0	31:15	**Reserved** Default Value: 0000000000000000b Access: RO
	14	**Reserved1** Default Value: 0b Access: RO
	13:11	**Page Faulting Mode** Default Value: 000b Access: R/W This fields controls the page faulting mode that will be used in the memory interface block for the given request coming from this surface: 000: Use the global page faulting mode from context descriptor (default) 001-111: Reserved
	10:8	**Skip Caching control** Default Value: 000b Access: R/W Defines the bit values to enable caching. Outcome overrides the LLC caching for the surface. If "0" - than corresponding address bit value is don't care Bit[8]=1: address bit[9] needs to be "0" to cache in target Bit[9]=1: address bit[10] needs to be "0" to cache in target Bit[10]=1: address bit[11] needs to be "0" to cache in target
	7	**Enable Skip Caching** Default Value: 0b Access: R/W Enable for the Skip cache mechanism 0: Not enabled 1: Enabled for LLC

BLT_MOCS_62 - Blitter MOCS Register62

	6	**Dont allocate on miss** Default Value: 0b Access: R/W Controls defined for RO surfaces in mind, where if the target cache is missed - don't bring the line (applicable to LLC/eDRAM). 0: Allocate on MISS (normal cache behavior) 1: Do NOT allocate on MISS
	5:4	**LRU management** Default Value: 11b Access: R/W This field allows the selection of AGE parameter for a given surface in LLC or eLLC. . If a particular allocation is done at youngest age 3 it tends to stay longer in the cache as compared to older age allocations - 2, 1 or 0. This option is given to driver to be able to decide which surfaces are more likely to generate HITs, hence need to be replaced least often in caches. 11: Good chance of generating hits. 10: Poor chance of generating hits 01: Don't change the LRU if it is a HIT 00: Reserved
	3:2	**Target Cache** Default Value: 01b Access: R/W This field allows the choice of LLC vs eLLC for caching 00: eLLC Only 01: LLC Only 10: LLC/eLLC Allowed 11: LLC/eLLC Allowed
	1:0	**LLC/eDRAM cacheability control** Default Value: 11b Access: R/W Memory type information used in LLC/eDRAM. 00: Use Cacheability Controls from page table / UC with Fence (if coherent cycle) 01: Uncacheable (UC) - non-cacheable 10: Writethrough (WT) 11: Writeback (WB)

Blitter MOCS Register63

BLT_MOCS_63 - Blitter MOCS Register63

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x0000003B [KBL]
Size (in bits):	32
Address:	0CCFCh

MOCS register

DWord	Bit	Description
0	31:15	**Reserved** Default Value: 0000000000000000b Access: RO
	14	**Reserved1** Default Value: 0b Access: RO
	13:11	**Page Faulting Mode** Default Value: 000b Access: R/W This fields controls the page faulting mode that will be used in the memory interface block for the given request coming from this surface: 000: Use the global page faulting mode from context descriptor (default) 001-111: Reserved
	10:8	**Skip Caching control** Default Value: 000b Access: R/W Defines the bit values to enable caching. Outcome overrides the LLC caching for the surface. If "0" - than corresponding address bit value is don't care Bit[8]=1: address bit[9] needs to be "0" to cache in target Bit[9]=1: address bit[10] needs to be "0" to cache in target Bit[10]=1: address bit[11] needs to be "0" to cache in target
	7	**Enable Skip Caching** Default Value: 0b Access: R/W Enable for the Skip cache mechanism 0: Not enabled 1: Enabled for LLC

BLT_MOCS_63 - Blitter MOCS Register63

	6	**Dont allocate on miss** Default Value: 0b Access: R/W Controls defined for RO surfaces in mind, where if the target cache is missed - don't bring the line (applicable to LLC/eDRAM). 0: Allocate on MISS (normal cache behavior) 1: Do NOT allocate on MISS
	5:4	**LRU management** Default Value: 11b Access: R/W This field allows the selection of AGE parameter for a given surface in LLC or eLLC. . If a particular allocation is done at youngest age 3 it tends to stay longer in the cache as compared to older age allocations - 2, 1 or 0. This option is given to driver to be able to decide which surfaces are more likely to generate HITs, hence need to be replaced least often in caches. 11: Good chance of generating hits. 10: Poor chance of generating hits 01: Don't change the LRU if it is a HIT 00: Reserved

	1:0	**LLC/eDRAM cacheability control** Default Value: 11b Access: R/W Memory type information used in LLC/eDRAM. 00: Use Cacheability Controls from page table / UC with Fence (if coherent cycle) 01: Uncacheable (UC) - non-cacheable 10: Writethrough (WT) 11: Writeback (WB)

Blitter TLB Control Register

BTCR - Blitter TLB Control Register

Register Space:	MMIO: 0/2/0
Default Value:	0x00000000
Size (in bits):	32
Address:	0426Ch

DWord	Bit	Description
0	31:1	**Reserved** Default Value: 00000000000000000000000000000000b Access: RO
	0	**Invalidate TLBs on the corresponding Engine** Default Value: 0b Access: R/W SW writes 1 to invalidate the TLBs for the associated engine and HW clears the bit when invalidation is complete. To ensure proper invalidation of the TLBs, SW has to ensure the corresponding engine's HW pipeline is flushed and cleared from all its memory accesses. Otherwise HW cannot guarantee the proper invalidation for TLBs. This bit is self clear.

BLT Context Element Descriptor (High Part)

BLT_CTX_EDR_H - BLT Context Element Descriptor (High Part)		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	04504h	
DWord	**Bit**	**Description**
0	31:0	**BLT Context Element Descriptor (High Part)** Default Value: 00000000h Access: R/W

BLT Context Element Descriptor (Low Part)

BLT_CTX_EDR_L - BLT Context Element Descriptor (Low Part)		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000009	
Size (in bits):	32	
Address:	04500h	
DWord	**Bit**	**Description**
0	31:0	**BLT Context Element Descriptor (Low Part)** Default Value: 00000009h Access: R/W

BLT Fault Counter

BLT_FAULT_CNTR - BLT Fault Counter		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	045B8h	
DWord	**Bit**	**Description**
0	31:0	**BLT Fault Counter** Default Value: 00000000h Access: RO This counter only applies to advance context when fault and stream mode is selected.

BLT Fixed Counter

BLT_FIXED_CNTR - BLT Fixed Counter		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	045BCh	
DWord	**Bit**	**Description**
0	31:0	**BLT Fixed Counter** Default Value: 00000000h Access: RO This counter only applies to advance context when fault and stream mode is selected.

BLT PDP0/PML4/PASID Descriptor (High Part)

BLT_CTX_PDP0_H - BLT PDP0/PML4/PASID Descriptor (High Part)

Register Space:	MMIO: 0/2/0
Default Value:	0x00000000
Size (in bits):	32
Address:	0450Ch

DWord	Bit	Description
0	31:0	**BLT PDP0/PML4/PASID Descriptor (High Part)** Default Value: 00000000h Access: R/W

BLT PDP0/PML4/PASID Descriptor (Low Part)

BLT_CTX_PDP0_L - BLT PDP0/PML4/PASID Descriptor (Low Part)

Register Space:	MMIO: 0/2/0
Default Value:	0x00000000
Size (in bits):	32
Address:	04508h

DWord	Bit	Description
0	31:0	**BLT PDP0/PML4/PASID Descriptor (Low Part)** Default Value: 00000000h Access: R/W

BLT PDP1 Descriptor Register (High Part)

BLT_CTX_PDP1_H - BLT PDP1 Descriptor Register (High Part)		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	04514h	
DWord	**Bit**	**Description**
0	31:0	**BLT PDP1 Descriptor Register (High Part)** Default Value: 00000000h Access: R/W

BLT PDP1 Descriptor Register (Low Part)

BLT_CTX_PDP1_L - BLT PDP1 Descriptor Register (Low Part)		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	04510h	
DWord	**Bit**	**Description**
0	31:0	**BLT PDP1 Descriptor Register (Low Part)** Default Value: 00000000h Access: R/W

BLT PDP2 Descriptor Register (High Part)

BLT_CTX_PDP2_H - BLT PDP2 Descriptor Register (High Part)		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	0451Ch	
DWord	**Bit**	**Description**
0	31:0	**BLT PDP2 Descriptor Register (High Part)** Default Value: 00000000h Access: R/W

BLT PDP2 Descriptor Register (Low Part)

BLT_CTX_PDP2_L - BLT PDP2 Descriptor Register (Low Part)		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	04518h	
DWord	**Bit**	**Description**
0	31:0	**BLT PDP2 Descriptor Register (Low Part)** Default Value: 00000000h Access: R/W

BLT PDP3 Descriptor Register (High Part)

BLT_CTX_PDP3_H - BLT PDP3 Descriptor Register (High Part)		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	04524h	
DWord	**Bit**	**Description**
0	31:0	**BLT PDP3 Descriptor Register (High Part)** Default Value: 00000000h Access: R/W

BLT PDP3 Descriptor Register (Low Part)

BLT_CTX_PDP3_L - BLT PDP3 Descriptor Register (Low Part)		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	04520h	
DWord	**Bit**	**Description**
0	31:0	**BLT PDP3 Descriptor Register (Low Part)** Default Value: 00000000h Access: R/W

Boolean_Counter_B0

OAPERF_B0 - Boolean_Counter_B0	
Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	02920h

This register enables the current live value of performance counter B0 to be read. Since what conditions cause B0 to increment are defined by the programming of CEC0-0/CEC0-1, please refer to the description of these registers and the values they hold to determine what event is reported via this register.

DWord	Bit	Description
0	31:0	**Considerations** Format: U32 This 32-bit field returns bits 31:0 of the live performance counter value when read. Note that there is no "latch and hold" mechanism for performance counters when they are accessed through MMIO, so the value returned from this register may be different on back-to-back reads.

Boolean_Counter_B1

OAPERF_B1 - Boolean_Counter_B1	
Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	02924h

This register enables the current live value of performance counter B1 to be read. Since what conditions cause B1 to increment are defined by the programming of CEC1-0/CEC1-1, please refer to the description of these registers and the values they hold to determine what event is reported via this register.

DWord	Bit	Description
0	31:0	**Considerations** Format: U32 This 32-bit field returns bits 31:0 of the live performance counter value when read. Note that there is no "latch and hold" mechanism for performance counters when they are accessed through MMIO, so the value returned from this register may be different on back-to-back reads.

Boolean_Counter_B2

OAPERF_B2 - Boolean_Counter_B2	
Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	02928h

This register enables the current live value of performance counter B2 to be read. Since what conditions cause B2 to increment are defined by the programming of CEC0-0/CEC0-1, please refer to the description of these registers and the values they hold to determine what event is reported via this register.

DWord	Bit	Description
0	31:0	**Considerations** Format: U32 This 32-bit field returns bits 31:0 of the live performance counter value when read. Note that there is no "latch and hold" mechanism for performance counters when they are accessed through MMIO, so the value returned from this register may be different on back-to-back reads.

Boolean_Counter_B3

OAPERF_B3 - Boolean_Counter_B3

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	0292Ch

This register enables the current live value of performance counter B3 to be read. Since what conditions cause B3 to increment are defined by the programming of CEC0-0/CEC0-1, please refer to the description of these registers and the values they hold to determine what event is reported via this register.

DWord	Bit	Description
0	31:0	**Considerations** Format: U32 This 32-bit field returns bits 31:0 of the live performance counter value when read. Note that there is no "latch and hold" mechanism for performance counters when they are accessed through MMIO, so the value returned from this register may be different on back-to-back reads.

Boolean_Counter_B4

OAPERF_B4 - Boolean_Counter_B4	
Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	02930h

This register enables the current live value of performance counter B4 to be read. Since what conditions cause B4 to increment are defined by the programming of CEC0-0/CEC0-1, please refer to the description of these registers and the values they hold to determine what event is reported via this register.

DWord	Bit	Description
0	31:0	**Considerations** Format: U32 This 32-bit field returns bits 31:0 of the live performance counter value when read. Note that there is no "latch and hold" mechanism for performance counters when they are accessed through MMIO, so the value returned from this register may be different on back-to-back reads.

Boolean_Counter_B5

OAPERF_B5 - Boolean_Counter_B5

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	02934h

This register enables the current live value of performance counter B5 to be read. Since what conditions cause B5 to increment are defined by the programming of CEC0-0/CEC0-1, please refer to the description of these registers and the values they hold to determine what event is reported via this register.

DWord	Bit	Description
0	31:0	**Considerations** Format: U32 This 32-bit field returns bits 31:0 of the live performance counter value when read. Note that there is no "latch and hold" mechanism for performance counters when they are accessed through MMIO, so the value returned from this register may be different on back-to-back reads.

Boolean_Counter_B6

OAPERF_B6 - Boolean_Counter_B6	
Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	02938h

This register enables the current live value of performance counter B6 to be read. Since what conditions cause B6 to increment are defined by the programming of CEC0-0/CEC0-1, please refer to the description of these registers and the values they hold to determine what event is reported via this register.

DWord	Bit	Description
0	31:0	**Considerations** Format: U32 This 32-bit field returns bits 31:0 of the live performance counter value when read. Note that there is no "latch and hold" mechanism for performance counters when they are accessed through MMIO, so the value returned from this register may be different on back-to-back reads.

Boolean_Counter_B7

OAPERF_B7 - Boolean_Counter_B7

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	0293Ch

This register enables the current live value of performance counter B7 to be read. Since what conditions cause B7 to increment are defined by the programming of CEC0-0/CEC0-1, please refer to the description of these registers and the values they hold to determine what event is reported via this register.

DWord	Bit	Description
0	31:0	**Considerations** Format: U32 This 32-bit field returns bits 31:0 of the live performance counter value when read. Note that there is no "latch and hold" mechanism for performance counters when they are accessed through MMIO, so the value returned from this register may be different on back-to-back reads.

BOOT VECTOR

BOOTMSG - BOOT VECTOR

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Size (in bits):	32
Address:	08504h

Boot Message Register
This register gets locked by the Hardware once written and is cleared only during the reset. This is extra protection given against Illegal Programming.

DWord	Bit	Description
0	31:0	**Boot Vector Message** Access: R/W Lock Boot vector is pass through. MBC gets the boot message from GPMunit and forwards it to MSQC. Breakdown of message is done in MSQC. Details: if b[26] = 1 C6SliceA = b[20:17]; C6SliceB= d[13:10] C6Way = 0 C6Area = 0 if b[26] = 0 C6Way = b[25:21], C6Slice = d[20:17]; C6Area = d[17:10] Context Restore = b[6] Reset Type = b[6:5] Ring Stop ID = b[4:0]

BTB Not Consumed By RCS

BTP_PRODUCE_COUNT - BTB Not Consumed By RCS

Register Space:	MMIO: 0/2/0
Source:	RenderCS
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Trusted Type:	1
Address:	02480h

This register keeps track of the outstanding BTP produced by RS which are not yet consumed by Render Command Streamer.
This register is part of the render context save and restore.

Programming Notes

This register should not be programmed by SW.

DWord	Bit	Description
0	31:0	**BTP Produce Count** This register keeps track of the outstanding BTP produced by RS which are not yet consumed by Render Command Streamer. This register is part of the render context save and restore.

BTP Commands Parsed By RCS

BTP_PARSE_COUNT - BTP Commands Parsed By RCS

Register Space:	MMIO: 0/2/0
Source:	RenderCS
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Trusted Type:	1
Address:	02490h

This register keeps track of the BTP commands parsed by RCS prior to encountering the Draw Call in an RS enabled Batch Buffer which has BTP Pool Alloc Valid. BTP parse count should be less then equal to the BTP produce count for Command Streamer to make progress on a 3D_PRIMITIVE command. BTP Parse count is subtracted from the BTP Produce Count upon parsing 3D_PRIMITIVE command. This register is part of the render context save and restore. This register should not be programmed by SW.

DWord	Bit	Description
0	31:0	**BTP Parse Count** This register keeps track of the BTP commands parsed by RCS prior to encountering the Draw Call in an RS enabled Batch Buffer which has BTP Pool Alloc Valid. BTP parse count should be less then equal to the BTP produce count for Command Streamer to make progress on a 3D_PRIMITIVE command. BTP Parse count is subtracted from the BTP Produce Count upon parsing 3D_PRIMITIVE command.

Built In Self Test

BIST_0_2_0_PCI - Built In Self Test		
Register Space:	PCI: 0/2/0	
Source:	BSpec	
Default Value:	0x00000000	
Size (in bits):	8	
Address:	0000Fh	
This register is used for control and status of Built In Self Test (BIST).		
DWord	**Bit**	**Description**
0	7	**BIST Supported** Default Value: 0b Access: RO BIST is not supported. This bit is hardwired to 0.
	6:0	**Reserved** Format: MBZ

Cache Line Size

CLS_0_2_0_PCI - Cache Line Size		
Register Space:	PCI: 0/2/0	
Source:	BSpec	
Default Value:	0x00000000	
Size (in bits):	8	
Address:	0000Ch	
DWord	**Bit**	**Description**
0	7:0	**Cache Line Size** Default Value: 00000000b Access: R/W This register is not reset by FLR. Implemented for PCIe compliant devices for legacy compatibility but has no effect on any PCIe device behavior.

Cache Mode Register 0

CACHE_MODE_0 - Cache Mode Register 0

Register Space:	MMIO: 0/2/0
Source:	RenderCS
Default Value:	0x00000000 [KBL]
Access:	R/W
Size (in bits):	32
Address:	07000h

Description

This register is used to control the operation of the Render and Sampler L2 Caches. All reserved bits are implemented as read/write.
Before changing the value of this register, GFX pipeline must be idle i.e. full flush is required.
This Register is saved and restored as part of Context.

RegisterType = MMIO_SVL

DWord	Bit	Description
0	31:16	**Mask** Access: WO Format: Mask[15:0] A 1 in a bit in this field allows the modification of the corresponding bit in Bits 15:0.
	15	**Sampler L2 Disable** Access: r/w Format: Disable 0h **[Default]** – Sampler L2 Cache Enabled. 1h – Sampler L2 Cache Disabled. All accesses are treated as misses.
	14:12	**MSAA Compression Plane Number Threshold for eLLC** Access: r/w 0h threshold0 **[Default]** – Cache only planeID = 0 in eLLC. 1h threshold1 – Cache only planeID = 0, 1 in eLLC. 2h threshold2 – Cache only planeID = 0..2 in eLLC. 3h threshold3 – Cache only planeID = 0..3 in eLLC. 4h threshold4 – Cache only planeID = 0..4 in eLLC. 5h threshold5 – Cache only planeID = 0..5 in eLLC.

CACHE_MODE_0 - Cache Mode Register 0

6h	threshold6	Cache only planeID = 0..6 in eLLC.
7h	threshold7	Cache only planeID = 0..7 in eLLC.

Programming Notes
This bit-field is programmed based on MSAA. When MSAA compression is enabled, these settings affect HW, else it is ignored. For 16X MSAA only lower 8 planes can be cached in eLLC.

11 **Sampler Set Remmapping for 3D Disable**

Access:	r/w

Value	Name	Description
0h	Enable Set Remap **[Default]**	Set remapping for 3d enabled
1h	Disable Set Remap	Set remapping for 3d disabled

10 **Reserved**

Access:	r/w
Format:	PBC

9 **Sampler L2 TLB Prefetch Enable**

Access:	r/w

Value	Name	Description
0h	**[Default]**	TLB Prefetch Disabled
1h		TLB Prefetch Enabled

8 **Reserved**

7:6 **Sampler L2 Request Arbitration**

Access:	r/w
Format:	U2

Value	Name	Description
00b		Round Robin
01b		Fetch are Highest Priority
10b		Constants are Highest Priority
11b		Reserved

5 **STC PMA Optimization Enable**

Access:	r/w
Format:	Enable

Clearing this bit will force the STC cache to wait for pending retirement of pixels at the HZ-read stage and do the STC-test for Non-promoted, R-computed and Computed depth modes instead of postponing the STC-test to RCPFE.

CACHE_MODE_0 - Cache Mode Register 0

Value	Name	Description
0h	Disable **[Default]**	STC PMA optimization is disabled.
1h	Enable	STC PMA optimization is enabled.

4 **RCC Eviction Policy**

Access:	r/w
Format:	Disable

If this bit is set, RCCunit will have LRA as replacement policy. The default value i.e. (when this bit is reset) indicates that non-LRA eviction policy. This bit must be reset. LRA replacement policy is not supported.

Programming Notes
If this bit is set to "1", bit 7 of 0x7010h must also be set to "1".

3 **Reserved**

2 **Hierarchical Z RAW Stall Optimization Disable**

Access:	r/w
Format:	U1

The Hierarchical Z RAW Stall Optimization allows non-overlapping polygons in the same 8x4 pixel/sample area to be processed without stalling waiting for the earlier ones to write to Hierarchical Z buffer.

Value	Name	Description
0h	Enable **[Default]**	Enables the hierarchical Z RAW Stall Optimization.
1h	Disable	Disables the hierarchical Z RAW Stall Optimization.

Programming Notes
This bit must be set to 1 to disable the Hierarchical Z RAW stall optimization.

1 **Disable clock gating in the pixel backend**

Access:	r/w
Format:	Disable

MCL related clock gating is disabled in the pixel backend. Before setting this bit to 1, the instruction/state caches must be invalidated. [DevGT:{WKA}]

0 **Null tile fix disable**

Access:	r/w

Instead of dropping non dirty cachelines at alloc point, we allow the cacheline till the mem wrbk point, so that null status can be reset.

Value	Name	Description
0	**[Default]**	Null tile fix enabled
1		Null tile fix disable

Cache Mode Register 1

CACHE_MODE_1 - Cache Mode Register 1

Register Space:	MMIO: 0/2/0
Source:	RenderCS
Default Value:	0x00002980 [KBL]
Access:	R/W
Size (in bits):	32
Address:	07004h

Description
RegisterType: MMIO_SVL
Before changing the value of this register, GFX pipeline must be idle; i.e., full flush is required. This Register is saved and restored as part of Context.

DWord	Bit	Description
0	31:16	**Mask** Access: WO Mask: MASK Format: Mask[15:0] Must be set to modify corresponding data bit. Reads to this field returns zero.
	15	**Color Compression Disable** Access: r/w Setting this bit causes Lossless Render Target Color Compression to be disabled in Classic Clear (1x) Mode of Operation. Default value, i.e. resetting this bit, Enables Color Compression in Classic Clear Mode (1x) when CCS is Enabled. Value / Name: 0h: Enable **[Default]** 1h: Disable **Programming Notes** The Below programming forces Color Compression to be disabled for MSAA modes explicitly as a HW WA. When switching from 1x ==> MSAA. Program this bit to 1 When switching from MSAA ==> 1x. Program this bit to 0
	14	**Blend Optimization Fix Disable** This bit when reset, enables blend optimization fix. If this bit is set, it disables the blend optimization fix and may exhibit corruption on alpha components in the render target under some conditions.

CACHE_MODE_1 - Cache Mode Register 1

13 **NP EARLY Z FAILS DISABLE**

Access:	r/w

Value	Name	Description
0h	Disable	When NP PMA FIX ENABLE = 1, clearing this bit disables IZ to conservatively fail pixels.
1h	Enable **[Default]**	When NP PMA FIX ENABLE = 1, IZ does conservatively fail any NP pixels.

12 **HIZ Eviction Policy**

Access:	r/w
Format:	U1

If this bit is set, Hizunit will have LRA as replacement policy. The default value i.e. (when this bit is reset) indicates the non-LRA eviction policy. For performance reasons, this bit must be reset.

Value	Name	Description
0h	**[Default]**	Non-LRA eviction Policy
1h		LRA eviction Policy

Programming Notes
If this bit is set to "1", bit 3 of 0x7010h must also be set to "1"

11 **NP PMA FIX ENABLE**

Access:	r/w

Value	Name	Description
0h	Disable	Enables stalling PMA behavior for NP depth pixels in the early depth pipeline. (Legacy behavior)
1h	Enable **[Default]**	Enables non-stalling PMA behavior for NP depth pixels in the early depth pipeline.

Programming Notes
PMA Optimization Enable bit can be programmed to 0 to disable this optimization.

10 **Reserved**

9 **MSC RAW Hazard Avoidance Bit**

Access:	r/w
Format:	Enable

When this field is set, MSC will enable RAW Hazard prevention mechanism, when lossless compression is enabled.

Value	Name	Programming Notes
0h	**[Default]**	

CACHE_MODE_1 - Cache Mode Register 1

1h		This field should be programmed to 1 only if need arise to avoid RAW hazard when lossless compression is enabled

8:7 **Sampler Cache Set XOR selection**

Access:	r/w
Format:	U2

These bits have an impact only when the Sampler cache is configured in 16 way set associative mode. If the cache is being used for immediate data or for blitter data these bits have no effect.

Value	Name	Description
00b	None	No XOR.
01b	Scheme 1	New_set_mask[3:0] = Tiled_address[16:13]. New_set[3:0] less than or = New_set_mask[3:0] ^Old_set[3:0]. Rationale: These bits can distinguish among 16 different equivalent classes of virtual pages. These bits also represent the lsb for tile rows ranging from a pitch of 1 tile to 16 tiles.
10b	Scheme 2	New_set_mask[3] = Tiled_address[17] ^ Tiled_address[16]. New_set_mask[2] = Tiled_address[16] ^ Tiled_address[15]. New_set_mask[1] = Tiled_address[15] ^ Tiled_address[14]. New_set_mask[0] = Tiled_address[14] ^ Tiled_address[13]. New_set[3:0] less than or = New_set_mask[3:0] ^ Old_set[3:0]. Rationale: More bits on each XOR can give better statistical uniformity on sets and since two lsbs are taken for each tile row size, it reduces the chance of aliasing on sets.
11b	Scheme 3 **[Default]**	New_set_mask[3] = Tiled_address[22] ^ Tiled_address[21] ^ Tiled_address[20] ^ Tiled_address[19]. New_set_mask[2] = Tiled_address[18] ^ Tiled_address[17] ^ Tiled_address[16]. New_set_mask[1] = Tiled_address[15] ^ Tiled_address[14]. New_set_mask[0] = Tiled_address[13]. New_set[3:0] less than or = New_set_mask[3:0] ^ Old_set[3:0]. Rationale: More bits on each XOR can give better statistical uniformity on sets and since each XOR has different bits, it reduces the chance of aliasing on sets even more.

6 **4X4 RCPFE-STC Optimization Disable**

Access:	r/w
Format:	Disable

Value	Name	Description
0h	**[Default]**	Enables two contiguous 4x2s to be collected as 4X4 access for STC interface. This allows for less bank collision and less RAM power on STC.
1h		Disables this optimization and therefore only one valid 4x2 is sent to STC on the 4X4 interface.

CACHE_MODE_1 - Cache Mode Register 1

Restriction
Restriction This bit must be set.

5 MCS Cache Disable

Access:	r/w
Format:	Disable

For Programming restrictions please refer to the 3D Pipeline.

Value	Name	Description
0h	**[Default]**	MCS cache enabled. It allows RTs with MCS buffer enabled to be rendered using either MSAA compression for MSRT OR with color clear feature for non MSRT.
1h		MCS cache is disabled. Hence no MSAA compression for MSRT and no color clear for non-MSRT.

4 Float Blend Optimization Enable

Access:	r/w
Format:	Enable

Value	Name	Description
0h	**[Default]**	Disables blend optimization for floating point RTs.
1h		Enables blend optimization for floating point RTs.

3 Depth Read Hit Write-Only Optimization Disable

Access:	r/w
Format:	Disable

Value	Name	Description
0h	**[Default]**	Read Hit Write-only optimization is enabled in the Depth cache (RCZ).
1h		Read Hit Write-only optimization is disabled in the Depth cache (RCZ).

2 RCZ Read after expansion control fix 2

Access:	r/w
Format:	Enable

Value	Name	Description
0h	**[Default]**	RCZ will suppress the read request to memory if it was allocated as a expansion Cacheline
1h		RCZ will always issue a read request to memory, even if it was previously allocated as expansion Cacheline

CACHE_MODE_1 - Cache Mode Register 1

	1	**Partial Resolve Disable in VC** Access: r/w Format: Disable **Value / Name / Description** 0h **[Default]** Partial resolve in the Victim Cache enabled. 1h Partial evictions of cachelines with compression disabled from pixel backend (RCC) will not be resolved in the Victim Cache in CC in order to extend the resolve queue in GAM. Compression enabled cases will ignore this bit and will always be resolved in the VC.
	0	**Reserved**

Capabilities Control

CAPCTRL0_0_2_0_PCI - Capabilities Control

Register Space:	PCI: 0/2/0
Source:	BSpec
Default Value:	0x0000010C
Size (in bits):	16
Address:	00042h

DWord	Bit	Description
0	11:8	**CAPID Version** Default Value: 0001b Access: RO This field is hardwired to the value 1h to identify the first revision of the CAPID register definition.
	7:0	**CAPID Length** Default Value: 00001100b Access: RO This field is hardwired to the value 0Ch to indicate the structure length (12 bytes).

Capabilities Pointer

CAPPOINT_0_2_0_PCI - Capabilities Pointer

Register Space:	PCI: 0/2/0
Source:	BSpec
Default Value:	0x00000040
Size (in bits):	8
Address:	00034h

This register points to a linked list of capabilities implemented by this device.

DWord	Bit	Description
0	7:0	**Capabilities Pointer Value** Default Value: 01000000b Access: RO This field contains an offset into the function's PCI Configuration Space for the first item in the New Capabilities Linked List, the CAPID0 register at offset 40h.

Capability Identifier

CAPID0_0_2_0_PCI - Capability Identifier

Register Space:	PCI: 0/2/0
Source:	BSpec
Default Value:	0x00007009
Size (in bits):	16
Address:	00040h

DWord	Bit	Description
0	15:8	**Next Capability Pointer** Default Value: 01110000b Access: RO This field is hardwired to point to the next PCI Capability structure, the PCIe Capabilities structure at 70h.
	7:0	**Capability Identifier** Default Value: 00001001b Access: RO This field is hardwired to the value 09h to identify the CAP_ID assigned by the PCI SIG for vendor dependent capability pointers.

CDCLK_CTL

CDCLK_CTL

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x080002A1 [KBL]
Access:	R/W
Size (in bits):	32
Address:	46000h-46003h
Name:	CD Clock Control
ShortName:	CDCLK_CTL
Power:	PG0
Reset:	global

This register is not reset by the device 2 FLR.

Restriction
Restriction : These fields should only be changed as part of the Display Sequences for Changing CD Clock Frequency.

DWord	Bit	Description
0	31:28	**Reserved** Format: MBZ
	27:26	**CD Frequency Select** This field, together with the DPLL0 VCO setting, selects the frequency for CD clock. The DPLL0 VCO setting is programmed through DPLL_CTRL1.

Value	Name	Description
00b	450 or 432 MHz	If DPLL0 VCO 8100 (450 MHz CD, 900 MHz CD2X); If DPLL0 VCO 8640 (432 MHz CD, 864 MHz CD2X);
01b	540 MHz	540 MHz CD, 1080 MHz CD2X
10b	337.5 or 308.57 MHz **[Default]**	If DPLL0 VCO 8100 (337.5 MHz CD, 675 MHz CD2X); If DPLL0 VCO 8640 (308.57 MHz CD, 617.14 MHz CD2X);
11b	675 or 617.14 MHz	If DPLL0 VCO 8100 (675 MHz CD, 1350 MHz CD2X); If DPLL0 VCO 8640 (617.14 MHz CD, 1234.28 MHz CD2X);

Restriction
Restriction : The Display CD Clock Frequency Limit fuse indicates the maximum allowed CD clock frequency. Software must not select any frequency higher than the maximum that is allowed. If software incorrectly selects a higher frequency, hardware will override to the lowest frequency.

	25:20	**Reserved** Format: MBZ

CDCLK_CTL

	19	**Reserved**
	18	**Reserved**
	17	**Reserved**
	16	**SSA Precharge Enable** This field is unused. **Value** / **Name**: 0b – Disable
	15:11	**Reserved** Format: MBZ
	10:0	**CD Frequency Decimal** Format: U10.1 This field selects the decimal value of the frequency for CD clock, which is used to generate divided down clocks for some display engine timers. This value is represented in a 10.1 format with 10 integer bits and 1 fractional bit. Program this field to match the CD frequency chosen by the CD Frequency Select (considering the DPLL0 VCO that is being used), minus one.

Value	Name
01 0011 0011 1b	308.57 MHz CD
01 0101 0000 1b	337.5 MHz CD **[Default]**
01 1010 1111 0b	432 MHz CD
01 1100 0001 0b	450 MHz CD
10 0001 1011 0b	540 MHz CD
10 0110 1000 0b	617.14 MHz CD
10 1010 0010 0b	675 MHz CD

CGE_CTRL

CGE_CTRL

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	Double Buffered
Size (in bits):	32
Double Buffer Update Point:	Start of vertical blank

Address:	49080h-49083h

Reset:	soft
Address:	49290h-492A3h
Name:	Pipe Color Gamut Enhancement Weights
ShortName:	CGE_WEIGHT_C
Power:	PG2
Reset:	soft

These are the weights contained in the lookup up table (LUT) used in pipe color gamut enhancement.
LUT index 0 contains the weight for the least saturated colors, and LUT index 16 contains the weight for the most saturated colors.
Weight values can range from 00000b (100% of the enhanced output color is from the pipe gamma and CSC output corrected color) to 100000b (100% of the enhanced output color is from the pipe gamma and CSC input color).

Restriction
Restriction : The weight values should only be changed while color gamut enhancement is disabled, otherwise screen artifacts may show temporarily.

Class Code

CC_0_2_0_PCI - Class Code

Register Space:	PCI: 0/2/0
Source:	BSpec
Default Value:	0x00030000
Size (in bits):	24
Address:	00009h

This register contains the device programming interface information related to the Sub-Class Code and Base Class Code definition for the IGD. This register also contains the Base Class Code and the function sub-class in relation to the Base Class Code.

DWord	Bit	Description
0	23:16	**Base Class Code** Default Value: 00000011b Access: RO Variant This is an 8-bit value that indicates the base class code. When MGGC0[VAMEN] is 0 this code has the value 03h, indicating a Display Controller. When MGGC0[VAMEN] is 1 this code has the value 04h, indicating a Multimedia Device.
	15:8	**Sub-Class Code** Default Value: 00000000b Access: RO Variant When MGGC0[VAMEN] is 0 this value will be determined based on Device 0 GGC register, GMS and IVD fields. 00h: VGA compatible 80h: Non VGA (GMS = "00h" or IVD = "1b") When MGGC0[VAMEN] is 1, this value is 80h, indicating other multimedia device.
	7:0	**Programming Interface** Default Value: 00000000b Access: RO When MGGC0[VAMEN] is 0 this value is 00h, indicating a Display Controller. When MGGC0[VAMEN] is 1 this value is 00h, indicating a NOP.

Clipper Invocation Counter

CL_INVOCATION_COUNT - Clipper Invocation Counter	
Register Space:	MMIO: 0/2/0
Source:	RenderCS
Default Value:	0x00000000, 0x00000000
Access:	R/W
Size (in bits):	64
Trusted Type:	1
Address:	02338h

This register stores the count of objects entering the Clipper stage. This register is part of the context save and restore.

DWord	Bit	Description
0	63:32	**CL Invocation Count Report UDW** Number of objects entering the clipper stage. Updated only when Statistics Enable is set in CLIP_STATE (see the Clipper Chapter in the 3D Volume.)
	31:0	**CL Invocation Count Report LDW** Number of objects entering the clipper stage. Updated only when Statistics Enable is set in CLIP_STATE (see the Clipper Chapter in the 3D Volume.)

Clipper Primitives Counter

CL_PRIMITIVES_COUNT - Clipper Primitives Counter	
Register Space:	MMIO: 0/2/0
Source:	RenderCS
Default Value:	0x00000000, 0x00000000
Access:	R/W
Size (in bits):	64
Trusted Type:	1
Address:	02340h

This register reflects the total number of primitives that have been output by the clipper. This register is part of the context save and restore.

DWord	Bit	Description
0	63:32	**Clipped Primitives Output Count UDW** Total number of primitives output by the clipper stage. This count is updated for every primitive output by the clipper stage, as long as Statistics Enable is set in SF_STATE (see the Clipper and SF Chapters in the 3D Volume.)
	31:0	**Clipped Primitives Output Count LDW** Total number of primitives output by the clipper stage. This count is updated for every primitive output by the clipper stage, as long as Statistics Enable is set in SF_STATE (see the Clipper and SF Chapters in the 3D Volume.)

Clock Gating Messages

CGMSG - Clock Gating Messages

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Size (in bits):	32
Address:	08104h

Clock Gating Messages Register

DWord	Bit	Description
0	31:16	**Message Mask** Access: RO Message Mask In order to write to bits 15:0, the corresponding message mask bits must be written. For example, for bit 14 to be set, bit 30 needs to be 1 : 40004000
	15:10	**Reserved** Access: RO Reserved
	9	**Media sampler Clock gating control message** Access: R/W Gate Media sampler Clock Message : '0' : Clock Un-gate Request (un-gates the scmsclk clock) '1' : Clock Gate Request (gates the scmsclk clock)
	8	**SFC 1 Clock gating control message** Access: R/W Gate SFC 1 (2nd Vbox) Clock gate Message : '0' : SFC 1 Clock Un-gate Request (un-gates the cmclk clock in the 2nd Media block) '1' : SFC 1 Clock Gate Request (gates the cmclk clockin the 2nd Media block)
	7	**SFC 0 Clock gating control message** Access: R/W Gate SFC 0 (1st Vbox) Clock gate Message : '0' : SFC 0 Clock Un-gate Request (un-gates the cmclk clock in the 1st Media block) '1' : SFC 0 Clock Gate Request (gates the cmclk clockin the 1st Media block)

CGMSG - Clock Gating Messages

	6	**Media 1 Clock gating control message** Access: R/W Gate Media 1 (2nd Vbox) Clock Message : '0' : Media 1 Clock Un-gate Request (un-gates the cmclk clock in the 2n Media block) '1' : Media 1 Clock Gate Request (gates the cmclk clockin the 2nd Media block)
	5	**Reserved**
	4	**Reserved**
	3	**Fix Function Clock gating Control Message** Access: R/W Gate Fix Clock Message : '0' : Fix Clock Un-gate Request (un-gates the cfclk/cf2xclk clock) '1' : Fix Clock Gate Request (gates the cfclk/cf2xclk clock)
	2	**VEbox Clock gating Control message** Access: R/W Gate VE-box Clock Message : '0' : VEbox Clock Un-gate Request (un-gates the cvclk clock) '1' : VEbox Clock Gate Request (gates the cvclk clock)
	1	**Media 0 Clock Gating Control Message** Access: R/W Gate Media Clock Message : '0' : Media 0 Clock Un-gate Request (un-gates the cmclk clock) '1' : Media 0 Clock Gate Request (gates the cmclk clock)
	0	**Row Clock Gating Control Message** Access: R/W Gate Row Clocks Message : '0' : Row Clock Un-gate Request (un-gates the crclk and cr2xclk clocks) '1' : Row Clock Gate Request (gates the crclk and cr2xclk clocks)

Color/Depth Write FIFO Watermarks

CZWMRK - Color/Depth Write FIFO Watermarks

Register Space:	MMIO: 0/2/0
Source:	RenderCS
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Trusted Type:	1
Address:	04060h

This register is directly mapped to the current Virtual Addresses in the MTTLB (Texture and constant cache TLB).

DWord	Bit	Description
0	31:24	**Reserved** Format: MBZ
	23:18	**Color Wr Burst Size** This is the maximum size of the requests burst, from the last High Watermark trip, before reevaluating the High Watermark again.
	17:16	**Reserved** Format: MBZ
	15:12	**Color Wr FIFO High Watermark** This is the number of accumulated Color writes that will trigger a Burst of Z Writes.
	11:6	**Z Wr Burst Size** This is the maximum size of the requests burst, from the last High Watermark trip, before reevaluating the High Watermark again.
	5:4	**Reserved** Format: MBZ
	3:0	**Z Wr FIFO High Watermark** This is the number of accumulated Depth writes that will trigger a Burst of Z Writes.

Config to MCI HI

CFGTOMCIDFTHI - Config to MCI HI			
Register Space:	MMIO: 0/2/0		
Source:	BSpec		
Default Value:	0x00000000		
Size (in bits):	32		
Address:	098A0h		
Config to MCI and DFT Ring			
DWord	**Bit**	**Description**	
0	31	**CFG to MCI HI dispatch**	
		Access:	R/WC
	30	**CFG to MCI HI error clear**	
		Access:	R/WC
	29:20	**RSVD_29_20**	
		Access:	R/WC
	19:0	**MCI DFT Ring Write data**	
		Access:	R/WC

Config to MCI LO

CFGTOMCIDFTLO - Config to MCI LO		
Register Space:	MMIO: 0/2/0	
Source:	BSpec	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	0989Ch	
Config to MCI and DFT Ring		
DWord	**Bit**	**Description**
0	31	**CFG to MCI LO dispatch** Access: R/WC
	30:0	**MCI DFT Ring Write data** Access: R/WC

Config to MCI STATUS1

CFGTOMCIDFTSTATUS1 - Config to MCI STATUS1		
Register Space:	MMIO: 0/2/0	
Source:	BSpec	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	098A4h	
Config to MCI and DFT Ring		
DWord	**Bit**	**Description**
0	31:5	**RSVD_31_5** Access: RO
	4	**Report fifo empty** Access: RO
	3	**Reserved**
	2	**Reserved**
	1	**mci fifo overflow** Access: RO
	0	**Report fifo overflow** Access: RO

Configuration Register0 for RPMunit

CONFIG0 - Configuration Register0 for RPMunit

Register Space:	MMIO: 0/2/0
Default Value:	0x00000000
Size (in bits):	32
Address:	00D00h

Lock bit LOCK applies to all RW/L fields in this register. Lock is overridden during context restore.

DWord	Bit	Description
0	31	**Lock for RW/L Fields in this Register** Access: R/W Lock 0 = Bits of CONFIG0 register are R/W. 1 = All bits of CONFIG0 register are RO (including this lock bit). Once written to 1, the lock is set and cannot be cleared (i.e., writing a 0 will not clear the lock). Lock is reset on a restore after context is captured.
	30	**Engineering Sample/Pre-Production part Indicator** Access: R/W Lock Bit30 will be written by BIOS to indicate production/ES sample indication - polarity matches the CPU MSR SR 0xce[27] 1'b0 - production part. 1'b1 - engineering sample/pre-production part.
	29:5	**Placeholder Bits Config0** Access: R/W Lock Placeholder bits for implementation or ECO loops.
	4	**Prevent PowerGate Disable Config Bit** Access: R/W Lock Prevents Powergate License disabling config programming 0xD30[1] 'b0 - PowerGate License handshake enabled /disabled as per 0xD30[1] (default) 'b1 - PowerGate License disable config programming with bit 0xD30[0] is disabled. PowerGate license handshake is always enabled.
	3	**Reserved**
	2	**Reserved**
	1	**Reserved**
	0	**Disable TSC Synchronization** Access: R/W Lock 'b0 - TSC synchronization enabled in GT (default) 'b1 - TSC synchronization DISABLED in GT

Configuration Register1 for RPMunit

CONFIG1 - Configuration Register1 for RPMunit		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	00D04h	
Lock bit LOCK applies to all RW/L fields in this register. Lock is overridden during context restore.		
DWord	**Bit**	**Description**
0	31	**Lock for RW/L Fields in this Register** Access: R/W Lock 0 = Bits of CONFIG0 register are R/W. 1 = All bits of CONFIG0 register are RO (including this lock bit). Once written to 1, the lock is set and cannot be cleared (i.e., writing a 0 will not clear the lock). Lock is reset on a restore after context is captured.
	30:9	**Placeholder Bits BitField** Access: R/W Lock Placeholder bits for implementation or ECO loops.
	8:0	**Placeholder Bits L3FREQTHRESH** Access: R/W Lock Placeholder bits for implementation or ECO loops.

Configuration Register for RCPunit

RCPCONFIG - Configuration Register for RCPunit

Register Space:	MMIO: 0/2/0
Default Value:	0x0000000F
Size (in bits):	32
Address:	00D08h

Unit Level Clock Gating Control Registers

DWord	Bit	Description
0	31:5	**Placeholder Bits Config0 ECO Loops** Access: R/W Lock Placeholder bits for implementation or ECO loops.
	4	**Reserved**
	3	**RPMunit Clock Gating Disable in Uncore Well** Default Value: 1b Access: R/W Clock Gating Disable Control: '0': Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality). '1': Clock Gating Disabled. (i.e., clocks are toggling, always) (DEFAULT).
	2	**MGSRunit Clock Gating Disable in Uncore Well** Default Value: 1b Access: R/W Clock Gating Disable Control: '0': Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality). '1': Clock Gating Disabled. (i.e., clocks are toggling, always) (DEFAULT).
	1	**MDRBunit Clock Gating Disable in Uncore Well** Default Value: 1b Access: R/W Clock Gating Disable Control: '0': Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality). '1': Clock Gating Disabled. (i.e., clocks are toggling, always) (DEFAULT).

RCPCONFIG - Configuration Register for RCPunit

	0	**MCRunit Clock Gating Disable in Uncore Well** Default Value: 1b Access: R/W Clock Gating Disable Control: '0': Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality). '1': Clock Gating Disabled. (i.e., clocks are toggling, always) (DEFAULT).

Context Load Protocol Register BLT

BLT_CTX_LD_PRTCL - Context Load Protocol Register BLT		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000 [KBL]	
Size (in bits):	32	
Address:	04014h	
DWord	**Bit**	**Description**
0	31:16	**Mask Bits** Default Value: 0000h Access: RO
	15	**Context Load Protocol Register - BCS 15** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	14	**Context Load Protocol Register - BCS 14** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	13	**Context Load Protocol Register - BCS 13** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	12	**Context Load Protocol Register - BCS 12** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	11	**Context Load Protocol Register - BCS 11** Default Value: 0b Access: R/W For Future Use. This bit is self clear.

BLT_CTX_LD_PRTCL - Context Load Protocol Register BLT

	10	**Context Load Protocol Register - BCS 10** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	9	**Context Load Protocol Register - BCS 9** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	8	**Context Load Protocol Register - BCS 8** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	7	**Context Load Protocol Register - BCS 7** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	6	**Context Load Protocol Register - BCS 6** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	5	**Context Load Protocol Register - BCS 5** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	4	**Context Load Protocol Register - BCS 4** Default Value: 0b Access: R/W For Future Use. This bit is self clear.

BLT_CTX_LD_PRTCL - Context Load Protocol Register BLT

	3	**Context Load Protocol Register - BCS 3** Default Value: 0b Access: R/W Bit 3 = Context Complete. Only valid with Bit 2 asserted and indicates whether the context switching out as complete vs. incomplete. This bit is self clear.
	2	**Context Load Protocol Register - BCS 2** Default Value: 0b Access: R/W Context Load Protocol Register (Written by BCS) Bit 2 = Request from BCS to GAM for context save readiness. GAM will acknowledge appropriated steps taken. This bit is self clear.
	1	**Context Load Protocol Register - BCS 1** Default Value: 0b Access: R/W Context Load Protocol Register (Written by BCS) Bit 1 = Context Launched. This bit is self clear.
	0	**Context Load Protocol Register - BCS 0** Default Value: 0b Access: R/W Context Load Protocol Register (Written by BCS) Bit 0 = Context Available. This bit is self clear.

Context Load Protocol Register CS

GFX_CTX_LD_PRTCL - Context Load Protocol Register CS

Register Space:	MMIO: 0/2/0
Default Value:	0x00000000 [KBL]
Size (in bits):	32
Address:	04004h

DWord	Bit	Description
0	31:16	**Mask Bits** Default Value: 0000h Access: RO
	15	**Context Load Protocol Register - CS 15** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	14	**Context Load Protocol Register - CS 14** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	13	**Context Load Protocol Register - CS 13** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	12	**Context Load Protocol Register - CS 12** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	11	**Context Load Protocol Register - CS 11** Default Value: 0b Access: R/W For Future Use. This bit is self clear.

GFX_CTX_LD_PRTCL - Context Load Protocol Register CS

	10	**Context Load Protocol Register - CS 10** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	9	**Context Load Protocol Register - CS 9** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	8	**Context Load Protocol Register - CS 8** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	7	**Context Load Protocol Register - CS 7** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	6	**Context Load Protocol Register - CS 6** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	5	**Context Load Protocol Register - CS 5** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	4	**Context Load Protocol Register - CS 4** Default Value: 0b Access: R/W For Future Use. This bit is self clear.

GFX_CTX_LD_PRTCL - Context Load Protocol Register CS

	3	**Context Load Protocol Register - CS 3** Default Value: 0b Access: R/W Bit 3 = Context Complete. Only valid with Bit 2 asserted and indicates whether the context switching out as complete vs. incomplete. This bit is self clear.
	2	**Context Load Protocol Register - CS 2** Default Value: 0b Access: R/W Context Load Protocol Register (Written by CS) Bit 2 = Request from CS to GAM for context save readiness. GAM will acknowledge appropriated steps taken. This bit is self clear.
	1	**Context Load Protocol Register - CS 1** Default Value: 0b Access: R/W Context Load Protocol Register (Written by CS) Bit 1 = Context Launched. This bit is self clear.
	0	**Context Load Protocol Register - CS 0** Default Value: 0b Access: R/W Context Load Protocol Register (Written by CS) Bit 0 = Context Available. This bit is self clear.

Context Load Protocol Register VCS0

MFX0_CTX_LD_PRTCL - Context Load Protocol Register VCS0		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000 [KBL]	
Size (in bits):	32	
Address:	04008h	

DWord	Bit	Description
0	31:16	**Mask Bits** Default Value: 0000h Access: RO
	15	**Context Load Protocol Register - VCS0 15** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	14	**Context Load Protocol Register - VCS0 14** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	13	**Context Load Protocol Register - VCS0 13** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	12	**Context Load Protocol Register - VCS0 12** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	11	**Context Load Protocol Register - VCS0 11** Default Value: 0b Access: R/W For Future Use.

MFX0_CTX_LD_PRTCL - Context Load Protocol Register VCS0

		This bit is self clear.
	10	**Context Load Protocol Register - VCS0 10** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	9	**Context Load Protocol Register - VCS0 9** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	8	**Context Load Protocol Register - VCS0 8** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	7	**Context Load Protocol Register - VCS0 7** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	6	**Context Load Protocol Register - VCS0 6** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	5	**Context Load Protocol Register - VCS0 5** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	4	**Context Load Protocol Register - VCS0 4**

MFX0_CTX_LD_PRTCL - Context Load Protocol Register VCS0

	Default Value:	0b
	Access:	R/W

For Future Use.
This bit is self clear.

3 — Context Load Protocol Register - VCS0 3

Default Value:	0b
Access:	R/W

Bit 3 = Context Complete. Only valid with Bit 2 asserted and indicates whether the context switching out as complete vs. incomplete.
This bit is self clear.

2 — Context Load Protocol Register - VCS0 2

Default Value:	0b
Access:	R/W

Context Load Protocol Register
(Written by VCS0)
Bit 2 = Request from VCS0 to GAM for context save readiness. GAM will acknowledge appropriated steps taken.
This bit is self clear.

1 — Context Load Protocol Register - VCS0 1

Default Value:	0b
Access:	R/W

Context Load Protocol Register
(Written by VCS0)
Bit 1 = Context Launched.
This bit is self clear.

0 — Context Load Protocol Register - VCS0 0

Default Value:	0b
Access:	R/W

Context Load Protocol Register
(Written by VCS0)
Bit 0 = Context Available.
This bit is self clear.

Context Load Protocol Register VCS1

MFX1_CTX_LD_PRTCL - Context Load Protocol Register VCS1

Register Space:	MMIO: 0/2/0
Default Value:	0x00000000 [KBL]
Size (in bits):	32
Address:	0400Ch

DWord	Bit	Description
0	31:16	**Mask Bits** Default Value: 0000h Access: RO
	15	**Context Load Protocol Register - VCS1 15** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	14	**Context Load Protocol Register - VCS1 14** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	13	**Context Load Protocol Register - VCS1 13** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	12	**Context Load Protocol Register - VCS1 12** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	11	**Context Load Protocol Register - VCS1 11** Default Value: 0b Access: R/W For Future Use.

MFX1_CTX_LD_PRTCL - Context Load Protocol Register VCS1

		This bit is self clear.
	10	**Context Load Protocol Register - VCS1 10** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	9	**Context Load Protocol Register - VCS1 9** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	8	**Context Load Protocol Register - VCS1 8** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	7	**Context Load Protocol Register - VCS1 7** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	6	**Context Load Protocol Register - VCS1 6** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	5	**Context Load Protocol Register - VCS1 5** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	4	**Context Load Protocol Register - VCS1 4**

MFX1_CTX_LD_PRTCL - Context Load Protocol Register VCS1

	Default Value:	0b
	Access:	R/W

For Future Use.
This bit is self clear.

3 — **Context Load Protocol Register - VCS1 3**

Default Value:	0b
Access:	R/W

Bit 3 = Context Complete. Only valid with Bit 2 asserted and indicates whether the context switching out as complete vs. incomplete.
This bit is self clear.

2 — **Context Load Protocol Register - VCS1 2**

Default Value:	0b
Access:	R/W

Context Load Protocol Register
(Written by VCS1)
Bit 2 = Request from VCS1 to GAM for context save readiness. GAM will acknowledge appropriated steps taken.
This bit is self clear.

1 — **Context Load Protocol Register - VCS1 1**

Default Value:	0b
Access:	R/W

Context Load Protocol Register
(Written by VCS1)
Bit 1 = Context Launched
This bit is self clear.

0 — **Context Load Protocol Register - VCS1 0**

Default Value:	0b
Access:	R/W

Context Load Protocol Register
(Written by VCS1)
Bit 0 = Context Available.
This bit is self clear.

Context Load Protocol Register VEBX

VEBX_CTX_LD_PRTCL - Context Load Protocol Register VEBX		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000 [KBL]	
Size (in bits):	32	
Address:	04010h	

DWord	Bit	Description
0	31:16	**Mask Bits** Default Value: 0000h Access: RO
	15	**Context Load Protocol Register - VEBX 15** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	14	**Context Load Protocol Register - VEBX 14** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	13	**Context Load Protocol Register - VEBX 13** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	12	**Context Load Protocol Register - VEBX 12** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	11	**Context Load Protocol Register - VEBX 11** Default Value: 0b Access: R/W For Future Use.

VEBX_CTX_LD_PRTCL - Context Load Protocol Register VEBX

		This bit is self clear.
	10	**Context Load Protocol Register - VEBX 10** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	9	**Context Load Protocol Register - VEBX 9** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	8	**Context Load Protocol Register - VEBX 8** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	7	**Context Load Protocol Register - VEBX 7** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	6	**Context Load Protocol Register - VEBX 6** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	5	**Context Load Protocol Register - VEBX 5** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	4	**Context Load Protocol Register - VEBX 4**

VEBX_CTX_LD_PRTCL - Context Load Protocol Register VEBX

	Default Value:	0b
	Access:	R/W

For Future Use.
This bit is self clear.

3 — Context Load Protocol Register - VEBX 3

Default Value:	0b
Access:	R/W

Bit 3 = Context Complete. Only valid with Bit 2 asserted and indicates whether the context switching out as complete vs. incomplete.
This bit is self clear.

2 — Context Load Protocol Register - VEBX 2

Default Value:	0b
Access:	R/W

Context Load Protocol Register
(Written by VEBX)
Bit 2 = Request from VEBX to GAM for context save readiness. GAM will acknowledge appropriated steps taken.
This bit is self clear.

1 — Context Load Protocol Register - VEBX 1

Default Value:	0b
Access:	R/W

Context Load Protocol Register
(Written by VEBX)
Bit 1 = Context Launched.
This bit is self clear.

0 — Context Load Protocol Register - VEBX 0

Default Value:	0b
Access:	R/W

Context Load Protocol Register
(Written by VEBX)
Bit 0 = Context Available.
This bit is self clear.

Context Restore Request To TDL

TDL_CONTEXT_RESTORE - Context Restore Request To TDL

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	WO
Size (in bits):	32
Address:	0E440h

DWord	Bit	Description
0	31:17	**Reserved** Format: MBZ
	16	**Context Restore Mask** Value: 1 — Name: — Description: Bit 0 and bit 16 both need to be 1 for Context restore request
	15:1	**Reserved** Format: MBZ
	0	**Context Restore** Value: 1 — Name: — Description: Bit 0 and bit 16 both need to be 1 for Context restore request

Context Save Request To TDL

TDL_CONTEXT_SAVE - Context Save Request To TDL	
Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	WO
Size (in bits):	32
Address:	0E4FCh

DWord	Bit	Description
0	31:17	**Reserved** Format: MBZ
	16	**Context Save Mask** Value: 1 — Name: — Description: Bit 0 and Bit 16 both need to be '1' for Context Save Request
	15:1	**Reserved** Format: MBZ
	0	**Context Save** Value: 1 — Name: — Description: Bit 0 and Bit 16 both need to be '1' for Context Save Request

Context Sizes

CXT_SIZE - Context Sizes

Register Space:	MMIO: 0/2/0
Source:	RenderCS
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Trusted Type:	1
Address:	021A8h

The actual size of a logical rendering context is the amount of data stored/restored during a context switch and is measured in 64B cache lines.

This register will be power context save/restored. Note that this register will default to the correct value, so software should not have to modify it.

DWord	Bit	Description
0	31:28	**Reserved** Format: MBZ
	7:0	**Reserved** Format: MBZ

Context Status1 for RCS-BE

CS_CONTEXT_STATUS1 - Context Status1 for RCS-BE

Register Space:	MMIO: 0/2/0
Source:	RenderCS
Default Value:	0x00000000
Access:	r/w
Size (in bits):	32
Trusted Type:	1
Address:	02184h

This register is for maintaining HW internal state of RCS-BE per context. This register is context save/restore per context. This register should not be written by SW.

DWord	Bit	Description
0	31:16	**Mask Bits** Access: WO Format: Mask Must be set to modify corresponding bit in Bits 15:0. (All implemented bits)
	15:14	**Reserved** Format: PBC
	13:8	**Reserved** Format: PBC
	7	**Preempted Batch Buffer RS Control Stop Flag** Format: Flag This field specifies RS Control Stop Flag when a batch buffer is preempted. This is for HW internal use and should not be written by SW. This bit gets reset when RS_PREEMPTED field of RS_PREEMPT_STATUS is written Zero. This bit is set by: • Ctx restore of this bit • MI_RS_CONTROL_STOP (except for the ctx restore command) This bit is cleared by: • MI_RS_CONTROL_START • Any Batch start except resubmitted RS batch • A batch end that doesn't include preemption • Ctx save Writing 0 to bit[0] of the RS STATUS register

CS_CONTEXT_STATUS1 - Context Status1 for RCS-BE

	6	**Pending Indirect State Dirty Bit** Format: U1 This field keeps track of whether or not an indirect state pointer command has been parsed in the current context. Clears either on a context save or explicitly through a flush command.
	5:0	**Pending Indirect State Counter** Access: RO Format: U6 This field keeps track of the maximum number of indirect state pointers pending in the system. When the register is saved/restored, it saves either a value of 1 or 0.

Context Status Buffer Contents

CTXT_ST_BUF - Context Status Buffer Contents

Address:	1C3A8h-1C3ABh
Name:	Context Timestamp Count
ShortName:	CTX_TIMESTAMP_VCSUNIT1

Address:	223A8h-223ABh
Name:	Context Timestamp Count
ShortName:	CTX_TIMESTAMP_BCSUNIT

This register provides a mechanism to obtain cumulative run time of a GPU context on HW. This register gets context save/restored on a context switch. SW must reset this register on very first submission of a context to HW, then afterwards gets context save/restored maintaining the cumulative run time of the corresponding context.
This register (effectively) counts at a constant frequency by adjusting the increment amount according to the actual reference clock frequency. SW therefore does not need to know the reference clock frequency. This register gets reset on an engine reset.

This register is context save restore on a context switch.

DWord	Bit	Description
0	31:0	**Timestamp Value** Format: U32 The granularity of this toggle is at the rate of the bit 3 in the "Reported Timestamp Count" register(0x2358).. The toggle will be 8 times slower that "Reported Timestamp Count". The granularity of the time stamp base unit for "Reported Timestamp Count" is defined in the “Timestamp Bases[SKL+]” subsection in Power Management chapter.

Control Register for Fault and Halt

FH_MODE - Control Register for Fault and Halt

Register Space:	MMIO: 0/2/0
Default Value:	0x00000000
Size (in bits):	32
Address:	042A4h

This register is used to control the different fault and halt modes.

DWord	Bit	Description
0	31	**Disable Blocking Page Fault** Default Value: 0b Access: R/W When disabled h/w would not set the "blocking fault" bit in the streaming page fault descriptor for the fault and halt generated page faults. FH_MODE: 0: Enable "blocking page fault" indicator for Fault and Halt 1: Disable "blocking page fault" indicator for Fault and Halt
	30	**Enable Forward Progress under F and H based page faults - Render engine only** Default Value: 0b Access: R/W Once set, the page walker will not wait for accesses that are hitting page faults on fault and halt cases, and marking accesses as "invalid" making forward progress. Such case may corrupt the frame or may require TDR if surface is CRITICAL. Invalid accesses will return garbage content. GFX Driver can set this bit in the middle of an active context, h/w should clear the bit when an active context completes. Usage model will be as driver hits a fault and halt and interrupts the driver, driver will set this bit is it needs forward progress. The behavior should only be applicable to the running context. FWDPROG: 0: Forwards progress under fault and halt is only possible with page response. 1: Enable forward progress under falt and halt w/o the need of paging services.
	29	**Enable Interrupt Generation** Default Value: 0b Access: R/W Enable interrupt generation on fault and halt page when resume mode is enabled: An interrupt can be generated on page fault with the fault and halt mode when hardware is programmed to resume(rather than wait/halt). The generation of interrupt needs to be explicitly enabled via this register bit. ENINTR: 0: No interrupt is generated on fault and halt page fault.

FH_MODE - Control Register for Fault and Halt

		1: Enable interrupt generation for fault and halt based page faults when h/w is programmed to resume.
	28:0	**Reserved FH_MODE Bits 28** Default Value: 00000000000000000000000000000b Access: R/W Future Use.

Count Active Channels Dispatched

TS_GPGPU_THREADS_DISPATCHED - Count Active Channels Dispatched

Register Space:	MMIO: 0/2/0
Source:	RenderCS
Default Value:	0x00000000, 0x00000000
Access:	R/W
Size (in bits):	64
Trusted Type:	1
Address:	02290h

This register is used to count the number of active channels that TS sends for dispatch. For each dispatch the active bits in the execution mask are summed and added to this register. This register is reset when a write occurs to 2290h

DWord	Bit	Description
0	63:32	**GPGPU_THREADS_DISPATCHED UDW** Format: U32 This count is increased by the number of active bits in the execution mask each time the TS sends a GPGPU dispatch.
	31:0	**GPGPU_THREADS_DISPATCHED LDW** Format: U32 This count is increased by the number of active bits in the execution mask each time the TS sends a GPGPU dispatch.

Power:	PG2
Reset:	soft
Address:	49240h-4924Bh
Name:	Pipe CSC Post-Offsets
ShortName:	CSC_POSTOFF_C
Power:	PG2
Reset:	soft

The post-offset is intended to add an offset from 0 on the Y or RGB channels and to convert UV channels from 2's complement to excess 0.5 as they exit pipe color space conversion (CSC).

DWord	Bit	Description
0	31:13	**Reserved** Format: MBZ
	12:0	**PostCSC High Offset** This value is used to give an offset to the high color channel as it exits CSC logic. The value is a 2's complement fraction allowing offsets between -1 and +1 (exclusive).
1	31:13	**Reserved** Format: MBZ

CSC_POSTOFF		
	12:0	**PostCSC Medium Offset** This value is used to give an offset to the medium color channel as it exits CSC logic. The value is a 2's complement fraction allowing offsets between -1 and +1 (exclusive).
2	31:13	**Reserved** Format: MBZ
	12:0	**PostCSC Low Offset** This value is used to give an offset to the low color channel as it exits CSC logic. The value is a 2's complement fraction allowing offsets between -1 and +1 (exclusive).

CSC_PREOFF

CSC_PREOFF	
Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000, 0x00000000, 0x00000000
Access:	Double Buffered
Size (in bits):	96
Double Buffer Update Point:	Start of vertical blank after armed
Double Buffer Armed By:	Write to CSC_MODE
Address:	49030h-4903Bh
Name:	Pipe CSC Pre-Offsets
ShortName:	CSC_PREOFF_A
Power:	PG1
Reset:	soft
Address:	49130h-4913Bh
Name:	Pipe CSC Pre-Offsets
ShortName:	CSC_PREOFF_B
Power:	PG2
Reset:	soft
Address:	49230h-4923Bh
Name:	Pipe CSC Pre-Offsets
ShortName:	CSC_PREOFF_C
Power:	PG2
Reset:	soft

The pre-offset is intended to remove an offset from 0 on the Y or RGB channels and to convert UV channels from excess 0.5 to 2's complement as they enter pipe color space conversion (CSC).

DWord	Bit	Description
0	31:13	**Reserved** Format: MBZ
	12:0	**PreCSC High Offset** This value is used to give an offset to the high color channel as it enters CSC logic. The value is a 2's complement fraction allowing offsets between -1 and +1 (exclusive).
1	31:13	**Reserved** Format: MBZ

CSC_PREOFF		
	12:0	**PreCSC Medium Offset** This value is used to give an offset to the medium color channel as it enters CSC logic. The value is a 2's complement fraction allowing offsets between -1 and +1 (exclusive).
2	31:13	**Reserved** Format: MBZ
	12:0	**PreCSC Low Offset** This value is used to give an offset to the low color channel as it enters CSC logic. The value is a 2's complement fraction allowing offsets between -1 and +1 (exclusive).

CSPREEMPT

CSPREEMPT - CSPREEMPT

Name:	Cursor Base Address
ShortName:	CUR_BASE_C
Power:	PG2
Reset:	soft

Writes to this register arm cursor registers for this pipe.

DWord	Bit	Description
0	31:12	**Cursor Base 31 12** Format: GraphicsAddress[31:12] This field specifies bits 31:12 of the graphics address of the base of the cursor for hi-res mode. When performing 180 degree rotation, this address does not need to change, hardware will internally offset to start from the last pixel of the last line of the cursor. **Workaround** Workaround : To prevent false VT-d type 6 errors, use 64KB address alignment and allocate an extra 2 Page Table Entries (PTEs) beyond the end of the displayed surface. Only the PTEs will be used, not the pages themselves. **Restriction**

CUR_BASE		
		Restriction : The cursor surface address must be 4K byte aligned. The cursor must be in linear memory, it cannot be tiled.
	11:7	**Reserved**
	6:4	**Reserved**
	3	**Reserved**
	2	**Reserved**
	1:0	**Reserved**

CUR_CTL

CUR_CTL

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	Double Buffered
Size (in bits):	32
Double Buffer Update Point:	Start of vertical blank or pipe not enabled; after armed
Double Buffer Armed By:	Write to CUR_BASE or cursor not enabled

Address:	70080h-70083h
Name:	Cursor Control
ShortName:	CUR_CTL_A
Power:	PG1
Reset:	soft

Address:	71080h-71083h
Name:	Cursor Control
ShortName:	CUR_CTL_B
Power:	PG2
Reset:	soft

Address:	72080h-72083h
Name:	Cursor Control
ShortName:	CUR_CTL_C
Power:	PG2
Reset:	soft

The cursor is enabled by programming a valid cursor mode in the cursor mode select fields.
The cursor is disabled by programming all 0s in the cursor mode select fields.

DWord	Bit	Description
0	31:28	**Reserved**
	27	**Reserved**
	26	**Gamma Enable** This bit enables pipe gamma correction for the cursor pixel data. In VGA pop-up operation, the cursor data will always bypass gamma. Value: 0b — Name: Disable

CUR_CTL

	1b	Enable

25 Reserved

24 Pipe CSC Enable

This bit enables pipe color space conversion for the cursor pixel data.

Value	Name
0b	Disable
1b	Enable

23 Allow Double Buffer Update Disable

Access:	R/W

This field controls whether double buffer updates are allowed to be disabled for this cursor. The DOUBLE_BUFFER_CTL register can be configured to globally disable double buffer updates for resources that allow them to be disabled.

Value	Name
0b	Not Allowed
1b	Allowed

22:16 Reserved

Format:	MBZ

15 180 Rotation

This mode causes the cursor image to be rotated 180 degrees.
In addition to setting this bit, the cursor position must be adjusted to match the physical orientation of the display.

Value	Name
0b	No rotation
1b	180 degree rotation

Restriction
Restriction : Only 32 bits per pixel cursors can be rotated. This field must be zero when the cursor format is 2 bits per pixel.

14 Trickle Feed Enable

Value	Name
0b	Enable
1b	Disable

Restriction
Restriction : Do not program this field to 1b.

13:12 Reserved

11:10 Force Alpha Plane Select

This field selects which planes the cursor alpha value will be forced for. It is used together with

CUR_CTL

the Force Alpha Value field.

Value	Name	Description
00b	Disable	Disable alpha forcing
01b	Pipe CSC Enabled	Enable alpha forcing where cursor overlaps a plane that has enabled pipe CSC
10b	Pipe CSC Disabled	Enable alpha forcing where cursor overlaps plane that has disabled pipe CSC
11b	Reserved	Reserved

9:8 **Force Alpha Value**

This field controls the behavior of cursor when alpha blending onto certain plane pixels.
It is used together with the Force Alpha Plane Select field.

Value	Name	Description
00b	Disable	Cursor pixels alpha blend normally over any plane.
01b	50	Cursor pixels with alpha >= 50% are made fully opaque where they overlap the selected plane(s). Cursor pixels with alpha < 50% are made fully transparent where they overlap the selected plane(s).
10b	75	Cursor pixels with alpha >= 75% are made fully opaque where they overlap the selected plane(s). Cursor pixels with alpha < 75% are made fully transparent where they overlap the selected plane(s).
11b	100	Cursor pixels with alpha = 100% are made fully opaque where they overlap the selected plane(s). Cursor pixels with alpha < 100% are made fully transparent where they overlap the selected plane(s).

Restriction
Restriction : Force Alpha is only for use with ARGB cursor formats.

7:6 **Reserved**

5:0 **Cursor Mode Select**

This field selects the cursor mode.
Cursor is disabled when the selection is 000000b and enabled when the selection is any other value.
The cursor vertical size can be overriden by the size reduction mode.

Value	Name	Description
000000b	Disable	Cursor is disabled
000010b	128x128 32bpp AND/INV	128x128 32bpp AND/INVERT
000011b	256x256 32bpp AND/INV	256x256 32bpp AND/INVERT
000100b	64x64 2bpp 3-color	64x64 2bpp Indexed 3-color and transparency
000101b	64x64 2bpp 2-color	64x64 2bpp Indexed AND/XOR 2-color

CUR_CTL

000110b	64x64 2bpp 4-color	64x64 2bpp Indexed 4-color

100111b	64x64 32bpp ARGB	64x64 32bpp ARGB (8:8:8:8 MSB-A:R:G:B)
Others	Reserved	Reserved

Programming Notes

INVERT, XOR, and alpha blends may not look as expected when the plane underlying the cursor is YUV or extended range RGB.
Out of range RGB values will be clamped prior to alpha blending, INVERT, or XOR with cursor.
It is recommended to use Force Alpha when cursor is alpha blending onto an plane of a different color space or extended gamut.

The AND/INVERT format uses the most significant byte (MSB) to control the color.
If MSB is 0xFF: Cursor is opaque. Show cursor color from three least significant bytes.
If MSB is 0x00: Cursor is transparent. Three least significant bytes must be zero.
If MSB is not 0x00 or 0xFF: Cursor inverts the color of the surface underneath.

The AND/XOR format uses the most significant byte (MSB) to control the color.
If MSB is 0xFF: Cursor is opaque. Show cursor color from three least significant bytes.
If MSB is 0x00: Cursor is transparent. Three least significant bytes must be zero.
If MSB is not 0x00 or 0xFF: The three least significant bytes are XOR'd with the color of the surface underneath.

CUR_FBC_CTL

CUR_FBC_CTL

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	Double Buffered
Size (in bits):	32
Double Buffer Update Point:	Start of vertical blank or pipe not enabled; after armed
Double Buffer Armed By:	Write to CUR_BASE or cursor not enabled

The cursor palette provides color information when using the indexed cursor modes.
There are 4 instances of this register format per cursor.
The table below describes how the cursor mode and index value will select between the cursor palette colors, AND/XOR, transparency, and destination invert.

Index Value	2 color mode	3 color mode	4 color mode
00	CUR_PAL 0	CUR_PAL 0	CUR_PAL 0
01	CUR_PAL 1	CUR_PAL 1	CUR_PAL 1
10	Transparent	Transparent	CUR_PAL 2
11	Invert Destination	CUR_PAL 3	CUR_PAL 3

DWord	Bit	Description
0	31:24	**Reserved**

CUR_PAL		
	23:16	**Palette Red** This field is the cursor palette red value
	15:8	**Palette Green** This field is the cursor palette green value.
	7:0	**Palette Blue** This field is the cursor palette blue value.

CUR_POS

CUR_POS

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	Double Buffered
Size (in bits):	32
Double Buffer Update Point:	Start of vertical blank or pipe not enabled

Address:	70088h-7008Bh
Name:	Cursor Position
ShortName:	CUR_POS_A
Power:	PG1
Reset:	soft

Address:	71088h-7108Bh
Name:	Cursor Position
ShortName:	CUR_POS_B
Power:	PG2
Reset:	soft

Address:	72088h-7208Bh
Name:	Cursor Position
ShortName:	CUR_POS_C
Power:	PG2
Reset:	soft

This register specifies the screen position of the cursor.
The origin of the cursor position is always the upper left corner of the display pipe source image area.
When performing 180 degree rotation, the cursor image is rotated by hardware, but the position is not, so it should be adjusted if it is desired to maintain the same apparent position on a physically rotated display.

Restriction
Restriction : The cursor must have at least a single pixel positioned over the pipe source area.

DWord	Bit	Description
0	31	**Y Position Sign** This specifies the sign of the vertical position of the cursor upper left corner.
	30:28	**Reserved** Format: MBZ

CUR_POS		
	27:16	**Y Position Magnitude** This specifies the magnitude of the vertical position of the cursor upper left corner in lines.
	15	**X Position Sign** This specifies the sign of the horizontal position of the cursor upper left corner.
	14:13	**Reserved** Format: MBZ
	12:0	**X Position Magnitude** This specifies the magnitude of the horizontal position of the cursor upper left corner in pixels.

CUR_SURFLIVE

CUR_SURFLIVE	
Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Address:	700ACh-700AFh
Name:	Cursor Live Base Address
ShortName:	CUR_SURFLIVE_A
Power:	PG1
Reset:	soft
Address:	710ACh-710AFh
Name:	Cursor Live Base Address
ShortName:	CUR_SURFLIVE_B
Power:	PG2
Reset:	soft
Address:	720ACh-720AFh
Name:	Cursor Live Base Address
ShortName:	CUR_SURFLIVE_C
Power:	PG2
Reset:	soft

There is one instance of this register for each pipe.

DWord	Bit	Description
0	31:12	**Live Surface Base Address** This gives the live value of the surface base address as being currently used for the cursor.
	11:0	**Reserved** Format: MBZ

Name:	Current Context Register
ShortName:	CCID_VCSUNIT1

Address:	22180h-22183h
Name:	Current Context Register
ShortName:	CCID_BCSUNIT

Description	Source
This register contains the 4 KB-aligned Graphics Memory Address to which the engine must save/restore its state during IDLE sequencing. This register should be programmed only in ringbuffer mode of scheduling.	
On SKL and its derivatives context address programmed should support a memory surface of size 4KB and with memory surface initialized to zeros (0x0).	BlitterCS, VideoCS, VideoCS2, VideoEnhancementCS

Programming Notes	Source
The CCID register must be written directly (via MMIO) or MI_LOAD_REGISTER_IMMEDIATE command as part of the initialization sequence of the command streamer in ring buffer mode of scheduling.	BlitterCS, VideoCS, VideoCS2, VideoEnhancementCS
The CCID register must not be written directly (via MMIO) unless the Command Streamer is completely idle (i.e., the Ring Buffer is empty and the pipeline is idle). Note that, under normal conditions, the CCID register should only be updated from the command stream using the MI_SET_CONTEXT command.	RenderCS

DWord	Bit	Description

CCID - Current Context Register

0 | 31:12 | Context Address

Format:	GraphicsAddress[31:12]

This field contains the 4 KB-aligned Graphics Memory Address to which the engine must save/restore its state during IDLE sequencing.

11:10 | Reserved

1h	Valid	The other fields of this register are valid.

Customizable Event Creation 0-0

CEC0-0 - Customizable Event Creation 0-0

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	02770h

This register is used to define custom counter event 0, bit definitions in this register refer to the CEC block diagram in the Custom Event Counters section.

DWord	Bit	Description
0	31:21	**Negate** Format: U11 The 11-bit array defined in this field allows input bus bits [10:0] to be individually negated in order to facilitate more complicated custom event creation (e.g. A & (!B | !C)). Note that LSB of this field affects bit 0 of the selected input bus. **Value** / **Name** / **Description** / **Programming Notes** 0b / Pass-through / Input bit is passed through to comparator as is / 1b / Negated / Input bit is negated before passing to comparator / Workaround : If the input bit is negated using any bit in this field, then the corresponding Consderations bit in the CEC0-1 register must also be set.
	20:19	**Source Select** Format: U2 Selects the input signals to the Boolean event definition logic (see block diagram in the Custom Event Counters section). **Value** / **Name** / **Description** 01b / Prev Event / Selects the conditioned/flopped input from the last CEC block as the input bus to CEC0 block 11b / Reserved /
	18:3	**Compare Value** Format: U16 The value in this field is compared the 16-bit conditioned input bus that are fed into the comparator (see block diagram in the Custom Event Counters section). The type of comparison that is done is controlled by the Compare Function. When the compare function is true, then the signal for the custom event is asserted. This signal in turn can be counted by the B0 performance counter or fed into other CEC blocks.

CEC0-0 - Customizable Event Creation 0-0

	2:0	**Compare Function** Format: U3 This field selects the function used by the CEC0 comparator when comparing the compare value to the value active on the CEC0 conditioned input bus (see block diagram in the Custom Event Counters section).

Value	Name	Description
000b	Any Are Equal	Compare and assert output if any are equal (Can be used as OR function)
001b	Greater Than	Compare and assert output if greater than
010b	Equal	Compare and assert output if equal to (Can also be used as AND function)
011b	Greater Than or Equal	Compare and assert output if greater than or equal
100b	Less Than	Compare and assert output if less than
101b	Not Equal	Compare and assert output if not equal
110b	Less Than or Equal	Compare and assert output if less than or equal
111b	Reserved	

Customizable Event Creation 1-0

CEC1-0 - Customizable Event Creation 1-0

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	02778h

This register is used to define custom counter event 1, bit definitions in this register refer to the CEC block diagram in the Custom Event Counters section.

DWord	Bit	Description
0	31:21	**Negate** Format: U11 The 11-bit array defined in this field allows input bus bits [10:0] to be individually negated in order to facilitate more complicated custom event creation (e.g. A & (!B | !C)). Note that LSB of this field affects bit 0 of the selected input bus. **Value / Name / Description / Programming Notes** 0b / Pass-through / Input bit is passed through to comparator as is / 1b / Negated / Input bit is negated before passing to comparator / Workaround : If the input bit is negated using any bit in this field, then the corresponding Consderations bit in the CEC1-1 register must also be set.
	20:19	**Source Select** Format: U2 Selects the input signals to the Boolean event definition logic (see block diagram in the Custom Event Counters section). **Value / Name / Description** 01b / Prev Event / Selects the conditioned/flopped input from the previous CEC block as the input bus to this CEC block 11b / Reserved /
	18:3	**Compare Value** Format: U16 The value in this field is compared the 16-bit conditioned input bus that are fed into the comparator (see block diagram in the Custom Event Counters section). The type of comparison that is done is controlled by the Compare Function. When the compare function is true, then the signal for the custom event is asserted. This signal in turn can be counted by the B0 performance counter or fed into other CEC blocks.

CEC1-0 - Customizable Event Creation 1-0

	2:0	**Compare Function** Format: U3 This field selects the function used by the CEC comparator when comparing the compare value to the value active on the CEC conditioned input bus (see block diagram in the Custom Event Counters section).

Value	Name	Description
000b	Any Are Equal	Compare and assert output if any are equal (Can be used as OR function)
001b	Greater Than	Compare and assert output if greater than
010b	Equal	Compare and assert output if equal to (Can also be used as AND function)
011b	Greater Than or Equal	Compare and assert output if greater than or equal
100b	Less Than	Compare and assert output if less than
101b	Not Equal	Compare and assert output if not equal
110b	Less Than or Equal	Compare and assert output if less than or equal
111b	Reserved	

Customizable Event Creation 1-1

CEC1-1 - Customizable Event Creation 1-1

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	0277Ch

This register configures the input conditioning portion of CEC (custom event creation) block 1, bit definitions in this register refer to the CEC block diagram.

DWord	Bit	Description
0	31:16	**Considerations** This 16-bit field allows individual bits of the bus selected as the input to CEC block to be delayed by 1 clock relative to the non-delayed bits in the bus (see block diagram in the Custom Event Counters section). See CEC0-1 register definition for an example use case.

Value	Name	Description
0b	Live	Input bit is not delayed by 1 clock before event calculation
1b	Delayed	Input bit is delayed by 1 clock before event calculation

DWord	Bit	Description
0	15:0	**Mask** This 16-bit field allows individual input bits to be ignored in custom event calculation. See block diagram in the Custom Event Counters section for more details on where this field is used.

Value	Name	Description
0b	Unmasked	Input bit is considered in event calculation
1b	Masked	Input bit is ignored in event calculation

Customizable Event Creation 2-0

CEC2-0 - Customizable Event Creation 2-0

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	02780h

This register is used to define custom counter event 2, bit definitions in this register refer to the CEC block diagram in the Custom Event Counters section.

DWord	Bit	Description
0	31:21	**Negate** Format: U11 The 11-bit array defined in this field allows input bus bits [10:0] to be individually negated in order to facilitate more complicated custom event creation (e.g. A & (!B | !C)). Note that LSB of this field affects bit 0 of the selected input bus. **Value** / **Name** / **Description** / **Programming Notes** 0b / Pass-through / Input bit is passed through to comparator as is / 1b / Negated / Input bit is negated before passing to comparator / Workaround : If the input bit is negated using any bit in this field, then the corresponding Consderations bit in the CEC2-1 register must also be set.
	20:19	**Source Select** Format: U2 Selects the input signals to the Boolean event definition logic (see block diagram in the Custom Event Counters section). **Value** / **Name** / **Description** 01b / Prev Event / Selects the conditioned/flopped input from the previous CEC block as the input bus to this CEC block 11b / Reserved /
	18:3	**Compare Value** Format: U16 The value in this field is compared the 16-bit conditioned input bus that are fed into the comparator (see block diagram in the Custom Event Counters section). The type of comparison that is done is controlled by the Compare Function. When the compare function is true, then the signal for the custom event is asserted. This signal in turn can be counted by the B0 performance counter or fed into other CEC blocks.

CEC2-0 - Customizable Event Creation 2-0

	2:0	**Compare Function** Format: U3 This field selects the function used by the CEC comparator when comparing the compare value to the value active on the CEC conditioned input bus (see block diagram in the Custom Event Counters section).

Value	Name	Description
000b	Any Are Equal	Compare and assert output if any are equal (Can be used as OR function)
001b	Greater Than	Compare and assert output if greater than
010b	Equal	Compare and assert output if equal to (Can also be used as AND function)
011b	Greater Than or Equal	Compare and assert output if greater than or equal
100b	Less Than	Compare and assert output if less than
101b	Not Equal	Compare and assert output if not equal
110b	Less Than or Equal	Compare and assert output if less than or equal
111b	Reserved	

Customizable Event Creation 2-1

CEC2-1 - Customizable Event Creation 2-1

This register is used to define custom counter event 6, bit definitions in this register refer to the CEC block diagram in the Custom Event Counters section.

DWord	Bit	Description
0	31:21	**Negate** Format: U11 The 11-bit array defined in this field allows input bus bits [10:0] to be individually negated in order to facilitate more complicated custom event creation (e.g. A & (!B | !C)). Note that LSB of this field affects bit 0 of the selected input bus. **Value** / **Name** / **Description** / **Programming Notes** 0b / Pass-through / Input bit is passed through to comparator as is / 1b / Negated / Input bit is negated before passing to comparator / Workaround : If the input bit is negated using any bit in this field, then the corresponding Consderations bit in the CEC6-1 register must also be set.
	20:19	**Source Select** Format: U2 Selects the input signals to the Boolean event definition logic (see block diagram in the Custom Event Counters section). **Value** / **Name** / **Description** 01b / Prev Event / Selects the conditioned/flopped input from the previous CEC block as the input bus to this CEC block 11b / Reserved /
	18:3	**Compare Value** Format: U16 The value in this field is compared the 16-bit conditioned input bus that are fed into the comparator (see block diagram in the Custom Event Counters section). The type of comparison that is done is controlled by the Compare Function. When the compare function is true, then the signal for the custom event is asserted. This signal in turn can be counted by the B0 performance counter or fed into other CEC blocks.

CEC6-0 - Customizable Event Creation 6-0

	2:0	**Compare Function** Format: U3 This field selects the function used by the CEC comparator when comparing the compare value to the value active on the CEC conditioned input bus (see block diagram in the Custom Event Counters section).

Value	Name	Description
000b	Any Are Equal	Compare and assert output if any are equal (Can be used as OR function)
001b	Greater Than	Compare and assert output if greater than
010b	Equal	Compare and assert output if equal to (Can also be used as AND function)
011b	Greater Than or Equal	Compare and assert output if greater than or equal
100b	Less Than	Compare and assert output if less than
101b	Not Equal	Compare and assert output if not equal
110b	Less Than or Equal	Compare and assert output if less than or equal
111b	Reserved	

Customizable Event Creation 6-1

CEC6-1 - Customizable Event Creation 6-1

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	027A4h

This register configures the input conditioning portion of CEC (custom event creation) block 6, bit definitions in this register refer to the CEC block diagram in the Custom Event Counters section.

DWord	Bit	Description
0	31:16	**Considerations** This 16-bit field allows individual bits of the bus selected as the input to CEC block to be delayed by 1 clock relative to the non-delayed bits in the bus (see block diagram in the Custom Event Counters section). See CEC0-1 register definition for an example use case.
	15:0	**Mask** This 16-bit field allows individual input bits to be ignored in custom event calculation. See block diagram in the Custom Event Counters section for more details on where this field is used.

Bit 31:16 values:

Value	Name	Description
0b	Live	Input bit is not delayed by 1 clock before event calculation
1b	Delayed	Input bit is delayed by 1 clock before event calculation

Bit 15:0 values:

Value	Name	Description
0b	Unmasked	Input bit is considered in event calculation
1b	Masked	Input bit is ignored in event calculation

Customizable Event Creation 7-0

CEC7-0 - Customizable Event Creation 7-0

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	027A8h

This register is used to define custom counter event 7, bit definitions in this register refer to the CEC block diagram in the Custom Event Counters section.

DWord	Bit	Description
0	31:21	**Negate** Format: U11 The 11-bit array defined in this field allows input bus bits [10:0] to be individually negated in order to facilitate more complicated custom event creation (e.g. A & (!B | !C)). Note that LSB of this field affects bit 0 of the selected input bus. **Value** / **Name** / **Description** / **Programming Notes** 0b / Pass-through / Input bit is passed through to comparator as is / 1b / Negated / Input bit is negated before passing to comparator / Workaround : If the input bit is negated using any bit in this field, then the corresponding Consderations bit in the CEC7-1 register must also be set.
	20:19	**Source Select** Format: U2 Selects the input signals to the Boolean event definition logic (see block diagram in the Custom Event Counters section). **Value** / **Name** / **Description** 01b / Prev Event / Selects the conditioned/flopped input from the previous CEC block as the input bus to this CEC block 11b / Reserved /
	18:3	**Compare Value** Format: U16 The value in this field is compared the 16-bit conditioned input bus that are fed into the comparator (see block diagram in the Custom Event Counters section). The type of comparison that is done is controlled by the Compare Function. When the compare function is true, then the signal for the custom event is asserted. This signal in turn can be counted by the B0 performance counter or fed into other CEC blocks.

CEC7-0 - Customizable Event Creation 7-0

2:0 **Compare Function**

Format:	U3

This field selects the function used by the CEC comparator when comparing the compare value to the value active on the CEC conditioned input bus (see block diagram in the Custom Event Counters section).

Value	Name	Description
000b	Any Are Equal	Compare and assert output if any are equal (Can be used as OR function)
001b	Greater Than	Compare and assert output if greater than
010b	Equal	Compare and assert output if equal to (Can also be used as AND function)
011b	Greater Than or Equal	Compare and assert output if greater than or equal
100b	Less Than	Compare and assert output if less than
101b	Not Equal	Compare and assert output if not equal
110b	Less Than or Equal	Compare and assert output if less than or equal
111b	Reserved

DWord	Bit	Description
0	31	**Send Busy** Access: R/W Set Writing this bit with 1b initiates the transaction, when read this bit will be a 1b until the transmission completes. The transaction is completed when the response is received or when a timeout occurs. This is a sticky bit. Write a 1b to this bit to set it and initiate the transaction. Hardware will clear it when the transaction completes. **Restriction** Restriction : Do not change any fields while Send Busy is asserted.

DDI_AUX_CTL

	Do not write a 1b again until transaction completes. Restriction : Mutex must be acquired through DDI_AUX_MUTEX before initiating an AUX channel transaction.
30	**Done** Access: R/WC A sticky bit that indicates the transaction has completed. Write a 1 to this bit to clear the event

Value	Name
0b	Not done
1b	Done

29	**Interrupt on Done** Access: R/W Enable an interrupt when the transaction completes or times out.

Value	Name
0b	Enable
1b	Disable

28	**Time out error** Access: R/WC A sticky bit that indicates the transaction has timed out. Write a 1 to this bit to clear the event.

Value	Name
0b	Not error
1b	Error

27:26	**Time out timer value** Access: R/W Used to determine how long to wait for receiver response before timing out.

Value	Name
01b	600us
10b	800us
11b	1600us

25	**Receive error** Access: R/WC A sticky bit that indicates that the data received was corrupted, not in multiples of a full byte, or more than 20 bytes. Write a 1 to this bit to clear the event.

Value	Name
0b	Not Error

DDI_AUX_CTL

	1b	Error

24:20 Message Size

Access:	Write/Read Status

The value written to this field indicates the total number bytes to transmit (including the header).
The value read from this field indicates the number of bytes received, including the header, in the last transaction transaction.
Sync/Stop are not part of the message or the message size.
Reads of this field will give the response message size.
The read value will not be valid while Send/Busy bit 31 is asserted.

Restriction
Restriction : Message sizes of 0 or >20 are not allowed. Reads and writes are valid only when the done bit is set and timeout or receive error has not occurred.

19:16 Reserved

15 Reserved

14 Reserved

13 Reserved

12 Reserved

11 Reserved

10 Reserved

9:5 Fast Wake Sync Pulse Count

Default Value:	1 0001b 18 pulses
Access:	R/W

This field determines the total number of SYNC pulses sent during the SYNC phase of a fast wake transaction.
The value programmed is the number of pulses minus 1. When this is field is set to "n" the aux controller will send "n+1" SYNC pulses before transmitting the STOP pattern.

4:0 Sync Pulse Count

Default Value:	1 1111b 32 pulses
Access:	R/W

This field determines the total number of SYNC pulses sent during the SYNC phase of a standard transaction.
The value programmed is the number of pulses minus 1. When this is field is set to "n" the aux controller will send "n+1" SYNC pulses before transmitting the STOP pattern.

Restriction
Restriction : This field must be programmed to at least 25 decimal to send the minimum amount of pulses required for a standard transaction.

DDI_AUX_DATA

DDI_AUX_DATA	
Register Space:	MMIO: 0/2/0

There is one DDI Buffer Control per each DDI A/B/C/D/E/F.

Do not read or write the register when the associated power well is disabled.

DWord	Bit	Description

DDI_BUF_CTL

0 / 31 — DDI Buffer Enable

This bit enables the DDI buffer.

Value	Name
0b	Disable
1b	Enable

30 — Reserved

Format:	MBZ

29:28 — Reserved

27:24 — DP Vswing Emp Sel

Description
These bits are used to select the voltage swing and emphasis for DisplayPort.
This field is ignored for HDMI and DVI. The values programmed in DDI_BUF_TRANS determine the voltage swing and emphasis for each selection.

Value	Name	Description
0000b-1000b	Select 0 - Select 8	Select from buffer translations 0 through 8. Valid with all DDIs.
1001b	Select 9	Select buffer translation 9. Valid only with DDIA and DDIE.

23:17 — Reserved

Format:	MBZ

16 — Port Reversal

This field enables lane reversal within the port. Lane reversal swaps the data on the lanes as they are output from the port.

Value	Name
0b	Not reversed
1b	Reversed

Programming Notes
DDI B, C, D, and F reversal always swaps the four lanes, so lane 0 is swapped with lane 3, and lane 1 is swapped with lane 2. If DDIA Lane Capability Control selects DDIA x2, then DDI A reversal swaps the two lanes, so lane 0 is swapped with lane 1. If DDIA Lane Capability Control selects DDIA x4, then DDI A reversal swaps the four lanes, so lane 0 is swapped with lane 3, and lane 1 is swapped with lane 2.

Restriction
Restriction : This field must not be changed while the DDI is enabled. DDI E does not support reversal.

DDI_BUF_CTL

15:8 Reserved

Format:	MBZ

7 DDI Idle Status

Access:	RO

This bit indicates when the DDI buffer is idle.

Value	Name
0b	Buffer Not Idle
1b	Buffer Idle

6:5 Reserved

Format:	MBZ

4 DDIA Lane Capability Control

This bit selects how lanes are shared between DDI A and DDI E.
This field is only used in the DDI A instance of this register.
See the DDI A and DDI E lane mapping table in the Introduction section.

Value	Name	Description
0b	DDIA x2	DDI A supports 2 lanes and DDI E supports 2 lanes
1b	DDIA x4	DDI A supports 4 lanes and DDI E is not used

Restriction
Restriction : This field must be programmed at system boot based on board configuration and may not be changed afterwards.

3:1 DP Port Width Selection

Description
This bit selects the number of lanes to be enabled on the DDI link for DisplayPort.

Value	Name	Description
000b	x1	x1 Mode
001b	x2	x2 Mode
011b	x4	x4 Mode Not allowed with DDI E, some restrictions with DDI A
Others	Reserved	Reserved

Programming Notes
DDI E only supports x1 and x2 when DDI_BUF_CTL_A DDIA Lane Capability Control is set to DDIA x2, otherwise DDI E is not supported. DDI A (EDP) supports x1, x2, and x4 when DDI_BUF_CTL_A DDIA Lane Capability Control is set to DDIA x4, otherwise DDI A only supports x1 and x2.

DDI_BUF_CTL

Restriction
Restriction : When in DisplayPort mode the value selected here must match the value selected in TRANS_DDI_FUNC_CTL attached to this DDI.
Restriction : This field must not be changed while the DDI is enabled.

0 Init Display Detected

Access:	RO

Strap indicating whether a display was detected on this port during initialization. It signifies the level of the port detect pin at boot. This bit is only informative. It does not prevent this port from being enabled in hardware. This field only indicates the DDIA detection. Detection for other ports is read from SFUSE_STRAP.

Value	Name	Description
0b	Not Detected	Digital display not detected during initialization
1b	Detected	Digital display detected during initialization

DDI_BUF_TRANS

DDI_BUF_TRANS	
Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000018, 0x00000000
Access:	R/W
Size (in bits):	64
Address:	64E00h-64E4Fh
Name:	DDI A Buffer Translation
ShortName:	DDI_BUF_TRANS_A_*
Power:	PG1
Reset:	global
Address:	64E60h-64EAFh
Name:	DDI B Buffer Translation
ShortName:	DDI_BUF_TRANS_B_*

Address:	64F20h-64F6Fh
Name:	DDI D Buffer Translation
ShortName:	DDI_BUF_TRANS_D_*
Power:	PG1
Reset:	global
Address:	64F80h-64FCFh
Name:	DDI E Buffer Translation
ShortName:	DDI_BUF_TRANS_E_*
Power:	PG1
Reset:	global

Description
These registers define the DDI buffer settings required for different voltage swing and emphasis selections. In HDMI or DVI mode the HDMI/DVI translation registers are automatically selected.
In DisplayPort mode the DDI Buffer Control register programming will select which of these registers is used to

DDI_BUF_TRANS

drive the buffer.
For each DDI A/B/C/D/E there are 10 instances of this 2 DWord register format.
For DDI B/C/D, the first 9 instances (18 Dwords) are entries 0-8 which are used for DisplayPort, and the last instance (2 Dwords) is entry 9 which is used for HDMI and DVI.
For DDI A and DDI E, the 10 instances (20 DWords) are entries 0-9 which are used for DisplayPort.

Programming Notes

The recommended values are listed below this table.

Restriction

Restriction : These registers must be programmed with valid values prior to enabling DDI_BUF_CTL.

DWord	Bit	Description
0	31	**Balance Leg Enable** This field controls the Balance Leg enable for the DDI buffer. Value: 0b — Name: Disable Value: 1b — Name: Enable
	30:18	**Reserved** Format: MBZ
	17:0	**DeEmp Level** Default Value: 00018h This field controls the De-emphasis level for the DDI buffer.
1	31:21	**Reserved** Format: MBZ
	20:16	**VRef Sel** This field controls the voltage reference select for the DDI buffer. Value: 00000b — Name: **[Default]**
	15:11	**Reserved** Format: MBZ
	10:0	**Vswing** Default Value: 00000000000b This field controls the voltage swing for the DDI buffer.

DE_PIPE_INTERRUPT

DE_PIPE_INTERRUPT	
Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Size (in bits):	32
Address:	44400h-4440Fh
Name:	Display Engine Pipe A Interrupts
ShortName:	DE_PIPE_INTERRUPT_A
Power:	PG1
Reset:	soft
Address:	44410h-4441Fh
Name:	Display Engine Pipe B Interrupts
ShortName:	DE_PIPE_INTERRUPT_B
Power:	PG2
Reset:	soft
Address:	44420h-4442Fh
Name:	Display Engine Pipe C Interrupts
ShortName:	DE_PIPE_INTERRUPT_C
Power:	PG2
Reset:	soft

Description

This table indicates which events are mapped to each bit of the Display Engine Pipe Interrupt registers.
The IER enabled Display Engine Pipe Interrupt IIR (sticky) bits are ORed together to generate the DE_Pipe Interrupts Pending bit in the Master Interrupt Control register.
There is one full set of Display Engine Pipe interrupts per display pipes A/B/C.
The STEREO3D_EVENT_MASK selects between left eye and right eye reporting of vertical blank, vertical sync, and scanline events in stereo 3D modes.

0x44400 = ISR A, 0x44410 = ISR B, 0x44420 = ISR C
0x44404 = IMR A, 0x44414 = IMR B, 0x44424 = IMR C
0x44408 = IIR A, 0x44418 = IIR B, 0x44428 = IIR C
0x4440C = IER A, 0x4441C = IER B, 0x4442C = IER C

DWord	Bit	Description
0	31	**Underrun** The ISR is an active high pulse when there is an underrun on the transcoder attached to this pipe.
	30	**Unused_Int_30** These interrupts are currently unused.

DE_PIPE_INTERRUPT

	29	**Reserved**
	28	**Reserved**
	27:20	**Unused_Int_27_20** These interrupts are currently unused.
	19	**Reserved**
	18	**Reserved**
	17	**Reserved**
	16	**Reserved**
	15:13	**Unused_Int_15_13** These interrupts are currently unused.
	12	**DPST_Histogram_event** The ISR is an active high pulse on the DPST Histogram event on this pipe.
	11	**Cursor_GTT_Fault_Status** The ISR is an active high pulse when a GTT fault is detected for the cursor on this pipe.
	10	**Plane4_GTT_Fault_Status** **Description** The ISR is an active high pulse when a GTT fault is detected for plane 4 on this pipe. Not all pipes a have plane 4.
	9	**Plane3_GTT_Fault_Status** **Description** The ISR is an active high pulse when a GTT fault is detected for plane 3 on this pipe. Not all pipes a have plane 3.
	8	**Plane2_GTT_Fault_Status** The ISR is an active high pulse when a GTT fault is detected for plane 2 on this pipe.
	7	**Plane1_GTT_Fault_Status** The ISR is an active high pulse when a GTT fault is detected for plane 1 on this pipe.
	6	**Plane4_Flip_Done** **Description** The ISR is an active high pulse when the flip is done for plane 4 on this pipe. Not all pipes have a plane 4.
	5	**Plane3_Flip_Done** **Description** The ISR is an active high pulse when the flip is done for plane 3 on this pipe. Not all pipes have a plane 3.
	4	**Plane2_Flip_Done** The ISR is an active high pulse when the flip is done for plane 2 on this pipe.
	3	**Plane1_Flip_Done** The ISR is an active high pulse when the flip is done for plane 1 on this pipe.

DE_PIPE_INTERRUPT		
	2	**Scan_Line_Event** The ISR is an active high pulse on the scan line event of the transcoder attached to this pipe.
	1	**Vsync** The ISR is an active high level for the duration of the vertical sync of the transcoder attached to this pipe.
	0	**Vblank** The ISR is an active high level for the duration of the vertical blank of the transcoder attached to this pipe.

DE_RR_DEST

DE_RR_DEST	
Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	44058h-4405Bh
Name:	Render Response Destination
ShortName:	DE_RR_DEST
Power:	PG0
Reset:	soft

This register selects the destination of certain render responses that may go to CS, BCS, or both.
In order for a response to be sent to a particular destination, the event most occur, the event must be unmasked, and that destination must be selected.

DWord	Bit	Description
0	31:6	**Reserved** Format: MBZ
	5:4	**Pipe C Vertical Blank Destination** This field selects the destination for the render response sent on pipe C start of vertical blank. Value / Name: 00b CS; 01b BCS; 10b,11b Both CS and BCS
	3:2	**Pipe B Vertical Blank Destination** This field selects the destination for the render response sent on pipe B start of vertical blank. Value / Name: 00b CS; 01b BCS; 10b,11b Both CS and BCS
	1:0	**Pipe A Vertical Blank Destination** This field selects the destination for the render response sent on pipe A start of vertical blank. Value / Name: 00b CS; 01b BCS; 10b,11b Both CS and BCS

DE_RRMR

DE_RRMR

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x2077EFEF
Access:	R/W
Size (in bits):	32
Address:	44050h-44053h
Name:	Render Response Mask
ShortName:	DE_RRMR
Power:	PG0
Reset:	soft

This register contains a bit mask which selects which events cause and are reported in the render response message.
See the render response message definition table to find the source event for each bit.
The render response message is sent from the display engine to the render command streamer (CS) or blitter command streamer (BCS). The message is used to inform CS and BCS of certain display events.
This register is used to control which render response message bits are masked or unmasked.
Unmasked bits will cause a render response message to be sent and will be reported in that message.
Masked bits will not be reported and will not cause a render response message to be sent.
Vertical blank events occur periodically while the associated display pipe timing generator is running and will be reported in a render response to CS or BCS (depending on DE_RR_DEST destination selection) if un-masked here.
Scanline events occur after they have been initiated through MMIO writes or LRI to the Display Load Scan Lines register.
A flip event will be reported in a render response to CS if un-masked here and the Display Load Scanline source is CS.
A flip event will be reported in a render response to BCS if un-masked here and the Display Load Scanline source is BCS.
Flip done events occur after they have been initiated through MI_DISPLAY_FLIP or MMIO write to plane surface address registers.
A flip event will be reported in a render response to CS if un-masked here and the flip source is CS.
A flip event will be reported in a render response to BCS if un-masked here and the flip source is BCS.

Programming Notes

Programming this register can be done through MMIO or a command streamer LOAD_REGISTER_IMMEDIATE (LRI) command.
When using LRI care must be taken to follow all the programming rules for LRI targetting the display engine.
Unmasked events will wake GT as they occur, so for improved power savings it is recommended to only unmask events that are required.

Restriction

Restriction : Events must be unmasked prior to waiting for them with a MI_WAIT_FOR_EVENT ring command, or

DE_RRMR

in the case of flips or scanlines, prior to starting the flip or loading the scanline.

DWord	Bit	Description

	17:0	**DecoupReg5DW1Addr** Access: R/W Decouple Register 5 DW1, Decoupled Address.

Decouple Register 6 DW0

DECOUPREG6DW0 - Decouple Register 6 DW0		
Register Space:	MMIO: 0/2/0	
Source:	BSpec	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	00F30h-00F33h	
DWord	**Bit**	**Description**
0	31:0	**DecoupReg6DW0Data** Access: R/W Decouple Register 6 DW0 Data.

Decouple Register 6 DW1

DECOUPREG6DW1 - Decouple Register 6 DW1		
Register Space:	MMIO: 0/2/0	
Source:	BSpec	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	00F34h-00F37h	
DWord	**Bit**	**Description**
0	31	**DecoupReg6DW1GO** Access: R/W Decouple Register 6 DW1 Go_Status Bit, Software writes this bit to 1 when it is ready for the command to be processed, Hardware clears this bit to 0 when the command is complete, Software must not read data or write the next command when this bit is 1.
	30	**Reserved**
	29:28	**DecoupReg6DW1PD** Access: R/W Decouple Register 6 DW1, 00 = GTI/Blitter, 01 = Render, 10= Media , 11= All Domains, Identifies the target power domain that must be awake before proceeding with the cycle.
	27:24	**DecoupReg6DW1OP** Access: R/W Decouple Register 6 DW1, 0000 = Write, 0001 = Read, All others undefined (GT will ignore command and set go/status=0) Decouple Register.
	23:20	**DecoupReg6DW1BE** Access: R/W Decouple Register 6 DW1, Decoupled byte enables. Provided for legacy/workaround purposes only; GT only supports full dword accesses.
	19:18	**Reserved**
	17:0	**DecoupReg6DW1Addr** Access: R/W Decouple Register 6 DW1, Decoupled Address.

Decouple Register 7 DW0

DECOUPREG7DW0 - Decouple Register 7 DW0		
Register Space:	MMIO: 0/2/0	
Source:	BSpec	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	00F38h-00F3Bh	
DWord	**Bit**	**Description**
0	31:0	**DecoupReg7DW0Data** Access: R/W Decouple Register 7 DW0 Data.

Decouple Register 7 DW1

DECOUPREG7DW1 - Decouple Register 7 DW1		
Register Space:	MMIO: 0/2/0	
Source:	BSpec

DE Misc Interrupt Definition

DE Misc Interrupt Definition	
Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Size (in bits):	32
Address:	44460h-4446Fh
Name:	Display Engine Miscellaneous Interrupts
ShortName:	DE_MISC_INTERRUPT
Power:	PG0
Reset:	soft

This table indicates which events are mapped to each bit of the Display Engine Miscellaneous Interrupt registers.
0x44460 = ISR
0x44464 = IMR
0x44468 = IIR
0x4446C = IER

DWord	Bit	Description
0	31	**Poison** The ISR is an active high pulse on receiving the poison response to a memory transaction.
	30	**ECC_Double_Error** The ISR is an active high level while any of the ECC Double Error status bits are set.
	29	**Invalid_GTT_page_table_entry** The ISR is an active high pulse on receiving the iMPH invalid GTT page table entry indication.
	28	**Invalid_page_table_entry_data** The ISR is an active high pulse on receiving the iMPH invalid page table entry data indication.
	27	**GSE** The ISR is an active high pulse on the GSE system level event.
	26	**Camera Interrupt Event** This interrupt is not supported.
	25	**Reserved**
	24	**Reserved**
	23	**WD0_Interrupts_Combined** The ISR is an active high level while any of the WD0_IIR bits are set.
	22	**SVM Device Mode PRQ Event** The ISR is an active high pulse on receiving the iMPH SVM Device Mode PRQ event indication. This event indicates that a GT advanced context encountered a recoverable page fault.
	21	**SVM Device Mode VTD Fault** The ISR is an active high pulse on receiving the iMPH SVM Device Mode VT-d fault indication. This event indicates GT encountered a non-recoverable translation fault.

DE Misc Interrupt Definition		
	20	**SVM Device Mode Wait Descriptor Completion** The ISR is an active high pulse on receiving the iMPH SVM Device Mode Wait Descriptor Completion indication. This event indicates that IMPH completed Invalidation Wait Descriptor.
	19	**SRD_Interrupts_Combined** The ISR is an active high level while any of the SRD_IIR bits are set.
	18	**Reserved** Format: MBZ
	17:16	**Reserved** Format: MBZ
	15	**GTC_Interrupts_Combined** The ISR is an active high level while any of the GTC_IIR bits are set.
	14:9	**Reserved** Format: MBZ
	8	**Reserved** Format: MBZ
	7:4	**Reserved** Format: MBZ
	3:1	**Reserved** Format: MBZ
	0	**Reserved** Format: MBZ

DE Port Interrupt Definition

DE Port Interrupt Definition	
Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Size (in bits):	32
Address:	44440h-4444Fh
Name:	Display Engine Port Interrupts
ShortName:	DE_PORT_INTERRUPT
Power:	PG0
Reset:	soft

This table indicates which events are mapped to each bit of the Display Engine Port Interrupt registers.
0x44440 = ISR
0x44444 = IMR
0x44448 = IIR
0x4444C = IER

DWord	Bit	Description
0	31	**MIPI C** The ISR is an active high level indicating an interrupt is set in MIPIC_INTR_STAT_REG or MIPIC_INTR_STAT_REG_1.
	30	**MIPI A** The ISR is an active high level indicating an interrupt is set in MIPIA_INTR_STAT_REG or MIPIA_INTR_STAT_REG_1.
	29	**Reserved**
	28	**Reserved**
	27	**AUX Channel D** The ISR is an active high pulse on the AUX DDI D done event. This event will not occur for SRD AUX done.
	26	**AUX Channel C** The ISR is an active high pulse on the AUX DDI C done event. This event will not occur for SRD AUX done.
	25	**AUX Channel B** The ISR is an active high pulse on the AUX DDI B done event. This event will not occur for SRD AUX done.
	24:23	**Reserved**
	22:12	**Reserved**
	11:10	**Reserved**
	9:8	**Reserved**

DE Port Interrupt Definition		
	7:6	**Reserved**
	5	**DDI C Hotplug** The ISR gives the live state of the DDI HPD pin when the HPD input is enabled. The IIR is set if a short or long pulse is detected when HPD input is enabled. This field is unused in projects that have a PCH.
	4	**DDI B Hotplug** The ISR gives the live state of the DDI HPD pin when the HPD input is enabled. The IIR is set if a short or long pulse is detected when HPD input is enabled. This field is unused in projects that have a PCH.
	3	**DDI A Hotplug** The ISR gives the live state of the DDI HPD pin when the HPD input is enabled. The IIR is set if a short or long pulse is detected when HPD input is enabled. This field is unused in projects that have a PCH.
	2	**Reserved**
	1	**Reserved**
	0	**AUX_Channel_A** The ISR is an active high pulse on the AUX DDI A done event. This event will not occur for SRD AUX done.

	0	**Host Bridge** Default Value: 1b Access: RO

Device Identification

DID2_0_2_0_PCI - Device Identification

Register Space:	PCI: 0/2/0
Source:	BSpec
Default Value:	0x00001916
Size (in bits):	16
Address:	00002h

This register combined with the Vendor Identification register uniquely identifies any PCI device.

DWord	Bit	Description
0	15:8	**Device Identification Number MSB** Default Value: 00011001b Access: R/W Firmware Only This is the upper part of a 16 bit value assigned to the Graphics device.
	7:0	**Device Identification Number SKU** Default Value: 00010110b Access: RO Variant Firmware Only These are bits 7:0 of the 16 bit value assigned to the Graphics device.

DFSDONE

DFSDONE	
Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	51080h-51083h
Name:	Display Fuse Done
ShortName:	DFSDONE
Power:	PG0
Reset:	global

This register is not reset by FLR.

DWord	Bit	Description
0	31:1	**Reserved** Format: MBZ
	0	**Download Done** This field indicates when fuse download is complete. 0b – Note Done 1b – Done

DFSM

DFSM

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	51000h-51003h
Name:	Display Fuse
ShortName:	DFSM
Power:	PG0
Reset:	global

This register contains fuse and strap settings for display.
This register is not reset by FLR.

DWord	Bit	Description
0	31	**Internal Graphics Disable** This bit indicates whether internal graphics capability is disabled. Value: 0b – Name: Enable – Description: Internal Graphics Enabled Value: 1b – Name: Disable – Description: Internal Graphics Disabled
	30	**Internal Display Disable** This bit indicates whether the display pipe A (first pipe) capability is disabled. Value: 0b – Name: Enable – Description: Pipe A Capability Enabled Value: 1b – Name: Disable – Description: Pipe A Capability Disabled
	29	**Reserved**
	28	**Display PipeC Disable** This bit indicates whether the display pipe C (third pipe) capability is disabled. Value: 0b – Name: Enable – Description: Pipe C Capability Enabled Value: 1b – Name: Disable – Description: Pipe C Capability Disabled
	27	**Display PM Disable** This bit indicates whether the display power management FBC and DPST capabilities are disabled. Value: 0b – Name: Enable – Description: PM Capability Enabled Value: 1b – Name: Disable – Description: PM Capability Disabled

DFSM

26	**Display eDP Disable** This bit indicates whether the display embedded DisplayPort eDP DDIA capability is disabled.

Value	Name	Description
0b	Enable	eDP Capability Enabled
1b	Disable	eDP Capability Disabled

25	**Reserved**
24:23	**Display CDCLK Limit** This field indicates the maximum allowed CD clock frequency.

Value	Name	Description
00b	675 MHz	Maximum frequency is 675 MHz. All frequencies are allowed.
01b	540 MHz	Maximum frequency is 540 MHz.
10b	450 MHz	Maximum frequency is 450 MHz.
11b	337.5 MHz	Maximum frequency is 337.5 MHz.

Restriction
Restriction : Display software should not select any frequency higher than the maximum that is allowed. If software incorrectly selects a higher frequency, display hardware will internally override the selection to the lowest frequency.

22	**Display Spare**
21	**Spare 21** This bit indicates whether the display pipe B (second pipe) capability is disabled.

Value	Name
0b	Pipe B Capability Enabled
1b	Pipe B Capability Disabled

20	**Display WD Disable** This bit indicates whether the display WD capability is disabled.

Value	Name	Description
0b	Enable	WD Capability Enabled
1b	Disable	WD Capability Disabled

19	**Spare 19**
18	**Spare 18**
17	**Spare 17**
16	**Spare 16**
15	**Spare 15**
14	**Spare 14**
13	**Spare 13**
12	**Spare 12**

DFSM

	11	**Spare 11**
	10	**Spare 10**
	9	**Spare 9**
	8	**Spare 8**
	7	**Spare 7**
	6	**Display RSB Enable** This bit indicates whether the remote screen blanking feature is enabled in the display engine.

Value	Name	Description
0b	Disable	RSB Capability Disabled
1b	Enable	RSB Capability Enabled

	5	**Spare 5**
	4	**Spare 4**
	3	**Spare 3**
	2	**Spare 2**
	1	**Reserved**
	0	**Display Audio Codec Disable** This bit indicates whether the display audio codec capability is disabled.

Value	Name	Description
0b	Enable	Audio Codec Capability Enabled
1b	Disable	Audio Codec Capability Disabled

DISPIO_CR_TX_BMU_CR0

ShortName:	DISPLAY_MESSAGE_FORWARD_STATUS_VCSUNIT1

Address:	222E8h-222EBh
Name:	Display Message Forward Status Register
ShortName:	DISPLAY_MESSAGE_FORWARD_STATUS_BCSUNIT

This register stores the internal HW status flags related to display message forward logic. This register should not be accessed by SW. This register is part of power context image.
Note: Even though this register exists in VideoCS and VideoEnhancementCS, individual bit driven functionality is not supported.

DOUBLE_BUFFER_CTL

DOUBLE_BUFFER_CTL	
Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	44500h-44503h
Name:	Double Buffer Control
ShortName:	DOUBLE_BUFFER_CTL
Power:	PG0
Reset:	soft

This register together with the Allow Double Buffer Disable fields in the plane control registers allows for the double buffer update of registers in multiple resources to be synchronized together for an atomic update.

Programming Notes

Sequence for synchronizing the double buffer updates of multiple resources:
1. Set the Allow Double Buffer Update Disable field for each resource to be synchronized together and write the appropriate register to arm and trigger the update. Set the Global Double Buffer Update Disable field. The order in which these fields are set does not matter.
2. Program the registers that need to be synchronized together.
3. Clear the Global Double Buffer Update Disable field. Any pending updates will take place at the next periodic udate event.
4. If a resource no longer needs to be synchronized, clear the Allow Double Buffer Update Disable field for that resource and write the appropriate register to arm and trigger the update. If the resource will continue to be synchronized, the field can remain set and does not need to be set again when returning to step 1 of this sequence.

DWord	Bit	Description
0	31:1	**Reserved** Format: MBZ
	0	**Global Double Buffer Update Disable** This field controls whether the double buffer update is disabled for the resources which have allowed it to be disabled. This only disables the double buffer update for periodic events, like the start of vertical blank. It does not change the behavior for constant events, like pipe not enabled. This applies to MMIO register updates as well as command streamer initiated flips. When the double buffer update is disabled, the values written into the double buffered registers will not take effect at the periodic update event. After the double buffer update is no longer disabled, any pending updates will take place at the next periodic update event. Asynchronous flips initiated by MMIO or command streamers are not effected by disabling double

DOUBLE_BUFFER_CTL

buffering.
Synchronous flips (regular and stereo 3D) initiated by MMIO or command streamers will not complete or give the flip done indication while double buffering is disabled for a plane. They will complete and give the flip done at the next start of vertical blank (selectable right or left eye vertical blank when using stereo 3D) after the double buffering is re-enabled.

Value	Name
0b	Not Disabled
1b	Disabled

DP_TP_CTL

DP_TP_CTL		
Register Space:	MMIO: 0/2/0	
Source:	BSpec

DWord	Bit	Description
0	31	**Transport Enable** This bit enables the DisplayPort transport function.

DP_TP_CTL

Value	Name
0b	Disable
1b	Enable

30 Reserved

Format:	MBZ

29:28 Reserved

27 Transport Mode Select

Description
This bit selects between DisplayPort SST and MST modes of operation. This bit is ignored by DDI A (EDP) and DDI E since they do not support multistreaming.

Value	Name	Description
0b	SST mode	DisplayPort SST mode
1b	MST mode	DisplayPort MST mode

Restriction
Restriction : The DisplayPort mode (SST or MST) selected here must match the mode selected in the Transcoder DDI Function Control registers for the transcoders attached to this transport. This field must not be changed while the DDI function is enabled.

26 Reserved

Format:	MBZ

25 Force ACT

Description
This bit forces DisplayPort MST ACT to be sent one time at the next link frame boundary. After ACT is sent, as indicated in the ACT sent status bit, this bit can be cleared and set again to send ACT again. This bit is ignored by DDI A (EDP) and DDI E since they do not support multistreaming.

Value	Name	Description
0b	Do not force	Do not force ACT to be sent
1b	Force	Force ACT to be sent one time

24:21 Reserved

Format:	MBZ

20:19 Reserved

Format:	MBZ

DP_TP_CTL

18 Enhanced Framing Enable

Description
This bit selects enhanced framing for DisplayPort SST.
Hardware internally enables enhanced framing for DisplayPort MST.

Value	Name
0b	Disabled
1b	Enabled

Restriction
Restriction : In DisplayPort MST mode this bit must be set to Disabled. This field must not be changed while the DDI function is enabled.

17:16 Reserved

Format:	MBZ

15 Reserved

Format:	MBZ

14:11 Reserved

Format:	MBZ

10:8 DP Link Training Enable

These bits are used for DisplayPort link initialization as defined in the DisplayPort specification. DP_TP_STATUS has an indication that the required number of idle patterns has been sent.

Value	Name	Description
000b	Pattern 1	Training Pattern 1 enabled
001b	Pattern 2	Training Pattern 2 enabled
010b	Idle	Idle Pattern enabled
011b	Normal	Link not in training: Send normal pixels
100b	Pattern 3	Training Pattern 3 enabled
Others	Reserved	Reserved

Restriction
Restriction : When enabling the port, it must be turned on with pattern 1 enabled. When retraining a link, the port must be disabled, then re-enabled with pattern 1 enabled.

7 Reserved

DP_TP_CTL

	6	**Alternate SR Enable** This bit enables the DisplayPort Alternate Scrambler Reset, intended for use only with embedded DisplayPort receivers.

Value	Name
0b	Disable
1b	Enable

Restriction
Restriction : This field must not be changed while the DDI function is enabled.

	5:0	**Reserved**

Format:	MBZ

DP_TP_STATUS

DP_TP_STATUS	
Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	64144h-64147h
Name:	DDI B DisplayPort Transport Status
ShortName:	DP_TP_STATUS_B
Power:	PG2
Reset:	soft
Address:	64244h-64247h
Name:	DDI C DisplayPort Transport Status
ShortName:	DP_TP_STATUS_C
Power:	PG2
Reset:	soft
Address:	64344h-64347h
Name:	DDI D DisplayPort Transport Status

Reset:	soft
Address:	64444h-64447h
Name:	DDI E DisplayPort Transport Status
ShortName:	DP_TP_STATUS_E
Power:	PG2
Reset:	soft

There is one DisplayPort Transport Status register per each DDI B/C/D/E/F. DDI A does not have a status register.

DWord	Bit	Description
0	31:29	**Reserved** Format: MBZ
	28	**Reserved**
	27	**Idle Link Frame Status** Access: R/WC This bit indicates if a link frame boundary has been sent in idle pattern.

DP_TP_STATUS

This is a sticky bit, cleared by writing 1b to it.

Value	Name
0b	Idle link frame not sent
1b	Idle link frame sent

26 **Active Link Frame Status**

Access:	R/WC

This bit indicates if a link frame boundary has been sent in active (at least one VC enabled).
This is a sticky bit, cleared by writing 1b to it.

Value	Name
0b	Active link frame not sent
1b	Active link frame sent

25 **Min Idles Sent**

Access:	RO

This bit indicates that the minimum required number of idle patterns has been sent when DP_TP_CTL is set to send idle patterns.
This bit will clear itself when DP_TP_CTL is not longer set to send idle patterns.

Value	Name
0b	Min idles not sent
1b	Min idles sent

24 **ACT Sent Status**

Access:	R/WC

This bit indicates if DisplayPort MST ACT has been sent.
This is a sticky bit, cleared by writing 1b to it.

Value	Name
0b	ACT not sent
1b	ACT sent

23 **Mode Status**

Access:	RO

This bit indicates what mode the transport is currently in.

Value	Name	Description
0b	SST	Single-stream mode
1b	MST	Multi-stream mode

22:18 **Reserved**

Format:	MBZ

17:16 **Streams Enabled**

Access:	RO

This field indicates the number of streams (transcoders) enabled on this port during multistream

DP_TP_STATUS

operation.
This field should be ignored in single stream mode.

Value	Name	Description
00b	Zero	Zero streams enabled
01b	One	One stream enabled
10b	Two	Two streams enabled
11b	Three	Three streams enabled

15:13 **Reserved**

Format:	MBZ

12 **Reserved**

Format:	MBZ

11:10 **Reserved**

Format:	MBZ

9:8 **Payload Mapping VC2**

Access:	RO

This field indicates which transcoder is mapped to Virtual Channel 2 during multistream operation.
This field should be ignored if the number of streams enabled is less than three.
This field should be ignored in single stream mode.

Value	Name	Description
00b	A	Transcoder A mapped to this VC
01b	B	Transcoder B mapped to this VC
10b	C	Transcoder C mapped to this VC
11b	Reserved	Reserved

7:6 **Reserved**

Format:	MBZ

5:4 **Payload Mapping VC1**

Access:	RO

This field indicates which transcoder is mapped to Virtual Channel 1 during multistream operation.
This field should be ignored if the number of streams enabled is less than two.
This field should be ignored in single stream mode.

Value	Name	Description
00b	A	Transcoder A mapped to this VC
01b	B	Transcoder B mapped to this VC
10b	C	Transcoder C mapped to this VC
11b	Reserved	Reserved

DP_TP_STATUS

	3:2	**Reserved** Format: MBZ
	1:0	**Payload Mapping VC0** Access: RO This field indicates which transcoder is mapped to Virtual Channel 0 during multistream operation. This field should be ignored if the number of streams enabled is less than one. This field should be ignored in single stream mode.

Value	Name	Description
00b	A	Transcoder A mapped to this VC
01b	B	Transcoder B mapped to this VC
10b	C	Transcoder C mapped to this VC
11b	Reserved	Reserved

This register, together with DPLL_CFGCR1, is used to configure the frequency for DPLL1, DPLL2, and DPLL3, when DPLL_CTRL1 override is enabled and set to HDMI mode.
This register is not reset by the device 2 FLR.

Programming Notes

P0 is P, P1 is Q, P2 is K.
The post divider is P*Q*K (P0*P1*P2).

DWord	Bit	Description
0	31:16	**Reserved** Format: MBZ
	15:8	**Qdiv Ratio** This field specifies the Q (P1) divider ratio. This field is only used when Qdiv Mode is set to Enable to get a divider value other than 1.
	7	**Qdiv Mode** This field enables the Q (P1) divider when the ratio is not 1. Value / Name / Description

DPLL_CFGCR2

0b	Disable	Q divider = 1
1b	Enable	Q divider = Qdiv Ratio

Restriction
Restriction : If K (P2) is not 2, Q (P1) MUST be 1 to ensure 50% duty cycle.

6:5 **Kdiv**

This field specifies the K (P2) divider ratio.

Value	Name
00b	5
01b	2
10b	3
11b	1

4:2 **Pdiv**

This field specifies the P (P0) divider ratio.

Value	Name	Programming Notes
000b	1	Restriction : P (P0) can only be 1 if Q (P1) is also 1.
001b	2	
010b	3	
100b	7	

1:0 **Central Frequency**

This field specifies the center frequency.

Value	Name
00b	9600 MHz
01b	9000 MHz
10b	Reserved
11b	8400 MHz

DPLL_CTRL1

DPST_BIN

DPST_BIN	
Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	Double Buffered
Size (in bits):	32
Double Buffer Update Point:	Start of vertical blank

Access to this address are steered to the correct register by programming the Bin Register Function Select and the Bin Register Index.
Updates take place at the start of vertical blank.

DWord	Bit	Description
0	31	**Busy Bit** If (DPST_CTL:Bin Register Function Select = Threshold Count) {This is a read only bit. If set, the engine is busy and the rest of the register is undefined. If clear, the register contains valid data.} Else (Image Enhancement) {This bit is reserved.}
	30:24	**Reserved**
	23:0	**Data** If (DPST_CTL : Bin Register Function Select = Threshold Count) {Bits 23:0 are read only bits. They indicate the total number of pixels in this bin. The bin value is updated when guardband interrupt delay is met, and is not valid until after a histogram event has occurred. The bin value will stop incrementing once the maximum has been reached.} Else (Image Enhancement) {Bits 23:10 are reserved and should be written as zeroes. Bits 9:0 are R/W double-buffered and program the correction value for this bin. Writes to this register are double buffered on the next vblank. The value written here is the 10bit corrected channel value for the lowest point of the bin.}

DPST_CTL

DPST_CTL

Register Space: MMIO: 0/2/0
Source: BSpec
Default Value: 0x00000000
Access: R/W
Size (in bits): 32

DWord	Bit	Description
0	31	**IE Histogram Enable** This bit enables the Image Enhancement histogram logic to collect data. The collected data will be valid after a histogram event has occurred. **Value** / **Name** 0b – Disable 1b – Enable **Programming Notes** If histogram is enabled while no planes are enabled on the pipe, it may get an incorrect pixel count for a frame.
	30:28	**Reserved**
	27	**IE Modification Table Enable** This bit enables the Image Enhancement modification table. When enabled, modifications begin after the next vertical blank. **Value** / **Name** 0b – Disable 1b – Enable
	26:25	**Reserved**
	24	**Histogram Mode Select** **Value** / **Name** / **Description** 0b – YUV – YUV Luma Mode 1b – HSV – HSV Intensity Mode
	23:16	**Reserved**
	15	**IE Table Value Format** This field indicates what format is used for the image enhancement table values. **Value** / **Name** / **Description** 0b – 1.9 – 1 integer and 9 fractional bits 1b – 2.8 – 2 integer and 8 fractional bits

DPST_CTL

	14:13	**Enhancement mode** Value / Name / Description 00b / Direct / Direct look up mode 01b / Additive / Additive mode 10b / Multiplicative / Multiplicative mode 11b / Reserved / Reserved
	12	**Reserved**
	11	**Bin Register Function Select** This field indicates what data is being written to or read from the bin data register. Value / Name / Description 0b / TC / Threshold Count. A read from the bin data register returns that bin's threshold value from the most recent vblank load event (guardband threshold trip). Valid range for the Bin Index is 0 to 31. 1b / IE / Image Enhancement Value. Valid range for the Bin Index is 0 to 32
	10:7	**Reserved**
	6:0	**Bin Register Index** This field indicates the bin number whose data can be accessed through the bin data register. This value is automatically incremented by a read or a write to the bin data register if the busy bit is not set.

DPST_GUARD

DPST_GUARD

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	Double Buffered
Size (in bits):	32
Double Buffer Update Point:	Start of vertical blank

Updates take place at the start of vertical blank.

DWord	Bit	Description
0	31	**Histogram Interrupt enable** Value / Name / Description: 0b / Disable / Disabled 1b / Enable / This generates a histogram interrupt once a Histogram event occurs.
	30	**Histogram Event status** Access: R/WC When a Histogram event has occurred, this will get set by the hardware. For any more Histogram events to occur, clear this bit by writing a '1'. Value / Name / Description: 0b / Not Occurred / Histogram event has not occurred 1b / Occured / Histogram event has occurred
	29:22	**Guardband Interrupt Delay** An interrupt is always generated after this many consecutive frames of the guardband threshold being surpassed. This value is double buffered on start of vblank. Restriction Restriction : A value of 0 is invalid.
	21:0	**Threshold Guardband** This value is used to determine the guardband for the threshold interrupt generation. This single value is used for all the segments. This value is double buffered on start of vblank. This value is shifted left 2 bits (multiplied by 4) for use with the 24 bit bin values.

Driver Media Force Wake Ack

DRIVER_MEDIA_FWAKE_ACK - Driver Media Force Wake Ack	
Register Space:	MMIO: 0/2/0
Default Value:	0x00000000
Size (in bits):	32
Address:	00D88h

Message registers have bit-wise masking applied for writes. The register consists of 16 bits of data in [15:0], and 16 bits of corresponding masks in [31:16].
To set bit0, for example, the data would be 0x0001_0001.
To clear bit0, for example, the data would be 0x0001_0000.
Note that mask bit is the data bit offset + 16. Message registers are protected from non-GT writes via the Message Channel.

DWord	Bit	Description
0	31:16	**Reserved** Access: RO
	15:0	**GPM Driver Media ForceWake Ack** Access: R/W 1'b0 : GT Media Can be powered down (default) 1'b1 : GT Media cannot be powered down

Driver Render Force Wake Ack

DRIVER_RENDER_FWAKE_ACK - Driver Render Force Wake Ack

Register Space:	MMIO: 0/2/0
Default Value:	0x00000000
Size (in bits):	32
Address:	00D84h

Message registers have bit-wise masking applied for writes. The register consists of 16 bits of data in [15:0], and 16 bits of corresponding masks in [31:16].
To set bit0, for example, the data would be 0x0001_0001.
To clear bit0, for example, the data would be 0x0001_0000.
Note that mask bit is the data bit offset + 16. Message registers are protected from non-GT writes via the Message Channel.

DWord	Bit	Description
0	31:16	**Reserved** Access: RO
	15:0	**GPM Driver ForceWake Ack** Access: R/W 1'b0 : GT Render Can be powered down (default) 1'b1 : GT Render cannot be powered down

DS Invocation Counter

DS_INVOCATION_COUNT - DS Invocation Counter	
Register Space:	MMIO: 0/2/0
Source:	RenderCS
Default Value:	0x00000000, 0x00000000
Access:	R/W
Size (in bits):	64
Trusted Type:	1
Address:	02308h

This register stores the number of domain points shaded by the DS threads. Domain points which hit in the DS cache will not cause this register to increment. Note that the spawning of a DS thread which shades two domain points will cause this counter to increment by two.This register is part of the context save and restore.

DWord	Bit	Description
0	63:32	**DS Invocation Count UDW** Number of domain points shaded by the DS threads. Updated only when DS Function Enable and Statistics Enable are set in 3DSTATE_DS
	31:0	**DS Invocation Count LDW** Number of domain points shaded by the DS threads. Updated only when DS Function Enable and Statistics Enable are set in 3DSTATE_DS

DSSM

DSSM

DX9 Constants Not Consumed By RCS

DX9CONST_PRODUCE_COUNT - DX9 Constants Not Consumed By RCS

Register Space:	MMIO: 0/2/0
Source:	RenderCS
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Trusted Type:	1
Address:	02484h

This register keeps track of the outstanding DX9 Constants produced by RS which are not yet consumed by Render Command Streamer. This register is part of the render context save and restore. This register should not be programmed by SW.

DWord	Bit	Description
0	31:0	**DX9 Constants Produce Count** This register keeps track of the outstanding DX9 Constants produced by RS which are not yet consumed by Render Command Streamer. This register is part of the render context save and restore.

DX9 Constants Prsed By RCS

DX9CONST_PARSE_COUNT - DX9 Constants Prsed By RCS

Register Space:	MMIO: 0/2/0
Source:	RenderCS
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Trusted Type:	1
Address:	02494h

This register keeps track of the DX9 Constant commands parsed by RCS prior to encountering the Draw Call in an RS enabled Batch Buffer which has DX9 Pool Alloc Valid. DX9 parse count should be less then equal to the DX9 produce count for Command Streamer to make progress on a 3D_PRIMITIVE command. DX9 Parse count is subtracted from the DX9 Produce Count upon parsing 3D_PRIMITIVE command. This register is part of the render context save and restore. This register should not be programmed by SW.

DWord	Bit	Description
0	31:0	**DX9 Constants Produce Count** This register keeps track of the DX9 Constant commands parsed by RCS prior to encountering the Draw Call in an RS enabled Batch Buffer which has DX9 Pool Alloc Valid. DX9 parse count should be less then equal to the DX9 produce count for Command Streamer to make progress on a 3D_PRIMITIVE command. DX9 Parse count is subtracted from the DX9 Produce Count upon parsing 3D_PRIMITIVE command.

Element Information: The register is populated by command streamer and consumed by GAM

DWord	Bit	Description
0	63:32	**Context ID** Context identification number assigned to separate this context from others. Context IDs needs to be recycled in such a way that there could not be two active context with the same ID. This is a unique identification number by which a context is identified and referenced
	31:12	**LRCA** Command Streamer Only
	11:9	**Function Number** GFX device is considered to be on Bus0 with device number of 2. Function number is normally assigned as "0" however for gfx virtualization; there would be different function numbers which needs to be attached to context. Not used in Gen8.
	8	**Privileged Context / GGTT vs PPGTT mode** In Legacy Context: Defines the page tables to be used. This is how page walker come to know PPGTT vs GGTT selection for the entire context. In Advanced Context: Defines the privilege level for the context

Value	Name	Description
0h	**[Default]**	Use Global GTT (In Legacy Context)

ELEM_DESCRIPTOR - Element Descriptor Register

		User Mode Context (In Advanced Context)
1h		Use Per-Process GTT (In Legacy Context) Supervisor Mode Context (In Advanced Context)

7:6 Fault Model

Value	Name	Description
00h	**[Default]**	Fault and Hang. Same mode as gen7.5
01h		Fault and Halt/Wait. Same mode as gen7.5
10h		Fault and Stream and Switch
11h		Reserved.

5 Deeper IA coherency Support

In Advanced Context: Defines the level of IA coherency

Value	Name	Description
0h	**[Default]**	IA coherency is provided at LLC level for all streams of GPU (i.e. gen7.5 like mode)
1h		IA coherency is provided at L3 level for EU data accesses of GPU

4 A and D Support / 32 and 64b Address Support

In Legacy Context: Defines 32b vs 64b (48b canonical) addressing format
In Advanced Context: Defines A/D bit support

Value	Name	Description
0h	**[Default]**	32b addressing format (In Legacy Context) A/D bit management in page tables is NOT supported (In Advanced Context)
1h		64b (48b canonical) addressing format (In Legacy Context) A/D bit management in page tables is supported (In Advanced Context)

3 Context Type: Legacy vs Advanced

Defines the context type.
Note that: Bits [8:4] differs in functions when legacy vs advanced context modes are selected.

Value	Name	Description
0h	**[Default]**	Advanced Context: Defines the rest of the advanced capabilities (i.e. OS page table support, fault models...). Note that advanced context is not bounded to GPGPU.
1h		Legacy Context: Defines the context as legacy mode which is similar to prior generations of gen8.

2 FR

Command Streamer Specific

ELEM_DESCRIPTOR - Element Descriptor Register

	1	**Scheduling Mode** Value / Name / Description 0h / **[Default]** / Indicates execlist mode of scheduling. 1h / / Indicates Ring Buffer mode of scheduling.
	0	**Valid** Indicates that element descriptor is valid. If GAM is programmed with an invalid descriptor, it will continue but flag an error.

EMRR Mask LSB

EMRRMASK_LSB - EMRR Mask LSB		
Register Space:	MMIO: 0/2/0	
Source:	BSpec	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	09208h	
EMRR Mask Value		
DWord	**Bit**	**Description**
0	31:12	**EMRR_MASK_LSB** Access: RO EMRR MASK VALUE.
	11	**EMRR ENABLE** Access: RO EMRR Enable.
	10	**EMRR LOCK** Access: RO EMRR LOCK bit.
	9:0	**Spares** Access: RO

EMRR Mask MSB

EMRRMASK_MSB - EMRR Mask MSB		
Register Space:	MMIO: 0/2/0	
Source:	BSpec	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	0920Ch	
EMRR Mask Value		
DWord	**Bit**	**Description**
0	31:7	**Spares** Access: RO
	6:0	**EMRR_MASK_MSB** Access: RO EMRR MASK VALUE.

Error Identity Register

EIR - Error Identity Register

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	r/w
Size (in bits):	32
Address:	020B0h-020B3h
Name:	Error Identity Register
ShortName:	EIR_RCSUNIT
Address:	120B0h-120B3h
Name:	Error Identity Register
ShortName:	EIR_VCSUNIT0
Address:	1A0B0h-1A0B3h
Name:	Error Identity Register
ShortName:	EIR_VECSUNIT
Address:	1C0B0h-1C0B3h
Name:	Error Identity Register
ShortName:	EIR_VCSUNIT1
Address:	220B0h-220B3h
Name:	Error Identity Register
ShortName:	EIR_BCSUNIT

The EIR register contains the persistent values of Hardware-Detected Error Condition bits. Any bit set in this register will cause the Master Error bit in the ISR to be set. The EIR register is also used by software to clear detected errors (by writing a 1 to the appropriate bit(s)), except for the unrecoverable bits described.)

DWord	Bit	Description
0	31:16	**Mask** Access: WO Format: Mask
	15:0	**Error Identity Bits** Format: Array of Error condition bits See the table titled Hardware-Detected Error Bits. This register contains the persistent values of ESR error status bits that are unmasked via the EMR register. (See Table Table 3-3. Hardware-Detected Error Bits). The logical OR of all (defined) bits in this register is reported in the Master Error bit of the Interrupt Status Register. In order to clear an error condition, software must first clear the error by writing a 1 to the appropriate bit(s) in this field. If required, software should then proceed to clear the Master Error bit of the IIR.

EIR - Error Identity Register

Reserved bits are RO.

Value	Name
1h	Error occurred

Programming Notes
Writing a 1 to a set bit will cause that error condition to be cleared. However, neither the Page Table Error bit (Bit 4) nor the Instruction Error bit (Bit 0) can be cleared except by reset (i.e., it is a fatal error).

Error Mask Register

EMR - Error Mask Register

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0xFFFFFFFF
Access:	R/W
Size (in bits):	32

Address:	020B4h-020B7h
Name:	Error Mask Register
ShortName:	EMR_RCSUNIT

Address:	120B4h-120B7h
Name:	Error Mask Register
ShortName:	EMR_VCSUNIT0

Address:	1A0B4h-1A0B7h
Name:	Error Mask Register
ShortName:	EMR_VECSUNIT

Address:	1C0B4h-1C0B7h
Name:	Error Mask Register
ShortName:	EMR_VCSUNIT1

Address:	220B4h-220B7h
Name:	Error Mask Register
ShortName:	EMR_BCSUNIT

The EMR register is used by software to control which Error Status Register bits are masked or unmasked. Unmasked bits will be reported in the EIR, thus setting the Master Error ISR bit and possibly triggering a CPU interrupt, and will persist in the EIR until cleared by software. Masked bits will not be reported in the EIR and therefore cannot generate Master Error conditions or CPU interrupts. Reserved bits are RO.

DWord	Bit	Description
0	31:8	**Reserved** Default Value: FFFFFFh Format: Must Be One **Programming Notes** These bits are not implemented in HW and must be set to '1'
	7:0	**Error Mask Bits** Format: Array of error condition mask bits See the table titled Hardware-Detected Error Bits.

EMR - Error Mask Register

This register contains a bit mask that selects which error condition bits (from the ESR) are reported in the EIR.

Value	Name	Description
FFh	**[Default]**	
0h	Not Masked	Will be reported in the EIR
1h	Masked	Will not be reported in the EIR

Error Reporting Register

ERR - Error Reporting Register		
Register Space:	MMIO: 0/2/0	
Source:	BSpec	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	0B42Ch	
DWord	**Bit**	**Description**
0	31:5	**Reserved** Access: RO Reserved.
	4	**First Content Buffer Ready 0** Access: R/W First Content Buffer Ready 0 (FRSNTBFR0). First Content Buffer Ready: This bit gets set by the HW when the buffer is completely filled up and cleared by the driver when the contents of this buffer are copied out of memory. Is set by lpfc_lpconf_buffer0_ready (pulse). lpconf_lpfc_buffer0_ready (static signal to lpfc).
	3	**Second Buffer ready slice 0** Access: R/W Second Content Buffer Ready slice 0 (SCNBFR0). Second Content Buffer Ready: This bit gets set by the HW when the buffer is completely filled up and cleared by the driver when the contents of this buffer are copied out of memory. Is set by lpfc_lpconf_buffer1_ready (pulse). lpconf_lpfc_buffer1_ready (static signal to lpfc).
	2	**Write Expire Error Slice 0** Access: R/W Write Expired Error slice 0 (WEERR0). Write Expired Error: If DMA controller could not get a chance to push the write of 64Bytes to LTISEQ and data gets clobbered with the new expiration of the save timer, this error bit is set to indicate something went wrong. Signal -lpfc_lpconf_wrexp_error.
	1	**Buffer full Error Slice 0** Access: R/W Buffer full Error Slice 0 (BFFLERR0). Set by lpfc_lpconf_error_buffer_full. When all buffers are full lpfc sets this bit or if only 1 buffer is enabled then lpfc sets this bit when the buffer is full.

ERR - Error Reporting Register

	0	**Reserved** Access: RO Reserved.

Error Status Register

ESR - Error Status Register

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	RO
Size (in bits):	32

Address:	020B8h-020BBh
Name:	Error Status Register
ShortName:	ESR_RCSUNIT

Address:	120B8h-120BBh
Name:	Error Status Register
ShortName:	ESR_VCSUNIT0

Address:	1A0B8h-1A0BBh
Name:	Error Status Register
ShortName:	ESR_VECSUNIT

Address:	1C0B8h-1C0BBh
Name:	Error Status Register
ShortName:	ESR_VCSUNIT1

Address:	220B8h-220BBh
Name:	Error Status Register
ShortName:	ESR_BCSUNIT

The ESR register contains the current values of all Hardware-Detected Error condition bits (these are all by definition persistent). The EMR register selects which of these error conditions are reported in the persistent EIR (i.e., set bits must be cleared by software) and thereby causing a Master Error interrupt condition to be reported in the ISR.

DWord	Bit	Description
0	31:16	**Reserved** Format: MBZ
	15:0	**Error Status Bits** Format: Array of error condition bits See the table titled Hardware-Detected Error Bits. This register contains the non-persistent values of all hardware-detected error condition bits. Value: 1h — Name: Error Condition Detected

EU_GRF_CLEAR

EU_GRF_CLEAR - EU_GRF_CLEAR			
Register Space:	MMIO: 0/2/0		
Source:	BSpec		
Default Value:	0x00000000		
Size (in bits):	32		
Address:	0E550h		
Name:	EU_GRF_CLEAR		
ShortName:	EU_GRF_CLEAR		
This is a basic register template			
DWord	**Bit**	**Description**	
0	31:0	**GRF_CLEAR**	
		Default Value:	0000000000000000b
		Access:	RO

EU_STALL PER SUBSLICE

EUMETRICS_EVENT0 - EU_STALL PER SUBSLICE	
Register Space:	MMIO: 0/2/0
Default Value:	0x00000000
Size (in bits):	32
Address:	00D8Ch

This register mirrors an accumulating count for EU Metric Event0.
It is enabled by configuration bits in GPMunit and SPMunits.
Note that count is never cleared and delta should be calculated by sampling the initial register value at the start and subtracting that value off from the final sample value.

DWord	Bit	Description
0	31:0	**EU Metric Event Count** Access: RO

EU Mask Programming

TD_PM_MODE_EUCOUNT - EU Mask Programming

Register Space:	MMIO: 0/2/0

Default Value:	0x00000088
Size (in bits):	32
Address:	2460Ch

DWord	Bit	Description
0	31	**power up control Lock** Access: R/W Lock 0 = Bits of EU PAIR 0 POWERUPFSMCTL register are R/W 1 = All bits of EU PAIR 0 POWERUPFSMCTL register are RO (including this lock bit) Once written to 1, the lock is set and cannot be cleared (that is, writing a 0 will not clear the lock). These bits are not reset on FLR.
	30:9	**Reserved** Access: RO Reserved
	8:6	**Power UP state 3** Default Value: 010b Access: R/W Lock This will be the 3rd state after power is turned ON in the well Encodings: 000 = Clock Ungate 001 = Firewall OFF 010 = De-assert resets 1xx = Rsvd for future Default - De-assert resets 3'b000: 10ns (or 1 bclk)
	5:3	**Power UP state 2** Default Value: 001b Access: R/W Lock This will be the 2nd state after power is turned ON in the well Encodings: 000 = Clock Ungate 001 = Firewall OFF 010 = De-assert resets

POWERUPFSMCTL - EU PAIR 0 Power on FSM control register with lock

		1xx = Rsvd for future Default - Firewall OFF
	2:0	**Power UP state 1** Default Value: 000b Access: R/W Lock This will be the 1st state after power is turned ON in the well Encodings: 000 = Clock Ungate 001 = Firewall OFF 010 = De-assert resets 1xx = Rsvd for future Default - Clock Ungate

EU PAIR 1 PFET control register with lock

PFETCTL - EU PAIR 1 PFET control register with lock

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x0001000A [KBL]
Size (in bits):	32
Address:	24688h

DWord	Bit	Description
0	31	**PFET Control Lock** Access: R/W Lock 0 = Bits of EU PAIR 1 PFETCTL register are R/W 1 = All bits of EU PAIR 1 PFETCTL register are RO (including this lock bit) Once written to 1, the lock is set and cannot be cleared (i.e., writing a 0 will not clear the lock). These bits are not reset on FLR.
	30:21	**Reserved** Access: RO Reserved
	20	**Power Well Status** Access: R/WC 0 = Well is powered Down 1 = Well is powered up Once written to 1, the lock is set and cannot be cleared (i.e., writing a 0 will not clear the lock). These bits are not reset on FLR.
	19	**Powergood timer error** Access: R/WC 0 = Well is powered Down 1 = Well is powered up Once written to 1, the lock is set and cannot be cleared (i.e., writing a 0 will not clear the lock). These bits are not reset on FLR.
	18:16	**Delay from enabling secondary PFETs to power good.** Access: R/W Lock Delay from enabling secondary PFETs to power good 3'b000: 40ns 3'b001: 80ns 3'b010: 160ns 3'b011: 320ns

PFETCTL - EU PAIR 1 PFET control register with lock

3'b100: 640ns
3'b101: 1280ns
3'b110: 2560ns
3'b111: 5120ns

Value	Name
001b	**[Default]**

15:13 **Time period last primay pfet strobe to secondary pfet strobe**

Access:	R/W Lock

Time period last primay pfet strobe to secondary pfet strobe
3'b000: 10ns (or 1 bclk)
3'b001: 20ns (or 2 bclk)
3'b010: 30ns (or 3 bclk)
3'b111: 80ns (or 8 bclk)

12:10 **Time period b/w two adjacent strobes**

Access:	R/W Lock

Time period b/w two adjacent strobes to the primary FETs
3'b000: 10ns (or 1 bclk)
3'b001: 20ns (or 2 bclk)
3'b010: 30ns (or 3 bclk)
3'b111: 80ns (or 8 bclk)

9:7 **FET setup margin from enable to strobe**

Access:	R/W Lock

Setup margin in design before sampling enable event at the first pre-charge sequencer/shift register flop
3'b000: 10ns (or 1 bclk)
3'b001: 20ns (or 2 bclk)
3'b010: 30ns (or 3 bclk)
3'b111: 80ns (or 8 bclk)

6:0 **Number of flops to enable primary FETs**

Default Value:	0001010b
Access:	R/W Lock

Number of flops to enable primary FETs. For a setting of N there will be N+1 total strobes generated
7'b0000000: 10 Flops to be strobed
7'b0000001: 11 Flops to be strobed
7'b0000010: 12 Flops to be strobed
7'b0001111: 26 Flops to be strobed

For a setting of N there will be N+1 total strobes generated 7'b0000000: 10 Flops to be strobed 7'b0000001: 11 Flops to be strobed 7'b0000010: 12 Flops to be strobed 7'b0001111: 26 Flops to be strobed

EU PAIR 3 Power Context Save request

PGCTXREQ - EU PAIR 3 Power Context Save request		
Register Space:	MMIO: 0/2/0	
Source:	BSpec	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	24784h	
DWord	**Bit**	**Description**
0	31:16	**Message Mask** Access: RO Message Mask bots for lower 16 bits
	15:10	**Reserved** Access: RO Reserved
	9	**Power context save request** Access: R/W Set Power Context Save Request 1'b0 : Power context save is not being requested <default> 1'b1 : Power context save is being requested CPUnit self-clears this bit upon sampling.
	8:0	**Power Context Save request crdit count** Access: R/W QWord Credits for Power Context Save Request Minimum Credits = 1 : Unit may send 1 QWord pair (enough for first LRI at least) Maximum Credits = 511 : Unit may send 511 QWord pairs A QWord pair is defined as a 32-bit register address and the corresponding 32-bits of register data. Note that the LRI header and END commands are 64-bits each (32-bit command followed by 32-bit NOOP) and will consume one QWord credit. Only valid with PWRCTX_SAVE_REQ (Bit9).

