

Restrictions
The CD clock frequency impacts the maximum supported pixel rate and display watermark programming. The CD clock frequency must be at least twice the frequency of the Azalia BCLK. Do not select the CD clock frequencies that have been restricted by the Display CDCLK Limit fuse (register DFSM).
Sequence for Changing CD Clock Frequency
1. Disable all display engine functions using the full mode set disable sequence on all pipes, ports, and planes. • Includes Global Time Code 2. Inform power controller of upcoming frequency change a. Ensure any previous GT Driver Mailbox transaction is complete. b. Write GT Driver Mailbox Data0 (GTTMMADDR offset 0x138128) = 0x00000003. c. Write GT Driver Mailbox Data1 (GTTMMADDR offset 0x13812C) = 0x00000000. d. Write GT Driver Mailbox Interface (GTTMMADDR offset 0x138124) = 0x80000007.

Restrictions
e. Poll GT Driver Mailbox Interface for Run/Busy indication cleared (bit 31 = 0). • Timeout after 150 us. Do not change CD clock frequency if there is a timeout. f. Read GT Driver Mailbox Data0, if bit 0 is 0x1, continue, else go to step b. • If the condition in step f is not satisfied after cycling through steps b-f for 3 ms (typically <200 us), timeout and do not change CD clock frequency. 3. Change CDCLK_CTL register CD Frequency Select and CD Frequency Decimal to the desired frequency • The frequency change will complete within a few clock cycles. 4. Inform power controller of the selected frequency a. Write GT Driver Mailbox Data0 with the frequency selection. • If selecting 337.5 or 308.57 MHz CD clock, or disabling CD clock PLL, write 0x00000000. • If selecting 450 or 432 MHz CD clock, write 0x00000001. • If selecting 540 MHz CD clock, write 0x00000002. • If selecting 675 or 617.14 MHz CD clock, write 0x00000003. b. Write GT Driver Mailbox Data1 = 0x00000000. c. Write GT Driver Mailbox Interface = 0x80000007. • The power controller should complete within 100 us, but there is no need for display software to wait for that. 5. Update programming of register fields that are based on CD clock frequency Programming can be delayed to when the features are enabled. • Utility pin backlight frequency and duty cycle in the BLC_PWM_DATA register.

Resets

NDE_RSTWRN_OPT

The north and south display engines are reset by PCI Function Level Resets (FLR) and the chip level resets.

An FLR for Bus:Device:Function 0:2:0 resets the north and south display engines and audio codec and most of the related MMIO, PCI, and I/O configuration registers.

Display configuration registers that are reset by both the chip level reset and by FLR are marked as using the "soft" reset in the programming specification.

Display configuration registers that are reset only by the chip level reset and *not* by FLR are marked as using the "global" reset in the programming specification.

The south display engine runs panel power down sequencing (if configured to do so) before resetting.

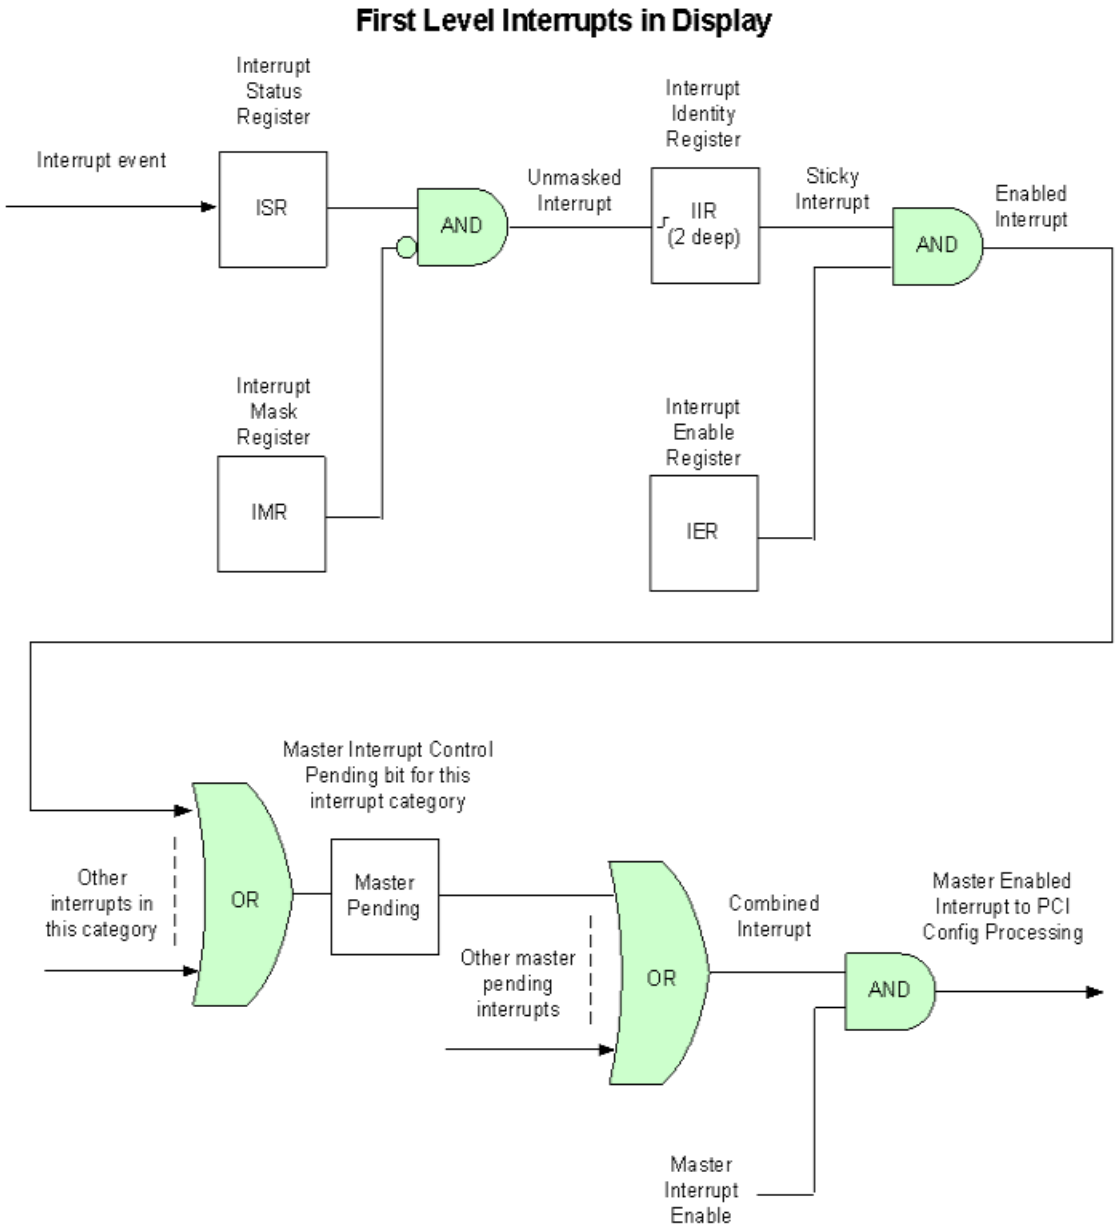
INTERRUPT Structure

Interrupt Flow



1. For every first level interrupt bit
    a. The interrupt event comes in to the interrupt handling logic.
        - There may be more levels of interrupt handling behind each event. For example, the PCH Display interrupt event is the result of the SDE interrupt registers.
    b. The interrupt event goes to the Interrupt Status Register (ISR) where live status can be read back.
        - The live status is mainly useful for hotplug interrupts where it gives the live state of the hotplug line.
        - The live status is not useful for pulse interrupt events due to the short period that the status will be present.
    c. The interrupt event is ANDed with the inverted Interrupt Mask Register (IMR) to create the unmasked interrupt.
        - Only unmasked interrupts will proceed.
    d. The unmasked interrupt rising edge sets the sticky bit in the Interrupt Indentity Register (IIR).
        - The IIR can be cleared by writing a 1 to it.
        - The IIR can queue up to two interrupt events. When the IIR is cleared, it will set itself again if a second event was stored.
    e. The sticky interrupt is ANDed with the Interrupt Enable Register (IER) to create the enabled interrupt.
        - Only enabled interrupts will proceed.
2. All enabled interrupts are then ORed by category (Pipe, Audio Codec, Render, etc.) to create a combined interrupt which is then visible in one of the Master Interrupt Control Register (MASTER_INT_CTL) pending category bits.
3. All pending interrupts are then ORed to create the combined interrupt.
4. The combined interrupt is ANDed with the Master Interrupt Enable (MASTER_INT_CTL Bit 31) to create the master enabled interrupt.
    - Only a master enabled interrupt will proceed.
5. The master enabled interrupt then goes to PCI device 2 configuration registers PCISTS2, PCICMD2, and MC which control the MSI and line interrupt.

A Function Level Reset (FLR) or Warm Reset will reset all graphics interrupt logic, causing the master enabled interrupt to de-assert which can cause the MSI or line interrupt to de-assert.

Interrupt Service Routine

1. Disable Master Interrupt Control
    - Clear bit 31 of MASTER_INT_CTL (0x44200)
    - This is required to prevent missing any interrupts occurring back to back or during the service routine

2. Find the category of interrupt that is pending
    - Read MASTER_INT_CTL (0x44200) and record which interrupt pending category bits are set
3. Find the source(s) of the interrupt and clear the Interrupt Identity bits (IIR)
    - Read the IIR associated with each pending interrupt category, record which bits are set, then write back 1s to clear the bits that are set.
4. Process the interrupt(s) that had bits set in the IIRs
5. Re-enable Master Interrupt Control
    - Set bit 31 of MASTER_INT_CTL (0x44200)

Backlight

This section refers to the CPU display backlight control. For PCH display backlight control, see South Display Engine Registers.

The backlight PWM output frequency is determined by the PWM clock frequency, increment, and frequency divider.

PWM output frequency = PWM clock frequency / PWM increment / PWM frequency divider

The frequency divider must be greater than or equal to the number of brightness levels required by software; typically 100 or 256.

Description
PWM clock frequency = CD clock frequency = 308.57 to 675 MHz PWM increment = 128 or 8, selectable by software PWM frequency divider maximum = 2^16 PWM output frequency range with PWM clock frequency 308.57 MHz and 100 brightness levels and increment 128 = 37 to 24,107 Hz PWM output frequency range with PWM clock frequency 308.57 MHz and 100 brightness levels and increment 8 = 589 to 385,713 Hz PWM output frequency range with PWM clock frequency 308.57 MHz and 256 brightness levels and increment 128 = 37 to 9,417 Hz PWM output frequency range with PWM clock frequency 308.57 MHz and 256 brightness levels and increment 8 = 589 to 150,669 Hz

Backlight Enabling Sequence

Description
1. Enable utility pin, select PWM mode, and set polarity in UTIL_PIN_CTL Util Pin Enable, Util Pin Mode, and Util Pin Output Polarity. 2. Set frequency and duty cycle in BLC_PWM_DATA Backlight Frequency and Backlight Duty Cycle. 3. Enable PWM output and set granularity in BLC_PWM_CTL PWM Enable and PWM granularity. ... 4. Change duty cycle as needed in BLC_PWM_DATA Backlight Duty Cycle.

If needed, granularity and polarity can be programmed earlier than shown.

Workaround	
Context:	FBC
To prevent missed invalidations around the time FBC is being enabled, FBC render tracking must use the "Render Tracking With Nuke" method.	

FBC Overview

Frame Buffer Compression (FBC) gives a lossless compression of the display frame buffer to save power by reducing system memory read bandwidth and increasing the time between display engine reads to system memory.

FBC is only available on specific plane(s), depending on project. See FBC_CTL for details. FBC compresses pixels for the plane(s) it is attached to as they are displayed. The compressed data is written into the Compressed Frame Buffer (CFB) in graphics data stolen memory. The compressed data is then read the next time the same line needs to be displayed. Changes to the display front buffer (currently displayed

memory surface) through host aperture (GMADR) tiling fences (on projects that support that), render (RCS), and blitter (BCS) are tracked and cause the compressed lines to be invalidated and recompressed. Flips or changes to plane size and panning cause the entire buffer to be recompressed (nuke).

FBC Compression Limit

The FBC compression limit reduces the size of the Compressed Frame Buffer (CFB) by limiting which lines will be compressed. This is used when the graphics stolen memory available for the FBC CFB is smaller than the size of the original uncompressed frame buffer. There is also a FBC compressed vertical limit, listed in FBC_CTL, which is the maximum number of lines FBC can compress. Lines beyond the vertical limit do not need to be accounted for in the CFB size.

When the compression limit is 1:1, every line is written to the CFB, so the CFB width is the same as the original uncompressed frame buffer.

When the compression limit is 2:1, only lines that compress to 1/2 their original size will be written to the CFB, so the CFB width can be 1/2 the original uncompressed frame buffer.

When the compression limit is 4:1, only lines that compress to 1/4 their original size will be written to the CFB, so the CFB width can be 1/4 the original uncompressed frame buffer.

CFB size = ((Stride of plane uncompressed surface / FBC compression limit) * MIN(FBC compressed vertical limit, plane vertical source size)

FBC Programming Overview

1. Set up the compressed frame buffer.
    - The compressed buffer resides in graphics data stolen memory.
    - The stolen memory must be contiguous and un-cached.
    - The stolen memory needed for compressed frame buffer must be greater or equal to CFB size (calculation above).
    - Manage the compressed buffer size at run-time by balancing other graphics memory needs with the FBC allocation, and implement appropriate memory needs prioritization schemes.
2. Tracking for CPU host front buffer modifications through aperture fences (on projects that support that)
    - Setup System Agent (SA) registers to track CPU modifications on the display front buffer.
3. Tracking for display front buffer rendering
    - Setup Target Base Address, Front Buffer Target, and Address Valid for FBC
    - Enable Address Valid before rendering to the front buffer.
    - If needed, send nuke LRIs after each render submission to the display front buffer
4. Tracking from display front buffer BLTs
    - Setup Target Base Address and Address Valid for FBC
    - Enable Address Valid when BLTs target the display front buffer and disable when BLTs do not target the display front buffer

- Send nuke LRI or cache clean LRI after each blitter submission to the display front buffer

LRI commands to display address 0x50380 are used as part of the render and blitter tracking. Those LRIs must be followed SRM commands to the same address.

LRI to address 0x50380 with data 0x00000004 tells FBC to nuke and invalidate the entire compressed buffer.

LRI to address 0x50380 with data 0x00000002 tells FBC that previous blitter submissions have been flushed to memory and the invalidate lines can now be recompressed.

Render and blitter tracking can invalidate individual lines or nuke the entire buffer. The nuke method is used for workarounds.

Render Tracking With Nuke

- Software must send the nuke LRI after each render to the display front buffer

1. Render commands that touch the display front buffer
    a. Render submission
    b. PIPE_CONTROL
    c. LRI to address 0x50380 with data 0x00000004 (nuke)
    d. SRM to read address 0x50380 and store to a scratch page
2. More render commands that touch the display front buffer
    a. Render submission
    b. PIPE_CONTROL
    c. LRI to address 0x50380 with data 0x00000004 (nuke)
    d. SRM to read address 0x50380 and store to a scratch page
3. Render commands that do not touch the display front buffer
    a. Render submission
    b. PIPE_CONTROL

Render Tracking Without Nuke

- Render tracking must be setup by software, then hardware will track FBC line invalidations automatically.

1. Render commands that potentially touch the display front buffer
    a. LRIs to FBC_RT_BASE_ADDR_REGISTER_<UPPER,LOWER> with display front buffer address, front buffer target=1, base address valid for FBC=1
    b. PIPE_CONTROL to ensure LRI takes effect
    c. Render submission
    d. PIPE_CONTROL

2. More render commands that touch the display front buffer
    a. Render submission
    b. PIPE_CONTROL
3. Render commands that do not touch the display front buffer
    a. Optional: LRIs to FBC_RT_BASE_ADDR_REGISTER_<UPPER,LOWER> with base address valid for FBC=0. Optional because hardware will detect that the render is not to the display front buffer address.
    b. Optional: PIPE_CONTROL to ensure LRI takes effect
    c. Render submission
    d. PIPE_CONTROL

Blitter Tracking With Nuke

- Software must send the nuke LRI after each BLT to the display front buffer. Never set 221d0h bit 3 (Address Valid for FBC).

1. BLT commands that touch the display front buffer
    a. BLT submission
    b. MI_FLUSH_DW
    c. LRI to address 0x50380 with data 0x00000004 (nuke)
    d. SRM to read address 0x50380 and store to a scratch page
2. More BLT commands that touch the display front buffer (can leave Address Valid set from previous)
    a. BLT submission
    b. MI_FLUSH_DW
    c. LRI to address 0x50380 with data 0x00000004 (nuke)
    d. SRM to read address 0x50380 and store to a scratch page
3. BLT commands that do not touch the display front buffer
    a. BLT submission
    b. MI_FLUSH_DW

Blitter Tracking Without Nuke

- Blitter tracking must be enabled by software only when BLTs touch the display front buffer. Software must send the cache clean LRI after each BLT to the display front buffer.

1. BLT commands that definitely touch the front buffer
    a. LRI to address 221d0h to set bit 3 (Address Valid for FBC)
    b. MI_FLUSH_DW to ensure LRI takes effect
    c. BLT submission

    d. MI_FLUSH_DW
    e. LRI to address 0x50380 with data 0x00000002 (cache clean)
    f. SRM to read address 0x50380 and store to a scratch page
2. More BLT commands that touch the front buffer (can leave Address Valid for FBC set from previous)
    a. BLT submission
    b. MI_FLUSH_DW
    c. LRI to address 0x50380 with data 0x00000002 (cache clean)
    d. SRM to read address 0x50380 and store to a scratch page
3. BLT commands that do not touch the front buffer (must clear Address Valid for FBC)
    a. LRI to address 221d0h to set bit 3 (Address Valid for FBC)
    b. MI_FLUSH_DW to ensure LRI takes effect
    c. BLT submission
    d. MI_FLUSH_DW

CPU Host Aperture Tracking

- Host tracking must be setup by software, then hardware will track FBC line invalidations to the specified tiling fence.

1. Program Y offset from the CPU fence to the Display Buffer base in DPFC_CPU_FENCE_OFFSET.
2. Program CPU fence ID and enable CPU fence tracking in DPFC_CONTROL_SA.

Disable CPU Fence tracking in DPFC_CONTROL_SA if no tiling fence is mapped to display buffer.

Display Plane Enabling with FBC

- FBC has to be enabled after the attached display plane is enabled.
- This is the general sequence. See FBC_CTL for any workarounds.

1. Enable display plane
2. Enable FBC as described in FBC_CTL register

Display Plane Disabling with FBC

- FBC has to be disabled prior to FBC attached display plane disabling.
- This is the general sequence. See FBC_CTL for any workarounds.

1. Disable FBC as described in FBC_CTL register
2. Disable display plane.

Watermarks

The watermark registers are used to control the display to memory request timing. The watermarks must be programmed according to the Display Watermark Programming section.

Description or Link
WM_PIPE, WM_LP, and WM_LP_SPR have been replaced by PLANE_WM and moved into the planes section.
WM_MISC **WM_LINETIME**

DC States

DC_STATE_EN

Power Wells

When a power well is disabled (powered down), access to any registers in the power well will complete, but write data will be dropped and read data will be all zeroes.

The power well enable requests from all sources are logically ORd together to enable a power well, so the power well will only disable after all sources have requested the power well to disable.

Register Link
PWR_WELL_CTL

Pipe

Color Space Conversion

CSC_COEFF

CSC COEFFICIENT FORMAT

CSC_PREOFF

CSC_POSTOFF

CSC_MODE

The high color channel is the most significant bits of the color. The low color channel is the least significant bits of the color. The medium color channel is the bits between high and low. For example: In RGB modes Red is in the High channel, Green in Medium, and Blue in Low. In YUV modes, V is in the High channel, Y in Medium, and U in Low.

The color space conversion registers are double buffered and are updated on the start of vertical blank following a write to the CSC Mode register for the respective pipe.

The matrix equations are as follows:

OutputHigh = (CoefficientRY * InputHigh) + (CoefficientGY * InputMedium) + (CoefficientBY * InputLow)

OutputMedium = (CoefficientRU * InputHigh) + (CoefficientGU * InputMedium) + (CoefficientBU * InputLow)

OutputLow = (CoefficientRV * InputHigh) + (CoefficientGV * InputMedium) + (CoefficientBV * InputLow)

Example programming for RGB to YUV is in the following table:

The input is RGB on high, medium, and low channels respectively and the desired YUV output is VYU on high, medium, and low channels respectively.

Program CSC_MODE to put gamma before CSC.

Program the CSC Post-Offsets to +1/2, +1/16, and +1/2 for high, medium, and low channels respectively.

The coefficients and pre and post offsets can be scaled if desired.

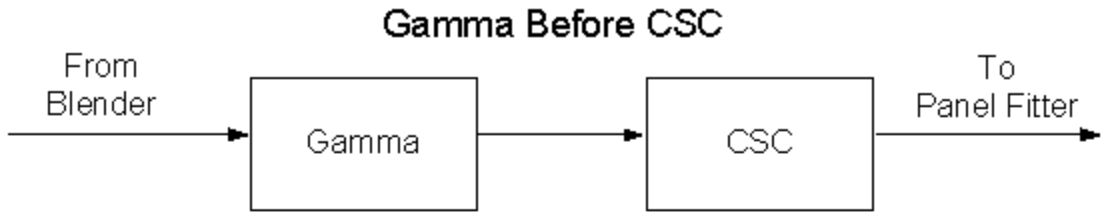
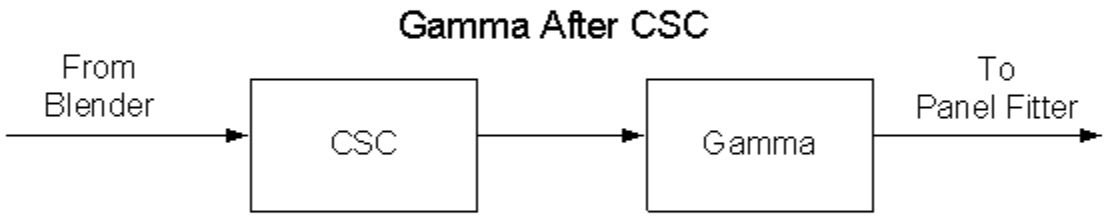
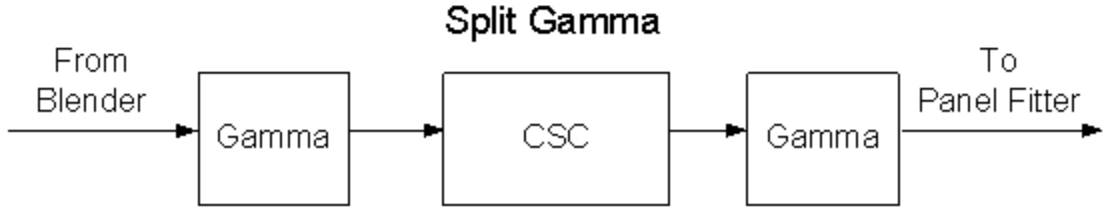
The pipe gamma and color space conversion blocks can be placed in three different arrangements:

- Gamma before CSC: Selected through the CSC Mode register. Mostly used for RGB to YUV conversion.
- Gamma after CSC: Selected through the CSC Mode register. Mostly used for YUV to RGB conversion or linear RGB to RGB conversion. Can be used with pipe color gamut enhancement.
- Split gamma: Selected through the Gamma Mode register. Mostly used for RGB to RGB conversion. Can be used with pipe color gamut enhancement. The pipe gamma enable per plane will control whether a plane will go through both gamma blocks. It is not possible to send a plane through one gamma block and not the other.

In either arrangement, the final output of the pipe gamma and CSC and gamut enhancement logic is clamped to fit in the 0 to 1.0 range before going to the ports.







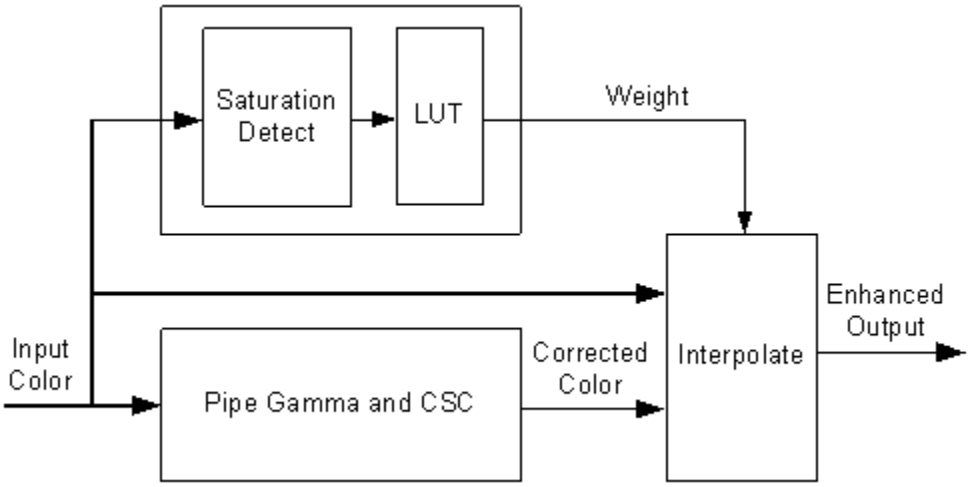
Pipe Color Gamut Enhancement

Pipe color gamut enhancement is used to enhance display of standard gamut content on wide gamut displays. It processes the color value from before and after the pipe gamma and color space correction blocks to create the color gamut enhanced output. The typical usage is to output the pipe gamma and CSC corrected color for areas of low saturated content and the input (not gamma or CSC corrected) color for areas of high saturated content. It is not recommended to use color gamut enhancement with wide gamut inputs.

CGE_CTRL

CGE_WEIGHT

The pipe Gamma and CSC must be programmed to either the split gamma mode or gamma after CSC mode when using pipe color gamut enhancement.



The saturation level of the pipe gamma and CSC input color is detected and used to index into a look up table (LUT) containing programmable weights. The saturation values are linearly distributed across the LUT indexes from the lowest index for lowest saturation to the highest index for highest saturation.

The enhanced output color is created by using the weight value to interpolate between the input color and corrected color. See the following table of weights to amount of input or corrected color used to create the enhanced output color.

Weighting of input and corrected colors

Weight from LUT	Amount of Input Color in Enhanced Output	Amount of Corrected Color in Enhanced Output
00 0000b (minimum)	0%	100%
...	...	...
00 1000b	25%	75%
...	...	...

DPST_GUARD

Pipe Palette and Gamma

The display palette provides a means to correct the gamma of an image stored in a frame buffer to match the gamma of the monitor or presentation device. Additionally, the display palette provide a method for converting indexed data values to color values for VGA and 8-bpp indexed display modes. The display palette is located after the plane blender. Using the individual plane gamma enables, the blended pixels can go through or bypass the palette on a pixel by pixel basis.

PAL_LGC

PAL_PREC_INDEX

PAL_PREC_DATA

PAL_GC_MAX

PAL_EXT_GC_MAX

GAMMA_MODE

If any gamma value to be programmed exceeds the maximum allowable value in the associated gamma register, then the programmed value must be clamped to the maximum allowable value.

Programming Modes

The display palette can be accessed through multiple methods and operate in one of four different modes as follows.

8 bit legacy palette/gamma mode:

This provides a palette mode for indexed pixel data formats (VGA and primary plane 8 bpp) and gamma correction for legacy programming requirements.

All input values are clamped to the 0.0 to 1.0 range before the palette/gamma calculation. It is not recommended to use legacy palette mode with extended range formats.

For input values greater than or equal to 0 and less than 1.0, the input value is used to directly lookup the result value from one of the 256 palette/gamma entries. The 256 entries are stored in the legacy palette with 8 bits per color in a 0.8 format with 0 integer and 8 fractional bits.

The legacy palette is programmable through both MMIO and VGA I/O registers. Through VGA I/O, the palette can look as though there are only 6 bits per color component, depending on programming of other VGA I/O registers.

10 bit gamma mode:

This provides the highest quality gamma for pixel data formats of 30 bits per pixel or less.

All input values are clamped to the greater than -3.0 and less than 3.0 range before the gamma calculation.

For input values greater than or equal to 0 and less than 1.0, the input value is used to directly lookup the result value from one of the first 1024 gamma entries. The first 1024 entries are stored in the precision palette with 10 bits per color in a 0.10 format with 0 integer and 10 fractional bits.

For input values greater than or equal to 1.0 and less than 3.0, the input value is used to linearly interpolate between the 1024th and 1025th gamma entries to create the result value. The 1025th entry is stored in the PAL_EXT_GC_MAX register with 19 bits per color in a 3.16 format with 3 integer and 16 fractional bits.

For negative input values, gamma is mirrored along the X-axis, giving the same result as positive input values, except for a negative sign. When gamma input may be negative, the first gamma point should be programmed to a value of 0.0 in order to have a symmetric mirroring.

Split gamma mode:

Split gamma mode is composed of two gamma functions. The first gamma is before pipe color space conversion (CSC) and the second is after CSC. This split gamma mode permits mapping to linear gamma, then color space conversion, then mapping to monitor gamma. This provides the highest quality pipe color space conversion and gamma correction for inputs with non-linear gamma.

First gamma (before CSC):

All input values are clamped to the greater than -3.0 and less than 3.0 range before the gamma calculation.

For input values greater than or equal to 0 and less than 1.0, the input value is used to directly lookup the result value from one of the first 512 gamma entries. The first 512 entries are stored in the precision palette indexes 0 to 511 with 10 bits per color in a 0.10 format with 0 integer and 10 fractional bits.

For input values greater than or equal to 1.0 and less than 3.0, the input value is used to linearly interpolate between the 512th and 513th gamma entries to create the result value. The 513th entry is stored in the PAL_EXT_GC_MAX register with 19 bits per color in a 3.16 format with 3 integer and 16 fractional bits.

For negative input values, gamma is mirrored along the X-axis, giving the same result as positive input values, except for a negative sign. When gamma input may be negative, the first gamma point should be programmed to a value of 0.0 in order to have a symmetric mirroring.

Second gamma (after CSC):

All input values are clamped to the 0.0 to 1.0 range before the gamma calculation.

For input values greater than or equal to 0 and less than 1.0, the input value is used to directly lookup the result value from one of the first 512 gamma entries. The first 512 entries are stored in the precision palette indexes 512 to 1023 with 10 bits per color in a 0.10 format with 0 integer and 10 fractional bits.

12 bit interpolated gamma mode:

This provides the highest quality gamma for pixel data formats greater than 30 bits per pixel.

The gamma correction curve is represented by specifying a set of gamma entry reference points spaced equally along the curve for values between -1 and 1. For extended values there is an extended gamma entry reference point at the maximum allowed input value.

All input values are clamped to the greater than -3.0 and less than 3.0 range before the gamma calculation.

For input values greater than or equal to 0 and less than 1.0, the input value is used to linearly interpolate between two adjacent points of the first 513 gamma entries to create the result value. The first 512 entries are stored in the precision palette with 16 bits per color in a 0.16 format with 0 integer and 16 fractional bits (upper 10 bits in odd indexes, lower 6 bits in even indexes). The 513th entry is stored in the PAL_GC_MAX register with 17 bits per color in a 1.16 format with 1 integer and 16 fractional bits.

For input values greater than or equal to 1.0 and less than 3.0, the input value is used to linearly interpolate between the 513th and 514th gamma entries to create the result value. The 514th entry is stored in the PAL_EXT_GC_MAX register with 19 bits per color in a 3.16 format with 3 integer and 16 fractional bits.

For negative input values, gamma is mirrored along the X-axis, giving the same result as positive input values, except for a negative sign. When gamma input may be negative, the first gamma point should be programmed to a value of 0.0 in order to have a symmetric mirroring.

To program the gamma correction entries, calculate the desired gamma curve for inputs from 0 to 3.0. The curve must be flat or increasing, never decreasing. For inputs of 0 to 1.0, multiply the input value by 512 to find the gamma entry number, then store the desired gamma result in that entry. For inputs greater than 1.0 and less than or equal to 3.0, store the result for an input of 3.0 in the 514th gamma entry.

Render/Display Decompression

GT Render engines uses a lossless scheme to compress the color Render targets. The goal of the compression is to reduce the memory bandwidth. The memory foot print increases slightly due to the need of the control surface.

- Decompression is supported on plane 1 and plane 2 of pipe A and pipe B with RGB8888 surface formats.
- Decompression is supported only in legacy tile Y and tile Yf surfaces.
- Decompression support is limited to left-right cache line pair mode. Top-bottom mode is not supported.
- When render decompression is enabled, display engine internally converts the Async flips to Sync flips.
- Decompression is not supported with 90/270 degree rotation.

Color Control Surface

The Color Control Surface (CCS) contains the compression status of the cache-line pairs**.** The compression state of the cache-line pair is specified by 2 bits in the CCS. Each CCS cache-line represents an area on the main surface of 16 x16 sets of 128 byte Y-tiled cache-line-pairs. CCS is always Y tiled. The

address of CCS surface is specified as an offset from the start of the Render Target main surface. CCS stride is programmed separately independent of the main surface stride.

Decompression Programming

When compressed Render targets are presented to Display, the display decompression must be enabled. Along with main surface programming, the following additional programming is required to enable the decompression

- **Decompression Enable**

Decompression is enabled by programming the 'Render Decomp' bit in the PLANE_CTL register.

- **Color Control Surface Distance**

The start of the CCS surface is programmed as the distance in bytes from the start of the main surface in the PLANE_AUX_DIST register. The CCS is always placed after the main surface and is 4K page aligned.

- **Color Control Surface Stride**

The CCS stride is programmed in the PLANE_AUX_DIST register.

Plane Rotation Programming

This topic provides programming information for plane rotation.

The 180 rotation mode is unchanged and will continue to use the same programming. In the 180 rotation mode display hardware is responsible for walking the pages in the reverse order. The cacheline walk within the page is also reversed. The 90 and 270 rotation modes require more complicated page walk mechanism. The page walk is made transparent to the hardware by providing a different set of page translations (remapped GTT) for the same rendered surface. The remapping completely abstracts the page walk away from the hardware and the hardware walks the pages as if there is no rotation. Hardware is still responsible for handling the the walk within the page appropriately. Also, the 90, 270 Rotation requires a new parameter - surface height. The changes needed in the driver programming is discussed below.

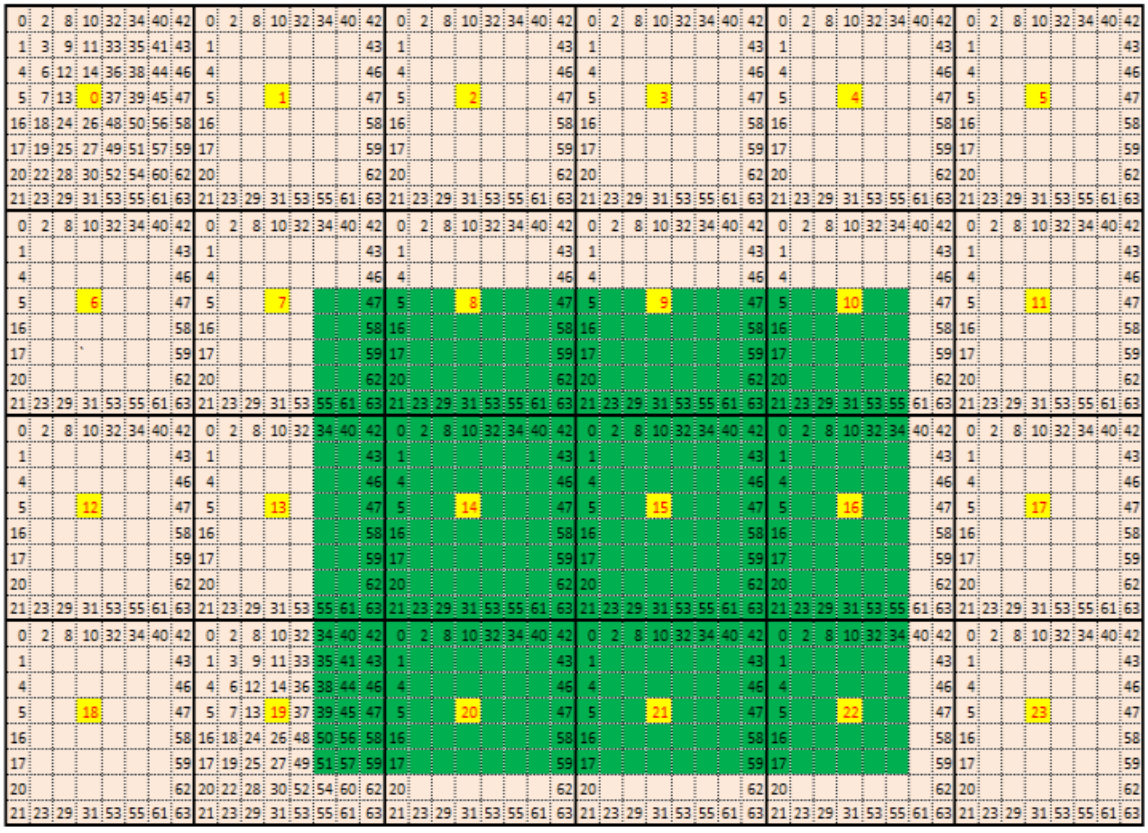
90 Rotation

For the 90 rotation programming, the plane parameters must use the following mapping