EU PAIR 3 Power Down FSM control register with lock

POWERDNFSMCTL - EU PAIR 3 Power Down FSM control register with lock

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000088
Size (in bits):	32
Address:	24790h

DWord	Bit	Description
0	31	**power down control Lock** Access: R/W Lock 0 = Bits of EU PAIR 3 POWERDNFSMCTL register are R/W 1 = All bits of EU PAIR 3 POWERDNFSMCTL register are RO (including this lock bit) Once written to 1, the lock is set and cannot be cleared (i.e., writing a 0 will not clear the lock). These bits are not reset on FLR.
	30:13	**Reserved** Access: RO Reserved
	12	**Leave firewall disabled** Access: R/W Lock When This bit is set SPC will not firewall the gated domain for a power down flow. But it will pretend to complete the flow with PM Encodings: 0 = Default mode, i.e firewall gated domain to ungated domain crossing during power down flows 1 = Leave firewall disabled, i.e dont firewall the gated domain, but complete logical flow
	11	**Leave reset de-asserted** Access: R/W Lock When This bit is set SPC will not assert reset for power off flow. But it will pretend to complete the flow with PM Encodings: 0 = Default mode, i.e assert resets during power down flows 1 = Leave reset de-asserted mode, i.e dont assert reset, but complete logical flow

POWERDNFSMCTL - EU PAIR 3 Power Down FSM control register with lock

	10	**Leave CLKs ON** Access: R/W Lock When This bit is set SPC will not gate clks for power off flow. But it will pretend to complete the flow with PM Encodings: 0 = Default mode, i.e gate clocks during power down flows 1 = Leave CLKS ON mode, i.e dont clock gate, but complete logical flow
	9	**Leave FET On** Access: R/W Lock When This bit is set SPC will not turn off the PFET eventhough it will complete the flow with PM Encodings: 0 = Default mode, i.e power off fets during power down flows 1 = Leave ON mode, i.e dont power off pfet, but complete logical flow **Programming Notes** This bit should be programmed before the powerup sequence is initiated for EUP3.
	8:6	**Power Down state 3** Default Value: 010b Access: R/W Lock This will be the 3rd state before power is turned OFF in the well Encodings: 000 = Assert Reset 001 = Firewall ON 010 = Gate clocks 1xx = Rsvd for future Default : Gate Clocks
	5:3	**Power Down state 2** Default Value: 001b Access: R/W Lock This will be the 2nd state before power is turned OFF in the well Encodings: 000 = Assert Reset 001 = Firewall ON 010 = Gate clocks 1xx = Rsvd for future Default :Firewall ON

POWERDNFSMCTL - EU PAIR 3 Power Down FSM control register with lock

	2:0	**Power Down state 1** Default Value: 000b Access: R/W Lock This will be the 1st state before power is turned OFF in the well Encodings: 000 = Assert Reset 001 = Firewall ON 010 = Gate clocks 1xx = Rsvd for future Default : Assert Reset

Name:	RCS Execlist Status
ShortName:	EXECLIST_STATUS_BCSUNIT

This register contains the pointers and full indicator for the Execlist Queue and the context ID of the currently running context.
DefaultValue = UUUU UUU1h (4:0 default to 00001b, others UNDEFINED).

DWord	Bit	Description
0	63:32	**Current Context ID** Format: U32 Contains the context ID of the currently running context.
	31:30	**Reserved** Format: MBZ
	29:28	**Reserved** Format: MBZ

EXECLIST_STATUS - Execlist Status

27 Reserved

Format:	MBZ

26:19 Reserved

Format:	MBZ

18 Reserved

17 Reserved

16 Arbitration Enable

Format:	U1

This field reflects the Arbitration Flag set by the MI_ARB_ON_OFF command in Command Streamer.

15:14 Current Active Element Status

Format:	U2

Points at the element being executed in current Execlist (if there is one).

Value	Name
00b	No Active Element being executed
01b	Element0 of current execlist being executed
10b	Element1 of current execlist being executed
11b	Reserved

13:5 Last Context Switch Reason

Access:	R/W
Format:	U9

This field contains the switch reason for the last context to switch away, as captured in the Context Status Dword, bits 8:0.

Programming Notes
This field should not written by SW.

4 Execlist 0 Valid

Format:	Flag

This bit is set when the first DW for this Execlist port 0 is written through the submission port, and will not be cleared till the CSB is updated and the command stream is switching to the next execution list. If no execution list is pending, the transition of this bit from one to zero guarentees there will be no preemption on the next submission.

Value	Name
0	Invalid **[Default]**
1	Valid

EXECLIST_STATUS - Execlist Status

3 — Execlist 1 Valid

Format:	Flag

This bit is set when the first DW for this Execlist port 1 is written through the submission port, and will not be cleared till the CSB is updated and the command stream is switching to the next execution list. If no execution list is pending, the transition of this bit from one to zero guarentees there will be no preemption on the next submission.

Value	Name
0	Invalid **[Default]**
1	Valid

2 — Execlist Queue Full

When [Execlist Write Pointer] and [Current Execlist Pointer] are equal, this bit differentiates between Queue Full and Queue Empty.

Value	Name	Description
0	Execlist Queue Empty **[Default]**	
1	Execlist Queue Full	There is a current and a pending execlist.

1 — Execlist Write Pointer

Format:	ExeclistContentsIndex

Determines which Execlist will be the next submitted to. When a new execlist is submitted, this pointer increments to point to the next execlist slot.

0 — Current Execlist Pointer

Default Value:	1h
Format:	ExeclistContentsIndex

Points at the currently executing Execlist (if there is one). This pointer advances when the first context of new execlist is restored.

Execlist Submit Port Register

EXECLIST_SUBMITPORT - Execlist Submit Port Register	
Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	WO
Size (in bits):	32
Address:	02230h-02233h
Name:	Execlist Submit Port Register
ShortName:	EXECLIST_SUBMITPORT_RCSUNIT
Address:	12230h-12233h
Name:	Execlist Submit Port Register
ShortName:	EXECLIST_SUBMITPORT_VCSUNIT0
Address:	1A230h-1A233h
Name:	Execlist Submit Port Register
ShortName:	EXECLIST_SUBMITPORT_VECSUNIT
Address:	1C230h-1C233h
Name:	Execlist Submit Port Register
ShortName:	EXECLIST_SUBMITPORT_VCSUNIT1
Address:	22230h-22233h
Name:	Execlist Submit Port Register
ShortName:	EXECLIST_SUBMITPORT_BCSUNIT

SW should submit a new pending execlist to this register. The DWs of the context descriptors must be written in a specific order: Element 1 must be written first and then Element 0. For each Element, DW1 must be written first followed by DW0. Context descriptors for both the elements must be written even if only one context are being submitted. The valid bits of the unused context descriptors should be set to 0.

Order of DW Submission to the Execlist Port
Element 1, High Dword
Element 1, Low Dword
Element 0, High Dword
Element 0, Low Dword

If a execlist of only one element is being submitted, it must be submitted in Element 0. It is UNDEFINED to submit a execlist with the valid bit of Element 0 clear (an "empty" execlist). It is possible that one or all of the contexts submitted in a execlists are "empty"; that is, have head and tail pointers equal to each other indicating no commands to be run. All of the valid bits in the Execlist Element Status Registers for the "about to be submitted" execlist will be cleared when the first DW (DW1 of Element 1) is written to the submit port. Submission of the Element 0 Context Descriptor low Dword with the valid bit set is interpreted as a request to switch (as soon as possible) to the new execlist, i.e., a pre-emption request.

EXECLIST_SUBMITPORT - Execlist Submit Port Register

If a submitted Execlist's Element 0 Context Descriptor LRCA matches the LRCA of the currently executing context, then the newly submitted execlist will become the currently executing execlist without any context switch and without any impact to the executing context except that it will re-sample the tail pointer from the context image. This is done in case more commands have been inserted into its ring buffer between the first execlist submission and the 2nd.

Programming Notes
SW must ensure the contexts submitted to the both the context descriptors in the execlist are different, i.e SW must not submit the same context descriptor to both the elements of the execlist.

DWord	Bit	Description
0	31:0	**Context Descriptor DW** Format: Context Descriptor See "Context Descriptor Format" for format. The element that this DW is submitted as and whether it is the high DW or the low DW is determined by order. This register must be written to 4 times in order to submit a execlist.

Execute Condition Code Register

EXCC - Execute Condition Code Register

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	r/w
Size (in bits):	32
Trusted Type:	1

Address:	02028h-0202Bh
Name:	Execute Condition Code Register
ShortName:	EXCC_RCSUNIT

Address:	12028h-1202Bh

Name:	Execute Condition Code Register
ShortName:	EXCC_VCSUNIT1

Address:	22028h-2202Bh
Name:	Execute Condition Code Register
ShortName:	EXCC_BCSUNIT

This register contains user defined and hardware generated conditions that are used by MI_WAIT_FOR_EVENT commands. An MI_WAIT_FOR_EVENT instruction excludes the executing ring from arbitration if the selected event evaluates to a 1, while instruction is discarded if the condition evaluates to a 0. Once excluded a ring is enabled into arbitration when the selected condition evaluates to a 0.

This register also contains control for the invalidation of indirect state pointers on context restore.

DWord	Bit	Description
0	31:16	**Mask** Access: WO Format: Mask These bits serves as a write enable for bits 15:0. If this register is written with any of these bits clear the corresponding bit in the field 15:0 will not be modified. Reading these bits always returns 0s.
	15	**Reserved** Format: MBZ

EXCC - Execute Condition Code Register

	14	**Context Wait for V-blank on Pipe-C** Source: RenderCS, BlitterCS This field when set indicates the corresponding context has executed MI_WAIT_FOR_EVENT with "Display Pipe C Vertical Blank Wait Enable" set. This is an internal HW flag and should not be accessed by SW.
	13	**Context Wait for V-blank on Pipe-B** Source: RenderCS, BlitterCS This field when set indicates the corresponding context has executed MI_WAIT_FOR_EVENT with "Display Pipe B Vertical Blank Wait Enable" set. This is an internal HW flag and should not be accessed by SW.

Access:	R/W
Size (in bits):	32
Address:	43200h-43203h
Name:	FBC Compressed Buffer Address
ShortName:	FBC_CFB_BASE
Power:	PG1
Reset:	soft

Restriction

Restriction : The contents of this register must not be changed while compression is enabled.

DWord	Bit	Description
0	31:28	**Reserved** Format: MBZ
	27:12	**CFB Offset Address** This register specifies bits 27:12 of the offset of the Compressed Frame Buffer from the base of stolen memory. **Restriction** Restriction : The buffer must be 4K byte aligned. The offset must be greater than 4K bytes, avoiding the first 4KB of stolen memory.
	11:0	**Reserved** Format: MBZ

FBC_CTL

FBC_CTL

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	43208h-4320Bh
Name:	FBC Control
ShortName:	FBC_CTL
Power:	PG1
Reset:	soft

Description

FBC is tied to Plane 1 A.

Programming Notes

Frame Buffer Compression is only supported with surfaces up to 4096 pixels x 4096 lines and plane sizes up to 4096 pixels x 4096 lines.

The FBC compressed vertical limit is 2560 lines, after which the remaining lines will be displayed correctly, but will not be compressed.

Restriction

Restriction : The contents of this register must not be changed, except the enable bit, while compression is enabled. Frame Buffer Compression is only supported with 16bpp and 32bpp 8:8:8 RGB plane source pixel formats. It is not supported with any other format. The 16bpp format requires the compression ratio to be set to 2:1 or 4:1.

Restriction :
Frame Buffer Compression is not supported with interlaced fetch.
With plane 90/270 rotation, all frame buffer modifications will result in full frame invalidation and recompression. FBC should not be enabled with RGB 16bpp plane formats when plane 90/270 rotation is enabled.
Frame Buffer Compression is not supported when the plane width is smaller than 35 pixels.

DWord	Bit	Description
0	31	**Enable FBC** This bit is used to globally enable FBC function at the next Vertical Blank start. FBC should not be enabled when the pipe is disabled.

Value	Name
0b	Disable
1b	Enable

FBC_CTL

Workaround

When FBC is enabled and the plane surface format is in linear, tile Y legacy or tile YF, the display register 4208Ch bit 13 must be set to 1b and bits 12:0 must be programmed with the compressed buffer stride value.
The compressed buffer stride must be calculated using the following equation:
Compressed buffer stride = ceiling [(at least plane width in pixels) / (32 * compression limit factor)] * 8
At least plane width = a value greater than or equal to the width of the plane. Software may choose to use a greater value in order to handle cases where the plane width is changing from frame to frame, especially because 4208C is not double-buffered and can't be changed on the fly while FBC is enabled. Compression limit factor is either 1, 2 or 4 based on the Compression Limit field.

30:29 **Reserved**

Format:	MBZ

28 **CPU Fence Enable**

Value	Name	Description
0b	No CPU Disp Buf	Display Buffer is not in a CPU fence. No modifications are allowed from CPU to the Display Buffer.
1b	CPU Disp Buf	Display Buffer exists in a CPU fence.

27:25 **Reserved**

Format:	MBZ

24:16 **Reserved**

15 **Reserved**

14:11 **Reserved**

Format:	MBZ

10 **Reserved**

9:8 **Reserved**

7:6 **Compression Limit**

This register sets a minimum limit on compression. This determines the maximum size of the compressed frame buffer. Display lines that do not meet the compression limit will not be compressed, so the best compression will be achieved with a 1:1 ratio.

Compression Ratio 1, Pixel Format 16 bpp - Not Supported
Compression Ratio 1, Pixel Format 32 bpp - Supported (CFB=FB)
Compression Ratio 1/2, Pixel Format 16 bpp - Supported (CFB=FB)
Compression Ratio 1/2, Pixel Format 32 bpp - Supported (CFB=1/2 FB)
Compression Ratio 1/4, Pixel Format 16 bpp - Supported (CFB=1/2 FB)
Compression Ratio 1/4, Pixel Format 32 bpp - Supported (CFB=1/4 FB)

FB = Frame Buffer Size
CFB = Compressed Frame Buffer Size

Value	Name	Description

FBC_CTL

00b	1:1	Compressed buffer is the same size as the uncompressed buffer.
01b	2:1	Compressed buffer is one half the size of the uncompressed buffer.
10b	4:1	Compressed buffer is one quarter the size of the uncompressed buffer.
11b	Reserved	Reserved

5:4 **Write Back Watermark**

The compressed data write back engine waits for this number of entries to be ready before writing the data out to memory.

Value	Name	Description
00b	4	4 entries
01b	8	8 entries
10b	16	16 entries
11b	32	32 entries

3:0 **CPU Fence Number**

Value	Name
0000b	Fence 0

Restriction
Restriction : This field must be programmed to 0000b.

FBC_RT_BASE_ADDR_REGISTER

FBC_RT_BASE_ADDR_REGISTER - FBC_RT_BASE_ADDR_REGISTER

Register Space:	MMIO: 0/2/0
Source:	RenderCS
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	07020h

This Register is saved and restored as part of Context.

DWord	Bit	Description
0	31:12	**FBC RT Base Address** Access: R/W Format: PPGraphicsAddress[31:12] 4KB aligned Base Address as mapped in the PPGTT or in the GGTT for the render target. This base address must be the one that is either front buffer or the back-buffer (a flip target). It must be programmed before any draw call binding that render target base address.
	11:2	**Reserved** Access: R/W Format: PBC
	1	**FBC Front Buffer Target** Access: R/W Format: Enable Value / Name / Description: 0h **[Default]** FBC is targeting the Back Buffer for compression. This buffer can be cached in the MLC/LLC, so a GFDT flush is required before FBC can begin compression. 1h FBC is targeting the Font Buffer for compression. This buffer cannot be cached in the MLC/LLC. FBC compression can begin after any RC flush.
	0	**PPGTT Render Target Base Address Valid for FBC** Access: R/W Format: Enable Value / Name / Description: 0h **[Default]** Base address in this register [31:12] is not valid and therefore FBC will not get any modifications from rendering. 1h Base address in this register [31:12] is valid and HW needs to compare the current render target base address with this base address to provide modifications to FBC.

FBC_RT_BASE_ADDR_REGISTER_UPPER

FBC_RT_BASE_ADDR_REGISTER_UPPER - FBC_RT_BASE_ADDR_REGISTER_UPPER

Register Space:	MMIO: 0/2/0
Source:	RenderCS
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	07024h

This Register is saved and restored as part of Context.

DWord	Bit	Description
0	31:16	**Reserved** Access: R/W Format: PBC
	15:0	**FBC RT Base Address High** Access: R/W Format: BaseAddress[47:32] Must be set to modify corresponding data bit. Reads to this field returns zero. Upper 4KB aligned Base Address as mapped in the PPGTT or in the GGTT for the render target. This base address must be the one that is either front buffer or the back-buffer (a flip target). It can be only programmed once per context. **Programming Notes** It must be programmed before any draw call binding that render target base address.

FBC LLC Config Read Control Register

FBC_LLC_READ_CTRL - FBC LLC Config Read Control Register

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x000000FF
Size (in bits):	32
Address:	09044h

Frame Buffer Cache Readiness Status Poll Config Register. ONly applicable for KBL family

DWord	Bit	Description
0	31	**FBC LLC Config Read Control Register Lock** Access: R/W Lock 0 = Bits of FBC_CTRL Register are R/W. 1 = All bits of FBC_CTRL Register are RO (including this lock bit). Once written to 1, the lock is set and cannot be cleared (i.e., writing a 0 does not clear the lock). These bits are not reset on FLR.
	30	**FBC LLC Config Start Value** Access: R/W Lock PCU_CR_LLC_CONFIG Read Cycle Interval in microseconds. 1'b0 - Treat LLC as partially open on reset (boot or C6 exit) (Default). 1'b1 - Treat LLC as fully open on reset (boot or C6 exit). This must not be set unless coordinated with Uncore.
	29:16	**Reserved** Access: RO Reserved.
	15:0	**FBC LLC Config Read Interval** Default Value: 00FFh Access: R/W Lock PCU_CR_LLC_CONFIG Read Cycle Interval in microseconds . 0x0000: Do not read PCU_CR_LLC_CONFIG (use Start Value only). 0x0001-0xFFFF : Read PCU_CR_LLC_CONFIG at the specified interval, until LLC_FULLY_OPEN=1. Default: 0xFF (approx 170us).

Fence Control Register

MFCR - Fence Control Register

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00070000
Size (in bits):	32
Address:	09070h

Fence Control Register

DWord	Bit	Description
0	31	**Fuse Override Lock** Access: R/W Lock SW Fuse Override Lock Bit
	30:25	**ECORSVD** Access: R/W ECO purposes Reserved
	24:23	**GT VBOX DISABLE FUSE OVERRIDE** Access: R/W Lock S/W GT Vbox Disable Fuse Override Bits
	22	**Reserved**
	21:19	**GT SUBSLICE DISABLE FUSE OVERRIDE** Access: R/W Lock SW GT SubSlice Disable Fuse Override Bits
	18:16	**GT SLICE ENABLE FUSE OVERRIDE** Default Value: 111b Access: R/W Lock SW GT Slice Enable Fuse Override Bits
	15:5	**RSVD** Access: RO
	4	**Reserved**
	3	**Reserved**
	2	**Write/Read Port Block** Access: R/W 0 - Dont Block the R/W port when Query is started. 1 - Block the R/W port until the Memory Fence is completed. This is applicable for only Memory Fence.

MFCR - Fence Control Register

	1	**LLC Query Enable** Access: R/W 0 - Query for 16 Ways. 1 - Query for 32 Ways. No Flexing.
	0	**Fence Controller GFDT Mode** Access: R/W Fence Controller GFDT Mode. 0 - Single bit GFDT mode. 1 - Two bit GFDT mode.

FF Performance

FF_PERF - FF Performance

Register Space:	MMIO: 0/2/0
Source:	RenderCS, PositionCS
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Trusted Type:	1
Address:	06B1Ch
Name:	Render CS FF Performance
ShortName:	RCS_FF_PERF

DWord	Bit	Description
0	31:16	**Mask** Access: WO Format: Mask[15:0] Must be set to modify corresponding bit in Bits 15:0. (All implemented bits)
	15:11	**Reserved** Access: r/w Format: PBC
	10:8	**Throttle counter value** Access: r/w Format: Disable Counter value defining how many clocks the interface needs to be slowed down. Value: 0h — Name: **[Default]** — Description: Masked by default.
	7:3	**Reserved** Access: r/w Format: PBC
	2	**Enable throttling for SF-WM interface** Access: r/w Format: Disable Value: 0h — Name: Disable — Description: No throttling Value: 1h — Name: Enable — Description: Enable throttling in all SF-WM interfaces

FF_PERF - FF Performance

1 Enable throttling for SF-SBE interface

Access:	r/w
Format:	Disable

Value	Name	Description
0h	Disable	No throttling
1h	Enable	Enable throttling in all SF-SBE interfaces

0 Enable throttling for CL-SF interface

Access:	r/w
Format:	Disable

Value	Name	Description
0h	Disable	No throttling
1h	Enable	Enable throttling in all CL-SF interfaces

Restriction
Restriction : This bit must not be set. SW may choose to use SF-SBE throttle interface(bit 1) to achive the same effect.

First Buffer Size and Start

FBSS - First Buffer Size and Start

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Size (in bits):	32
Address:	0B420h

LPFCREG02 - First Buffer Size and Start

DWord	Bit	Description
0	31:16	**First Virtual Buffer Base** Access: R/W First Virtual Buffer Base: Programmed by driver to allocate a memory space for performance data storage. The buffer size should be aligned to the size of the memory allocated so it naturally aligns to the base (i.e. for 128KB bit[16]=0, 256KB bit[17:16]=0, 512KB bit[18:16]=0). Signal - lpconf_lpfc_virtual_base0 [31:16].
	15:12	**First Buffer Size** Access: R/W First Buffer Size: Determines the allowed buffer size for performance data storage. 0000b: 64KB. 0001b: 128KB. 0010b: 256KB. 0011b: 512KB. ... 1111b: 2GB. Signal - lpconf_lpfc_buffer_size0 [3:0].
	11:4	**Reserved** Access: RO Reserved.
	2	**Frame count and Draw call enable** Access: R/W Enables the replacement of a specific L3 performance counter value in the reported data with a 16-bit tag created from the concatenation of the "Frame Count" and "Draw Call Number" programmable bitfields in the "Frame Count and Draw Call Number" register. The exact counter replaced is dependent on the programmed value of the "Counter Enabling Selection" bitfield. The replaced counter is always the last one, except in the case only a single performance counter is enabled for reporting (in which no replacement occurs): CNTRENSEL Value / Replaced Event Counter 00 / No Replacement 01 / Counter 1 10 / Counter 3

FBSS - First Buffer Size and Start

		11 Counter 7
	1	**Reserved**
	0	**Master Counter Enable** Access: R/W Master Counter Enable: This is the global enable for performance tracking. Once set, it kicks off all performance tracking mechanism. Signal - lpconf_lpfc_master_cnt_en. This bit is used by all slices.

Flexible EU Event Control 0

EU_PERF_CNT_CTL0 - Flexible EU Event Control 0

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	0E458h

This register configures flexible EU event 0/1. Please refer to the description of the flexible EU events for more details on supported events. Please note that this register is render context saved/restored.

DWord	Bit	Description
0	31:24	**Reserved** Format: MBZ
	23:20	**Fine Event Filter Select EU event 1** Format: U4 This field controls which fine event filter is applied to the coarsely filtered increment event when creating flexible EU event 1. Note that the fine event filter is logically applied after the coarse event filter.

These registers are privilege registers and are not allowed to be written from non-privilege batch buffer. These are global registers and power context save/restored.

DWord	Bit	Description
0	31	**Reserved** Format: MBZ
	30:26	**Reserved** Format: MBZ
	25:2	**Non Privilege Register Address** Format: MmioAddress[25:2] This field contains the MMIO offset of a register. MMIO offset programmed in this field will be treated as a non-privilege register by render command streamer while processing register writes from a non-privilege batch buffer. This register provides programmability is to extend the non-privilege register table mentioned in MI_BATCH_BUFFER_START command in render command streamer. Value: 825h — Name: **[Default]**
	1:0	**Reserved** Format: MBZ

Frame Buffer Cache Definition Register

FBCDR - Frame Buffer Cache Definition Register

Register Space:	MMIO: 0/2/0
Default Value:	0x00000000
Size (in bits):	32
Address:	04068h

DWord	Bit	Description
0	31:25	**Reserved** Default Value: 0000000b Access: R/W
	24:23	**Arbitration of LLCWBInv v/s Memory Writes** Default Value: 00b Access: R/W A round robin is enabled to inject LLCWbInv cycles to memory write stream. The conflicts are handled with programming the round robin mechanism. 00b: 1 memory write and 1 LLCWbInv. 01b: 2 memory writes and 1 LLCWbInv 10b: 4 memory writes and 1 LLCWbInv 11b: 8 memory writes and 1 LLCWbInv
	22:18	**Inside CBO** Default Value: 00000b Access: R/W CBO ID is added in LLC to separate the banks of LLC in a given slice. GFX driver will set the corresponding bits to enable the toggling of CBOID during flushing [22]: Enable h/w to toggle of CBOID[4] during flush. [21]: Enable h/w to toggle of CBOID[3] during flush. [20]: Enable h/w to toggle of CBOID[2] during flush. [19]: Enable h/w to toggle of CBOID[1] during flush. [18]: Enable h/w to toggle of CBOID[0] during flush. Setting the corresponding bit would mean h/w has to permute the corresponding bit for CBOID during flush, else h/w will keep the corresponding bit as "0" Note: For SKL 2-core system, only bit[18] needs to be set. For SKL 4-core system, bits [19:18] needs to be set.
	17:16	**Inside CBOID Enable** Default Value: 00b Access: R/W Inside CBO ID is added in LLC to separate the banks of LLC in a given slice. GFX driver will set the corresponding bits to enable the toggling of Inside CBOID during flushing:

FBCDR - Frame Buffer Cache Definition Register

		[17]: Enable h/w to toggle of InsideCBOID[1] during flush. [16]: Enable h/w to toggle of InsideCBOID[0] during flush. Setting the corresponding bit would mean h/w has to permute the corresponding bit for InsideCBOID during flush, else h/w will keep the corresponding bit as "0". Note: For SKL client this field needs to be programmed as "01"
	15:0	**Frame Buffer Caching enabled ways** Default Value: 0000h Access: R/W The Last Level cache is a 16 way structure where some of the ways are armed to allocate Frame Buffer Data. This determination is done via assigning a QOS value for Frame Buffer and QOS assignments for ways. Each bit corresponds to a way in this definition. Bit[15]: Way#15 is enabled to allocate Frame Buffer Data. Bit[14]: Way#14 is enabled to allocate Frame Buffer Data. Bit[13]: Way#13 is enabled to allocate Frame Buffer Data. Bit[12]: Way#12 is enabled to allocate Frame Buffer Data. Bit[11]: Way#11 is enabled to allocate Frame Buffer Data. Bit[10]: Way#10 is enabled to allocate Frame Buffer Data. Bit[9]: Way#9 is enabled to allocate Frame Buffer Data. Bit[8]: Way#8 is enabled to allocate Frame Buffer Data. Bit[7]: Way#7 is enabled to allocate Frame Buffer Data. Bit[6]: Way#6 is enabled to allocate Frame Buffer Data. Bit[5]: Way#5 is enabled to allocate Frame Buffer Data. Bit[4]: Way#4 is enabled to allocate Frame Buffer Data. Bit[3]: Way#3 is enabled to allocate Frame Buffer Data. Bit[2]: Way#2 is enabled to allocate Frame Buffer Data. Bit[1]: Way#1 is enabled to allocate Frame Buffer Data. Bit[0]: Way#0 is enabled to allocate Frame Buffer Data.

Frame count and Draw call number

FCDCN - Frame count and Draw call number

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Size (in bits):	32
Address:	0B430h

DWord	Bit	Description
0	31:16	**Reserved** Access: RO
	15:8	**Frame Number** Access: R/W Frame number is the first of two reporting tags that software (i.e. driver) may populate in order to provide reference points during L3 performance reporting modes. Should the "Frame Count and Draw Call Enable" bit (FCDCE) in the "First Buffer Size and Start" register be set, LPFC will selectively replace one of the reporting events with this programmable tag (in addition to the "Draw Call Number" field below). Software may use this to provide reference points for L3 performance counts when parsing the resulting data stream to align reported counts to higher-level operations. The original incarnation called for software to increment this value with each frame, however, the field is generic and may be used for any tagging purpose.
	7:0	**Draw call number** Access: R/W The draw call number is the second programmable reporting tag provided by LPFC. With this second programmable tag, a more granular sampling boundary may be created by software, or it may be used to provide an alternative reference point for tracking L3 performance. The original incarnation called for software to increment this value with every draw call, but the field is generic and may be used for any similar purpose.

FUSE_STATUS

FUSE_STATUS

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Address:	42000h-42003h
Name:	Fuse Status
ShortName:	FUSE_STATUS
Power:	PG0
Reset:	global

This register is on the ungated clock and the chip reset, not the FLR reset.

DWord	Bit	Description
0	31	**Fuse Download Status** Access: RO This field indicates the status of fuse and strap download to the Display Engine. After fuse and strap download, fuses will be distributed within the Display Engine. 0b – Not Done 1b – Done
	30:28	**Reserved**
	27	**Fuse PG0 Distribution Status** Access: RO This field indicates the status of fuse distribution to power well #0. 0b – Not Done 1b – Done
	26	**Fuse PG1 Distribution Status** Access: RO This field indicates the status of fuse distribution to power well #1. 0b – Not Done 1b – Done
	25	**Fuse PG2 Distribution Status** Access: RO This field indicates the status of fuse distribution to power well #2.

FUSE_STATUS

		Value	Name
		0b	Not Done
		1b	Done
	24:0	**Reserved**	

GAB Arbitration Programmable

GAB_AP - GAB Arbitration Programmable		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	040F0h	
DWord	**Bit**	**Description**
0	31:0	**Reserved**

GAB LRA 0

GAB_LRA_0 - GAB LRA 0

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x1F100F00
Size (in bits):	32
Address:	04A70h

DWord	Bit	Description
0	31:29	**Reserved** Default Value: 000b Access: RO
	28:24	**GAB LRA1 Max** Default Value: 11111b Access: R/W Maximum value of programmable LRA1.
	23:21	**Reserved** Default Value: 000b Access: RO
	20:16	**GAB LRA1 Min** Default Value: 10000b Access: R/W Minimum value of programmable LRA1.
	15:13	**Reserved** Default Value: 000b Access: RO
	12:8	**GAB LRA0 Max** Default Value: 01111b Access: R/W Maximum value of programmable LRA0.
	7:5	**Reserved** Default Value: 000b Access: RO

GAB_LRA_0 - GAB LRA 0

	4:0	**GABLRA0 Min** Default Value: 00000b Access: R/W Minimum value of programmable LRA0.

GAB LRA 1

GAB_LRA_1 - GAB LRA 1

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000001
Size (in bits):	32
Address:	04A74h

DWord	Bit	Description
0	31:4	**Reserved** Default Value: 0000000h Access: RO
	3:2	**BLB** Default Value: 00b Access: R/W Which LRA should BLB use.
	1:0	**BCS** Default Value: 01b Access: R/W Which LRA should BCS use.

GAB unit Control Register

GAB_CTL_REG - GAB unit Control Register

Register Space:	MMIO: 0/2/0
Source:	BlitterCS
Default Value:	0x000000BF
Access:	R/W
Size (in bits):	32
Address:	24000h

DefaultValue=FF0000BFh Trusted Type = 1

DWord	Bit	Description
0	31:9	**Reserved**
	8	**Continue after Page Fault** Value / Name / Description: 1 / GAB Set / Ipon receiving a page fault when requesting an address translation, GAB will set address bit 39 to 1 and continue. 0 / GAB Hang / GAB will hang on a page fault. Default = b0.
	7:6	**PPGTT BCS TLB LRA MIN** Default Value: 10b TLB Depth Partitioning Register In PP GTT Mode.
	5:4	**GAB write request priority signal value used in GAC arbitration** Default Value: 11b
	3:2	**GAB read only request priority signal value used in GAC arbitration** Default Value: 11b
	1:0	**GAB read request priority signal value used in GAC arbitration** Default Value: 11b

GAC_GAM Arbitration Counters Register 0

ARB_GAC_GAM_REQCNTS0 - GAC_GAM Arbitration Counters Register 0

	2:0	**Goto field for entry 6 when request vector is 00b**

GAFS MAX URB READ EVENT

GAFS_MAX_URBRD - GAFS MAX URB READ EVENT		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	00DB4h	
This register mirrors an accumulating count for Unslice FF control It is enabled by configuration bits in GPMunit and SPMunits. Note that count is never cleared and delta should be calculated by sampling the initial register value at the start and subtracting that value off from the final sample value.		
DWord	**Bit**	**Description**
0	31:0	**Unslice FF Event Count** Access: RO

GAM and SA Communication Register

GAMSACOMREG - GAM and SA Communication Register

Register Space:	MMIO: 0/2/0
Default Value:	0x00000000
Size (in bits):	32
Address:	042A0h

DWord	Bit	Description
0	31:16	**Mask Bits** Default Value: 0000h Access: RO Mask Bits act as Write Enables for the bits[15:0] of this register.
	15	**GAM and SA Communication Register 15** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	14	**GAM and SA Communication Register 14** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	13	**GAM and SA Communication Register 13** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	12	**GAM and SA Communication Register 12** Default Value: 0b Access: R/W For Future Use. This bit is self clear.

GAMSACOMREG - GAM and SA Communication Register

	11	**GAM and SA Communication Register 11** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	10	**GAM and SA Communication Register 10** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	9	**GAM and SA Communication Register 9** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	8	**GAM and SA Communication Register 8** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	7	**GAM and SA Communication Register 7** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	6	**GAM and SA Communication Register 6** Default Value: 0b Access: R/W For Future Use. This bit is self clear.

GAMSACOMREG - GAM and SA Communication Register

	5	**GAM and SA Communication Register 5** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	4	**GAM and SA Communication Register 4** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	3	**GAM and SA Communication Register 3** Default Value: 0b Access: R/W For Future Use. This bit is self clear.
	2	**GAM and SA Communication Register 2** Default Value: 0b Access: R/W Bit2 - Root Table Address Update Request. This bit is self clear.
	1	**GAM and SA Communication Register 1** Default Value: 0b Access: R/W Bit1 - Queued Descriptor Request. This bit is self clear.
	0	**GAM and SA Communication Register 0** Default Value: 0b Access: R/W Bit0 - Context Cache Invalidator Request. This bit is self clear.

GAM Context Save

GAM_CTX - GAM Context Save

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Size (in bits):	32
Address:	04FFCh

DWord	Bit	Description
0	31:16	**Mask Bits** Default Value: 0000h Access: RO
	15:2	**Reserved** Default Value: 0000h Access: RO Reserved Bits for future use
	1	**Context Save Start - Chunk2** Default Value: 0b Access: R/W Context Save start for chunk2 Bit[1] Context Save Request start 1'b0 : Context save is not being requested 1'b1 : Context save is being requested When a 1 is written to this bit , with the corresponding mask bit set, it will kick off a context save. Once the save is complete the bit will be cleared. GAMunit on receiving this message sends the Chunk-2 (Cachelines following Chunk1) of context image to CS
	0	**Context Save Start - Chunk1** Default Value: 0b Access: R/W Context Save start for chunk1 Bit[1] Context Save Request start 1'b0 : Context save is not being requested 1'b1 : Context save is being requested When a 1 is written to this bit , with the corresponding mask bit set, it will kick off a context save. Once the save is complete the bit will be cleared. GAMunit on receiving this message sends the Chunk-1 (first 8 Cachelines of its context image) of context image to CS

GAM Context Save Register

GAM_CTX - GAM Context Save Register		
Register Space:	MMIO: 0/2/0	
Source:	RenderCS	
Default Value:	0x00000000	
Access:	RO	
Size (in bits):	32	
Address:	04FFCh	
This register is used to send messages to enable context saving. This register may not be written from CPU. Bits [0] and [1] getting set are mutually exclusive.		
DWord	**Bit**	**Description**
0	31:16	**Masks** Format: Mask[15:0] A 1 in a bit in this field allows the modification of the corresponding bit in bits 15:0.
	15:2	**Reserved** Format: MBZ
	1	**Context Save Start - Chunk2** Format: Enable When a 1 is written to this bit , with the corresponding mask bit set, it will kick off a context save. Once the save is complete the bit will be cleared. GAMunit on receiving this message sends the Chunk-2 (Cachelines following Chunk1) of context image to CS.
	0	**Context Save Start - Chunk1** Format: Enable When a 1 is written to this bit with the corresponding mask bit set, it will kick off a context save. Once the save is complete the bit will be cleared. GAMunit on receiving this message sends the Chunk-1 (first 8 Cachelines of its context image) of context image to CS.

Gam Fub Done1 Lookup Register

DONE1_REG - Gam Fub Done1 Lookup Register		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	0407Ch	
DWord	**Bit**	**Description**
0	31:0	**Gam Fub Done1 Lookup Reg** Default Value: 00000000h Access: RO GAM Done1 signals.

Gam Fub Done Lookup Register

DONE_REG - Gam Fub Done Lookup Register		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	040B0h	
DWord	**Bit**	**Description**
0	31:0	**Gam Fub Done Lookup Reg** Default Value: 00000000h Access: RO 31 CVS Credit Fifo is empty. 30 CVS TLB does not have any cycles. 29 Z Credit fifo is empty. 28 ZTLB does not have any cycles. 27 RCC Credit Fifo is empty. 26 RCC TLB does not have any cycles. 25 L3 Credit fifo is empty. 24 L3 TLB does not have any cycles. 23 VLF Credit fifo is empty. 22 VLF TLB does not have any cycles. 21 CASC Credit fifo empty. 20 CASC TLB does not have any cycles. 19 Miss Fub Done. 18 Read Stream Done. 17 Read Steam Fifo is empty. 16 Recycle Fifo in rstrm is empty. 15 TLB Pend Done. 14 TLB Pend PQ Array is done. 13 TLB pend PB Array is done. 12 Read route fub is done. 11 Gafm Data fifo is empty. 10 GAP data fifo is empty. 9 GAC data fifo is empty. 8 Wrdp is done with all the cycles. 7 Wrdp RID fifo is empty. 6 No hold from midarb to RTSTRM. 5 No hold from TLBPEND to MIDARB. 3 Tied to "1" - to be defined. 2 Fence FSM are IDLE. 1 Non PD Load Done. 0 Tied to "1" - to be defined.

GAMMA_MODE

GAMMA_MODE	
Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	Double Buffered
Size (in bits):	32
Double Buffer Update Point:	Start of vertical blank
Address:	4A480h-4A483h
Name:	Pipe Gamma Mode
ShortName:	GAMMA_MODE_A
Power:	PG1
Reset:	soft
Address:	4AC80h-4AC83h
Name:	Pipe Gamma Mode
ShortName:	GAMMA_MODE_B
Power:	PG2
Reset:	soft
Address:	4B480h-4B483h
Name:	Pipe Gamma Mode
ShortName:	GAMMA_MODE_C
Power:	PG2
Reset:	soft

DWord	Bit	Description	
0	31:16	**Reserved**	
		Format:	MBZ
	15	**Reserved**	
	14:2	**Reserved**	
		Format:	MBZ

GAMMA_MODE

	1:0	**Gamma Mode** This field selects which mode the pipe palette/gamma correction logic works in. Other gamma units, such as in the planes, are unaffected by this bit.

Value	Name	Description
00b	8 bit	8-bit Legacy Palette Mode
01b	10 bit	10-bit Precision Palette Mode
10b	12 bit	12-bit Interpolated Gamma Mode
11b	Split	Split Gamma Mode (separate pipe gamma functions before and after pipe CSC)

GAM Put Delay

GAM_PUT_DLY - GAM Put Delay		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	0401Ch	
Number of clocks to wait between puts		
DWord	**Bit**	**Description**
0	31:0	**GAM PUT DELAY** Default Value: 00000000h Access: R/W

GAMT_DONE Register

GAMT_DONE - GAMT_DONE Register

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Size (in bits):	32
Address:	04AC0h

DWord	Bit	Description
0	31:0	**GAMT_DONE Register** Default Value: 00000000h Access: RO 31: vebxtlb_all_done_f 30: cvstlb_all_done_f 29: ztlb_all_done_f 28: l3tlb_all_done_f 27: rcctlb_all_done_f 26: mfxtlb_all_done_f 25: vlftlb_all_done_f 24: bwgtlb_all_done_f 23: gamwrrb_all_done_f 22: mfxsl1tlb_all_done_f 21: vlfsl1tlb_all_done_f 20: bwgtlb_fifo_empty 19: l3tlb_fifo_empty 18: ztlb_fifo_empty 17: rcctlb_fifo_empty 16: cvstlb_fifo_empty 15: vebxtlb_fifo_empty 14: mfxtlb_fifo_empty 13: mfxsl1tlb_fifo_empty 12: vlfsl1tlb_fifo_empty 11: vlftlb_fifo_empty 10: wrdp_gafm_fifo_empty 9: wrdp_gap_fifo_empty 8: wrdp_gacfg_fifo_empty 7: wrdp_cs_fifo_empty 6: wrdp_vecs_fifo_empty 5: wrdp_oacs_fifo_empty 4: wrdp_gacv_fifo_empty 3: Tied to 1 2: Tied to 1 1: Tied to 1 0: Tied to 1

GAMT_ECO_REG_RO_IA

GAMT_ECO_REG_RO_IA - GAMT_ECO_REG_RO_IA	
Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Size (in bits):	32
Address:	04AB4h

DWord	Bit	Description
0	31:0	**GAMTECO_REG_RO_IA** Default Value: 00000000h Access: RO This register is for ECO usage. RO register with IA Access Type on DEV reset.

GAMT_ECO_REG_RW_IA

GAMT_ECO_REG_RW_IA - GAMT_ECO_REG_RW_IA

Register Space:	MMIO: 0/2/0
Source:	BSpec
	0x0000AB1B
Size (in bits):	32
Address:	04AB0h

Programmable Request Count - VEBX and BLT

DWord	Bit	Description
0	31	**TLBINV_PRESENT_DIS** Default Value: 0b Access: R/W Bit[31] = 0 : Default TLB invalidation of valid and present entries only Bit[31] = 1 : Default TLB invalidation of valid entries (pre SKL C0 behaviour)
	30	**BYPASS_HDC_INV** Default Value: 0b Access: R/W Bit[30] = 0 : Default wait for all the HDC acks before sending the ack to GAMW Bit[30] = 1 : GAMT does not wait for all ACK in case of reset in progress; kill acks cycles coming during the window
	29:0	**GAMTECO_REG_RW_IA** Default Value: 00000000000000101010110001101 1b Access: R/W Bit[29] = 0 : Enables fixes in GACB unit related to TSV usage of flush_start, fifo_empty signals Bit[29] = 1 : Disables fixes in GACB unit related to TSV usage of flush_start, fifo_empty signals Bit[28] = 0 : Enables a fix in GACBH unit related to flush signals Bit[28] = 1 : Disables a fix in GACBH unit related to flush signals Bit[27:26] = Control bits to select address hash modes in GACBH unit 00 : Hash bit = addr_bit[6] 01 : Hash bit = xor (addr_bits[9], addr_bits[6]) 10 : Hash bit = xor (addr_bits[11 : 6]) 11 : Hash bit = xor (addr_bits[20 : 6]) Bit[25] = Reserved Bit[24] = 0 : Enables a fix in GACBH unit related to flush signals Bit[24] = 1 : Disables a fix in GACBH unit related to flush signals Bit[23] = Reserved Bit[22:19] = Reserved Bit[18] = Enable support for In-Place decompresssion feature Bit[17:16] = Reserved. Bit[15:8] = Number of max outstanding cycles (Misses and Hits not present) that can be allowed to potentially fault = 171.

GAMT_ECO_REG_RW_IA - GAMT_ECO_REG_RW_IA		
		Bit[7:6] = Reserved. Bit[5:0] = Number of max outstanding misses that can be allowed to potentially fault = 27.

GAMT Arbiter Mode Control

GAMTARBMODE - GAMT Arbiter Mode Control

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000 [KBL]
Size (in bits):	32
Address:	04A08h

DWord	Bit	Description
0	31:16	**Mask Bits** Default Value: 0000h Access: RO
	15	**GAMT Arbiter Mode Control 15** Default Value: 0b Access: R/W For Future Use
	14	**GAMT Arbiter Mode Control 14** Default Value: 0b Access: R/W 0 - Cache the TLB even if there is a FAULT in GAMW read return. 1 - Don't Cache the TLB if there is a fault in GAMW return.
	13	**GAMT Arbiter Mode Control 13** Default Value: 0b Access: R/W 0 - VEBXTLB clock gate enabled. 1 - VEBXTLB clock gate disabled.
	12	**GAMT Arbiter Mode Control 12** Default Value: 0b Access: R/W 0 - MFXSL1TLB clock gate enabled. 1 - MFXSL1TLB clock gate disabled.
	11	**GAMT Arbiter Mode Control 11** Default Value: 0b Access: R/W 0 - VLFSL1TLB clock gate enabled. 1 - VLFSL1TLB clock gate disabled.

GAMTARBMODE - GAMT Arbiter Mode Control

	10	**GAMT Arbiter Mode Control 10** Default Value: 0b Access: R/W 0 - gamwrrb clock gate enabled. 1 - gamwrrb clock gate disabled.
	9	**GAMT Arbiter Mode Control 9** Default Value: 0b Access: R/W 0 - BWGTLB clock gate enabled. 1 - BWGTLB clock gate disabled.
	8	**GAMT Arbiter Mode Control 8** Default Value: 0b Access: R/W 0 - VLFTLB clock gate enabled. 1 - VLFTLB clock gate disabled.
	7	**GAMT Arbiter Mode Control 7** Default Value: 0b Access: R/W 0 - MFXTLB clock gate enabled. 1 - MFXTLB clock gate disabled.
	6	**GAMT Arbiter Mode Control 6** Default Value: 0b Access: R/W 0 - RCCTLB clock gate enabled. 1 - RCCTLB clock gate disabled.
	5	**GAMT Arbiter Mode Control 5** Default Value: 0b Access: R/W 0 - L3TLB clock gate enabled. 1 - L3TLB clock gate disabled. To update bit 5, a value of 0x00200020 needs to be written.

GAMTARBMODE - GAMT Arbiter Mode Control

	4	**GAMT Arbiter Mode Control 4** Default Value: 0b Access: R/W 0 - ZTLB clock gate enabled. 1 - ZTLB clock gate disabled.
	3	**GAMT Arbiter Mode Control 3** Default Value: 0b Access: R/W 0 - CVS clock gate enabled. 1 - CVS clock gate disabled.
	2	**GAMT Arbiter Mode Control 2** Default Value: 0b Access: R/W 0 - No reg_hdc_inval_ack_force - take the value from client. 1 - reg_hdc_inval_ack_force - force value to 1 - disregard client value.
	1	**GAMT Arbiter Mode Control 1** Default Value: 0b Access: R/W Bit [1]: Address Swizzling for Tiled Surfaces. This register location is updated via GFX Driver prior to enabling DRAM accesses. Driver needs to obtain the need for memory address swizzling via DRAM configuration registers and set the following bits (in Display Engine and Render/Media access streams). 0: No address Swizzling. 1: Address bit[1] needs to be swizzled for tiled surfaces.
	0	**GAMT Arbiter Mode Control 0** Default Value: 0b Access: R/W Bit[0]: GAM to Bypass GTT Translation. GAM to Bypass GTT Translation and pass logical addresses through with 0's padded on the MSBs to form the Physical Address.

GAM Virtualization Enable Register

GAM_VFX_EN - GAM Virtualization Enable Register

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Size (in bits):	32
Address:	041FCh

This register enables virtualization for GAM

DWord	Bit	Description
0	31:1	**Extra Bits** Default Value: 00000000h Access: R/W Reserved for future use
	0	**Virtualization Enable** Default Value: 0b Access: R/W 1'b0 -- Virtualization is not enabled 1'b1 -- Virtualization is enabled

GAMW_ECO_BUS_RO_IA

GAMW_ECO_BUS_RO_IA - GAMW_ECO_BUS_RO_IA		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	0408Ch	
DWord	**Bit**	**Description**
0	31:0	**GAMWECO_BUS_RO_IA** Default Value: 00000000h Access: RO This register is for ECO usage. RO register with IA Access Type on BUS reset.

GAMW_ECO_BUS_RW_IA

GAMW_ECO_BUS_RW_IA - GAMW_ECO_BUS_RW_IA		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	04084h	
DWord	**Bit**	**Description**
0	31:0	**GAMWECO_BUS_RW_IA** Default Value: 00000000h Access: R/W This register is for ECO usage. RW register with IA Access Type on BUS reset.

GAMW_ECO_DEV_RO_IA

GAMW_ECO_DEV_RO_IA - GAMW_ECO_DEV_RO_IA		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	04088h	
DWord	**Bit**	**Description**
0	31:0	**GAMWECO_DEV_RO_IA** Default Value: 00000000h Access: RO This register is for ECO usage. RO register with IA Access Type on DEV reset.

GAMW_ECO_DEV_RW_IA

GAMW_ECO_DEV_RW_IA - GAMW_ECO_DEV_RW_IA		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	04080h	
DWord	**Bit**	**Description**
0	31:0	**GAMWECO_DEV_RW_IA** Default Value: 00000000h Access: R/W This register is for ECO usage. RW register with IA Access Type on DEV reset.

GAMW Power Context Save

PWRCTXSAVE - GAMW Power Context Save

Register Space:	MMIO: 0/2/0
Default Value:	0x00000000
Size (in bits):	32
Address:	04000h

DWord	Bit	Description
0	31:16	**Mask Bits** Default Value: 0000h Access: RO Mask Bits act as Write Enables for the bits[15:0] of this register.
	15	**Extra Bits15** Default Value: 0b Access: R/W Extra Bits for future use.
	14	**Extra Bits14** Default Value: 0b Access: R/W Extra Bits for future use.
	13	**Extra Bits13** Default Value: 0b Access: R/W Extra Bits for future use.
	12	**Extra Bits12** Default Value: 0b Access: R/W Extra Bits for future use.
	11	**Extra Bits11** Default Value: 0b Access: R/W Extra Bits for future use.

PWRCTXSAVE - GAMW Power Context Save

	10	**Extra Bits10** Default Value: 0b Access: R/W Extra Bits for future use.
	9	**Power Context Save Request** Default Value: 0b Access: R/W Power Context Save Bit[9] Power Context Save Request 1'b0: Power context save is not being requested (default). 1'b1: Power context save is being requested. Unit needs to self-clear this bit upon sampling. This bit is self clear.
	8:0	**Power Context Save Quad Word Credits** Default Value: 000000000b Access: R/W Power Context Save Bits[8:0] QWord Credits for Power Context Save Request An initial length packet is required per power context save session, but that packet does not consume a credit. See protocol description for more details. Minimum Credits = 1: Unit may send 1 QWord pair. Maximum Credits = 511: Unit may send 511 QWord pairs. A QWord pair is defined as a 32-bit register address and the corresponding 32-bits of register data. Only valid with PWRCTX_SAVE_REQ (Bit9).

Gather Constants Not Consumed By RCS

GATHER_CONST_PRODUCE_COUNT - Gather Constants Not Consumed By RCS

Register Space:	MMIO: 0/2/0
Source:	RenderCS
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Trusted Type:	1
Address:	0248Ch

This register keeps track of the outstanding Gather Constants produced by RS which are not yet consumed by Render Command Streamer. This register is part of the render context save and restore. This register should not be programmed by SW.

DWord	Bit	Description
0	31:0	**Gather Constants Produce Count** This register keeps track of the outstanding Gather Constants produced by RS which are not yet consumed by Render Command Streamer. This register is part of the render context save and restore.

GDR Per Client Write Drop Enables

WR_DROP_MODE - GDR Per Client Write Drop Enables

Register Space:	MMIO: 0/2/0
Default Value:	0x00000000
Size (in bits):	32
Address:	040B4h

DWord	Bit	Description
0	31:0	**GDR Per Client Write Drop Enables** Default Value: 00000000h Access: R/W 31 RSVD: Future use. 30 MBC write drop disable (0) or enable (1). 29 CS write drop disable (0) or enable (1). 28 SOL write drop disable (0) or enable (1). 27 RS write drop disable (0) or enable (1). 26 RCC write drop disable (0) or enable (1). 25 MSC write drop disable (0) or enable (1). 24 All L3 clients write drop disable (0) or enable (1). 23 STC write drop disable (0) or enable (1). 22 HIZ write drop disable (0) or enable (1). 21 RCZ write drop disable (0) or enable (1). 20 GAFS write drop disable (0) or enable (1). 19 GPM write drop disable (0) or enable (1). 18 GCP write drop disable (0) or enable (1). 17 VCS write drop disable (0) or enable (1). 16 BSP write drop disable (0) or enable (1). 15 VCR write drop disable (0) or enable (1). 14 VMX_RS write drop disable (0) or enable (1). 13 VMX_BS write drop disable (0) or enable (1). 12 VMX_RA write drop disable (0) or enable (1). 11 VMX_VDS write drop disable (0) or enable (1). 10 VLF_RS write drop disable (0) or enable (1). 9 VLF_FW write drop disable (0) or enable (1). 8 VECS write drop disable (0) or enable (1). 7 VEO write drop disable (0) or enable (1). 5 uC (DMA) write drop disable (0) or enable (1). 4 BCS write drop disable (0) or enable (1). 3 BLB write drop disable (0) or enable (1). 2 W_BSP write drop disable (0) or enable (1). 1 W_VMX_RS write drop disable (0) or enable (1). 0 W_VMX_BS write drop disable (0) or enable (1).

GDR Per Client Write Drop Enables-2

WR_DROP_MODE2 - GDR Per Client Write Drop Enables-2		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	040B8h	
DWord	**Bit**	**Description**
0	31:0	**GDR Per Client Write Drop Enables-2** Default Value: 00000000h Access: R/W 31:23 RSVD: Future use. 22 BLB2 write drop disable (0) or enable (1). 21 HLF_FW write drop disable (0) or enable (1). 20 HLF_RS write drop disable (0) or enable (1). 19 HPP write drop disable (0) or enable (1). 18 HUC_DMA write drop disable (0) or enable (1). 17 HHI_IndirectHeader write drop disable (0) or enable (1). 16 HHI_Streamout write drop disable (0) or enable (1). 15 HHI_Bitstream write drop disable (0) or enable (1). 14 MFL_VLF_FW write drop disable (0) or enable (1). 13 MFL_VLF_RS write drop disable (0) or enable (1). 12 MFL_VMX_RA write drop disable (0) or enable (1). 11 MFL_VMX_RS write drop disable (0) or enable (1). 10 VD_ENC_SO write drop disable (0) or enable (1). 9 VD_ENC_RS write drop disable (0) or enable (1). 8 SFC_FW_VE write drop disable (0) or enable (1). 7 SFC_LB_VE write drop disable (0) or enable (1). 6 SFC_FW_VD write drop disable (0) or enable (1). 5 SFC_LB_VD write drop disable (0) or enable (1). 4 VOP write drop disable (0) or enable (1). 3 VDS write drop disable (0) or enable (1). 2 OA write drop disable (0) or enable (1). 1 VFE write drop disable (0) or enable (1). 0 VF write drop disable (0) or enable (1).

GDR Write Drop

GDR_WR_DRP - GDR Write Drop		
Register Space:	MMIO: 0/2/0	
Default Value:	0x80000000	
Size (in bits):	32	
Address:	04020h	

DWord	Bit	Description
0	31:0	**GDR_WRITE_DROP** Access: R/W Value: 80000000h — Name: **[Default]**

General Purpose Register

CS_GPR - General Purpose Register

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000, 0x00000000
Access:	R/W
Size (in bits):	1024
Address:	02600h-0267Fh
Name:	General Purpose Register
ShortName:	CS_GPR_RCSUNIT
Address:	12600h-1267Fh
Name:	General Purpose Register
ShortName:	CS_GPR_VCSUNIT0
Address:	1A600h-1A67Fh
Name:	General Purpose Register

GFX Arbiter Client Priority Control

GFX_PRIO_CTRL - GFX Arbiter Client Priority Control

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x880A2D10
Size (in bits):	32
Address:	04A00h

DWord	Bit	Description
0	31:27	**Read Rstrm Max Reject** Default Value: 10001b Access: R/W
	26:21	**Extra Bits** Default Value: 000000b Access: R/W
	20:18	**sol_gam_priority** Default Value: 010b Access: R/W Client Priority Control Bits - Lowest Bit [18] is NOT Used.
	17:15	**veo_gam_priority** Default Value: 100b Access: R/W Client Priority Control Bits - Lowest Bit [15] is NOT Used.
	14:12	**vfw_gam_priority** Default Value: 010b Access: R/W Client Priority Control Bits - Lowest Bit [12] is NOT Used.
	11:9	**gapc_gam_c_priority** Default Value: 110b Access: R/W Client Priority Control Bits - Lowest Bit [9] is NOT Used.
	8:6	**gapc_gam_z_priority** Default Value: 100b Access: R/W Client Priority Control Bits - Lowest Bit [6] is NOT Used.

GFX_PRIO_CTRL - GFX Arbiter Client Priority Control

	5:3	**gapc_gam_l3_priority** Default Value: 010b Access: R/W Client Priority Control Bits - Lowest Bit [3] is NOT Used.
	2:0	**csrsvf_gam_priority** Default Value: 000b Access: R/W Client Priority Control Bits - Lowest Bit [0] is NOT Used.

GFX Context Element Descriptor (High Part)

GFX_CTX_EDR_H - GFX Context Element Descriptor (High Part)		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	04404h	
DWord	**Bit**	**Description**
0	31:0	**GFX Context Element Descriptor (High Part)** Default Value: 00000000h Access: R/W Bit[63:32] - Context ID: Context identification number assigned to separate this context from others. Context IDs need to be recycled in such a way that there cannot be two active contexts with the same ID. This is a unique identification number by which a context is identified and referenced.

GFX Context Element Descriptor (Low Part)

GFX_CTX_EDR_L - GFX Context Element Descriptor (Low Part)

Register Space:	MMIO: 0/2/0
Default Value:	0x00000009
Size (in bits):	32
Address:	04400h

DWord	Bit	Description
0	31:0	**GFX Context Element Descriptor (Low Part)** Default Value: 00000009h Access: R/W Bit[31:12] - LRCA: Command Streamer Only. Bit[8] - Privileged Context / GGTT vs PPGTT mode: Differs in legacy vs advanced context modes: In Legacy Context: Defines the page tables to be used. This is how page walker comes to know PPGTT vs GGTT selection for the entire context. 0: Use Global GTT. 1: Use Per-Process GTT. In Advanced Context: Defines the privilege level for the context. 0: User mode context. 1: Supervisor mode context. Bit[5] - Deeper IA coherency Support: In Advanced Context: Defines the level of IA coherency. 0: IA coherency is provided at LLC level for all streams of GPU (i.e. Gen7.5 like mode). 1: IA coherency is provided at L3 level for EU data accesses of GPU. Bit[4] - A and D Support / 32 and 64b Address Support: Differs in legacy vs advanced context modes: In Legacy Context: Defines 32b vs 64b (48b canonical) addressing format: 0: 32b addressing format. 1: 64b (48b canonical) addressing format. In Advanced Context: Defines A and D bit support: 0: A and D bit management in page tables is NOT supported. 1: A and D bit management in page tables is supported. Bit[3] - Context Type: Legacy vs Advanced: Defines the context type 0: Advanced Context: Defines the rest of the advanced capabilities (i.e. OS page table support, fault models). Note that advanced context is not bounded to GPGPU. 1: Legacy Context: Defines the context as legacy mode which is similar to prior generations of Gen8. Note that: Bits [8:4] differs in functions when legacy vs advanced context modes are selected. Bit[2] - FR: Command streamer specific.

GFX_CTX_EDR_L - GFX Context Element Descriptor (Low Part)		
		Bit[1] - Scheduling Mode: 1: Indicates execlist mode of scheduling. 0: Indicates Ring Buffer mode of scheduling. Bit[0] - Valid: Indicates that element descriptor is valid. If GAM is programmed with an invalid descriptor, it continues but flags an error.

GFX Fault Counter

GFX_FAULT_CNTR - GFX Fault Counter

Register Space:	MMIO: 0/2/0
Default Value:	0x00000000
Size (in bits):	32
Address:	045A0h

DWord	Bit	Description
0	31:0	**GFX Fault Counter** Default Value: 00000000h Access: RO This counter only applies to advance context when fault and stream mode is selected.

GFX Fixed Counter

GFX_FIXED_CNTR - GFX Fixed Counter		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	045A4h	
DWord	**Bit**	**Description**
0	31:0	**GFX Fixed Counter** Default Value: 00000000h Access: RO This counter only applies to advance context when fault and stream mode is selected.

GFX PDP0/PML4/PASID Descriptor (High Part)

GFX_CTX_PDP0_H - GFX PDP0/PML4/PASID Descriptor (High Part)

Register Space:	MMIO: 0/2/0
Default Value:	0x00000000
Size (in bits):	32
Address:	0440Ch

DWord	Bit	Description
0	31:0	**GFX PDP0/PML4/PASID Descriptor (High Part)** Default Value: 00000000h Access: R/W PDP0/PML4/PASID: This register can contain three values which depend on the element descriptor definition. PASID[19:0]: Populated in the first 20bits of the register and selected when Advanced Context flag is set. PML4[38:12]: Pointer to base address of PML4 and selected when Legacy Context flag is set and 64b address support is selected. PDP0[38:12]: Pointer to one of the four page directory pointer (lowest) and defines the first 0-1GB of memory mapping. Note: This is a guest physical address.

GFX PDP0/PML4/PASID Descriptor (Low Part)

GFX_CTX_PDP0_L - GFX PDP0/PML4/PASID Descriptor (Low Part)

Register Space:	MMIO: 0/2/0
Default Value:	0x00000000
Size (in bits):	32
Address:	04408h

DWord	Bit	Description
0	31:0	**GFX PDP0/PML4/PASID Descriptor (Low Part)** Default Value: 00000000h Access: R/W PDP0/PML4/PASID: This register can contain three values which depend on the element descriptor definition. PASID[19:0]: Populated in the first 20 bits of the register and selected when Advanced Context flag is set. PML4[38:12]: Pointer to base address of PML4 and selected when Legacy Context flag is set and 64b address support is selected. PDP0[38:12]: Pointer to one of the four page directory pointer (lowest) and defines the first 0-1GB of memory mapping. Note: This is a guest physical address.

GFX PDP1 Descriptor Register (High Part)

GFX_CTX_PDP1_H - GFX PDP1 Descriptor Register (High Part)		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	04414h	
DWord	**Bit**	**Description**
0	31:0	**GFX PDP1 Descriptor Register (High Part)** Default Value: 00000000h Access: R/W Pointer to one of the four page directory pointer (lowest+1) and defines the first 1-2GB of memory mapping. Note: This is a guest physical address.

GFX PDP1 Descriptor Register (Low Part)

GFX_CTX_PDP1_L - GFX PDP1 Descriptor Register (Low Part)		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	04410h	
DWord	**Bit**	**Description**
0	31:0	**GFX PDP1 Descriptor Register (Low Part)** Default Value: 00000000h Access: R/W Pointer to one of the four page directory pointer (lowest+1) and defines the first 1-2GB of memory mapping. Note: This is a guest physical address.

GFX PDP2 Descriptor Register (High Part)

GFX_CTX_PDP2_H - GFX PDP2 Descriptor Register (High Part)		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	0441Ch	
DWord	**Bit**	**Description**
0	31:0	**GFX PDP2 Descriptor Register (High Part)** Default Value: 00000000h Access: R/W Pointer to one of the four page directory pointer (lowest+2) and defines the first 2-3GB of memory mapping. Note: This is a guest physical address.

GFX PDP2 Descriptor Register (Low Part)

GFX_CTX_PDP2_L - GFX PDP2 Descriptor Register (Low Part)		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	04418h	
DWord	**Bit**	**Description**
0	31:0	**GFX PDP2 Descriptor Register (Low Part)** Default Value: 00000000h Access: R/W Pointer to one of the four page directory pointer (lowest+2) and defines the first 2-3GB of memory mapping. Note: This is a guest physical address.

GFX PDP3 Descriptor Register (High Part)

GFX_CTX_PDP3_H - GFX PDP3 Descriptor Register (High Part)		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	04424h	
DWord	**Bit**	**Description**
0	31:0	**GFX PDP3 Descriptor Register (High Part)** Default Value: 00000000h Access: R/W Pointer to one of the four page directory pointer (lowest+3) and defines the first 3-4GB of memory mapping. Note: This is a guest physical address.

GFX PDP3 Descriptor Register (Low Part)

GFX_CTX_PDP3_L - GFX PDP3 Descriptor Register (Low Part)		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	04420h	
DWord	**Bit**	**Description**
0	31:0	**GFX PDP3 Descriptor Register (Low Part)** Default Value: 00000000h Access: R/W Pointer to one of the four page directory pointer (lowest+3) and defines the first 3-4GB of memory mapping. Note: This is a guest physical address.

Global Invalidation Register

GLBLINVL - Global Invalidation Register		
Register Space:	MMIO: 0/2/0	
Source:	BSpec	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	0B404h	
DWord	**Bit**	**Description**
0	31:10	**Reserved** Access: RO Reserved.
	9:3	**Reserved**
	2	**Cross sync read disable** Access: R/W Ipconf_crs_sync_dis: Cross Sync Read Disable (CSRD). Cross Sync Read Disable (CSRD): Cross Sync Read Disable: upon a SYNC from HDC, follow with a write to cross SYNC Push and read to the same address. When set read is disabled. This bit needs to be programmed to 1 to disable fence operation for GSYNC. This is a workaround for GSYNC fence cycle encountering page fault.
	1	**Disables hashing function** Access: R/W Disables hashing function (DISHHF): Disables hashing function to generate bank_id[1:0] for L3$ bank accessing, and forces the use of address[7:6] for bank_id[1:0]. 0: (default) Hash function enabled to generate L3$ bank IDs. 1: L3$ address[7:6] used as L3$ bank IDs. Ipconf_csr_l3bankidhashdis. (This bit needs to set corresponding bit lncf_csr_l3bankidhashdis in LNCF.)
	0	**Reserved**

Global System Interrupt Routine

EU_GLOBAL_SIP - Global System Interrupt Routine

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	0E42Ch

DWord	Bit	Description
0	31:3	**Global SIP** Format: GraphicsAddress[31:3] Specifies the base address for System Interrupt Routine that over-rides the SIP set by the state (STATE_SIP).
	2:1	**Reserved** Format: PBC
	0	**Global SIP Enable** The bit specifies if the System Routine starts from the Global SIP provided by the DW OR the SIP provided by the state (STATE_SIP) Value / Name: 0 – SIP used is from STATE_EIP 1 – SIP used is from MMIO register

GMBUS0

GMBUS0

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32

Address:	C5100h-C5103h
Name:	GMBUS0 Clock/Port Select
ShortName:	GMBUS0
Power:	Always on
Reset:	soft

This register controls the clock rate of the serial bus and the device the controller is connected to.
This register should be configured before the first data valid bit is set.

DWord	Bit	Description
0	31:12	**Reserved** Format: MBZ
	11	**Reserved**
	10:8	**GMBUS Rate Select** This field selects the rate that the GMBUS will run at. It also defines the AC timing parameters used. Value / Name: 000b: 100 KHz 001b: 50 KHz Others: Reserved **Restriction** Restriction : It should only be changed between transfers when the GMBUS is idle.
	7	**Reserved** Format: MBZ
	6	**Byte Count Override** **Description** This field overrides the byte count to allow burst reads of greater than 511 bytes. See the GMBUS and GPIO page for programming instructions. Field not valid until KBLPCH-H A0, SPT-LP D1, SPT-H E1

GMBUS0

		Value / **Name** 0b / Disable 1b / Enable
	5	**Reserved** Format: MBZ
	4:3	**Reserved** Format: MBZ
	2:0	**Pin Pair Select** This field selects a GMBUS pin pair for use in the GMBUS communication. See the table of GPIO Pin Usages to determine which pin pairs are supported and their intended functions.

Value	Name
000b	None (Disabled)
100b	DDIC
101b	DDIB
110b	DDID

GMBUS1

GMBUS1

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	R/W Protect
Size (in bits):	32
Address:	C5104h-C5107h
Name:	GMBUS1 Command/Status
ShortName:	GMBUS1
Power:	Always on
Reset:	soft

This register lets the software indicate to the GMBUS controller the slave device address, register index, and indicate when the data write is complete.
When the SW_CLR_INT bit is asserted, all writes to the GMBUS2, GMBUS3, and GMBUS4 registers are discarded. The GMBUS1 register writes to any other bit except the SW_CLR_INT are also lost.
Reads to these registers always work normally regardless of the state of the SW_CLR_INT bit.

DWord	Bit	Description
0	31	**Software Clear Interrupt** Access: R/W (SW_CLR_INT) This bit must be clear for normal operation. Setting the bit then clearing it acts as local reset to the GMBUS controller. This bit is commonly used by software to clear a BUS_ERROR when a slave device delivers a NACK. **Value / Name / Description** 0b / Clear HW_RDY / If this bit is written as a zero when its current state is a one, will clear the HW_RDY bit and allows register writes to be accepted to the GMBUS registers (Write Protect Off). This bit is cleared to zero when an event causes the HW_RDY bit transition to occur. 1b / Assert HW_RDY / Asserted by software after servicing the GMBUS interrupt. Setting this bit causes the INT status bit to be cleared. Setting (1) this bit also asserts the HW_RDY bit (until this bit is written with a 0). When this bit is set, no writes to GMBUS registers will cause the contents to change with the exception of this bit which can be written.
	30	**Software Ready** (SW_RDY) Data handshake bit used in conjunction with HW_RDY bit. **Value / Name / Description** 0b / De-Assert / De-asserted via the assertion event for HW_RDY bit

GMBUS1

1b	SW Assert	When asserted by software, results in de-assertion of HW_RDY bit

29 Enable Timeout

(ENT) Enables timeout for slave response.

When this bit is enabled and the slave device response has exceeded the timeout period, the GMBUS Slave Stall Timeout Error interrupt bit is set.

Value	Name
0b	Disable
1b	Enable

28 Reserved

Format:	MBZ

27:25 Bus Cycle Select

GMBUS cycle will always consist of a START followed by Slave Address, followed by an optional read or write data phase. A read cycle with an index will consist of a START followed by a Slave Address a WRITE indication and the INDEX and then a RESTART with a Slave Address and an optional read data phase. The GMBUS cycle will terminate either with a STOP or by entering a wait state. The WAIT state is exited by generating a STOP or by starting another GMBUS cycle. This can only cause a STOP to be generated if a GMBUS cycle is generated, the GMBUS is currently in a data phase, or it is in a WAIT phase.

The three bits can be decoded as follows:

27 = STOP generated

26 = INDEX used

25 = Cycle ends in a WAIT

Value	Name	Description
000b	No cycle	No GMBUS cycle is generated
001b	No Index, No Stop, Wait	GMBUS cycle is generated without an INDEX, with no STOP, and ends with a WAIT
010b	Reserved	Reserved
011b	Index, No Stop, Wait	GMBUS cycle is generated with an INDEX, with no STOP, and ends with a WAIT
100b	Gen Stop	Generates a STOP if currently in a WAIT or after the completion of the current byte if active
101b	No Index, Stop	GMBUS cycle is generated without an INDEX and with a STOP
110b	Reserved	Reserved
111b	Index, Stop	GMBUS cycle is generated with an INDEX and with a STOP

24:16 Total Byte Count

This determines the total number of bytes to be transferred during the DATA phase of a GMBUS cycle.

The DATA phase can be prematurely terminated by generating a STOP while in the DATA phase (see Bus Cycle Select).

Restriction

GMBUS1

		Restriction : Do not change the value of this field during GMBUS cycles transactions. The byte count must not be zero.
	15:8	**8 bit Slave Register Index** (INDEX) This field specifies the 8-bits of index to be used for the generated bus write transaction or the index used for the WRITE portion of the WRITE/READ pair. It only has an effect if the enable Index bit is set. **Restriction** Restriction : Do not change the value of this field during GMBUS cycles transactions.
	7:0	**Slave Address And Direction** Bits 7:1 = 7-bit GMBUS Slave Address (SADDR): When a GMBUS cycle is to be generated using the Bus Cycle Select field, this field specifies the value of the slave address that is to be sent out. For use with 10-bit slave address devices, set this value to 11110XXb (where the last two bits (XX) are the two MSBs of the 10-bit address) and the slave direction bit to a write. This is followed by the first data byte being the 8 LSBs of the 10-bit slave address. Bit 0 = Slave Direction Bit: When a GMBUS cycle is to be generated based on the Bus Cycle Select, this bit determines if the operation will be a read or a write. A read operation with the index enabled will perform a write with just the index followed by a re-start and a read. A 1 indicates that a Read from the slave device operation is to be performed. A 0 indicates that a Write to the slave device operation is to be performed.

Value	Name
00000001b	General Call Address
00000000b	Start Byte
0000001Xb	CBUS Address
11110XXXb	10-Bit Addressing
Others	Reserved

GMBUS2

GMBUS2

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000800
Access:	R/W Protect
Size (in bits):	32
Address:	C5108h-C510Bh
Name:	GMBUS2 Status
ShortName:	GMBUS2
Power:	Always on
Reset:	soft

When the SW_CLR_INT bit is asserted, all writes to this registet are discarded. Reads to this register always work normally regardless of the state of the SW_CLR_INT bit.

DWord	Bit	Description
0	31:16	**Reserved** Format: MBZ
	15	**INUSE** Software wishing to arbitrate for the GMBUS resource can poll this bit until it reads a zero and will then own usage of the GMBUS controller. This bit has no effect on the hardware, and is only used as semaphore among various independent software threads. Writing a one to this bit is software's indication that the software use of this resource is now terminated and it is available for other clients.
	14	**Hardware Wait Phase** Access: RO Once in a WAIT_PHASE, the software can now choose to generate a STOP cycle or a repeated start (RESTART) cycle followed by another GMBUS transaction. Wait phase is entered at the end of the current transaction when that transaction is selected not to terminate with a STOP.

Value	Name	Description
0b	GMBUS is Acquired	Read operation that contains a zero in this bit position indicates that the GMBUS engine is now acquired and the subsequent reads of this register will now have this bit set. Writing a 0 to this bit has no effect.
1b	GMBUS in Use	Read operation that contains a one for this bit indicates that the GMBUS is currently allocated to someone else and "In use". Once set, a write of a 1 to this bit indicates that the software has relinquished the GMBUS resource and will reset the value of this bit to a 0.

GMBUS2

Value	Name
0b	Not in a wait phase
1b	In wait phase

13 **Slave Stall Timeout Error**

Access:	RO

This bit indicates that a slave stall timeout has occurred. It is tied to the Enable Timeout (ENT) bit.

Value	Name
0b	No Slave Timeout
1b	Slave Timeout

12 **GMBUS Interrupt Status**

Access:	RO

This bit indicates that an event that causes a GMBUS interrupt has occurred. The interrupt can be caused by one of the interrupt types enabled in the GMBUS4 register

Value	Name
0b	No Interrupt
1b	Interrupt

11 **Hardware Ready**

Access:	RO

(HW_RDY) This provides a method of detecting when the current software client routine can proceed with the next step in a sequence of GMBUS operations.
This data handshake bit is used in conjunction with the SW_RDY bit.
When this bit is asserted by the GMBUS controller, it results in the de-assertion of the SW_RDY bit.
This bit resumes to normal operation when the SW_CLR_INT bit is written to a 0.

Value	Name	Description
0b	0	Condition required for assertion has not occurred or when this bit is a one and: - SW_RDY bit has been asserted - During a GMBUS read transaction, after the each read of the data register - During a GMBUS write transaction, after each write of the data register - SW_CLR_INT bit has been cleared
1b	1 **[Default]**	This bit is asserted under the following conditions: - After a reset or when the transaction is aborted by the setting of the SW_CLR_INT bit - When an active GMBUS cycle has terminated with a STOP - When during a GMBUS write transaction, the data register needs and can accept another four bytes of data - During a GMBUS read transaction, this bit is asserted when the data register has four bytes of new data or the read transaction DATA phase is

GMBUS2

		complete and the data register contains the last few bytes of the read data

10 NAK Indicator

Access:	RO

MAK is indicated by hardware if any expected device acknowledge is not received from the slave within the timeout.

Value	Name
0b	No bus error
1b	NAK occurred

9 GMBUS Active

Access:	RO

(GA) This is a status bit that indicates whether the GMBUS controller is in an IDLE state or not. Active states are the START, ADDRESS, INDEX, DATA, WAIT, or STOP Phase.

Value	Name
0b	Idle
1b	Active

8:0 Current Byte Count

Access:	RO

Can be used to determine the number of bytes currently transmitted/received by the GMBUS controller hardware.

Hardware sets it to zero at the start of a GMBUS transaction data transfer and incremented after the completion of each byte of the data phase.

Note that because reads have internal storage, the byte count on a read operation may be ahead of the data that has been accepted from the data register.

GMBUS3

GMBUS3	
Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	R/W Protect
Size (in bits):	32
Double Buffer Update Point:	HW_RDY
Address:	C510Ch-C510Fh
Name:	GMBUS3 Data Buffer
ShortName:	GMBUS3
Power:	Always on
Reset:	soft

This is the data read/write register. This register is double buffered.
Bit 0 is the first bit sent or read, bit 7 is the 8th bit sent or read, all the way through bit 31 being the 32nd bit sent or read.
For GMBUS write operations with a non-zero byte count, this register should be written with the data before the GMBUS cycle is initiated.
For byte counts that are greater than four bytes, this register will be written with subsequent data only after the HW_RDY status bit is set indicating that the register is now ready for additional data.
For GMBUS read operations, software should wait until the HW_RDY bit indicates that the register contains the next set of valid read data before reading this register.
When the SW_CLR_INT bit is asserted, all writes to this registet are discarded. Reads to this register always work normally regardless of the state of the SW_CLR_INT bit.

DWord	Bit	Description
0	31:24	**Data Byte 3**
	23:16	**Data Byte 2**
	15:8	**Data Byte 1**
	7:0	**Data Byte 0**

GMBUS4

GMBUS4	
Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	R/W Protect
Size (in bits):	32
Address:	C5110h-C5113h
Name:	GMBUS4 Interrupt Mask
ShortName:	GMBUS4
Power:	Always on
Reset:	soft

When the SW_CLR_INT bit is asserted, all writes to this registet are discarded. Reads to this register always work normally regardless of the state of the SW_CLR_INT bit.

DWord	Bit	Description
0	31:5	**Reserved** Format: MBZ
	4:0	**Interrupt Mask** This field specifies which GMBUS interrupts events may contribute to the setting of GMBUS interrupt status bit in the second level interrupt status register. For writes, the HW Ready (HWRDY) interrupt indicates that software can write the next DWORD. It does NOT mean that the transfer of data to the slave device has completed. The IDLE or HW wait interrupt may be used to detect the end of writing data to the slave device. The HWRDY interrupt may be used for gmbus write cycles only to detect when to write the next DWORD after the first two DWORDs have been written to GMBUS3. For reads, the HWRDY interrupt indicates the arrival of the next dword.

Value	Name
0XXXXb	Slave Stall Timeout Interrupt Disable
1XXXXb	Slave Stall Timeout Interrupt Enable
X0XXXb	NAK Interrupt Disable
X1XXXb	NAK Interrupt Enable
XX0XXb	Idle Interrupt Disable
XX1XXb	Idle Interrupt Enable
XXX0Xb	HW Wait Interrupt (cycle without a stop has completed) Disable
XXX1Xb	W Wait Interrupt (cycle without a stop has completed) Enable
XXXX0b	HW Ready (Data transferred) Interrupt Disable
XXXX1b	HW Ready (Data transferred) Interrupt Enable

GMBUS5

GMBUS5		
Register Space:	MMIO: 0/2/0	
Source:	BSpec	
Default Value:	0x00000000	
Access:	R/W	
Size (in bits):	32	
Address:	C5120h-C5123h	
Name:	GMBUS5 2 Byte Index	
ShortName:	GMBUS5	
Power:	Always on	
Reset:	soft	
This register provides a method for the software indicate to the GMBUS controller the 2 byte device index.		
DWord	**Bit**	**Description**
0	31	**2 Byte Index Enable** When this bit is asserted (1), then bits 15:0 are used as the index. Bits 15:8 are used in the first byte which is the most significant index bits. The slave index in the GMBUS1<15:8> are ignored. Bits 7:0 are used in the second byte which is the least significant index bits.
	30:16	**Reserved** Format: MBZ
	15:0	**2 Byte Slave Index** This is the 2 byte index used in all GMBUS accesses when bit 31 is asserted (1).

GMCH Graphics Control

GGC_0_0_0_PCI - GMCH Graphics Control

Register Space:	PCI: 0/0/0
Source:	BSpec
Default Value:	0x00000500
Size (in bits):	16
Address:	00050h

All the bits in this register are LT lockable.

DWord	Bit	Description
0	15:8	**Graphics Mode Select** Default Value: 00000101b Access: R/W Lock This field is used to select the amount of Main Memory that is pre-allocated to support the Internal Graphics device in VGA (non-linear) and Native (linear) modes. The BIOS ensures that memory is pre-allocated only when Internal graphics is enabled. Hardware does not clear or set any of these bits automatically based on IGD being disabled/enabled. BIOS Requirement: BIOS must not set this field to 0h if IVD (bit 1 of this register) is 0. BIOS Requirement: Given new sizes allow down to 8MB allocation, BIOS has to ensure there is sufficient space for WOPCM and basic GFX Stolen functions. 00h:0MB 01h:32MB 02h:64MB 03h:96MB 04h:128MB 05h:160MB (default) 06h:192MB 07h:224MB 08h:256MB 09h:288MB 0Ah:320MB 0Bh:352MB 0Ch:384MB 0Dh:416MB 0Eh:448MB 0Fh:480MB 10h:512MB 11h - 1Fh: Reserved 20h:1024MB 21h - 2Fh: Reserved 30h:1536MB 31h - 3Fh: Reserved 40h: 2048MB

GGC_0_0_0_PCI - GMCH Graphics Control

		41h - EFh: Reserved F0h: 4MB F1h: 8MB F2h: 12MB F3h: 16MB F4h: 20MB F5h: 24MB F6h: 28MB F7h: 32MB F8h: 36MB F9h: 40MB FAh: 44MB FBh: 48MB FCh: 52MB FDh: 56MB FEh: 60MB FFh: Reserved Hardware functionality in case of programming this value to Reserved is not guaranteed.
	7:6	**GTT Graphics Memory Size** Default Value: 00b Access: R/W Lock This field is used to select the amount of Main Memory that is pre-allocated to support the Internal Graphics Translation Table. The BIOS ensures that memory is pre-allocated only when Internal graphics is enabled. GSM is assumed to be a contiguous physical DRAM space with DSM, and BIOS needs to allocate a contiguous memory chunk. Hardware will derive the base of GSM from DSM only using the GSM size programmed in the register. Hardware functionality in case of programming this value to Reserved is not guaranteed. 0x0: No Preallocated Memory 0x1: 2MB of Preallocated Memory 0x2: 4MB of Preallocated Memory 0x3: 8MB of Preallocated Memory
	5:3	**Reserved** Format: MBZ
	2	**Versatile Acceleration Mode Enable** Default Value: 0b Access: R/W Lock Enables the use of the iGFX engines for Versatile Acceleration. 0 - iGFX engines are in iGFX Mode. Device 2 Class Code is 030000h. 1 - iGFX engines are in Versatile Acceleration Mode. Device 2 Class Code is 048000h.

GGC_0_0_0_PCI - GMCH Graphics Control

	1	**IGD VGA Disable** Default Value: 0b Access: R/W Lock 0: Enable. Device 2 (IGD) claims VGA memory and IO cycles, the Sub-Class Code within Device 2 Class Code register is 00. 1: Disable. Device 2 (IGD) does not claim VGA cycles (Mem and IO), and the Sub- Class Code field within Device 2 function 0 Class Code register is 80. BIOS Requirement: BIOS must not set this bit to 0 if the GMS field pre-allocates no memory. This bit MUST be set to 1 if Device 2 is disabled either via a fuse or fuse override (CAPID0_A[IGD] = 1) or via a register (DEVEN[3] = 0).
	0	**GGC Lock** Default Value: 0b Access: R/W Key Lock When set to 1b, this bit will lock all bits in this register.

Go Protocol GAM Request

GO_GAM_REQ - Go Protocol GAM Request

Address:	C5024h-C5027h
Name:	GPIO Control 5
ShortName:	GPIO_CTL_5
Power:	Always on
Reset:	soft

The register controls a pair of pins that can be used for general purpose control, but usually is designated for specific functions according to the requirements of the device and the system that the device is in.
Each pin of the two pin pair is designated as a clock or data for descriptive purposes. See the table at the beginning of this section to determine which pins/registers are supported and their intended functions.
Board design variations are possible and would affect the usage of these pins.
There are multiple instances of this register to support each of the GPIO pin pairs.

DWord	Bit	Description
0	31:13	**Reserved** Format: MBZ
	12	**GPIO Data In** Default Value: Ub Undefined (read only depends on I/O pin) Access: RO This is the value that is sampled on the GPIO_Data pin as an input. This bit is undefined at reset.

GPIO_CTL

11 GPIO Data Value

Default Value:	1b
Access:	R/W

This is the value that should be place on the GPIO Data pin as an output.
This value is only written into the register if GPIO DATA MASK is also asserted.
The value will appear on the pin if this data value is actually written to this register and the GPIO Data DIRECTION VALUE contains a value that will configure the pin as an output.
The default of '1' mimics the I2C external pull-ups.

10 GPIO Data Mask

Access:	WO

This is a mask bit to determine whether the GPIO DATA VALUE bit should be written into the register.

Value	Name
0b	Dot NOT write
1b	Write

9 GPIO Data Direction Value

Access:	R/W

This is the value that should be used to define the output enable of the GPIO Data pin.
This value is only written into the register if GPIO Data DIRECTION MASK is also asserted.
The value that will appear on the pin is defined by what is in the register for the GPIO DATA VALUE bit.

Value	Name
0b	Input
1b	Output

8 GPIO Data Direction Mask

Access:	WO

This is a mask bit to determine whether the GPIO Data DIRECTION VALUE bit should be written into the register.

Value	Name
0b	Dot NOT write
1b	Write

7:5 Reserved

Format:	MBZ

4 GPIO Clock Data In

Default Value:	Ub Undefined (read only depends on I/O pin)
Access:	RO

This is the value that is sampled on the GPIO Clock pin as an input.
This bit is undefined at reset.

GPIO_CTL

3 GPIO Clock Data Value

Default Value:	1b
Access:	R/W

This is the value that should be place on the GPIO Clk pin as an output.
This value is only written into the register if GPIO Clock DATA MASK is also asserted.
The value will appear on the pin if this data value is actually written to this register and the GPIO Clock DIRECTION VALUE contains a value that will configure the pin as an output.
The default of '1' mimics the I2C external pull-ups.

2 GPIO Clock Data Mask

Access:	WO

This is a mask bit to determine whether the GPIO Clock DATA VALUE bit should be written into the register.

Value	Name
0b	Dot NOT write
1b	Write

1 GPIO Clock Direction Value

Access:	R/W

This is the value that should be used to define the output enable of the GPIO Clock pin.
This value is only written into the register if GPIO Clock DIRECTION MASK is also asserted.
The value that will appear on the pin is defined by what is in the register for the GPIO Clock DATA VALUE bit.

Value	Name
0b	Input
1b	Output

0 GPIO Clock Direction Mask

Access:	WO

This is a mask bit to determine whether the GPIO Clock DIRECTION VALUE bit should be written into the register.

Value	Name
0b	Dot NOT write
1b	Write

GPM POWERGATE LICENSE REQUEST

GPM_POWERGATE_LICENSE_REQ - GPM POWERGATE LICENSE REQUEST

Register Space:	MMIO: 0/2/0
Default Value:	0x00000000
Size (in bits):	32
Address:	00C0Ch

GPM-RPM PowerGate License Request
RPM Detects change in PowerGate License Request, forwards the request to PCU on C2U Event Bus

DWord	Bit	Description

GP Thread Time

GP_THREAD_TIME - GP Thread Time	
Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Address:	054C4h
Name:	GP Thread Time
ShortName:	GP_THREAD_TIME

Reading this register returns the cumulative GP context execution time. This register uses the same clock frequency as CTX_TIMESTAMP, but differs from CTX_TIMESTAMP because it excludes the execution time during preemption save or restore. This register gets context save/restored on a context switch.
The granularity of this toggle is at the rate of the bit 3 in the "Reported Timestamp Count" register(0x2358). The toggle will be 8 times slower that "Reported Timestamp Count".

DWord	Bit	Description
0	31:0	**Timestamp Value** Access: RO Number of clock ticks that the context has run.

GPU_Ticks_Counter

GPU_TICKS - GPU_Ticks_Counter	
Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	02910h

Reading this register returns the live value of the GPU ticks counter that is sampled and included in the performance counter report header. It increments every GFX clock and hence the number of increments per second changes with GFX frequency.

DWord	Bit	Description
0	31:0	**Considerations** Format: U32 This 32-bit field returns bits 31:0 of the GPU tick counter value when read. Note that there is no "latch and hold" mechanism for performance counters when they are accessed through MMIO, so the value returned from this register may be different on back-to-back reads.

Graphics Device Reset Control

GDRST - Graphics Device Reset Control

FENCE - Graphics Memory Fence Table Register

Name:	FENCE_29
Address:	1000F0h-1000F7h
Name:	FENCE_30
Address:	1000F8h-1000FFh
Name:	FENCE_31

The graphics device performs address translation from linear space to tiled space for a CPU access to graphics memory (See Memory Interface Functions chapter for information on these memory layouts) using the fence registers. Note that the fence registers are used only for CPU accesses to gfx memory. Graphics rendering/display pipelines use Per Surface Tiling (PST) parameters (found in SURFACE_STATE - see the Sampling Engine chapter) to access tiled gfx memory.

The intent of tiling is to locate graphics data that are close (in X and Y surface axes) in one physical memory page while still locating some amount of line oriented data sequentially in memory for display efficiency. All 3D rendering is done such that the QWords of any one span are all located in the same memory page, improving rendering performance. Applications view surfaces as linear, hence when the cpu access a surface that is tiled, the gfx hardware must perform linear to tiled address conversion and access the correct physical memory location(s) to get the data.

Tiled memory is supported for rendering and display surfaces located in graphics memory. A tiled memory surface is a surface that has a width and height that are subsets of the tiled region's pitch and height. The device maintains the constants required by the memory interface to perform the address translations. Each tiled region can have a different pitch and size. The CPU-memory interface needs the surface pitch and tile height to perform the address translation. It uses the GMAddr (PCI-BAR) offset address to compare with the fence start and end address, to determine if the rendering surface is tiled. The tiled address is generated based on the tile orientation determined from the matching fence register. Fence ranges are at least 4 KB aligned. Note that the fence registers are used only for CPU accesses to graphics memory.

A Tile represents 4 KB of memory. Tile height is 8 rows for X major tiles and 32 rows for Y major tiles. Tile Pitch is 512Bs for X major tiles and 128Bs for Y major tiles. The surface pitch is programmed in 128B units such that the pitch is an integer multiple of "tile pitch".

Engine restrictions on tile surface usage are detailed in Surface Placement Restrictions (Memory Interface Functions). Note that X major tiles can be used for Sampler, Color, Depth, motion compensation references and motion compensation destination, Display, Overlay, GDI Blt source and destination surfaces. Y major tiles can be used for Sampler, depth, color and motion compensation assuming they do not need to be displayed. GDI Blit operations, overlay and display cannot used Tiled Y orientations.

A "PST" graphics surface that will also be accessed via fence needs its base address to be tile row aligned.

Hardware handles the flushing of any pending cycles when software changes the fence upper/lower bounds.

Fence Table Registers occupy the address range specified above. Each Fence Table Register has the following format.

FENCE registers are not reset by a graphics reset. They will maintain their values unless a full reset is performed.

DWord	Bit	Description
0	63:44	**Fence Upper Bound** Format: GraphicsAddress[31:12] Bits 31:12 of the ending Graphics Address of the fence region. Fence regions must be aligned to a 4KB page. This address represents the last 4KB page of the fence region (Upper Bound is included in the fence region).

FENCE - Graphics Memory Fence Table Register

	Graphics Address is the offset within GMADR space.
43	**Reserved** Format: MBZ
42:32	**Fence Pitch** Format: U10-1 Width in 128 bytes This field specifies the width (pitch) of the fence region in multiple of "tile width". For Tile X this field must be programmed to a multiple of 512B ("003" is the minimum value) and for Tile Y this field must be programmed to a multiple of 128B ("000" is the minimum value). 000h = 128B 001h = 256B ... 3FFh = 128KB ... 7FFh = 256KB
31:12	**Fence Lower Bound** Format: GraphicsAddress[31:12] Bits 31:12 of the starting Graphics Address of the fence region. Fence regions must be aligned to 4KB. This address represents the first 4KB page of the fence region (Lowe Bound is included in the fence region). Graphics Address is the offset within GMADR space.
11:2	**Reserved** Format: MBZ
1	**Tile Walk** This field specifies the spatial ordering of QWords within tiles.

Value	Name	Description
0h	MI_TILE_XMAJOR	Consecutive SWords (32 Bytes) sequenced in the X direction
1h	MI_TILE_YMAJOR	Consecutive OWords (16 Bytes) sequenced in the Y direction

0	**Fence Valid** Format: MI_FenceValid This field specifies whether or not this fence register defines a fence region.

Value	Name
0h	MI_FENCE_INVALID
1h	MI_FENCE_VALID

Graphics Memory Range Address

GMADR_0_2_0_PCI - Graphics Memory Range Address

Register Space:	PCI: 0/2/0
Source:	BSpec
Default Value:	0x0000000C, 0x00000000
Size (in bits):	64
Address:	00018h

GMADR is the PCI aperture used by S/W to access tiled GFX surfaces in a linear fashion.

DWord	Bit	Description
0	63:39	**Reserved for Memory Base Address** Default Value: 000000000000000000000000b Access: R/W Must be set to 0 since addressing above 512GB is not supported.
	38:32	**Memory Base Address** Default Value: 0000000b Access: R/W Set by the OS, these bits correspond to address signals [38:32].
	31	**4096 MB Address Mask** Default Value: 0b Access: R/W Lock FLR Resettable This bit is either part of the Memory Base Address (R/W) or part of the Address Mask (RO) depending on the value of MSAC.APSZ. RO and forced to 0 when MSAC.APSZ >= 4096MB. (i.e. MSAC.APSZ[4]=1)
	30	**2048 MB Address Mask** Default Value: 0b Access: R/W Lock FLR Resettable This bit is either part of the Memory Base Address (R/W) or part of the Address Mask (RO) depending on the value of MSAC.APSZ. RO and forced to 0 when MSAC.APSZ >= 2048MB. (i.e. MSAC.APSZ[3]=1)
	29	**1024 MB Address Mask** Default Value: 0b Access: R/W Lock FLR Resettable

GMADR_0_2_0_PCI - Graphics Memory Range Address

	This bit is either part of the Memory Base Address (R/W) or part of the Address Mask (RO) depending on the value of MSAC.APSZ. RO and forced to 0 when MSAC.APSZ >= 1024MB. (i.e. MSAC.APSZ[2]=1)
28	**512MB Address Mask** Default Value: 0b Access: R/W Lock FLR Resettable This bit is either part of the Memory Base Address (R/W) or part of the Address Mask (RO) depending on the value of MSAC.APSZ. RO and forced to 0 when MSAC.APSZ >= 512MB. (i.e. MSAC.APSZ[1]=1)
27	**256 MB Address Mask** Default Value: 0b Access: R/W Lock FLR Resettable This bit is either part of the Memory Base Address (R/W) or part of the Address Mask (RO) depending on the value of MSAC.APSZ. RO and forced to 0 when MSAC.APSZ >= 256MB. (i.e. MSAC.APSZ[0]=1)
26:4	**Address Mask** Default Value: 00000000000000000000000b Access: RO Hardwired to 0s to indicate at least 128MB address range.
3	**Prefetchable Memory** Default Value: 1b Access: RO Hardwired to 1 to enable prefetching.
2:1	**Memory Type** Default Value: 10b Access: RO Hardwired to 2h to indicate 64 bit base address.
0	**Memory/IO Space** Default Value: 0b Access: RO Hardwired to 0 to indicate memory space.

	5:4	**LRU management** Default Value: 11b Access: R/W This field allows the selection of AGE parameter for a given surface in LLC or eLLC. . If a particular allocation is done at youngest age 3 it tends to stay longer in the cache as compared to older age allocations - 2, 1 or 0. This option is given to driver to be able to decide which surfaces are more likely to generate HITs, hence need to be replaced least often in caches. 11: Good chance of generating hits. 10: Poor chance of generating hits 01: Don't change the LRU if it is a HIT 00: Reserved
	3:2	**Target Cache** Default Value: 01b Access: R/W This field allows the choice of LLC vs eLLC for caching 00: eLLC Only 01: LLC Only 10: LLC/eLLC Allowed 11: LLC/eLLC Allowed
	1:0	**LLC/eDRAM cacheability control** Default Value: 11b Access: R/W Memory type information used in LLC/eDRAM. 00: Use Cacheability Controls from page table / UC with Fence (if coherent cycle) 01: Uncacheable (UC) - non-cacheable 10: Writethrough (WT) 11: Writeback (WB)

Graphics MOCS Register63

GFX_MOCS_63 - Graphics MOCS Register63

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x0000003B [KBL]
Size (in bits):	32
Address:	0C8FCh

MOCS register

DWord	Bit	Description
0	31:15	**Reserved** Default Value: 0000000000000000b Access: RO
	14	**Reserved1** Default Value: 0b Access: RO
	13:11	**Page Faulting Mode** Default Value: 000b Access: R/W This fields controls the page faulting mode that will be used in the memory interface block for the given request coming from this surface: 000: Use the global page faulting mode from context descriptor (default) 001-111: Reserved
	10:8	**Skip Caching control** Default Value: 000b Access: R/W Defines the bit values to enable caching. Outcome overrides the LLC caching for the surface. If "0" - than corresponding address bit value is don't care Bit[8]=1: address bit[9] needs to be "0" to cache in target Bit[9]=1: address bit[10] needs to be "0" to cache in target Bit[10]=1: address bit[11] needs to be "0" to cache in target
	7	**Enable Skip Caching** Default Value: 0b Access: R/W Enable for the Skip cache mechanism 0: Not enabled 1: Enabled for LLC

GFX_MOCS_63 - Graphics MOCS Register63

	6	**Dont allocate on miss** Default Value: 0b Access: R/W Controls defined for RO surfaces in mind, where if the target cache is missed - don't bring the line (applicable to LLC/eDRAM). 0: Allocate on MISS (normal cache behavior) 1: Do NOT allocate on MISS
	5:4	**LRU management** Default Value: 11b Access: R/W This field allows the selection of AGE parameter for a given surface in LLC or eLLC. . If a particular allocation is done at youngest age 3 it tends to stay longer in the cache as compared to older age allocations - 2, 1 or 0. This option is given to driver to be able to decide which surfaces are more likely to generate HITs, hence need to be replaced least often in caches. 11: Good chance of generating hits. 10: Poor chance of generating hits 01: Don't change the LRU if it is a HIT 00: Reserved
	3:2	**Target Cache** Default Value: 10b Access: R/W This field allows the choice of LLC vs eLLC for caching 00: eLLC Only 01: LLC Only 10: LLC/eLLC Allowed 11: LLC/eLLC Allowed
	1:0	**LLC/eDRAM cacheability control** Default Value: 11b Access: R/W Memory type information used in LLC/eDRAM. 00: Use Cacheability Controls from page table / UC with Fence (if coherent cycle) 01: Uncacheable (UC) - non-cacheable 10: Writethrough (WT) 11: Writeback (WB)

Graphics Mode Register

GFX_MODE - Graphics Mode Register

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	r/w
Size (in bits):	32
Trusted Type:	1

Address:	0229Ch-0229Fh
Name:	Graphics Mode Register
ShortName:	GFX_MODE_RCSUNIT

Address:	1229Ch-1229Fh
Name:	Graphics Mode Register
ShortName:	GFX_MODE_VCSUNIT0

Address:	1A29Ch-1A29Fh
Name:	Graphics Mode Register
ShortName:	GFX_MODE_VECSUNIT

Address:	1C29Ch-1C29Fh
Name:	Graphics Mode Register
ShortName:	GFX_MODE_VCSUNIT1

Address:	2229Ch-2229Fh
Name:	Graphics Mode Register
ShortName:	GFX_MODE_BCSUNIT

This register contains a control bit for the new execlist and 2-level PPGTT functions.

DWord	Bit	Description
0	31:16	**Mask** Access: WO Format: Mask Must be set to modify corresponding bit in Bits 15:0. (All implemented bits)
	15	**Execlist Enable** Mask: MMIO#31 When set, software can utilize the execlist registers to load a context into hardware. MI_SET_CONTEXT and MI_ARB_CHECK commands will be converted to NOOP if parsed. When this bit is clear, the Execlist mechanism cannot be used. The context must be loaded via MI_SET_CONTEXT and the ring must be loaded via MMIO access. **Programming Notes**

GFX_MODE - Graphics Mode Register

This bit is *not* intended to be changed dynamically. Changing the value of this bit while rendering is in progress will have UNDEFINED results. This bit should be changed only after a full reset and before submitting *any* commands to the device.

14 **Reserved**

13 **Reserved**

Format:	PBC

12 **Reserved**

11 **Reserved**

10 **Reserved**

Format:	PBC

9 **Per-Process GTT Enable**

Format:	Enable

Per-Process GTT Enable

Value	Name	Description
0h	PPGTT Disable **[Default]**	When clear, the Global GTT will be used to translate memory access from designated commands and for commands that select the PPGTT as their translation space.
1h	PPGTT Enable	When set, the PPGTT will be used to translate memory access from designated commands and for commands that select the PPGTT as their translation space.

Programming Notes

This bit is used for enabling PPGTT access in Ring Buffer mode of scheduling. Privilege field in context descriptor states the same in Execlist Mode of scheduling. This field should be set before programming PDP0/1/2/3 registers in order to set the PPGTT translation of memory access.

Programming this bit doesn't enable or disable the PPGTT translation of memory access immediately; the change comes in to affect only when the Page Directory registers are programmed. Programming this bit must be followed by programming Page Directory Registers in order to enable or disable the PPGTT translation of memory access.

8 **Reserved**

8 **Reserved**

Source:	BlitterCS, VideoCS, VideoCS2, VideoEnhancementCS
Format:	PBC

7 **64Bit Virtual Addressing Enable**

Format:	Enable

64Bit Virtual Addressing Enable

Value	Name	Description
0h	64Bit Virtual Addressing	When clear indicates GFX operating in 32bit Virtual

GFX_MODE - Graphics Mode Register

	Disable **[Default]**	Addressing for PPGTT based memory access.
1h	64Bit Virtual Addressing Enable	When Set indicates GFX operating in 64bit (48bit Canonical) Virtual Addressing for PPGTT based memory access.

Programming Notes

This bit is only valid when PPGTT is enabled in ring buffer mode of scheduling. Context Descriptor has a similar bit to control 64bit virtual addressing in execlist mode of scheduling. Whether this field is set or clear virtual addresses translated through GGTT are always 32Bit. This field should be programmed before enabling PPGTT access. When this field is not set or for GGTT virtual addresses, Graphics Address [47:32] field of any commands or register exercised by SW should be programmed to 0x0.

6:5 **Reserved**

4 **Reserved**

3 **Reserved**

Format:	MBZ

2:1 **Reserved**

Format:	PBC

0 **Privilege Check Disable**

Format:	Enable

This field when set, disables Privilege Violation checks on non-privileged batch buffers. When set Privileged commands are allowed to be executed from non-privileged batch buffers.

Graphics System Event

GSE_0_2_0_PCI - Graphics System Event	
Register Space:	PCI: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Size (in bits):	32
Address:	000E4h

This register can be accessed by either Byte, Word, or Dword PCI config cycles. A write to this register will cause the Graphics System Event display interrupt if it is enabled and unmasked in the display interrupt registers.

DWord	Bit	Description
0	31:24	**GSE Scratch Trigger 3** Default Value: 00000000b Access: R/W
	23:16	**GSE Scratch Trigger 2** Default Value: 00000000b Access: R/W
	15:8	**GSE Scratch Trigger 1** Default Value: 00000000b Access: R/W
	7:0	**GSE Scratch Trigger 0** Default Value: 00000000b Access: R/W

Graphics Translation Table Memory Mapped Range Address

GTTMMADR_0_2_0_PCI - Graphics Translation Table Memory Mapped Range Address

Register Space:	PCI: 0/2/0
Source:	BSpec
Default Value:	0x00000004, 0x00000000
Size (in bits):	64
Address:	00010h

This register requests allocation for the combined Graphics Translation Table Modification Range and Memory Mapped Range. The range requires 16 MB combined for MMIO and Global GTT aperture, with 2MB of that used by MMIO, 6MB reserved, and 8MB used by GTT.

GTTADR will begin at (GTTMMADR + 8 MB) while the MMIO base address will be the same as GTTMMADR. The region between (GTTMMADR + 2MB) - (GTTMMADR + 8MB) is reserved.

For the Global GTT, this range is defined as a memory BAR in graphics device config space. It is an alias into which software is required to write Page Table Entry values (PTEs). Software may read PTE values from the global Graphics Translation Table (GTT). PTEs cannot be written directly into the global GTT memory area.

The device snoops writes to this region in order to invalidate any cached translations within the various TLB's implemented on-chip.

The allocation is for 16MB and the base address is defined by bits [38:24].

Note: Per PCI enumeration requirements, to determine the size of a BAR software should write all 1s to the BAR, read it back and see how many of the lower bits read as 0 (meaning that they didn't take the 1s). This indicates the size of the BAR. In order for this to work bits 63 down to the size of the BAR need to be writable to 1s.

DWord	Bit	Description
0	63:39	**Reserved for Memory Base Address** Default Value: 00000000000000000000000b Access: R/W Must be set to 0 since addressing above 512GB is not supported.
	38:24	**Memory Base Address** Default Value: 000000000000000b Access: R/W Set by the OS, these bits correspond to address signals [38:24].
	23:4	**Address Mask** Default Value: 0000000000000000000b Access: RO Hardwired to 0s to indicate at least 16MB address range.

GTTMMADR_0_2_0_PCI - Graphics Translation Table Memory Mapped Range Address

	3	**Prefetchable Memory** Default Value: 0b Access: RO Hardwired to 0 to prevent prefetching.
	2:1	**Memory Type** Default Value: 10b Access: RO Hardwired to 2h to indicate 64 bit base address.
	0	**Memory/IO Space** Default Value: 0b Access: RO Hardwired to 0 to indicate memory space.

GSA_AUDIO_BDF

GSA_AUDIO_BDF

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00100000
Access:	R/W
Size (in bits):	32
Address:	1300B0h-1300B3h
Name:	GSA Audio BDF
ShortName:	GSA_AUDIO_BDF
Power:	PG0
Reset:	global

BIOS must program this register with the PCI Bus, Device, and Function of the PCH audio device and set the lock.
Access is a variant of RW-L.
When Lock is not set (bit 0 = 0) the register can be written by any source.
After lock is set (bit 0 = 1), only writes from firmware (cfgspace 0x11111 and srcID 0x10) will update the register values. Writes from other sources will complete without updating the register values.
Any source can read the register.
This register is not reset by the device 2 FLR.

DWord	Bit	Description
0	31:24	**Bus** Default Value: 00000000b Access is RW-L. This field specifies the PCI bus number of the PCH audio device.
	23:19	**Device** Default Value: 00010b Access is RW-L. This field specifies the PCI device number of the PCH audio device.
	18:16	**Function** Default Value: 000b Access is RW-L. This field specifies the PCI function number of the PCH audio device.
	15:1	**Reserved** Format: MBZ
	0	**Lock** Access is RW-KL. This field locks all writeable settings in this register, including itself. Value: 0b — Name: Unlock Value: 1b — Name: Lock

GSA_TOUCH_BDF

GSA_TOUCH_BDF

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00100000
Access:	R/W
Size (in bits):	32
Address:	1300B4h-1300B7h
Name:	GSA Touch BDF
ShortName:	GSA_TOUCH_BDF
Power:	PG0
Reset:	global

BIOS must program this register with the PCI Bus, Device, and Function that the Display Engine should use for communication with the PCH touch device, and set the lock.
Access is a variant of RW-L.
When Lock is not set (bit 0 = 0) the register can be written by any source.
After lock is set (bit 0 = 1), only writes from firmware (cfgspace 0x11111 and srcID 0x10) will update the register values. Writes from other sources will complete without updating the register values.
Any source can read the register.
This register is not reset by the device 2 FLR.

DWord	Bit	Description
0	31:24	**Bus** Default Value: 00000000b Access is RW-L. This field specifies the PCI bus number.
	23:19	**Device** Default Value: 00010b Access is RW-L. This field specifies the PCI device number.
	18:16	**Function** Default Value: 000b Access is RW-L. This field specifies the PCI function number.
	15:1	**Reserved** Format: MBZ
	0	**Lock** Access is RW-KL. This field locks all writeable settings in this register, including itself. 0b: Unlock 1b: Lock

GS Invocation Counter

GS_INVOCATION_COUNT - GS Invocation Counter	
Register Space:	MMIO: 0/2/0
Source:	RenderCS
Default Value:	0x00000000, 0x00000000
Access:	R/W
Size (in bits):	64
Trusted Type:	1
Address:	02328h

This register stores the number of objects that are part of geometry shader threads. This register is part of the context save and restore.

DWord	Bit	Description
0	63:32	**GS Invocation Count UDW** Number of objects that are dispatched as a geometry shader threads invoked by the GS stage. Updated only when **Statistics Enable** is set in GS_STATE (see the Geometry Shader Chapter in the 3D Volume.)
	31:0	**GS Invocation Count LDW** Number of objects that are dispatched as a geometry shader threads invoked by the GS stage. Updated only when **Statistics Enable** is set in GS_STATE (see the Geometry Shader Chapter in the 3D Volume.)

GS Primitives Counter

GS_PRIMITIVES_COUNT - GS Primitives Counter		
Register Space:	MMIO: 0/2/0	
Source:	RenderCS	
Default Value:	0x00000000, 0x00000000	
Access:	R/W	
Size (in bits):	64	
Trusted Type:	1	
Address:	02330h	
This register reflects the total number of primitives that have been output by the Geometry Shader stage. This register is part of the context save and restore..		
DWord	**Bit**	**Description**
0	63:32	**GS Primitives Count UDW** Total number of primitives output by the geometry stage. Updated only when Statistics Enable is set in GS_STATE (see the Geometry Shader Chapter in the 3D Volume.)
	31:0	**GS Primitives Count LDW** Total number of primitives output by the geometry stage. Updated only when Statistics Enable is set in GS_STATE (see the Geometry Shader Chapter in the 3D Volume.)

GT4 Mode Control Register

GT4MODECTL - GT4 Mode Control Register		
Register Space:	MMIO: 0/2/0	
Source:	BSpec	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	09038h	
GT4 Mode Control Register		
DWord	**Bit**	**Description**
0	31:18	**RSVD** Access: R/W
	17:10	**Reserved**
	9:2	**Reserved**
	1:0	**GT4 Mode Control** Access: R/W GT4 Usage mode: 00b: Non-GT4. 01b: GT4 is used in Alternate Frame rendering Mode (AFR). 10b: Basic Split Frame rendering Mode (SFR). 11b: Complex Split Frame rendering Mode (SFR w/ CBR).

GTC_CTL

GTC_CTL	
Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	67000h-67003h
Name:	Global Time Code Control
ShortName:	GTC_CTL
Power:	PG1
Reset:	soft

DWord	Bit	Description
0	31	**GTC Function Enable** This bit enables the GTC counter. Value / Name: 0b – Disable 1b – Enable Restriction: Restriction : Enable this bit before enabling GTC controller operation on a port with a GTC capable device.
	30:29	**Reserved** Format: MBZ
	28:13	**Reserved**
	12:1	**Reserved** Format: MBZ
	0	**Reserved**

GTC_DDA_M

GTC_DDA_M		
Register Space:	MMIO: 0/2/0	
Source:	BSpec	
Default Value:	0x00000000	
Access:	R/W	
Size (in bits):	32	
Address:	67010h-67013h	
Name:	Global Time Code DDA M	
ShortName:	GTC_DDA_M	
Power:	PG1	
Reset:	soft	
DWord	**Bit**	**Description**
0	31:24	**Reserved**
	23:0	**GTC DDA M** This field is used to program the M value of the GTC DDA. The ratio of M to N programmed depends on the GTC reference clock. The DDA programmed values are related by the following formula: 1/(accumulator increment) = Reference Clock * DDA_M / DDA_N

GTC_DDA_N

GTC_DDA_N		
Register Space:	MMIO: 0/2/0	
Source:	BSpec	
Default Value:	0x00000000	
Access:	R/W	
Size (in bits):	32	
Address:	67014h-67017h	
Name:	Global Time Code DDA N	
ShortName:	GTC_DDA_N	
Power:	PG1	
Reset:	soft	
DWord	**Bit**	**Description**
0	31:24	**GTC Accum Inc** Format: U7.1 This field is the GTC accumulator increment value in nanoseconds each time the DDA trips. It is programmed in 7.1 fixed point binary format where the LSB represents 0.5ns increment.
	23:0	**GTC DDA N** This field is used to program the N value of the GTC DDA. The ratio of M to N programmed depends on the GTC reference clock and should not result in any accumulation error in any 10ms interval period. The DDA programmed values are related by the following formula: 1/(accumulator increment) = Reference Clock * DDA_M / DDA_N

GTC_IIR

GTC_IIR	
Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	R/WC
Size (in bits):	32
Address:	67058h-6705Bh
Name:	Global Time Code Interrupt Identity
ShortName:	GTC_IIR
Power:	PG1
Reset:	soft

See the GTC interrupt bit definition to find the source event for each interrupt bit.

DWord	Bit	Description
0	31:0	**Interrupt Identity Bits** This field holds the persistent values of the GTC interrupt bits which are unmasked by the GTC_IMR. Bits set in this register will propagate to the GTC interrupt in the Display Engine Miscellaneous Interrupts. Bits set in this register will remain set (persist) until the interrupt condition is cleared by writing a '1' to the appropriate bits.

Value	Name
0b	Condition Not Detected
1b	Condition Detected

GTC_IMR

GTC_IMR	
Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0xFFFFFFFF
Access:	R/W
Size (in bits):	32
Address:	67054h-67057h
Name:	Global Time Code Interrupt Mask
ShortName:	GTC_IMR
Power:	PG1
Reset:	soft

See the GTC interrupt bit definition to find the source event for each interrupt bit.

DWord	Bit	Description
0	31:0	**Interrupt Mask Bits** This field contains a bit mask which selects which GTC events are reported int the GTC IIR.

Value	Name
0b	Not Masked
1b	Masked
FFFFFFFFh	All interrupts masked **[Default]**

GTC_LIVE

GTC_LIVE		
Register Space:	MMIO: 0/2/0	
Source:	BSpec	
Default Value:	0x00000000	
Access:	RO	
Size (in bits):	32	
Address:	67020h-67023h	
Name:	Global Time Code Live	
ShortName:	GTC_LIVE	
Power:	PG1	
Reset:	soft	
DWord	**Bit**	**Description**
0	31:0	**GTC Live Value** This field contains the live current value of the GTC. It is inactive when the GTC controller function is disabled. This register also samples and holds the live GTC value following a Audio Time Capture (ATC) event until software reads this register. A subsequent read of this register will reflect the live value.

GTC_PORT_CTL

GTC_PORT_CTL	
Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	64070h-64073h
Name:	DDI A GTC Port Control
ShortName:	GTC_PORT_CTL_A
Power:	PG1

Reset:	soft

DWord	Bit	Description
0	31	**Port Global Time Code Enable** This bit enables the GTC controller to start lock acquisition phase with remote GTC sink connected to this port. This bit has no effect if the GTC controller is disabled. **Value** / **Name** 0b – Disable 1b – Enable **Restriction**

GTC_PORT_CTL

		Restriction : The Maintenance Phase Enable bit must be initially written as '0' when this bit is set.
	30:25	**Reserved**
	24	**Maintenance Phase Enable** This bit is used by software to transition from lock acquisition to lock maintenance phase. The GTC controller generates an interrupt at the end of the lock phase as determined by lock acquisition duration field. Software shall read the sink device GTC lock done bit. If set, software shall set this bit to '1' after first writing the GTC skew value to the RX GTC skew DPCD offset with GTC skew enable bit set to '1'.

Value	Name	Description
0b	Lock	Lock acquisition phase. The controller writes or reads GTC every 1ms.
1b	Maintain	Lock maintenance phase. The controller writes or reads GTC every 10ms.

	23:1	**Reserved**
	0	**Port RX Lock Done** This bit indicates the remote GTC sink has achieved lock. This bit shall be written by software after reading remote GTC sink DPCD register. This bit shall be cleared by software when GTC controller is reset from lock maintenance mode to lock acquisition mode or when the controller is disabled.

Value	Name
0b	Not Locked
1b	Locked

GTC_PORT_MISC

GTC_PORT_MISC		
Register Space:	MMIO: 0/2/0	
Source:	BSpec

Address:	64380h-64383h
Name:	DDI D GTC Port TX Previous
ShortName:	GTC_PORT_TX_PREV_D
Power:	PG2
Reset:	soft

Description
There is one instance of this register per port A, B, C, D and F.

DWord	Bit	Description
0	31:0	**Global Time Code Port TX Previous** This field contains the previous local GTC value sampled at Aux sync point. It is transferred from the GTC_PORT_TX_CURR register when the current value is updated.

GTFORCEAWAKE

GTFORCEAWAKE	
Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	130090h-130093h
Name:	GT Force Awake
ShortName:	GTFORCEAWAKE
Power:	PG0
Reset:	soft

DWord	Bit	Description
0	31:1	**Reserved**
	0	**Force Awake** This field is no longer used. The multiple force wake mechanism has replaced it. Refer to MULTIFORCEWAKE 0xA188 register description for the usage.

GT Function Level Reset Control Message

FLRCTLMSG - GT Function Level Reset Control Message		
Register Space:	MMIO: 0/2/0	
Source:	BSpec	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	08100h	
GT FLR Control Register		
DWord	**Bit**	**Description**
0	31:16	**Message Mask** Access: RO Message Mask In order to write to bits 15:0, the corresponding message mask bits must be written. For example, for bit 14 to be set, bit 30 needs to be 1 : 40004000
	15:1	**Reserved** Access: RO Reserved
	0	**Initiate GT Function Level Reset Message** Access: R/W Set GT Function Level Reset (FLR) 1: Initiate GT FLR - This is a Non-Posted message to reset Render, Media, Blitter and GTI-Device domains. - This bit is cleared by the CPunit upon completion of the reset.

GT Interrupt 0 Definition

GT Interrupt 0 Definition	
Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Size (in bits):	32
Address:	44300h-4430Fh
Name:	GT 0 Interrupts
ShortName:	GT_0_INTERRUPT
Power:	PG0
Reset:	soft

This table indicates which events are mapped to each bit of the GT Interrupt 0 registers.
Bits 15:0 are used for Render CS.
Bits 31:16 are used for Blitter CS.
The IER enabled Render Interrupt IIR (sticky) bits are ORed together to generate the Render Interrupts Pending bit in the Master Interrupt Control register.
The IER enabled Blitter Interrupt IIR (sticky) bits are ORed together to generate the Blitter Interrupts Pending bit in the Master Interrupt Control register.
0x44300 = ISR

GTI PFET control register with lock

PFETCTL - GTI PFET control register with lock

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x0004005A [KBL]
Size (in bits):	32
Address:	24008h

DWord	Bit	Description
0	31	**PFET Control Lock** Access: R/W Lock 0 = Bits of GTI PFETCTL register are R/W 1 = All bits of GTI PFETCTL register are RO (including this lock bit) Once written to 1, the lock is set and cannot be cleared (that is, writing a 0 will not clear the lock). These bits are not reset on FLR.
	30:23	**Reserved** Access: RO Reserved
	22	**Leave firewall disabled** Access: R/W Lock When this bit is set SPC will not firewall the gated domain for a power down flow. But it will pretend to complete the flow with PM. Encodings: 0 = Default mode, that is, firewall gated domain to ungated domain crossing during power down flows 1 = Leave firewall disabled, that is, don't firewall the gated domain, but complete logical flow
	21	**Leave FET On** Access: R/W Lock When This bit is set SPC will not turn off the PFET eventhough it will complete the flow with PM Encodings: 0 = Default mode, that is, power off fets during power down flows 1 = Leave ON mode, that is, don't power off pfet, but complete logical flow **Programming Notes** This bit should be programmed before the powerup sequence is initiated for GTI.
	20	**Power Well Status** Access: R/WC 0 = Well is powered Down 1 = Well is powered Up Once written to 1, the lock is set and cannot be cleared (that is, writing a 0 will not clear the lock). These bits are not reset on FLR.

PFETCTL - GTI PFET control register with lock

	19	**Powergood timer error** Access: R/WC 0 = Well is powered Down 1 = Well is powered Up Once written to 1, the lock is set and cannot be cleared (that is, writing a 0 will not clear the lock). These bits are not reset on FLR.
	18:16	**Delay from enabling secondary PFETs to power good** Access: R/W Lock Delay from enabling secondary PFETs to power good 3'b000: SKL - 40ns 3'b001: SKL - 80ns, 3'b010: SKL - 160ns 3'b011: SKL - 320ns, 3'b100: SKL - 640ns 3'b101: SKL - 1280ns 3'b110: SKL - 2560ns 3'b111: SKL - 5120ns **Value** / **Name**: 100b / **[Default]**
	15:13	**Time period last primay pfet strobe to secondary pfet strobe** Access: R/W Lock Time period last primary pfet strobe to secondary pfet strobe 3'b000: SKL - 10ns (or 1 bclk) 3'b001: SKL - 20ns (or 2 bclk)) 3'b010: SKL - 30ns (or 3 bclk) 3'b111: SKL - 80ns (or 8 bclk)
	12:10	**Time period b/w two adjacent strobes** Access: R/W Lock Time period b/w two adjacent strobes to the primary FETs 3'b000: SKL - 10ns (or 1 bclk) 3'b001: SKL - 20ns (or 2 bclk) 3'b010: SKL - 30ns (or 3 bclk) 3'b111: SKL - 80ns (or 8 bclk)
	9:7	**FET setup margin from enable to strobe** Access: R/W Lock Setup margin in design before sampling enable event at the first pre-charge sequencer/shift register flop 3'b000: SKL - 10ns (or 1 bclk) 3'b001: SKL - 20ns (or 2 bclk) 3'b010: SKL - 30ns (or 3 bclk) 3'b111: SKL - 80ns (or 8 bclk)

PFETCTL - GTI PFET control register with lock

	6:0	**Number of flops to enable primary FETs** Access: R/W Lock Number of flops to enable primary FETs. For a setting of N there will be N+1 total strobes generated 7'b0000000: 10 Flops to be strobed 7'b0000001: 11 Flops to be strobed 7'b0000010: 12 Flops to be strobed 7'b0001111: 26 Flops to be strobed

Value	Name
1011010b	**[Default]**

GTI Power Gate Control Request

PGCTLREQ - GTI Power Gate Control Request		
Register Space:	MMIO: 0/2/0	
Source:	BSpec	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	24000h	
Clock Gating Messages Register		
DWord	**Bit**	**Description**
0	31:16	**Message Mask** Access: RO Message Mask - To write to bits 15:0, the corresponding message mask bits must be written. For example, for bit 14 to be set, bit 30 needs to be 1 : 40004000
	15:1	**Reserved** Access: RO Reserved
	0	**Power Gate Request** Access: R/W Media1 power well request: '0' : Initiate Power Down request '1' : Initiate Power UP req

GT Mode Register

GT_MODE - GT Mode Register

Register Space:	MMIO: 0/2/0
Source:	RenderCS
Default Value:	0x00000000 [KBL]
Access:	R/W
Size (in bits):	32
Trusted Type:	1
Address:	07008h

This Register is used to control the 6EU and 12EU configuration for GT.
Writing 0x01FF01FF to this register enables the 6EU mode.

DWord	Bit	Description
0	31:16	**Mask** Access: WO Format: Mask[15:0] Must be set to modify corresponding bit in Bits 15:0. (All implemented bits)
	15	**EU Local Thread Checking Enable** Access: r/w This field configures the EU local thread checking. If enable the stateless access will be checked against the local thread's scratch space size and start address. 0h – Disable **[Default]** – EU local thread checking is disabled. 1h – Enable – EU local thread checking is enabled.
	14:13	**SFR mode** Access: r/w Format: U2 This field must be zero when not in GT4(SFR) configuration i.e GTB_rendermode fuse set to SFR.
	12:11	**Cross Slice Hashing Mode** Access: r/w Format: U2

Value	Name	Description	Programming Notes
0h	Normal Mode **[Default]**	GT3: 16x16 Hashing enabled GT2 or lower modes: No cross slice hashing	

GT_MODE - GT Mode Register

1h	Cross Slice Hashing Disable	Disables the cross slice hashing	
2h	32x16 Hahsing	32x16 Pixel hashing across slices	
3h	32X32 hashing	32X32 pixel hashing across slices	This setting must be used when sub-slice hashing mode is 16x16.

Programming Notes
Normal mode of operation in GT3 mode will be to use either 16x16 Hashing or 32x32 Hashing.

10 **Reserved**

Access:	r/w
Format:	PBC

9:8 **Subslice Hashing Mode**

Access:	r/w
Format:	U2

This field defines hashing modes across subslices.

Value	Name	Description
0h	**[Default]**	8X8 hashing
1h		16x4 hashing
2h		8x4 hashing
3h		16x16 hashing

7 **Reserved**

Access:	r/w
Format:	PBC

7 **Reserved**

Access:	r/w
Format:	PBC

7 **Bindless Surface Base Address Select**

Access:	r/w
Format:	Enable

This field selects Bindless_Surface_State_Base_Addr versus Dynamic_State_Base_Addr for sampler state heap base address. It only applies when Bindless Surfaces are being enabled via the BTI encoding.

Value	Name	Description
0h	Disable **[Default]**	Selects Dynanmic State Base Addr for Sampler State.
1h	Enable	Selects Bindless Surface Base Address for Sampler State

GT_MODE - GT Mode Register

	6	**Reserved** Access: r/w Format: PBC
	5:4	**Slice2 IZ Hashing: 7 EU subslice encoding** Access: r/w These bits control 3-way sub-slice hashing by conveying which sub-slice has 7 EUs.

Value	Name	Description
0h	**[Default]**	All subslices have equal number of EUs.
1h		Subslice 2 has 7 EUs.
2h		Subslice 1 has 7 EU.
3h		Subslice 0 has 7 EUs.

Programming Notes
SW must program these bits based on EU Disable Fuses in Slice 2.

	3:2	**Slice1 IZ Hashing: 7 EU subslice encoding** Access: r/w These bits control 3-way sub-slice hashing by conveying which sub-slice has 7 EUs.

Value	Name	Description
0h	**[Default]**	All subslices have equal number of EUs.
1h		Subslice 2 has 7 EUs.
2h		Subslice 1 has 7 EUs.
3h		Subslice 0 has 7 EUs.

Programming Notes
SW must program these bits based on EU Disable Fuses in Slice 1.

	1:0	**Slice 0 IZ Hashing: 7 EU subslice encoding** Access: r/w These bits control 3-way sub-slice hashing by conveying which sub-slice has 7 EUs.

Value	Name	Description
0h	**[Default]**	All subslices have equal number of EUs.
1h		Subslice 2 has 7 EUs.
2h		Subslice 1 has 7 EUs.
3h		Subslice 0 has 7 EUs.

Programming Notes
SW must program these bits based on EU Disable Fuses in Slice 0.

GTSCRATCH

GTT Cache Enable

GTT_CACHE_EN - GTT Cache Enable

Register Space:	MMIO: 0/2/0
Default Value:	0x00000000 [KBL]
Size (in bits):	32
Address:	04024h

Enable GTT Cache for respective client(s), A0: Must program/observed this to all 0 due to Big Pages Bug 1898112

DWord	Bit	Description
0	31:0	**GTT Cache Enable for CS** Access: R/W Enable GTT Caching for all the client(s) below: 31: BLIT Engine (overrides individual enables of the units) 30: VEBX Engine (overrides individual enables of the units) 29: MFX Engine (overrides individual enables of the units) 28: GFX Engine (overrides individual enables of the units) 27-15: Reserved 14: VMCunit 13: VLFunit 12: BLBunit 11: VFWunit 10: VEOunit 9: HIZunit 8: RCZunit 7: RCCunit 6: ISCunit 5: DCunit 4: MTunit 3: SOLunit 2: VFunit 1: RSunit 0: CSunit Value: 00000000h — Name: **[Default]**

Hardware Scratch Read Write

HSRW_0_2_0_PCI - Hardware Scratch Read Write

Register Space:	PCI: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Size (in bits):	16
Address:	00060h

This register is reserved as a HW scratchpad.

DWord	Bit	Description
0	15:0	**Reserved R/W** Default Value: 0000000000000000b Access: R/W Reserved for future usage.

Hardware Status Mask Register

HWSTAM - Hardware Status Mask Register

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0xFFFFFFFF
Access:	R/W
Size (in bits):	32
Trusted Type:	1
Address:	02098h-0209Bh
Name:	Hardware Status Mask Register
ShortName:	HWSTAM_RCSUNIT
Address:	12098h-1209Bh
Name:	Hardware Status Mask Register
ShortName:	HWSTAM_VCSUNIT0
Address:	1A098h-1A09Bh
Name:	Hardware Status Mask Register
ShortName:	HWSTAM_VECSUNIT
Address:	1C098h-1C09Bh
Name:	Hardware Status Mask Register
ShortName:	HWSTAM_VCSUNIT1
Address:	22098h-2209Bh
Name:	Hardware Status Mask Register
ShortName:	HWSTAM_BCSUNIT

The HWSTAM register has the same format as the Interrupt Control Registers. The bits in this register are mask bits that prevent the corresponding bits in the Interrupt Status Register from generating a Hardware Status Write (PCI write cycle). Any unmasked interrupt bit (HWSTAM bit set to 0) will allow the Interrupt Status Register to be written to the ISR location (within the memory page specified by the Hardware Status Page Address Register) when that Interrupt Status Register bit changes state.

Programming Notes

- To write the interrupt to the HWSP, the corresponding IMR bit must also be clear (enabled).
- At most 1 bit can be unmasked at any given time.

DWord	Bit	Description
0	31:0	**Hardware Status Mask** Format: Array of Masks Refer to the Interrupt Control Register section for bit definitions. Reserved bits are RO.

HWSTAM - Hardware Status Mask Register

Value	Name
FFFFFFFFh	**[Default]**

Hardware Status Page Address Register

HWS_PGA - Hardware Status Page Address Register

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Trusted Type:	1

Address:	02080h-02083h
Name:	Hardware Status Page Address Register
ShortName:	HWS_PGA_RCSUNIT

Address:	12080h-12083h
Name:	Hardware Status Page Address Register
ShortName:	HWS_PGA_VCSUNIT0

Address:	1A080h-1A083h
Name:	Hardware Status Page Address Register
ShortName:	HWS_PGA_VECSUNIT

Address:	1C080h-1C083h
Name:	Hardware Status Page Address Register
ShortName:	HWS_PGA_VCSUNIT1

Address:	22080h-22083h
Name:	Hardware Status Page Address Register
ShortName:	HWS_PGA_BCSUNIT

This register is used to program the 4 KB-aligned System Memory address of the Hardware Status Page used to report hardware status into (typically cacheable) System Memory.

DWord	Bit	Description
0	31:12	**Address** Format: GraphicsAddress[31:12] This field is used by SW to specify Bits 31:12 of the 4 KB-aligned System Memory address of the 4 KB page known as the Hardware Status Page. The Global GTT is used to map this page from the graphics virtual address to physical address. **Programming Notes** If the Per-Process Virtual Address Space and Exec List Enable bit is set, HW requires that the status page is programmed to allow for the context switch status to be reported.
	11:0	**Reserved** Format: MBZ

HCP Bitstream Output Minimal Size Padding Count Report Register

HCP_MINSIZE_PADDING_COUNT - HCP Bitstream Output Minimal Size Padding Count Report Register

Register Space:	MMIO: 0/2/0
Source:	VideoCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	1E9B4h

This register stores the count in bytes of **minimal size padding insertion. It is primarily provided for statistical data gathering.** This register is part of the context save and restore.

DWord	Bit	Description
0	31:0	**HCP MinSize Padding Count** Format: U32 Total number of bytes in the bitstream output contributing to minimal size padding operation. This count is updated each time when the padding count is incremented.

HCP CABAC Status

HCP_CABAC_STATUS - HCP CABAC Status

Register Space:	MMIO: 0/2/0
Source:	VideoCS
Default Value:	0x00000000
Size (in bits):	32
Trusted Type:	1
Address:	1E904h

HCP CABAC status.

DWord	Bit	Description
0	31:12	**Reserved** Format: MBZ
	11	**Temporal Direction Motion Vector Out-of-Bound Error** Default Value: 0 Access: RO Format: U1 This flag indicates motion vectors calculated from the Temporal Direct Motion vector is larger than the allowed range.
	10:7	**Reserved** Format: MBZ
	6	**Motion Vector Delta SE** Default Value: 0 Access: RO Format: U1 This flag indicates out-of-bound motion vector delta SEs coded in the bit-stream.
	5	**Delta QP SE** Default Value: 0 Access: RO Format: U1 This flag indicates leading-one overflow during CABAC decode of cu_qp_delta_abs.
	4	**Residual Error** Default Value: 0 Access: RO Format: U1 This flag indicates out-of-bound absolute coefficient level SEs coded in the bit-stream.

HCP_CABAC_STATUS - HCP CABAC Status

	3	**Slice and Error** Default Value: 0 Access: RO Format: U1 This flag indicates a pre-mature end to the slice or an inconsistent end of slice on the last Ctb of a slice.
	2:1	**Reserved** Format: MBZ
	0	**Ctb Concealment Flag** Default Value: 0 Access: RO Format: U1 Each pulse from this flag indicates one Ctb is concealed by the HCP.

HCP Decode Status

HCP_DEC_STATUS - HCP Decode Status

Register Space:	MMIO: 0/2/0
Source:	VideoCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	1E900h

HCP Decode status.

DWord	Bit	Description
0	31:18	**Number of Ctbs Concealed** Default Value: 0 Format: U14 This 16-bit field indicates the number of Ctbs concealed during the decoding of the current frame. This field is cleared with the HCP_PIPE_MODE_SELECT command.
	17	**Frame Dec Active** Default Value: 0 Format: U1 This flag indicates that the decoder hardware is actively decoding a picture.
	16	**Indirect Bitstream ObjectAccess Upper Bound Error** Default Value: 0 Format: U1 This flag indicates that the upper bound bit-stream address was reached.
	15:0	**Bit-stream Error Flags** Default Value: 0 Format: U16 This 16-bit field indicates the number of bit stream errors detected for each bit field indicated in the CABAC Status register.

HCP Frame BitStream BIN Count

HCP_BIN_CT - HCP Frame BitStream BIN Count

Register Space:	MMIO: 0/2/0
Source:	VideoCS
Default Value:	0x723BA5C0
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	1E980h

This register stores the number of BINs decoded in a frame.
This register is not part of hardware context save and restore.

DWord	Bit	Description
0	31:0	**HCP Frame Bit-stream BIN Count** Default Value: 723ba5c0h Format: U32 Total number of BINs decoded/ in current frame. This number is used with frame performance count to derive Bin/clk.

HCP Frame Motion Comp Miss Count

HCP_MISS_CT - HCP Frame Motion Comp Miss Count

Register Space:	MMIO: 0/2/0
Source:	VideoCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	1E988h

This register stores the total number of cacheline hits occurred in the motion compensation cache per frame.

This register is not part of hardware context save and restore.

DWord	Bit	Description
0	31:16	**Reserved** Format: MBZ
	15:0	**HCP Frame Motion Comp cache miss Count** Format: U16 Total number of CL misses occurred in the 12KB cache of the motion compensation engine per frame. This number is used along with **HCP Frame Motion Comp Read Count** to derive motion comp cache miss/hit ratio.

HCP Frame Motion Comp Read Count

HCP_READ_CT - HCP Frame Motion Comp Read Count

Register Space:	MMIO: 0/2/0
Source:	VideoCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	1E984h

This register stores the total number of reference picture read requests made by the Motion Compensation engine per frame.

This register is not part of hardware context save and restore.

DWord	Bit	Description
0	31:20	**Reserved** Format: MBZ
	19:0	**HCP Frame Motion Comp CL read request Count** Format: U20 Total number of reference picture read requests by the motion compensation engine per frame.

HCP Frame Performance Count

HCP_FRAME_PERF_CNT - HCP Frame Performance Count

Register Space:	MMIO: 0/2/0
Source:	VideoCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	1E960h

This register stores the number of clock cycles spent decoding/encoding the current frame.

This register is not part of hardware context save and restore.

DWord	Bit	Description
0	31:0	**Count** Format: U32 Total number of clocks between frame start and frame end. This count is incremented on crm_clk.

HCP Image Status Control

HCP_IMAGE_STATUS_CONTROL - HCP Image Status Control

Register Space:	MMIO: 0/2/0
Source:	VideoCS
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Trusted Type:	1
Address:	1E9BCh

DWord	Bit	Description
0	31:24	**Cumulative Frame Delta QP/QIndex** Format: S7 Used for Frame Level Multi-pass Rate Control. HEVC: cu_qp = input (first pass) cu_qp + Cumulative Frame Delta Qp. Pak does clamping to max value based on bitdepth. Bit31 is the sign bit. VP9: cu_qindex = input (first pass) cu_qindex + Cumulative Frame Delta Qindex. Pak does clamping to -127..127 after adding. Bit31 is the sign bit.
	23	**Reserved** Format: MBZ
	22:16	**Cumulative Frame Delta LF** Access: RO Format: S6 Used for Frame Level Multi-pass Rate Control. LF_level = input (first pass) LF_level + Cumulative Frame Delta LF level. Pak does clamping to -63..63 after adding.
	15:12	**Reserved** Format: MBZ
	11:8	**Total Num-Pass** Format: U4
	7:3	**Reserved** Format: MBZ
	2	**Frame Bit Count Violate - under run** Access: RO Format: U1 This can trigger Frame Level Multi-pass Rate Control. Set to 1 if frame bit count is less than or equal to FrameBitRateMin

HCP_IMAGE_STATUS_CONTROL - HCP Image Status Control

	1	**Frame Bit Count Violate - over run** Access: RO Format: U1 This can trigger Frame Level Multi-pass Rate Control. Set to 1 if frame bit count is less than or equal to FrameBitRateMax
	0	**LCU Bit Count Violate- overrun**

HCP Image Status Mask

HCP_IMAGE_STATUS_MASK - HCP Image Status Mask		
Register Space:	MMIO: 0/2/0	
Source:	VideoCS	
Default Value:	0x00000000	
Access:	RO	
Size (in bits):	32	
Trusted Type:	1	
Address:	1E9B8h	
This register stores the image status(flags).		
DWord	**Bit**	**Description**
0	31:3	**Reserved** Format: MBZ
	2	**FrameBitRateMinReportMask** Same as **FrameSzUnderStatusEn** in HCP_PIC_STATE.
	1	**FrameBitRateMaxReportMask** Same as **FrameSzOverStatusEn** in HCP_PIC_STATE.
	0	**FrameLcuMaxReportMask**

HCP Memory Latency Count1

HCP_LAT_CT1 - HCP Memory Latency Count1

Register Space:	MMIO: 0/2/0
Source:	VideoCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	1E968h

This register stores the max and min memory latency counts reported on reference read requests.

This register is not part of hardware context save and restore.

DWord	Bit	Description
0	31:24	**Max Request Count** Format: U8 This field indicates the maximum number of requests allowed by the memory sub-system channel.
	23:16	**Current Request Count** Format: U8 This field indicates the number of requests currently outstanding in the memory sub-system. This field should report with a value of zero at the end of frame; otherwise the motion compensation engine is most likely hung waiting for read data to be returned from sub-system.
	15:8	**HCP Reference picture read request - Max Latency Count in 8xMedia clock cycles** Format: U8 This field reports the maximum memory latency count on all reference reads requested by the motion compensation engine.
	7:0	**HCP Reference picture read request - Min Latency Count in 8xMedia clock cycles** Format: U8 This field reports the minimum memory latency count on all reference reads requested by the motion compensation engine.

HCP Memory Latency Count2

HCP_LAT_CT2 - HCP Memory Latency Count2

Register Space:	MMIO: 0/2/0
Source:	VideoCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	1E96Ch

This register stores the accumulative memory latency count on reference picture read requests.

This register is not part of hardware context save and restore.

DWord	Bit	Description
0	25:0	**HCP Reference picture read request** Format: U26 **Accumulative Memory Latency Count for the entire frame in 8xMedia clock cycles.** The accumulative memory latency count of all reference reads requested by motion compensative engine per frame. This number is used with **HCP Frame Motion Comp Read Count** to derive average memory latency.

HCP Memory Latency Count3

HCP_LAT_CT3 - HCP Memory Latency Count3

Register Space:	MMIO: 0/2/0
Source:	VideoCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	1E970h

This register stores the max and min memory latency counts reported on row-stored/bit-stream read requests. Max and current requests into memory sub-system engine.

This register is not part of hardware context save and restore.

DWord	Bit	Description
0	31:24	**Max Request Count** Format: U8 This field indicates the maximum number of requests allowed by the memory sub-system channel.
	23:16	**Current Request Count** Format: U8 This field indicates the number of requests currently outstanding in the memory sub-system. This field should report with a value of zero at the end of frame; otherwise the pre-fetch engine most likely hung waiting for read data to be returned from sub-system.
	15:8	**HCP row-stored/bit-stream read request - Max Latency Count in 8xMedia clock cycles** Format: U8 This field reports the maximum memory latency count on all row-stored/bit-stream reads requested by the memory pre-fetch engine.
	7:0	**HCP row-stored/bit-stream read request - Min Latency Count in 8xMedia clock cycles** Format: U8 This field reports the minimum memory latency count on all row-stored/bit-stream reads requested by the memory pre-fetch engine.

HCP Memory Latency Count4

HCP_LAT_CT4 - HCP Memory Latency Count4

Register Space:	MMIO: 0/2/0
Source:	VideoCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	1E974h

This register stores the accumulative memory latency count on row-stored/bit-stream read requests.

This register is not part of hardware context save and restore.

DWord	Bit	Description
0	31:0	**HCP row-stored/bit-stream read request** Format: U32 **Accumulative Memory Latency Count for the entire frame in 8xMedia clock cycles.** The accumulative memory latency count of all row-stored/bit-stream reads requested by pre-fetch engine per frame. This number is used with **Frame row-stored/bit-stream memory read count** to derive average memory latency.

HCP Memory Latency Count5

HCP_LAT_CT5 - HCP Memory Latency Count5

Register Space:	MMIO: 0/2/0
Source:	VideoCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	1E978h

This register stores the max and min memory latency counts reported on PAK Object read requests. Max and current requests into memory sub-system engine.

This register is not part of hardware context save and restore.

DWord	Bit	Description
0	31:24	**Max Request Count** Format: U8 This field indicates the maximum number of requests allowed by the memory sub-system channel.
	23:16	**Current Request Count** Format: U8 This field indicates the number of requests currently outstanding in the memory sub-system. This field should report with a value of zero at the end of frame; otherwise the pre-fetch engine most likely hung waiting for read data to be returned from sub-system.
	15:8	**MFX PAK Object read request - Max Latency Count in 8xMedia clock cycles** Format: U8 This field reports the maximum memory latency count on all PAK Object reads requested by the memory pre-fetch engine.
	7:0	**MFX PAK Object read request - Min Latency Count in 8xMedia clock cycles** Format: U8 This field reports the minimum memory latency count on all PAK Object reads requested by the memory pre-fetch engine.

HCP Memory Latency Count6

HCP_LAT_CT6 - HCP Memory Latency Count6

Register Space:	MMIO: 0/2/0
Source:	VideoCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	1E97Ch

This register stores the max and min memory latency counts reported on Source Pixel read requests. Max and current requests into memory sub-system engine.

This register is not part of hardware context save and restore.

DWord	Bit	Description
0	31:24	**Max Request Count** Format: U8 This field indicates the maximum number of requests allowed by the memory sub-system channel.
	23:16	**Current Request Count** Format: U8 This field indicates the number of requests currently outstanding in the memory sub-system. This field should report with a value of zero at the end of frame; otherwise the pre-fetch engine most likely hung waiting for read data to be returned from sub-system.
	15:8	**FX Source Pixel read request - Max Latency Count in 8xMedia clock cycles** Format: U8 This field reports the maximum memory latency count on all Source Pixel reads requested by the memory pre-fetch engine. .
	7:0	**MFX Source Pixel read request - Min Latency Count in 8xMedia clock cycles** Format: U8 This field reports the minimum memory latency count on all Source Pixel reads requested by the memory pre-fetch engine.

HCP Picture Checksum cIdx0

HCP_PICTURE_CHECKSUM_CIDX0 - HCP Picture Checksum cIdx0

Register Space:	MMIO: 0/2/0
Source:	VideoCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	1E91Ch

- The HCP Picture Checksum cIdx0 register reports the 32-bit unsigned picture checksum for cIdx=0 calculated by the HCP hardware and whose algorithm is defined in Annex D of the HEVC standard specification.
- This calculated value is updated at the end of the frame.

DWord	Bit	Description
0	31:0	**Picture checksum cIdx0** Default Value: 0 Format: U32

HCP Picture Checksum cIdx1

HCP_PICTURE_CHECKSUM_CIDX1 - HCP Picture Checksum cIdx1	
Register Space:	MMIO: 0/2/0
Source:	VideoCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	1E920h

- The HCP Picture Checksum cIdx1 register reports the 32-bit unsigned picture checksum for cIdx=1 calculated by the HCP hardware and whose algorithm is defined in Annex D of the HEVC standard specification.
- This calculated value is updated at the end of the frame.

DWord	Bit	Description
0	31:0	**Picture checksum cIdx1** Default Value: 0 Format: U32

HCP Picture Checksum cIdx2

HCP_PICTURE_CHECKSUM_CIDX2 - HCP Picture Checksum cIdx2

Register Space:	MMIO: 0/2/0
Source:	VideoCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	1E924h

- The HCP Picture Checksum cIdx2 register reports the 32-bit unsigned picture checksum for cIdx=2 calculated by the HCP hardware and whose algorithm is defined in Annex D of the HEVC standard specification.
- This calculated value is updated at the end of the frame.

DWord	Bit	Description
0	31:0	**Picture checksum cIdx2** Default Value: 0 Format: U32

HCP Qp Status Count

HCP_QP_STATUS_COUNT - HCP Qp Status Count		
Register Space:	MMIO: 0/2/0	
Source:	VideoCS	
Default Value:	0x00000000, 0x00000000	
Access:	RO	
Size (in bits):	64	
Trusted Type:	1	
Address:	1E9C0h	

DWord	Bit	Description
0	31:24	**Reserved** Format: MBZ
	23:0	**Cumulative QP** Format: U24 Cumulative QP for all LCU of a Frame (Can be used for computing average QP).
1	31:12	**Reserved**
	11:6	**Frame Max CU QP**
	5:0	**Frame Min CU QP**

HCP Reported Bitstream Output CABAC Bin Count Register

HCP_CABAC_BIN_COUNT_FRAME - HCP Reported Bitstream Output CABAC Bin Count Register

Register Space:	MMIO: 0/2/0
Source:	VideoCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	1E9ACh

This register stores the count of number of bins per frame.

DWord	Bit	Description
0	31:0	**HCP Cabac Bin Count** Default Value: 0 Format: U32 Total number of BINs in the bitstream output per frame from the encoder. This count is updated for every time the bin counter is incremented and its reset at image start.

HCP Slice Performance Count

HCP_SLICE_PERF_CNT - HCP Slice Performance Count

Register Space:	MMIO: 0/2/0
Source:	VideoCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	1E964h

This register stores the number of clock cycles spent decoding/encoding the current slice.

This register is not part of hardware context save and restore.

DWord	Bit	Description
0	31:0	**Count** Format: U32 Total number of clocks between slice start and slice end. This count is incremented on crm_clk.

HCP Unit Done

HCP_UNIT_DONE - HCP Unit Done	
Register Space:	MMIO: 0/2/0
Source:	VideoCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Trusted Type:	1
Address:	1E9D8h

DWord	Bit	Description
0	31:25	**Reserved** Format: MBZ
	24:15	**Reserved** Format: MBZ
	14:11	**Reserved** Format: MBZ
	10:9	**Reserved**
	5	**HLC unit done** Format: U1
	4	**HLE unit done** Format: U1
	3	**HFQ unit done** Format: U1
	2	**HFT unit done** Format: U1
	1	**HRS unit done** Format: U1
	0	**HPO unit done** Format: U1

HDC TLB REQUEST CONTROL REGISTER

HDCTLB_REQ_CTRL - HDC TLB REQUEST CONTROL REGISTER		
Register Space:	MMIO: 0/2/0	
Source:	BSpec	
Default Value:	0x00000000	
Size (in bits):	32	
This is a basic register template		
DWord	**Bit**	**Description**
0	31:19	**Reserved** Default Value: 0000000000000b Access: RO

HDPORT_STATE

HDPORT_STATE

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Address:	45050h-45053h
Name:	HDPORT State
ShortName:	HDPORT_STATE
Power:	PG0
Reset:	soft

This register is used to indicate when display resources have been pre-empted by hardware for the HDPORT feature. The usage is set during boot, before BIOS or software is active.
The list of DPLLs and DDIs in this register many not accurately reflect the total number of DPLLs and DDIs supported by display engine. HDPORT will not use any DPLL or DDI not listed here. It will not use any DPLL or DDI that is listed here, but not supported by the particular product or SKU.

Restriction
Restriction : Display software must not use resources that are marked as being used by HDPORT.

DWord	Bit	Description
0	31:16	**Reserved** Format: MBZ
	15	**DPLL2 Used** This field indicates whether DPLL 2 is being used by HDPORT. 0b – Not used 1b – Used
	14	**DPLL3 Used** This field indicates whether DPLL 3 is being used by HDPORT. 0b – Not used 1b – Used
	13	**DPLL1 Used** This field indicates whether DPLL 1 is being used by HDPORT. 0b – Not used 1b – Used

HDPORT_STATE

	12	**DPLL0 Used** This field indicates whether DPLL 0 is being used by HDPORT. **Value** / **Name** 0b – Not used 1b – Used
	11	**Spare 11**
	10	**Spare 10**
	9	**Spare 9**
	8	**DDI3 Type** This field indicates whether DDI 3 (DDI D) is being used in HDMI or DP mode by HDPORT. **Value** / **Name** 0b – DP 1b – HDMI
	7	**DDI3 Used** This field indicates whether DDI 3 (DDI D) is being used by HDPORT. **Value** / **Name** 0b – Not used 1b – Used
	6	**DDI2 Type** This field indicates whether DDI 2 (DDI C) is being used in HDMI or DP mode by HDPORT. **Value** / **Name** 0b – DP 1b – HDMI
	5	**DDI2 Used** This field indicates whether DDI 2 (DDI C) is being used by HDPORT. **Value** / **Name** 0b – Not used 1b – Used
	4	**DDI1 Type** This field indicates whether DDI 1 (DDI B) is being used by the HDPORT in HDMI or DP mode. **Value** / **Name** 0b – DP 1b – HDMI

HDPORT_STATE

	3	**DDI1 Used** This field indicates whether DDI 1 (DDI B) is being used by HDPORT. **Value** / **Name** 0b – Not used 1b – Used
	2	**DDI0 Type** This field indicates whether DDI 0 (DDI A and DDI E) is being used in HDMI or DP mode by HDPORT. **Value** / **Name** 0b – DP 1b – HDMI
	1	**DDI0 Used** This field indicates whether DDI 0 (DDI A and DDI E) is being used by HDPORT. **Value** / **Name** 0b – Not used 1b – Used
	0	**HDPORT Enabled** This field indicates whether HDPORT is enabled. **Value** / **Name** 0b – Disabled 1b – Enabled

Header Type

HDR2_0_2_0_PCI - Header Type

Register Space:	PCI: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Size (in bits):	8
Address:	0000Eh

This register contains the Header Type of the IGD.