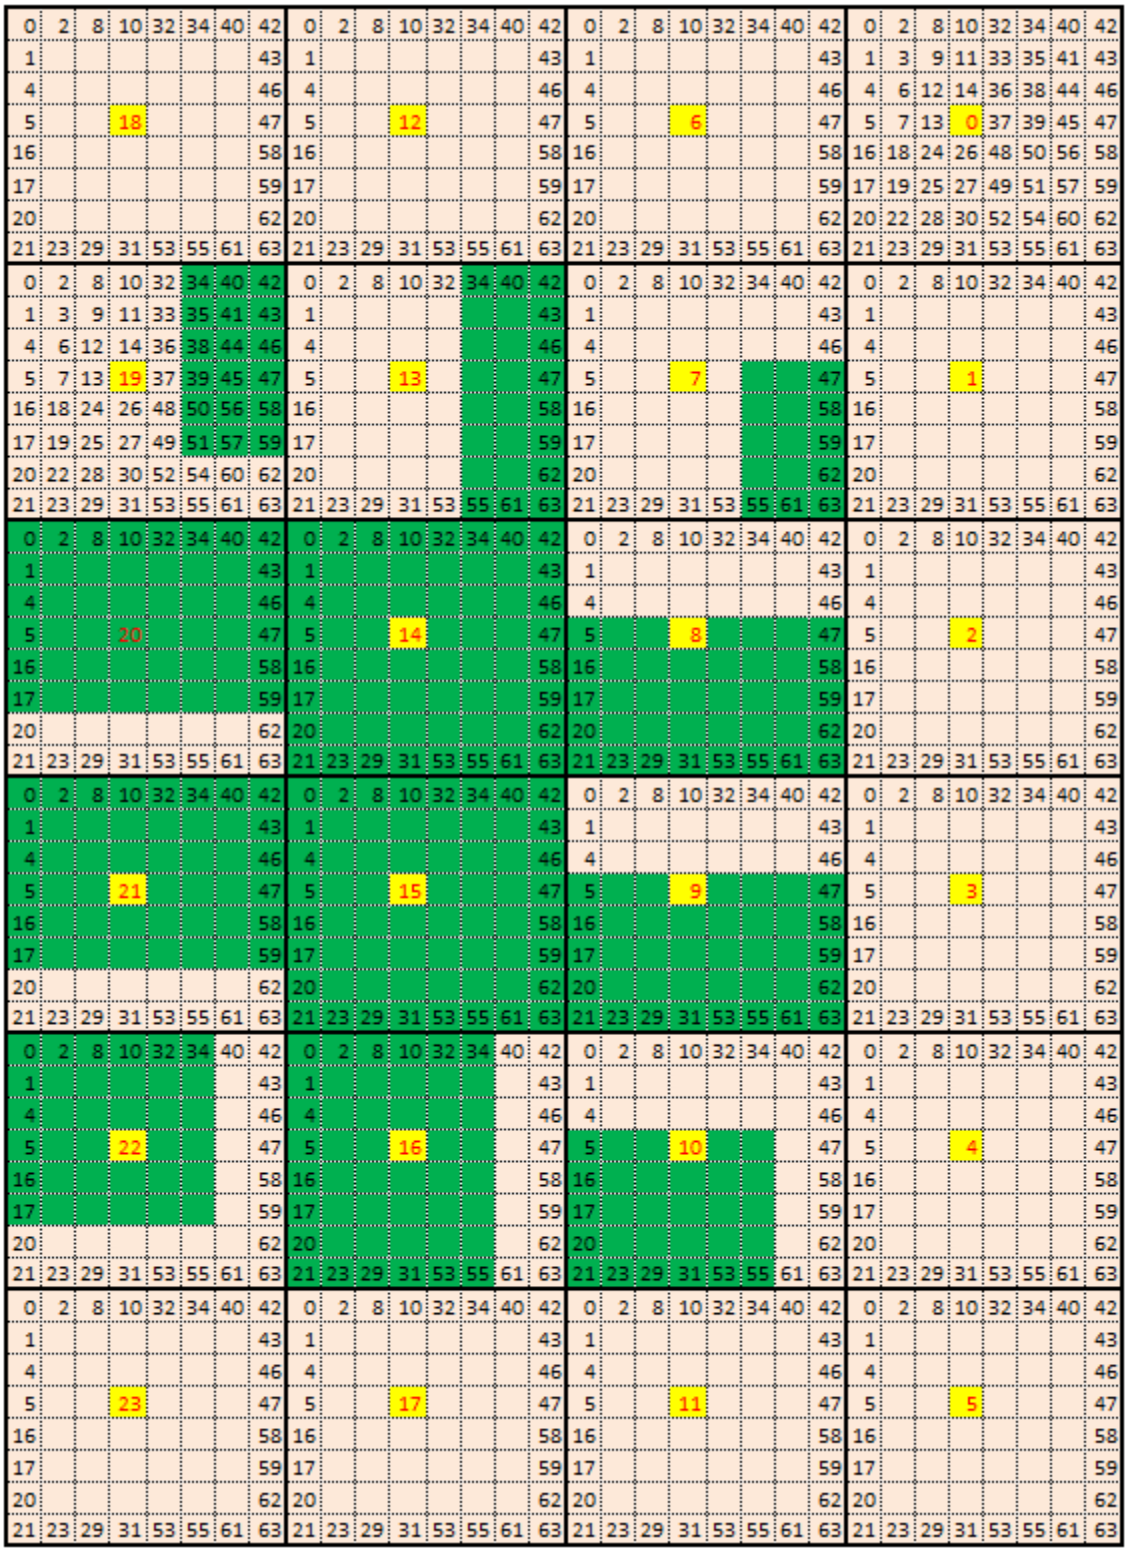
- Base address = New address (remapped GTT)
- Stride = Surface height in tiles
- Plane Width = Plane Height
- Plane Height = Plane Width
- X offset = (Surface height in tiles * tile height) - Plane Y offset - Plane Height *[Note: the calculated X offset will always be >= 0 since Plane Y Offset + Plane Height <= Surface Height in lines]*

- Y offset = X offset
- Driver can enable the Scaler, as needed, to fit the rotated content in to the pipe active display area.

Sample surface in frame buffer (Yf tiled)



Page access sequence in the rotated 90 mode



Example

Let us assume the following display programming for a single pipe – single plane, Yf tiled, non-rotated, 1920 x 1200, 4Bpp with the plane panned (100, 150), covering full active area and scaler not enabled.

GTT mapping

Here is a sample GTT mapping for 90 rotation mode.

Original GTT

Assumed Surface base = 0x200000

0x200000 = page 0

0x201000 = page 1

0x202000 = page 2

0x203000 = page 3

…

Remapped Display GTT – 90 rotation

Assumed new Surface base = 0x400000

0x400000 = page 18

0x401000 = page 12

0x402000 = page 6

0x403000 = page 0

Register programming for non-rotated scenario

- *PLANE_SURF->Surface Base Address = 0x200000*
- *PLANE_STRIDE->Stride = 60* [(1920 * 4)/128] [(width *bpp)/tile width]
- *PLANE_SIZE->Width = 1920*
- *PLANE_SIZE->Height = 1200*
- *PLANE_OFFSET->Start X Position = 100*
- *PLANE_OFFSET->Start Y Position = 150*
- *Surface Height in tiles (assumed) = 50 (allocated surface height in number of scan lines/tile height. For plane height = 1200, the surface height should be a minimum of 38 tiles (ceiling (1200/32). When panning is used, the rendered frame buffer surface will be larger than the plane size. Here, let us assume that the rendered surface height in tiles = 50).*

The programming changes to following for a 90 rotation scenario

- *PLANE_SURF->Surface Base Address = 0x400000* [uses remapped GTT]
- *PLANE_STRIDE->Stride = 50* [Surface height in tiles (assumed earlier)]
- *PLANE_SIZE->Width = 1200* [non-rotated Height]

- *PLANE_SIZE->Height* = *1920* [non-rotated Width]
- *PLANE_OFFSET->Start X Position* = *250* [(50*32)-150-1200] [(Surface height * tile height) – non rotated Y position – non rotated Height]
- *PLANE_OFFSET->Start Y Position* = *100* [non-rotated X position]

The scaler should be programmed appropriately to fit the rotated plane in the pipe active area and the window position should be adjusted if it is desired to maintain the same apparent position on a physically rotated display.

270 rotation

Uses the same GTT remapping and register programming as 90 rotation mode with the Plane control register rotation mode set as 270.

Display Buffer Programming

This topic describes display buffer allocation and shows a basic allocation method for single and multi-pipe modes. The display driver can choose to use more advanced allocation techniques as desired.

Display Buffer Allocation

Allocation of the display buffer is programmable for each display plane, using the buffer start and buffer end values in PLANE_BUF_CFG_.

Proper display buffer allocation is important for Display hardware to function correctly. Optimal allocation provides better display residency in memory low power modes. Display Buffer allocation must be recalculated and programmed when pipes/planes get enabled or disabled.

Display Buffer Size

Display Buffer Size	Total Display Buffer Blocks	Fixed Bypass Path Allocation in Blocks	Blocks Available for Driver Programming
448 KB	896	4	0 - 891

Each display buffer block is 8 cache lines.

Allocation Requirements

Allocation must not overlap between any enabled planes.

A minimum allocation is required for any enabled plane. See Minimum Allocation Requirements below.

A gap between allocation for enabled planes is allowed.

The allocation for enabled planes should be as large as possible to allow for higher watermarks and better residency in memory power saving modes.

Minimum Allocation Requirements

Allocation for each enabled plane must meet these minimum requirements.

Planes using Linear or X tiled memory formats must allocate a minimum of 8 blocks.

Planes using Y tiled memory formats must allocate blocks for a minimum number of scanlines worth of data. The formula and table of minimum scanlines is below.

Y tiled minimum allocation = Ceiling [(4 * Plane source width * Plane Bpp)/512] * MinScanLines/4 + 3

	Minimum Scanlines for Y Tile	
Plane Bpp	0/180 Rotation	90/270 Rotation
1	8	32
2	8	16
4	8	8
8	8	4

Basic Allocation Method

These are basic methods that can be used for single and multi-pipe modes. For optimal power usage, the display driver can choose to use more advanced allocation techniques as desired.

Single Pipe

Allocate a fixed number of blocks to cursors and then allocate the remaining blocks among planes, based on each plane's data rate.

BlocksAvailable = TotalBlocksAvailable

1. Allocate 32 blocks for cursor

The driver frequently enables and disables the cursor or changes the cursor pixel format. Fixed allocation is preferred for cursor to minimize the buffer re-allocation. More allocation might be required to support deeper low power states (based on the results of watermark calculations).

CursorBufAlloc = 32

BlocksAvailable = BlocksAvailable – 32

2. Check for minimum buffer requirement

For each enabled plane

If Y tiled

MinScanLines = Look up minimum scanlines needed from the table

*PlaneMinAlloc = Ceiling [(4*Plane width*Bpp)/512] * MinScanLines/4 + 3*

Else

PlaneMinAlloc = 8

If sum of PlaneMinAlloc > BlocksAvailable

Error - Display Mode can't be supported.

The driver can change the number of enabled planes or the plane configuration and rerun the algorithm.

3. Calculate Relative Data Rate for planes

In this step the driver may want to use the expected maximum plane source sizes so it does not have to reallocate for a plane that is changing size.

For each enabled plane

If PlaneScalerEnabled

*PlaneScaleFactor = (Plane width/Scaler window X size) * (Plane height/Scaler window Y size)*

Else

PlaneScaleFactor = 1

*PlaneRelativeDataRate = Plane height * Plane width * plane source bytes per pixel * PlaneScaleFactor*

4. Allocate blocks for enabled planes as per the Data rate ratio.

For each plane that needs allocation (PlaneBlockAllocFinal == false)

*PlaneBufAlloc = floor (BlocksAvailable * PlaneRelativeDataRate/Sum of PlaneRelativeDataRate of all planes that need allocation).*

*floor - rounds down to an integer value dropping the fractional part.

5. Adjust for minimum allocation requirement

AdjustmentRequired = false

For each plane needs allocation (PlaneBlockAllocFinal == false)

If PlaneBufAlloc < PlaneMinAlloc

AdjustmentRequired = true

PlaneBufAlloc = PlaneMinAlloc

PlaneBlockAllocFinal = true

BlocksAvailable = BlocksAvailable - PlaneMinAlloc

If AdjustmentRequired = true

Go back to step 4

Multi-Pipe

NumPipes = Total number of display pipes in the hardware

Allocate a fixed number of blocks to cursors, allocate *1/NumPipes* of the remaining blocks to each pipe, then calculate each pipe individually as in the Single Pipe case.

1. Allocate 8 blocks for cursor per pipe

The driver frequently enables and disables the cursor or changes the cursor pixel format. Fixed allocation is preferred for cursor to minimize the buffer re-allocation. More allocation might be required to support deeper low power states (based on the results of watermark calculations).

For each enabled cursor

CursorBufAlloc = 8

*BlocksAvailable = TotalBlocksAvailable - (8 * NumPipes)*

2. Distribute the blocks equally among the pipes

   BlocksAvailable = BlocksAvailable/NumPipes

3. Assign blocks to the planes

   For each pipe

Perform Single Pipe sequence, starting from step 2.

Buffer allocation re-distribution

When an additional pipe is getting enabled, or an existing pipe requires more buffer to support a new mode or is disabled, buffer reallocation may be necessary for proper display functionality. Whenever a portion of the allocated buffer is taken away from one pipe and allocated to a different pipe, the following sequence should be followed to make sure that there are no buffer allocation overlaps at any point of time.

1. *For each pipe whose allocation is reduced*
   a. *Program the new buffer allocation.*
   b. *Wait for VBlank of that pipe for new allocation to update.*
2. *For each pipe whose allocation is increased*
   a. *Program the new buffer allocation.*
   b. *Wait for VBlank of that pipe for new allocation to update.*

Display Buffer Allocation and Watermark programming prior to OS boot

Basic programming of the display buffer and watermarks to allow limited display usage prior to OS boot:

This will prevent package power saving states from enabling.

Supported usages:

- Up to 3 pipes enabled at once
- Up to one universal plane enabled per pipe. No cursor.
- Linear or Xtile memory
- Any RGB frame buffer pixel format 32bpp or less, without render compression
- Any screen resolution
- Downscaling less than or equal to 12.5%

Allocate 160 blocks per pipe.

Pipe A: 0-159, Pipe B: 160-319, Pipe C: 320-479

PLANE_BUF_CFG_<plane number>_A = 0x009F0000

PLANE_BUF_CFG_<plane number>_B = 0x013F00A0

PLANE_BUF_CFG_<plane number>_C = 0x01DF0140

Set level 0 watermarks for any enabled plane to 160 blocks and 2 lines.

PLANE_WM_<plane number>_<pipe>_0 = 0x800080A0

The higher level watermarks for any enabled plane must have bit 31=0 to keep the low power watermarks disabled.

VGA

The VGA Control register is located here. The VGA I/O registers are located in the VGA Registers document.

Transcoder MN Values

Description
These values are used for DisplayPort.

There is one instance of these registers per each transcoder.

For dynamic switching between multiple refresh rates, M/N values may be reprogrammed on the fly. The link N should be programmed last to trigger the update of all the data and link M and N registers and then the new M/N values will be used in the next frame that is output.

DATAM

DATAN

LINKM

LINKN

Clocks:

ls_clk is the link symbol clock. i.e. 270 MHz for HBR2.

strm_clk is the stream clock, which is the video pixel rate or dot clock.

cdclk is the core display clock.

The link only operates in Synchronous Clock mode. The link clock and stream clock are synchronous and the link M and N values stay constant for a given pixel rate.

Calculation of TU:

TU is the Transfer Unit.

TU size calculation (applies to SST only)

TU size for reduced blanking cases may vary and the following formula should be used in such cases.

TU size = MIN(INT((Horizontal Blank Width * ls_clk/strm_clk)-2), 64)

Example 1:

ls_clk = 810 MHz

strm_clk = 1025.766 MHz

Horizontal Blank = 80 pixels (Reduced Blanking v2 timings)

Calculated TU size = MIN(INT(63.1-2),64) = 61

Actual TU size = 61

So, in this example TU size becomes 61.

Example 2:

ls_clk = 810 MHz

strm_clk = 923.221 MHz

Horizontal Blank = 80 pixels (Reduced Blanking v2 timings)

TU size = MIN(INT(70.18-2),64) = 64

Calculation of Data M, and Data N:

Note that for 4:2:0 format the number of bytes per pixel will be half the number of bytes of RGB pixel.

Active/TU Size = Payload/Capacity = Data M/N

Compression Ratio (CR) = DisplayPort Compression enabled ? min(ratio1,ratio2) : 1

- ratio1 = Compressor BW / Link BW = (cdclk * bytes per pixel) / (ls_clk * number of lanes)
- ratio2 = (Horizontal active in pixels * bytes per pixel / 4) / ((Horizontal active in pixels * bytes per pixel / 8) +2)

Data M/N = (strm_clk * bytes per pixel) / (CR * ls_clk * number of lanes)

Calculation of Link M and Link N:

Link M/N = strm_clk / ls_clk

Restriction on clocks and number of lanes:

- Number of lanes >= INT(strm_clk * bytes per pixel / ls_clk)

Restrictions on the Virtual Channel (VC) payload size in DisplayPort MST mode

- In a x1 lane config, each pipe stream on the link must use a VC payload size that is a multiple of 4.

- In a x2 lane config, each pipe stream on the link must use a VC payload size that is a multiple of 2.
- In a x4 lane config, each pipe stream on the link must use a VC payload size that is a multiple of 1.

Transcoder Video Data Island Packet

Data Island Packet (DIP) is a mechanism that allows data to be sent over a digital port during blanking, according to the HDMI and DisplayPort specifications. This includes header, payload, checksum, and ECC information.

Each type of Video DIP will be sent once each frame while it is enabled.

HB = Header Byte, DB = Data Byte, RO = Read Only

The audio subsystem is also capable of sending Data Island Packets. These packets are programmed by the audio driver and can be read by in MMIO space via the audio control state and audio HDMI widget data island registers.

Video DIP data write sequence:

1. Wait for 1 VSync to ensure completion of any pending video DIP transmissions
2. Disable the video DIP being updated (disable VDSC before updating PPS DIP)
3. Program video DIP data buffer registers for DIP being updated
4. Enable the video DIP

The video DIP data and ECC buffers may be read at any time.

DIP data buffer registers must be programmed with valid data before enabling the DIP.

Partial DIPs are never sent out while the port is enabled. Disabling the DIP at the same time it is being transferred will result in the DIP being completed before the function is disabled.

Shutting off the port on which DIP is being transmitted will result in partial transfer of DIP data. There is no need to switch off the DIP enable bit if the port transmitting DIP is disabled.

When disabling both the DIP port and DIP transmission, first disable the port and then disable DIP.

Enabling a DIP function at the same time that the DIP would have been sent out (had it already been enabled) will result in the DIP being sent on the following frame.

For HDMI, even if no DIP is enabled, a single Null DIP will be sent at the same point in the stream that DIP packets would have been sent.

Panel Self Refresh

This section is about Panel Self Refresh (PSR). PSR1 at one point was named Self Refreshing Display (SRD).

PSR1 enable sequence:

- Prerequisite: The associated transcoder and port are running.

1. Configure FBC host and render tracking. The FBC function does not need to be enabled in FBC_CTL.
2. Program Transcoder EDP VSC DIP data with a valid setting for SRD/PSR.
3. Configure and enable SRD_CTL.

PSR1 disable sequence:

- Prerequisite: The associated transcoder and port are running.

1. Disable SRD_CTL.
2. Wait for SRD_STATUS to show SRD is Idle. This will take up to one full frame time (1/refresh rate), plus SRD exit training time (max of 6ms), plus SRD aux channel handshake (max of 1.5ms).

PSR2 disable sequence:

1. Program PSR2_CTL reset Psr2Enable, SelectiveUpdateTrackingEnable bits.
2. Disable GTC if required.
3. Wait for PSR2_STATUS to show PSR2 is Idle. This will take up to one full frame time (1/refresh rate), plus exit training time (max of 6ms), plus aux channel handshake (max of 1.5ms).

Transcoder Port Sync

Feature Description

PORT SYNC is a transcoder level feature. This mode forces two or more transcoders to be in sync with one transcoder master and one or more transcoder slaves. In the case of DP/eDP, the master is unaware that it is operating in Port Sync mode. Only the slave is aware that it is operating in this mode. Hence, port sync mode is only enabled in the slave transcoder.

DP/eDP Port Sync Restrictions

1. The slave and master transcoders and associated ports must have identical parameters and properties.
2. They must be connected to the same PLL, have the same color format, link width (number of lanes enabled), resolution, refresh rate, dot clock, TU size, M and N programming, etc.
3. Port Sync Mode must only be enabled with DisplayPort SST.
4. PSR would need to be disabled when port sync mode is enabled.
5. Port Sync Mode Master Select must be programmed with a valid value when Port sync Mode is enabled.

Audio

This section describes Audio features.

Audio Bios Programming Sequence

Codec Verb Table

For each codec present on the High Definition Audio codec link, a corresponding pre-defined “Codec Verb Table” must be available to System BIOS. The Codec Verb Tables are based on codec specific information (coded datasheet) and platform design specific information (schematics) and are built by System BIOS writers and platform designers. The table contains a list of 32-bit “Verb”s (command and data payload) to be sent to the corresponding codec over the High Definition Audio codec link.

Below is a sample High Definition Audio Codec Verb Table for a platform with 1 codec at codec address 01h.