DWord	Bit	Description
0	7	**Multi Function Status** Default Value: 0b Access: RO Indicates if the device is a Multi-Function Device. The Value of this register is hardwired to 0, internal graphics is a single function.
	6:0	**Header Code** Default Value: 0000000b Access: RO This is a 7-bit value that indicates the Header Code for the IGD. This code is hardwired to the value 00h, indicating a type 0 configuration space format.

HEVC GAM Slave Counter High part

HEVC_GAM_SLAVE_CTR_H - HEVC GAM Slave Counter High part

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Size (in bits):	32
Address:	04880h
Name:	HEVC slave counter high for VDBOX0
ShortName:	HEVC_VDBOX0_CTR_H
Address:	04884h
Name:	HEVC slave counter high for VDBOX1
ShortName:	HEVC_VDBOX1_CTR_H
Address:	04888h
Name:	HEVC slave counter high for VDBOX2
ShortName:	HEVC_VDBOX2_CTR_H
Address:	0488Ch
Name:	HEVC slave counter high for VDBOX3
ShortName:	HEVC_VDBOX3_CTR_H
Address:	04890h
Name:	HEVC slave counter high for VDBOX4
ShortName:	HEVC_VDBOX4_CTR_H
Address:	04894h
Name:	HEVC slave counter high for VDBOX5
ShortName:	HEVC_VDBOX5_CTR_H
Address:	04898h
Name:	HEVC slave counter high for VDBOX6
ShortName:	HEVC_VDBOX6_CTR_H
Address:	0489Ch
Name:	HEVC slave counter high for VDBOX7
ShortName:	HEVC_VDBOX7_CTR_H

DWord	Bit	Description
0	31:0	**HEVC GAM SLave Counter High** Default Value: 00000000h Access: R/W HEVC GAM Slave counter[63:32]

HEVC GAM Slave Counter Low part

HEVC_GAM_SLAVE_CTR_L - HEVC GAM Slave Counter Low part

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Size (in bits):	32
Address:	04840h
Name:	HEVC slave counter low for VDBOX0
ShortName:	HEVC_VDBOX0_CTR_L
Address:	04844h
Name:	HEVC slave counter low for VDBOX1
ShortName:	HEVC_VDBOX1_CTR_L
Address:	04848h
Name:	HEVC slave counter low for VDBOX2
ShortName:	HEVC_VDBOX2_CTR_L
Address:	0484Ch
Name:	HEVC slave counter low for VDBOX3
ShortName:	HEVC_VDBOX3_CTR_L
Address:	04850h
Name:	HEVC slave counter low for VDBOX4
ShortName:	HEVC_VDBOX4_CTR_L
Address:	04854h
Name:	HEVC slave counter low for VDBOX5
ShortName:	HEVC_VDBOX5_CTR_L
Address:	04858h
Name:	HEVC slave counter low for VDBOX6
ShortName:	HEVC_VDBOX6_CTR_L
Address:	0485Ch
Name:	HEVC slave counter low for VDBOX7
ShortName:	HEVC_VDBOX7_CTR_L

DWord	Bit	Description
0	31:0	**HEVC GAM SLave Counter Low** Default Value: 00000000h Access: R/W HEVC GAM Slave counter[31:0]

HEVC Local APIC Retry Vector

HEVC_LAPIC_RETRY_VECT - HEVC Local APIC Retry Vector

Register Space:	MMIO: 0/2/0
Source:	VideoCS
Default Value:	0x00000000
Access:	RO
Size (in bits):	32
Address:	0D594h

Holds the 4 last retry interrupt vectors. The retry vector register holds the last 4 values acknowledged as an interrupt retry. Retries are errors in hardware and are not expected. HUCINT handles retries by logging the interrupt vector in this register. No interrupt is actually retried, and the interrupt stimulus will be lost if a retry occurs. The system will hang eventually. A 2-bit counter (starting at reset value of 0) is used to point to the slot/byte location from which to load the next retry vector (into the 4 available slots) in sequence. This means if a 5th retry vector shows up, it will be loaded into slot 0 again (as the counter wraps around), over-writing the retry vector which existed there in slot_0.

DWord	Bit	Description
0	31:24	**Vector Slot 3** Format: U8
	23:16	**Vector Slot 2** Format: U8
	15:8	**Vector Slot 1** Format: U8
	7:0	**Vector Slot 0** Format: U8

HEVC Microcontroller Header Info

HUC_UKERNEL_HDR_INFO - HEVC Microcontroller Header Info

Register Space:	MMIO: 0/2/0
Source:	VideoCS
Default Value:	0x00000000
Size (in bits):	32
Address:	0D014h
Access:	RO
Address:	FFE0D014h
Access:	R/W

The Address 0D014h is accessible in the MCI register space

DWord	Bit	Description
0	31:10	**Reserved** Format: MBZ
	9:2	**Kernel ID** Access: RO Format: U8 Kernel specified by the HUC_IMEM_STATE command.
	1	**Reserved** Format: MBZ
	0	**uKernel Header Valid** Access: RO Format: U1 A value of 1 indicates that the register contents are loaded successfully and Kernel ID field is valid.

HS Invocation Counter

HS_INVOCATION_COUNT - HS Invocation Counter	
Register Space:	MMIO: 0/2/0
Source:	RenderCS
Default Value:	0x00000000, 0x00000000
Access:	R/W
Size (in bits):	64
Trusted Type:	1
Address:	02300h

This register stores the number of patch objects processed by the HS unit. E.g., A PATCHLIST_2 topology with 6 vertices would cause this counter to increment by 3 (there are 3 2-vertex patch objects in that topology).This register is part of the context save and restore.

DWord	Bit	Description
0	63:32	**HS Invocation Count UDW** Number of patch objects processed by the HS stage. Updated only when HS Enable and HS Statistics Enable are set in 3DSTATE_HS
	31:0	**HS Invocation Count LDW** Number of patch objects processed by the HS stage. Updated only when HS Enable and HS Statistics Enable are set in 3DSTATE_HS

IA32 MTRR FIX4K_C0000 High

MTRR_FIX4K_C0000_H - IA32 MTRR FIX4K_C0000 High		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	0F13Ch	
Fixed MTRR to identify (C0000-C8000h).		
DWord	**Bit**	**Description**
0	31:0	**Range0 to Range7 Memory Type** Default Value: 00000000h Access: R/W Bit[63:56]: Identifies the memory type 00h-FFh of range#7. Bit[55:48]: Identifies the memory type 00h-FFh of range#6. Bit[47:40]: Identifies the memory type 00h-FFh of range#5. Bit[39:32]: Identifies the memory type 00h-FFh of range#4.

IA32 MTRR FIX4K_C0000 Low

MTRR_FIX4K_C0000_L - IA32 MTRR FIX4K_C0000 Low		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	0F138h	
Fixed MTRR to identify (C0000-C8000h).		
DWord	**Bit**	**Description**
0	31:0	**Range0 to Range7 Memory Type** Default Value: 00000000h Access: R/W Bit[31:24]: Identifies the memory type 00h-FFh of range#3. Bit[23:16]: Identifies the memory type 00h-FFh of range#2. Bit[15:8]: Identifies the memory type 00h-FFh of range#1. Bit[7:0]: Identifies the memory type 00h-FFh of range#0.

IA32 MTRR FIX4K_C8000 High

MTRR_FIX4K_C8000_H - IA32 MTRR FIX4K_C8000 High		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	0F144h	
Fixed MTRR to identify (C8000-D0000h).		
DWord	**Bit**	**Description**
0	31:0	**Range0 to Range7 Memory Type** Default Value: 00000000h Access: R/W Bit[63:56]: Identifies the memory type 00h-FFh of range#7. Bit[55:48]: Identifies the memory type 00h-FFh of range#6. Bit[47:40]: Identifies the memory type 00h-FFh of range#5. Bit[39:32]: Identifies the memory type 00h-FFh of range#4.

IA32 MTRR FIX4K_C8000 Low

MTRR_FIX4K_C8000_L - IA32 MTRR FIX4K_C8000 Low		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	0F140h	
Fixed MTRR to identify (C8000-D0000h).		
DWord	**Bit**	**Description**
0	31:0	**Range0 to Range7 Memory Type** Default Value: 00000000h Access: R/W Bit[31:24]: Identifies the memory type 00h-FFh of range#3. Bit[23:16]: Identifies the memory type 00h-FFh of range#2. Bit[15:8]: Identifies the memory type 00h-FFh of range#1. Bit[7:0]: Identifies the memory type 00h-FFh of range#0.

IA32 MTRR FIX4K_D0000 High

MTRR_FIX4K_D0000_H - IA32 MTRR FIX4K_D0000 High		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	0F14Ch	
Fixed MTRR to identify (D0000-D8000h)		
DWord	**Bit**	**Description**
0	31:0	**Range0 to Range7 Memory Type** Default Value: 00000000h Access: R/W Bit[63:56]: Identifies the memory type 00h-FFh of range#7. Bit[55:48]: Identifies the memory type 00h-FFh of range#6. Bit[47:40]: Identifies the memory type 00h-FFh of range#5. Bit[39:32]: Identifies the memory type 00h-FFh of range#4.

IA32 MTRR FIX4K_D0000 Low

MTRR_FIX4K_D0000_L - IA32 MTRR FIX4K_D0000 Low		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	0F148h	
Fixed MTRR to identify (D0000-D8000h)		
DWord	**Bit**	**Description**
0	31:0	**Range0 to Range7 Memory Type** Default Value: 00000000h Access: R/W Bit[31:24]: Identifies the memory type 00h-FFh of range#3. Bit[23:16]: Identifies the memory type 00h-FFh of range#2. Bit[15:8]: Identifies the memory type 00h-FFh of range#1. Bit[7:0]: Identifies the memory type 00h-FFh of range#0.

IA32 MTRR FIX4K_D8000 High

MTRR_FIX4K_D8000_H - IA32 MTRR FIX4K_D8000 High		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000

Address:	0F130h	
Fixed MTRR to identify 768K-1024K of the main memory (A0000-C0000h).		
DWord	**Bit**	**Description**
0	31:0	**Range0 to Range7 Memory Type** Default Value: 00000000h Access: R/W Bit[31:24]: Identifies the memory type 00h-FFh of range#3. Bit[23:16]: Identifies the memory type 00h-FFh of range#2. Bit[15:8]: Identifies the memory type 00h-FFh of range#1. Bit[7:0]: Identifies the memory type 00h-FFh of range#0.

IA32 MTRR FIX64K_00000 High

MTRR_FIX64K_00000_H - IA32 MTRR FIX64K_00000 High		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	0F124h	
Fixed MTRR to identify 0-512K of the main memory (0-80000h).		
DWord	**Bit**	**Description**
0	31:0	**Range0 to Range7 Memory Type** Default Value: 00000000h Access: R/W Bit[63:56]: Identifies the memory type 00h-FFh of range#7. Bit[55:48]: Identifies the memory type 00h-FFh of range#6. Bit[47:40]: Identifies the memory type 00h-FFh of range#5. Bit[39:32]: Identifies the memory type 00h-FFh of range#4.

IA32 MTRR FIX64K_00000 Low

MTRR_FIX64K_00000_L - IA32 MTRR FIX64K_00000 Low		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	0F120h	
Fixed MTRR to identify 0-512K of the main memory (0-80000h).		
DWord	**Bit**	**Description**
0	31:0	**Range0 to Range7 Memory Type** Default Value: 00000000h Access: R/W Bit[31:24]: Identifies the memory type 00h-FFh of range#3. Bit[23:16]: Identifies the memory type 00h-FFh of range#2. Bit[15:8]: Identifies the memory type 00h-FFh of range#1. Bit[7:0]: Identifies the memory type 00h-FFh of range#0.

IA32 MTRR PHYSBASE0 High

MTRR_PHYSBASE0_H - IA32 MTRR PHYSBASE0 High

Register Space:	MMIO: 0/2/0
Default Value:	0x00000000
Size (in bits):	32
Address:	0F184h

Variable MTRR0

DWord	Bit	Description
0	31:7	**Reserved** Default Value: 00000000000000000000000000b Access: RO
	6:0	**PhysBase** Default Value: 0000000b Access: R/W Physical Base address[38:32] of the variable MTRR.

IA32 MTRR PHYSBASE0 Low

MTRR_PHYSBASE0_L - IA32 MTRR PHYSBASE0 Low

Register Space:	MMIO: 0/2/0
Default Value:	0x00000000
Size (in bits):	32
Address:	0F180h

Variable MTRR0

DWord	Bit	Description
0	31:12	**PhysBase** Default Value: 00000h Access: R/W Physical Base address[31:0] of the variable MTRR.
	11:8	**Reserved** Default Value: 0000b Access: RO
	7:0	**Memory Type** Default Value: 00h Access: R/W Identifies the memory type 00h-FFh.

IA32 MTRR PHYSBASE1 High

MTRR_PHYSBASE1_H - IA32 MTRR PHYSBASE1 High

Register Space:	MMIO: 0/2/0
Default Value:	0x00000000
Size (in bits):	32
Address:	0F194h

Variable MTRR1

DWord	Bit	Description
0	31:7	**Reserved** Default Value: 00000000000000000000000000b Access: RO
	6:0	**PhysBase** Default Value: 0000000b Access: R/W Physical Base address[38:32] of the variable MTRR.

IA32 MTRR PHYSBASE1 Low

MTRR_PHYSBASE1_L - IA32 MTRR PHYSBASE1 Low

Register Space:	MMIO: 0/2/0
Default Value:	0x00000000
Size (in bits):	32
Address:	0F190h

Variable MTRR1

DWord	Bit	Description
0	31:12	**PhysBase** Default Value: 00000h Access: R/W Physical Base address[31:0] of the variable MTRR.
	11:8	**Reserved** Default Value: 0000b Access: RO
	7:0	**Memory Type** Default Value: 00h Access: R/W Identifies the memory type 00h-FFh.

IA32 MTRR PHYSBASE2 High

MTRR_PHYSBASE2_H - IA32 MTRR PHYSBASE2 High		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	0F1A4h	
Variable MTRR2		
DWord	**Bit**	**Description**
0	31:7	**Reserved** Default Value: 00000000000000000000000000b Access: RO
	6:0	**PhysBase** Default Value: 0000000b Access: R/W Physical Base address[38:32] of the variable MTRR.

IA32 MTRR PHYSBASE2 Low

MTRR_PHYSBASE2_L - IA32 MTRR PHYSBASE2 Low

Register Space:	MMIO: 0/2/0
Default Value:	0x00000000
Size (in bits):	32
Address:	0F1A0h

Variable MTRR2

DWord	Bit	Description
0	31:12	**PhysBase** Default Value: 00000h Access: R/W Physical Base address[31:0] of the variable MTRR.
	11:8	**Reserved** Default Value: 0000b Access: RO
	7:0	**Memory Type** Default Value: 00h Access: R/W Identifies the memory type 00h-FFh.

IA32 MTRR PHYSBASE3 High

MTRR_PHYSBASE3_H - IA32 MTRR PHYSBASE3 High

Register Space:	MMIO: 0/2/0
Default Value:	0x00000000
Size (in bits):	32
Address:	0F1B4h

Variable MTRR3

DWord	Bit	Description
0	31:7	**Reserved** Default Value: 00000000000000000000000000b Access: RO
	6:0	**PhysBase** Default Value: 0000000b Access: R/W Physical Base address[38:32] of the variable MTRR.

IA32 MTRR PHYSBASE3 Low

MTRR_PHYSBASE3_L - IA32 MTRR PHYSBASE3 Low		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	0F1B0h	
Variable MTRR3		
DWord	**Bit**	**Description**
0	31:12	**PhysBase** Default Value: 00000h Access: R/W Physical Base address[31:0] of the variable MTRR.
	11:8	**Reserved** Default Value: 0000b Access: RO
	7:0	**Memory Type** Default Value: 00h Access: R/W Identifies the memory type 00h-FFh.

IA32 MTRR PHYSBASE4 High

MTRR_PHYSBASE4_H - IA32 MTRR PHYSBASE4 High		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	0F1C4h	
Variable MTRR4		

DWord	Bit	Description
0	31:7	**Reserved** Default Value: 00000000000000000000000000b Access: RO
	6:0	**PhysBase** Default Value: 0000000b Access: R/W Physical Base address[38:32] of the variable MTRR.

IA32 MTRR PHYSBASE4 Low

MTRR_PHYSBASE4_L - IA32 MTRR PHYSBASE4 Low

Register Space:	MMIO: 0/2/0
Default Value:	0x00000000
Size (in bits):	32
Address:	0F1C0h

Variable MTRR4

DWord	Bit	Description
0	31:12	**PhysBase** Default Value: 00000h Access: R/W Physical Base address[31:0] of the variable MTRR.
	11:8	**Reserved** Default Value: 0000b Access: RO
	7:0	**Memory Type** Default Value: 00h Access: R/W Identifies the memory type 00h-FFh

IA32 MTRR PHYSBASE5 High

MTRR_PHYSBASE5_H - IA32 MTRR PHYSBASE5 High		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	0F1D4h	
Variable MTRR5		
DWord	**Bit**	**Description**
0	31:7	**Reserved** Default Value: 00000000000000000000000000b Access: RO
	6:0	**PhysBase** Default Value: 0000000b Access: R/W Physical Base address[38:32] of the variable MTRR.

IA32 MTRR PHYSBASE5 Low

MTRR_PHYSBASE5_L - IA32 MTRR PHYSBASE5 Low		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	0F1D0h	
Variable MTRR5		
DWord	**Bit**	**Description**
0	31:12	**PhysBase** Default Value: 00000h Access: R/W Physical Base address[31:0] of the variable MTRR.
	11:8	**Reserved** Default Value: 0000b Access: RO
	7:0	**Memory Type** Default Value: 00h Access: R/W Identifies the memory type 00h-FFh.

IA32 MTRR PHYSBASE6 High

MTRR_PHYSBASE6_H - IA32 MTRR PHYSBASE6 High		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	0F1E4h	
Variable MTRR6		
DWord	**Bit**	**Description**
0	31:7	**Reserved** Default Value: 0000000000000000000000000b Access: RO
	6:0	**PhysBase** Default Value: 0000000b Access: R/W Physical Base address[38:32] of the variable MTRR.

IA32 MTRR PHYSBASE6 Low

MTRR_PHYSBASE6_L - IA32 MTRR PHYSBASE6 Low

Register Space:	MMIO: 0/2/0
Default Value:	0x00000000
Size (in bits):	32
Address:	0F1E0h

Variable MTRR6

DWord	Bit	Description
0	31:12	**PhysBase** Default Value: 00000h Access: R/W Physical Base address[31:0] of the variable MTRR.
	11:8	**Reserved** Default Value: 0000b Access: RO
	7:0	**Memory Type** Default Value: 00h Access: R/W Identifies the memory type 00h-FFh.

IA32 MTRR PHYSBASE7 High

MTRR_PHYSBASE7_H - IA32 MTRR PHYSBASE7 High

Register Space:	MMIO: 0/2/0
Default Value:	0x00000000
Size (in bits):	32
Address:	0F1F4h

Variable MTRR7

DWord	Bit	Description
0	31:7	**Reserved** Default Value: 00000000000000000000000000b Access: RO
	6:0	**PhysBase** Default Value: 0000000b Access: R/W Physical Base address[38:32] of the variable MTRR.

IA32 MTRR PHYSBASE7 Low

MTRR_PHYSBASE7_L - IA32 MTRR PHYSBASE7 Low

Register Space:	MMIO: 0/2/0
Default Value:	0x00000000
Size (in bits):	32
Address:	0F1F0h

Variable MTRR7

DWord	Bit	Description
0	31:12	**PhysBase** Default Value: 00000h Access: R/W Physical Base address[31:0] of the variable MTRR.
	11:8	**Reserved** Default Value: 0000b Access: RO
	7:0	**Memory Type** Default Value: 00h Access: R/W Identifies the memory type 00h-FFh.

IA32 MTRR PHYSBASE8 High

MTRR_PHYSBASE8_H - IA32 MTRR PHYSBASE8 High

Register Space:	MMIO: 0/2/0
Default Value:	0x00000000
Size (in bits):	32
Address:	0F204h

Variable MTRR8

DWord	Bit	Description
0	31:7	**Reserved** Default Value: 00000000000000000000000000b Access: RO
	6:0	**PhysBase** Default Value: 0000000b Access: R/W Physical Base address[38:32] of the variable MTRR.

IA32 MTRR PHYSBASE8 Low

MTRR_PHYSBASE8_L - IA32 MTRR PHYSBASE8 Low

Register Space:	MMIO: 0/2/0
Default Value:	0x00000000
Size (in bits):	32
Address:	0F200h

Variable MTRR8

DWord	Bit	Description
0	31:12	**PhysBase** Default Value: 00000h Access: R/W Physical Base address[31:0] of the variable MTRR
	11:8	**Reserved** Default Value: 0000b Access: RO
	7:0	**Memory Type** Default Value: 00h Access: R/W Identifies the memory type 00h-FFh.

IA32 MTRR PHYSBASE9 High

MTRR_PHYSBASE9_H - IA32 MTRR PHYSBASE9 High		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	0F214h	
Variable MTRR9		

DWord	Bit	Description
0	31:7	**Reserved** Default Value: 00000000000000000000000000b Access: RO
	6:0	**PhysBase** Default Value: 0000000b Access: R/W Physical Base address[38:32] of the variable MTRR.

IA32 MTRR PHYSBASE9 Low

MTRR_PHYSBASE9_L - IA32 MTRR PHYSBASE9 Low

Register Space:	MMIO: 0/2/0
Default Value:	0x00000000
Size (in bits):	32
Address:	0F210h

Variable MTRR9

DWord	Bit	Description
0	31:12	**PhysBase** Default Value: 00000h Access: R/W Physical Base address[31:0] of the variable MTRR.
	11:8	**Reserved** Default Value: 0000b Access: RO
	7:0	**Memory Type** Default Value: 00h Access: R/W Identifies the memory type 00h-FFh.

IA32 MTRR PHYSMASK0 High

MTRR_PHYSMASK0_H - IA32 MTRR PHYSMASK0 High		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	0F18Ch	
Variable MTRR0		

DWord	Bit	Description
0	31:7	**Reserved** Default Value: 00000000000000000000000000b Access: RO
	6:0	**PhysMask** Default Value: 0000000b Access: R/W Physical MASK for the address[38:32] of the variable MTRR.

IA32 MTRR PHYSMASK0 Low

MTRR_PHYSMASK0_L - IA32 MTRR PHYSMASK0 Low

Register Space:	MMIO: 0/2/0
Default Value:	0x00000000
Size (in bits):	32
Address:	0F188h

Variable MTRR0

DWord	Bit	Description
0	31:12	**PhysMask** Default Value: 00000h Access: R/W Physical MASK for the address[31:0] of the variable MTRR.
	11	**Valid** Default Value: 0b Access: R/W Valid bit showing that MTRR decode is active.
	10:0	**Reserved** Default Value: 00000000000b Access: RO

IA32 MTRR PHYSMASK1 High

MTRR_PHYSMASK1_H - IA32 MTRR PHYSMASK1 High		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	0F19Ch	
Variable MTRR1		
DWord	**Bit**	**Description**
0	31:7	**Reserved** Default Value: 00000000000000000000000000b Access: RO
	6:0	**PhysMask** Default Value: 0000000b Access: R/W Physical MASK for the address[38:32] of the variable MTRR.

IA32 MTRR PHYSMASK1 Low

MTRR_PHYSMASK1_L - IA32 MTRR PHYSMASK1 Low

Register Space:	MMIO: 0/2/0
Default Value:	0x00000000
Size (in bits):	32
Address:	0F198h

Variable MTRR1

DWord	Bit	Description
0	31:12	**PhysMask** Default Value: 00000h Access: R/W Physical MASK for the address[31:0] of the variable MTRR.
	11	**Valid** Default Value: 0b Access: R/W Valid bit showing that MTRR decode is active.
	10:0	**Reserved** Default Value: 00000000000b Access: RO

IA32 MTRR PHYSMASK2 High

MTRR_PHYSMASK2_H - IA32 MTRR PHYSMASK2 High		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	0F1ACh	
Variable MTRR2		
DWord	**Bit**	**Description**
0	31:7	**Reserved** Default Value: 00000000000000000000000000b Access: RO
	6:0	**PhysMask** Default Value: 0000000b Access: R/W Physical MASK for the address[38:32] of the variable MTRR.

IA32 MTRR PHYSMASK2 Low

MTRR_PHYSMASK2_L - IA32 MTRR PHYSMASK2 Low		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	0F1A8h	
Variable MTRR2		
DWord	**Bit**	**Description**
0	31:12	**PhysMask** Default Value: 00000h Access: R/W Physical MASK for the address[31:0] of the variable MTRR.
	11	**Valid** Default Value: 0b Access: R/W Valid bit showing that MTRR decode is active.
	10:0	**Reserved** Default Value: 00000000000b Access: RO

IA32 MTRR PHYSMASK3 High

MTRR_PHYSMASK3_H - IA32 MTRR PHYSMASK3 High		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	0F1BCh	
Variable MTRR3		
DWord	**Bit**	**Description**
0	31:7	**Reserved** Default Value: 00000000000000000000000000b Access: RO
	6:0	**PhysMask** Default Value: 0000000b Access: R/W Physical MASK for the address[38:32] of the variable MTRR.

IA32 MTRR PHYSMASK3 Low

MTRR_PHYSMASK3_L - IA32 MTRR PHYSMASK3 Low		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000

MTRR_PHYSMASK8_L - IA32 MTRR PHYSMASK8 Low

Register Space:	MMIO: 0/2/0
Default Value:	0x00000000
Size (in bits):	32
Address:	0F208h

Variable MTRR8

DWord	Bit	Description
0	31:12	**PhysMask** Default Value: 00000h Access: R/W Physical MASK for the address[31:0] of the variable MTRR.
	11	**Valid** Default Value: 0b Access: R/W Valid bit showing that MTRR decode is active.
	10:0	**Reserved** Default Value: 00000000000b Access: RO

IA32 MTRR PHYSMASK9 High

MTRR_PHYSMASK9_H - IA32 MTRR PHYSMASK9 High		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	0F21Ch	
Variable MTRR9		
DWord	**Bit**	**Description**
0	31:7	**Reserved** Default Value: 00000000000000000000000000b Access: RO
	6:0	**PhysMask** Default Value: 0000000b Access: R/W Physical MASK for the address[38:32] of the variable MTRR.

IA32 MTRR PHYSMASK9 Low

MTRR_PHYSMASK9_L - IA32 MTRR PHYSMASK9 Low

Register Space:	MMIO: 0/2/0
Default Value:	0x00000000
Size (in bits):	32
Address:	0F218h

Variable MTRR9

DWord	Bit	Description
0	31:12	**PhysMask** Default Value: 00000h Access: R/W Physical MASK for the address[31:0] of the variable MTRR.
	11	**Valid** Default Value: 0b Access: R/W Valid bit showing that MTRR decode is active.
	10:0	**Reserved** Default Value: 00000000000b Access: RO

IA Vertices Count

IA_VERTICES_COUNT - IA Vertices Count	
Register Space:	MMIO: 0/2/0
Source:	RenderCS
Default Value:	0x00000000, 0x00000000
Access:	R/W
Size (in bits):	64
Trusted Type:	1
Address:	02310h

This register stores the count of vertices processed by VF. This register is part of the context save and restore.

DWord	Bit	Description
0	63:32	**IA Vertices Count Report UDW** Total number of vertices fetched by the VF stage. This count is updated for every input vertex as long as Statistics Enable is set in VF_STATE (see the Vertex Fetch Chapter in the 3D Volume.)
	31:0	**IA Vertices Count Report LDW** Total number of vertices fetched by the VF stage. This count is updated for every input vertex as long as Statistics Enable is set in VF_STATE (see the Vertex Fetch Chapter in the 3D Volume.)

IDI Cacheable Register

IDICA - IDI Cacheable Register

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Size (in bits):	32
Address:	09014h

Cacheable

DWord	Bit	Description
0	31:30	**LLCWBCA** Access: R/W NOTE - THIS SHOULD ALWAYS BE PROGRAMMED TO 00b.
	29:28	**LLCPRFOCA** Access: R/W NOTE - THIS SHOULD ALWAYS BE PROGRAMMED TO 00b.
	27:26	**LLCPCCA** Access: R/W NOTE - THIS SHOULD ALWAYS BE PROGRAMMED TO 00b.
	25:24	**LLCPDCA** Access: R/W NOTE - THIS SHOULD ALWAYS BE PROGRAMMED TO 00b.
	23:22	**CLFCA** Access: R/W NOTE - THIS SHOULD ALWAYS BE PROGRAMMED TO 00b.
	21:20	**POCA** Access: R/W NOTE - THIS SHOULD ALWAYS BE PROGRAMMED TO 00b.
	19:18	**ITMCA** Access: R/W NOTE - THIS SHOULD ALWAYS BE PROGRAMMED TO 00b.
	17:16	**WCILFCA** Access: R/W NOTE - THIS SHOULD ALWAYS BE PROGRAMMED TO 00b.
	15:14	**WILCA** Access: R/W NOTE - THIS SHOULD ALWAYS BE PROGRAMMED TO 00b. CANNOT BE FLEXED.

IDICA - IDI Cacheable Register

	13:12	**WCILCA** Access: R/W >NOTE - THIS SHOULD ALWAYS BE PROGRAMMED TO 00b. CANNOT BE FLEXED.
	11:10	**WBMCA** Access: R/W NOTE - THIS SHOULD ALWAYS BE PROGRAMMED TO 00b.
	9:8	**RFOCA** Access: R/W NOTE - THIS SHOULD ALWAYS BE PROGRAMMED TO 00b.
	7:6	**PORINCA** Access: R/W NOTE - THIS SHOULD ALWAYS BE PROGRAMMED TO 00b.
	5:4	**PRDCA** Access: R/W NOTE - THIS SHOULD ALWAYS BE PROGRAMMED TO 00b.
	3:2	**DRDCA** Access: R/W 00b: Whatever the logic decides (so force feature is disabled) - Default. 01b: Always drive 0. 10b: Always drive 1. 11b: Reserved.
	1:0	**CRDCA** Access: R/W 00b: Whatever the logic decides (so force feature is disabled) - Default. 01b: Always drive 0. 10b: Always drive 1. 11b: Reserved.

IDI Control register

IDICR - IDI Control register		
Register Space:	MMIO: 0/2/0	
Source:	BSpec	
Default Value:	0x00000181	
Size (in bits):	32	
Address:	09008h	
DWord	**Bit**	**Description**
0	31:24	**Spares** Access: R/W ECO purposes and Reserved.
	23:22	**QOS setting for Frame Buffer Caching** Access: R/W The value determines the quality of service setting of Frame Buffers while being cached in Last Level Cache/eDRAM. GFX Driver has to set the value of QOS after enabling Frame Buffer caching and deciding which ways of LLC is allocated for which QOS values. 00 : QOS setting of 00 used for Frame Buffers 01 : QOS setting of 01 used for Frame Buffers 10 : QOS setting of 10 used for Frame Buffers 11 : QOS setting of 11 used for Frame Buffers
	21:16	**IDI HASH MASK** Access: R/W IDI HASH MASK: When a corresponding bit is set, the address line going into HASH for CBO ID calculation is forced to logic0. 21=> Address Bit[11] 20=> Address Bit[10] 19=> Address Bit[9] 18=> Address Bit[8] 17=> Address Bit[7] 16=> Address Bit[6] Note: It is required for GFX Driver to set [19:16] to 1 when eDRAM configuration is enabled. For Skylake, S/W is not needed to program this register as eDRAM is a memory side cache.
	15	**GFX Data regulation** Access: R/W BGF data regulation for incoming streams with chunkID detection.
	14:10	**Reserved**

IDICR - IDI Control register

	9	**RSVD** Access: RO
	8	**Push Write Enable** Default Value: 1b Access: R/W Push Write Enable: Push writes are a new mechanism to deliver write data to Uncore. It provides two advantages. 1) Reduced TAG pass requirements 2) Only way to allocate into eLLC without going thru LLC. The downside is the fact that push writes are weakly ordered which means a synchronizing event is required to guarantee consistency of data.
	7	**Snoop Request control** Default Value: 1b Access: R/W 1: Snoop is allowed only when there are no Pending response. 0: Means after every 24 u2c response we allow one snoop request to bypass.
	6:4	**LRUHint** Access: R/W 000b: No LRUHint command sent to uncore. It is reserved. 001b: If LRUHint is asserted from SQ with a read or write command, IDI dispatcher chooses to send an LlcPrefData. 101b: If LRUHint is asserted from SQ with a read or write command, IDI dispatcher chooses to send an LLCPrefCode command on the C2U request channel. 010b: If LRUHint is asserted from SQ with a read/write command, IDI dispatcher chooses to send an LlcPrefRFO command on the C2U request channel. 011b: If LRUHint is asserted from SQ with a read, IDI dispatcher chooses to send LlcPrefData command on the C2U request channel. If LRUHint is asserted from SQ with a write, IDI dispatcher chooses to send LlcPrefRFO command on the C2U request channel. 111b: If LRUHint is asserted from SQ with a read, IDI dispatcher chooses to send LLCPrefCode command on the C2U request channel. If LRUHint is asserted from SQ with a write, IDI dispatcher chooses to send LlcPrefRFO command on the C2U request channel.
	3	**RSVD** Access: RO
	2	**Resport 1 disable** Access: R/W 0: Default value - Both the Response ports on the BGF side are enabled. 1: Rsp Port1 Disable - Response Port1 is disable on the BGF Side.

IDICR - IDI Control register

	1:0	**SQ Grant Counter** Default Value: 01b Access: R/W SQ grant counter - 2-bit grant counter for SQ requests 00b: 1 grant. 01b: 2 grants. 10b: 4 grants. 11b: 8 grants.

IDI HASH Mask Register

DRBIDI3 - IDI HASH Mask Register

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Size (in bits):	32
Address:	01948h

DWord	Bit	Description
0	31:10	**Reserved** Access: RO Reserved
	9:8	**Reserved**
	7:6	**Reserved** Access: RO Reserved
	5:0	**IDI HASH MASK** Access: R/W When corresponding MASK bit is set, the masked address bit going into HASH calculator is forced to be logic0. 21=> Address Bit[11] 20=> Address Bit[10] 19=> Address Bit[9] 18=> Address Bit[8] 17=> Address Bit[7] 16=> Address Bit[6] For Gen8 with 128MB eDRAM eLLC, bits[5:0] should be set to 001111 (matching 9008[21:16] IDI hash mask) In SKL, it is no longer needed for s/w to program this field given that eDRAM is a memory side cache

IDI Look up Register

IDILK2 - IDI Look up Register

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Size (in bits):	32
Address:	08514h

IDI Look up Register

DWord	Bit	Description
0	31:30	**Spares** Access: R/W Lock
	28	**Colloc bit for Slice 5** Access: R/W Lock Co-located indicates that the Collocated Cbo should receive this request.
	27	**Direction bit for Slice 5** Access: R/W Lock In Half ring uncore topologies this indicates if the 1: Going Up. 0: Going Down.
	26	**Polarity bit for Slice 5** Access: R/W Lock Polarity based on the current core Slice ID and the Destination Cbo ID - should this request be sent to the rings in Even or Odd cycles (this is basically the Distance between the source and destination). 1 - Even. 0 - Odd.
	25	**For Me for Slice 5** Access: R/W Lock The next slice the Target of this request (MyNeigbourId == DestCboId).
	24	**Spares2** Access: R/W Lock Reserved for Slice 4.

IDILK2 - IDI Look up Register

	23	**Colloc bit for Slice 4** Access: R/W Lock Co-located indicates that the Collocated Cbo should receive this request.
	22	**Direction bit for Slice 4** Access: R/W Lock In Half ring uncore topologies this indicates if the 1: Going Up. 0: Going Down.
	21	**Polarity Bit for Slice 4** Access: R/W Lock Polarity based on the current core Slice ID and the Destination Cbo ID - should this request be sent to the rings in Even or Odd cycles (this is basically the Distance between the source and destination). 1 - Even. 0 - Odd.
	20	**For Me bit for Slice 4** Access: R/W Lock The next slice the Target of this request (MyNeigbourId == DestCboId).
	19	**Spare for Slice 3** Access: R/W Lock Reserved for Slice 3.
	18	**Colloc bit for Slice 3** Access: R/W Lock Co-located indicates that the Collocated Cbo should receive this request.
	17	**Direction bit for S3** Access: R/W Lock In Half ring uncore topologies this indicates if the 1: Going Up. 0: Going Down.
	16	**Polarity Bit for Slice 3** Access: R/W Lock Polarity based on the current core Slice ID and the Destination Cbo ID - should this request be sent to the rings in Even or Odd cycles (this is basically the Distance between the source and destination).

IDILK2 - IDI Look up Register

		1 - Even. 0 - Odd.
	15	**For Me Bit for Slice 3** Access: R/W Lock The next slice the Target of this request (MyNeigbourId == DestCboId).
	14	**Spare for Slice 2** Access: R/W Lock Reserved for Slice 2.
	13	**Colloc bit for Slice 2** Access: R/W Lock Co-located indicates that the Collocated Cbo should receive this request.
	12	**Direction Bit for Slice 2** Access: R/W Lock In Half ring uncore topologies this indicates if the 1: Going Up. 0: Going Down.
	11	**Polarity Bit for Slice 2** Access: R/W Lock Polarity based on the current core Slice ID and the Destination Cbo ID - should this request be sent to the rings in Even or Odd cycles (this is basically the Distance between the source and destination). 1 - Even. 0 - Odd.
	10	**For me Bit for Slice 2** Access: R/W Lock The next slice the Target of this request (MyNeigbourId == DestCboId).
	9	**Spare for Slice 1** Access: R/W Lock Reserved for Slice 1.
	8	**Colloc Bit for Slice 1** Access: R/W Lock Co-located indicates that the Collocated Cbo should receive this request.

IDILK2 - IDI Look up Register

	7	**Direction Bit for Slice 1** Access: R/W Lock In Half ring uncore topologies this indicates if the 1: Going Up. 0: Going Down.
	6	**Polarity Bit for Slice 1** Access: R/W Lock Polarity based on the current core Slice ID and the Destination Cbo ID - should this request be sent to the rings in Even or Odd cycles (this is basically the Distance between the source and destination). 1 - Even. 0 - Odd.
	5	**For Me Bit for Slice 1** Access: R/W Lock The next slice the Target of this request (MyNeigbourId == DestCboId).
	4	**Spare for Slice 0** Access: R/W Lock Reserved for Slice 0.
	3	**Colloc Bit for Slice 0** Access: R/W Lock Co-located indicates that the Collocated Cbo should receive this request.
	2	**Direction Bit in Slice0** Access: R/W Lock Direction bit for Slice0: In Half ring uncore topologies this indicates if the request needs to be driven on the Up going (1) or the down (0) going ring direction. For Full ring it indicates Clock-wise (1) or counter clock-wise directions. 1: Going Up. 0: Going Down.
	1	**Polarity Bit for Slice 0** Access: R/W Lock Polarity based on the current core Slice ID and the Destination Cbo ID - should this request be sent to the rings in Even or Odd cycles (this is basically the Distance between the source and destination). 1 - Even.

IDILK2 - IDI Look up Register		
		0 - Odd.
	0	**For Me bit for Slice0** Access: R/W Lock The next slice the Target of this request (MyNeigbourId == DestCboId).

IDILook up Table register

IDILK1 - IDILook up Table register

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Size (in bits):	32
Address:	08510h

IDI Look Up register I

DWord	Bit	Description
0	31:21	**Spares** Access: R/W Lock
	20:16	**GT Logical ID** Access: R/W Lock Logical ID for GT.
	15:14	**Spares1** Access: R/W Lock Reserved for SA slice.
	13	**Colloc bit for SA Slice** Access: R/W Lock Co-located indicates that the Collocated Cbo should receive this request.
	12	**Direction Bit for SA** Access: R/W Lock In Half ring uncore topologies this indicates if the request needs to be driven on the Up going (1) or the down (0) going ring direction. For Full ring it indicates Clock-wise (1) or counter clock-wise directions. 1: Going Up. 0: Going Down.
	11	**Polarity bit for SA Slice** Access: R/W Lock Polarity based on the current core Slice ID and the Destination Cbo ID - should this request be sent to the rings in Even or Odd cycles (this is basically the Distance between the source and destination). 1 - Even. 0 - Odd.

IDILK1 - IDILook up Table register

	10	**For Me bit for SA** Access: R/W Lock The next slice the Target of this request (MyNeigbourId == DestCboId).
	9:5	**Number of LLC SA Slices** Access: R/W Lock Number of Slice information in the system. This register contains the number of LLC cache slices on the RING. Default: 0000b.
	4:0	**Colocated Slice ID for GT** Access: R/W Lock This register contains the ID of the slice that is servicing GT's co-located cycles. The default is for slice0 to service GT.

IDI MESSAGES

IDIMSG - IDI MESSAGES

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Size (in bits):	32
Address:	08500h

IDI Message Register

DWord	Bit	Description
0	31:16	**Mask Bits** Access: RO Reserved.
	15:13	**RSVD** Access: RO
	12	**MCHECK COMPLETE** Access: R/W iMPH writes to this bit to initiate MCHECK COMPLETE Routine (PPPE flow). MBCunit will clear this bit once the PPPE flow is complete
	11	**Spare** Access: R/W Spare Messaging Bit with self-clear.
	10	**MBC Busy ACK** Access: R/W 1 - Busy ACK from GPMunit(Non-Idle). 0 - Non Busy ACK from Gpmunit (Idle). This bit is valid only if 26th Bit is set.
	9	**Reserved**
	8	**Reserved**
	7	**RSVD** Access: RO
	6	**Request to Block IDI** Access: R/W Block and Unblock IDI Request - usually done during CPD Entry and Exits. This is valid only if 22nd bit is set. Block IDI - CPD Entry = 1. Unblock IDI CPD Exit = 0.

IDIMSG - IDI MESSAGES

	5	**Unblock MMIO ack** Access: R/W Unblock MMIO ACK coming from SA. This is valid only if 21st bit is set.
	4	**Mbcunit Arbitration request/Release ACK** Access: R/W Arbitration request is sent during the MAE update. The ack is received from GPMunit. This is valid only if 20th bit is set. Arb req ack = 1. Arb release ack = 0.
	3	**IDI Shutdown request** Access: R/W IDI Shutdown Request from GPM to MBCunit. This is valid only if the 19th bit is set.
	2	**IDI Wakeup Message** Access: R/W IDI wakeup message from PM to MBCunit. This is valid only if 18th bit is set.
	1	**Credit Active De-assertreq ACK** Access: R/W Credit Active De-assertreq ACK - GPMunit sends to the MBCunit. This is valid only if the 17th bit of this register is set.
	0	**Reserved**

IDI Self Snoop Register

IDISLFSNP - IDI Self Snoop Register

IDISLFSNP - IDI Self Snoop Register

	1:0	**CRDSP** Access: R/W 00b: Whatever the logic decides (so force feature is disabled) - Default. 01b: Always drive 0. 10b: Always drive 1. 11b: Reserved.

Idle Switch Delay

IDLEDLY - Idle Switch Delay

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	0223Ch-0223Fh
Name:	Idle Switch Delay
ShortName:	IDLEDLY_RCSUNIT
Address:	1223Ch-1223Fh
Name:	Idle Switch Delay
ShortName:	IDLEDLY_VCSUNIT0
Address:	1A23Ch-1A23Fh
Name:	Idle Switch Delay
ShortName:	IDLEDLY_VECSUNIT
Address:	1C23Ch-1C23Fh
Name:	Idle Switch Delay
ShortName:	IDLEDLY_VCSUNIT1
Address:	2223Ch-2223Fh
Name:	Idle Switch Delay
ShortName:	IDLEDLY_BCSUNIT

The IDLEDLY register contains an Idle Delay field which specifies eight times the time stamp base units allowed for command streamer to wait before a context is switched out leading to IDLE state in Execlist mode, i.e following this context switch there is no active element available in HW to execute. Refer "Time Stamp Bases[SKL+]" subsection in Power Management chapter for time stamp base unit granularity. Example: An IDLE Delay count of "2" with Time stamp base unit value of 80ns would mean an idle delay wait of 1280ns (2*8*80). A default value of 0, means that by default, there is no restriction to wait on a context switch leading to IDLE. This register has no significance when Execlists are not enabled.

DWord	Bit	Description
0	31:21	**Reserved** Format: MBZ
	20:0	**IDLE Delay** Format: U21 Eight times the time stamp base units allowed. Refer "Time Stamp Bases[SKL]" subsection in Power Management chapter for time stamp base unit granularity. Example: An IDLE Delay count of "2" with Time stamp base unit value of 80ns would mean an idle delay wait of 1280ns (2*8*80).

Indirect Context Offset Pointer

INDIRECT_CTX_OFFSET - Indirect Context Offset Pointer

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000980 [KBL]
Access:	R/W
Size (in bits):	32
Trusted Type:	1
Address:	021C8h-021CBh
Name:	Indirect Context Offset Pointer
ShortName:	INDIRECT_CTX_OFFSET_RCSUNIT
Address:	121C8h-121CBh
Name:	Indirect Context Offset Pointer
ShortName:	INDIRECT_CTX_OFFSET_VCSUNIT0
Address:	1A1C8h-1A1CBh
Name:	Indirect Context Offset Pointer
ShortName:	INDIRECT_CTX_OFFSET_VECSUNIT
Address:	1C1C8h-1C1CBh
Name:	Indirect Context Offset Pointer
ShortName:	INDIRECT_CTX_OFFSET_VCSUNIT1
Address:	221C8h-221CBh
Name:	Indirect Context Offset Pointer
ShortName:	INDIRECT_CTX_OFFSET_BCSUNIT

This register is used to program the offset where commands RCS_INDIRECT_CTX points to will be executed as part of engine context restore.

Programming Notes	Source
BlitterCS/VideoCS/VideoCS2/VideoEnhancementCS: This register functionality is not supported and must not be programmed for these command streamers.	BlitterCS, VideoCS, VideoCS2, VideoEnhancementCS
Offset of Indirect CS context must be always programmed to a command boundary and cacheline boundary inside the context image.	
Indirect context pointer itself is restored during context restore and hence Indirect Context Offset must not be programmed with value less than 0x5.	

DWord	Bit	Description	
0	31:16	**Reserved**	
		Format:	MBZ

INDIRECT_CTX_OFFSET - Indirect Context Offset Pointer

	15:6	**Offset of Indirect CS Context** Format: U10 This is the cache line offset for the Indirect CS context. This defaults to execute between CS and SVG context. It is not valid to program this to a value that is greater or equal to the starting offset for RS context. If context must be programmed at the end of engine context then program then use BB_PER_CTX_PTR. **Value** / **Name** 26h / **[Default]**
	5:0	**Reserved** Format: MBZ

Indirect Context Pointer

INDIRECT_CTX - Indirect Context Pointer

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Trusted Type:	1

Address:	021C4h-021C7h
Name:	Indirect Context Pointer
ShortName:	INDIRECT_CTX_RCSUNIT

Address:	121C4h-121C7h

Name:	Indirect Context Pointer
ShortName:	INDIRECT_CTX_VCSUNIT1

Address:	221C4h-221C7h
Name:	Indirect Context Pointer
ShortName:	INDIRECT_CTX_BCSUNIT

This register is used to program the indirect address to be executed between CS and SVG engine context if enabled. This will only get executed due to regular context save/restore and not during power restore. This register is part of the execution list context and will be executed per context. Only supported if execution list is enabled. There is no preempting workloads within this context.

Programming Notes	Source
BlitterCS/VideoCS/VideoCS2/VideoEnhancementCS: This register functionality is not supported and must not be programmed for these command streamers.	BlitterCS, VideoCS, VideoCS2, VideoEnhancementCS
The following commands are not supported within Render CS indirect context: **Command Name** MI_WAIT_FOR_EVENT MI_SEMAPHORE_SIGNAL MI_ARB_CHECK MI_RS_CONTROL	RenderCS

DWord	Bit	Description
0	31:6	**Indirect CS Context Address** Format: GraphicsAddress[31:6] Pointer to the Context in memory to be executed as a batch.
	5:0	**Size of Indirect CS Context** Format: U6 This is the size of the Indirect Context for CS. This size supports up to 63 cache lines worth of commands where a cache line is 64B. If programmed to zero then the indirect fetch of the CS context is disabled. Value: [0,63] Name:

INF unit Level Clock Gating Control 9560

INFCGCTL9560 - INF unit Level Clock Gating Control 9560

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x000000FF
Size (in bits):	32
Address:	09560h

Unit Level Clock Gating Disable bits

DWord	Bit	Description
0	31:8	**Reserved** Access: R/W Reserved
	7	**CPMAunit Clock Gating Disable** Default Value: 1b Access: R/W CPMAunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	6	**GTFSunit Clock Gating Disable** Default Value: 1b Access: R/W GTFSunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
	5	**RPMunit Clock Gating Disable** Default Value: 1b Access: R/W RPMunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)

INFCGCTL9560 - INF unit Level Clock Gating Control 9560

4	**MBGFUCunit Clock Gating Disable** Default Value: 1b Access: R/W MBGFUCunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
3	**CGPSFunit Clock Gating Disable** Default Value: 1b Access: R/W CGPSFunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
2	**MDRBunit Clock Gating Disable** Default Value: 1b Access: R/W MDRBunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
1	**MGSRunit Clock Gating Disable** Default Value: 1b Access: R/W MGSRunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)
0	**MRCunit Clock Gating Disable** Default Value: 1b Access: R/W MRCunit Clock Gating Disable Control: '0' : Clock Gating Enabled. (i.e., clocks can be gated when they are not required to toggle for functionality) '1' : Clock Gating Disabled. (i.e., clocks are toggling, always)

Instruction Parser Mode Register

INSTPM - Instruction Parser Mode Register

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	r/w
Size (in bits):	32
Trusted Type:	1

Address:	020C0h-020C3h
Name:	Instruction Parser Mode Register
ShortName:	INSTPM_RCSUNIT

Address:	120C0h-120C3h
Name:	Instruction Parser Mode Register
ShortName:	INSTPM_VCSUNIT0

Address:	1A0C0h-1A0C3h
Name:	Instruction Parser Mode Register
ShortName:	INSTPM_VECSUNIT

Address:	1C0C0h-1C0C3h
Name:	Instruction Parser Mode Register
ShortName:	INSTPM_VCSUNIT1

Address:	220C0h-220C3h
Name:	Instruction Parser Mode Register
ShortName:	INSTPM_BCSUNIT

The INSTPM register is used to control the operation of the Instruction Parser. Certain classes of instructions can be disabled (ignored) - often useful for detecting performance bottlenecks. Also, Synchronizing Flush operations can be initiated - useful for ensuring the completion (vs. only parsing) of rendering instructions.

Programming Notes

- If an instruction type is disabled, the parser will read those instructions but not process them.
- Error checking will be performed even if the instruction is ignored.
- All Reserved bits are implemented.
- This Register is saved and restored as part of Context.

DWord	Bit	Description
0	31:16	**Mask** Access: WO Format: Mask

INSTPM - Instruction Parser Mode Register

		Masks: These bits serve as write enables for bits 15:0. If this register is written with any of these bits clear the corresponding bit in the field 15:0 will not be modified. Reading these bits always returns 0s.
	15:14	**Reserved** Format: MBZ
	13	**Reserved** Format: MBZ
	12	**Reserved** Format: MBZ
	11	**CLFLUSH Toggle** Source: RenderCS Access: RO Format: U1 This bit changes polarity each time the MI_CLFLUSH command completes. This bit is Read Only.
	11	**Reserved** Source: BlitterCS, VideoCS, VideoCS2, VideoEnhancementCS Format: MBZ
	10	**Implied Atomic Fences To Write Fences** Format: U1 If set, all implied atomic fences generated by Render Command Streamer during various operations (Flushes, Context Switch) are converted to regular write fences. Setting this bit will affect data ordering functionalityf. When reset HW behaves as expected.
	9:0	**Reserved** Format: MBZ

Internal GAM State

INTSTATE - Internal GAM State		
Register Space:	MMIO: 0/2/0	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	040C0h	
DWord	**Bit**	**Description**
0	31:0	**Reserved**

Interrupt Line

INTRLINE_0_2_0_PCI - Interrupt Line	
Register Space:	PCI: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Size (in bits):	8
Address:	0003Ch

This register is used to communicate interrupt line routing information. The device itself does not use this value, rather it is used by device drivers and operating systems to determine priority and vector information.

DWord	Bit	Description
0	7:0	**Interrupt Connection** Default Value: 00000000b Access: R/W Used to communicate interrupt line routing information. POST software writes the routing information into this register as it initializes and configures the system. The value in this register indicates to which input of the system interrupt controller the device's interrupt pin is connected.

Interrupt Mask Register

IMR - Interrupt Mask Register

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0xFFFFFFFF
Access:	R/W
Size (in bits):	32

Address:	020A8h-020ABh
Name:	Interrupt Mask Register
ShortName:	IMR_RCSUNIT

Address:	120A8h-120ABh
Name:	Interrupt Mask Register
ShortName:	IMR_VCSUNIT0

Address:	1A0A8h-1A0ABh
Name:	Interrupt Mask Register
ShortName:	IMR_VECSUNIT

Address:	1C0A8h-1C0ABh
Name:	Interrupt Mask Register
ShortName:	IMR_VCSUNIT1

Address:	220A8h-220ABh
Name:	Interrupt Mask Register
ShortName:	IMR_BCSUNIT

The IMR register is used by software to control which Interrupt Status Register bits are masked or unmasked. Unmasked bits will be reported in the IIR, possibly triggering a CPU interrupt, and will persist in the IIR until cleared by software. Masked bits will not be reported in the IIR and therefore cannot generate CPU interrupts.

DWord	Bit	Description
0	31:0	**Interrupt Mask Bits** Format: InterruptMask[32] Refer to the Interrupt Control Register section for bit definitions. This field contains a bit mask which selects which interrupt bits (from the ISR) are reported in the IIR. Reserved bits in the Interrupt Control Register are RO.

Value	Name	Description
FFFF FFFFh	**[Default]**	
0h	Not Masked	Will be reported in the IIR
1h	Masked	Will not be reported in the IIR

Interrupt Pin

INTRPIN_0_2_0_PCI - Interrupt Pin		
Register Space:	PCI: 0/2/0	
Source:	BSpec	
Default Value:	0x00000001	
Size (in bits):	8	
Address:	0003Dh	
This register tells which interrupt pin the device uses.		
DWord	**Bit**	**Description**
0	7:0	**Interrupt Pin** Default Value: 00000001b Access: RO As a single function device, the IGD specifies INTA# as its interrupt pin. Hardwired to 01h = INTA#.

I/O Base Address

IOBAR_0_2_0_PCI - I/O Base Address

Register Space:	PCI: 0/2/0
Source:	BSpec
Default Value:	0x00000001
Size (in bits):	32
Address:	00020h

This register provides the Base offset of the I/O registers within Device #2. Bits 15:6 are programmable allowing the I/O Base to be located anywhere in 16bit I/O Address Space. Bits 2:1 are fixed and return zero; bit 0 is hardwired to a one indicating that 8 bytes of I/O space are decoded. Access to the 8Bs of IO space is allowed in PM state D0 when IO Enable (PCICMD bit 0) set. Access is disallowed in PM states D1-D3 or if IO Enable is clear or if Device #2 is turned off or if Internal graphics is disabled through the fuse or fuse override mechanisms.
Note that access to this IO BAR is independent of VGA functionality within Device #2.
If accesses to this IO bar is allowed then all 8, 16 or 32 bit IO cycles from IA cores that falls within the 8B are claimed.

DWord	Bit	Description
0	15:6	**IO Base Address** Default Value: 0000000000b Access: R/W Set by the OS, these bits correspond to address signals [15:6].
	5:3	**Reserved** Format: MBZ
	2:1	**Memory Type** Default Value: 00b Access: RO Hardwired to 0s to indicate 32-bit address.
	0	**Memory/IO Space** Default Value: 1b Access: RO Hardwired to "1" to indicate IO space.

IPC PER SUBSLICE

EUMETRICS_EVENT1 - IPC PER SUBSLICE	
Register Space:	MMIO: 0/2/0
Default Value:	0x00000000
Size (in bits):	32
Address:	00D90h

This register mirrors an accumulating count for EU Metric Event1.
It is enabled by configuration bits in GPMunit and SPMunits.
Note that count is never cleared and delta should be calculated by sampling the initial register value at the start and subtracting that value off from the final sample value.

DWord	Bit	Description
0	31:0	**EU Metric Event Count** Access: RO

KCR GAM slave counter High part

KCR_CTR_SLAVE_H - KCR GAM slave counter High part		
Register Space:	MMIO: 0/2/0	
Source:	BSpec	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	0482Ch	
DWord	**Bit**	**Description**
0	31:0	**KCR Slave Counter High** Default Value: 00000000h Access: R/W Slave High counter[63:32] for KCR

KCR GAM slave counter Low part

KCR_CTR_SLAVE_L - KCR GAM slave counter Low part		
Register Space:	MMIO: 0/2/0	
Source:	BSpec	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	04828h	
DWord	**Bit**	**Description**
0	31:0	**KCR Slave Counter Low** Default Value: 00000000h Access: R/W Slave Low counter[31:0] for KCR

L3 Bank Status

L3STAT - L3 Bank Status

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Size (in bits):	32
Address:	0B128h

L3 Status register

DWord	Bit	Description
0	31	**L3 Fill Access Status bit** Access: RO This register is Hardware Set and Clear. Set condition: set when the first command is seen on LTCC-LTCD interface. Reset condition: reset when the first Pipeline Flush command is seen on the LTCC-LTCD interface. Reset condition: This Flag will be reset only if we have atleast 1 modified line in the cache written by DC client.
	30	**Texture access Status bit** Access: RO This register is Hardware Set and Clear Set condition : set when the first command is seen on LTCC-LTCD interface. Reset condition : reset when the first Pipeline Flush command is seen on the LTCC-LTCD interface.
	29	**Constant access Status bit** Access: RO This register is Hardware Set and Clear Set condition : set when the first command is seen on LTCC-LTCD interface. Reset condition : reset when the first Pipeline Flush command is seen on the LTCC-LTCD interface.
	28	**State access Status bit** Access: RO This register is Hardware Set and Clear Set condition : set when the first command is seen on LTCC-LTCD interface. Reset condition : reset when the first Pipeline Flush command is seen on the LTCC-LTCD interface.
	27	**EU data traffic access Status bit** Access: RO This register is Hardware Set and Clear Set condition : set when the first command is seen on LTCC-LTCD interface. Reset condition : reset when the first Pipeline Flush command is seen on the LTCC-LTCD interface.

L3STAT - L3 Bank Status		
	26	**IA coherent access Status bit** Access: RO This register is Hardware Set and Clear Set condition : set when the first command is seen on LTCC-LTCD interface. Reset condition : reset when the first Pipeline Flush command is seen on the LTCC-LTCD interface.
	25:0	**Reserved** Access: RO

L3 Control Register

L3CNTLREG - L3 Control Register

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000 [KBL]
Access:	R/W
Size (in bits):	32
Address:	07034h

Programming Notes

The L3 allocation programming should assign all ways of the cache with no left over ways. Refer to L3 section for the recommended settings.

Any L3 configuration change that reduces the data cache allocation when strong IA coherency is used requires the full flush of L3 prior to the programming update.
An explicit or implicit flush of L3 (DC Flush) through the command streamer doesn't result in flushing/invalidating the IA Coherent lines from L3. However this can be achieved by setting the "**Pipe line flush Coherent lines**" control bit in the "L3SQCREG4" register.

DWord	Bit	Description
0	31:25	**All L3 Client Pool** Access: R/W Number of ways allocated for the all client pool. This is a combined pool for all clients. Value: 30h — Name: **[Default]** **Programming Notes** When this field is non-zero, **DC Way Assignment** and **Read Only Client Pool** should be 0KB.
	24:18	**DC Way Assignment** Access: R/W Number of ways allocated for DC. Note this allocation is only for DC data types. **Programming Notes** Note: This field must be 0KB if All L3 Client Pool is non-zero. **Please refer to L3 HAS for valid programming values**
	17:11	**Read Only Client Pool** Access: R/W Number of ways allocated for Read Only L3 clients. This is a combined pool for all Read Only clients. **Programming Notes** Note: This field must be 0KB if All L3 Client Pool is non-zero. **Please refer to L3 HAS for valid programming values**

L3CNTLREG - L3 Control Register

10 Reserved

Access:	R/W
Format:	PBC

9 Error Detection Behavior Control

Access:	R/W
Format:	Enable

The L3 error detection can be enabled to hang the GPU on a non-recoverable error due to SER type events. Such option will be used when corresponding context has data consistency requirements.

Once error detection is enabled, s/w has to initialize URB or SLM to all 0's (based on usage model) prior to execution of the workload. Initialization is required to clean up the error detection logic and syndrome tracking.

Value	Name	Description
0h	**[Default]**	RTL does not hang on parity errors or double bit error
1h		RTL enforces a hang on parity errors or double bit error

8 GPGPU L3 Credit Mode Enable

Access:	R/W
Format:	Enable

This bit is required to be enabled under GPGPU workloads to provide the MAX latency coverage from L3 cache. It will override the registers 0xB100[18:14] and 0xB100[23:19], to 0 and the maximum value respectively.

7:1 URB Allocation

Access:	R/W

Number of ways allocated for URB usage

Value	Name
30h	**[Default]**

Programming Notes
Please refer to L3 HAS for valid programming values. At least one way needs to be programmed in L3 space.

0 SLM Mode Enable

Access:	R/W
Format:	Enable

When enabled, a 64KB (per bank) region of L3 is reserved for SLM.

L3 Control Register1

L3CNTLREG1 - L3 Control Register1

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x8007FFF0 [KBL]
Size (in bits):	32
Address:	0B10Ch

DWord	Bit	Description
0	31:28	**Data Fifo Depth Control** Access: R/W Data Fifo Depth Control (TS mode). Value cannot be zero for normal operation. lbcf_csr_lc_datafifo_depth[3:0]. Value: 1000b — Name: **[Default]**
	27:24	**Data Clock off time** Access: R/W Description: Data Clock off time (DATACLKOFF): Data Clock off time - Data block is shut off after these many number of clocks programmed in this register bits. lbcf_csr_lc_dataclkoff_time[3:0]. Min value to be 4'h0100. It should be between 4'h4 : 4'hf. Value: 1100b — Name: **[Default]**
	23:20	**TAG CLK OFF TIME** Access: R/W Description: TAG CLK OFF TIME (TAGCLKOFF): TAG Clock Off time. This is the time, which Clock gating Logic checks before it turns off the clock. lbcf_csr_lc_tagclkoff_time[3:0]. Value can be between 4'h4 - 4'hf.

L3CNTLREG1 - L3 Control Register1

Value	Name
0100b	**[Default]**

19 **L3 Aging Disable Bit**

Default Value:	0b
Access:	R/W

L3 Aging Disable Bit (L3AGDIS):
Aging Disable.
lbcf_csr_lc_agingdis.

18:15 **Fill aging**

Default Value:	1111b
Access:	R/W

Fill aging (L3AGF):
Aging Counter for Fill.
lbcf_csr_lc_fill_aging_cnt[3:0].
If bit B103.19 is 0 then this register value has to be nonzero.

14:11 **Aging Counter for Read 1 Port**

Default Value:	1111b
Access:	R/W

Aging Counter for Read 1 Port (L3AGR1):
Aging Counter for Read 1 Port.
lbcf_csr_lc_r1_aging_cnt[3:0].
If bit B103.19 is 0 then this register value has to be nonzero.

10:7 **L3 Aging Counter for R0**

Default Value:	1111b
Access:	R/W

L3 Aging Counter for R0 (L3AGR0):
Aging Counter for R0 Port.
lbcf_csr_lc_r0_aging_cnt[3:0].
If bit B103.19 is 0 then this register value has to be nonzero.

6:4 **L3 Aging Counter for SNOOP**

Default Value:	111b
Access:	R/W

L3 Aging Counter for SNOOP:
Aging Counter for Snoop Port.
lbcf_csr_lc_snp_aging_cnt[3:0].

L3CNTLREG1 - L3 Control Register1

	3:0	**Reserved** Default Value: 0000b Access: RO Reserved.

0	31:30	**L3 3D** Default Value: 00b Access: R/W Which LRA should L3 use.
	29:20	**L3 LRA1 Min 3D** Default Value: 0001010000b Access: R/W Minimum value of programmable LRA1.
	19:10	**L3 LRA0 Max 3D** Default Value: 0001001111b Access: R/W Maximum value of programmable LRA0.
	9:0	**L3 LRA0 Min 3D** Default Value: 0000000000b Access: R/W Minimum value of programmable LRA0.

L3 LRA 1 3D

L3_LRA_1_3D - L3 LRA 1 3D

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x66F2D0B3 [KBL]
Size (in bits):	32
Address:	04A14h

DWord	Bit	Description
0	31:30	**DC 3D** Default Value: 01b Access: R/W Which LRA should DC use.
	29:20	**L3 LRA2 Max 3D** Default Value: 1001101111b Access: R/W Maximum value of programmable LRA2.
	19:10	**L3 LRA2 Min 3D** Default Value: 0010110100b Access: R/W Minimum value of programmable LRA2.
	9:0	**L3 LRA1 Max 3D** Default Value: 0010110011b Access: R/W Maximum value of programmable LRA1.

L3 LRA 2 3D

L3_LRA_2_3D - L3 LRA 2 3D		
Register Space:	MMIO: 0/2/0	
Source:	BSpec	
Default Value:	0x00000002	
Size (in bits):	32	
Address:	04A18h	
DWord	**Bit**	**Description**
0	31:2	**Reserved** Default Value: 00000000000000000000000000000000b Access: RO
	1:0	**Texture 3D** Default Value: 10b Access: R/W Which LRA should Texture use.

L3 LRA 2 3D

L3_LRA_2_3D - L3 LRA 2 3D

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x009FE70E
Size (in bits):	32
Address:	04A18h

DWord	Bit	Description
0	31:24	**Reserved** Default Value: 00000000b Access: RO
	23:14	**L3 LRA3 Max 3D** Default Value: 1001111111b Access: R/W Maximum value of programmable LRA2. If L3LRA3Min_3D == L3LRA3Max_3D , GATR LRA is disabled, GATR cycles are mapped to L3LRA0 If L3LRA3Min_3D == L3LRA3Max_3D , GATR LRA is disabled, L3LRA2Max_3D will default to L3LRA3Max_3D to reuse GATR entries
	13:4	**L3 LRA3 Min 3D** Default Value: 1001110000b Access: R/W Minimum value of programmable LRA3.
	3:2	**GATR_3D** Default Value: 11b Access: R/W Which LRA should GATR use.
	1:0	**Texture 3D** Default Value: 10b Access: R/W Which LRA should Texture use.

L3 SLM Register

L3SLMREG - L3 SLM Register

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x40000000
Size (in bits):	32
Address:	0B110h

DWord	Bit	Description
0	31	**Disable Periodic SLM/SQ slot allocation** Default Value: 0b Access: R/W Disable Periodic SLM/SQ slot allocation: When cfg_lslm_livelock_fairarb_dis=1 lslm unit always has the higher priority and lslm_lsqc_block to lsqcunit is asserted as long as there are requests in SLM FIFO. lbcf_csr_lslm_livelock_fairarb_dis.
	30:26	**LSLM_SQ_PENDING_MAX** Default Value: 10000b Access: R/W If lslmunit has read data to be sent to lcbrunit this cfg register specifies the maximum number of clocks for which LSLMunit can block SQ request from being sent o lcbrunit. Default value = 8. Value cannot be zero. lbcf_csr_lslm_sqpend_max[4:0].
	25	**LSLM address disable** Default Value: 0b Access: R/W 0 - Enable b2b addr matching fix. lslmunit should not block the cycle in fifo if there is a match in the pipeline. 1 - Disable b2b addr matching fix. lslmunit should block the cycle in fifo if there is a match in the pipeline. lbcf_csr_lslm_same_addr_dis. Default = 0.
	24:0	**Reserved** Access: RO

L3 SQC register 4

L3SQCREG4 - L3 SQC register 4		
Register Space:	MMIO: 0/2/0	
Source:	BSpec	
Default Value:	0x40400000 [KBL]	
Size (in bits):	32	
Address:	0B118h	

DWord	Bit	Description
0	31	**Reserved**
	30	**L3SQ URB Read CAM Match Disable** Default Value: 1b Access: R/W L3SQ URB Read CAM Match Disable (SQURBRDCAMDIS): Disables the L3SQ Cam Match ability for URB Reads. By disabling, this allows a performance mode where URB reads are not dependent upon one another but only on any previous URB writes to the same address. This allows many URB reads to the same cacheline at any given time instead of serializing the requests. 1 = URB Read CAM matching is disabled; multiple URB reads to the same cacheline are allowed to be concurrent (default). 0 = URB Read CAM matching is enabled; multiple URB reads to the same cacheline are serialized. lbcf_csr_lsqc_urbrdcam_dis.
	29:28	**Traffic regulation in LSQC for URB lookup traffic** Default Value: 00b Access: R/W Traffic regulation in LSQC for URB lookup traffic (URB lookups are issued to ltcc these many clocks apart). 00b - Continuous. 01b - 4 clocks apart. 10b - 8 clocks apart. 11b - 16 clocks apart. lbcf_lsqc_urb_traffic.
	27	**LQSC RO PERF DIS** Default Value: 0b Access: R/W Default: 0. when set, RO performance mode is disabled and all Reads proceed only after Parent recycles. lbcf_csr_lsqc_roperf_dis.

L3SQCREG4 - L3 SQC register 4

26 Order Cam Snp Reject

Default Value:	0b
Access:	R/W

Default: 0.
when set, all slots resulting in matches to snp addr result in snprsp as REJECT instead of MISS.
lbcf_csr_lsqc_ordercam_snpreject.

25 LQSC RW PERF DIS

Default Value:	0b
Access:	R/W

Default: 0.
0: Performance mode is enabled.
when set, Rd to RW performance mode is disabled and all cycles proceed only after Parent recycles.

lbcf_csr_lsqc_rwperf_dis.

24 LSQC read rtrn local crdt pre-consume disable

Default Value:	0b
Access:	R/W

0 - Default, LSQD consumes the LNE local slicecredit when read return pending.
1 - LSQD consumes read rtrn credit in the clock it is ready to send read return data.
lbcf_csr_lsqd_rdtrn_precrdt_dis.

23 LSQC Mem Write sqcam HITM response disable

Default Value:	0b
Access:	R/W

0 - Default.
1 - This disables any Memory Write from cache with HitM tag response to respond for SQCAMs.
lbcf_csr_lsqc_sqcam_l3tagrsphitm_dis.

22 Non-IA coherent atomics enable

Default Value:	1b
Access:	R/W

0: Atomics in GTI.
1: Atomics in L3 (non-IA atomic) (default).
lbcf_csr_lsqc_glblatmcs_l3.
Value of this bit should be same as LNCF register bit 0xb008[0].
Value of this bit should be same as LBCF register bit 0xb11c[8].

L3SQCREG4 - L3 SQC register 4

21	**Pipe line flush Coherent lines** Default Value: 0b Access: R/W 1: Treat pipeline flush as invalidating even coherent lines along with non coherent lines . 0: Flush invalidates non coherent lines only. lbcf_csr_lsqc_pipeflush_coh.
20:6	**Reserved** Access: RO
5	**Reserved2** Access: RO
4	**Reserved** Access: RO
3	**lslm flush denorm** Default Value: 0b Access: R/W lbcf_csr_lslm_flush_denorm_to_zero When this bit is enabled (1b), Floating Point SLM atomics output will be flushed to zero if it is a De-Norm.
2	**lsqc disable sla coh** Default Value: 0b Access: R/W lbcf_lsqc_disable_sla_coh If this bit is set to 1b, it will disable Short loop atomics access for Coherent atomics.
1	**lsqc disable sla** Default Value: 0b Access: R/W lbcf_lsqc_disable_sla If this bit is set to 1b, it will disable Short loop atomics access for Coherent and non-coherent atomics.
0	**lsqd flush denorm** Default Value: 0b Access: R/W lbcf_csr_lsqd_flush_denorm_to_zero When this bit is enabled (1b), Floating Point atomics output will be flushed to zero if it is a De-Norm.

	13:10	**Reserved** Access: RO Reserved.
	9	**L3SQ Read Once Enable for Sampler Client** Access: R/W L3SQ Read Once Enable for Sampler Client (SQROE): Enables Read Once indications to L3 Cache from SQ. Once enabled, any reads from Sampler client (MT) are sent as Read Once. 0 = (default) Reads from Sampler clients issue Read to L3 Cache. 1 = Reads from Sampler clients issue Read Once to L3 Cache. lbcf_csr_sampler_readonce_en.
	8:6	**Reserved** Access: RO Reserved.

L3SQCREG1 - L3 SQC registers 1

	5:3	**L3SQ Outstanding L3 Fills** Access: R/W L3SQ Outstanding L3 Fills (SQOUTSL3F): Identifies the number of L3 Fills that can be outstanding before SQ throttles the fill requests to L3 Cache. This is not an exact limit, but instead it is used as a threshold to throttling. Once the fill count is greater than or equal to the threshold, then no fills are issued until the fill responses are received to bring the outstanding count back below the threshold. 000b = (default) No limit. 001b = 1 fill. 010b = 2 fills. 011b = 4 fills. 100b = 8 fills. 101b = 16 fills. 11Xb = Reserved. lbcf_csr_lsqc_outs_fill[2:0].
	2:0	**L3SQ Outstanding L3 Lookups** Access: R/W L3SQ Outstanding L3 Lookups (SQOUTSL3L): Identifies the number of L3 lookups that can be outstanding before SQ throttles the lookup requests to L3 Cache. This is not an exact limit, but instead it is used as a threshold to throttling. once the lookup count is greater than or equal to the threshold, then no lookups are issued until the lookup responses are received to bring the outstanding count back below the threshold. 000b = (default) No limit. 001b = 1 lookup. 010b = 2 lookups. 011b = 4 lookups. 100b = 8 lookups. 101b = 16 lookups. 11Xb = Reserved. lbcf_csr_lsqc_outs_lookup[2:0].

L3 SQC registers 2

L3SQCREG2 - L3 SQC registers 2		
Register Space:	MMIO: 0/2/0	
Source:	BSpec	
Default Value:	0x00004567	
Size (in bits):	32	
Address:	0B104h	
DWord	**Bit**	**Description**
0	31:17	**Reserved** Access: RO Reserved.
	16	**L3SQ Priority Selection Disable** Access: R/W L3SQ Priority Selection Disable (SQPRIDIS): Enables the use of priority selection based on client ID decodes. If disabled, all cycles in SQ are treated as same priority. 0 = (default) Priority selection is enabled. 1 = Priority selection is disabled. Should not be set when RO perf mode is enabled (by default this is enabled which is bit[27] of B118-B11Bh). lbcf_csr_priority_cnt_disable.
	15	**L3SQ Priority 3 Pool Count Disable** Access: R/W L3SQ Priority 3 Pool Count Disable (SQPRI3CNTDIS): When set, priority3 pool becomes unlimited. And priority3 pool count value should not be used in reset of the remaining counters. 0 = (default) Priority 3 pool count is enabled. 1 = Priority 3 pool count is disabled. Should not be set when RO perf mode is enabled (by default this is enabled which is bit[27] of B118-B11Bh). lbcf_csr_priority3_cnt_disable.
	14:12	**L3SQ Priority 3 Pool Counter** Default Value: 100b Access: R/W L3SQ Priority 3 Pool Counter (SQPRI3CNT): The count of cycles is selected from priority3 pool before switching to other priority pools. Count is used as the power of 2. 000b = 1 request.

L3SQCREG2 - L3 SQC registers 2

		001b = 2 requests. 010b = 4 requests. 011b = 8 requests. ... 111b = 128 requests. Ibcf_csr_priority3_cnt[2:0].
	11	**L3SQ Priority 2 Pool Count Disable** Access: R/W L3SQ Priority 2 Pool Count Disable (SQPRI2CNTDIS): When set, priority2 pool becomes unlimited. And priority2 pool count value should not be used in reset of the remaining counters. 0 = (default) Priority 2 pool count is enabled. 1 = Priority 2 pool count is disabled. Should not be set when RO perf mode is enabled (by default this is enabled which is bit[27] of B118-B11Bh). Ibcf_csr_priority2_cnt_disable.
	10:8	**L3SQ Priority 2 Pool Counter** Default Value: 101b Access: R/W L3SQ Priority 2 Pool Counter (SQPRI2CNT): The count of cycles is selected from priority2 pool before switching to other priority pools. Count is used as the power of 2. 000b = 1 request. 001b = 2 requests. 010b = 4 requests. 011b = 8 requests. ... 111b = 128 requests. Ibcf_csr_priority2_cnt[2:0].
	7	**L3SQ Priority 1 Pool Count Disable** Access: R/W L3SQ Priority 1 Pool Count Disable (SQPRI1CNTDIS): When set, priority1 pool becomes unlimited. And priority1 pool count value should not be used in reset of the remaining counters. 0 = (default) Priority 1 pool count is enabled. 1 = Priority 1 pool count is disabled. Should not be set when RO perf mode is enabled (by default this is enabled which is bit[27] of B118-B11Bh). Ibcf_csr_priority1_cnt_disable.

L3SQCREG2 - L3 SQC registers 2

	6:4	**L3SQ Priority 1 Pool Counter** Default Value: 110b Access: R/W L3SQ Priority 1 Pool Counter (SQPRI1CNT): The count of cycles is selected from priority1 pool before switching to other priority pools. Count is used as the power of 2. 000b = 1 request. 001b = 2 requests. 010b = 4 requests. 011b = 8 requests. ... 111b = 128 requests. Ibcf_csr_priority1_cnt[2:0].
	3	**L3SQ Priority 0 Pool Count Disable** Access: R/W L3SQ Priority 0 Pool Count Disable (SQPRI0CNTDIS): When set, priority0 pool becomes unlimited. And priority0 pool count value should not be used in reset of the remaining counters. 0 = (default) Priority 0 pool count is enabled. 1 = Priority 0 pool count is disabled. Should not be set when RO perf mode is enabled (by default this is enabled which is bit[27] of B118-B11Bh). Ibcf_csr_priority0_cnt_disable.
	2:0	**L3SQ Priority 0 Pool Counter** Default Value: 111b Access: R/W L3SQ Priority 0 Pool Counter (SQPRI0CNT): The count of cycles is selected from priority0 pool before switching to other priority pools. Count is used as the power of 2. 000b = 1 request. 001b = 2 requests. 010b = 4 requests. 011b = 8 requests. ... 111b = (default) 128 requests. Ibcf_csr_priority0_cnt[2:0].

L3SQCREG3 - L3 SQC registers 3

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00001ABF
Size (in bits):	32
Address:	0B108h

DWord	Bit	Description
0	31:30	**Reserved** Access: RO Reserved.
	29:28	**SOLunit Priority Value** Access: R/W SOLunit Priority Value (SQSOLPRIVAL): Identifies the priority value for all cycles that are initiated by SOLunit. Priority is used in the L3 Super Queue (L3SQ). 00b = Priority 0 (default). 01b = Priority 1. 10b = Priority 2. 11b = Priority 3. lbcf_csr_sol_priority[1:0].
	27:26	**GSunit Priority Value** Access: R/W GSunit Priority Value (SQGSPRIVAL): Identifies the priority value for all cycles that are initiated by GSunit. Priority is used in the L3 Super Queue (L3SQ). 00b = Priority 0 (default). 01b = Priority 1. 10b = Priority 2. 11b = Priority 3. lbcf_csr_gs_priority[1:0].
	25:24	**TEunit Priority Value** Access: R/W TEunit Priority Value (SQTEPRIVAL): Identifies the priority value for all cycles that are initiated by TEunit. Priority is used in the L3 Super Queue (L3SQ). 00b = Priority 0 (default).

L3SQCREG3 - L3 SQC registers 3

		01b = Priority 1. 10b = Priority 2. 11b = Priority 3. lbcf_csr_te_priority[1:0].
	23:22	**CLunit Priority Value** Access: R/W CLunit Priority Value (SQCLPRIVAL): Identifies the priority value for all cycles that are initiated by CLunit. Priority is used in the L3 Super Queue (L3SQ). 00b = Priority 0 (default). 01b = Priority 1. 10b = Priority 2. 11b = Priority 3. lbcf_csr_cl_priority[1:0].
	21:20	**TSunit Priority Value** Access: R/W TSunit Priority Value (SQTSPRIVAL): Identifies the priority value for all cycles that are initiated by TSunit. Priority is used in the L3 Super Queue (L3SQ). 00b = Priority 0 (default). 01b = Priority 1. 10b = Priority 2. 11b = Priority 3. lbcf_csr_ts_priority[1:0].
	19:18	**SFunit Priority Value** Access: R/W SFunit Priority Value (SQSFPRIVAL): Identifies the priority value for all cycles that are initiated by SFunit. Priority is used in the L3 Super Queue (L3SQ). 00b = Priority 0 (default). 01b = Priority 1. 10b = Priority 2. 11b = Priority 3. lbcf_csr_sf_priority[1:0].
	17:16	**SVSM Priority Value** Access: R/W SVSM Priority Value (SQSVSMPRIVAL): Identifies the priority value for all cycles that are initiated by SVSM. Priority is used in the L3 Super Queue (L3SQ).

L3SQCREG3 - L3 SQC registers 3

		00b = Priority 0 (default). 01b = Priority 1. 10b = Priority 2. 11b = Priority 3. lbcf_csr_svsm_priority[1:0].
	15:14	**SARB Priority Value** Access: R/W SARB Priority Value (SQSARBPRIVAL): Identifies the priority value for all cycles that are initiated by State Arbiter (SARB). Priority is used in the L3 Super Queue (L3SQ). 00b = Priority 0 (default). 01b = Priority 1. 10b = Priority 2. 11b = Priority 3. lbcf_csr_sarb_priority[1:0].
	13:12	**SBE Priority Value** Default Value: 01b Access: R/W SBE Priority Value (SQSBEPRIVAL): Identifies the priority value for all cycles that are initiated by SBE. Priority is used in the L3 Super Queue (L3SQ). 00b = Priority 0. 01b = Priority 1 (default). 10b = Priority 2. 11b = Priority 3. lbcf_csr_sbe_priority[1:0].
	11:10	**IC$ Priority Value** Default Value: 10b Access: R/W IC$ Priority Value (SQICPRIVAL): Identifies the priority value for all cycles that are initiated by Instruction Cache (IC$). Priority is used in the L3 Super Queue (L3SQ). 00b = Priority 0. 01b = Priority 1. 10b = Priority 2 (default). 11b = Priority 3. lbcf_csr_ic_priority[1:0].

L3SQCREG3 - L3 SQC registers 3

	9:8	**TDL Priority Value** Default Value: 10b Access: R/W TDL Priority Value (SQTDLPRIVAL): Identifies the priority value for all cycles that are initiated by TDL. Priority is used in the L3 Super Queue (L3SQ). 00b = Priority 0. 01b = Priority 1. 10b = Priority 2 (default). 11b = Priority 3. lbcf_csr_tdl_priority[1:0].
	7:6	**DCunit Priority Value** Default Value: 10b Access: R/W DCunit Priority Value (SQDCPRIVAL): Identifies the priority value for all cycles that are initiated by DC. Priority is used in the L3 Super Queue (L3SQ). 00b = Priority 0. 01b = Priority 1. 10b = Priority 2 (default). 11b = Priority 3. lbcf_csr_dc_priority[1:0].
	5:4	**DAPR Priority Value** Default Value: 11b Access: R/W DAPR Priority Value (SQDAPRPRIVAL): Identifies the priority value for all cycles that are initiated by DAPR. Priority is used in the L3 Super Queue (L3SQ). 00b = Priority 0. 01b = Priority 1. 10b = Priority 2. 11b = Priority 3 (default). lbcf_csr_dapr_priority[1:0].
	3:2	**MTunit Priority Value** Default Value: 11b Access: R/W MTunit Priority Value (SQMTPRIVAL): Identifies the priority value for all cycles that are initiated by Sampler (MT). Priority is used in the L3 Super Queue (L3SQ).

L3SQCREG3 - L3 SQC registers 3

		00b = Priority 0. 01b = Priority 1. 10b = Priority 2. 11b = Priority 3 (default). lbcf_csr_mt_priority[1:0].
	1:0	**LSQCunit Priority Value** Default Value: 11b Access: R/W LSQCunit Priority Value (SQPRIVAL): Identifies the priority value for all cycles that are initiated by Super Queue (L3 Evictions). Priority is used in the L3 Super Queue (L3SQ). 00b = Priority 0. 01b = Priority 1. 10b = Priority 2. 11b = Priority 3 (default). lbcf_csr_lsqc_priority[1:0].

LBCF config save msg

LBCFCSR - LBCF config save msg		
Register Space:	MMIO: 0/2/0	
Source:	BSpec	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	0B2FCh	
This register is not context saved and is written by PM unit.		
DWord	**Bit**	**Description**
0	31:10	**Reserved** Access: RO
	9:0	**Context save bit** Access: R/W Hardware Clear Bit[9]: Power Context Save Request. 0: Power context save is not being requested (default). 1: Power context save is being requested. Unit needs to self-clear this bit upon sampling. Bits[8:0]: QWord Credits for Power Context Save Request. Minimum Credits = 1: Unit may send 1 QWord pair (enough for first LRI at least). Maximum Credits = 511: Unit may send 511 QWord pairs. A QWord pair is defined as a 32-bit register address and the corresponding 32-bits of register data. Note that the LRI header and END commands are 64-bits each (32-bit command followed by 32-bit NOOP) and consumes one QWord credit. Only valid with PWRCTX_SAVE_REQ (Bit9).

LBS config bits

LBSREG - LBS config bits

Register Space:	MMIO: 0/2/0
Source:	BSpec

Address:	0B124h

Config Bits for LBS unit

DWord	Bit	Description
0	31:27	**Retry timer for lookup into LSQC** Default Value: 01000b Access: R/W Time between receiving Reject Response from LSQC and doing a snoop lookup request again onto LSQCunit. 00000b: 0 clocks. 00001b: 1 clocks. 00010b: 2 clocks. ... 01000b: 8 clocks (default value). ... 11111b: 32 clocks. lbcf_retry_timer[4:0].
	26	**Recycle parent faster in R/W perf mode** Default Value: 1b Access: R/W Arc into recycle as soon as parent becomes eligible to be recycled. 0: Disabled (recycle possible only when parent is recycled). 1: Enabled (default). lbcf_csr_lsqc_rwperf_quickrec.
	25	**Perf mode for Writes to same address** Default Value: 1b Access: R/W Performance improvement for writes to same address in L3: 0 - Performance mode is not enabled. 1 - Performance mode is enabled (default). lbcf_csr_lsqc_erlyrec.
	24:0	**Reserved** Access: RO

LCPLL1_CTL

LCPLL1_CTL

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	46010h-46013h
Name:	LCPLL 1 Control
ShortName:	LCPLL1_CTL
Power:	PG0
Reset:	global

The register is used to enable DPLL0 for driving the display core clock (CDCLK), the core display 2X clock (CD2XCLK), and the DDI ports.
DPLL frequency and port mapping programming is done through the DPLL_CTRL* registers.
This register is not reset by the device 2 FLR.

Restriction
Restriction : These fields must not be changed while any port or CDCLK is using DPLL0.

DWord	Bit	Description
0	31	**PLL Enable** This field enables or disables DPLL0. Value / Name: 0b Disable; 1b Enable Restriction : Configure DPLL0 frequency prior to enabling.
	30	**PLL Lock** Access: RO This read only bit indicates the status of the DPLL0 lock. Value / Name: 0b Not locked or not enabled; 1b Locked
	29:28	**Reserved**
	27:0	**Reserved** Format: MBZ

LCPLL2_CTL

LCPLL2_CTL

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32

Address:	46014h-46017h
Name:	LCPLL 2 Control
ShortName:	LCPLL2_CTL
Power:	PG0
Reset:	soft

The register is used to enable DPLL1 for driving the DDI ports.
DPLL frequency, SSC, and port mapping programming is done through the DPLL_CTRL* and DPLL*_CFGCR* registers.

Restriction
Restriction : These fields must not be changed while any port is using DPLL1.

DWord	Bit	Description
0	31	**PLL Enable** This bit enables or disables DPLL1. Value: 0b – Disable; 1b – Enable Restriction : Configure DPLL1 frequency and SSC prior to enabling.
	30	**Reserved** Format: MBZ
	29:28	**Reserved**
	27:0	**Reserved** Format: MBZ

LINKM

LINKM	
Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	60040h-60043h
Name:	Transcoder A Link M Value 1
ShortName:	TRANS_LINKM1_A
Power:	PG2
Reset:	soft
Address:	61040h-61043h
Name:	Transcoder B Link M Value 1
ShortName:	TRANS_LINKM1_B
Power:	PG2
Reset:	soft
Address:	62040h-62043h
Name:	Transcoder C Link M Value 1
ShortName:	TRANS_LINKM1_C
Power:	PG2
Reset:	soft
Address:	6F040h-6F043h
Name:	Transcoder EDP Link M Value 1
ShortName:	TRANS_LINKM1_EDP
Power:	PG1
Reset:	soft

Description

There is one instance of this register for each transcoder A/B/C/EDP. This register is double buffered to update on the next MSA after LINKN is written.

DWord	Bit	Description
0	31:24	**Reserved** Format: MBZ
	23:0	**Link M value** This field is the link M value for external transmission in the Main Stream Attributes.

LINKN

LINKN	
Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	60044h-60047h
Name:	Transcoder A Link N Value 1
ShortName:	TRANS_LINKN1_A
Power:	PG2

Power:	PG1
Reset:	soft

Description

There is one instance of this register for each transcoder A/B/C/EDP. This register is double buffered to update on the next MSA after written. **Writes to this register arm M/N registers for this transcoder.**

DWord	Bit	Description
0	31:24	**Reserved** Format: MBZ
	23:0	**Link N value** This field is the link N value for external transmission in the Main Stream Attributes and VB-ID.

LNCF config save msg

LNCFCSR - LNCF config save msg		
Register Space:	MMIO: 0/2/0	
Source:	BSpec	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	0B0FCh	
This register is not context saved and is written by pm unit.		
DWord	**Bit**	**Description**
0	31:10	**Reserved** Access: RO
	9:0	**Context save bit** Access: R/W Hardware Clear Bit[9]. Power Context Save Request 0: Power context save is not being requested (default). 1: Power context save is being requested. Unit needs to self-clear this bit upon sampling. Bits[8:0]. QWord Credits for Power Context Save Request. Minimum Credits = 1: Unit may send 1 QWord pair (enough for first LRI at least). Maximum Credits = 511: Unit may send 511 QWord pairs. A QWord pair is defined as a 32-bit register address and the corresponding 32-bits of register data. Note that the LRI header and END commands are 64-bits each (32-bit command followed by 32-bit NOOP) and consume one QWord credit. Only valid with PWRCTX_SAVE_REQ (Bit9).

LNCF MOCS Register 0

LNCFCMOCS0 - LNCF MOCS Register 0

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00100000
Size (in bits):	32
Address:	0B020h

This register is for Mocs index

DWord	Bit	Description
0	31:22	**Reserved** Access: RO
	21:16	**MOCS upper data** Default Value: 010000b Access: R/W [21:20] - L3 Cacheability Control (L3CC): Memory type information used in L3. This field is combined with the additional two bits that are sent by HDC based on binding table index. For all other L3 requesters, this field is the primary source of L3 cache controls. 00: Use binding table index for direct EU accesses - for rest it is reserved. 01: Uncacheable (UC) - non-cacheable 10: Writethrough (WT) 11: Writeback (WB) [19:17] - Skip Caching Control (SCC) Defines the bit values to enable caching. Outcome overrides the L3/LLC caching for the surface. If "0", then corresponding address bit value is don't care Bit[1]=1: address bit[9] needs to be '0' to cache in target Bit[2]=1: address bit[10] needs to be '0' to cache in target Bit[3]=1: address bit[11] needs to be '0' to cache in target [16] - Enable Skip Caching (ESC) Enable for the Skip cache mechanism Skip caching needs to be disabled in SKLT 0: Not enabled 1: Enabled for L3 LNCF MOCS implementation does not support write to individual MOCS index. S/W needs to write both upper and lower index together. If S/W needs to write to a single index, it should read,merge and write it back.
	15:6	**Reserved** Access: RO

LNCFCMOCS0 - LNCF MOCS Register 0

	5:0	**MOCS lower data** Default Value: 000000b Access: R/W [5:4] - L3 Cacheability Control (L3CC): Memory type information used in L3. This field is combined with the additional two bits that are sent by HDC based on binding table index. For all other L3 requesters, this field is the primary source of L3 cache controls. 00: Use binding table index for direct EU accesses - for rest it is reserved. 01: Uncacheable (UC) - non-cacheable 10: Writethrough (WT) 11: Writeback (WB) [3:1] - Skip Caching Control (SCC) Defines the bit values to enable caching. Outcome overrides the L3/LLC caching for the surface. If "0", then corresponding address bit value is don't care Bit[1]=1: address bit[9] needs to be '0' to cache in target Bit[2]=1: address bit[10] needs to be '0' to cache in target Bit[3]=1: address bit[11] needs to be '0' to cache in target [0] - Enable Skip Caching (ESC) Enable for the Skip cache mechanism Skip caching needs to be disabled in SKLT 0: Not enabled 1: Enabled for L3 LNCF MOCS implementation does not support write to individual MOCS index. S/W needs to write both upper and lower index together. If S/W needs to write to a single index, it should read,merge and write it back.

LNCF MOCS Register 0

DWord	**Bit**	**Description**
0	31:22	**Reserved** Access: RO
	21:16	**MOCS upper data** Default Value: 000000b Access: R/W Refer LNCF MOCS Register 0 for detailed description LNCF MOCS implementation does not support write to individual MOCS index. S/W needs to write both upper and lower index together. If S/W needs to write to a single index, it should read,merge and write it back.
	15:6	**Reserved** Access: RO
	5:0	**MOCS lower data** Default Value: 000000b Access: R/W Refer LNCF MOCS Register 0 for detailed description LNCF MOCS implementation does not support write to individual MOCS index. S/W needs to write both upper and lower index together. If S/W needs to write to a single index, it should read,merge and write it back.

LNCF MOCS Register 8

LNCFCMOCS8 - LNCF MOCS Register 8

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00100000
Size (in bits):	32
Address:	0B040h

This register is for Mocs index

DWord	Bit	Description
0	31:22	**Reserved** Access: RO
	21:16	**MOCS upper data** Default Value: 010000b Access: R/W Refer LNCF MOCS Register 0 for detailed description LNCF MOCS implementation does not support write to individual MOCS index. S/W needs to write both upper and lower index together. If S/W needs to write to a single index, it should read,merge and write it back.
	15:6	**Reserved** Access: RO
	5:0	**MOCS lower data** Default Value: 000000b Access: R/W Refer LNCF MOCS Register 0 for detailed description LNCF MOCS implementation does not support write to individual MOCS index. S/W needs to write both upper and lower index together. If S/W needs to write to a single index, it should read,merge and write it back.

LNCF MOCS Register 8

LNCFCMOCS8 - LNCF MOCS Register 8		
Register Space:	MMIO: 0/2/0	
Source:	BSpec	
Default Value:	0x00100000	
Size (in bits):	32	
Address:	0B040h	
This register is for Mocs index		
DWord	**Bit**	**Description**
0	31:22	**Reserved** Access: RO
	21:16	**MOCS upper data** Default Value: 010000b Access: R/W Refer LNCF MOCS Register 0 for detailed description LNCF MOCS implementation does not support write to individual MOCS index. S/W needs to write both upper and lower index together. If S/W needs to write to a single index, it should read,merge and write it back.
	15:6	**Reserved** Access: RO
	5:0	**MOCS lower data** Default Value: 000000b Access: R/W Refer LNCF MOCS Register 0 for detailed description LNCF MOCS implementation does not support write to individual MOCS index. S/W needs to write both upper and lower index together. If S/W needs to write to a single index, it should read,merge and write it back.

LNCF MOCS Register 9

LNCFCMOCS9 - LNCF MOCS Register 9

Register Space:	MMIO: 0/2/0
Source:	BSpec
Default Value:	0x00170013
Size (in bits):	32
Address:	0B044h

This register is for Mocs index

DWord	Bit	Description
0	31:22	**Reserved** Access: RO
	21:16	**MOCS upper data** Default Value: 010111b Access: R/W Refer LNCF MOCS Register 0 for detailed description LNCF MOCS implementation does not support write to individual MOCS index. S/W needs to write both upper and lower index together. If S/W needs to write to a single index, it should read,merge and write it back.
	15:6	**Reserved** Access: RO
	5:0	**MOCS lower data** Default Value: 010011b Access: R/W Refer LNCF MOCS Register 0 for detailed description LNCF MOCS implementation does not support write to individual MOCS index. S/W needs to write both upper and lower index together. If S/W needs to write to a single index, it should read,merge and write it back.

LNCF MOCS Register 9

LNCFCMOCS9 - LNCF MOCS Register 9

Register Space:	MMIO: 0/2/0
Source:	RenderCS
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	02438h-0243Bh

DWord	Bit	Description
0	31:0	**Instance Count** This register is used to store the Instance Count of the 3D_PRIMITIVE command when Load Indirect Enable is set.

Load Indirect Start Instance

3DPRIM_START_INSTANCE - Load Indirect Start Instance	
Register Space:	MMIO: 0/2/0
Source:	RenderCS
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	0243Ch-0243Fh

DWord	Bit	Description
0	31:0	**Start Vertex** Format: U32 This register is used to store the Start Instance of the 3D_PRIMITIVE command when Load Indirect Enable is set.

Load Indirect Start Vertex

3DPRIM_START_VERTEX - Load Indirect Start Vertex	
Register Space:	MMIO: 0/2/0
Source:	RenderCS
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	02430h-02433h

DWord	Bit	Description
0	31:0	**Start Vertex** Format: U32 This register is used to store the Start Vertex of the 3D_PRIMITIVE command when Load Indirect Enable is set.

Load Indirect Vertex Count

3DPRIM_VERTEX_COUNT - Load Indirect Vertex Count	
Register Space:	MMIO: 0/2/0
Source:	RenderCS
Default Value:	0x00000000
Access:	R/W
Size (in bits):	32
Address:	02434h-02437h

DWord	Bit	Description
0	31:0	**Vertex Count** Format: U32 This register is used to store the Vertex Count of the 3D_PRIMITIVE command when Load Indirect Enable is set.

LPFC control register

LPFCCNTL - LPFC control register		
Register Space:	MMIO: 0/2/0	
Source:	BSpec	
Default Value:	0x00000000	
Size (in bits):	32	
Address:	0B01Ch	
LPFC control register.		
DWord	**Bit**	**Description**
0	31	**LPFC enable signal** Access: R/W LPPC event collection enable signal. Incf_lpfc_cnt_en.
	30	**LPFC Global enable signal** Access: R/W LPFCSL unit global enable signal. 0b - LPFCSL unit is disabled. 1b - LPFCSL unit is enabled. Incf_lpfc_gbl_en
	29:0	**Reserved** Access: RO Reserved.

VGA and Extended VGA Registers

This section describes the registers and the functional operation notations for the observable registers in the VGA section. This functionality is provided as a means for support of legacy applications and operating systems. It is important to note that these registers in general have the desired effects only when running VGA display modes.

The main exceptions to this are the palette interface which allows real mode DOS applications and full screen VGA applications under an OS control running in high resolution (non-VGA) modes to access the palette through the VGA register mechanisms and the use of the ST01 status bits that determine when the VGA enters display enable and sync periods. Other exceptions include the register bits that control the memory accesses through the A000:0000 and B000:0000 memory segments which are used during operating system emulation of VGA for "DOS box" applications. Some of the functions of the VGA are enabled or defeated through the programming of the VGA control register bits that are located in the MMIO register space.

Given the legacy nature of this function, it has been adapted to the changing environment that it must operate within. The three most notable changes are the addition of high resolution display mode support, new operating system support, and the use of fixed resolution display devices (such as LCD panels). Additional control bits in the PCI Config space will affect the ability to access the registers and memory aperture associated with VGA.

Mode of Operation	VGA Disable	VGA Display	VGA Registers	Palette (VGA)	VGA Memory	VGA Banking
VGA DOS	No	Yes	Yes	Yes	Yes	No
HiRes DOS	Yes	No	Yes	Yes	No	Yes
Fullscreen DOS	Yes/No	No/Yes	Yes	Yes	Yes	Yes
DOS Emulation	Yes	No	Yes	Yes	Yes	Yes

VGA Display Mode	Dot Clock Select	Dot Clock Range	132 Column Text Support	9-Dot Disable Support	Main Use
Native	VGA Clock Select	25/28 MHz	No	No	Analog CRT (VGA connector)
Centered	Fixed at display Requirements	Product Specific	No	Yes	Digital Display
Upper Left Corner	Fixed at display Requirements	Product Specific	No	Yes	Internal Panel

Native, Centered, and Upper Left Corner support varies from product to product.

Even in the native VGA display operational modes, not all combinations of bit settings result in functional operating modes. VGA display modes have the restriction that they can be used only when all other display planes are disabled.

These registers are accessed via I/O space. The I/O space resides in the PCI compatibility hole and uses only the addresses that were part of the original VGA I/O space (which includes EGA and MDA emulation). Accesses to the VGA I/O addresses are steered to the proper bus and rely on proper setup of bridge registers. Extended VGA registers such as GR10 and GR11 use additional indexes for the already defined I/O addresses. VGA register accesses are allowed as 8 or 16 bit naturally aligned transactions only. Word transactions must have the least significant bit of the address set to zero. DWORD I/O operations should not be performed on these registers.

Some products may support access to these registers through MMIO. The access method varies and is documented elsewhere.

General Control and Status Registers

The setup, enable, and general registers are all directly accessible by the CPU. A sub indexing scheme is not used to read from and write to these registers.

Name	Function	Read		Write	
		I/O	Memory Offset	I/O	Memory Offset
ST00	VGA Input Status Register 0	3C2h	3C2h	--	--
ST01	VGA Input Status Register 1	3BAh/3DAh[1]	3BAh/3DAh[1]	--	--
FCR	VGA Feature Control Register	3CAh	3CAh	3BAh/3DAh[1]	3BAh/3DAh[1]
MSR	VGA Miscellaneous Output Register	3CCh	3CCh	3C2h	3C2h

[1] The address selection for ST01 reads and FCR writes is dependent on CGA or MDA emulation mode as selected via the MSR register.

Various bits in these registers provide control over the real-time status of the horizontal sync signal, the horizontal retrace interval, the vertical sync signal, and the vertical retrace interval. The horizontal retrace interval is the period during the drawing of each scan line containing active video data, when the active video data is not being displayed. This period includes the horizontal front and back porches, and the horizontal sync pulse. The horizontal retrace interval is always longer than the horizontal sync pulse. The vertical retrace interval is the period during which the scan lines not containing active video data are drawn. This includes the vertical front porch, back porch, and the vertical sync pulse. The vertical retrace interval is normally longer than the vertical sync pulse.

ST00 - Input Status 0

I/O (and Memory Offset) Address: 3C2h

Default: 00h

Attributes: Read Only

Bit	Descriptions
7	**CRT Interrupt Pending.** This bit is here for EGA compatibility and **will always return zero**. The generation of interrupts was originally enabled, through bits [4,5] of the Vertical Retrace End Register (CR11). This ability to generate interrupts at the start of the vertical retrace interval is a feature that is typically unused by DOS software and therefore is only supported through other means for use under a operating system support. 0 = CRT (vertical retrace interval) interrupt is not pending. 1 = CRT (vertical retrace interval) interrupt is pending
6:5	**Reserved.** Read as 0s.
4	**RGB Comparator / Sense.** This bit is here for compatibility and **will always return one**. Monitor detection must be done be done through the programming of registers in the MMIO space. 0 = Below threshold 1 = Above threshold
3:0	**Reserved.** Read as 0s.

ST01 - Input Status 1

I/O (and Memory Offset) Address: 3BAh/3DAh

Default: 00h

Attributes: Read Only

The address selection is dependent on CGA or MDA emulation mode as selected via the MSR register.

Bit	Descriptions
7	**Reserved (as per VGA specification).** Read as 0s.
6	**Reserved.** Read as 0.
5:4	**Video Feedback 1, 0.** These bits are connected to 2 of the 8 color bits sent to the palette. Bits 4 and 5 of the Color Plane Enable Register (AR12) selects which two of the 8 possible color bits become connected to these 2 bits of this register. These bits exist for EGA compatibility.
3	**Vertical Retrace/Video.** 0 = VSYNC inactive (Indicates that a vertical retrace interval is not taking place). 1 = VSYNC active (Indicates that a vertical retrace interval is taking place). VGA pixel generation is not locked to the display output but is loosely coupled. A VSYNC indication may not occur during the actual VSYNC going to the display but during the VSYNC that is generated as part of the VGA pixel generation. The exact relationship will vary with the VGA display operational mode. This status bit will remain active when the VGA is disabled and the device is running in high resolution modes (non-VGA) to allow for applications that (now incorrectly) use these status registers bits. In this case, the status will come from the pipe that the VGA is assigned to. Bits 4 and 5 of the Vertical Retrace End Register (CR11) previously could program this bit to generate an interrupt at the start of the vertical retrace interval. This ability to generate interrupts at the start of the vertical retrace interval is a feature that is largely unused by legacy software. Interrupts are not supported through the VGA register bits.
2:1	**Reserved.** Read as 0s.

Bit	Descriptions
0	**Display Enable Output.** Display Enable is a status bit (bit 0) in VGA Input Status Register 1 that indicates when either a horizontal retrace interval or a vertical retrace interval is taking place. This bit was used with the EGA graphics system (and the ones that preceded it, including MDA and CGA). In those cases, it was important to check the status of this bit to ensure that one or the other retrace intervals was taking place before reading from or writing to the frame buffer. In these earlier systems, reading from or writing to the frame buffer at times outside the retrace intervals meant that the CRT controller would be denied access to the frame buffer. Those behaviors resulted in either "snow" or a flickering display. This bit provides compatibility with software designed for those early graphics controllers. This bit is currently used in DOS applications that access the palette to prevent the sparkle associated with read and write accesses to the palette RAM with the same address on the same clock cycle. **This status bit remains active when the VGA display is disabled and the device is running in high resolution modes (non-VGA) to allow for applications that (now considered incorrect) use these status registers bits. In this case, the status will come from the pipe that the VGA is assigned to. When in panel fitting VGA or centered VGA operation, the meaning of these bits will not be consistent with native VGA timings.** 0 = Active display data is being sent to the display. Neither a horizontal retrace interval or a vertical retrace interval is currently taking place. 1 = Either a horizontal retrace interval (horizontal blanking) or a vertical retrace interval (vertical blanking) is currently taking place.

FCR - Feature Control

I/O (and Memory Offset) Address: 3BAh/3DAh - Write; 3CAh - Read

Default: 00h

Attributes: See Address above

The I/O address used for writes is dependent on CGA or MDA emulation mode as selected via the MSR register. In the original EGA, bits 0 and 1 were used as part of the feature connector interface. Feature connector is not supported in these devices and those bits will always read as zero.

Bit	Descriptions
7:4	**Reserved.** Read as 0.
3	**VSYNC Control.** This bit is provided for compatibility only and has no other function. Reads and writes to this bit have no effect other than to change the value of this bit. The previous definition of this bit selected the output on the VSYNC pin. 0 = Was used to set VSYNC output on the VSYNC pin (default). 1 = Was used to set the logical 'OR' of VSYNC and Display Enable output on the VSYNC pin. This capability was not typically very useful.
2:0	**Reserved.** Read as 0.

MSR - Miscellaneous Output

I/O (and Memory Offset) Address: 3C2h - Write; 3CCh - Read

Default: 00h

Attributes: See Address above

Bit	Descriptions
7	**CRT VSYNC Polarity.** This is a legacy function that is used in native VGA modes. For most cases, sync polarity will be controlled by the port control bits. The VGA settings can be optionally selected for compatibility with the original VGA when used in the VGA native mode. Sync polarity was used in VGA to signal the monitor how many lines of active display are being generated. 0 = Positive Polarity (default). 1 = Negative Polarity.
6	**CRT HSYNC Polarity.** This is a legacy function that is used in native VGA modes. For most cases, sync polarity will be controlled by the port control bits. The VGA settings can be optionally selected for compatibility with the original VGA when used in the VGA native mode. 0 = Positive Polarity (default). 1 = Negative Polarity
5	**Page Select.** In Odd/Even Memory Map Mode 1 (GR6), this bit selects the upper or lower 64 KB page in display memory for CPU access: 0 = Upper page (default) 1 = Lower page. Selects between two 64KB pages of frame buffer memory during standard VGA odd/even modes (modes 0h through 5h). Bit 1 of register GR06 can also program this bit in other modes. This bit is would normally set to 1 by the software.
4	**Reserved.** Read as 0.
3:2	**Clock Select.** These bits can select the dot clock source for the CRT interface. The bits should be used to select the dot clock in standard native VGA modes only. When in the centering or upper left corner modes, these bits should be set to have no effect on the clock rate. The actual frequencies that these bits select, if they have any affect at all, is programmable through the DPLL MMIO registers. 00 = CLK0, 25.175 MHz (for standard VGA modes with 640 pixel (8-dot) horizontal resolution) (default) 01 = CLK1, 28.322 MHz. (for standard VGA modes with 720 pixel (9-dot) horizontal resolution) 10 = Was used to select an external clock (now unused) 11 = Reserved

Bit	Descriptions
1	**A0000-BFFFFh Memory Access Enable.** VGA Compatibility bit enables access to video memory (frame buffer) at A0000-BFFFFh. When disabled, accesses to VGA memory are blocked in this region. This bit is independent of and does not block CPU access to the video linear frame buffer at other addresses. 0 = Prevent CPU access to memory/registers/ROM through the A0000-BFFFF VGA memory aperture (default). 1 = Allow CPU access to memory/registers/ROM through the A0000-BFFFF VGA memory aperture. This memory must be mapped as UC by the CPU.
0	**I/O Address Select.** This bit selects 3Bxh or 3Dxh as the I/O address for the CRT Controller registers, the Feature Control Register (FCR), and Input Status Register 1 (ST01). Presently ignored (whole range is claimed), but will "ignore" 3Bx for color configuration or 3Dx for monochrome. It is typical in AGP chipsets to shadow this bit and properly steer I/O cycles to the proper bus for operation where a MDA exists on another bus such as ISA. 0 = Select 3Bxh I/O address (MDA emulation) (default). 1 = Select 3Dxh I/O address (CGA emulation).

In standard VGA modes using the analog VGA connector, bits 7 and 6 indicate which of the three standard VGA vertical resolutions the standard VGA display should use. Extended modes, including those with a vertical resolution of 480 scan lines, may use a setting of 0 for both of these bits. Different connector standards and timing standards specify the proper use of sync polarity. This setting was "reserved" in the VGA standard.

Analog CRT Display Sync Polarities

V	H	Display	Horizontal Frequency	Vertical Frequency
P	P	200 Line	15.7 KHz	60 Hz
N	P	350 Line	21.8 KHz	60 Hz
P	N	400 Line	31.5 KHz	70 Hz
N	N	480 Line	31.5 KHz	60 Hz

Sequencer Registers

The sequencer registers are accessed via either I/O space or Memory space. To access registers the VGA Sequencer Index register (SRX) at I/O address 3C4h (or memory address 3C4h) is written with the index of the desired register. Then the desired register is accessed through the data port for the sequencer registers at I/O address 3C5 (or memory address 3C5).

SRX - Sequencer Index

I/O (and Memory Offset) Address: 3C4h

Default: 00h

Attributes: Read/Write

Bit	Description
7:3	**Reserved.** Read as 0s.
2:0	**Sequencer Index.** This field contains a 3-bit Sequencer Index value used to access sequencer data registers at indices 0 through 7.

SR00 - Sequencer Reset

I/O (and Memory Offset) Address: 3C5h(Index=00h)

Default: 00h

Attributes: Read/Write

Bit	Descriptions
7:2	**Reserved.** Read as 0.
1	**Reserved.** Reserved for VGA compatibility (was reset).
0	**Reserved.** Reserved for VGA compatibility. (was reset)

SR01 - Clocking Mode

I/O (and Memory Offset) Address: 3C5h (Index=01h)

Default: 00h

Attributes: Read/Write

Bit	Descriptions
7:6	**Reserved.** Read as 0s.
5	**Screen Off.** 0 = Normal Operation (default). 1 = Disables video output (blanks the screen) and turns off display data fetches. Synchronization pulses to the display, however, are maintained. Setting this bit to 1 had been used as a way to more rapidly update and improve CPU access performance to the frame buffer during VGA modes. In non-VGA modes (VGA Disable=1), this bit has no effect. Before the VGA is disabled through the MMIO VGA control register, this bit should be set to stop the memory accesses from the display. The following sequence must be used when disabling the VGA plane. 1. Write SR01 to set bit 5 = 1 to disable video output. 2. Wait for 100us. 3. Disable the VGA plane via Bit 31 of the MMIO VGA control register (location found in the MMIO display register programming specification).
4	**Shift 4.** 0 = Load video shift registers every 1 or 2 character clocks (depending on bit 2 of this register) (default). 1 = Load shift registers every 4th character clock.
3	**Dot Clock Divide.** Setting this bit to 1 stretches doubles all horizontal timing periods that are specified in the VGA horizontal CRTC registers. This bit is used in standard VGA 40-column text modes to stretch timings to create horizontal resolutions of either 320 or 360 pixels (as opposed to 640 or 720 pixels, normally used in standard VGA 80-column text modes). The effect of this is that there will actually be twice the number of pixels sent to the display per line. 0 = Pixel clock is left unaltered (used for 640 (720) pixel modes); (default). 1 = Pixel clock divided by 2 (used for 320 (360) pixel modes).
2	**Shift Load.** Bit 4 of this register must be 0 for this bit to be effective. 0 = Load video data shift registers every character clock (default). 1 = Load video data shift registers every other character clock.
1	**Reserved.** Read as 0.

Bit	Descriptions
0	**8/9 Dot Clocks.** This bit determines whether a character clock is 8 or 9 dot clocks long if clock doubling is disabled and 16 or 18 clocks if it is. This also changes the interpretation of the pixel panning values (see chart). An additional control bit determines if this bit is to be ignored and 8-dot characters are to be used always. The 9-dot disable would be used when doubling the horizontal pixels on a 1280 wide display or non-doubling on a 640 wide display. Panning however will occur according to the expected outcome. 0 = 9 dot clocks (9 horizontal pixels) per character in text modes with a horizontal resolution of 720 pixels. 1 = 8 dot clocks (8 horizontal pixels) per character in text or graphics modes with a horizontal resolution of 640 pixels.

SR02 - Plane/Map Mask

I/O (and Memory Offset) Address: 3C5h (Index=02h)

Default: 00h

Attributes: Read/Write

Bit	Descriptions
7:4	**Reserved.** Read as 0s.
3:0	**Memory Planes [3:0] Processor Write Access Enable.** In both the Odd/Even Mode and the Chain 4 Mode, these bits still control access to the corresponding color plane. 0 = Disable. 1 = Enable. This register is referred to in the VGA standard as the Map Mask Register.

SR03 - Character Font

I/O (and Memory Offset) Address: 3C5h (index=03h)

Default: 00h

Attributes: Read/Write

In text modes, bit 3 of the video data's attribute byte normally controls the foreground intensity. This bit may be redefined to control switching between character sets. This latter function is enabled whenever there is a difference in the values of the Character Font Select A and the Character Font Select B bits. If the two values are the same, the character select function is disabled and attribute bit 3 controls the foreground intensity.

Bit 1 of the Memory Mode Register (SR04) must be set to 1 for the character font select function of this register to be active. Otherwise, only character maps 0 and 4 are available.

SR04 - Memory Mode Register

I/O (and Memory Offset) Address: 3C5h (index=04h)

Default: 00h

Attributes: Read/Write

Bit	Description
7:4	**Reserved.** Read as 0.
3	**Chain 4 Mode.** The selections made by this bit affect both CPU Read and write accesses to the frame buffer. 0 = The manner in which the frame buffer memory is mapped is determined by the setting of bit 2 of this register (default). 1 = The frame buffer memory is mapped in such a way that the function of address bits 0 and 1 are altered so that they select planes 0 through 3. This setting is used in mode x13 to allow all four planes to be accessed via sequential addresses.
2	**Odd/Even Mode.** Bit 3 of this register must be set to 0 for this bit to be effective. The selections made by this bit affect only non-paged CPU accesses to the frame buffer through the VGA aperture. 0 = The frame buffer memory is mapped in such a way that the function of address bit 0 such that even addresses select planes 0 and 2 and odd addresses select planes 1 and 3 (default). 1 = Addresses sequentially access data within a bit map, and the choice of which map is accessed is made according to the value of the Plane Mask Register (SR02).
1	**Extended Memory Enable.** This bit must be set to 1 to enable the selection and use of character maps in plane 2 via the Character Map Select Register (SR03). 0 = Disable CPU accesses to more than the first 64KB of VGA standard memory (default). 1 = Enable CPU accesses to the rest of the 256KB total VGA memory beyond the first 64KB.
0	**Reserved.** Read as 0.

SR07 - Horizontal Character Counter Reset

I/O (and Memory Offset) Address: 3C5h (index=07h)

Default: 00h

Attributes: Read/Write

For standard VGAs, writing this register (with any data) causes the horizontal character counter to be held in reset (the character counter output will remain 0). It remained in reset until a write occurred to any other sequencer register location with SRX set to an index of 0 through 6. In this implementation that sequence has no such special effect.

The vertical line counter is clocked by a signal derived from the horizontal display enable (which does not occur if the horizontal counter is held in reset). Therefore, if a write occurs to this register during the vertical retrace interval, both the horizontal and vertical counters will be set to 0. A write to any other sequencer register location (with SRX set to an index of 0 through 6) may then be used to start both counters with reasonable synchronization to an external event via software control. Although this was a standard VGA register, it was not documented.

Bit	Description
7:0	**Horizontal Character Counter.**

Graphics Controller Registers

The graphics controller registers are accessed via either I/O space or Memory space. Accesses to the registers of the VGA Graphics Controller are done through the use of address 3CEh (or memory address 3CEh) written with the index of the desired register. Then the desired register is accessed through the data port for the graphics controller registers at I/O address 3CFh (or memory address 3CFh). Indexes 10 and 11 should only be accessed through the I/O space only.

GRX - GRX Graphics Controller Index Register

I/O (and Memory Offset) Address: 3CEh

Default: 000UUUUUb (U=Undefined)

Attributes: Read/Write

Bit	Description
7:5	**Reserved.** Read as 0.
4:0	**Graphics Controller Register Index.** This field selects any one of the graphics controller registers (GR00-GR18) to be accessed via the data port at I/O (or memory offset) location 3CFh.

GR00 - Set/Reset Register

I/O (and Memory Offset) Address: 3CFh (index=00h)

Default: 0Uh (U=Undefined)

Attributes: Read/Write

Bit	Description
7:4	**Reserved.** Read as 0.
3:0	**Set/Reset Plane [3:0].** When the Write Mode bits (bits 0 and 1) of the Graphics Mode Register (GR05) are set to select Write Mode 0, all 8 bits of each byte of each memory plane are set to either 1 or 0 as specified in the corresponding bit in this register, if the corresponding bit in the Enable Set/Reset Register (GR01) is set to 1. When the Write Mode bits (bits 0 and 1) of the Graphics Mode Register (GR05) are set to select Write Mode 3, all CPU data written to the frame buffer is rotated, then logically ANDed with the contents of the Bit Mask Register (GR08), and then treated as the addressed data's bit mask, while value of these four bits of this register are treated as the color value.

GR01 - Enable Set/Reset Register

I/O (and Memory Offset) Address: 3CFh (Index=01h)

Default: 0Uh (U=Undefined)

Attributes: Read/Write

Bit	Description
7:4	**Reserved.** Read as 0.
3:0	**Enable Set/Reset Plane [3:0].** This register works in conjunction with the Set/Reset Register (GR00). The Write Mode bits (bits 0 and 1) must be set for Write Mode 0 for this register to have any effect. 0 = The corresponding memory plane can be read from or written to by the CPU without any special bitwise operations taking place. 1 = The corresponding memory plane is set to 0 or 1 as specified in the Set/Reset Register (GR00).

GR02 - Color Compare Register

I/O (and Memory Offset) Address: 3CFh (Index=02h)

Default: 0Uh (U=Undefined)

Attributes: Read/Write

Bit	Description
7:4	**Reserved.** Read as 0.
3:0	**Color Compare Plane [3:0].** When the Read Mode bit (bit 3) of the Graphics Mode Register (GR05) is set to select Read Mode 1, all 8 bits of each byte of each of the 4 memory planes of the frame buffer corresponding to the address from which a CPU read access is being performed are compared to the corresponding bits in this register (if the corresponding bit in the Color Don't Care Register (GR07) is set to 1). The value that the CPU receives from the read access is an 8-bit value that shows the result of this comparison, wherein value of 1 in a given bit position indicates that all of the corresponding bits in the bytes across all of the memory planes that were included in the comparison had the same value as their memory plane's respective bits in this register.

GR03 - Data Rotate Register

I/O (and Memory Offset) Address: 3CFh (Index=03h)

Default: 0Uh (U=Undefined)

Attributes: Read/Write

Bit	Description
7:5	**Reserved.** Read as 0.
4:3	**Function Select.** These bits specify the logical function (if any) to be performed on data that is meant to be written to the frame buffer (using the contents of the memory read latch) just before it is actually stored in the frame buffer at the intended address location. 00 = Data being written to the frame buffer remains unchanged, and is simply stored in the frame buffer. 01 = Data being written to the frame buffer is logically ANDed with the data in the memory read latch before it is actually stored in the frame buffer. 10 = Data being written to the frame buffer is logically ORed with the data in the memory read latch before it is actually stored in the frame buffer. 11 = Data being written to the frame buffer is logically XORed with the data in the memory read latch before it is actually stored in the frame buffer.
2:0	**Rotate Count.** These bits specify the number of bits to the right to rotate any data that is meant to be written to the frame buffer just before it is actually stored in the frame buffer at the intended address location.

GR04 - Read Plane Select Register

I/O (and Memory Offset) Address: 3CFh (Index=04h)

Default: 0Uh (U=Undefined)

Attributes: Read/Write

Bit	Description
7:2	**Reserved.** Read as 0.
1:0	**Read Plane Select.** These two bits select the memory plane from which the CPU reads data in Read Mode 0. In Odd/Even Mode, bit 0 of this register is ignored. In Chain 4 Mode, both bits 1 and 0 of this register are ignored. The four memory planes are selected as follows: 00 = Plane 0

Bit	Description
	01 = Plane 1 10 = Plane 2 11 = Plane 3 These two bits also select which of the four memory read latches may be read via the Memory read Latch Data Register (CR22). The choice of memory read latch corresponds to the choice of plane specified in the table above. The Memory Read Latch Data register and this additional function served by 2 bits are features of the VGA standard that were never documented.

GR05 - Graphics Mode Register

I/O (and Memory Offset) Address: 3CFh (Index=05h)

Default: 0UUU U0UUb (U=Undefined)

Attributes: Read/Write

Bit	Description
7	**Reserved.** Read as 0.
6:5	**Shift Register Control.** In standard VGA modes, pixel data is transferred from the 4 graphics memory planes to the palette via a set of 4 serial output bits. These 2 bits of this register control the format in which data in the 4 memory planes is serialized for these transfers to the palette. **Bits [6:5]=00** One bit of data at a time from parallel bytes in each of the 4 memory planes is transferred to the palette via the 4 serial output bits, with 1 of each of the serial output bits corresponding to a memory plane. This provides a 4-bit value on each transfer for 1 pixel, making possible a choice of 1 of 16 colors per pixel. Serial Out / 1st Xfer / 2nd Xfer / 3rd Xfer / 4th Xfer / 5th Xfer / 6th Xfer / 7th Xfer / 8th Xfer Bit 3 / plane3 bit7 / plane3 bit6 / plane3 bit5 / plane3 bit4 / plane3 bit3 / plane3 bit2 / plane3 bit1 / plane3 bit0 Bit 2 / plane2 bit7 / plane2 bit6 / plane2 bit5 / plane2 bit4 / plane2 bit3 / plane2 bit2 / plane2 bit1 / plane2 bit0 Bit 1 / plane1 bit7 / plane1 bit6 / plane1 bit5 / plane1 bit4 / plane1 bit3 / plane1 bit2 / plane1 bit1 / plane1 bit0 Bit 0 / plane0 bit7 / plane0 bit6 / plane0 bit5 / plane0 bit4 / plane0 bit3 / plane0 bit2 / plane0 bit1 / plane0 bit0

Bit	Description
	Bits [6:5]=01 Two bits of data at a time from parallel bytes in each of the 4 memory planes are transferred to the palette in a pattern that alternates per byte between memory planes 0 and 2, and memory planes 1 and 3. First the even-numbered and odd-numbered bits of a byte in memory plane 0 are transferred via serial output bits 0 and 1, respectively, while the even-numbered and odd-numbered bits of a byte in memory plane 2 are transferred via serial output bits 2 and 3. Next, the even-numbered and odd-numbered bits of a byte in memory plane 1 are transferred via serial output bits 0 and 1, respectively, while the even-numbered and odd-numbered bits of memory plane 3 are transferred via serial out bits 1 and 3. This provides a pair of 2-bit values (one 2-bit value for each of 2 pixels) on each transfer, making possible a choice of 1 of 4 colors per pixel. Serial Out 1st Xfer 2nd Xfer 3rd Xfer 4th Xfer 5th Xfer 6th Xfer 7th Xfer 8th Xfer Bit 3 plane2 bit7 plane2 bit5 plane2 bit3 plane2 bit1 plane3 bi7t plane3 bit5 plane3 bit3 plane3 bit1 Bit 2 plane2 bit6 plane2 bit4 plane2 bit2 plane2 bit0 plane3 bit6 plane3 bit4 plane3 bit2 plane3 bit0 Bit 1 plane0 bit7 plane0 bit5 plane0 bit3 plane0 bit1 plane1 bit7 plane1 bit5 plane1 bit3 plane1 bit1 Bit 0 plane0 bit6 plane0 bit4 plane0 bit2 plane0 bit0 plane1 bit6 plane1 bit4 plane1 bit2 plane1 bit0 This alternating pattern is meant to accommodate the use of the Odd/Even mode of organizing the 4 memory planes, which is used by standard VGA modes 2h and 3h. **Bits [6:5]=1x** Four bits of data at a time from parallel bytes in each of the 4 memory planes are transferred to the palette in a pattern that iterates per byte through memory planes 0 through 3. First the 4 most significant bits of a byte in memory plane 0 are transferred via the 4 serial output bits, followed by the 4 least significant bits of the same byte. Next, the same transfers occur from the parallel byte in memory planes 1, 2 and lastly, 3. Each transfer provides either the upper or lower half of an 8 bit value for the color for each pixel, making possible a choice of 1 of 256 colors per pixel. This is the setting used in mode x13. Serial Out 1st Xfer 2nd Xfer 3rd Xfer 4th Xfer 5th Xfer 6th Xfer 7th Xfer 8th Xfer Bit 3 plane0 plane0 plane1 plane1 plane2 plane2 plane3 plane3

Bit	Description
	<table><tr><td></td><td>bit7</td><td>bit3</td><td>bit7</td><td>bit3</td><td>bit7</td><td>bit3</td><td>bit7</td><td>b3it</td></tr><tr><td>Bit 2</td><td>plane0 bit6</td><td>plane0 bit2</td><td>plane1 bit6</td><td>plane1 bit2</td><td>plane2 bit6</td><td>plane2 bit2</td><td>plane3 bit6</td><td>plane3 bit2</td></tr><tr><td>Bit 1</td><td>plane0 bit5</td><td>plane0 bit1</td><td>plane1 bit5</td><td>plane1 bit1</td><td>plane2 bit5</td><td>plane2 bit1</td><td>plane3 bit5</td><td>plane3 bit1</td></tr><tr><td>Bit 0</td><td>plane0 bit4</td><td>plane0 bit0</td><td>plane1 bit4</td><td>plane1 bit0</td><td>plane2 bit4</td><td>plane2 bit0</td><td>plane3 bit4</td><td>plane3 bit0</td></tr></table> This pattern is meant to accommodate mode 13h, a standard VGA 256-color graphics mode.
4	**Odd/Even Mode.** 0 = Addresses sequentially access data within a bit map, and the choice of which map is accessed is made according to the value of the Plane Mask Register (SR02). 1 = The frame buffer is mapped in such a way that the function of address bit 0 is such that even addresses select memory planes 0 and 2 and odd addresses select memory planes 1 and 3. This works in a way that is the inverse of (and is normally set to be the opposite of) bit 2 of the Memory Mode Register (SR02).
3	**Read Mode.** 0 = During a CPU read from the frame buffer, the value returned to the CPU is the memory plane selected by bits 1 and 0 of the Read Plane Select Regist 1 = During a CPU read from the frame buffer, all 8 bits of the byte in each of the 4 memory planes corresponding to the address from which a CPU read access is being performed are compared to the corresponding bits in this register (if the corresponding bit in the Color Don't Care Register (GR07) is set to 1). The value that the CPU receives from the read access is an 8-bit value that shows the result of this comparison. A value of 1 in a given bit position indicates that all of the corresponding bits in the bytes across all 4 of the memory planes that were included in the comparison had the same value as their memory plane's respective bits in this register.
2	**Reserved.** Read as 0.

Bit	Description
1:0	**Write Mode.** 00 = Write Mode 0 - During a CPU write to the frame buffer, the addressed byte in each of the 4 memory planes is written with the CPU write data after it has been rotated by the number of counts specified in the Data Rotate Register (GR03). If, however, the bit(s) in the Enable Set/Reset Register (GR01) corresponding to one or more of the memory planes is set to 1, then those memory planes will be written to with the data stored in the corresponding bits in the Set/Reset Register (GR00). 01 = Write Mode 1 - During a CPU write to the frame buffer, the addressed byte in each of the 4 memory planes is written to with the data stored in the memory read latches. (The memory read latches stores an unaltered copy of the data last read from any location in the frame buffer.) 10 = Write Mode 2 - During a CPU write to the frame buffer, the least significant 4 data bits of the CPU write data is treated as the color value for the pixels in the addressed byte in all 4 memory planes. The 8 bits of the Bit Mask Register (GR08) are used to selectively enable or disable the ability to write to the corresponding bit in each of the 4 memory planes that correspond to a given pixel. A setting of 0 in a bit in the Bit Mask Register at a given bit position causes the bits in the corresponding bit positions in the addressed byte in all 4 memory planes to be written with value of their counterparts in the memory read latches. A setting of 1 in a Bit Mask Register at a given bit position causes the bits in the corresponding bit positions in the addressed byte in all 4 memory planes to be written with the 4 bits taken from the CPU write data to thereby cause the pixel corresponding to these bits to be set to the color value. 11 = Write Mode 3 - During a CPU write to the frame buffer, the CPU write data is logically ANDed with the contents of the Bit Mask Register (GR08). The result of this ANDing is treated as the bit mask used in writing the contents of the Set/Reset Register (GR00) are written to addressed byte in all 4 memory planes.

GR06 - Miscellaneous Register

I/O (and Memory Offset) Address: 3CFh (Index=06h)

Default: 0Uh (U=Undefined)

Attributes: Read/Write

Bit	Description
7:4	**Reserved.** Read as 0s.
3:2	**Memory Map Mode.** These 2 bits control the mapping of the VGA address range for frame buffer into the CPU address space as follows: 00 = A0000h - BFFFFh 01 = A0000h - AFFFFh 10 = B0000h - B7FFFh 11 = B8000h - BFFFFh This function is used in standard VGA modes, extended VGA modes (132 column text), and in non-VGA modes (hi-res). 132 column text modes are no longer supported. VGA aperture memory accesses are also controlled by the PCI configuration Memory Enable bit and MSR<1>. For accesses using GR10 and GR11 to paged VGA RAM or to device MMIO registers, set these bits to 01 to select the (A0000-AFFFF) range. The CPU must map this memory as uncacheable (UC).
1	**Chain Odd/Even.** This bit provides the ability to alter the interpretation of address bit A0, so that it may be used in selecting between the odd-numbered memory planes (planes 1 and 3) and the even-numbered memory planes (planes 0 and 2). 0 = A0 functions normally. 1 = A0 is switched with a high order address bit, in terms of how it is used in address decoding. The result is that A0 is used to determine which memory plane is being accessed (A0=0 for planes 0 and 2 and A0=1 for planes 1 and 3).

Bit	Description
0	**Graphics/Text Mode.** This is one of two bits that are used to determine if the VGA is operating in text or graphics modes. The other bit is in AR10[0], these two bits need to be programmed in a consistent manner to achieve the proper results. 0 = Text mode. 1 = Graphics mode.

GR07 - Color Don't Care Register

I/O (and Memory Offset) Address: 3CFh (Index=07h)

Default: 0Uh (U=Undefined)

Attributes: Read/Write

Bit	Description
7:4	**Reserved.** Read as 0.
3:0	**Ignore Color Plane [3:0].** These bits have effect only when bit 3 of the Graphics Mode Register (GR05) is set to 1 to select read mode 1. 0 = The corresponding bit in the Color Compare Register (GR02) will not be included in color comparisons. 1 = The corresponding bit in the Color Compare Register (GR02) is used in color comparisons.

GR08 - Bit Mask Register

I/O (and Memory Offset) Address: 3CFh (Index=08h)

Default: Undefined

Attributes: Read/Write

Bit	Description
7:0	**Bit Mask.** 0 = The corresponding bit in each of the 4 memory planes is written to with the corresponding bit in the memory read latches. 1 = Manipulation of the corresponding bit in each of the 4 memory planes via other mechanisms is enabled. This bit mask applies to any writes to the addressed byte of any or all of the 4 memory planes, simultaneously. This bit mask is applicable to any data written into the frame buffer by the CPU, including data that is also subject to rotation, logical functions (AND, OR, XOR), and Set/Reset. To perform a proper read-modify-write cycle into frame buffer, each byte must first be read from the frame buffer by the CPU (and this will cause it to be stored in the memory read latches), this Bit Mask Register must be set, and the new data then written into the frame buffer by the CPU.

GR10 - Address Mapping

I/O (avoid MMIO access) Address: 3CFh (Index=10h)

Default: 00h

Attributes: R/W

This register should only be accessed using I/O operations and never be accessed through the A/B segment addressing map, I/O space register map, or direct MMIO operations.

Bit	Description
7:4	**Page Select Extension - Unused** These bits form the upper bits of a 12-bit page selection value. When combined with the GR11 <7:0> bits they define the offset into stolen memory to the 64KB page that is accessible via the VGA Memory paging mechanism. These bits are ignored.
3	**Reserved**

Bit	Description
2:1	**Paging Map Target.** When paging is enabled, these bits determine the target for data cycle accesses through the VGA memory aperture. VGA graphics memory starts from the base of graphics data stolen memory defined in the PCI configuration BDSM register. VGA display uses the first four 64KB pages of VGA graphics memory. 00 = VGA Graphics Memory 01 = Reserved 10 = Reserved 11 = Reserved
0	**Page Mapping Enable.** This mode allows the mapping of the VGA memory address space. Once this is enabled, no VGA memory address swizzle will be performed, addresses are directly mapped to memory. A single paging register is used to map the 64KB [A0000:AFFFF] window. An internal address is generated using GR11 as the address lines extension to the lower address lines of the access A[15:2]. When mapping is enabled, the B0000:BFFFF area must be disabled using GR06<3:2>=01. The use of addresses in the A0000-BFFFF range require that both the graphics device PCI configuration memory enable and MSR<1> be enabled. 0 = Disable (default) 1 = Enable

GR11 - Page Selector

I/O (avoid MMIO access) Address: 3CFh (Index=11h)

Default: 00h

Attributes: R/W

Bit	Description
7	**Reserved**
6:0	**Page Select.** When concatenated with the GR10<7:4> bits, selects a 64KB window within target area when Page Mapping is enabled (GR10[0]=1). This requires that the graphics device PCI configuration space memory enable, the GR06<3:2> bits to be 01 (select A0000-AFFFF only), and the MSR<1:1> bit to be set. This register provides the Address[22:16] bits for the access. VGA paging of frame buffer memory is for non-VGA packed modes only and should not be enabled when using basic VGA modes. This register should only be accessed using I/O operations.

GR18 - Software Flags

I/O (and Memory Offset) Address: 3CFh (Index=18h)

Default: 00

Attributes: R/W

Bit	Description
7:0	**Software Flags.** Used as scratch pad space in video BIOS. These bits are separate from the bits which appear in the memory mapped IO space. They are used specifically by the SMI BIOS which does not have access to memory mapped IO at the time they are required. These register bits have no effect on H/W operation.

Attribute Controller Registers

Unlike the other sets of indexed registers, the attribute controller registers are not accessed through a scheme employing entirely separate index and data ports. I/O address 3C0h (or memory address 3C0h) is used both as the read and write for the index register, and as the write address for the data port. I/O address 3C1h (or memory address 3C1h) is the read address for the data port.

To write to the attribute controller registers, the index of the desired register must be written to I/O address 3C0h (or memory address 3C0h), and then the data is written to the very same I/O (memory) address. A flip-flop alternates with each write to I/O address 3C0h (or memory address 3C0h) to change its function from writing the index to writing the actual data, and back again. This flip-flop may be deliberately set so that I/O address 3C0h (or memory address 3C0h) is set to write to the index (which provides a way to set it to a known state) by performing a read operation from Input Status Register 1 (ST01) at I/O address 3BAh (or memory address 3BAh) or 3DAh (or memory address 3DAh), depending on whether the graphics system has been set to emulate an MDA or a CGA as per MSR[0].

To read from the attribute controller registers, the index of the desired register must be written to I/O address 3C0h (or memory address 3C0h), and then the data is read from I/O address 3C1h (or memory address 3C1h). A read operation from I/O address 3C1h (or memory address 3C1h) does not reset the flip-flop to writing to the index. Only a write to 3C0h (or memory address 3C0h) or a read from 3BAh or 3DAh (or memory address 3BAh or 3DAh), as described above, will toggle the flip-flop back to writing to the index.

ARX - Attribute Controller Index Register

I/O (and Memory Offset) Address: 3C0h

Default: 00UU UUUUb (U=Undefined)

Attributes: Read/Write

Bit	Description
7:6	**Reserved.** Read as 0s.
5	**Video Enable.** In the VGA standard, this is called the "Palette Address Source" bit. Clearing this bit will cause the VGA display data to become all 00 index values. For the default palette, this will cause a black screen. The video timing signals continue. Another control bit will turn video off and stop the data fetches. 0 = Disable. Attribute controller color registers (AR[00:0F]) can be accessed by the CPU. 1 = Enable. Attribute controller color registers (AR[00:0F]) are inaccessible by the CPU.
4:0	**Attribute Controller Register Index.** These five bits are used to select any one of the attribute controller registers (AR[00:14]), to be accessed.

AR[00:0F] - Palette Registers [0:F]

I/O (and Memory Offset) Address: Read at 3C1h and Write at 3C0h; (index=00h-0Fh)

Default: 00UU UUUUb (U=Undefined)

Attributes: Read/Write

Bit	Description
7:6	**Reserved.** Read as 0.
5:0	**Palette Bits P[5:0].** In each of these 16 registers, these are the lower 6 of 8 bits that are used to map either text attributes or pixel color input values (for modes that use 16 colors) to the 256 possible colors available to be selected in the palette. Bits 3 and 2 of the Color Select Register (AR14) supply bits P7 and P6 for the values contained in all 16 of these registers. Bits 1 and 0 of the Color Select Register (AR14) can also replace bits P5 and P4 for the values contained in all 16 of these registers, if bit 7 of the Mode Control Register (AR10) is set to 1.

AR10 - Mode Control Register

I/O (and Memory Offset) Address:	Read at 3C1h and Write at 3C0h; (index=10h)
Default:	UUh (U=Undefined)
Attributes:	Read/Write

Bit	Description
7	**Palette Bits P5, P4 Select.** **0** = P5 and P4 for each of the 16 selected colors (for modes that use 16 colors) are individually provided by bits 5 and 4 of their corresponding Palette Registers (AR[00:0F]). **1** = P5 and P4 for all 16 of the selected colors (for modes that use 16 colors) are provided by bits 1 and 0 of Color Select Register (AR14).
6	**Pixel Width/Clock Select.** **0** = Six bits of video data (translated from 4 bits via the palette) are output every dot clock. **1** = Two sets of 4 bits of data are assembled to generate 8 bits of video data which is output every other dot clock, and the Palette Registers (AR[00:0F]) are bypassed. This bit is set to 0 for all of the standard VGA modes, except mode 13h.
5	**Pixel Panning Compatibility.** **0** = Scroll both the upper and lower screen regions horizontally as specified in the Pixel Panning Register (AR13). **1** = Scroll only the upper screen region horizontally as specified in the Pixel Panning Register (AR13). This bit has application only when split-screen mode is being used, where the display area is divided into distinct upper and lower regions which function somewhat like separate displays.
4	**Reserved.** Read as 0.
3	**Enable Blinking/Select Background Intensity.** **0** = Disables blinking in graphics modes, and for text modes, sets bit 7 of the character attribute bytes to control background intensity, instead of blinking. **1** = Enables blinking in graphics modes and for text modes, sets bit 7 of the character attribute bytes to control blinking, instead of background intensity. The blinking rate is derived by dividing the VSYNC signal. The Blink Rate Control field of the VGA control register defines the blinking rate.

Bit	Description
2	**Enable Line Graphics Character Code.** **0** = Every 9th pixel of a horizontal line (i.e., the last pixel of each horizontal line of each 9-pixel wide character box) is assigned the same attributes as the background of the character of which the given pixel is a part. **1** = Every 9th pixel of a horizontal line (i.e., the last pixel of each horizontal line of each 9-pixel wide character box) is assigned the same attributes as the 8th pixel if the character of which the given pixel is a part. This setting is intended to accommodate the line-drawing characters of the PC's extended ASCII character set -- characters with an extended ASCII code in the range of B0h to DFh. In some literature describing the VGA standard, the range of extended ASCII codes that are said to include the line-drawing characters is mistakenly specified as C0h to DFh, rather than the correct range of B0h to DFh.
1	**Select Display Type.** **0** = Attribute bytes in text modes are interpreted as they would be for a color display. **1** = Attribute bytes in text modes are interpreted as they would be for a monochrome display.
0	**Graphics/Alphanumeric Mode.** This bit (along with GR06[0]) select either graphics mode or text mode. These two bits must be programmed in a consistent manner to achieve the desired results. **0** = Alphanumeric (text) mode. **1** = Graphics mode.

AR11 - Overscan Color Register

I/O (and Memory Offset) Address: Read at 3C1h and Write at 3C0h; (index=11h)

Default: UUh (U=Undefined)

Attributes: Read/Write

Bit	Description
7:0	**Overscan.** These 8 bits select the overscan (border) color index value. The actual border color will be determined by the contents of the palette at the selected index. The border color is displayed between the end of active and the beginning of blank or the end of blank and the beginning of active on CRT type devices driven from the DAC output port. For native VGA modes on digital display ports there is the option of including the border in the active region or not depending on a control bit in the port control register. For centered VGA modes, the VGA control register determines if the border is included in the centered region or not. For monochrome displays, this value should be set to 00h.

AR12 - Memory Plane Enable Register

I/O (and Memory Offset) Address: Read at 3C1h and Write at 3C0h; (index=12h)

Default: 00UU UUUUb (U=Undefined)

Attributes: Read/Write

Bit	Description
7:6	**Reserved.** Read as 0.
5:4	**Video Status Mux.** These 2 bits are used to select 2 of the 8 possible palette bits (P7-P0) to be made available to be read via bits 5 and 4 of the Input Status Register 1 (ST01). The table below shows the possible choices. Bit [5:4] / ST01 Bit 5 / ST01 Bit 4 00 / P2 (default) / P0 (default) 01 / P5 / P4 10 / P3 / P1 11 / P7 / P6 These bits are typically unused by current software; they are provided for EGA compatibility.
3:0	**Enable Plane [3:0].** These 4 bits individually enable the use of each of the 4 memory planes in providing 1 of the 4 bits used in video output to select 1 of 16 possible colors from the palette to be displayed. 0 = Disable the use of the corresponding memory plane in video output to select colors, forcing the bit that the corresponding memory plane would have provided to a value of 0. 1 = Enable the use of the corresponding memory plane in video output to select colors. AR12 is referred to in the VGA standard as the Color Plane Enable Register.

AR13 - Horizontal Pixel Panning Register

I/O (and Memory Offset) Address: Read at 3C1h and Write at 3C0h; (index=13h)

Default: 0Uh (U=Undefined)

Attributes: Read/Write

Bit	Description
7:4	**Reserved.**
3:0	**Horizontal Pixel Shift 3-0.** This field holds a 4-bit value that selects the number of pixels by which the image is shifted horizontally to the left. This function is available in both text and graphics modes and allows for pixel panning. In text modes with a 9-pixel wide character box, the image can be shifted up to 9 pixels to the left. In text modes with an 8-pixel wide character box, and in graphics modes other than those with 256 colors, the image can be shifted up to 8 pixels to the left. A pseudo 9-bit mode is when the 9-dot character is selected but overridden by the VGA control bit. In standard VGA mode 13h (where bit 6 of the Mode Control Register, AR10, is set to 1 to support 256 colors), bit 0 of this register must remain set to 0, and the image may be shifted up to only 4 pixels to the left. In this mode, the number of pixels by which the image is shifted can be further controlled using bits 6 and 5 of the Preset Row Scan Register (CR08).

Number of Pixels Shifted				
Bits [3:0]	**9-dot**	**Pseudo 9-dot**	**8-dot**	**256-Color**
0	1	1	0	0
1	2	2	1	Undefined
2	3	3	2	1
3	4	4	3	Undefined
4	5	5	4	2
5	6	6	5	Undefined
6	7	7	6	3
7	8	7	7	Undefined
8	0	0	Undefined	Undefined

AR14 - Color Select Register

I/O (and Memory Offset) Address: Read at 3C1h and Write at 3C0h; (index=14h)

Default: 0Uh (U=Undefined)

Attributes: Read/Write

Bit	Description
7:4	**Reserved.**
3:2	**Palette Bits P[7:6].** These are the 2 upper-most of the 8 bits that are used to map either text attributes or pixel color input values (for modes that use 16 colors) to the 256 possible colors contained in the palette. These 2 bits are common to all 16 sets of bits P5 through P0 that are individually supplied by Palette Registers 0-F (AR[00:0F]).
1:0	**Alternate Palette Bits P[5:4].** These 2 bits can be used as an alternate version of palette bits P5 and P4. Unlike the P5 and P4 bits that are individually supplied by Palette Registers 0-F (AR[00:0F]), these 2 alternate palette bits are common to all 16 of Palette Registers. Bit 7 of the Mode Control Register (AR10) is used to select between the use of either the P5 and P4 bits that are individually supplied by the 16 Palette Registers or these 2 alternate palette bits.

VGA Color Palette Registers

In devices that have multiple display pipes, there is one palette for each display pipe. These palettes are the same for VGA modes and non-VGA modes. Accesses through VGA register methods can optionally read or write from either one.

For each palette, the color data stored in these 256 color data positions can be accessed only through a complex sub-addressing scheme, using a data register and two index registers. The Palette Data Register at I/O address 3C9h (or memory address offset 3C1h) is the data port. The Palette Read Index Register at I/O address 3C7h (or memory address offset 3C7h) and the Palette Write Index Register at I/O address 3C8h (or memory address offset 3C8h) are the two index registers. The Palette Read Index Register is the index register that is used to choose the color data position that is to be read from via the data port, while the Palette Write Index Register is the index register that is used to choose the color data position that is to be written to through the same data port. This arrangement allows the same data port to be used for reading from and writing to two different color data positions. Reading and writing the color data at a color data position involves three successive reads or writes since the color data stored at each color data position consists of three bytes.

To read a palette color data position, the index of the desired color data position must first be written to the Palette Read Index Register. Then all three bytes of data in a given color data position may be read at the Palette Data Register. The first byte read from the Palette Data Register retrieves the 8-bit value specifying the intensity of the red color component. The second and third bytes read are the corresponding 8-bit values for the green and blue color components respectively. After completing the third read operation, the Palette Read Index Register is automatically incremented so that the data of the next color data position becomes accessible for being read. This allows the contents of all of the 256 color data positions of the palette to be read in sequence. This is done by specifying only the index of the 0th color data position in the Palette Read Index Register, and then simply performing 768 successive reads from the Palette Data Register.

Writing a color data position, entails a very similar procedure. The index of the desired color data position must first be written to the Palette Write Index Register. Then all three bytes of data to specify a given color may be written to the Palette Data Register. The first byte written to the Palette Data Register specifies the intensity of the red color component, the second byte specifies the intensity for the green color component, and the third byte specifies the same for the blue color component. One important detail is that all three of these bytes must be written before the hardware will actually update these three values in the given color data position. When all three bytes have been written, the Palette Write Index Register is automatically incremented so that the data of the next color data position becomes accessible for being written. This allows the contents of all of the 256 color data positions of the palette to be written in sequence. This is done by specifying only the index of the 0th color data position in the Palette Write Index Register, and then simply performing 768 successive writes to the Palette Data Register.

DACMASK - Pixel Data Mask Register

I/O (and Memory Offset) Address: 3C6h

Default: Undefined

Attributes: Read/Write

Bit	Description
7:0	**Pixel Data Mask.** In indexed-color mode, the 8 bits of this register are logically ANDed with the 8 bits of pixel data received from the frame buffer for each pixel. The result of this ANDing process becomes the actual index used to select color data positions within the palette. This has the effect of limiting the choice of color data positions that may be specified by the incoming 8-bit data. 0 = Corresponding bit in the resulting 8-bit index being forced to 0. 1 = Allows the corresponding bit in the resulting index to reflect the actual value of the corresponding bit in the incoming 8-bit pixel data.

DACSTATE - DAC State Register

I/O (and Memory Offset) Address: 3C7h

Default: 00h

Attributes: Read Only

Bit	Description
7:2	**Reserved.** Read as 0.
1:0	**DACState.** This field indicates which of the two index registers was most recently written. **Bits [1:0]** Index Register Indicated 00 = Palette Write Index Register at I/O Address 3C7h (default) 01 = Reserved 10 = Reserved 11 = Palette Read Index Register at I/O Address 3C8h

DACRX - Palette Read Index Register

I/O (and Memory Offset) Address: 3C7h

Default: 00h

Attributes: Write Only

Bit	Description
7:0	**Palette Read Index.** The 8-bit index value programmed into this register chooses which of 256 standard color data positions within the palette are to be made accessible for being read from via the Palette Data Register (DACDATA). The index value held in this register is automatically incremented when all three bytes of the color data position selected by the current index have been read. A write to this register will abort a uncompleted palette write sequence. This register allows access to the palette even when running non-VGA display modes.