;Sample HIGH DEFINITION AUDIO Codec Verb Table

;Codec Address (CAd) = 02h

;Codec Vendor: XYZ Company

;VenID DevID:

```

dd 20878100h

Codec Initialization Programming Sequence

After System BIOS has determined the presence of High Definition Audio codecs, it must follow the programming sequence below to update the codec with the correct jack information specific to the platform for the High Definition Audio driver to retrieve and use later.

There are two ways to send verbs to and receive response data from codecs over the High Definition Audio codec link: using CORB/RIRB (Command Output Ring Buffer / Response Input Ring Buffer) or using the Immediate Command/Immediate Response register pair. The sequence below uses the latter which does not require the availability of a memory buffer.

System BIOS should ensure that the High Definition Audio HDBAR D27:F0:10-17h contains a valid address value and is enabled by setting D27:F0:04h[1]. System BIOS must ensure program as mentioned in section 9.6, and then the Controller Reset# bit of Global Control register in memory-mapped space (HDBAR+08h[0]) is set to 1b and read back as 1b. Additional delay might be required to allow codec coming out of reset prior to subsequent operations, please contact your codec vendor for detail. When clearing this bit and setting it afterward, BIOS must ensure that minimum link timing requirements (minimum RESET# assertion time, etc.) are met.

Note: To initialize codec Bios should set the bit 15 of the register 0X65F10h of the Display MMIO to 1. This bit needs to be after the controller is brought out of reset. BIOS should wait for Controller to detect the wake event and recognize the Codec.

For each High Definition Audio codec present as indicated by HDBAR + 0Eh[3:0], System BIOS should perform the codec initialization as described below:

1. Read the VendorID/DeviceID pair from the attached codec.

- Verify that the ICB bit, HDBAR + 68h[0], is 0.
- Write verb 200F0000h (dword) to the IC register, HDBAR + 60h, where: ‘2’ (bits 31:28) represents the codec address (CAd).
- Program HDBAR + 68h[1:0] to 11b to send the verb to the codec.

- Poll the ICB bit, HDBAR+68h[0] until it returns 0 indicating the verb has been sent to the codec. BIOS may write HDBAR + 68h[0] to a 0 if the bit fails to return to 0 after a reasonable timeout period.
- If HDBAR + 68h[1] = 1b indicating the response data from the codec is now valid, read HDBAR + 64h; the data is the VID/DID value returned by the codec.

2. Check against internal list to determine if there is a stored verb table which matches the CAd/VID/DID information.

Steps 1 and 2 are System BIOS implementation-specific steps and can be done in different ways. If a System BIOS has prior knowledge of a fixed platform/codec combination (e.g., for a System BIOS having 3 stored verb tables for 3 known codecs at known codec addresses on a known platform), a simple pre-defined codec-to-table matching can be used and steps 1 and 2 can be eliminated. For a System BIOS to support multiple codec/platform combinations, an internal match-list might be needed to match a platform/codec combination to a codec verb table.

3. If there is a match, send the entire list of verbs in the matching verb table one by one to the codec.

- Verify the ICB bit, HDBAR + 68h[0] is 0.
- Write the next verb (dword) in the table to HDBAR + 60h.
- Program HDBAR + 68h[1:0] to 11b to send the verb to codec.
- Poll the ICB bit, HDBAR + 68h[0] until it returns 0 indicating the verb has been sent to the codec. BIOS may write HDBAR + 68h[0] to a 0 if the bit fails to return to 0 after a reasonable timeout period.
- Repeat the steps until all the verbs in the table have been sent.

Some verbs in the table may be dependent on certain platform-specific conditions. For example, for the sample table above, the verbs for Pin Complex 7 and 8 (NID=14,16 respectively) should be sent only if the Front Panel Jacks are present and connected on the platform, which may be indicated by a software flag that is controlled by a certain GPIO pin.

Audio Programming Sequence for Link wakeup

The following audio programming sequences are to be used for preventing the Unsolicited responses when 3 pin link is awake.

Display Audio codec generates a wake event whenever the power well (PGx - power well in which Display Audio codec HW resides) is powered up. If the link is already running, this wake event is considered as unsolicited response by audio controller in PCH. This may sometimes be considered as unnecessary URs. To avoid such URs following programming should be followed by SW. This sequence assumes communication between Audio and GFX drivers without HW to indicate Audio codec power well status.

Power down sequence:

1. Unplug event
2. PD goes low

3. PG2 low

4. Audio link should go low (there should be a communication between GFX driver and Audio Driver to turn off the link)

    1. To turn off iDisp-A link:
    2. Power off iDisp-A codec. Follow the PW2 turn off sequence.
    3. In HD Audio Controller (PCH) Program LCTL1.SPA = 0.
    4. Wait for LCTL1.CPA = 0 to indicate the link has clock stopped.

Power up sequence:

1. Plug event

2. PG2 goes high

3. Audio link to be enabled (there should be a communication between GFX driver and Audio Driver to turn on the link)

    1. To turn on iDisp-A link:
    2. In HD Audio Controller (PCH) Program LCTL1.SPA = 1.
    3. Wait for LCTL1.CPA = 1 to indicate the link has clock running.

4. Check WAKESTS[2] = 1 to indicate the codec wake up occurs

5. PD bit set

6. Codec awake. Continue with codec init.

Audio Programming Sequence

The following HDMI and DisplayPort audio programming sequences are to be used when enabling or disabling audio or temporarily disabling audio during a display mode set.

The audio codec and audio controller disable sequences must be followed prior to disabling the transcoder or port in a display mode set.

The audio codec and controller enable sequences can be followed after the transcoder is enabled and the port is enabled and completed link training (not sending training or idle patterns if DisplayPort).

The audio controller and audio codec sequences may be done in parallel or serial. In general, the change in ELDV/PD in the codec sequence will generate an unsolicited response to the audio controller driver to indicate that the controller sequence should start, but other mechanisms may be used. SW should make sure to set the Inactive (IA) bit to 0 before setting PD to 1.

Audio codec disable sequence:

- Disable sample fabrication

    - Set AUD_MISC_CTRL Sample_Fabrication_EN (bit 2) to "0".
- Disable timestamps
    - Set AUD_CONFIG N_value_index (bit 29) to "0" for HDMI or "1" for DisplayPort.
    - Set N_programming_enable (bit 28) to "1"
    - Set Upper_N_value and Lower_N_value (bits 27:20, 15:4) to all "0"s.
- Disable ELDV and ELD buffer
    - Set AUD_PIN_ELD_CP_VLD ELD_valid (bit 0, 4, or 8 based on which port is used) to "0"
- Wait for 2 vertical blanks
- Optional: Disable audio PD (Presence Detect)
    - Software may choose to skip this in order to keep PD enabled during a resolution switch.
    - Set AUD_PIN_ELD_CP_VLD Audio_Inactive (bit 3, 7, or 11) to "1". SW does not need to set this bit to enable Inactive bit.
    - Set AUD_PIN_ELD_CP_VLD Audio_Output_Enable (bit 2, 6, or 10) to "0".

Audio controller disable sequence:

- Program Stream ID to 0 - Verb ID 706
- Disable audio info frames transmission - Verb ID 732
- Disable Digen - Verb ID 70D
- Program the codec to D3 state if needed.
- Audio driver may stop the audio controller DMA engine at this point if needed, but not required.

Audio codec enable sequence:

- Enable audio Presence Detect
    - Set AUD_PIN_ELD_CP_VLD Audio_Inactive (bit 3, 7, or 11) to "0".
    - Set AUD_PIN_ELD_CP_VLD Audio_Output_Enable (bit 2, 6, or 10) to "1".
- Wait for 1 vertical blank
- Load ELD buffer and Enable ELDV
    - Set AUD_PIN_ELD_CP_VLD ELD_valid (bit 0, 4, or 8 based on which port is used) to "1".
- Enable timestamps
    - Set AUD_CONFIG N_value_index (bit 29) to "0" for HDMI or "1" for DisplayPort.
    - Set N_programming_enable (bit 28) to "0".
    - Program Upper_N_value and Lower_N_value (bits 27:20, 15:4) if a non-default N value is needed.
- Enable sample fabrication if this feature is needed
    - Set AUD_MISC_CTRL Sample_Fabrication_EN (bit 2) to "1".

Audio controller enable sequence:

- Program the codec to D0 state if in D3 state.

- Program Stream ID to non zero - Verb ID 706
- Enable audio info frames transmission - Verb ID 732
- Enable Digen - Verb ID 70D
- If audio controller DMA engine is stopped, audio driver can start the DMA engine at this point.

DDI Buffer

There is one instance of these registers per each DDI.

DDI_BUF_CTL

DDI_BUF_TRANS

DISPIO_CR_TX_BMU_CR0

DDI_BUF_TRANS and DISPIO_CR_TX_BMU_CR0 are programmed with the voltage swing values for each port. They can be configured in advance of the display mode set. The recommended values are listed below.

For DisplayPort, DDI_BUF_CTL is programmed during the mode set to select between the voltage swings pre-programmed in DDI_BUF_TRANS.

HDMI always uses the voltage swing programmed in DDI_BUF_TRANS entry 9.

I_boost

I_boost increases the I/O current, boosting the swing level. There are three I_boost values, in order of increasing boost; 0x1, 0x3, and 0x7.

I_boost can be configured separately for each port and can be enabled or disabled separately for each voltage swing level.

I_boost is configured by programming DISPIO_CR_TX_BMU_CR0 tx_blnclegdisbl=0x00 and tx_blnclegsctl_<selected DDI>=<I_boost value; 0x1, 0x3, or 0x7>. It is then enabled when DDI_BUF_CTL selects a voltage swing entry that has DDI_BUF_TRANS_<entry> Balance Leg Enable=0x1. For DDIA with x4 capability (DDI_BUF_CTL DDIA Lane Capability Control = DDIA x4), the I_boost value has to be programmed in both tx_blnclegsctl_0 and tx_blnclegsctl_4.

The recommended buffer translation programming only uses I_boost for a few entries. A customer may request increased I_boost beyond the recommended values by specifying an I_boost value of 0x1, 0x3, or 0x7 to be applied to all swing entries for a port, then software needs to configure I_boost to that specified value and set DDI_BUF_TRANS_<all entries> Balance Leg Enable=0x1 for that port. This selection overrides the recommended I_boost settings.

Programming Note	
Context:	DDI Buffer
KBL re-uses SKL values, except where specific KBL values are listed.

DDI AUX Channel

DDI_AUX_CTL

DDI_AUX_DATA

DDI_AUX_MUTEX

AUX programming sequence

A general purpose AUX functional programming sequence is provided below.

AUX Functional Sequence

Step	Description	Register	Notes
1	Display must already be initialized.		Power well1 enabled cdclk enabled IO powered up as needed for Aux on this project
1b	Power well containing Aux logic powered up	PWR_WELL_CTL	High level power well partitioning shown in display overview diagram
2	Disable DC5 and DC6 before a DDI A AUX channel transaction is sent.	DC_STATE_EN	PG1 may disable automatically for DC5 or DC6.
Skip step 3, 4 if PSR1/SRD, PSR2 or GTC are NOT enabled. Do not skip step 3,4 if PSR1/SRD, PSR2 or GTC are enabled.			
3	Enable MUTEX without changing MUTEX status	DDI_AUX_MUTEX[31]='1'	
4	Read MUTEX status	DDI_AUX_MUTEX[30]	If MUTEX status is '1', wait for 500 us and poll for MUTEX status == '0'.
5	Program AUX data registers.	DDI_AUX_DATA_*_[0-4]	
6	Program control to configure AUX and START transaction.	DDI_AUX_CTL_*	Timeout timer value must be at least 600us. Timer values: 0: 400us 1: 600 us 2: 800 us 3: 1600 us START trigger: DDI_AUX_CTL_*[31]='1'
7	Wait for AUX transaction complete.		AUX Transaction complete interrupt if set OR when DDI_AUX_CTL_*[31:30] = '01'.
8	Check that receive data has no errors	DDI_AUX_CTL_*[25]	If set: write a '1' to clear this bit and skip reading AUX data registers.
9	Read AUX data register	DDI_AUX_DATA_*_[0-4]	Condition: Aux Channel Control Register Send/Busy bit is NOT asserted
10	Clear status flags	DDI_AUX_CTL_*[30]	Transaction done status

Step	Description	Register	Notes
Skip step 11 if PSR1/SRD, PSR2 or GTC are NOT enabled. Do not skip step 11 if PSR1/SRD, PSR2 or GTC are enabled.			
11	Release MUTEX	DDI_AUX_MUTEX[31:30]= "11" OR DDI_AUX_MUTEX[31:30]="01"	Release with (is optional) or without disabling MUTEX function.

DisplayPort Transport

There is one instance of these registers per each DDI.

GTC Target Frequency Selection

For GTC top level logic, CDCLK is taken as an input and scaled to a "target frequency" which has a period which is an exact multiple of 0.5ns. This period is also known as the accumulator increment.

Once a target frequency + accumulator increment is selected, an M and N value can be picked and fine tuned to achieve the scaling from CDCLK to target frequency.

In order for the accumulated GTC Live value to match exactly with the real passage of time, the following must be true:

The target frequency selected must be the CLOSEST possible selection to CDCLK. This corresponds to rounding the accumulator increment to the NEAREST 0.5ns increment with respect to the period of CDCLK.

Example

	Frequency	Period
Given CDCLK	337.500 MHz	2.96 ns
1st closest target frequency/increment	333.333 MHz	3.00 ns
2nd closest target frequency/increment	400.000 MHz	2.50 ns
3rd closest target frequency/increment	285.714 MHz	3.50 ns
4th closest target frequency/increment	500.000 MHz	2.00 ns

Only using the 1st closest target frequency 333.333MHz / accumulator increment of 3.00 ns will result in the GTC Live Value correctly tracking the real passage of time.

Example Calculation Flow:

1. Find the period of CDCLK -- for 337.5 MHz = 2.96 ns.
2. Round to the nearest 0.5 ns -- 3.00 ns (this is your accumulator increment value).
3. Find the “target frequency” from the rounded period value of step 2 -- 333.333 MHz is the “target frequency”.
4. Find the ratio of target frequency / CDCLK = 0.987654321.
5. Choose M and N to satisfy M / N = same ratio as step 4.

South Display Engine Registers

The South Display Engine supports Hot Plug Detection, GPIO, GMBUS, Panel Power Sequencing, and Backlight Modulation.

Terminology

Access Field	Description	Should be implemented as
R/W (Read/Write)	The value written into this register will control hardware and is the same value that will be read.	Write data is stored. Read is from the stored data. Stored value is used to control hardware.
Reserved	Unused register bit. Don't assume a value for these bits. Writes have no effect.	Write data is ignored. Read is zero.
MBZ (Must Be Zero)	Always write a zero to this register.	May be implemented as Reserved or as R/W.
PBC (Preserve Bit Contents)	Software must write the original value back to this bit. This allows new features to be added using these bits.	May be implemented as Reserved or as R/W.
Read Only	The read value is determined by hardware. Writes to this bit have no effect.	Write data is ignored. Read is from a status signal or some other internal source.
Write Only	The value written into this register will control hardware. Reads return zero.	Write data is stored. Read is zero. Stored value is used to control hardware.
R/W Clear (Read/Write Clear)	Sticky status bit. Hardware will set the bit, software can clear it with a write of 1b.	Internal hardware events set a sticky bit. Read is from the sticky bit. A write of 1b clears the sticky bit.
Double Buffered	Write when desired and the written value will take effect at the time of the double buffer update point. Reads will return the written value, which is not necessarily the value being currently used to control hardware. Some have a specific arming sequence where a write to another register is required before the update can take place. This is used to ensure atomic updates of several registers.	Two stages of registers used. Write data is stored into first stage. Read is from the first stage stored data. First stage stored value is transferred to second stage storage at the double buffer update point. Second stage stored value is used to control hardware. Arm/disarm logic may be used for some registers to control the double buffer update point.
Write/Read Status	The value written into this register will control hardware. The read value is determined by hardware.	Write data is stored. Stored value is used to control hardware. Read is from a status signal or some

Access Field	Description	Should be implemented as
		other internal source.

Backlight

This section refers to the PCH display backlight control. For CPU display backlight control, see North Display Engine Registers.

The backlight PWM output frequency is determined by the PWM clock frequency, increment, and frequency divider.

PWM output frequency = PWM clock frequency / PWM increment / PWM frequency divider

The frequency divider minimum must be greater than or equal to the number of brightness levels required by software; typically 100 or 256.

Description
PWM clock frequency = 24 MHz PWM increment = 128 or 16, selectable by software PWM frequency divider maximum = 65,536 PWM output frequency range with 100 brightness levels and increment 128 = 3 to 1,875 Hz PWM output frequency range with 100 brightness levels and increment 16 = 23 to 15,000 Hz PWM output frequency range with 256 brightness levels and increment 128 = 3 to 732 Hz PWM output frequency range with 256 brightness levels and increment 16 = 23 to 5,859 Hz
PWM clock frequency = Raw clock frequency = 19.2, 24, or 38.4 MHz. Value is found in SFUSE_STRAP. PWM increment = 1 PWM frequency divider maximum = 2^32 PWM output frequency range with 100 brightness levels and 19.2 MHz clock = 0.0004 to 192,000 Hz

Description
PWM output frequency range with 100 brightness levels and 24 MHz clock = 0.0006 to 240,000 Hz
PWM output frequency range with 100 brightness levels and 38.4 MHz clock = 0.0009 to 384,000 Hz
PWM output frequency range with 256 brightness levels and 19.2 MHz clock = 0.0004 to 75,000 Hz
PWM output frequency range with 256 brightness levels and 24 MHz clock = 0.0006 to 93,750 Hz
PWM output frequency range with 256 brightness levels and 38.4 MHz clock = 0.0009 to 150,000 Hz

Backlight Enabling Sequence

Description
1. Set frequency and duty cycle in SBLC_PWM_CTL2 Backlight Modulation Frequency and Backlight Duty Cycle.
2. Set granularity in 0xC2000 bit 0 (0 = 16, 1 = 128).
3. Enable PWM output and set polarity in SBLC_PWM_CTL1 PWM PCH Enable and Backlight Polarity.
...
4. Change duty cycle as needed in SBLC_PWM_CTL2 Backlight Duty Cycle.

If needed, granularity, polarity, and override can be programmed earlier than shown.

GMBUS and GPIO

Registers

Description
GPIO_CTL - GPIO Control
GMBUS0 - GMBUS Clock/Port Select
GMBUS1 - GMBUS Command/Status
GMBUS2 - GMBUS Status
GMBUS3 - GMBUS Data Buffer
GMBUS4 - GMBUS Interrupt Mask
GMBUS5 - GMBUS 2 Byte Index

Pin Usage

These GPIO pins allow the support of simple query and control functions such as DDC interface protocols. The GMBUS controller can be used to run the interface protocol, or the GPIO pins can be manually programmed for a "bit banging" interface.

The following tables describe the expected GPIO pin to register mapping. OEMs have the ability to remap these functions onto other pins as long as the hardware limitations are observed. The GPIO pins may also be muxed with other functions such that they are only available when the other function is not being used.