DACWX - Palette Write Index Register

I/O (and Memory Offset) Address: 3C8h

Default: 00h

Attributes: Write Only

Bit	Description
7:0	**Palette Write Index.** The 8-bit index value programmed into this register chooses which of 256 standard color data positions within the palette are to be made accessible for being written via the Palette Data Register (DACDATA). The index value held in this register is automatically incremented when all three bytes of the color data position selected by the current index have been written. This register allows access to the palette even when running non-VGA display modes.

DACDATA - Palette Data Register

I/O (and Memory Offset) Address: 3C9h

Default: Undefined

Attributes: Read/Write

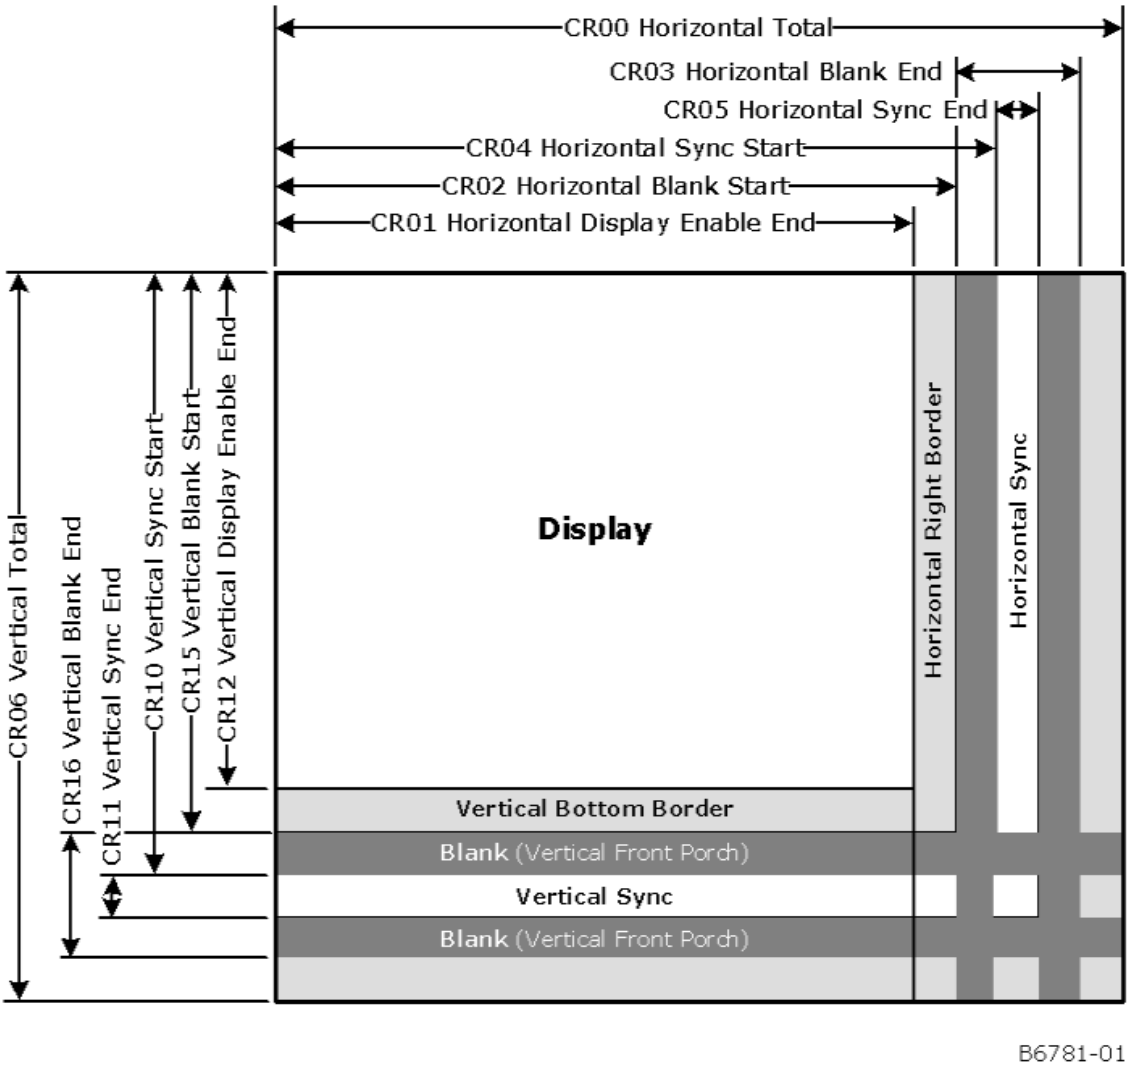
Bit	Description
7:0	**Palette Data.** This byte-wide data port provides read or write access to the three bytes of data of each color data position selected using the Palette Read Index Register (DACRX) or the Palette Write Index Register (DACWX). The three bytes in each color data position are read or written in three successive read or write operations. The first byte read or written specifies the intensity of the red component of the color specified in the selected color data position. The second byte is for the green component, and the third byte is for the blue component. When writing data to a color data position, all three bytes must be written before the hardware will actually update the three bytes of the selected color data position. When reading or writing to a color data position, ensure that neither the Palette Read Index Register (DACRX) or the Palette Write Index Register (DACWX) are written to before all three bytes are read or written. A write to either of these two registers causes the circuitry that automatically cycles through providing access to the bytes for red, green and blue components to be reset such that the byte for the red component is the one that will be accessed by the next read or write operation via this register. This register allows access to the palette even when running non-VGA display modes. Writes to the palette can cause sparkle if not done during inactive video periods. This sparkle is caused by an attempt to write and read the same address on the same cycle. Anti-sparkle circuits will substitute the previous pixel value for the read output.

CRT Controller Register

For native VGA modes, the CRTC registers determine the display timing that is to be used. In centered VGA modes, these registers determine the size of the VGA image that is to be centered in the larger timing generator defined rectangle.

The CRT controller registers are accessed by writing the index of the desired register into the CRT Controller Index Register at I/O address 3B4h or 3D4h, depending on whether the graphics system is configured for MDA or CGA emulation. The desired register is then accessed through the data port for the CRT controller registers located at I/O address 3B5h or 3D5h, again depending upon the choice of MDA or CGA emulation as per MSR[0]. For memory mapped accesses, the Index register is at 3B4h (MDA mode) or 3D3h (CGA mode) and the data port is accessed at 3B5h (MDA mode) or 3D5h (CGA mode).

The following figure shows display fields and dimensions and the particular CRxx register that provides the control.



Group 0 Protection: In the original VGA, CR[0:7] could be made write-protected by CR11[7]. In BIOS code, this write protection is set following each mode change. Other protection groups have no current use, and would not be used going forward by the BIOS or by drivers. They are the result of an industry fad some years ago to attempt to write protect other groups of registers; however, all such schemes were chip specific. Only the write protection (Group 0 Protection) is supported.

CRX - CRT Controller Index Register

I/O (and Memory Offset) Address: 3B4h/3D4h

Default: 0Uh (U=Undefined)

Attributes: Read/Write

Bit	Description
7	**Reserved.** Read as 0.
6:0	**CRT Controller Index.** These 7 bits are used to select any one of the CRT controller registers to be accessed via the data port at I/O location 3B5h or 3D5h, depending upon whether the graphics system is configured for MDA or CGA emulation. The data port memory address offsets are 3B5h/3D5h.

CR00 - Horizontal Total Register

I/O (and Memory Offset) Address: 3B5h/3D5h (index=00h)

Default: 00h

Attributes: Read/Write (Group 0 Protection)

Bit	Description
7:0	**Horizontal Total.** This register is used to specify the total length of each scan line. This encompasses both the part of the scan line that is within the active display area and the part that is outside of it. Programming this register to a zero has the effect of stopping the fetching of display data. This field should be programmed with a value equal to the total number of character clocks within the entire length of a scan line, minus 5.

CR01 - Horizontal Display Enable End Register

I/O (and Memory Offset) Address: 3B5h/3D5h (index=01h)

Default: Undefined

Attributes: Read/Write (Group 0 Protection)

Bit	Description
7:0	**Horizontal Display Enable End.** This register is used to specify the end of the part of the scan line that is within the active display area relative to its beginning. In other words, this is the horizontal width of the active display area. This field should be programmed with a value equal to the number of character clocks that occur within the horizontal active display area, minus 1. Horizontal display enable will go active at the beginning of each line during vertical active area, it will go inactive based on the programming of this register or the programming of the horizontal total (CR00) register. When this register value is programmed to a number that is larger than the total number of characters on a line, display enable will be active for all but the last character of the horizontal display line.

CR02 - Horizontal Blanking Start Register

I/O (and Memory Offset) Address: 3B5h/3D5h (index=02h)

Default: Undefined

Attributes: Read/Write (Group 0 Protection)

Bit	Description
7:0	**Horizontal Blanking Start.** This register is used to specify the beginning of the horizontal blanking period relative to the beginning of the active display area of a scan line. Horizontal blanking should always be set to start no sooner than after the end of horizontal active. This field should be programmed with a value equal to the number of character clocks that occur on a scan line from the beginning of the active display area to the beginning of the horizontal blanking.

CR03 - Horizontal Blanking End Register

I/O (and Memory Offset) Address: 3B5h/3D5h (index=03h)

Default: 1UUU UUUUb (U=Undefined)

Attributes: Read/Write (Group 0 Protection)

Bit	Description
7	**Reserved.** Values written to this bit are ignored, and to maintain consistency with the VGA standard, a value of 1 is returned when this bit is read. At one time, this bit was used to enable access to certain light pen registers. At that time, setting this bit to 0 provided this access, but setting this bit to 1 was necessary for normal operation.
6:5	**Display Enable Skew Control.** Defines the degree to which the start and end of the active display area are delayed along the length of a scan line to compensate for internal pipeline delays. These 2 bits describe the delay in terms of a number character clocks. **Bit [6:5]** Amount of Delay 00 = no delay 01 = delayed by 1 character clock 10 = delayed by 2 character clocks 11 = delayed by 3 character clocks
4:0	**Horizontal Blanking End Bits [4:0].** This field provides the 5 least significant bits of a 6-bit value that specifies the end of the blanking period relative to its beginning on a single scan line. Bit 7 of the Horizontal Sync End Register (CR05) supplies the most significant bit. This 6-bit value should be programmed to be equal to the least significant 6 bits of the result of adding the length of the blanking period in terms of character clocks to the value specified in the Horizontal Blanking Start Register (CR02). End of blanking should occur before horizontal total.

CR04 - Horizontal Sync Start Register

I/O (and Memory Offset) Address: 3B5h/3D5h (index=04h)

Default: Undefined

Attributes: Read/Write (Group 0 Protection)

Bit	Description
7:0	**Horizontal Sync Start** This register is used to specify the position of the beginning of the horizontal sync pulse relative to the start of the active display area on a scan line. This field should be set equal to the number of character clocks that occur from beginning of the active display area to the beginning of the horizontal sync pulse on a single scan line. Horizontal sync should always occur at least 2 clocks after the start of horizontal blank and 2 clocks before the end of horizontal blank. The actual start of sync will also be affected by both the horizontal sync skew register field and whether it is a text or graphics mode.

CR05 - Horizontal Sync End Register

I/O (and Memory Offset) Address: 3B5h/3D5h (index=05h)

Default: 00h

Attributes: Read/Write (Group 0 Protection)

Bit	Description
7	**Horizontal Blanking End Bit 5.** This bit provides the most significant bit of a 6-bit value that specifies the end of the horizontal blanking period relative to its beginning. Bits [4:0] of Horizontal Blanking End Register (CR03) supplies the 5 least significant bits. See CR03[4:0] for further details. This 6-bit value should be set to the least significant 6 bits of the result of adding the length of the blanking period in terms of character clocks to the value specified in the Horizontal Blanking Start Register (CR02).
6:5	**Horizontal Sync Delay.** This field defines the degree to which the start and end of the horizontal sync pulse are delayed to compensate for internal pipeline delays. This capability is supplied to implement VGA compatibility. These field describes the delay in terms of a number character clocks. **Bit [6:5] — Amount of Delay** 00 — no delay 01 — delayed by 1 character clock 10 — delayed by 2 character clocks 11 — delayed by 3 character clocks
4:0	**Horizontal Sync End.** This field provides the 5 least significant bits of a 5-bit value that specifies the end of the horizontal sync pulse relative to its beginning. A value equal to the 5 least significant bits of the horizontal character counter value at which time the horizontal retrace signal becomes inactive (logical 0). Thus, this 5-bit value specifies the width of the horizontal sync pulse. To obtain a retrace signal of W, the following algorithm is used: Value of Horizontal Sync start Register (CR04) + width of horizontal retrace signal in character clock units = 5 bit result to be programmed in this field

CR06 - Vertical Total Register

I/O (and Memory Offset) Address: 3B5h/3D5h (index=06h)

Default: 00h

Attributes: Read/Write (Group 0 Protection)

Bit	Description
7:0	**Vertical Total Bits [7:0].** This field provides the 8 least significant bits of either a 10-bit or 12-bit value that specifies the total number of scan lines. This includes the scan lines both inside and outside of the active display area. In standard VGA modes, the vertical total is specified with a 10-bit value. The 8 least significant bits of this value are supplied by these 8 bits of this register, and the 2 most significant bits are supplied by bits 5 and 0 of the Overflow Register (CR07).

CR07 - Overflow Register (Vertical)

I/O (and Memory Offset) Address: 3B5h/3D5h (index=07h)

Default: UU0U UUU0b (U=Undefined)

Attributes: Read/Write (Group 0 Protection on bits [7:5, 3:0])

Bit	Description
7	**Vertical Sync Start Bit 9.** The vertical sync start is a 10-bit that specifies the beginning of the vertical sync pulse relative to the beginning of the active display area. The 8 least significant bits of this value are supplied by bits [7:0] of the Vertical Sync Start Register (CR10), and the most and second-most significant bits are supplied by this bit and bit 2, respectively, of this register. This 10-bit value should be programmed to be equal to the number of scan lines from the beginning of the active display area to the start of the vertical sync pulse. Since the active display area always starts on the 0th scan line, this number should be equal to the number of the scan line on which the vertical sync pulse begins.
6	**Vertical Display Enable End Bit 9.** The vertical display enable end is a 10-bit that specifies the number of the last scan line within the active display area. In standard VGA modes, the vertical display enable end is specified with a 10-bit value. The 8 least significant bits of this value are supplied by bits [7:0] of the Vertical Display Enable End Register (CR12), and the most and second-most significant bits are supplied by this bit and bit 1, respectively, of this register. This 10-bit value should be programmed to be equal to the number of the last scan line within in the active display area. Since the active display area always starts on the 0th scan line, this number should be equal to the total number of scan lines within the active display area, minus 1.
5	**Vertical Total Bit 9.** The vertical total is a 10-bit value that specifies the total number of scan lines. This includes the scan lines both inside and outside of the active display area. The 8 least significant bits of this value are supplied by bits [7:0] of the Vertical Total Register (CR06), and the most and second-most significant bits are supplied by this bit and bit 0, respectively, of this register. This 10-bit value should be programmed equal to the total number of scan lines, minus 2.

Bit	Description
4	**Line Compare Bit 8.** This bit provides the second most significant bit of a 10-bit value that specifies the scan line at which the memory address counter restarts at the value of 0. Bit 6 of the Maximum Scan Line Register (CR09) supplies the most significant bit, and bits 7-0 of the Line Compare Register (CR18) supply the 8 least significant bits. Normally, this 10-bit value is set to specify a scan line after the last scan line of the active display area. When this 10-bit value is set to specify a scan line within the active display area, it causes that scan line and all subsequent scan lines in the active display area to display video data starting at the very first byte of the frame buffer. The result is what appears to be a screen split into a top and bottom part, with the image in the top part being repeated in the bottom part. When used in cooperation with the Start Address High Register (CR0C) and the Start Address Low Register (CR0D), it is possible to create a split display, as described earlier, but with the top and bottom parts displaying different data. The top part will display what data exists in the frame buffer starting at the address specified in the two aforementioned start address registers, while the bottom part will display what data exists in the frame buffer starting at the first byte of the frame buffer.
3	**Vertical Blanking Start Bit 8.** The vertical blanking start is a 10-bit that specifies the beginning of the vertical blanking period relative to the beginning of the active display area. The 8 least significant bits of this value are supplied by bits [7:0] of the Vertical Blanking Start Register (CR15), and the most and second-most significant bits are supplied by bit 5 of the Maximum Scan Line Register (CR09) and this bit of this register, respectively. This 10-bit value should be programmed to be equal to the number of scan lines from the beginning of the active display area to the beginning of the blanking period. Since the active display area always starts on the 0th scan line, this number should be equal to the number of the scan line on which the vertical blanking period begins.
2	**Vertical Sync Start Bit 8.** The vertical sync start is a 10-bit value that specifies the beginning of the vertical sync pulse relative to the beginning of the active display area. The 8 least significant bits of this value are supplied by bits [7:0] of the Vertical Sync Start Register (CR10), and the most and second-most significant bits are supplied by bit 7 and this bit, respectively, of this register. This 10-bit value should be programmed to be equal to the number of scan lines from the beginning of the active display area to the start of the vertical sync pulse. Since the active display area always starts on the 0th scan line, this number should be equal to the number of the scan line on which the vertical sync pulse begins.

Bit	Description
1	**Vertical Display Enable End Bit 8.** The vertical display enable end is a 10-bit value that specifies the number of the last scan line within the active display area. The 8 least significant bits of this value are supplied by bits [7:0] of the Vertical Display Enable End Register (CR12), and the two most significant bits are supplied by bit 6 and this bit, respectively, of this register. This 10-bit or value should be programmed to be equal to the number of the last scan line within in the active display area. Since the active display area always starts on the 0th scan line, this number should be equal to the total number of scan lines within the active display area, minus 1.
0	**Vertical Total Bit 8.** The vertical total is a 10-bit value that specifies the total number of scan lines. This includes the scan lines both inside and outside of the active display area. The 8 least significant bits of this value are supplied by bits [7:0] of the Vertical Total Register (CR06), and the most and second-most significant bits are supplied by bit 5 and this bit, respectively, of this register. This 10-bit value should be programmed to be equal to the total number of scan lines, minus 2.

CR08 - Preset Row Scan Register

I/O (and Memory Offset) Address: 3B5h/3D5h (index=08h)

Default: 0UUU UUUUb (U=Undefined)

Attributes: Read/Write

Bit	Description
7	**Reserved.** Read as 0s.
6:5	**Byte Panning.** This field holds a 2-bit value that selects number of bytes (up to 3) by which the image is shifted horizontally to the left on the screen. This function is available in both text and graphics modes. In text modes with a 9-pixel wide character box, the image can be shifted up to 27 pixels to the left, in increments of 9 pixels. In text modes with an 8-pixel wide character box, and in all standard VGA graphics modes, the image can be shifted up to 24 pixels to the left, in increments of 8 pixels. When the Nine dot disable bit of the VGA control register is set, the pixel shift will be equivalent to the 8-dot mode. The image can be shifted still further, in increments of individual pixels, through the use of bits [3:0] of the Horizontal Pixel Panning Register (AR13).
4:0	**Starting Row Scan Count.** This field specifies which horizontal line of pixels within the character boxes of the characters used on the top-most row of text on the display will be used as the top-most scan line. The horizontal lines of pixels of a character box are numbered from top to bottom, with the top-most line of pixels being number 0. If a horizontal line of the these character boxes other than the top-most line is specified, then the horizontal lines of the character box above the specified line of the character box will not be displayed as part of the top-most row of text characters on the display. Normally, the value specified by these 5 bits should be 0, so that all of the horizontal lines of pixels within these character boxes will be displayed in the top-most row of text, ensuring that the characters in the top-most row of text do not look as though they have been cut off at the top.

Number of Pixels Shifted

Bit [6:5]	9-Pixel Text	8-Pixel Text & Graphics
00	0	0
01	9	8
10	18	16
11	27	24

CR09 - Maximum Scan Line Register

I/O (and Memory Offset) Address: 3B5h/3D5h (index=09h)

Default: 00h

Attributes: Read/Write

Bit	Description
7	**Double Scanning Enable.** 0 = Disable. When disabled, the clock to the row scan counter is equal to the horizontal scan rate. This is the normal setting for many of the standard VGA modes. 1 = Enable. When enabled, the clock to the row scan counter is divided by 2. This is normally used to allow CGA-compatible modes that have only 200 scan lines of active video data to be displayed as 400 scan lines (each scan line is displayed twice).
6	**Line Compare Bit 9.** This bit provides the most significant bit of a 10-bit value that specifies the scan line at which the memory address counter restarts at the value of 0. Bit 4 of the Overflow Register (CR07) supplies the second most significant bit, and bits 7-0 of the Line Compare Register (CR18) supply the 8 least significant bits. Normally, this 10-bit value is set to specify a scan line after the last scan line of the active display area. When this 10-bit value is set to specify a scan line within the active display area, it causes that scan line and all subsequent scan lines in the active display area to display video data starting at the very first byte of the frame buffer. The result is what appears to be a screen split into a top and bottom part, with the image in the top part being repeated in the bottom part. When used in cooperation with the Start Address High Register (CR0C) and the Start Address Low Register (CR0D), it is possible to create a split display, as described earlier, but with the top and bottom parts displaying different data. The top part will display whatever data exists in the frame buffer starting at the address specified in the two aforementioned start address registers, while the bottom part will display whatever data exists in the frame buffer starting at the first byte of the frame buffer.
5	**Vertical Blanking Start Bit 9.** The vertical blanking start is a 10-bit value that specifies the beginning of the vertical blanking period relative to the beginning of the active display area. The 8 least significant bits of this value are supplied by bits [7:0] of the Vertical Blanking Start Register (CR15), and the most and second-most significant bits are supplied by this bit and bit 3 of the Overflow Register (CR07), respectively. This 10-bit value should be programmed to be equal to the number of scan line from the beginning of the active display area to the beginning of the blanking period. Since the active display area always starts on the 0th scan line, this number should be equal to the number of the scan line on which the vertical blanking period begins.

Bit	Description
4:0	**Starting Row Scan Count.** This field provides all 5 bits of a 5-bit value that specifies the number of scan lines in a horizontal row of text. This value should be programmed to be equal to the number of scan lines in a horizontal row of text, minus 1.

CR0A - Text Cursor Start Register

I/O (and Memory Offset) Address: 3B5h/3D5h (index=0Ah)

Default: 00UU UUUUb (U=Undefined)

Attributes: Read/Write

Bit	Description
7:6	**Reserved.** Read as 0.
5	**Text Cursor Off.** This text cursor exists only in text modes, so this register is entirely ignored in graphics modes. 0 = Enables the text cursor. 1 = Disables the text cursor.
4:0	**Text Cursor Start.** This field specifies which horizontal line of pixels in a character box is to be used to display the first horizontal line of the cursor in text mode. The horizontal lines of pixels in a character box are numbered from top to bottom, with the top-most line being number 0. The value specified by these 5 bits should be the number of the first horizontal line of pixels on which the cursor is to be shown.

CR0B - Text Cursor End Register

I/O (and Memory Offset) Address: 3B5h/3D5h (index=0Bh)

Default: 0UUU UUUUb (U=Undefined)

Attributes: Read/Write

Bit	Description
7	**Reserved.** Read as 0.
6:5	**Text Cursor Skew.** This field specifies the degree to which the start and end of each horizontal line of pixels making up the cursor is delayed to compensate for internal pipeline delays. These 2 bits describe the delay in terms of a number character clocks. **Bit [6:5]** Amount of Delay 00 = No delay 01 = Delayed by 1 character clock 10 = Delayed by 2 character clocks 11 = Delayed by 3 character clocks
4:0	**Text Cursor End.** This field specifies which horizontal line of pixels in a character box is to be used to display the last horizontal line of the cursor in text mode. The horizontal lines of pixels in a character box are numbered from top to bottom, with the top-most line being number 0. The value specified by these 5 bits should be the number of the last horizontal line of pixels on which the cursor is to be shown.

CR0C - Start Address High Register

I/O (and Memory Offset) Address: 3B5h/3D5h (index=0Ch)

Default: Undefined

Attributes: Read/Write

Bit	Description
7:0	**Start Address Bits [15:8].**This register provides either bits 15 through 8 of a 16-bit value that specifies the memory address offset from the beginning of the frame buffer at which the data to be shown in the active display area begins. (default is 0) In standard VGA modes, the start address is specified with a 16-bit value. The eight bits of this register provide the eight most significant bits of this value, while the eight bits of the Start Address Low Register (CR0D) provide the eight least significant bits.

CR0D - Start Address Low Register

I/O (and Memory Offset) Address: 3B5h/3D5h (index=0Dh)

Default: Undefined

Attributes: Read/Write

Bit	Description
7:0	**Start Address Bits [7:0]** This register provides either bits 7 through 0 of a 16 bit value that specifies the memory address offset from the beginning of the frame buffer at which the data to be shown in the active display area begins. (default is 0) In standard VGA modes the start address is specified with a 16-bit value. The eight bits of the Start Address High Register (CR0C) provide the eight most significant bits of this value, while the eight bits of this register provide the eight least significant bits.

CR0E - Text Cursor Location High Register

I/O (and Memory Offset) Address: 3B5h/3D5h (index=0Eh)

Default: Undefined

Attributes: Read/Write

Bit	Description
7:0	**Text Cursor Location Bits [15:8].** This field provides the 8 most significant bits of a 16-bit value that specifies the address offset from the beginning of the frame buffer at which the text cursor is located. Bit 7:0 of the Text Cursor Location Low Register (CR0F) provide the 8 least significant bits.

CR0F - Text Cursor Location Low Register

I/O (and Memory Offset) Address: 3B5h/3D5h (index=0Fh)

Default: Undefined

Attributes: Read/Write

Bit	Description
7:0	**Text Cursor Location Bits [7:0].** This field provides the 8 least significant bits of a 16-bit value that specifies the address offset from the beginning of the frame buffer at which the text cursor is located. Bits 7:0 of the Text Cursor Location High Register (CR0E) provide the 8 most significant bits.

CR10 - Vertical Sync Start Register

I/O (and Memory Offset) Address: 3B5h/3D5h (index=10h)

Default: Undefined

Attributes: Read/Write

Bit	Description
7:0	**Vertical Sync Start Bits [7:0].** This register provides the 8 least significant bits of a 10-bit that specifies the beginning of the vertical sync pulse relative to the beginning of the active display area of a screen. In standard VGA modes, this value is described in 10 bits with bits [7,2] of the Overflow Register (CR07) supplying the 2 most significant bits. This 10-bit value should equal the vertical sync start in terms of the number of scan lines from the beginning of the active display area to the beginning of the vertical sync pulse. Since the active display area always starts on the 0th scan line, this number should be equal to the number of the scan line on which the vertical sync pulse begins.

CR11 - Vertical Sync End Register

I/O (and Memory Offset) Address: 3B5h/3D5h (index=11h)

Default: 0U00 UUUUb (U=Undefined)

Attributes: Read/Write

Bit	Description
7	**Protect Registers [0:7].** The ability to write to Bit 4 of the Overflow Register (CR07) is not affected by this bit (i.e., bit 4 of the Overflow Register is always writeable). 0 = Enable writes to registers CR[00:07]. (default) 1 = Disable writes to registers CR[00:07].
6	**Reserved.** In the VGA standard, this bit was used to switch between 3 and 5 frame buffer refresh cycles during the time required to draw each horizontal line.
5	**Vertical Interrupt Enable.** This bit is reserved for compatibility only. While this bit may be written or read, it's value will have no effect. VGA does not provide an interrupt signal which would be connected to an input of the system's interrupt controller. Bit 7 of Input Status Register 0 (ST00) originally indicated the status of the vertical retrace interrupt. 0 = Enable the generation of an interrupt at the beginning of each vertical retrace period. 1 = Disable the generation of an interrupt at the beginning of each vertical retrace period.
4	**Vertical Interrupt Clear.** This is reserved for compatibility only. VGA does not provide an interrupt signal which would be connected to an input of the system's interrupt controller. 0 = Setting this bit to 0 clears a pending vertical retrace interrupt. This bit must be set back to 1 to enable the generation of another vertical retrace interrupt.
3:0	**Vertical Sync End.** This 4-bit field provides a 4-bit value that specifies the end of the vertical sync pulse relative to its beginning. This 4-bit value should be set to the least significant 4 bits of the result of adding the length of the vertical sync pulse in terms of the number of scan lines that occur within the length of the vertical sync pulse to the value that specifies the beginning of the vertical sync pulse (see the description of the Vertical Sync Start Register for more details).

CR12 - Vertical Display Enable End Register

I/O (and Memory Offset) Address: 3B5h/3D5h (index=12h)

Default: Undefined

Attributes: Read/Write

Bit	Description
7:0	**Vertical Display Enable End Bits [7:0].** This register provides the 8 least significant bits of a 10-bit value that specifies the number of the last scan line within the active display area. In standard VGA modes, this value is described in 10 bits with bits [6,1] of the Overflow Register (CR07) supplying the two most significant bits. This 10-bit value should be programmed to be equal to the number of the last scan line within in the active display area. Since the active display area always starts on the 0th scan line, this number should be equal to the total number of scan lines within the active display area,minus 1.

CR13 - Offset Register

I/O (and Memory Offset) Address: 3B5h/3D5h (index=13h)

Default: Undefined

Attributes: Read/Write

Bit	Description
7:0	**Offset Bits [7:0].** This register provides either all 8 bits of an 8-bit value that specifies the number of words or DWords of frame buffer memory occupied by each horizontal row of characters. Whether this value is interpreted as the number of words or DWords is determined by the settings of the bits in the Clocking Mode Register (SR01). In standard VGA modes, the offset is described with an 8-bit value, all the bits of which are provided by this register. This 8-bit value should be programmed to be equal to either the number of words or DWords (depending on the setting of the bits in the Clocking Mode Register, SR01) of frame buffer memory that is occupied by each horizontal row of characters.

CR14 - Underline Location Register

I/O (and Memory Offset) Address: 3B5h/3D5h (index=14h)

Default: 0UUU UUUUb (U=Undefined)

Attributes: Read/Write

Bit	Description
7	**Reserved.** Read as 0.
6	**DWord Mode.** 0 = Frame buffer addresses are interpreted by the frame buffer address decoder as being either byte addresses or word addresses, depending on the setting of bit 6 of the CRT Mode Control Register (CR17). 1 = Frame buffer addresses are interpreted by the frame buffer address decoder as being DWord addresses, regardless of the setting of bit 6 of the CRT Mode Control Register (CR17). This bit is used in conjunction with bits 6 and 5 of the CRT Mode Control Register (CR17) to select how frame buffer addresses from the CPU are interpreted by the frame buffer address decoder as shown below: **CR14[6] / CR17[6] / Addressing Mode** 0 / 0 / Word Mode 0 / 1 / Byte Mode 1 / 0 / DWord Mode 1 / 1 / DWord Mode
5	**Count By 4.** 0 = The memory address counter is incremented either every character clock or every other character clock, depending upon the setting of bit 3 of the CRT Mode Control Register. 1 = The memory address counter is incremented either every 4 character clocks or every 2 character clocks, depending upon the setting of bit 3 of the CRT Mode Control Register. . This is used in mode x13 to allow for using all four planes. This bit is used in conjunction with bit 3 of the CRT Mode Control Register (CR17) to select the number of character clocks are required to cause the memory address counter to be incremented as shown, below: **CR14[5] / CR17[3] / Addressing Incrementing Interval** 0 / 0 / every character clock 0 / 1 / every 2 character clocks 1 / 0 / every 4 character clocks 1 / 1 / every 2 character clocks

Bit	Description
4:0	**Underline Location.** This field specifies which horizontal line of pixels in a character box is to be used to display a character underline in text mode. The horizontal lines of pixels in a character box are numbered from top to bottom, with the top-most line being number 0. The value specified by these 5 bits should be the number of the horizontal line on which the character underline mark is to be shown.

CR15 - Vertical Blanking Start Register

I/O (and Memory Offset) Address: 3B5h/3D5h (index=15h)

Default: Undefined

Attributes: Read/Write

Bit	Description
7:0	**Vertical Blanking Start Bits [7:0].** This register provides the 8 least significant bits of a 10-bit value that specifies the beginning of the vertical blanking period relative to the beginning of the active display area of the screen. In standard VGA modes, the vertical blanking start is specified with a 10-bit value. The most and second-most significant bits of this value are supplied by bit 5 of the Maximum Scan Line Register (CR09) and bit 3 of the Overflow Register (CR07), respectively. This 10-bit value should be programmed to be equal the number of scan lines from the beginning of the active display area to the beginning of the vertical blanking period. Since the active display area always starts on the 0th scan line, this number should be equal to the number of the scan line on which vertical blanking begins.

CR16 - Vertical Blanking End Register

I/O (and Memory Offset) Address: 3B5h/3D5h (index=16h)

Default: Undefined

Attributes: Read/Write

This register provides a 8-bit value that specifies the end of the vertical blanking period relative to its beginning.

Bit	Description
7:0	**Vertical Blanking End Bits [7:0].** This 8-bit value should be set equal to the least significant 8 bits of the result of adding the length of the vertical blanking period in terms of the number of scan lines that occur within the length of the vertical blanking period to the value that specifies the beginning of the vertical blanking period (see the description of the Vertical Blanking Start Register for details).

CR17 - CRT Mode Control

I/O (and Memory Offset) Address: 3B5h/3D5h (index=17h)

Default: 0UU0 UUUUb (U=Undefined)

Attributes: Read/Write

Bit	Description
7	**CRT Controller Reset.** This bit has no effect except in native VGA modes (non-centered). 0 = Forces horizontal and vertical sync signals to be inactive. No other registers or outputs are affected. 1 = Permits normal operation.
6	**Word Mode or Byte Mode.** 0 = The memory address counter's output bits are shifted by 1 bit position before being passed on to the frame buffer address decoder such that they are made into word-aligned addresses when bit 6 of the Underline Location Register (CR17) is set to 0. 1 = The memory address counter's output bits remain unshifted before being passed on to the frame buffer address decoder such that they remain byte-aligned addresses when bit 6 of the Underline Location Register (CR17) is set to 0. This bit is used in conjunction with bits 6 and 5 of the CRT Mode Control Register (CR17) to control how frame buffer addresses from the memory address counter are interpreted by the frame buffer address decoder as shown below: CR14[6] CR17[6] **Address Mode** 0 0 Word Mode - Addresses from the memory address counter are shifted once to become word-aligned 0 1 Byte Mode - Addresses from the memory address counter are not shifted 1 0 DWord Mode - Addresses from the memory address counter are shifted twice to become DWord-aligned 1 1 DWord Mode - Addresses from the memory address counter are shifted twice to become DWord-aligned
5	**Address Wrap.** This bit is only effective when word mode is made active by setting bit 6 in both the Underline Location Register and this register to 0. 0 = Wrap frame buffer address at 16 KB. This is used in CGA-compatible modes. 1 = No wrapping of frame buffer addresses.

Bit	Description
4	**Reserved.** Read as 0.
3	**Count By 2.** This bit is used in conjunction with bit 5 of the Underline Location Register (CR14) to select the number of character clocks are required to cause the memory address counter to be incremented. 0 = The memory address counter is incremented either every character clock or every 4 character clocks, depending upon the setting of bit 5 of the Underline Location Register. 1 = The memory address counter is incremented either every other clock. CR14[5] CR17[3] Address Incrementing interval 0 0 every character clock 0 1 every 2 character clocks 1 0 every 4 character clocks 1 1 every 2 character clocks
2	**Horizontal Retrace Select.** This bit provides a way of effectively doubling the vertical resolution by allowing the vertical timing counter to be clocked by the horizontal retrace clock divided by 2 (usually, it would be undivided). 0 = The vertical timing counter is clocked by the horizontal retrace clock. 1 = The vertical timing counter is clocked by the horizontal retrace clock divided by 2.
1	**Select Row Scan Counter.** 0 = A substitution takes place, where bit 14 of the 16-bit memory address generated of the memory address counter (after the stage at which these 16 bits may have already been shifted to accommodate word or DWord addressing) is replaced with bit 1 of the row scan counter at a stage just before this address is presented to the frame buffer address decoder. 1 = No substitution takes place. See following tables.
0	**Compatibility Mode Support.** 0 = A substitution takes place, where bit 13 of the 16-bit memory address generated of the memory address counter (after the stage at which these 16 bits may have already been shifted to accommodate word or DWord addressing) is replaced with bit 0 of the row scan counter at a stage just before this address is presented to the frame buffer address decoder. 1 = No substitution takes place. See following tables.

The following tables show the possible ways in which the address bits from the memory address counter can be shifted and/or reorganized before being presented to the frame buffer address decoder. First, the

address bits generated by the memory address counter are reorganized, if need be, to accommodate byte, word or DWord modes. The resulting reorganized outputs (MAOut15-MAOut0) from the memory address counter may also be further manipulated with the substitution of bits from the row scan counter (RSOut1 and RSOut0) before finally being presented to the input bits of the frame buffer address decoder (FBIn15-FBIn0).

CR18 - Line Compare Register

I/O (and Memory Offset) Address: 3B5h/3D5h (index=18h)

Default: Undefined

Attributes: Read/Write

Bit	Description
7:0	**Line Compare Bits [7:0].** This register provides the 8 least significant bits of a 10-bit value that specifies the scan line at which the memory address counter restarts at the value of 0. Bit 6 of the Maximum Scan Line Register (CR09) supplies the most significant bit, and bit 4 of the Overflow Register (CR07) supplies the second most significant bit. Normally, this 10-bit value is set to specify a scan line after the last scan line of the active display area. When this 10-bit value is set to specify a scan line within the active display area, it causes that scan line and all subsequent scan lines in the active display area to display video data starting at the very first byte of the frame buffer. The result is what appears to be a screen split into a top and bottom part, with the image in the top part being repeated in the bottom part. (This register is only used in split screening modes, and this is not a problem because split screening is not actually used for extended modes. As a result, there is no benefit to extending the existing overflow bits for higher resolutions.) When used in cooperation with the Start Address High Register (CR0C) and the Start Address Low Register (CR0D), it is possible to create a split display, as described earlier, but with the top and bottom parts displaying different data. The top part will display whatever data exists in the frame buffer starting at the address specified in the two aforementioned start address registers, while the bottom part will display whatever data exists in the frame buffer starting at the first byte of the frame buffer.

CR22 - Memory Read Latch Data Register

I/O (and Memory Offset) Address: 3B5h/3D5h (index=22h)

Default: 00h

Attributes: Read Only

Bit	Description
7:0	**Memory Read Latch Data.** This field provides the value currently stored in 1 of the four memory read latches. Bits 1 and 0 of the Read Map Select Register (GR04) select which of the four memory read latches may be read via this register.

CR24 - Toggle State of Attribute Controller Register

I/O (and Memory Offset) Address: 3B5h/3D5h (index=24h)

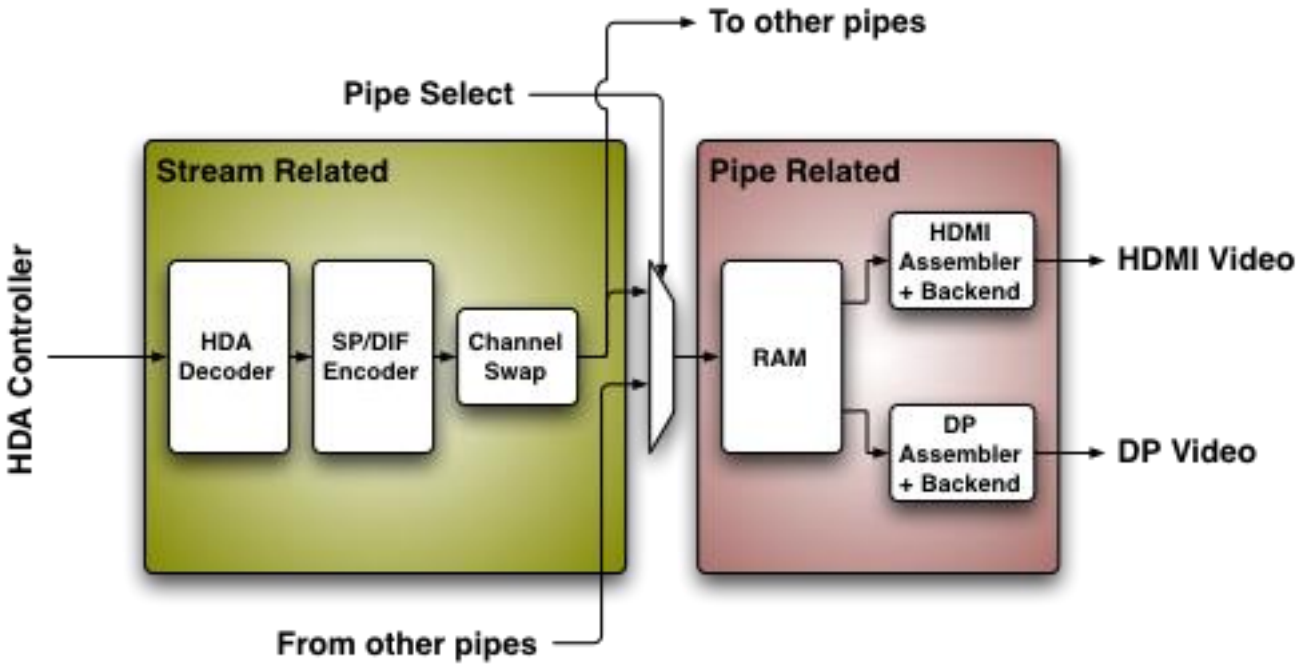
Default: 00h

Attributes: Read Only

Bit	Description
7	**Toggle Status.** Indicates where the last write to attribute register was to: 0 = index port 1 = data port
6:0	**Reserved.** Read as 0.

Display Audio Codec Verbs

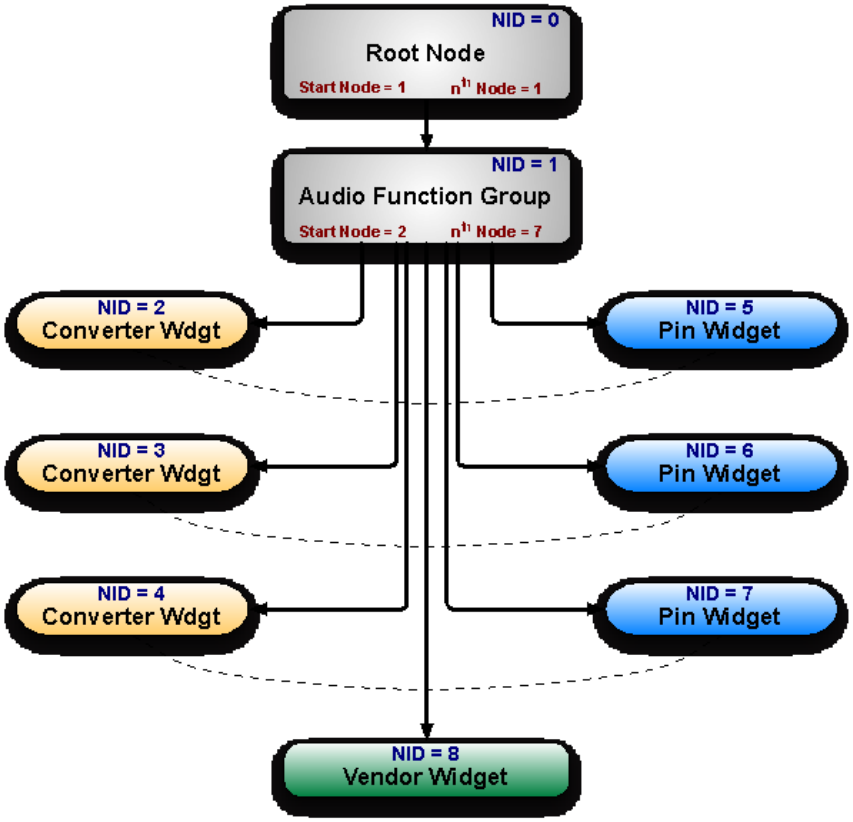
Block Diagram



Codec Node Hierarchy

The diagram below shows the hierarchy of the internal codec. The codec is presented as a single codec with multiple endpoints. By operating as a single codec, only one driver needs to be loaded on the system.

Inside the codec are three "converter widgets" and three "pin widgets", responsible for taking data from HD Audio DMA engines and placing into an HDMI/DP stream. Each pin widget has a 1-1 connection to a converter widget (as indicated by the dotted lines in the diagram).



Programming

Programming of the codec is performed by "verbs" as described in the HD Audio specification. These verbs travel over the internal HD Audio link at a rate of 1 verb per frame. A verb can either come from the CORB, with responses using the RIRB, or using an immediate command and response mechanism (ICR). Device 2 contains its own copy of an ICR mechanism as a back-door into the audio codec.

Node ID 00h Root Node Verbs

The root node only contains a single verb - the "Get Parameters" verb at F00h.

F00h - Get Parameters

Parameter	Symbol	Register Name
00h	PARAM_VID	Vendor ID
02h	PARAM_RID	Revision ID
04h	PARAM_SNC	Subordinate Node Count

Parameter 00h: VID - Vendor ID

Bit	Reset	Description
31:16	8086h	**Vendor ID (VID):** Indicates the 16-bit Vendor ID values used to identify the codec to the PnP subsystem.
15:00	2809h	**Device ID (DID):** Indicates the 16-bit Device ID values used to identify the codec to the PnP subsystem. It is 280Bh for KBL

Parameter 02h: RID - Revision ID

Bit	Reset	Description
31:24	*0*	*Reserved*
23:20	1h	**Major Revision (MJR):** Indicates the major revision number (left of the decimal) of the High Definition Audio Specification to which the codec is fully compliant.
19:16	0h	**Minor Revision (MNR):** Indicates the minor revision number (right of the decimal) or "dot number" of the High Definition Audio Specification to which the codec is fully compliant.
15:08	00h	**Revision ID (RID):** Indicates the vendor's revision number for this given Device ID.
07:00	00h	**Stepping ID (SID):** Indicates optional vendor stepping number within the revision.

Parameter 04h: PARAM_SNC - Subordinate Node Count

Bit	Reset	Description
31:24	*0*	*Reserved*
23:16	0h	**Starting Node Number (SNN):** Indicates the first sub-node's ID is 01h.
15:08	00h	Reserved
07:00	01h	**Total Number of Nodes (TNN):** Indicates one sub-node

F37h GET CCF - Get Current Clock Frequency

Bits	Default	Description
31:6	0	*Reserved*
05	0	**Current Clock 192 MHz (C192)**: Indicates the current clock is 192 MHz. Reserved for Display Codec
04	1	**Current Clock 96 MHz (C96)**: Indicates the current clock is 96 MHz.
03	0	**Current Clock 48 MHz (C48)**: Indicates the current clock is 48 MHz.
02	0	**Current Clock 24 MHz (C24)**: Indicates the current clock is 24 MHz. Reserved for Display Codec
01	0	**Current Clock 12 MHz (C12)**: Indicates the current clock is 12 MHz. Reserved for Display Codec
00	0	**Current Clock 6 MHz (C6)**: Indicates the current clock is 6 MHz. Reserved for Display Codec

Node ID 01h Audio Function Group Verbs

Set Verb	Get Verb	Symbol	Name
-	F00h	GET PARAM	Get Parameters
705h	F05h	SET_PS / GET_PS	Set Power State
-	F20h	GET_SSID	Get Subsystem ID
720h	F20h	SET_SSID0	Set/Get Subsystem ID
721h	F21h	SET_SSID1	Set/Get Subsystem ID
722h	F22h	SET_SSID2	Set//Get Subsystem ID
723h	F23h	SET_SSID3	Set/Get Subsystem ID
724h	F24h	SET CCF	Set/Get Current Clock Frequency

F00h Get Parameters

Parameter	Symbol	Register Name
04h	PARAM_SNC	Subordinate Node Count
05h	PARAM_FGT	Function Group Type
08h	PARAM_FGC	Function Group Capabilities
0Fh	PARAM SPS	Supported Power States

Parameter 04h: PARAM_SNC - Subordinate Node Count

Bit	Reset	Description
31:24	*0*	*Reserved*
23:16	02h	**Start Node Number (SNN):** Indicates the start node number of widget or functional nodes in the Functional Group.
15:08	*0*	*Reserved*
07:00	07h	**Total Number of Nodes (TNN):** Indicates 7 widgets in the Functional Group. (HDMI/DP converters (3) + HDMI/DP pins (3) + Vendor Defined Widget (1)).

Parameter 05h: PARAM_FGT - Function Group Type

Bit	Reset	Description
31:09	*0*	*Reserved*
08	0	**Unsolicited Capable (UC):** Not capable of generating an unsolicited response.
07:00	01h	**Node Type (NT):** Indicates Audio Function Group.

Parameter 08h: PARAM_FGC - Function Group Capability

Bit	Reset	Description
31:04	*0*	*Reserved*
03:00	00h	**Output Delay (OD)**Output Delay.

Parameter 0Fh: PARAM_SPS - Supported Power States

Bit	Reset	Description
31	1	**Extended Power State Supported (EPSS):** Indicates support for low power states
30	1	**Clock Stop (CS):** Indicates support for D3 when clock is stopped.
29:04	*0*	*Reserved*
03	1	**D3 Supported (D3S):** Indicates support for D3.
02	0	**D2 Supported (D2S):** Indicates no support for D2.
01	0	**D1 Supported (D1S):** Indicates no support for D1.
00	1	**D0 Supported (D0S):** Indicates support for D0.

Parameter 16h: PARAM_A2CAP - Azalia 2 Capabilities

Bits	Reset	Description
31:17	*0*	*Reserved*
16	0	**Independent Codec Clock (ICC):** When set, this indicates that the codec generates its own clock, which may drift from the link clock. When cleared, the codec's clock is locked to the link clock.
15:06	*0*	*Reserved*
05	*0*	*Reserved for 192 MHz support.*
04	1	**96MHz Supported (S96):** Indicates 96 MHz clock is supported.
03	1	**48MHz Supported (S48):** Indicates 48 MHz clock is supported.This bit must always be set.
02	0	**24MHz Supported (S24):** Indicates 24 MHz clock is supported. Reserved for Display Codec
01	0	**12MHz Supported (S12):** Indicates 12 MHz clock is supported. Reserved for Display Codec
00	0	**6MHz Supported (S6)**Indicates 6 MHz clock is supported. Reserved for Display Codec

705h SET_PS - Set Power State

Bits	Description
07:02	Reserved
01:00	**Requested Power State (RPS):** Only D0 (00) and D3 (11) may be requested

F05h GET_PS - Get Power State

Bits	Reset	Description
31:11	0	Reserved
10	0	**Settings Reset (SR):** Haswell does not change the default values.
09	1	**Clock Stop OK (CSOK):** Clock stopping in D3 is OK
08	0	**Error (ERR):** No error will ever be reported.
07:06	0	Reserved
05:04	11	**Actual Power State (APS):** Indicates the current power state of the node.
03:02	0	Reserved
01:00	11	**Requested Power State (CPS):** Reflects value written with SET_PS verb.

F20h GET SSID - Get Subsystem ID0

Bits	Reset	Description
31:00	80860101h	**Subsystem ID (SSID):** Reports the sub-system ID set via SET_SSIDx verbs.

720h SET SSID0 - Set Subsystem ID0

Bits	Description
07:00	Subsystem ID Bits [7:0]

721h SET SSID1 - Set Subsystem ID1

Bits	Description
07:00	Subsystem ID Bits [15:8]

722h SET SSID2 - Set Subsystem ID2

Bits	Description
07:00	Subsystem ID Bits [23:16]

723h SET SSID3 - Set Subsystem ID3

Bits	Description
07:00	Subsystem ID Bits [31:24]

724h SET CCF - Set Current Clock Frequency

Bits	Description
07:06	Reserved
05	**Set Clock 192 MHz (S192)**: Set clock to 192 MHz.
04	**Set Clock 96 MHz (S96)**: Set clock to 96 MHz
03	**Set Clock 48 MHz (S48)**: Set clock to 48 MHz
02	**Set Clock 24 MHz (S24)**: Set clock to 24 MHz
01	**Set Clock 12 MHz (S12)**: Set clock to 12 MHz
00	**Set Clock 6 MHz (S6)**: Set clock to 6 MHz

F24h GET CCF - Get Current Clock Frequency

Bits	Bits	Description
31:06	0	*Reserved*
05	0	**Current Clock 192 MHz (C192)**: Indicates the current clock is 192 MHz.
04	0	**Current Clock 96 MHz (C96)**: Indicates the current clock is 96 MHz.
03	0	**Current Clock 48 MHz (C48)**: Indicates the current clock is 48 MHz.
02	0	**Current Clock 24 MHz (C24)**: Indicates the current clock is 24 MHz.
01	0	**Current Clock 12 MHz (C12)**: Indicates the current clock is 12 MHz.
00	0	**Current Clock 6 MHz (C6)**: Indicates the current clock is 6 MHz.

7FFh SET Function Group Reset

Bits	Reset	Description
07:00	00h	The Function Reset command causes the functional unit, and all widgets associated with the functional unit, to return to their power-on reset values. Note that some controls such as the Configuration Default controls should not be reset with this command. It is also possible that certain other controls, such as Caller-ID, should not be reset. This command does not affect the Link interface logic, which must be reset with the link RST# signal. Therefore, a codec must not initiate a Status Change request on the link.

Parameter 09h: AWC - Audio Widget Capabilities

Bits	Reset	Description
31:24	0	Reserved
23:20	0h	**Widget Type (TYPE):** Indicates this is an audio output widget
19:16		Sample Delay in Widget (DELAY):
15:13	011	**Channel Count Extension (CCE):** These three bits, combined with STRO, indicate that there are 8 channels supported.
11	0	**L-R Swap (LRS):** Indicates no left/right channel swap.
10	1	**Power Control (PC):** Indicates power state control
09	1	**Digital (DIG):** Indicates support for digital streams.
08	0	**Connection List (CL):** Indicates no connection list
07	0	**Unsolicited Capable (UC):** Indicates support for unsolicited responses.
06	0	**Processing Widget (PW):** Indicates no support for processing
05	0	**Stripe (STRP):** Indicates striping not supported.
04	1	**Format Override (FO):** Indicates support for formatting
03	1	**Amp Parameter Override (APO):** Indicates no amplifier support.
02	0	**Out Amp Present (OAP):** Indicates no output amplifier present.
01	0	**In Amp Present (IAP):** Indicates no input amplifier present.
00	1	**Stereo (STRO):** Indicates a stereo widget

Parameter 0Ah: PSB - PCM Sizes and Bit Rates

Bits	Reset	Description
31:21	0	*Reserved*
20	1	**32-bit Support (B32):** Indicates 32-bit samples supported
19	1	**24-bit Support (B24):** Indicates 24-bit samples supported
18	0	**20-bit Support (B20):** Indicates 20-bit samples supported
17	1	**16-bit Support (B16):** Indicates 16-bit samples supported
16	0	**8-bit Support (B8):** Indicates 8-bit samples not supported
15:12	0	*Reserved*
11	0	**384 kHz Support (R12):** Indicates 384 kHz not supported
10	1	**192 kHz Support (R11):** Indicates 192 kHz supported
09	1	**176.4 kHz Support (R10):** Indicates 176.4 kHz supported
08	1	**96 kHz Support (R9):** Indicates 96 kHz supported
07	1	**88.2 kHz Support (R8):** Indicates 88.2 kHz supported
06	1	**48 kHz Support (R7):** Indicates 48 kHz supported
05	1	**44.1 kHz Support (R6):** Indicates 44.1 kHz supported
04	1	**32 kHz Support (R5):** Indicates 32 kHz supported
03	0	**22.05 kHz Support (R4):** Indicates 22.05 kHz not supported
02	0	**16 kHz Support (R3):** Indicates 16 kHz not supported
01	0	**11.025 kHz Support (R2):** Indicates 11.025 kHz not supported
00	0	**8 kHz Support (R1):** Indicates 8 kHz not supported

Parameter 0Bh: SF - Stream Formats

Bits	Reset	Description
31:03	0	*Reserved*
02	1	**AC3 Support (AC3):** Indicates AC3 stream format is supported
01	0	**Float32 Support (F32):** Indicates float32 stream format not supported
00	1	**PCM Support (PCM):** Indicates PCM format is supported.

Parameter 0Fh: PARAM_SPS - Supported Power States

Bit	Reset	Description
31	1	**Extended Power State Supported (EPSS):** Indicates support for low power states
30:04	0	*Reserved*
03	1	**D3 Supported (D3S):** Indicates support for D3.
02	0	**D2 Supported (D2S):** Indicates no support for D2.
01	0	**D1 Supported (D1S):** Indicates no support for D1.
00	1	**D0 Supported (D0S):** Indicates support for D0.

705h SET_PS - Set Power State

Bits	Description
07:02	Reserved
01:00	**Requested Power State (RPS):** Only D0 (00) and D3 (11) may be requested

F05h GET_PS - Get Power State

Bits	Reset	Description
31:11	0	Reserved
10	0	**Settings Reset (SR):** ???
09	0	**Clock Stop OK (CSOK):** Clock stopping in D3 is not OK

Bits	Reset	Description
08	0	**Error (ERR):** No error will ever be reported.
07:06	0	Reserved
05:04	11	**Actual Power State (APS):** Indicates the current power state of the node.
03:02	0	Reserved
01:00	11	**Requested Power State (CPS):** Reflects value written with SET_PS verb.

706hF06h GETSET_CSID - GetSet Channel and Stream ID

Bits	Reset	Description
07:04	0h	**Stream ID (SID):** Link stream used by the converter for data output.
03:00	0h	**Lowest Channel Number (LCN):** Lowest channel used by the converter.

Digital Converter Verbs

F0Dh: GET_DC - Get Digital Converter

Bits	Reset	Description
31:24	0	Reserved
23	1	**Keep Alive (KA):** See SET_DC3.KA
22:20	0	Reserved
19:16	0h	**IEC Coding Type (ICT):** See SET_DC3.ICT
15	0	Reserved
14:08	00h	**Category Code (CC):** See SET_DC1.CC
07	0	**Level (LVL):** See SET_DC1.LVL
06	0	**Professional (PRO):** See SET_DC1.PRO
05	0	**Audio is not PCM (AUDIO):** See SET_DC1.AUDIO
04	0	**Copyright (COPY):** See SET_DC1.COPY
03	0	**Pre-emphasis (PRE):** See SET_DC1.PRE

Bits	Reset	Description
02	0	**Validity Configuration (VCFG):** See SET_DC1.VCFG
01	0	**Validity (V):** See SET_DC1.V
00	1	**Digital Enable (DIGEN):** See SET_DC1.DIGEN

70Dh: SET_DC1 - Set Digital Converter 1

Bits	Description
07	**Level (LVL):** S/PDIF IEC Generation Level.
06	**Professional (PRO):** When set, indicates professional use of channel.
05	**Audio is not PCM (AUDIO):** When set, data is non-PCM format.
04	**Copyright (COPY):** When set, copyright asserted.
03	**Pre-emphasis (PRE):** When set, enables filter pre-emphasis.
02	**Validity Configuration (VCFG):** Determines S/PDIF transmitter behavior when data is not being transmitted.
01	**Validity (V):** Affects the validity flag transmitted in each sub-frame, and enables S/PDIF transmitter to maintain connection during error or mute conditions.
00	**Digital Enable (DIGEN):** When set, enables digital content

70Eh: Digital Converter 2

Bits	Description
07	Reserved
06:00	**Category Code (CC):** S/PDIF IEC Category Code.

73Eh: Digital Converter 3

Bits	Description
07	Keep Alive
06:04	Reserved
03:00	IEC Coding Type

73Fh: Digital Converter 4

Bits	Description
07:00	Reserved

72DhF2Dh GETSET_CCC - GetSet Converter Channel Count

Bits	Reset	Description
07:04	0	Reserved
03:00	0000	Converter Channel Count 1 (0th order)

Node ID 05h 06h 07h Pin Widget Verbs

Set Verb	Get Verb	Symbol	Verb Name
3h	-	SET_AM	Set Amplifier Mute
-	Bh	GET_AM	Get Amplifier Mute
-	F00h	-	Get Parameters
701h	F01h	SET_CSC / GET_CSC	Set/Get Connection Select Control
-	F02h	-	Get Connection List Entry
705h	F05h	SET_PS / GET_PS	Set/Get Power State
707h	F07h	SET_PWC / GET_PWC	Set/Get Pin Widget Control
708h	F08h	SET_UE / GET_UE	Set/Get Unsolicited Response Enable
-	F09h	-	Get Pin Sense
71Ch	-	SET_CD0	Set Configuration Default Byte 0
71Dh	-	SET_CD1	Set Configuration Default Byte 1
71Eh	-	SET_CD2	Set Configuration Default Byte 2
71Fh	-	SET_CD3	Set Configuration Default Byte 3
-	F1Ch	GET_CD	Get Configuration Default
-	F2Eh	GET_HDIS	Get HDMI/DP Info Size
730h	F30h	SET_HII / GET_HII	Set/Get HDMI Info Index
731h	F31h	SET_HID / GET_HID	Set/Get HDMI Info Data
732h	F32h	SET_HITC / GET_HITC	Set/Get HDMI Info Transmit Control
733h	F33h	SET_PC / GET_PC	Set/Get Protection Control
734h	F34h	SET_CCM / GET_CCM	Set/Get Converter Channel Map
735h	F35h	SET_DS / GET_DS	Set/Get Device Select
-	F36h	GET_DDLE	Get Display Device List Entry
73Ch	F3Ch	SET_DPID / GET_DPID	Set/Get DisplayPort Stream ID

3h SET_AM - Set Amplifier Mute

Bits	Bits	Description
15	0	**Set Output Amp (SOA):**.
14	0	**Set Input Amp (SIA):**.
13	0	**Set Left Amp (SLA):**.
12	0	**Set Right Amp (SRA):**.
11:08	0h	**Index (IDX):**
07	1	**Mute (MUTE):** When set, amp muted.
06:00	0	*Reserved*

B8h GET_AM - Get Amplifier Mute

Bits	Bits	Description
31:08	0	*Reserved*
07	1	**Mute (MUTE):** When set, amp muted.
06:00	0	*Reserved*

F00h Get Parameters

Parameter	Symbol	Register Name
09h	PARAM_AWC	Audio Widget Capabilities
0Ch	PARAM_PC	Pin Capabilities
0Eh	PARAM_CLL	Connection List Length
12h	PARAM OAC	Output Amplifier Capabilities
15h	PARAM_DLL	Device List Length
0Fh	PARAM_SPS	Supported Power States

Parameter 09h: AWC - Audio Widget Capabilities

Bits	Reset	Description
31:24	0	Reserved
23:20	4h	**Widget Type (TYPE):** Indicates this is a pin complex widget
19:16	0	**Sample Delay in Widget (DELAY):** No delay through the pin widget.
15:13	011	**Channel Count Extension (CCE):** This field, combined with STRO, indicate 8 channels supported.
11	0	**L-R Swap (LRS):** Indicates no left/right channel swap.
10	1	**Power Control (PC):** Indicates power state control
09	1	**Digital (DIG):** Indicates support for digital streams.
08	1	**Connection List (CL):** Indicates a connection list
07	1	**Unsolicited Capable (UC):** Indicates support for unsolicited responses.
06	0	**Processing Widget (PW):** Indicates no support for processing
05	0	**Stripe (STRP):** Indicates striping not supported.
04	0	**Format Override (FO):** Indicates no support for formatting
03	1	**Amp Parameter Override (APO):** Indicates no amplifier override support.
02	1	**Out Amp Present (OAP):** Indicates no output amplifier present.
01	0	**In Amp Present (IAP):** Indicates no input amplifier present.
00	1	**Stereo (STRO):** Indicates a stereo widget

Parameter 0Ch: PC - Pin Capabilities

Bits	Reset	Description
31:28	0	*Reserved*
27	1	**High Bit Rate (HBR):** Indicates support for high bit-rate audio

Bits	Reset	Description
26	0	*Reserved*
25	1	**Multi Stream Capable (MSC):** Indicates support for DisplayPort Multistream. Will be zero in vanilla mode.
24	1	**DisplayPort (DP):** Indicates support for DisplayPort
23:08	0	*Reserved*
07	1	**HDMI (HDMI):** Indicates support for HDMI
06:05	0	*Reserved*
04	1	**Output Capable (OC):** Pin is output capable
03	0	*Reserved*
02	1	**Presence Detect Capable (PDC):** Indicates capability for presence detection
01:00	0	*Reserved*

Parameter 0Eh: CLL - Connection List Length

Bits	Reset	Description
31:08	0	*Reserved*
07	0	**Long Form (LF):** Indicates connection list is short form
06:00	03h	**Length (LEN):** Indicates there is one item in the connection list.

Parameter 12h: OAC - Output Amplifier Capabilities

Bits	Reset	Description
31	1	**Mute Capable (MC):** Muting is capable on this pin
30:00	0	Reserved

Parameter 15h: DLL - Device List Length

Bits	Reset	Description
31:06	0	*Reserved*
05:00	00h	**Length (LEN):** Indicates no devices

Parameter 0Fh: PARAM_SPS - Supported Power States

Bit	Reset	Description
31	1	**Extended Power State Supported (EPSS):** Indicates support for low power states
30:04	0	*Reserved*
03	1	**D3 Supported (D3S):** Indicates support for D3.
02	0	**D2 Supported (D2S):** Indicates no support for D2.
01	0	**D1 Supported (D1S):** Indicates no support for D1.
00	1	**D0 Supported (D0S):** Indicates support for D0.

701hF01h SETGET_CSC - SetGet Connection Select Control

Bits	Reset	Description
07:00	00h	**Connection Select Control (CSC):**

F02h GET_CLE - Get Connection List Entry

Bits	Reset	Description
31:08	0	Reserved
07:00	Varies	**Connection List Entry (CLE):** 02h for NodeID 05h, 03h for NodeID 06h, and 04h for NodeID 07h.

705h SET_PS - Set Power State

Bits	Description
07:02	Reserved
01:00	**Requested Power State (RPS):** Only D0 (00) and D3 (11) may be requested

F05h GET_PS - Get Power State

Bits	Reset	Description
31:11	0	Reserved
10	0	**Settings Reset (SR):** Haswell does not change the default values.
09	0	**Clock Stop OK (CSOK):** Clock stopping in D3 is not OK
08	0	**Error (ERR):** No error will ever be reported.
07:06	0	Reserved
05:04	11	**Actual Power State (APS):** Indicates the current power state of the node.
03:02	0	Reserved
01:00	11	**Requested Power State (CPS):** Reflects value written with SET_PS verb.

707hF07h SETGET_PWC - SetGet Pin Widget Control

Bits	Reset	Description
07	0	Reserved
06	1	**Out Enable (OE):** When set, the audio is enabled
05:02	0	Reserved
01:00	00	**Encoded Packet Type (EPT):**

708hF08h SETGET_UE - SetGet Unsolicited Enable

Bits	Description
07	**Unsolicited Enable (UE):** When set, unsolicited responses are allowed
06	Reserved
05:00	**Tag (TAG):**

F09h GET_PS - Get Pin Sense

Bits	Reset	Description
31	0	**Presence Detect (PD):** When set presence is detected on this pin.
30	0	**ELD Value (ELDV):**
29	0	**Inactive (INA):**
28:00	28:00	Reserved

71Ch SET_CD0 - Set Configuration Default Byte 0

Bits	Description
07:04	Default Association (DA):
03:00	Sequence (SEQ):

71Dh SET_CD1 - Set Configuration Default Byte 1

Bits	Description
07:04	Color (COL):
03:00	Miscellaneous (MISC):

71Eh SET_CD2 - Set Configuration Default Byte 2

Bits	Description
07:04	Default Device (DD):
03:00	Connection Type (CT):

71Fh SET_CD3 - Set Configuration Default Byte 3

Bits	Description
07:06	**Port Connectivity (PC):** External connectivity of the pin complex. • 00 = Connected to jack • 01 = No physical connection • 10 = Fixed function device (integrated speaker, mic, etc.) • 11 = Both a jack and internal connection
05:00	**Location (LOC):**

Bits	Description

	Bits 3:0										
Bits 5:4	0h: N/A	1h: Rear	2h: Front	3h: Left	4h: Right	5h: Top	6h: Bottom	7h: Special	8h: Special	9h: Special	Ah-Fh Reserved
00: External	Y	Y	Y	Y	Y	Y	Y	Y	Y		
01: Internal	Y							Y	Y	Y	
10: Separate Chassis	Y	Y	Y	Y	Y	Y	Y				
11: Other	Y						Y	Y	Y		

F1Ch GET_CD - Get Configuration Default

Bits	Description
31:30	**Port Connectivity (PC):** See SET_CD3.PC
29:24	**Location (L):** See SET_CD3.L
23:20	**Default Device (DD):** See Set_CD2.DD
19:16	**Connection Type (CT):** See Set_CD2.CT
15:12	**Color (COL):** See SET_CD1.COL
11:08	**Miscellaneous (MISC):** See SET_CD1.MISC
07:04	**Default Association (DA):** See SET_CD0.DA
03:00	**Sequence (SEQ):** See SET_CD0.SEQ

F2Eh HDMIDP Info Size

Bits	Reset	Description
31:08	0	Reset
07:00	Varies	**Size (SZ):** Indexes 0 - 3 return 1Eh, index 1000 returns 53h, others reserved.

F2Fh Get ELD Data

Parameter	Symbol	Register Name
07:0h	PARAM_INDX	ELD DATA Index

Parameter nn: ELD Data

Bits	Reset	Description
31:00	0	ELD Data

730hF30h SETGET_HII - SetGet HDMI Info Index

Bits	Reset	Description
07:05	000	**Infoframe Packet Index (IPI):** Value / Name / Value / Name 000 / Audio / 011 / GP3 001 / GP / 100 / GP4 010 / GP2 / Others / Reserved
04:00	00h	**Byte Offset Index Pointer (BOI):**

731hF31h SETGET_HID - SetGet HDMI Info Data

Bits	Reset	Description
07:00	00h	**Data (DATA):** Data at current index pointed to from SET_HII verb.

732hF32h SETGET_HITC - SetGet HDMI Info Transmit Control

Bits	Reset	Description
07:06	00	**InfoFrame Control Current Indexed Frame (IFCCIF):** • 00 = Disable Transmit • 01 = Reserved • 10 = Transmit Once • 11 = Best Effort
05:00	0	*Reserved*

733h SET_PC - Set Protection Control

Bits	Description
07:03	**Unsolicited Response Sub Tag (URST):** Subtag to use for unsolicited responsed.
02	Reserved

734hF34h SETGET_CCM - GetSet Converter Channel Map

Bits	Reset	Description
07:04	0h	Converter Channel (CC):
03:00	0h	Slot (SN):

735h SET_DS - Set Device Select

Bits	Reset	Description
07:06	0	*Reserved*
05:00	00h	**Device (D):** 000001, 000010 (based upon number of devices present)

F35h: GET_DS - Get Device Select

Bits	Description
31:12	**Reserved:** Set to 0
11:06	**SinK Device ID:** Sink Device ID in the multi stream topology of the DP hierarchy. Device attached to Pipe A will have ID of "00000", PipeB will have "00001" and Pipe C will have "00010".
05:00	**Device (D):**Device Entry index currently set

F36h GET_DDLE - Get Display Device List Entry

Bits	Bits	Description
31:12	0	*Reserved*
11	0	**Reserved?**
10	0	**IA of Entry 2**
09	0	**ELDV of Entry 2**

Bits	Bits	Description
08	0	**PD of Entry 2**
07	0	**Reserved?**
06	0	**IA of Entry 1**
05	0	**ELDV of Entry 1**
04	0	**PD of Entry 1**
03	0	**Reserved?**
02	0	**IA of Entry 0**
01	0	**ELDV of Entry 0**
00	0	**PD of Entry 0**

73ChF3Ch SETGET_DPID - SetGet DisplayPort Stream ID

Bits	Reset	Description
07:03	00h	**Tag (TAG):** Represents the SSID that will go in the lower 5 bits of the SSID
02:00	000	**Index (IDX):** Pointer to program multiple SSID

Node ID 08h Intel Vendor Widget Verbs

Set Verb	Get Verb	Symbol	Verb Name
-	F00h	GET_PARAM	Get Parameters
-	F80h	GET_HDPS	Get HDMI/DP Status
781h	F81h	SET_HVV / GET_HVV	Set/Get iDisp Codec Vendor Verb
782h	-	SET_GTCT	Set GTC Trigger
-	F83h	GET_CWC	Get Captured Wall Clock
	F84h	GET_CGTC	Get Captured GTC Value
	F85h	GET_GOF	Get GTC Offset Value
785h	-	SET_GOF0	Set GTC Offset Value Byte 0
786h	-	SET_GOF1	Set GTC Offset Value Byte 1
787h	-	SET_GOF2	Set GTC Offset Value Byte 2
788h	-	SET_GOF3	Set GTC Offset Value Byte 3

Set Verb	Get Verb	Symbol	Verb Name
789h	F89h	SET_GDI / GET_GDI	Set/Get GTC Offset Device Index

F00h Get Parameters

Parameter	Symbol	Register Name
09h	PARAM_AWC	Audio Widget Capabilities

Parameter 09h: AWC - Audio Widget Capabilities

Bits	Reset	Description
31:24	0	Reserved
23:20	Fh	**Widget Type (TYPE):** Indicates this is a vendor defined widget
19:00	0	Reserved

71Eh SET_GET_GFXMAILBOX - Set Get GFX MAILBOX Byte 2

71Eh: SET GFX MAILBOXM

Bits	Default	Description
07:00	00	Contents to be defined by GFX driver and audio driver

F1Eh: GET GFX MAILBOX

Bits	Default	Description
31:24	00h	Other values of 71F, verbs
23:16	00h	Contents to be defined by GFX driver and audio driver
15:00	0000h	Other values of 71D, 71C verb

728h SET CLOCK OFF - Set Clock Off Command

Bits	Description
07:00	Data is Irrelevant

708hF08h SETGET_UE - SetGet Unsolicited Enable

Bits	Description
07	**Unsolicited Enable (UE):** When set, unsolicited responses from GFX MAIL BOX register writes are allowed.
06	Reserved
05:00	**Tag (TAG):** Tag for GFX Mail box register unsol responses.

781hF81h GETSET_VV - GetSet iDisp Codec Vendor Verb

Bits	Bits	Description
07:06	0	**Port Select:** This filed is programmed to select the port to be exposed to the inbox driver in the vanilla mode. Will not reset on double function group reset. 00 -> Port B 01 -> Port C 10 -> Port D 11 -> Reserved
05:04	0	**Reserved**
03	0	**Enable WFA:** When Set, WFA mode is enabled**.** Will not reset on double function group reset.
02	0	**Reserved**
01	0	**Enable DP1.2 Features (EDP12):** When set, DP1.2 features are enabled.Will not reset on double function group reset.
00	0	**Enable 3rd Pin and Converter Widget (E3P):** When set, the second and third pin and converter widget is enabled and can respond to HD Audio Verbs. When cleared, the second and third pin and converter widget is disabled and cannot respond to HD Audio verbs.Will not reset on double function group reset.

782h SET_GTCT - Set GTC Trigger

Bits	Bits	Description
07:00	0	**Any data:** The value of this field is irrelevant. The access of the SET causes a capture to occur.

F83h GET_CGTC - Get Captured GTC Value

Bits	Bits	Description
07	0	**GTC Value:** 32-bit GTC value captured on the SET_GTCT verb

F84h GET_CWC - Get Captured Wall Clock Value

Bits	Bits	Description
31:00	0	**Wall Clock Value:** 32-bit wall clock value captured on the SET_GTCT verb

F85h GET GOF - Get GTC Offset Value

Bits	Reset	Description
31:00	0h	**Value (VAL):** Reports the GTC Offset Value.

785h SET GOF0 - Set GTC Offset Value Byte 0

Bits	Description
07:00	GTC Offset Value Bits [7:0]

786h SET GOF1 - Set GTC Offset Value Byte 1

Bits	Description
07:00	GTC Offset Value Bits [15:8]

787h SET GOF2 - Set GTC Offset Value Byte 2

Bits	Description
07:00	GTC Offset Value Bits [23:16]

788h SET GOF3 - GTC Offset Value Byte 3

Bits	Description
07:00	GTC Offset Value Bits [31:24]

789hF89h SETGET_GDI - SetGet GTC Device Index

Bits	Reset	Description
07:06	0	*Reserved*
05:00	00h	**Device (D):** 000001, 000010 (based upon number of devices present) This is the pipe based. 000000 i s pipeA and so on and so forth.

3h SET_AM - Set Amplifier Mute

Bits	Bits	Description
15	0	**Set Output Amp (SOA):**.
14	0	**Set Input Amp (SIA):**.

Bits	Bits	Description
13	0	**Set Left Amp (SLA):**.
12	0	**Set Right Amp (SRA):**.
11:08	0h	**Index (IDX):**
07	1	**Mute (MUTE):** When set, amp muted.
06:00	0	*Reserved*

B8h GET_AM - Get Amplifier Mute

Bits	Bits	Description
31:08	0	*Reserved*
07	1	**Mute (MUTE):** When set, amp muted.
06:00	0	*Reserved*

F00h Get Parameters

Parameter	Symbol	Register Name
09h	PARAM_AWC	Audio Widget Capabilities
0Ch	PARAM_PC	Pin Capabilities
0Eh	PARAM_CLL	Connection List Length
12h	PARAM OAC	Output Amplifier Capabilities
0Fh	PARAM_PS	Suppoted Power States

Parameter 09h: AWC - Audio Widget Capabilities

Bits	Reset	Description
31:24	0	Reserved
23:20	4h	**Widget Type (TYPE):** Indicates this is a pin complex widget
19:16	0	**Sample Delay in Widget (DELAY):** No delay through the pin widget.
15:13	011	**Channel Count Extension (CCE):** This field, combined with STRO, indicate 8 channels supported.

Bits	Reset	Description
11	0	**L-R Swap (LRS):** Indicates no left/right channel swap.
10	1	**Power Control (PC):** Indicates power state control
09	1	**Digital (DIG):** Indicates support for digital streams.
08	1	**Connection List (CL):** Indicates a connection list
07	1	**Unsolicited Capable (UC):** Indicates support for unsolicited responses.
06	0	**Processing Widget (PW):** Indicates no support for processing
05	0	**Stripe (STRP):** Indicates striping not supported.
04	0	**Format Override (FO):** Indicates no support for formatting
03	1	**Amp Parameter Override (APO):** Indicates no amplifier override support.
02	1	**Out Amp Present (OAP):** Indicates no output amplifier present.
01	0	**In Amp Present (IAP):** Indicates no input amplifier present.
00	1	**Stereo (STRO):** Indicates a stereo widget

Parameter 0Ch: PC - Pin Capabilities

Bits	Reset	Description
31:28	0	*Reserved*
27	1	**High Bit Rate (HBR):** Indicates support for high bit-rate audio
26	0	*Reserved*
25	0	*MST capable (DP1.2)*
24	1	**DisplayPort (DP):** Indicates support for DisplayPort
23:08	0	*Reserved*
07	1	**HDMI (HDMI):** Indicates support for HDMI

Bits	Reset	Description
06:05	0	*Reserved*
04	1	**Output Capable (OC):** Pin is output capable
03	0	*Reserved*
02	1	**Presence Detect Capable (PDC):** Indicates capability for presence detection
01:00	0	*Reserved*

Parameter 0Eh: CLL - Connection List Length

Bits	Reset	Description
31:08	0	*Reserved*
07	0	**Long Form (LF):** Indicates connection list is short form
06:00	03h	**Length (LEN):** Indicates there is one item in the connection list.

Parameter 12h: OAC - Output Amplifier Capabilities

Bits	Reset	Description
31	1	**Mute Capable (MC):** Muting is capable on this pin
30:00	0	Reserved

Parameter 0Fh: PARAM_SPS - Supported Power States

Bit	Reset	Description
31	1	**Extended Power State Supported (EPSS):** Indicates support for low power states
30:04	0	*Reserved*
03	1	**D3 Supported (D3S):** Indicates support for D3.
02	0	**D2 Supported (D2S):** Indicates no support for D2.
01	0	**D1 Supported (D1S):** Indicates no support for D1.

Bit	Reset	Description
00	1	**D0 Supported (D0S):** Indicates support for D0.

701hF01h SETGET_CSC - SetGet Connection Select Control

Bits	Reset	Description
07:00	00h	**Connection Select Control (CSC)**

F02h GET_CLE - Get Connection List Entry

Bits	Reset	Description
31:24	0	Reserved
23:16	100	**Connection List Entry (CLE):** Hardwired to Converter ID 4
15:08	011	**Connection List Entry (CLE)**: Hardwired to Converter ID 3
07:00	010	**Connection List Entry (CLE)**: Hardwired to Converter ID 2

705h SET_PS - Set Power State

Bits	Description
07:02	Reserved
01:00	**Requested Power State (RPS):** Only D0 (00) and D3 (11) may be requested

F05h GET_PS - Get Power State

Bits	Reset	Description
31:11	0	Reserved
10	0	**Settings Reset (SR):** Haswell does not change the default values.
09	0	**Clock Stop OK (CSOK):** Clock stopping in D3 is not OK
08	0	**Error (ERR):** No error will ever be reported.
07:06	0	Reserved
05:04	11	**Actual Power State (APS):** Indicates the current power state of the node.

Bits	Reset	Description
03:02	0	Reserved
01:00	11	**Requested Power State (CPS):** Reflects value written with SET_PS verb.

707hF07h SETGET_PWC - SetGet Pin Widget Control

Bits	Reset	Description
07	0	Reserved
06	1	**Out Enable (OE):** When set, the audio is enabled
05:02	0	Reserved
01:00	00	**Encoded Packet Type (EPT)**

708hF08h SETGET_UE - SetGet Unsolicited Enable

Bits	Description
07	**Unsolicited Enable (UE):** When set, unsolicited responses are allowed
06	Reserved
05:00	**Tag (TAG)**

F09h GET_PS - Get Pin Sense

Bits	Reset	Description
31	0	**Presence Detect (PD):** When set presence is detected on this pin.
30	0	**ELD Value (ELDV)**
29	0	**Inactive (INA)**
28:00	28:00	Reserved

71Ch SET_CD0 - Set Configuration Default Byte 0

Bits	Description
07:04	**Default Association (DA)**
03:00	**Sequence (SEQ)**

71Dh SET_CD1 - Set Configuration Default Byte 1

Bits	Description
07:04	**Color (COL)**
03:00	**Miscellaneous (MISC)**

71Eh SET_CD2 - Set Configuration Default Byte 2

Bits	Description
07:04	**Default Device (DD)**
03:00	**Connection Type (CT)**

71Fh SET_CD3 - Set Configuration Default Byte 3

<table>

F2Fh Get ELD Data

Parameter	Symbol	Register Name
07:0h	PARAM_INDX	ELD DATA Index

Parameter nn: ELD Data

Bits	Reset	Description
31:00	0	ELD Data

733h SET_PC - Set Protection Control

Bits	Description
07:03	**Unsolicited Response Sub Tag (URST):** Subtag to use for unsolicited responsed.
02	Reserved

734hF34h SETGET_CCM - GetSet Converter Channel Map

Bits	Reset	Description
07:04	0h	**Converter Channel (CC)**
03:00	0h	**Slot (SN)**

740hF40h SETGET PTS Offset Byte0

Bits	Reset	Description
07:00	00h	**PTS B0(PTSB0):** Bits 7:0 of the 32 bit 2's complement offset value. Should be added to the PTS value before sending to the circular buffer in the PES packet. Get verb will give the 32 bits value

741hF41h SETGET PTS Offset Byte1

Bits	Reset	Description
07:00	00h	**PTS B1(PTSB1):** Bits 15:8 of the 32 bit 2's complement offset value. Should be added to the PTS value before sending to the circular buffer in the PES packet. Get verb will give the 32 bits value

742hF42h SETGET PTS Offset Byte2

Bits	Reset	Description
07:00	00h	**PTS B2(PTSB2):** Bits 23:16 of the 32 bit 2's complement offset value. Should be added to the PTS value before sending to the circular buffer in the PES packet. Get verb will give the 32 bits value

743hF43h SETGET PTS Offset Byte3

Bits	Reset	Description
07:00	00h	**PTS B3(PTSB3):** Bits 31:24 of the 32 bit 2's complement offset value. Should be added to the PTS value before sending to the circular buffer in the PES packet. Get verb will give the 32 bits value

North Display Engine Registers

This chapter contains the register descriptions for the display portion of a family of graphics devices.

These registers vary by devices within the family of devices, so special attention needs to be paid to which devices use which registers and register fields.

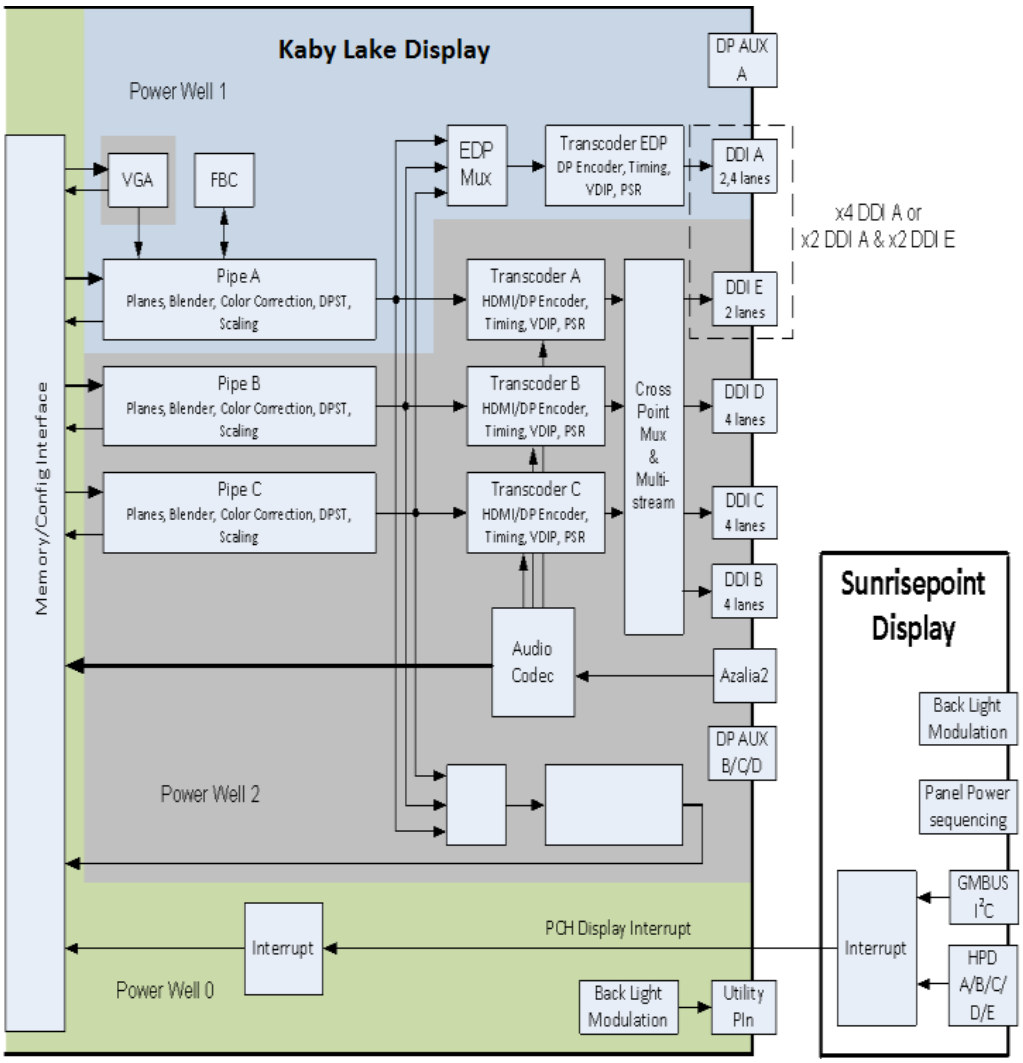
Different devices within the family may add, modify, or delete registers or register fields relative to another device in the same family based on the supported functions of that device.

This chapter contains the register descriptions for the display portion of a family of graphics devices.

These registers vary by devices within the family of devices, so special attention needs to be paid to which devices use which registers and register fields.

Different devices within the family may add, modify, or delete registers or register fields relative to another device in the same family based on the supported functions of that device.

Display Connections

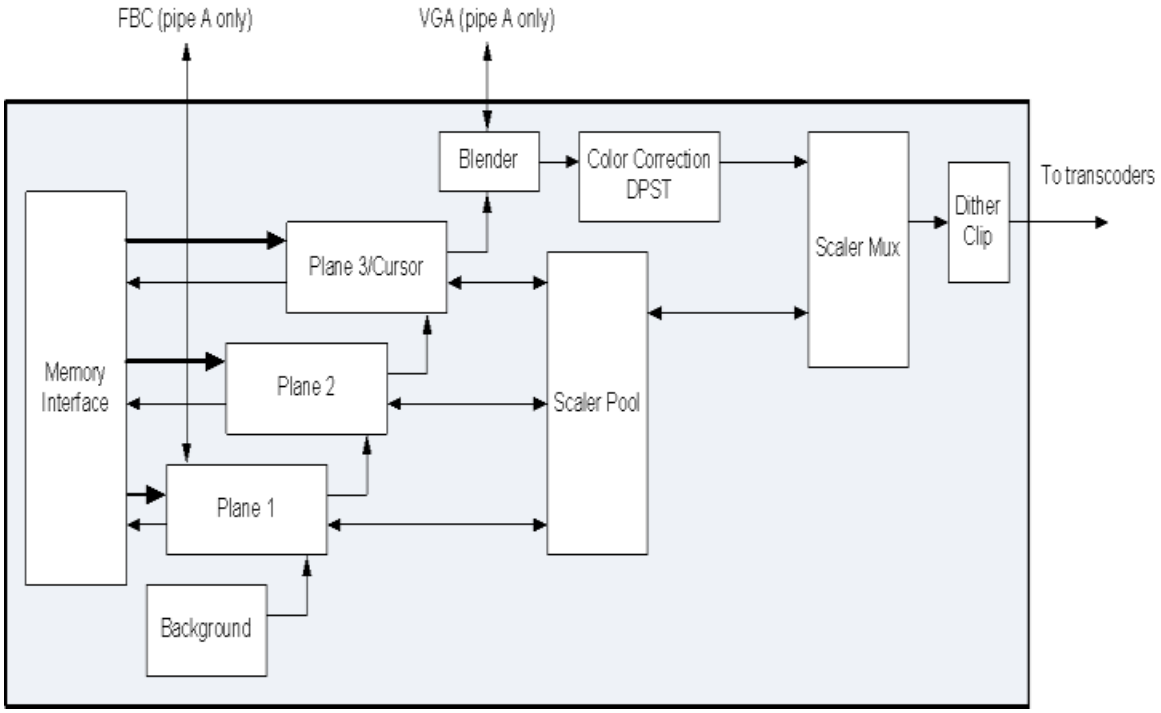


The front end of the display contains the pipes. There are three instances which are referred to as Pipe A, Pipe B, and Pipe C.

The pipes connect to the transcoders. There are five instances which are referred to as Transcoder A, Transcoder B, Transcoder C, Transcoder EDP, and Transcoder WD0.

The transcoders connect to the DDIs. There are five instances which are referred to as DDI A, DDI B, DDI C, DDI D, and DDI E.

Display Pipes



The display pipes contain the planes, blending, color correction, DPST, scaling, dithering, and clipping.

Each display pipe has three planes and a cursor. Each plane can be used as a sprite, primary, or overlay.

The background color that is seen under the bottom most plane is programmable.

The plane blending follows a fixed Z-order. Plane 1 is the bottom most plane and higher numbered planes stack on top of it.

The cursor and top most plane are mutually exclusive and cannot be both enabled at the same time.

Pipe A and Pipe B each have two pipe scalers. Pipe C has one pipe scaler.

Each pipe scaler can be assigned to scale an individual plane or scale the blended output.

Display Transcoders

The display transcoders contain the timing generators, port encoders, Audio/Video mixers, Video Data Island Packet mixers, and Panel Self Refresh controllers.

Transcoder EDP does not support HDMI, DVI, or Audio.

Transcoder WD0 only supports display capture and write back to memory.

Audio

The Azalia interface provides data to the audio codec.

The audio codec connects to the Audio/Video mixers in the transcoders.

DDIs

The DDIs contain the DisplayPort transport control and other port logic to interface to the DDI physical pins.

DDI A, DDI B, DDI C, and DDI D support lane reversal where the internal lane to package lane mapping is swapped.

DDI E does not support lane reversal.

DDI A and DDI E do not support DisplayPort multistream.

DDI A and DDI E share 2 lanes. DDI A is capable of supporting up to 4 lanes when DDI E is not connected, but only 2 lanes when DDI E is connected. DDI E is capable of supporting up to 2 lanes when connected. Dynamic switching between the two configurations is not supported.

DisplayPort A and E Lane Mapping:

Package Pin	Non-Reversed when DDI A is x4 capable	Reversed when DDI A is x4 capable	Non-Reversed when DDI A is x2 capable	Reversed when DDI A is x2 capable
DDIA/DDIE 3	Port A Main Link Lane 3	Port A Main Link Lane 0	Port E Main Link Lane 1	Port E Main Link Lane 1
DDIA/DDIE 2	Port A Main Link Lane 2	Port A Main Link Lane 1	Port E Main Link Lane 0	Port E Main Link Lane 0
DDIA/DDIE 1	Port A Main Link Lane 1	Port A Main Link Lane 2	Port A Main Link Lane 1	Port A Main Link Lane 0
DDIA/DDIE 0	Port A Main Link Lane 0	Port A Main Link Lane 3	Port A Main Link Lane 0	Port A Main Link Lane 1

DisplayPort B, C, and D Lane Mapping:

Package Pin	Non-Reversed	Reversed
DDI 3	Main Link Lane 3	Main Link Lane 0
DDI 2	Main Link Lane 2	Main Link Lane 1
DDI 1	Main Link Lane 1	Main Link Lane 2
DDI 0	Main Link Lane 0	Main Link Lane 3

HDMI/DVI TMDS Lane Mapping:

Package Pin	Non-Reversed	Reversed
DDI 3	TMDS Clock	TMDS Data2
DDI 2	TMDS Data0	TMDS Data1
DDI 1	TMDS Data1	TMDS Data0
DDI 0	TMDS Data2	TMDS Clock

DDI Equivalent Names:

DDI Name	Equivalent Names
DDI A	Port 0, DDI-A, DDIA, Port A, DDI0, eDP
DDI B	Port 1, DDI-B, DDIB, Port B, DDI1
DDI C	Port 2, DDI-C, DDIC, Port C, DDI2
DDI D	Port 3, DDI-D, DDID, Port D, DDI3
DDI E	Port 4, DDI-E, DDIE, Port E, DDI4

Pipe to Transcoder to DDI Mappings

Twin modes are not supported.

Any pipe can drive any single DDI.

With DisplayPort multistream it is possible to have multiple pipes driving a single DDI. DDI B, DDI C, and DDI D support multistream. DDI A and DDI E do not support multistream.

Pipe A can connect to either Transcoder A, Transcoder EDP, or Transcoder WD0, but not more than one simultaneously.

Pipe B can connect to either Transcoder B, Transcoder EDP, or Transcoder WD0, but not more than one simultaneously.

Pipe C can connect to either Transcoder C, Transcoder EDP, or Transcoder WD0, but not more than one simultaneously.

Transcoder A is tied to Pipe A.

Transcoder B is tied to Pipe B.

Transcoder C is tied to Pipe C.

Transcoder EDP can connect to Pipe A, Pipe B, or Pipe C, but only one at a time.

Transcoder WD0 can connect to Pipe A, Pipe B, or Pipe C, but only one at a time.

Transcoder A can connect to DDI B, DDI C, DDI D, or DDI E, but only one at a time.

Transcoder B can connect to DDI B, DDI C, DDI D, or DDI E, but only one at a time.

Transcoder C can connect to DDI B, DDI C, DDI D, or DDI E, but only one at a time.

Transcoder EDP can connect only to DDI A.

Transcoder WD0 does not connect to any DDI. Transcoder WD0 output only goes to memory write back.

DDI A can connect only to Transcoder EDP. DDI A does not support DisplayPort multistream.

DDI B can connect to Transcoder A, Transcoder B, or Transcoder C, individually or simultaneously if DisplayPort multistream is used.

DDI C can connect to Transcoder A, Transcoder B, or Transcoder C, individually or simultaneously if DisplayPort multistream is used.

DDI D can connect to Transcoder A, Transcoder B, or Transcoder C, individually or simultaneously if DisplayPort multistream is used.

DDI E can connect to Transcoder A, Transcoder B, or Transcoder C, individually.

Terminology

Term	Description
DP	DisplayPort
SST, DP SST	DisplayPort Single Stream Transport
MST, DP MST	DisplayPort Multi Stream Transport

Register Access Field	Description	Implementation
R/W (Read/Write)	The value written into this register will control hardware and is the same value that will be read.	Write data is stored. Read is from the stored data. Stored value is used to control hardware.
Reserved	Unused register bit. Don't assume a value for these bits. Writes have no effect.	Write data is ignored. Read is zero.
MBZ (Must Be Zero)	Always write a zero to this register.	May be implemented as Reserved or as R/W.
PBC (Preserve Bit Contents)	Software must write the original value back to this bit. This allows new features to be added using these bits.	May be implemented as Reserved or as R/W.
Read Only	The read value is determined by hardware. Writes to this bit have no effect.	Write data is ignored. Read is from a status signal or some other internal source.
Write Only	The value written into this register will control hardware. Reads return zero.	Write data is stored. Read is zero. Stored value is used to control hardware.
R/W Clear (Read/Write Clear)	Sticky status bit. Hardware will set the bit, software can clear it with a write of 1b.	Internal hardware events set a sticky bit. Read is from the sticky bit. A write of 1b clears the sticky bit.
R/W Set (Read/Write Set)	Sticky status bit. Software can set the bit with a write of 1b. Hardware will clear the bit.	A write of 1b sets a sticky bit. Internal hardware events clear a sticky bit. Read is from the sticky bit.

Register Access Field	Description	Implementation
Double Buffered	Write when desired and the written value will take effect at the time of the update point specified in the 'Double Buffer Update Point' parameter. Reads will return the written value, which is not necessarily the value being currently used to control hardware. Some have a specific arming sequence where a write to another register, specified in the 'Double Buffer Armed By' parameter, is required before the update can take place. Once the armed by register is written to, the written values of all registers controlled by that arming will take effect at the time of the double buffer update point. This is used to ensure atomic updates of several registers. Note: Once armed, by write to the armed by register, the registers controlled by this arming should not be changed until the double buffer update point is reached. If changed, this will disarm the sequence and will require another write to the armed by register to get it to the armed status again.	Two stages of registers used. Write data is stored into first stage. Read is from the first stage stored data. First stage stored value is transferred to second stage storage at the double buffer update point. Second stage stored value is used to control hardware. Arm/disarm logic may be used for some registers to control the double buffer update point.
Write/Read Status	The value written into this register will control hardware. The read value is determined by hardware.	Write data is stored. Stored value is used to control hardware. Read is from a status signal or some other internal source.

Mode Set

A mode set sequence is the programming sequence that must be followed when enabling or disabling output to a display. There are several different mode set sequences documented in the following sections. The sequence to use depends on which type of port is being enabled or disabled.

Sequences to Initialize Display

These sequences are used to initialize the display engine before any display engine functions can be enabled.

Most display engine functions will not operate while display is not initialized. Only basic PCI, I/O, and MMIO register read/write operations are supported when display is not initialized.

Initialize Sequence

1. Enable PCH Reset Handshake
    a. Set NDE_RSTWRN_OPT RST PCH Handshake En to 1b.
2. Enable Power Well 1 (PG1) and Misc IO Power
    a. Poll for FUSE_STATUS Fuse PG0 Distribution Status = 1b.
        - Timeout and fail after 5 us.
    b. Set PWR_WELL_CTL Power Well 1 Request and Misc IO Power Request to 1b.
    c. Poll for PWR_WELL_CTL Power Well 1 State and Misc IO Power State = 1b.
        - Timeout and fail after 10 us.
    d. Poll for FUSE_STATUS Fuse PG1 Distribution Status = 1b.
        - Timeout and fail after 5 us.
3. Enable CDCLK PLL
    a. Set CDCLK_CTL CD Frequency Select to the minimum.
    b. Configure DPLL0 link rate to the rate required for the eDP panel, or 810 MHz (DP 1.62 GHz) if there is no eDP panel.
    c. Set LCPLL1_CTL PLL enable to 1b.
    d. Poll for LCPLL1_CTL PLL lock = 1b.
        - Timeout and fail after 5 ms.
4. Follow Sequences for Changing CD Clock Frequency
5. Enable DBUF
    a. Set DBUF_CTL DBUF Power Request to 1b.
    b. Poll for DBUF_CTL DBUF Power State = 1b.
        - Timeout and fail after 10 us.

Un-initialize Sequence

1. Disable all display engine functions using the full mode set disable sequence on all pipes, transcoders, ports, planes, and power well 2 (PG2).
2. Disable DBUF
    a. Clear DBUF_CTL DBUF Power Request to 0b.
    b. Poll for DBUF_CTL DBUF Power State = 0b.
        - Timeout and fail after 10 us.
3. Disable CDCLK PLL
    a. Clear LCPLL1_CTL PLL enable to 0b.
    b. Poll for LCPLL1_CTL PLL lock = 0b.
        - Timeout and fail after 1 ms.
4. Disable Power Well 1 (PG1) and Misc IO Power
    a. Clear PWR_WELL_CTL Power Well 1 Request and Misc IO Power Request to 0b.
    b. Wait for 10us. Do not poll for the power well to disable. Other clients may be keeping it enabled.

Sequences for DisplayPort

This topic describes how to enable and disable DisplayPort.

Enable Sequence

Display must already be initialized

DDIA Lane Capability Control must be configured prior to enabling any ports or port clocks

1. **Enable Power Wells**

If not PipeA+DDIA - Enable Power Well 2 a. Enable PWR_WELL_CTL Power Well 2 Request b. Wait for PWR_WELL_CTL Power Well 2 State = Enabled, timeout after 20 us c. Wait for FUSE_STATUS FUSE PG2 Distribution Status = Done, timeout after 1 us

2. **If panel power sequencing is required - Enable Panel Power**
    a. Enable panel power sequencing
    b. Wait for panel power sequencing to reach the enabled state
3. **Enable Port PLL**
    a. If PLL is not already enabled, follow port clock programming sequence from Clocks section
    b. If PLL to port mapping is flexible, configure PLL to port mapping to direct the PLL output to the DDI

4. **If IO power is controlled through PWR_WELL_CTL - Enable IO Power**
    a. Enable PWR_WELL_CTL DDI IO Power Request for the DDI that will be used
    b. Wait for PWR_WELL_CTL DDI IO Power Request = Enabled, timeout after 20 us
5. **Enable and Train DisplayPort**
    a. Configure and enable DP_TP_CTL with link training pattern 1 selected
    b. Configure voltage swing and related IO settings. Refer to DDI Buffer section.
    c. Configure and enable DDI_BUF_CTL
    d. Gen9: Wait >518 us for buffers to enable before starting training or allow for longer time in TP1 before software timeout.
    e. Follow DisplayPort specification training sequence (see notes for failure handling)
    f. If DisplayPort multi-stream - Set DP_TP_CTL link training to Idle Pattern, wait for 5 idle patterns (DP_TP_STATUS Min_Idles_Sent) (timeout after 800 us)
    g. Set DP_TP_CTL link training to Normal.
6. **Enable Planes, Pipe, and Transcoder (repeat to add multiple pipes on a single port for multi-streaming)**
    a. If DisplayPort multi-stream - use AUX to program receiver VC Payload ID table to add stream
    b. Configure Transcoder Clock Select to direct the Port clock to the Transcoder
    c. Configure and enable planes (VGA or hires). This can be done later if desired.
    d. If VGA - Clear VGA I/O register SR01 bit 5
    e. Enable panel fitter if needed (must be enabled for VGA)
    f. Configure transcoder timings, M/N/TU/VC payload size, and other pipe and transcoder settings
    g. Configure and enable TRANS_DDI_FUNC_CTL
    h. If DisplayPort multistream - Enable pipe VC payload allocation in TRANS_DDI_FUNC_CTL
    i. If DisplayPort multistream - Wait for ACT sent status in DP_TP_STATUS and receiver DPCD (timeout after >410us)
    j. Configure and enable TRANS_CONF
    k. If panel power sequencing is required - Enable panel backlight

SRD and/or Audio can be enabled after everything is complete. Follow the audio enable sequence in the audio registers section.

Notes

Changing voltage swing during link training:

- Change the swing setting following the DDI Buffer section. The port does not need to be disabled.

Changing port width (lane count) or frequency during link training:

1. Follow Disable Sequence for DisplayPort to Disable Port

2. If PLL frequency needs to change, Follow Disable Sequence for DisplayPort to Disable PLL, then follow Enable Sequence for DisplayPort to Enable PLL, using the new frequency settings
3. Follow Enable Sequence for DisplayPort to Enable and Train DisplayPort, using the new port width settings

If the mode set fails, follow the disable sequence to disable everything that had been enabled up to the failing point.

Enabling DisplayPort Sync Mode

See TRANS_DDI_FUNC_CTL Port Sync Mode Enable for restrictions.

1. Follow the enable sequence for the DisplayPort slave, but skip the step that sets DP_TP_CTL link training to Normal (stay in Idle Pattern).
    - Set TRANS_DDI_FUNC_CTL Port Sync Mode Master Select and Port Sync Mode Enable when configuring and enabling TRANS_DDI_FUNC_CTL.
2. Wait 200 uS.
3. Follow the enable sequence for the DisplayPort master, but skip the step that sets DP_TP_CTL link training to Normal (stay in Idle Pattern).
4. Set DisplayPort slave DP_TP_CTL link training to Normal.
5. Set DisplayPort master DP_TP_CTL link training to Normal.

Software may need to use DOUBLE_BUFFER_CTL to ensure updates to plane and pipe registers will take place in the same frame.

For example: If pipe A and pipe B are synchronized together and software needs the surface addresses for two planes to update at the same time, software should use DOUBLE_BUFFER_CTL when writing the surface address registers for both planes, otherwise there is a possibility that the updates could be split across a vertical blank such that one plane would update on the current vertical blank and the other plane would update on the next vertical blank.

Disable Sequence

SRD and Audio must be disabled first. Follow the audio disable sequence in the audio registers section.

1. **If panel power sequencing is required - Disable panel backlight**
2. **Disable Planes, Pipe, and Transcoder (repeat to remove multiple pipes from a single port for multi-streaming)**
    a. If VGA
        i. Set VGA I/O register SR01 bit 5 for screen off
        ii. Wait for 100 us
    b. Disable planes (VGA or hires)
    c. Disable TRANS_CONF

d. Wait for off status in TRANS_CONF, timeout after two frame times
e. If DisplayPort multistream - use AUX to program receiver VC Payload ID table to delete stream
f. If done with this VC payload
    i. Disable VC payload allocation in TRANS_DDI_FUNC_CTL
    ii. Wait for ACT sent status in DP_TP_STATUS and receiver DPCD
g. Disable TRANS_DDI_FUNC_CTL with DDI_Select set to None
h. Disable panel fitter
i. Configure Transcoder Clock Select to direct no clock to the transcoder

3. **Disable Port (all pipes and VC payloads on this port must already be disabled)**
    a. Disable DDI_BUF_CTL
    b. Disable DP_TP_CTL (do not set port to idle when disabling)
    c. Gen9: Wait 8 us or poll on DDI_BUF_CTL Idle Status for buffers to return to idle
4. **If panel power sequencing is required - Disable Panel Power**
    a. Disable panel power sequencing
5. **If IO power is controlled through PWR_WELL_CTL - Disable IO Power**
    a. Disable PWR_WELL_CTL DDI IO Power Request for the DDI that was used
6. **Disable Port PLL**
    a. If PLL to port mapping is flexible, configure PLL to port mapping to direct no clock to the DDI
    b. If this PLL is no longer needed, follow PLL disable sequence from Clocks section
7. **Disable Power Wells**
    a. If no required resource is in the power well - Disable PWR_WELL_CTL Power Well 2 Request

Disabling DisplayPort Sync Mode

1. Follow the disable sequence for the DisplayPort slave.
2. Follow the disable sequence for the DisplayPort master.

Sequences for HDMI and DVI

This topic describes how to enable and disable HDMI and DVI.

Enable Sequence

Display must already be initialized

1. **Enable Power Wells**
   a. Enable PWR_WELL_CTL Power Well 2 Request
   b. Wait for PWR_WELL_CTL Power Well 2 State = Enabled, timeout after 20 us
   c. Wait for FUSE_STATUS FUSE PG2 Distribution Status = Done, timeout after 1 us
2. **Enable Port PLL**
   a. If PLL is not already enabled, follow port clock programming sequence from Clocks section
   b. If PLL to port mapping is flexible, configure PLL to port mapping to direct the PLL output to the DDI
3. **If IO power is controlled through PWR_WELL_CTL - Enable IO Power**
   a. Enable PWR_WELL_CTL DDI IO Power Request for the DDI that will be used
   b. Wait for PWR_WELL_CTL DDI IO Power Request = Enabled, timeout after 20 us
4. **Enable Planes, Pipe, and Transcoder**
   a. Configure Transcoder Clock Select to direct the Port clock to the Transcoder
   b. Configure and enable planes (VGA or hires). This can be done later if desired.
   c. If VGA - Clear VGA I/O register SR01 bit 5
   d. Enable panel fitter if needed (must be enabled for VGA)
   e. Configure transcoder timings and other pipe and transcoder settings
   f. Configure and enable TRANS_DDI_FUNC_CTL
   g. Configure and enable TRANS_CONF
5. **Enable Port**
   a. Configure voltage swing and related IO settings. Refer to the DDI Buffer section.
   b. Configure and enable DDI_BUF_CTL

Audio can be enabled after everything is complete. Follow the audio enable sequence in the audio registers section.

Notes

If the mode set fails, follow the disable sequence to disable everything that had been enabled up to the failing point.

Disable Sequence

Audio must be disabled first. Follow the audio disable sequence in the audio registers section.

1. **Disable Planes, Pipe, and Transcoder**
    a. If VGA
        i. Set VGA I/O register SR01 bit 5 for screen off
        ii. Wait for 100 us
    b. Disable planes (VGA or hires)
    c. Disable TRANS_CONF
    d. Wait for off status in TRANS_CONF, timeout after two frame times
    e. Disable TRANS_DDI_FUNC_CTL with DDI_Select set to None
    f. Disable panel fitter
    g. Configure Transcoder Clock Select to direct no clock to the transcoder
2. **Disable Port**
    a. Disable DDI_BUF_CTL
3. **If IO power is controlled through PWR_WELL_CTL - Disable IO Power**
    a. Disable PWR_WELL_CTL DDI IO Power Request for the DDI that was used used
4. **Disable Port PLL**
    a. If PLL to port mapping is flexible, configure PLL to port mapping to direct no clock to the DDI
    b. If this PLL is no longer needed, disable it
5. **Disable Power Wells**

a. If no required resource is in the power well - Disable PWR_WELL_CTL Power Well 2 Request

Sequences for Display C5 and C6

Display C5 (DC5) is a power saving state where hardware dynamically disables power well 1 and the CDCLK PLL and saves the associated registers.

DC5 can be entered when software allows it, power well 2 is disabled, and hardware detects that all pipes are disabled or pipe A is enabled with PSR active.

Display C6 (DC6) is a deeper power saving state where hardware dynamically disables power well 0 and saves the associated registers.

DC6 can be entered when software allows it, the conditions for DC5 are met, and the PCU allows DC6.

DC6 cannot be used if the backlight is being driven from the display utility pin.

Core CPUs support DC5 and DC6.

The context save and restore program is reset on cold boot, warm reset, PCI function level reset, and hibernate/suspend.

Sequence to Allow DC5 or DC6

1. Load the correct stepping specific Display Context Save and Restore (CSR) program from the binary package.
    a. Read the package header and extract the correct individual firmware. Binary package format details can be found in sections below.
    b. Skip the header section at the start of the program binary.
    c. Copy the payload into **Display CSR Program Storage** .
    d. Perform the MMIO writes specified in the header section.
2. Configure display engine to have power well 2 disabled, following the appropriate mode set disable sequences for any ports using power well 2. This can be done earlier if desired.
3. Set display register 0x45520 bit 1 to 1b. It does not need to be cleared at any time.
4. Set DC_STATE_EN Dynamic DC State Enable = "Enable up to DC5" for DC5 or "Enable up to DC6" for DC6.

Programming Note	
Context:	Display C5 and C6
Do not switch between "Enable up to DC5" and "Enable up to DC6" without moving to "Disable" and reloading the CSR program in between. Disable DC5/DC6 during mode set and re-enable after the mode set programming is completed. MMIO accesses have more latency when DC5/DC6 is enabled. For optimal performance, disable DC5/DC6 when programming a set of registers and re-enable them after the programming is completed.	

Sequence to Disallow DC5 and DC6

1. Set DC_STATE_EN Dynamic DC State Enable = "Disable".

DMC Firmware Package

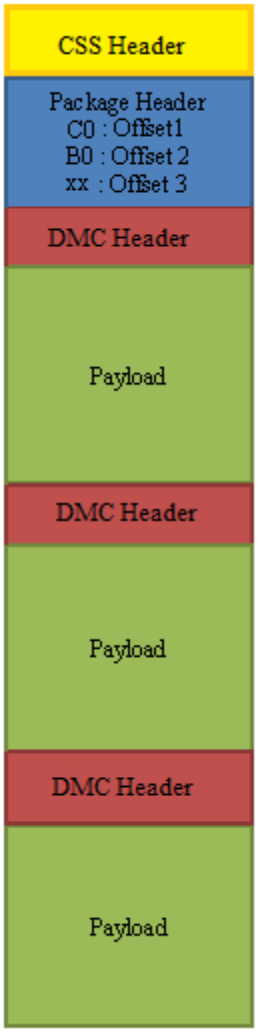
Display Micro-Controller firmware package includes all the firmwares that are required for different steppings of the product. The stepping dependent firmwares are all packaged and released as a single binary package. The package contains the CSS header, followed by the package header and the actual DMC firmwares.

Packaged firmware uses the following naming convention - <project>_dmc_ver<major>_<minor>.bin. The major version will get incremented whenever there is a change in the header layout and would require an update to the driver firmware loading module.

Major version 1

CSS Header	1.0
Package Header	1
DMC Header	1

Package Layout



CSS Header

```
typedef struct _CssHeader {
      uint32_t     moduleType;                    // 0x09 for DMC
      uint32_t     headerLen;                     // CSS header length in dwords
      uint32_t     headerVer;                     // 0x10000
      uint32_t     moduleID;                      // Not used
      uint32_t     moduleVendor;                  // Not used
      uint32_t     date;                          // YYYYMMDD(YYYY « 16 + MM « 8
+ DD)
      uint32_t     size;                          // Total dmc fw binary size in
dwords - (CSS_Headerlen + PackageHeaderLen + dmc FWsLen)/4
      uint32_t     keySize;                       // Not used
      uint32_t     modulusSize;                   // Not used
      uint32_t     exponentSize;                  // Not used
      uint32_t     reserved1[12];                 // Not used
      uint32_t     version;                       // Major Minor
      uint32_t     reserved2[8];                  // Not used
      uint32_t     uKernelHeaderInfo;             // Not used
} CssHeader;
```

Package Header

Package header contains the firmware/stepping mapping table and the corresponding firmware offsets to the individual binaries, within the package. Mapping table will list the exceptions first, followed by the default entries. An Offset value of "0xFFFFFFFF" in the mapping table indicates that there is no firmware available/supported for that stepping. The offsets to the individual binary are DWord aligned. The first individual binary starts at an offset value of "0x00000000" after the CSS Header and the Package Header.

Stepping/Version mapping example

Stepping	FW Version
A1	1.1
B*	1.6
**	2.3

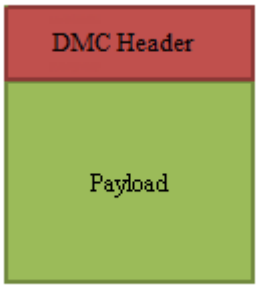
```
typedef struct _PackageHeader {
      uint8_t      headerLen;                     // DMC package header length
in dwords
      uint8_t      headerVer;                     // 0x01
```

```
      uint8_t      reserved[10];                    // Reserved
      uint32_t     numEntries;                      // Number of valid entries in
the FWInfo array below
      struct _FWInfo_ {
            uint16_t     reserved1;                 // Reserved
            char         stepping;                  // Stepping (A, B, C, ..., *).
* is a wildcard
            char         substepping;               // Sub-stepping (0, 1, ...,
*). * is a wildcard
            uint32_t     offset;                    // FW offset within the
package
            uint32_t     reserved2;                 // Reserved
      } FWInfo[20];
} PackageHeader;
```

DMC firmware binary

Each individual DMC firmware binary has a header followed by a payload whose size is specified in the header section. Along with the version, length, firmware size etc. the header section also specifies a list of MMIO addresses and data. These MMIO write cycles, in the 0x80000 - 0x8FFFF address range, should be executed as part of the initial CSR program setup.

DMC firmware Layout



```
for i = 1 to <mmioCount>
      Perform MMIO write to address <mmioaddr[i]> with data <mmiodata[i]>
typedef struct _DMCHeader {
     uint32_t    reserved;              // 0x40403E3E
     uint8_t     headerLen;             // DMC binary header length in bytes
     uint8_t     headerVer;             // 0x01
     uint16_t    dmccVer;               // Reserved
     uint32_t    project;               // Major, Minor
```

```
    uint32_t    fwSize;                 // Firmware program size (excluding header)
    in dwords
    uint32_t    fwVersion;              // Major Minor version
    uint32_t    mmioCount;              // Number of valid MMIO cycles present in
    the MMIO address and data arrays below.
    uint32_t    mmioaddr[8];            // MMIO address
    uint32_t    mmiodata[8];            // MMIO data
    unint8_t    dfile[32];              // Reserved
    uint32_t    reserved1[2];           // Reserved
} DMCHeader;
```

Display Resolution Support

A display resolution is only supported if it meets all the restrictions below for Maximum Pipe Pixel Rate, Maximum Port Link Rate, Maximum Memory Read Bandwidth, and Maximum Watermark.

Maximum Pipe Pixel Rate

The display resolution must fit within the maximum pixel rate output from the pipe. Make sure that the display pipe is able to feed pixels at a rate required to support the desired resolution.

For each enabled plane on the pipe {

If plane scaling enabled {

Horizontal down scale amount = Maximum[1, plane horizontal size / scaler horizontal window size]

Vertical down scale amount = Maximum[1, plane vertical size / scaler vertical window size]

Plane down scale amount = Horizontal down scale amount * Vertical down scale amount

Plane Ratio = 1 / Plane down scale amount

}

Else {

Plane Ratio = 1

}

If plane source pixel format is 64 bits per pixel {

Plane Ratio = Plane Ratio * 8/9

}

}

Pipe Ratio = Minimum Plane Ratio of all enabled planes on the pipe

If pipe scaling is enabled {

Horizontal down scale amount = Maximum[1, pipe horizontal source size / scaler horizontal window size]

Vertical down scale amount = Maximum[1, pipe vertical source size / scaler vertical window size]

Note: The progressive fetch - interlace display mode is equivalent to a 2.0 vertical down scale

Pipe down scale amount = Horizontal down scale amount * Vertical down scale amount

Pipe Ratio = Pipe Ratio / Pipe down scale amount

}

Pipe maximum pixel rate = CDCLK frequency * Pipe Ratio // See the display clocks section for the supported CDCLK frequencies.

Maximum Port Link Rate

The display resolution must fit within the maximum link rate for each port type.

Port Type	Maximum Link Bit Rate
eDP/DP	HBR2 5.4 GHz
HDMI	3 GHz
DVI	1.65 GHz
MIPI DSI	1.066 GHz

Maximum Memory Read Bandwidth

The display resolution must not exceed the available system memory bandwidth, considering factors like thermal throttling and bandwidth available for other memory clients.

For each pipe {

For each plane enabled on the pipe { // cursor can be ignored

Plane bandwidth MB/s = pixel rate MHz * source pixel format in bytes * plane down scale amount * pipe down scale amount

Total display bandwidth MB/s = Total display bandwidth + Plane bandwidth

}

}

Raw system memory bandwidth = (# of memory channels * memory frequency * 8 bytes)

If Total display bandwidth > system memory bandwidth available for display {Bandwidth is exceeded}

Programming Note	
Context:	Display Resolution Support
Do not use more than 60% of raw system memory bandwidth for display.	

Maximum Watermark

The display resolution must not exceed the level 0 maximum watermark value. See the volume on Watermark Programming.

Display Resolution Capabilities

These are examples of common resolutions that meet all the resolution restrictions for up to 3 simultaneous displays, 4 primary or sprite planes with 32bpp pixel format, and 1 cursor, with no panel fitter down scaling.

Attribute	CD 675 MHz	CD 540 MHz	CD 450 MHz	CD 337.5 MHz
eDP/DP x4 single stream	3840x2560 60Hz 24Bpp[4] 4096x2304 60Hz 24Bpp[4]	3840x2160 60Hz 30Bpp[4]	3200x2000 60Hz 30Bpp[3]	2880x1620 60Hz 30Bpp[2] 4096x2160 30Hz 30Bpp[2]
HDMI	Same as entry to the right	Same as entry to the right	Same as entry to the right	4Kx2K 24-30Hz 24Bpp[2]
DVI	Same as entry to the right	Same as entry to the right	Same as entry to the right	1920x1200 60Hz 24Bpp[1]

Each entry is showing the highest common resolutions at that CD clock frequency step. Lower resolutions are also supported. Higher, less common, resolutions can also work, but need to be calculated individually.

eDP, DP, DVI, and MIPI DSI are calculated using CVT 1.2 RB1 blanking and pixel rate.

HDMI is calculated using HDMI specification blanking and pixel rate.

Bpp is referring to the port output bits per pixel.

[1]Requires at least single channel DDR3 1333 for 3 simultaneous displays

[2]Requires at least single channel DDR3 1600 for 3 simultaneous displays

[3]Requires at least dual channel DDR3 1333 for 3 simultaneous displays

[4]Requires at least dual channel DDR3 1600 for 3 simultaneous displays

Examples

Example pipe pixel rate:

Plane 1 enabled at 32bpp, plane 2 enabled at 16bpp, pipe scaling enabled and down scale amount 1.12, and CDCLK 450 MHz:

Plane 1 ratio = 1

Plane 2 ratio = 1

Pipe ratio = Minimum[1, 1] = 1

Pipe ratio = 1/1.12 = 0.89

Pipe maximum pixel rate = 450 MHz * 0.89 = 400.5 MHz

Example pipe pixel rate:

Plane 1 enabled at 64bpp and plane down scale amount 1.25, plane 2 enabled at 32bpp, no panel fitting enabled, and CDCLK 540 MHz:

Plane 1 ratio = 1/1.25 * 8/9 = 0.71

Plane 2 ratio = 1

Pipe ratio = Minimum[1, 0.71] = 0.71

Pipe maximum pixel rate = 540 MHz * 0.71 = 383.4 MHz

Example memory bandwidth:

System memory bandwidth available for display = 4000 MB/s

Pipe A - Plane 1 enabled at 32bpp, plane 2 enabled at 16bpp, scaling disabled, pixel rate 148.5 MHz

Pipe B - Plane 1 enabled at 32bpp, scaling disabled, pixel rate 148.5 MHz

Pipe C - Plane 1 enabled at 32bpp, scaling disabled, pixel rate 148.5 MHz

Pipe A - Plane 1 bandwidth = 148.5 * 4 bytes = 594 MB/s

Pipe A - Plane 2 bandwidth = 148.5 * 2 bytes = 297 MB/s

Pipe B - Plane 1 bandwidth = 148.5 * 4 bytes = 594 MB/s

Pipe C - Plane 1 bandwidth = 148.5 * 4 bytes = 594 MB/s

Total display bandwidth = 594 + 297 + 594 + 594 = 2079 MB/s

System memory bandwidth available for display not exceeded

Example memory bandwidth:

System memory bandwidth available for display = 4000 MB/s

Pipe A - Plane 1 enabled at 32bpp, plane 2 plane enabled at 32bpp, pipe scaling enabled and down scale amount 1.12, pixel rate 414.5 MHz

Pipe B - Plane 1 enabled at 32bpp, scaling disabled, pixel rate 414.5 MHz

Pipe C - Plane 1 enabled at 32bpp, scaling disabled, pixel rate 414.5 MHz

Pipe A - Plane 1 bandwidth = 414.5 * 4 bytes * 1.12 = 1863 MB/s

Pipe A - Plane 2 bandwidth = 414.5 * 4 bytes * 1.12 = 1863 MB/s

Pipe B - Plane 1 bandwidth = 414.5 * 4 bytes = 1658 MB/s

Pipe C - Plane 1 bandwidth = 414.5 * 4 bytes = 1658 MB/s

Total display bandwidth = 1863 + 1863 + 1658 + 1658 = 7042 MB/s

System memory bandwidth available for display **exceeded**

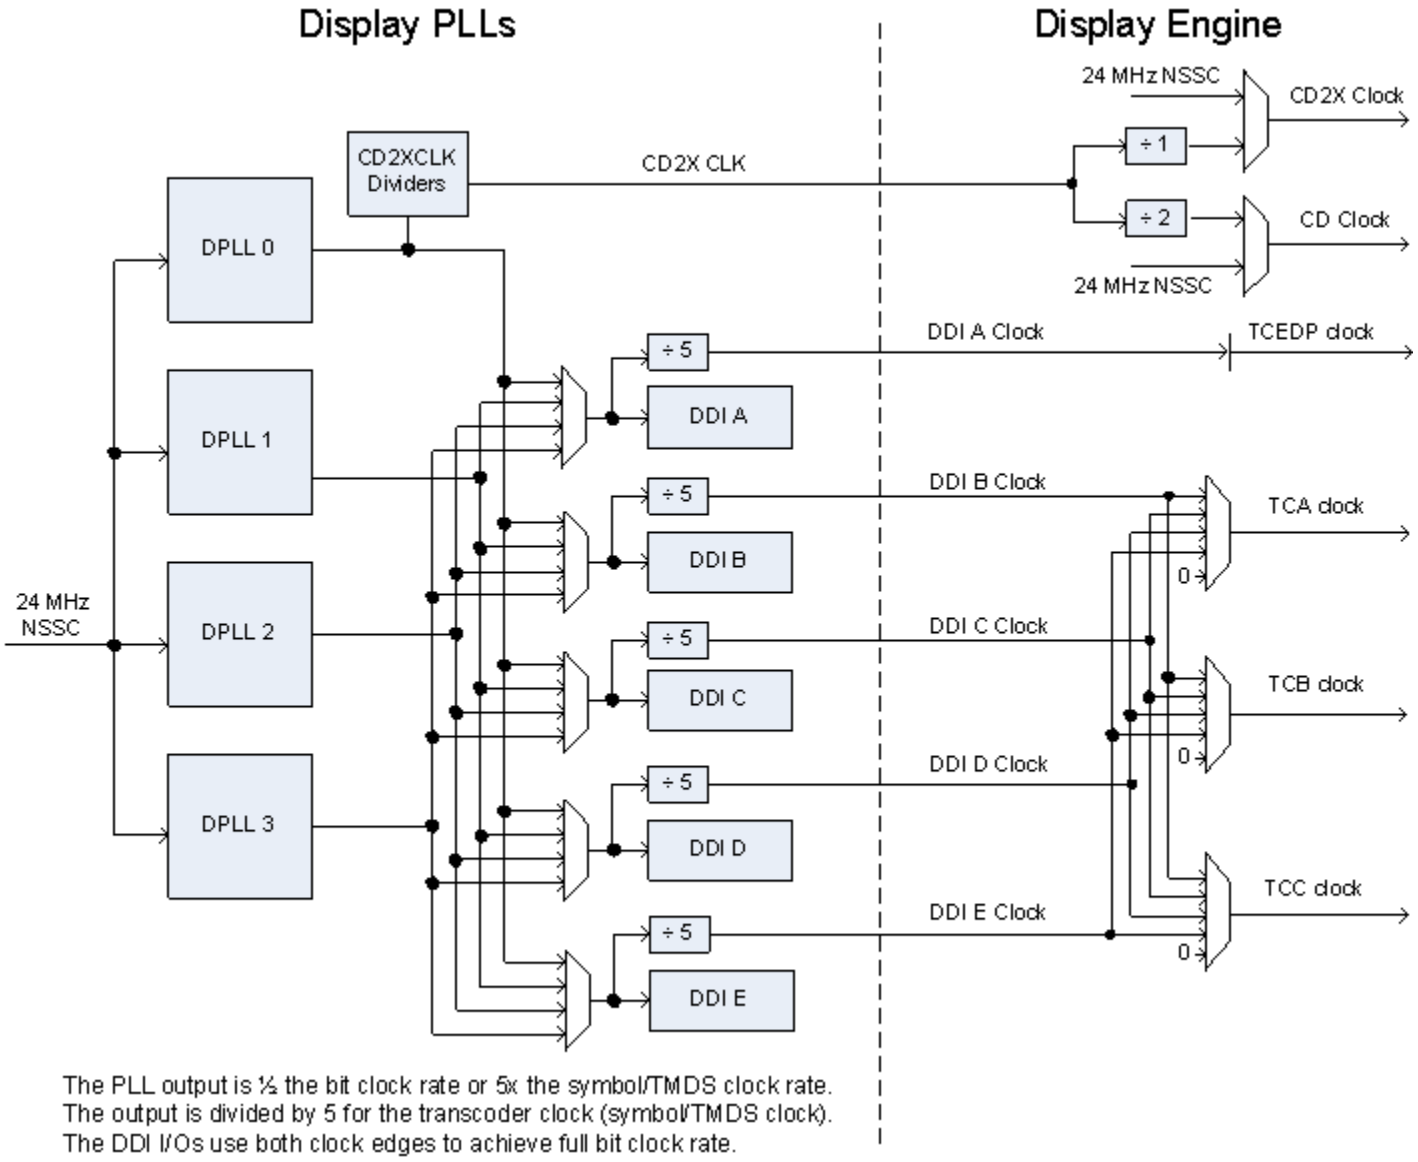
Overview of Supported Display Clock Paths



The display engine clocking structure has multiple PLLs and clocks. The flow is from reference to PLL to DDI (port) clock to transcoder clock.

Display Engine Clock Reference

There is one display engine clock reference.

	Non-SSC (NSSC) Reference
Usage	Non-spread spectrum reference for DPLL and alternate source for CD and CD2X clocks
Frequency	24 MHz
Default After Reset	Enabled
Programming	Not programmable by display software.

Display Engine PLLs

There are four display engine PLLs (DPLLs).

The PLL output frequencies are 5x the symbol/TMDS rate, which is 1/2 the bit rate.

The PLL output is divided by 5 to become the symbol/TMDS clock frequency used in the display engine.

Both edges of the PLL output are used in the DDI I/Os to double the frequency to bit clock rate.

A single PLL output may be used by multiple DDI ports simultaneously if those DDI ports all require the same frequency and spread characteristics.

	DPLL0 (LCPLL 1)	DPLL1 (LCPLL 2), DPLL2 (WRPLL 1), DPLL3 (WRPLL 2)
Usage	Sources for DDI clocks and CD clock	Source for DDI clocks
Input	Non-SSC reference	Non-SSC reference
Frequency	Programmable selection in the range 0.1 to 2.7 GHz (0.2 to 5.4 GHz bit rate). CD clock usage does not allow spread spectrum to be used.	Programmable selection in the range 0.1 to 2.7 GHz (0.2 to 5.4 GHz bit rate). Spread spectrum can be added if needed.
Default After Reset	Disabled	Disabled
Programming	DPLL enable and frequency must be programmed by software when enabling and disabling a display. Frequency programming is done through the DPLL_CTRL1 register. Enable is programmed through the LCPLL1_CTL register. See the section on Port Clock Programming.	DPLL enable, SSC enable, and frequency must be programmed by software when enabling and disabling a display. Frequency and SSC programming is done through the DPLL_CTRL1 and DPLL*_CFGCR* registers. Enables are programmed through the LCPLL2_CTL and WRPLL_CTL registers. See the section on Port Clock Programming.

Recommended PLL Selection

Avoid changing frequencies on DPLL 0 since that requires DPLL 0 to be disabled, which impacts CDCLK and requires display features to be disabled.

Use DPLL 2 as a last choice because that PLL can be taken by HDPORT in some cases. See register HDPORT_STATE.

- For eDP Non-SSC, use DPLL 0 with frequency set to match the eDP panel requirement.
- For eDP SSC or external displays, use DPLLs 1, 3, 2 in that order, depending on the availability.
- If DPLL 0 is not used for eDP, run DPLL 0 in DisplayPort mode with link rate 810 MHz (DP 1.62 GHz). This will select VCO 8100 for generating CDCLK.

DDI Clocks

There is one DDI clock tied to each DDI port.

A single DDI clock output may be used by multiple transcoders simultaneously for DisplayPort Multi-streaming.

	DDI clocks A, B, C, D, and E
Usage	DDI ports I/O bit clock and symbol/TMDS clock, source for transcoder clocks
Input	Programmable selection between the DPLLs
Frequency	DPLL frequency
Default After Reset	Disabled
Programming	Mapping of DPLL to DDI must be programmed by software when enabling and disabling a display. Programming is done through the DPLL_CTRL2 registers. See the section on Port Clock Programming.

Transcoder Clocks

There is one Transcoder clock tied to each display transcoder, except Transcoder WD which uses only CD clock.

	Transcoder clock EDP	Transcoder clocks A, B, C
Usage	Transcoder EDP symbol clock	Transcoders A, B, and C symbol/TMDS clocks
Input	Always uses DDI A clock	Programmable selection between DDI clocks B, C, D, and E.
Frequency	PLL output frequency divided by 5	PLL output frequency divided by 5
Default After Reset	Connected to DDI A Clock	Disabled

Programming	Not programmable.	Mapping of DDI to Transcoder must be programmed by software when enabling and disabling a display. Programming is done through the TRANS_CLK_SEL registers.

CD Clock

CD clock refers to the Core Display clock which includes the Core Display 1X Clock (CD clock, CDclk, cdclk, CDCLK) and the Core Display 2X Clock (CD2X clock, cd2xclk, CD2XCLK).

	CD clock
Usage	Clocking for most display engine functions
Input	DPLL0 CD2X output (with several frequency options) and Non-SSC reference.
Frequency	Non-SSC reference - 24 MHz CD, 24 MHz CD2X DPLL0 with VCO 8100: • 450 MHz CD, 900 MHz CD2X • 540 MHz CD, 1080 MHz CD2X • 337.5 MHz CD, 675 MHz CD2X • 675 MHz CD, 1350 MHz CD2X DPLL0 with VCO 8640: • 432 MHz CD, 864 MHz CD2X • 540 MHz CD, 1080 MHz CD2X • 308.57 MHz CD, 617.14 MHz CD2X • 617.14 MHz CD, 1234.28 MHz CD2X
Default After Reset	Enabled with the Non-SSC reference - 24 MHz CD, 24 MHz CD2X
Programming	CD clock cannot be disabled. CD clock frequency must be programmed by software when enabling and disabling a display. Programming is done through the CDCLK_CTL register.

Port Clock Programming

DisplayPort Programming

DisplayPort PLL Enable Sequence

1. Configure DPLL_CTRL1 to enable programming, set SSC enable/disable (no SSC for DPLL0), select DP mode, and set link rate.
2. Read back DPLL_CTRL1 to ensure writes completed before the next step.
3. Enable DPLL through LCPLL1_CTL (DPLL0), LCPLL2_CTL (DPLL1), WRPLL_CTL1 (DPLL2), or WRPL_CTL2 (DPLL3).
4. Wait for PLL lock status in DPLL_STATUS.
5. For each DDI that will use this DPLL. Configure DPLL_CTRL2 to turn on the clock for the DDI and map the DPLL to the DDI.

DisplayPort PLL Disable Sequence

1. For each DDI that was using this DPLL. Configure DPLL_CTRL2 to turn off the clock for the DDI.
2. Disable DPLL through LCPLL1_CTL (DPLL0), LCPLL2_CTL (DPLL1), WRPLL_CTL1 (DPLL2), or WRPL_CTL2 (DPLL3).

Example of DisplayPort on DDIA using HBR 2.7 GHz link rate with SSC

DPLL0 does not support SSC, so this case must use one of the other DPLLs. This example assumes DPLL1 is available.

1. Configure DPLL1 in the DPLL_CTRL1 register
   - DPLL1 Override = 1b (Enable)
   - DPLL1 Link Rate = 001b (1350 MHz - DP 2.7 GHz)
   - DPLL1 SSC = 1b (Enable)
   - DPLL1 HDMI Mode = 0b (DP mode)
2. Read back DPLL_CTRL1 to ensure writes completed
3. Enable DPLL1 in the LCPLL2_CTL register
   - PLL Enable = 1b (Enabled)
4. Wait for PLL lock status in DPLL_STATUS
5. Configure DPLL1 mapping to DDIA in the DPLL_CTRL2 register
   - DDIA Select Override = 1b (Enable)
   - DDIA Clock Select = 01b (DPLL1)
   - DDIA Clock Off = 0b (On)

HDMI and DVI Programming

HDMI and DVI PLL Enable Sequence

1. Configure DPLL_CTRL1 to enable programming, disable SSC, and use HDMI mode.
2. Configure DPLL_CFGCR1 to enable programming and set DCO frequency.
3. Configure DPLL_CFGCR2 to set the dividers and DCO central frequency.
4. Read back DPLL_CTRL1, DPLL_CFGCR1, and DPLL_CFGCR2 ensure writes completed before the next step.
5. Enable DPLL through LCPLL2_CTL (DPLL1), WRPLL_CTL1 (DPLL2), or WRPL_CTL2 (DPLL3).
6. Wait for PLL lock status in DPLL_STATUS.
7. For each DDI that will use this DPLL. Configure DPLL_CTRL2 to turn on the clock for the DDI and map the DPLL to the DDI.

HDMI and DVI PLL Disable Sequence

1. For each DDI that was using this DPLL. Configure DPLL_CTRL2 to turn off the clock for the DDI.
2. Disable DPLL through LCPLL2_CTL (DPLL1), WRPLL_CTL1 (DPLL2), or WRPL_CTL2 (DPLL3).

Formula for HDMI and DVI DPLL Programming

Reference frequency = 24 MHz.

Symbol clock frequency MHz = DCO Frequency / (P0 * P1 * P2) / 5.

AFE clock = Symbol clock frequency MHz * 5 = DCO Frequency / (P0 * P1 * P2).

P2 can be 1, 2, 3, or 5.

If P2 != 2, then P1 must be 1. Else P1 can be 1 to 255.

If P1 == 1, then P0 can be 1, 2, 3, or 7. Else P0 can be 2, 3, or 7.

An even value for the divider (P0 * P1 * P2) is preferred.

DCO central frequency must be 8400, 9000, or 9600 MHz.

DCO frequency must be within +1% or -6% of DCO central frequency. It is preferred to get as close to the DCO central frequency as possible, but using an even divider value takes precedence.

Note: If the desired symbol clock frequency cannot be achieved with the valid values of P0, P1, P2, and DCO frequencies, use a different screen resolution with a different symbol clock frequency.

Algorithm to Find HDMI and DVI DPLL Programming

1. Find AFE clock
2. For each legal divider (P*Q*K), find the DCO. Try even dividers first. Only use odd dividers if a good even is not found.

3. Try the DCO with each central frequency.
4. Select the divider and central frequency that gives the DCO with minimum deviation from DCO central frequency and fits within the +1% and -6% requirement.
5. Find the P, Q, K values to create that divider.

Pseudo-code for HDMI and DVI DPLL Programming

```
 Minimum Positive Deviation = 1%
 Minimum Negative Deviation = 6%
 Chosen Central Frequency = NONE
 AFE Clock = 5 * Symbol Clock MHz
 Even Candidate Dividers[] = { 4, 6, 8, 10, 12, 14, 16, 18, 20, 24, 28, 30, 32, 36, 40, 42,

Example of DVI on DDIB using 113.309 MHz symbol clock

This example assumes DPLL3 is available.

Frequency programming algorithm finds DCO central frequency = 9000 MHz, P0=2, P1=4, P2=2, DCO Frequency = 9064.72

1. Configure DPLL3 in the DPLL_CTRL1 register
    - DPLL3 Override = 1b (Enable)
    - DPLL3 SSC = 0b (Disable)
    - DPLL3 HDMI Mode = 1b (HDMI mode)
2. Configure DPLL3 in the DPLL3_CFGCR1 register

    DCO Integer = INT(9064.72/24) = 377

    DCO Fraction = INT(((9064.72/24) - DCO Integer) * 2^15) = 22,828

    - Frequency Enable = 1b (Enable)
    - DCO Fraction = 592Ch (22828)
    - DCO Integer = 179h (377)
3. Configure DPLL3 in the DPLL3_CFGCR2 register
    - Qdiv Ratio = P1 = 04h (4)
    - Qdiv Mode = 1b (Enable)
    - Kdiv = P2 = 01b (2)
    - Pdiv = P0 = 001b (2)
    - Central Frequency = 01b (9000 MHz)
4. Read back DPLL_CTL1, DPLL3_CFGCR1, and DPLL3_CFGCR2 to ensure writes completed
5. Enable DPLL3 in the WRPLL_CTL2 register
    - PLL Enable = 1b (Enabled)
6. Wait for PLL lock in DPLL_STATUS
7. Configure DPLL3 mapping to DDIB in the DPLL_CTRL2 register
    - DDIB Select Override = 1b (Enable)
    - DDIB Clock Select = 11b (DPLL3)
    - DDIB Clock Off = 0b (On)

Example of HDMI on DDIC using 296.703 MHz symbol clock

This example assumes DPLL2 is available.

Frequency programming algorithm finds DCO central frequency = 9000 MHz, P0=1, P1=3, P2=2, DCO Frequency = 8901.09

1. Configure DPLL2 in the DPLL_CTRL1 register
    - DPLL2 Override = 1b (Enable)
    - DPLL2 SSC = 0b (Disable)
    - DPLL2 HDMI Mode = 1b (HDMI mode)

2. Configure DPLL2 in the DPLL2_CFGCR1 register

   DCO Integer = INT(8901.09/24) = 370

   DCO Fraction = INT(((8901.09/24) - DCO Integer) * 2^15) = 28,794

   - Frequency Enable = 1b (Enable)
   - DCO Fraction = 707Ah (28794)
   - DCO Integer = 172h (370)
3. Configure DPLL2 in the DPLL2_CFGCR2 register
   - Qdiv Mode = 0b (Disable) // P1=1
   - Kdiv = P2 = 01b (2)
   - Pdiv = P0 = 010b (3)
   - Central Frequency = 01b (9000 MHz)
4. Read back DPLL_CTL1, DPLL2_CFGCR1, and DPLL2_CFGCR2 to ensure writes completed
5. Enable DPLL2 in the WRPLL_CTL1 register
   - PLL Enable = 1b (Enabled)
6. Wait for PLL lock status in DPLL_STATUS
7. Configure DPLL2 mapping to DDIC in the DPLL_CTRL2 register
   - DDIC Select Override = 1b (Enable)
   - DDIC Clock Select = 10b (DPLL2)
   - DDIC Clock Off = 0b (On)

Sequences for Changing CD Clock Frequency

The CD clock frequency can be programmed to select between several frequencies.

Restrictions
The CD clock frequency impacts the maximum supported pixel rate and display watermark programming. The CD clock frequency must be at least twice the frequency of the Azalia BCLK. Do not select the CD clock frequencies that have been restricted by the Display CDCLK Limit fuse (register DFSM).
Sequence for Changing CD Clock Frequency
1. Disable all display engine functions using the full mode set disable sequence on all pipes, ports, and planes. • Includes Global Time Code 2. Inform power controller of upcoming frequency change a. Ensure any previous GT Driver Mailbox transaction is complete. b. Write GT Driver Mailbox Data0 (GTTMMADDR offset 0x138128) = 0x00000003. c. Write GT Driver Mailbox Data1 (GTTMMADDR offset 0x13812C) = 0x00000000. d. Write GT Driver Mailbox Interface (GTTMMADDR offset 0x138124) = 0x80000007.

Restrictions
e. Poll GT Driver Mailbox Interface for Run/Busy indication cleared (bit 31 = 0). • Timeout after 150 us. Do not change CD clock frequency if there is a timeout. f. Read GT Driver Mailbox Data0, if bit 0 is 0x1, continue, else go to step b. • If the condition in step f is not satisfied after cycling through steps b-f for 3 ms (typically <200 us), timeout and do not change CD clock frequency. 3. Change CDCLK_CTL register CD Frequency Select and CD Frequency Decimal to the desired frequency • The frequency change will complete within a few clock cycles. 4. Inform power controller of the selected frequency a. Write GT Driver Mailbox Data0 with the frequency selection. • If selecting 337.5 or 308.57 MHz CD clock, or disabling CD clock PLL, write 0x00000000. • If selecting 450 or 432 MHz CD clock, write 0x00000001. • If selecting 540 MHz CD clock, write 0x00000002. • If selecting 675 or 617.14 MHz CD clock, write 0x00000003. b. Write GT Driver Mailbox Data1 = 0x00000000. c. Write GT Driver Mailbox Interface = 0x80000007. • The power controller should complete within 100 us, but there is no need for display software to wait for that. 5. Update programming of register fields that are based on CD clock frequency Programming can be delayed to when the features are enabled. • Utility pin backlight frequency and duty cycle in the BLC_PWM_DATA register.

Resets

NDE_RSTWRN_OPT

The north and south display engines are reset by PCI Function Level Resets (FLR) and the chip level resets.

An FLR for Bus:Device:Function 0:2:0 resets the north and south display engines and audio codec and most of the related MMIO, PCI, and I/O configuration registers.

Display configuration registers that are reset by both the chip level reset and by FLR are marked as using the "soft" reset in the programming specification.

Display configuration registers that are reset only by the chip level reset and *not* by FLR are marked as using the "global" reset in the programming specification.

The south display engine runs panel power down sequencing (if configured to do so) before resetting.

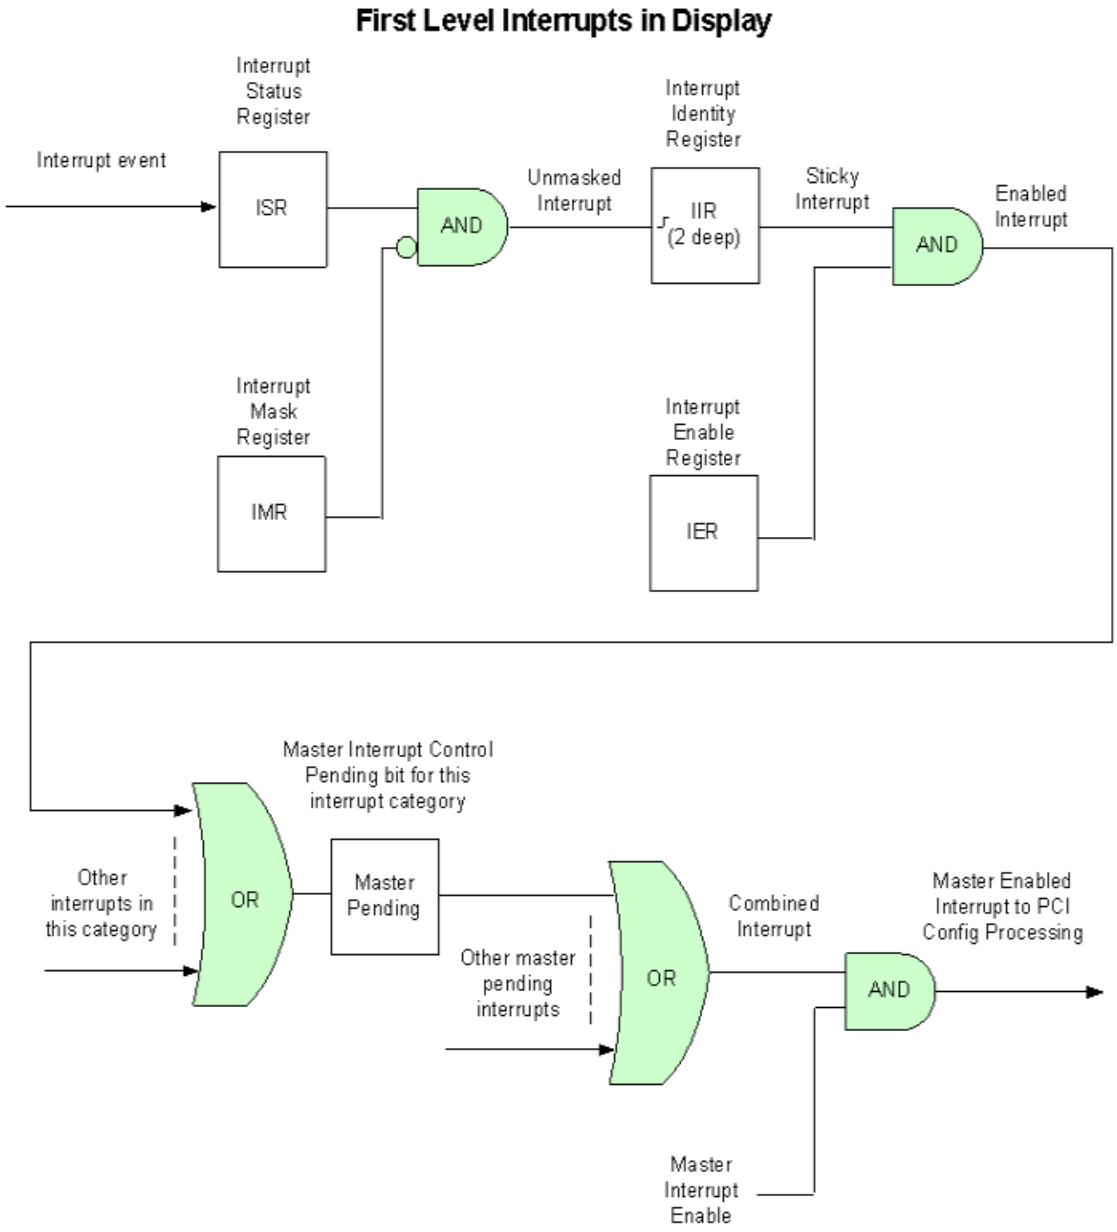
INTERRUPT Structure

Interrupt Flow



1. For every first level interrupt bit
    a. The interrupt event comes in to the interrupt handling logic.
        - There may be more levels of interrupt handling behind each event. For example, the PCH Display interrupt event is the result of the SDE interrupt registers.
    b. The interrupt event goes to the Interrupt Status Register (ISR) where live status can be read back.
        - The live status is mainly useful for hotplug interrupts where it gives the live state of the hotplug line.
        - The live status is not useful for pulse interrupt events due to the short period that the status will be present.
    c. The interrupt event is ANDed with the inverted Interrupt Mask Register (IMR) to create the unmasked interrupt.
        - Only unmasked interrupts will proceed.
    d. The unmasked interrupt rising edge sets the sticky bit in the Interrupt Indentity Register (IIR).
        - The IIR can be cleared by writing a 1 to it.
        - The IIR can queue up to two interrupt events. When the IIR is cleared, it will set itself again if a second event was stored.
    e. The sticky interrupt is ANDed with the Interrupt Enable Register (IER) to create the enabled interrupt.
        - Only enabled interrupts will proceed.
2. All enabled interrupts are then ORed by category (Pipe, Audio Codec, Render, etc.) to create a combined interrupt which is then visible in one of the Master Interrupt Control Register (MASTER_INT_CTL) pending category bits.
3. All pending interrupts are then ORed to create the combined interrupt.
4. The combined interrupt is ANDed with the Master Interrupt Enable (MASTER_INT_CTL Bit 31) to create the master enabled interrupt.
    - Only a master enabled interrupt will proceed.
5. The master enabled interrupt then goes to PCI device 2 configuration registers PCISTS2, PCICMD2, and MC which control the MSI and line interrupt.

A Function Level Reset (FLR) or Warm Reset will reset all graphics interrupt logic, causing the master enabled interrupt to de-assert which can cause the MSI or line interrupt to de-assert.

Interrupt Service Routine

1. Disable Master Interrupt Control
    - Clear bit 31 of MASTER_INT_CTL (0x44200)
    - This is required to prevent missing any interrupts occurring back to back or during the service routine

2. Find the category of interrupt that is pending
    - Read MASTER_INT_CTL (0x44200) and record which interrupt pending category bits are set
3. Find the source(s) of the interrupt and clear the Interrupt Identity bits (IIR)
    - Read the IIR associated with each pending interrupt category, record which bits are set, then write back 1s to clear the bits that are set.
4. Process the interrupt(s) that had bits set in the IIRs
5. Re-enable Master Interrupt Control
    - Set bit 31 of MASTER_INT_CTL (0x44200)

Backlight

This section refers to the CPU display backlight control. For PCH display backlight control, see South Display Engine Registers.

The backlight PWM output frequency is determined by the PWM clock frequency, increment, and frequency divider.

PWM output frequency = PWM clock frequency / PWM increment / PWM frequency divider

The frequency divider must be greater than or equal to the number of brightness levels required by software; typically 100 or 256.

Description
PWM clock frequency = CD clock frequency = 308.57 to 675 MHz PWM increment = 128 or 8, selectable by software PWM frequency divider maximum = 2^16 PWM output frequency range with PWM clock frequency 308.57 MHz and 100 brightness levels and increment 128 = 37 to 24,107 Hz PWM output frequency range with PWM clock frequency 308.57 MHz and 100 brightness levels and increment 8 = 589 to 385,713 Hz PWM output frequency range with PWM clock frequency 308.57 MHz and 256 brightness levels and increment 128 = 37 to 9,417 Hz PWM output frequency range with PWM clock frequency 308.57 MHz and 256 brightness levels and increment 8 = 589 to 150,669 Hz

Backlight Enabling Sequence

Description
1. Enable utility pin, select PWM mode, and set polarity in UTIL_PIN_CTL Util Pin Enable, Util Pin Mode, and Util Pin Output Polarity. 2. Set frequency and duty cycle in BLC_PWM_DATA Backlight Frequency and Backlight Duty Cycle. 3. Enable PWM output and set granularity in BLC_PWM_CTL PWM Enable and PWM granularity. ... 4. Change duty cycle as needed in BLC_PWM_DATA Backlight Duty Cycle.

If needed, granularity and polarity can be programmed earlier than shown.

Workaround	
Context:	FBC
To prevent missed invalidations around the time FBC is being enabled, FBC render tracking must use the "Render Tracking With Nuke" method.	

FBC Overview

Frame Buffer Compression (FBC) gives a lossless compression of the display frame buffer to save power by reducing system memory read bandwidth and increasing the time between display engine reads to system memory.

FBC is only available on specific plane(s), depending on project. See FBC_CTL for details. FBC compresses pixels for the plane(s) it is attached to as they are displayed. The compressed data is written into the Compressed Frame Buffer (CFB) in graphics data stolen memory. The compressed data is then read the next time the same line needs to be displayed. Changes to the display front buffer (currently displayed

memory surface) through host aperture (GMADR) tiling fences (on projects that support that), render (RCS), and blitter (BCS) are tracked and cause the compressed lines to be invalidated and recompressed. Flips or changes to plane size and panning cause the entire buffer to be recompressed (nuke).

FBC Compression Limit

The FBC compression limit reduces the size of the Compressed Frame Buffer (CFB) by limiting which lines will be compressed. This is used when the graphics stolen memory available for the FBC CFB is smaller than the size of the original uncompressed frame buffer. There is also a FBC compressed vertical limit, listed in FBC_CTL, which is the maximum number of lines FBC can compress. Lines beyond the vertical limit do not need to be accounted for in the CFB size.

When the compression limit is 1:1, every line is written to the CFB, so the CFB width is the same as the original uncompressed frame buffer.

When the compression limit is 2:1, only lines that compress to 1/2 their original size will be written to the CFB, so the CFB width can be 1/2 the original uncompressed frame buffer.

When the compression limit is 4:1, only lines that compress to 1/4 their original size will be written to the CFB, so the CFB width can be 1/4 the original uncompressed frame buffer.

CFB size = ((Stride of plane uncompressed surface / FBC compression limit) * MIN(FBC compressed vertical limit, plane vertical source size)

FBC Programming Overview

1. Set up the compressed frame buffer.
    - The compressed buffer resides in graphics data stolen memory.
    - The stolen memory must be contiguous and un-cached.
    - The stolen memory needed for compressed frame buffer must be greater or equal to CFB size (calculation above).
    - Manage the compressed buffer size at run-time by balancing other graphics memory needs with the FBC allocation, and implement appropriate memory needs prioritization schemes.
2. Tracking for CPU host front buffer modifications through aperture fences (on projects that support that)
    - Setup System Agent (SA) registers to track CPU modifications on the display front buffer.
3. Tracking for display front buffer rendering
    - Setup Target Base Address, Front Buffer Target, and Address Valid for FBC
    - Enable Address Valid before rendering to the front buffer.
    - If needed, send nuke LRIs after each render submission to the display front buffer
4. Tracking from display front buffer BLTs
    - Setup Target Base Address and Address Valid for FBC
    - Enable Address Valid when BLTs target the display front buffer and disable when BLTs do not target the display front buffer

- Send nuke LRI or cache clean LRI after each blitter submission to the display front buffer

LRI commands to display address 0x50380 are used as part of the render and blitter tracking. Those LRIs must be followed SRM commands to the same address.

LRI to address 0x50380 with data 0x00000004 tells FBC to nuke and invalidate the entire compressed buffer.

LRI to address 0x50380 with data 0x00000002 tells FBC that previous blitter submissions have been flushed to memory and the invalidate lines can now be recompressed.

Render and blitter tracking can invalidate individual lines or nuke the entire buffer. The nuke method is used for workarounds.

Render Tracking With Nuke

- Software must send the nuke LRI after each render to the display front buffer

1. Render commands that touch the display front buffer
    a. Render submission
    b. PIPE_CONTROL
    c. LRI to address 0x50380 with data 0x00000004 (nuke)
    d. SRM to read address 0x50380 and store to a scratch page
2. More render commands that touch the display front buffer
    a. Render submission
    b. PIPE_CONTROL
    c. LRI to address 0x50380 with data 0x00000004 (nuke)
    d. SRM to read address 0x50380 and store to a scratch page
3. Render commands that do not touch the display front buffer
    a. Render submission
    b. PIPE_CONTROL

Render Tracking Without Nuke

- Render tracking must be setup by software, then hardware will track FBC line invalidations automatically.

1. Render commands that potentially touch the display front buffer
    a. LRIs to FBC_RT_BASE_ADDR_REGISTER_<UPPER,LOWER> with display front buffer address, front buffer target=1, base address valid for FBC=1
    b. PIPE_CONTROL to ensure LRI takes effect
    c. Render submission
    d. PIPE_CONTROL

2. More render commands that touch the display front buffer
    a. Render submission
    b. PIPE_CONTROL
3. Render commands that do not touch the display front buffer
    a. Optional: LRIs to FBC_RT_BASE_ADDR_REGISTER_<UPPER,LOWER> with base address valid for FBC=0. Optional because hardware will detect that the render is not to the display front buffer address.
    b. Optional: PIPE_CONTROL to ensure LRI takes effect
    c. Render submission
    d. PIPE_CONTROL

Blitter Tracking With Nuke

- Software must send the nuke LRI after each BLT to the display front buffer. Never set 221d0h bit 3 (Address Valid for FBC).

1. BLT commands that touch the display front buffer
    a. BLT submission
    b. MI_FLUSH_DW
    c. LRI to address 0x50380 with data 0x00000004 (nuke)
    d. SRM to read address 0x50380 and store to a scratch page
2. More BLT commands that touch the display front buffer (can leave Address Valid set from previous)
    a. BLT submission
    b. MI_FLUSH_DW
    c. LRI to address 0x50380 with data 0x00000004 (nuke)
    d. SRM to read address 0x50380 and store to a scratch page
3. BLT commands that do not touch the display front buffer
    a. BLT submission
    b. MI_FLUSH_DW

Blitter Tracking Without Nuke

- Blitter tracking must be enabled by software only when BLTs touch the display front buffer. Software must send the cache clean LRI after each BLT to the display front buffer.

1. BLT commands that definitely touch the front buffer
    a. LRI to address 221d0h to set bit 3 (Address Valid for FBC)
    b. MI_FLUSH_DW to ensure LRI takes effect
    c. BLT submission

   d. MI_FLUSH_DW
   e. LRI to address 0x50380 with data 0x00000002 (cache clean)
   f. SRM to read address 0x50380 and store to a scratch page
2. More BLT commands that touch the front buffer (can leave Address Valid for FBC set from previous)
   a. BLT submission
   b. MI_FLUSH_DW
   c. LRI to address 0x50380 with data 0x00000002 (cache clean)
   d. SRM to read address 0x50380 and store to a scratch page
3. BLT commands that do not touch the front buffer (must clear Address Valid for FBC)
   a. LRI to address 221d0h to set bit 3 (Address Valid for FBC)
   b. MI_FLUSH_DW to ensure LRI takes effect
   c. BLT submission
   d. MI_FLUSH_DW

CPU Host Aperture Tracking

- Host tracking must be setup by software, then hardware will track FBC line invalidations to the specified tiling fence.

1. Program Y offset from the CPU fence to the Display Buffer base in DPFC_CPU_FENCE_OFFSET.
2. Program CPU fence ID and enable CPU fence tracking in DPFC_CONTROL_SA.

Disable CPU Fence tracking in DPFC_CONTROL_SA if no tiling fence is mapped to display buffer.

Display Plane Enabling with FBC

- FBC has to be enabled after the attached display plane is enabled.
- This is the general sequence. See FBC_CTL for any workarounds.

1. Enable display plane
2. Enable FBC as described in FBC_CTL register

Display Plane Disabling with FBC

- FBC has to be disabled prior to FBC attached display plane disabling.
- This is the general sequence. See FBC_CTL for any workarounds.

1. Disable FBC as described in FBC_CTL register
2. Disable display plane.

Watermarks

The watermark registers are used to control the display to memory request timing. The watermarks must be programmed according to the Display Watermark Programming section.

Description or Link
WM_PIPE, WM_LP, and WM_LP_SPR have been replaced by PLANE_WM and moved into the planes section.
WM_MISC **WM_LINETIME**

DC States

DC_STATE_EN

Power Wells

When a power well is disabled (powered down), access to any registers in the power well will complete, but write data will be dropped and read data will be all zeroes.

The power well enable requests from all sources are logically ORd together to enable a power well, so the power well will only disable after all sources have requested the power well to disable.

Register Link
PWR_WELL_CTL

Pipe

Color Space Conversion

CSC_COEFF

CSC COEFFICIENT FORMAT

CSC_PREOFF

CSC_POSTOFF

CSC_MODE

The high color channel is the most significant bits of the color. The low color channel is the least significant bits of the color. The medium color channel is the bits between high and low. For example: In RGB modes Red is in the High channel, Green in Medium, and Blue in Low. In YUV modes, V is in the High channel, Y in Medium, and U in Low.

The color space conversion registers are double buffered and are updated on the start of vertical blank following a write to the CSC Mode register for the respective pipe.

The matrix equations are as follows:

OutputHigh = (CoefficientRY * InputHigh) + (CoefficientGY * InputMedium) + (CoefficientBY * InputLow)

OutputMedium = (CoefficientRU * InputHigh) + (CoefficientGU * InputMedium) + (CoefficientBU * InputLow)

OutputLow = (CoefficientRV * InputHigh) + (CoefficientGV * InputMedium) + (CoefficientBV * InputLow)

Example programming for RGB to YUV is in the following table:

The input is RGB on high, medium, and low channels respectively and the desired YUV output is VYU on high, medium, and low channels respectively.

Program CSC_MODE to put gamma before CSC.

Program the CSC Post-Offsets to +1/2, +1/16, and +1/2 for high, medium, and low channels respectively.

The coefficients and pre and post offsets can be scaled if desired.

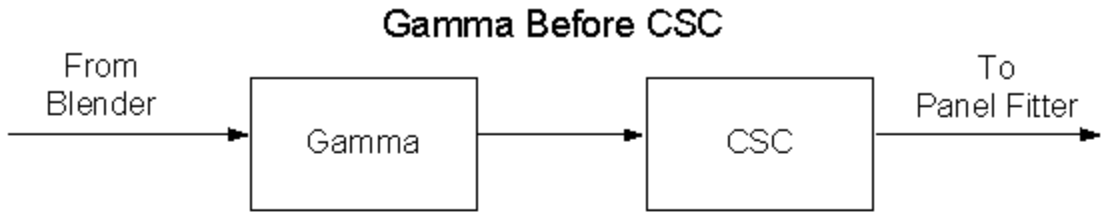
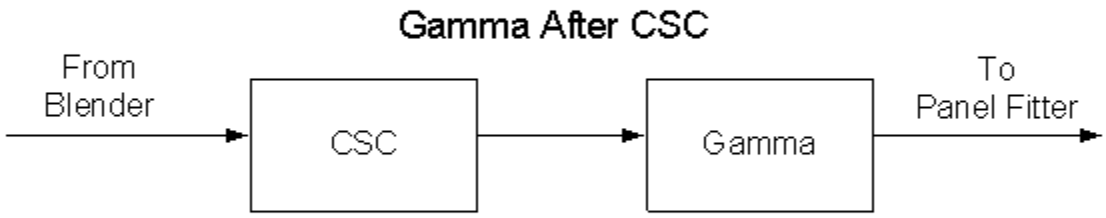
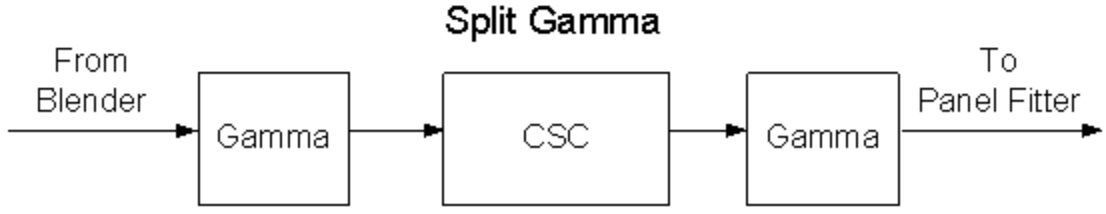
The pipe gamma and color space conversion blocks can be placed in three different arrangements:

- Gamma before CSC: Selected through the CSC Mode register. Mostly used for RGB to YUV conversion.
- Gamma after CSC: Selected through the CSC Mode register. Mostly used for YUV to RGB conversion or linear RGB to RGB conversion. Can be used with pipe color gamut enhancement.
- Split gamma: Selected through the Gamma Mode register. Mostly used for RGB to RGB conversion. Can be used with pipe color gamut enhancement. The pipe gamma enable per plane will control whether a plane will go through both gamma blocks. It is not possible to send a plane through one gamma block and not the other.

In either arrangement, the final output of the pipe gamma and CSC and gamut enhancement logic is clamped to fit in the 0 to 1.0 range before going to the ports.







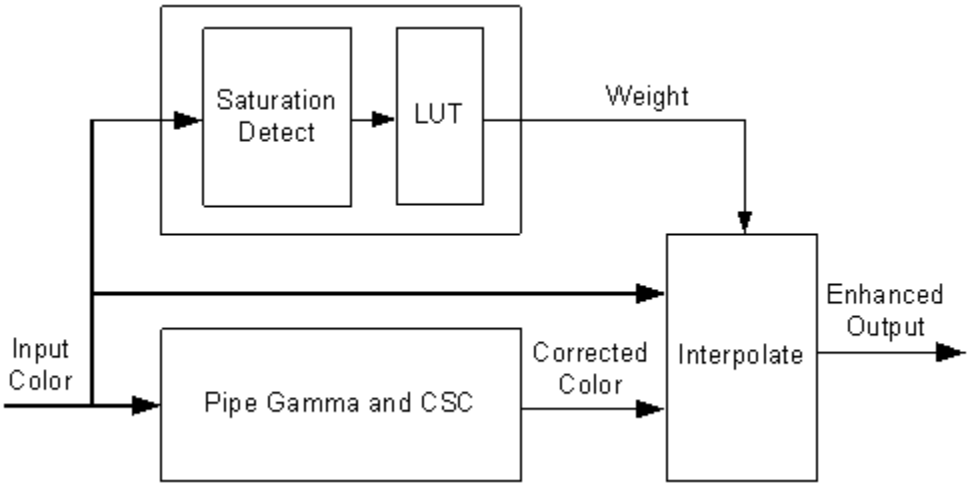
Pipe Color Gamut Enhancement

Pipe color gamut enhancement is used to enhance display of standard gamut content on wide gamut displays. It processes the color value from before and after the pipe gamma and color space correction blocks to create the color gamut enhanced output. The typical usage is to output the pipe gamma and CSC corrected color for areas of low saturated content and the input (not gamma or CSC corrected) color for areas of high saturated content. It is not recommended to use color gamut enhancement with wide gamut inputs.

CGE_CTRL

CGE_WEIGHT

The pipe Gamma and CSC must be programmed to either the split gamma mode or gamma after CSC mode when using pipe color gamut enhancement.



The saturation level of the pipe gamma and CSC input color is detected and used to index into a look up table (LUT) containing programmable weights. The saturation values are linearly distributed across the LUT indexes from the lowest index for lowest saturation to the highest index for highest saturation.

The enhanced output color is created by using the weight value to interpolate between the input color and corrected color. See the following table of weights to amount of input or corrected color used to create the enhanced output color.

Weighting of input and corrected colors

Weight from LUT	Amount of Input Color in Enhanced Output	Amount of Corrected Color in Enhanced Output
00 0000b (minimum)	0%	100%
...	...	...

Pipe Palette and Gamma

The display palette provides a means to correct the gamma of an image stored in a frame buffer to match the gamma of the monitor or presentation device. Additionally, the display palette provide a method for converting indexed data values to color values for VGA and 8-bpp indexed display modes. The display palette is located after the plane blender. Using the individual plane gamma enables, the blended pixels can go through or bypass the palette on a pixel by pixel basis.

PAL_LGC

PAL_PREC_DATA

PAL_GC_MAX

PAL_EXT_GC_MAX

GAMMA_MODE

If any gamma value to be programmed exceeds the maximum allowable value in the associated gamma register, then the programmed value must be clamped to the maximum allowable value.

Programming Modes

The display palette can be accessed through multiple methods and operate in one of four different modes as follows.

8 bit legacy palette/gamma mode:

This provides a palette mode for indexed pixel data formats (VGA and primary plane 8 bpp) and gamma correction for legacy programming requirements.

All input values are clamped to the 0.0 to 1.0 range before the palette/gamma calculation. It is not recommended to use legacy palette mode with extended range formats.

For input values greater than or equal to 0 and less than 1.0, the input value is used to directly lookup the result value from one of the 256 palette/gamma entries. The 256 entries are stored in the legacy palette with 8 bits per color in a 0.8 format with 0 integer and 8 fractional bits.

The legacy palette is programmable through both MMIO and VGA I/O registers. Through VGA I/O, the palette can look as though there are only 6 bits per color component, depending on programming of other VGA I/O registers.

10 bit gamma mode:

This provides the highest quality gamma for pixel data formats of 30 bits per pixel or less.

All input values are clamped to the greater than -3.0 and less than 3.0 range before the gamma calculation.

For input values greater than or equal to 0 and less than 1.0, the input value is used to directly lookup the result value from one of the first 1024 gamma entries. The first 1024 entries are stored in the precision palette with 10 bits per color in a 0.10 format with 0 integer and 10 fractional bits.

For input values greater than or equal to 1.0 and less than 3.0, the input value is used to linearly interpolate between the 1024th and 1025th gamma entries to create the result value. The 1025th entry is stored in the PAL_EXT_GC_MAX register with 19 bits per color in a 3.16 format with 3 integer and 16 fractional bits.

For negative input values, gamma is mirrored along the X-axis, giving the same result as positive input values, except for a negative sign. When gamma input may be negative, the first gamma point should be programmed to a value of 0.0 in order to have a symmetric mirroring.

Split gamma mode:

Split gamma mode is composed of two gamma functions. The first gamma is before pipe color space conversion (CSC) and the second is after CSC. This split gamma mode permits mapping to linear gamma, then color space conversion, then mapping to monitor gamma. This provides the highest quality pipe color space conversion and gamma correction for inputs with non-linear gamma.

First gamma (before CSC):

All input values are clamped to the greater than -3.0 and less than 3.0 range before the gamma calculation.

For input values greater than or equal to 0 and less than 1.0, the input value is used to directly lookup the result value from one of the first 512 gamma entries. The first 512 entries are stored in the precision palette indexes 0 to 511 with 10 bits per color in a 0.10 format with 0 integer and 10 fractional bits.

For input values greater than or equal to 1.0 and less than 3.0, the input value is used to linearly interpolate between the 512th and 513th gamma entries to create the result value. The 513th entry is stored in the PAL_EXT_GC_MAX register with 19 bits per color in a 3.16 format with 3 integer and 16 fractional bits.

For negative input values, gamma is mirrored along the X-axis, giving the same result as positive input values, except for a negative sign. When gamma input may be negative, the first gamma point should be programmed to a value of 0.0 in order to have a symmetric mirroring.

Second gamma (after CSC):

All input values are clamped to the 0.0 to 1.0 range before the gamma calculation.

For input values greater than or equal to 0 and less than 1.0, the input value is used to directly lookup the result value from one of the first 512 gamma entries. The first 512 entries are stored in the precision palette indexes 512 to 1023 with 10 bits per color in a 0.10 format with 0 integer and 10 fractional bits.

12 bit interpolated gamma mode:

This provides the highest quality gamma for pixel data formats greater than 30 bits per pixel.

The gamma correction curve is represented by specifying a set of gamma entry reference points spaced equally along the curve for values between -1 and 1. For extended values there is an extended gamma entry reference point at the maximum allowed input value.

All input values are clamped to the greater than -3.0 and less than 3.0 range before the gamma calculation.

For input values greater than or equal to 0 and less than 1.0, the input value is used to linearly interpolate between two adjacent points of the first 513 gamma entries to create the result value. The first 512 entries are stored in the precision palette with 16 bits per color in a 0.16 format with 0 integer and 16 fractional bits (upper 10 bits in odd indexes, lower 6 bits in even indexes). The 513th entry is stored in the PAL_GC_MAX register with 17 bits per color in a 1.16 format with 1 integer and 16 fractional bits.

For input values greater than or equal to 1.0 and less than 3.0, the input value is used to linearly interpolate between the 513th and 514th gamma entries to create the result value. The 514th entry is stored in the PAL_EXT_GC_MAX register with 19 bits per color in a 3.16 format with 3 integer and 16 fractional bits.

For negative input values, gamma is mirrored along the X-axis, giving the same result as positive input values, except for a negative sign. When gamma input may be negative, the first gamma point should be programmed to a value of 0.0 in order to have a symmetric mirroring.

To program the gamma correction entries, calculate the desired gamma curve for inputs from 0 to 3.0. The curve must be flat or increasing, never decreasing. For inputs of 0 to 1.0, multiply the input value by 512 to find the gamma entry number, then store the desired gamma result in that entry. For inputs greater than 1.0 and less than or equal to 3.0, store the result for an input of 3.0 in the 514th gamma entry.

Render/Display Decompression

GT Render engines uses a lossless scheme to compress the color Render targets. The goal of the compression is to reduce the memory bandwidth. The memory foot print increases slightly due to the need of the control surface.

- Decompression is supported on plane 1 and plane 2 of pipe A and pipe B with RGB8888 surface formats.
- Decompression is supported only in legacy tile Y and tile Yf surfaces.
- Decompression support is limited to left-right cache line pair mode. Top-bottom mode is not supported.
- When render decompression is enabled, display engine internally converts the Async flips to Sync flips.
- Decompression is not supported with 90/270 degree rotation.

Color Control Surface

The Color Control Surface (CCS) contains the compression status of the cache-line pairs**.** The compression state of the cache-line pair is specified by 2 bits in the CCS. Each CCS cache-line represents an area on the main surface of 16 x16 sets of 128 byte Y-tiled cache-line-pairs. CCS is always Y tiled. The

address of CCS surface is specified as an offset from the start of the Render Target main surface. CCS stride is programmed separately independent of the main surface stride.

Decompression Programming

When compressed Render targets are presented to Display, the display decompression must be enabled. Along with main surface programming, the following additional programming is required to enable the decompression

- **Decompression Enable**

Decompression is enabled by programming the 'Render Decomp' bit in the PLANE_CTL register.

- **Color Control Surface Distance**

The start of the CCS surface is programmed as the distance in bytes from the start of the main surface in the PLANE_AUX_DIST register. The CCS is always placed after the main surface and is 4K page aligned.

- **Color Control Surface Stride**

The CCS stride is programmed in the PLANE_AUX_DIST register.

Plane Rotation Programming

This topic provides programming information for plane rotation.

The 180 rotation mode is unchanged and will continue to use the same programming. In the 180 rotation mode display hardware is responsible for walking the pages in the reverse order. The cacheline walk within the page is also reversed. The 90 and 270 rotation modes require more complicated page walk mechanism. The page walk is made transparent to the hardware by providing a different set of page translations (remapped GTT) for the same rendered surface. The remapping completely abstracts the page walk away from the hardware and the hardware walks the pages as if there is no rotation. Hardware is still responsible for handling the the walk within the page appropriately. Also, the 90, 270 Rotation requires a new parameter - surface height. The changes needed in the driver programming is discussed below.

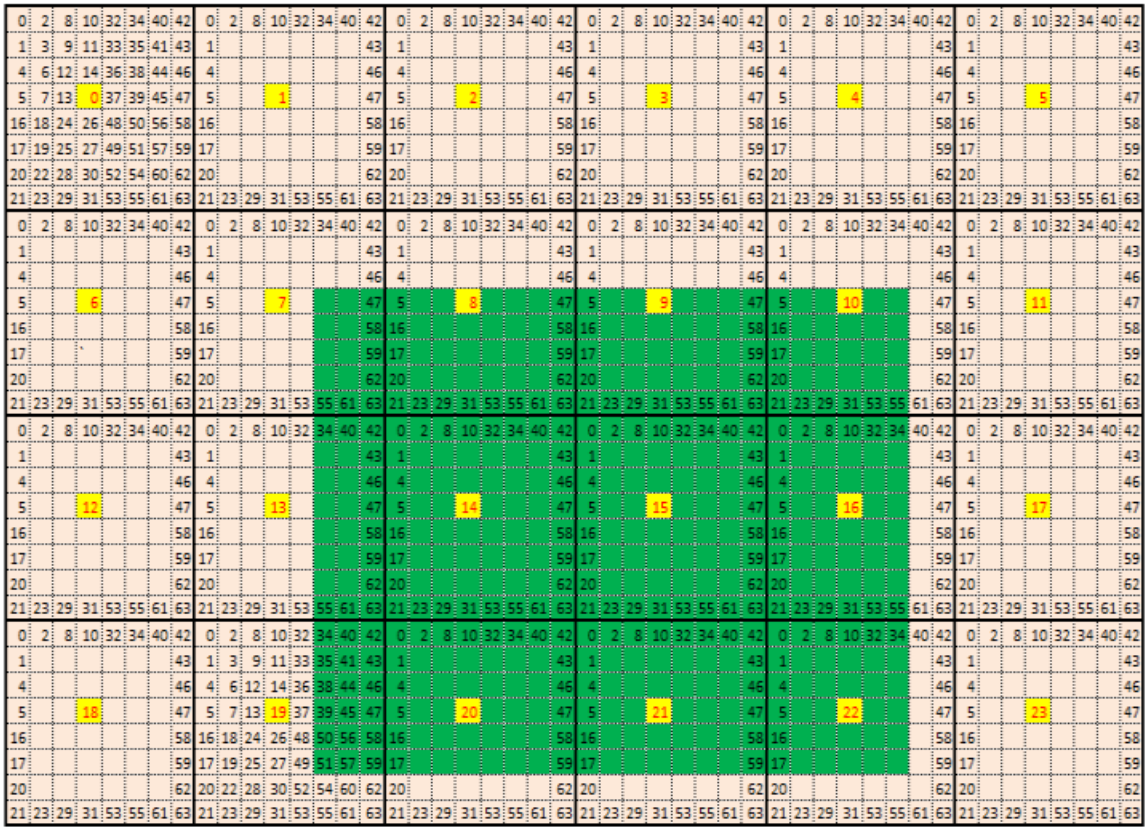
90 Rotation

For the 90 rotation programming, the plane parameters must use the following mapping

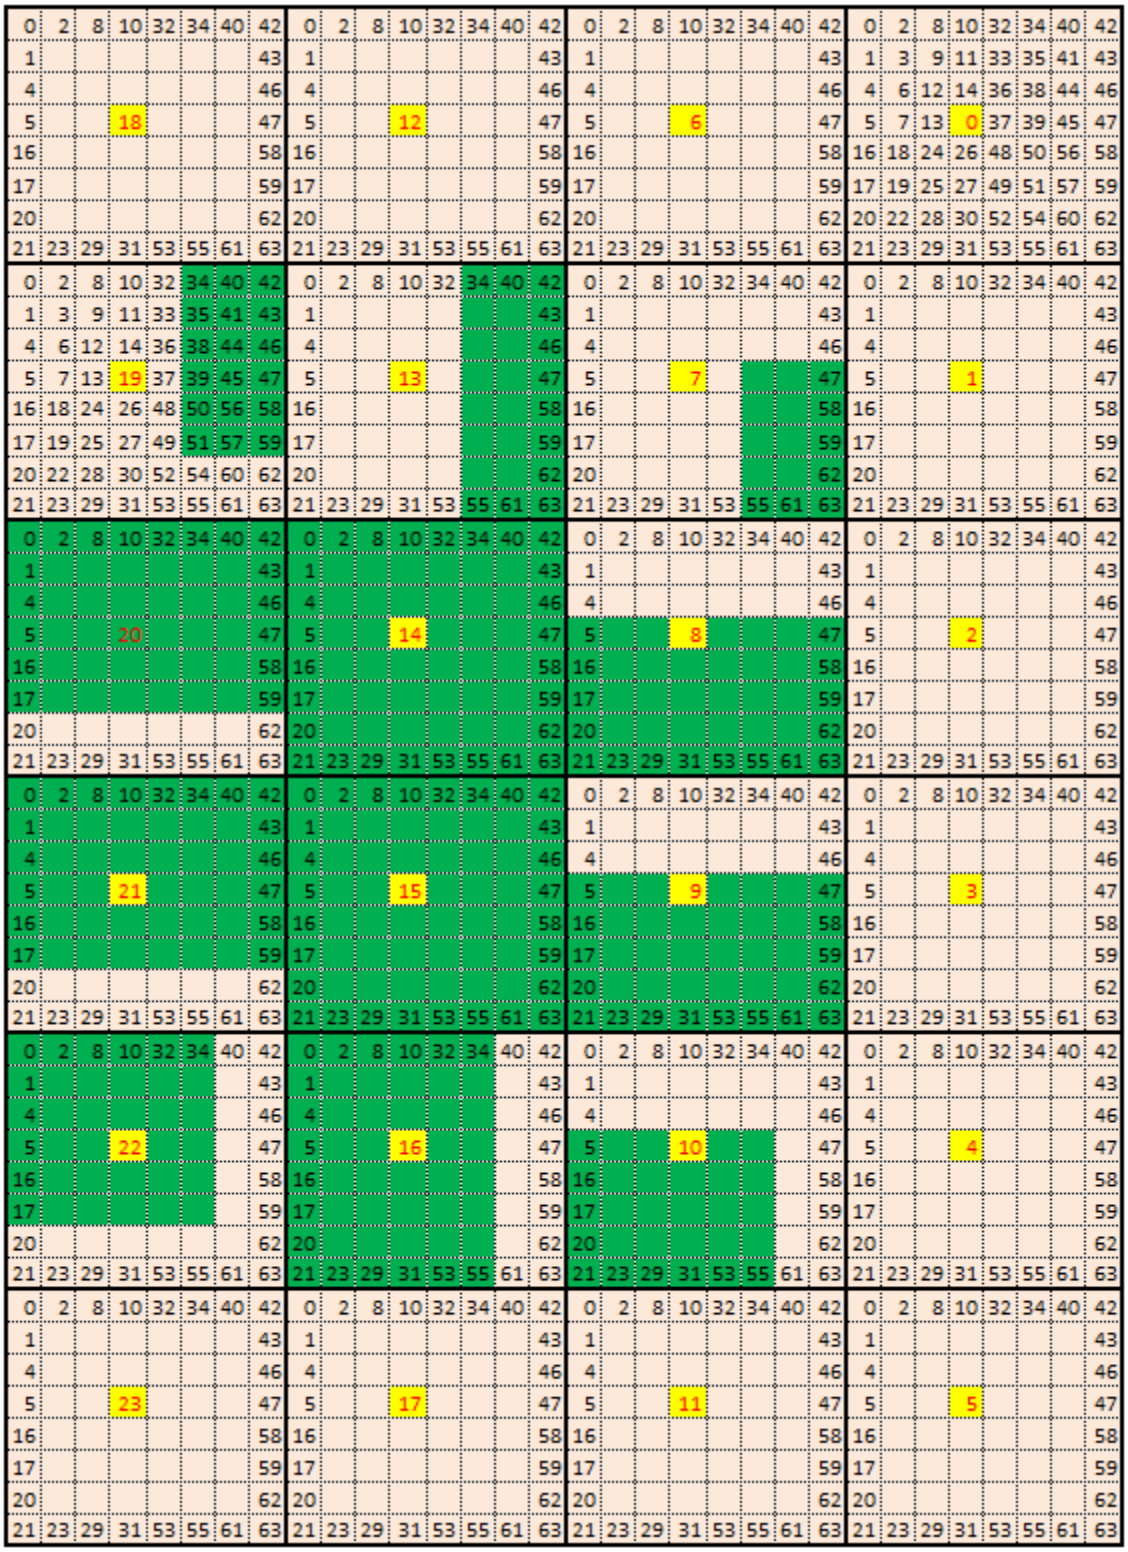
- Base address = New address (remapped GTT)
- Stride = Surface height in tiles
- Plane Width = Plane Height
- Plane Height = Plane Width
- X offset = (Surface height in tiles * tile height) - Plane Y offset - Plane Height *[Note: the calculated X offset will always be >= 0 since Plane Y Offset + Plane Height <= Surface Height in lines]*

- Y offset = X offset
- Driver can enable the Scaler, as needed, to fit the rotated content in to the pipe active display area.

Sample surface in frame buffer (Yf tiled)



Page access sequence in the rotated 90 mode



Example

Let us assume the following display programming for a single pipe – single plane, Yf tiled, non-rotated, 1920 x 1200, 4Bpp with the plane panned (100, 150), covering full active area and scaler not enabled.

GTT mapping

Here is a sample GTT mapping for 90 rotation mode.

Original GTT

Assumed Surface base = 0x200000

0x200000 = page 0

0x201000 = page 1

0x202000 = page 2

0x203000 = page 3

…

Remapped Display GTT – 90 rotation

Assumed new Surface base = 0x400000

0x400000 = page 18

0x401000 = page 12

0x402000 = page 6

0x403000 = page 0

Register programming for non-rotated scenario

- *PLANE_SURF->Surface Base Address = 0x200000*
- *PLANE_STRIDE->Stride = 60* [(1920 * 4)/128] [(width *bpp)/tile width]
- *PLANE_SIZE->Width = 1920*
- *PLANE_SIZE->Height = 1200*
- *PLANE_OFFSET->Start X Position = 100*
- *PLANE_OFFSET->Start Y Position = 150*
- *Surface Height in tiles (assumed) = 50 (allocated surface height in number of scan lines/tile height. For plane height = 1200, the surface height should be a minimum of 38 tiles (ceiling (1200/32). When panning is used, the rendered frame buffer surface will be larger than the plane size. Here, let us assume that the rendered surface height in tiles = 50).*

The programming changes to following for a 90 rotation scenario

- *PLANE_SURF->Surface Base Address = 0x400000* [uses remapped GTT]
- *PLANE_STRIDE->Stride = 50* [Surface height in tiles (assumed earlier)]
- *PLANE_SIZE->Width = 1200* [non-rotated Height]

- *PLANE_SIZE->Height* = *1920* [non-rotated Width]
- *PLANE_OFFSET->Start X Position* = *250* [(50*32)-150-1200] [(Surface height * tile height) – non rotated Y position – non rotated Height]
- *PLANE_OFFSET->Start Y Position* = *100* [non-rotated X position]

The scaler should be programmed appropriately to fit the rotated plane in the pipe active area and the window position should be adjusted if it is desired to maintain the same apparent position on a physically rotated display.

270 rotation

Uses the same GTT remapping and register programming as 90 rotation mode with the Plane control register rotation mode set as 270.

Display Buffer Programming

This topic describes display buffer allocation and shows a basic allocation method for single and multi-pipe modes. The display driver can choose to use more advanced allocation techniques as desired.

Display Buffer Allocation

Allocation of the display buffer is programmable for each display plane, using the buffer start and buffer end values in PLANE_BUF_CFG_.

Proper display buffer allocation is important for Display hardware to function correctly. Optimal allocation provides better display residency in memory low power modes. Display Buffer allocation must be recalculated and programmed when pipes/planes get enabled or disabled.

Display Buffer Size

Display Buffer Size	Total Display Buffer Blocks	Fixed Bypass Path Allocation in Blocks	Blocks Available for Driver Programming
448 KB	896	4	0 - 891

Each display buffer block is 8 cache lines.

Allocation Requirements

Allocation must not overlap between any enabled planes.

A minimum allocation is required for any enabled plane. See Minimum Allocation Requirements below.

A gap between allocation for enabled planes is allowed.

The allocation for enabled planes should be as large as possible to allow for higher watermarks and better residency in memory power saving modes.

Minimum Allocation Requirements

Allocation for each enabled plane must meet these minimum requirements.

Planes using Linear or X tiled memory formats must allocate a minimum of 8 blocks.

Planes using Y tiled memory formats must allocate blocks for a minimum number of scanlines worth of data. The formula and table of minimum scanlines is below.

Y tiled minimum allocation = Ceiling [(4 * Plane source width * Plane Bpp)/512] * MinScanLines/4 + 3

	Minimum Scanlines for Y Tile	
Plane Bpp	0/180 Rotation	90/270 Rotation
1	8	32
2	8	16
4	8	8
8	8	4

Basic Allocation Method

These are basic methods that can be used for single and multi-pipe modes. For optimal power usage, the display driver can choose to use more advanced allocation techniques as desired.

Single Pipe

Allocate a fixed number of blocks to cursors and then allocate the remaining blocks among planes, based on each plane's data rate.

BlocksAvailable = TotalBlocksAvailable

1. Allocate 32 blocks for cursor

The driver frequently enables and disables the cursor or changes the cursor pixel format. Fixed allocation is preferred for cursor to minimize the buffer re-allocation. More allocation might be required to support deeper low power states (based on the results of watermark calculations).

CursorBufAlloc = 32

BlocksAvailable = BlocksAvailable – 32

2. Check for minimum buffer requirement

For each enabled plane

If Y tiled

MinScanLines = Look up minimum scanlines needed from the table

*PlaneMinAlloc = Ceiling [(4*Plane width*Bpp)/512] * MinScanLines/4 + 3*

Else

PlaneMinAlloc = 8

If sum of PlaneMinAlloc > BlocksAvailable

Error - Display Mode can't be supported.

The driver can change the number of enabled planes or the plane configuration and rerun the algorithm.

3. Calculate Relative Data Rate for planes

In this step the driver may want to use the expected maximum plane source sizes so it does not have to reallocate for a plane that is changing size.

For each enabled plane

If PlaneScalerEnabled

*PlaneScaleFactor = (Plane width/Scaler window X size) * (Plane height/Scaler window Y size)*

Else

PlaneScaleFactor = 1

*PlaneRelativeDataRate = Plane height * Plane width * plane source bytes per pixel * PlaneScaleFactor*

4. Allocate blocks for enabled planes as per the Data rate ratio.

For each plane that needs allocation (PlaneBlockAllocFinal == false)

*PlaneBufAlloc = floor (BlocksAvailable * PlaneRelativeDataRate/Sum of PlaneRelativeDataRate of all planes that need allocation).*

*floor - rounds down to an integer value dropping the fractional part.

5. Adjust for minimum allocation requirement

AdjustmentRequired = false

For each plane needs allocation (PlaneBlockAllocFinal == false)

If PlaneBufAlloc < PlaneMinAlloc

AdjustmentRequired = true

PlaneBufAlloc = PlaneMinAlloc

PlaneBlockAllocFinal = true

BlocksAvailable = BlocksAvailable - PlaneMinAlloc

If AdjustmentRequired = true

Go back to step 4

Multi-Pipe

NumPipes = Total number of display pipes in the hardware

Allocate a fixed number of blocks to cursors, allocate *1/NumPipes* of the remaining blocks to each pipe, then calculate each pipe individually as in the Single Pipe case.

1. Allocate 8 blocks for cursor per pipe

The driver frequently enables and disables the cursor or changes the cursor pixel format. Fixed allocation is preferred for cursor to minimize the buffer re-allocation. More allocation might be required to support deeper low power states (based on the results of watermark calculations).

For each enabled cursor

CursorBufAlloc = 8

*BlocksAvailable = TotalBlocksAvailable - (8 * NumPipes)*

2. Distribute the blocks equally among the pipes

   BlocksAvailable = BlocksAvailable/NumPipes

3. Assign blocks to the planes

   For each pipe

Perform Single Pipe sequence, starting from step 2.

Buffer allocation re-distribution

When an additional pipe is getting enabled, or an existing pipe requires more buffer to support a new mode or is disabled, buffer reallocation may be necessary for proper display functionality. Whenever a portion of the allocated buffer is taken away from one pipe and allocated to a different pipe, the following sequence should be followed to make sure that there are no buffer allocation overlaps at any point of time.

1. *For each pipe whose allocation is reduced*
   a. *Program the new buffer allocation.*
   b. *Wait for VBlank of that pipe for new allocation to update.*
2. *For each pipe whose allocation is increased*
   a. *Program the new buffer allocation.*
   b. *Wait for VBlank of that pipe for new allocation to update.*

Display Buffer Allocation and Watermark programming prior to OS boot

Basic programming of the display buffer and watermarks to allow limited display usage prior to OS boot:

This will prevent package power saving states from enabling.

Supported usages:

- Up to 3 pipes enabled at once
- Up to one universal plane enabled per pipe. No cursor.
- Linear or Xtile memory
- Any RGB frame buffer pixel format 32bpp or less, without render compression
- Any screen resolution
- Downscaling less than or equal to 12.5%

Allocate 160 blocks per pipe.

Pipe A: 0-159, Pipe B: 160-319, Pipe C: 320-479

PLANE_BUF_CFG_<plane number>_A = 0x009F0000

PLANE_BUF_CFG_<plane number>_B = 0x013F00A0

PLANE_BUF_CFG_<plane number>_C = 0x01DF0140

Set level 0 watermarks for any enabled plane to 160 blocks and 2 lines.

PLANE_WM_<plane number>_<pipe>_0 = 0x800080A0

The higher level watermarks for any enabled plane must have bit 31=0 to keep the low power watermarks disabled.

strm_clk is the stream clock, which is the video pixel rate or dot clock.

cdclk is the core display clock.

The link only operates in Synchronous Clock mode. The link clock and stream clock are synchronous and the link M and N values stay constant for a given pixel rate.

Calculation of TU:

TU is the Transfer Unit.

TU size calculation (applies to SST only)

TU size for reduced blanking cases may vary and the following formula should be used in such cases.

TU size = MIN(INT((Horizontal Blank Width * ls_clk/strm_clk)-2), 64)

Example 1:

ls_clk = 810 MHz

strm_clk = 1025.766 MHz

Horizontal Blank = 80 pixels (Reduced Blanking v2 timings)

Calculated TU size = MIN(INT(63.1-2),64) = 61

Actual TU size = 61

So, in this example TU size becomes 61.

Example 2:

ls_clk = 810 MHz

strm_clk = 923.221 MHz

Horizontal Blank = 80 pixels (Reduced Blanking v2 timings)

TU size = MIN(INT(70.18-2),64) = 64

Calculation of Data M, and Data N:

Note that for 4:2:0 format the number of bytes per pixel will be half the number of bytes of RGB pixel.

Active/TU Size = Payload/Capacity = Data M/N

Compression Ratio (CR) = DisplayPort Compression enabled ? min(ratio1,ratio2) : 1

- ratio1 = Compressor BW / Link BW = (cdclk * bytes per pixel) / (ls_clk * number of lanes)
- ratio2 = (Horizontal active in pixels * bytes per pixel / 4) / ((Horizontal active in pixels * bytes per pixel / 8) +2)

Data M/N = (strm_clk * bytes per pixel) / (CR * ls_clk * number of lanes)

Calculation of Link M and Link N:

Link M/N = strm_clk / ls_clk

Restriction on clocks and number of lanes:

- Number of lanes >= INT(strm_clk * bytes per pixel / ls_clk)

Restrictions on the Virtual Channel (VC) payload size in DisplayPort MST mode

- In a x1 lane config, each pipe stream on the link must use a VC payload size that is a multiple of 4.

- In a x2 lane config, each pipe stream on the link must use a VC payload size that is a multiple of 2.
- In a x4 lane config, each pipe stream on the link must use a VC payload size that is a multiple of 1.

Transcoder Video Data Island Packet

Data Island Packet (DIP) is a mechanism that allows data to be sent over a digital port during blanking, according to the HDMI and DisplayPort specifications. This includes header, payload, checksum, and ECC information.

Each type of Video DIP will be sent once each frame while it is enabled.

HB = Header Byte, DB = Data Byte, RO = Read Only

The audio subsystem is also capable of sending Data Island Packets. These packets are programmed by the audio driver and can be read by in MMIO space via the audio control state and audio HDMI widget data island registers.

Video DIP data write sequence:

1. Wait for 1 VSync to ensure completion of any pending video DIP transmissions
2. Disable the video DIP being updated (disable VDSC before updating PPS DIP)
3. Program video DIP data buffer registers for DIP being updated
4. Enable the video DIP

The video DIP data and ECC buffers may be read at any time.

DIP data buffer registers must be programmed with valid data before enabling the DIP.

Partial DIPs are never sent out while the port is enabled. Disabling the DIP at the same time it is being transferred will result in the DIP being completed before the function is disabled.

Shutting off the port on which DIP is being transmitted will result in partial transfer of DIP data. There is no need to switch off the DIP enable bit if the port transmitting DIP is disabled.

When disabling both the DIP port and DIP transmission, first disable the port and then disable DIP.

Enabling a DIP function at the same time that the DIP would have been sent out (had it already been enabled) will result in the DIP being sent on the following frame.

For HDMI, even if no DIP is enabled, a single Null DIP will be sent at the same point in the stream that DIP packets would have been sent.

TRANS_MSA_MISC

Panel Self Refresh

This section is about Panel Self Refresh (PSR). PSR1 at one point was named Self Refreshing Display (SRD).

PSR1 enable sequence:

- Prerequisite: The associated transcoder and port are running.

1. Configure FBC host and render tracking. The FBC function does not need to be enabled in FBC_CTL.
2. Program Transcoder EDP VSC DIP data with a valid setting for SRD/PSR.
3. Configure and enable SRD_CTL.

PSR1 disable sequence:

- Prerequisite: The associated transcoder and port are running.

1. Disable SRD_CTL.
2. Wait for SRD_STATUS to show SRD is Idle. This will take up to one full frame time (1/refresh rate), plus SRD exit training time (max of 6ms), plus SRD aux channel handshake (max of 1.5ms).

PSR2 disable sequence:

1. Program PSR2_CTL reset Psr2Enable, SelectiveUpdateTrackingEnable bits.
2. Disable GTC if required.
3. Wait for PSR2_STATUS to show PSR2 is Idle. This will take up to one full frame time (1/refresh rate), plus exit training time (max of 6ms), plus aux channel handshake (max of 1.5ms).

Transcoder Port Sync

Feature Description

PORT SYNC is a transcoder level feature. This mode forces two or more transcoders to be in sync with one transcoder master and one or more transcoder slaves. In the case of DP/eDP, the master is unaware that it is operating in Port Sync mode. Only the slave is aware that it is operating in this mode. Hence, port sync mode is only enabled in the slave transcoder.

DP/eDP Port Sync Restrictions

1. The slave and master transcoders and associated ports must have identical parameters and properties.
2. They must be connected to the same PLL, have the same color format, link width (number of lanes enabled), resolution, refresh rate, dot clock, TU size, M and N programming, etc.
3. Port Sync Mode must only be enabled with DisplayPort SST.
4. PSR would need to be disabled when port sync mode is enabled.
5. Port Sync Mode Master Select must be programmed with a valid value when Port sync Mode is enabled.

Audio

This section describes Audio features.

Audio Bios Programming Sequence

Codec Verb Table

For each codec present on the High Definition Audio codec link, a corresponding pre-defined “Codec Verb Table” must be available to System BIOS. The Codec Verb Tables are based on codec specific information (coded datasheet) and platform design specific information (schematics) and are built by System BIOS writers and platform designers. The table contains a list of 32-bit “Verb”s (command and data payload) to be sent to the corresponding codec over the High Definition Audio codec link.

Below is a sample High Definition Audio Codec Verb Table for a platform with 1 codec at codec address 01h.

;Sample HIGH DEFINITION AUDIO Codec Verb Table

;Codec Address (CAd) = 02h

;Codec Vendor: XYZ Company

;VenID DevID:

```
    dd 12345678h
;-----------------------------------------------------
; FrontPanel_Supported?   ; 1=Supported ,0=Not supported
    db  01h
; # of Rear Panel Pin Complexes
   dw 000Ch
; # of Front Panel Pin Complexes
dw 0002h
;-----------------------------------------------------
```

Note: Set the bit 15 of register offset 0x65F10h of the Display Audio offset. Wait for the Codec to generate the wake event to the controller.

Follwing verbs should be send to the codec using the PIO method described in the below sections 9.1.3.

VerbTable0:

```
    ;Enable the third converter and Pin first (NID 08h)
     dd 20878101h
       //
// Audio Verb Table - 0x80862805
//
// Pin Widget 5 - PORT B
0x20571C10,
0x20571D00,

0x20871F18

;disable the third converter and third Pin (NID 08h - upto gen9)

dd 20878100h

Codec Initialization Programming Sequence

After System BIOS has determined the presence of High Definition Audio codecs, it must follow the programming sequence below to update the codec with the correct jack information specific to the platform for the High Definition Audio driver to retrieve and use later.

There are two ways to send verbs to and receive response data from codecs over the High Definition Audio codec link: using CORB/RIRB (Command Output Ring Buffer / Response Input Ring Buffer) or using the Immediate Command/Immediate Response register pair. The sequence below uses the latter which does not require the availability of a memory buffer.

System BIOS should ensure that the High Definition Audio HDBAR D27:F0:10-17h contains a valid address value and is enabled by setting D27:F0:04h[1]. System BIOS must ensure program as mentioned in section 9.6, and then the Controller Reset# bit of Global Control register in memory-mapped space (HDBAR+08h[0]) is set to 1b and read back as 1b. Additional delay might be required to allow codec coming out of reset prior to subsequent operations, please contact your codec vendor for detail. When clearing this bit and setting it afterward, BIOS must ensure that minimum link timing requirements (minimum RESET# assertion time, etc.) are met.

Note: To initialize codec Bios should set the bit 15 of the register 0X65F10h of the Display MMIO to 1. This bit needs to be after the controller is brought out of reset. BIOS should wait for Controller to detect the wake event and recognize the Codec.

For each High Definition Audio codec present as indicated by HDBAR + 0Eh[3:0], System BIOS should perform the codec initialization as described below:

1. Read the VendorID/DeviceID pair from the attached codec.

- Verify that the ICB bit, HDBAR + 68h[0], is 0.
- Write verb 200F0000h (dword) to the IC register, HDBAR + 60h, where: ‘2’ (bits 31:28) represents the codec address (CAd).
- Program HDBAR + 68h[1:0] to 11b to send the verb to the codec.

- Poll the ICB bit, HDBAR+68h[0] until it returns 0 indicating the verb has been sent to the codec. BIOS may write HDBAR + 68h[0] to a 0 if the bit fails to return to 0 after a reasonable timeout period.
- If HDBAR + 68h[1] = 1b indicating the response data from the codec is now valid, read HDBAR + 64h; the data is the VID/DID value returned by the codec.

2. Check against internal list to determine if there is a stored verb table which matches the CAd/VID/DID information.

Steps 1 and 2 are System BIOS implementation-specific steps and can be done in different ways. If a System BIOS has prior knowledge of a fixed platform/codec combination (e.g., for a System BIOS having 3 stored verb tables for 3 known codecs at known codec addresses on a known platform), a simple pre-defined codec-to-table matching can be used and steps 1 and 2 can be eliminated. For a System BIOS to support multiple codec/platform combinations, an internal match-list might be needed to match a platform/codec combination to a codec verb table.

3. If there is a match, send the entire list of verbs in the matching verb table one by one to the codec.

- Verify the ICB bit, HDBAR + 68h[0] is 0.
- Write the next verb (dword) in the table to HDBAR + 60h.
- Program HDBAR + 68h[1:0] to 11b to send the verb to codec.
- Poll the ICB bit, HDBAR + 68h[0] until it returns 0 indicating the verb has been sent to the codec. BIOS may write HDBAR + 68h[0] to a 0 if the bit fails to return to 0 after a reasonable timeout period.
- Repeat the steps until all the verbs in the table have been sent.

Some verbs in the table may be dependent on certain platform-specific conditions. For example, for the sample table above, the verbs for Pin Complex 7 and 8 (NID=14,16 respectively) should be sent only if the Front Panel Jacks are present and connected on the platform, which may be indicated by a software flag that is controlled by a certain GPIO pin.

Audio Programming Sequence for Link wakeup

The following audio programming sequences are to be used for preventing the Unsolicited responses when 3 pin link is awake.

Display Audio codec generates a wake event whenever the power well (PGx - power well in which Display Audio codec HW resides) is powered up. If the link is already running, this wake event is considered as unsolicited response by audio controller in PCH. This may sometimes be considered as unnecessary URs. To avoid such URs following programming should be followed by SW. This sequence assumes communication between Audio and GFX drivers without HW to indicate Audio codec power well status.

Power down sequence:

1. Unplug event
2. PD goes low

3. PG2 low

4. Audio link should go low (there should be a communication between GFX driver and Audio Driver to turn off the link)

    1. To turn off iDisp-A link:
    2. Power off iDisp-A codec. Follow the PW2 turn off sequence.
    3. In HD Audio Controller (PCH) Program LCTL1.SPA = 0.
    4. Wait for LCTL1.CPA = 0 to indicate the link has clock stopped.

Power up sequence:

1. Plug event

2. PG2 goes high

3. Audio link to be enabled (there should be a communication between GFX driver and Audio Driver to turn on the link)

    1. To turn on iDisp-A link:
    2. In HD Audio Controller (PCH) Program LCTL1.SPA = 1.
    3. Wait for LCTL1.CPA = 1 to indicate the link has clock running.

4. Check WAKESTS[2] = 1 to indicate the codec wake up occurs

5. PD bit set

6. Codec awake. Continue with codec init.

Audio Programming Sequence

The following HDMI and DisplayPort audio programming sequences are to be used when enabling or disabling audio or temporarily disabling audio during a display mode set.

The audio codec and audio controller disable sequences must be followed prior to disabling the transcoder or port in a display mode set.

The audio codec and controller enable sequences can be followed after the transcoder is enabled and the port is enabled and completed link training (not sending training or idle patterns if DisplayPort).

The audio controller and audio codec sequences may be done in parallel or serial. In general, the change in ELDV/PD in the codec sequence will generate an unsolicited response to the audio controller driver to indicate that the controller sequence should start, but other mechanisms may be used. SW should make sure to set the Inactive (IA) bit to 0 before setting PD to 1.

Audio codec disable sequence:

- Disable sample fabrication

    - Set AUD_MISC_CTRL Sample_Fabrication_EN (bit 2) to "0".
- Disable timestamps
    - Set AUD_CONFIG N_value_index (bit 29) to "0" for HDMI or "1" for DisplayPort.
    - Set N_programming_enable (bit 28) to "1"
    - Set Upper_N_value and Lower_N_value (bits 27:20, 15:4) to all "0"s.
- Disable ELDV and ELD buffer
    - Set AUD_PIN_ELD_CP_VLD ELD_valid (bit 0, 4, or 8 based on which port is used) to "0"
- Wait for 2 vertical blanks
- Optional: Disable audio PD (Presence Detect)
    - Software may choose to skip this in order to keep PD enabled during a resolution switch.
    - Set AUD_PIN_ELD_CP_VLD Audio_Inactive (bit 3, 7, or 11) to "1". SW does not need to set this bit to enable Inactive bit.
    - Set AUD_PIN_ELD_CP_VLD Audio_Output_Enable (bit 2, 6, or 10) to "0".

Audio controller disable sequence:

- Program Stream ID to 0 - Verb ID 706
- Disable audio info frames transmission - Verb ID 732
- Disable Digen - Verb ID 70D
- Program the codec to D3 state if needed.
- Audio driver may stop the audio controller DMA engine at this point if needed, but not required.

Audio codec enable sequence:

- Enable audio Presence Detect
    - Set AUD_PIN_ELD_CP_VLD Audio_Inactive (bit 3, 7, or 11) to "0".
    - Set AUD_PIN_ELD_CP_VLD Audio_Output_Enable (bit 2, 6, or 10) to "1".
- Wait for 1 vertical blank
- Load ELD buffer and Enable ELDV
    - Set AUD_PIN_ELD_CP_VLD ELD_valid (bit 0, 4, or 8 based on which port is used) to "1".
- Enable timestamps
    - Set AUD_CONFIG N_value_index (bit 29) to "0" for HDMI or "1" for DisplayPort.
    - Set N_programming_enable (bit 28) to "0".
    - Program Upper_N_value and Lower_N_value (bits 27:20, 15:4) if a non-default N value is needed.
- Enable sample fabrication if this feature is needed
    - Set AUD_MISC_CTRL Sample_Fabrication_EN (bit 2) to "1".

Audio controller enable sequence:

- Program the codec to D0 state if in D3 state.

- Program Stream ID to non zero - Verb ID 706
- Enable audio info frames transmission - Verb ID 732
- Enable Digen - Verb ID 70D
- If audio controller DMA engine is stopped, audio driver can start the DMA engine at this point.

Digital Display Interface

DDI Buffer

There is one instance of these registers per each DDI.

DDI_BUF_CTL

DDI_BUF_TRANS

DISPIO_CR_TX_BMU_CR0

DDI_BUF_TRANS and DISPIO_CR_TX_BMU_CR0 are programmed with the voltage swing values for each port. They can be configured in advance of the display mode set. The recommended values are listed below.

For DisplayPort, DDI_BUF_CTL is programmed during the mode set to select between the voltage swings pre-programmed in DDI_BUF_TRANS.

HDMI always uses the voltage swing programmed in DDI_BUF_TRANS entry 9.

I_boost

I_boost increases the I/O current, boosting the swing level. There are three I_boost values, in order of increasing boost; 0x1, 0x3, and 0x7.

I_boost can be configured separately for each port and can be enabled or disabled separately for each voltage swing level.

I_boost is configured by programming DISPIO_CR_TX_BMU_CR0 tx_blnclegdisbl=0x00 and tx_blnclegsctl_<selected DDI>=<I_boost value; 0x1, 0x3, or 0x7>. It is then enabled when DDI_BUF_CTL selects a voltage swing entry that has DDI_BUF_TRANS_<entry> Balance Leg Enable=0x1. For DDIA with x4 capability (DDI_BUF_CTL DDIA Lane Capability Control = DDIA x4), the I_boost value has to be programmed in both tx_blnclegsctl_0 and tx_blnclegsctl_4.

The recommended buffer translation programming only uses I_boost for a few entries. A customer may request increased I_boost beyond the recommended values by specifying an I_boost value of 0x1, 0x3, or 0x7 to be applied to all swing entries for a port, then software needs to configure I_boost to that specified value and set DDI_BUF_TRANS_<all entries> Balance Leg Enable=0x1 for that port. This selection overrides the recommended I_boost settings.

Programming Note	
Context:	DDI Buffer
KBL re-uses SKL values, except where specific KBL values are listed.

DDI AUX Channel

DDI_AUX_CTL

DDI_AUX_DATA

DDI_AUX_MUTEX

AUX programming sequence

A general purpose AUX functional programming sequence is provided below.

AUX Functional Sequence

Step	Description	Register	Notes
1	Display must already be initialized.		Power well1 enabled cdclk enabled IO powered up as needed for Aux on this project
1b	Power well containing Aux logic powered up	PWR_WELL_CTL	High level power well partitioning shown in display overview diagram
2	Disable DC5 and DC6 before a DDI A AUX channel transaction is sent.	DC_STATE_EN	PG1 may disable automatically for DC5 or DC6.
Skip step 3, 4 if PSR1/SRD, PSR2 or GTC are NOT enabled. Do not skip step 3,4 if PSR1/SRD, PSR2 or GTC are enabled.			
3	Enable MUTEX without changing MUTEX status	DDI_AUX_MUTEX[31]='1'	
4	Read MUTEX status	DDI_AUX_MUTEX[30]	If MUTEX status is '1', wait for 500 us and poll for MUTEX status == '0'.
5	Program AUX data registers.	DDI_AUX_DATA_*_[0-4]	
6	Program control to configure AUX and START transaction.	DDI_AUX_CTL_*	Timeout timer value must be at least 600us. Timer values: 0: 400us 1: 600 us 2: 800 us 3: 1600 us START trigger: DDI_AUX_CTL_*[31]='1'
7	Wait for AUX transaction complete.		AUX Transaction complete interrupt if set OR when DDI_AUX_CTL_*[31:30] = '01'.
8	Check that receive data has no errors	DDI_AUX_CTL_*[25]	If set: write a '1' to clear this bit and skip reading AUX data registers.
9	Read AUX data register	DDI_AUX_DATA_*_[0-4]	Condition: Aux Channel Control Register Send/Busy bit is NOT asserted
10	Clear status flags	DDI_AUX_CTL_*[30]	Transaction done status

Step	Description	Register	Notes
Skip step 11 if PSR1/SRD, PSR2 or GTC are NOT enabled. Do not skip step 11 if PSR1/SRD, PSR2 or GTC are enabled.			
11	Release MUTEX	DDI_AUX_MUTEX[31:30]= "11" OR DDI_AUX_MUTEX[31:30]="01"	Release with (is optional) or without disabling MUTEX function.

DisplayPort Transport

There is one instance of these registers per each DDI.

GTC Target Frequency Selection

For GTC top level logic, CDCLK is taken as an input and scaled to a "target frequency" which has a period which is an exact multiple of 0.5ns. This period is also known as the accumulator increment.

Once a target frequency + accumulator increment is selected, an M and N value can be picked and fine tuned to achieve the scaling from CDCLK to target frequency.

In order for the accumulated GTC Live value to match exactly with the real passage of time, the following must be true:

The target frequency selected must be the CLOSEST possible selection to CDCLK. This corresponds to rounding the accumulator increment to the NEAREST 0.5ns increment with respect to the period of CDCLK.

Example

	Frequency	Period
Given CDCLK	337.500 MHz	2.96 ns
1st closest target frequency/increment	333.333 MHz	3.00 ns
2nd closest target frequency/increment	400.000 MHz	2.50 ns
3rd closest target frequency/increment	285.714 MHz	3.50 ns
4th closest target frequency/increment	500.000 MHz	2.00 ns

Only using the 1st closest target frequency 333.333MHz / accumulator increment of 3.00 ns will result in the GTC Live Value correctly tracking the real passage of time.

Example Calculation Flow:

1. Find the period of CDCLK -- for 337.5 MHz = 2.96 ns.
2. Round to the nearest 0.5 ns -- 3.00 ns (this is your accumulator increment value).
3. Find the “target frequency” from the rounded period value of step 2 -- 333.333 MHz is the “target frequency”.
4. Find the ratio of target frequency / CDCLK = 0.987654321.
5. Choose M and N to satisfy M / N = same ratio as step 4.

South Display Engine Registers

The South Display Engine supports Hot Plug Detection, GPIO, GMBUS, Panel Power Sequencing, and Backlight Modulation.

Terminology

Access Field	Description	Should be implemented as
R/W (Read/Write)	The value written into this register will control hardware and is the same value that will be read.	Write data is stored. Read is from the stored data. Stored value is used to control hardware.
Reserved	Unused register bit. Don't assume a value for these bits. Writes have no effect.	Write data is ignored. Read is zero.
MBZ (Must Be Zero)	Always write a zero to this register.	May be implemented as Reserved or as R/W.
PBC (Preserve Bit Contents)	Software must write the original value back to this bit. This allows new features to be added using these bits.	May be implemented as Reserved or as R/W.
Read Only	The read value is determined by hardware. Writes to this bit have no effect.	Write data is ignored. Read is from a status signal or some other internal source.
Write Only	The value written into this register will control hardware. Reads return zero.	Write data is stored. Read is zero. Stored value is used to control hardware.
R/W Clear (Read/Write Clear)	Sticky status bit. Hardware will set the bit, software can clear it with a write of 1b.	Internal hardware events set a sticky bit. Read is from the sticky bit. A write of 1b clears the sticky bit.
Double Buffered	Write when desired and the written value will take effect at the time of the double buffer update point. Reads will return the written value, which is not necessarily the value being currently used to control hardware. Some have a specific arming sequence where a write to another register is required before the update can take place. This is used to ensure atomic updates of several registers.	Two stages of registers used. Write data is stored into first stage. Read is from the first stage stored data. First stage stored value is transferred to second stage storage at the double buffer update point. Second stage stored value is used to control hardware. Arm/disarm logic may be used for some registers to control the double buffer update point.
Write/Read Status	The value written into this register will control hardware. The read value is determined by hardware.	Write data is stored. Stored value is used to control hardware. Read is from a status signal or some

Access Field	Description	Should be implemented as
		other internal source.

Shared Functions

Backlight

This section refers to the PCH display backlight control. For CPU display backlight control, see North Display Engine Registers.

The backlight PWM output frequency is determined by the PWM clock frequency, increment, and frequency divider.

PWM output frequency = PWM clock frequency / PWM increment / PWM frequency divider

The frequency divider minimum must be greater than or equal to the number of brightness levels required by software; typically 100 or 256.

Description
PWM clock frequency = 24 MHz PWM increment = 128 or 16, selectable by software PWM frequency divider maximum = 65,536 PWM output frequency range with 100 brightness levels and increment 128 = 3 to 1,875 Hz PWM output frequency range with 100 brightness levels and increment 16 = 23 to 15,000 Hz PWM output frequency range with 256 brightness levels and increment 128 = 3 to 732 Hz PWM output frequency range with 256 brightness levels and increment 16 = 23 to 5,859 Hz
PWM clock frequency = Raw clock frequency = 19.2, 24, or 38.4 MHz. Value is found in SFUSE_STRAP. PWM increment = 1 PWM frequency divider maximum = 2^32 PWM output frequency range with 100 brightness levels and 19.2 MHz clock = 0.0004 to 192,000 Hz

Description
PWM output frequency range with 100 brightness levels and 24 MHz clock = 0.0006 to 240,000 Hz
PWM output frequency range with 100 brightness levels and 38.4 MHz clock = 0.0009 to 384,000 Hz
PWM output frequency range with 256 brightness levels and 19.2 MHz clock = 0.0004 to 75,000 Hz
PWM output frequency range with 256 brightness levels and 24 MHz clock = 0.0006 to 93,750 Hz
PWM output frequency range with 256 brightness levels and 38.4 MHz clock = 0.0009 to 150,000 Hz

Backlight Enabling Sequence

Description
1. Set frequency and duty cycle in SBLC_PWM_CTL2 Backlight Modulation Frequency and Backlight Duty Cycle.
2. Set granularity in 0xC2000 bit 0 (0 = 16, 1 = 128).
3. Enable PWM output and set polarity in SBLC_PWM_CTL1 PWM PCH Enable and Backlight Polarity.
...
4. Change duty cycle as needed in SBLC_PWM_CTL2 Backlight Duty Cycle.

If needed, granularity, polarity, and override can be programmed earlier than shown.

Backlight Registers

Description
SBLC_PWM_CTL1
SBLC_PWM_CTL2

GMBUS and GPIO

Registers

Description
GPIO_CTL - GPIO Control
GMBUS0 - GMBUS Clock/Port Select
GMBUS1 - GMBUS Command/Status
GMBUS2 - GMBUS Status
GMBUS3 - GMBUS Data Buffer
GMBUS4 - GMBUS Interrupt Mask
GMBUS5 - GMBUS 2 Byte Index

Pin Usage

These GPIO pins allow the support of simple query and control functions such as DDC interface protocols. The GMBUS controller can be used to run the interface protocol, or the GPIO pins can be manually programmed for a "bit banging" interface.

The following tables describe the expected GPIO pin to register mapping. OEMs have the ability to remap these functions onto other pins as long as the hardware limitations are observed. The GPIO pins may also be muxed with other functions such that they are only available when the other function is not being used.

Port #	Name	Pin	Pull up/down	Description
5	DDID CTLDATA	DDPD_CTRLDATA	No (Weak pull down on reset)	DDC for port D. Digital port D present strap is set if pin is 1 at rising edge of PCH_PWROK.
	DDID CTLCLK	DDPD_CTRLCLK	No	
4	DDIB CTLDATA	DDPB_CTRLDATA	No (Weak pull down on reset)	DDC for port B. Digital port B present strap is set if pin is 1 at rising edge of PCH_PWROK.
	DDIB CTLCLK	DDPB_CTRLCLK	No	
3	DDIC CTLDATA	DDPC_CTRLDATA	No (Weak pull down	DDC for port C. Digital port C present strap is set if pin is 1 at rising edge of PCH_PWROK.

			on reset)	
	DDIC CTLCLK	DDPC_CTRLCLK	No	

GPIO Programming for I2C Bit Bashing

To drive GPIO pin low, program direction to "out" and data value to "0", along with mask bits.

To drive GPIO pin high (tristate to allow external pull up to activate), program direction to "in", along with mask bit. No need to set data value to "1".

GMBUS Controller Programming Interface

The GMBUS (Graphic Management Bus) is used to access/control devices connected to the GPIO pins.

Basic features:

1. I²C compatible.
2. Bus clock frequency of 50 KHz or 100 KHz.
3. Attaches to any of the GPIO pin pairs.
4. 7-bit or 10-bit Slave Address and 8-bit or 16-bit index.
5. Double buffered data register and a 9 bit counter support 0 byte to 256 byte transfers.
6. Supports stalls generated by the slave device pulling down the clock line (Slave Stall), or delaying the slave acknowledge response.
7. Status register indicates error conditions, data buffer busy, time out, and data complete acknowledgement.
8. Detects and reports time out conditions for a stall from a slave device, or a delayed or missing slave acknowledge.
9. Interrupts may optionally be generated.
10. Does not directly support segment pointer addressing as defined by the Enhanced Display Data Channel standard.

Segment pointer addressing as defined by the Enhanced Display Data Channel standard:

1. Use bit bashing (manual GPIO programming) to complete segment pointer write **without terminating in a stop or wait cycle**.
2. Terminate bit bashing phase with both I²C lines pulled high by tri-stating the data line before the clock line. Follow EDDC requirement for response received from slave device.
3. Initiate GMBUS cycle as required to transfer EDID following normal procedure.

Sequence for GMBUS Burst Reads Greater Than 511 Bytes

- Not available until KBLPCH-H A0, SPT-LP D1, SPT-H E1

1. X=number of bytes to read.
2. Set byte count override bit GMBUS0 bit 6.
3. Set total byte count field in GMBUS1 to 511.
4. Read X bytes.
5. Issue GMBUS stop by writing 100b to GMBUS1 Bus Cycle Select.
6. Clear byte count override bit.

Example with 526 bytes

1. X=526.
2. Set byte count override bit GMBUS0 bit 6.
3. Set total byte count field in GMBUS1 to 511.
4. Read 526 bytes.
5. Write 100b to GMBUS1 Bus Cycle Select.

   Clear byte count override bit.

Display Watermark Programming

Watermark Overview

The display watermarks are used to control the display engine memory request behavior.

Description
The default settings of the watermark configuration registers will **not** allow the display engine to operate. The watermark values must be properly calculated and programmed in order to enable a display and achieve optimum power and performance. Incorrectly programmed watermark values can result in screen corruption.

The watermarks should be calculated and programmed when any of the watermark calculation inputs change. This includes planes enabling or disabling, plane source format or size changing, etc.

Besides programming the watermark registers, there are other display configuration requirements and registers that must be programmed in order for the display to operate in a low power mode, and there are memory controller configuration requirements which are not documented here.

Watermark Calculations

The display watermarks are calculated using information from the display configuration and memory latencies. The watermarks must be calculated and programmed before enabling a plane or changing a plane configuration.

For YUV 420 Planar formats, only the Y surface watermark value is calculated and programmed. Though the UV surface watermark value is not programmed seperately, it must be calculated to make sure that the UV buffer allocation satisfies the latency requirments.

The ceiling function rounds any non-integer value up to the next greater integer. Example: ceiling[0.3]=1, ceiling[2.1]=3, ceiling[4.8]=5, ceiling[4]=4

Watermark Algorithm

1. Retrieve memory latency values
    - See the Memory Values section to find the memory latency values
    - The memory values do not change after boot, so software may cache them to avoid re-reading
2. For each enabled pipe (run each time pipe configuration changes)
    A. Calculate adjusted pipe pixel rate
        I. Adjusted pipe pixel rate = pixel rate for the screen resolution
            - If there will be dynamic switching between refresh rates, either use the fastest pixel rate, or re-calculate using the current pixel rate when the refresh rate is switched
            - If plane 90 or 270 rotation is enabled, use the rotated width and height in pixel rate calculations.
        II. If TRANS_CONF Interlaced Mode == PF-ID, adjusted pipe pixel rate = adjusted pipe pixel rate * 2
        III. If pipe scaling enabled, adjusted pipe pixel rate = adjusted pipe pixel rate * pipe down scale amount
            - See the Scaling section to find the down scale amount
    B. Program WM_LINETIME Line Time = roundup[8 * pipe horizontal total pixels / adjusted pipe pixel rate MHz]
3. For each enabled plane (run each time pipe or plane configuration changes)
    A. Calculate adjusted plane pixel rate
        I. Adjusted plane pixel rate = adjusted pipe pixel rate
        II. If plane scaling enabled, adjusted plane pixel rate = adjusted plane pixel rate * plane down scale amount
            - See the Scaling section to find the down scale amount
    B. For each valid memory latency level

Plane Bytes per pixel	Minimum Scanlines for Y Tile	
	0/180 Rotation	90/270 Rotation
1 or NV12	4	16
2, P0xx, or YUV422	4	8
4	4	4
8	4	N/A

        I. Calculate method 1
            - Method 1 = memory latency microseconds * adjusted plane pixel rate MHz * plane source bytes per pixel / 512
        II. Calculate method 2

- plane bytes per line = plane source width pixels * plane source bytes per pixel
- Calculate plane blocks per line
  - If plane memory format is Linear
    - plane blocks per line = ceiling[plane bytes per line / 512] + 1
  - Else If plane memory format is Y tile
    - plane blocks per line = ceiling[Minimum Scanlines for Y tile * plane bytes per line / 512]/Minimum Scanlines for Y tile
  - Else
    - plane blocks per line = ceiling[plane bytes per line / 512]
- Method 2 = ceiling[(memory latency microseconds * adjusted plane pixel rate MHz) / Pipe horizontal total number of pixels] * plane blocks per line

III. Calculate Y tile minimum

- Y tile minimum = Minimum Scanlines for Y tile * plane blocks per line

IV. Select the watermark result

- If plane memory format is X tile or linear
  - If (((plane source bytes per pixel * pipe horizontal total number of pixels) / 512) < 1) AND ((plane bytes per line / 512) < 1) // Special case for unrealistically small horizontal total
    - Selected Result Blocks = Method 2
  - Else If (plane buffer allocation / plane blocks per line) >=1
    - Selected Result Blocks = minimum[Method 1, Method 2]
  - Else
    - Selected Result Blocks = Method 1
- Else // Y tile
  - Selected Result Blocks = maximum[Method 2, Y tile minimum]
-

V. Convert result to blocks and lines

- Result Blocks = ceiling[Selected Result Blocks] + 1
- Result Lines = ceiling[Selected Result Blocks / plane blocks per line]

this applies to all Gen9 projects

If latency level 1 through 7 and Y tile:

Result Blocks = Result Blocks + Y tile minimum

Result Lines = Result Lines + Minimum Scanlines for Y tile

If latency level 1 through 7 and not Y tile:

- Result Blocks = Result Blocks + 1

This applies to all Gen9 projects

If Render Decompression enabled and latency level 0:

Result Blocks = Result Blocks + Y tile minimum

// For latency levels 1 through 7 ensure that the their result lines/blocks >= latency level 0 lines/blocks.

For latency levels 1 through 7

If latency level result blocks < latency level 0 blocks

latency level result blocks = latency level 0 blocks

If latency level result lines < latency level 0 lines

- latency level result lines = latency level 0 lines

VI. Compare against the maximum
- If (Result Blocks >= plane buffer allocation), maximum exceeded for this latency level
- If latency level 1 through 7
  - If (Result Lines > 31), maximum exceeded for this latency level
- For YUV 420 Planar formats, perform the above check for both Y and UV planes.

4. For transition watermark

A. Calculate transition offset
- Transition Offset Blocks = Transition minimum + Transition amount
- See Transition Watermark section for transition minimum and transition amount

B. Calculate transition Y tile minimum
- Transition Y tile minimum = 2 * memory latency level 0 Y tiled minimum

C. Select the watermark result
- If plane memory format is X tile or linear
  - Result Blocks = Memory latency level 0 Selected Result Blocks + Transition Offset Blocks
- Else // Y tile
  - Result Blocks = maximum[Memory latency level 0 Selected Result Blocks, Transition Y tile minimum] + Transition Offset Blocks

D. Convert result to blocks
- Result Blocks = ceiling[Result Blocks] + 1

This applies to all Gen9 projects

If not Y tile:

- Result Blocks = Result Blocks + 1
-

E. Compare against the maximum

- If (Result Blocks >= plane buffer allocation), maximum exceeded for transition watermark
- For YUV 420 Planar formats, perform the above check for both Y and UV planes.

5. Program watermark registers
   A. For each latency level 0 to 7
      - If memory latency for this level is invalid, or the maximum was exceeded for this level or any previous level, program PLANE_WM_<latency level> Enable = 0
        - **If watermark latency level 0 exceeds the maximum, the plane must not be enabled.**
      - Else program PLANE_WM_<latency level> Enable = 1, Lines = Result Lines, Blocks = Result Blocks
        - The latency level 0 Lines value is ignored by hardware in Gen9
   B. For transition watermark
      - If the maximum was exceeded for the transition watermark, program PLANE_WM_TRANS Enable = 0
      - Else program PLANE_WM_TRANS Enable = 1, Blocks = Transition Result Blocks
        - The transition watermark Lines value is ignored by hardware
   C. Write the plane surface base address register to trigger update of the watermarks and other plane double buffered registers. This should be done only after all plane configuration is configured to match the new watermark values.

Transition Watermark

The transition watermark is used for Isochronous Priority Control (IPC). When IPC is enabled (ARB_CTL2 Enable IPC), plane read requests are sent at high priority until filling above the transition watermark, then the requests are sent at lower priority until dropping below the level 0 watermark. The lower priority requests allow other memory clients to have better memory access. If the transition watermark is not enabled, the plane behaves as if the transition watermark was programmed to the top of the plane buffer allocation. When IPC is disabled, all plane read requests are sent at high priority.

The transition watermark is programmed as a tunable amount above the level 0 watermark. Tuning to higher values will tend to cause longer periods of high priority reads followed by longer periods of lower priority reads. Tuning to lower values will tend to cause shorter periods of high and lower priority reads. The exact behavior depends on the memory bandwidth, display bandwidth, and other memory traffic in the system.

The transition watermark has a minimum value to ensure the demote does not happen before enough data has been read to meet the level 0 watermark requirements.

Transition Minimum
14 Blocks

Scaling

A scaler (pipe or plane scaler) is down scaling when it is enabled and the scaler input size is greater than the scaler output size.

Down scaling effectively increases the pixel rate. Up scaling does not reduce the pixel rate.

For plane scaling, the scaler input size is the plane size and the output size is the scaler window size.

For pipe scaling, the scaler input size is the pipe source size and the output size is the scaler window size.

Horizontal down scale amount = maximum[1, Horizontal source size / Horizontal destination size]

Vertical down scale amount = maximum[1, Vertical source size / Vertical destination size]

Total down scale amount = Horizontal down scale amount * Vertical down scale amount

Workaround	
Context:	Watermark Calculations

Workaround when calculating watermarks

Calculate arbitrated display bandwith:

For each pipe {

For each plane, except cursor, enabled on the pipe {

Plane bandwidth MB/s = pixel rate MHz * source pixel format in bytes * plane down scale amount * pipe down scale amount

}

Pipe bandwidth MB/s = Number of planes, except cursor, enabled on the pipe * Max(bandwidth from each plane) // find plane with highest bandwidth and multiply with number of enabled planes

}

Arbitrated display bandwidth = Number of pipes enabled * Max(bandwidth from each pipe) // find pipe with highest bandwidth and multiply with number of enabled pipes

If there is any Ytile plane enabled and arbitrated display bandwidth > 20% of raw system memory bandwidth (# memory channels * memory frequency * channel width in bytes) {

Double Ytile planes minimum lines and program all watermark levels accordingly. Do not change the latency values.

Increase Xtile planes watermark latency for all levels by 15us

}

If memory is dual channel single rank, Xtile limit = 35%, else Xtile limit = 60%

If there is no Ytile plane enabled and arbitrated display bandwidth > (Xtile limit * raw system memory bandwidth) {

Increase Xtile planes watermark latency for all levels by 15uS

}

System Agent Geyserville (SAGV)

On core CPUs, SAGV dynamically adjusts the system agent voltage and clock frequencies depending on power and performance requirements. The display engine access to system memory is blocked during the adjustment time.

SAGV defaults to enabled. Software must use the GT-driver pcode mailbox to disable SAGV when the display engine is not able to tolerate the blocking time.

See the Memory Values section to find the SAGV block time.

Requirement before plane enabling or configuration change: Disable SAGV if any enabled plane will not be able to enable watermarks for memory latency >= SAGV block time, or any transcoder is interlaced. Else, enable SAGV.

If software ensures single pipe configurations always have enough data buffer allocation to tolerate SAGV, it can then simply disable SAGV anytime multiple display pipes are enabled or interlace is enabled, and re-enable SAGV when switching back to a single, non-interlaced pipe.

Sequence to Disable SAGV

1. Ensure any previous GT Driver Mailbox transaction is complete.
2. Write GT Driver Mailbox Data Low = 0x00000000.
3. Write GT Driver Mailbox Interface = 0x80000021.
4. Poll for GT Driver Mailbox Interface Run/Busy == 0x0.
    - Timeout and fail after 150 us.
5. Read GT Driver Mailbox Data Low, if bit 0 == 0x1, continue, else go to step 2.
    - If the condition in step 5 is not satisfied after cycling through steps 2-5 for 1 ms (typically <200 us), timeout and fail.
6. Continue with plane and pipe programming.

Sequence to Enable SAGV

1. Ensure any previous GT Driver Mailbox transaction is complete.
2. Write GT Driver Mailbox Data Low = 0x00000003.
3. Write GT Driver Mailbox Interface = 0x80000021.
4. Continue with plane and pipe programming. There is no need to wait for SAGV enabling to complete.

Examples

Example pixel rate adjustments:

Pixel rate for screen resolution is 130 MHz. No interlacing. Pipe scale 1920x1080 pipe source size to 1714x1120 scaler window size. Plane scale 1920x1080 plane size to 800x600 scaler window size.

Pipe horizontal down scale amount = maximum[1, 1920 / 1714] = 1.12

Pipe vertical down scale amount = maximum[1, 1080 / 1120] = 1 **// Max condition was hit**

Pipe total down scale amount = 1.12 * 1 = 1.12

Adjusted pipe pixel rate = 130 MHz * 1.12 = 145.6 MHz

Plane horizontal down scale amount = maximum[1, 1920 / 800] = 2.4

Plane vertical down scale amount = maximum[1, 1080 / 600] = 1.8

Plane total down scale amount = 2.4 * 1.8 = 4.32

Adjusted plane pixel rate = 145.6 MHz * 4.32 = 628.99 MHz

Example method, block, and line calculations:

Plane source 4 Bpp, Plane X tile, Plane source width 1920 pixels, Horizontal total 2200 pixels, Adjusted plane pixel rate 148.5 MHz, memory latency 7.5 us

Method 1 = 148.5 MHz * 4 Bpp * 7.5 us / 512 = 8.7 blocks

Plane bytes per line = 1920 pixels * 4 Bpp = 7680 Bytes/line

Plane blocks per lines = ceiling[7680 / 512] = 15 blocks

Method 2 = ceiling[(7.5 us * 148.5 MHz) / 2200 pixels] * 15 blocks = 15 blocks

Y tile minimum = 4 * 15 blocks = 60 blocks

Result Blocks = minimum[8.7 blocks, 15 blocks] = 8.7 blocks // X tile so does not use Y tile minimum

Result Blocks = ceiling[8.7 blocks] + 1 block = 10 blocks

Result Lines = ceiling[8.7 blocks / 15] = 1 lines

Memory Values

Retrieve Memory Latency Data

1. Ensure any previous GT Driver Mailbox transaction is complete.
2. Write GT Driver Mailbox Data0=0x0000_0000 (first set of latency values) and GT Driver Mailbox Data1=0x0000_0000
3. Write GT Driver Mailbox Interface Run/Busy=1, Address Control=All 0s, Command/Error Code=06h
4. Poll GT Driver Mailbox Interface for Run/Busy indication=0b and Command/Error Code=00h (success)
    - Timeout after 100 us and do not enable display planes.
5. Read GT Driver Mailbox Data0 for the first set of memory latency values
6. Write GT Driver Mailbox Data0=0x0000_0001 (second set of latency values) and GT Driver Mailbox Data1=0x0000_0000
7. Write GT Driver Mailbox Interface Run/Busy=1, Address Control=All 0s, Command/Error Code=06h
8. Poll GT Driver Mailbox Interface for Run/Busy indication=0b and Command/Error Code=00h (success)
    - Timeout after 100 us and do not enable display planes.
9. Read GT Driver Mailbox Data0 for the second set of memory latency values

Memory Latency Data Definition

First Set		
Data0 Bit	**Name**	**Description**
31:24	Level 3	Number of microseconds for level 3.
23:16	Level 2	Number of microseconds for level 2.
15:8	Level 1	Number of microseconds for level 1.
7:0	Level 0	Number of microseconds for level 0.

Second Set		
Data0 Bit	**Name**	**Description**
31:24	Level 7	Number of microseconds for level 7.
23:16	Level 6	Number of microseconds for level 6.
15:8	Level 5	Number of microseconds for level 5.
7:0	Level 4	Number of microseconds for level 4.

If level 1 or any higher level has a value of 0x00, that level and any higher levels are unused and invalid, so the associated watermark registers must not be enabled.

It is allowed to have the same value in adjacent levels.

Workaround	
Context:	Display Watermark Programming
The mailbox response data may not account for memory read latency. If the mailbox response data for level 0 is 0us, add 2 microseconds to the result for each valid level.	

SAGV Block Time

SAGV Block Time
30 us

3DSTATE_AMFS_POINTERS_REMOVED

3DSTATE_AMFS_POINTERS_REMOVED		
Source:	BSpec	
Size (in bits):	32	
Default Value:	0x00000000	
DWord	**Bit**	**Description**
0	31:0	**Reserved** Format: MBZ

3DSTATE_CONSTANT_ALL_DATA

3DSTATE_CONSTANT_ALL_DATA		
Source:	RenderCS	
Size (in bits):	64	
Default Value:	0x00000000, 0x00000000	
DWord	**Bit**	**Description**
0..1	63:5	**Pointer To Constant Buffer** Format: GraphicsAddress63-5 The value of this field is the virtual address of the location of the push constant buffer. **Programming Notes** Constant buffers must be allocated in linear (not tiled) graphics memory.
	4:0	**Constant Buffer Read Length** Format: U5 This field specifies the length of the constant data to be loaded from memory in 256-bit units. **Programming Notes** • The sum of the read length fields for all pointers must be less than or equal to the size of 64 • Zero means there no data to fetch for this buffer pointer.

3DSTATE_CONSTANT(Body)

3DSTATE_CONSTANT(Body)		
Source:	RenderCS	
Size (in bits):	320	
Default Value:	0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000	
DWord	**Bit**	**Description**
0	31:16	**Constant Buffer 1 Read Length** Format: U16 read length This field specifies the length of the constant data to be loaded from memory in 256-bit units. **Programming Notes** • The sum of all four read length fields must be less than or equal to the size of 64 • Setting the value of the register to zero will disable buffer 1. • If disabled, the **Pointer to Constant Buffer 1** must be programmed to zero. if gather constant are enabled, this field must be non-zero if a there was a preceding corresponding 3DSTATE_GATHER_CONSTANT_*., otherwise this field must be zero.
	15:0	**Constant Buffer 0 Read Length** Format: U16 read length This field specifies the length of the constant data to be loaded from memory in 256-bit units. **Programming Notes** • The sum of all four read length fields must be less than or equal to the size of 64 • Setting the value of the register to zero will disable buffer 0. • If disabled, the **Pointer to Constant Buffer 0** must be programmed to zero.
1	31:16	**Constant Buffer 3 Read Length** Format: U16 read length This field specifies the length of the constant data to be loaded from memory in 256-bit units. **Programming Notes** • The sum of all four read length fields must be less than or equal to the size of 64 • Setting the value of the register to zero will disable buffer 3. • If disabled, the **Pointer to Constant Buffer 3** must be programmed to zero.
	15:0	**Constant Buffer 2 Read Length** Format: U16 read length This field specifies the length of the constant data to be loaded from memory in 256-bit units. **Programming Notes**

3DSTATE_CONSTANT(Body)

		• The sum of all four read length fields must be less than or equal to the size of 64 • Setting the value of the register to zero will disable buffer 2. • If disabled, the **Pointer to Constant Buffer 2** must be programmed to zero.
2..3	63:5	**Pointer To Constant Buffer 0** Format: GraphicsAddress63-5 **Description** When CONSTANT_BUFFER Address Offset Disable in CS_DEBUG_MODE2 register is set, the value of this field is the virtual address of the location of the push constant buffer. GraphicsAddress [63:48] are ignored by the HW and assumed to be in correct canonical form [63:48] == [47]. When CONSTANT_BUFFER Address Offset Disable in CS_DEBUG_MODE2 register is cleared, the value of this field is the offset into the Dynamic State Base Address. Only [47:5] of the field are added to the base address to generate the virtual address to be fetched from memory.
	4:0	**Reserved** Format: MBZ
4..5	63:5	**Pointer To Constant Buffer 1** Format: GraphicsAddress63-5 This field points to the location of Constant Buffer 1. If gather constants are enabled This field is an offset of constant Buffer1 from the Gather Pool BASE ADDRESS. If gather constants is disabled, the value of this field is the virtual address of the location of the push constant buffer. GraphicsAddress [63:48] are ignored by the HW and assumed to be in correct canonical form [63:48] == [47]. **Programming Notes** Constant buffers must be allocated in linear (not tiled) graphics memory.
	4:0	**Reserved** Format: MBZ
6..7	63:5	**Pointer To Constant Buffer 2** Format: GraphicsAddress63-5 The value of this field is the virtual address of the location of the push constant buffer 2. GraphicsAddress [63:48] are ignored by the HW and assumed to be in correct canonical form [63:48] == [47]. **Programming Notes** Constant buffers must be allocated in linear (not tiled) graphics memory.

3DSTATE_CONSTANT(Body)		
	4:0	**Reserved** Format: MBZ
8..9	63:5	**Pointer To Constant Buffer 3** Format: GraphicsAddress63-5 The value of this field is the virtual address of the location of the push constant buffer 3. GraphicsAddress [63:48] are ignored by the HW and assumed to be in correct canonical form [63:48] == [47]. **Programming Notes** Constant buffers must be allocated in linear (not tiled) graphics memory.
	4:0	**Reserved** Format: MBZ

A32 Buffer Base Address Message Header Control

MHC_A32_BBA - A32 Buffer Base Address Message Header Control

Source: BSpec
Size (in bits): 32
Default Value: 0x00000000

DWord	Bit	Description
0	31:10	**Buffer Base Address Offset** Format: GeneralStateOffset[31:10] Specifies the base address offset page [31:10] for A32 stateless messages. **Restriction** Restriction : When using stateless A32 Data Port messages, General State Base Address[47:12] + Buffer Base Address[31:10] must be less than 2^48. It is illegal for this to be greater or equal than 2^48.
	9:0	**Reserved** Format: MBZ Ignored.

A32 Scaled Header Present Message Descriptor Control Field

MDC_A32_MHP - A32 Scaled Header Present Message Descriptor Control Field

Source:	BSpec
Size (in bits):	1
Default Value:	0x00000000

DWord	Bit	Description
0	0	**Message Header Present** Format: Enumeration Specifies if the message uses the optional message header to modify the access type and address calculation, in combination with the MDC_A32_SSO field.

Value	Name	Description
0h	No	Message header is not present. The Sideband Scale Offset field from the Message Descriptor are used as offsets with the Address Payload.
1h	Yes	Message header is present. It specifies a Base Address Offset and a Scale pitch to use with each of the offsets from the Address Payload.

Programming Notes
The access is an SLM access if the Sideband Scale Offset is enabled when the Message Header is not present; otherwise the access is a A32 access.

A32 Sideband Scale and Offset Enable Message Descriptor Control Field

MDC_A32_SBSO - A32 Sideband Scale and Offset Enable Message Descriptor Control Field

Source: BSpec
Size (in bits): 8
Default Value: 0x00000000

DWord	Bit	Description
0	7	**Sideband Offset Enable** Format: Enable When set, enables adding the 16-bit offset from the Sideband to all the offsets in the Address Payload for the A32 or SLM access. The 16-bit Sideband Offset is specified in the extended function control field in the SEND instruction. **Programming Notes** If set and a Message Header is not present, then the access is an SLM access and the Sideband Offset and Scale are used as offsets with the Address Payload. Otherwise, the access is an A32 access, and either or both of the Message Header and Sideband Offsets are added to the offsets in the Address Payload.
	6:0	**Scale** Format: U7 Specifies the scale pitch to be used for SLM messages as (#bytes-1). **Programming Notes** If this is a A32 message, this field is ignored and the scale pitch is supplied by the Message Header. If this is an A32 message and no Message Header present, then the scale is 0 (i.e. pitch = 1 byte).

A64 Data Size Message Descriptor Control Field

MDC_A64_DS - A64 Data Size Message Descriptor Control Field

Source: BSpec
Size (in bits): 2
Default Value: 0x00000000

DWord	Bit	Description
0	1:0	**Data Size** Format: Enumeration Specifies the number of data elements to be read or written

Value	Name	Description	Programming Notes
00h	DE1	1 data element (B, DW, QW)	
01h	DE2	2 data elements (B, DW, QW)	
02h	DE4	4 data elements (B, DW, QW)	
03h	DE8	8 data elements (B, DW, QW)	Restriction : This setting is supported for DW and QW but not for B. For bytes, the maximum number of data elements is 4.

Restriction
Restriction : The number of elements is constrained by SIMD Mode and Data Width. The max data payload limit is 256B: 2 elements SIMD16 QW, 4 elements SIMD16 DW, or 4 elements SIMD8 QW.

A64 Dual Oword Block Message Header

MH_A64_OWDB - A64 Dual Oword Block Message Header

Source: DataPort 1

Size (in bits): 256

Default Value: 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000

DWord	Bit	Description
0..1	63:0	**BlockOffset0** Format: U64 Specifies the U64 byte offset of Oword Block 0. **Programming Notes** If the BlockOffset is not in the 48-bit canonical address range, the access is Out-of-Bounds. **Restriction** Restriction : The byte offset must be aligned to the message's data type. Dwords have [1:0] = 0, Qwords have [2:0] = 0, and Hwords have [4:0] = 0.
2..3	63:0	**BlockOffset1** Format: U64 Specifies the U64 byte offset of Oword Block 1. **Programming Notes** If the BlockOffset is not in the 48-bit canonical address range, the access is Out-of-Bounds. **Restriction** Restriction : The byte offset must be aligned to the message's data type. Dwords have [1:0] = 0, Qwords have [2:0] = 0, and Hwords have [4:0] = 0.
4..7	127:0	**Reserved** Format: Ignore Ignored

A64 Hword Block Message Header

MH_A64_HWB - A64 Hword Block Message Header

Source: DataPort 1

Size (in bits): 256

Default Value: 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000

DWord	Bit	Description
0..1	63:0	**BlockOffset** Format: U64 Specifies the U64 byte offset of Oword block. **Programming Notes** If the BlockOffset is not in the 48-bit canonical address range, the access is Out-of-Bounds. **Restriction** Restriction : The byte offset must be aligned to the message's data type. Dwords have [1:0] = 0, Qwords have [2:0] = 0, and Hwords have [4:0] = 0.
2..4	95:0	**Reserved** Format: Ignore Ignored
5	31:0	**Hword Channel Mode** Format: MHC_A64_CMODE Specifies the Hword Channel Mode
6..7	63:0	**Reserved** Format: Ignore Ignored

A64 Hword Data Blocks Message Descriptor Control Field

MDC_A64_DB_HW - A64 Hword Data Blocks Message Descriptor Control Field

Source: BSpec
Size (in bits): 3
Default Value: 0x00000001

DWord	Bit	Description
0	2:0	**Data Blocks** Format: Enumeration Specifies the number of Hwords to be read or written

Value	Name	Description
01h	HW1 **[Default]**	1 Hword block
02h	HW2	2 Hword blocks
03h	HW4	4 Hword blocks
04h	HW8	8 Hword blocks
Others	Reserved	Ignored

A64 Oword Block Message Header

MH_A64_OWB - A64 Oword Block Message Header

Source: DataPort 1

Size (in bits): 256

Default Value: 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000

DWord	Bit	Description
0..1	63:0	**BlockOffset** Format: U64 Specifies the U64 byte offset of Oword block. **Programming Notes** If the BlockOffset is not in the 48-bit canonical address range, the access is Out-of-Bounds. **Restriction** Restriction : The byte offset must be aligned to the message's data type. Dwords have [1:0] = 0, Qwords have [2:0] = 0, and Hwords have [4:0] = 0.
2..7	191:0	**Reserved** Format: Ignore Ignored

A64 Oword Data Blocks Message Descriptor Control Field

MDC_A64_DB_OW - A64 Oword Data Blocks Message Descriptor Control Field

Source: BSpec
Size (in bits): 3
Default Value: 0x00000000

DWord	Bit	Description
0	2:0	**Data Blocks** Format: Enumeration Specifies the number of Oword blocks to be read or written

Value	Name	Description
00h	OW1L	1 Oword, read into or written from the low 128 bits of the destination register
01h	OW1U	1 Oword, read into or written from the high 128 bits of the destination register
02h	OW2	2 Owords
03h	OW4	4 Owords
04h	OW8	8 Owords
Others	Reserved	Ignored

A64 Oword Dual Data Blocks Message Descriptor Control Field

MDC_A64_DB_OWD - A64 Oword Dual Data Blocks Message Descriptor Control Field

Source: BSpec
Size (in bits): 3
Default Value: 0x00000001

DWord	Bit	Description
0	2:0	**Data Blocks** Format: Enumeration Specifies the number of Oword blocks to be read or written

Value	Name	Description
01h	OWD1 **[Default]**	1 Hword register, 2 Owords
03h	OWD4	4 Hword registers, 8 Owords
Others	Reserved	Ignored

A64 Scaled Data Port 2 Message Header

MH2_A64 - A64 Scaled Data Port 2 Message Header

Source: DataPort 2

Size (in bits): 256

Default Value: 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000

DWord	Bit	Description
0	31:0	**Surface Pitch** Format: MHC_PITCH Specifies the 16-bit surface pitch to use with scaled A64 stateless messages.
1..3	95:0	**Reserved** Format: Ignore Ignored
4..5	63:0	**Buffer Base Address** Format: GraphicsAddress[63:0] Specifies the surface base address[63:0] for scaled A64 stateless messages. The address must be Dword aligned (bits [1:0] = 0). **Programming Notes** If the Buffer Base Address is not in 48-bit canonical form, the access is Out-of-Bounds. Stateless A64 bounds checking rules specify that any address calculation that crosses the canonical address boundary is treated as out-of-bounds. A64 address calculations always use positive offsets, and do not support programming language constructs with negative offsets or indices (e.g. array[-1]).
6..7	63:0	**Reserved** Format: Ignore Ignored

A64 Scaled Header Present Message Descriptor Control Field

MDC_A64_MHP - A64 Scaled Header Present Message Descriptor Control Field

Source: BSpec
Size (in bits): 1
Default Value: 0x00000000

DWord	Bit	Description
0	0	**Message Header Present** Format: Enumeration Specifies if the message uses the optional message header to modify the A64 address calculation, in combination with MDC_A64_SSO field. **Value / Name / Description** 0h / No / Message header is not present 1h / Yes / Message header is present **Programming Notes** The access is Out-of-Bounds if the SideBand Offset is enabled when the Message Header is not present.

A64 Sideband Scale and Offset Enable Message Descriptor Control Field

MDC_A64_SBSO - A64 Sideband Scale and Offset Enable Message Descriptor Control Field

Source: BSpec
Size (in bits): 8
Default Value: 0x00000000

DWord	Bit	Description
0	7	**Sideband Offset Enable** Format: Enable If set, the Sideband Offset is added to the Message Header's Base Address Offset. The 16-bit Sideband Offset is specified in the extended function control field in the SEND instruction. **Programming Notes** It is an illegal A64 encoding to enable the SideBand Offset when the Message Header is not present. That encoding combination is an SLM access in A32 message, but in an A64 message the illegal access is handled as Out-of-Bounds.
	6:0	**Reserved** Format: MBZ Ignored

AddrSubRegNum

AddrSubRegNum		
Source:	EuIsa	
Size (in bits):	4	
Default Value:	0x00000000	

Address Subregister Number
This field provides the subregister number for the address register. The address register contains 8 sub-registers. The size of each subregister is one word. The address register contains the register address of the operand, when the operand is in register-indirect addressing mode.
This field applies to the destination operand and the source operands. It is ignored (or not present in the instruction word) for an immediate source operand.
This field is present if the operand is in register-indirect addressing mode; it is not present if the operand is directly addressed.
An address subregister used for indirect addressing is often called an index register.

DWord	Bit	Description
0	3:0	**Address Subregister Number**

Value	Name
0-15	Address Subregister Number

AMFS_STATE_REMOVED

AMFS_STATE_REMOVED		
Source:	RenderCS	
Size (in bits):	32	
Default Value:	0x00000000	

DWord	Bit	Description
0	31:0	**Reserved** Format: MBZ

Any Binding Table Index Message Descriptor Control Field

MDC_BTS_SLM_A32 - Any Binding Table Index Message Descriptor Control Field

Source: BSpec
Size (in bits): 8
Default Value: 0x00000000

DWord	Bit	Description
0	7:0	**Binding Table Index** Format: Enumeration Specifies the surface for the message, which can be Surface State Model, SLM or Stateless.

Value	Name	Description
00h-0EFh	BTS	Index of Binding Table State Surfaces
F0h-0FBh	Reserved	Reserved for future use
0FCh	SSO	Specifies a Surface State Offset supplied by the extended message descriptor
0FEh	SLM	Specifies an SLM access
0FFh	A32_A64	Specifies a A32 or A64 Stateless access that is locally coherent (coherent within a thread group)
0FDh	A32_A64_NC	Specifies a A32 or A64 Stateless access that is non-coherent (coherent within a thread).

Restriction
Restriction : When using A32_A64_NC, SW must ensure that 2 threads do not both access the same cache line (64B)

Atomic Float Binary Operation Message Descriptor Control Field

MDC_FOP2 - Atomic Float Binary Operation Message Descriptor Control Field

Source: BSpec
Size (in bits): 2
Default Value: 0x00000001

DWord	Bit	Description
0	1:0	**Atomic Float Operation Type** Format: Enumeration Specifies the atomic float binary operation to be performed

Value	Name	Description	Programming Notes
01h	AOP_FMAX **[Default]**	new_dst = fmax(old_dst, src0)	The fmax operation implements the IEEE specification, which differs slightly from the DX specifications when a source operand is a sNaN. fmax(x,qNaN) = fmax(qNaN,x) = x fmax(x,sNaN) = fmax(sNaN,x) = quietize(sNaN) fmax(sNaN,sNaN) = fmax(sNaN,qNaN) = fmax(qNan,sNaN) = quietize(sNaN) fmax(qNaN,qNan) = qNaN Fmax with sNaN operand returns sNaN instead of quietize(sNaN) Fmax(-0,+0) = -0. Should be +0, to match EU Fmax instruction.
02h	AOP_FMIN	new_dst = fmin(old_dst, src0)	The fmin operation implements the IEEE specification, which differs slightly from the DX specifications when a source operand is a sNaN. fmin(x,qNaN) = fmin(qNaN,x) = x fmin(x,sNaN) = fmin(sNaN,x) = quietize(sNaN) fmin(sNaN,sNaN) = fmin(sNaN,qNaN) = fmin(qNan,sNaN) = quietize(sNaN) fmin(qNaN,qNan) = qNaN Fmin with sNaN operand returns sNaN instead of quietize(sNaN) Fmin(+0,-0) = +0. Should be -0, to match EU Fmin instruction.
Others	Reserved	Ignored	

Programming Notes
When Return Data Control is set, old_dst is returned.

Atomic Float Trinary Operation Message Descriptor Control Field

MDC_FOP3 - Atomic Float Trinary Operation Message Descriptor Control Field

Source: BSpec
Size (in bits): 2
Default Value: 0x00000003

DWord	Bit	Description
0	1:0	**Atomic Float Operation Type** Format: Enumeration Specifies the atomic float trinary operation to be performed

Value	Name	Description	Programming Notes
03h	AOP_FCMPWR **[Default]**	new_dst = (src0 == old_dst) ? src1 : old_dst	The fcmpwr operation performs the comparison using IEEE specification rules, and performs the store as a raw move (so SNaN is not quietized). fcmpwr(NaN,x,y) = NaN fcmpwr(x, NaN,y) = x fcmpwr(x,x, NaN) = NaN
Others	Reserved	Ignored	

Programming Notes
When Return Data Control is set, old_dst is returned.

Atomic Integer Binary Operation Message Descriptor Control Field

MDC_AOP2 - Atomic Integer Binary Operation Message Descriptor Control Field

Source: BSpec
Size (in bits): 4
Default Value: 0x00000001

DWord	Bit	Description
0	3:0	**Atomic Integer Operation Type** Format: Enumeration Specifies the atomic integer binary operation to be performed

Value	Name	Description
01h	AOP_AND **[Default]**	new_dst = old_dst AND src0
02h	AOP_OR	new_dst = old_dst | src0
03h	AOP_XOR	new_dst = old_dst ^ src0
04h	AOP_MOV	new_dst = src0
07h	AOP_ADD	new_dst = old_dst + src0
08h	AOP_SUB	new_dst = old_dst - src0
09h	AOP_REVSUB	new_dst = src0 - old_dst
0Ah	AOP_IMAX	new_dst = imax(old_dst, src0)
0Bh	AOP_IMIN	new_dst = imin(old_dst, src0)
0Ch	AOP_UMAX	new_dst = umax(old_dst, src0)
0Dh	AOP_UMIN	new_dst = umin(old_dst, src0)
Others	Reserved	Ignored

Programming Notes
When Return Data Control is set, old_dst is returned.

Atomic Integer Trinary Operation Message Descriptor Control Field

MDC_AOP3 - Atomic Integer Trinary Operation Message Descriptor Control Field

Source: BSpec
Size (in bits): 4
Default Value: 0x0000000E

DWord	Bit	Description
0	3:0	**Atomic Integer Operation Type** Format: Enumeration Specifies the atomic integer trinary operation to be performed

Value	Name	Description
00h	AOP_CMPWR_2W	new_dst = (src0_2W == old_dst_2W) ? src1_2W : old_dst_2W
0Eh	AOP_CMPWR **[Default]**	new_dst = (src0 == old_dst) ? src1 : old_dst
Others	Reserved	Ignored

Programming Notes
When Return Data Control is set, old_dst is returned.

Atomic Integer Unary Operation Message Descriptor Control Field

MDC_AOP1 - Atomic Integer Unary Operation Message Descriptor Control Field

Source: BSpec
Size (in bits): 4
Default Value: 0x00000005

DWord	Bit	Description
0	3:0	**Atomic Integer Operation Type** Format: Enumeration Specifies the atomic integer unary operation to be performed

Value	Name	Description
05h	AOP_INC **[Default]**	new_dst = old_dst + 1
06h	AOP_DEC	new_dst = old_dst - 1
0Fh	AOP_PREDEC	new_dst = old_dst - 1
Others	Reserved	Ignored

Programming Notes
When Return Data Control is set, new_dst is returned by AOP_PREDEC and otherwise old_dst is returned.

DWord	**Bit**	**Description**
0	31:24	**Reserved** Format: MBZ
	23:16	**Binding Table Index** Format: U8 This field specifies the index of binding table entry that will be updated.
	15:0	**Surface State Pointer** Format: SurfaceStateOffset[21:6]RENDER_SURFACE_STATE Surface State Pointer. This address points to a surface state block. This pointer is relative to the Surface State Base Address.

BINDING_TABLE_STATE

BINDING_TABLE_STATE		
Source:	BSpec	
Size (in bits):	32	
Default Value:	0x00000000	
The binding table binds surfaces to logical resource indices used by shaders and other compute engine kernels. It is stored as an array of up to 256 elements, each of which contains one dword as defined here. The start of each element is spaced one dword apart. The first element of the binding table is aligned to a 64-byte boundary. Binding table indexes beyond 256 will automatically be mapped to entry 0 by the HW, w/ the exception of any messages which support the special indexes 240 through 255, inclusive.		
DWord	**Bit**	**Description**
0	31:6	**Surface State Pointer** Format: SurfaceStateOffset[31:6] This 64-byte aligned address points to a surface state block. This pointer is relative to the **Surface State Base Address**

Bit Definition for Interrupt Control Registers - Blitter

Bit Definition for Interrupt Control Registers - Blitter		
Source:	BlitterCS	
Size (in bits):	32	
Default Value:	0x00000000	
DWord	**Bit**	**Description**
0	31:28	**Reserved** Format: MBZ These bits may be assigned to interrupts on future products/steppings.
	27	**Wait on Semaphore** Exec-List Scheduling: Set when MI_SEMAPHORE_WAIT command is un-successful and when "Inhibit Synchronous Context Switch" is set. Scheduler can use this interrupt to preempt the context waiting on semaphore wait. Ring Buffer Scheduling: Set when MI_SEMAPHORE_WAIT command is un-successful.
	26:25	**Reserved** Format: MBZ
	24	**Context Switch Interrupt** Set when a context switch has just occurred. Exec-List Enable bit needs to be set for this interrupt to occur.
	23	**Reserved** Format: MBZ
	22	**Timeout Counter Expired** Set when the Blitter Command Streamer timeout counter has reached the timeout threshold value. This feature is not POR and SW must never unmask (enable) this interrupt via BCS_IMR.
	21	**Reserved** Format: MBZ
	20	**MI_FLUSH_DW Notify Interrupt** The Pipe Control packet (Fences) specified in 3D pipeline document may optionally generate an Interrupt. The Store QW associated with a fence is completed ahead of the interrupt.
	19	**Blitter Command Parser Master Error** When this status bit is set, it indicates that the hardware has detected an error. It is set by the device upon an error condition and cleared by a CPU write of a one to the appropriate bit contained in the Error ID register followed by a write of a one to this bit in the IIR. Further information on the source of the error comes from the "Error Status Register" which along with the "Error Mask Register" determine which error conditions will cause the error status bit to be set and the interrupt to occur. **Page Table Error:** Indicates a page table error. **Instruction Parser Error:** The Blitter Instruction Parser encounters an error while parsing an instruction.

Bit Definition for Interrupt Control Registers - Blitter		
	18:17	**Reserved** Format: MBZ
	16	**Blitter Command Parser User Interrupt** This status bit is set when an MI_USER_INTERRUPT instruction is executed on the Blitter Command Parser. Note that instruction execution is not halted and proceeds normally. A mechanism such as an MI_STORE_DATA instruction is required to associate a particular meaning to a user interrupt.
	15:0	**Reserved** Format: MBZ

BLEND_STATE

BLEND_STATE

Source:	BSpec
Size (in bits):	544
Default Value:	0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000

The blend state is stored as a structure containing a common DWORD that applies to all RTs and an array of up to 8 elements, each of which contains the two DWords for each. The start of each element is spaced 2 DWords apart. The blend state is aligned to a 64-byte boundary, which is pointed to by a field in 3DSTATE_BLEND_STATE_POINTERS. The 3-bit Render Target Index field in the Render Target Write data port message header is used to select which of the 8 elements from BLEND_STATE that is used on the current message.

DWord	Bit	Description
0	31	**Alpha To Coverage Enable** Format: Enable If set, Source0 Alpha is converted to a temporary 1/2/4-bit coverage mask and the mask bit corresponding to the sample# ANDed with the sample mask bit. If set, sample coverage is computed based on src0 alpha value. Value of 0 disables all samples and value of 1 enables all samples for that pixel. The same coverage needs to apply to all the RTs in MRT case. Further, any value of src0 alpha between 0 and 1 monotonically increases the number of enabled pixels.The field is applied to all the RTs in MRT case.
	30	**Independent Alpha Blend Enable** Format: Enable When enabled, the other fields in this instruction control the combination of the alpha components in the Color Buffer Blend stage. When disabled, the alpha components are combined in the same fashion as the color components.The field is applied to all the RTs in MRT case.
	29	**Alpha To One Enable** Format: Enable If set, Source0 Alpha is set to 1.0f after (possibly) being used to generate the AlphaToCoverage coverage mask.If Dual Source Blending is enabled, this bit must be disabled.The field is applied to all the RTs in MRT case.
	28	**Alpha To Coverage Dither Enable** Format: Enable If set, sample coverage is computed based on src0 alpha value and it modulates the sample coverage based on screen coordinates. Value of 0 disables all samples and value of 1 enables all samples for that pixel. The same coverage needs to apply to all the RTs in MRT case. Further, any

BLEND_STATE

		value of src0 alpha between 0 and 1 monotonically increases the number of enabled pixels. If AlphaToCoverage is disabled, AlphaToCoverage Dither does not have any impact.The field is applied to all the RTs in MRT case.
	27	**Alpha Test Enable** Format: Enable Enables the AlphaTest function of the Pixel Processing pipeline.The field is applied to all the RTs in MRT case. **Programming Notes** Alpha Test can only be enabled if Pixel Shader outputs a float alpha value. Alpha Test is applied independently on each render target by comparing that render target's alpha value against the alpha reference value. If the alpha test fails, the corresponding pixel write will be supressed only for that render target. The depth/stencil update will occur if alpha test passes for any render target.
	26:24	**Alpha Test Function** Format: 3D_Compare_Function This field specifies the comparison function used in the AlphaTest functionThe field is applied to all the RTs in MRT case.
	23	**Color Dither Enable** Format: Enable Enables dithering of colors (including any alpha component) before they are written to the Color Buffer. The field is applied to all the RTs in MRT case. **Programming Notes** For YUV render target formats, this field must be programmed to 0.
	22:21	**X Dither Offset** Format: U2 Specifies offset to apply to pixel X coordinate LSBs when accessing dither table.The field is applied to all the RTs in MRT case.
	20:19	**Y Dither Offset** Format: U2 Specifies offset to apply to pixel Y coordinate LSBs when accessing dither table.The field is applied to all the RTs in MRT case.
	18:0	**Reserved** Format: MBZ

BLEND_STATE_ENTRY

BLEND_STATE_ENTRY

Source: BSpec
Size (in bits): 64
Default Value: 0x00000000, 0x00000000

DWord	Bit	Description
0..1	63	**Logic Op Enable** Format: Enable Enables the LogicOp function of the Pixel Processing pipeline. **Programming Notes** Enabling LogicOp and Color Buffer Blending at the same time is UNDEFINED
	62:59	**Logic Op Function** Format: 3D_Logic_Op_Function This field specifies the function to be performed (when enabled) in the Logic Op stage of the Pixel Processing pipeline. Note that the encoding of this field is one less than the corresponding "R2_" ROP code defined in WINGDI.H, and is a rather contorted mapping of the OpenGL LogicOp encodings. However, this field was defined such that, when the 4 bits are replicated to 8 bits, they coincide with the ROP codes used in the Blter. Note: if the Logic Op Function does not depend on "D", the dest buffer is not read.
	58:37	**Reserved** Format: MBZ
	36	**Pre-Blend Source Only Clamp Enable** Format: Enable This field specifies whether the source(s) are clamped prior to blending, regardless of whether blending is enabled. If DISABLED, no clamping is performed prior to blending. If ENABLED, only source0 and source 1, if dual source is enabled, are clamped prior to the blend to the range specified by Color Clamp Range. **Value / Name / Description** 0 / Disabled / No clamping is performed prior to blending. 1 / Enabled / Only Source(s) are clamped prior to blend function. Other inputs to blend must be clamped according to the behavior specified for "pre-blend color clamp disable" in the pre-blend color clamping table . **Programming Notes** This field is ignored (treated as DISABLED) for UINT and SINT RT surface formats. Blending is not supported for those RT surface formats. **When this bit is enabled Pre-Blend Color Clamp Enable must be disabled.**

BLEND_STATE_ENTRY

35:34 **Color Clamp Range**

Specifies the clamped range used in Pre-Blend and Post-Blend Color Clamp functions if one or both of those functions are enabled. Note that this range selection is shared between those functions. This field is ignored if both of the Color Clamp Enables are disabled

Value	Name	Description
0	COLORCLAMP_UNORM	Clamp Range [0,1]
1	COLORCLAMP_SNORM	Clamp Range [-1,1]
2	COLORCLAMP_RTFORMAT	Clamp to the range of the RT surface format (Note: The Alpha component is clamped to FLOAT16 for R11G11B10_FLOAT format). Unsigned Floating Point components are clamped to positive zero.
3	Reserved	Reserved

33 **Pre-Blend Color Clamp Enable**

Format:	Enable

This field specifies whether the source, destination and constant color channels are clamped prior to blending, regardless of whether blending is enabled.If DISABLED, no clamping is performed prior to blending.If ENABLED, all inputs to the blend function are clamped prior to the blend to the range specified by Color Clamp Range.

Value	Name	Description
0	Disabled	No clamping is performed prior to blending.
1	Enabled	All inputs to the blend function are clamped prior to the blend to the range specified by Color Clamp Range.

Programming Notes
See table in Pre-Blending Color Clamp subsection for programming restrictions as a function of RT format. This field is ignored (treated as DISABLED) for UINT and SINT RT surface formats. Blending is not supported for those RT surface formats. The device will automatically clamp source color channels to the respective RT surface range.

32 **Post-Blend Color Clamp Enable**

Format:	Enable

Regardless of whether this clamping is enabled, the blending output channels will be clamped to the RT surface format just prior to being written.

Programming Notes
This field is ignored (treated as DISABLED) for UINT and SINT RT surface formats. Blending is not supported for those RT surface formats. Post Blend Clamp Enable must be programmed identical to Pre Blend Clamp Enable. The device will automatically clamp source color channels to the respective RT surface range. **When this bit is enabled Pre-Blend Source Only Clamp Enable must be disabled.**

BLEND_STATE_ENTRY

	31	**Color Buffer Blend Enable** Format: Enable Enables the ColorBufferBlending (nee "alpha blending") function of the Pixel Processing Pipeline for this render target. **Programming Notes** Enabling LogicOp and ColorBufferBlending at the same time is UNDEFINED
	30:26	**Source Blend Factor** Format: 3D_Color_Buffer_Blend_Factor Controls the "source factor" in the ColorBufferBlending function.Refer to Source Alpha Blend Factor for encodings.
	25:21	**Destination Blend Factor** Format: 3D_Color_Buffer_Blend_Factor Controls the "destination factor" in the ColorBufferBlending function. Refer to Source Alpha Blend Factor for encodings.
	20:18	**Color Blend Function** Format: 3D_Color_Buffer_Blend_Function This field specifies the function used to combine the color components in the ColorBufferBlending function of the Pixel Processing Pipeline. If Independent Alpha Blend Enable is disabled, this field will also control the blending of the alpha components in the ColorBufferBlending function.
	17:13	**Source Alpha Blend Factor** Format: 3D_Color_Buffer_Blend_Factor Controls the "source factor" in alpha Color Buffer Blending stage.Note: For the source/destination alpha blend factors, the encodings indicating "COLOR" are the same as the encodings indicating "ALPHA", as the alpha component of the color is selected.
	12:8	**Destination Alpha Blend Factor** Format: 3D_Color_Buffer_Blend_Factor Controls the "destination factor" in alpha Color Buffer Blending stage. Refer to Source Alpha Blend Factor for encodings.
	7:5	**Alpha Blend Function** Format: 3D_Color_Buffer_Blend_Function This field specifies the function used to combine the alpha components in the Color Buffer blend stage of the Pixel Pipeline when the IndependentAlphaBlend state is enabled.

BLEND_STATE_ENTRY

	4	**Reserved** Format: MBZ
	3	**Write Disable Alpha** Format: Disable This field controls the writing of the alpha component into the Render Target. **Value** / **Name** / **Description** 0b / Enabled / Alpha component can be overwritten 1b / Disabled / Writes to the color buffer will not modify Alpha. **Programming Notes** For YUV surfaces, this field must be set to 0B (enabled).
	2	**Write Disable Red** Format: Disable This field controls the writing of the red component into the Render Target. **Value** / **Name** / **Description** 0b / Enabled / Red component can be overwritten 1b / Disabled / Writes to the color buffer will not modify Red. **Programming Notes** For YUV surfaces, this field must be set to 0B (enabled).
	1	**Write Disable Green** Format: Disable This field controls the writing of the green component into the Render Target. **Value** / **Name** / **Description** 0b / Enabled / Green component can be overwritten 1b / Disabled / Writes to the color buffer will not modify Green. **Programming Notes** For YUV surfaces, this field must be set to 0B (enabled).

BLEND_STATE_ENTRY

0 **Write Disable Blue**

Format:	Disable

This field controls the writing of the Blue component into the Render Target.

Value	Name	Description
0b	Enabled	Blue component can be overwritten
1b	Disabled	Writes to the color buffer will not modify Blue.

Programming Notes
For YUV surfaces, this field must be set to 0B (enabled).

Block Dimensions Message Header Control

MHC_BDIM - Block Dimensions Message Header Control

Source: BSpec
Size (in bits): 32
Default Value: 0x00000000

DWord	Bit	Description
0	31:22	**Reserved** Format: Ignore Ignored
	21:20	**Block Height** Format: Enumeration Height in rows of block being accessed. Range = [0,3] representing 1 to 8 rows.

Value	Name	Description
0h	H1	Block height = 1 row
1h	H2	Block height = 2 rows
2h	H4	Block height = 4 rows
03h	H8	Block height = 8 rows

DWord	Bit	Description
	19:2	**Reserved** Format: Ignore Ignored
	1:0	**Block Width** Format: Enumeration Width in Dwords of block being accessed. Range = [0,3] representing 1 to 8 Dwords.

Value	Name	Description
0h	W1	Block width = 1 Dword
1h	W2	Block width = 2 Dwords
2h	W4	Block width = 4 Dwords
03h	W8	Block width = 8 Dwords

Block Message Header

MH_BTS_GO - Block Message Header

Source: DataPort 0

Size (in bits): 256

Default Value: 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000

DWord	Bit	Description
0..1	63:0	**Reserved** Format: Ignore Ignored
2	31:0	**Global Offset** Format: U32 Specifies the global element index into the buffer, in units of Hwords, Owords, Dwords, or Bytes (depending on the message). **Programming Notes** The Global Offset for the Aligned Block operations is specified as a Dword-aligned byte offset (offset bits [1:0] = 0), Oword-aligned byte offset (offset bits [3:0]=0), or Hword-aligned byte offset (offset bits [4:0]=0). If the address offset calculated with the Global Offset is greater than the Surface Size, then the access is Out-of-Bounds.
3..7	159:0	**Reserved** Format: Ignore Ignored

BR00 - BLT Opcode and Control

BR00 - BLT Opcode and Control

Source: BlitterCS
Size (in bits): 32
Default Value: 0x00000000

DWord	Bit	Description
0	31	**BLT Engine Busy** This bit indicates whether the BLT Engine is busy (1) or idle (0). This bit is replicated in the SETUP BLT Opcode and Control register. Value: 0 — Name: Idle **[Default]** Value: 1 — Name: Busy
	30	**Setup Instruction Instruction** Default Value: 0 The current instruction performs clipping (1).
	29	**Setup Monochrome Pattern** This bit is decoded from the Setup instruction opcode to identify whether a color (0) or monochrome (1) pattern is used with the SCANLINE_BLT instruction. Value: 0 — Name: Color **[Default]** Value: 1 — Name: Monochrome
	28:22	**Instruction Target (Opcode)** Default Value: 0000000b This is the contents of the Instruction Target field from the last BLT instruction. This field is used by the BLT Engine state machine to identify the BLT instruction it is to perform. The opcode specifies whether the source and pattern operands are color or monochrome.
	21:20	**32bpp Byte Mask** This field is only used for 32bpp. Value: 00b — Name: **[Default]** Value: 1xb — Name: Write Alpha Channel Value: x1b — Name: Write RGB Channel

BR00 - BLT Opcode and Control

19:17 Monochrome Source Start

Default Value:	000b

This field indicates the starting monochrome pixel bit position within a byte per scan line of the source operand. The monochrome source is word aligned which means that at the end of the scan line all bits should be discarded until the next word boundary.

16 Bit/Byte Packed

Byte packed is for the NT driver.

Value	Name
0b	Bit **[Default]**
1b	Byte

15 Src Tiling Enable

Value	Name
0b	Tiling Disabled (Linear) **[Default]**
1b	Tiling enabled: Tile-X or Tile-Y

14:12 Horizontal Pattern Seed

Default Value:	0b

This field indicates the pattern pixel position which corresponds to X = 0.

11 Dest Tiling Enable

When set to '1', this means that Blitter is executing in Tiled mode. If '0' it means that Blitter is in Linear mode. Pre-Dev Blitter never executes in Tiled-Y mode, DevGT+ Blitter supports both Tile-X and Tile-Y modes. On reset, this bit will be '0'. This definition applies to only X, Y Blits.

Value	Name
0b	Tiling Disabled (Linear blit) **[Default]**
1b	Tiling enabled: Tile-X or Tile-Y

10:8 Transparency Range Mode

These bits control whether or not the byte(s) at the destination corresponding to a given pixel will be conditionally written, and what those conditions are. This feature can make it possible to perform various masking functions in order to selectively write or preserve graphics data already at the destination.

Value	Name	Description
xx0b	**[Default]**	No color transparency mode enabled. This causes normal operation with regard to writing data to the destination.

BR00 - BLT Opcode and Control

		001b		[Source color transparency] The Transparency Color Low: (Pixel Greater or Equal) (source background register) and the Transparency Color High: (Pixel Less or Equal) (source foreground register) are compared to the source pixels. The range comparisons are done on each component (R, G, B) and then logically ANDed. If the source pixel components are not within the range defined by the Transparency Color registers, then the byte(s) at the destination corresponding to the current pixel are written with the result of the bit-wise operation.
		011b		[Source and Alpha color transparency] The Transparency Color Low: (Pixel Greater or Equal) (source background register) and the Transparency Color High: (Pixel Less or Equal) (source foreground register) are compared to the source pixels. The range comparisons are done on each component (A, R, G, B) and then logically ANDed. If the source pixel components are not within the range defined by the Transparency Color registers, then the byte(s) at the destination corresponding to the current pixel are written with the result of the bit-wise operation."
		101b		[Destination and Alpha color transparency] The Transparency Color Low: (Pixel Greater or Equal) (source background register) and the Transparency Color High: (Pixel Less or Equal) (source foreground register) are compared to the destination pixels. The range comparisons are done on each component (A, R, G, B) and then logically ANDed. If the destination pixels are within the range, then the byte(s) at the destination corresponding to the current pixel are written with the result of the bit-wise operation.
		111b		[Destination color transparency] The Transparency Color Low: (Pixel Greater or Equal) (source background register) and the Transparency Color High: (Pixel Less or Equal) (source foreground register) are compared to the destination pixels. The range comparisons are done on each component (R, G, B) and then logically ANDed. If the destination pixels are within the range, then the byte(s) at the destination corresponding to the current pixel are written with the result of the bit-wise operation.
	7:5	**Pattern Vertical Seed**		
		Default Value:	000b	
		This field specifies the pattern scan line which corresponds to Y=0.		
	4	**Destination Read Modify Write**		
		Default Value:	0b	
		This bit is decoded from the last instruction's opcode field and Destination Transparency Mode to identify whether a Destination read is needed.		

BR00 - BLT Opcode and Control

	3	**Color Source** Default Value: 0b This bit is decoded from the last instructions opcode field to identify whether a color (1) source is used.
	2	**Monochrome Source** Default Value: 0b This bit is decoded from the last instructions opcode field to identify whether a monochrome (1) source is used.
	1	**Color Pattern** Default Value: 0b This bit is decoded from the last instructions opcode field to identify whether a color (1) pattern is used.
	0	**Monochrome Pattern** Default Value: 0b This bit is decoded from the last instructions opcode field to identify whether a monochrome (1) pattern is used.

BR01 - Setup BLT Raster OP, Control, and Destination Offset

BR01 - Setup BLT Raster OP, Control, and Destination Offset

Source: BlitterCS
Size (in bits): 32
Default Value: 0x00000000

DWord	Bit	Description
0	31	**Solid Pattern Select** This bit applies only when the pattern data is monochrome. This bit determines whether or not the BLT Engine actually performs read operations from the frame buffer in order to load the pattern data. Use of this feature to prevent these read operations can increase BLT Engine performance, if use of the pattern data is indeed not necessary. The BLT Engine is configured to accept either monochrome or color pattern data via the opcode field.

Value	Name	Description
0b	**[Default]**	This causes normal operation with regard to the use of the pattern data. The BLT Engine proceeds with the process of reading the pattern data, and the pattern data is used as the pattern operand for all bit-wise operations.
1b		The BLT Engine forgoes the process of reading the pattern data, the presumption is made that all of the bits of the pattern data are set to 0, and the pattern operand for all bit-wise operations is forced to the background color specified in the Color Expansion Background Color Register.

	30	**Clipping Enabled**

Value	Name
0b	**[Default]**
1b	

	29	**Monochrome Source Transparency Mode** This bit applies only when the source data is in monochrome. This bit determines whether or not the byte(s) at the destination corresponding to the pixel to which a given bit of the source data also corresponds will actually be written if that source data bit has the value of 0. This feature can make it possible to use the source as a transparency mask. The BLT Engine is configured to accepted either monochrome or color source data via the opcode field.

Value	Name	Description
0b	**[Default]**	This causes normal operation with regard to the use of the source data. Wherever a bit in the source data has the value of 0, the color specified in the background color register is used as the source operand in the bit-wise operation for the pixel corresponding to the source data bit, and the bytes at the destination corresponding to that pixel are written with the result.
1b		Wherever a bit in the source data has the value of 0, the byte(s) at the destination corresponding to the pixel to which the source data bit also corresponds are simply not written, and the data at those byte(s) at the destination are allowed to remain unchanged.

BR01 - Setup BLT Raster OP, Control, and Destination Offset

28 **Monochrome Pattern Transparency Mode**

This bit applies only when the pattern data is monochrome. This bit determines whether or not the byte(s) at the destination corresponding to the pixel to which a given bit of the pattern data also corresponds will actually be written if that pattern data bit has the value of 1. This feature can make it possible to use the pattern as a transparency mask. The BLT Engine is configured to accepted either monochrome or color pattern data via the opcode field.

Value	Name	Description
0b	**[Default]**	This causes normal operation with regard to the use of the pattern data. Wherever a bit in the pattern data has the value of 0, the color specified in the background color register is used as the pattern operand in the bit-wise operation for the pixel corresponding to the pattern data bit, and the bytes at the destination corresponding to that pixel are written with the result.
1b		Wherever a bit in the pattern data has the value of 0, the byte(s) at the destination corresponding to the pixel to which the pattern data bit also corresponds are simply not written, and the data at those byte(s) at the destination are allowed to remain unchanged.

27:26 **32bpp Byte Mask**

This bit applies only when the pattern data is monochrome. This bit determines whether or not the byte(s) at the destination corresponding to the pixel to which a given bit of the pattern data also corresponds will actually be written if that pattern data bit has the value of 1. This feature can make it possible to use the pattern as a transparency mask. The BLT Engine is configured to accepted either monochrome or color pattern data via the opcode field.

Value	Name
00b	**[Default]**
1xb	Write Alpha Channel
x1b	Write RGB Channel

25:24 **Color Depth**

Value	Name
00b	8 Bit Color Depth **[Default]**
01b	16 Bit Color Depth
10b	Alternate 16 Bit Color Depth
11b	32 Bit Color Depth

23:16 **Raster Operation Select**

These 8 bits are used to select which one of 256 possible raster operations is to be performed by the BLT Engine.

15:0 **Destination Pitch (Offset)**

For non-XY Blits, the signed 16bit field allows for specifying upto + 32Kbytes signed pitches in bytes (same as before). For X, Y Blits with tiled-X surfaces, the pitch for Destination will be 512Byte aligned and should be programmable upto + 128Kbytes. For X, Y Blits with tiled-Y surfaces, the pitch for Destination will be 128Byte aligned and should be programmable upto + 128Kbytes. In this case, this 16bit signed pitch field is used to specify upto + 32KDWords. For X, Y

BR01 - Setup BLT Raster OP, Control, and Destination Offset		
		blits with nontiled surfaces (linear surfaces), this 16bit field can be programmed to byte specification of upto + 32Kbytes (same as before). These 16 bits store the signed memory address offset value by which the destination address originally specified in the Destination Address Register is incremented or decremented as each scan line's worth of destination data is written into the frame buffer by the BLT Engine, so that the destination address will point to the next memory address to which the next scan line's worth of destination data is to be written. If the intended destination of a BLT operation is within on-screen frame buffer memory, this offset is normally set so that each subsequent scan line's worth of destination data lines up vertically with the destination data in the scan line, above. However, if the intended destination of a BLT operation is within off-screen memory, this offset can be set so that each subsequent scan line's worth of destination data is stored at a location immediately after the location where the destination data for the last scan line ended, in order to create a single contiguous block of bytes of destination data at the destination.

BR05 - Setup Expansion Background Color

BR05 - Setup Expansion Background Color		
Source:	BlitterCS	
Size (in bits):	32	
Default Value:	0x00000000	
DWord	**Bit**	**Description**
0	31:0	**Setup Expansion Background Color Bits** These bits provide the one, two, or four bytes worth of color data that select the background color to be used in the color expansion of monochrome pattern or source data for either the SCANLINE_BLT or TEXT_BLT instructions. BR05 is also used as the solid pattern for the PIXEL_BLT instruction. Whether one, two, or three bytes worth of color data is needed depends upon the color depth to which the BLT Engine has been set. For a color depth of 32bpp, 16bpp and 8bpp, bits [31:0], [15:0] and [7:0], respectively, are used.

BR06 - Setup Expansion Foreground Color

BR06 - Setup Expansion Foreground Color		
Source:	BlitterCS	
Size (in bits):	32	
Default Value:	0x00000000	
DWord	**Bit**	**Description**
0	31:0	**Setup Expansion Foreground Color Bits** These bits provide the one, two, or four bytes worth of color data that select the foreground color to be used in the color expansion of monochrome pattern or source data for either the SCANLINE_BLT or TEXT_BLT instructions. Whether one, two, or three bytes worth of color data is needed depends upon the color depth to which the BLT Engine has been set. For a color depth of 32bpp, 16bpp and 8bpp, bits [31:0], [15:0] and [7:0], respectively, are used.

BR07 - Setup Blit Color Pattern Address Lower Order Address bits

BR07 - Setup Blit Color Pattern Address Lower Order Address bits

Source: BlitterCS
Size (in bits): 32
Default Value: 0x00000000

DWord	Bit	Description
0	31:6	**Setup Blit Color Pattern Address** Format: GraphicsAddress[31:6] Lower 32bits of the 48bit addressing. These 26 bits specify the starting address of the (8X8) pixel color **pattern from the SETUP_BLT instruction.** This register works identically to the Pattern Address register (BR15), but this version is **only used with the SCANLINE_BLT instruction execution** (the actual programming for this, is done in XY_SETUP_BLT command). The pattern data must be located in linear memory. The pattern data must be located on a pattern-size boundary. The pattern is always of 8x8 pixels, and therefore, its size is dependent upon its pixel depth. The pixel depth may be 8, 16, or 32 bits per pixel if the pattern is in color (the pixel depth of a color pattern must match the pixel depth to which the graphics system has been set). Monochrome patterns require 8 bytes and is supplied through the instruction. Color patterns of 8, 16, and 32 bits per pixel color depth must start on 64-byte, 128-byte and 256-byte boundaries, respectively. The Pattern Base Address programmed, must always be Cache Line (64byte) aligned.
	5:0	**Reserved** Format: MBZ

BR09 - Destination Address Lower Order Address Bits

BR09 - Destination Address Lower Order Address Bits		
Source:	BlitterCS	
Size (in bits):	32	
Default Value:	0x00000000	
DWord	**Bit**	**Description**
0	31:0	**Destination Address Bits** Format: GraphicsAddress[31:0] When tiling is enabled for XY-blits, this base address should be limited to 4KB. when tiling is disabled for XY-blits, this base address should be CL (64byte) aligned. These lower 32bits of the 48bit address, which specify the starting pixel address of the destination data. This register is also the working destination address register for the lower 32bits of the address, and changes as the BLT Engine performs the accesses. Used as the scan line address (Destination Y Address and Destination Y1 Address) for BLT instructions: PIXEL_BLT, SCANLINE_BLT, and TEXT_BLT. In this case the address points to the first pixel in a scan line and is compared with the ClipRect Y1 and Y2 address registers to determine whether the scan line should be written or not. The Destination Y1 address is the top scan line to be written for text. Note that for non-XY blits (COLOR_BLT, SRC_COPY_BLT), this address points to the first byte to be written. Note: Some instructions affect only one scan line (requiring only one coordinate); other instructions affect multiple scan lines and need both coordinates.

BR11 - BLT Source Pitch (Offset)

BR11 - BLT Source Pitch (Offset)		
Source:	BlitterCS	
Size (in bits):	32	
Default Value:	0x00000000	
DWord	**Bit**	**Description**
0	31:16	**Reserved**
	15:0	**Source Pitch (Offset)** For non-XY Blits with color source operand (SRC_COPY_BLT), the signed 16bit field allows for specifying upto + 32Kbytes signed pitch in bytes (same as before). For X, Y Blits with tiled-X surfaces, the pitch for Color Source will be 512Byte aligned and should be programmable upto + 128Kbytes. For X, Y Blits with tiled-Y surfaces, the pitch for Color Source will be 128Byte aligned and should be programmable upto + 128Kbytes. In this case, this 16bit signed pitch field is used to specify upto + 32KDWords. For X, Y blits with nontiled color source surfaces (linear surfaces), this 16bit field can be programmed to byte specification of upto + 32Kbytes (same as before). When the color source data is located within the frame buffer or AGP aperture, these signed 16 bits store the memory address offset (pitch) value by which the source address originally specified in the Source Address Register is incremented or decremented as each scan line's worth of source data is read from the frame buffer by the BLT Engine, so that the source address will point to the next memory address from which the next scan line's worth of source data is to be read. Note that if the intended source of a BLT operation is within on-screen frame buffer memory, this offset is normally set to accommodate the fact that each subsequent scan line's worth of source data lines up vertically with the source data in the scan line, above. However, if the intended source of a BLT operation is within off-screen memory, this offset can be set to accommodate a situation in which the source data exists as a single contiguous block of bytes where in each subsequent scan line's worth of source data is stored at a location immediately after the location where the source data for the last scan line ended.

BR12 - Source Address Lower order Address bits

BR12 - Source Address Lower order Address bits		
Source:	BlitterCS	
Size (in bits):	32	
Default Value:	0x00000000	
DWord	**Bit**	**Description**
0	31:0	**Source Address Bits** Format: GraphicsAddress[31:0] Lower 32bits of the 48bit addressing. When tiling is enabled for XY-blits with Color source surfaces, this base address should be aligned to 4KB. When tiling is disabled for XY-blits, this base address should be CL (64byte) aligned. Note that for non-XY blit with Color Source (SRC_COPY_BLT), this address points to the first byte to be read. These lower 32bits of the 48bit address, specify the starting pixel address of the color source data. The lower 3 bits are used to indicate the position of the first valid byte within the first Quadword of the source data. If this Source happens to be a Monosource surface, then this Monosource Base Address programmed, must always be Cache Line (64byte) aligned.

BR13 - BLT Raster OP, Control, and Destination Pitch

BR13 - BLT Raster OP, Control, and Destination Pitch

Source: BlitterCS
Size (in bits): 32
Default Value: 0x00000000

DWord	Bit	Description
0	31	**Solid Pattern Select** This bit applies only when the pattern data is monochrome. This bit determines whether or not the BLT Engine actually performs read operations from the frame buffer in order to load the pattern data. Use of this feature to prevent these read operations can increase BLT Engine performance, if use of the pattern data is indeed not necessary. The BLT Engine is configured to accept either monochrome or color pattern data via the opcode field.

Value	Name	Description
0	**[Default]**	This causes normal operation with regard to the use of the pattern data. The BLT Engine proceeds with the process of reading the pattern data, and the pattern data is used as the pattern operand for all bit-wise operations.
1		The BLT Engine forgoes the process of reading the pattern data, the presumption is made that all of the bits of the pattern data are set to 0, and the pattern operand for all bit-wise operations is forced to the background color specified in the Color Expansion Background Color Register.

30	**Clipping Enabled**
Default Value:	0

29	**Monochrome Source Transparency Mode** This bit applies only when the source data is in monochrome. This bit determines whether or not the byte(s) at the destination corresponding to the pixel to which a given bit of the source data also corresponds will actually be written if that source data bit has the value of 0. This feature can make it possible to use the source as a transparency mask. The BLT Engine is configured to accepted either monochrome or color source data via the opcode field.

Value	Name	Description
0	**[Default]**	This causes normal operation with regard to the use of the source data. Wherever a bit in the source data has the value of 0, the color specified in the background color register is used as the source operand in the bit-wise operation for the pixel corresponding to the source data bit, and the bytes at the destination corresponding to that pixel are written with the result.
1		Where a bit in the source data has the value of 0, the byte(s) at the destination corresponding to the pixel to which the source data bit also corresponds are simply not written, and the data at those byte(s) at the destination are allowed to remain unchanged.

BR13 - BLT Raster OP, Control, and Destination Pitch

28 **Monochrome Pattern Transparency Mode**

This bit applies only when the pattern data is monochrome. This bit determines whether or not the byte(s) at the destination corresponding to the pixel to which a given bit of the pattern data also corresponds will actually be written if that pattern data bit has the value of 1. This feature can make it possible to use the pattern as a transparency mask. The BLT Engine is configured to accepted either monochrome or color pattern data via the opcode in the Opcode and Control register.

Value	Name	Description
0	**[Default]**	This causes normal operation with regard to the use of the pattern data. Where a bit in the pattern data has the value of 0, the color specified in the background color register is used as the pattern operand in the bit-wise operation for the pixel corresponding to the pattern data bit, and the bytes at the destination corresponding to that pixel are written with the result.
1		Wherever a bit in the pattern data has the value of 0, the byte(s) at the destination corresponding to the pixel to which the pattern data bit also corresponds are simply not written, and the data at those byte(s) at the destination are allowed to remain unchanged.

27:26 **32bpp Byte Mask**

This field is only used for 32bpp.

Value	Name
00b	**[Default]**
1xb	Write Alpha Channel
x1b	Write RGB Channel

25:24 **Color Depth**

Value	Name
00b	8 Bit Color Depth **[Default]**
01b	16 Bit Color Depth
10b	24 Bit Color Depth
11b	Reserved

23:16 **Raster Operation Select**

Default Value:	00000000b

These 8 bits are used to select which one of 256 possible raster operations is to be performed by the BLT Engine.

BR13 - BLT Raster OP, Control, and Destination Pitch		
	15:0	**Destination Pitch(Offset)** These 16 bits store the signed memory address offset value by which the destination address originally specified in the Destination Address Register is incremented or decremented as each scan line's worth of destination data is written into the frame buffer by the BLT Engine, so that the destination address will point to the next memory address to which the next scan line's worth of destination data is to be written. If the intended destination of a BLT operation is within on-screen frame buffer memory, this offset is normally set so that each subsequent scan line's worth of destination data lines up vertically with the destination data in the scan line, above. However, if the intended destination of a BLT operation is within off-screen memory, this offset can be set so that each subsequent scan line's worth of destination data is stored at a location immediately after the location where the destination data for the last scan line ended, in order to create a single contiguous block of bytes of destination data at the destination.

BR14 - Destination Width and Height

BR14 - Destination Width and Height		
Source:	BlitterCS	
Size (in bits):	32	
Default Value:	0x00000000	
BR14 contains the values for the height and width of the data to be BLT. If these values are not correct, such that the BLT Engine is either expecting data it does not receive or receives data it did not expect, the system can hang.		
DWord	**Bit**	**Description**
0	31:29	**Reserved**
	28:16	**Destination Height** These 13 bits specify the height of the destination data in terms of the number of scan lines. This is a working register.
	15:13	**Reserved**
	12:0	**Destination Byte Width** These 13 bits specify the width of the destination data in terms of the number of bytes per scan line. The number of pixels per scan line into which this value translates depends upon the color depth to which the graphics system has been set.

BR15 - Color Pattern Address Lower order Address bits

BR15 - Color Pattern Address Lower order Address bits

Source: BlitterCS
Size (in bits): 32
Default Value: 0x00000000

DWord	Bit	Description
0	31:6	**Color Pattern Address** Format: GraphicsAddress[31:6] Lower 32bits of the 48bit addressing. There is no change to the Color Pattern address specification due to Non-Power-of-2 change. It remains the same as before. The pattern data must be located in linear memory. These 26 bits specify the starting address of the (8X8) pixel color pattern. The pattern data must be located on a pattern-size boundary. The pattern is always of 8x8 pixels, and therefore, its size is dependent upon its pixel depth. The pixel depth may be 8, 16, or 32 bits per pixel if the pattern is in color (the pixel depth of a color pattern must match the pixel depth to which the graphics system has been set). Monochrome patterns require 8 bytes and are applied through the instruction. Color patterns of 8, 16, and 32 bits per pixel color depth must start on 64-byte, 128-byte and 256-byte boundaries, respectively. The Pattern Base Address programmed, must always be Cache Line (64byte) aligned.
	5:0	**Reserved** Format: MBZ

BR16 - Pattern Expansion Background and Solid Pattern Color

BR16 - Pattern Expansion Background and Solid Pattern Color		
Source:	BlitterCS	
Size (in bits):	32	
Default Value:	0x00000000	
DWord	**Bit**	**Description**
0	31:0	**Pattern Expansion Background Color Bits** These bits provide the one, two, or four bytes worth of color data that select the background color to be used in the color expansion of monochrome pattern data during BLT operations. Whether one, two, or four bytes worth of color data is needed depends upon the color depth to which the BLT Engine has been set. For a color depth of 32bpp, 16bpp and 8bpp, bits [31:0], [15:0] and [7:0], respectively, are used.

BR17 - Pattern Expansion Foreground Color

BR17 - Pattern Expansion Foreground Color		
Source:	BlitterCS	
Size (in bits):	32	
Default Value:	0x00000000	
DWord	**Bit**	**Description**
0	31:0	**Pattern Expansion Background Color Bits** These bits provide the one, two, or four bytes worth of color data that select the foreground color to be used in the color expansion of monochrome pattern data during BLT operations. Whether one, two, or four bytes worth of color data is needed depends upon the color depth to which the BLT Engine has been set. For a color depth of 32bpp, 16bpp and 8bpp, bits [31:0], [15:0] and [7:0], respectively, are used.

BR18 - Source Expansion Background and Destination Color

BR18 - Source Expansion Background and Destination Color		
Source:	BlitterCS	
Size (in bits):	32	
Default Value:	0x00000000	
DWord	**Bit**	**Description**
0	31:0	**Source Expansion Background Color Bits** These bits provide the one, two, or four bytes worth of color data that select the background color to be used in the color expansion of monochrome source data during BLT operations. This register is also used to support destination transparency mode and Solid color fill. Whether one, two, three, or four bytes worth of color data is needed depends upon the color depth to which the BLT Engine has been set. For a color depth of 32bpp, 16bpp and 8bpp, bits [31:0], [15:0] and [7:0], respectively, are used.

BR19 - Source Expansion Foreground Color

BR19 - Source Expansion Foreground Color		
Source:	BlitterCS	
Size (in bits):	32	
Default Value:	0x00000000	
DWord	**Bit**	**Description**
0	31:0	**Pattern/Source Expansion Foreground Color Bits** These bits provide the one, two, or four bytes worth of color data that select the foreground color to be used in the color expansion of monochrome source data during BLT operations. Whether one, two, or four bytes worth of color data is needed depends upon the color depth to which the BLT Engine has been set. For a color depth of 32bpp, 16bpp and 8bpp, bits [31:0], [15:0] and [7:0], respectively, are used.

BR27 - Destination Higher Order Address

BR27 - Destination Higher Order Address

Source:	BlitterCS
Size (in bits):	32
Default Value:	0x00000000

Upper 32 bits of the starting pixel address for the destination data. This structure is also the working location for the upper bits of the destination address, and changes as the BLT Engine performs the accesses. See BR09 for the lower 32 bits. When tiling is enabled for XY-blits, this base address should be limited to 4KB. Otherwise for XY blits, there is no restriction and it is same as before.

Used as the scan line address (Destination Y Address and Destination Y1 Address) for BLT instructions: PIXEL_BLT, SCANLINE_BLT, and TEXT_BLT. In this case the address points to the first pixel in a scan line and is compared with the ClipRect Y1 and Y2 address registers to determine whether the scan line should be written or not. The Destination Y1 address is the top scan line to be written for text.