Port #	Name	Pin	Pull up/down	Description
5	DDID CTLDATA	DDPD_CTRLDATA	No (Weak pull down on reset)	DDC for port D. Digital port D present strap is set if pin is 1 at rising edge of PCH_PWROK.
	DDID CTLCLK	DDPD_CTRLCLK	No	
4	DDIB CTLDATA	DDPB_CTRLDATA	No (Weak pull down on reset)	DDC for port B. Digital port B present strap is set if pin is 1 at rising edge of PCH_PWROK.
	DDIB CTLCLK	DDPB_CTRLCLK	No	
3	DDIC CTLDATA	DDPC_CTRLDATA	No (Weak pull down	DDC for port C. Digital port C present strap is set if pin is 1 at rising edge of PCH_PWROK.

			on reset)	
	DDIC CTLCLK	DDPC_CTRLCLK	No	

GPIO Programming for I2C Bit Bashing

To drive GPIO pin low, program direction to "out" and data value to "0", along with mask bits.

To drive GPIO pin high (tristate to allow external pull up to activate), program direction to "in", along with mask bit. No need to set data value to "1".

GMBUS Controller Programming Interface

The GMBUS (Graphic Management Bus) is used to access/control devices connected to the GPIO pins.

Basic features:

1. I^2C compatible.
2. Bus clock frequency of 50 KHz or 100 KHz.
3. Attaches to any of the GPIO pin pairs.
4. 7-bit or 10-bit Slave Address and 8-bit or 16-bit index.
5. Double buffered data register and a 9 bit counter support 0 byte to 256 byte transfers.
6. Supports stalls generated by the slave device pulling down the clock line (Slave Stall), or delaying the slave acknowledge response.
7. Status register indicates error conditions, data buffer busy, time out, and data complete acknowledgement.
8. Detects and reports time out conditions for a stall from a slave device, or a delayed or missing slave acknowledge.
9. Interrupts may optionally be generated.
10. Does not directly support segment pointer addressing as defined by the Enhanced Display Data Channel standard.

Segment pointer addressing as defined by the Enhanced Display Data Channel standard:

1. Use bit bashing (manual GPIO programming) to complete segment pointer write **without terminating in a stop or wait cycle**.
2. Terminate bit bashing phase with both I^2C lines pulled high by tri-stating the data line before the clock line. Follow EDDC requirement for response received from slave device.
3. Initiate GMBUS cycle as required to transfer EDID following normal procedure.

Sequence for GMBUS Burst Reads Greater Than 511 Bytes

- Not available until KBLPCH-H A0, SPT-LP D1, SPT-H E1

1. X=number of bytes to read.
2. Set byte count override bit GMBUS0 bit 6.
3. Set total byte count field in GMBUS1 to 511.
4. Read X bytes.
5. Issue GMBUS stop by writing 100b to GMBUS1 Bus Cycle Select.
6. Clear byte count override bit.

Example with 526 bytes

1. X=526.
2. Set byte count override bit GMBUS0 bit 6.
3. Set total byte count field in GMBUS1 to 511.
4. Read 526 bytes.
5. Write 100b to GMBUS1 Bus Cycle Select.

   Clear byte count override bit.

Display Watermark Programming

Watermark Overview

The display watermarks are used to control the display engine memory request behavior.

Description
The default settings of the watermark configuration registers will **not** allow the display engine to operate. The watermark values must be properly calculated and programmed in order to enable a display and achieve optimum power and performance. Incorrectly programmed watermark values can result in screen corruption.

The watermarks should be calculated and programmed when any of the watermark calculation inputs change. This includes planes enabling or disabling, plane source format or size changing, etc.

Besides programming the watermark registers, there are other display configuration requirements and registers that must be programmed in order for the display to operate in a low power mode, and there are memory controller configuration requirements which are not documented here.

Watermark Calculations

The display watermarks are calculated using information from the display configuration and memory latencies. The watermarks must be calculated and programmed before enabling a plane or changing a plane configuration.

For YUV 420 Planar formats, only the Y surface watermark value is calculated and programmed. Though the UV surface watermark value is not programmed seperately, it must be calculated to make sure that the UV buffer allocation satisfies the latency requirments.

The ceiling function rounds any non-integer value up to the next greater integer. Example: ceiling[0.3]=1, ceiling[2.1]=3, ceiling[4.8]=5, ceiling[4]=4

Watermark Algorithm

1. Retrieve memory latency values
    - See the Memory Values section to find the memory latency values
    - The memory values do not change after boot, so software may cache them to avoid re-reading
2. For each enabled pipe (run each time pipe configuration changes)
    A. Calculate adjusted pipe pixel rate
        I. Adjusted pipe pixel rate = pixel rate for the screen resolution
            - If there will be dynamic switching between refresh rates, either use the fastest pixel rate, or re-calculate using the current pixel rate when the refresh rate is switched
            - If plane 90 or 270 rotation is enabled, use the rotated width and height in pixel rate calculations.
        II. If TRANS_CONF Interlaced Mode == PF-ID, adjusted pipe pixel rate = adjusted pipe pixel rate * 2
        III. If pipe scaling enabled, adjusted pipe pixel rate = adjusted pipe pixel rate * pipe down scale amount
            - See the Scaling section to find the down scale amount
    B. Program WM_LINETIME Line Time = roundup[8 * pipe horizontal total pixels / adjusted pipe pixel rate MHz]
3. For each enabled plane (run each time pipe or plane configuration changes)
    A. Calculate adjusted plane pixel rate
        I. Adjusted plane pixel rate = adjusted pipe pixel rate
        II. If plane scaling enabled, adjusted plane pixel rate = adjusted plane pixel rate * plane down scale amount
            - See the Scaling section to find the down scale amount
    B. For each valid memory latency level

Plane Bytes per pixel	Minimum Scanlines for Y Tile	
	0/180 Rotation	90/270 Rotation
1 or NV12	4	16
2, P0xx, or YUV422	4	8
4	4	4
8	4	N/A

        I. Calculate method 1
            - Method 1 = memory latency microseconds * adjusted plane pixel rate MHz * plane source bytes per pixel / 512
        II. Calculate method 2

- plane bytes per line = plane source width pixels * plane source bytes per pixel
- Calculate plane blocks per line
  - If plane memory format is Linear
    - plane blocks per line = ceiling[plane bytes per line / 512] + 1
  - Else If plane memory format is Y tile
    - plane blocks per line = ceiling[Minimum Scanlines for Y tile * plane bytes per line / 512]/Minimum Scanlines for Y tile
  - Else
    - plane blocks per line = ceiling[plane bytes per line / 512]
- Method 2 = ceiling[(memory latency microseconds * adjusted plane pixel rate MHz) / Pipe horizontal total number of pixels] * plane blocks per line

III. Calculate Y tile minimum

- Y tile minimum = Minimum Scanlines for Y tile * plane blocks per line

IV. Select the watermark result

- If plane memory format is X tile or linear
  - If (((plane source bytes per pixel * pipe horizontal total number of pixels) / 512) < 1) AND ((plane bytes per line / 512) < 1) // Special case for unrealistically small horizontal total
    - Selected Result Blocks = Method 2
  - Else If (plane buffer allocation / plane blocks per line) >=1
    - Selected Result Blocks = minimum[Method 1, Method 2]
  - Else
    - Selected Result Blocks = Method 1
- Else // Y tile
  - Selected Result Blocks = maximum[Method 2, Y tile minimum]
-

V. Convert result to blocks and lines

- Result Blocks = ceiling[Selected Result Blocks] + 1
- Result Lines = ceiling[Selected Result Blocks / plane blocks per line]

this applies to all Gen9 projects

If latency level 1 through 7 and Y tile:

Result Blocks = Result Blocks + Y tile minimum

Result Lines = Result Lines + Minimum Scanlines for Y tile

If latency level 1 through 7 and not Y tile:

- Result Blocks = Result Blocks + 1

This applies to all Gen9 projects

If Render Decompression enabled and latency level 0:

Result Blocks = Result Blocks + Y tile minimum

// For latency levels 1 through 7 ensure that the their result lines/blocks >= latency level 0 lines/blocks.

For latency levels 1 through 7

If latency level result blocks < latency level 0 blocks

latency level result blocks = latency level 0 blocks

If latency level result lines < latency level 0 lines

- latency level result lines = latency level 0 lines

VI. Compare against the maximum
- If (Result Blocks >= plane buffer allocation), maximum exceeded for this latency level
- If latency level 1 through 7
  - If (Result Lines > 31), maximum exceeded for this latency level
- For YUV 420 Planar formats, perform the above check for both Y and UV planes.

4. For transition watermark

A. Calculate transition offset
- Transition Offset Blocks = Transition minimum + Transition amount
- See Transition Watermark section for transition minimum and transition amount

B. Calculate transition Y tile minimum
- Transition Y tile minimum = 2 * memory latency level 0 Y tiled minimum

C. Select the watermark result
- If plane memory format is X tile or linear
  - Result Blocks = Memory latency level 0 Selected Result Blocks + Transition Offset Blocks
- Else // Y tile
  - Result Blocks = maximum[Memory latency level 0 Selected Result Blocks, Transition Y tile minimum] + Transition Offset Blocks

D. Convert result to blocks
- Result Blocks = ceiling[Result Blocks] + 1

This applies to all Gen9 projects

If not Y tile:

- Result Blocks = Result Blocks + 1
-

E. Compare against the maximum

- If (Result Blocks >= plane buffer allocation), maximum exceeded for transition watermark
- For YUV 420 Planar formats, perform the above check for both Y and UV planes.

5. Program watermark registers
   A. For each latency level 0 to 7
      - If memory latency for this level is invalid, or the maximum was exceeded for this level or any previous level, program PLANE_WM_<latency level> Enable = 0
        - **If watermark latency level 0 exceeds the maximum, the plane must not be enabled.**
      - Else program PLANE_WM_<latency level> Enable = 1, Lines = Result Lines, Blocks = Result Blocks
        - The latency level 0 Lines value is ignored by hardware in Gen9
   B. For transition watermark
      - If the maximum was exceeded for the transition watermark, program PLANE_WM_TRANS Enable = 0
      - Else program PLANE_WM_TRANS Enable = 1, Blocks = Transition Result Blocks
        - The transition watermark Lines value is ignored by hardware
   C. Write the plane surface base address register to trigger update of the watermarks and other plane double buffered registers. This should be done only after all plane configuration is configured to match the new watermark values.

Transition Watermark

The transition watermark is used for Isochronous Priority Control (IPC). When IPC is enabled (ARB_CTL2 Enable IPC), plane read requests are sent at high priority until filling above the transition watermark, then the requests are sent at lower priority until dropping below the level 0 watermark. The lower priority requests allow other memory clients to have better memory access. If the transition watermark is not enabled, the plane behaves as if the transition watermark was programmed to the top of the plane buffer allocation. When IPC is disabled, all plane read requests are sent at high priority.

The transition watermark is programmed as a tunable amount above the level 0 watermark. Tuning to higher values will tend to cause longer periods of high priority reads followed by longer periods of lower priority reads. Tuning to lower values will tend to cause shorter periods of high and lower priority reads. The exact behavior depends on the memory bandwidth, display bandwidth, and other memory traffic in the system.

The transition watermark has a minimum value to ensure the demote does not happen before enough data has been read to meet the level 0 watermark requirements.

Transition Minimum
14 Blocks

Scaling

A scaler (pipe or plane scaler) is down scaling when it is enabled and the scaler input size is greater than the scaler output size.

Down scaling effectively increases the pixel rate. Up scaling does not reduce the pixel rate.

For plane scaling, the scaler input size is the plane size and the output size is the scaler window size.

For pipe scaling, the scaler input size is the pipe source size and the output size is the scaler window size.

Horizontal down scale amount = maximum[1, Horizontal source size / Horizontal destination size]

Vertical down scale amount = maximum[1, Vertical source size / Vertical destination size]

Total down scale amount = Horizontal down scale amount * Vertical down scale amount

Workaround	
Context:	Watermark Calculations

Workaround when calculating watermarks

Calculate arbitrated display bandwith:

For each pipe {

For each plane, except cursor, enabled on the pipe {

Plane bandwidth MB/s = pixel rate MHz * source pixel format in bytes * plane down scale amount * pipe down scale amount

}

Pipe bandwidth MB/s = Number of planes, except cursor, enabled on the pipe * Max(bandwidth from each plane) // find plane with highest bandwidth and multiply with number of enabled planes

}

Arbitrated display bandwidth = Number of pipes enabled * Max(bandwidth from each pipe) // find pipe with highest bandwidth and multiply with number of enabled pipes

If there is any Ytile plane enabled and arbitrated display bandwidth > 20% of raw system memory bandwidth (# memory channels * memory frequency * channel width in bytes) {

Double Ytile planes minimum lines and program all watermark levels accordingly. Do not change the latency values.

Increase Xtile planes watermark latency for all levels by 15us

}

If memory is dual channel single rank, Xtile limit = 35%, else Xtile limit = 60%

If there is no Ytile plane enabled and arbitrated display bandwidth > (Xtile limit * raw system memory bandwidth) {

Increase Xtile planes watermark latency for all levels by 15uS

}

System Agent Geyserville (SAGV)

On core CPUs, SAGV dynamically adjusts the system agent voltage and clock frequencies depending on power and performance requirements. The display engine access to system memory is blocked during the adjustment time.

SAGV defaults to enabled. Software must use the GT-driver pcode mailbox to disable SAGV when the display engine is not able to tolerate the blocking time.

See the Memory Values section to find the SAGV block time.

Requirement before plane enabling or configuration change: Disable SAGV if any enabled plane will not be able to enable watermarks for memory latency >= SAGV block time, or any transcoder is interlaced. Else, enable SAGV.

If software ensures single pipe configurations always have enough data buffer allocation to tolerate SAGV, it can then simply disable SAGV anytime multiple display pipes are enabled or interlace is enabled, and re-enable SAGV when switching back to a single, non-interlaced pipe.

Sequence to Disable SAGV

1. Ensure any previous GT Driver Mailbox transaction is complete.
2. Write GT Driver Mailbox Data Low = 0x00000000.
3. Write GT Driver Mailbox Interface = 0x80000021.
4. Poll for GT Driver Mailbox Interface Run/Busy == 0x0.
    - Timeout and fail after 150 us.
5. Read GT Driver Mailbox Data Low, if bit 0 == 0x1, continue, else go to step 2.
    - If the condition in step 5 is not satisfied after cycling through steps 2-5 for 1 ms (typically <200 us), timeout and fail.
6. Continue with plane and pipe programming.

Sequence to Enable SAGV

1. Ensure any previous GT Driver Mailbox transaction is complete.
2. Write GT Driver Mailbox Data Low = 0x00000003.
3. Write GT Driver Mailbox Interface = 0x80000021.
4. Continue with plane and pipe programming. There is no need to wait for SAGV enabling to complete.

Examples

Example pixel rate adjustments:

Pixel rate for screen resolution is 130 MHz. No interlacing. Pipe scale 1920x1080 pipe source size to 1714x1120 scaler window size. Plane scale 1920x1080 plane size to 800x600 scaler window size.

Pipe horizontal down scale amount = maximum[1, 1920 / 1714] = 1.12

Pipe vertical down scale amount = maximum[1, 1080 / 1120] = 1 **// Max condition was hit**

Pipe total down scale amount = 1.12 * 1 = 1.12

Adjusted pipe pixel rate = 130 MHz * 1.12 = 145.6 MHz

Plane horizontal down scale amount = maximum[1, 1920 / 800] = 2.4

Plane vertical down scale amount = maximum[1, 1080 / 600] = 1.8

Plane total down scale amount = 2.4 * 1.8 = 4.32

Adjusted plane pixel rate = 145.6 MHz * 4.32 = 628.99 MHz

Example method, block, and line calculations:

Plane source 4 Bpp, Plane X tile, Plane source width 1920 pixels, Horizontal total 2200 pixels, Adjusted plane pixel rate 148.5 MHz, memory latency 7.5 us

Method 1 = 148.5 MHz * 4 Bpp * 7.5 us / 512 = 8.7 blocks

Plane bytes per line = 1920 pixels * 4 Bpp = 7680 Bytes/line

Plane blocks per lines = ceiling[7680 / 512] = 15 blocks

Method 2 = ceiling[(7.5 us * 148.5 MHz) / 2200 pixels] * 15 blocks = 15 blocks

Y tile minimum = 4 * 15 blocks = 60 blocks

Result Blocks = minimum[8.7 blocks, 15 blocks] = 8.7 blocks // X tile so does not use Y tile minimum

Result Blocks = ceiling[8.7 blocks] + 1 block = 10 blocks

Result Lines = ceiling[8.7 blocks / 15] = 1 lines

Memory Values

Retrieve Memory Latency Data

1. Ensure any previous GT Driver Mailbox transaction is complete.
2. Write GT Driver Mailbox Data0=0x0000_0000 (first set of latency values) and GT Driver Mailbox Data1=0x0000_0000
3. Write GT Driver Mailbox Interface Run/Busy=1, Address Control=All 0s, Command/Error Code=06h
4. Poll GT Driver Mailbox Interface for Run/Busy indication=0b and Command/Error Code=00h (success)
    - Timeout after 100 us and do not enable display planes.
5. Read GT Driver Mailbox Data0 for the first set of memory latency values
6. Write GT Driver Mailbox Data0=0x0000_0001 (second set of latency values) and GT Driver Mailbox Data1=0x0000_0000
7. Write GT Driver Mailbox Interface Run/Busy=1, Address Control=All 0s, Command/Error Code=06h
8. Poll GT Driver Mailbox Interface for Run/Busy indication=0b and Command/Error Code=00h (success)
    - Timeout after 100 us and do not enable display planes.
9. Read GT Driver Mailbox Data0 for the second set of memory latency values

Memory Latency Data Definition

First Set		
Data0 Bit	**Name**	**Description**
31:24	Level 3	Number of microseconds for level 3.
23:16	Level 2	Number of microseconds for level 2.
15:8	Level 1	Number of microseconds for level 1.
7:0	Level 0	Number of microseconds for level 0.

Second Set		
Data0 Bit	**Name**	**Description**
31:24	Level 7	Number of microseconds for level 7.
23:16	Level 6	Number of microseconds for level 6.
15:8	Level 5	Number of microseconds for level 5.
7:0	Level 4	Number of microseconds for level 4.

If level 1 or any higher level has a value of 0x00, that level and any higher levels are unused and invalid, so the associated watermark registers must not be enabled.

It is allowed to have the same value in adjacent levels.

Workaround	
Context:	Display Watermark Programming
The mailbox response data may not account for memory read latency. If the mailbox response data for level 0 is 0us, add 2 microseconds to the result for each valid level.	

SAGV Block Time

SAGV Block Time
30 us

Slice Registers and Die Recovery **1**

SW Virtualization Reserved MMIO range **1**

Slice Registers and Die Recovery

When slice 0 is disabled (for example, GT3 fused to GT2 with a slice 0 fault), any read to a slice-located MMIO register must be directed to slice 1, otherwise data of '0' will be returned. This applies to SRM cycles from any command streamer.

MMIO Range Start	MMIO Range End	Unit Description
00005500	00005FFF	WMBE
00007000	00007FFF	SVL
00009400	000097FF	CP unit reg. file - Copy in Slice Common (in all slices)
0000B000	0000B0FF	L3 unique status registers for each slice (unicast per GT).
0000B100	0000B3FF	L3 bank config space (multicast copy per bank and slice)
0000E000	0000E0FF	DM
0000E100	0000E1FF	SC
0000E200	0000E3FF	GWL (inst. 0)
0000E200	0000E3FF	GWL (inst. 1)
0000E200	0000E3FF	GWL (inst. 2)
0000E400	0000E7FF	TDL

SW Virtualization Reserved MMIO range

The MMIO address range from 0x178000 thru 0x178FFF is reserved for communication between a VMM and the GPU Driver executing on a Virtual Machine.

HW does not actually implement anything within this range. Instead, in a SW Virtualized environment, if a VM driver issues a read to this MMIO address range, the VMM will trap that access, and provide whatever data it wishes to pass to the VM driver. In a non-SW-Virtualizated environment (including an SR-IOV Virtualized environment), reads will return zeros, like any other unimplemented MMIO address. Writes to this range are always ignored.

It is important that no "real" HW MMIO register be defined within this range, as it would be inaccessable in a SW-virtualized environment.

Observability Overview

As GFX-enabled systems and usage models have grown in complexity over time, a number of hardware features have been added to provide more insight into hardware behavior while running a commercially available operating system. This chapter documents these features with pointers to relevant sections in other chapters. Supported observability features include:

Feature
Performance counters
Internal node tracing

Note: This chapter describes the registers and instructions used to monitor GPU performance. Please review other volumes in this specification to understand the terms, functionality and details for specific Intel graphics devices.

Trace

This section contains the following contents:

Performance Visibility

Motivation For Hardware-Assisted Performance Visibility

As the focus on GFX performance and programmability has increased over time, the need for hardware (HW) support to rapidly identify bottlenecks in HW and efficiently tune the work sent to same has become correspondingly important. This part of the BSpec describes the HW support for Performance Visibility.

Performance Event Counting

An earlier generation introduced dedicated GFX performance counters to address key issues associated with existing chipset CHAPs counters (lack of synchronization with GFX rendering work and low sampling frequency achievable when sampling via CPU MMIO read). Furthermore, reliance on SoC assets created a cross-IP dependency that was difficult to manage well. Hence, the approach since that earlier generation has been to use dedicated counters managed by the graphics device driver for graphics performance measurement. The dedicated counter values are written to memory whenever an MI_REPORT_PERF_COUNT command is placed in the ring buffer.

While this approach eliminated much of the error associated with the previous approaches, it is still limited to sampling the counters only at the boundaries between ring commands. This inherently limited the ability of performance analysis tools to drill down into a primitive, which can contain thousands of triangles and require several hundreds of milliseconds to render.

Additionally, Intel design and architecture teams found that the existing silicon-based performance analysis tools provided only a general idea of where a problem may exist but were not able to pin point a problem. This was generally because the counter values are integrated across a very large time period, washing out the dynamic behavior of the workload.

Gen7 enhanced the aggregating counters to support the additional thread types generated by DX11 workloads. The high rate at which interesting internal events can occur motivated adding an interrupt-generation capability so that HW could notify SW when the data buffer was approaching full.

Gen7.5 enhances support for high reporting frequencies by increasing the report buffer size in order to allow SW sufficient time between performance monitoring interrupts, enabling single run histogramming support for events like pixels per polygon. Desire for more flexibility in custom event creation drove addition of 4 more Boolean counters.

Issues with SNB support drove enhancements to enable performance monitoring with RC6 enabled, different report buffer ring wrap behavior, and MMIO visibility into performance counters.

Gen8 enhances functionality of aggregating counters for EUs by providing some flexibility in what quantities are aggregated across all EUs including more quantities relevant to GPGPU workloads. Since several of the previously defined aggregating counters had not delivered very much value on earlier projects, the overall number of A-counters has gone down even though aggregating counters for sampler/pixel-level functionality have been added/redefined. Custom counter creation has been enhanced by adding the ability to negate a signal at the input of the Boolean logic. Given that the increased complexity of GFX workloads and number of EUs in GT2/GT3 could lead to more frequent counter overflows, the width A-counters has increased to 40 bits. HW optimizations have also modified the SW interface slightly.

OA Programming Guidelines

In order for OA counters to increment the 'Counter Stop-Resume Mechanism' bit of the OACTXCONTROL register must be set. This requires a RCS context with this bit set be loaded, and either RCS force wake be enabled or the RCS context be left active for the duration of the window this counter is needed for.

If GT is running with decoupled unslice / slice frequencies, the following restrictions apply:

- C counters cannot be used for counting slice events.
- Max of 7 slice signals can be counted together.

Note that counting unslice events is unaffected.

HW Support

This section contains various reporting counters and registers for hardware support for Performance Visibility.

Performance Counter Registers

Register
OACONTROL - Observation Architecture Control
OACTXCONTROL - Observation Architecture Control per Context
OACTXID - Observation Architecture Control Context ID
OA_IMR - OA Interrupt Mask Register
OASTATUS - Observation Architecture Status Register
OAHEADPTR - Observation Architecture Head Pointer
OATAILPTR - Observation Architecture Tail Pointer
OABUFFER - Observation Architecture Buffer
OASTARTTRIG_COUNTER - Observation Architecture Start Trigger Counter
OARPTTRIG_COUNTER - Observation Architecture Report Trigger Counter
OAREPORTTRIG2 - Observation Architecture Report Trigger 2
OAREPORTTRIG6 - Observation Architecture Report Trigger 6

OA Interrupt Control Registers

The Interrupt Control Registers listed below all share the same bit definition. The bit definition is as follows:

Bit	Description
31:29	**Reserved. MBZ:** These bits may be assigned to interrupts on future products/steppings.
28	**Performance Monitoring Buffer Half-Full Interrupt:** For internal trigger (timer based) reporting, if the report buffer crosses the half full limit, this interrupt is generated.
27:0	**Reserved: MBZ (These bits must be never set by OA, these bit could be allocated to some other unit)**

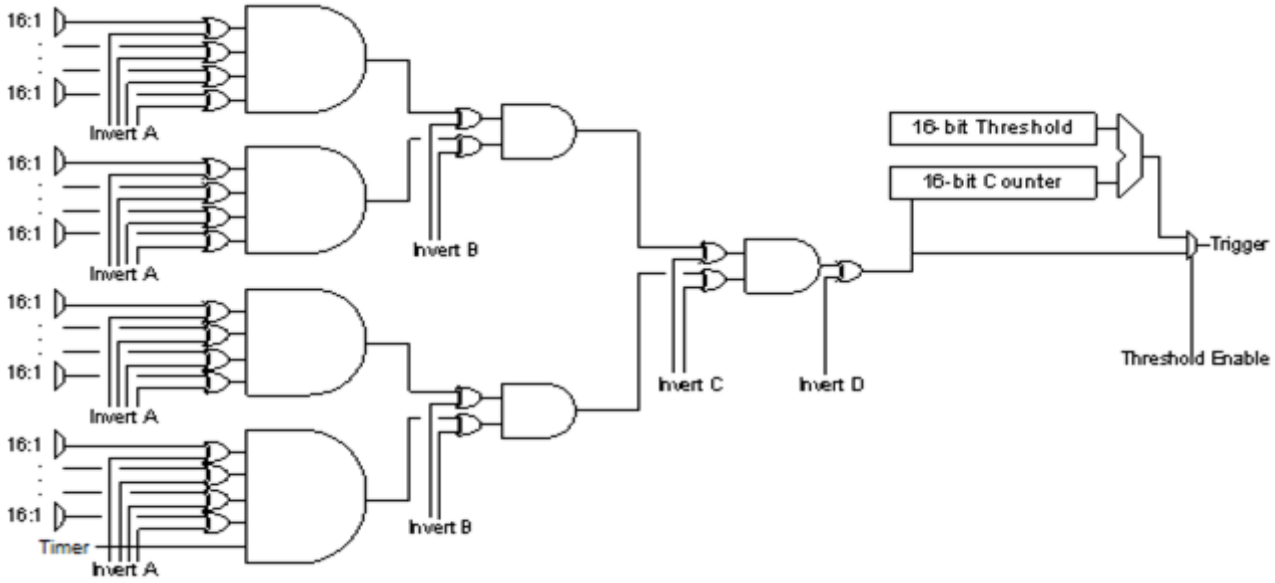
Performance Counter Reporting

When either the MI_REPORT_PERF_COUNT command is received or the internal report trigger logic fires, a snapshot of the performance counter values is written to memory. The format used by HW for such reports is selected using the Counter Select field within the **OACONTROL** register. The organization and number of report formats vary per project and are detailed in the following section. In the following layouts, the RPT_ID is always stored in the lowest addressed DWORD.

OA contains logic to control when performance counter values are reported to memory. This functionality is controlled using the OA report trigger and OA start trigger registers. More detailed register descriptions are included in the Hardware Programming interface. The block diagram below illustrates the logic these registers control.



Note that counters which are 40 bits wide in BDW are split in the report format into low DWORD and high byte chunks for simplicity of HW implementation as well as SW-friendly alignment of report data. The performance counter read logically done before writing out report data for these 40-bit counters is guaranteed to be an atomic operation, the counter data is simply swizzled as it is being packed into the report.

Due to OA being located in render power well, render power well shutdown must be disabled for proper performance counter functionality when only workloads which do not exercise render logic (e.g. certain media workloads) are running.

Aggregating Counters

The table below described the desired high-level functionality from each of the aggregating counters.

Note that there is no counter of 2x2s sent to pixel shader, this is based on the assumption that the pixel shader invocation pipeline statistics counter increments for partially lit 2x2s as well and hence does not require a duplicate performance counter.

Counter #	Event	Description
A1	# of Vertex Shader Threads Dispatched	Count of VS threads dispatched to EUs **[Register] Aggregate Perf Counter A1**
A2	# of Hull Shader Threads Dispatched	Count of HS threads dispatched to EUs **[Register] Aggregate Perf Counter A2**
A3	# of Domain Shader Threads Dispatched	Count of DS threads dispatched to EUs **[Register] Aggregate Perf Counter A3**
A4	# of GPGPU Threads Dispatched	Count of GPGPU threads dispatched to EUs **[Register] Aggregate Perf Counter A4**
A5	# of Geometry Shader Threads Dispatched	Count of GS threads dispatched to EUs **[Register] Aggregate Perf Counter A5**
A6	# of Pixel Shader Threads Dispatched	Count of PS threads dispatched to EUs **[Register] Aggregate Perf Counter A6**
A7	Aggregating EU counter 0	User-defined (details in Flexible EU Event Counters section) **[Register] Aggregate Perf Counter A7**
A8	Aggregating EU counter 1	User-defined (details in Flexible EU Event Counters section) **[Register] Aggregate Perf Counter A8**
A9	Aggregating EU counter 2	User-defined (details in Flexible EU Event Counters section) **[Register] Aggregate Perf Counter A9**
A10	Aggregating EU counter 3	User-defined (details in Flexible EU Event Counters section) **[Register] Aggregate Perf Counter A10**
A11	Aggregating EU counter 4	User-defined (details in Flexible EU Event Counters section) **[Register] Aggregate Perf Counter A11**
A12	Aggregating EU counter 5	User-defined (details in Flexible EU Event Counters section) **[Register] Aggregate Perf Counter A12**

Counter #	Event	Description
A13	Aggregating EU counter 6	User-defined (details in Flexible EU Event Counters section) **[Register] Aggregate Perf Counter A13**
A14	Aggregating EU counter 7	User-defined (details in Flexible EU Event Counters section) **[Register] Aggregate Perf Counter A14**
A15	Aggregating EU counter 8	User-defined (details in Flexible EU Event Counters section) **[Register] Aggregate Perf Counter A15**
A16	Aggregating EU counter 9	User-defined (details in Flexible EU Event Counters section) **[Register] Aggregate Perf Counter A16**
A17	Aggregating EU counter 10	User-defined (details in Flexible EU Event Counters section) **[Register] Aggregate Perf Counter A17**
A18	Aggregating EU counter 11	User-defined (details in Flexible EU Event Counters section) **[Register] Aggregate Perf Counter A18**
A19	Aggregating EU counter 12	User-defined (details in Flexible EU Event Counters section) **[Register] Aggregate Perf Counter A19**
A20	Aggregating EU counter 13	User-defined (details in Flexible EU Event Counters section) **[Register] Aggregate Perf Counter A20**
A21	2x2s Rasterized	Count of the number of samples of 2x2 pixel blocks generated from the input geometry before any pixel-level tests have been applied. (Please note that 2x2s may be in terms of pixels or in terms of samples depending on project but are consistent between A21-A27.) **[Register] Aggregate Perf Counter A21**
A22	2x2s Failing Fast pre-PS Tests	Count of the number of samples failing fast "early" (i.e. before pixel shader execution) tests (counted at 2x2 granularity). (Please note that 2x2s may be in terms of pixels or in terms of samples depending on project but are consistent between A21-A27.) **[Register] Aggregate Perf Counter A22**
A24	2x2s Killed in PS	Number of samples entirely killed in the pixel shader as a result of explicit instructions in the kernel (counted in 2x2 granularity). (Please note that 2x2s may be in terms of pixels or in terms of samples depending on project but are consistent between A21-A27.) **[Register] Aggregate Perf Counter A24**

Counter #	Event	Description
A25	2x2s Failing post-PS Tests	Number of samples that entirely fail "late" tests (i.e. tests that can only be performed after pixel shader execution). Counted at 2x2 granularity. (Please note that 2x2s may be in terms of pixels or in terms of samples depending on project but are consistent between A21-A27.) **[Register] Aggregate Perf Counter A25**
A26	2x2s Written To Render Target	Number of samples that are written to render target.(counted at 2x2 granularity). MRT case will report multiple writes per 2x2 processed by the pixel shader. (Please note that 2x2s may be in terms of pixels or in terms of samples depending on project but are consistent between A21-A27.) **[Register] Aggregate Perf Counter A26**
A27	Blended 2x2s Written to Render Target	Number of samples of blendable that are written to render target.(counted at 2x2 granularity). MRT case will report multiple writes per 2x2 processed by the pixel shader. (Please note that 2x2s may be in terms of pixels or in terms of samples depending on project but are consistent between A21-A27.) **[Register] Aggregate Perf Counter A27**
A28	2x2s Requested from Sampler	Aggregated total 2x2 texel blocks requested from all EUs to all instances of sampler logic. **[Register] Aggregate Perf Counter A28**
A29	Sampler L1 Misses	Aggregated misses from all sampler L1 caches. Please note that the number of L1 accesses varies with requested filtering mode and in other implementation specific ways. Hence it is not possible in general to draw a direct relationship between A28 and A29. However, a high number of sampler L1 misses relative to texel 2x2s requested frequently degrades sampler performance. **[Register] Aggregate Perf Counter A29**
A30	SLM Reads	Total read requests from an EU to SLM (including reads generated by atomic operations). **[Register] Aggregate Perf Counter A30**
A31	SLM Writes	Total write requests from an EU to SLM (including writes generated by atomic operations). **[Register] Aggregate Perf Counter A31**
A32	Other Shader Memory Accesses	Aggregated total requests from all EUs to memory surfaces other than render target or texture surfaces (e.g. shader constants). **[Register] Aggregate Perf Counter A32**

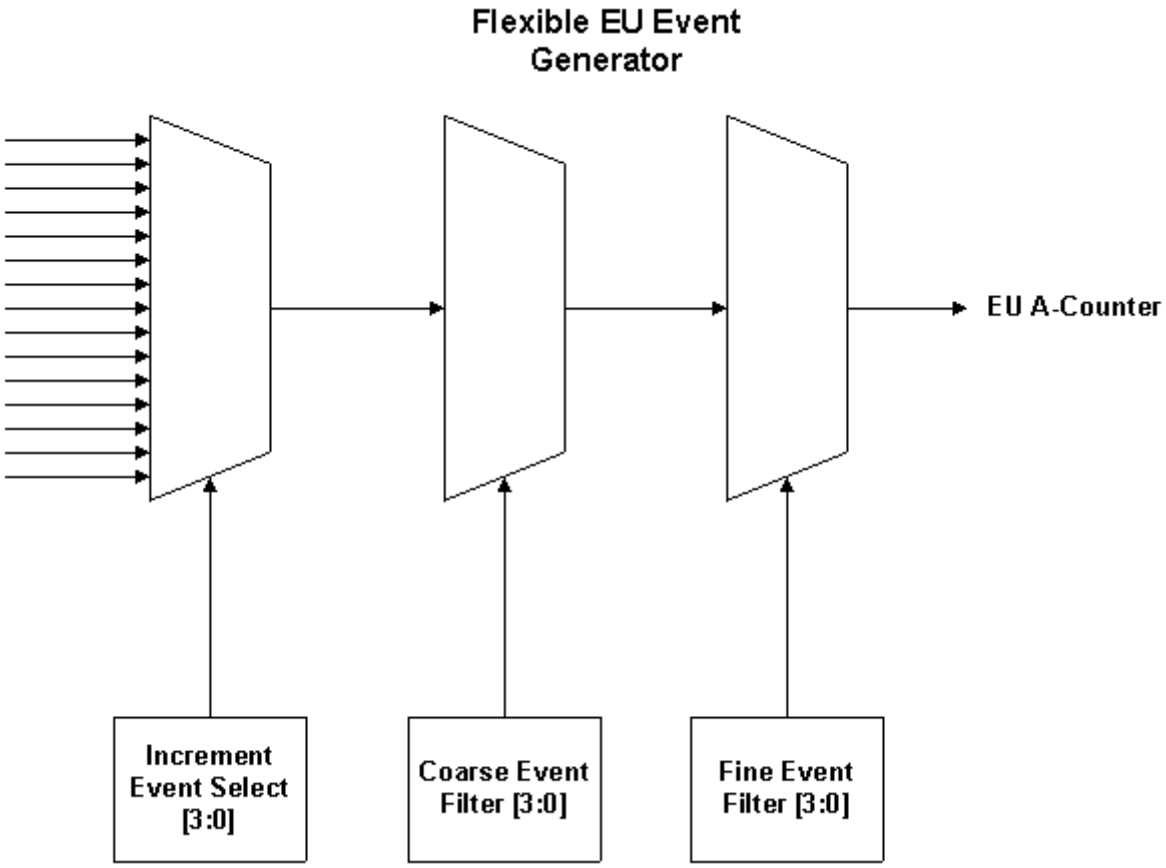
Counter #	Event	Description
A33	Other Shader Memory Accesses That Miss First-Level Cache	Aggregated total requests from all EUs to memory surfaces other than render target or texture surfaces (e.g. shader constants) that miss first-level cache. **[Register] Aggregate Perf Counter A33**
A34	Atomic Accesses	Aggregated total atomic accesses from all EUs. This counter increments on atomic accesses to both SLM and URB. **[Register] Aggregate Perf Counter A34**
A35	Barrier Messages	Aggregated total kernel barrier messages from all Eus (one per thread in barrier). **[Register] Aggregate Perf Counter A35**

Flexible EU Event Counters

Since EU performance events are most interesting in many cases when aggregated across all EUs and many interesting EU performance events are limited to certain APIs (e.g. hull shader kernel stats only applicable when running a DX11+ workload), BDW adds some additional flexibility to the aggregated counters coming from the EU array.

The following block diagram shows the high-level flow that generates each flexible EU event.

Note that no support is provided for differences between flexible EU event programming between EUs because the resulting output from each EU is eventually merged into a single OA counter anyway.



Supported Increment Events

Increment Event	Encoding	Notes
EU FPU0 Pipeline Active	0b0000	Signal that is high on every EU clock where the EU FPU0 pipeline is actively executing a Gen ISA instruction.
EU FPU1 Pipeline Active	0b0001	Signal that is high on every EU clock where the EU FPU1 pipeline is actively executing a Gen ISA instruction.
EU SEND Pipeline Active	0b0010	Signal that is high on every EU clock where the EU send pipeline is actively executing a Gen ISA instruction. Only fine event filters 0b0000,0b0101, 0b0110, 0b0111, 0b1000, 0b1001, and 0b1010 are supported with this increment event.
EU FPU0 & FPU1 Pipelines Concurrently Active	0b0011	Signal that is high on every EU clock where the EU FPU0 and FPU1 pipelines are both actively executing a Gen ISA instruction. Only coarse event filters 0b0000, 0b0111, and 0b1000 are supported with this increment event. Only fine event filters 0b0000, 0b0111, 0b1000, 0b1001, and 0b1010 are supported with this increment event.
Some EU Pipeline Active	0b0100	Signal that is high on every EU clock where at least one EU pipeline is actively executing a Gen ISA instruction. Only coarse event filters 0b0000, 0b0111, and 0b1000 are supported with this increment event. Only fine event filters 0b0000,0b0101, 0b0110, 0b0111, 0b1000, 0b1001, and 0b1010 are supported with this increment event.
At Least 1 Thread	0b0101	Signal that is high on every EU clock where at least one thread is loaded but no

Increment Event	Encoding	Notes
Loaded But No EU Pipeline Active		EU pipeline is actively executing a Gen ISA instruction. Only coarse event filters 0b0000, 0b0111, and 0b1000 are supported with this increment event. Only fine event filters 0b0000, 0b0111, 0b1000, 0b1001, and 0b1010 are supported with this increment event.
Threads loaded integrator == max threads for current HW SKU	0b1000	Implies an accumulator which increases every EU clock by the number of loaded threads, signal pulses high for one clock when the accumulator exceeds a multiple of the number of thread slots (e.g. for a 8-thread EU, signal pulses high every clock where the increment causes a 3-bit accumulator to overflow). Only coarse event filters 0b0000, 0b0111, and 0b1000 are supported with this increment event. Only fine event filters 0b0000, 0b0111, 0b1000, 0b1001, and 0b1010 are supported with this increment event. **Note:** There were no C steppings for the BDW GPU, so this increment event is supported for BDW:*:E0 and later. **Note:** A thread slot is considered to be "loaded" once the EU receives the transparent header. Hence, time spent transferring additional thread header data phases (e.g. push constants and vertex attribute data) will count towards thead occupancy.