Note that for non-XY blits (COLOR_BLT, SRC_COPY_BLT), the destination address points to the first byte to be written. This structure is always the last location written for a BLT drawing instruction. Writing to BR27 starts the BLT engine execution. Note: Some instructions affect only one scan line (requiring only one coordinate); other instructions affect multiple scan lines and need both coordinates.

GraphicsAddress is a 64-bit value [63:0], but only a portion of it is used by hardware. The uppermost reserved bits are ignored and MBZ.

DWord	Bit	Description
0	31:16	**Reserved** Format: MBZ
	15:0	**Destination Address Upper DWORD** Format: GraphicsAddress[47:32]

BR28 - Source Higher Order Address

BR28 - Source Higher Order Address			
Source:	BlitterCS		
Size (in bits):	32		
Default Value:	0x00000000		
DWord		**Bit**	**Description**
0 Upper 32 bits of the Source address, specifying the starting pixel address of the color or mono source data. When tiling is enabled for XY-blits with Color source surfaces, this base address should be limited to 4KB. Otherwise for XY blits, there is no restriction and it is same as before, including for monosource and text blits. Note that for non-XY blit with Color Source (SRC_COPY_BLT), this address points to the first byte to be read. GraphicsAddress is a 64-bit value [63:0], but only a portion of it is used by hardware. The uppermost reserved bits are ignored and MBZ.		31:16	**Reserved** Format: MBZ
		15:0	**Source Address Upper DWORD** Format: GraphicsAddress[47:32]

BR29 - Color Pattern Higher Order Address

BR29 - Color Pattern Higher Order Address			
Source:	BlitterCS		
Size (in bits):	32		
Default Value:	0x00000000		
DWord		**Bit**	**Description**
0 Upper 32 bits of the Color Pattern address, specifying the starting location of the (8X8) pixel pattern. GraphicsAddress is a 64-bit value [63:0], but only a portion of it is used by hardware. The uppermost reserved bits are ignored and MBZ.		31:16	**Reserved** Format: MBZ
		15:0	**Color Pattern Address Upper DWORD** Format: GraphicsAddress[47:32]

BR30 - Setup Blit Color Pattern Higher Order Address

BR30 - Setup Blit Color Pattern Higher Order Address		
Source:	BlitterCS	
Size (in bits):	32	
Default Value:	0x00000000	
DWord	**Bit**	**Description**
0 Upper 32 bits of the Color Pattern address, specifying the starting location of the (8X8) pixel pattern. GraphicsAddress is a 64-bit value [63:0], but only a portion of it is used by hardware. The uppermost reserved bits are ignored and MBZ.	31:16	**Reserved** Format: MBZ
	15:0	**Setup Blit Color Pattern Upper DWORD** Format: GraphicsAddress[47:32]

Byte Masked Media Block Message Header

MH_MBBM - Byte Masked Media Block Message Header

Source: DataPort 1

Size (in bits): 256

Default Value: 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000

DWord	Bit	Description
0	31:0	**X Offset** Format: S31 X offset (in bytes) of the upper left corner of the block into the surface. **Programming Notes** Must be DWord aligned (Bits 1:0 MBZ) for the write form of the message.
1	31:0	**Y Offset** Format: S31 Y offset (in rows) of the upper left corner of the block into the surface.
2	31:0	**Media Block Message Control** Format: MHC_MBBM_CONTROL Specifies the Byte Masked message subtype and its additional input parameters.
3	31:0	**Byte Mask** Format: U32 Specifies the Byte Mask for writes when Message Mode field is BYTE_MASK. **Programming Notes** The Byte mask applies horizontally to each row of output: bit 0 for byte 0, through bit 31 for byte 31.
4	31:0	**FFTID** Format: MHC_FFTID Fixed Function Thread ID
5..7	95:0	**Reserved** Format: Ignore Ignored

Byte Masked Media Block Message Header Control

MHC_MBBM_CONTROL - Byte Masked Media Block Message Header Control

Source: BSpec
Size (in bits): 32
Default Value: 0x00000000

DWord	Bit	Description
0	31:30	**Message Mode** Format: Enumeration Specifies the Media Block Write Message subtype is Byte Masked. Value / Name / Description: 02h / BYTE_MASK / The Block Height and Block Width fields are specified in this Dword. The Byte Mask qualifies which bytes are written. Others / Reserved / Reserved.
	29	**Reserved** Format: Ignore Ignored
	28:24	**Sub-Register Offset** Format: U5 This field is ignored (reserved) for Media Block Write message.
	23:22	**Reserved** Format: Ignore Ignored
	21:16	**Block Height** Format: U6 Height in rows of block being accessed. Range = [0,63] representing 1 to 64 rows Restriction Restriction : If Block Width (bytes), then Maximum Block Height (rows) is constrained by (# Dwords width) * (# rows) <= 64 Dwords.
	15:10	**Reserved** Format: Ignore Ignored

MHC_MBBM_CONTROL - Byte Masked Media Block Message Header Control

	9:8	**Register Pitch Control** Format: U2 This field is ignored (reserved) for a Media Block Write message.
	7:6	**Reserved** Format: Ignore Ignored
	5:0	**Block Width** Format: U6 Width in bytes of the block being accessed. Range = [0,31] representing 1 to 32 Bytes. **Programming Notes** Must be DWord aligned for Media Block Write message.

CC_VIEWPORT

CC_VIEWPORT

Source: BSpec
Size (in bits): 64
Default Value: 0x00000000, 0x00000000

The viewport state is stored as an array of up to 16 elements, each of which contains the DWords described here. The start of each element is spaced 2 DWords apart. The first element of the viewport state array is aligned to a 32-byte boundary. The Minimum and Maximum Depth legal value ranges are dependant on the depth buffer format.

DWord	Bit	Description
0	31:0	**Minimum Depth** Format: IEEE_Float Indicates the minimum depth. The interpolated or computed depth is clamped to this value prior to the depth test. **Programming Notes** The Minimum depth value must be less-than-or-equal to the Maximum depth value. The Minimum depth value cannot be NAN (Not-A-Number). For All depth formats:Minimum depth value must not be less than 0.0, also it may not be -0.0 (negative zero)
1	31:0	**Maximum Depth** Format: IEEE_Float Indicates the maximum depth. The interpolated or computed depth is clamped to this value prior to the depth test. **Programming Notes** The Maximum depth value cannot be smaller than Minimum depth value. The Maximum depth value cannot be NAN (Not-A-Number). For all depth formats: The Maximum depth value must be between +0.0to +1.0.

Channel Mask Message Descriptor Control Field

MDC_CMASK - Channel Mask Message Descriptor Control Field

Source: BSpec
Size (in bits): 4
Default Value: 0x00000000

DWord	Bit	Description
0	3:0	**Mask** Format: Enumeration For the read message, indicates that which channels are read from the surface and included in the writeback message. For the write message, indicates which channels are included in the message payload and written to the surface.

Value	Name	Description
00h	RGBA **[Default]**	Red, Green, Blue, and Alpha are included
01h	GBA	Green, Blue, and Alpha are included
02h	RBA	Red, Blue, and Alpha are included
03h	BA	Blue and Alpha are included
04h	RGA	Red, Green, and Alpha are included
05h	GA	Green and Alpha are included
06h	RA	Red and Alpha are included
07h	A	Alpha is included
08h	RGB	Red, Green, and Blue are included
09h	GB	Green and Blue are included
0Ah	RB	Red and Blue are included
0Bh	B	Blue is included
0Ch	RG	Red and Green are included
0Dh	G	Green is included
0Eh	R	Red is included
0Fh	Reserved	Ignored

Channel Mode Message Descriptor Control Field

MDC_CMODE - Channel Mode Message Descriptor Control Field

Source: BSpec
Size (in bits): 1
Default Value: 0x00000000

DWord	Bit	Description
0	0	**Channel Mode** Format: Enumeration Two modes of channel-enable are provided: a SIMD8 or SIMD16 Dword channel serial view of a register, and a SIMD4x2 view of a register.

Value	Name	Description
0	Oword	All 4 Dwords are read or written if one or more of these channels are enabled
1	Dword	Each Dword is read or written only if its corresponding channel is enabled.

Clock Gating Disable Format

Clock Gating Disable Format		
Source:	BSpec	
Size (in bits):	1	
Default Value:	0x00000000	
DWord	**Bit**	**Description**
0	0	**Clock_Gate_Disable**

Value	Name	Description
0b	Enable	Clock gating controlled by unit logic
1b	Disable	Disable clock gating function

Clock Gating Disable Format

Clock Gating Disable Format

Source: BSpec
Size (in bits): 1
Default Value: 0x00000000

DWord	Bit	Description
0	0	**Clock Gate Disable**

Value	Name	Description
0b	Enable	Clock gating controlled by unit enabling logic
1b	Disable	Disable clock gating function

COLOR_CALC_STATE

COLOR_CALC_STATE

Source: BSpec
Size (in bits): 192
Default Value: 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000

This definition is pointed to by a field in 3DSTATE_CC_STATE_POINTERS, and stored at a 64-byte aligned boundary.

DWord	Bit	Description
0	31:16	**Reserved** Format: MBZ
	15	**Round Disable Function Disable** Format: Disable Disables the round-disable function of the color calculator. Value 0 – Name: Cancelled – Description: Dithering is cancelled based on the data used by blend to avoid drift. Value 1 – Name: Not Cancelled – Description: Dithering is NOT cancelled.
	14:1	**Reserved** Format: MBZ
	0	**Alpha Test Format** This field selects the format for Alpha Reference Value and the format in which Alpha Test is performed. Value 0h – Name: ALPHATEST_UNORM8 – Description: UNorm8 Value 1h – Name: ALPHATEST_FLOAT32 – Description: Float32 **Programming Notes** Alpha-test format is independent of RT format. When PS outputs UNIT/SINT alpha-value, it will be treated as IEEE 32bit float number for the purpose of alpha-test.
1	31:0	**Alpha Reference Value As UNORM8** Exists If: [Alpha Test Format] == 'ALPHATEST_UNORM8' Format: UNORM8 Upper 24 bits MBZ This field specifies the alpha reference value to compare against in the Alpha Test function.
	31:0	**Alpha Reference Value As FLOAT32** Exists If: [Alpha Test Format] == 'ALPHATEST_FLOAT32' Format: IEEE_Float This field specifies the alpha reference value to compare against in the Alpha Test function.

COLOR_CALC_STATE		
2	31:0	**Blend Constant Color Red** Format: IEEE_Float This field specifies the Red channel of the Constant Color used in Color Buffer Blending.
3	31:0	**Blend Constant Color Green** Format: IEEE_Float This field specifies the Green channel of the Constant Color used in Color Buffer Blending.
4	31:0	**Blend Constant Color Blue** Format: IEEE_Float This field specifies the Blue channel of the Constant Color used in Color Buffer Blending.
5	31:0	**Blend Constant Color Alpha** Format: IEEE_Float This field specifies the Alpha channel of the Constant Color used in Color Buffer Blending.

COLOR_PROCESSING_STATE - ACE State

COLOR_PROCESSING_STATE - ACE State

Source: BSpec

Size (in bits): 416

Default Value: 0x00000068, 0x4C382410, 0x9C887460, 0xEBD8C4B0, 0x604C3824, 0xB09C8874, 0x0000D8C4, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000

This state structure contains the ACE state used by the color processing function.
It corresponds to DW29..DW41 of the Color Processing State.

DWord	Bit	Description
0	31:7	**Reserved** Format: MBZ
	6:2	**Skin Threshold** Format: U5 Used for Y analysis (min/max) for pixels which are higher than skin threshold. Value / Name: 1-31 26 **[Default]**
	1	**Full Image Histogram** Default Value: 0 Format: Enable Used to ignore the area of interest for full image histogram.
	0	**ACE Enable** Format: Enable
1	31:24	**Y3** Default Value: 76 Format: U8 The value of the y_pixel for point 3 in PWL.
	23:16	**Y2** Default Value: 56 Format: U8 The value of the y_pixel for point 2 in PWL.

COLOR_PROCESSING_STATE - ACE State

	15:8	**Y1** Default Value: 36 Format: U8 The value of the y_pixel for point 1 in PWL.
	7:0	**Ymin** Default Value: 16 Format: U8 The value of the y_pixel for point 0 in PWL.
2	31:24	**Y7** Default Value: 156 Format: U8 The value of the y_pixel for point 7 in PWL.
	23:16	**Y6** Default Value: 136 Format: U8 The value of the y_pixel for point 6 in PWL.
	15:8	**Y5** Default Value: 116 Format: U8 The value of the y_pixel for point 5 in PWL.
	7:0	**Y4** Default Value: 96 Format: U8 The value of the y_pixel for point 4 in PWL.
3	31:24	**Ymax** Default Value: 235 Format: U8 The value of the y_pixel for point 11 in PWL.
	23:16	**Y10** Default Value: 216 Format: U8 The value of the y_pixel for point 10 in PWL.

COLOR_PROCESSING_STATE - ACE State

	15:8	**Y9** Default Value: 196 Format: U8 The value of the y_pixel for point 9 in PWL.
	7:0	**Y8** Default Value: 176 Format: U8 The value of the y_pixel for point 8 in PWL.
4	31:24	**B4** Default Value: 96 Format: U8 The value of the bias for point 4 in PWL.
	23:16	**B3** Default Value: 76 Format: U8 The value of the bias for point 3 in PWL.
	15:8	**B2** Default Value: 56 Format: U8 The value of the bias for point 2 in PWL.
	7:0	**B1** Default Value: 36 Format: U8 The value of the bias for point 1 in PWL.
5	31:24	**B8** Default Value: 176 Format: U8 The value of the bias for point 8 in PWL.
	23:16	**B7** Default Value: 156 Format: U8 The value of the bias for point 7 in PWL.

COLOR_PROCESSING_STATE - ACE State		
	15:8	**B6** Default Value: 136 Format: U8 The value of the bias for point 6 in PWL.
	7:0	**B5** Default Value: 116 Format: U8 The value of the bias for point 5 in PWL.
6	31:16	**Reserved** Format: MBZ
	15:8	**B10** Default Value: 216 Format: U8 The value of the bias for point 10 in PWL.
	7:0	**B9** Default Value: 196 Format: U8 The value of the bias for point 9 in PWL.
7	31:27	**Reserved** Format: MBZ
	26:16	**S1** Format: U1.10 The value of the slope for point 1 in PWL. The default is 1024/1024.
	15:11	**Reserved** Format: MBZ
	10:0	**S0** Format: U1.10 The value of the slope for point 0 in PWL. The default is 1024/1024.

COLOR_PROCESSING_STATE - ACE State		
	26:16	**S3** Format: U1.10 The value of the slope for point 3 in PWL. The default is 1024/1024.
	15:11	**Reserved** Format: MBZ
	10:0	**S2** Format: U1.10 The value of the slope for point 2 in PWL. The default is 1024/1024.
9	31:27	**Reserved** Format: MBZ
	26:16	**S5** Format: U1.10 The value of the slope for point 5 in PWL. The default is 1024/1024.
	15:11	**Reserved** Format: MBZ
	10:0	**S4** Format: U1.10 The value of the slope for point 4 in PWL. The default is 1024/1024.
10	31:27	**Reserved** Format: MBZ
	26:16	**S7** Format: U1.10 The value of the slope for point 7 in PWL. The default is 1024/1024.
	15:11	**Reserved** Format: MBZ
	10:0	**S6** Format: U1.10 The value of the slope for point 6 in PWL. The default is 1024/1024.

COLOR_PROCESSING_STATE - ACE State		
11	31:27	**Reserved** Format: MBZ
	26:16	**S9** Format: U1.10 The value of the slope for point 9 in PWL. The default is 1024/1024.
	15:11	**Reserved** Format: MBZ
	10:0	**S8** Format: U1.10 The value of the slope for point 8 in PWL. The default is 1024/1024.
12	31:11	**Reserved** Format: MBZ
	10:0	**S10** Format: U1.10 The value of the slope for point 10 in PWL. The default is 1024/1024.

COLOR_PROCESSING_STATE - CSC State

COLOR_PROCESSING_STATE - CSC State

Source: BSpec

Size (in bits): 288

Default Value: 0x00002000, 0x00000000, 0x00000400, 0x00000000, 0x000004B4, 0x00000000, 0x00000000, 0x00000000, 0x00000000

This state structure contains the CSC state used by the color processing function.
It corresponds to DW55..DW63 of the Color Processing State.

DWord	Bit	Description
0	31:29	**Reserved** Format: MBZ
	28:16	**C1** Default Value: 0 Format: S2.10 2's complement Transform coefficient
	15:3	**C0** Default Value: 1024 Format: S2.10 2's complement Transform coefficient
	2	**YUV_IN** Default Value: 0 Format: YUV CSC input offset enable.
	1	**YUV_OUT** Default Value: 0 Format: RGB CSC output offset enable.
	0	**Transform Enable** Format: Enable
1	31:26	**Reserved** Format: MBZ

COLOR_PROCESSING_STATE - CSC State

	25:13	**C3** Default Value: 0 Format: S2.10 2's complement Transform coefficient.
	12:0	**C2** Default Value: 0 Format: S2.10 2's complement Transform coefficient.
2	31:26	**Reserved** Format: MBZ
	25:13	**C5** Default Value: 0 Format: S2.10 2's complement Transform coefficient.
	12:0	**C4** Default Value: 1024 Format: S2.10 2's complement Transform coefficient.
3	31:26	**Reserved** Format: MBZ
	25:13	**C7** Default Value: 0 Format: S2.10 2's complement Transform coefficient.
	12:0	**C6** Default Value: 0 Format: S2.10 2's complement Transform coefficient.
4	31:13	**Reserved** Format: MBZ

COLOR_PROCESSING_STATE - CSC State

	12:0	**C8** Default Value: 1204 Format: S2.10 2's complement Transform coefficient.
5	31:20	**Reserved** Format: MBZ
	19:10	**Offset out 1** Default Value: 0 Format: S9 2's complement Offset Out for Y/R.
	9:0	**Offset In 1** Default Value: 0 Format: S9 2's complement Offset in for Y/R.
6	31:20	**Reserved** Format: MBZ
	19:10	**Offset out 2** Default Value: 0 Format: S9 2's complement Offset out for U/G.
	9:0	**Offset in 2** Default Value: 0 Format: S9 2's complement Offset in for U/G.
7	31:20	**Reserved** Format: MBZ
	19:10	**Offset out 3** Default Value: 0 Format: S9 2's complement Offset out for V/B.

COLOR_PROCESSING_STATE - CSC State

	9:0	**Offset in 3** Default Value: 0 Format: S9 2's complement Offset in for V/B.
8	31:17	**Reserved** Format: MBZ
	16	**Alpha from State Select** Format: U1 Enumerated Type Value / Name / Description 0 / Alpha is taken from message 1 / Alpha is taken from state
	15:0	**Color Pipe Alpha** Format: U16

COLOR_PROCESSING_STATE - PROCAMP State

COLOR_PROCESSING_STATE - PROCAMP State

Source: BSpec
Size (in bits): 64
Default Value: 0x00020001, 0x01000000

This state structure contains the PROCAMP state used by the color processing function.
It corresponds to DW53..DW54 of the Color Processing State.

DWord	Bit	Description
0	31:28	**Reserved** Format: MBZ
	27:17	**Contrast** Default Value: 1 Format: U4.7 Contrast magnitude.
	16:13	**Reserved** Format: MBZ
	12:1	**Brightness** Default Value: 0 Format: S7.4 2's complement Brightness magnitude.
	0	**PROCAMP Enable** Default Value: 1 Format: Enable
1	31:16	**Cos_c_s** Default Value: 256 Format: S7.8 2's complement UV multiplication cosine factor.
	15:0	**Sin_c_s** Default Value: 0 Format: S7.8 2's complement UV multiplication sine factor.

COLOR_PROCESSING_STATE - STD/STE State

COLOR_PROCESSING_STATE - STD/STE State

Source: BSpec

Size (in bits): 928

Default Value: 0x9A6E39F0, 0x400C0000, 0x00001180, 0xFE2F2E00, 0x000000FF, 0x00140000, 0xD82E0000, 0x8285ECEC, 0x00008282, 0x00000000, 0x02117000, 0xA38FEC96, 0x00008CC8, 0x00000000, 0x01478000, 0x0007C300, 0x00000000, 0x00000000, 0x1C180000, 0x00000000, 0x00000000, 0x00000000, 0x0007CF80, 0x00000000, 0x00000000, 0x1C080000, 0x00000000, 0x00000000, 0x00000000

This state structure contains the STD/STE state used by the color processing function.

DWord	Bit	Description
0	31:24	**V_Mid** Default Value: 154 Format: U8 Rectangle middle-point V coordinate
	23:16	**U_Mid** Default Value: 110 Format: U8 Rectangle middle-point U coordinate
	15:10	**Hue Max** Default Value: 14 Format: U6 Rectangle half width
	9:4	**Sat Max** Default Value: 31 Format: U6 Rectangle half length.
	3	**Reserved** Format: MBZ
	2	**Output Control** 0 – Output Pixels **[Default]** 1 – Output STD Decisions

COLOR_PROCESSING_STATE - STD/STE State

	1	**STE Enable** Format: Enable
	0	**STD Enable** Format: Enable
1	31	**Reserved** Format: MBZ
	30:28	**Diamond Margin** Default Value: 4 Format: U3
	27:21	**Diamond du** Default Value: 0 Format: S6 2's complement Rhombus center shift in the sat-direction, relative to the rectangle center.
	20:18	**HS Margin** Default Value: 3 Format: U3
	17:10	**Cos(α)** Format: S0.7 2's Compliment The default is 79/128
	9:8	**Reserved** Format: MBZ
	7:0	**Sin(α)** Format: S0.7 2's Compliment The default is 101/128
2	31:21	**Reserved** Format: MBZ
	20:13	**Diamond Alpha** Format: U2.6 1 / tan(β) The default is 100/64

COLOR_PROCESSING_STATE - STD/STE State

	12:7	**Diamond Th** Default Value: 35 Format: U6 Half length of the rhombus axis in the sat-direction.
	6:0	**Diamond dv** Default Value: 0 Format: S6 2's complement
3	31:24	**Y_point_3** Default Value: 254 Format: U8 Third point of the Y piecewise linear membership function.
	23:16	**Y_point_2** Default Value: 47 Format: U8 Second point of the Y piecewise linear membership function.
	15:8	**Y_point_1** Default Value: 46 Format: U8 First point of the Y piecewise linear membership function.
	7	**VY_STD_Enable** Format: Enable Enables STD in the VY subspace.
	6:0	**Reserved** Format: MBZ
4	31:18	**Reserved** Format: MBZ
	17:13	**Y_Slope_2** Format: U2.3 Slope between points Y3 and Y4. The default is 31/8.

COLOR_PROCESSING_STATE - STD/STE State

	12:8	**Y_Slope_1** Format: U2.3 Slope between points Y1 and Y2. The default is 31/8.
	7:0	**Y_point_4** Default Value: 255 Format: U8 Fourth point of the Y piecewise linear membership function
5	31:16	**INV_skin_types_margin** Format: U0.16 1/(2* Skin_types_margin) Value: 20 – Name: **[Default]** – Description: Skin_Type_margin
	15:0	**Inverse Margin VYL** Format: U0.16 1 / Margin_VYL The default is 3300/65536
6	31:24	**P1L** Default Value: 216 Format: U8 Y Point 1 of the lower part of the detection PWLF.
	23:16	**P0L** Default Value: 46 Format: U8 Y Point 0 of the lower part of the detection PWLF.
	15:0	**Inverse Margin VYU** Format: U0.16 1 / Margin_VYU The default is 1600/65536.
7	31:24	**B1L** Default Value: 130 Format: U8 V Bias 1 of the lower part of the detection PWLF.

COLOR_PROCESSING_STATE - STD/STE State

	23:16	**B0L** Default Value: 133 Format: U8 V Bias 0 of the lower part of the detection PWLF.
	15:8	**P3L** Default Value: 236 Format: U8 Y Point 3 of the lower part of the detection PWLF.
	7:0	**P2L** Default Value: 236 Format: U8 Y point 2 of the lower part of the detection PWLF.
8	31:27	**Reserved** Format: MBZ
	26:16	**S0L** Format: S2.8 2's complement Slope 0 of the lower part of the detection PWLF. The default is -5/256.
	15:8	**B3L** Default Value: 130 Format: U8 V Bias 3 of the lower part of the detection PWLF.
	7:0	**B2L** Default Value: 130 Format: U8 V Bias 2 of the lower part of the detection PWLF.
9	31:22	**Reserved** Format: MBZ
	21:11	**S2L** Format: S2.8 2's complement Slope 2 of the lower part of the detection PWLF. The default is 0/256.

COLOR_PROCESSING_STATE - STD/STE State		
	10:0	**S1L** Format: S2.8 2's complement Slope 1 of the lower part of the detection PWLF. The default is 0/256.
10	31:27	**Reserved** Format: MBZ
	26:19	**P1U** Default Value: 66 Format: U8 Y Point 1 of the upper part of the detection PWLF.
	18:11	**P0U** Default Value: 46 Format: U8 Y Point 0 of the upper part of the detection PWLF.
	10:0	**S3L** Format: S2.8 2's complement Slope 3 of the lower part of the detection PWLF. The default is 0/256.
11	31:24	**B1U** Default Value: 163 Format: U8 V Bias 1 of the upper part of the detection PWLF.
	23:16	**B0U** Default Value: 143 Format: U8 V Bias 0 of the upper part of the detection PWLF.
	15:8	**P3U** Default Value: 236 Format: U8 Y Point 3 of the upper part of the detection PWLF.

COLOR_PROCESSING_STATE - STD/STE State		
	7:0	**P2U** Default Value: 150 Format: U8 Y Point 2 of the upper part of the detection PWLF.
12	31:27	**Reserved** Format: MBZ
	26:16	**S0U** Format: S2.8 2's complement Slope 0 of the upper part of the detection PWLF. The default is 256/256.
	15:8	**B3U** Default Value: 140 Format: U8 V Bias 3 of the upper part of the detection PWLF.
	7:0	**B2U** Default Value: 200 Format: U8 V Bias 2 of the upper part of the detection PWLF.
13	31:22	**Reserved** Format: MBZ
	21:11	**S2U** Format: S2.8 2's complement Slope 2 of the upper part of the detection PWLF. The default is -179/256.
	10:0	**S1U** Format: S2.8 2's complement Slope 1 of the upper part of the detection PWLF. The default is -113/256.
14	31:28	**Reserved** Format: MBZ

COLOR_PROCESSING_STATE - STD/STE State

	27:20	**Skin Types Margin** Default Value: 20 Format: U8 Skin types Y margin.
	19:12	**Skin Types Thresh** Default Value: 120 Format: U8 Skin types Y threshold.
	11	**Skin Type Enable** Format: Enable Treat differently bright and dark skin types. 0 **[Default]** Disable
	10:0	**S3U** Format: S2.8 2's complement Slope 3 of the upper part of the detection PWLF. The default is 0/256.
15	31	**Reserved** Format: MBZ
	30:21	**SATB1** Format: S7.2 2's complement First bias for the saturation PWLF (bright skin). The default is -8/4.
	20:14	**SATP3** Default Value: 31 Format: S6 2's complement Third point for the saturation PWLF (bright skin).
	13:7	**SATP2** Default Value: 6 Format: S6 2's complement Second point for the saturation PWLF (bright skin).

COLOR_PROCESSING_STATE - STD/STE State

	6:0	**SATP1** Format: S6 2's complement First point for the saturation PWLF (bright skin). The default is -6.
16	31	**Reserved** Format: MBZ
	30:20	**SATS0** Format: U3.8 Zeroth slope for the saturation PWLF (bright skin). The default is 297/256.
	19:10	**SATB3** Format: S7.2 2's complement Third bias for the saturation PWLF (bright skin). The default is 124/4.
	9:0	**SATB2** Format: S7.2 2's complement Second bias for the saturation PWLF (bright skin). The default is 8/4.
17	31:22	**Reserved** Format: MBZ
	21:11	**SATS2** Format: U3.8 Second slope for the saturation PWLF (bright skin). The default is 297/256.
	10:0	**SATS1** Format: U3.8 First slope for the saturation PWLF (bright skin). The default is 85/256.
18	31:25	**HUEP3** Default Value: 14 Format: S6 2's complement Third point for the hue PWLF (bright skin)

COLOR_PROCESSING_STATE - STD/STE State

	24:18	**HUEP2** Default Value: 6 Format: S6 2's complement Second point for the hue PWLF (bright skin)
	17:11	**HUEP1** Format: S6 2's complement First point for the hue PWLF (bright skin). The default is -6.
	10:0	**SATS3** Format: U3.8 Thrid slope for the saturation PWLF (bright skin). The default is 256/256.
19	31:30	**Reserved** Format: MBZ
	29:20	**HUEB3** Format: S7.2 2's complement Third bias for the hue PWLF (bright skin). The default is 56/4.
	19:10	**HUEB2** Format: S7.2 2's complement Second bias for the hue PWLF (bright skin). The default is 8/4.
	9:0	**HUEB1** Format: S7.2 2's complement First bias for the hue PWLF (bright skin). The default is -8/4.
20	31:22	**Reserved** Format: MBZ
	21:11	**HUES1** Format: U3.8 First slope for the hue PWLF (bright skin) The default is 85/256.

COLOR_PROCESSING_STATE - STD/STE State

	10:0	**HUES0** Format: U3.8 Zeroth slope for the hue PWLF (bright skin) The default is 384/256.
21	31:22	**Reserved** Format: MBZ
	21:11	**HUES3** Format: U3.8 Third slope for the hue PWLF (bright skin) The default is 256/256.
	10:0	**HUES2** Format: U3.8 Second slope for the hue PWLF (bright skin) The default is 384/256.
22	31	**Reserved** Format: MBZ
	30:21	**SATB1_DARK** Format: S7.2 2's complement First bias for the saturation PWLF (dark skin) The default is 0/4.
	20:14	**SATP3_DARK** Default Value: 31 Format: S6 2's complement Third point for the saturation PWLF (dark skin)
	13:7	**SATP2_DARK** Default Value: 31 Format: S6 2's complement Second point for the saturation PWLF (dark skin)
	6:0	**SATP1_DARK** Format: S6 2's complement First point for the saturation PWLF (dark skin). The default is -11.

COLOR_PROCESSING_STATE - STD/STE State		
23	31	**Reserved** Format: MBZ
	30:20	**SATS0_DARK** Format: U3.8 Zeroth slope for the saturation PWLF (dark skin). The default is 397/256.
	19:10	**SATB3_DARK** Format: S7.2 2's complement Third bias for the saturation PWLF (dark skin). The default is 124/4.
	9:0	**SATB2_DARK** Format: S7.2 2's complement Second bias for the saturation PWLF (dark skin). The default is 124/4.
24	31:22	**Reserved** Format: MBZ
	21:11	**SATS2_DARK** Format: U3.8 Second slope for the saturation PWLF (dark skin). The default is 256/256.
	10:0	**SATS1_DARK** Format: U3.8 First slope for the saturation PWLF (dark skin). The default is 189/256.
25	31:25	**HUEP3_DARK** Default Value: 14 Format: S6 2's complement Third point for the hue PWLF (dark skin).
	24:18	**HUEP2_DARK** Default Value: 2 Format: S6 2's complement Third point for the hue PWLF (dark skin).

COLOR_PROCESSING_STATE - STD/STE State

	17:11	**HUEP1_DARK** Default Value: 0 Format: S6 2's complement Third point for the hue PWLF (dark skin).
	10:0	**SATS3_DARK** Format: U3.8 Third slope for the saturation PWLF (dark skin). The default is 256/256.
26	31:30	**Reserved** Format: MBZ
	29:20	**HUEB3_DARK** Format: S7.2 2's complement Third bias for the hue PWLF (dark skin). The default is 56/4.
	19:10	**HUEB2_DARK** Format: S7.2 2's complement Second bias for the hue PWLF (dark skin). The default is 0/4.
	9:0	**HUEB1_DARK** Format: S7.2 2's complement First bias for the hue PWLF (dark skin). The default is 0/4.
27	31:22	**Reserved** Format: MBZ
	21:11	**HUES1_DARK** Format: U3.8 First slope for the hue PWLF (dark skin). The default is 0/256.
	10:0	**HUES0_DARK** Format: U3.8 Zeroth slope for the hue PWLF (dark skin). The default is 256/256.

COLOR_PROCESSING_STATE - STD/STE State		
28	31:22	**Reserved** Format: MBZ
	21:11	**HUES3_DARK** Format: U3.8 Third slope for the hue PWLF (dark skin). The default is 256/256.
	10:0	**HUES2_DARK** Format: U3.8 Second slope for the hue PWLF (dark skin). The default is 299/256.

COLOR_PROCESSING_STATE - TCC State

COLOR_PROCESSING_STATE - TCC State

Source: BSpec

Size (in bits): 352

Default Value: 0xDCDCDC00, 0xDCDCDC00, 0x1E34CC91, 0x3E3CCE91, 0x02E80195, 0x0197046B, 0x01790174, 0x00096000, 0x00000000, 0x03030000, 0x009201C0

This state structure contains the TCC state used by the color processing function.
It corresponds to DW42..DW52 of the Color Processing State.

DWord	Bit	Description
0	31:24	**SatFactor3** Default Value: 220 Format: U1.7 The saturation factor for yellow.
	23:16	**SatFactor2** Default Value: 220 Format: U1.7 The saturation factor for red.
	15:8	**SatFactor1** Default Value: 220 Format: U1.7 The saturation factor for magenta.
	7	**TCC Enable** Format: Enable
	6:0	**Reserved** Format: MBZ
1	31:24	**SatFactor6** Default Value: 220 Format: U1.7 The saturation factor for blue.
	23:16	**SatFactor5** Default Value: 220 Format: U1.7 The saturation factor for cyan.

COLOR_PROCESSING_STATE - TCC State		
	15:8	**SatFactor4** Default Value: 220 Format: U1.7 The saturation factor for green.
	7:0	**Reserved** Format: MBZ
2	31:30	**Reserved** Format: MBZ
	29:20	**Base Color 3** Default Value: 483 Format: U10
	19:10	**Base Color 2** Default Value: 307 Format: U10
	9:0	**Base Color 1** Default Value: 145 Format: U10
3	31:30	**Reserved** Format: MBZ
	29:20	**Base Color 6** Default Value: 995 Format: U10
	19:10	**Base Color 5** Default Value: 819 Format: U10
	9:0	**Base Color 4** Default Value: 657 Format: U10
4	31:16	**Color Transit Slope 23** Default Value: 744 Format: U0.16 The calculation result of 1 / (BC3 - BC2) [1/62]

COLOR_PROCESSING_STATE - TCC State

	15:0	**Color Transit Slope 12** Default Value: 405 Format: U0.16 The calculation result of 1 / (BC2 - BC1) [1/57]
5	31:16	**Color Transit Slope 45** Default Value: 407 Format: U0.16 The calculation result of 1 / (BC5 - BC4) [1/57]
	15:0	**Color Transit Slope 34** Default Value: 1131 Format: U0.16 The calculation result of 1 / (BC4 - BC3) [1/61]
6	31:16	**Color Transit Slope 61** Default Value: 377 Format: U0.16 The calculation result of 1 / (BC1 - BC6) [1/62]
	15:0	**Color Transit Slope 56** Default Value: 372 Format: U0.16 The calculation result of 1 / (BC6 - BC5) [1/62]
7	31:22	**Color Bias 3** Default Value: 0 Format: U2.8 Color bias for BaseColor3.
	21:12	**Color Bias 2** Default Value: 150 Format: U2.8 Color bias for BaseColor2.
	11:2	**Color Bias 1** Default Value: 0 Format: U2.8 Color bias for BaseColor1.

COLOR_PROCESSING_STATE - TCC State

	1:0	**Reserved** Format: MBZ
8	31:22	**Color Bias 6** Default Value: 0 Format: U2.8 Color bias for BaseColor6.
	21:12	**Color Bias 5** Default Value: 0 Format: U2.8 Color bias for BaseColor5.
	11:2	**ColorBias4** Default Value: 0 Format: U2.8 Color bias for BaseColor4.
	1:0	**Reserved** Format: MBZ
9	31	**Reserved** Format: MBZ
	30:24	**UV Threshold** Default Value: 3 Format: U7 Low UV threshold.
	23:19	**Reserved** Format: MBZ
	18:16	**UV Threshold Bits** Default Value: 3 Format: U3 Low UV transition width bits.
	15:13	**Reserved** Format: MBZ

COLOR_PROCESSING_STATE - TCC State		
	12:8	**STE Threshold** Default Value: 0 Format: U5 Skin tone pixels enhancement threshold.
	7:3	**Reserved** Format: MBZ
	2:0	**STE Slope Bits** Default Value: 0 Format: U3 Skin tone pixels enhancement slope bits.
10	31:16	**Inverse UVMax Color** Default Value: 146 Format: U0.16 1 / UVMaxColor. Used for the SFs2 calculation.
	15:9	**Reserved** Format: MBZ
	8:0	**UVMax Color** Default Value: 448 Format: U9 The maximum absolute value of the legal UV pixels. Used for the SFs2 calculation.

Color Calculator State Pointer Message Header Control

MHC_RT_CCSP - Color Calculator State Pointer Message Header Control

Source:	BSpec
Size (in bits):	32
Default Value:	0x00000000

DWord	Bit	Description
0	31:6	**Color Calculator State Pointer** Format: GeneralStateOffset[31:6] Specifies the 64-byte aligned point to the color calculator state. This pointer is relative to the General State Base Address.
	5:0	**Reserved** Format: Ignore Ignored

Color Code Message Header Control

MHC_RT_CC - Color Code Message Header Control

Source: BSpec
Size (in bits): 32
Default Value: 0x00000000

DWord	Bit	Description
0	31:10	**Reserved** Format: Ignore Ignored
	9:8	**Color Code** Format: U2 This ID is assigned by the Windower unit and is used to track synchronizing events. Reserved for HW implementation use
	7:0	**FFTID** Format: U8 This ID is assigned by the fixed function unit and is a unique identifier for the thread. It is used to free up resources used by the thread upon thread completion.

Context Descriptor Format

Context Descriptor Format

Source:	BSpec
Size (in bits):	64
Default Value:	0x00000000, 0x00000000

This is the format of context descriptors which make up submitted execlists.

DWord	Bit	Description

0..1	63:32	**Context ID**
		Description
		Context ID is a unique field assigned by GFX driver when a new context is created by which it is identified across all hierarchies of SW and HW.
		• Context ID is used for semaphore signaling by hardware and software.
		• Context ID matching is used by hardware to detect Lite Restore.
		• Context ID is used by hardware for page fault reporting and response with IOMMU.
		• Context switch reason and the associated Context ID are reported to Context Switch Status Buffer by hardware on a context switch.
		Context ID[31:0] (bits[63:32] of the context descriptor) are used for comparing during lite restore, semaphore signaling and context specific OA enabling.
		Context ID which is a 32 bit field is further divided in to three segments described below:
		• **Bits[63:55] (Bits 31:23 of Context ID)** is referred to as GroupID. GroupId+PASID combination of a context must be a unique identifier for contexts that are active in the system. The definition of active context is listed as:
		  • Any Context that is already submitted to h/w or already running in h/w.
		  • Any Context that hit page faults, was preempted (didn't run to context complete), and is waiting to be resubmitted pending IOMMU "last in group" response.
		  • Any Context that has experienced reset but not all faults are responded to.
		• **Bit[54] (Bit 22 of Context ID)** – MBZ for SW programming; this bit is used by hardware to distinguish between F&H vs F&S page requests and response messages to and from IOMMU. This bit is used by hardware on receiving page response to properly manage the page fault counters
		• **Bit[53] (Bit 21 of Context ID)** – MBZ from SW programming, is reserved for future hardware use.
		• **Bits[52:32] (Bits 20:0 of Context ID)** are for software use-only and must be unique field assigned by GFX driver when a new context is created.
		Context ID is reported by hardware to OABUFFER along with the performance statistics counters, Context ID is used for filtering the statistics on per context basis.

Context Descriptor Format

	31:12	**Logical Ring Context Address (LRCA)** Format: GraphicsAddress[31:12] This field contains the 4 KB-aligned address of the Logical Ring Context associated with this execlist element. LRCA must be always programmed in GGTT memory.
	11:9	**Reserved** Format: MBZ
	8	**Privilege Access** This field when set indicates PPGTT enabled in legacy context mode. In advanced context mode this field is reserved and must be zero.
	7:6	**Fault Handling** Source: CommandStreamer

Value	Name	Description
0h	Fault and Hang	Fault model is not supported and fault occurrence is treated as catastrophic. GAM indicates Fault Error to Command streamer. Fault Error interrupt is reported to scheduler. Command Streamer will not initiate context switch on occurrence of Fault Error.
1h	Fault and Halt	In this mode of operation faults are detected and corrected in the Page Walker. The client unit is stalled until the fault is corrected. The command streamer cannot preempt the context until the page fault condition is corrected and the access is completed. Restriction : When both coherent memory accesses are present in L3 memory fabric and OS-managed SVM is enabled, there are TLB invalidate deadlock conditions that require Fault-and-Stream fault mode instead of Fault-and-Halt.
2h	Fault and Stream	In this mode of operation faults are allowed on EU memory accesses. Page Walker will directly work with memory page handler to fix the faults on the fly for these surfaces. Command streamer is not aware of the fault service being done by page walker and goes with its normal execution rules for context switch. On completion of flush during context switch CS explicitly requests acknowledge message to Page Walker before proceeding further. Page Walker acknowledges Command Streamer once it is done on a clean boundary. Page Walker asserts Fault Error on occurrence of non recoverable fault or access violations (Command Streamer access, VFunit access, etc) to Command Streamer; this is the same as Fault and Hang behavior.
Others	Reserved	Reserved

Programming Notes
When execlist mode is set to "Legacy Context mode" Fault Handling mode must be set to "Fault and Hang."

Context Descriptor Format

		For proper programming for Page Fault modes, refer to memory interface section of the Bspec for the corresponding generation.
	5	**Reserved** Format: MBZ
	4:3	**Addressing Mode & Legacy Context** Format: U2 Legacy context set indicates GPU is operating in legacy context mode of operation and doesn't support any SVM features. Legacy context reset indicates GPU is operating in advanced context mode of operation and support SVM features. Based on the Context mode set Addressing mode is interpreted appropriately. The table below summarizes the combinations supported. GFX engine always uses 32b virtual addressing mode when translated using GGTT irrespective of below options.
	2	**Force Restore** Setting this bit will force a context restore operation when switching to this context even if the LRCA in the CCID register (normally the LRCA of the last context from the prior execlist) matches this one. Note that it is legal (and likely desirable) for the **Render Context Restore Inhibit** bit (part of the CTXT_SR_CTL register) in the context image being restored to also be set. The "ring" context is being forced to be restored from a newly initialized context despite a possible LRCA match. However, the render context for such a newly initialized context will likely be uninitialized and so should not be restored.

Value	Name	Description
00b	Advanced Context with no A/D support	GPU is enabled for advanced context mode and supports SVM features. GPU DOESN'T support Access and Dirty bit management in page tables. GPU supports 64b(48bit canonical) PPGTT graphics virtual addressing. PDP0_DESCRIPTOR contains the PASID (process address space identifier) and other PDP Descriptors are ignored.
01b	Legacy Context with no 64 bit VA support	GPU is enabled for legacy context mode of operation and DOESN'T support any SVM features. GPU supports 32b PPGTT graphics virtual addressing. PDP*_DESCRIPTOR contains the base address to 4GB of memory space supported.
10b	Advanced Context with A/D support	GPU is enabled for advanced context mode and supports SVM features. GPU DOES support Access and Dirty bit management in page tables. GPU supports 64b (48bit canonical) PPGTT graphics virtual addressing. PDP0_DESCRIPTOR contains the PASID (process address space identifier) and other PDP Descriptors are ignored.
11b	Legacy Context with 64 bit VA support	GPU is enabled for legacy context mode of operation and DOESN'T support any SVM features. GPU supports 64b (48bit canonical) PPGTT graphics virtual addressing and PDP0_DESCRIPTOR contains the base address to PML4 and other PDP Descriptors are ignored.

Context Descriptor Format		
	1	**Force PD Restore** Setting this bit will cause the on-chip page directory to be reloaded from the PD image in memory even on an LRCA match. No other operations of context restore will occur on an LRCA match, however. Software should set this bit if it has updated a context's page directory and wants the context to begin using the new page directory without having to switch away from it (to another context) and back again. Setting this bit will have no effect if **Force Restore** is also set; a complete context restore (including the PD) will be performed.
	0	**Valid** Set if this register holds a valid context descriptor. SW should set this bit in the Element registers that it has set up to contain valid context descriptors. Any execlist elements that are not used in a submitted execlist must have this bit clear.

Context Status

Context Status

Source: BSpec
Size (in bits): 64
Default Value: 0x00000000, 0x00000000

DWord	Bit	Description
0	63:32	**Context ID** Format: U32 The format of Context ID (sub-fields) described in "Context Descriptor Format".

Context Status

15 — Lite Restore

Format:	Enable

This bit is only valid only when Preempted bit is set.
When set, this bit indicates that a given context got preempted with the same context resulting in Lite Restore in HW.

14:12 — Display Plane Additional

This indicates the display plane for which Wait on Scanline/V-Blank/Sync Flip has been executed leading to context switch.
This field is only valid when one of the "Wait on Scanline" or "Wait on Vblnak" or "Wait on sync Flip" is set.
(Future - could remove the Sprites and move to bits 19:16)

Value	Name	Exists If
0h	Display Plane-1	[Wait on V-blank]==0
0h	Display Pipe-A	[Wait on V-blank]==1
1h	Display Plane-2	[Wait on V-blank]==0
1h	Display Pipe-B	[Wait on V-blank]==1
2h	Display Plane-3	[Wait on V-blank]==0
2h	Display Pipe-C	[Wait on V-blank]==1
3h	Display Plane-4	
4h	Display Plane-5	
5h	Display Plane-6	

11 — Semaphore Wait Mode

Value	Name
0h	Signal Mode
1h	Poll Mode

10:9 — Reserved

Format:	MBZ

8 — Wait on Scanline

7 — Wait on Semaphore

6 — Wait on V-blank

5 — Wait on Sync Flip

4 — Context Complete
Element is completely processed (Head eqv to Tail) and resulted in a context switch.

3 — ACTIVE to IDLE
Following this context switch there is no active element available in HW to execute

Context Status		
	2	**Element Switch** Context Switch happened from first element in the current execlist to the second element of the same execlist
	1	**Preempted** Submission of a new execlist has resulted in context switch. The switch is from element in current execlist to element in pending execlist
	0	**IDLE to ACTIVE** Execlist submitted when HW is IDLE. When this bit is set rest of the fields in CSQ are not valid.

CSC COEFFICIENT FORMAT

CSC COEFFICIENT FORMAT

Source: BSpec
Size (in bits): 16
Default Value: 0x00000000

Coefficients for the CSC are stored in sign-exponent-mantissa format.
Two CSC coefficients are stored in each dword, the table below show the data packing in each dword.

Data Port 0 Message Types

MT_DP0 - Data Port 0 Message Types

Source: DataPort 0
Size (in bits): 5
Default Value: 0x00000000

Lists all the Message Types in a Data Port 0 Message Descriptor [18:14].
The Legacy messages are encoded in Data Port 0 with Bit 18 set to zero. The Message Header is optional for many (but not all) of these operations.
The Scratch Block messages are encoded in Data Port 0 with Bit 18 set to one. A Message Header is required.

DWord	Bit	Description
0	4	**Legacy DAP-DC Message** Format: Enumeration Legacy Message

Value	Name	Description
0h	No **[Default]**	Legacy DAP-DC Message
1h	Reserved	Scratch Block Message, descriptor uses different Message Type encoding

Data Port 2 Extended Message Descriptor

DP2_EXTDESC - Data Port 2 Extended Message Descriptor

Source: BSpec
Size (in bits): 32
Default Value: 0x00000000

DWord	Bit	Description
0	31:16	**Sideband Offset** Format: U16 Specifies the 16-bit offset from the Sideband added to all the offsets in the Address Payload for DP2 messages.
	15:11	**Reserved** Format: MBZ Ignored
	10:0	**Execution Unit Extended Message Descriptor Definition** Format: Execution_Unit_Extended_Message_Descriptor EU uses this information as part of the SEND instruction.

Data Port 2 Message Types

MT_DP2 - Data Port 2 Message Types

Source: DataPort 2

Size (in bits): 5

Default Value: 0x00000002

Lists all the Message Types in a Data Port 2 Message Descriptor [18:14]. Scaled operations are on Data Port 2. They provide a pitch-scaled data address calculation for SLM Stateless address models. The Message Header is forbidden for SLM operations.

DWord	Bit	Description
0	4:1	**Message Type** Format: Enumeration Specifies type of message

Value	Name	Description
01h	MT2R_US **[Default]**	Untyped Surface Read message
02h	MT2R_A64_SB	A64 Scattered Read message
03h	MT2R_A64_US	A64 Untyped Surface Read message
04h	MT2R_BS	Byte Scattered Read message
09h	MT2W_US	Untyped Surface Write message
0Ah	MT2W_A64_US	A64 Untyped Surface Write message

Default Value: 0x00000000

DWord	Bit	Description
0	31:0	**Address1** Format: IEEE_FP Format: UNORM24 Format: UNORM16 When this field contains 24-bit UNORM, the upper 8-bits are reserved (0's) When this field contains 16-bit UNORM the upper 16-bits are reserved (0's)

Display Engine Render Response Message Definition

Display Engine Render Response Message Definition

Source: BSpec
Size (in bits): 32
Default Value: 0x00000000

The Display Engine Render Response Registers use bit definitions from this table.

Programming Notes

Some events can be sent to CS (Render Command Streamer) or BCS (Blitter Command Streamer). For render response messages sending flip done or scanline events, the destination, CS or BCS, is selected depending on the initiator of the flip or the load scanline command. For render response messages sending vertical blank events, the destinations, CS or BCS, or both CS and BCS,is selected depending on the DE_RR_DEST setting. Command Streamer Plane number to the Display Plane name mapping is available in the **Display Plane Capability and Interoperability section**.

The STEREO3D_EVENT_MASK selects between left eye and right eye reporting of vertical blank and scanline events in stereo 3D modes.

	0	**Pipe_A_Scanline_Event** This event is reported on the start of the selected scan line for the transcoder attached to Pipe A.

DstRegNum

DstRegNum	
Source:	Eulsa
Size (in bits):	8
Default Value:	0x00000000

Description

Register Number
The register number for the operand. For a GRF register, is the part of a register address that aligns to a 256-bit (32-byte) boundary. For an ARF register, this field is encoded such that MSBs identify the architecture register type and LSBs provide the register number.
An ARF register can only be dst or src0. Any src1 or src2 operands cannot be ARF registers.
RegNum and SubRegNum together provide the byte-aligned address for the origin of a register region. RegNum provides bits 12:5 of that address. For one-source and two-source instructions, SubregNum provides bits 4:0. For three-source instructions, the address must be DWord-aligned; SubRegNum provides bits 4:2 of the address and bits 1:0 are zero.
This field is present for the direct addressing mode and not present for indirect addressing.
This field applies to both source and destination operands.

DWord	Bit	Description
0	7:0	**Destination Register Number**

Value	Name	Description
0-127	If {Dst/Src0/Src1/Src2}.RegFile==GRF	
0-0ffh	If {Dst/Src0/Src1/Src2}.RegFile==ARF	This field is used to encode the architecture register as well as providing the register number. See GEN Execution Environment chapter for details.

DstSubRegNum

DstSubRegNum

Source: Eulsa

Size (in bits): 5

Default Value: 0x00000000

Programming Notes

Note: The recommended instruction syntax uses subregister numbers within the GRF in units of actual data element size, corresponding to the data type used. For example for the F (Float) type, the assembler syntax uses subregister numbers 0 to 7, corresponding to subregister byte addresses of 0 to 28 in steps of 4, the element size.

DWord	Bit	Description
0	4:0	**Destination Sub Register Number** Value: 0-31, Name: If {Dst/Src0/Src1/Src2}.RegFile==GRF, Description: Value: 0-0ffh, Name: If {Dst/Src0/Src1/Src2}.RegFile==ARF, Description: This field is used to encode the architecture register as well as providing the register number. See GEN Execution Environment chapter for details.

Dword Data Payload Register

MDCR_DW - Dword Data Payload Register

Source: BSpec
Size (in bits): 256
Default Value: 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000

	0	**Reserved**
1	31:17	**Reserved** Format: MBZ

Encoder Control State Parameters0

	16	**GOP-level indirect user-defined NAL data packet - enable** GOP-level user defined NAL packet is inserted during the first frame of a GOP if this field is enabled. **Value** / **Name** / **Description** 0 / Disable / Disable insertion of indirect NAL data packet 1 / Enable / Enable insertion of indirect NAL data packet **Programming Notes** Recommended value is 0. Header contains several NAL units. AVC spec needs AUD NAL to be the first NAL for a frame. If GOP header and Frame headers are enabled and both have AUD NAL it would lead to incorrect bit stream. Multiple NAL data packets can be programmed within the GOP-level indirect surface. A linked list data structure is allocated multiple elements (NAL packets) in contiguous memory. Each element consists of link descriptor fields and datum. The first four bytes of each element contain the link descriptor fields: Byte 0: length_in_bytes[7:0] -- LSB length of data element/NAL packet. Byte 1: length_in_bytes[15:8] -- MSB length of data element/NAL packet. Byte 2: <{7'b000_0000, last_NAL} -- Bit 0 indicates the current element is the last element of the link list. Byte 3: Reserved -- Reserved- MBZ Datum starts at Byte 4 of each element: Byte 4: NAL_START Byte 5: ... Byte N: NAL_END Case 1: last_NAL =1 all the bytes through ByteN would be sent to BSP. Case 2: last_NAL =0 and ByteN is CL alighned (N mod 64 =0). Next NAL descriptor starts at N 1 Byte. Case 3: last_NAL = 0 and ByteN is not CL aligned zero bytes stuffed till next NAL descriptor (63 – (N mod 64) bytes of zeros). Note: empty/zero datum is not allowed
	15:0	**Reserved**
2	31:17	**Reserved** Format: MBZ
	16	**Frame-level indirect user-defined NAL data packet - enable** Frame-level user defined NAL packet is inserted during the first frame of a frame if this field is enabled. **Value** / **Name** / **Description** 0 / Disable / Disable insertion of indirect NAL data packet 1 / Enable / Enable insertion of indirect NAL data packet **Programming Notes**

Encoder Control State Parameters0

		The recommended value is 1. As mentioned in GOP header enable, enabling GOP header and frame header causes problem. Enabling only frame header is safe and sufficient.
		Multiple NAL data packets can be programmed within the frame-level indirect surface. A linked list data structure is allocated multiple elements (NAL packets) in contiguous memory. Each element consists of link descriptor fields and datum. The first four bytes of each element contain the link descriptor fields: Byte 0: length_in_bytes[7:0] -- LSB length of data element/NAL packet. Byte 1: length_in_bytes[15:8] -- MSB length of data element/NAL packet. Byte 2: <{7'b000_0000, last_NAL} -- Bit 0 indicates the current element is the last element of the link list. Byte 3: Reserved -- Reserved- MBZ Datum starts at Byte 4 of each element: Byte 4: NAL_START Byte 5: ... Byte N: NAL_END Note: empty/zero datum is not allowed
	15:0	**Reserved**
3	31:0	**Reserved** Format: MBZ
4	31:0	**Reserved** Format: MBZ
5	31:16	**GOP size parameter** Number of (P-Frames + 1) per GOP structure.

Value	Name	Description
0		Infinite number of P-frames followed by an initial I-frame(IDR)
1		GOP structure will contain one IDR frame. HME and IME inter predictions are disabled.
2		One IDR + one P-frame per GOP
3-FFFFh		This parameter indicates the number of frames within the GOP structure. Each GOP will have one IDR frame follows by the value of the parameter minus one P-frames.

	15:4	**Reserved** Format: MBZ
	3:0	**log2 Maximum Frame Number Minus4** This field specifies the value of the variable MaxFrameNum that is used in Frame_Num count for every frame and must match the definition of log2_max_frame_num_minus field in SPS NAL packet.

Value	Name
0-12	

Encoder Control State Parameters0

		Programming Notes The same value should be set for log2_max_pic_order_cnt_lsb_minus4 field in SPS NAL packet.
6	31:0	**Reserved** Format: MBZ
7	31	**Transform 8x8 Flag** This field indicates that 8x8 transform can be used within the frame. **Value** / **Name** / **Description** 0 / 4x4 Integer Transform / The MB must be set to 4x4 transform. 1 / 8x8 Integer Transform / The MB could be coded with 8x8 transform. **Programming Notes** When this field is set to 1, The transform_size_8x8_flag syntax element, if present in the output bit stream, is the same as this field; However, whether transform_szie_8x8_flag is present or not in the output bit stream depends on several other conditions. Hardware set MB level transform8x8 flag to 1 for two conditions: • It might be 1 if IntraMbFlag = INTRA and IntraMbMode = INTRA_8x8 • It must be 1 if IntraMbFlag = INTER and there is no sub partition size less than 8x8 Otherwise, this field must be set to 0. For Intra MB if transform8x8 = 0, hardware will always honor it, thus intra8x8 will be the winner. If transform8x8 = 0, Intra16x16 prediction Enable or Intra4x4 prediction Enable MUST be true.
	30:29	**Reserved** Format: MBZ
	28:24	**Second Chroma QP Offset, Chroma_qp_offset [9:5]** Format: S4 **Range:** -12 to +12 According to AVC Spec. It specifies the offset for determining QP Cr from QP Y. It is set to the upper 5 bits of the value of the syntax element (Chroma_qp_offset[9:0]) read from the current active PPS. • Chroma_qp_offset [9:5] - second_chroma_qp_offset_bits **Programming Notes** To ensure that the MB size doesn't exceed 3200 bits, Cr/Cb QP cannot go below 10. The Value of MinQp for Luma and Chroma Offset is programmed in such a way to ensure this. E.g. If chroma offset = -5, MinQp should be >= 15. This would ensure that the Final Chroma QP >= (-5+15 = 10).
	23:21	**Reserved** Format: MBZ

Encoder Control State Parameters0

	20:16	**Chroma QP Offset, Chroma_qp_offset[4:0]** Format: S4 **Range:** -12 to +12 According to AVC Spec. It specifies the offset for determining QP Cb from QP Y.It is set to the lower 5 bits of the value of the syntax element (Chroma_qp_offset[9:0]) read from the current active PPS. • Chroma_qp_offset [4:0] - chroma_qp_offset_bits (from the current active PPS) **Programming Notes** To ensure that the MB size doesn't exceed 3200 bits, Cr/Cb QP cannot go below 10. The Value of MinQp for Luma and Chroma Offset is programmed in such a way to ensure this. E.g. If chroma offset = -5, MinQp should be >= 15. This would ensure that the Final Chroma QP >= (-5+15 = 10).
	15:8	**Reserved** Format: MBZ
	7	**Round Inter Enable** Format: Enable **Programming Notes** Recommended driver setting is 0. When rounding Inter is disabled, a value of 2/8 is used for rounding inter coefficients.
	6:4	**Rounding Inter (N)** Format: **RoundingPrecisionTable_3_Bits** **Programming Notes** Hardware default this field to 2 if "Round Inter Enable" is disable.
	3	**Round Intra Enable** Format: Enable **Programming Notes** Recommended driver setting is 0. When rounding Intra is disabled, a value of 4/8 is used for rounding intra coefficients.
	2:0	**Rounding Intra (N)** Format: **RoundingPrecisionTable_3_Bits** **Programming Notes** Hardware default this field to 4 if "Round Intra Enable" is disable.

Encoder Control State Parameters0

8	31:0	**Reserved** Format: MBZ
9	31:19	**Reserved** Format: MBZ
	18:16	**Slice Pattern Per MB Row** The field should be set according to the following table and the MB row size. In cases where row cannot be divided evenly, round up to the nearest MB to achieve the indicated number of slices per row. For purposes of this clause, the rate of macroblocks/second is the rate that applies to the video being transmitted, according to the definition in the AVC standard, That is: the macroblock rate = ceiling(frame width, 16)/16 * ceiling(frame height, 16)/16 * (frames/second). Slice size Must be larger than 4MB.

Macroblocks/second Rate	Slice Pattern
rate < 250,000	1 row = 1 slice
250,000 <= rate < 500,000	1 row = 2 equal slices
500,000 <= rate < 1,000,000	1 row = 4 equal slices
1,000,000 <= rate < 2,100,000	1 row = 8 equal slices
2,100,000 <= rate	1 row = 16 equal slices

Value	Name	Description
0		1 slice per MB row
1		2 slice per MB row
2		4 slice per MB row
3		8 slice per MB row
4		16 slice per MB row

Default Value: 0x00000000, 0x00000000, 0x00000000, 0x00000000

Description

The per block data is intended for use by the video encoder and consists of 16 bytes of Denoise block data and FMD variances.
Much of the data is encoded as an 8-bit mantissa with the leading 1 removed and a 4-bit shift.
To recover the original 17-bit integer this code can be used:
If (exp != 0)
Number = ((0x100 | Mantissa) « exp) » 7;
else
Number = mantissa;

The values for STAD, SHCM and SVCM for each 4x4 are shited down by 2 bits to make 14-bit values before being summed for the 16x4 block to make a 16-bit value. The result is then converted into the mantissa/exp format.

DWord	Bit	Description

EU_INSTRUCTION_COMPACT_TWO_SRC

EU_INSTRUCTION_COMPACT_TWO_SRC

Source:	EuIsa
Size (in bits):	64
Default Value:	0x00000000, 0x00000000

The following table describes the EU compact instruction format. The compact instruction format for 1 or 2-source instructions is essentially identical to the compact instruction format for earlier generations, but the compact fields expand to somewhat different fields in the native instruction format, as the native instruction format changed.

DWord	Bit	Description
0..1	63:56	**Src1.RegNum** Exists If: ([DataTypeIndex][Src1.RegFile]!='IMM') Format: **SrcRegNum** Maps to 108:101 (Src1.RegNum)
	63:56	**Src1.RegNum** Exists If: ([DataTypeIndex][Src1.RegFile]=='IMM') Maps to 103:96 (Imm32[7:0])
	55:48	**Src0.RegNum** Format: **SrcRegNum** Maps to 76:69 (Src0.RegNum)
	47:40	**Dst.RegNum** Format: **DstRegNum** Maps to 60:53 (Dst.RegNum)
	39:35	**Src1Index** Exists If: ([DataTypeIndex][Src1.RegFile]!='IMM') Format: **SrcIndex** If not an immediate operand, lookup one of 32 12-bit values that maps to bits 120:109. That value is used (from MSB to LSB) for the Src1.VertStride, various Src1 bit fields based on AccessMode (Src1.ChanSel[7:4], Src1.Width, Src1.HorzStride), Src1.AddrMode, and Src1.SrcMod bit fields Maps to 120:109

EU_INSTRUCTION_COMPACT_TWO_SRC

39:35 Src1Index

Exists If:	([DataTypeIndex][Src1.RegFile]=='IMM')

If an immediate operand, there is no lookup. Determines bits 127:104 (Imm32[31:8]) as follows: map bits 39:35 directly to bits 108:104. Sign extend to fill bits 127:109. Compact format bit 39 is thus copied to all of bits 127:108 for an immediate operand.

Maps to 127:104

34:30 Src0Index

Format:	SrcIndex

Lookup one of 32 12-bit values. That value is used (from MSB to LSB) for the Src0.VertStride, various Src0 bit fields based on AccessMode (Src0.ChanSel[7:4], Src0.Width, Src0.HorzStride), Src0.AddrMode, and Src0.SrcMod bit fields. Note that this field spans a DWord boundary within the QWord compacted instruction.

Maps to 88:77

29 Compaction Control

Format:	CmptCtrl

28 Reserved

Format:	MBZ

27:24 Reserved

Exists If:	(Property[Conditional Modifier]=='false')
Format:	MBZ

27:24 Conditional Modifier

Exists If:	(Property[Conditional Modifier]=='true')
Format:	CondModifier

23 Accumulator Write Control

Format:	AccWrCtrl

22:18 SubRegIndex

Lookup one of 32 15-bit values. That value is used (from MSB to LSB) for various fields for Src1, Src0, and Dst, including ChanEn/ChanSel, SubRegNum, and AddrImm[4] or AddrImm[4:0], depending on AddrMode and AccessMode.

Maps to 100:96, 68:64, 52:48

Value	Name	Description
0	000000000000000	0 | 0 | 0 |
1	000000000000001	0.x | 0.xx | 0.xx
2	000000000001000	8 | 0 | 0 |
3	000000000001111	0.xyzw | 0.xx | 0.xx

EU_INSTRUCTION_COMPACT_TWO_SRC		
	7	**DebugCtrl** Format: DebugCtrl
	6:0	**Opcode**

EU_INSTRUCTION_CONTROLS_A

EU_INSTRUCTION_CONTROLS_A

Source: EuIsa
Size (in bits): 16
Default Value: 0x00000000

DWord	Bit	Description
0	15:13	**ExecSize** Format: **ExecSize** This field determines the number of channels operating in parallel for this instruction. The size cannot exceed the maximum number of channels allowed for the given data type.
	12	**PredInv** Exists If: (Property[Predication]=='true') This field, together with PredCtrl, enables and controls the generation of the predication mask for the instruction. When it is set, the predication uses the inverse of the predication bits generated according to setting of Predicate Control. In other words, effect of PredInv happens after PredCtrl. This field is ignored by hardware if Predicate Control is set to 0000 - there is no predication. PMask is the final predication mask produced by the effects of both fields.
		Value / **Name** / **Description** 0 / Positive **[Default]** / Positive polarity of predication. Use the predication mask produced by PredCtrl 1 / Negative / Negative polarity of predication. If PredCtrl is nonzero, invert the predication mask.
	12	**Reserved** Exists If: (Property[Predication]=='false')
	11:8	**PredCtrl** Exists If: (Property[Predication]=='true') Format: **PredCtrl** This field, together with PredInv, enables and controls the generation of the predication mask for the instruction. It allows per-channel conditional execution of the instruction based on the content of the selected flag register. Encoding depends on the access mode. In Align16 access mode, there are eight encodings (including no predication). All encodings are based on group-of-4 predicate bits, including channel sequential, replication swizzles and horizontal any|all operations. The same configuration is repeated for each group-of-4 execution channels.
	11:8	**Reserved** Exists If: (Property[Predication]=='false') Format: **PredCtrl**

EU_INSTRUCTION_CONTROLS_A

	7:6	**Thread Control** Format: **ThreadCtrl** Thread Control. This field provides explicit control for thread switching. If this field is set to 00b, it is up to the GEN execution units to manage thread switching. This is the normal (and unnamed) mode. In this mode, for example, if the current instruction cannot proceed due to operand dependencies, the EU switches to the next available thread to fill the compute pipe. In another example, if the current instruction is ready to go, however, there is another thread with higher priority that also has an instruction ready, the EU switches to that thread. If this field is set to Switch, a forced thread switch occurs after the current instruction is executed and before the next instruction. In addition, a long delay (longer than the execution pipe latency) is introduced for the current thread. Particularly, the instruction queue of the current thread is flushed after the current instruction is dispatched for execution. Switch is designed primarily as a safety feature in case there are race conditions for certain instructions.
	5:4	**QtrCtrl** Format: **QtrCtrl** **Quarter Control.** This field provides explicit control for ARF selection. This field combined with NibCtrl and ExecSize determines which channels are used for the ARF registers.
	3	**NibCtrl** Nibble Control. This field is used in some instructions along with QtrCtrl. See the description of QtrCtrl below. NibCtrl is only used for SIMD4 instructions with a DF (Double Float) source or destination.

Value	Name	Description
0	Odd	Use an odd 1/8th for DMask/VMask and ARF (first, third, fifth, or seventh depending on QtrCtrl).
1	Even	Use an even 1/8th for DMask/VMask and ARF (second, fourth, sixth, or eighth depending on QtrCtrl).

Programming Notes
Note that if eighths are given zero-based indices from 0 to 7, then NibCtrl = 0 indicates even indices and NibCtrl = 1 indicates odd indices.

EU_INSTRUCTION_CONTROLS_A

	2:1	**DepCtrl** Format: DepCtrl Destination Dependency Control. This field selectively disables destination dependency check and clear for this instruction. When it is set to 00, normal destination dependency control is performed for the instruction - hardware checks for destination hazards to ensure data integrity. Specifically, destination register dependency check is conducted before the instruction is made ready for execution. After the instruction is executed, the destination register scoreboard will be cleared when the destination operands retire. When bit 10 is set (NoDDClr), the destination register scoreboard will NOT be cleared when the destination operands retire. When bit 11 is set (NoDDChk), hardware does not check for destination register dependency before the instruction is made ready for execution. NoDDClr and NoDDChk are not mutual exclusive. When this field is not all-zero, hardware does not protect against destination hazards for the instruction. This is typically used to assemble data in a fine grained fashion (e.g. matrix-vector compute with dot-product instructions), where the data integrity is guaranteed by software based on the intended usage of instruction sequences.
	0	**AccessMode** Access Mode. This field determines the operand access for the instruction. It applies to all source and destination operands. When it is cleared (Align1), the instruction uses byte-aligned addressing for source and destination operands. Source swizzle control and destination mask control are not supported. When it is set (Align16), the instruction uses 16-byte-aligned addressing for all source and destination operands. Source swizzle control and destination mask control are supported in this mode.

Value	Name
0	Align1 **[Default]**
1	Align16

EU_INSTRUCTION_CONTROLS_B

EU_INSTRUCTION_CONTROLS_B

Source: Eulsa
Size (in bits): 4
Default Value: 0x00000000

DWord	Bit	Description
0	3	**Saturate** Exists If: (Property[Saturation]=='true') Enables or disables destination saturation. When it is set, output values to the destination register are saturated. The saturation operation depends on the destination data type. Saturation is the operation that converts any value outside the saturation target range for the data type to the closest value in the target range. For a floating-point destination type, the saturation target range is [0.0, 1.0]. For a floating-point NaN, there is no *closest value*; any NaN saturates to 0.0. Note that enabling Saturate overrides all of the NaN propagation behaviors described for various numeric instructions. Any floating-point number greater than 1.0, including +INF, saturates to 1.0. Any negative floating-point number, including -INF, saturates to 0.0. Any floating-point number in the range 0.0 to 1.0 is not changed by saturation. For an integer destination type, the maximum range for that type is the saturation target range. For example, the saturation range for B (Signed Byte Integer) is [-128, 127]. When Saturate is clear, destination values are not saturated. For example, a wrapped result (modulo) is output to the destination for an overflowed integer value. See the Numeric Data Typessection for information about data types and their ranges. Value / Name / Description 0 / No destination modification **[Default]** / 1 / sat / Saturate the output
	3	**Reserved** Exists If: (Property[Saturation]=='false') Format: MBZ
	2	**DebugCtrl** This field allows the insertion of a breakpoint at the current instruction. When the bit is set, hardware automatically stores the current IP in CR register and jumps to the System IP (SIP) BEFORE executing the current instruction. Value / Name 0 / No Breakpoint **[Default]** 1 / Breakpoint

EU_INSTRUCTION_CONTROLS_B

	1	**CmptCtrl** Compaction Control Indicates whether the instruction is compacted to the 64-bit compact instruction format. When this bit is set, the 64-bit compact instruction format is used. The EU decodes the compact format using lookup tables internal to the hardware, but documented for use by software tools. Only some instruction variations can be compacted, the variations supported by those lookup tables and the compact format. See EU Compact Instruction Format for more information.

Value	Name	Description
0	NoCompaction	No compaction. 128-bit native instruction supporting all instruction options.
1	Compacted	Compaction is enabled. 64-bit compact instruction supporting only some instruction variations.

	0	**AccWrCtrl** AccWrCtrl. This field allows per instruction accumulator write control.

Value	Name	Description
0	Don't write to ACC **[Default]**	
1	Update ACC	Write result to the ACC, and destination

EU_INSTRUCTION_SOURCES_REG_REG

30:27 **Src1.SrcType**

Format:	SrcType

This field specifies the numeric data type of the source operand src1. The bits of a source operand are interpreted as the identified numeric data type, rather than coerced into a type implied by the operator. Depending on RegFile field of the source operand, there are two different encoding for this field. If a source is a register operand, this field follows the Source Register Type Encoding. If a source is an immediate operand, this field follows the Source Immediate Type Encoding.

Value	Name
11b	Reserved

Programming Notes
Both source operands, src0 and src1, support immediate types, but only one immediate is allowed for a given instruction and it must be the last operand.
Halfbyte integer vector (v) type can only be used in instructions in packed-word execution mode. Therefore, in a two-source instruction where src1 is of type :v, src0 must be of type :b, :ub, :w, or :uw.

26:25 **Src1.RegFile**

Format:	RegFile

24:0 **Source 0**

Exists If:	(Structure[EU_INSTRUCTION_CONTROLS_A][AccessMode]=='Align16') AND (Structure[EU_INSTRUCTION_OPERAND_CONTROLS][Src0.RegFile]!='IMM')
Format:	EU_INSTRUCTION_OPERAND_SRC_REG_ALIGN16

24:0 **Source 0**

Exists If:	(Structure[EU_INSTRUCTION_CONTROLS_A][AccessMode]=='Align1') AND (Structure[EU_INSTRUCTION_OPERAND_CONTROLS][Src0.RegFile]!='IMM')
Format:	EU_INSTRUCTION_OPERAND_SRC_REG_ALIGN1

Execution_Unit_Extended_Message_Descriptor

0	31:20	**Reserved** Format: MBZ
	15:12	**Reserved** Format: MBZ
	9:6	**Extended Message Length** Format: U4 This field specifies the number of 256-bit GRF registers starting from <src1> to be sent out on the request message payload. Valid value ranges from 0 to 15. Must be 0 when <src1> is null register.
	5	**End of Thread** This field, if set, indicates that this is the final message of the thread and the thread's resources can be reclaimed.
	4	**Reserved** Format: MBZ
	3:0	**Target Function ID** This field indicates the function unit for which the message is intended. *Refer to "GPU Overview" document for the mapping of Shared Function IDs*

Extended Message Descriptor - Sampling Engine

Extended Message Descriptor - Sampling Engine		
Source:	BSpec	
Size (in bits):	32	
Default Value:	0x00000000	
DWord	**Bit**	**Description**
0	31:12	**Bindless Surface Offset** Format: BindlessSurfaceOffset[25:6] Specifies the bindless surface offset if the **Binding Table Index** is set to 252. Ignored otherwise. The bindless surface offset is added to the **Bindless Surface Base Address** as bits 25:6 of the byte-based address. The resulting address is the location of SURFACE_STATE for this message.
	11	**Reserved** Format: MBZ
	10:0	**Execution Unit Extended Message Descriptor Definition** Format: Execution_Unit_Extended_Message_Descriptor

GATHER_CONSTANT_ENTRY

GATHER_CONSTANT_ENTRY		
Source:	RenderCS	
Size (in bits):	16	
Default Value:	0x00000000	
DWord	**Bit**	**Description**
0	15:8	**Constant Buffer Offset** Format: Offset[7:0]ConstantBuffer This field specifies the Offset in 128-bit units of the 128b entry fetched from the constant buffer for this entry (including when **On-Die Table Read Enable** is set).
	7:4	**Channel Mask** Mask: Mask[3:0] Format: ConstantBuffer Each bit of this field correspond to the 4 channels of each entry fetched from memory. When the bit is a 1, the corresponding 32-bit value is loaded in FF's push constant buffer. When the bit is a 0, the corresponding 32-bit value is not loaded. If this field is zero it means the entry is not used.
	3:0	**Binding Table Index Offset** Format: Constant Buffer Index offset [3:0]Surface State for ConstantBuffer This field specifies the Binding Table index offset from the **Constant Buffer Binding Table Block** starting point in the Binding Table. This value is added to the **Constant Buffer Binding Table Block** will result in the Binding Table Index pointing to the surface state containing the constant buffer to be referenced. If **VS Constant Buffer Dx9 Enable** is set then a value of '1' specifies that the fetch to the constant buffer should be offset by 4KB in order to address the upper 4K of the constant buffer. Any value greater than '1' is invalid when **VS Constant Buffer Dx9 Enable** is set.

GraphicsAddress63-0

GA63-0 - GraphicsAddress63-0		
Source:	BSpec	
Size (in bits):	64	
Default Value:	0x00000000, 0x00000000	
DWord	**Bit**	**Description**
0..1 GraphicsAddress is a 64-bit value [63:0], but only a portion of it is used by hardware. The upper reserved bits are ignored and must be zero. For the specified product generations, use 48-bit addressing.	63:48	**Reserved** Format: MBZ
	47:0	**GraphicsAddress47-0** Format: GraphicsAddress[47:0]

GraphicsAddress63-1

GA63-1 - GraphicsAddress63-1

Source:	BSpec
Size (in bits):	63
Default Value:	0x00000000, 0x00000000

This structure is intended to define the upper bits of the GraphicsAddress, when bit 0 is already defined in the referring register. So bit 0 of this structure should correspond to bit 1 of the full GraphicsAddress.

DWord	Bit	Description
0..1 GraphicsAddress is a 64-bit value [63:0], but only a portion of it is used by hardware. The upper reserved bits are ignored and must be zero. Some GraphicsAddress fields only specify the upper address bits. For example GraphicsAddress[47:12] would be a 4KB page address.	62:47	**Reserved** Format: MBZ
	46:0	**GraphicsAddress47-1** Format: GraphicsAddress[47:1] Bits 47:1 of a 48-bit GraphicsAddress. Look for bit 0 definition in the referring register.

GraphicsAddress63-2

GA63-2 - GraphicsAddress63-2

Source:	BSpec
Size (in bits):	62
Default Value:	0x00000000, 0x00000000

This structure is intended to define the upper bits of the GraphicsAddress, when bits 1:0 are already defined in the referring register. So bit 0 of this structure should correspond to bit 2 of the full GraphicsAddress.

DWord	Bit	Description
0..1 GraphicsAddress is a 64-bit value [63:0], but only a portion of it is used by hardware. The upper reserved bits are ignored and must be zero. Some GraphicsAddress fields only specify the upper address bits. For example GraphicsAddress[47:12] would be a 4KB page address.	61:46	**Reserved** Format: MBZ
	45:0	**GraphicsAddress47-2** Format: GraphicsAddress[47:2] Bits 47:2 of a 48-bit GraphicsAddress. Look for the definition of bits 1:0 in the referring register.

GraphicsAddress63-3

GA63-3 - GraphicsAddress63-3		
Source:	BSpec	
Size (in bits):	61	
Default Value:	0x00000000, 0x00000000	
This structure is intended to define the upper bits of the GraphicsAddress, when bits 2:0 are already defined in the referring register. So bit 0 of this structure should correspond to bit 3 of the full GraphicsAddress.		
DWord	**Bit**	**Description**
0..1 GraphicsAddress is a 64-bit value [63:0], but only a portion of it is used by hardware. The upper reserved bits are ignored and must be zero. Some GraphicsAddress fields only specify the upper address bits. For example GraphicsAddress[47:12] would be a 4KB page address.	60:45	**Reserved** Format: MBZ
	44:0	**GraphicsAddress47-3** Format: GraphicsAddress[47:3] Bits 47:2 of a 48-bit GraphicsAddress. Look for the definition of bits 2:0 in the referring register.

GraphicsAddress63-4

GA63-4 - GraphicsAddress63-4

Source:	BSpec
Size (in bits):	60
Default Value:	0x00000000, 0x00000000

This structure is intended to define the upper bits of the GraphicsAddress, when bits 3:0 are already defined in the referring register. So bit 0 of this structure should correspond to bit 4 of the full GraphicsAddress.

DWord	Bit	Description
0..1 GraphicsAddress is a 64-bit value [63:0], but only a portion of it is used by hardware. The upper reserved bits are ignored and must be zero. Some GraphicsAddress fields only specify the upper address bits. For example GraphicsAddress[47:12] would be a 4KB page address.	59:44	**Reserved** Format: MBZ
	43:0	**GraphicsAddress47-4** Format: GraphicsAddress[47:4] Bits 47:4 of a 48-bit GraphicsAddress. Look for the definition of bits 3:0 in the referring register.

GraphicsAddress63-5

GA63-5 - GraphicsAddress63-5		
Source:	BSpec	
Size (in bits):	59	
Default Value:	0x00000000, 0x00000000	
This structure is intended to define the upper bits of the GraphicsAddress, when bits 4:0 are already defined in the referring register. So bit 0 of this structure should correspond to bit 5 of the full GraphicsAddress.		
DWord	**Bit**	**Description**
0..1 GraphicsAddress is a 64-bit value [63:0], but only a portion of it is used by hardware. The upper reserved bits are ignored and must be zero. Some GraphicsAddress fields only specify the upper address bits. For example GraphicsAddress[47:12] would be a 4KB page address.	58:43	**Reserved** Format: MBZ
	42:0	**GraphicsAddress47-5** Format: GraphicsAddress[47:5] Bits 47:5 of a 48-bit GraphicsAddress. Look for the definition of bits 4:0 in the referring register.

GraphicsAddress63-6

GA63-6 - GraphicsAddress63-6

Source:	BSpec
Size (in bits):	58
Default Value:	0x00000000, 0x00000000

This structure is intended to define the upper bits of the GraphicsAddress, when bits 5:0 are already defined in the referring register. So bit 0 of this structure should correspond to bit 6 of the full GraphicsAddress.

DWord	Bit	Description
0..1 GraphicsAddress is a 64-bit value [63:0], but only a portion of it is used by hardware. The upper reserved bits are ignored and must be zero. Some GraphicsAddress fields only specify the upper address bits. For example GraphicsAddress[47:12] would be a 4KB page address.	57:42	**Reserved** Format: MBZ
	41:0	**GraphicsAddress47-6** Format: GraphicsAddress[47:6] Bits 47:6 of a 48-bit GraphicsAddress. Look for the definition of bits 5:0 in the referring register.

GraphicsAddress63-12

GA63-12 - GraphicsAddress63-12		
Source:	BSpec	
Size (in bits):	52	
Default Value:	0x00000000, 0x00000000	
This structure is intended to define the upper bits of the GraphicsAddress, when bits 11:0 are already defined in the referring register. So bit 0 of this structure should correspond to bit 12 of the full GraphicsAddress.		
DWord	**Bit**	**Description**
0..1 GraphicsAddress is a 64-bit value [63:0], but only a portion of it is used by hardware. The upper reserved bits are ignored and must be zero. Some GraphicsAddress fields only specify the upper address bits. For example GraphicsAddress[47:12] would be a 4KB page address.	51:36	**Reserved** Format: MBZ
	35:0	**GraphicsAddress47-12** Format: GraphicsAddress[47:12] Bits 47:12 of a 48-bit GraphicsAddress. Look for the definition of bits 11:0 in the referring register.

GTC Interrupt Bit Definition

GTC Interrupt Bit Definition		
Source:	BSpec	
Size (in bits):	32	
Default Value:	0x00000000	
The GTC Interrupt Registers all share the same bit definitions from this table.		
DWord	**Bit**	**Description**
0	31:26	**Reserved** Format: MBZ
	25	**GTC Lock Loss** GTC has lost lock with a remote GTC sink. The difference between the local and remote GTC has exceeded programmed threshold.
	24	**GTC Aux Rx Error portA** An aux channel error occurred during GTC transfer with remote GTC sink attached to this port.
	23	**GTC Update Complete portA** A hardware initiated GTC update has completed with a sink attached to this port.
	22	**Reserved** Format: MBZ
	21:20	**Reserved**
	19:18	**Reserved**
	17	**GTC Aux Rx Error portD** An aux channel error occured during GTC transfer with remote GTC sink attached to this port.
	16	**GTC Update Complete portD** A hardware initiated GTC update has completed with a sink attached to this port.
	15:10	**Reserved** Format: MBZ
	9	**GTC Aux Rx Error portC** An aux channel error occurred during GTC transfer with remote GTC sink attached to this port.
	8	**GTC Update Complete portC** A hardware initiated GTC update has completed with a sink attached to this port.
	7:2	**Reserved** Format: MBZ
	1	**GTC Aux Rx Error portB** An aux channel error occurred during GTC transfer with remote GTC sink attached to this port.
	0	**GTC Update Complete portB** A hardware initiated GTC update has completed with a sink attached to this port.

Hardware-Detected Error Bit Definitions

Hardware-Detected Error Bit Definitions

Source: RenderCS
Size (in bits): 32
Default Value: 0x00000000

DWord	Bit	Description
0	31:8	**Reserved** Format: MBZ
	7	**Reserved**
	6:3	**Reserved**
	2	**Command Privilege Violation Error** This bit is set if a command classified as privileged is parsed in a non-privileged batch buffer. The command will be converted to a NOOP and parsing will continue.
	1	**Reserved** Format: MBZ
	0	**Instruction Error** This bit is set when the Renderer Instruction Parser detects an error while parsing an instruction. Instruction errors include: • Client ID value (Bits 31:29 of the Header) is not supported (only MI, 2D and 3D are supported). • Defeatured MI Instruction Opcodes: **Value** / **Name** / **Description** 1 / / Instruction Error detected **Programming Notes** This error indications cannot be cleared except by reset (i.e., it is a fatal error).

DWord	Bit	Description
0	0	**Message Header Present** Format: Enumeration Indicates the message forbids a message header. Value / Name / Description 0h / No **[Default]** / Message header is not present 1h / Reserved / Not used

Header Present Message Descriptor Control Field

MDC_MHP - Header Present Message Descriptor Control Field

Source: BSpec
Size (in bits): 1
Default Value: 0x00000000

DWord	Bit	Description
0	0	**Message Header Present** Format: Enumeration Specifies if the message uses the optional message header. Value / Name / Description: 0h / No / Message header is not present 1h / Yes / Message header is present

Header Required Message Descriptor Control Field

MDC_MHR - Header Required Message Descriptor Control Field

Source:	BSpec
Size (in bits):	1
Default Value:	0x00000001

DWord	Bit	Description
0	0	**Message Header Present** Format: Enumeration Indicates the message requires a message header. 0h – Reserved – Not used 1h – Yes **[Default]** – Message header is present

HEVC_ARBITRATION_PRIORITY

HEVC_ARBITRATION_PRIORITY

Source: BSpec
Size (in bits): 2
Default Value: 0x00000000

This field controls the priority of arbitration used in the GAC/GAM pipeline for this surface.

DWord	Bit	Description
0	1:0	**Priority** Format: U2 Value / Name: 00b — Highest priority 01b — Second highest priority 10b — Third highest priority 11b — Lowest priority

HW Generated BINDING_TABLE_STATE

HW Generated BINDING_TABLE_STATE

Source:	BSpec
Size (in bits):	16
Default Value:	0x00000000

Description

The binding table binds surfaces to logical resource indices used by shaders and other compute engine kernels. The HW generated Binding_Table_State have different format than the SW generated Binding_Table_State. The HW generated Binding_Table_State is stored as an array of 256 elements, each of which contains one word as defined here. The start of each element is spaced one word apart. The first element of the binding table is aligned to a 64-byte boundary. Binding table indexes beyond 256 will automatically be mapped to entry 0 by the HW, w/ the exception of any messages which support the special indexes 240 through 255, inclusive.

DWord	Bit	Description
0	15:0	**Surface State Pointer** Format: SurfaceStateOffset[21:6]

MDP_HW1 - Hword 1 Block Data Payload		
Source:	BSpec	
Size (in bits):	256	
Default Value:	0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000	
DWord	**Bit**	**Description**
0.0-0.7	255:0	**Hword** Format: U256 Specifies the Hword data

Hword 2 Block Data Payload

MDP_HW2 - Hword 2 Block Data Payload

Source:	BSpec
Size (in bits):	512
Default Value:	0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000

DWord	Bit	Description
0.0-0.7	255:0	**Hword0** Format: U256 Specifies the Hword data for element 0
1.0-1.7	255:0	**Hword1** Format: U256 Specifies the Hword data for element 1

Hword 4 Block Data Payload

MDP_HW4 - Hword 4 Block Data Payload

Source: BSpec

Size (in bits): 1024

Default Value: 0x00000000, 0x00000000

DWord	Bit	Description
0.0-0.7	255:0	**Hword0** Format: U256 Specifies the Hword data for element 0
1.0-1.7	255:0	**Hword1** Format: U256 Specifies the Hword data for element 1
2.0-2.7	255:0	**Hword2** Format: U256 Specifies the Hword data for element 2
3.0-3.7	255:0	**Hword3** Format: U256 Specifies the Hword data for element 3

Hword 8 Block Data Payload

MDP_HW8 - Hword 8 Block Data Payload

Source:	BSpec
Size (in bits):	2048
Default Value:	0x00000000, 0x00000000, 0x00000000,

MDP_HW8 - Hword 8 Block Data Payload		
6.0-6.7	255:0	**Hword6** Format: U256 Specifies the Hword data for element 6
7.0-7.7	255:0	**Hword7** Format: U256 Specifies the Hword data for element 7

Hword Channel Mode Message Header Control

MHC_A64_CMODE - Hword Channel Mode Message Header Control

Source: BSpec
Size (in bits): 32
Default Value: 0x00000000

DWord	Bit	Description
0	31	**Reserved** Format: MDC_CMODE Specifies whether the read or write operation occurs on all 4 Dwords if any of those channel enables are set, or else only on the dwords whose corresponding channel enable is set.
	30:0	**Reserved** Format: Ignore Ignored

Hword Register Blocks Message Descriptor Control Field

MDC_DB_HW - Hword Register Blocks Message Descriptor Control Field

Source: BSpec
Size (in bits): 2
Default Value: 0x00000000

DWord	Bit	Description
0	1:0	**Register Blocks** Format: Enumeration Specifies the number of Hword blocks to be read or written

Value	Name	Description
00h	HW1	1 Hword register
01h	HW2	2 Hword registers
02h	HW4	4 Hword registers
03h	HW8	8 Hword registers

Ignored Message Header

MH_IGNORE - Ignored Message Header		
Source:	DataPort 0	
Size (in bits):	256	
Default Value:	0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000	
Some messages require a message header or have an optional message header, but do not use any information in the header.		
DWord	**Bit**	**Description**
0..7	255:0	**Reserved** Format: Ignore Ignored

Inline Data Description for MFD_AVC_BSD_Object

Inline Data Description for MFD_AVC_BSD_Object

Source: VideoCS

Size (in bits): 96

Default Value: 0x00000000, 0x00000000, 0x00000000

This structure includes all the required Slice Header parameters and error handling settings for AVC_BSD_OBJECT Command (DW3..DW5).

DWord	Bit	Description
0	31	**Concealment Method** This field specifies the method used for concealment when error is detected. If set, a copy from collocated macroblock location is performed from the concealment reference indicated by the ConCeal_Pic_Id field. If it is not set, a copy from the current picture is performed using Intra 16x16 Prediction method. Value / Name / Description: 0 — Intra 16x16 Prediction 1 — Inter P Copy
	30	**Init Current MB Number** When set, the current Slice_Start_MB_Num, Slice_MB_Start_Hor_Pos and Slice_MB_Start_Vert_Pos fields will be used to initialize the Current_MB_Number register. This effectively disables the concealment capability.
	29	**Intra PredMode (4x4/8x8 Luma) Error Control Bit** This field controls if AVC decoder will fix Intra Prediction Mode if the decoded value is incorrect according to MB position Value / Name / Description: 0 — AVC decoder will detect and fix IntraPredMode (4x4/8x8 Luma) Errors. 1 — AVC decoder will NOT detect IntraPredMode (4x4/8x8 Luma) Errors. The wrong IntraPredMode value will be retaind.
	28:27	**MB Error Concealment B Temporal Prediction mode** These two bits control how the reference L0/L1 are overridden in B temporal slice. Value / Name / Description: 00b — **[Default]** — Both Reference Indexes L0/L1 are forced to 0 during Concealment 01b — Only Reference Index L1 is forced to 0; Reference Index L0 is forced to -1 10b — Only Reference Index L0 is forced to 0; Reference Index L1 is forced to -1 11b — Reserved — Invalid
	26	**Reserved** Format: MBZ

Inline Data Description for MFD_AVC_BSD_Object

25 — MB Error Concealment B Temporal Motion Vectors Override Enable Flag

During MB Error Concealment on B slice with Temporal Direct Prediction, motion vectors are forced to 0 to improve image quality.

This bit can be set to preserve the original weight prediction.

Value	Name	Description
0	**[Default]**	Predicted Motion Vectors are used during MB Concealment
1		Motion Vectors are Overridden to 0 during MB Concealment

24 — MB Error Concealment B Temporal Weight Prediction Disable Flag

During MB Error Concealment on B slice with Temporal Direct Prediction, weight prediction is disabled to improve image quality.

This bit can be set to preserve the original weight prediction.

Value	Name	Description
0	**[Default]**	Weight Prediction is Disabled during MB Concealment
1		Weight Prediction will not be overridden during MB Concealment

23:22 — Reserved

Format:	MBZ

21:16 — Concealment Picture ID

This field identifies the picture in the reference list to be used for concealment. This field is only valid if **Concealment Method** is Inter P Copy.

Bit Filed	Value	Defenition
21	0	Frame Picture
21	1	Field picture
20:16	All	Frame Store Index[4:0]

15 — Reserved

Format:	MBZ

14 — BSD Premature Complete Error Handling

BSD Premature Complete Error occurs in situation where the Slice decode is completed but there are still data in the bitstream.

Value	Name	Description
1		Set the interrupt to the driver (provide MMIO registers for MB address R/W)
0		Ignore the error and continue (masked the interrupt), assume the hardware automatically performs the error handling

13 — Reserved

Format:	MBZ

Inline Data Description for MFD_AVC_BSD_Object

12 — MPR Error (MV out of range) Handling

Software must follow the action for each Value as follow:

Value	Name	Description
1		Set the interrupt to the driver (provide MMIO registers for MB address R/W)
0		Ignore the error and continue (masked the interrupt), assume the hardware automatically performs the error handling

11 — Reserved

Format:	MBZ

10 — Entropy Error Handling

Software must follow the action for each Value as follow:

Value	Name	Description
1		Set the interrupt to the driver (provide MMIO registers for MB address R/W).
0		Ignore the error and continue (masked the interrupt), assume the hardware automatically perform the error handling.

9 — Reserved

Format:	MBZ

8 — MB Header Error Handling

Software must follow the action for each Value as follow:

Value	Name	Description
1		Set the interrupt to the driver (provide MMIO registers for MB address R/W).
0		Ignore the error and continue (masked the interrupt), assume the hardware automatically perform the error concealment.

7:6 — MB Error Concealment B Spatial Prediction mode

These two bits control how the reference L0/L1 are overridden in B spatial slice.

Value	Name	Description
00b	**[Default]**	Both Reference Indexes L0/L1 are forced to 0 during Concealment
01b		Only Reference Index L1 is forced to 0; Reference Index L0 is forced to -1
10b		Only Reference Index L0 is forced to 0; Reference Index L1 is forced to -1
11b	Reserved	Invalid

5 — Reserved

Format:	MBZ

4 — MB Error Concealment B Spatial Motion Vectors Override Disable Flag

During MB Error Concealment on B slice with Spatial Direct Prediction, motion vectors are forced to 0 to improve image quality.

This bit can be set to use the predicted motion vectors instead.

This bit does not affect normal decoded MB.

Value	Name	Description
0	**[Default]**	Motion Vectors are Overridden to 0 during MB Concealment

Inline Data Description for MFD_AVC_BSD_Object

		1 | | Predicted Motion Vectors are used during MB Concealment
	3	**MB Error Concealment B Spatial Weight Prediction Disable Flag** During MB Error Concealment on B slice with Spatial Direct Prediction, weight prediction is disabled to improve image quality. This bit can be set to preserve the original weight prediction. This bit does not affect normal decoded MB. Value | Name | Description 0 | **[Default]** | Weight Prediction is Disabled during MB Concealment. 1 | | Weight Prediction will not be overridden during MB Concealment.
	2	**Reserved** Format: | MBZ
	1	**MB Error Concealment P Slice Motion Vectors Override Disable Flag** During MB Error Concealment on P slice, motion vectors are forced to 0 to improve image quality. This bit can be set to use the predicted motion vectors instead. This bit does not affect normal decoded MB. Value | Name | Description 0 | **[Default]** | Motion Vectors are Overridden to 0 during MB Concealment 1 | | Predicted Motion Vectors are used during MB Concealment
	0	**MB Error Concealment P Slice Weight Prediction Disable Flag** During MB Error Concealment on P slice, weight prediction is disabled to improve image quality. This bit can be set to preserve the original weight prediction. This bit does not affect normal decoded MB. Value | Name | Description 0 | **[Default]** | Weight Prediction is Disabled during MB Concealment. 1 | | Weight Prediction will not be overridden during MB Concealment.
1	31:16	**First MB Byte Offset of Slice Data or Slice Header** Programming Notes MFX supports only DXVA2 Long and Short Format.
	15:8	**Reserved** Format: | MBZ
	7	**Fix Prev Mb Skipped** Enables an alternative method for decoding mb_skipped, to cope with an encoder that codes a skipped MB as a direct MB with no coefficient.
	6:5	**Reserved** Format: | MBZ Programming Notes

Inline Data Description for MFD_AVC_BSD_Object

		Please note that the field MUST be set to '0' at this time.
	4	**Emulation Prevention Byte Present** Value / Name / Description 0 / / H/W needs to perform Emulation Byte Removal 1 / / H/W does not need to perform Emulation Byte Removal
	3	**LastSlice Flag** It is needed for both error concealment at the end of a picture (so, no more phantom slice. It is also needed to know to set the last MB in a picture correctly. Value / Name / Description 1 / / If the current Slice to be decoded is the very last slice of the current picture. 0 / / If the current Slice to be decoded is any slice other than the very last slice of the current picture
	2:0	**First Macroblock (MB)Bit Offset** Exists If: //AVC Long Format Only Format: U3 This field provides the bit offset of the first macroblock of the Slice in the first byte of the input compressed bitstream.
2	31	**I Slice Concealment Mode** This field controls how AVC decoder handle MB concealment in I Slice Value / Name 0 / Intra Concealment 1 / Inter Concealment **Programming Notes** If this field is set to "1" (Inter Concealment), driver must provide a valid reference picture (programmed using "Concealment Reference Picture" field) for concealment reference picture. In this mode, weight prediction is disabled and motion vectors are forced to 0 as well.
	30	**Reserved** Format: MBZ
	29:24	**Concealment Reference Picture + Field Bit** Format: U6 This field provides the concealment reference picture for hardware to conceal in case driver wants to specify one concealment picture. This field matches with the DPB order sent to hardware. This field applies to all I/P/B slices Bit Filed / Value / Defenition 29 / MBZ / is reserved for future expansion

Inline Data Description for MFD_AVC_BSD_Object

28:25	All	Reference PIcture Number
24	All	Field Bit(if the current picture is a field picture [Frame picture must be 0]

23 P Slice Concealment Mode

This field controls how AVC decoder handle MB concealment in P Slice

Value	Name
1	Intra Concealment
0	Inter Concealment

22:19 Reserved

Format:	MBZ

18:16 P Slice Inter Concealment Mode

This field controls how AVC decoder select reference picture for Concealment in P Slice.

Value	Name	Description
000b		Top of Reference List L0 (Use top entry of Reference List L0)
001b		Driver Specified Concealment Reference
010b		Predicted Reference (Use reference picture predicted using P-Skip Algorithm)
011b		Temporal Closest (Using POC to select the closest forward picture) [For L0: Closest POC smaller than current POC]
100b		First Long Term Picture in Reference List L0 (If no long term picture available, use Temporal Closest Picture)
101b-111b	Reserved	

15 B Slice Concealment Mode

This field controls how AVC decoder handle MB concealment in B Slice

Value	Name
1	Intra Concealment
0	Inter Concealment

14 Reserved

Format:	MBZ

13:12 B Slice Inter Direct Type Concealment Mode

AVC decoder can use Spatial or Temporal Direct for B Skip/Direct.

This field determine can override the mode on how AVC decoder handles MB concealment in B slice.

Value	Name	Description
00b		Use Default Direct Type (slice programmed direct type)
01b		Forced to Spatial Direct Only
10b		Forced to Temporal Direct Only

Inline Data Description for MFD_AVC_BSD_Object

11b		Spatial Direct without Temporal Componenet (MovingBlock information)

11 — Reserved

Format:	MBZ

10:8 — B Slice Spatial Inter Concealment Mode

This field controls how AVC decoder select reference picture for Spatial Inter Concealment in B Slice.

Value	Name	Description
000b		Top of Reference List L0/L1 (Use top entry of Reference List L0/L1).
001b		Driver Specified Concealment Reference
011b		Temporal Closest (Using POC to select the closest forward picture) [For L0: Closest POC smaller than current POC] [For L1: Closest POC larger than current POC]
100b		" First Long Term Picture in Reference List L0/L1 (If no long term picture available, use Temporal Closest Picture)
101b-111b	Reserved	

7 — Reserved

Format:	MBZ

6:4 — B Slice Temporal Inter Concealment Mode

This field controls how AVC decoder select reference picture for Temporal Inter Concealment in B Slice

Value	Name	Description
000b		Top of Reference List L0/L1 (Use top entry of Reference List L0/L1)
001b		Driver Specified Concealment Reference
010b		Predicted Reference (Use reference picture predicted using B-Skip Algorithm)
011b		" Temporal Closest (Using POC to select the closest forward picture) [For L0: Closest POC smaller than current POC] [For L1: Closest POC larger than current POC]
100b		First Long Term Picture in Reference List L0/L1 (If no long term picture available, use Temporal Closest Picture)
101b-111b	Reserved	

3:2 — Reserved

Format:	MBZ

1 — Intra 8x8/4x4 Prediction Error Concealment Control Bit

This field controls if AVC goes into MB concealment mode (next MB) when an error is detected on Intra8x8/4x4 Prediction Mode (these 2 modes have fixed coding so it may not affect the bitstream.

Inline Data Description for MFD_AVC_BSD_Object

Value	Name	Description
0		AVC decoder will NOT go into MB concealment when Intra8x8/4x4 Prediction mode is incorrect.
1		AVC decoder will go into MB concealment when Intra8x8/4x4 Prediction mode is incorrect.

0

Intra Prediction Error Control Bit (applied to Intra16x16/Intra8x8/Intra4x4 Luma and Chroma)

This field controls if AVC decoder will fix Intra Prediction Mode if the decoded value is incorrect according to MB position.

Value	Name	Description
0		AVC decoder will detect and fix Intra Prediction Mode Errors.
1		AVC decoder will retain the Intra Prediction value decoded from bitstream.

Size (in bits): 384

Default Value: 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000

This structure corresponds to Dw3..6 of MFX_VP8_PAK_OBJECT Command.

DWord	Bit	Description
0	31:23	**Reserved** Format: MBZ
	22:20	**MV Format(Motion Vector Size)** Exists If: //IntraMbFlag = 0 This field specifies the size and format of the output motion vectors. Value / Name / Description: 000b – Intra MB – No Motion vectors 100b – Inter Predict MB (Unpacked Motion Vector Mode) – Sixteen Motion Vectors Per MacroBlock Others – Reserved **Programming Notes** This field MBZ, when the **IntraMbFlag = 1**.
	19:18	**SegmentID** Format: U2 Segment number 0-3
	17	**Enable Coeff Clamp** Value / Name / Description: 1 – Magnitude of coefficients of the current MB is clamped based on the clamping matrix after quantization 0 – No Clamping
	16:14	**Reserved** Format: MBZ
	13	**Intra MB Flag** This field specifies whether the current macroblock is an Intra (I) Macroblock. For Key pictures (IsKyeFrameFlag DW2, bit[5] of MFX_VP8_PIC_STATE), this field must be set to 1. Value / Name: 0h – INTER (Inter MacroBlock)

Inline Data Description - VP8 PAK OBJECT

		1h: INTRA (Intra MacroBlock)

Programming Notes
For I-picture MB (Intra MB Flag =1), this field must be set to 1.

12:11 **RefPicSelect**

This field specifies which reference pic (among Last Frame, Golden Frame and Alt Frame) is selected for the current macroblock when Intra MB Flag = 0 .

Value	Name
00b	Last Frame
01b	Golden Frame
10b	Alt Frame

10:8 **MB Type 3-Bits - Inter/Intra MB**

MB Type 3 Bits [10:8] specifies InterMB MV mode configurations: 16x16 or 2 16x8 or 4 8x8 or 16 4x4 when Intra MB Flag = 0 and bit [8] = IntraMB mode configurations: 4x4 or 16x16 when Intra MB Flag = 1

Value	Name	Description
000b	16x16	**Inter MB** Only DW 6 bits 3:0 are used to indicate MVMode, MVMode can't be split
001b	2 16x8 (mv_Top Bottom)	**Inter MB [10:8]** Split MV is inferred. DW5 bits[3:0] are used for MVMode for first 16x8 partition, DW6 bits[3:0] are used for MVMode for second 16x8 partition.
010b	2 8 x16 (mv_left_right)	**Inter MB [10:8]** Split MV is inferred. DW5 bits[3:0] are used for MVMode for first 8x16 partition, DW5 bits[11:8] are used for MVMode for second 8x16 partition.
011b	4 8x8 (mv_quarters)	**Inter MB [10:8]** Split MV is inferred. DW5 bits[3:0] are used for MVMode for first 8x8 partition. DW5 bits[11:8] are used for MvMode for second 8x8 partition. DW6 bits[3:0] are used for MVMode for third 8x8 partition. DW6 bits[11:8] are used for MVMode for fourth 8x8 partition.
100b	16 4x4 (mv_16)	**Inter MB [10:8]** Split MV is inferred. There are 16 partitions. Each Sub-block uses 4 bits in DW6 and DW7.
0b	16x16	**Intra MB [8]** Only DW5, bits[3:0] are used for Y mode. For B_PRED, "16 4x4" should be used which implies B_PRED mode.
1b	16 4x4	**Intra MB [8]** All bits in DW5 and DW6 are used to represent B_PRED modes (Bmodes) in each sub-blocks.

Inline Data Description - VP8 PAK OBJECT

	5:0	**Reserved** Format: MBZ
1	31:16	**Reserved** Format: MBZ
	15:0	**Kernel Start Pointer High** Format: InstructionBaseOffset[47:32]Kernel This field specifies the high 16 bits of starting address of the Kernel Pointer.
2	31:20	**Reserved** Format: MBZ
	19	**Denorm Mode** This field specifies how Float denormalized numbers are handles in the dispatched thread. Value / Name / Description: 0h / Ftz / Float denorms will be flushed to zero when appearing as inputs; denorms will never come out of instructions. Double precision float and half precision float numbers are not flushed to zero. 1h / SetByKernel / Denorms will be handled in by kernel.
	18	**Single Program Flow** Specifies whether the kernel program has a single program flow (SIMDnxm with m = 1) or multiple program flows (SIMDnxm with m > 1). Value / Name: 0h / Multiple 1h / Single
	17	**Thread Priority** Specifies the priority of the thread for dispatch. Value / Name:

INTERFACE_DESCRIPTOR_DATA

		0h: Normal Priority 1h: High Priority
	16	**Floating Point Mode** Specifies the floating point mode used by the dispatched thread. Value: 0h — Name: IEEE-754 Value: 1h — Name: Alternate
	15:14	**Reserved** Format: MBZ
	13	**Illegal Opcode Exception Enable** Format: Enable This bit gets loaded into EU CR0.1[12] (note the bit # difference). See *Exceptions and ISA Execution Environment*.
	12	**Reserved** Format: MBZ
	11	**Mask Stack Exception Enable** Format: Enable This bit gets loaded into EU CR0.1[11]. See *Exceptions and ISA Execution Environment*.
	10:8	**Reserved** Format: MBZ
	7	**Software Exception Enable** Format: Enable This bit gets loaded into EU CR0.1[13] (note the bit # difference). See *Exceptions and ISA Execution Environment*.
	6:0	**Reserved** Format: MBZ
3	31:5	**Sampler State Pointer** Format: DynamicStateOffset[31:5]SAMPLER_STATE Specifies the 32-byte aligned address offset of the sampler state table. This pointer is relative to the **Dynamic State Base Address.** *This field is ignored for child threads.*
	4:2	**Sampler Count** Format: U3 Specifies how many samplers (in multiples of 4) the kernel uses. Used only for prefetching the

INTERFACE_DESCRIPTOR_DATA

associated sampler state entries.
This field is ignored for child threads.
If this field is not zero, sampler state is prefetched for the first instance of a root thread upon the startup of the media pipeline.

Value	Name
[0,4]	
0h	No samplers used
1h	Between 1 and 4 samplers used
2h	Between 5 and 8 samplers used
3h	Between 9 and 12 samplers used
4h	Between 13 and 16 samplers used

1:0 Reserved

Format:	MBZ

4 — 31:16 Reserved

Format:	MBZ

15:5 Binding Table Pointer

Format:	SurfaceStateOffset[15:5]BINDING_TABLE_STATE*256

Description
Specifies the 32-byte aligned address of the binding table. This pointer is relative to the **Surface State Base Address**. *This field is ignored for child threads.*

4:0 Binding Table Entry Count

Format:	U5

Specifies how many binding table entries the kernel uses. Used only for prefetching of the binding table entries and associated surface state.
This field is ignored for child threads.
If this field is not zero, binding table and surface state are prefetched for the first instance of a root thread upon the startup of the media pipeline.

Value	Name
[0,31]	

Programming Notes
The maximum number of prefetched binding table entries is limited to 31. For kernels using a large number of binding table entries, it may be wise to set this field to zero to avoid prefetching too many entries and thrashing the state cache.

5 — 31:16 Constant/Indirect URB Entry Read Length

Format:	U16

Specifies the amount of URB data read and passed in the thread payload for the Constant or

INTERFACE_DESCRIPTOR_DATA

Indirect URB entry, in 8-DW register increments. A value 0 means that no Constant or Indirect URB Entry will be loaded. The Constant URB Entry Read Offset field will then be ignored. In GPGPU mode this describes how much data is delivered in a single dispatch. Multiple dispatches in a thread group will deliver constant data offset by this value. The total amount of constant data is (Constant URB Read Length * Number of Threads in GPGPU Thread Group + Cross-Thread Constant Data Read Length).

If **Cross-Thread Constant Data Read Length** for Indirect is greater than 0, then this field must also be greater than 0. The allowed combinations are:

Constant/Indirect URB Entry Read Length **Entry Read Length**	Cross-Thread Constant **Data Read Length**	Notes
=0	=0	No Payload
>0	=0	Per-thread payload only
>0	>0	Both kinds of payload
=0	>0	Only for CURBE payloads

Value	Name
[0,63]	

15:0 **Constant URB Entry Read Offset**

Format:	U16

Specifies the offset (in 8-DW units) at which Constant URB data is to be read from the URB before being included in the thread payload.

Value	Name	Description
[0,1983]		Indicating [0,1983] 256-bit register increments. ROB has 64KB of storage; 2048 entries. However, lowest 64 entries are reserved for VFE/TS to store interface descriptor data. Hence, (URB Entry Read Offset + Read Length) shall not exceed 1984.

6 31:24 **Reserved**

Format:	MBZ

23:22 **Rounding Mode**

Format:	U2

Value	Name	Description
00b	RTNE **[Default]**	Round to Nearest Even
01b	RU	Round toward +Infinity
10b	RD	Round toward -Infinity
11b	RTZ	Round toward Zero

INTERFACE_DESCRIPTOR_DATA

21 Barrier Enable

Format:	Enable

This field specifies whether the thread group requires a barrier. If not, it can be dispatched without allocating one.

20:16 Shared Local Memory Size

Format:	U5

This field indicates how much Shared Local Memory the thread group requires. The amount is specified in 4k blocks, but only powers of 2 are allowed: 0, 4k, 8k, 16k, 32k and 64k per half-slice.

Uses a different encoding to allow encodings for the new 1k and 2k SLM sizes.

Value	Name	Description
0	Encodes 0K	No SLM used
1	Encodes 1K	
2	Encodes 2K	
3	Encodes 4K	
4	Encodes 8K	
5	Encodes 16K	
6	Encodes 32K	
7	Encodes 64K	

15 Global Barrier Enable

Format:	Enable

Description
This field when set indicates that the thread group associated with this barrier is allowed to cross sub-slices with a performance penalty. When this field is clear, the thread group is dispatched to a single sub-slice or pool. Note that SLM should not be used with a Global Barrier since SLM is always forced to a single sub-slice or pool. The Barrier Enable bit must be set to enable the barrier, since this bit only specifies the type of barrier.
Restriction : Global barriers cannot be used. Must be zero.

14:13 Reserved

Format:	MBZ

12:10 Reserved

Format:	MBZ

INTERFACE_DESCRIPTOR_DATA

	9:0	**Number of Threads in GPGPU Thread Group** Format: U10 Specifies the number of threads that are in this thread group. The minimum value is 1, while the maximum value is the number of threads in a subslice for local barriers. See vol1b Configurations for the number of threads per subslice for different products. The maximum value for global barriers is limited by the number of threads in the system, or by 511, whichever is lower. This field should not be set to 0 even if the barrier is disabled, since an accurate value is needed for proper pre-emption.
7	31:8	**Reserved** Format: MBZ
	7:0	**Cross-Thread Constant Data Read Length** Format: U8 Specifies the amount of constant data in CURBE in 8-DW register increments which will be sent to every thread in the thread group in addition to the per thread ids specified by **Constant URB Entry Read Length**. **Value** [0,127] — **Name**

INTERRUPT

INTERRUPT

Source: BSpec
Access: RO, R/W, R/WC, R/W
Size (in bits): 128
Default Value: 0x00000000, 0xFFFFFFFF, 0x00000000, 0x00000000

See the Interrupt Definition Tables to find the source event for each interrupt bit.
There are multiple instances of this register format.

DWord	Bit	Description
0	31:0	**ISR** Access: RO These are the Interrupt Status Register Bits. This field contains the non-persistent values of the interrupt status bits. The IMR selects which of these interrupt conditions are reported in the persistent IIR **Value** / **Name** 0b – Condition Doesn't exist 1b – Condition Exists **Restriction** Restriction : Some inputs to this register are short pulses. Do not use this register to sample these conditions.
1	31:0	**IMR** Access: R/W These are the Interrupt Mask Register Bits. This field contains a bit mask which selects which interrupt bits from the ISR are reported in the IIR. **Value** / **Name** FFFFFFFFh – All interrupts masked **[Default]** 0b – Not Masked 1b – Masked **Restriction** Restriction : For GT interrupts DO NOT use this register to mask interrupt events. Instead program this IMR to all 0s and use the individual GT command streamer MASK bits in the GT register space. This prevents unneeded messaging to DE.
2	31:0	**IIR** Access: R/WC These are the Interrupt Identity Register Bits.

<table>
<tr><th colspan="3">INTERRUPT</th></tr>
<tr><td></td><td></td><td>This field holds the persistent values of the interrupt bits from the ISR which are unmasked by the IMR.
The IER enables an interrupt to be generated when the corresponding bit in the IIR becomes set. A disabled interrupt will still appear in the IIR.
Bits set in this register will remain set (persist) until the interrupt condition is cleared by writing a '1' to the appropriate bits.
<table>
<tr><th>Value</th><th>Name</th></tr>
<tr><td>0b</td><td>Condition Not Detected</td></tr>
<tr><td>1b</td><td>Condition Detected</td></tr>
</table>
<table>
<tr><th>Programming Notes</th></tr>
<tr><td>For each bit, the IIR can store a second pending interrupt if two or more of the same interrupt conditions occur before the first condition is cleared. Upon clearing the first interrupt, the IIR bit will momentarily go low, then return high to indicate there is second interrupt pending.</td></tr>
</table></td></tr>
<tr><td>3</td><td>31:0</td><td>IER
<table>
<tr><td>Access:</td><td>R/W</td></tr>
</table>
These are the Interrupt Enable Register Bits.
The field enables an interrupt to be generated when the corresponding bit in the IIR becomes set. A disabled interrupt will still appear in the IIR.
<table>
<tr><th>Value</th><th>Name</th></tr>
<tr><td>0b</td><td>Disabled</td></tr>
<tr><td>1b</td><td>Enabled</td></tr>
</table>
<table>
<tr><th>Programming Notes</th></tr>
<tr><td>The master interrupt enable must be set to 1b for any of these enabled interrupts to propagate to PCI device 2 interrupt processing.</td></tr>
</table></td></tr>
</table>

Invalidate After Read Message Descriptor Control Field

MDC_IAR - Invalidate After Read Message Descriptor Control Field

Source:	BSpec
Size (in bits):	1
Default Value:	0x00000000

DWord	Bit	Description
0	0	**Reserved** Format: MBZ Previously, this Enable field was intended to optimize scratch and spill/fill read messages, where the memory was only used by a single thread and did not need to be maintained after the thread completed. If enabled, it caused all lines in the L3 cache accessed by the message to be invalidated after the read occurred, regardless of whether the line contained modified data. It was intended as a performance hint indicating that the data would no longer be used to avoid writing back data to memory.

JPEG

JPEG		
Source:	VideoCS	
Size (in bits):	16	
Default Value:	0x00000000	
DWord	**Bit**	**Description**
0	15:5	**Reserved** Format: MBZ
	4	**Inconsistent VLD SE Error** This flag indicates an inconsistent SE coded in the bit-stream. Bit-stream does not match any entries in the hauffman table.
	3	**Extra Block Error** This flag indicates extra block coded within an ECS data boundary.
	2	**Missing block Error** This flag indicates one or more blocks are missing within an ECS data boundary.
	1	**Extra ECS Error** This flag indicates extra ECS' coded in the bit-stream SCAN payload data.
	0	**Missing ECS Error** This flag indicates one or more ECS' are missing from the bit-stream SCAN payload data.

LOD Message Address Payload Control

MACD_LOD - LOD Message Address Payload Control

Source: BSpec
Size (in bits): 32
Default Value: 0x00000000

DWord	Bit	Description
0	31:4	**Reserved** Format: MBZ Ignored
	3:0	**LOD** Format: U4 Specifies the LOD for this slot. Value: [0,14] — Name: — Description: representing LOD

Lower Oword Block Data Payload

MDP_OW1L - Lower Oword Block Data Payload		
Source:	BSpec	
Size (in bits):	256	
Default Value:	0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000	
DWord	**Bit**	**Description**
0.0-0.3	127:0	**Oword** Format: U128 Specifies the upper Oword data element
0.4-0.7	127:0	**Reserved** Format: Ignore Ignored

LRI Data Entry

LRI_DATA - LRI Data Entry

Source: RenderCS

Size (in bits): 64

Default Value: 0x00000000, 0x00000000

Each LRI command header is followed by LRI_DATA entries. Each of these entries is a pair of Dwords: the MMIO register address and the data to be written.

DWord	Bit	Description
0..1	63:55	**Reserved** Format: MBZ
	54:32	**MMIO** Format: U23 **Programming Notes** Bits [1:0] MBZ
	31:0	**Data** Format: U32

MEDIA_SURFACE_STATE

MEDIA_SURFACE_STATE

Source:	BSpec
Exists If:	//([MessageType] == 'Deinterlace') OR ([MessageType] == 'Sample_8x8')
Size (in bits):	256
Default Value:	0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000

This is the SURFACE_STATE used by only deinterlace, sample_8x8, and VME messages.

DWord	Bit	Description
0	31:30	**Rotation** Value / Name: 00b — No Rotation or 0 Degree 01b — 90 Degree Rotation 10b — 180 Degree Rotation 11b — 270 Degree Rotation **Programming Notes** Rotation is only supported only with AVS function messages and not with HDC direct write and 16x8 AVS messages.
	29:27	**Reserved** Format: MBZ
	26:20	**X Offset** Exists If: //[Surface Format] is one of Planar Formats Format: PixelOffset[8:2] This field specifies the horizontal offset in pixels from the **Surface Base Address** to the start (origin) of the surface. This field effectively loosens the alignment restrictions on the origin of tiled surfaces. Previously, tiled surface origin was (by definition) located at the base address, and thus needed to satisfy the 4KB base address alignment restriction. Now the origin can be specified at a finer (4-wide x 4-high pixel) resolution. Value / Name / Description: [0,508] — In multiples of 4 (low 2 bits missing) **Programming Notes** For linear surfaces and Packed Formats, this field must be zero. For **Surface Format** with 8 bits per element, this field must be a multiple of 16. For **Surface Format** with 16 bits per element, this field must be a multiple of 8.

MEDIA_SURFACE_STATE

	26:16	**Reserved** Exists If: //[Surface Format] is not one of Planar Formats Format: MBZ
	19:16	**Y Offset** Exists If: //[Surface Format] is one of Planar Formats Format: RowOffset[5:2] This field specifies the vertical offset in rows from the **Surface Base Address** to the start of the surface. (See additional description in the **X Offset** field) **Value** / **Name** / **Description**: [0,28] / / In multiples of 4 (low two bits missing) **Programming Notes**: For linear surfaces and Packed Formats, this field must be zero.
	15:12	**Reserved** Format: MBZ
	11:0	**Reserved** Format: MBZ
1	31:18	**Height** Format: U14-1 This field specifies the height of the surface in units of pixels. For PLANAR surface formats, this field indicates the height of the Y (luma) plane. **Value** / **Name** / **Description** / **Exists If**: [0,16383] / / representing heights [1,16384] / [Surface Type] != FM_STRBUF_* **Programming Notes**: Height (field value + 1) must be a multiple of 2 for PLANAR_420 surfaces.If Vertical Line Stride is 1, this field indicates the height of the field, not the height of the frame.
	17:4	**Width** Format: U14-1 This field specifies the width of the surface in units of pixels. For PLANAR surface formats, this field indicates the width of the Y (luma) plane. **Value** / **Name** / **Description** / **Exists If**: [0,16383] / / representing widths [1,16384] / [Surface Type] != FM_STRBUF_* **Programming Notes**: • The Width specified by this field multiplied by the pixel size in bytes must be less than or equal to the surface pitch (specified in bytes via the Surface Pitch field). • Width (field value + 1) must be a multiple of 2 for PLANAR_420, PLANAR_422, and all

MEDIA_SURFACE_STATE

YCRCB_* and Y16_UNORM surfaces, and must be a multiple of 4 for PLANAR_411 and Y8_UNORM_VA surfaces.

- For deinterlace messages, the Width (field value + 1) must be a multiple of 8.

- For Y8_UNORM_VA format width should be in multiple of 4, for Y16_UNORM_VA format width should be in multiple of 2, for Y1_UNORM format width should be in multiple of 32
- When Address Control = Mirror, the total width should be in multiple of 4bytes.

Width (field value + 1) must be a multiple of 2 for PLANAR_420_16

3:2 **Picture Structure**

Specifies the encoding of the current picture.

Value	Name
00b	Frame Picture
01b	Top Field Picture
10b	Bottom Field Picture
11b	Invalid, not allowed

1:0 **Cr(V)/Cb(U) Pixel Offset V Direction**

Default Value:	0
Format:	U0.2

Description
Specifies the distance to the U/V values with respect to the even numbered Y channels in the V direction

Programming Notes
This field is ignored for all formats except PLANAR_420_8
This offset has been increased from 2 bits to 3 bits to support U1.2 format, and the MSB bit is added as Pixel Offset V Direction MSB in DWord 2. Valid values for the combined field range from 0 to 4.

2 31:27 **Surface Format**

Description
Specifies the format of the surface. All of the Y and G channels will use table 0 and all of the Cr/Cb/R/B channels will use table 1.
Note: Y8_UNORM_VA, Y16_UNORM and Y16_SNORM are used for all functions of sample_8x8 except AVS where rest of the formats are not used. These two formats are packed as 32bits in L1 though the individual pixels are either 8bpp or 16bpp respectively.

Value	Name	Description

MEDIA_SURFACE_STATE

0	YCRCB_NORMAL	
1	YCRCB_SWAPUVY	
2	YCRCB_SWAPUV	
3	YCRCB_SWAPY	
4	PLANAR_420_8	
5	Y8_UNORM_VA	Sample_8x8 only except AVS
6	Y16_SNORM	Sample_8x8 only except AVS
7	Y16_UNORM_VA	Sample_8x8 only except AVS
8	R10G10B10A2_UNORM	Sample_8x8 only
9	R8G8B8A8_UNORM	Sample_8x8 AVS only
10	R8B8_UNORM (CrCb)	Sample_8x8 AVS only
11	R8_UNORM (Cr/Cb)	Sample_8x8 AVS only
12	Y8_UNORM	Sample_8x8 AVS only
13	A8Y8U8V8_UNORM	Sample_8x8 AVS only
14	B8G8R8A8_UNORM	Sample_8x8 AVS only
15	R16G16B16A16	Sample_8x8 AVS only
16	Y1_UNORM	Sample_8x8 only for boolean surfaces (1bit/pixel)
17	Y32_UNORM	For Integral Image (32bpp)
18	PLANAR_422_8	Sample_8x8 AVS only
Others	Reserved	

26 **Interleave Chroma**

Format:	Enable

This field indicates that the chroma fields are interleaved in a single plane rather than stored as two separate planes. This field is only used for PLANAR surface formats.

25 **Cr(V)/Cb(U) Pixel Offset U Direction**

Default Value:	0
Format:	U0.1

Description

Specifies the distance to the U/V values with respect to the even numbered Y channels in the U direction

Programming Notes

This field must be zero for all formats except PLANAR_420_8, PLANAR_422_8, YCRCB_NORMAL, YCRCB_SWAPUVY, YCRCB_SWAPUV, YCRCB_SWAPY.

MEDIA_SURFACE_STATE

24 **Cr(V)/Cb(U) Pixel Offset V Direction MSB**

Default Value:	0
Format:	U1

Description
Specifies the distance to the U/V values with respect to the even numbered Y channels in the V direction

Programming Notes
This field must be zero for all formats except PLANAR_420_8.
This offset has been increased from 2 bits to 3 bits as U1.2 format and this bit is used in conjunction with the bits in the Cr(V)/Cb(U) Pixel Offset V Direction field in DWord 1, which contain the rest of the bits for offset V-direction. Valid values for the combined field range from 0 to 4.

23 **Memory Compression Mode**

Distinguishes Vertical from Horizontal compression.

Value	Name	Description
0	Horizontal Compression Mode **[Default]**	
1	Vertical Compression Mode	

22 **Memory Compression Enable**

Format:	Enable

This surface may contain compressed or compressible pixels. Memory compression will be attempted for writes to this surface. Reads from this surface will check for compressed data.

Programming Notes
The compression control must have 0 value for non-tileY modes.
Please refer to vol1a Memory Data Formats chapter -- section Media Memory Compression for more details, including format restrictions.

21 **Address Control**

Value	Name	Description
0	CLAMP	Clamp
1	MIRROR	Mirror

20:3 **Surface Pitch**

Format:	U18-1 pitch in Bytes

This field specifies the surface pitch in (#Bytes - 1).

Value	Name	Description
[0,262143]		For other linear surfaces: representing [1B, 256KB]
[511, 262143]		For X-tiled surface: representing [512B, 256KB] = [1 tile, 512 tiles]
[127, 262143]		For Y-tiled surfaces: representing [128B, 256KB] = [1 tile, 2048 tiles]

MEDIA_SURFACE_STATE

Programming Notes
For tiled surfaces, the pitch must be a multiple of the tile widthIf Half Pitch for Chroma is set, this field must be a multiple of two tile widths for tiled surfaces, or a multiple of 2 bytes for linear surfaces.The Surface Pitches of current picture and reference picture should be declared as the identical type in VDI mode with identical Height, Width and Format.
If Media Memory Compression is enabled, the following max pitch size restriction must be honored. For larger resolution, Media Memory compression Must be disabled. Tiling Mode Pixel Format Max Frame Width (bytes) Max Frame Width (pixels) Max Pitch (bytes) Legacy 4K 8bpp 16k 16k 16k + 127 16bpp 16k 8k 16k + 127 32bpp 16k 4k 16k + 127 64bpp 16k 2k 16k + 127 128bpp 16k 1k 16k + 127 TileYF 8bpp 8k 8k 8k + 63 16bpp 16k 8k 16k + 127 32bpp 16k 4k 16k + 127 64bpp 16k 2k 16k + 255 128bpp 16k 1k 16k + 255 TileYS 8bpp 16k 16k 16k + 255 16bpp 16k 8k 16k + 511 32bpp 16k 4k 16k + 511 64bpp 16k 2k 16k + 1023 128bpp 16k 1k 16k + 1023

2 **Half Pitch for Chroma**

Format:	Enable

This field indicates that the chroma plane(s) will use a pitch equal to half the value specified in the Surface Pitch field. This field is only used for PLANAR surface formats.

Programming Notes
Must be Zero as this field is not used.

1:0 **Tile Mode**

Format:	U2 Enumerated Type

This field specifies the type of memory tiling (Linear, WMajor, XMajor, or YMajor) employed to tile this surface. See Memory Interface Functions for details on memory tiling and restrictions.

Value	Name	Description
0h	TILEMODE_LINEAR	Linear mode (no tiling)
1h	Reserved	Reserved
2h	TILEMODE_XMAJOR	X major tiling
3h	TILEMODE_YMAJOR	Y major tiling

Programming Notes

- Refer to *Memory Data Formats* for restrictions on TileMode direction for the various buffer types. (Of particular interest is the fact that YMAJOR tiling is not supported for display/overlay buffers).
- The corresponding cache(s) must be invalidated before a previously accessed surface is accessed again with an altered state of this field.
- Linear surfaces can be mapped to Main Memory (uncached) or System Memory (cacheable, snooped). Tiled (X/Y/W) surfaces can only be mapped to Main Memory.

MEDIA_SURFACE_STATE

3	31:30	**Reserved** Format: MBZ
	29:16	**X Offset for U(Cb)** Format: U14 Pixel Offset **Description** For non planar surfaces this field specifies the horizontal offset in pixels from the Surface Base Address to the start (origin) of the surface. For Planar surfaces this field specifies the horizontal offset in pixels from the Y-plane origin to the start (origin) of the U(Cb) plane or the interleaved UV plane if Interleave Chroma is enabled. Resultant X-offset = 'X-offset of the surface (Y-plane)' + 'X offset for U(Cb)' For TileYS and TileYF this offset should be integral multiple of Tile width of Luma plane. **Programming Notes** For PLANAR_420 and PLANAR_422 surface formats, this field must indicate an even number of pixels.
	15:14	**Reserved** Format: MBZ
	13:0	**Y Offset for U(Cb)** Format: U14 Row Offset **Description** For non planar surfaces this field specifies the vertical offset in pixels from the Surface Base Address to the start (origin) of the surface. For Planar surfaces this field specifies the vertical offset in rows from the Y-plane origin to the start (origin) of the U(Cb) plane or the interleaved UV plane if Interleave Chroma is enabled. Resultant X-offset = 'Y-offset of the surface (Y-plane)' + 'Y offset for U(Cb)' For TileYS and TileYF this offset should be integral multiple of Tile width of Luma plane. **Programming Notes** This field must be aligned by 4 bit[1:0] = 00 This field must be aligned by 4 bit[1:0] = 00 for all format besides PLANAR_420_*
4	31:30	**Reserved** Format: MBZ
	29:16	**X Offset for V(Cr)** Exists If: //([Surface Format] is one of planar) AND ([Interleave Chroma] == '0') Format: U14 Pixel Offset

MEDIA_SURFACE_STATE

		Description For Planar surfaces this field specifies the horizontal offset in pixels from the Y-plane origin to the start (origin) of the V(Cb) plane. Resultant X-offset = 'X-offset of the surface (Y-plane)' + 'X offset for V(Cb)' For TileYS and TileYF this offset should be integral multiple of Tile width of Luma plane. **Programming Notes** For PLANAR_420 and PLANAR_422 surface formats, this field must indicate an even number of pixels.
	15	**Reserved** Format: MBZ
	14:0	**Y Offset for V(Cr)** Exists If: //([Surface Format] is one of planar) AND ([Interleave Chroma] == '0') Format: U15 Row Offset **Description** For Planar surfaces this field specifies the vertical offset in rows from the Y-plane origin to the start (origin) of the V(Cb) plane. Resultant Y-offset = 'Y-offset of the surface (Y-plane)' + 'Y offset for V(Cb)' For TileYS and TileYF this offset should be integral multiple of Tile width of Luma plane. **Programming Notes** This field must indicate a multiple of 4 (bit 0 & 1 = 00).
5	31	**Vertical Line Stride** Format: U1 in lines to skip between logically adjacent lines For Surfaces accessed via the sample_8x8 message:Specifies number of lines (0 or 1) to skip between logically adjacent lines - provides support of interleaved (field) surfaces as textures.For Other Surfaces:Vertical Line Stride must be zero.
	30	**Vertical Line Stride Offset** Format: U1 in lines of initial offset (when Vertical Line Stride == 1) For Surfaces accessed via the sample_8x8 message: Specifies the offset of the initial line from the beginning of the buffer. For Other Surfaces: Vertical Line Stride Offset must be zero. **Programming Notes** This field must be set to 0 if Vertical Line Stride is 0.
	29:24	**Reserved** Format: MBZ

MEDIA_SURFACE_STATE

	23:20	**Reserved** Format: MBZ
	19:18	**Tiled Resource Mode** Format: U2 **For Sampling Engine, Render Target, and Typed/Untyped Surfaces:** This field specifies the tiled resource mode. **For other surfaces:** This field is ignored.

Value	Name	Description
0h	TRMODE_NONE	No tiled resource
1h	TRMODE_TILEYF	4KB tiled resources
2h	TRMODE_TILEYS	64KB tiled resources
3h	Reserved	

Programming Notes
If **Tile Mode** is not set to TILEMODE_YMAJOR, this field must be set to TRMODE_NONE.
If this field is not set to TRMODE_NONE, the **Surface Format** must be one with 8, 16, 32, 64, or 128 bits per element, or one of the compressed texture modes (BC*, ETC*, EAC*, ASTC*). Additionally, YCRCB* formats are supported and treated as 16 bits per element, and the PLANAR_420_8 and PLANAR_422_8 formats are supported and treated as 8 bits per element on the Y plane and 16 bits per element on the UV plane (if **Interleave Chroma** is enabled) or 8 bits per element on the U and V planes (if **Interleave Chroma** is disabled.

	17:7	**Reserved** Format: MBZ
	6:0	**Surface Memory Object Control State** Default Value: 0h DefaultVaueDesc Format: **MEMORY_OBJECT_CONTROL_STATE** This 7-bit field is used in various state commands and indirect state objects to define cacheability and other attributes related to memory objects.
6	31:0	**Surface Base Address** Format: GraphicsAddress[31:0] Specifies the low 32 bits of the byte-aligned base address of the surface.

Programming Notes
For SURFTYPE_BUFFER render targets, this field specifies the base address of first element of the surface. The surface is interpreted as a simple array of that single element type. The address must be naturally-aligned to the element size (e.g., a buffer containing R32G32B32A32_FLOAT elements must be 16-byte aligned).For SURFTYPE_BUFFER non-rendertarget surfaces, this field specifies the base address of the first element of the surface, computed in software by adding the surface base address to the byte offset of the element in the buffer.Mipmapped, cube and

MEDIA_SURFACE_STATE

		3D sampling engine surfaces are stored in a 'monolithic' (fixed) format, and only require a single address for the base texture.Linear render target surface base addresses must be element-size aligned, for non-YUV surface formats, or a multiple of 2 element-sizes for YUV surface formats. Other linear surfaces have no alignment requirements (byte alignment is sufficient.)Linear depth buffer surface base addresses must be 64-byte aligned. Note that while render targets (color) can be SURFTYPE_BUFFER, depth buffers cannot.Tiled surface base addresses must be 4KB-aligned. Note that only the offsets from Surface Base Address are tiled, Surface Base Address itself is not transformed using the tiling algorithm.For tiled surfaces, the actual start of the surface can be offset from the Surface Base Address by the X Offset and Y Offset fields.Certain message types used to access surfaces have more stringent alignment requirements. Please refer to the specific message documentation for additional restrictions.
7	31:16	**Reserved** Format: MBZ
	15:0	**Surface Base Address High** Format: GraphicsAddress[47:32] Specifies the high 16 bits of the byte-aligned base address of the surface. Refer to Surface Base Address [31:0] for programming notes applying to this field.

MEMORY_OBJECT_CONTROL_STATE

MEMORY_OBJECT_CONTROL_STATE		
Source:	BSpec	
Size (in bits):	7	
Default Value:	0x00000000	
DWord	**Bit**	**Description**
0	6:1	**Index to MOCS Tables** The index to define the L3 and system cache memory properties. The details of the controls are further defined in L3 and Page walker (memory interface) control registers. The field is defined to populate 64 different surface controls to be used concurrently. Related control registers can be updated during runtime.
	0	**Reserved**

MemoryAddressAttributes

MemoryAddressAttributes

Source: BSpec
Size (in bits): 32
Default Value: 0x00000000

This field controls the priority of arbitration used in the GAC/GAM pipeline for this surface. It defines the 32-bit memory address attributes for the third DWord of the HCP command buffer address.

DWord	Bit	Description
0	31:15	**Reserved** Format: MBZ
	14:13	**Base Address - Tiled Resource Mode** Format: U2 **For Media Surfaces:** This field specifies the tiled resource mode. Value / Name / Description: 00b / TRMODE_NONE / TileY resources 01b / TRMODE_TILEYF / 4KB tiled resources 10b / TRMODE_TILEYS / 64KB tiled resources 11b / Reserved /
	12	**Base Address - Row Store Scratch Buffer Cache Select** Format: U1 This field controls if the Row Store is going to store inside Media Cache (rowstore cache) or to LLC. Value / Name / Description: 0 / / Buffer going to LLC. 1 / / Buffer going to Internal Media Storage.
	11	**Reserved** Format: MBZ
	10	**Base Address - Memory Compression Mode** Format: U1 Distinguishes vertical from horizontal compression. Please refer to vol1a **Memory Data Formats chapter - section** media Memory Compression for more details. Value / Name: 0b / Horizontal Compression Mode **Programming Notes** Must be zero; vertical compression is not supported.

MemoryAddressAttributes		
	9	**Base Address - Memory Compression Enable** Format: Enable Memory compression will be attempted for this surface.
	8:7	**Base Address - Arbitration Priority Control** Format: HEVC_ARBITRATION_PRIORITY
	6:1	**Base Address - Index to Memory Object Control State (MOCS) Tables** Format: U6 The index to define the L3 and system cache memory properties. The details of the controls are further defined in L3 and Page walker (memory interface) control registers. The field is defined to populate 64 different surface controls to be used concurrently. Related control registers can be updated during runtime.
	0	**Reserved**

Merged Media Block Message Header

MH_MBM - Merged Media Block Message Header

Source: DataPort 1

Size (in bits): 256

Default Value: 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000

DWord	Bit	Description
0	31:0	**X Offset** Format: S31 X offset (in bytes) of the upper left corner of the block into the surface.
1	31:0	**Y Offset** Format: S31 Y offset (in rows) of the upper left corner of the block into the surface.
2	31:0	**Merged Media Block Message Control** Format: MHC_MBM_CONTROL Specifies the Merged message subtype and additional input parameters.
3	31:0	**Mask** Format: U32 The Mask is ignored by the Merged Media Block message: all Dwords are always returned on reads, and always enabled to be written on writes.
4	31:0	**FFTID** Format: MHC_FFTID Fixed Function Thread ID
5..7	95:0	**Reserved** Format: Ignore Ignored

Merged Media Block Message Header Control

MHC_MBM_CONTROL - Merged Media Block Message Header Control

Source: BSpec
Size (in bits): 32
Default Value: 0x00000000

DWord	Bit	Description
0	31:30	**Message Mode** Format: Enumeration Specifies the Media Block Read message is Normal subtype. Value / Name / Description: 00h / Normal / The Block Height and Block Width fields are specified in this Dword. The Mask is ignofed by a media block read message. Others / Reserved / Reserved.
	29	**Reserved** Format: Ignore Ignored
	28:24	**Sub-Register Offset** Format: U5 Provides the sub-register offset in unit of bytes of a Merged Media Block Read message. This field is ignored (reserved) for a media block write message. Range = [0, 28]. Only a multiple of BasePitch, including 0, is valid. **Programming Notes** Sub-Register Offset and Register Pitch Control allow software to assembly multiple media block reads directly into a shared GRF register set. For example, if both are set to zero, the read data are written to GRF registers, aligning to the least significant bits of the first register, and the register pitch is equal to the next power-of-2 that is greater than or equal to the Block Width. If Register Pitch Control is non-zero, multiple media block read messages sharing the same Register Pitch Control but with different Sub-Register Offset can fill in the same set of GRF registers with media block data line interleaved. **Restriction** Restriction : For the Sampler Cache Data, this field must be zero. Restriction : BasePitch is defined as the next the power-of-2 that is greater than or equal to the Block Width. Minimum BasePitch is 1 DWord. Sub-Register Offset must be aligned to BasePitch (therefore will be a multiple of DWords as well). When Register Pitch Control = 0, Sub-Register Offset must align to BasePitch*Block

MHC_MBM_CONTROL - Merged Media Block Message Header Control

		Height. ensuring the output fits in a single GRF register. In general (and specifically when Sub-Register Offset is greater than 0), when the resulting data will cross a GRF register boundary, the data must be placed symmetrically between GRF registers.
	23:22	**Reserved** Format: Ignore Ignored
	21:16	**Block Height** Format: U6 Height in rows of block being accessed. Range = [0,63] representing 1 to 64 rows **Restriction** Restriction : If Block Width (bytes), then Maximum Block Height (rows) is constrained by (# Dwords width) * (# rows) <= 64 Dwords.
	15:10	**Reserved** Format: Ignore Ignored
	9:8	**Register Pitch Control** Format: U2 Controls the register pitch for a Merged Media Block Read message. This field is ignored (reserved) for a media block write message. Register Pitch Control is only allowed to be non-zero when Block Width is a multiple of DWords. Restriction : Register Pitch Control must be zero when SLICE_COMMON_ECO_CHICKEN1::DisableMediaMessageFix is set. Restriction : For the Sampler Cache Data, this field must be zero.

Value	Name	Description
0h	RPC_1 **[Default]**	1 Block
1h	RPC_2	2 Blocks
3h	RPC_4	4 Blocks

Restriction

Restriction :
BasePitch is defined as the next the power-of-2 that is greater than or equal to the Block Width. The effective register pitch (RPC*BasePitch)+SRO must be less than or equal to 32 bytes (to fit in a single GRF register).

MHC_MBM_CONTROL - Merged Media Block Message Header Control		
	7:6	**Reserved** Format: Ignore Ignored
	5:0	**Block Width** Format: U6 Width in bytes of the block being accessed. Range = [0,31] representing 1 to 32 Bytes.

Message Descriptor - Render Target Write

Message Descriptor - Render Target Write

Source: BSpec
Size (in bits): 32
Default Value: 0x00000000

DWord	Bit	Description
0	31	**Reserved** Format: MBZ
	30	**Data Format** Format: U1 Value / Name / Description: 0 – Single Precision – 32b 1 – Half Precision – 16b **Programming Notes** This field is applicable for Render Target Write Messages ONLY.
	29:14	**Reserved** Format: MBZ
	13	**Per-Sample PS outputs enable** This bit must not be set when Render Target is not bound to pixel-shader OR when Render Target is not multisampled. This bit must be set when PS runs at sample-frequency i.e. pixel shader dispatch mode is PER_SAMPLE. By setting this bit, PS sends Render Target Write Message that outputs color, depth(optional) and stencil(optional) phases on per sample basis for each slot. When Render Target is multisampled and this bit is reset, Render Target outputs color, depth(optional) and stencil(optional) at pixel frequency. It should be noted that the latter case is applicable for only per-pixel PS invocation.
	12	**Last Render Target Select** This bit must be set on the last render target write message sent for each group of pixels. For single render target pixel shaders, this bit is set on all render target write messages. For multiple render target pixel shaders, this bit is set only on messages sent to the last render target. This bit must be zero for SIMD8 Image Write message. **Programming Notes** In general, when threads are not launched by 3D FF, this bit must be zero.
	11	**Slot Group Select** This field selects whether slots 15:0 or slots 31:16 are used for bypassed data. Bypassed data includes the antialias alpha, multisample coverage mask, and if the header is not present also includes the X/Y addresses and pixel enables. For 8- and 16-pixel dispatches, SLOTGRP_LO must be selected on every message. For 32-pixel dispatches, this field must be set

Message Descriptor - Render Target Write

correctly for each message based on which slots are currently being processed.

Value	Name	Description
0	SLOTGRP_LO	choose bypassed data for slots 15:0
1	SLOTGRP_HI	choose bypassed data for slots 31:16

Programming Notes
For SIMD8 Image Write message thsi field MBZ.

10:8 **Message Type**

This field specifies the type of render target message.

For the SIMD8_DUALSRC_xx messages, the low bit indicates which slots to use for the pixel enables, X/Y addresses, and oMask.

Value	Name	Description
000b	SIMD16	SIMD16 single source message
001b	SIMD16_REPDATA	SIMD16 single source message with replicated data
010b	SIMD8_DUALSRC_LO	SIMD8 dual source message, use slots 7:0
011b	SIMD8_DUALSRC_HI	SIMD8 dual source message, use slots 15:8
100b	SIMD8_LO	SIMD8 single source message, use slots 7:0
111b	SIMD16_REPDATA_TM	It's only supported when accessing *Tiled Memory*. Using this Message Type to access linear *(Untiled)* memory is UNDEFINED.

Programming Notes
the above slots indicated are within the 16 slots selected by **Slot Group Select**. If SLOTGRP_HI is selected, the SIMD8 message types above reference slots 23:16 or 31:24 instead of 7:0 or 15:8, respectively.
SIMD16_REPDATA message must not be used in SIMD8 pixel-shaders.

7:0 **Reserved**

Format:	MBZ

Message Descriptor - Sampling Engine

Message Descriptor - Sampling Engine

Source: BSpec
Size (in bits): 32
Default Value: 0x00000000

DWord	Bit	Description
0	31	**EOT**
	30	**Return Format** Format: U1 Value / Name / Description: 0 / 32-bit / Return data is 32b 1 / 16-bit / Return data is 16b **Programming Notes** This field must be set to 32-bit for messages with SIMD Mode of SIMD4x2 or SIMD32/64. This field must be set to 32 for resinfo, LOD and sampleinfo messages. This message must be set to 32-bit for ld_mcs
	29	**Reserved** Format: MBZ
	28:25	**Message Length** Format: U4 This field specifies the number of 256-bit GRF registers starting from (src) to be sent out on the request message payload. Value / Name: [1,15] **Programming Notes** A value of 0 is considered erroneous.
	24:20	**Response Length** Format: U5 This field indicates the number of 256-bit registers expected in the message response. Value / Name: [0,16] **Programming Notes** A value 0 indicates that the request message does not expect any response. The largest

Message Descriptor - Sampling Engine

		response supported is 16 GRF registers.
	19	**Header Present** Format: Enable **Description** Specifies whether the message includes a header phase. If the header is not present (this field is zero), all of the fields normally contained in the header are assumed to be 0. If the header is not present, in some cases the **Write Channel Mask** fields are set according to the Response Length. For more details, please refer to the **Payload Parameter Definition**section, under *vol5c Shared Functions* .
	18:17	**SIMD Mode[1:0]** Format: U2 Specifies the SIMD mode of the message being sent. **Programming Notes** The SIMD Mode Extension field in the message header distinguishes between SIMD8D and SIMD4x2 modes.
	16:12	**Message Type** Format: U5 Specifies the type of message being sent. For more details, please refer to **Message Format** section for the definition of these 5 bits..
	11:8	**Sampler Index** Format: U4 Specifies the index into the sampler state table. Ignored for ld, resinfo, sampleinfo, and cache_flush type messages. **Value** / **Name**: [0,15] **Programming Notes** • For the deinterlace message, this field must be a multiple of 2 (even). • For the sample_8x8 message, this field must be a multiple of 4.
	7:0	**Binding Table Index** Format: U8 Specifies the index into the **binding table**. Ignored for cache_flush type messages. Values of 255 and 253 indicate stateless. 254 indicates SLM. 252 indicates bindless. **Value** / **Name**: [0,255]

MFD_MPEG2_BSD_OBJECT Inline Data Description

MFD_MPEG2_BSD_OBJECT Inline Data Description

Source: VideoCS
Size (in bits): 64
Default Value: 0x00000000, 0x00000000

DW0..1 corresponds to DW3..4 of the MFD_MPEG2_BSD_OBJECT.

DWord	Bit	Description
0	31:24	**Slice Horizontal Position** Format: U8 in Macroblocks This field indicates the horizontal position of the first macroblock in the slice.
	23:16	**Slice Vertical Position** Format: U8 in Macroblocks This field indicates the vertical position of the first macroblock in the slice.
	15:8	**Macroblock Count** Format: U8 in Macroblocks This field indicates the number of macroblocks in the slice, including skipped macroblocks.
	7	**Slice Concealment Override Bit** This bit forces hardware to handle the current slice in Conceal or Deocde Mode. If this bit is set to one, VIN will force the current slice to do concealment or to decode from bitstream regardless if the slice boundary has errors or not. Value / Name / Description: 1h — VIN will use driver-provided "Slice Concealment Type" regardless of valid slice boundary 0h — Driver must program "Slice Concealment Type" to '0'. VIN will set "Slice Concealment Type" depending if the slice boundary has error or not
	6	**Slice Concealment Type Bit** This bit can be forced by driver ("Slice Concealment Override Bit") or set by VINunit depending on slice boundary errors. Value / Name / Description: 1h — VMD will conceal all MBs of the slice regardless of bitstream. (If driver does not force the value of this bit, VIN will set this bit depending on slice boundary error. If the next slice position of the current slice is out-of-bound or the same or earlier than the current slice start position, VIN will set this bit for the next slice) 0h — VMD will decode MBs from the bitstream until the bitstream is run-out. Then VMD will conceal the remaining MBs. **Programming Notes** VIN can turn this bit from 0 to 1 internally if "Slice Concealment Disable Bit" is "0" and VIN detects slice boundary errors.

MFD_MPEG2_BSD_OBJECT Inline Data Description

	5	**Last Pic Slice** This bit is added to support error concealment at the end of a picture. **Value** / **Name** / **Description** 1h / / The current Slice is the last Slice of the entire picture 0h / / The current Slice is not the last Slice of current picture
	4	**Reserved**
	3	**Is Last MB** **Value** / **Name** / **Description** 1h / / The current MB is the last MB in the current Slice 0h / / The current MB is not the last MB in the current Slice
	2:0	**First Macroblock Bit Offset** Format: U3 This field provides the bit offset of the first macroblock in the first byte of the input bitstream.
1	31:29	**Reserved** Format: MBZ
	28:24	**Quantizer Scale Code** Format: U5 This field sets the quantizer scale code of the inverse quantizer. It remains in effect until changed by a decoded quantizer scale code in a macroblock. This field is decoded from the slice header by host software.
	23:17	**Reserved** Format: MBZ
	16:8	**Next Slice Vertical Position** Format: U9 in macroblocks This field indicates the vertical position (in macroblock units) of the first macroblock in the next slice. **Programming Notes** This field is primarily used for error concealment. In the case that current slice is the last slice, this field should set to the height of the picture (field picture will be in height of field) (since y-direction is zero-based numbering).
	7:0	**Next Slice Horizontal Position** Format: U8 in macroblocks This field indicates the horizontal position (in macroblock units) of the first macroblock in the next slice. **Programming Notes** This field is primarily used for error concealment. In the case that current slice is the last slice, this field should set 0.