Supported Coarse Event Filters

Coarse Event Filter	Encoding	Notes
No mask	0b0000	Never masks increment event.
VS Thread Filter	0b0001	For increment events 0b0000/0b0001/0b0010, masks increment events unless the FFID which dispatched the currently executing thread equals FFID of VS.
HS Thread Filter	0b0010	For increment events 0b0000/0b0001/0b0010, masks increment event unless the FFID which dispatched the currently executing thread equals FFID of HS.
DS Thread Filter	0b0011	For increment events 0b0000/0b0001/0b0010, masks increment event unless the FFID which dispatched the currently executing thread equals FFID of DS.
GS Thread Filter	0b0100	For increment events 0b0000/0b0001/0b0010, masks increment event unless the FFID which dispatched the currently executing thread equals FFID of GS.
PS Thread Filter	0b0101	For increment events 0b0000/0b0001/0b0010, masks increment event unless the FFID which dispatched the currently executing thread equals FFID of PS.
TS Thread Filter	0b0110	For increment events 0b0000/0b0001/0b0010, masks increment event unless the FFID which dispatched the currently executing thread equals FFID of TS.

Coarse Event Filter	Encoding	Notes
Row = 0	0b0111	Masks increment event unless the row ID for this EU is 0 (control register is in TDL so only have to check within quarter-slice).
Row = 1	0b1000	Masks increment event unless the row ID for this EU is 1 (control register is in TDL so only have to check within quarter-slice).

Fine Event Filters

Fine Event Filter	Encoding	Notes
None	0b0000	Never mask increment event.
Cycles where hybrid instructions are being executed	0b0001	Masks increment event unless the instruction(s) being executed on the pipeline(s) selected by the increment event are hybrid instructions.
Cycles where ternary instructions are being executed	0b0010	Masks increment event unless the instruction(s) being executed on the pipeline(s) selected by the increment event are ternary instructions.
Cycles where binary instructions are being executed	0b0011	Masks increment event unless the instruction(s) being executed on the pipeline(s) selected by the increment event are binary instructions.
Cycles where mov instructions are being executed	0b0100	Masks increment event unless the instruction(s) being executed on the pipeline(s) selected by the increment event are mov instructions.
Cycles where sends start being executed	0b0101	Masks increment event unless the instruction(s) being executed on the pipeline(s) selected by the increment event are send start of dispatch. Note that if this fine event filter is used in combination with increment events not related to the EU send pipeline (e.g. FPU0 active), the associated flexible event counter will increment in an implementation-specific manner.
EU# = 0b00	0b0111	Masks increment event unless the EU number for this EU is 0b00.
EU# = 0b01	0b1000	Masks increment event unless the EU number for this EU is 0b01.
EU# = 0b10	0b1001	Masks increment event unless the EU number for this EU is 0b10.
EU# = 0b11	0b1010	Masks increment event unless the EU number for this EU is 0b11.

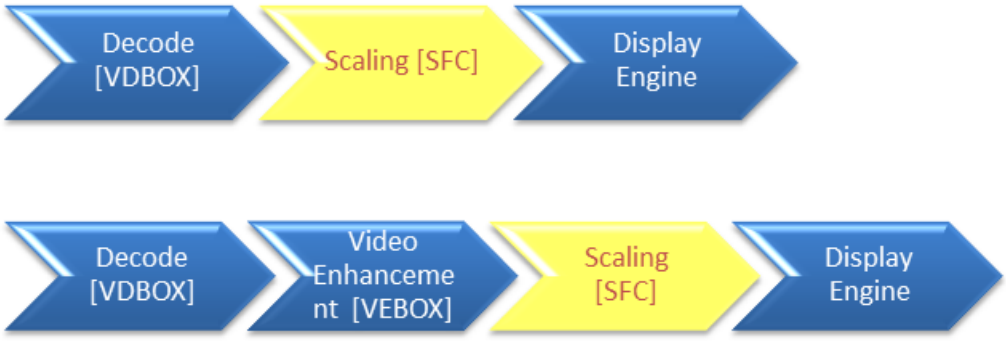
SFC Overview

Scaler & Format Converter (SFC) pipeline is introduced as a multi-format scaling engine to accelerate several media usages and achieve ultra low-power video playback.

Ultra Low-Power Usages

Several power saving techniques are brought into consideration and incorporated into the architecture of SFC pipeline: offloading from EU to fixed function to reduce Cdyn power, memory traffic reduction to lower IO and DDR power, and native surface support between acceleration engines.

Two ultra low–power playback modes are introduced to achieve sub 1-Watt solution: Decode->Scale-> Display (sprite) and Decode-> Image Enhancement-> Scale-> Display (sprite).



- In these two usages, SFC is fed by the decoder (VDBOX) and image enhancer (VEBOX) directly instead of writing to memory and read back from memory. A direct data bus is added between VD-to-SFC and VE-to-SFC. SFC will also include an internal store buffer to capture overlap pixel data between column/rows. In another word, the only IO traffic to DDR is the final scaled surface writes. All input and intermediate traffics related to SFC engine are confined inside GT and not expose to external components.
- EU-less usage: SFC is a fixed function engine architects to run concurrently along VDBOX or VEBOX. i.e. Decode and scaling will be happening at the same time, or Image enhancement and scaling will be occurring at the same time. It saves power by offloading the scaling workload off the media render engine to this dedicated engine which is much smaller.
- In both cases, scaling operation is the last processing step before final pixels are presented by the display engine. SFC is designed to generate output format native to display engine. This reduces the memory traffic caused by elimination of the extra memory copy used to convert the format incompatibility between engines. In addition, SFC supports 90 degree clockwise rotation of the final pixel surface for tablet space.

- SFC pipeline is chained together with VDBOX and VEBOX with direct interface and ability to run concurrently. VDBOX/VEBOX sends control parameters and pixel data directly to SFC through direct interface. This help reduces the IO and package power by eliminating the traffic to memory, and allows VD/VE to run concurrently along with SFC pipeline. SFC pipeline is a shared resource that can be called and accessed by VDBOX or VEBOX. A lock must be placed and granted with an acknowledgement ahead of transferring data to SFC. On completion, the lock must be removed to free up the shared resource (SFC).

SFC Commands Definition

This section contains definitions for commands used with the scaler and format converter (SFC). These commands are sent from the VDBOX/VEBOX to the SFC pipeline.

Display Workarounds **19**

Workarounds

This page lists all BSpec narrative workarounds for Gen9 (SKL/BXT/GLK/GLV). Note that the functional area for each item is listed below, so you can search on this value or other content on this page. Also note that a "BSpec ID" has been assigned to make it easier to reference these items.

BSpec ID	Functional Area/Component		Workaround Name	Workaround Description	Valid Steppings
0538	KMD		WaSkipStolenMemoryFirstPage	WA to skip the first page of stolen memory due to sporadic HW write on *CS Idle	KBL: SIWA_UNTIL_B0
0550	KMD		WaForceEnableNonCoherent	Must Force Non-Coherent whenever executing a 3D context. This is a workaround for a possible hang in the unlikely event a TLB invalidation occurs during a PSD flush. Set masked bit 4 in 0x7300 during boot.	KBL: UNTIL_D0
0551	KMD		WaDisableMidThreadPreempt	Disable GPGPU thread-level (a.k.a. mid-thread) preemption on parts (until B0) since validation was minimal on those parts.	KBL: SIWA_FOREVER
0556	KMD		Wa4x4STCOptimizationDisable	HIZ/STC hang in hawx frames. W/A: Disable 4x4 RCPFE-STC optimization and therefore only send one valid 4x4 to STC on 4x4 interface. This will require setting bit 6 of reg. 0x7004. Must be done at boot and all save/restore paths.	SIWA_FOREVER
0566	KMD		WaModifyVFEStateAfterGPGPUPreemption	GPGPU preemption hang or corruption issue. This WA must be applied before re-submitting a GPGPU preempted workload. SW needs to do two things.	KBL: SIWA_UNTIL_D0

BSpec ID	Functional Area/Component		Workaround Name	Workaround Description	Valid Steppings
				1. SW should detect if VFE unit in the context image have LRI commands to 0x54AC and 0x54B0. SW does that by checking if the LRI header at context image offste (0x0E90) <in VFE> is 0x11001003 and the two MMIO offsets in this LRI is 0x54AC and 0x54B0. If so, do this- D0 (LRI header): 0x1100_1003 -> 0x1100_ 1001 D1 (1st MMIO offset): 0x0000_54AC -> Leave this dword untouched D2 (1st MMIO offset value): 54AC_DATA -> Leave this dword untouched D3 (2nd MMIO offset): 0x0000_54B0 -> Overwrite to 0x0 D4 (2nd MMIO offset value): 54B0_DATA -> Overwrite to 0x0 2. Apart from it SW must also increment the Batch Buffer Address by Walker Command Length so that CS moves to the command following it. Size of Walker should be 0xF *	

BSpec ID	Functional Area/Component		Workaround Name	Workaround Description	Valid Steppings
				sizeof(DWORD) = 0x3C Bytes	
0572	KMD	RTL	WaFlushCoherentL3CacheLinesAtContextSwitch	Coherent L3 cache lines are not getting flushed during context switch which is causing issues like corruption. Need to set bit 21 of MMIO b118, then send PC with DC flush and then reset bit 21 of b118. This programming sequence needs to be part of the indirect context WA BB	SIWA_FOREVER
0574	KMD		WaDisableSDEUnitClockGating	WA for GPGPU workload hang for which requirement is to disable SDE Unit clock gating. This is done by setting bit 14 of MMIO 9430.	KBL: SIWA_UNTIL_B0
0581	KMD		WaSetVfGuardbandPreemptionVertexCount	Workaround for potential 3d preemption bug that can cause data corruption. Driver should write to register 0x83A4 (preemption vertex count) and set a value of 0x20. At boot, write 0xffff0020 to 0x83a4 (it's a masked register).	KBL: SIWA_UNTIL_B0
0590	KMD		WaSkipInvalidSubmitsFromOS	For Invalid submits from OS - simply report fence completion without submitting the DMA buffer to GPU.	SIWA_FOREVER
0592	3D		SKL_Z_16X_ALIGNMENT	TileY cannot be used for MSAA 8x or 16x with multiple MIP levels. The fallback is to use TileYF. Tile YS would also be suitable.	
0673	3D		WaStallBeforePostSyncOpOnGPGPU	Preemption mid-thread focused test failures.	SIWA_FOREVER

BSpec ID	Functional Area/Component		Workaround Name	Workaround Description	Valid Steppings
				WA: PIPECONTROL command with "Command Streamer Stall Enable"must be programmed prior to programming MI_SEMAPHORE_SIGNAL command with Post-Sync Operation set in GPGPU mode of operation (i.e when PIPELINE_SELECT command is set to GPGPU mode of operation). PIPECONTROL command with "Command Streamer Stall Enable"must be programmed prior to programming MI_ATOMIC command with Post-Sync Operation set in GPGPU mode of operation (i.e when PIPELINE_SELECT command is set to GPGPU mode of operation). PIPECONTROL command with "Command Streamer Stall Enable"must be programmed prior to programming a PIPECONTROL command with Post Sync Op in GPGPU mode of operation (i.e when PIPELINE_SELECT command is set to GPGPU mode of operation).	

BSpec ID	Functional Area/Component		Workaround Name	Workaround Description	Valid Steppings
0675	3D		WaFlushBefore3DSTATEGS	GS_SIMD8_OTHANDLE_RELAX test hanging due to an issue in gs_trg clock gating logic. WA: Add state_osb_statedv into trg_cg equation.	SIWA_FOREVER
0677	3D		WaDisableLosslessCompressionForSampleL	Sampler Throughput drop with lossless enabled for 0% & 50%, compression tests with 100%bypass. WA: Disabe double-fetch.	SIWA_FOREVER
0680	3D		WaDisableSamplerL2BypassForTextureCompressedFormats	RTL DM producing Xs for SC output. WA: Disable Bypass on some of the compressed formats.	SIWA_FOREVER
0681	3D		WaCompressedResourceSamplerPbeMediaNewHashMode	BXT GFXDRV: Hot spotting issue with render target compression. WA: Align lossless compressed resource allocations to 2MB or have fixed virtual addresses. This WA is specifically for steppings where HW will not fix.	KBL:SIWA_FOREVER
0683	3D		WaCompressedResourceDisplayNewHashMode	BXT GFXDRV: Hot spotting issue with render target compression. WA: Align lossless compressed resource allocations to 2MB or have fixed virtual addresses. This WA is specifically for steppings where HW will not fix.	KBL:SIWA_FOREVER

BSpec ID	Functional Area/Component		Workaround Name	Workaround Description	Valid Steppings
0689	3D		WaPipeControlBeforeVFCacheInvalidationEnable	Vf randomly decodes nullprim packets as state packets causing illegal internal states in it. WA: B2B control packets to be sent when VS_cache_enable is programmed to be enabled. First control packet with bit11 as '0' and the next control packet with bit11 as '1'.	SIWA_FOREVER
0693	3D		WaEnableTiledResourceTranslationTables	Support for Sparse Tiled Resources under SVM	KBL:SIWA_FOREVER
0695	3D		WaIndependentAlphaBlend	GFX SV: optHizClear test miscompares in B0 silicon. WA: Fixed optimization case for independent alpha to look at src values for RGB and Alpha values separately. Fixed the src0dest1 case for alpha component to look at src_alpha_is_zero instead of src_is_zero.	KBL:SIWA_FOREVER
0696	3D		WaBindlessSurfaceStateModifyEnable	Missing "Size Modify Enable" Bit For Bindless Sizes in STATE_BASE_ADDRESS. WA: The suggested WA is that when NOT setting the modify enable bit for Bindless Surface State Base Address, program the dword length to “Eh”instead of “11h”and zero out the last 3 DW or not send them.	SIWA_FOREVER

BSpec ID	Functional Area/Component		Workaround Name	Workaround Description	Valid Steppings
0699	3D		WaAtomicFlushOnInterfaceDescriptor	GPGPU Preemption - Hang on Barrier WA: VFE need to make sure that all previous indirect prefetches are done after VFE state command. MI_ATOMIC_FLUSH need to be programmed between ID load commands or curbe load commands if it back to back.	KBL:SIWA_FOREVER
0701	3D		WaStructuredBufferAsRawBufferOverride	BSpec restricts Data Port access using Untyped Surface Read/Write to RAW surface format only. WA: Raw format support added in svsmunit.	KBL:SIWA_FOREVER
0702	3D			False Inexact IEEE flag set by SP to UQ mov. WA: Cannot use flags with float2int convertion with non-RTZ rounding mode.	
0714	Media	VTQ		Trellis quantization performance improvements introduced a bug. The bug results in Hang condition when Chroma Trellis is disabled and Trellis is enabled. The bug is fixed in KBL B0.	KBL A0
0744	3D		WaDisableRTReadsfor1DSurfaces	Failing to implement the following WA will lead to pixel corruptions due to accesses to WA : If RenderSurfaceState::Surface Type == SURFTYPE_1D, SW must ensure that Pixel Shaders do not generate RT reads.	KBL:SIWA_A0

BSpec ID	Functional Area/Component		Workaround Name	Workaround Description	Valid Steppings
0752	3D		WaSamplerResponseLengthMustBeGreaterThan1	Dcs_pwc_rc signal is not set when notify clear comes out of phase WA: disable MMIO reads from GW & all sampler sends in GPGPU workloads with response length of 1.	KBL:SIWA_FROM_A0
0756	Media	HEVC		VP9 Decoder 8Kx8K SV test failing with miscompare at 2nd frame. WA: Frame size supported in BXT is 4Kx4K.	KBL:SIWA_FROM:A0
0827				Moved to Display Workaround page	
0828				Moved to Display Workaround page	
0831	KMD		WaDisableSamplerPowerBypassForSOPingPong	SI can get stuck ping ponging rows in a 2-2-2 fashion instead of 1-1-1 leading to a ~3% performance reduction. WA: Disable sampler power bypass to avoid negatively impacting SO 'ping-pong' performance.	KBL: SIWA_FOREVER
0837	GAM		WaSpuriousIOMMUFaults	GT GAM HW prefetches context (or extended context) entry when a context is loaded, root pointer is updated or when there is a context cache flush. This prefetch happens without a memory transaction from the context. On this prefetch, if the context entry is a NULL (P=0), HW will generate a fault – invalid context entry. However, it is legal to have a NULL context entry, as long as no	KBL:ALL

BSpec ID	Functional Area/Component		Workaround Name	Workaround Description	Valid Steppings
				memory references are done via that context entry. WA: To avoid these spurious DMA faults, SW should mark the context entry as present (not a NULL entry), and mark the page tables as not present.	
0838	GTI			MGSR hang when MsgCh cycle arrives a couple clocks after IOSF SB shadow request. This is being brought up into the SW WA section for completeness. 0xD00[3:1] already indicate that bits should be set by SW. WA: Enable 0x0D00[3:1] fixes in SW for all Gen9 products.	KBL:ALL

0860	GTI	GAM		When only the coherent flush FSM and HDC invalidation FSMs are active, GAM can turn off the clocks after receiving COH flush done even if HDC	KBL:A0,B0

BSpec ID	Functional Area/Component		Workaround Name	Workaround Description	Valid Steppings
				FSM is active. This can cause invalidation end to not be sent to HDC after HDC FSM completes. WA: Turn off GAM clock gating by setting 0x9400[22] to '1	
0864	GTI	GAM		When only the coherent flush FSM and HDC invalidation FSMs are active, GAM can turn off the clocks after receiving COH flush done even if HDC FSM is active. This can cause invalidation end to not be sent to HDC after HDC FSM completes. WA: Turn off GAM clock gating by setting 0x9400[22] to '1	KBL:A0/B0
0865	GTI	GAM		The dynamic credit sharing between engines has an issue which can cause the credits to be lost. When sufficient credits are lost the BW through GAM can get severely limited and can eventually block all the transactions and hang. WA: Turn off dynamic credit sharing by setting 0x4AB8[28] to '1	KBL:A0/B0

BSpec ID	Functional Area/Component		Workaround Name	Workaround Description	Valid Steppings
0866	GTI	GAM		Issue here is with QBI and GFXIDLE - If QBI is in progress and we get GFXIDLE, it will be ACKED and it will make CTX inactive. Once CTX will go inactive it will make all pasid/ctxid match flags zero which is one of the condition for generating hdc_end for QBI. QBI will end but HD will not see end due to this Flag. WA: CS to send invalidation to GAM before indicating IDLE, GAM can handle future QBI's without involving HDC and this bug wont be exposed. Insert Pipecontrol with invalidation flag set at the end of the ring, batch. Same is required while pre-empting the existing WL.	KBL:A0/B0
0867	GTI	GAM		When HDC/EUs are set to Faul&Halt mode, the commit interface between HDC and EUs are disabled. If coherency is enabled, we can have coherent cycles in the fabric when an external invalidation arrives, and can lead into the GAM coherent deadlock scenario if GAM resources are full. GAM deadlock coherent_flush will	KBL:ALL

BSpec ID	Functional Area/Component		Workaround Name	Workaround Description	Valid Steppings
				kick in to resolve the deadlock. However, this requires EUs to re-dispatch the coherent cycles that were killed. If HDC/EU are in Fault&Halt mode, this re-start is not possible from the EUs. Do not use Fault&Halt as the fault mode in HDC/EU	
0868				Moved to Display Workaround page	
0870				Moved to Display Workaround page	
0871				Moved to Display Workaround page	
0872	3D	CS		Global Workaround Batch Buffer will not execute when enabled and Execution List mode is enabled. WA: Do not enable Global WABB when in Execution List mode.	KBL:ALL (except GT4)
0873				Moved to Display Workaround page	
0875	GTI	GAM		When there is a TLB invalidation with a Fence, GAM blocks the arbiters to drain the fabric for the Fence. Once the fabric is drained, the TLBs are invalidated, as well as a HDC TLB invalidation request is sent to the HDC. GAM expects an ack for this from HDC. If there are cycles in HDC that has already used the address translations, they need to be drained from HDC	KBL:A0/B0

BSpec ID	Functional Area/Component		Workaround Name	Workaround Description	Valid Steppings
				before it can send the Ack. GAM is supposed to unblock the arbiters at this stage to allow for these cycles to drain. However, when TRTT is enabled, the arbiter is GATR does not get unblocked until the HDC inval Ack is completed. This causes a deadlock where HDC cannot send the Ack as there are cycles that needs to drain. In general when CS issues a Fence Inval, there should not be any pending cycles in HDC if a CS stall is put in before and after the fence inval. However, in the case of lite restore, Fence Inval can happen asynchronously, potentially leaving pending cycles. The WAs for this issue are: 1. Disable TRTT – so the fabric does not continue to get blocked in GATR after the fence 2. Disable lite restore – so we do not have asynchronous fence inval events. Also need to have a CS stall before and after CS fence inval. SW is planning on having both Was available, and #1 as the default.	

BSpec ID	Functional Area/Component		Workaround Name	Workaround Description	Valid Steppings
0876	GTI	CS	WaForceCsStallOnTimestampQueryOrDepthCount	Due to known HW issue specific to GT4; on a specific incident (few HW events must happens on the same clock under certain programming conditions) address, data and control fields corresponding to a PIPECONTROL command will get registered wrongly in hardware. Following this incident Fence Reports, Depth Statistic Report (Occlusion Query) and time_stamp reports will get corrupted leading to OS/KMD/UMD hangs. **Workaround (option-1):** PIEPCONTROL command programmed with "Post Sync Operation" set to "Write Timestamp" or "Write Depth Query" must also set "Command Streamer stall Enable" to '1'. **Workaround (option-2):** Software must memorize the event of programming "Post Sync Operation" set to "Write Timestamp" or "Write Depth Query" and must set "Pipecontrol Flush Enable" on next PIPECONTROL programmed. Note: Since the passing on the memorized event between UMD and	KBL:GT4 (all GT4 SKU's)

BSpec ID	Functional Area/Component		Workaround Name	Workaround Description	Valid Steppings
				KMD (ring buffer and batch buffer) is difficult, one way it could be addressed in following way. KMD must always program the first PIPECONTROL being programmed in the ringbuffer following the MI_BATCH_BUFFER_START with "Pipecontrol Flush Enable" set. KMD must always program PIPECONTROL with "Pipecontrol Flush Enable" set prior to programming MI_BATCH_BUFFER_START in the ring buffer. **OR** UMD must always program the first PIPECONTROL in the batch buffer with "Pipecontrol Flush Enable" set and must always program the last command in every dispatch of the batch buffer to a PIPECONTROL with "Pipecontrol Flush Enable" set.	
0877	3D	Pixel Shader	WaSendDummyConstantsForPS	Hang possible when pixel shader dispatched with only header phases (R0-R2) WA: Enable a non-header phase (e.g. push constant) when dispatch would have been header-only.	KBL:ALL

0908	SFC	SFC Crop Limitation for VEBOX+SFC Mode	WaDisableSFCSrcCrop	Below are the cases to switch from SFC to Render for VEBOX+SFC mode Case 1. ((SurfaceHeight > 1120) && (Top > 1120)) Case 2. ((SurfaceHeight > 1120) && (Bottom < SurfaceHeight)) Case 3. ((SurfaceHeight > 1120) && (Left > 0)) Case 4. ((SurfaceHeight > 1120) && (Right < SurfaceWidth))	KBL A0
0909	GS PrimID bug with Tessellation	Peter Doyle		GS Clock gating must be disabled under the following conditions: Tessellation enabled, GS enabled, GS PrimitiveID enabled.	KBL: ALL

BSpec ID	Functional Area/Component		Workaround Name	Workaround Description	Valid Steppings
0910	GAM	Niran Cooray		When DINVE=0 in the ext context entry PASID state table is not used. But, HW reads the PASIDSTPTR from the context entry and goes through SL translations, if NESTE is enabled. If the SL translation returns invalid, all transactions from that engine is considered invalid. WA: Have a valid GPA for the PASIDSTPTR which has a valid GPA->HPA mapping in the SL tables. This SL translation need to have R=W=1 permissions	KBL:UNTIL_GT2: A0-C0 KBL:UNTIL_GT3: D0 KBL:UNTIL_GT4: E0
0915	HDC	Atomic Counter		Hang occurs with Atomic Counter message with binary operations (i.e. have a separate data operand), in some dynamic load situations. WA: Replace use of hidden counter with an explicit counter location, and then use a typed or untyped Dword Atomic operation message instead.	KBL:ALL
0917	GTI	GAM		Reset of an engine (non render) does not complete when there is a continuous stream of traffic comes from another engine. Another flavor of this issue is with VEBox, where VEBox reset does not complete when there's continuous polling happening	KBL: UNTIL_F0

BSpec ID	Functional Area/Component		Workaround Name	Workaround Description	Valid Steppings
				from VECS. The second flavor is seen with MI_SEMAPHORE_WAIT. WA: 1. for the first case (reset of A blocked due to traffic from B), the only workaround is to stall/stop engine B that is continuously generating traffic. 2. for the second case, the polling period need to be increased to let HW identify the fabric idleness and complete the Go=0 Ack for reset. Increase the poll interval in VECS_SEMA_WAIT_POLL (0x1A24C). Setting this to ius resolves the issue.	

Display Workarounds

This page lists all BSpec workarounds for Display. Note that the functional area for each item is listed below, so you can search on this value or other content on this page. Also note that a "BSpec ID" has been assigned to make it easier to reference these items.

BSpec ID	Functional Area/Component		Workaround Name	Workaround Description	Valid Steppings
0342	Display	DisplayPort		Not a workaround, this is required programming for all projects. DP MST requires certain VC payload size values. VC payload must be multiple of 4 in x1 lane config, 2 in x2, 1 in x4. See transcoder M/N Values.	All
0346	Display	DisplayPort		Aux channel transactions get intermittent NAK errors with some receivers. WA: Do not use the 400us Aux timeout. Increase DDI_AUX_CTL bits 27:26 Time out timer value to at least 600us 01b when doing DDI aux transactions. Merged with #0347 This becomes standard required programming for all subsequent projects.	All
0371	Display	Panel fitter	WaPanelFitterDownscale	Not a workaround, this is required programming for all projects. When using panel fitter downscaling (pipe source size is larger than panel fitter window size) the maximum supported pixel rate will be reduced by the downscale amount, and watermarks must be adjusted. Use panel fitter scale amount when calculating maximum pixel rate and watermarks.	All

BSpec ID	Functional Area/Component		Workaround Name	Workaround Description	Valid Steppings
0373	Display	Panel power sequencing	WaVDDOverrideT4Power	Not a workaround, this is required programming for all projects. When software clears the panel power sequencing VDD override bit from 1 to 0 (disable VDD override) it must ensure that T4 power cycle delay is met before setting the bit to 1 again. Use software timers to ensure T4 delay is met or use full panel power enable and not the VDD override.	All
386	Display	PSR		PSR single frame update - When single frame update is enabled, the PSR CRC must be disabled for panel compatibility.	All
0387	Display	PSR		PSR single frame update - Mask register write events when using single frame update. This becomes standard required programming for all subsequent projects.	All
0388	Display	PSR		PSR power saving - Mask PSR max timeout when PSR CRC is enabled. This becomes standard required programming for all subsequent projects.	All
0471	Power	FBC		First line of FBC getting corrupted when FBC compressed frame buffer offset is programmed to zero. Command streamers are doing flush writes to base of stolen. WA: New restriction to program FBC compressed frame buffer offset to at least 4KB. See	All

BSpec ID	Functional Area/Component		Workaround Name	Workaround Description	Valid Steppings
				FBC_CFB_BASE in North Display Registers. Additionally software must not use this first 4KB of graphics data stolen memory for anything else. This becomes standard required programming for all subsequent projects.	
0477	Power	IPC		IPC (Isoch Priority Control) may cause underflows. WA: Do not enable IPC in register ARB_CTL2	All
0482	Power	PSR		The following sequence is needed when disabling PSR Single Frame Update to workaround cases where the remote frame buffer update indicator becomes stuck if there is a single frame update exit event (pipe register write) around the time that single frame update is being disabled. 1. Set 0x420B0 bit 11 to mask off flips. 2. Set PIPE_MISC bit 21 to mask off pipe register writes. 3. Clear SRD_CTL bit 31 to 0 to disable PSR. 4. Wait for 2 vertical blanks for PSR to completely disable. 5. Clear SRD_CTL bit 30 to 0 disable Single Frame Update. 6. Restore PIPE_MISC bit 21.	All

BSpec ID	Functional Area/Component		Workaround Name	Workaround Description	Valid Steppings
				7. Restore 0x420B0 bit 11. PSR can now be re-enabled if needed.	
0484	Power	Watermarks		Watermark memory latency data retrieved from GT driver mailbox data may not account for memory read latency. Depending on mailbox response, add 2 microseconds to the result for each level to compensate. This becomes standard required programming for all subsequent projects.	All
0485	Power	Watermarks		Notable Bspec correction. Not a workaround. Watermark memory latency data retrieved from GT driver mailbox data had incorrect dword ordering in earlier versions of the BSpec. BSpec is now corrected to show the first set of data has latency levels 0-3 and second set has levels 4-7. This becomes standard required programming for all subsequent projects.	All
0529	Display	FBC		Corruption in some cases when FBC is enabled and the plane surface format is in linear, tile Y legacy, or tile Yf WA: Display register 4208Ch bit 13 must be set to 1b and bits 12:0 must be programmed with the compressed buffer stride value. The compressed buffer stride must be calculated using the following	All

BSpec ID	Functional Area/Component		Workaround Name	Workaround Description	Valid Steppings
				equation: Compressed buffer stride = ceiling [(at least plane width in pixels) / (32 * compression limit factor)] * 8 At least plane width = a value greater than or equal to the width of the plane. Software may choose to use a greater value in order to handle cases where the plane width is changing from frame to frame, especially because 4208C is not double-buffered and can't be changed on the fly while FBC is enabled. Compression limit factor is either 1, 2 or 4 based on the FBC_CTL Compression Limit field.	
0531	Display	Render Compression		Render decompression is broken when plane widths greater than 3840 are used with horizontal panning. WA: When the render compression is enabled with plane width greater than 3840 and horizontal panning (Start X Position in the PLANE_OFFSET register is not 0), the stride programmed in the PLANE_STRIDE register must be multiple of 4.	All
0562	Power	FBC		FBC sometimes causes screen corruption with package C states. WA: 'FBC Watermark Disable' bit in ARB_CTL register must be set to 1b.	All
0827	Display	Planes		Switching the plane format from NV12 to RGB and leaving system idle results in display underrun and corruption.	All

BSpec ID	Functional Area/Component		Workaround Name	Workaround Description	Valid Steppings
				WA: Set the bit 15 & bit 19 to 1b in the CLKGATE_DIS_PSL register for the pipe in which NV12 plane is enabled.	
0828	Display	PSR2		PSR2 screen corruptions when multiple regions are updated in a single frame. WA: Set 0x42080 bit 3 = 1 before enabling PSR2. The register can safely remain set when PSR2 is disabled.	All
0840	Display	Watermarks SAGV		Programming needed for SAGV to prevent underflows in multi-display scenarios. See Display Watermark Programming - Watermark Calculations section. This becomes standard required programming for subsequent core projects.	All
0851	Display	FBC	WaFbcNukeOn3DBlt	To prevent missed invalidations around the time FBC is being enabled, FBC render tracking must use the "Render Tracking With Nuke" method. See Frame Buffer Compression page.	All
0856	Display	Memory Bandwidth		Display underflow with high resolutions and multiple displays. WA: Restrict display configurations to fit within system memory bandwidth threshold specifed in the Display Mode Set -> Display Resolution Support page. Increase watermarks at some system memory bandwidth thresholds. See Display Watermark Calculations.	All

BSpec ID	Functional Area/Component		Workaround Name	Workaround Description	Valid Steppings
				The restriction to fit within memory bandwidth threshold is required programming for all subsequent projects. The threshold can change from project to project and will be listed on the Display Resolution Support page.	
0857	Display	Planes		Display underrun issues with Y & Yf Tiling. WA: Set the bit 13 of MMIO register 0x46430 to 1b.	All
0859	Display	FBC	WaFbcWakeMemOn	This workaround helps to achieve better idle power savings when FBC is enabled. WA: Set ARB_CTL FBC Memory Wake to 1'b1.	All
0868	Display	GMBUS		4 block EDID failures. WA: Set 0x4653C[14] = 0x1 to disable clock gating when the north display GMBUS function is used. Set 0xC2020[31]=0x1 to disable clock gating when the south display GMBUS function is used.	All
0873	Display	FBC		Screen corruption observed with FBC when the front buffer is updated by host modify. WA: To prevent missed host invalidations around the time FBC is being enabled, enable Nuke on modify. Set bit 23 of MMIO register 0x43224 to 1'b1.	All

BSpec ID	Functional Area/Component		Workaround Name	Workaround Description	Valid Steppings
0880	Display	Clocks		Timeout for display cdclk mailbox programming increased from 1ms to 3ms to account for some corner cases that can exceed 1ms. This becomes standard required programming for all subsequent projects.	ALL
0881	Display	Clocks		Display PLL workaround for signal integrity when using the 2.16 or 4.32 GHz eDP link rate together with spread spectrum clocking. The GT driver pcode mailbox has to be programmed to override some DPLL internal values. See Display -> North Display Engine Registers -> Clocks -> Port Clock Programming.	All
0883	Display	FBC	WaFbcHighMemBwCorruptionAvoidance	When FBC is enabled sometimes screen corruptions/system hangs observed under high memory bandwidth conditions. WA: Set the bit 8 of MMIO register 0x43224 to 1b. Set ARB_CTL FBC Memory Wake to 1b (from #0859). This memory wake setting is also preferred for better power savings with FBC.	KBL:*:A KBL:*:B
0893	Display	Memory Bandwidth		Display underflow with high resolutions and multiple displays when using dual channel single rank memory. WA: Increase watermarks at some system memory bandwidth thresholds. See Display Watermark Calculations.	All

BSpec ID	Functional Area/Component		Workaround Name	Workaround Description	Valid Steppings
1106	Display	NV12, Rotation, Horizontal flip		Display corruption/color shift observed when using NV12 with 270 rotation or 90 rotation + horizontal flip. WA: NV12 with 270 rotation or 90 rotation + horizontal flip requires the programmed plane height to be a multiple of 4.	All
1107	Display	Transition Watermark		Transition watermarks must not be enabled.	All
1110	Display	FBC + PSR/PSR2		Missing flips when FBC is enabled with PSR link off/PSR2 deep sleep scenarios. WA: When FBC is enabled with PSR/PSR2, set bit 30 of MMIO register 0x420CC to 1b.	KBL:*:A KBL:*:B
1125	Display	Watermarks, render compression		Render compression watermark adjustment. This was a late addition to the Bspec, but not previously tracked as a workaround. See the Watermark Calculations page for details. WA: If Render Decompression enabled and latency level 0: Result Blocks = Result Blocks + Y tile minimum. Then ensure that the result blocks for higher latency levels are all at least as high as the new level 0.	All
1126	Display	Watermarks		Watermark adjustment. This was a late addition to the Bspec, but not previously tracked as a workaround. See the Watermark Calculations page for details.	All

BSpec ID	Functional Area/Component		Workaround Name	Workaround Description	Valid Steppings
				WA: If latency level 1 through 7 and Y tile: Result Blocks = Result Blocks + Y tile minimum; Result Lines = Result Lines + Minimum Scanlines for Y tile If latency level 1 through 7 and not Y tile: Result Blocks = Result Blocks + 1	
1131	Display	VTd		Display underflow and flicker when VTd is enabled with a frame buffer having a mix of VTd 4K, 2MB and 1GB pages. WA: When VTd is enabled, all the extra dummy PTE entries must be mapped to pages of same size (4K, 1GB or 2MB). All the extra entries shall map to the same dummy page. This dummy page padding is required immediately after the display active fetch area. If any of the display features (like panning, clipping, collage displays, planar YUV surfaces) can't meet the above requirement it must not be enabled. See PLANE_SURF restrictions for Extra Page Table Entries allocation requirements.	All
1132	Display	64bpp		Bandwidth limitations in the display data buffer output can cause underflow with 64bpp pixel formats when multiple planes are enabled at high resolutions. The 64 bits per pixel source pixel format can only be used on a single plane and when only a single pipe is enabled.	All

BSpec ID	Functional Area/Component		Workaround Name	Workaround Description	Valid Steppings
1134	Display	GMBUS		GMBUS bit bashing failures because GPIO pin is unexpectedly in busy state. WA: When starting bit bashing, first write GPIO_CTL = 0x00000404.	All
1136	Display	PSR		Display underrun with PSR single frame update and planes with less than watermark level 7. WA: When using PSR single frame update, all enabled planes must have enabled up to watermark level 7. If any plane cannot support level 7, then single frame update cannot be enabled.	KBL:*:A KBL:*:B
1141	Power	IPC		IPC (Isoch Priority Control) may cause underflows. WA: When IPC is enabled, watermark latency values must be increased by 4us across all levels. This brings level 0 up to 6us..	All
1142	Display			Underruns found with FBC, but also could impact cases without FBC. WA: Before enabling display planes or cursor, program 0x42084 bits 14:13=10b and 0x42080 bit 22=1b. Keep this value while planes or cursor are enabled. The value is ignored while planes and cursor are all disabled. The same programming is used with and without FBC.	KBL:SIWA_FROM_C0
1143	HDMI			For HDMI the voltage swing programming for a port is locked at the value used when the port is first enabled after boot or package C10. Override programming is needed to allow the swing to change after that point, such as for DP++ ports or	All

BSpec ID	Functional Area/Component		Workaround Name	Workaround Description	Valid Steppings
				electrical validation. 1. Just before enabling DDI_BUF_CTL for HDMI in the port enable sequence. 2. Set override for this DDI. o DDIB: 0x420C0 19:18 = 11b o DDIC: 0x420C4 19:18 = 11b o DDID: 0x420C8 19:18 = 11b o DDIA: 0x420CC 19:18 = 11b 3. Wait 1us for DDI to pick up the swing value. 4. Clear override for this DDI to 00b. 5. Continue with enabling DDI_BUF_CTL.	

1144	Audio			DisplayPort audio corruption or video underflow with some clock frequencies and audio configurations.
				
				WA:
				
				If (DP port width x4 AND link rate HBR2 AND CDCLK frequency < 432 MHz) {
				
				If (audio clock frequency >96 KHz OR 8 audio channels used OR audio configuration unknown) {
				
				DisplayPort audio cannot be enabled at this CDCLK frequency.
					All

BSpec ID	Functional Area/Component		Workaround Name	Workaround Description	Valid Steppings

				}
				
				Else {
				
				Set register (0x420C0 for audio on transcoder A, 0x420C4 for transcoder B, 0x420C8 for transcoder C) bit 13 to 1 before enabling DisplayPort audio.
				
				}
				
				}