MPEG2

MPEG2		
Source:	VideoCS

	4:0	**hw_263_vop_quant** MPEG4-2 SE: vop_quant (short header format only)
43	31:5	**Reserved** Format: MBZ
	4:0	**hw_263_gob_number** MPEG4-2 SE: gob_number (short header format only)
44	31:0	**hw_263_num_gobs_in_vop** Derived from Table 6-29 in the MPEG4-2 standard specification (short header format only)
45	31:0	**hw_263_num_macroblocks_in_gob** Derived from Table 6-29 in the MPEG4-2 standard specification (short header format only)

MPEG4-2_Inline_DMEM		
46	31:1	**Reserved** Format: MBZ
	0	**hw_263_gob_header_empty** MPEG4-2 SE: gob_header_empty (short header format only)
47	31:1	**Reserved** Format: MBZ
	0	**hw_263_gob_frame_id** MPEG4-2 SE: gob_frame_id (short header format only)
48	31:9	**Reserved** Format: MBZ
	8:0	**hw_263_quant_scale** MPEG4-2 SE: quant_scale (short header format only)
49	31:0	**hw_263_num_rows_in_gob** Refer to Table 6-29 in the MPEG4-2 standard specification, vop_height/(16*num_gobs_in_vop) (short header format only)

MSAA Sample Number Message Address Control

MACD_MSAA_SN - MSAA Sample Number Message Address Control

Source: BSpec
Size (in bits): 32
Default Value: 0x00000000

DWord	Bit	Description
0	31:4	**Reserved** Format: MBZ Ignored
	3:0	**Sample Number** Format: U4 Specifies the sample number for the slot. If the sample number is larger than the **Number of Multisamples** in the Surface State, then the access is out of bounds.

MsgDescpt31

MsgDescpt31

Source: Eulsa
Size (in bits): 29
Default Value: 0x00000000

DWord	Bit	Description
0	28:25	**Message Length** This field specifies the number of 256-bit MRF registers starting from <curr_dest> to be sent out on the request message payload. Valid value ranges from 1 to 15. A value of 0 is considered erroneous. Value: 1-15 — Name: Number of MRF Registers
	24:20	**Response Length** This field indicates the number of 256-bit registers expected in the message response. The valid value ranges from 0 to 16. A value 0 indicates that the request message does not expect any response. The largest response supported is 16 GRF registers. Value: 0-16 — Name: Number of Registers
	19	**Header Present** Format: Enable If set, indicates that the message includes a header. Depending on the target shared function, this field may be restricted to either enabled or disabled. Refer to the specific shared function section for details.
	18:0	**Function Control** This field is intended to control the target function unit. Refer to the section on the specific target function unit for details on the contents of this field.

Normal Media Block Message Header

MH_MB - Normal Media Block Message Header

Source: DataPort 1

Size (in bits): 256

Default Value: 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000

DWord	Bit	Description
0	31:0	**X Offset** Format: S31 X offset (in bytes) of the upper left corner of the block into the surface. **Programming Notes** Must be DWord aligned (Bits 1:0 MBZ) for the write form of the message.
1	31:0	**Y Offset** Format: S31 Y offset (in rows) of the upper left corner of the block into the surface.
2	31:0	**Normal Media Block Message Control** Format: MHC_MB_CONTROL Specifies the Normal message subtype and additional input parameters.
3	31:0	**Mask** Format: U32 The Mask is ignored by the Normal Media Block message: all Dwords are always returned on reads, and always enabled to be written on writes.
4	31:0	**FFTID** Format: MHC_FFTID Fixed Function Thread ID
5..7	95:0	**Reserved** Format: Ignore Ignored

Normal Media Block Message Header Control

MHC_MB_CONTROL - Normal Media Block Message Header Control

Source: BSpec
Size (in bits): 32
Default Value: 0x00000000

DWord	Bit	Description
0	31:30	**Message Mode** Format: Enumeration Specifies the interpretation of M0.3 (Pixel or Byte Mask). For the Sampler Cache Data Port, this field is ignored, behaving as if always set to NORMAL. **Value / Name / Description** 00h / Normal / The Block Height and Block Width fields are specified in this Dword. The Mask is ignored by a media block read message and behaves as if it is set to all ones for a media block write message. Others / Reserved / Reserved. **Programming Notes** The Media Block Read message is Normal subtype when both Sub-Register Offset and Register Pitch Control are zero. The Media Block Read message is Merged subtype when either Sub-Register Offset or Register Pitch Control are non-zero.
	29	**Reserved** Format: Ignore Ignored
	28:24	**Sub-Register Offset** Format: MBZ The sub-register offset must be 0 for Normal Media Block Read message subtype. This field is ignored (reserved) for a media block write message.
	23:22	**Reserved** Format: Ignore Ignored

MHC_MB_CONTROL - Normal Media Block Message Header Control

	21:16	**Block Height** Format: U6 Height in rows of block being accessed. Range = [0,63] representing 1 to 64 rows **Restriction** Restriction : If Block Width (bytes), then Maximum Block Height (rows) is constrained by (# Dwords width) * (# rows) <= 64 Dwords.
	15:10	**Reserved** Format: Ignore Ignored
	9:8	**Register Pitch Control** Format: MBZ The register pitch must be 0 for a Normal Media Block Read message. This field is ignored (reserved) for a media block write message.
	7:6	**Reserved** Format: Ignore Ignored
	5:0	**Block Width** Format: U6 Width in bytes of the block being accessed. For normal Media Block Writes, Range = [0,63] representing 1 to 64 Bytes. For normal Media Block Reads and for masked and merged Media Block messages, Range = [0,31] representing 1 to 32 Bytes. **Programming Notes** Must be DWord aligned for the write form of the message.

oMask Message Data Payload Register

MDPR_OMASK - oMask Message Data Payload Register

Source: BSpec
Size (in bits): 256
Default Value: 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000

DWord	Bit	Description
0	31:16	**oMask1** Format: U16 oMask for Pixels [15:0] of Slot 1. Not used for Slot Group HI.
	15:0	**oMask0** Format: U16 oMask for Pixels [15:0] of Slot 0. Not used for Slot Group HI.
1	31:16	**oMask3** Format: U16 oMask for Pixels [15:0] of Slot 3. Not used for Slot Group HI.
	15:0	**oMask2** Format: U16 oMask for Pixels [15:0] of Slot 2. Not used for Slot Group HI.
2	31:16	**oMask5** Format: U16 oMask for Pixels [15:0] of Slot 5. Not used for Slot Group HI.
	15:0	**oMask4** Format: U16 oMask for Pixels [15:0] of Slot 4. Not used for Slot Group HI.
3	31:16	**oMask7** Format: U16 oMask for Pixels [15:0] of Slot 7. Not used for Slot Group HI.
	15:0	**oMask6** Format: U16 oMask for Pixels [15:0] of Slot 6. Not used for Slot Group HI.

MDPR_OMASK - oMask Message Data Payload Register		
4	31:16	**oMask9** Format: U16 oMask for Pixels [15:0] of Slot 9. Used only if Slot Group HI or SIMD16.
	15:0	**oMask8** Format: U16 oMask for Pixels [15:0] of Slot 8. Used only if Slot Group HI or SIMD16.
5	31:16	**oMask11** Format: U16 oMask for Pixels [15:0] of Slot 11. Used only if Slot Group HI or SIMD16.
	15:0	**oMask10** Format: U16 oMask for Pixels [15:0] of Slot 10. Used only if Slot Group HI or SIMD16.
6	31:16	**oMask13** Format: U16 oMask for Pixels [15:0] of Slot 13. Used only if Slot Group HI or SIMD16.
	15:0	**oMask12** Format: U16 oMask for Pixels [15:0] of Slot 12. Used only if Slot Group HI or SIMD16.
7	31:16	**oMask15** Format: U16 oMask for Pixels [15:0] of Slot 15. Used only if Slot Group HI or SIMD16.
	15:0	**oMask14** Format: U16 oMask for Pixels [15:0] of Slot 14. Used only if Slot Group HI or SIMD16.

MDP_A64_AOP8_OW2 - Oword A64 SIMD8 Atomic Operation CMPWR16B Message Data Payload		
5.0-5.7	255:0	**Slot[3:2] Src1** Format: MDCR_OW Specifies the Slot [3:2] Source 1 data
6.0-6.7	255:0	**Slot[5:4] Src1** Format: MDCR_OW Specifies the Slot [5:4] Source 1 data
7.0-7.7	255:0	**Slot[7:6] Src1** Format: MDCR_OW Specifies the Slot [7:6] Source 1 data

Oword Data Blocks Message Descriptor Control Field

MDC_DB_OW - Oword Data Blocks Message Descriptor Control Field

Source: BSpec
Size (in bits): 3
Default Value: 0x00000000

DWord	Bit	Description
0	2:0	**Data Blocks** Format: Enumeration Specifies the number of Oword blocks to be read or written

Value	Name	Description
00h	OW1L	1 Oword, read into or written from the low 128 bits of the destination register
01h	OW1U	1 Oword, read into or written from the high 128 bits of the destination register
02h	OW2	2 Owords
03h	OW4	4 Owords
04h	OW8	8 Owords
Others	Reserved	Ignored

Oword Data Payload Register

MDCR_OW - Oword Data Payload Register		
Source:	BSpec	
Size (in bits):	256	
Default Value:	0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000	
DWord	**Bit**	**Description**
0.0-0.3	127:0	**Oword0** Format: U128 Specifies the slot 0 data in this payload register
0.4-0.7	127:0	**Oword1** Format: U128 Specifies the slot 1 data in this payload register

Oword Dual Data Blocks Message Descriptor Control Field

MDC_DB_OWD - Oword Dual Data Blocks Message Descriptor Control Field

Source: BSpec
Size (in bits): 2
Default Value: 0x00000000

DWord	Bit	Description
0	1:0	**OW Dual Data Blocks** Format: Enumeration Specifies the number of Oword Blocks to be read or written

Value	Name	Description
00h	OWD1	1 Hword register, 2 Owords
02h	OWD4	4 Hword registers, 8 Owords
Others	Reserved	Ignored

PALETTE_ENTRY

PALETTE_ENTRY		
Source:	RenderCS	
Size (in bits):	32	
Default Value:	0x00000000	
DWord	**Bit**	**Description**
0	31:24	**Alpha** Format: U8 Alpha channel value for this entry in the texture color palette.
	23:16	**Red** Format: U8 Red channel value for this entry in the texture color palette.
	15:8	**Green** Format: U8 Green channel value for this entry in the texture color palette.
	7:0	**Blue** Format: U8 Blue channel value for this entry in the texture color palette.

Per Thread Scratch Space Message Header Control

MHC_PTSS - Per Thread Scratch Space Message Header Control

Source: BSpec
Size (in bits): 32
Default Value: 0x00000000

DWord	Bit	Description
0	31:4	**Reserved** Format: Ignore Ignored
	3:0	**Per Thread Scratch Space** Format: U4 Specifies the amount of scratch space allowed to be used by this thread for messages in which the Binding Table Index is Stateless model, otherwise this field is ignored.The data port will use this to bounds check scratch space messages. Value range = [0,11] represents [1KB, 2MB] in powers of two. **Programming Notes** Writes out of bounds will be ignored. Reads out of bounds will return 0.

PIXEL_HASH_TABLE_1BIT_32ENTRY

PIXEL_HASH_TABLE_1BIT_32ENTRY

Source: BSpec
Size (in bits): 32
Default Value: 0x00000000

Description
2-way pixel hashing table. Table is 32-entries:8X,4Y in [Y][X] format. Each entry is a single bit that indicates which sub-slice hardware block the indicated xy pixel block is mapped.
pixelhash_id maps to subslice. A value of 0 indicates the first enabled subslice. A value of 1 indicates the second enabled subslice.

DWord	Bit	Description
0	31:24	**Pixel Hashing Table Entries y[3]x[7:0]** Format: U8 Indicates the pixelhash_id for the pixel block that has y=3 and x=7..0
	23:16	**Pixel Hashing Table Entries y[2]x[7:0]** Format: U8 Indicates the pixelhash_id for the pixel block that has y=2 and x=7..0
	15:8	**Pixel Hashing Table Entries y[1]x[7:0]** Format: U8 Indicates the pixelhash_id for the pixel block that has y=1 and x=7..0
	7:0	**Pixel Hashing Table Entries y[0]x[7:0]** Format: U8 Indicates the pixelhash_id for the pixel block that has y=0 and x=7..0

PIXEL_HASH_TABLE_1BIT_64ENTRY

PIXEL_HASH_TABLE_1BIT_64ENTRY	
Source:	BSpec
Size (in bits):	64
Default Value:	0x00000000, 0x00000000

Description
2-way pixel hashing table. Table is 64-entries:8X,8Y in [Y][X] format. Each entry is a single bit that indicates which sub-slice hardware block the indicated xy pixel block is mapped.
pixelhash_id maps to subslice. A value of 0 indicates the first enabled subslice. A value of 1 indicates the second enabled subslice.

DWord	Bit	Description
0	31:24	**Pixel Hashing Table Entries y[3]x[7:0]** Format: U8 Indicates the pixelhash_id for the pixel block that has y=3 and x=7..0

PIXEL_HASH_TABLE_2BIT_128ENTRY

PIXEL_HASH_TABLE_2BIT_128ENTRY

Source: BSpec

Size (in bits): 256

Default Value: 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000

Description
3-wayor 4-way pixel hashing table. Table is 128-entries:8X,8Y in [Y][X] format. Each entry is two bits that indicates which sub-slice hardware block the indicated xy pixel block is mapped.
pixelhash_id maps to subslice. A value of 0 indicates the first enabled subslice. A value of 1 indicates the second enabled subslice.

Pixel Masked Media Block Message Header

MH_MBPM - Pixel Masked Media Block Message Header

Source: DataPort 1

Size (in bits): 256

Default Value: 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000

DWord	Bit	Description
0	31:0	**X Offset** Format: S31 X offset (in bytes) of the upper left corner of the block into the surface. **Programming Notes** When Message Mode is set to PIXEL_MASK, this field must be a multiple of 32.
1	31:0	**Y Offset** Format: S31 Y offset (in rows) of the upper left corner of the block into the surface. **Programming Notes** When Message Mode is set to PIXEL_MASK, this field must be a multiple of 4.
2	31:0	**Media Block Message Control** Format: MHC_MBPM_CONTROL Specifies the message subtype is Pixel Masked.
3	31:0	**Pixel Mask** Format: U32 Specifies the Pixel Mask for writes when Message Mode field is PIXEL_MASK. **Programming Notes** The Pixel Mask applies to the 2x2 square tiles (UL, UR, LL, LR), which themselves tiled (UL, UR, LL, LR) and then repeated on the right for the remaining 16-bits to cover a 4 row 8 column area.
4	31:0	**FFTID** Format: MHC_FFTID Fixed Function Thread ID
5..7	95:0	**Reserved** Format: Ignore Ignored

Pixel Masked Media Block Message Header Control

MHC_MBPM_CONTROL - Pixel Masked Media Block Message Header Control

Source: BSpec
Size (in bits): 32
Default Value: 0x00000000

DWord	Bit	Description
0	31:30	**Message Mode** Format: Enumeration Specifies the Media Block Write Message subtype is Pixel Masked. Value / Name / Description: 01h / PIXEL_MASK / Use the Pixel Mask in the Message Header. The Block Height and Block Width are ignored and behave as if they are set to 4 rows and 32 bytes, respectively. Others / Reserved / Reserved.
	29	**Reserved** Format: Ignore Ignored
	28:24	**Sub-Register Offset** Format: MBZ The sub-register offset must be 0 for Pixel Masked Media Block message subtype.
	23:22	**Reserved** Format: Ignore Ignored
	21:16	**Block Height** Format: U6 This field is ignored (reserved) for a Pixel Masked media block write message.
	15:10	**Reserved** Format: Ignore Ignored
	9:8	**Register Pitch Control** Format: MBZ The register pitch must be 0 for a Pixel Masked Media Block message.

MHC_MBPM_CONTROL - Pixel Masked Media Block Message Header Control

	7:6	**Reserved** Format: Ignore Ignored
	5:0	**Block Width** Format: U6 This field is ignored (reserved) for a Pixel Masked media block write message.

Pixel Sample Mask Message Header Control

MHC_PSM - Pixel Sample Mask Message Header Control

Source: BSpec
Size (in bits): 32
Default Value: 0x0000FFFF

DWord	Bit	Description
0	31:16	**Reserved** Format: Ignore Ignored
	15:0	**Pixel Sample Mask** Default Value: 0FFFFh Default Format: U16 SIMD16 and SIMD8 messages. All 16 bits are used for SIMD16. For untyped SIMD8 messages, the low 8 bits of field are used. If the header is not delivered, this field defaults to all ones. This field is ignored for SIMD4x2 messages.

Pixel Sample Mask Render Target Message Header Control

Default Value:	0x00000000

DWord	Bit	Description
0	31:16	**Dispatched Pixel/Sample Enables** Format: U16 One bit per pixel (or sample within pixel) indicating which pixels/samples were originally enabled when the thread was dispatched. The Dispatched Pixel/Sample Enables must be unmodified from the ones sent when the pixel shader thread was initiated. If the Dispatched Pixel/Sample Enables are modified, behavior is undefined. **Programming Notes** When operating in PER_SAMPLE mode these bits correspond to samples, not pixels. Each subspan slot (4 bits) corresponds to a specific sample location for the subspan. Note that in NUMSAMPLES_1 mode, a pixel and sample are synonomous. When operating in PER_PIXEL mode, this field is ignored, and instead the SampleEnableMask (obtained via bypass) are used to clear the Depth Scoreboard.
	15:0	**Pixel/Sample Enables** Format: U16 Specifies which pixels/samples are still lit based on kill instruction activity in the pixel shader. This mask is AND'd with the Dispatched Pixel/Sample Enables mask, and that is used to control actual accesses to the color buffer. Pixels/samples will be dropped on masked writes, and the GRF is not modified for masked reads. **Programming Notes** When operating in PER_SAMPLE mode these bits correspond to samples, not pixels, as the PS is run per-sample. Each subspan slot (4 bits) corresponds to a specific sample location for the subspan. When operating in PER_PIXEL mode, these bits still correspond to pixels, as the PS is run per-pixel. Each pixel's mask bit is replicated according to Number of Multisamples and combined with other masks to control writes to the multisample locations.

Power Clock State Format

Power Clock State Format

Source: RenderCS
Size (in bits): 31
Default Value: 0x00000088

Known Uses

- R_PWR_CLK_STATE - Render Power Clock State Register
- PM_PWR_CLK_STATE - PM Power Clock State Request (Intended, in GT/GTI space, not yet in use)
- PM_PWR_CLK_STATE (Intended, in GT/GTI space, not yet in use)

DWord	Bit	Description
0	30:20	**Reserved** Access: RO Format: MBZ
	19	**Reserved** Access: RO Format: MBZ
	18	**Enable Slice Count Request** Access: R/W Enable Slice Count Request. Value / Name / Description 0h / Disable / Use async PMunit slice count request. 1h / Enable / Use SliceCount from this register.
	17:15	**Slice Count Request** Access: R/W Slice Count Request. This is limited to the number of slices in a given SKU. Value / Name / Description 001b / / 1 slice. 010b / / 2 slices. 011b / / 3 slices. 100b / / 4 slices. 101b / / 5 slices. Hardware will revert to 4 slices 110b / / 6 slices.

Power Clock State Format

	14:12	**Reserved** Access: RO Format: MBZ
	11:8	**Reserved** Access: RO Format: MBZ
	8	**Reserved** Access: RO
	7:4	**EUmax** Access: R/W Maximum number of EUs to power (per subslice if multiple subslices enabled). To specify an exact number of subslices, set EUmax equal to EUmin.

Value	Name	Description
0010b		2 EUs
0100b		4 EUs
0110b		6 EUs
1000b	**[Default]**	8 EUs

Programming Notes
EUmin and EUmax need to be even and odd numbers are illegal; hardware will clip odd EU counts to an even value.

	3:0	**EUmin** Access: R/W Minimum number of EUs to power (per subslice if multiple subslices enabled). To specify an exact number of subslices, set EUmax equal to EUmin.

Value	Name	Description
0010b		2 EUs
0100b		4 EUs
0110b		6 EUs
1000b	**[Default]**	8 EUs

Programming Notes
EUmin and EUmax need to be even and odd numbers are illegal; hardware will clip odd EU counts to an even value.

PPHWSP_LAYOUT - PPHWSP_LAYOUT

		The contents of the Ring Buffer Head Pointer register (register DWord 1) are written to this location either as result of an MI_REPORT_HEAD instruction or as the result of an "automatic report" (see RINGBUF registers).
5..15	31:0	**Reserved**
16	0	**Cumulative Context Run Time** This has the cumulative run time of the context on HW. HW reports CTX_TIMESTAMP to this location on a context switch. This value is written after the context save is complete. The value that is saved in the context image does not include the time between the saving of the cumulative value to context to the time we complete the save. If required for the value to always increment and not take the context save into consideration, driver must look at the value in the context image.
17	31:1	**Reserved**
	0	**Element Switch** Value / Name / Description 0 / / Indicates the context is not submitted as the first element in the execlist. 1 / / Indicates the corresponding context has been submitted as first element of the execlist. Preempt Request Received Timestamp is the time when the pending execlist has been submitted to HW. Note that across multiple submissions a given context could be first or second element of an execlist. This bit will get set if the context has been submitted as the first element in the execlist.
18..19	63:0	**Preempt Request Received Timestamp** TIMESTAMP register sampled on preemption request is reported.
20..21	63:0	**Context Restore Complete Timestamp** TIMESTAMP register sampled on context restore complete is reported.
22..23	63:0	**Context Save Finished Timestamp** TIMESTAMP register sampled on context save completion is reported.
24..27	127:0	**MI_SEMAPHORE_WAIT** MI_SEMAPHORE_WAIT command on which the context got switched out due to semaphore wait. This field is only valid and must be looked at when the context switch reason in context status buffer is stated as "Wait on Semaphore".

RENDER_SURFACE_STATE

RENDER_SURFACE_STATE

Source:	BSpec
Exists If:	//[MessageType] != 'Sample_8x8'
Size (in bits):	512
Default Value:	0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000

This is the normal surface state used by all messages that use SURFACE_STATE except those that use MEDIA_SURFACE_STATE.

DWord	Bit	Description
0	31:29	**Surface Type** This field defines the type of the surface.

Value	Name	Description
0h	SURFTYPE_1D	Defines a 1-dimensional map or array of maps
1h	SURFTYPE_2D	Defines a 2-dimensional map or array of maps
2h	SURFTYPE_3D	Defines a 3-dimensional (volumetric) map
3h	SURFTYPE_CUBE	Defines a cube map or array of cube maps
4h	SURFTYPE_BUFFER	Defines an element in a buffer
5h	SURFTYPE_STRBUF	Defines a structured buffer surface
6h	Reserved	
7h	SURFTYPE_NULL	Defines a null surface

Programming Notes

A null surface is used in instances where an actual surface is not bound. When a write message is generated to a null surface, no actual surface is written to. When a read message (including any sampling engine message) is generated to a null surface, the result is all zeros. Note that a null surface type is allowed to be used with all messages, even if it is not specificially indicated as supported. All of the remaining fields in surface state are ignored for null surfaces, with the following exceptions:

- **Width, Height, Depth, LOD,** and **Render Target View Extent** fields must match the depth buffer's corresponding state for all render target surfaces, including null.

All sampling engine and data port messages support null surfaces with the above behavior, even if not mentioned as specifically supported, except for the following:

- The **Surface Type** of a surface used as a render target (accessed via the Data Port's Render Target Write message) must be the same as the **Surface Type** of all other render targets and of the depth buffer (defined in 3DSTATE_DEPTH_BUFFER), unless either the depth buffer or render targets are SURFTYPE_NULL.

RENDER_SURFACE_STATE

	28	**Surface Array** Format: Enable This field, if enabled, indicates that the surface is an array. **Programming Notes** If this field is *enabled*, the **Surface Type** must be SURFTYPE_1D, SURFTYPE_2D, or SURFTYPE_CUBE. If this field is *disabled* and **Surface Type** is SURFTYPE_1D, SURFTYPE_2D, or SURFTYPE_CUBE, the **Depth** field must be set to zero.
	27	**ASTC_Enable** Format: Enable This field, if enabled, indicates that the surface is one of ASTC compression formats. **Programming Notes** If this field is *enabled*, the definition of **Surface Format** encoding will follow a new convention defined by ASTC. If this field is *disabled*, the definition of **Surface Format** will follow the legacy convention defined in non-ASTC style.
	26:18	**Surface Format** Format: SURFACE_FORMAT **Description** This field specifies the format of the surface or element within this surface. This field is ignored for all data port messages other than the render target message and streamed vertex buffer write message. Some forms of the media block messages use the surface format. If **ASTC_Enable** is set to 0, the supported formats and their encoding is listed in the table (x) in Section (y); Otherwise the supported formats and their encoding is listed in the table (x+1) in Section (y). **Programming Notes** If **ASTC_Enable** is set to 0: YUV (YCRCB) surfaces used as render targets can only be rendered to using 3DPRIM_RECTLIST with even X coordinates on all of its vertices, and the pixel shader cannot kill pixels. If **Number of Multisamples** is set to a value other than MULTISAMPLECOUNT_1, this field cannot be set to the following formats: • Any compressed texture format (BC*, DXT*, FXT*, ETC*, EAC*) • Any YCRCB* format This field cannot ASTC format if the **Surface Type** is SURFTYPE_BUFFER or SURFTYPE_STRBUF This field cannot be ASTC format if the **Surface Type** is SURFTYPE_1D. This field cannot be a YUV (YCRCB*) or compressed (BC*, DXT*, FXT*, ETC*, EAC*) format if the **Surface Type** is SURFTYPE_BUFFER or SURFTYPE_STRBUF This field cannot be a planar YUV (PLANAR_*) or compressed (BC*, DXT*, FXT*, ETC*, EAC*) format if the **Surface Type** is SURFTYPE_1D.

RENDER_SURFACE_STATE

17:16 **Surface Vertical Alignment**

Description
For Sampling Engine and Render Target Surfaces: This field specifies the vertical alignment requirement in elements for the surface. Refer to the "Memory Data Formats" chapter for details on how this field changes the layout of the surface in memory. An *element* is defined as a pixel in uncompresed surface formats, and as a compression block in compressed surface formats. For MSFMT_DEPTH_STENCIL type multisampled surfaces, an element is a sample.
This field is used for 2D, CUBE, and 3D surface alignment when Tiled Resource Mode is TRMODE_NONE (Tiled Resource Mode is disabled). This field is ignored for 1D surfaces and also when Tiled Resource Mode is not TRMODE_NONE (e.g. Tiled Resource Mode is enabled). See the appropriate Alignment table in the "Surface Layout and Tiling" section under Common Surface Formats for the table of alignment values for Tiled Resrouces.
For other surfaces: This field is ignored.

Value	Name	Description
0h	Reserved	Reserved
1h	VALIGN 4	Vertical alignment factor j = 4
2h	VALIGN 8	Vertical alignment factor j = 8
3h	VALIGN 16	Vertical alignment factor j = 16

Programming Notes
This field is intended to be set to VALIGN_4 if the surface was rendered as a depth buffer, for a multisampled (4x) render target, or for a multisampled (8x) render target, since these surfaces support only alignment of 4. Use of VALIGN_4 for other surfaces is supported, but increases memory usage.
This field is intended to be set to VALIGN_8 only if the surface was rendered as a stencil buffer, since stencil buffer surfaces support only alignment of 8. If set to VALIGN_8, Surface Format must be R8_UINT.
For uncompressed surfaces, the units of "j" are rows of pixels on the physical surface. For compressed texture formats, the units of "j" are in compression blocks, thus each increment in "j" is equal to h pixels, where h is the height of the compression block in pixels.

15:14 **Surface Horizontal Alignment**

Description
For Sampling Engine and Render Target Surfaces: This field specifies the horizontal alignment requirement for the surface.
This field is used for alignment when LOD >= Mip Tail Start LOD This field is ignored when Tiled Resource Mode is not TRMODE_NONE (i.e. Tiled Resources are enabled). See the "Surface Layout and Tiling" section under Common Surface Formats for the table of alignment values for Tile Resrouces.

RENDER_SURFACE_STATE

For other surfaces:
This field is ignored.

Value	Name	Description
0h	Reserved	Reserved
1h	HALIGN 4	Horizontal alignment factor j = 4
2h	HALIGN 8	Horizontal alignment factor j = 8
3h	HALIGN 16	Horizontal alignment factor j = 16

Programming Notes

This field is intended to be set to HALIGN_8 only if the surface was rendered as a depth buffer with Z16 format or a stencil buffer. In this case it must be set to HALIGN_8 since these surfaces support only alignment of 8. For Z32 formats it must be set ot HALIGN_4. Use of HALIGN_8 for other surfaces is supported, but increases memory usage.
For uncompressed surfaces, the units of "i" are pixels on the physical surface. For compressed texture formats, the units of "i" are in compression blocks, thus each increment in "i" is equal to w pixels, where w is the width of the compression block in pixels.

When Auxiliary Surface Mode is set to AUX_CCS_D or AUX_CCS_E, HALIGN 16 must be used.

13:12 **Tile Mode**
This field specifies the type of memory tiling (Linear, WMajor, XMajor, or YMajor) employed to tile this surface. See *Memory Interface Functions* for details on memory tiling and restrictions.

Value	Name	Description
0h	LINEAR	Linear mode (no tiling)
1h	WMAJOR	W major tiling
2h	XMAJOR	X major tiling
3h	YMAJOR	Y major tiling

Programming Notes

- Refer to *Memory Data Formats* for restrictions on *TileMode* direction for the various buffer types. (Of particular interest is the fact that YMAJOR tiling is not supported for display/overlay buffers).
- The corresponding cache(s) must be invalidated before a previously accessed surface is accessed again with an altered state of this field.
- Use of WMAJOR is valid only for sampling engine, Data Cache Data Port and render target surfaces and **Surface Format** must be R8_UINT. Vertical Line Stride must be zero. In addition to W tiling, this mode implies that the surface is stored as a stencil buffer. Refer to *Memory Data Formats* section for details on stencil buffer surface layout.
- Linear surfaces can be mapped to Main Memory (uncached) or System Memory (cacheable, snooped). Tiled (X/Y/W) surfaces can only be mapped to Main Memory.
- If **Surface Type** is SURFTYPE_BUFFER, this field must be TILEMODE_LINEAR

RENDER_SURFACE_STATE

- If **Number of Multisamples** is not MULTISAMPLECOUNT_1, this field must be YMAJOR.

If **Surface Type** is SURFTYPE_STRBUF, this field must be TILEMODE_LINEAR.

If **Surface Type** is SURFTYPE_1D this field must be TILEMODE_LINEAR, unless **Sampler Legacy 1D Map Layout Disable** is set to 0, in which case TILEMODE_YMAJOR and TILEMODE_WMAJOR are also allowed. **Tiled Resource Mode** must be set to TRMODE_NONE for these cases.

TILEMODE_XMAJOR is only allowed if Surface Type is SURFTYPE_2D.

If **Surface Format** is ASTC*, this field must be TILEMODE_YMAJOR.

11 **Vertical Line Stride**

Format:	U1 In lines to skip between logically adjacent lines

For 2D Non-Array Surfaces accessed via the Sampling Engine or Data Cache Data Port: Specifies number of lines (0 or 1) to skip between logically adjacent lines - provides support of interleaved (field) surfaces as textures.
For Other Surfaces: Vertical Line Stride must be zero.

Programming Notes

This bit must not be set if the surface format is a compressed type (BCn*, FXT1, ETC*, EAC*).

This bit must not be set if the surface format is compressed type ASTC*.

This bit must not be set if the **Auxiliary Surface Mode** is not AUX_NONE.

If this bit is set on a sampling engine surface, the mip mode filter must be set to MIPFILTER_NONE and the min and mag mode filter cannot be set to MAPFILTER_FLEXIBLE.

10 **Vertical Line Stride Offset**

Format:	U1 In lines of initial offset (when Vertical Line Stride == 1)

For 2D Non-Array Surfaces accessed via the Sampling Engine or Data Cache Data Port: Specifies the offset of the initial line from the beginning of the buffer. Ignored when Vertical **Line Stride** is 0.
For Other Surfaces:
Vertical Line Stride Offset must be zero.

9 **Sampler L2 out of order mode Disable**

Format:	Disable

If disabled this will forced formats which would have bypassed the L2 and been filled into the L1 out of order to be cached in the L2 and send in order to the L1. In general that is any format which is expaned 1:2 in L1 or not expanded at all. This would include all lossless compressed cases
For all other formats this will have no affect.

8 **Render Cache Read Write Mode**
For Surfaces accessed via the Data Port to Render Cache:
This field specifies the way Render Cache treats a write request. If unset, Render Cache allocates a write-only cache line for a write miss. If set, Render Cache allocates a read-write cache line for a

RENDER_SURFACE_STATE

write miss.

For Surfaces accessed via the Sampling Engine or Data Port to Texture Cache or Data Cache:

This field is reserved : MBZ

Value	Name	Description
0h	Write-Only Cache	Allocating write-only cache for a write miss
1h	Read-Write Cache	Allocating read-write cache for a write miss

Programming Notes
This field is provided for performance optimization for Render Cache read/write accesses (from Gen4 EU's point of view).

7:6 **Media Boundary Pixel Mode**

For 2D Non-Array Surfaces accessed via the Data Port Media Block Read Message or Data Port Transpose Read message:

This field enables control of which rows are returned on vertical out-of-bounds reads using the Data Port Media Block Read Message or Data Port Transpose Read message. In the description below, frame mode refers to **Vertical Line Stride** = 0, field mode is **Vertical Line Stride** = 1 in which only the even or odd rows are addressable. The frame refers to the entire surface, while the field refers only to the even or odd rows within the surface.

For Other Surfaces:

Reserved : MBZ

Value	Name	Description
0h	NORMAL_MODE	The row returned on an out-of-bound access is the closest row in the frame or field. Rows from the opposite field are never returned.
1h	Reserved	
2h	PROGRESSIVE_FRAME	The row returned on an out-of-bound access is the closest row in the frame, even if in field mode.
3h	INTERLACED_FRAME	In field mode, the row returned on an out-of-bound access is the closest row in the field. In frame mode, even out-of-bound rows return the nearest even row while odd out-of-bound rows return the nearest odd row.

5 **Cube Face Enable - Negative X**

Exists If:	[Surface Type] == 'SURFTYPE_CUBE'
Format:	Enable

For SURFTYPE_CUBE Surfaces accessed via the Sampling Engine:

This field enable the individual face of a cube map. Enabling a face indicates that the face is present in the cube map, while disabling it indicates that that face is represented by the texture map's border color. Refer to Memory Data Formats for the correlation between faces and the cube map memory layout. Note that storage for disabled faces must be provided.

Programming Notes

RENDER_SURFACE_STATE

		When TEXCOORDMODE_CLAMP is used when accessing a cube map, this field must be programmed to 1b (face enabled).
	4	**Cube Face Enable - Positive X** Exists If: [Surface Type] == 'SURFTYPE_CUBE' Format: Enable **For SURFTYPE_CUBE Surfaces accessed via the Sampling Engine:** This field enable the individual face of a cube map. Enabling a face indicates that the face is present in the cube map, while disabling it indicates that that face is represented by the texture map's border color. Refer to Memory Data Formats for the correlation between faces and the cube map memory layout. Note that storage for disabled faces must be provided. **Programming Notes** When TEXCOORDMODE_CLAMP is used when accessing a cube map, this field must be programmed to 1b (face enabled).
	3	**Cube Face Enable - Negative Y** Exists If: [Surface Type] == 'SURFTYPE_CUBE' Format: Enable **For SURFTYPE_CUBE Surfaces accessed via the Sampling Engine:** This field enable the individual face of a cube map. Enabling a face indicates that the face is present in the cube map, while disabling it indicates that that face is represented by the texture map's border color. Refer to Memory Data Formats for the correlation between faces and the cube map memory layout. Note that storage for disabled faces must be provided. **Programming Notes** When TEXCOORDMODE_CLAMP is used when accessing a cube map, this field must be programmed to 1b (face enabled).
	2	**Cube Face Enable - Positive Y** Exists If: [Surface Type] == 'SURFTYPE_CUBE' Format: Enable **For SURFTYPE_CUBE Surfaces accessed via the Sampling Engine:** This field enable the individual face of a cube map. Enabling a face indicates that the face is present in the cube map, while disabling it indicates that that face is represented by the texture map's border color. Refer to Memory Data Formats for the correlation between faces and the cube map memory layout. Note that storage for disabled faces must be provided. **Programming Notes** When TEXCOORDMODE_CLAMP is used when accessing a cube map, this field must be programmed to 1b (face enabled).
	1	**Cube Face Enable - Negative Z** Exists If: [Surface Type] == 'SURFTYPE_CUBE' Format: Enable **For SURFTYPE_CUBE Surfaces accessed via the Sampling Engine:** This field enable the individual face of a cube map. Enabling a face indicates that the face is

RENDER_SURFACE_STATE

present in the cube map, while disabling it indicates that that face is represented by the texture map's border color. Refer to Memory Data Formats for the correlation between faces and the cube map memory layout. Note that storage for disabled faces must be provided.

Programming Notes

When TEXCOORDMODE_CLAMP is used when accessing a cube map, this field must be programmed to 1b (face enabled).

5:0 Reserved

Exists If:	[Surface Type] != 'SURFTYPE_CUBE'
Format:	MBZ

0 Cube Face Enable - Positive Z

Exists If:	[Surface Type] == 'SURFTYPE_CUBE'
Format:	Enable

For SURFTYPE_CUBE Surfaces accessed via the Sampling Engine:

This field enable the individual face of a cube map. Enabling a face indicates that the face is present in the cube map, while disabling it indicates that that face is represented by the texture map's border color. Refer to Memory Data Formats for the correlation between faces and the cube map memory layout. Note that storage for disabled faces must be provided.

Programming Notes

When TEXCOORDMODE_CLAMP is used when accessing a cube map, this field must be programmed to 1b (face enabled).

1 31 Reserved

Format:	MBZ

30:24 Memory Object Control State

Format:	MEMORY_OBJECT_CONTROL_STATE

Specifies the memory object control state for this surface and the associated Auxiliary surface (if any).

23:19 Base Mip Level

Format:	U4.1

Range: [0.0, 14.0]

Specifies which mip level is considered the "base" level when determining mag-vs-min filter and selecting the "base" mip level.

Programming Notes

This field also exists in SAMPLER_STATE. If both fields are zero, the Base Mip Level is zero. If one is nonzero, Base Mip Level is the nonzero field. It is illegal to have both Base Mip Level fields nonzero.

RENDER_SURFACE_STATE

	18	**Reserved** Format: MBZ
	17	**Reserved** Format: MBZ
	16	**Reserved** Format: MBZ
	15	**Reserved** Format: MBZ
	14:0	**Surface QPitch** Format: QPitch[16:2]

Description

The interpretation of this field is dependent on Surface Type as follows:

- SURFTYPE_1D: distance in *pixels* between array slices
- SURFTYPE_2D/CUBE: distance in *rows* between array slices. For Quilted Textures this field specifies the distance in rows between *quilt* slices. For compressed texture formats, one row contains a complete compression block vertically.
- SURFTYPE_3D: distance in *rows* between R-slices [**Note:** these *rows* are only in the vertical dimension without considering the depth dimension]. For compressed texture formats, one row contains a complete compression block vertically.
- Other surface types: field is ignored

Value	Name	Description
[4h,1FFFCh]		in multiples of 4 (low 2 bits missing)

Programming Notes

For Surface Type 1D: This field must be set to an integer multiple of the **Surface Horizontal Alignment**
For Surface Type 2D, CUBE: This field must be set to an integer multiple of the **Surface Vertical Alignment**
For Surface Type 3D: *Tile Mode != Linear:* This field must be set to an integer multiple of the tile height (2^Cv) *Tile Mode == Linear:* This field must be set to an integer multiple of the Surface Vertical Alignment
Note: for compressed textures (BC*, FXT1, ETC*, EAC*), this field is in units of rows of compression blocks.

Note: for the compressed texture ASTC Surface Format, this field is in units of rows of compression blocks.

Software must ensure that this field is set to a value sufficiently large such that the array slices in the surface do not overlap. Refer to the Memory Data Formats section for information on

RENDER_SURFACE_STATE

how surfaces are stored in memory.

2 | 31:30 **Reserved**

Format:	MBZ

29:16 **Height**

Format:	U14-1

This field specifies the height of the surface, minus 1. If the surface is MIP-mapped, this field contains the height of the base MIP level. For buffers, this field specifies a portion of the buffer size.

Value	Name	Description	Exists If
[0,0]		must be zero	[Surface Type] == 'SURFTYPE_1D'
[0,16383]		height of surface - 1 (y/v dimension)	[SurfaceType] == 'SURFTYPE_2D'
[0,16383]		height of surface - 1 (y/v dimension)	[SurfaceType] == 'SURFTYPE_3D'
[0,16383]		height of surface - 1 (y/v dimension)	[SurfaceType] == 'SURFTYPE_CUBE'
[0,16383]		contains bits [20:7] of the number of entries in the buffer - 1	([SurfaceType] == 'SURFTYPE_BUFFER') || ([SurfaceType] == 'SURFTYPE_STRBUF')

Programming Notes

For typed buffer and structured buffer surfaces, the number of entries in the buffer ranges from 1 to 2^{27}. For raw buffer surfaces, the number of entries in the buffer is the number of bytes which can range from 1 to 2^{30}. After subtracting one from the number of entries, software must place the fields of the resulting 27-bit value into the **Height, Width**, and **Depth** fields as indicated, right-justified in each field. Unused upper bits must be set to zero.

If **Vertical Line Stride** is 1, this field indicates the height of the field, not the height of the frame

The **Height** of a render target must be the same as the **Height** of the other render targets and the depth buffer (defined in 3DSTATE_DEPTH_BUFFER), unless **Surface Type** is SURFTYPE_1D or SURFTYPE_2D with **Depth** = 0 (non-array) and **LOD** = 0 (non-mip mapped).

If this surface in memory is accessed with Vertical Line Stride set to both 0 and 1, this field must be an even value when Vertical Line Stride is 0.

If Media Pixel Boundary Mode is not set to NORMAL_MODE, this field must be an even value.

If Surface Format is PLANAR*, see **Planar Memory Organization** section for restrictions on the value of this field.

15:14 **Reserved**

Format:	MBZ

RENDER_SURFACE_STATE

13:0 **Width**

Format:	U14-1

Description
This field specifies the width of the surface, minus 1. If the surface is MIP-mapped, this field specifies the width of the base MIP level. The width is specified in units of pixels or texels. For buffers, this field specifies a portion of the buffer size.
For surfaces accessed with the Media Block Read/Write message, this field is in units of DWords.
For surfaces accessed with the Transpose Read Message, this field is in units of DWords.

Value	Name	Description	Exists If
[0,16383]		width of surface - 1 (x/u dimension)	[SurfaceType] == 'SURFTYPE_1D'
[0,16383]		width of surface - 1 (x/u dimension)	[SurfaceType] == 'SURFTYPE_2D'
[0,16383]		width of surface - 1 (x/u dimension)	[SurfaceType] == 'SURFTYPE_3D'
[0,16383]		width of surface - 1 (x/u dimension)	[SurfaceType] == 'SURFTYPE_CUBE'
[0,127]		contains bits [6:0] of the number of entries in the buffer - 1	([SurfaceType] == 'SURFTYPE_BUFFER') || ([SurfaceType] == 'SURFTYPE_STRBUF')

Programming Notes

- For surface types other than SURFTYPE_BUFFER or STRBUF The Width specified by this field must be less than or equal to the surface pitch (specified in bytes via the Surface Pitch field).
- For cube maps, Width must be set equal to the Height.
- For MONO8 textures, Width must be a multiple of 32 texels.
- The **Width** of a render target must be the same as the **Width** of the other render target(s) and the depth buffer (defined in 3DSTATE_DEPTH_BUFFER), unless **Surface Type** is SURFTYPE_1D or SURFTYPE_2D with **Depth** = 0 (non-array) and **LOD** = 0 (non-mip mapped).
- The **Width** of a render target with YUV surface format must be a multiple of 2.
- For SURFTYPE_BUFFER: The low two bits of this field must be 11 if the Surface Format is RAW (the size of the buffer must be a multiple of 4 bytes).

If **Surface Format** is PLANAR*, this field must be a multiple of 2

RENDER_SURFACE_STATE

3 — 31:21 Depth

Format:	U11-1

This field specifies the total number of levels, minus 1, for a volume texture or the number of array elements, minus 1, allowed to be accessed starting at the **Minimum Array Element** for arrayed surfaces. If the volume texture is MIP-mapped, this field specifies the depth of the base MIP level. For buffers, this field specifies a portion of the buffer size.

Value	Name	Description	Exists If
[0,2047]		number of array elements - 1	[SurfaceType] == 'SURFTYPE_1D'
[0,2047]		number of array elements - 1	[SurfaceType] == 'SURFTYPE_2D'
[0,2047]		depth of surface - 1 (z/r dimension)	[SurfaceType] == 'SURFTYPE_3D'
[0,340]		number of array elements - 1 [see programming notes for range]	[SurfaceType] == 'SURFTYPE_CUBE'
[0,2047]		contains bits [31:21] of the number of entries in the buffer - 1	([SurfaceType] == SURFTYPE_BUFFER) OR ([SurfaceType] == 'SURFTYPE_STRBUF')

Programming Notes

The **Depth** of a render target must be the same as the **Depth** of the other render target(s) and of the depth buffer (defined in 3DSTATE_DEPTH_BUFFER).

For SURFTYPE_CUBE: For Sampling Engine Surfaces and Typed Data Port Surfaces, the range of this field is [0,340], indicating the number of cube array elements (equal to the number of underlying 2D array elements divided by 6). For other surfaces, this field must be zero.

For SURFTYPE_1D, 2D, and CUBE: The range of this field is reduced by one for each increase from zero of **Minimum Array Element**. For example, if **Minimum Array Element** is set to 1024 on a 2D surface, the range of this field is reduced to [0,1023].

20 — Reserved

Format:	MBZ

19 — Reserved

Format:	MBZ

18 — Reserved

Format:	MBZ

17:0 — Surface Pitch

Format:	U18-1 Pitch in #Bytes

Surface Pitch Range:

- For surfaces of type SURFTYPE_BUFFER: [0,2047] -> [1B, 2048B]
- For surfaces of type SURFTYPE_STRBUF: [0,2047] -> [1B, 2048B]
- For other linear surfaces: [0, 262143] -> [1B, 256KB]

RENDER_SURFACE_STATE

- For X-tiled surface: [511, 262143] -> [512B, 256KB] = [1 tile, 512 tiles]
- For Y-tiled surfaces: [127, 262143]->[128B, 256KB] = [1 tile, 2048 tiles]
- For W-tiled surfaces: [127, 262143]->[128B, 256KB] = [1 tile, 2048 tiles]
- For TileYF and TileYS surfaces, the range is dependent on the Cu parameter (refer to *Memory Data Formats* section for the definition of the Cu parameter depending on the case). The range in bytes is [2^{Cu}-1,262143] -> [(2^{Cu})B,256KB] = [1 tile, 256KB/(2^{Cu}) tiles]

This field specifies the surface pitch in (#Bytes - 1).
For surfaces of type SURFTYPE_BUFFER and SURFTYPE_STRBUF, this field indicates the size of the structure.

Programming Notes

- For linear *render target* surfaces and surfaces accessed with the typed data port messages, the pitch must be a multiple of the element size for non-YUV surface formats. Pitch must be a multiple of 2 * element size for YUV surface formats.
- For untyped data port messages, which are only supported with **Surface Type** SURFTYPE_BUFFER, the pitch is ignored and assumed to be 1 byte.
- For linear surfaces with **Surface Type** of SURFTYPE_STRBUF, the pitch must be a multiple of 4 bytes.
- For linear surfaces with **Surface Type** of SURFTYPE_BUFFER and **Surface Format** RAW, the pitch must be 1 byte.
- For other linear surfaces, the pitch can be any multiple of bytes.
- For tiled surfaces, the pitch must be a multiple of the tile width.

If the surface is a stencil buffer (and thus has **Tile Mode** set to TILEMODE_WMAJOR), the pitch must be set to 2x the value computed based on width, as the stencil buffer is stored with two rows interleaved. For details on the separate stencil buffer storage format in memory, see GPU Overview (vol1a), Memory Data Formats, Surface Layout, 2D Surfaces, Stencil Buffer Layout (section 8.20.4.8).

- The width of a tile depends on the surface format if Tiled Resource Enable is enabled. Refer to the Tiled Resource Enable field to determine which sub-mode applies to the surface format in use, and determine the Cu parameter from the Surface Layout section. The tile width is equal to 2^Cu bytes.
- For surfaces of type SURFTYPE_1D, this field is ignored.

The following table indicates the maximum byte width, frame width, and pitch size allowed when memory compression is on.

Tiling Mode	Pixel Format	Max Frame Width (bytes)	Max Frame Width (pixels)	Max Pitch (bytes)
Legacy 4K	8bpp	16k	16k	16k + 127
	16bpp	16k	8k	16k + 127
	32bpp	16k	4k	16k + 127

RENDER_SURFACE_STATE

		64bpp	16k	2k	16k + 127
		128bpp	16k	1k	16k + 127
	TileYF	8bpp	8k	8k	8k + 63
		16bpp	16k	8k	16k + 127
		32bpp	16k	4k	16k + 127
		64bpp	16k	2k	16k + 255
		128bpp	16k	1k	16k + 255
	TileYS	8bpp	16k	16k	16k + 255
		16bpp	16k	8k	16k + 511
		32bpp	16k	4k	16k + 511
		64bpp	16k	2k	16k + 1023
		128bpp	16k	1k	16k + 1023

4 — 31 — Reserved

Exists If:	[Surface Type] != 'SURFTYPE_STRBUF'
Format:	MBZ

4 — 30:29 — Render Target And Sample Unorm Rotation

Exists If:	[Surface Type] != 'SURFTYPE_STRBUF'

Description

For Render Target Surfaces:
This field specifies the rotation of this render target surface when being written to memory.

For sample_unorm Messages: This field specifies the rotation of the data returned by sampler for sample_unorm message.

For Other Surfaces:
This field is ignored.

Value	Name	Description
0h	0DEG	No rotation (0 degrees)
1h	90DEG	Rotate by 90 degrees
2h	180DEG	Rotate by 180 degrees [for sample_unorm message]
3h	270DEG	Rotate by 270 degrees

Programming Notes

Programming Notes for Render Target Surfaces only

- Rotation is not supported for render targets of any type other than simple, non-mip-mapped, non-array 2D surfaces. The surface must be using tiled with X major.
- **Width** and **Height** fields apply to the dimensions of the surface before rotation.

RENDER_SURFACE_STATE

- For 90 and 270 degree rotated surfaces, the **Height** (rather than the **Width**) must be less than or equal to the **Surface Pitch** (specified in bytes).
- For 90 and 270 degree rotated surfaces, the actual **Height** and **Width** of the surface in pixels (not the field value which is decremented) must both be even.

Rotation is supported only for surfaces with the following surface formats: B5G6R5_UNORM, B5G6R5_UNORM_SRGB, R8G8B8A8_UNORM, R8G8B8A8_UNORM_SRGB, B8G8R8[A|X]8_UNORM, B8G8R8[A|X]8_UNORM_SRGB, B10G10R10[A|X]2_UNORM, B10G10R10A2_UNORM_SRGB, R10G10B10A2_UNORM, R10G10B10A2_UNORM_SRGB, R16G16B16A16_FLOAT, R16G16B16X16_FLOAT

28:18 **Minimum Array Element**

Exists If:	[Surface Type] != 'SURFTYPE_STRBUF'
Format:	U11

Description

17:7 **Render Target View Extent**

Exists If:	[Surface Type] != 'SURFTYPE_STRBUF'
Format:	U11-1

Range [0,2047] to indicate extent of [1,2048]
For Render Target and Typed Dataport 3D Surfaces:
This field indicates the extent of the accessible 'R' coordinates minus 1 on the LOD currently being rendered to.
For Render Target and Typed Dataport 1D and 2D Surfaces:
This field must be set to the same value as the Depth field.
For Other Surfaces:
This field is ignored.

6 **Multisampled Surface Storage Format**

Exists If:	[Surface Type] != 'SURFTYPE_STRBUF'

This field indicates the storage format of the multisampled surface.

Value	Name	Description
0h	MSS	Multsampled surface was/is rendered as a render target
1h	DEPTH_STENCIL	Multisampled surface was rendered as a depth or stencil buffer

Programming Notes

- All multisampled render target surfaces must have this field set to MSFMT_MSS
- IF this field is MSFMT_DEPTH_STENCIL, the only sampling engine messages allowed are

RENDER_SURFACE_STATE

"ld2dms", "resinfo", and "sampleinfo".

- This field is ignored if **Number of Multisamples** is MULTISAMPLECOUNT_1

5:3 Number of Multisamples

Exists If:	[Surface Type] != 'SURFTYPE_STRBUF'

This field indicates the number of multisamples on the surface.

Value	Name
0h	MULTISAMPLECOUNT_1
1h	MULTISAMPLECOUNT_2
2h	MULTISAMPLECOUNT_4
3h	MULTISAMPLECOUNT_8
4h	MULTISAMPLECOUNT_16
5h-7h	Reserved

Programming Notes

If this field is any value other than MULTISAMPLECOUNT_1, the **Surface Type** must be SURFTYPE_2D

This field must be set to MULTISAMPLECOUNT_1 unless the surface is a Sampling Engine surface or Render Target surface.

31:0 Reserved

Exists If:	[Surface Type] == 'SURFTYPE_STRBUF'
Format:	MBZ

2:0 Multisample Position Palette Index

Exists If:	[Surface Type] != 'SURFTYPE_STRBUF'

This field indicates the index into the sample position palette that the multisampled surface is using. This field is only used as a return value for the sampleinfo message, and is otherwise not used by hardware.

Value	Name
[0,7]	

5 31:25 X Offset

Format:	PixelOffset[8:2]

This field specifies the horizontal offset in pixels from the **Surface Base Address** to the start (origin) of the surface.

This field effectively loosens the alignment restrictions on the origin of tiled surfaces. Previously, tiled surface origin was (by definition) located at the base address, and thus needed to satisfy the 4KB base address alignment restriction. Now the origin can be specified at a finer (4-wide x 4-high pixel) resolution.

Value	Name	Description
[0,508]		In multiples of 4 (low 2 bits missing)

RENDER_SURFACE_STATE

Programming Notes

- For linear surfaces, this field must be zero.
- For surfaces accessed with the *Data Port Media Block Read/Write* message, the pixel size is assumed to be 32 bits in width.
- For surfaces accessed with the **Data Port Transpose Read message**, the pixel size is assumed to be 32 bits in width.
- For **Surface Format** with other than 8, 16, 32, 64, or 128 bits per pixel, this field must be zero.
- If **Render Target Rotation** is set to other than RTROTATE_0DEG, this field must be zero.
- If **Surface Type** not SURFTYPE_2D, this field must be zero.
- If **MIP Count** is not zero, this field must be zero.
- If **Number of Multisamples** is not MULTISAMPLECOUNT_1, this field must be zero.
- If **Surface Array** is enabled, this field must be zero.
- If **Auxiliary Surface Mode** is not AUX_NONE, this field must be zero.
- If **Surface Vertical Alignment** is VALIGN_8, this field must be a multiple of 8.
- For **Surface Format** with 8 bits per element, this field must be a multiple of 16.
- For **Surface Format** with 16 bits per element, this field must be a multiple of 8.

- If **Tiled Resource Mode** is not TRMODE_NONE, this field must be zero.

24 **Reserved**

Format:	MBZ

23:21 **Y Offset**

Format:	RowOffset[4:2]

This field specifies the vertical offset in rows from the **Surface Base Address** to the start of the surface. (See additional description in the **X Offset** field.)

Value	Name	Description
[0,28]		In multiples of 4 (low two bits missing)

Programming Notes

- For linear surfaces, this field must be zero.
- For render targets in which the **Render Target Array Index** is not zero, this field must be zero.
- For **Surface Format** with other than 8, 16, 32, 64, or 128 bits per pixel, this field must be zero.
- If **Render Target Rotation** is set to other than RTROTATE_0DEG, this field must be zero.
- If **Surface Type** not SURFTYPE_2D, this field must be zero.

RENDER_SURFACE_STATE

- If **MIP Count** is not zero, this field must be zero.
- If **Number of Multisamples** is not MULTISAMPLECOUNT_1, this field must be zero.
- If **Surface Array** is enabled, this field must be zero.
- If **Auxiliary Surface Mode** is not AUX_NONE, this field must be zero.

- If **Tiled Resource Mode** is not TRMODE_NONE, this field must be zero.

This field must be zero if Surface Format is Planar and the U and V planes are half-pitch (e.g. YV12 format).

20 **EWA Disable For Cube**

Format:	Disable

Specifies if EWA mode for LOD quality improvement needs to be disabled for cube maps.

Value	Name	Description
0h	Enable **[Default]**	EWA is enabled for cube maps
1h	Disable	EWA is disabled for cube maps

Programming Notes

This field indicates if EWA mode for LOD quality improvement needs to be disabled for cube maps.
By default EWA would be on for cube maps hence this field must be 0. If there is any spec violation seen with EWA on cube maps then this field must be set to 1 to disable EWA for cubes.

19:18 **Tiled Resource Mode**

For Sampling Engine, Render Target, and Typed/Untyped Surfaces:
This field specifies the tiled resource mode.

For other surfaces:
This field is ignored.

Value	Name	Description	Exists If
0h	NONE	No tiled resource	
1h	4KB	4KB tiled resources	[SurfaceType] == 'SURFTYPE_1D'
2h	64KB	64KB tiled resources	[SurfaceType] == 'SURFTYPE_1D'
1h	TILEYF	4KB tiled resources	[SurfaceType] != 'SURFTYPE_1D'
2h	TILEYS	64KB tiled resources	[SurfaceType] != 'SURFTYPE_1D'
3h	Reserved		

Programming Notes

If **Tile Mode** is not set to TILEMODE_YMAJOR, this field must be set to TRMODE_NONE, unless the Surface Type is SURFTYPE_1D.

If this field is not set to TRMODE_NONE, the **Surface Format** must be one with 8, 16, 32, 64, or

RENDER_SURFACE_STATE

128 bits per element, or one of the compressed texture modes (BC*, ETC*, EAC*, ASTC*). Additionally, YCRCB* formats are supported and treated as 16 bits per element, and the PLANAR_420_8 format is support and treated as 8 bits per element on the Y plane and 16 bits per element on the UV plane (if **Separate UV Plane Enable** is disabled) or 8 bits per element on the U and V planes (if **Separate UV Plane Enable** is enabled).

If this field is set to TRMODE_NONE, the surface cannot contain any null pages unless **Surface Type** is BUFFER or STRBUF. A BUFFER or STRBUF surface with null pages must have **Surface Base Address** and **Surface Pitch** set to an integer multiple of the element size, and **Surface Format** must be one with 8, 16, 32, 64, or 128 bits per element.

If **Surface Format** is PLANAR, the surface cannot contain any null pages.

17:16 **Reserved**

Format:	MBZ

15 **Reserved**

Format:	MBZ

14 **Coherency Type**

Specifies the type of coherency maintained for this surface.

Value	Name	Description
0h	GPU coherent	Surface memory is kept coherent with GPU threads using GPU read/write ordering rules. Surface memory is backed by system memory but is not kept coherent with CPU (LLC).
1h	IA coherent	Surface memory is kept coherent with CPU (LLC).

Programming Notes

This field may optionally be 1 (IA coherent) for messages sent to SFID_DP_DC0 or SFID_DP_DC1 or SFID_DP_DC2. This field is typically set to 0 (GPU coherent) if the context is operating in a non-SVM legacy mode (for example, Ring Buffer or a Execlist using 32-bit Virtual Address Legacy Context PPGTT32).

If the surface is not IA coherent, then it is possible that data written to Null Tile address will be cached, and then a later read to that same address might return a non-zero value. If a value is cached for a Null Tile address, the data will be eventually be discarded when the cache line is evicted. If the surface is IA coherent, then the cache line never contains a non-zero value, and Null Tile reads always return zero.

13:12 **Reserved**

Format:	MBZ

11:8 **Mip Tail Start LOD**

Format:	U4 in LOD Units

For Sampling Engine, Render Target, and Typed Surfaces:

This field indicates which LOD is the first one in the MIP tail if **Tiled Resource Mode** is not TRMODE_NONE. The MIP tail has a different layout than the rest of the surface. Refer to the

RENDER_SURFACE_STATE

Memory Data Formats section for more details.

For other surfaces:

This field is ignored.

Programming Notes
This field must be zero if the **Surface Format** is MONO8
This field is ignored if **Tiled Resource Mode** is TRMODE_NONE.
If **Tiled Resource Mode** is not TRMODE_NONE, this field must be set to ensure that mips within the mip tail do not overlap given the storage algorithms given in the Memory Data Formats section.
If **Tiled Resource Mode** is not TRMODE_NONE, to disable the Mip Tail this field must be set to a mip that larger than those present in the surface (i.e. 15). This is recommended for non-mip-mapped surfaces.
The following table indicates the *maximum* size of the mip that is set to be the Mip Tail Start LOD for various cases:

Surface Type	Tiling Mode	#MS	Bits Per Element				
			8	16	32	64	128
1D	64KB	1	16384	8192	4096	2048	1024
	4KB	1	1024	512	256	128	64
2D/ CUBE	TIleYS	1	128x256	128x128	64x128	64x64	32x64
		2	128x128	128x64	64x64	64x32	32x32
		4	64x128	64x64	32x64	32x32	16x32
		8	64x64	64x32	32x32	32x16	16x16
		16	32x64	32x32	16x32	16x16	8x16
	TileYF	any	32x64	32x32	16x32	16x16	8x16
3D	TIleYS	1	32x32x32	16x32x32	16x32x16	16x16x16	8x16x16
	TIleYF	1	16x8x16	8x8x16	8x8x8	8x4x8	4x4x8

7:4 **Surface Min LOD**

Format:	U4 In LOD Units

For Sampling Engine and Typed Surfaces:

This field indicates the most detailed LOD that can be accessed as part of this surface. This field is added to the delivered LOD (*sample_l, ld*, or *resinfo* message types) before it is used to address the surface.

For Other Surfaces:

This field is ignored.

Programming Notes
This field must be zero if the **Surface Format** is MONO8

RENDER_SURFACE_STATE

	3:0	**MIP Count / LOD** Format: **Sampling Engine and Typed Surfaces:** U4 in (LOD units - 1) **Render Target Surfaces:** U4 in LOD units Range **Sampling Engine and Typed Surfaces:** [0,14] representing [1,15] MIP levels **Render Target Surfaces:** [0,14] representing LOD **Other Surfaces:** [0] **For Sampling Engine and Typed Surfaces:** This field indicates the number of MIP levels allowed to be accessed starting at **Surface Min LOD**, which must be less than or equal to the number of MIP levels actually stored in memory for this surface. For sample* messages, the mip map access is clamped to be between the mipmap specified by the integer bits of the Min LOD and the ceiling of the value specified here. For ld* messages, out-of-bounds behavior results for LODs outside of the range specified in this field. **For Render Target Surfaces:** This field defines the MIP level that is currently being rendered into. This is the absolute MIP level on the surface and is not relative to the **Surface Min LOD** field, which is ignored for render target surfaces. **For Other Surfaces:** This field is reserved : MBZ **Programming Notes** The **LOD** of a render target must be the same as the **LOD** of the other render target(s) and of the depth buffer (defined in 3DSTATE_DEPTH_BUFFER). For render targets with YUV surface formats, the **LOD** must be zero. For sampling engine surfaces with YCRCB* or PLANAR* surface format, **MIP Count** must be zero.
6	31	**Reserved** Exists If: ([Surface Format] != 'PLANAR') Format: MBZ
	31	**Separate UV Plane Enable** Exists If: ([Surface Format] == 'PLANAR') Format: Enable If enabled, this field indicates that the U and V are present as separate planes. If disabled, the UV data is interleaved on a single plane. **Programming Notes** This field must be disabled (separate UV planes are not supported). See the section "Planar Memory Organization" for a description of how the size and location of the chroma planes (U and V) are calculated.

RENDER_SURFACE_STATE

30 Reserved

Exists If:	([Surface Format] == 'PLANAR')
Format:	MBZ

30:16 Auxiliary Surface QPitch

Exists If:	([Surface Format] != 'PLANAR')
Format:	QPitch[16:2]

This field specifies the distance in rows between array slices on the auxiliary surface.

Value	Name	Description
[4h,1FFFCh]		in multiples of 4 (low 2 bits missing)

Programming Notes
This field must be set to an integer multiple of the **Surface Vertical Alignment**
Software must ensure that this field is set to a value sufficiently large such that the array slices in the auxiliary surface do not overlap. Refer to the Memory Data Formats section for information on how surfaces are stored in memory.
For non-multisampled render target's CCS auxiliary surface, QPitch must be computed with Horizontal Alignment = 128 and Surface Vertical Alignment = 256. These alignments are only for CCS buffer and not for associated render target.

29:16 X Offset for U or UV Plane

Exists If:	([Surface Format] == 'PLANAR')
Format:	U14

This field specifies the horizontal offset in pixels from the **Surface Base Address** to the start (origin) of the U plane or interleaved UV plane, depending on the setting of **Separate UV Plane Enable**.

Programming Notes
This field must be a multiple of 4 (bits 1:0 MBZ).
If **Tiled Resource Mode** is enabled, this field must be a multiple of the tile width in pixels.
Auxiliary Surface Mode is forced to AUX_NONE.

15 Reserved

Format:	MBZ

14 Reserved

Exists If:	([Surface Format] == 'PLANAR')
Format:	MBZ

14:12 Reserved

Exists If:	([Surface Format] != 'PLANAR')
Format:	MBZ

RENDER_SURFACE_STATE

11:3 **Auxiliary Surface Pitch**

Exists If:	([Surface Format] != 'PLANAR')
Format:	U9-1 Pitch in #Tiles

This field specifies the Auxiliary surface pitch in (#Tiles - 1).

Value	Name	Description
[0, 511]		-> [1 tile, 512 tiles]

13:0 **Y Offset for U or UV Plane**

Exists If:	([Surface Format] == 'PLANAR')
Format:	U14

This field specifies the vertical offset in rows from the **Surface Base Address** to the start (origin) of the U plane or interleaved UV plane, depending on the setting of **Separate UV Plane Enable**.

Programming Notes
For surfaces where **Surface Format** = PLANAR* and **Separate UV Plane** is Enabled, the Y Offset must be programmed in multiples of **half-rows**. For example, for a surface where Y is physically followed by U and then V in memory, the Y Offset to U plane would be (2*Y-Height). For all other PLANAR YUV formats this is programmed in multiples of full rows.
For all format besides PLANAR_420_* This field must be a multiple of 4 (bits 1:0 MBZ). For formats PLANAR_420_* with separate chroma planes (e.g. YV12) this field must be multiple of 4 if U plane is the first chroma plane after the Y (luma) plane. It can be a multiple of 2 if it is the second chroma plane in memory. For formats PLANAR_420_* with interleaved chroma planes (e.g. NV12) this field can be multiple of 2.
If **Tiled Resource Mode** is enabled, this field must be a multiple of the tile height in rows.
Auxiliary Surface Mode is forced to AUX_NONE.

Workaround
Workaround : For formats PLANAR_420_* when this field is not a multiple of 4 the Out-of-Bounds Supression check must be disabled (HALF_SLICE_CHICKEN3[5] must be set to 1) to avoid false out of bound detection.

2:0 **Auxiliary Surface Mode**

Exists If:	([Surface Format] != 'PLANAR')
Format:	U3

Specifies what type of surface the Auxiliary surface is. The Auxiliary surface has its own base address and pitch, but otherwise shares or overrides other fields set for the primary surface, detailed in the programming notes below.

Value	Name	Description
0h	AUX_NONE	No Auxiliary surface is used
1h	AUX_CCS_D	The Auxiliary surface is a CCS (Color Control Surface) with compression disabled or an MCS with compression enabled, depending on **Number of Multisamples**. MCS (Multisample Control Surface) is a special type of CCS.

RENDER_SURFACE_STATE

2h	AUX_APPEND	The Auxiliary surface is an append buffer
3h	AUX_HIZ	The Auxiliary surface is a hierarchical depth buffer
4h	Reserved	
5h	AUX_CCS_E	The Auxiliary surface is a CCS with compression enabled or an MCS with compression enabled, depending on **Number of Multisamples**.
6h-7h	Reserved	

Programming Notes

The CCS and hierarchical depth Auxiliary surface shares **Height, Width, Depth, Surface Type, Surface Array, Surface Min LOD, MIP Count / LOD, Surface Object Control State, Resource Min LOD**, and **Minimum Array Element** with the primary surface. The hierarchical depth Auxiliary surface uses **Surface Horizontal Alignment** of 16, **Surface Vertical Alignment** of 8, regardless of the primary surface's values for these fields. **X & Y Offset** are set to zero for the purpose of accessing the Auxiliary surface. If this field is set to AUX_HIZ, **Surface Format** must be be one of the following: R32_FLOAT, R24_UNORM_X8_TYPELESS, or R16_UNORM, and the format must match the format used when the surface was used as a depth buffer (with R channel corresponding to D channel).

CCS and hierarchical depth Auxiliary surfaces are TileY with **Tiled Resource Mode** of TRMODE_NONE regardless of the tile mode of the primary surface, and **Mip Tail Start LOD** is ignored for these surfaces.

The CCS Auxiliary surface for non-multisampled render targets has Horizontal Alignment = 128 and Vertical alignment = 64.

The CCS Auxiliary surface for **Number of Multisamples** > 1 uses **Surface Horizontal Alignment** of 16 and **Surface Vertical Alignment** of 4 regardless of the primary surface's values for these fields.

If this field is set to AUX_HIZ, **Number of Multisamples** must be MULTISAMPLECOUNT_1, and Surface Type cannot be SURFTYPE_3D.

If **Number of Multisamples** is MULTISAMPLECOUNT_1, AUX_CCS_E setting is only allowed if **Surface Format** is supported for Render Target Compression. This setting enables render target compression.

If **Number of Multisamples** is MULTISAMPLECOUNT_1, AUX_CCS_D setting is only allowed if **Surface Format** supported for Fast Clear. In addition, if the surface is bound to the sampling engine, **Surface Format** must be supported for Render Target Compression for surfaces bound to the sampling engine. For render target surfaces, this setting disables render target compression. For sampling engine surfaces, this mode behaves the same as AUX_CCS_E.

If **Number of Multisamples** is *not* MULTISAMPLECOUNT_1, both AUX_CCS_E and AUX_CCS_D settings indicate that the auxiliary surface is a multisample control surface (MCS), and multisample compression is enabled.

If **Number of Multisamples** is MULTISAMPLECOUNT_1, and if **Tiled Resource Mode** is NOT TRMODE_NONE, then, if CCS tile is NULL, Render Target Tiles represented by that CCS tile are assumed to be NULL by HW.

RENDER_SURFACE_STATE

7 — 31 — Memory Compression Mode

Distinguishes Vertical from Horizontal compression.

Value	Name	Description
0	Horizontal **[Default]**	
1	Vertical	

30 — Memory Compression Enable

Format:	Enable

This surface may contain compressed or compressible pixels. Memory compression will be attempted for writes to this surface. Reads from this surface will check for compressed data.

Programming Notes
The compression control must have 0 value for non-tileY modes. The Memory Compression Enable can be non-zero only for the surface state that has media messages. That is for 3d case the compression control bits will be 0 in normal surface state but can be non-zero in normal surface state for media messages. E.g. sample_unorm.
The only sampler messages supported with memory compression enabled are *sample_8x8*, *sample_unorm*, and SIMD16 *sample*.
Please refer to vol1a Memory Data Formats chapter >section Media Memory Compression for more details, including format restrictions.

29 — Reserved

Format:	MBZ

28 — Reserved

27:25 — Shader Channel Select Red

Format:	**Shader Channel Select** Enumerated Type

Specifies which surface channel is read or written in the Red shader channel.

Programming Notes
The Shader channel selects also define which shader channels are written to which surface channel. If the Shader channel select is SCS_ZERO or SCS_ONE then it is not written to the surface. If the shader channel select is SCS_RED it is written to the surface red channel and so on. If more than one shader channel select is set to the same surface channel only the first shader channel in RGBA order will be written. Each shader channel select must be set to the same surface channel (R = SCS_RED, G = SCS_GREEN, B = SCS_BLUE, A = SCS_ALPHA) if the surface is accessed via the sampler's sample_unorm* or sample_8x8 messages.
The Shader Channel Select fields do not affect the following sampling engine message types: resinfo, sampleinfo, LOD, and ld_mcs. These messages behave as if each Shader Channel Select is set to the same color surface channel.
For the sampling engine *gather4** messages, the Gather4 Source Channel Select field in the message header defines which channel's Shader Channel Select is used to select the surface channel to be sampled. Other Shader Channel Select fields are ignored.
For the sampling engine *sample*_c* and *gather4*_c* messages, the compare operation always occurs on the red channel from the surface regardless of the setting of the Shader Channel

RENDER_SURFACE_STATE

		Select fields. For Render Target, Red, Green and Blue Shader Channel Selects MUST be such that only valid components can be swapped i.e. only change the order of components in the pixel. Any other values for these Shader Channel Select fields are not valid for Render Targets. This also means that there MUST not be multiple shader channels mapped to the same RT channel. When multiple Channel selects have the same value and shader channel is disabled, disable channel writes 0s to memory. This behavior does not match with Data Port message via HDC. The output channel is undefined if the source is to a channel is not present for the current surface format. For example, If the surface format is R16_float and the shader channel select green specifies green as the source the output is undefined. It should instead select 0 which is the default for a missing color channel..
	24:22	**Shader Channel Select Green** Format: **Shader Channel Select** Enumerated Type See **Shader Channel Select Red** for details.
	21:19	**Shader Channel Select Blue** Format: **Shader Channel Select** Enumerated Type See **Shader Channel Select Red** for details.
	18:16	**Shader Channel Select Alpha** Format: **Shader Channel Select** Enumerated Type See **Shader Channel Select Red** for details. **Programming Notes** For Render Target, this field MUST be programmed to value = SCS_ALPHA.
	15:12	**Reserved** Format: MBZ
	11:0	**Resource Min LOD** Format: U4.8 in LOD units **For Sampling Engine Surfaces:** This field indicates the most detailed LOD that is present in the resource underlying the surface. Refer to the "LOD Computation Pseudocode" section for the use of this field. **For Other Surfaces:** This field is ignored. **Value** / **Name**: [0,14] **Programming Notes** This field must be zero if the **Surface Format** is MONO8 This field must be zero if the **ChromaKey Enable** is enabled in the associated sampler.

RENDER_SURFACE_STATE

8..9	63:0	**Surface Base Address** Format: GraphicsAddress[63:0]SurfaceBase Specifies the byte-aligned base address of the surface. **Programming Notes** • For SURFTYPE_BUFFER render targets, this field specifies the base address of first element of the surface. The surface is interpreted as a simple array of that single element type. The address must be naturally-aligned to the element size (e.g., a buffer containing R32G32B32A32_FLOAT elements must be 16-byte aligned). • For SURFTYPE_BUFFER non-rendertarget surfaces, this field specifies the base address of the first element of the surface, computed in software by adding the surface base address to the byte offset of the element in the buffer. The base address must be aligned to element size. • Linear depth buffer surface base addresses must be 64-byte aligned. Note that while render targets (color) can be SURFTYPE_BUFFER, depth buffers cannot. • Mipmapped surfaces are stored in a "monolithic" (fixed) format, and only require a single address for the base MIP. All other MIPs are positioned relative to the base MIP. • The Base Address for linear (non-tiled) render target surfaces and surfaces accessed with the typed surface read/write data port messages must be element-size aligned for Non-YUV surface formats, or a multiple of 2 element-sizes for YUV surface formats. • Other linear (non-tiled) surfaces have no alignment requirements (byte alignment is sufficient). • For tiled surfaces, the actual start of the surface can be offset from the Surface Base Address by the X Offset and Y Offset fields. Tiles are inherently page-aligned (4K or 64K). • Certain message types used to access surfaces have more stringent alignment requirements. Please refer to the specific data-port message documentation for additional restrictions. Tiled surface base addresses must be 4KB-aligned. Note that only the offsets from Surface Base Address are tiled, Surface Base Address itself is not transformed using the tiling algorithm. Tiled surface base addresses must be tile aligned (64KB aligned for TileYS, 4KB aligned for all other tile modes). For 1D surfaces, the base address must be 64KB aligned if Tiled Resource Mode is TRMODE_64KB, and 4KB aligned if Tiled Resource Mode is TRMODE_4KB. Compressed (BC*, ASTC, etc.) surface data is usually copied by re-describing each MIP/slice as a separate surface, using a size-equivalent RGBA format. But a MIP/slice within a packed **MIP**

RENDER_SURFACE_STATE

		Tail doesn't have the tile-aligned **Surface Base Address** required for the re-description. This case must be specially handled by re-describing the packed **MIP Tail** as a single-MIP surface with the width/pitch/height/depth of a single tile, and then use drawing geometry to "reach out" to the desired tail slot (*x*, *y*, *z*) offset.
10..11	63:62	**Reserved** Exists If: ([Surface Format] == 'PLANAR') Format: MBZ
	61:48	**X Offset for V Plane** Exists If: ([Surface Format] == 'PLANAR') Format: U14 This field specifies the horizontal offset in pixels from the **Surface Base Address** to the start (origin) of the V plane. **Programming Notes** This field must be a multiple of 4 (bits 1:0 MBZ). If **Tiled Resource Mode** is enabled, this field must be a multiple of the tile width in pixels. This field is ignored if **Separate UV Plane Enable** is disabled.
	47:46	**Reserved** Exists If: ([Surface Format] == 'PLANAR') Format: MBZ
	45:32	**Y Offset for V Plane** Exists If: ([Surface Format] == 'PLANAR') Format: U14 This field specifies the vertical offset in rows from the **Surface Base Address** to the start (origin) of the V plane. **Programming Notes** For surfaces where **Surface Format** = PLANAR* and **Separate UV Plane** is Enabled, the Y Offset must be programmed in multiples of **half-rows**. For example, for a surface where Y is physically followed by U and then V in memory, the Y Offset to V plane would be (2*Y-Height+ U-Height). For all other PLANAR YUV formats this is programmed in multiples of full rows (e.g Y-Height + U-Height). For all format besides PLANAR_420_* This field must be a multiple of 4 (bits 1:0 MBZ). For formats PLANAR_420_* this field must be multiple of 4 if U plane is the first chroma plane after the Y (luma) plane. It can be a multiple of 2 if it is the second chroma plane. For formats PLANAR_420_* when this field is not a multiple of 4 the Out-of-Bounds Supression check must be disabled (HALF_SLICE_CHICKEN3[5] must be set to 1) to avoid false out of bound detection. If **Tiled Resource Mode** is enabled, this field must be a multiple of the tile height in rows. This field is ignored if **Separate UV Plane Enable** is disabled.

RENDER_SURFACE_STATE

	31:21	**Auxiliary Table Index for Media Compressed Surface** Exists If: [Memory Compression Enable] ==1 This field is valid only if Media Memory Compression is on for the surface(Memory Compression Enable == 1). In that case, the Auxiliary Surface Base address is never expected to be used and hence can be overloaded. This represents the 11 bit index into the table in memory which maps the surface to the auxiliary base address.
	63:12	**Auxiliary Surface Base Address** Exists If: ([Surface Format] != 'PLANAR') AND [Memory Compression Enable] == 0 Format: GraphicsAddress[63:12] Specifies the 4kbyte-aligned base address of the Auxiliary surface associated with the primary surface specified in other SURFACE_STATE fields.
	11	**Reserved** Format: MBZ
	10	**Reserved** Format: MBZ
	9:5	**Quilt Height** Format: U5 This field specifies the height of a quilted texture in units of quilt slices. Refer to the section on Quilted Textures for more details.

Value	Name	Description
[0,31]		representing height of quilt - 1 (y/v dimension)

Programming Notes

Programming Notes

- Only power-of-2 **Quilt Height** and **Quilt Width** values are allowed: (1,2,4,8,16,32) mapping to (0,1,3,7,15,31) values in the fields.
- A surface is defined as a quilted texture if either **Quilt Height** or **Quilt Width** is nonzero (actual field value, not the incremented value).
- A quilted texture
  - is only supported by the sampling engine (other shared functions will ignore the **Quilt Width** and **Quilt Height** field, behaving as if they are set to zero).
  - must have a **Surface Type** of SURFTYPE_2D.
  - must have **Number of Multisamples** set to NUMSAMPLES_1.
  - must have **Vertical Line Stride** set to 0.
  - must have **Auxiliary Surface Mode** set to AUX_NONE.
  - **Depth** indicates the array dimension of the quilted texture if **Surface Array** is enabled. The valid range of **Depth** is [0, 2048 / (QuiltWidth * QuiltHeight) - 1], i.e.

RENDER_SURFACE_STATE

the total number of underlying array slices including quilt slices cannot exceed 2048.

- cannot be accessed with any ld* message type or using a sampler with the **Non-Normalized Coordinate Enable** field enabled.

4:0 Quilt Width

Format:	U5

This field specifies the width of a quilted texture in units of quilt slices. Refer to the section on Quilted Textures for more details.

Value	Name	Description
[0,31]		representing width of quilt - 1 (x/u dimension)

12 31:0 Reserved

Exists If:	([Auxiliary Surface Mode] != 'AUX_CCS_D') AND ([Auxiliary Surface Mode] != 'AUX_CCS_E') AND ([Auxiliary Surface Mode] != 'AUX_HIZ)
Format:	MBZ

31:0 Red Clear Color

Exists If:	[Auxiliary Surface Mode] == 'AUX_CCS_D' OR [Auxiliary Surface Mode] == 'AUX_CCS_E'
Format:	S31 (2's complement) for all SINT surface formats
Format:	U32 for all UINT surface formats
Format:	IEEE_FP for all other surface formats

For Sampling Engine Surfaces and Render Targets with Auxiliary Surface Mode set to AUX_CCS:

Specifies the clear value for the red channel.

For Other Surfaces:

This field is ignored.

Programming Notes
If Number of Multisamples is not MULTISAMPLECOUNT_1, only 0/1 values allowed
If Number of Multisamples is MULTISAMPLECOUNT_1 AND if this RT is fast cleared with non-0/1 clear value, this RT must be partially resolved (refer to Partial Resolve operation) before binding this surface to Sampler.

31:0 Hierarchical Depth Clear Value

Exists If:	[Auxiliary Surface Mode] == 'AUX_HIZ'
Format:	IEEE_Float

If **Auxiliary Surface Mode** is AUX_HIZ, this field specifies the depth clear value associated with this surface. If disabled, this field is ignored.

RENDER_SURFACE_STATE

13	31:0	**Green Clear Color** Exists If: [Auxiliary Surface Mode] == 'AUX_CCS_D' OR [Auxiliary Surface Mode] == 'AUX_CCS_E' Format: S31 (2's complement) for all SINT surface formats Format: U32 for all UINT surface formats Format: IEEE_FP for all other surface formats **For Sampling Engine Surfaces and Render Targets with Auxiliary Surface Mode set to AUX_CCS:** Specifies the clear value for the green channel. **For Other Surfaces:** This field is ignored. **Programming Notes** If programmed to non 0/1 values, SW must ensure a render target partial resolve pass before binding a cleared RT to texture.
	31:0	**Reserved** Exists If: [Auxiliary Surface Mode] == 'AUX_HIZ' Format: MBZ
14	31:0	**Blue Clear Color** Exists If: [Auxiliary Surface Mode] == 'AUX_CCS_D' OR [Auxiliary Surface Mode] == 'AUX_CCS_E' Format: S31 (2's complement) for all SINT surface formats Format: U32 for all UINT surface formats Format: IEEE_FP for all other surface formats **For Sampling Engine Surfaces and Render Targets with Auxiliary Surface Mode set to AUX_CCS:** Specifies the clear value for the blue channel. **For Other Surfaces:** This field is ignored. **Programming Notes** If programmed to non 0/1 values, SW must ensure a render target partial resolve pass before binding a cleared RT to texture.
	31:0	**Reserved** Exists If: [Auxiliary Surface Mode] == 'AUX_HIZ' Format: MBZ

RENDER_SURFACE_STATE

15	31:0	**Alpha Clear Color** Exists If: [Auxiliary Surface Mode] == 'AUX_CCS_D' OR [Auxiliary Surface Mode] == 'AUX_CCS_E' Format: S31 (2's complement) for all SINT surface formats Format: U32 for all UINT surface formats Format: IEEE_FP for all other surface formats **For Sampling Engine Surfaces and Render Targets with Auxiliary Surface Mode set to AUX_CCS:** Specifies the clear value for the alpha channel. **For Other Surfaces:** This field is ignored. **Programming Notes** If programmed to non 0/1 values, SW must ensure a render target partial resolve pass before binding a cleared RT to texture.
	31:0	**Reserved** Exists If: [Auxiliary Surface Mode] == 'AUX_HIZ' Format: MBZ

Render Data Port Message Types

MT_DP_RT - Render Data Port Message Types

Source:	Render Cache DataPort
Size (in bits):	5
Default Value:	0x0000000C

Lists all the Message Types in a Render Data Port Message Descriptor [18:14].

DWord	Bit	Description
0	4	**Reserved** Format: MBZ Ignored
	3:0	**Message Type** Format: Enumeration Specifies type of message

Render Target Message Header Control

MHC_RT_C0 - Render Target Message Header Control

Source: BSpec
Size (in bits): 32
Default Value: 0x00000000

DWord	Bit	Description
0	31	**Reserved** Format: Ignore Ignored
	30:27	**Viewport Index** Format: U4 For Render Target Write message, specifies the index of the viewport currently being used. Range = [0,15] Ignored by Render Target Read message.
	26:16	**Render Target Array Index** Format: U11 Specifies the array index to be used for the following surface types: SURFTYPE_1D: specifies the array index. Range = [0,511] SURFTYPE_2D: specifies the array index. Range = [0,511] SURFTYPE_3D: specifies the Z or R coordinate. Range = [0,2047] SURFTYPE_BUFFER: must be zero. SURFTYPE_CUBE: specifies the face identifier. Mapping (0,+x) (1,-x) (2,+y) (3,-y) (4,+z) (5,-z). **Programming Notes** The Render Target Array Index used by hardware for access to the Render Target is overridden with the Minimum Array Element defined in SURFACE_STATE if it is out of the range between Minimum Array Element and Depth. For cube surfaces, a depth value of 5 is used for this determination.
	15	**Front/Back Facing Polygon** Format: U1 Determines whether the polygon is front or back facing. Used by the render cache to determine which stencil test state to use. Value / Name / Description 0h / Front facing / All 1h / Back facing / All
	14	**Stencil Present to Render Target** Format: Enable For Render Target Write message, indicates that computed stencil is included in the message. Must be zero for Render Target Read message.

MHC_RT_C0 - Render Target Message Header Control

	13	**Source Depth Present to Render Target** Format: Enable For Render Target Write Message, indicates that source depth data is included in the message. Must be zero for Render Target Read message.
	12	**oMask to Render Target** Format: Enable For Render Target Write message, indicates that oMask data is present in the message and is to be used to mask off samples. Must be zero for Render Target Read message.
	11	**Source0 Alpha Present to Render Target** Format: Enable For Render Target Write message, indicates that Source0 Alpha (aka o0.a) data is included in RTWrite message. If present, these alpha values are used as inputs to AlphaTest and AlphaToCoverage functions. This is required to meet the API rules when writing to multiple render targets (MRTs). Must be zero for Render Target Read message. **Programming Notes** This bit should not be set when write to RT0, though sending and using redundant alpha will provide the correct results (at lower performance). This bit is not supported on Dual-Source Blend message types, as source0 alpha is already included in those messages. This bit is not supported on replicated data message types.
	10	**Reserved** Format: Ignore Ignored
	9:6	**Starting Sample Pair Index or Sample Index** Format: U4 When pixel shader is dispatched in per-sample mode or per-pixel mode with Per-Sample PS Enable bit cleared, this field indicates the index of the first sample pair of the dispatch. Range = [0,7]. When pixel shader is dispatched in per-pixel mode with Per-Sample PS Enable bit set, this field indicates the index of a sample referenced by per-sample RT read or RT write messages. Range = [0, 15].
	5:0	**Reserved** Format: Ignore Ignored

SAMPLER_BORDER_COLOR_STATE

SAMPLER_BORDER_COLOR_STATE

Source:	BSpec
Size (in bits):	128
Default Value:	0x00000000, 0x00000000, 0x00000000, 0x00000000

Description

The interpretation of the border color depends on the Texture Border Color Mode field in SAMPLER_STATE as follows:

- DX9 mode: The border color is 8-bit UNORM format, regardless of the surface format chosen. For surface formats with one or more channels missing (i.e. R5G6R5_UNORM is missing the alpha channel), the value from the border color, if selected, will be used even for the missing channels.
- DX10/OGL mode: the format of the border color depends on the format of the surface being sampled. If the map format is UINT, then the border color format is R32G32B32A32_UINT. If the map format is SINT, then the border color format is R32G32B32A32_SINT. Otherwise, the border color format is R32G32B32A32_FLOAT. For surface formats with one or more channels missing, the value from the border color is not used for the missing channels, resulting in these channels resulting in the overall default value (0 for colors and 1 for alpha) regardless of whether border color is chosen. The surface formats with "L" and "I" have special behavior with respect to the border color. The border color value used for the replicated channels (RGB for "L" formats and RGBA for "I" formats) comes from the red channel of border color. In these cases, the green and blue channels, and also alpha for "I", of the border color are ignored.The format of this state depends on the Texture Border Color Mode field.

Programming Notes

- DX9 mode is not supported for surfaces with more than 16 bits in any channel, other than 32-bit float formats which are supported.
- The conditions under which this color is used depend on the **Surface Type** - 1D/2D/3D surfaces use the border color when the coordinates extend beyond the surface extent; cube surfaces use the border color for "empty" (disabled) faces.
- The border color itself is accessed through the texture cache hierarchy rather than the state cache hierarchy. Thus, if the border color is changed in memory, the texture cache must be invalidated and the state cache does not need to be invalidated.
- MAPFILTER_MONO: The border color is ignored. Border color is fixed at a value of 0 by hardware.

SAMPLER_INDIRECT_STATE_BORDER_COLOR

SAMPLER_INDIRECT_STATE_BORDER_COLOR

Source:	BSpec
Size (in bits):	128
Default Value:	0x00000000, 0x00000000, 0x00000000, 0x00000000

This structure is a one version of the SAMPLER_INDIRECT_STATE structure, suitable for many needs.
An instance of this structure is pointed to by the **Indirect State Pointer** field in SAMPLER_STATE.
The interpretation of the border color depends on the **Texture Border Color Mode** field in SAMPLER_STATE as follows:

- In **DX9** mode, the border color is 8-bit UNORM format, regardless of the surface format chosen. For surface formats with one or more channels missing (i.e. R5G6R5_UNORM is missing the alpha channel), the value from the border color, if selected, will be used *even for the missing channels*.
- In **DX10/OGL** mode, the format of the border color is R32G32B32A32_FLOAT, R32G32B32A32_SINT, or R32G32B32A32_UINT, depending on the surface format chosen. For surface formats with one or more channels missing, the value from the border color is not used for the missing channels, resulting in these channels resulting in the overall default value (0 for colors and 1 for alpha) regardless of whether border color is chosen. The surface formats with "L" and "I" have special behavior with respect to the border color. The border color value used for the replicated channels (RGB for "L" formats and RGBA for "I" formats) comes from the *red* channel of border color. In these cases, the green and blue channels, and also alpha for "I", of the border color are ignored.

Programming Notes

- DX9 mode is not supported for surfaces with more than 16 bits in any channel, other than 32-bit float formats which are supported.
- The conditions under which this color is used depend on the **Surface Type** - 1D/2D/3D surfaces use the border color when the coordinates extend beyond the surface extent; cube surfaces use the border color for "empty" (disabled) faces.
- The border color itself is accessed through the texture cache hierarchy rather than the state cache hierarchy. Thus, if the border color is changed in memory, the texture cache must be invalidated and the state cache does not need to be invalidated.
- MAPFILTER_MONO: The border color is ignored. Border color is fixed at a value of 0 by hardware.

Default Value:	0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000

Note: There are three variations of this structure, defined separately because their payloads have different lengths. Currently only SAMPLER_INDIRECT_STATE_BORDER_COLOR is fully defined.
This structure is pointed to by **Indirect State Pointer** (SAMPLER_STATE).
The interpretation of the border color depends on the **Texture Border Color Mode** field in SAMPLER_STATE as follows:

- In **DX9** mode, the border color is 8-bit UNORM format, regardless of the surface format chosen. For surface formats with one or more channels missing (i.e. R5G6R5_UNORM is missing the alpha channel), the value from the border color, if selected, will be used *even for the missing channels*.
- In **DX10/OGL** mode, the format of the border color is R32G32B32A32_FLOAT, R32G32B32A32_SINT, or R32G32B32A32_UINT, depending on the surface format chosen. For surface formats with one or more channels missing, the value from the border color is not used for the missing channels, resulting in these channels resulting in the overall default value (0 for colors and 1 for alpha) regardless of whether border color is chosen. The surface formats with "L" and "I" have special behavior with respect to the border color. The border color value used for the replicated channels (RGB for "L" formats and RGBA for "I" formats) comes from the *red* channel of border color. In these cases, the green and blue channels, and also alpha for "I", of the border color are ignored.

The format of this state depends on the **Texture Border Color Mode** field.

Programming Notes

- DX9 mode is not supported for surfaces with more than 16 bits in any channel, other than 32-bit float formats which are supported.
- The conditions under which this color is used depend on the **Surface Type** - 1D/2D/3D surfaces use the border color when the coordinates extend beyond the surface extent; cube surfaces use the border color for "empty" (disabled) faces.
- The border color itself is accessed through the texture cache hierarchy rather than the state cache hierarchy. Thus, if the border color is changed in memory, the texture cache must be invalidated and the state cache does not need to be invalidated.
- MAPFILTER_MONO: The border color is ignored. Border color is fixed at a value of 0 by hardware.

SAMPLER_STATE_8x8_AVS

3 / 31 — Skin Tone Tuned IEF _ Enable

Default Value:	1
Format:	U1

Control bit to enable the skin tone tuned IEF.

3 / 30 — IEF4Smooth_Enable

Format:	U1

Value	Name	Description
0	**[Default]**	IEF is operating as a content adaptive detail filter based on 5x5 region
1		IEF is operating as a content adaptive smooth filter based on 3x3 region

3 / 29:28 — Enable 8-tap filter

Adaptive Filtering (Mode = 11) ExistsIf:
R10G10B10A2_UNORM R8G8B8A8_UNORM (AYUV also) R8B8G8A8_UNORM B8G8R8A8_UNORM R16G16B16A16

Enable 8-tap Filtering on UV channel (Mode = 10) ExistsIf:
R10G10B10A2_UNORM
R8G8B8A8_UNORM (AYUV also)
R8B8_UNORM (CrCb)
R8_UNORM
R8B8G8A8_UNORM
B8G8R8A8_UNORM
R16G16B16A16
Y8_UNORM

Value	Name	Description
00b		4-tap filter is only done on all channels.
01b		Enable 8-tap Adaptive filter on G-channel. 4-tap filter on other channels.
10b		8-tap filter is done on all channels (UV-ch uses the Y-coefficients)
11b		Enable 8-tap Adaptive filter all channels (UV-ch uses the Y-coefficients).

Programming Notes

For 00 and 10, are applicable for RGB surfaces only or surface without Y-ch.
In case it is a YUV surface it will default to adaptive mode automatically which is 01 and 11 respectively. Alpha channel is always bi-linear filter irrespective of the above modes.

Mode 01 and 00 are legacy support and are supported on all surface formats.

When Mode is 10 and Surface format is Y8_UNORM, Bypass X/Y Adaptive Filtering must be 1, and Default Sharp Level must be 255

Size (in bits):	128
Default Value:	0x00000000, 0x00000000, 0x00000000, 0x00000000

This is the normal sampler state used by all messages that use SAMPLER_STATE except sample_8x8 and deinterlace. The sampler state is stored as an array of up to 16 elements, each of which contains the dwords described here. The start of each element is spaced 4 dwords apart. The first element of the sampler state array is aligned to a 32-byte boundary.

DWord	Bit	Description
0	31	**Sampler Disable** Format: Disable This field allows the sampler to be disabled. If disabled, all output channels will return 0.
	30	**Reserved**
	29	**Texture Border Color Mode** For some surface formats, the 32 bit border color is decoded differently based on the border color mode. In addition, the default value of channels not included in the surface may be affected by this field. Refer to the "Sampler Output Channel Mapping" table for the values of these channels, and for surface formats that may only support one of these modes. Also refer to the definition of SAMPLER_BORDER_COLOR_STATE for more details on the behavior of the two modes defined by this field.

Value	Name	Description
0h	DX10/OGL	DX10/OGL mode for interpreting the border color
1h	DX9	DX9 and earlier mode for interpreting the border color

Programming Notes
This feild must not be set to DX9 if there are null tiles in use
This field is required to be the same for every message over a period of time. A flush of the sampler cache must occur before a message with the opposite state of this field is delivered.
This field must be set to DX9 mode when used with surfaces that have Surface Format P4A4_UNORM or A4P4_UNORM.
This field must be set to DX10/OGL mode when used with surfaces that have Surface Format YCRCB_SWAPUV or YCRCB_SWAPY.
This field must be set to DX10/OGL mode if **Surface Format** for the associated surface is UINT OR SINT.
This field must be set to DX10/OGL mode if REDUCTION_MINIMUM or REDUCTION_MAXIMUM or message type is sample_min or sample_max.

SAMPLER_STATE

28:27 **LOD PreClamp Mode**

This field determines whether the computed LOD is clamped to [max,min] mip level before the mag-vs-min determination is performed.
PRECLAMP_OGL: LOD pre-clamped to **Min LOD** and **Max LOD**
OpenGL API currently clamps LOD to the **Min LOD** and **Max LOD** (from Sampler State) prior to performing min/mag determination, and therefore it is expected that an OpenGL driver would need to set this field to PRECLAMP_OGL.

Value	Name	Description
0h	NONE	LOD PreClamp disabled
1h	Reserved	
2h	OGL	LOD PreClamp enabled (OGL mode)

26:22 **Coarse LOD Quality Mode**

Format:	U5

This field configures the coarse LOD image quality mode for the sample_d, sample_l, and sample_b messages in the sampling engine. In general, performance will increase and power consumption will decrease with each step of reduced quality (performance gain for sample_l and sample_b will be minimal).

Value	Name	Description
0h	Disabled	Full quality is enabled, matching prior products
01h-1Fh		Quality degrades with each larger value, performance improves with each larger value

Programming Notes
Although allowed, it is not recommended to program this field to a value greater than 17h to avoid masking the exponent which may generate incorrect LOD values.

21:20 **Mip Mode Filter**

Format:	U2 Enumerated Type

This field determines if and how mip map levels are chosen and/or combined when texture filtering.

Value	Name	Description
0h	NONE	Disable mip mapping - force use of the mipmap level corresponding to Min LOD.
1h	NEAREST	Nearest, Select the nearest mip map
2h	Reserved	
3h	LINEAR	Linearly interpolate between nearest mip maps (combined with linear min/mag filters this is analogous to "Trilinear" filtering).

Programming Notes

SAMPLER_STATE

		MIPFILTER_LINEAR is not supported for surface formats that do not support "Sampling Engine Filtering" as indicated in the Surface Formats table unless using the sample_c message type or minimum/maximum operation.
		Mip Mode Filter must be set to MIPFILTER_NONE or MIPFILTER_NEAREST if Surface Format for the associated surface is UINT or SINT. However, all settings of this field are allowed with UINT/SINT if a minimum or maximum operation is being performed.
		Mip Mode Filter must be set to MIPFILTER_NONE for Planar YUV surfaces.
	19:17	**Mag Mode Filter** Format: U3 Enumerated Type This field determines how texels are sampled/filtered when a texture is being "magnified" (enlarged). For volume maps, this filter mode selection also applies to the 3rd (inter-layer) dimension.

Value	Name	Description
0h	NEAREST	Sample the nearest texel
1h	LINEAR	Bilinearly filter the 4 nearest texels
2h	ANISOTROPIC	Perform an "anisotropic" filter on the chosen mip level
4h-5h	Reserved	
6h	MONO	Perform a monochrome convolution filter
7h	Reserved	

Programming Notes
Only MAPFILTER_NEAREST and MAPFILTER_LINEAR are supported for surfaces of type SURFTYPE_3D.
Only MAPFILTER_NEAREST is supported for surface formats that do not support "Sampling Engine Filtering" as indicated in the Surface Formats table unless using the sample_c message type or minimum/maximum operation.
MAPFILTER_MONO: Only CLAMP_BORDER texture addressing mode is supported. . Both Mag Mode Filter and Min Mode Filter must be programmed to MAPFILTER_MONO. Mip Mode Filter must be MIPFILTER_NONE. Only valid on surfaces with Surface Format MONO8 and with Surface Type SURFTYPE_2D.
MAPFILTER_ANISOTROPIC may cause artifacts at cube edges if enabled for cube maps with the TEXCOORDMODE_CUBE addressing mode.
MAPFILTER_ANISOTROPIC will be overridden to MAPFILTER_LINEAR when using a sample_l or sample_l_c message type or when Force LOD to Zero is set in the message header.
Both Mag Mode Filter and Min Mode Filter must be set to MAPFILTER_NEAREST if Surface Format for the associated surface is UINT or SINT. However, all settings of this field other than MAPFILTER_MONO are allowed with UINT/SINT if a minimum or maximum operation is being performed.

SAMPLER_STATE

16:14 Min Mode Filter

Format:	U3 Enumerated Type

This field determines how texels are sampled/filtered when a texture is being "minified" (shrunk). For volume maps, this filter mode selection also applies to the 3rd (inter-layer) dimension.See Mag Mode Filter

Value	Name	Description
0h	NEAREST	Sample the nearest texel
1h	LINEAR	Bilinearly filter the 4 nearest texels
2h	ANISOTROPIC	Perform an "anisotropic" filter on the chosen mip level
4h-5h	Reserved	
6h	MONO	Perform a monochrome convolution filter
7h	Reserved	

13:1 Texture LOD Bias

Format:	S4.8 2's complement

Range: [-16.0, 16.0)

This field specifies the signed bias value added to the calculated texture map LOD prior to min-vs-mag determination and mip-level clamping. Assuming mipmapping is enabled, a positive LOD bias will result in a somewhat blurrier image (using less-detailed mip levels) and possibly higher performance, while a negative bias will result in a somewhat crisper image (using more-detailed mip levels) and may lower performance.

Programming Notes

There is no requirement or need to offset the LOD Bias in order to produce a correct LOD for texture filtering (as was required for correct bilinear and anisotropic filtering in some legacy devices).

0 LOD algorithm

Format:	U1 Enumerated Type

Controls which algorithm is used for LOD calculation. Generally, the EWA approximation algorithm results in higher image quality than the legacy algorithm.

Value	Name	Description
0h	LEGACY	Use the legacy algorithm for anisotropic filtering
1h	EWA Approximation	Use the new EWA approximation algorithm for anisotropic filtering

1 31:20 Min LOD

Format:	U4.8 in LOD units

Range: [0.0, 14.0], where the upper limit is also bounded by the Max LOD.

This field specifies the minimum value used to clamp the computed LOD after LOD bias is applied. Note that the minification-vs.-magnification status is determined after LOD bias and

SAMPLER_STATE

before this maximum (resolution) mip clamping is applied.The integer bits of this field are used to control the "maximum" (highest resolution) mipmap level that may be accessed (where LOD 0 is the highest resolution map). The fractional bits of this value effectively clamp the inter-level trilinear blend factor when trilinear filtering is in use.

Programming Notes

If Min LOD is greater than Max LOD, Min LOD takes precedence, i.e. the resulting LOD will always be Min LOD.

This field must be zero if the Min or Mag Mode Filter is set to MAPFILTER_MONO

19:8 **Max LOD**

Format:	U4.8 in LOD units

Range: [0.0, 14.0]

This field specifies the maximum value used to clamp the computed LOD after LOD bias is applied. Note that the minification-vs.-magnification status is determined after LOD bias and before this minimum (resolution) mip clamping is applied.The integer bits of this field are used to control the "minimum" (lowest resolution) mipmap level that may be accessed.The fractional bits of this value effectively clamp the inter-level trilinear blend factor when trilinear filtering is in use.Force the mip map access to be between the mipmap specified by the integer bits of the Min LOD and the ceiling of the value specified here.

7 **ChromaKey Enable**

Format:	Enable This field enables the chroma key function.

Programming Notes

Supported only on a specific subset of surface formats. See section titled: "Surface Formats" in thsi volume for supported formats.
This field must be disabled if min or mag filter is MAPFILTER_MONO or MAPFILTER_ANISOTROPIC.
This field must be disabled if used with a surface of type SURFTYPE_3D.

6:5 **ChromaKey Index**

Format:	U2

Range: [0, 3]

This field specifies the index of the ChromaKey Table entry associated with this Sampler. This field is a "don't care" unless **ChromaKey Enable** is ENABLED.

4 **ChromaKey Mode**

Format:	U1 Enumerated Type

This field specifies the behavior of the device in the event of a ChromaKey match. This field is ignored if ChromaKey is disabled.

SAMPLER_STATE

KEYFILTER_REPLACE_BLACK:
In this mode, each texel that matches the chroma key is replaced with (0,0,0,0) (black with alpha=0) prior to filtering. For YCrCb surface formats, the black value is A=0, R(Cr)=0x80, G(Y)=0x10, B(Cb)=0x80. This will tend to darken/fade edges of keyed regions. Note that the pixel pipeline must be programmed to use the resulting filtered texel value to gain the intended effect, e.g., handle the case of a totally keyed-out region (filtered texel alpha==0) through use of alpha test, etc.

Value	Name	Description
0h	KEYFILTER_KILL_ON_ANY_MATCH	In this mode, if any contributing texel matches the chroma key, the corresponding pixel mask bit for that pixel is cleared. The result of this operation is observable only if the Killed Pixel Mask Return flag is set on the input message.
1h	KEYFILTER_REPLACE_BLACK	In this mode, each texel that matches the chroma key is replaced with (0,0,0,0) (black with alpha=0) prior to filtering. For YCrCb surface formats, the black value is A=0, R(Cr)=0x80, G(Y)=0x10, B(Cb)=0x80. This will tend to darken/fade edges of keyed regions. Note that the pixel pipeline must be programmed to use the resulting filtered texel value to gain the intended effect, e.g., handle the case of a totally keyed-out region (filtered texel alpha==0) through use of alpha test, etc.

3:1 **Shadow Function**

Format:	U3 Enumerated Type

This field is used for shadow mapping support via the sample_c message type, and specifies the specific comparison operation to be used. The comparison is between the texture sample red channel (except for alpha-only formats which use the alpha channel), and the "ref" value provided in the input message.

Value	Name
0h	PREFILTEROP ALWAYS
1h	PREFILTEROP NEVER
2h	PREFILTEROP LESS
3h	PREFILTEROP EQUAL
4h	PREFILTEROP LEQUAL
5h	PREFILTEROP GREATER
6h	PREFILTEROP NOTEQUAL
7h	PREFILTEROP GEQUAL

SAMPLER_STATE

	0	**Cube Surface Control Mode** Format: U1 Enumerated Type When sampling from a SURFTYPE_CUBE surface, this field controls whether the TC* Address Control Mode fields are interpreted as programmed or overridden to TEXCOORDMODE_CUBE. **Value** / **Name** 0h PROGRAMMED 1h OVERRIDE **Programming Notes** This field must be set to CUBECTRLMODE_PROGRAMMED
2	31:30	**Reserved**
	29:28	**Reserved**
	27:26	**Reserved**
	31:24	**Reserved**
	25:24	**Reserved**
	23:6	**Indirect State Pointer** **Description** This pointer is relative to the Dynamic State Base Address.
	5	**Reserved** Format: MBZ
	4	**Reserved**
	3	**Reserved**
	2	**Reserved**
	1	**Reserved**
	0	**LOD Clamp Magnification Mode** Format: U1 Enumerated Type This field allows the flexibility to control how LOD clamping is handled when in magnification mode. **Value** / **Name** / **Description** 0h MIPNONE When in magnification mode, Sampler will clamp LOD as if the **Mip Mode Filter** is MIPFILTER_NONE. This is how OpenGL defines magnification, and therefore it is expected that those drivers would not set this bit. 1h MIPFILTER When in magnification mode, Sampler will clamp LOD based on the value of **Mip Mode Filter**.
3	31:24	**Reserved**
	25:24	**Reserved** Format: MBZ

SAMPLER_STATE

23:22 **Reduction Type**

Format:	U2 Enumerated Type

This field defines the type of reduction that will be performed on the texels in the footprint defined by the **Min/Mag/Mip Filter Mode** fields. This field is ignored if **Reduction Type Enable** is disabled.

Value	Name	Description
0h	STD_FILTER	standard filter
1h	COMPARISON	comparison followed by standard filter
2h	MINIMUM	minimum of footprint
3h	MAXIMUM	maximum of footprint

Programming Notes
The following message types ignore this field: *sample_min, sample_max, sample_unorm*, resinfo, sampleinfo, LOD, ld*, sample_8x8*.
If the current min/mag filter mode is MAPFILTER_MONO, this field is ignored.
The *sample_c, sample_l_c, sample_d_c, sample_b_c, gather4_c*, and *gather4_po_c* message types, when used with STD_FILTER, MINIMUM, or MAXIMUM settings of this field, perform the operation of the message of the same name without the "_c". The ref parameter is ignored by hardware.
For message types not listed above, when used with COMPARISON setting of this field, perfom the operation of the message of the same name with "_c" included. The ref parameter used by the operation (since it is not delivered in the message) is set to zero.
Restrictions applying to the message whose behavior is being performed must be followed. For example, a sample message used with COMPARISON reduction filter must follow all of the restrictions of *sample_c*. An exception to this is the MINIMUM and MAXIMUM reduction types allow SURFTYPE_1D, 2D, 3D, and CUBE, including with **Surface Array** enabled, even though the sample_min/max messages only allow 2D.
Restrictions applying to the message delivered need not be followed. For example, a *sample_c* message used with STD_FILTER reduction filter needs to follow only the restrictions of sample, not the restrictions of *sample_c*.

21:19 **Maximum Anisotropy**

Format:	U3 Enumerated Type

This field clamps the maximum value of the anisotropy ratio used by the MAPFILTER_ANISOTROPIC filter (Min or Mag Mode Filter).

Value	Name	Description
0h	RATIO 2:1	At most a 2:1 aspect ratio filter is used
1h	RATIO 4:1	At most a 4:1 aspect ratio filter is used
2h	RATIO 6:1	At most a 6:1 aspect ratio filter is used
3h	RATIO 8:1	At most a 8:1 aspect ratio filter is used

SAMPLER_STATE

4h	RATIO 10:1	At most a 10:1 aspect ratio filter is used
5h	RATIO 12:1	At most a 12:1 aspect ratio filter is used
6h	RATIO 14:1	At most a 14:1 aspect ratio filter is used
7h	RATIO 16:1	At most a 16:1 aspect ratio filter is used

18 **U Address Mag Filter Rounding Enable**

Format:	Enable

Controls whether the texture address is rounded or truncated before being used to select texels to sample. Provides independent control of rounding on one texture address dimension (U/V/R) in either mag or min filter mode.

Programming Notes

Hardware will **not** force rounding enable.

17 **U Address Min Filter Rounding Enable**

Format:	Enable

Controls whether the texture address is rounded or truncated before being used to select texels to sample. Provides independent control of rounding on one texture address dimension (U/V/R) in either mag or min filter mode.

Programming Notes

Hardware will **not** force rounding enable.

16 **V Address Mag Filter Rounding Enable**

Format:	Enable

Controls whether the texture address is rounded or truncated before being used to select texels to sample. Provides independent control of rounding on one texture address dimension (U/V/R) in either mag or min filter mode.

Programming Notes

Hardware will **not** force rounding enable.

15 **V Address Min Filter Rounding Enable**

Format:	Enable

Controls whether the texture address is rounded or truncated before being used to select texels to sample. Provides independent control of rounding on one texture address dimension (U/V/R) in either mag or min filter mode.

Programming Notes

Hardware will **not** force rounding enable.

14 **R Address Mag Filter Rounding Enable**

Format:	Enable

Controls whether the texture address is rounded or truncated before being used to select texels to sample. Provides independent control of rounding on one texture address dimension (U/V/R) in either mag or min filter mode.

Programming Notes

SAMPLER_STATE

	Hardware will **not** force rounding enable.
13	**R Address Min Filter Rounding Enable** Format: Enable Controls whether the texture address is rounded or truncated before being used to select texels to sample. Provides independent control of rounding on one texture address dimension (U/V/R) in either mag or min filter mode. **Programming Notes** Hardware will **not** force rounding enable.
12:11	**Trilinear Filter Quality** Format: U2 Enumerated Type Selects the quality level for the trilinear filter.

Value	Name	Description
0	FULL	Full Quality. Both mip maps are sampled under all circumstances.
1	TRIQUAL_HIGH/MAG_CLAMP_MIPFILTER	High Quality. Same as full quality. When in magnification mode, Sampler will clamp LOD based on the value of **Mip Mode Filter**. If LOD values which are within 12.5% of an integer LOD value are rounded to that value prior to filtering and filtering effectively becomes the same as MIP Nearest.
2	MED	Medium Quality. If the contribution of one mip map is less than 25%, only the other mip map contributes. If LOD values which are within 16.67% of an integer LOD value are rounded to that value prior to filtering and filtering effectively becomes the same as MIP Nearest.
3	LOW	Low Quality. If the contribution of one mip map is less than 37.5%, only the other mip map contributes.p

10	**Non-normalized Coordinate Enable** Format: Enable This field, if enabled, specifies that the input coordinates (U/V/R) are in non-normalized space, where each integer increment is one texel on LOD 0. If disabled, coordinates are normalized, where the range 0 to 1 spans the entire surface. **Programming Notes** The following state must be set as indicated if this field is *enabled*: • TCX/Y/Z Address Control Mode must be TEXCOORDMODE_CLAMP, TEXCOORDMODE_HALF_BORDER, or TEXCOORDMODE_CLAMP_BORDER.

SAMPLER_STATE

- Surface Type must be SURFTYPE_2D or SURFTYPE_3D.
- Mag Mode Filter must be MAPFILTER_NEAREST or MAPFILTER_LINEAR.
- Min Mode Filter must be MAPFILTER_NEAREST or MAPFILTER_LINEAR.
- Mip Mode Filter must be MIPFILTER_NONE.
- Min LOD must be 0.
- Max LOD must be 0.
- MIP Count must be 0.
- Surface Min LOD must be 0.
- Texture LOD Bias must be 0.

9 **Reduction Type Enable**

Format:	Enable

This field enables the **Reduction Type** field to modify the behavior of messages based on its setting. If this field is disabled, all messages behave as defined and the **Reduction Type** field is ignored.

8:6 **TCX Address Control Mode**

Format:	**Texture Coordinate Mode** Enumerated Type

Controls how the 1st (TCX, aka U) component of input texture coordinates are mapped to texture map addresses - specifically, how coordinates "outside" the texture are handled (wrap/clamp/mirror). The setting of this field is subject to being overridden by the Cube Surface Control Mode field when sampling from a SURFTYPE_CUBE surface.

Programming Notes
When using cube map texture coordinates, each TC component must have the same Address Control Mode.
When TEXCOORDMODE_CUBE is not used accessing a cube map, the map's Cube Face Enable field must be programmed to 111111b (all faces enabled).
MAPFILTER_MONO: Texture addressing modes must all be set to TEXCOORDMODE_CLAMP_BORDER. The **Border Color** is ignored in this mode, a constant value of 0 is used for border color. Software must pad the border texels within the map itself with 0.
If **Surface Format** is PLANAR*, this field must be set to TEXCOORDMODE_CLAMP.

5:3 **TCY Address Control Mode**

Format:	**Texture Coordinate Mode** Enumerated Type

Controls how the 2nd (TCY, aka V) component of input texture coordinates are mapped to texture map addresses - specifically, how coordinates "outside" the texture are handled (wrap/clamp/mirror). See Address TCX Control Mode above for details

Programming Notes
If this field is set to TEXCOORDMODE_CLAMP_BORDER or TEXCOORDMODE_HALF_BORDER and a 1D surface is sampled, incorrect blending with the border color in the vertical direction may occur.

SAMPLER_STATE		
	2:0	**TCZ Address Control Mode** Format: **Texture Coordinate Mode** Enumerated Type Controls how the 3rd (TCZ) component of input texture coordinates are mapped to texture map addresses - specifically, how coordinates "outside" the texture are handled (wrap/clamp/mirror).See Address TCX Control Mode above for details

SCISSOR_RECT

SCISSOR_RECT

Source: RenderCS

Size (in bits): 64

Default Value: 0x00000000, 0x00000000

The viewport-specific state used by the SF unit (SCISSOR_RECT) is stored as an array of up to 16 elements, each of which contains the DWords described below. The start of each element is spaced 2 DWords apart. The location of first element of the array, as specified by Pointer to SCISSOR_RECT, is aligned to a 32-byte boundary.

DWord	Bit	Description
0	31:16	**Scissor Rectangle Y Min** Format: U16 Pixels from Drawing Rectangle origin (upper left corner) Specifies Y Min coordinate of (inclusive) Scissor Rectangle used for scissor test. Pixels with (Draw Rectangle-relative) Y coordinates less than Y Min will be clipped out if Scissor Rectangle is enabled. NOTE: If Y Min is set to a value greater than Y Max, all primitives will be discarded for this viewport. Value: [0,16383] — Name:
	15:0	**Scissor Rectangle X Min** Format: U16 Pixels from Drawing Rectangle origin (upper left corner) Specifies X Min coordinate of (inclusive) Scissor Rectangle used for scissor test. Pixels with (Draw Rectangle-relative) X coordinates less than X Min will be clipped out if Scissor Rectangle is enabled. NOTE: If X Min is set to a value greater than X Max, all primitives will be discarded for this viewport. Value: [0,16383] — Name:
1	31:16	**Scissor Rectangle Y Max** Format: U16 Pixels from Drawing Rectangle origin (upper left corner) Specifies Y Max coordinate of (inclusive) Scissor Rectangle used for scissor test. Pixels with (Draw Rectangle-relative) Y coordinates greater than Y Max will be clipped out if Scissor Rectangle is enabled. Value: [0,16383] — Name:
	15:0	**Scissor Rectangle X Max** Format: U16 Pixels from Drawing Rectangle origin (upper left corner) Specifies X Max coordinate of (inclusive) Scissor Rectangle used for scissor test. Pixels with (Draw Rectangle-relative) Y coordinates greater than X Max will be clipped out if Scissor Rectangle is enabled. Value: 0-16383 — Name:

Scratch Hword Block Message Header

MH_A32_HWB - Scratch Hword Block Message Header

Source: DataPort 0

Size (in bits): 256

Default Value: 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000

DWord	Bit	Description
0..2	95:0	**Reserved** Format: Ignore Ignored
3	31:0	**Per Thread Scratch Space** Format: MHC_PTSS Specifies amount of scratch space used by this thread, for Stateless bounds checking.
4	31:0	**Reserved** Format: Ignore Ignored
5	31:0	**Buffer Base Address** Format: MHC_A32_BBA Specifies the surface address offset page [31:10] for A32 stateless messages.
6..7	63:0	**Reserved** Format: Ignore Ignored

7	31:0	**Reserved** Format: MBZ
8	31:0	**X Min Clip Guardband** Format: IEEE_Float . This 32-bit float represents the XMin guardband boundary (normalized to Viewport.XMin == -1.0f). This corresponds to the left boundary of the NDC guardband.
9	31:0	**X Max Clip Guardband** Format: IEEE_Float This 32-bit float represents the XMax guardband boundary (normalized to Viewport..XMax == 1.0f). This corresponds to the right boundary of the NDC guardband.

SF_CLIP_VIEWPORT

10	31:0	**Y Min Clip Guardband** Format: IEEE_Float This 32-bit float represents the YMin guardband boundary (normalized to Viewport.YMin == -1.0f). This corresponds to the bottom boundary of the NDC guardband.
11	31:0	**Y Max Clip Guardband** Format: IEEE_Float This 32-bit float represents the YMax guardband boundary (normalized to Viewport.YMax == 1.0f). This corresponds to the top boundary of the NDC guardband.
12	31:0	**X Min ViewPort** Format: IEEE_Float This 32-bit float represents the Viewport.XMin. This is the X min of the viewport extents as programmed by API, and this value should be programmed in Screen Space coordinate and not as normalized coordinate.
13	31:0	**X Max ViewPort** Format: IEEE_Float This 32-bit float represents the Viewport.XMax. This is the X max of the viewport extents as programmed by API, and this value should be programmed in Screen Space coordinate and not as normalized coordinate.
14	31:0	**Y Min ViewPort** Format: IEEE_Float This 32-bit float represents the Viewport.YMin. This is the Y min of the viewport extents as programmed by API, and this value should be programmed in Screen Space coordinate and not as normalized coordinate.
15	31:0	**Y Max ViewPort** Format: IEEE_Float This 32-bit float represents the Viewport.Ymax. This is the Y max of the viewport extents as programmed by API, and this value should be programmed in Screen Space coordinate and not as normalized coordinate.

SF_OUTPUT_ATTRIBUTE_DETAIL

SF_OUTPUT_ATTRIBUTE_DETAIL		
Source:	RenderCS	
Size (in bits):	16	
Default Value:	0x00000000	
DWord	**Bit**	**Description**
0	15	**Component Override W** Format: Enable If set, the W component of this output Attribute is overridden by the W component of the constant vector specified by ConstantSource.
	14	**Component Override Z** Format: Enable If set, the Z component of this output Attribute is overridden by the Z component of the constant vector specified by ConstantSource.
	13	**Component Override Y** Format: Enable If set, the Y component of output Attribute is overridden by the Y component of the constant vector specified by ConstantSource.
	12	**Component Override X** Format: Enable If set, the X component of output Attribute is overridden by the X component of the constant vector specified by ConstantSource.
	11	**Swizzle Control Mode** Format: U1 Enumerated Type When Attribute Swizzle Enable is ENABLED, this bit controls whether attributes 0-15 or 16-31 are subject to the following swizzle controls: • Component Override X/Y/Z/W • Constant Source • Swizzle Select • Source Attribute • WrapShortest Enables Note that the Number of SF Output Attributes field specifies how many attributes are output. Note: This field does not impact any functions which provide separate states for all 32 attributes (e.g., Point sprite, Constant interpolation). Note: This field is only valid for the first indexed attribute (Attribute[0]). For all other indices, it is Reserved and MBZ.

SF_OUTPUT_ATTRIBUTE_DETAIL

10:9 Constant Source

Format:	U2 enumerated type

This state selects a constant vector which can be used to override individual components of this Attribute

Value	Name	Description
0h	CONST_0000	Constant.xyzw = 0.0,0.0,0.0,0.0
1h	CONST_0001_FLOAT	Constant.xyzw = 0.0,0.0,0.0,1.0
2h	CONST_1111_FLOAT	Constant.xyzw = 1.0,1.0,1.0,1.0
3h	PRIM_ID	Constant.xyzw = PrimID (replicated)

8 Reserved

Format:	MBZ

7:6 Swizzle Select

Format:	U2 enumerated type

This state, along with Source Attribute, specifies the source for this output Attribute.

Value	Name	Description
0h	INPUTATTR	This attribute is sourced from AttrInputReg[SourceAttribute]
1h	INPUTATTR_FACING	If the object is front-facing, this attribute is sourced from AttrInputReg[SourceAttribute]. If the object is back-facing, this attribute is sourced from AttrInputReg[SourceAttribute+1].
2h	INPUTATTR_W	This attribute is sourced from AttrInputReg[SourceAttribute]. The W component is copied to the X component.
3h	INPUTATTR_FACING_W	If the object is front-facing, this attribute is sourced from AttrInputReg[SourceAttribute]. If the object is back-facing, this attribute is sourced from AttrInputReg[SourceAttribute+1]. The W component is copied to the X component.

5 Reserved

Format:	MBZ

4:0 Source Attribute

Format:	U5

This field selects the source attribute for this Attribute. Source attribute 0 corresponds to the first 128 bits of data indicated by Vertex URB Entry Read Offset

Default Value: 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000

DWord	Bit	Description
0.0-0.1	63:0	**Offset0** Format: U64 Specifies the address offset for slot 0 in this payload register.
0.2-0.3	63:0	**Offset1** Format: U64 Specifies the address offset for slot 1 in this payload register.
0.4-0.5	63:0	**Offset2** Format: U64 Specifies the address offset for slot 2 in this payload register.
0.6-0.7	63:0	**Offset3** Format: U64 Specifies the address offset for slot 3 in this payload register.

SIMD8 32-Bit Address Payload

MAP32B_SIMD8 - SIMD8 32-Bit Address Payload		
Source:	BSpec	
Size (in bits):	256	
Default Value:	0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000	
DWord	**Bit**	**Description**
0.0-0.7	255:0	**Offset[7:0]** Format: **MACR_32b** Specifies the address offset for Slots [7:0].

SIMD8 64-Bit Address Payload

MAP64B_SIMD8 - SIMD8 64-Bit Address Payload

Source:	BSpec
Size (in bits):	512
Default Value:	0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000

DWord	Bit	Description
0.0-0.7	255:0	**Offset[3:0]** Format: **MACR_64b** Specifies the address offset for slots [3:0].
1.0-1.7	255:0	**Offset[7:4]** Format: **MACR_64b** Specifies the address offset for slots [7:4].

SIMD16 32-Bit Address Payload

MAP32B_SIMD16 - SIMD16 32-Bit Address Payload		
Source:	BSpec	
Size (in bits):	512	
Default Value:	0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000	
DWord	**Bit**	**Description**
0.0-0.7	255:0	**Offset[7:0]** Format: **MACR_32b** Specifies the address offset for slots [7:0].
1.0-1.7	255:0	**Offset[15:8]** Format: **MACR_32b** Specifies the address offset for slots [15:8].

SIMD16 64-Bit Address Payload

MAP64B_SIMD16 - SIMD16 64-Bit Address Payload

Source:	BSpec
Size (in bits):	1024
Default Value:	0x00000000, 0x00000000

DWord	Bit	Description
0.0-0.7	255:0	**Offset[3:0]** Format: **MACR_64b** Specifies the address offsets for slots [3:0].
1.0-1.7	255:0	**Offset[7:4]** Format: **MACR_64b** Specifies the address offsets for slots [7:4].
2.0-2.7	255:0	**Offset[11:8]** Format: **MACR_64b** Specifies the address offsets for slots [11:8].
3.0-3.7	255:0	**Offset[15:12]** Format: **MACR_64b** Specifies the address offsets for slots [15:12].

SIMD Mode 2 Message Descriptor Control Field

MDC_SM2 - SIMD Mode 2 Message Descriptor Control Field

Source: BSpec
Size (in bits): 1
Default Value: 0x00000000

DWord	Bit	Description
0	0	**SIMD Mode** Format: Enumeration Specifies the SIMD mode of the message (number of slots processed)

Value	Name	Description
00h	SIMD8	SIMD8
01h	SIMD16	SIMD16

SIMD Mode 3 Message Descriptor Control Field

MDC_SM3 - SIMD Mode 3 Message Descriptor Control Field

Source: BSpec
Size (in bits): 2
Default Value: 0x00000000

DWord	Bit	Description
0	1:0	**SIMD Mode** Format: Enumeration Specifies the SIMD mode of the message (number of slots processed)

Value	Name	Description
00h	SIMD4x2	SIMD4x2
01h	SIMD16	SIMD16
02h	SIMD8	SIMD8
03h	Reserved	Ignored

SLM Surface Pixel Mask Message Header

MH1_SLM_PSM - SLM Surface Pixel Mask Message Header

Source: DataPort 1

Size (in bits): 256

Default Value: 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x0000FFFF

DWord	Bit	Description
0..6	223:0	**Reserved** Format: Ignore Ignored
7	31:0	**Pixel Sample Mask** Format: MHC_PSM Specifies the 16-bit Pixel/Sample Mask used with SIMD16 and SIMD8 surfaces.

Slot Group 2 Message Descriptor Control Field

MDC_SG2 - Slot Group 2 Message Descriptor Control Field

Source: BSpec
Size (in bits): 1
Default Value: 0x00000000

DWord	Bit	Description
0	0	**SIMD Mode** Format: Enumeration Controls which 8 bits of Pixel/Sample Mask in the message header are ANDed with the execution mask to determine which slots are accessed. This field is ignored if the header is not present. Value / Name / Description 00h / SG8L / Use low 8 slots 01h / SG8U / Use high 8 slots

Slot Group 3 Message Descriptor Control Field

MDC_SG3 - Slot Group 3 Message Descriptor Control Field

Source: BSpec
Size (in bits): 2
Default Value: 0x00000000

DWord	Bit	Description
0	1:0	**SIMD Mode** Format: Enumeration Controls which 8 bits of Pixel/Sample Mask in the message header are ANDed with the execution mask to determine which slots are accessed. This field is ignored if the header is not present.

Value	Name	Description
00h	SG4x2	SIMD4x2
01h	SG8L	Use low 8 slots
02h	SG8U	Use high 8 slots
03h	Reserved	Ignored

Slot Group Select Render Cache Message Descriptor Control Field

MDC_RT_SGS - Slot Group Select Render Cache Message Descriptor Control Field

Source: BSpec
Size (in bits): 1
Default Value: 0x00000000

DWord	Bit	Description
0	0	**Slot Group Select** This field selects whether slots 15:0 or slots 31:16 are used for bypassed data. Bypassed data includes the antialias alpha, multisample coverage mask, and if the header is not present also includes the X/Y addresses and pixel enables. For 8- and 16-pixel dispatches, SLOTGRP_LO must be selected on every message. For 32-pixel dispatches, this field must be set correctly for each message based on which slots are currently being processed.

Value	Name	Description
00h	SLOTGRP_LO	Choose bypassed data for slots 15:0
01h	SLOTGRP_HI	Choose bypassed data for slots 31:16

SO_DECL

SO_DECL

Source: RenderCS

Size (in bits): 16

Default Value: 0x00000000

A list of SO_DECL structures are passed in the 3DSTATE_SO_DECL_LIST command. Each structure specifies either (a) the source and destination of an up-to-4-DWord appending write into an SO buffer, or (b) how many DWords to skip over in the destination SO buffer (i.e., a "hole" where the previous buffer contents are maintained).

DWord	Bit	Description
0	15:14	**Reserved** Format: MBZ
	13:12	**Output Buffer Slot** Format: U2 Buffer Index This field selects the destination output buffer slot.
	11	**Hole Flag** Format: Flag If set, the Component Mask field indirectly specifies a number of 32-bit locations to skip over (leave unmodified in memory) in the selected output buffer. The Register Index field is ignored. The only permitted Component Mask values are as follows: 0x0 No Dwords are skipped over (SO_DECL performs no operation) 0x1 (X) Skip 1 DWord 0x3 (XY) Skip 2 DWords 0x7 (XYZ) Skip 3 DWords 0xF (XYZW) Skip 4 DWords
	10	**Reserved** Format: MBZ
	9:4	**Register Index** Format: U6 128-bit granular offset into the source vertex read data If Hole Flag is clear, this field specifies the 128-bit offset into the source vertex data which supplies the source data to be written to the destination buffer, where the individual 32-component destination locations are selected by Component Mask. e.g., Register Index 0 corresponds with the first 128 bits of the data read from the vertex URB entry (as per corresponding Vertex Read Offset state) There is only enough internal storage for the 128-bit vertex header and 32 128-bit vertex attributes.

SO_DECL

Value	Name
[0,32]	
0h	**[Default]**

Programming Notes
It is the responsibility of software to map any API-visible source data specifications (e.g., vertex register number) into 128-bit granular URB read offsets.

3:0 **Component Mask**

Format:	MASK 4-bit Mask

This field is a 4-bit bitmask that selects which contiguous 32-bit component(s) are either written or skipped-over in the destination buffer.

If this field is zero the SO_DECL operation is effectively a no-op. No data will be appended to the destination and the destination buffer's write pointer will not be advanced.

If the **Hole Flag** is set, this field (if non-zero) indirectly specifies how much the destination buffer's write pointer should be advanced.See **Hole Flag** description above for restrictions on this field.

If the **Hole Flag** is clear, this field (if non-zero) selects which source components are to be written to the destination buffer. The components must be contiguous, e.g. YZW is legal, but XZW is not. The selected source components are written to the destination buffer starting at the current write pointer, and then the write pointer is advanced past the written data. E.g., if YZW is specified, the three (YZW) components of the source register will be written to the destination buffer at the current write pointer, and the write pointer will be advanced by 3 DWords.

Value	Name
0h	**[Default]**
xxx1b	SO_DECL_COMPMASK_X
xx1xb	SO_DECL_COMPMASK_Y
x1xxb	SO_DECL_COMPMASK_Z
1xxxb	SO_DECL_COMPMASK_W

SO_DECL_ENTRY

SO_DECL_ENTRY		
Source:	RenderCS	
Size (in bits):	64

DWord	**Bit**	**Description**
0..1	63:48	**Stream 3 Decl** Format: SO_DECL This field contains Stream 3 SO_DECL [n]
	47:32	**Stream 2 Decl** Format: SO_DECL This field contains Stream 2 SO_DECL [n]
	31:16	**Stream 1 Decl** Format: SO_DECL This field contains Stream 1 SO_DECL [n]
	15:0	**Stream 0 Decl** Format: SO_DECL This field contains Stream 0 SO_DECL [n]

Split_coding_unit_flags

Split_coding_unit_flags		
Source:	VideoCS	
Size (in bits):	21	
Default Value:	0x00000000	
Contains the split level flags, level 0 through 2.		
DWord	**Bit**	**Description**
0	20	**Split_flag_level0** Format: U1
	19:16	**Split_flag_level1** Format: U4 [19:16] is in raster order. Bit16 is for partition0 in raster order.
	15:12	**Split_flag_level2 level1part3** Format: U4 Split flags for bit19 partition. [15:12] is in raster order. Bit12 is for partition0 in raster order.
	11:8	**Split_flag_level2 level1part2** Format: U4 Split flags for bit18 partition. [11:8] is in raster order. Bit8 is for partition0 in raster order.
	7:4	**Split_flag_level2 level1part1** Format: U4 Split flags for bit17 partition. [7:4] is in raster order. Bit4 is for partition0 in raster order.
	3:0	**Split_flag_level2 level1part0** Format: U4 Split flags for bit16 partition. [3:0] is in raster order. Bit0 is for partition0 in raster order.

SplitBaseAddress4KByteAligned

SplitBaseAddress4KByteAligned		
Source:	BSpec	
Size (in bits):	64	
Default Value:	0x00000000, 0x00000000	
Specifies a 64-bit (48-bit canonical) 4K-byte aligned memory base address.		
DWord	**Bit**	**Description**
0	31:12	**Base Address Low** Format: GraphicsAddress[31:12]
	11:0	**Reserved** Format: MBZ
1 GraphicsAddress is a 64-bit value [63:0], but only a portion of it is used by hardware. The upper reserved bits are ignored and MBZ. Some GraphicsAddress fields only specify the upper address bits. For example, GraphicsAddress[47:12] is a 4KB page address.	31:16	**Reserved** Format: MBZ
	15:0	**Base Address High** Format: GraphicsAddress[47:32]

SplitBaseAddress64ByteAligned

SplitBaseAddress64ByteAligned		
Source:	BSpec	
Size (in bits):	64	
Default Value:	0x00000000, 0x00000000	
Specifies a 64-bit (48-bit canonical) 64-byte aligned memory base address.		
DWord	**Bit**	**Description**
0..1	63:6	**Base Address** Format: GraphicsAddress63-6
	5:0	**Base Address High** Format: MBZ

SrcRegNum

SrcRegNum

Source: Eulsa

Size (in bits): 8

Default Value: 0x00000000

Description

Register Number
The register number for the operand. For a GRF register, is the part of a register address that aligns to a 256-bit (32-byte) boundary. For an ARF register, this field is encoded such that MSBs identify the architecture register type and LSBs provide the register number.
An ARF register can only be dst or src0. Any src1 or src2 operands cannot be ARF registers.
RegNum and SubRegNum together provide the byte-aligned address for the origin of a register region. RegNum provides bits 12:5 of that address. For one-source and two-source instructions, SubregNum provides bits 4:0. For three-source instructions, the address must be DWord-aligned; SubRegNum provides bits 4:2 of the address and bits 1:0 are zero.
This field is present for the direct addressing mode and not present for indirect addressing.
This field applies to both source and destination operands.

DWord	Bit	Description
0	7:0	**Source Register Number**

Value	Name	Description
0-127	If {Dst/Src0/Src1/Src2}.RegFile==GRF	
0-0ffh	If {Dst/Src0/Src1/Src2}.RegFile==ARF	This field is used to encode the architecture register as well as providing the register number. See GEN Execution Environment chapter for details.

SrcSubRegNum

SrcSubRegNum

Source:	Eulsa
Size (in bits):	5
Default Value:	0x00000000

Description

Subregister Number
The subregister number for the operand. For a GRF register, is the byte address within a 256-bit (32-byte) register. For an ARF register, determines the sub-register number according to the specified encoding for the given architecture register.
RegNum and SubRegNum together provide the byte-aligned address for the origin of a GRF register region. RegNum provides bits 12:5 of that address. For one-source and two-source instructions, SubregNum provides bits 4:0. For three-source instructions, the address must be DWord-aligned; SubRegNum provides bits 4:2 of the address and bits 1:0 are zero.

Programming Notes

Note: The recommended instruction syntax uses subregister numbers within the GRF in units of actual data element size, corresponding to the data type used. For example for the F (Float) type, the assembler syntax uses subregister numbers 0 to 7, corresponding to subregister byte addresses of 0 to 28 in steps of 4, the element size.

DWord	Bit	Description
0	4:0	**Source Sub Register Number**

Value	Name	Description
0-31	If {Dst/Src0/Src1/Src2}.RegFile==GRF	
0-0ffh	If {Dst/Src0/Src1/Src2}.RegFile==ARF	This field is used to encode the architecture register as well as providing the register number. See GEN Execution Environment chapter for details.

SRD Interrupt Bit Definition

SRD Interrupt Bit Definition		
Source:	BSpec	
Size (in bits):	32	
Default Value:	0x00000000	
The SRD Interrupt Registers all share the same bit definitions from this table.		
DWord	**Bit**	**Description**
0	31:30	**Reserved**
	29:27	**Reserved**
	26	**Reserved**
	25	**SRD_Exit_C** This event occurs on the first blank start after SRD exit on transcoder C.
	24	**SRD_PreWarn_C** This event occurs two display frames prior to entering SRD on transcoder C.
	23	**Push Done C** This event occurs after double buffer update or Push done. After this interrupt, Logic is ready to receive another push frame indication.
	23	**Reserved**
	22:20	**Reserved**
	19	**Push Done B** This event occurs after double buffer update or Push done. After this interrupt, Logic is ready to receive another push frame indication.

	18	**Reserved**
	17	**SRD_Exit_B** This event occurs on the first blank start after SRD exit on transcoder B.
	16	**SRD_PreWarn_B** This event occurs two display frames prior to entering SRD on transcoder B.
	15:12	**Reserved**
	11	**Push Done A** This event occurs after double buffer update or Push done. After this interrupt, Logic is ready to receive another push frame indication.
	11	**Reserved**
	10	**Reserved**
	9	**SRD_Exit_A** This event occurs on the first blank start after SRD exit on transcoder A.
	8	**SRD_PreWarn_A** This event occurs two display frames prior to entering SRD on transcoder A.

SRD Interrupt Bit Definition		
	7:4	**Reserved**
	3	**Push Done EDP** This event occurs after double buffer update or Push done. After this interrupt, Logic is ready to receive another push frame indication.
	3	**Reserved**
	2	**SRD_Aux_Error_EDP** This event occurs on the rising edge of the SRD Aux error (receive error or timeout) indication.
	1	**SRD_Exit_EDP** This event occurs on the first blank start after SRD exit on transcoder EDP.
	0	**SRD_PreWarn_EDP** This event occurs two display frames prior to entering SRD on transcoder EDP.

Stateless Binding Table Index Message Descriptor Control Field

MDC_STATELESS - Stateless Binding Table Index Message Descriptor Control Field

Source: BSpec
Size (in bits): 8
Default Value: 0x000000FF

DWord	Bit	Description
0	7:0	**Binding Table Index** Format: Enumeration Specifies the message is Stateless

Value	Name	Description
0FFh	A32_A64 **[Default]**	Specifies a A32 or A64 Stateless access that is locally coherent (coherent within a thread group)
0FDh	A32_A64_NC	Specifies a A32 or A64 Stateless access that is non-coherent (coherent within a thread).
Others	Reserved	Ignored

Restriction
Restriction : When using A32_A64_NC, SW must ensure that 2 threads do not both access the same cache line (64B)

Stateless Block Message Header

MH_A32_GO - Stateless Block Message Header

Source: DataPort 0

Size (in bits): 256

Default Value: 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000

DWord	Bit	Description
0..1	63:0	**Reserved** Format: MBZ Ignored
2	31:0	**Global Offset** Format: U32 Specifies the global element index into the buffer, in units of Owords, Dwords, or Bytes (depending on the message). **Programming Notes** If the address offset calculated with the Buffer Base Address and Global Offset is greater than the PTSS size or the GeneralStateBufferSize, then the access is Out-of-Bounds.
3	31:0	**Per Thread Scratch Space** Format: MHC_PTSS Specifies amount of scratch space used by this thread, for Stateless bounds checking.
4	31:0	**Reserved** Format: MBZ Ignored
5	31:0	**Buffer Base Address** Format: MHC_A32_BBA **Description** Specifies the surface address offset page [31:10] for A32 stateless messages. Restriction : When using stateless A32 Data Port messages, General State Base Address[47:12] + Buffer Base Address[31:10] must be less than 2^48. It is illegal for this to be greater or equal than 2^48.
6..7	63:0	**Reserved** Format: MBZ Ignored

Stateless Scaled Data Port 2 Message Header

MH2_A32 - Stateless Scaled Data Port 2 Message Header

Source: DataPort 2

Size (in bits): 256

Default Value: 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000

DWord	Bit	Description
0	31:0	**Surface Pitch** Format: MHC_PITCH Specifies the 16-bit surface pitch to use with scaled A32 stateless messages.
1..4	127:0	**Reserved** Format: Ignore Ignored
5	31:2	**Buffer Base Address** Format: GeneralStateOffset[31:2] Specifies the surface address offset page [31:0] for scaled A32 stateless messages. The address must be Dword aligned (bits [1:0] = 0).
	1:0	**Reserved** Format: MBZ Ignored
6..7	63:0	**Reserved** Format: Ignore Ignored

Stateless Scaled Data Port 2 Pixel Mask Message Header

MH2_A32_PSM - Stateless Scaled Data Port 2 Pixel Mask Message Header

Source:	DataPort 2
Size (in bits):	256
Default Value:	0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x0000FFFF

DWord	Bit	Description
0	31:0	**Surface Pitch** Format: MHC_PITCH Specifies the 16-bit surface pitch to use with scaled A32 stateless messages.
1..4	127:0	**Reserved** Format: Ignore Ignored
5	31:0	**Buffer Base Address** Format: GeneralStateOffset[31:0] Specifies the surface address offset page [31:0] for scaled A32 stateless messages. The address must be Dword aligned (bits [1:0] = 0).
6	31:0	**Reserved** Format: Ignore Ignored
7	31:0	**Pixel Sample Mask** Format: MHC_PSM Specifies the 16-bit Pixel/Sample Mask used with SIMD16 and SIMD8 untyped surfaces.

Stateless Surface Message Header

MH1_A32 - Stateless Surface Message Header		
Source:	DataPort 1	
Size (in bits):	256	
Default Value:	0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000	
DWord	**Bit**	**Description**
0..4	159:0	**Reserved** Format: Ignore Ignored
5	31:0	**Buffer Base Address** Format: MHC_A32_BBA Specifies the surface address offset page [31:10] for A32 stateless messages.
6..7	63:0	**Reserved** Format: Ignore Ignored

Stateless Surface Pixel Mask Message Header

MH1_A32_PSM - Stateless Surface Pixel Mask Message Header

Source: DataPort 1

Size (in bits): 256

Default Value: 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x0000FFFF

DWord	Bit	Description
0..4	159:0	**Reserved** Format: Ignore Ignored
5	31:0	**Buffer Base Address** Format: MHC_A32_BBA Specifies the surface address offset page [31:10] for A32 stateless messages.
6	31:0	**Reserved** Format: Ignore Ignored
7	31:0	**Pixel Sample Mask** Format: MHC_PSM Specifies the 16-bit Pixel/Sample Mask used with SIMD16 and SIMD8 surfaces.

Stencil Message Data Payload Register

MDPR_STENCIL - Stencil Message Data Payload Register

Source: BSpec

Size (in bits): 256

Default Value: 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000

DWord	Bit	Description
0	31:24	**Stencil3** Format: U8 Stencil for Slot 3.
	23:16	**Stencil2** Format: U8 Stencil for Slot 2.

	23:16	**Stencil6** Format: U8 Stencil for Slot 6.
	15:8	**Stencil5** Format: U8 Stencil for Slot 5.
	7:0	**Stencil4** Format: U8 Stencil for Slot 4.

MDPR_STENCIL - Stencil Message Data Payload Register		
2..7	191:0	**Reserved** Format: Ignore Ignored

Subset Atomic Integer Trinary Operation Message Descriptor Control Field

MDC_AOP3S - Subset Atomic Integer Trinary Operation Message Descriptor Control Field

Source: BSpec
Size (in bits): 4
Default Value: 0x0000000E

DWord	Bit	Description
0	3:0	**Atomic Integer Operation Type** Format: Enumeration Specifies the atomic integer trinary operation to be performed

Value	Name	Description
0Eh	AOP_CMPWR **[Default]**	new_dst = (src0 == old_dst) ? src1 : old_dst
Others	Reserved	Ignored

Programming Notes
When Return Data Control is set, old_dst is returned.

Subset Reversed SIMD Mode 2 Message Descriptor Control Field

MDC_SM2RS - Subset Reversed SIMD Mode 2 Message Descriptor Control Field

Source:	BSpec
Size (in bits):	1
Default Value:	0x00000001

DWord	Bit	Description
0	0	**SIMD Mode** Format: Enumeration Specifies the SIMD mode of the message (number of slots processed)

Value	Name	Description
0h	Reserved	Not used
01h	SIMD8 **[Default]**	SIMD8

Subset SIMD Mode 2 Message Descriptor Control Field

MDC_SM2S - Subset SIMD Mode 2 Message Descriptor Control Field

Source: BSpec
Size (in bits): 1
Default Value: 0x00000000

DWord	Bit	Description
0	0	**SIMD Mode** Format: Enumeration Specifies the SIMD mode of the message (number of slots processed)

Value	Name	Description
00h	SIMD8	SIMD8
01h	Reserved	Ignored

Subset SIMD Mode 3 Message Descriptor Control Field

MDC_SM3S - Subset SIMD Mode 3 Message Descriptor Control Field

Source: BSpec
Size (in bits): 2
Default Value: 0x00000000

DWord	Bit	Description
0	1:0	**SIMD Mode** Format: Enumeration Specifies the SIMD mode of the message (number of slots processed)

Value	Name	Description
00h	SIMD4x2	SIMD4x2
01h	Reserved	Ignored
02h	SIMD8	SIMD8
03h	Reserved	Ignored

Subspan Render Target Message Header Control

MHC_RT_SUBSPAN - Subspan Render Target Message Header Control

Source: BSpec
Size (in bits): 32
Default Value: 0x00000000

DWord	Bit	Description
0	31:16	**Y** Format: U16 Y coordinate for upper-left pixel of this subspan
	15:0	**X** Format: U16 X coordinate for upper-left pixel of this subspan

Surface Binding Table Index Message Descriptor Control Field

MDC_BTS - Surface Binding Table Index Message Descriptor Control Field

Source:	BSpec
Size (in bits):	8
Default Value:	0x00000000

DWord	Bit	Description
0	7:0	**Binding Table Index** Format: Enumeration Specifies the Binding Table index for the message, which must be a Surface State Model.

Value	Name	Description
00h-0EFh	BTS	Index of Binding Table State Surfaces
F0h-0FBh	Reserved	Reserved for future use
0FCh	SSO	Specifies a Surface State Offset supplied by the extended message descriptor
Others	Reserved	Ignored

Surface or Stateless Binding Table Index Message Descriptor Control Field

MDC_BTS_A32 - Surface or Stateless Binding Table Index Message Descriptor Control Field

Source: BSpec
Size (in bits): 8
Default Value: 0x00000000

DWord	Bit	Description
0	7:0	**Binding Table Index** Format: Enumeration Specifies the surface for the message, either Surface State Model or Stateless.

Value	Name	Description
00h-0EFh	BTS	Index of Binding Table State Surfaces
F0h-0FBh	Reserved	Reserved for future use
0FCh	SSO	Specifies a Surface State Offset supplied by the extended message descriptor
0FFh	A32_A64	Specifies a A32 or A64 Stateless access that is locally coherent (coherent within a thread group)
0FDh	A32_A64_NC	Specifies a A32 or A64 Stateless access that is non-coherent (coherent within a thread).
Others	Reserved	Ignored

Restriction
Restriction : When using A32_A64_NC, SW must ensure that 2 threads do not both access the same cache line (64B)

Surface Pitch Message Header Control

MHC_PITCH - Surface Pitch Message Header Control

Source: BSpec
Size (in bits): 32
Default Value: 0x00000000

DWord	Bit	Description
0	31:16	**Reserved** Format: Ignore Ignored
	15:0	**Surface Pitch** Format: U16 Specifies the surface width (pitch) to be used for Stateless messages. The Surface Pitch is specified as (#items - 1). The items are specified in the message, and can be bytes, Dwords, or Qwords. The target element address offset is: BufferBaseAddress + U * (SurfacePitch+1) where U is the 32-bit element offset delivered in message address payload.

Surface Pixel Mask Message Header

MH1_BTS_PSM - Surface Pixel Mask Message Header

Source: DataPort 1

Size (in bits): 256

Default Value: 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x0000FFFF

DWord	Bit	Description
0..6	223:0	**Reserved** Format: Ignore Ignored
7	31:0	**Pixel Sample Mask** Format: MHC_PSM Specifies the 16-bit Pixel/Sample Mask used with SIMD16 and SIMD8 surfaces.

SW Generated BINDING_TABLE_STATE

SW Generated BINDING_TABLE_STATE

Source: BSpec
Size (in bits): 32
Default Value: 0x00000000

Description
The binding table binds surfaces to logical resource indices used by shaders and other compute engine kernels. It is stored as an array of up to 256 elements, each of which contains one dword as defined here. The start of each element is spaced one dword apart.
The first element of the binding table is aligned to a 64-byte boundary.
Binding table indexes beyond 256 will automatically be mapped to entry 0 by the HW, w/ the exception of any messages which support the special indexes 240 through 255, inclusive.

DWord	Bit	Description
0	31:6	**Surface State Pointer** Format: SurfaceStateOffset[31:6] This 64-byte aligned address points to a surface state block. This pointer is relative to the **Surface State Base Address**
	5	**Reserved** Format: MBZ
	4:0	**Reserved** Format: MBZ

Thread EOT Message Descriptor

TS_EOT - Thread EOT Message Descriptor

Source:	RenderCS
Size (in bits):	32
Default Value:	0x02000000

End of Thread message is sent to SFID_TS (07h) to end GPGPU and Media threads. The EU send instruction must also set the EOT control (bit 5) of the extended message descriptor.
This message is sent with single register message payload, which is a copy of the R0 thread payload sent with the thread dispatch.

DWord	Bit	Description
0	31:29	**Reserved** Format: MBZ
	28:25	**Message Length** Default Value: 1h One GRF Format: U4
	24:20	**Response Length** Default Value: 0h Zero GRF Format: U5
	19	**Header Present** Format: MBZ
	18:1	**Reserved** Format: MBZ
	0	**Message Type** Default Value: 0h End Thread Format: Opcode End of Thread message opcode

Thread Spawn Message Descriptor

Thread Spawn Message Descriptor

Source: RenderCS
Size (in bits): 32
Default Value: 0x00000000

DWord	Bit	Description
0	31:20	**Reserved** Format: MBZ
	19	**Header Present** Format: MBZ **Programming Notes** This bit MBZ for all Thread Spawner messages.
	18:5	**Reserved** Format: MBZ
	4	**Resource Select** This field specifies the resource associated with the action taken by the Opcode. Value / Name / Description / Exists If: 0 / Spawn Child / Spawn a Child Thread / [Opcode] == 'Spawn Thread' 1 / Spawn Root / Spawn a Root Thread / [Opcode] == 'Spawn Thread' 0 / Dereference Resource / The URB Handle is Dereferenced / [Opcode] == 'Dereference Resource' 1 / Keep Resource / The URBHhandle is NOT Dereferenced / [Opcode] == 'Dereference Resource'
	3:2	**Reserved** Format: MBZ
	1	**Requester Type** This field indicates whether the requesting thread is a root thread or a child thread. If it is a root thread, when Opcode is 0, FF managed resources are dereferenced. If it is a child thread and Opcode is 0, no resource is dereferenced; no action is required by the TS. Value / Name: 0 / Root Thread 1 / Child Thread
	0	**Opcode** Indicates the operation performed by the message. A root thread must terminate with a message to TS (Opcode == 0 and EOT == 1).

Thread Spawn Message Descriptor

A child thread should also terminate with such a message. A thread cannot terminate with an Opcode of "spawn thread".

Value	Name	Description
0	Dereference Resource	also used for end of thread
1	Spawn Thread	

TileW SIMD8 Data Control Dword

MDCD_TILEW - TileW SIMD8 Data Control Dword		
Source:	BSpec	
Size (in bits):	32	
Default Value:	0x00000000	
DWord	**Bit**	**Description**
0	31:8	**Reserved** Format: Ignore Ignored
	7:0	**Red** Format: U8 Specifies the value of the red channel to be read or written.

TileW SIMD8 Data Payload

0.7	31:0	**Red Slot7** Format: MDCD_TileW Specifies the Slot 7 red channel data

Transpose Message Header

MH_T - Transpose Message Header

Source: DataPort 1

Size (in bits): 256

Default Value: 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000

DWord	Bit	Description
0	31:0	**X Offset** Format: S31 X offset (in bytes) of the upper left corner of the block into the surface. **Programming Notes** This field must be a multiple of the Block Width in bytes. Must be DWORD aligned.
1	31:0	**Y Offset** Format: S31 Y offset (in rows) of the upper left corner of the block into the surface. **Programming Notes** This field must be a multiple of the Block Height.
2	31:0	**Block Dimensions** Format: MHC_BDIM The height and width of the block to transpose.
3..7	159:0	**Reserved** Format: Ignore Ignored

Untyped Write Channel Mask Message Descriptor Control Field

MDC_UW_CMASK - Untyped Write Channel Mask Message Descriptor Control Field

Source: BSpec
Size (in bits): 4
Default Value: 0x00000000

DWord	Bit	Description
0	3:0	**Mask** Format: Enumeration For untyped surface write messages, indicates which channels are included in the message payload and written to the surface.

Value	Name	Description
00h	RGBA **[Default]**	Red, Green, Blue, and Alpha are included
08h	RGB	Red, Green, and Blue are included
0Ch	RG	Red and Green are included
0Eh	R	Red is included
Others	Reserved	Ignored

Upper Oword Block Data Payload

MDP_OW1U - Upper Oword Block Data Payload		
Source:	BSpec	
Size (in bits):	256	
Default Value:	0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000	
DWord	**Bit**	**Description**
0.0-0.3	127:0	**Reserved** Format: Ignore Ignored
0.4-0.7	127:0	**Oword** Format: U128 Specifies the upper Oword data element

VC1

VC1		
Source:	VideoCS	
Size (in bits):	16	
Default Value:	0x00000000	
DWord	**Bit**	**Description**
0	15:8	**Reserved** Format: MBZ
	7	**Syncmarker Error** This flag indicates missing sync marker SEs coded in the bit-stream.
	6	**Mbmode SE Error** This flag indicates inconsistent Macroblock SEs coded in the bit-stream.
	5	**Transformtype SE Error** This flag indicates inconsistent transform type SEs coded in the bit-stream.
	4	**Coefficient Error** This flag indicates inconsistent Coefficient SEs coded in the bit-stream.
	3	**Motion Vector SE Error** This flag indicates inconsistent Motion Vector SEs coded in the bit-stream.
	2	**Coded Block Pattern CY SE Error** This flag indicates inconsistent CBPCY SEs coded in the bit-stream.
	1	**Mquant Error** This flag indicates inconsistent MQUANT SEs coded in the bit-stream.
	0	**MB Concealment Flag** . Each pulse from this flag indicates one MB is concealed by hardware.

VCS Hardware-Detected Error Bit Definitions

VCS Hardware-Detected Error Bit Definitions

Source: VideoCS
Size (in bits): 16
Default Value: 0x00000000

DWord	Bit	Description
0	15:3	**Reserved** Format: MBZ
	2	**Command Privilege Violation Error** This bit is set if a command classified as privileged is parsed in a non-privileged batch buffer. The command will be converted to a NOOP and parsing will continue.
	1	**Reserved** Format: MBZ
	0	**Instruction Error** This bit is set when the Renderer Instruction Parser detects an error while parsing an instruction. Instruction errors include: • Client ID value (Bits 31:29 of the Header) is not supported (only MI, 2D and 3D are supported). • Defeatured MI Instruction Opcodes: **Value** / **Name** / **Description** 1 / / Instruction Error detected **Programming Notes** This error indications cannot be cleared except by reset (i.e., it is a fatal error).

VEB_DI_IECP_COMMAND_SURFACE_CONTROL_BITS

VEB_DI_IECP_COMMAND_SURFACE_CONTROL_BITS

Source: VideoEnhancementCS
Size (in bits): 11
Default Value: 0x00000000

DWord	Bit	Description
0	10:9	**Tiled Resource Mode for Output Frame Surface Base Address** **For Media Surfaces:** This field specifies the tiled resource mode. Value / Name / Description: 0h / TRMODE_NONE / No tiled resource 1h / TRMODE_TILEYF / 4KB tiled resources 2h / TRMODE_TILEYS / 64KB tiled resources 3h / Reserved /
	8	**Memory Compression Mode** Description: Distinguishes Vertical from Horizontal compression. Value / Name: 0 / Horizontal Compression Mode 1 / Vertical Compression Mode
	7	**Memory Compression Enable** Format: Enable Memory compression will be attempted for this surface.
	6:1	**Index to Memory Object Control State (MOCS) Tables** The index to define the L3 and system cache memory properties. The details of the controls are further defined in L3 and Page walker (memory interface) control registers. The field is defined to populate 64 different surface controls to be used concurrently. Related control registers can be updated during runtime.
	0	**Reserved**

VEBOX_ACE_LACE_STATE

VEBOX_ACE_LACE_STATE

Source: VideoEnhancementCS

Size (in bits): 416

Default Value: 0x00000068, 0x4C382410, 0x9C887460, 0xEBD8C4B0, 0x604C3824, 0xB09C8874, 0x0000D8C4, 0x04000400, 0x04000400, 0x04000400, 0x04000400, 0x04000400, 0x00000400

This state structure contains the IECP State Table Contents for ACE state.

DWord	Bit	Description
0	31:16	**Min_ACE_luma** Format: U16
	15:14	**LACE Single Histogram Set** This bit tells LACE which frames will be included in the histogram when the Deinterlacer is enabled.

Value	Name	Description
00b	Current	The histogram includes only the current frame.
01b	Previous	The histogram includes only the previous frame.
10b	Current + Previous	The histogram includes pixels from both the current and previous frame.
11b	Previous + Current	The histogram includes the previous frame followed by the current frame.

Programming Notes
When the Deinterlacer is disabled, this field must be 00b. If **DI Output Frames** is set to only output a single field then the histogram can not be collected on the disabled field. This Field must be set to 00b when DN/DI First Frame is set to 1

	13	**LACE Histogram Size**

Value	Name
0	128-bin histogram
1	256-bin histogram

	12	**LACE Histogram Enable** Default Value: 0 This bit enables the collection of LACE histogram data. If this bit is 0 then only the ACE histogram will be collected.
	11:7	**Reserved** Format: MBZ

VEBOX_ACE_LACE_STATE

	6:2	**Skin Threshold** Format: U5 Used for Y analysis (min/max) for pixels which are higher than skin threshold. Value / Name [1,31] 26 **[Default]**
	1	**Reserved** Format: MBZ
	0	**ACE Enable** Format: Enable
1	31:24	**Y3** Default Value: 76 Format: U8 The value of the y_pixel for point 3 in PWL.
	23:16	**Y2** Default Value: 56 Format: U8 The value of the y_pixel for point 2 in PWL.
	15:8	**Y1** Default Value: 36 Format: U8 The value of the y_pixel for point 1 in PWL.
	7:0	**Ymin** Default Value: 16 Format: U8 The value of the y_pixel for point 0 in PWL.
2	31:24	**Y7** Default Value: 156 Format: U8 The value of the y_pixel for point 7 in PWL.

VEBOX_ACE_LACE_STATE

	23:16	**Y6** Default Value: 136 Format: U8 The value of the y_pixel for point 6 in PWL.
	15:8	**Y5** Default Value: 116 Format: U8 The value of the y_pixel for point 5 in PWL.
	7:0	**Y4** Default Value: 96 Format: U8 The value of the y_pixel for point 4 in PWL.
3	31:24	**Ymax** Default Value: 235 Format: U8 The value of the y_pixel for point 11 in PWL.
	23:16	**Y10** Default Value: 216 Format: U8 The value of the y_pixel for point 10 in PWL.
	15:8	**Y9** Default Value: 196 Format: U8 The value of the y_pixel for point 9 in PWL.
	7:0	**Y8** Default Value: 176 Format: U8 The value of the y_pixel for point 8 in PWL.
4	31:24	**B4** Default Value: 96 Format: U8 The value of the bias for point 4 in PWL.

VEBOX_ACE_LACE_STATE

	23:16	**B3** Default Value: 76 Format: U8 The value of the bias for point 3 in PWL.
	15:8	**B2** Default Value: 56 Format: U8 The value of the bias for point 2 in PWL.
	7:0	**B1** Default Value: 36 Format: U8 The value of the bias for point 1 in PWL.
5	31:24	**B8** Default Value: 176 Format: U8 The value of the bias for point 8 in PWL.
	23:16	**B7** Default Value: 156 Format: U8 The value of the bias for point 7 in PWL.
	15:8	**B6** Default Value: 136 Format: U8 The value of the bias for point 6 in PWL.
	7:0	**B5** Default Value: 116 Format: U8 The value of the bias for point 5 in PWL.
6	31:16	**Reserved** Format: MBZ

VEBOX_ACE_LACE_STATE

	15:8	**B10** Default Value: 216 Format: U8 The value of the bias for point 10 in PWL.
	7:0	**B9** Default Value: 196 Format: U8 The value of the bias for point 9 in PWL.
7	31:27	**Reserved** Format: MBZ
	26:16	**S1** Default Value: 1024 Format: U1.10 The value of the slope for point 1 in PWL The default is 1024/1024
	15:11	**Reserved** Format: MBZ
	10:0	**S0** Default Value: 1024 Format: U1.10 The value of the slope for point 0 in PWL The default is 1024/1024
8	31:27	**Reserved** Format: MBZ
	26:16	**S3** Default Value: 1024 Format: U1.10 The value of the slope for point 3 in PWL The default is 1024/1024
	15:11	**Reserved** Format: MBZ

VEBOX_ACE_LACE_STATE

	10:0	**S2** Default Value: 1024 Format: U1.10 The value of the slope for point 2 in PWL The default is 1024/1024
9	31:27	**Reserved** Format: MBZ
	26:16	**S5** Default Value: 1024 Format: U1.10 The value of the slope for point 5 in PWL The default is 1024/1024
	15:11	**Reserved** Format: MBZ
	10:0	**S4** Default Value: 1024 Format: U1.10 The value of the slope for point 4 in PWL The default is 1024/1024
10	31:27	**Reserved** Format: MBZ
	26:16	**S7** Default Value: 1024 Format: U1.10 The value of the slope for point 7 in PWL The default is 1024/1024
	15:11	**Reserved** Format: MBZ

VEBOX_ACE_LACE_STATE

	10:0	**S6** Default Value: 1024 Format: U1.10 The default is 1024/1024
11	31:27	**Reserved** Format: MBZ
	26:16	**S9** Default Value: 1024 Format: U1.10 The value of the slope for point 9 in PWL The default is 1024/1024
	15:11	**Reserved** Format: MBZ
	10:0	**S8** Default Value: 1024 Format: U1.10 The value of the slope for point 8 in PWL The default is 1024/1024
12	31:16	**Max_ACE_luma** Format: U16 The maximum luma for which ACE correction will be used.
	15:11	**Reserved** Format: MBZ
	10:0	**S10** Default Value: 1024 Format: U1.10 The value of the slope for point 10 in PWL.

VEBOX_ALPHA_AOI_STATE

VEBOX_ALPHA_AOI_STATE

Source: VideoEnhancementCS
Size (in bits): 96
Default Value: 0x00000000, 0x00030000, 0x00030000

This state structure contains the IECP State Table Contents for Fixed Alpha State and Area of Interest State.

DWord	Bit	Description
0	31:18	**Reserved** Format: MBZ
	17	**Full Image Histogram** Default Value: 0 Format: Enable Used to ignore the area of interest for a histogram across the full image. This applies to all statistics that are affected by AOI (Area of Interest).
	16	**Alpha from State Select** Format: U1 Enumerated type Value / Name: 0 – alpha is taken from message 1 – alpha is taken from state **Programming Notes** If the input format does not have alpha available and the output format provides alpha, this bit should be set to 1. This should be 0 when Alpha Plane Enable is 1.
	15:0	**Color Pipe Alpha** Format: U16 **Programming Notes** The 8 MSB of this field will be used for output formats that have 8-bits of alpha.
1	31:30	**Reserved** Format: MBZ
	29:16	**AOI Max X** Default Value: 3 Format: U14

VEBOX_ALPHA_AOI_STATE

		Area of Interest Minimum X - The ACE histogram and Skin Tone Detection statistic gathering will occur within the MinX/MinY to MaxX/MaxY area (inclusive). AOI must intersect the frame such that at least 1 pixel is in the AOI. The Area of Interest applies to the RGB Histogram and the White/Gray point sums as well. **Programming Notes** **This value must be a multiple of 4 minus 1.**
	15:14	**Reserved** Format: MBZ
	13:0	**AOI Min X** Default Value: 0 Format: U14 **Programming Notes** **This value must be a multiple of 4.**
2	31:30	**Reserved** Format: MBZ
	29:16	**AOI Max Y** Default Value: 3 Format: U14 **Programming Notes** **This value must be a multiple of 4 minus 1.**
	15:14	**Reserved** Format: MBZ
	13:0	**AOI Min Y** Default Value: 0 Format: U14 **Programming Notes** **This value must be a multiple of 4.**

VEBOX_CAPTURE_PIPE_STATE

VEBOX_CAPTURE_PIPE_STATE

Source: VideoEnhancementCS

Size (in bits): 224

Default Value: 0x0511FF23, 0xAA64AFAA, 0xE6FD4000, 0x00000000, 0x00000000, 0x00000000, 0x00000000

This command contains variables for controlling Demosaic and the White Balance Statistics.

DWord	Bit	Description
0	31:30	**Reserved** Format: MBZ
	29:24	**Good Pixel Threshold** Format: U6 The difference threshold between adjacent pixels for a pixel to be considered "good". Value: 5h — Name: **[Default]**
	23	**Reserved** Format: MBZ
	22:20	**Shift Min Cost** Default Value: 1h Format: U3 The amount to shift the H2/V2 versions of min_cost.
	19:16	**Green Imbalance Threshold** Default Value: 1h Format: U4
	15:8	**Average Color Threshold** Format: U8 The threshold between two colors in a pixel for the Avg interpolation to be considered. Value: FFh — Name: **[Default]** **Programming Notes** Must be set to 255.
	7:6	**Reserved** Format: U2

VEBOX_CAPTURE_PIPE_STATE

	5:0	**Good Pixel Neighbor Threshold** Default Value: 23h Format: U6 Number of comparisons with neighbor pixels which pass before a pixel is considered good.
1	31:28	**Scale For Min Cost** Default Value: Ah The amount to scale the min_cost difference during the confidence check.
	27:24	**Good Intesity Threshold** Default Value: Ah Format: U4
	23:16	**Bad Color Threshold 1** Default Value: 64h Format: U8 Color value threshold used during the bad pixel check.
	15:8	**Bad Color Threshold 2** Default Value: AFh Format: U8 Color value threshold used during the bad pixel check.
	7:4	**Number Big Pixel Threshold** Default Value: Ah Format: U4 Number of comparisons with neighbor pixels which pass before a pixel is considered good.
	3:0	**Bad Color Threshold 3** Default Value: Ah Format: U4 Color value threshold used during the bad pixel check.
2	31:24	**Y Bright Value** Default Value: E6h The whitepoint threshold percentile in the Y histogram. Any pixel with Y value above this could be a whitepoint. This is the larger of the calculated Ybright value and the Ythreshold value, which is the minimum Y required to be considered a white point. **Programming Notes**

VEBOX_CAPTURE_PIPE_STATE

		"00000000" is appended to the LSBs before comparing with Y.
	23:16	**Y Outlier Value** Default Value: FDh The outlier threshold percentile in the Y histogram. Any pixel with Y value above this either clipped or an outlier in the image. These points will not be included in the white patch calculation. **Programming Notes** "00000000" is appended to the LSBs before comparing with Y.
	15:8	**UV Threshold Value** The value denotes the maximum threshold of the ratio between U+V to Y can have to be considered a gray point. Value: [255,0] — Name: — Description: Encode a value from 255/256 to 0/256 Value: 64 — Name: **[Default]** — Description: 0.25 * 255 = 64
	7	**Black Point Offset Red MSB**
	6	**Black Point Offset Green Top MSB**
	5	**Black Point Offset Blue MSB**
	4	**Black Point Offset Green Bottom MSB**
	3	**RGB Histogram Enable** Enables the collection of RGB Histograms for Auto-white balance correction and other uses. **Programming Notes** This bit can be set without White Balance enable being set.
	2	**Vignette Correction Format** Defines what shift should be assumed for the **Vignette** Correction input values: Value: 0 — Name: U8.8 Value: 1 — Name: U4.12
	1	**Black Point Correction Enable** Format: Enable
	0	**White Balance Correction Enable** Format: Enable **Programming Notes** RGB Histogram enable must be set if this bit is set.
3	31:16	**Black Point Offset Red** Default Value: 0 Format: U16

VEBOX_CAPTURE_PIPE_STATE

		Value subtracted from Red pixels of Bayer pattern - combined with MSB to form a 2's complement signed number.
	15:0	**Black Point Offset Green Top** Default Value: 0 Format: U16 Value subtracted from the top Green pixels of Bayer pattern (X=1, Y=0 for Bayer Pattern #1) - combined with MSB to form a 2's complement signed number.
4	31:16	**Black Point Offset Blue** Default Value: 0 Format: U16 Value subtracted from Blue pixels of Bayer pattern - Combine with MSB to form a 2's complement signed number.
	15:0	**Black Point Offset Green Bottom** Default Value: 0 Format: U16 Value subtracted from the bottom Green pixels of Bayer pattern (X=0, Y=1 for Bayer Pattern #1) - combined with MSB to form a 2's complement signed number.
5	31:16	**White Balance Red Correction** Format: U4.12 The correction factor multiplied by the Red pixels of the Bayer pattern.
	15:0	**White Balance Green Top Correction** Format: U4.12 The correction factor multiplied by the top Green pixels of the Bayer pattern(X=1, Y=0 for Bayer Pattern #1).
6	31:16	**White Balance Blue Correction** Format: U4.12 The correction factor multiplied by the Blue pixels of the Bayer pattern.
	15:0	**White Balance Green Bottom Correction** Format: U4.12 The correction factor multiplied by the bottom Green pixels of the Bayer pattern (X=0, Y=1 for Bayer Pattern #1)

VEBOX_CCM_STATE

VEBOX_CCM_STATE

VEBOX_CSC_STATE

VEBOX_CSC_STATE

Source: VideoEnhancementCS

Size (in bits): 384

Default Value: 0x00010000, 0x00000000, 0x00000000, 0x00000000, 0x00010000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00010000, 0x00000000, 0x00000000, 0x00000000

This state structure contains the IECP State Table Contents for CSC state.

DWord	Bit	Description
0	31	**Transform Enable** Format: Enable
	30	**YUV_Channel_Swap** Default Value: 0 Format: Enable This bit should only be used with R8G8B8A8 output formats. When this bit is set, the YUV channels are swapped into the output RGB channels as shown in the following table to support B8G8R8A8 output on surface format R8G8B8A8: (, YUV_Channel_Swap) (, 0 --> 1) (Y, R --> B) (U, G --> G) (V, B --> R) **Programming Notes** This bit is to provide support for B8G8R8A8 output even though it is not supported in the surface format.
	29:19	**Reserved** Format: MBZ
	18:0	**C0** Default Value: 10000h or 1.0 Format: S2.16 2's complement Transform coefficient.
1	31:19	**Reserved** Format: MBZ

VEBOX_CSC_STATE

	18:0	**C1** Default Value: 0 Format: S2.16 2's complement Transform coefficient.
2	31:19	**Reserved** Format: MBZ
	18:0	**C2** Default Value: 0 Format: S2.16 2's complement Transform coefficient.
3	31:19	**Reserved** Format: MBZ
	18:0	**C3** Default Value: 0 Format: S2.16 2's complement Transform coefficient.
4	31:19	**Reserved** Format: MBZ
	18:0	**C4** Default Value: 10000h or 1.0 Format: S2.16 2's complement Transform coefficient.
5	31:19	**Reserved** Format: MBZ
	18:0	**C5** Default Value: 0 Format: S2.16 2's complement Transform coefficient.
6	31:19	**Reserved** Format: MBZ

VEBOX_CSC_STATE

	18:0	**C6** Default Value: 0 Format: S2.16 2's complement Transform coefficient.
7	31:19	**Reserved** Format: MBZ
	18:0	**C7** Default Value: 0 Format: S2.16 2's complement Transform coefficient.
8	31:19	**Reserved** Format: MBZ
	18:0	**C8** Default Value: 10000h or 1.0 Format: S2.16 2's complement Transform coefficient. The offset value is multiplied by 2 before being added to the output.
9	31:16	**Offset Out 1** Default Value: 0 Format: S15 2's Complement Offset in for Y/R. The offset value is multiplied by 2 before being added to the output.
	15:0	**Offset in 1** Default Value: 0 Format: S15 2's Complement Offset in for Y/R. The offset value is multiplied by 2 before being added to the output.
10	31:16	**Offset Out 2** Default Value: 0 Format: S15 2's Complement Offset out for U/G. The offset value is multiplied by 2 before being added to the output.
	15:0	**Offset in 2** Default Value: 0 Format: S15 2's Complement Offset out for U/G. The offset value is multiplied by 2 before being added to the output.

VEBOX_CSC_STATE		
11	31:16	**Offset Out 3** Default Value: 0 Format: S15 2's Complement Offset out for V/B. The offset value is multiplied by 2 before being added to the output.
	15:0	**Offset in 3** Default Value: 0 Format: S15 2's Complement Offset out for V/B. The offset value is multiplied by 2 before being added to the output.

Size (in bits): 576

Default Value: 0x00000800, 0x00000000, 0x00008000, 0x00010000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000254, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x005064A5

This state table is used by the *Denoise and Deinterlacer functions*.

- DW0 to 2 are for Temporal Denoise
- DW3 is for global noise estimate and hot pixel detection
- DW4 is for Chroma Denoise
- DW5 to 11 are for 5x5 spatial denoise
- DW12 to 17 are for Deinterlacer
- DW18 to 24 Reserved

DWord	Bit	Description
0	31:20	**Denoise STAD Threshold** Format: U12 Threshold for denoise sum of temporal absolute differences.
	19:12	**Denoise Maximum History** Format: U8 Maximum allowed value for denoise history. Value: [128,240] — Name:
	11:8	**Denoise History increase** Format: U4 Amount that denoise_history is increased by. MAX:15 Value: 8h — Name: **[Default]** Value: 15 — Description: Maximum Allowed
	7:5	**Reserved** Format: MBZ
	4:0	**Denoise Moving Pixel Threshold** Format: U5 Value — Name

VEBOX_DNDI_STATE

		[0,16]
1	31:20	**Denoise ASD Threshold** Format: U12 Threshold for denoise absolute sum of differences. Value: [0,1023]; Name:
	19:10	**Temporal Difference Threshold** Format: U10 **Programming Notes** 0 <(**Temporal Difference Threshold** - **Low Temporal Difference Threshold**) < = 256 except when both thresholds are set to 0.
	9:0	**Low Temporal Difference Threshold** Format: U10 **Programming Notes** 0 <(**Temporal Difference Threshold** - **Low Temporal Difference Threshold**) < = 256 except when both thresholds are set to 0.
2	31:29	**Reserved** Format: MBZ
	28	**Progressive DN** Format: Enable Indicates that the denoise algorithm should assume progressive input when filtering neighboring pixels. **This bit must be set if the input to Denoise is RGB.** Value 0: DN assumes interlaced video and filters alternate lines together Value 1: DN assumes progressive video and filters neighboring lines together **Programming Notes** **DI Enable** must be disabled when this field is enabled.
	27:16	**Denoise Threshold for Sum of Complexity Measure** Format: U12
	15:10	**Initial Denoise History** Default Value: 32 Format: U6 Initial value for Denoise history for both Luma and Chroma

VEBOX_DNDI_STATE

9:0 Reserved

Format:	MBZ

3 — 31:28 Hot Pixel Count

Format:	U4

Number of neighboring pixels different more than **Hot Pixel Threshold** before a pixel is considered hot.

Value	Name
[0,8]	

Programming Notes
0 will cause all pixels to be considered hot and will perform a median filter on the entire image.

27:20 Hot Pixel Threshold

Format:	U8

Threshold for a difference from the value of a neighboring pixel. Is shifted up to 16-bits before compare.

19:12 Block Noise Estimate Edge Threshold

Format:	U8

Threshold for detecting an edge in block noise estimate.

Value	Name	Description
16	**[Default]**	
255		Maximium Value

11:0 Block Noise Estimate Noise Threshold

Format:	U12

Threshold for noise maximum/minimum.

Value	Name
[0, 511]	

4 — 31:24 Reserved

Format:	MBZ

23:16 Chroma Denoise STAD Threshold

Format:	U8

Threshold for denoise sum of temporal absolute differences.

15:13 Reserved

Format:	MBZ

12 Chroma Denoise Enable

Value	Name	Description

VEBOX_DNDI_STATE

	30:16	**Offset_in_G** Default Value: 0 Format: S14 The input offset for green component
	15	**Reserved** Format: MBZ
	14:0	**Offset_in_R** Default Value: 0 Format: S14 The input offset for red component
33	31	**Reserved** Format: MBZ
	30:16	**Offset_out_B** Format: S2.12 The input offset for green component The default is -1246/4096
	15	**Reserved** Format: MBZ
	14:0	**Offset_in_B** Default Value: 0 Format: S14 The input offset for red component
34	31	**Reserved** Format: MBZ
	30:16	**Offset_out_G** Format: S2.12 The input offset for green component The default is -983/4096

VEBOX_GAMUT_STATE

	15	**Reserved** Format: MBZ
	14:0	**Offset_out_R** Format: S2.12 The input offset for red component The default is -974/4096
35	31	**Reserved** Format: MBZ
	30	**FullRangeMappingEnable** 0 – Basic Mode **[Default]** 1 – Advance Mode
	29:20	**d(in,default)** Default Value: 205 Format: U10 InnerTriangleMappingLength
	19:10	**d(out, default)** Default Value: 164 Format: U10 OuterTriangleMappingLength
	9:0	**d1(out)** Default Value: 287 Format: U10 OuterTriangleMappingLengthBelow
36	31	**xvYccDecEncEnable** This bit is valid only when ColorGamutCompressionnEnable is on. 1 – Both xvYcc decode and xvYcc encode are enabled **[Default]** 0 – To disable both xvYcc decode and xvYcc encode
	30:28	**CompressionLineShift** 3 – **[Default]** [0,4]

VEBOX_GAMUT_STATE

	27:10	**Reserved** Format: MBZ
	9:0	**d1(in)** Default Value: 820 Format: U10 InnerTriangleMappingLengthBelow
37	31:30	**GCC BasicModeSelection** **Value** / **Name** / **Description** 00b / Default / 01b / Scaling Factor / Used along with Dword66 Bits 28:11 10b / Single Axis Gamma Correction / Used along with Dword67 Bit 29 11b / Scaling factor with fixed luma / Used along with Dword37 Bits 28:11
	29	**LumaChormaOnlyCorrection** **Value** / **Name** 0 / Luma Only Correction **[Default]** 1 / Chorma Only Correction
	28:25	**Reserved** Format: MBZ
	24:11	**BasicModeScalingFactor** Format: U2.12 Used when FullRangeMappingEnable is in basic mode and base mode selection bit is set to scaling factor.
	10:1	**Reserved** Format: MBZ
	0	**Cpi Override** **Value** / **Name** 0 / **[Default]** 1 / Override Cpi calculation

VEBOX_IECP_STATE

VEBOX_IECP_STATE		
Source:	VideoEnhancementCS	
Size (in bits):	2912	
Default Value:	0x9A6E39F0, 0x00000000, 0x00000000, 0x00000000

VEBOX_IECP_STATE		
67..69	95:0	**Alpha/AOI State** Format: **VEBOX_ALPHA_AOI_STATE** For description of this state, refer to *Alpha State Section*.
70..78	287:0	**CCM State** Format: **VEBOX_CCM_STATE** For description of this state, refer to the CCM State section
79..90	383:0	**Front-end CSC** Format: **VEBOX_FRONT_END_CSC_STATE** For description of this state, refer to *Front-end CSC State Section*.

VEBOX_PROCAMP_STATE

VEBOX_PROCAMP_STATE

Source: VideoEnhancementCS
Size (in bits): 64
Default Value: 0x01000001, 0x01000000

This state structure contains the IECP State Table Contents for ProcAmp state.

DWord	Bit	Description
0	31:28	**Reserved** Format: MBZ
	27:17	**Contrast** Default Value: 80h = 1.0 in fixed point U4.7 Format: U4.7 Contrast magnitude.
	16:13	**Reserved** Format: MBZ
	12:1	**Brightness** Default Value: 0 or 0.0 Format: S7.4 2's complement Brightness magnitude.
	0	**PROCAMP Enable** Default Value: 1 Format: Enable
1	31:16	**Cos_c_s** Default Value: 256 Format: S7.8 2's complement UV multiplication cosine factor.
	15:0	**Sin_c_s** Default Value: 0 Format: S7.8 2's complement UV multiplication sine factor.

VEBOX_RGB_TO_GAMMA_CORRECTION

VEBOX_RGB_TO_GAMMA_CORRECTION		
Source:	VideoEnhancementCS	
Size (in bits):	64	
Default Value:	0x00000000, 0x00000000	
Color depth is 16 bits.		
DWord	**Bit**	**Description**
0..1	63:48	**B-ch Corrected Value** Default Value: 0h Format: U16
	47:32	**G-ch Corrected Value** Default Value: 0h Format: U16
	31:16	**R-ch Corrected Value** Default Value: 0h Format: U16
	15:0	**Pixel Value** Default Value: 0h Format: U16 **Programming Notes** N indicates the index into the table. Pixel value 0 and Pixel Value 63 should be always programmed to 0 and 0xFFFF respectively. Rest of the Pixel Values which are used for comparing with the input pixel value should be multiple of 4.

VEBOX_STD_STE_STATE

VEBOX_STD_STE_STATE

Source: VideoEnhancementCS

Size (in bits): 928

Default Value: 0x9A6E39F0, 0x400D3C65, 0x000C9180, 0xFE2F2E00, 0x0003FFFF, 0x00140000, 0xD82E0640, 0x8285ECEC, 0x07FB8282, 0x00000000, 0x02117000, 0xA38FEC96, 0x0100C8C8, 0x003A6871, 0x01478000, 0x0107C306, 0x1291F008, 0x00094855, 0x1C1BD100, 0x03802008, 0x0002A980, 0x00080180, 0x0007CFF5, 0x18D1F07C, 0x000800BD, 0x1C080100, 0x03800000, 0x0008012B, 0x0008012B

This state structure contains the state used by the STD/STE function.

DWord	Bit	Description
0	31:24	**V_Mid** Default Value: 154 Format: U8 Rectangle middle-point V coordinate.
	23:16	**U_Mid** Default Value: 110 Format: U8 Rectangle middle-point U coordinate.
	15:10	**Hue_Max** Default Value: 14 Format: U6 Rectangle half width.
	9:4	**Sat_Max** Default Value: 31 Format: U6 Rectangle half length.
	3	**Reserved** Format: MBZ
	2	**Output Control** Value 0: Output Pixels Value 1: Output STD Decisions

VEBOX_STD_STE_STATE

	1	**STE Enable** Format: Enable
	0	**STD Enable** Format: Enable **Programming Notes** This needs to be enabled if 'STD Score Output' is enabled.
1	31	**STD Score Output** Format: Enable
	30:28	**Diamond Margin** Default Value: 4 Format: U3
	27:21	**Diamond_du** Default Value: 0 Format: S6 2's complement Rhombus center shift in the sat-direction, relative to the rectangle center.
	20:18	**HS_margin** Default Value: 3 Format: U3 Defines rectangle margin.
	17:10	**Cos(α)** Default Value: 79 Format: S0.7 2's complement The default is 79/128
	9:8	**Reserved** Format: MBZ
	7:0	**Sin(α)** Default Value: 101 Format: S0.7 2's complement The default is 101/128
2	31:21	**Reserved** Format: MBZ

VEBOX_STD_STE_STATE

	20:13	**Diamond_alpha** Default Value: 100 Format: U2.6 1/tan(β) The default is 100/64
	12:7	**Diamond_Th** Default Value: 35 Format: U6 Half length of the rhombus axis in the sat-direction.
	6:0	**Diamond_dv** Default Value: 0 Format: S6 2's complement Rhombus center shift in the hue-direction, relative to the rectangle center.
3	31:24	**Y_point_3** Default Value: 254 Format: U8 Third point of the Y piecewise linear membership function.
	23:16	**Y_point_2** Default Value: 47 Format: U8 Second point of the Y piecewise linear membership function.
	15:8	**Y_point_1** Default Value: 46 Format: U8 First point of the Y piecewise linear membership function.
	7	**VY_STD_Enable** Format: Enable Enables STD in the VY subspace.
	6:0	**Reserved** Format: MBZ
4	31:18	**Reserved** Format: MBZ

VEBOX_STD_STE_STATE

	17:13	**Y_Slope_2** Default Value: 31 Format: U2.3 Slope between points Y3 and Y4. The default is 31/8
	12:8	**Y_Slope_1** Default Value: 31 Format: U2.3 Slope between points Y1 and Y2. The default is 31/8
	7:0	**Y_point_4** Default Value: 255 Format: U8 Fourth point of the Y piecewise linear membership function.
5	31:16	**INV_Skin_types_margin** Default Value: 20 Skin_Type_margin Format: U0.16 1/(2* Skin_types_margin)
	15:0	**INV_Margin_VYL** Format: U0.16 1 / Margin_VYL 1/ Margin_VYL = 3300/65536
6	31:24	**P1L** Default Value: 216 Format: U8 Y Point 1 of the lower part of the detection PWLF.
	23:16	**P0L** Default Value: 46 Format: U8 Y Point 0 of the lower part of the detection PWLF.

VEBOX_STD_STE_STATE

	15:0	**INV_Margin_VYU** Default Value: 1600 Format: U0.16 1 / Margin_VYU = 1600/65536
7	31:24	**B1L** Default Value: 130 Format: U8 V Bias 1 of the lower part of the detection PWLF.
	23:16	**B0L** Default Value: 133 Format: U8 V Bias 0 of the lower part of the detection PWLF.
	15:8	**P3L** Default Value: 236 Format: U8 Y Point 3 of the lower part of the detection PWLF.
	7:0	**P2L** Default Value: 236 Format: U8 Y Point 2 of the lower part of the detection PWLF.
8	31:27	**Reserved** Format: MBZ
	26:16	**S0L** Default Value: FFBh Format: S2.8 2's complement Slope 0 of the lower part of the detection PWLF. The default is -5/256
	15:8	**B3L** Default Value: 130 Format: U8 V Bias 3 of the lower part of the detection PWLF.

VEBOX_STD_STE_STATE

	7:0	**B2L** Default Value: 130 Format: U8 V Bias 2 of the lower part of the detection PWLF.
9	31:22	**Reserved** Format: MBZ
	21:11	**S2L** Default Value: 0 Format: S2.8 2's complement The default is 0/256
	10:0	**S1L** Default Value: 0 Format: S2.8 2's complement Slope 1 of the lower part of the detection PWLF. The default is 0/256
10	31:27	**Reserved** Format: MBZ
	26:19	**P1U** Default Value: 66 Format: U8 Y Point 1 of the upper part of the detection PWLF.
	18:11	**P0U** Default Value: 46 Format: U8 Y Point 0 of the upper part of the detection PWLF.
	10:0	**S3L** Default Value: 0 Format: S2.8 2's complement Slope 3 of the lower part of the detection PWLF. The default is 0/256

VEBOX_STD_STE_STATE

11	31:24	**B1U** Default Value: 163 Format: U8 V Bias 1 of the upper part of the detection PWLF.
	23:16	**B0U** Default Value: 143 Format: U8 V Bias 0 of the upper part of the detection PWLF.
	15:8	**P3U** Default Value: 236 Format: U8 Y Point 3 of the upper part of the detection PWLF.
	7:0	**P2U** Default Value: 150 Format: U8 Y Point 2 of the upper part of the detection PWLF.
12	31:27	**Reserved** Format: MBZ
	26:16	**S0U** Default Value: 256 Format: S2.8 2's complement Slope 0 of the upper part of the detection PWLF. The default is 256/256
	15:8	**B3U** Default Value: 200 Format: U8 V Bias 3 of the upper part of the detection PWLF.
	7:0	**B2U** Default Value: 200 Format: U8 V Bias 2 of the upper part of the detection PWLF.

VEBOX_STD_STE_STATE

13	31:22	**Reserved** Format: MBZ
	21:11	**S2U** Default Value: F4Dh Format: S2.8 2's complement Slope 2 of the upper part of the detection PWLF. The default is -179/256
	10:0	**S1U** Default Value: 113 Format: S2.8 Slope 1 of the upper part of the detection PWLF. The default is 113/256
14	31:28	**Reserved** Format: MBZ
	27:20	**Skin_types_margin** Default Value: 20 Format: U8 Skin types Y margin Restrict Skin_types_thresh >= Skin_types_margin > 0 Restrict (Skin_types_thresh + Skin_types_margin) <= 255
	19:12	**Skin_types_thresh** Default Value: 120 Format: U8 Skin types Y margin Restrict Skin_types_thresh >= Skin_types_margin > 0 Restrict (Skin_types_thresh + Skin_types_margin) <= 255
	11	**Skin_Types_Enable** Default Value: 0 Disable Format: Enable Treat differently bright and dark skin types
	10:0	**S3U** Default Value: 0 Format: S2.8 2's complement

VEBOX_STD_STE_STATE

		Slope 3 of the upper part of the detection PWLF. The default is 0/256
15	31	**Reserved** Format: MBZ
	30:21	**SATB1** Default Value: 8 Format: S7.2 2's complement First bias for the saturation PWLF (bright skin). The default is 8/4
	20:14	**SATP3** Default Value: 31 Format: S6 2's complement Third point for the saturation PWLF (bright skin).
	13:7	**SATP2** Default Value: 6 Format: S6 2's complement Second point for the saturation PWLF (bright skin).
	6:0	**SATP1** Default Value: 6 Format: S6 2's complement First point for the saturation PWLF (bright skin).
16	31	**Reserved** Format: MBZ
	30:20	**SATS0** Default Value: 297 Format: U3.8 Zeroth slope for the saturation PWLF (bright skin) The default is 297/256
	19:10	**SATB3** Default Value: 124 Format: S7.2 2's complement

VEBOX_STD_STE_STATE

		Third bias for the saturation PWLF (bright skin) The default is 124/4
	9:0	**SATB2** Default Value: 8 Format: S7.2 2's complement Second bias for the saturation PWLF (bright skin) The default is 8/4
17	31:22	**Reserved** Format: MBZ
	21:11	**SATS2** Default Value: 297 Format: U3.8 Second slope for the saturation PWLF (bright skin) The default is 297/256
	10:0	**SATS1** Default Value: 85 Format: U3.8 First slope for the saturation PWLF (bright skin) The default is 85/256
18	31:25	**HUEP3** Default Value: 14 Format: S6 2's complement Third point for the hue PWLF (bright skin)
	24:18	**HUEP2** Default Value: 6 Format: S6 2's complement Second point for the hue PWLF (bright skin)
	17:11	**HUEP1** Default Value: 7Ah -6 Format: S6 2's complement First point for the hue PWLF (bright skin)

VEBOX_STD_STE_STATE

VECS Hardware-Detected Error Bit Definitions

VECS Hardware-Detected Error Bit Definitions

Source: VideoEnhancementCS
Size (in bits): 16
Default Value: 0x00000000

DWord	Bit	Description
0	15:3	**Reserved** Format: MBZ
	2	**Command Privilege Violation Error** This bit is set if a command classified as privileged is parsed in a non-privileged batch buffer. The command will be converted to a NOOP and parsing will continue.
	1	**Reserved** Format: MBZ
	0	**Instruction Error** This bit is set when the Renderer Instruction Parser detects an error while parsing an instruction. Instruction errors include: • Client ID value (Bits 31:29 of the Header) is not supported (only MI, 2D and 3D are supported). • Defeatured MI Instruction Opcodes: **Value** / **Name** / **Description**: 1 / / Instruction Error detected **Programming Notes**: This error indications cannot be cleared except by reset (i.e., it is a fatal error).

VERTEX_BUFFER_STATE

VERTEX_BUFFER_STATE

Source: RenderCS
Size (in bits): 128
Default Value: 0x00000000, 0x00000000, 0x00000000, 0x00000000

This structure is used in 3DSTATE_VERTEX_BUFFERS to set the state associated with a VB. The VF function will use this state to determine how/where to extract vertex element data for all vertex elements associated with the VB.

DWord	Bit	Description
0	31:26	**Vertex Buffer Index** Format: U6 index This field contains an index value which selects the VB state being defined. Value: [0,32] — Name:
	25:23	**Reserved** Format: MBZ
	22:16	**Memory Object Control State** Format: MEMORY_OBJECT_CONTROL_STATE Specifies the memory object control state for this vertex buffer.
	15	**Reserved** Format: MBZ
	14	**Address Modify Enable** If set, the Buffer Starting Address field is used to update the state of this buffer. If clear, that field is ignored and the previously-programmed value is maintained.
	13	**Null Vertex Buffer** Format: Enable This field enabled causes any fetch for vertex data to return 0. Programming Notes: VERTEX_BUFFER_STATE.Null Vertex Buffer must be set when the VERTEX_BUFFER_STATE.Buffer Size is 0x0.
	12	**Reserved** Format: MBZ
	11:0	**Buffer Pitch** Format: U12 Count of bytes This field specifies the pitch in bytes of the structures accessed within the VB. This information is required in order to access elements in the VB via a structure index.

VERTEX_BUFFER_STATE

Value	Name	Description
[0,4095]		Bytes

Programming Notes

- Different VERTEX_BUFFER_STATE structures can refer to the same memory region using different Buffer Pitch values.
- See note on 64-bit float alignment in Buffer Starting Address.

1..2 | 63:0 | **Buffer Starting Address**

Format:	GraphicsAddress[63:0]Vertex_Buffer

This field contains the byte-aligned Graphics Address LSBs of the first element of interest within the VB. Software must program this value with the combination (sum) of the base address of the memory resource and the byte offset from the base address to the starting structure within the buffer.

If the Address ModifyEnable bit is clear, this field is ignored and the previous value of Buffer Starting Address for this buffer is maintained.

Programming Notes

- 64-bit floating point values must be 64-bit aligned in memory, or UNPREDICTABLE data will be fetched. When accessing an element containing 64-bit floating point values, the Buffer Starting Address and Source Element Offset values must add to a 64-bit aligned address, and BufferPitch must be a multiple of 64-bits.
- VBs can only be allocated in linear (not tiled) graphics memory.
- As computed index values are, by definition, interpreted as unsigned values, there is no issue with accesses to locations before (lower address value) the start of the buffer. However, these wrapped indices are subject to Max Index checking (see below).

3 | 31:0 | **Buffer Size**

Format:	U32 Count of bytes

This field specifies the size of the buffer in bytes. Vertex element accesses which straddle or go past the end of the buffer will return 0's for all elements.Note that BufferSize=0 indicates that there is no valid data in the buffer.

Value	Name
[0, FFFFFFFFh]	

VERTEX_ELEMENT_STATE

VERTEX_ELEMENT_STATE

Source:	RenderCS
Size (in bits):	64
Default Value:	0x00000000, 0x00000000

Description

This structure is used in 3DSTATE_VERTEX_ELEMENTS to set the state associated with a vertex element. A vertex element is defined as an entity supplying from one to four DWord vertex components, to be stored in the vertex URB entry.

The number of supported vertex elements is 34.

The VF function will use this state, and possibly the state of the associated vertex buffer, to fetch/generate the source vertex element data, perform any required format conversions, padding with zeros, and store the resulting destination vertex element data into the vertex URB entry.

Programming Notes

- The (new) 3DSTATE_VF_SGVS command is used to specify optional insertion of VertexID and/or InstanceID into the input vertex data, logically following the processing of the VERTEX_ELEMENT_STATE structures. The VFCOMP_STORE_VID/IID encodings are no longer available in VERTEX_ELEMENT_STATE.
- When SourceElementFormat is set to one of the *64*_PASSTHRU formats, 64-bit components are stored in the URB without any conversion. In this case, vertex elements must be written as 128 or 256 bits, with VFCOMP_STORE_0 being used to pad the output as required. E.g., if R64_PASSTHRU is used to copy a 64-bit Red component into the URB, Component 1 must be specified as VFCOMP_STORE_0 (with Components 2,3 set to VFCOMP_NOSTORE) in order to output a 128-bit vertex element, or Components 1-3 must be specified as VFCOMP_STORE_0 in order to output a 256-bit vertex element. Likewise, use of R64G64B64_PASSTHRU requires Component 3 to be specified as VFCOMP_STORE_0 in order to output a 256-bit vertex element.
- When SourceElementFormat is set to one of the *64*_PASSTHRU formats then VFCOMP_STORE_SRC must be used for every valid component.
- Any SourceElementFormat of *64*_PASSTHRU cannot be used with an element which has edge flag enabled.

The SourceElementFormat needs to be a single-component format with an element which has edge flag enabled.

DWord	Bit	Description
0	31:26	**Vertex Buffer Index** Format: U6 This field specifies which vertex buffer the element is sourced from. [0,32] — Up to 33 VBs are supported

VERTEX_ELEMENT_STATE

Programming Notes

It is possible for a vertex element to include only internally-generated data (VertexID, etc.), in which case the associated vertex buffer state is ignored.

25 **Valid**

Format:	Boolean

Value	Name	Description
1h	TRUE	this vertex element is used in vertex assembly
0h	FALSE	this vertex element is not used.

24:16 **Source Element Format**

Format:	SURFACE_FORMAT

Range: Valid formats are found in the 3D Primitive Processing FormatConversion portion of the vertex fetch chapter.

Format: The encoding of this field is identical the Surface Format field of the SURFACE_STATE structure, as described in the Sampler chapter.

This field specifies the format in which the memory-resident source data for this particular vertex element is stored in the memory buffer. This only applies to elements stored with VFCOMP_STORE_SRC component control. (All other component types have an explicit format).

15 **Edge Flag Enable**

Format:	Enable

Description

When ENABLED, the source element is interpreted as an EdgeFlag for the vertex. If the source element is zero, the EdgeFlag will be set to FALSE. If the source element is non-zero, the EdgeFlag will be set to TRUE. The EdgeFlag bit will travel down the fixed function pipeline along with the vertex handle, etc. and not be stored in the vertex data like the other vertex elements. Refer to the fixed function descriptions for how this EdgeFlag affects rendering.
Edge flags are supported for the following primitive topology types only, otherwise EdgeFlagEnable must not be ENABLED.

- 3DPRIM_TRILIST*
- 3DPRIM_TRISTRIP*
- 3DPRIM_TRIFAN*
- 3DPRIM_POLYGON

If this bit is DISABLED for all valid VERTEX_ELEMENTs, the vertex will be assigned a default EdgeFlag of TRUE.

Edge flags are supported for all primitive topology types.

Programming Notes

VERTEX_ELEMENT_STATE

- This bit must only be ENABLED on the last valid VERTEX_ELEMENT structure.
- When set, Component 0 Control must be set to VFCOMP_STORE_SRC, and Component 1-3 Control must be set to VFCOMP_NOSTORE.

	14:12	**Reserved** Format: MBZ
	11:0	**Source Element Offset** Format: U12 byte offset Byte offset of the source vertex element data in the structures comprising the vertex buffer. **Value**: [0,2047] **Name**: **Programming Notes**: See note on 64-bit float alignment in Buffer Starting Address.
1	31	**Reserved** Format: MBZ
	30:28	**Component 0 Control** Format: 3D_Vertex_Component_Control Refer to the 3D_Vertex_Component_Control table below

Default Value:	0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000, 0x00000000	
DWord	**Bit**	**Description**
0	31:8	**Reserved**
	7:0	**Reserved** Format: MBZ
1	31:0	**VFE Control** This field is used by VFE depending on the mode of operation. See the following tables for details. If VFE Mode = AVC-IT or AVC-MC, this field is valid as defined in Table 1 13. If VFE Mode = VC1-IT, this field is valid as defined in Table 1 14. Otherwise, this field is reserved.
2	31:0	**Interface Descriptor Remap Table** This field contains the interface descriptor remap table entries for the first 8 kernel indices. Each table entry has 4 bits, providing a remapping range of [0, 15]. The input of this table is the Interface Descriptor Offset within the MEDIA_OBJECT or MEDIA_OBJECT_EX command. As the table is limited to map the first 16 values, any Interface Descriptor Offset greater than 15 is not remapped. Bits 31:28: Remap for index = 7 Bits 27:24: Remap for index = 6 Bits 23:20: Remap for index = 5 Bits 19:16: Remap for index = 4 Bits 15:12: Remap for index = 3 Bits 11:8: Remap for index = 2 Bits 7:4: Remap for index = 1 Bits 3:0: Remap for index = 0
3	31:0	**Interface Descriptor Remap Table (cont)** This field contains the interface descriptor remap table entries for the next 8 kernel indices (index = 8...15). Each table entry has 4 bits, providing a remapping range of [0, 15]. Bits 31:28: Remap for index = 15 Bits 27:24: Remap for index = 14 Bits 23:20: Remap for index = 13 Bits 19:16: Remap for index = 12 Bits 15:12: Remap for index = 11 Bits 11:8: Remap for index = 10

VFE_STATE_EX

		Bits 7:4: Remap for index = 9 Bits 3:0: Remap for index = 8
4	31	**Scoreboard Enable** This field enables and disables the hardware scoreboard in the Media Pipeline. If this field is cleared, hardware ignores the following scoreboard state fields. This should be enabled at all times in the state and the scoreboard enable field in the MEDIA_OBJECT command should be use instead. If this field is disabled, the scratch space pointer calculation will be incorrect and any attempt to use the scoreboard later will result in a hardware hang. **Value** / **Name** 0 — Scoreboard disabled 1 — Scoreboard enabled
	30	**Scoreboard Type** This field selects the type of scoreboard in use. This field must be zero (stalling scoreboard) **Value** / **Name** 0 — Stalling Scoreboard 1 — Reserved (for Non-stalling scoreboard)
	29:8	**Reserved** Format: MBZ
	7:0	**Scoreboard Mask** Format: Boolean Each bit indicates the corresponding dependency scoreboard is enabled. The scoreboard is based on the relative (X, Y) distance from the current threads' (X, Y) position. **Value** / **Name** / **Description** [0,7] / Bit n / Score n is enabled
5	31:28	**Scoreboard 3 Delta Y** Format: S3 Relative vertical distance of the dependent instance assigned to scoreboard 3, in the form of 2's compliment.
	27:24	**Scoreboard 3 Delta X** Format: S3 Relative horizontal distance of the dependent instance assigned to scoreboard 3, in the form of 2's compliment.

Introduction

The integrated graphics component, specifically called the Graphics Processing Unit, or GPU, resides on the same chip die as the Central Processing Unit, or CPU, and communicates with the CPU via the on-chip bus, with internal memory and with output device(s). As Intel GPUs have evolved, they now occupy a significant percentage of space on the chip, and provide customers with high performance and low-power graphics processing, eliminating the need to purchase a separate video card for most users.

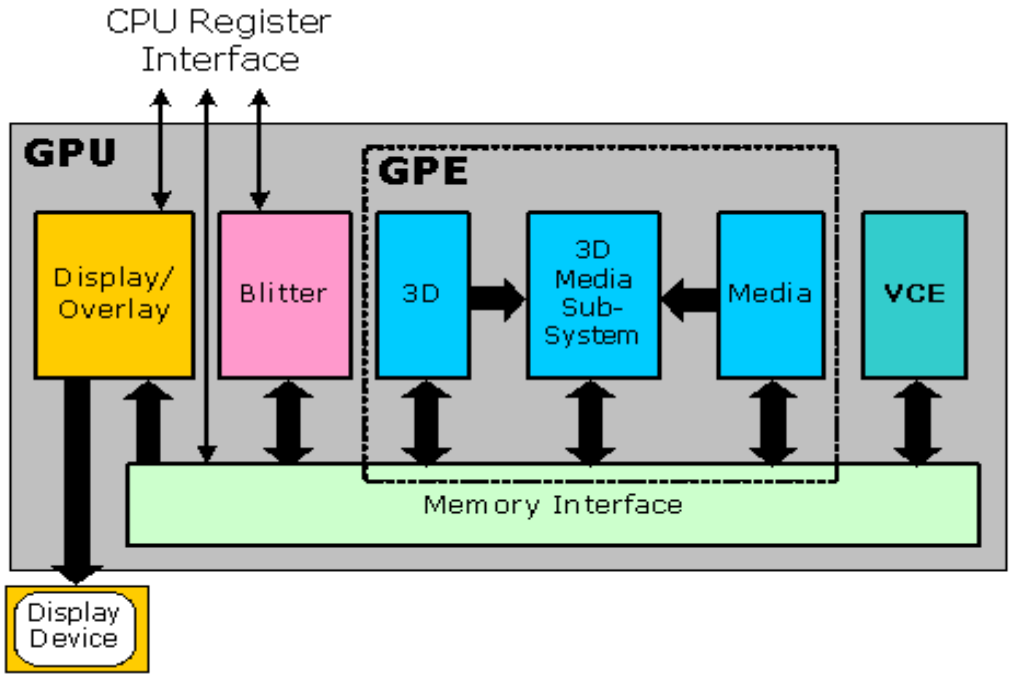
This Behavioral Specification, or BSpec for short, provides detailed narrative and referential information required by graphics device driver engineers and graphics API-level programmers to take advantage of the sophisticated architecture and programmability of the GPU.

Graphics Processing Unit (GPU)

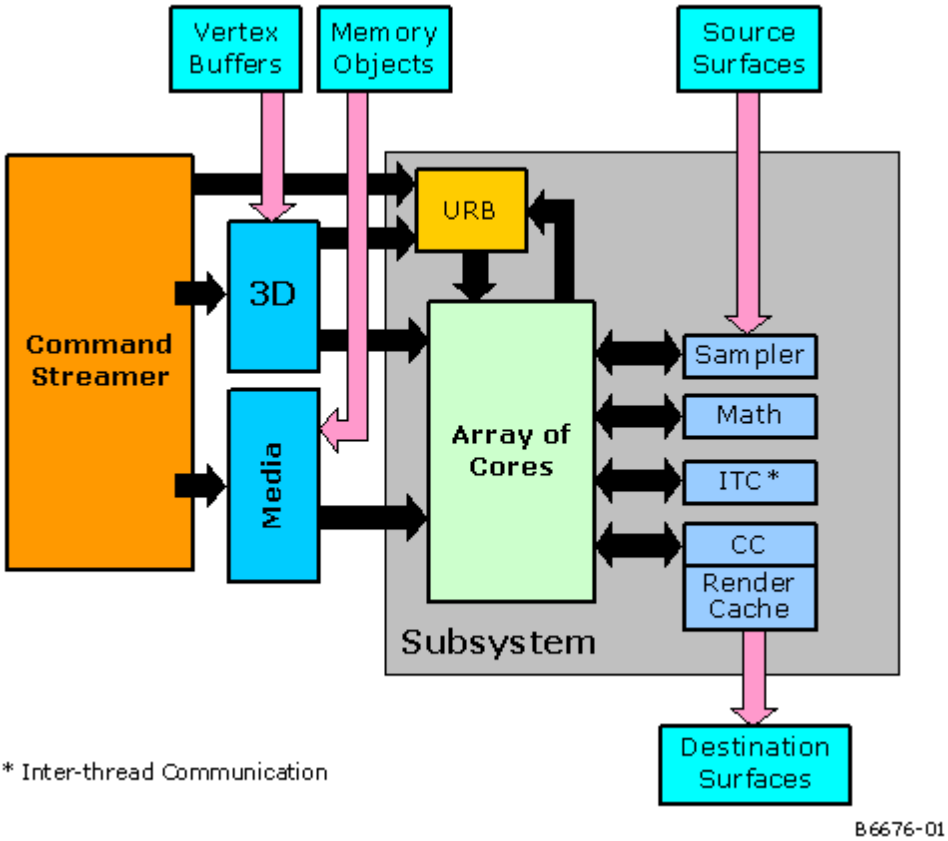
The Graphics Processing Unit is controlled by the CPU through a direct interface of memory-mapped IO registers, and indirectly by parsing commands that the CPU has placed in memory. The Display interface and Blitter (**bl**ock **i**mage **t**ransfer**er**) are controlled primarily by direct CPU register addresses, while the 3D and Media pipelines and the parallel Video Codec Engine (VCE) are controlled primarily through instruction lists in memory.

The subsystem contains an array of cores, or execution units, with a number of “shared functions”, which receive and process messages at the request of programs running on the cores. The shared functions perform critical tasks, such as sampling textures and updating the render target (usually the frame buffer). The cores themselves are described by an instruction set architecture, or ISA.

Block Diagram of the GPU



GPU Overview



The subsystem consists of an array of *execution units* (*EUs*, sometimes referred to as an array of *cores*) along with a set of *shared functions* outside the EUs that the EUs leverage for I/O and for complex computations. Programmers access the subsystem via the 3D or Media pipelines.

EUs are general-purpose programmable cores that support a rich instruction set that has been optimized to support various 3D API shader languages as well as media functions (primarily video) processing.

Shared functions are hardware units which serve to provide specialized supplemental functionality for the EUs. A shared function is implemented where the demand for a given specialized function is insufficient to justify the costs on a per-EU basis. Instead a single instantiation of that specialized function is implemented as a stand-alone entity outside the EUs and shared among the EUs.

Invocation of the shared functionality is performed via a communication mechanism called a *message*. A message is a small self-contained packet of information created by a kernel and directed to a specific shared function. The message is defined by a range of MRF registers that hold message operands, a destination shared function ID, a function-specific encoding of the desired operation, and a destination GRF register to which any writeback response is to be directed. Messages are dispatched to the shared function under software control via the send instruction. This instruction identifies the contents of the message and the GRF register locations to direct any response.

The message construction and delivery mechanisms are general in their definition and capable of supporting a wide variety of shared functions.

Command Stream (CS) Unit

The Command Stream (CS) unit manages the use of the 3D and Media pipelines; it performs switching between pipelines and forwarding command streams to the currently active pipeline. It manages allocation of the URB and helps support the Constant URB Entry (CURBE) function.

3D Pipeline

The 3D Pipeline provides specialized 3D primitive processing functions. These functions are provided by a pipeline of "fixed function" stages (units) and GEN threads spawned by these units. See *3D Pipeline Overview*.

Media Pipeline

The Media pipeline provides both specialized media-related processing functions and the ability to perform more general ("generic") functionality. These Media-specific functions are provided by a Video Front End (VFE) unit. A Thread Spawner (TS) unit is utilized to spawn GEN threads requested by the VFE unit, or as required when the pipeline is used for general processing. See *Media Pipeline Overview*.

Thread Dispatching

When the 3D and Media pipelines send requests for thread initiation to the Subsystem, the thread Dispatcher receives the requests. The dispatcher performs such tasks as arbitrating between concurrent requests, assigning requested threads to hardware threads on EUs, allocating register space in each EU among multiple threads, and initializing a thread's registers with data from the fixed functions and from the URB. This operation is largely transparent to software.

Execution Units (EUs)

The Execution Units (EUs) are the programmable shader units of the Gen Architecture. Each is a stand-alone programmable computational unit used for execution of 3D shaders and media/gpgpu kernels. Internally each is capable of multi-issue SIMD execution, and their hardware multi-threaded operation provides a very high-efficiency execution environment in the face of long data latencies typically associated with memory accesses. Each hardware thread within an EU has a dedicated large-capacity high-bandwidth register file (GRF) and associated independent thread-state. Execution is multi-issue per clock to pipelines capable of integer, single and double precision floating point operations, SIMD branch capability, logical operations, transcendental operations, and other miscellaneous operations. Communication to support units (shared functions) for operations such as texture sampling or scatter/gather load/stores is via 'messages' programmatically constructed and 'sent' to those functions, with dependency hardware causing the issuing thread to sleep until the requested data has been returned.

EU instance count varies by product generation, as well as by SKU within a given generation, and their capabilities have evolved over the many generation of the Gen Architecture.. Please see "Device Attributes" in the "Configuration" chapter for specific rates and capacities associated with Execution Units.

Shared Functions

Shared functions are hardware units that provide specialized supplemental functionality for the EUs. A shared function is implemented where the demand for a given specialized function is insufficient to justify the costs on a per-EU basis. Instead a single instantiation of that specialized function is implemented as a stand-alone entity outside the EUs and shared among the EUs.

Invocation of the shared functionality is performed via a communication mechanism called a message. A message is a small self-contained packet of information created by a kernel and directed to a specific shared function.

Programming Note	
Context:	Communication mechanism in shared functions
The message is defined by a range of Message Register File (MRF) registers that hold message operands, a destination shared function ID, a function-specific encoding of the desired operation, and a destination General Register File (GRF) register to which any writeback response is directed.	

Messages are dispatched to the shared function under software control via the *send* instruction. This instruction identifies the contents of the message and the GRF register locations to direct any response.

The message construction and delivery mechanisms are general in their definition and capable of supporting a wide variety of shared functions.

Fixed and Shared Function IDs

The following lists the assignments (encodings) of the Shared Function and Fixed Function IDs used within the GPE. A Shared Function is a valid target of a message initiated via a *send* instruction. A Fixed Function is an identifiable unit of the 3D or Media pipeline. Note that the Thread Spawner is both a Shared Function and Fixed Function.

Function IDs

[Enumeration] Fixed Function ID
[Enumeration] Shared Function ID

Register Address Maps

Graphics Register Address Map

This chapter provides address maps of the graphics controllers I/O and memory-mapped registers. Individual register bit field descriptions are provided in the following chapters. PCI configuration address maps and register bit descriptions are provided in the following chapter.

Memory and IO Space Registers

These are graphics MMIO ranges. Note that this is only a subset of the complete definition of the MMIO address space.

Range Start (Hex)	Range End (Hex)	Unit Owning the Range
00002000	00002FFF	Render/Generic Media Engine
00004000	00004FFF	Render/Generic Media Graphics Memory Arbiter

Indirect VGA and Extended VGA Register Indices

The registers listed in this section are indirectly accessed by programming an index value into the appropriate SRX, GRX, ARX, or CRX register. The index and data register address locations are listed in the previous section. Additional details concerning the indirect access mechanism are provided in the *VGA and Extended VGA Register Description* Chapter (see SRxx, GRxx, ARxx or CRxx sections).

2D Sequence Registers (3C4h / 3C5h)

Index	Sym	Description
00h	SR00	Sequencer Reset
01h	SR01	Clocking Mode
02h	SR02	Plane / Map Mask
03h	SR03	Character Font
04h	SR04	Memory Mode
07h	SR07	Horizontal Character Counter Reset

2D Graphics Controller Registers (3CEh / 3CFh)

Index	Sym	Register Name
00h	GR00	Set / Reset
01h	GR01	Enable Set / Reset
02h	GR02	Color Compare

Memory Object Overview

Any memory data accessed by the device is considered part of a *memory object* of some memory object type.

The following table lists the various memory objects types and an indication of their role in the system.

Memory Object Type	Role
Graphics Translation Table (GTT)	Contains PTEs used to translate "graphics addresses" into physical memory addresses.
Hardware Status Page	Cached page of sysmem used to provide fast driver synchronization.
Logical Context Buffer	Memory areas used to store (save/restore) images of hardware rendering contexts. Logical contexts are referenced via a pointer to the corresponding Logical Context Buffer.
Ring Buffers	Buffers used to transfer (DMA) instruction data to the device. Primary means of controlling rendering operations.
Batch Buffers	Buffers of instructions invoked indirectly from Ring Buffers.
State Descriptors	Contains state information in a prescribed layout format to be read by hardware. Many different state descriptor formats are supported.
Vertex Buffers	Buffers of 3D vertex data indirectly referenced through "indexed" 3D primitive instructions.
VGA Buffer (Must be mapped UC on PCI)	Graphics memory buffer used to drive the display output while in legacy VGA mode.
Display Surface	Memory buffer used to display images on display devices.
Overlay Surface	Memory buffer used to display overlaid images on display devices.
Overlay Register, Filter Coefficients	Memory area used to provide double-buffer for Overlay register and filter coefficient loading.
Cursor Surface	Hardware cursor pattern in memory.
2D Render Source	Surface used as primary input to 2D rendering operations.
2D Render R-M-W Destination	2D rendering output surface that is read in order to be combined in the rendering function. Destination surfaces that accessed via this Read-Modify-Write mode have somewhat different restrictions than Write-Only Destination surfaces.
2D Render Write-Only Destination	2D rendering output surface that is written but not read by the 2D rendering function. Destination surfaces that accessed via a Write-Only mode have somewhat different restrictions than Read-Modify-Write Destination surfaces.
2D Monochrome Source	1 bpp surfaces used as inputs to 2D rendering after being converted to foreground/background colors.
2D Color Pattern	8x8 pixel array used to supply the "pattern" input to 2D rendering functions.
DIB	"Device Independent Bitmap" surface containing "logical" pixel values that are converted (via LUTs) to physical colors.

Memory Object Type	Role
3D Color Buffer	Surface receiving color output of 3D rendering operations. May also be accessed via R-M-W (aka blending). Also referred to as a Render Target.
3D Depth Buffer	Surface used to hold per-pixel depth and stencil values used in 3D rendering operations. Accessed via RMW.
3D Texture Map	Color surface (or collection of surfaces) which provide texture data in 3D rendering operations.
"Non-3D" Texture	Surface read by Texture Samplers, though not in normal 3D rendering operations (for example, in video color conversion functions).
Motion Comp Surfaces	These are the Motion Comp reference pictures.
Motion Comp Correction Data Buffer	This is Motion Comp intra-coded or inter-coded correction data.

Hardware Status Page

The hardware status page is a naturally-aligned 4KB page residing in snooped system memory. This page exists primarily to allow the device to report status via PCI master writes – thereby allowing the driver to read/poll WB memory instead of UC reads of device registers or UC memory.

The address of this page is programmed via the HWS_PGA MI register. The definition of that register (in *Memory Interface Registers*) includes a description of the layout of the Hardware Status Page.

Memory Access Indirection

The GPE supports the indirection of certain graphics (GTT-mapped) memory accesses. This support comes in the form of two *base address* state variables used in certain memory address computations with the GPE.

The intent of this functionality is to support the dynamic relocation of certain driver-generated memory structures after command buffers have been generated but prior to the their submittal for execution. For example, as the driver builds the command stream it could append pipeline state descriptors, kernel binaries, etc. to a general state buffer. References to the individual items would be inserted in the command buffers as offsets from the base address of the state buffer. The state buffer could then be freely relocated prior to command buffer execution, with the driver only needing to specify the final base address of the state buffer. Two base addresses are provided to permit surface-related state (binding tables, surface state tables) to be maintained in a state buffer separate from the general state buffer.

While the use of these base addresses is unconditional, the indirection can be effectively disabled by setting the base addresses to zero. The following table lists the various GPE memory access paths and which base address (if any) is relevant.

Base Address Utilization

Base Address Used	Memory Accesses
General State Base Address	**DataPort Read/Write DataPort memory accesses resulting from 'stateless' DataPort Read/Write requests. See** *DataPort* **for a definition of the 'stateless' form of requests.**
Dynamic State Base Address	Sampler reads of SAMPLER_STATE data and associated SAMPLER_BORDER_COLOR_STATE.
	Viewport states used by CLIP, SF, and WM/CC
	COLOR_CALC_STATE, DEPTH_STENCIL_STATE, and BLEND_STATE
	Push Constants (depending on state of **INSTPM<CONSTANT_BUFFER Address Offset Disable>**)
Instruction Base Address	**Normal EU instruction stream** (non-system routine)
	System routine EU instruction stream (starting address = SIP)
Surface State Base Address	Sampler and DataPort reads of BINDING_TABLE_STATE, as referenced by BT pointers passed via 3DSTATE_BINDING_TABLE_POINTERS
	Sampler and DataPort reads of SURFACE_STATE data
Indirect Object Base Address	**MEDIA_OBJECT Indirect Data** accessed by the CS unit .
None	CS unit reads from **Ring Buffers**, **Batch Buffers**
	CS writes resulting from PIPE_CONTROL command
	All VF unit memory accesses (**Index Buffers**, **Vertex Buffers**)
	All Sampler **Surface Memory Data** accesses (texture fetch, etc.)
	All **DataPort memory accesses**except 'stateless' DataPort Read/Write requests (e.g., RT accesses.) See *DataPort* for a definition of the 'stateless' form of requests.
	Memory reads resulting from **STATE_PREFETCH** commands
	Any **physical memory access** by the device
	GTT-mapped accesses not included above (i.e., default)
	Push Constants (depeding on state of **INSTPM<CONSTANT_BUFFER Address Offset Disable>**)

The following notation is used in the BSpec to distinguish between addresses and offsets:

Notation	Definition
PhysicalAddress[n:m]	Corresponding bits of a physical graphics memory byte address (not mapped by a GTT)
GraphicsAddress[n:m]	Corresponding bits of an absolute, virtual graphics memory byte address (mapped by a GTT)
GeneralStateOffset[n:m]	Corresponding bits of a relative byte offset added to the General State Base Address value, the result of which is interpreted as a virtual graphics memory byte address (mapped by a GTT)
DynamicStateOffset[n:m]	Corresponding bits of a relative byte offset added to the Dynamic State Base Address value, the result of which is interpreted as a virtual graphics memory byte address (mapped by a GTT)

Notation	Definition
InstructionBaseOffset[n:m]	Corresponding bits of a relative byte offset added to the Instruction Base Address value, the result of which is interpreted as a virtual graphics memory byte address (mapped by a GTT)
SurfaceStateOffset[n:m]	Corresponding bits of a relative byte offset added to the Surface State Base Address value, the result of which is interpreted as a virtual graphics memory byte address (mapped by a GTT)

Instruction Ring Buffers

Instruction ring buffers are the memory areas used to pass instructions to the device. Refer to the Programming Interface chapter for a description of how these buffers are used to transport instructions.

The RINGBUF register sets (defined in Memory Interface Registers) are used to specify the ring buffer memory areas. The ring buffer must start on a 4KB boundary and be allocated in linear memory. The length of any one ring buffer is limited to 2MB.

Programming Note	
Context:	Instruction Ring Buffers in memory areas.
"Indirect" 3D primitive instructions (those that access vertex buffers) must reside in the same memory space as the vertex buffers.	

Instruction Batch Buffers

Instruction batch buffers are contiguous streams of instructions referenced via an MI_BATCH_BUFFER_START and related instructions (see Memory Interface Instructions, Programming Interface). They are used to transport instructions external to ring buffers.

Programming Note	
Context:	Instruction batch buffers in memory objects
Batch buffers can be tagged with any memory type when produced by IA. If WB memory type is used, it should be tagged with "snoop required" for GPU consumption (to trigger snoop from CPU cache).	

Programming Note	
Context:	Instruction batch buffers in memory objects
The batch buffer must be QWord aligned and a multiple of QWords in length. The ending address is the address of the last valid QWord in the buffer. The length of any single batch buffer is "virtually unlimited" (i.e., could theoretically be 4GB in length).	

Logical Contexts

This section is the lead section for the following subsections:

- BSD Logical Render Context Address (LRCA)
- Video Enhancement Logical Context Data
- Logical Contexts

BSD Logical Render Context Address (LRCA)

This section discusses the following topics for the BSD Logical Render Context Address (LRCA):

- Overall Context Layout
- Register State Context
- Ring Buffer
- Ring Context
- The Per-Process Hardware Status Page
- Video Engine Power Context

Overall Context Layout [

When Execlists are enabled, the Context Image for the media engine consists of two 4K pages:

- Per-Process HW Status Page (4K)
- Register State Context

When Execlists are disabled (ring buffer mode of scheduling) there is no concept of context for workloads submitted to the media engine, and hence there is no context image.

Register State context is explained in detail in the “Register State Context” Section.

Ring Buffer

Ring Buffer can exist anywhere in memory mapped via Global GTT. Ring buffer details are mentioned in the ring context area of LRCA (Ring Buffer - Start Address, Head Offset, Tail Pointer & Control Register) in the Execution List mode of scheduling.

Programming Note	
Context:	Ring buffers - ring context area of LRCA
Ring Buffer registers are directly programmed in the Ring Buffer mode of scheduling.	

Ring Context

Ring Context starts at 4K offset from LRCA. Ring context contains all the details that are needed to be initialized by SW for submitting a context to HW for execution (Ring Buffer Details, Page Directory Information ..etc). Ring context is five cachelines in size.

Programming Note	
Context:	Submitting a context to HW for execution.
The last cacheline of the ring context is specific for a given Engine and hence SW needs to populate it accordingly.	

Ring Context comprises of the EXECLIST CONTEXT, EXECLIST CONTEXT (PPGTT Base) of the register state context. In Ring Buffer mode of scheduling EXECLIST CONTEXT contents are save/restored as NOOPS by HW.

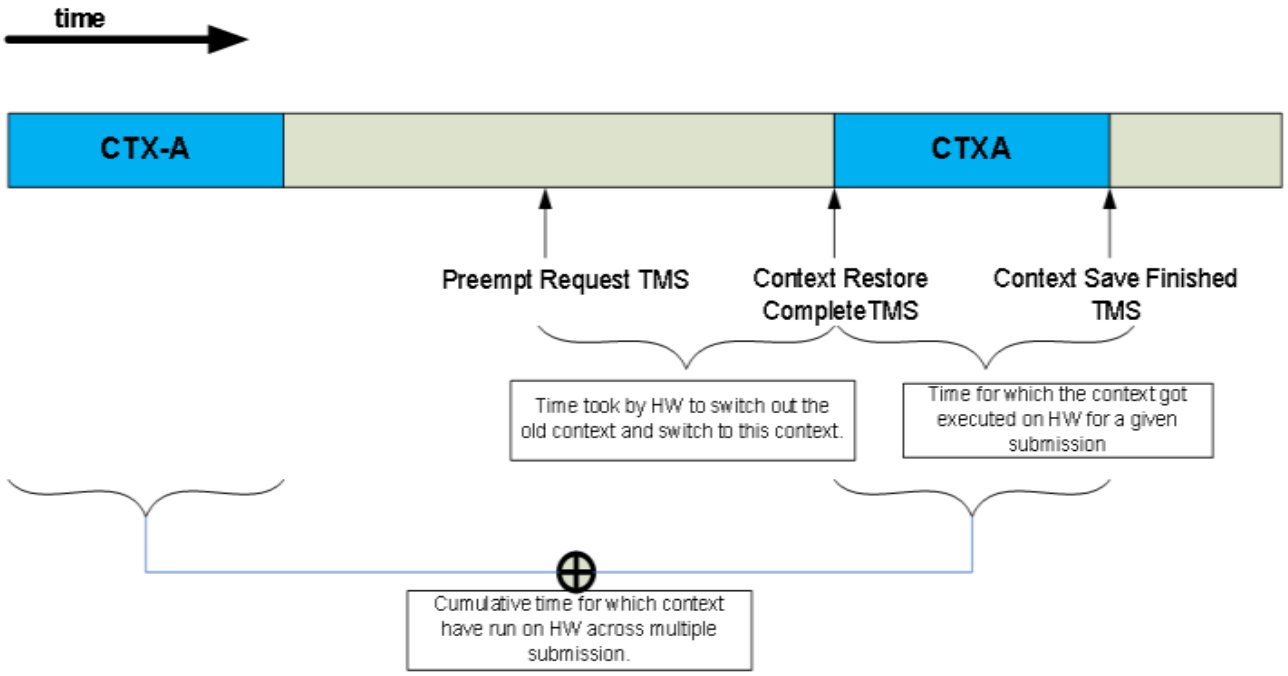
EXECLIST CONTEXT
EXECLIST CONTEXT(PPGTT Base)

The Per-Process Hardware Status

The layout of the Per-Process Hardware Status Page is defined at **PPHWSP_LAYOUT**.

The DWord offset values in the table are in decimal.

The figure below explains the different timestamp values reported to PPHWSP on a context switch.



This page is designed to be read by SW to glean additional details about a context beyond what it can get from the context status.

Accesses to this page are automatically treated as cacheable and snooped. It is therefore illegal to locate this page in any region where snooping is illegal (such as in stolen memory).

Video Engine Power Context

The table below captures the data from VCS power context save/restored by PM. Address offset in the below table is relative to the starting location of VCS in the overall power context image managed by PM.

Ring Buffer

Ring Buffer can exist anywhere in memory mapped via Global GTT. Ring buffer details are mentioned in the ring context area of LRCA (Ring Buffer - Start Address, Head Offset, Tail Pointer & Control Register) in

Execution List mode of scheduling. Ring Buffer registers are directly programmed in Ring Buffer mode of scheduling.

Ring Context

Ring Context starts at 4K offset from LRCA. Ring context contains all the details that are needed to be initialized by SW for submitting a context to HW for execution (Ring Buffer Details, Page Directory Information ..etc). Ring context is five cachelines in size.

Programming Note	
Context:	Submitting a context to HW for execution
The last cacheline of the ring context is specific for a given Engine and hence SW needs to populate it accordingly.	

Ring Context comprises of the EXECLIST CONTEXT, EXECLIST CONTEXT (PPGTT Base) of the register state context. In Ring Buffer mode of scheduling EXECLIST CONTEXT contents are save/restored as NOOPS by HW.

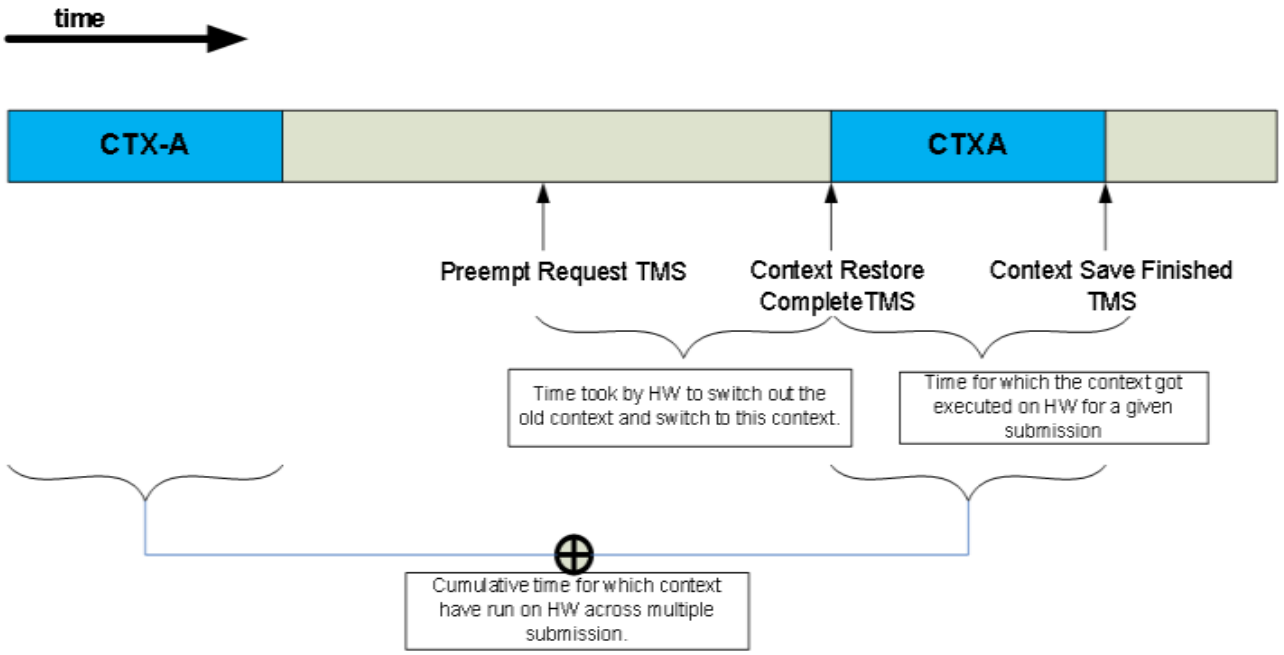
EXECLIST CONTEXT
EXECLIST CONTEXT(PPGTT Base)

The Per-Process Hardware Status Page

The layout of the Per-Process Hardware Status Page is defined at **PPHWSP_LAYOUT**.

The DWord offset values in the table are in decimal.

The figure below explains the different timestamp values reported to PPHWSP on a context switch.



This page is designed to be read by SW to glean additional details about a context beyond what it can get from the context status.

Accesses to this page are automatically treated as cacheable and snooped. It is therefore illegal to locate this page in any region where snooping is illegal (such as in stolen memory).

Blitter Engine Power Context

The table below captures the data from BCS power context save/restored by PM. Address offset in the below table is relative to the starting location of BCS in the overall power context image managed by PM.

Video Enhancement Logical Context Data

Context Layout

When Execlists are enabled, the Context Image for the Video Enhancement engine consists of two 4K pages:

- Per-Process HW Status Page (4K)
- Register State Context

When Execlists are disabled (ring buffer mode of scheduling) there is no concept of context for workloads submitted to media engine and hence there is no context image.

Register State context is explained in detail in the “Register State Context” Section.

Ring Context

Ring Context starts at 4K offset from LRCA. Ring context contains all the details that are needed to be initialized by SW for submitting a context to HW for execution (Ring Buffer Details, Page Directory Information ..etc). Ring context is five cachelines in size.

Programming Note	
Context:	Submitting a context to HW for execution
The last cacheline of the ring context is specific for a given Engine and hence SW needs to populate it accordingly.	

Ring Context comprises of the EXECLIST CONTEXT, EXECLIST CONTEXT (PPGTT Base) of the register state context. In Ring Buffer mode of scheduling EXECLIST CONTEXT contents are save/restored as NOOPS by HW.

Memory Data Formats

This chapter describes the attributes associated with the memory-resident data objects operated on by the graphics pipeline. This includes object types, pixel formats, memory layouts, and rules/restrictions placed on the dimensions, physical memory location, pitch, alignment, etc. with respect to the specific operations performed on the objects.

Unsigned Normalized (UNORM)

An unsigned normalized value with *n* bits is interpreted as a value between 0.0 and 1.0. The minimum value (all 0's) is interpreted as 0.0, the maximum value (all 1's) is interpreted as 1.0. Values in between are equally spaced. For example, a 2-bit UNORM value would have the four values 0, 1/3, 2/3, and 1.

If the incoming value is interpreted as an n-bit integer, the interpreted value can be calculated by dividing the integer by 2^n-1.

Gamma Conversion (SRGB)

Gamma conversion is only supported on UNORM formats. If this flag is included in the surface format name, it indicates that a reverse gamma conversion is to be done after the source surface is read, and a forward gamma conversion is to be done before the destination surface is written.

Signed Normalized (SNORM)

Programming Note	
Context:	Signed normalized value in memory data formats.
A signed normalized value with *n* bits is interpreted as a value between -1 and +1.0. If the incoming value is interpreted as a 2's-complement n-bit integer, the interpreted value can be calculated by dividing the integer by 2^{n-1}-1. The most negative value of -2^{n-1} will result in a value slightly smaller than -1.0. This value is clamped to -1.0; thus, there are two representations of -1.0 in SNORM format.	

Unsigned Integer (UINT/USCALED)

The UINT and USCALED formats interpret the source as an unsigned integer value with *n* bits with a range of 0 to 2^n-1.

The UINT formats copy the source value to the destination (zero-extending if required), keeping the value as an integer.

The USCALED formats convert the integer into the corresponding floating point value (e.g., 0x03 --> 3.0f). For 32-bit sources, the value is rounded to nearest even.

Signed Integer (SINT/SSCALED)

A signed integer value with *n* bits is interpreted as a 2's complement integer with a range of -2^{n-1} to $+2^{n-1}-1$.

The SINT formats copy the source value to the destination (sign-extending if required), keeping the value as an integer.

The SSCALED formats convert the integer into the corresponding floating point value (e.g., 0xFFFD --> -3.0f). For 32-bit sources, the value is rounded to nearest even.

Floating Point (FLOAT)

Refer to IEEE Standard 754 for Binary Floating-Point Arithmetic. The IA-32 Intel (R) Architecture Software Developer's Manual also describes floating point data types .

64-bit Floating Point

Bit	Description
63	**Sign (s)**
62:52	**Exponent (e)** Biased Exponent
51:0	**Fraction (f)** Does not include "hidden one"

The value of this data type is derived as:

- if e == b'11..11' and f != 0, then v is NaN regardless of s
- if e == b'11..11' and f == 0, then v = $(-1)^s$*infinity (signed infinity)
- if 0 < e < b'11..11', then v = $(-1)^s*2^{(e-1023)}*(1.f)$
- if e == 0 and f != 0, then v = $(-1)^s*2^{(e-1022)}*(0.f)$ (denormalized numbers)
- if e == 0 and f == 0, then v = $(-1)^s$*0 (signed zero)

32-bit Floating Point

Bit	Description
31	**Sign (s)**
30:23	**Exponent (e)** Biased Exponent
22:0	**Fraction (f)** Does not include "hidden one"

The value of this data type is derived as:

- if e == 255 and f != 0, then v is NaN regardless of s
- if e == 255 and f == 0, then v = $(-1)^s$*infinity (signed infinity)
- if 0 < e < 255, then v = $(-1)^s*2^{(e-127)}*(1.f)$
- if e == 0 and f != 0, then v = $(-1)^s*2^{(e-126)}*(0.f)$ (denormalized numbers)
- if e == 0 and f == 0, then v = $(-1)^s$*0 (signed zero)

16-bit Floating Point

Bit	Description
15	**Sign (s)**
14:10	**Exponent (e)** Biased Exponent
9:0	**Fraction (f)** Does not include "hidden one"

The value of this data type is derived as:

- if e == 31 and f != 0, then v is NaN regardless of s
- if e == 31 and f == 0, then v = $(-1)^s$*infinity (signed infinity)
- if 0 < e < 31, then v = $(-1)^s*2^{(e-15)}*(1.f)$
- if e == 0 and f != 0, then v = $(-1)^s*2^{(e-14)}*(0.f)$ (denormalized numbers)
- if e == 0 and f == 0, then v = $(-1)^s*0$ (signed zero)

The following table represents relationship between 32 bit and 16 bit floating point ranges:

flt32 exponent	Unbiased exponent	Normalization	flt16 exponent	flt16 fraction
255				
254	127			
...				
127+16	16	Infinity	31	1.1111111111
127+15	15	Max exponent	30	1.xxxxxxxxxx
127	0		15	1.xxxxxxxxxx
113	-14	Min exponent	1	1.xxxxxxxxxx
112		Denormalized	0	0.1xxxxxxxxx
111		Denormalized	0	0.01xxxxxxxx
110		Denormalized	0	0.001xxxxxxx
109		Denormalized	0	0.0001xxxxxx
108		Denormalized	0	0.00001xxxxx
107		Denormalized	0	0.000001xxxx
106		Denormalized	0	0.0000001xxx
115		Denormalized	0	0.00000001xx
114		Denormalized	0	0.000000001x
113		Denormalized	0	0.0000000001
112		Denormalized	0	0.0
...				
0			0	0.0

Conversion from the 32-bit floating point format to the 16-bit format should be done with round to nearest even.

11-bit Floating Point

Bits	Description
10:6	**Exponent (e):** Biased exponent (the bias depends on e)
5:0	**Fraction (f):** Fraction bits to the right of the binary point

The value v of an 11-bit floating-point number is calculated from e and f as:

- if e == 31 and f != 0 then v = NaN
- if e == 31 and f == 0 then v = +infinity
- if 0 < e < 31, then v = $2^{(e-15)}$*(1.f)
- if e == 0 and f != 0, then v = $2^{(e-14)}$*(0.f) (denormalized numbers)
- if e == 0 and f == 0, then v = 0 (zero)

There is no sign bit and negative values are not represented.

The 11-bit floating-point format has one more bit of fractional precision than the 10-bit floating-point format.

The maximum representable finite value is 1.111111b * 2^{15} = FE00h = 65024.

10-bit Floating Point

Bits	Description
9:5	**Exponent (e):** Biased exponent (the bias depends on e)
4:0	**Fraction (f):** Fraction bits to the right of the binary point

The value v of a 10-bit floating-point number is calculated from e and f as:

- if e == 31 and f != 0 then v = NaN
- if e == 31 and f == 0 then v = +infinity
- if 0 < e < 31, then v = $2^{(e-15)}$*(1.f)
- if e == 0 and f != 0, then v = $2^{(e-14)}$*(0.f) (denormalized numbers)
- if e == 0 and f == 0, then v = 0 (zero)

There is no sign bit and negative values are not represented.

The maximum representable finite value is 1.11111b * 2^{15} = FC00h = 64512.

Shared Exponent

The R9G9B9E5_SHAREDEXP format contains three channels that share an exponent. The three fractions assume an impled "0" rather than an implied "1" as in the other floating point formats. This format does not support infinity and NaN values. There are no sign bits, only positive numbers and zero can be represented. The value of each channel is determined as follows, where "f" is the fraction of the corresponding channel, and "e" is the shared exponent.

$v = (0.f)*2^{(e-15)}$

Bit	Description
31:27	**Exponent (e)** Biased Exponent
26:18	**Blue Fraction**
17:9	**Green Fraction**
8:0	**Red Fraction**

Memory Compression

Media Memory Compression

The software requirement when using media memory compression is to allocate each compressible surface one memory tile wider than is required based on the surface width plus normal byte padding (this approach is called "pitch+1"). The reason is each compressible surface needs an "extra" tile to the right edge of surface to store important compression control information. For example, if the surface is 1920x1088, this would normally be allocated by the driver to be 2048 bytes wide, or 16 tiles (for NV12 8bpp). Using this "pitch + 1", the pitch would be set to 17 instead of 16 (and the surface width remains unchanged, only pitch is increased).

The largest supported width will be 4K pixels for 2D RGBA 8bpp surfaces and 2x2K for S3D surfaces (for 4KB pages). E.g. the pitch would be set to 129 in these cases (128+1). NV12 4K would be 33 (28+1). The case of 64KB pages is the same: the driver will allocate 1 extra page to the right ("pitch + 1"), however now the 4K wide restriction is relaxed. With 64KB pages, the widest surface that supports memory compression is 16K for 2D RGBA 8bpp or 2x8K for S3D. E.g. the pitch would be set to 129 in these cases (128+1).

Steppings and Device IDs 10

Configurations Overview

The Intel "Gen" Graphics Architecture was first introduced to the market in 2004. Since that time, the architecture and implementation have evolved to add many new features, increase performance, and improve power efficiency.

Each product generation has its own configurations chapter. Each chapter has a section for each project, and each project contains the following subsections:

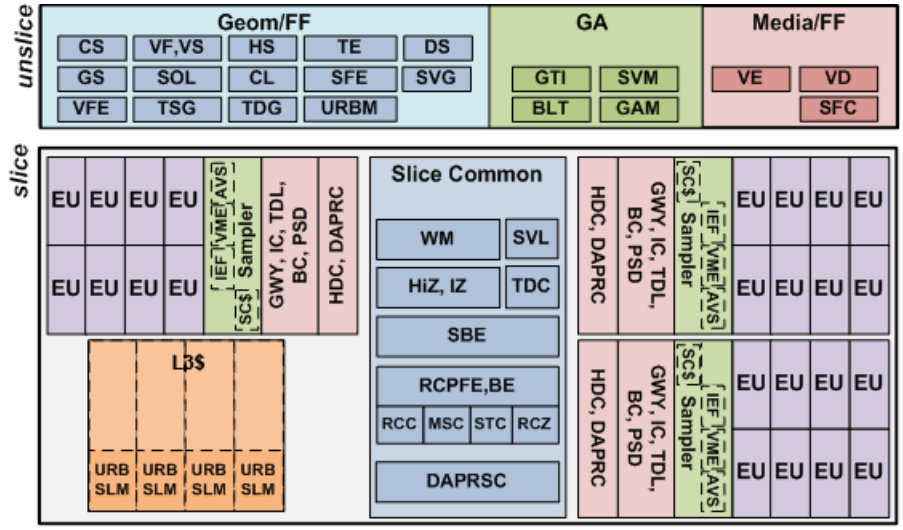
- Top Level Block Diagrams - Show basic feature blocks of the project's graphics architecture, for GT configurations.
- Device Attributes - List details of the graphics configuration options for each project.
- Steppings and Device IDs - Lists all of the current unique GT Die / Packages for a specific project.

Top Level Block Diagrams

The diagrams below show basic feature blocks of the Kaby Lake (KBL) graphics architecture.

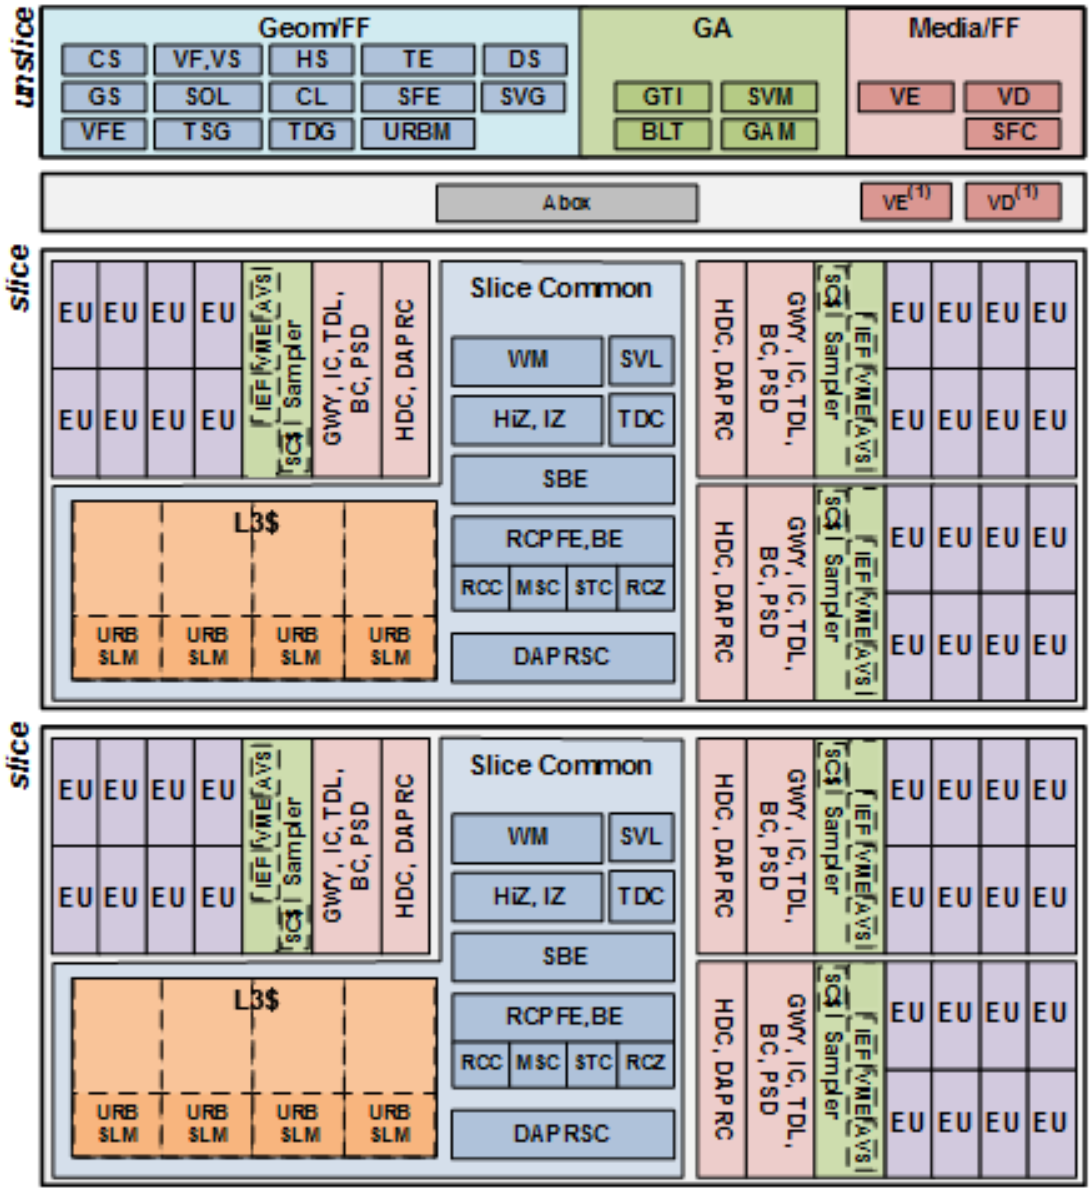
GT2 Configuration

The GT2 configuration contains one Unslice and one Slice with separate power domains for each, although they share a single clock domain.



GT3 Configuration

The GT3 configuration has an identical Unslice to GT2, except that it contains two Slices. Separate clock domains for the Unslice and Slice may be available depending on SKU. The L3 caches of each Slice combine to provide an aggregate L3 cache of twice the size and twice the bandwidth of a single instance. GT3 also has additional media blocks with second instance of VEBox and VDBox each.



This diagram is based on the following functional partitions:

(a) Geometry Fixed Functions (Geom/FF)

(b) Media Fixed Functions (Media/FF)

(c) Global Assets and GT Interface (GA)

(d) One or more Subslices (three shown)

(e) A Slice Common block

(f) An L3 Cache (L3$) block

Note that the combination of (a), (b), and (c) is typically referred to as the “unslice”, while a combination of (d), (e), and (f) is referred to as a compute “slice”.

The functionality in each of these groupings is further broken down as follows:

- Unslice – Fixed function pipelines for 3D, GPGPU, and Media operations, and interface to the outside world.
    - The 3D Geometry / Fixed Function (Geom/FF) block consisting of:
        - 3D fixed function pipeline (CS, VFVS, HS, TE, DS, GS, SOL, SL, SFE, SVG)
        - Video Front-End unit (VFE)
        - Thread Spawner unit (TSG) and the global Thread Dispatcher unit (TDG)
        - Unified Return Buffer Manager (URBM)
        -
    - Media fixed function assets:
        - Video Decode (VD) Box
        - Video Encode (VE) Box
        - Scaler & Format Converter (SFC)
    - The Global Assets (GA) block as the primary interface and memory stream gateway to the outside world, consisting of:
        - GT Interface (GTI)
        - State Variable Manager (SVM)
        - Blitter (BLT)
        - Graphics Arbiter (GAM)
- Subslice (three shown) – A compute unit with supporting fixed- or shared-function assets sufficient for the EU capability.
    - A bank of Execution Units (EUs) – eight per subslice shown
    - Sampler, supporting both media and 3D functions
    - Gateway (GWY)
    - Instruction cache (IC)
    - Local Thread Dispatcher (TDL)
    - Barycentric Calculator (BC)
    - Pixel Shader Dispatcher (PSD)
    - Data Cluster (HDC)
    - Dataport Render Cache (DAPRC) - two per subslice
- Slice Common – Scalable fixed function assets which support the compute horsepower provided two or more subslices.
    - 3D Fixed Function:
        - Windower/Mask unit (WM)
        - Hi-Z (HZ) and Intermediate Z (IZ)
        - Setup Backend (SBE)

        - RCPFE, BE
        - 3D stream caches (RCC, MSC, STC, RCZ)
    - Media Fixed Functions:
        - DAPRSC
        - SVL
        - TDC
- L3 Cache – backing L3 cache for certain memory streams emanating from subslices.
    - L3 Data cache with support for data, URB, and shared local memory (SLM)

Device Attributes

The following table lists detailed GT device attributes for proposed KBL SKUs.

NOTE: This information is preliminary, and subject to change.

Product Configuration Attribute Table				
Product Family	**KBL**			
Architectural Name *	**1x2x6**	**1x3x6**	**1x3x8**	**2x3x8**
SKU Name	**GT1F**	**GT1.5F**	**GT2**	**GT3**
Global Attributes				
Slice count	1	1	1	2
Subslice Count	2	3	3	6
EU/Subslice	6	6	8	8
EU count (total)	12	18	23 / 24 [b]	47 / 48 [b]
Thread Count	7	7	7	7
Thread Count (Total)	84	126	161 / 168	329 / 336
FLOPs/Clk - Half Precision, MAD (peak)	384	576	736 / 768	1504 / 1536
FLOPs/Clk - Single Precision, MAD (peak)	192	288	368 / 384	752 / 768
FLOPs/Clk - Double Precision, MAD (peak)	48	72	92 / 96	188 / 192
Unslice clocking (coupled/decoupled from Cr slice)	coupled	coupled	coupled	coupled
GTI / Ring Interfaces	1	1	1	1
GTI bandwidth (bytes/unslice-clk)	64: R	64: R	64: R	64: R
	64: W	64: W	64: W	64: W
eDRAM Support	N/A	N/A	N/A	0, 64MB
Graphics Virtual Address Range	48 bit	48 bit	48 bit	48 bit
Graphics Physical Address Range	39 bit	39 bit	39 bit	39 bit
Caches & Dedicated Memories				
L3 Cache, total size (bytes)	384K	768K	768K	1536K

Atomic Operations between GPU and IA 348

Introduction

The hardware supports three engines:

- The Render command streamer interfaces to 3D/IE and display streams.
- The Media command streamer interfaces to the fixed function media.
- The Blitter command streamer interfaces to the blit commands.

Software interfaces of all three engines are very similar and should only differ on engine-specific functionality.

Memory Views Glossary

Term	Definition
IOMMU	I/O Memory Mapping unit
SVM	Shared Virtual Memory, implies the same virtual memory view between the IA cores and processor graphics.
Page Walker (GAM)	GFX page walker which handles page level translations between GFX virtual memory to physical memory domain.

GPU Memory Interface

GPU memory interface functions are divided into 4 different major sections:

- Global Arbitration
- Memory Interface Functions
- Page Translations (GFX Page Walker)
- Ring Interface Functions (GTI)

GT Interface functions are covered at a different chapter/HAS and not part of this documentation. The following documentation is meant for GFX arbitration paths in accessing to memory/cache interfaces and page translations and page walker functions.

Global Arbitration

The global memory arbitration fabric is meant to be a hierarchal memory fabric where memory accesses from different stages of the pipeline are consolidated to a single interface towards GT's connection to CPU's ring interface.

The arbitration on the fabric is programmable via a simple per pipeline stage priority levels.

Programming Note	
Context:	Global Memory Arbitration
Arbitration allows 4 levels of arbitration where each pipeline level can be put into these 4 levels. Each consolidation stage simply follows the 4-level arbitration with grace periods to allow ahead of the pipeline to get a higher share of the memory bandwidth.	

The final arbitration takes places in GAM between parallel compute engines. Each engine (in some cases major pipeline stages are also separated, i.e. Z vs Color vs L3 vs Fixed Functions) gets a count in a grace period where its accesses are counted against a global pool. If a particular engine (or pipeline stage) exhausts its max allowed, it is dropped to a lower priority and goes to fixed pipeline based prioritization. Once all counts are expired, the grace period completes and resets.

The count values are programmable via MMIO (i.e. *_MAX_REQ_COUNT) registers with defaults favoring the pipeline order.

GFX MMIO – MCHBAR Aperture

Address: 140000h – 147FFFh

Default Value: Same as MCHBAR

Access: Aligned Word, Dword, or Qword Read/Write

This range defined in the graphics MMIO range is an alias with which graphics driver can read and write registers defined in the MCHBAR MMIO space claimed through Device #0. Attributes for registers defined within the MCHBAR space are preserved when the same registers are accessed via this space. Registers that the graphics driver requires access to are Rank Throttling, GMCH Throttling, Thermal Sensor, etc.

The Alias functions work for MMIO access from the CPU only. A command stream load register immediate will drop the data, and the store register immediate will return all Zeroes.

Graphics MMIO registers can be accessed through MMIO BARs in function #0 and function #1 in Device #2. The aliasing mechanism is turned off if memory access to the corresponding function is turned off via software or in certain power states.

Please refer to applicable EDS documentation of offset 140000h – 147FFFh for details of this register's format and behavior.

Graphics Memory Interface Functions

The major role of an integrated graphics device's Memory Interface (MI) function is to provide various client functions access to "graphics" memory used to store commands, surfaces, and other information used by the graphics device. This chapter describes the basic mechanisms and paths by which graphics memory is accessed.

Information not presented in this chapter includes:

- Microarchitectural and implementation-dependent features (e.g., internal buffering, caching, and arbitration policies).
- MI functions and paths specific to the operation of external (discrete) devices attached via external connections.
- MI functions essentially unrelated to the operation of the internal graphics devices, .e.g., traditional "chipset functions"
- GFX Page Walker and GT interface functions are covered in different chapters.

Graphics Memory Clients

The MI function provides memory access functionality to a number of external and internal graphics memory *clients*, as described in the table below.

Graphics Memory Clients

MI Client	Access Modes
Host Processor	Read/Write of Graphics Operands located in Main Memory. Graphics Memory is accessed using Device 2 Graphics Memory Range Addresses
External PEG Graphics Device	**Write-Only** of Graphics Operands located in Main Memory via the Graphics Aperture. (This client is not described in this chapter).
Peer PCI Device	**Write-Only** of Graphics Operands located in Main Memory. Graphics Memory is accessed using Device 2 Graphics Memory Range Addresses (i.e., mapped by GTT*). Note that DMI access to Graphics registers is not supported.*
Coherent Read/Write (internal)	Internally-generated snooped reads/writes.
Command Stream (internal)	DMA Read of graphics commands and related graphics data.
Vertex Stream (internal)	DMA Read of indexed vertex data from Vertex Buffers by the 3D Vertex Fetch (VF) Fixed Function.
Instruction/State Cache (internal)	Read of pipelined 3D rendering state used by the 3D/Media Functions and instructions executed by the EUs.
Render Cache (internal)	Read/Write of graphics data operated upon by the graphics rendering engines (Blt, 3D, MPEG, etc.) Read of render surface state.
Sampler Cache (internal)	Read of texture (and other sampled surface) data stored in graphics memory.

MI Client	Access Modes
Display/Overlay Engines (internal)	Read of display, overlay, cursor and VGA data.
Media Engines	Read and write of media content and media processing.
uController	Read/Write (DMA) functions for u-controller and scheduler.

Graphics Memory Addressing Overview

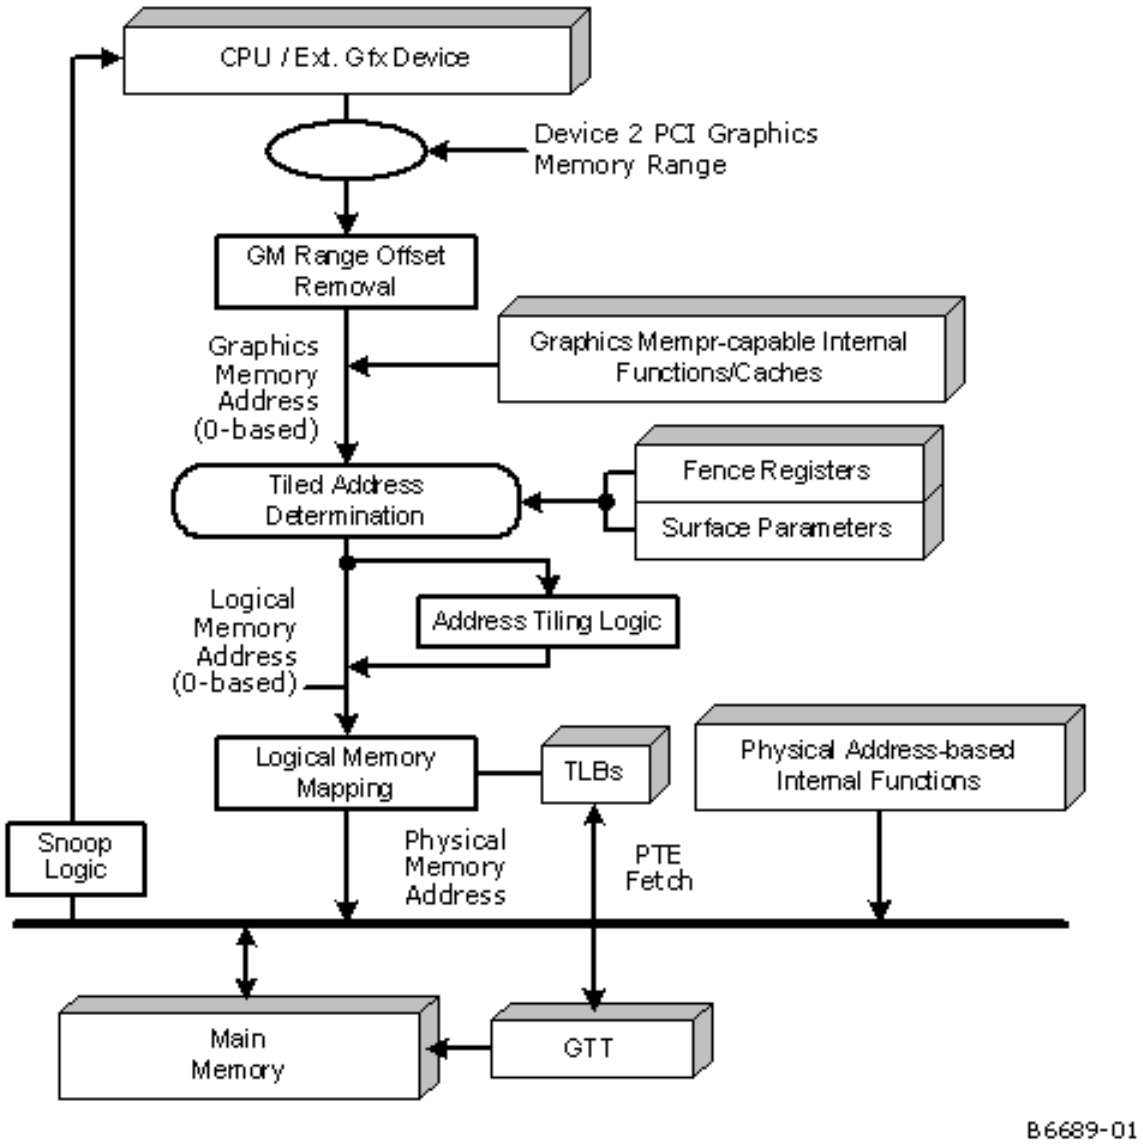
The Memory Interface function provides access to graphics memory (GM) clients. It accepts memory addresses of various types, performs a number of optional operations along *address paths*, and eventually performs reads and writes of graphics memory data using the resultant addresses. The remainder of this subsection will provide an overview of the graphics memory clients and address operations.

Graphics Address Path

Graphics Address Path shows the internal graphics memory address path, connection points, and optional operations performed on addresses. Externally-supplied addresses are normalized to zero-based *Graphics Memory* (*GM) addresses* (GM_Address). If the GM address is determined to be a tiled address (based on inclusion in a fenced region or via explicit surface parameters), *address tiling* is performed. At this point the address is considered a *Logical Memory address*, and is translated into a *Physical Memory address* via the GTT and associated TLBs. The physical memory location is then accessed.

CPU accesses to graphics memory are sent back on the ring to snoop. Hence pages that are mapped cacheable in the GTT will be coherent with the CPU cache if accessed through graphics memory aperture.

Graphics Memory Paths



The remainder of this chapter describes the basic features of the graphics memory address pipeline, namely Address Tiling, Logical Address Mapping, and Physical Memory types and allocation considerations.

Graphics Memory Address Spaces

The *Graphics Memory Address Spaces* table lists the five supported Graphics Memory Address Spaces. Note that the Graphics Memory Range Removal function is automatically performed to transform system addresses to internal, zero-based Graphics Addresses.

Graphics Memory Address Types

Address Type	Description	Range	Gen9
GMADR	Address range allocated via the Device 2 (integrated graphics device) GMADR register. The processor and other peer (DMI) devices utilize this address space to read/write graphics data that resides in Main Memory. This address is internally converted to a GM_Address.	This is a 4 GB BAR above physical memory.	128 MB, 256 MB, 512 MB, 1GB, 2GB, 4GB
GTTMMADR	The combined Graphics Translation Table Modification Range and Memory Mapped Range. The range requires 16 MB combined for MMIO and Global GTT aperture, with 8MB of that used by MMIO and 8MB used by GTT. GTTADR will begin at GTTMMADR 8MB while the MMIO base address will be the same as GTTMMADR. For the Global GTT, this range is defined as a memory BAR in graphics device config space. It is an alias into which software is required to write Page Table Entry values PTEs. Software may read PTE values from the global Graphics Translation Table GTT. PTEs cannot be written directly into the global GTT memory area.	This is a 16MB BAR above physical memory.	16 MB (2 MB MMIO + 6 MB reserved + 8 MB GGTT)
GSM	GTT Stolen Memory. It is an 8 MB (max) region taken out of physical memory to store the Global GTT entries for page translations specific to GFX driver use. It is accessible via GTTMMADR from the CPU path however GPU/DE can access the same region directly.	This is an 8 MB region in physical memory not visible to OS.	1 MB, 2 MB, 4 MB, 8 MB
DSM	Data stolen memory, the size is determined with GMS filed (8 bits) with MAX size of 4 GB. This is a stolen memory which can be accessed via GMADR for CPU and directly for GPU/DE. Size is programmable with 32 MB multiplier. First 4KB of DSM has to be reserved for GFX hardware use.	This is a max of 4 GB stolen physical memory for GFX data structures.	0 MB, 32 MB, 64 MB, 96 MB, ...4096MB

Next level breakdown for GTTMMADR is given below.

Software is allowed to use range x17_0000 to x17_FFFF as the Null range.

Address Tiling Function Introduction

When dealing with memory operands (e.g., graphics surfaces) that are inherently rectangular in nature, certain functions within the graphics device support the storage/access of the operands using alternative (tiled) memory formats to increase performance. This section describes these memory storage formats, why and when they should be used, and the behavioral mechanisms within the device to support them.

Legacy Tiling Modes:

- **TileY**: Used for most tiled surfaces when **TR_MODE**=TR_NONE.
- **TileX** : Used primarily for display surfaces.
- **TileW:** Used for Stencil surfaces.

Programming Note	
Context:	Address Tiling Function

Tiled Resource Tiling Modes

- **TileYF:** 4KB tiling mode based on TileY
- **TileYS:** 64KB tiling mode based on TileY

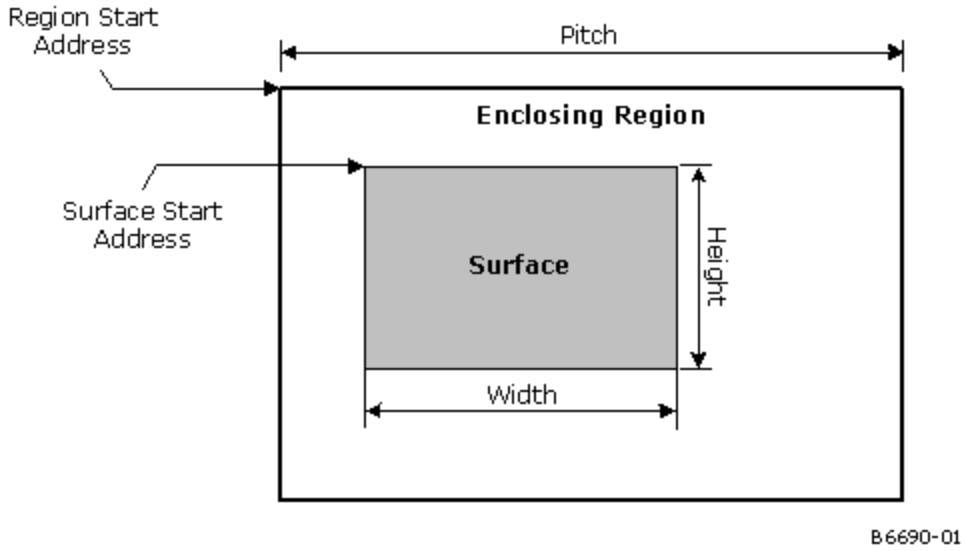
These modes are based on 4KB and 64KB tiles. The 64KB tile is made up of a 4x4 matrix of 4KB tiles. The 4KB tiles in general have a different layout as compared to the legacy modes, with the sub-mode defining the layout within the 4KB tile. The sub-modes are determined by the bits per element of the surface format. The Tiled Resource Mode field in SURFACE_STATE is used to select the new modes.

Tiled surface base addresses must be tile aligned (64KB aligned for TileYS, 4KB aligned for all other tile modes). For 1D surfaces, the base address must be 64KB aligned if **Tiled Resource Mode** is TRMODE_64KB, and 4KB aligned if **Tiled Resource Mode** is TRMODE_4KB. An exception to this tile alignment is when a SURFACE_STATE describes a single MIP within the MIP Tail of another surface, using a 64-bit or 128-bit **Surface Format**—then **Surface Base Address** can refer directly to the given MIP (e.g. to write to a non-renderable **Surface Format** by re-describing as an alternative surface).

Linear vs Tiled Storage

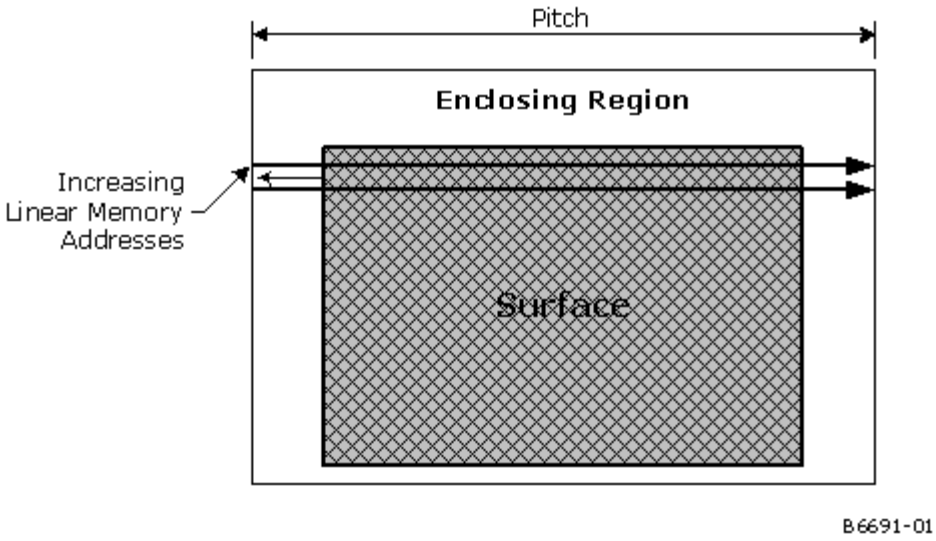
Regardless of the memory storage format, "rectangular" memory operands have a specific *width* and *height*, and are considered as residing within an enclosing rectangular region whose width is considered the *pitch* of the region and surfaces contained within. Surfaces stored within an enclosing region must have widths less than or equal to the region pitch (indeed the enclosing region may coincide exactly with the surface). *Rectangular Memory Operand Parameters* shows these parameters.

Rectangular Memory Operand Parameters



The simplest storage format is the *linear* format (see *Linear Surface Layout*), where each row of the operand is stored in sequentially increasing memory locations. If the surface width is less than the enclosing region's pitch, there will be additional memory storage between rows to accommodate the region's pitch. The pitch of the enclosing region determines the distance (in the memory address space) between vertically-adjacent operand elements (e.g., pixels, texels).

Linear Surface Layout

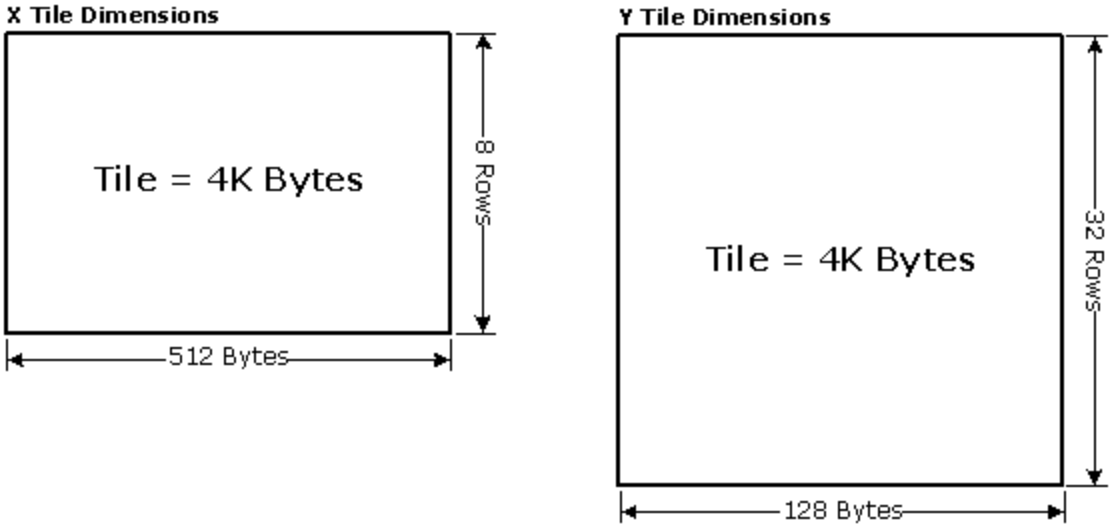


The linear format is best suited for 1-dimensional row-sequential access patterns (e.g., a display surface where each scanline is read sequentially). Here the fact that one object element may reside in a different memory page than its vertically-adjacent neighbors is not significant; all that matters is that horizontally-adjacent elements are stored contiguously. However, when a device function needs to access a 2D subregion within an operand (e.g., a read or write of a 4x4 pixel span by the 3D renderer, a read of a 2x2 texel block for bilinear filtering), having vertically-adjacent elements fall within different memory pages is to be avoided, as the page crossings required to complete the access typically incur increased memory latencies (and therefore lower performance).

One solution to this problem is to divide the enclosing region into an array of smaller rectangular regions, called memory *tiles*. Surface elements falling within a given tile will all be stored in the same physical memory page, thus eliminating page-crossing penalties for 2D subregion accesses within a tile and thereby increasing performance.

Tiles have a fixed 4KB size and are aligned to physical DRAM page boundaries. They are either 8 rows high by 512 bytes wide or 32 rows high by 128 bytes wide (see *Memory Tile Dimensions*). Note that the dimensions of tiles are irrespective of the data contained within – e.g., a tile can hold twice as many 16-bit pixels (256 pixels/row x 8 rows = 2K pixels) than 32-bit pixels (128 pixels/row x 8 rows = 1K pixels).

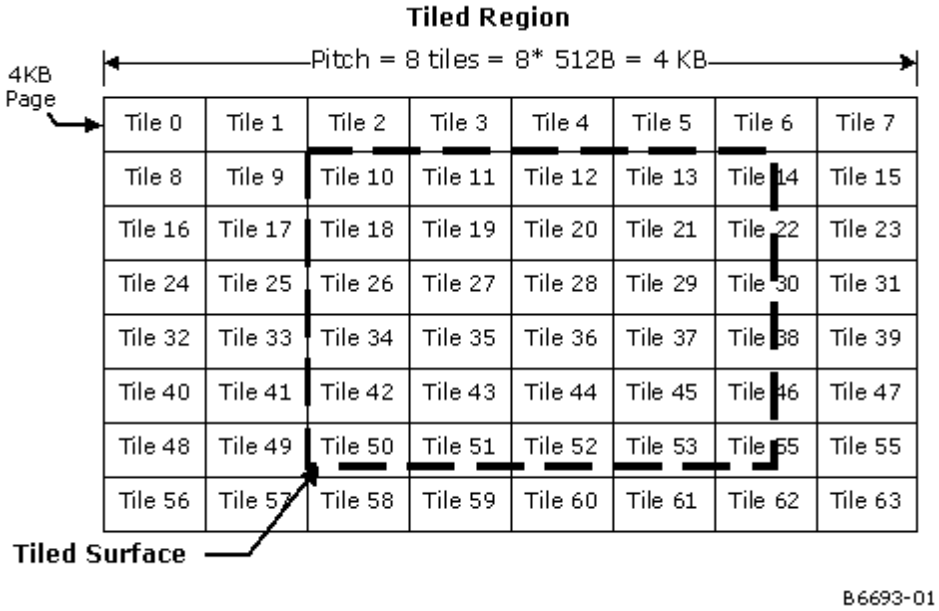
Memory Tile Dimensions



The pitch of a tiled enclosing region must be an integral number of tile widths. The 4KB tiles within a tiled region are stored sequentially in memory in row-major order.

The *Tiled Surface Layout* figure shows an example of a tiled surface located within a tiled region with a pitch of 8 tile widths (512 bytes * 8 = 4KB). Note that it is the *enclosing region* that is divided into tiles – the surface is not necessarily aligned or dimensioned to tile boundaries.

Tiled Surface Layout



Auxiliary Surfaces For Sampled Tiled Resources

For surfaces which are defined as Tiled Resources (TileYs or TileYf format), there may be auxiliary surfaces which are associated with the surface (e.g. HiZ, CCS or MCS). These auxiliary surfaces, while actually not defined as TileYs or TileYf will behave like tiled resources from the hardware perspective. It is possible for software to map and unmap tiles of auxiliary surfaces as tiles of the associated surface are mapped and unmapped. Below is a description how sampling to the mapped/unmapped tile resources is handled for the associated auxiliary surface. Normally, sampling unmapped tiles will return a NULL response to the requesting agent.

HiZ

A tile of HiZ data must be mapped to memory whenever any depth surface (Z) pixels associated with the HiZ tile are mapped. When all Z pixels associated with a HiZ tile are unmapped, the HiZ tile may be mapped or unmapped. Below is a table showing the responses for sampling to mapped and unmapped depth surfaces.

Responses for Sampling to A Depth-Surface Tiled Resource

Depth Surface Mapping	HiZ Surface Mapping	Sample Response
Mapped	Mapped	Normal Sample Response
Mapped	Unmapped	Undefined
Unmapped	Mapped	NULL Response
Unmapped	Unmapped	NULL Response

A "NULL Response" means that the sample returned will be all 0's and the **Null Pixel Mask** (if requested) will indicate the depth pixel is Null.

CCS

A tile of CCS (Color Control Surface) must be mapped to memory whenever color surface pixels associated with the CCS tile are mapped. When all color pixels associated with a CCS tile are unmapped, the CCS may be mapped or unmapped. CCS is used to indicate that the color surface is losslessly compressed. Below is a table showing the responses for sampling to mapped and unmapped.

Responses for Sampling to a Losslessly Compressed Color Surface That is a Tiled Resource

Color Surface Mapping	CCS Surface Mapping	Sample Response
Mapped	Mapped	Normal Response
Mapped	Unmapped	Undefined
Unmapped	Mapped	NULL Response
Unmapped	Unmapped	NULL Response

A "NULL Response" means that the sample returned will be all 0's and the **Null Pixel Mask** (if requested) will indicate the depth pixel is Null.

MCS

A tile of MCS(Multi-Sample Control Surface) must be mapped to memory whenever MSAA surface pixels associated with the CCS tile are mapped. When all MSAA pixels associated with a MCS tile are unmapped, the MCS may be mapped or unmapped. Below is a table showing the responses for sampling to mapped and unmapped.

Responses for Sampling to MSAA Tiled Resources

MSAA Surface Mapping	MCS Mapping	Sample Response
Mapped	Mapped	Normal Response
Mapped	Unmapped	Undefined Response
Unmapped	Mapped	NULL Response
Unmapped	Unmapped	NULL Response

A "NULL Response" means that the sample returned will be all 0's and the **Null Pixel Mask** (if requested) will indicate the depth pixel is Null.

Tile Formats

Multiple tile formats are supported by the Gen Core. The following sections define and describe these formats.

Tiling formats are controlled by programming the fields Tile_Mode and Tiled_Resource_Mode in the RENDER_SURFACE_STATE.

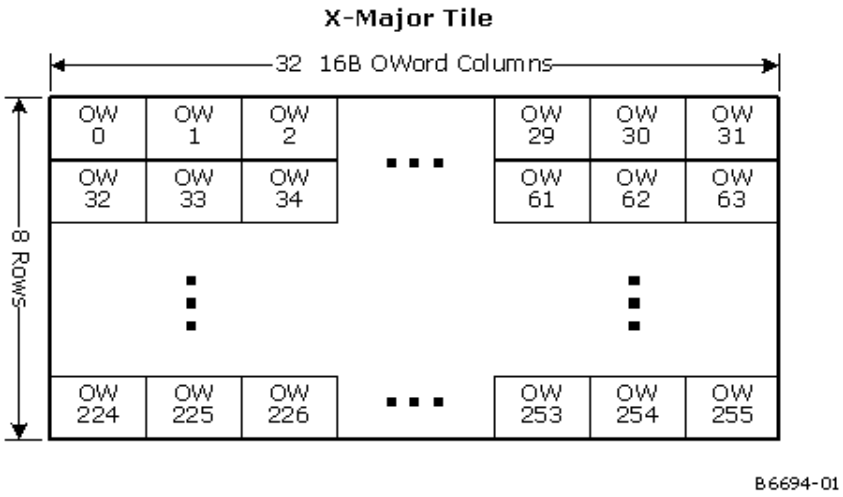
Tile-X Legacy Format

The legacy format Tile-X is a *X-Major* (row-major) storage of tile data units, as shown in the following figure. It is a 4KB tile which is subdivided into an 8-high by 32-wide array of 16-byte OWords . The selection of tile direction only impacts the internal organization of tile data, and does not affect how surfaces map onto tiles. Note that an X-major tiled region with a tile pitch of 1 tile is actually stored in a linear fashion.

Tile-X format is selected for a surface by programming the Tiled_Mode field in RENDER_SURFACE_STATE to XMAJOR.

For 3D sampling operation, a surface using Tile-X layout is generally lower performance the organization of texels in memory.

Tile X-Tile (X-Major) Layout



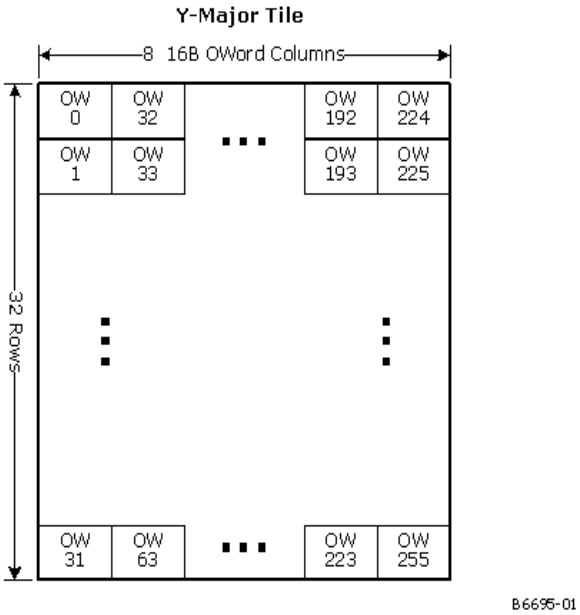
Tile-Y Legacy Format

The device supports Tile-Y legacy format which is *Y-Major* (column major) storage of tile data units, as shown in the following figure. A 4KB tile is subdivided 32-high by 8-wide array of OWords. The selection of tile direction only impacts the internal organization of tile data, and does not affect how surfaces map onto tiles.

Tile-Y surface format is selected by programming the Tile_Mode field in RENDER_SURFACE_STATE to YMAJOR.

Note that 3D sampling of a surface in Tile-Y format is usually has higher performance due to the layout of pixels.

Y-Major Tile Layout

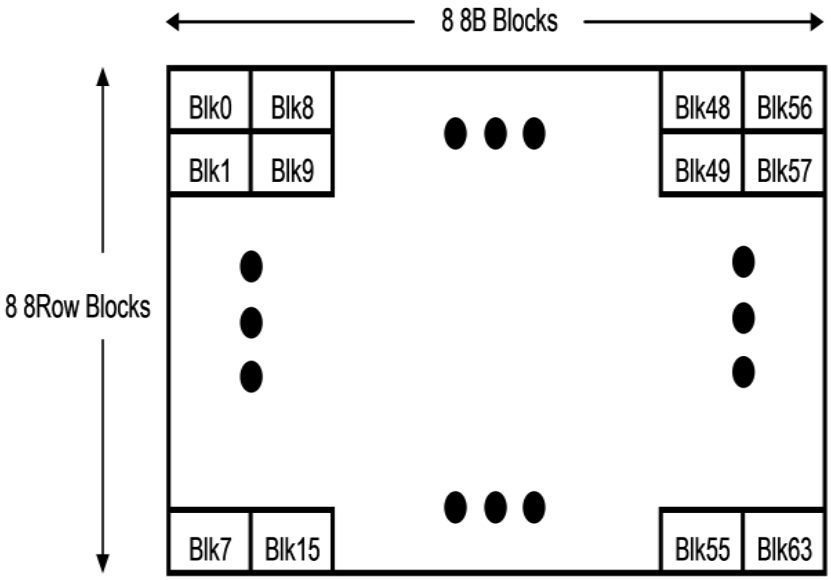


W-Major Tile Format

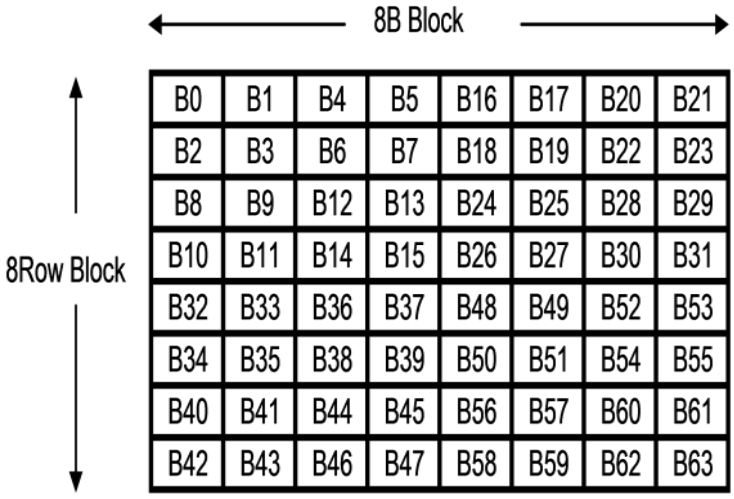
The device supports additional format *W-Major* storage of tile data units, as shown in the following figures. A 4KB tile is subdivided into 8-high by 8-wide array of Blocks for W-Major Tiles (W Tiles). Each Block is 8 rows by 8 bytes. The selection of tile direction only impacts the internal organization of tile data, and does not affect how surfaces map onto tiles. W-Major Tile Format is used for separate stencil.

Tile-W surface format is selected by programming the Tile_Mode field in the RENDER_SURFACE_STATE to WMAJOR.

W-Major Tile Layout



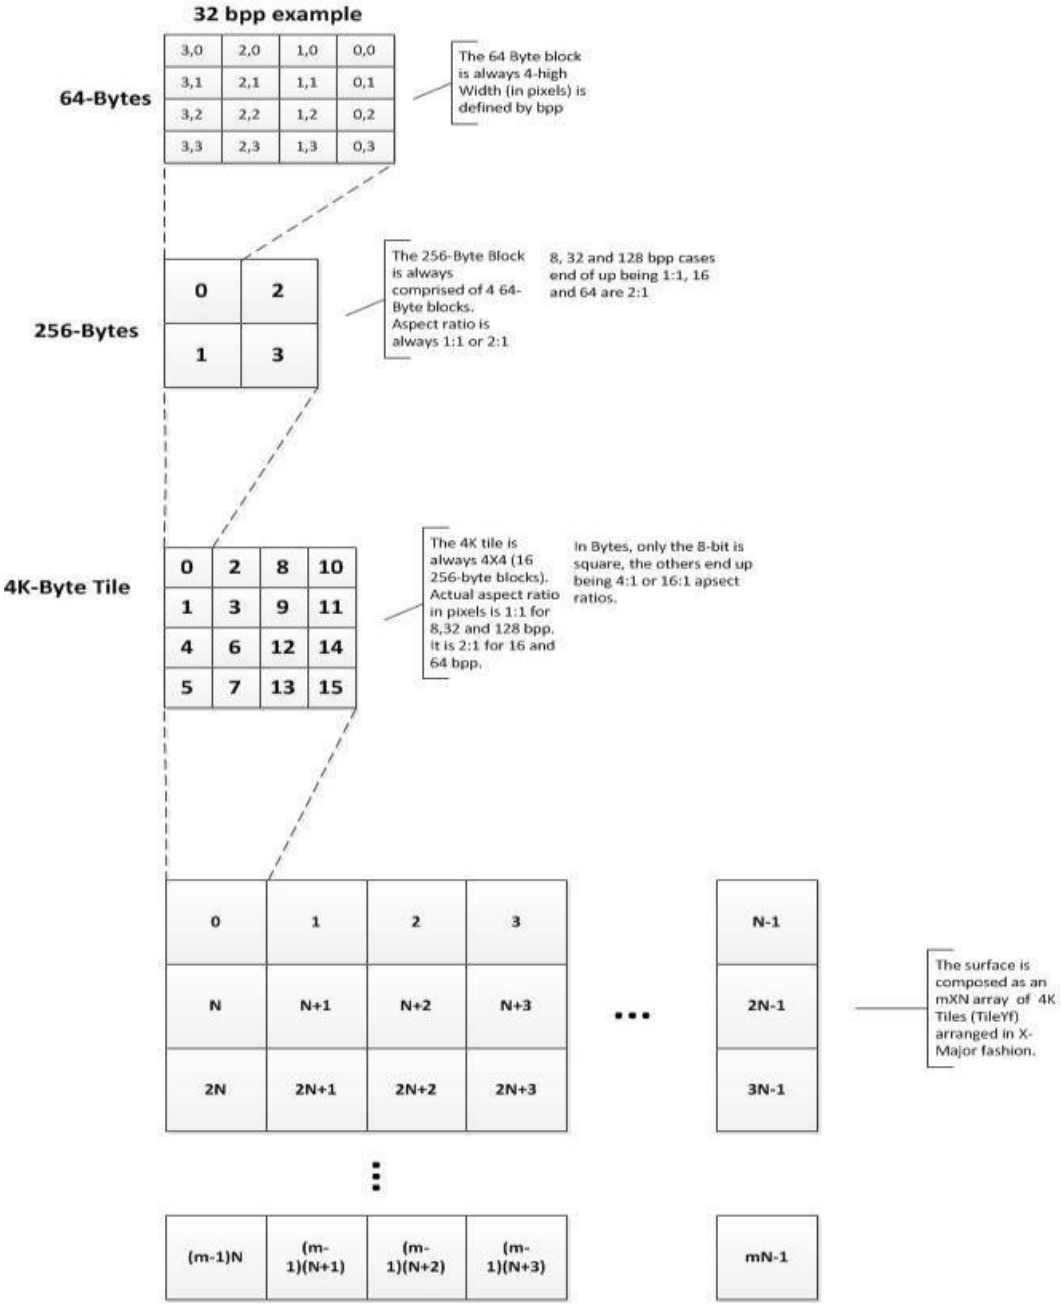
W-Major Block Layout



Tile-Yf Format

Tile-Yf is a 4K-Byte tile format (similar to Tile-Y), but organized in a different manner. Tile-Yf is selected by programming the Tile_Mode field in the RENDER_SURFACE_STATE to YMAJOR and the Tiled_Resource_Mode to TILEYF. The diagram below shows how pixels are mapped into the TileYf format for 2D surfaces, and it uses 32Bpp (bits per pixel) surface format as an example on a 2D surface which is N tiles wide and m tiles high. The exact aspect ratio will be dependent on the Bpp of the surface. Note that the TileYf format is identical to the TileYs up to the 4K-Byte tile size.

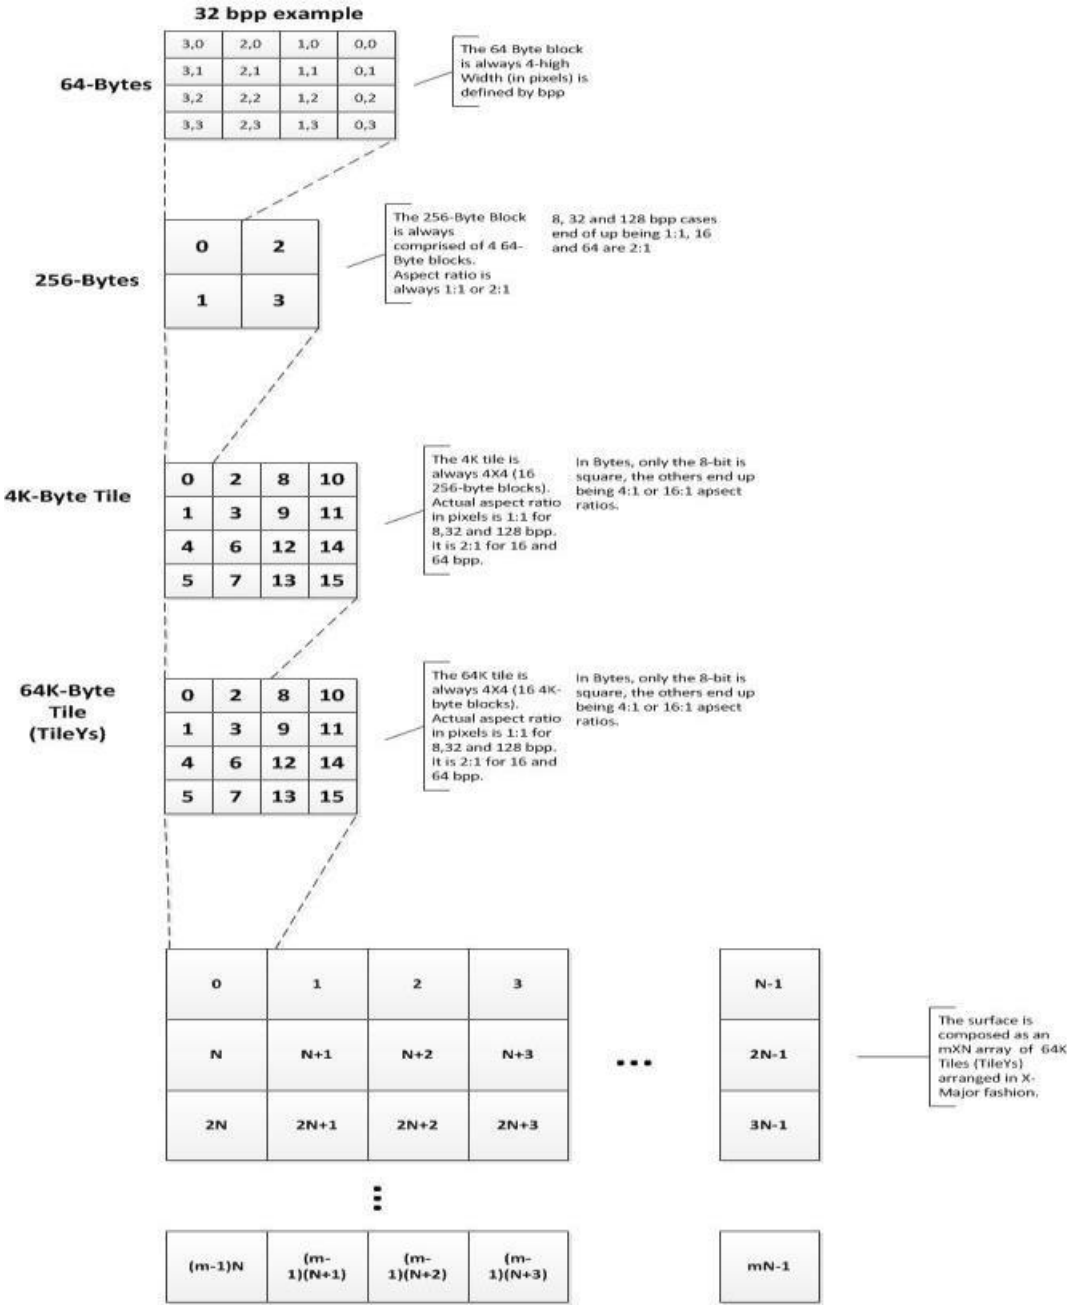
2D Tile Layout for TileYf



Tile-Ys Format

TileYs is a 64K-Byte tile size. It is enabled by programming the Tile_Mode field (in RENDER_SURFACE_STATE) to YMAJOR, and programming the Tiled_Resource_Mode to TILEYS. It is organized as shown below, and is composed of 4KByte blocks which have identical layout to the TileYf format. The diagram below shows how pixels are mapped into the TileYs format, and it uses 32Bpp (bits per pixel) surface format as an example on a 2D surface which is N tiles wide and m tiles high. The exact aspect ratio will be dependent on the Bpp of the surface.

Tile-Ys Layout



Tiling Algorithm

The following pseudo-code describes the algorithm for translating a tiled memory surface in graphics memory to an address in logical space.

The following new modes are supported for Tiled Resources (**TR_MODE** != TR_NONE) defined to enable tiled resources.

For more details about Mip Tails, see Surface Layout and Tiling in the Common Surface Formats section.

- **TileYF:** 4KB tiling mode based on TileY
- **TileYS:** 64KB tiling mode based on TileY

```
Inputs:
      LinearAddress(offset into regular or LT aperture in terms of bytes),
     Pitch(in terms of tiles),
             WalkY (1 for Y and 0 for X)
             WalkW (1 for W and 0 for the rest)

Static Parameters:
      TileH (Height of tile, 8 for X, 32 for Y and 64 for W),
      TileW (Width of Tile in bytes, 512 for X, 128 for Y and 64 for W)
      TileSize = TileH * TileW;
      RowSize = Pitch * TileSize;

If (Fenced) {
     LinearAddress = LinearAddress – FenceBaseAddress
     LinearAddrInTileW = LinearAddress div TileW;
     Xoffset_inTile = LinearAddress mod TileW;
       Y = LinearAddrInTileW div Pitch;
       X = LinearAddrInTileW mod Pitch + Xoffset_inTile;
}

// Internal graphics clients that access tiled memory already have the X, Y
// coordinates and can start here
YOff_Within_Tile = Y mod TileH;
XOff_Within_Tile = X mod TileW;
TileNumber_InY = Y div TileH;
TileNumber_InX = X div TileW;

      TiledOffsetY = RowSize * TileNumber_InY + TileSize * TileNumber_InX + TileH * 16 *
(XOff_Within_Tile div 16) +
             YOff_Within_Tile * 16 +
             (XOff_Within_Tile mod 16);

      TiledOffsetW = RowSize * TileNumber_InY +
             TileSize * TileNumber_InX +
             TileH * 8 * (XOff_Within_Tile div 8) +
             64 * (YOff_Within_Tile div 8) +
             32 * ((YOff_Within_Tile div 4) mod 2) +
             16 * ((XOff_Within_Tile div 4) mod 2) +
              8 * ((YOff_Within_Tile div 2) mod 2) +
              4 * ((XOff_Within_Tile div 2) mod 2) +
              2 * (YOff_Within_Tile mod 2) +
             (XOff_Within_Tile mod 2);

     TiledOffsetX = RowSize * TileNumber_InY + TileSize * TileNumber_InX + TileW *
YOff_Within_Tile + XOff_Within_Tile;
```

```
      TiledOffset = WalkW? TiledOffsetW : (WalkY? TiledOffsetY : TiledOffsetX);

        TiledAddress = Tiled? (BaseAddress + TiledOffset): (BaseAddress + Y*LinearPitch +
X);TiledAddress = (Tiled &&
              (Address Swizzling for Tiled-Surfaces == 01)) ?
              (WalkW || WalkY) ?
              (TiledAddress div 128) * 128 +
              (((TiledAddress div 64) mod 2) ^
              ((TiledAddress div 512) mod 2)) +
              (TiledAddress mod 32)
              :
              (TiledAddress div 128) * 128 +
              (((TiledAddress div 64) mod 2) ^
              ((TiledAddress div 512) mod 2)
              ((TiledAddress Div 1024) mod2) +
              (TiledAddress mod 32)
              :
              TiledAddress;
       }
```

Address Swizzling for Tiled-Surfaces is no longer used because the main memory controller has a more effective address swizzling algorithm.

For Address Swizzling for Tiled-Surfaces see ARB_MODE – Arbiter Mode Control register, ARB_CTL—Display Arbitration Control 1 and TILECTL - Tile Control register

The Y-Major tile formats have the characteristic that a surface element in an even row is located in the same aligned 64-byte cacheline as the surface element immediately below it (in the odd row). This spatial locality can be exploited to increase performance when reading 2x2 texel squares for bilinear texture filtering, or reading and writing aligned 4x4 pixel spans from the 3D Render pipeline.

On the other hand, the X-Major tile format has the characteristic that horizontally-adjacent elements are stored in sequential memory addresses. This spatial locality is advantageous when the surface is scanned in row-major order for operations like display refresh. For this reason, the Display and Overlay memory streams only support linear or X-Major tiled surfaces (Y-Major tiling is not supported by these functions). This has the side effect that 2D- or 3D-rendered surfaces must be stored in linear or X-Major tiled formats if they are to be displayed. Non-displayed surfaces, e.g., “rendered textures”, can also be stored in Y-Major order.

The following Psuedo Code Describes the algorithm for mapping TileYs and TileYf Tile Address to Byte Offset within a Tile. It describes the support for 2D for both TileYs and TileYf as well as MSAA 2D For TileYs.
